Brilliant engineering conceived and developed this electrical "Product of the Year"—the JETAIRE Circuit Breaker.

Power from mighty generating stations like the above does much of our work today. Transmission of the electricity from such remote waterfalls to our cities is by high voltage power lines.

The Westinghouse JETAIRE Circuit Breaker's function is to switch power as required, and to protect the generators and the power lines at all times. Uncontrolled, the flame produced by opening a high voltage line would be comparable to the blast from a military flame thrower.

But, the Westinghouse JETAIRE breaker, "Product of the Year", extinguishes it as easily and faster than you can puff out a match, by releasing a single blast of air that draws the arc, extinguishes the flame and opens the circuit.

Engineering triumphs like the JETAIRE, a radically new design of Circuit Breaker, demonstrate Canadian manufacturers' capacity to invent, to design, to develop, and to manufacture. At Westinghouse creative engineering is a tradition that thrives because Westinghouse attracts young men of creative calibre like Harvey McKeough and Carl Smith, brilliant Canadian engineers who developed the JETAIRE Circuit Breaker.

The Selection of

Boilers and their Auxiliaries

for Heating and Industrial Use

A. M. Bain, M.E.I.C.
Dominion Bridge Company Limited,
Montreal, Que.

This paper describes the principal considerations governing the choice of boilers and their auxiliaries. It is directed at the layman rather than the expert and may be of assistance to a prospective purchaser in his selection of the complex equipment of his boiler plant. The paper has been recommended by the Canadian Boiler Society (of which the author's company is a member) as being an unbiased treatment of the subject.

It has been found necessary in the preparation of this paper to limit its scope in order to keep it to a manageable length. For this reason, boilers in the following categories are touched on briefly, if at all.

(1) *Electric Power Plant Boilers.*—Because of their usually large capacity, high pressure, etc., they could be the subject of a separate paper, even as general as this one.

(2) *Waste Heat Boilers.*—Utilizing hot waste gases from many different industrial processes, as well as from internal combustion engines.

(3) *Oil Refinery Boilers.*—Burning excess combustible products from the refining process.

(4) *Boilers* burning other waste products, such as bark, wood shavings, sawdust, sugar cane (bagasse).

(5) *Recovery Boilers.*—Utilized widely in the wood pulp industry, to reclaim process chemicals by burning waste from liquors and, at the same time, generating large quantities of steam.

(6) *Incinerator Boilers.* — A highly specialized type burning garbage and other refuse.

(7) *Forced Circulation Boilers.* —Formerly used principally where space was at a premium and for waste-heat applications, but now extending also into the electric power plant field.

(8) *Electric Boilers.* — Used where surplus electric power exists, or where other fuels are not economically available.

We are left, therefore, with the subject of industrial boilers and heating boilers of the more or less standard varieties, fired by liquid, gaseous or solid fuels.

Definitions

Before discussing the factors affecting the selection of boilers and their auxiliaries, it seems advisable to establish the definitions of a few of the terms commonly used in the boiler trade.

Boiler.—To most people, a boiler is a device in or under which one lights a fire using some kind of fuel to produce steam under pressure in some kind of container. This definition is over-simplified, since many boilers used for heating purposes do not deliver steam but produce hot water for direct distribution to radiators. On the other hand, the waste-heat boiler has no fire in or under it. It is one of the inconsistencies of our language that a steam-producing boiler, in which boiling takes place, is now generally called a steam generator, while the hot water boiler, where boiling is not supposed to occur, is still called a boiler.

Working Pressure. — The pressure at which the boiler delivers steam or water to a header or line; measured in Canada in lb. per sq. inch gauge (p.s.i.g.).

Design Pressure.—The pressure for which the boiler is designed. This is usually a few pounds above the working pressure so that safety valves can also be set above it. Some users provide a substantial margin of design over working pressure to provide for the "rating down" which may some day be necessary due to wear or old age.

Heating Surface.—The surface area (usually expressed in square feet) of the hot gas side of tubes, headers, etc., exposed to the hot gases. An inconsistency arises here which causes considerable confusion in the minds of those unfamiliar with trade practice. In the fire-tube boiler field, manufacturers for many years have been selling boilers whose catalogue description is based on the surface area of tubes on the water side—that is, the outside. This means that one set of areas is used in catalogues, etc., while another set, about 5 per cent smaller, is used by the designer for heat-transfer calculations and the determination of safety valve sizes to meet the safety codes. Everyone agrees that this practice is confusing, but it is so firmly established that to change it uniformly throughout the trade is next to impossible.

Horse Power.—The term horse power, when applied to the sale and purchase of boilers, has two current meanings. The first and true meaning is the usual mechanical energy equivalent of the heat output of the boiler. This is known as the developed horse power. The second is a throw-back from the customs of the trade and is defined as 10 sq. ft. of heating surface equalling one nominal horse power. The first, depending on the boiler type and its firing equipment, may be anywhere from 125 to 300 per cent of the latter, or higher in special cases. This percentage is called the "boiler rating". The terms horse power and boiler rating are now becoming obsolete in connection with water-tube boilers, and the sooner we get rid of them from our fire-tube boiler terminology, the better. It should be emphasized here that the capacity of a boiler should not be judged by its heating surface, unless the disposition of that heating surface is also considered. Surfaces exposed to gas or flame radiation will absorb a great deal more heat than those gaining their heat by gas convection only. Also, gas velocity and gas direction relative to the tubes play a large part in the efficiency of heat pick-up.

Furnace Heat Release. — The amount of heat released by the burning of a fuel in a furnace, measured in B.t.u. per cubic foot per hour. This is a meaningless term by itself, but it does give the designer a rough and ready means of checking his furnace volume provided he has sufficient data on similarly-shaped furnaces burning the same fuel at hand.

Grate Heat Release.—This is defined as the amount of heat released by the burning of a fuel on a grate, measured in B.t.u. per square foot of effective grate area per hour. Here again the figure is of use to the designer, provided he has sufficient similar data and experience to fall back on.

Efficiency.—Efficiency may be defined as the ratio (per cent) of the heat which has been added to the steam or water in the boiler, divided by the heat content of the fuel burned. The difference between these two quantities is, of course, the various losses which inevitably occur. By far the largest of these is the heat which goes up the stack.

Watertube v. Firetube Selection

There are two main classes of boiler: fire tube and water tube; the difference between them is simple. In a fire tube boiler, the hot gases travel inside the tubes and the water is on the outside. In a water tube boiler, the gases are outside the tubes with the water on the inside. Figures 1 to 4 indicate the three most common types of f.t. boiler and one type of w.t. boiler.

Boilers are again divided into the two sub-classes: low-pressure heating boilers, and power boilers. These subclasses are dictated by the low pressure and power boiler safety codes, which require different design considerations and manufacturing procedures for each. Of these codes, the A.S.M.E. boiler codes are the governing ones on the North American continent. They are supplemented and clarified for use in Canada by the C.S.A. boiler and pressure vessels code. These codes are administered in the various provinces by the boiler and pressure vessels inspection branches of the appropriate provincial departments and under the boilers and pressure vessels Act of each province. The low pressure boiler code covers steam boilers up to 15 p.s.i.g. working pressure, and hot water boilers up to 160 p.s.i.g. working pressure, or 240° F. water temperature. The power boiler code covers boilers operating at higher pressure or temperature.

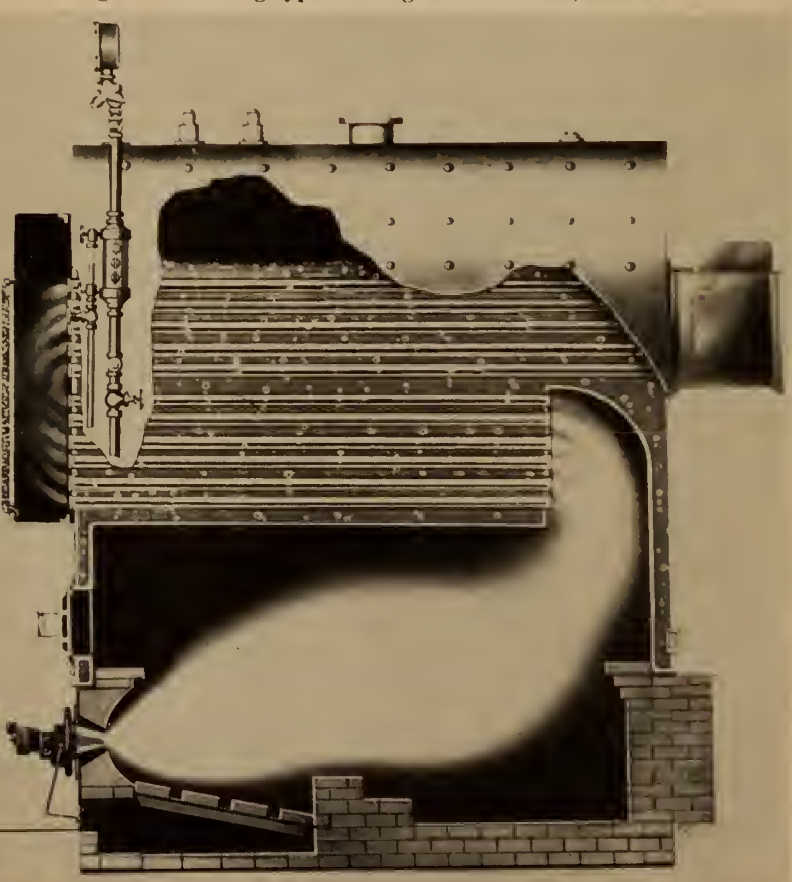
There are two principal considerations which govern the choice of fire tube versus water tube boilers: The most important of these is capacity, and the second, design pressure.

A fire tube boiler will become unmanageably large for capacities exceeding 12,000 to 15,000 pounds of steam per hour (p.p.h.), while a water tube boiler will become non-competitive in price if the capacity per unit is much under 10,000 p.p.h.

For the second consideration, design pressure, it has been found that for pressures exceeding about 250 p.s.i., the fire tube boiler shells and heads become too thick for good heat transfer, and the staying of flat surfaces becomes difficult and expensive. On the other hand, the water tube boiler, because of its higher first cost, becomes uneconomical in the low-pressure heating field.

It can be seen, then, that once the operating pressure is settled, there is only a narrow band of capacities between about 8,000 p.p.h. of steam and 15,000 p.p.h.,

Fig. 1. Waterleg type heating on brick base, oil fired.



where the choice between fire tube and water tube boilers is not clear-cut.

Within this band there are several secondary factors which singly or together will govern the final choice.

Of these factors, the size and shape of the unit is probably the most important since floor space and ceiling height are often restricted. In Fig. 5 and 6, the comparative sizes of the principal classes and types of boiler are illustrated and drawn to scale. Each one shown has a capacity of 10,000 p.p.h.

Fuel is another secondary factor affecting choice of class and type. For any one fuel or combination of fuels, furnace design requirements must be considered, and this will affect the boiler choice.

A third factor is that of demand. If the demand on the boiler is going to be continuous, or if a brief weekly shut-down for cleaning would be embarrassing, the water tube boiler should be chosen. It can, with proper operation, remain on the line for months at a time without shut-down.

The fourth factor, and the last one to be discussed here, is the problem of water treatment. The w.t. boiler, with its high steaming rate and small water content, is sensitive to scale-forming. It consequently requires more accurate and meticulous feedwater treatment than the f.t. boiler. This in turn demands a higher degree of skill in the operator than does the f.t. boiler with its larger water content and slower steaming rate.

Fire Tube Boiler Selection

(A) Suppose that our analysis of one job has led to the selection of a fire tube boiler of the low pressure heating type. In this field, the waterleg and the scotch type boilers predominate. The question of dimensions comes first and can soon be disposed of. It can be said that the waterleg type is always much higher, somewhat shorter, and about the same width as the scotch type. The first cost will be about the same. The scotch boiler, because of its furnace arrangement, is not normally used to burn coal, although this has been done successfully. The waterleg type can burn either oil, gas or coal, and can be readily converted from one to the other. It is, however, more difficult to keep clean in the water spaces, and when set on a brick base for oil firing, may require more brick maintenance. With these factors in mind, the choice between these two types should be easy.

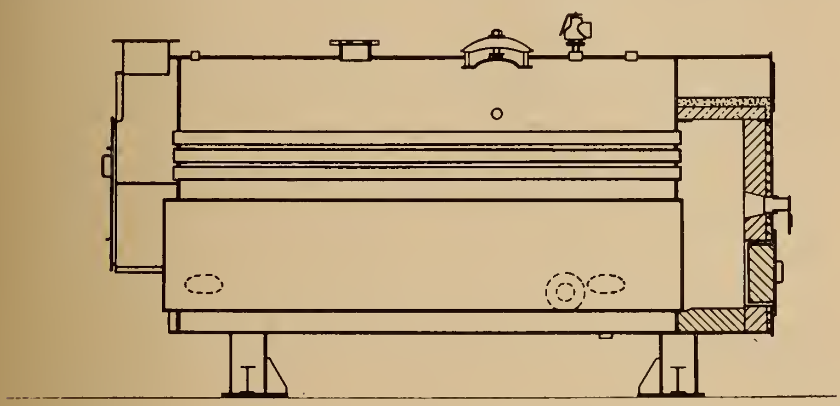


Fig. 2. Scotch dryback boiler, heating or power, oil fired.

Both types are suitable for either steam or water heating systems. The hot water boiler is much simpler to install and operate than the steam boiler. It is, however, at a disadvantage where the distribution system to the radiators is complicated, where the radiators must be kept small, and where steam in any quantity is needed for cooking or other reasons. It should be borne in mind when making a choice between steam and hot water boilers that one can always get hot water from a steam boiler through a heat exchanger but, with a water boiler, the temperature of the water is so limited that steam production from it is not practical. As a word of warning here, domestic hot water should not be taken from a closed hot water heating system on account of the make-up water endangering the boiler through scale formation or oxygen corrosion.

High-temperature high-pressure hot water for heating is being used more extensively now than heretofore and has much to recommend it for large central heating plants. The principle is simple in that there is a steam space maintained either in the boiler or in a collector drum. The water in the boiler is therefore kept at the steam saturation temperature corresponding to the pressure used (usually about 125 p.s.i.). Circulation through heat exchangers supplying hot water or steam to the radiators is effected by means of circulating pumps. The advantages over low-pressure hot water are that the main distribution lines are smaller and that high-pressure steam can be made available for laundries and the like, either through heat exchangers or directly from the collector drum. The principal disadvantage is its first cost since the boiler must be made to the power boiler code, heat exchangers supplied, and the pipelines made to withstand the higher pressures involved. The class of operator is required by law to be higher and adds to the operating cost.

(B) Suppose, alternatively, that the analysis of the job had indicated the need for a fire tube steam boiler operating at a pressure in excess of 15 p.s.i.g. This automatically puts it in the higher-priced power boiler field. Two typical cases would be that of a small institution requiring 100 to 125 p.s.i.g. for its laundry dryer rolls, and that of a food processing plant where the higher temperature of high-pressure steam speeds up the cooking process greatly. In both cases, the building heating requirements can be taken care of by low-pressure hot water or steam procured through heat exchangers or reducing valves respectively.

Although some types of waterleg boiler can be designed to meet the safety requirements of the power boiler code, the difficulty of doing adequate inspection and cleaning has decreased their popularity in this field. This leaves the scotch boiler competing with the H.R.T. type. The latter, because of its furnace arrangement, will usually be used if coal is to be burned. If oil or gas is to be the fuel, the scotch boiler has the advantage of compactness, lower brickwork maintenance, and lower first cost. It has therefore almost completely displaced the once-popular H.R.T. for this application.

Water Tube Boiler Selection

We will now proceed to the analysis of a job where one or more water tube boilers are to be used. So far, there has been no mention made of the important effect of load conditions on the size and number of boiler units and their desired efficiency. These factors will now be discussed in connection with a water tube boiler installation of the power type. Most of these remarks, however, apply with equal force to a fire tube boiler installation, but have been included here to avoid repetition.

As indicated in Figures 7 to 11, there are two principal "standard" types of w.t. boilers in common use today: the cross-drum type and the longitudinal drum type. Space and shape considerations will usually decide which is most suitable for the job. In general, the cross-drum, for the same capacity and efficiency, is higher, shorter, and about the same width as the longitudinal drum.

We can assume, of course, that the maximum continuous, as well as peak and minimum plant loads are established, together with the daily and seasonal load demand curve. From these data can be determined the load level at which most of the fuel will be burned. This is the level at which the boiler efficiency should be a maximum. It is obvious that for peak loads of short duration, it would not be economical to install a boiler with its highest efficiency at maximum load. This is particularly true if very low loads are to be handled at other times with the inevitable "low fire" difficulties of a too-large boiler.

There are two main factors to be considered when selecting the number and capacity of the boilers needed. These are: *(a)* standby requirements, and *(b)* load variation.

Standby requirements alter with the kind of service. For example, hospitals, and public buildings involving tenant occupancy, cannot take a chance on even a partial failure of their heating plant during the winter months. Consequently, they must have at all times idle capacity of some percentage of their maximum demand. W.t. boilers have reached a state of reliability where one idle boiler out of three is considered adequate standby. In small plants, this ratio, for reasons of economy, may be one idle out of two installed. Many process plants, such as distilleries and sugar refineries, where a partial failure of steam supply would be expensive to the process, use the same standby ratios as hospitals and institutions. Others, where partial failure would be merely an inconvenience or, at worst, a temporary reduction in production which could be made up later, do not provide for any *idle* capacity at maximum load. Instead, they provide *surplus* capacity. In a two-boiler installation, for instance, each boiler would have a capacity of about 65 to 75 per cent of the maximum load demand. If one of these boilers had to be shut down at a time of maximum demand, some non-essential services could be discontinued or reduced.

Seasonal load variation is often the deciding factor in choosing the number of units in a plant. It is difficult and uneconomical to operate a boiler at too small a fraction of its normal capacity. The efficiency drops drastically, and the flue gases tend to condense on and corrode breechings. In institutions and the like, where standby capacity is installed, the seasonal load variation is automatically provided for only if more than two units are installed, so that some of the two or more boilers which carry the maximum load in the winter can be shut down in the summer. It is not uncommon to see one out of three, or one out of four, such units carrying the entire summer's load at less than half capacity. It is worth considering, in such cases, the addition of a small fire tube boiler for summer use.

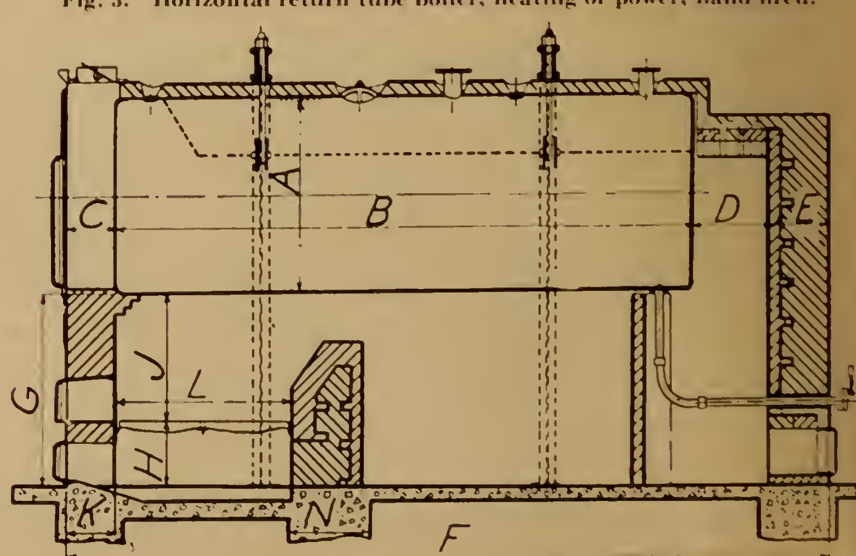
It should be noted also that the fewer the units used, the lower will be the first cost. Two boilers of a given capacity will cost about 50 per cent more than a single boiler of the same total capacity and their maintenance costs will be in about the same proportion. A good rule to follow is to use as few units as possible, taking into consideration standby and load variation requirements.

Before leaving the subject of w.t. boilers, it is worth mentioning efficiency. It was stated before that a boiler's maximum efficiency should be reached at the rating at which most of the fuel is to be burned, and that the boiler's heating surface should be decided on that basis. How high we should aim for efficiency is not always clearly understood. Higher efficiency can usually be obtained by increasing the heating surface, installing heat recovery equipment, or arranging the heating surface so more of it is exposed to direct flame radiation. All of these methods cost money and, unless the additional cost can be recovered in a reasonable time—say, 10 or 12 years (with interest)—it is not worth doing. Here is where the load variation comes in again. There may be two plants to be installed with identical maximum loads, one of which may have 50 to 100 per cent higher yearly load factor than the other and burns that much more fuel. Obviously, a high efficiency is economically more justified in one than in the other. More will be said about this later when economizers and air heaters are discussed.

Laws Affecting Operators

We will now discuss the effect

Fig. 3. Horizontal return tube boiler, heating or power, hand fired.



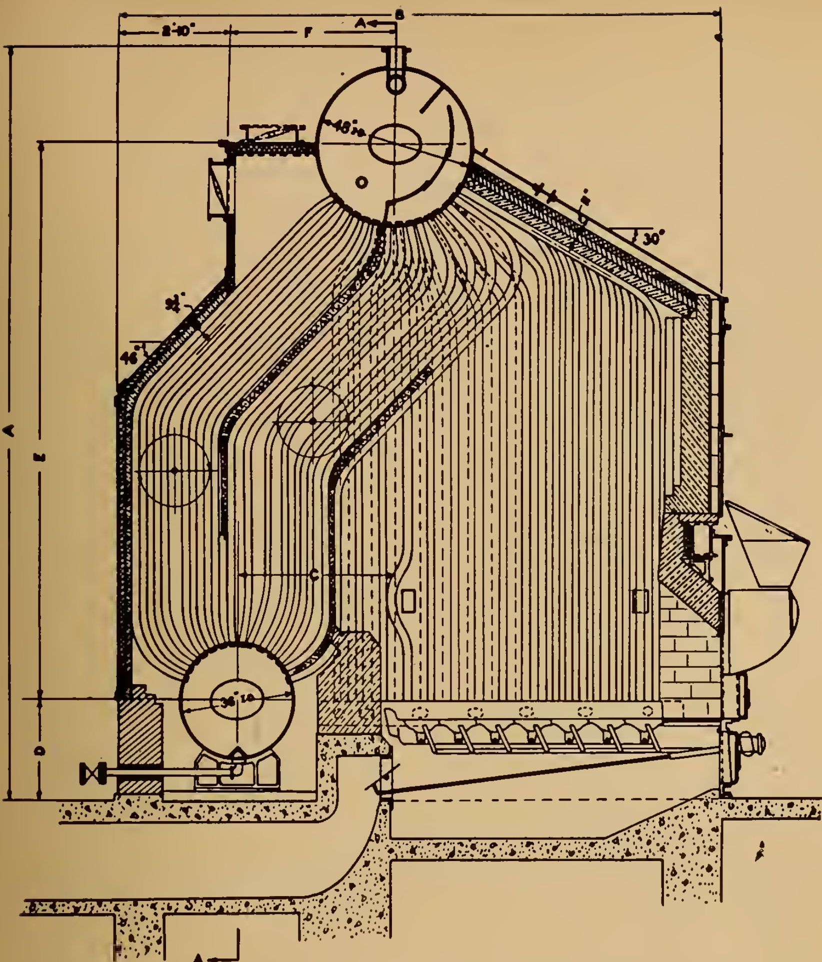


Fig. 4. Water tube boiler, cross drum type, spreader stoker.

of our Provincial laws on the selection of boilers, particularly as they affect the grade of operator required. This, of course, has a striking effect on operating cost. Each province has an Act and regulations stipulating the maximum total installed heating surface permitted for unattended boilers. The Provincial Acts give these limits in horse power rather than in heating surface. The Acts are somewhat confusing in that different classes and types of boiler have different defined values of horsepower. In Quebec and Ontario, for example, the following quantities are the maximum permissible heating surfaces for mechanically-fired, unattended boilers, in the low-pressure field:

H.R.T. boilers:	
Quebec:	900 sq. ft.
Ontario:	1125 sq. ft.
S.D.B. and Waterleg boilers:	
Quebec:	825 sq. ft.
Ontario:	900 sq. ft.
W.t. boilers:	
Quebec:	640 sq. ft.
Ontario:	750 sq. ft.

The corresponding limits for high pressure boilers are: Quebec, one fifth of the low pressure ones; Ontario, one third.

There are also limits established in the Provincial Acts for the maximum installed horsepower which each class of operating engineer is permitted to handle. In Quebec, for example, an operating engineer with second class papers can have charge of a high pressure water tube boiler plant, mechanically fired, with a total installed heating surface not exceeding 5100 sq. ft. In Ontario this figure is 6000, and in Alberta 5000.

It is apparent from the above that the plant designer should, after making his boiler choice, re-examine the sizes chosen from the point of view of legal requirements. Often, a slight increase in boiler rating, a small reduction in standby capacity, or a reduction in the provision for future load growth, will put the plant in another operator's class.

Package Boilers

Before passing on to the discussion of firing equipment, we will take a look at the modern trend toward "package" boiler units. A boiler, either fire tube or water tube, can be called a package unit if it is assembled in the manufacturer's shop complete with all necessary components such as brickwork and insulation, firing equipment, draught fan, combustion and water controls, fuel heaters and dumps, standard boiler trim and, frequently, feed water pumps and soot blowers. This package is so designed and arranged that it can be shipped to site as a unit without too much danger of damage in transit to its installed brickwork and the more fragile of its components. In theory, all that remains to be done once the boiler is in place is to connect up the water, steam, fuel and electric lines, push a button and you're away. In practice, this is almost true, since the equipment has already been shop tested, with the possible exception of the combustion controls. The test procedure of some manufacturers, for reasons of overall economy, do not include this. So far as the writer knows, most packages sold today are either oil or gas fired, or both, and cannot be converted to the use of coal.

The scotch dry-back type of boiler forms the basis for all fire tube packages. This type is enjoying a wide popularity in both the United States and in Canada at present and constitutes the vast majority of all packages sold. Water tube boiler packages are a recent innovation and are gaining in popularity, particularly in the United States, where the large market makes quantity-production methods practical and economical. Due to shipping weights and clearances, the water tube package is limited to the small and medium capacity field, the output varying between 7500 p.p.h. and 35,000 p.p.h. It is interesting to note here that a 30,000-p.p.h. package has a shipping weight of 40 tons. This presents no mean handling problem and points up the moral that no one should specify a water tube package without first checking on the handling facilities at the site and getting an approximate idea of what it is going to cost to move it from car or truck into place in the boiler room. It is certain that in many cases it would be cheaper to install a field-assembled unit instead of a package if all such fringe costs are included.

Fuel Selection

We will now proceed to the important question of fuel selection. A few years ago, most heating boilers and shell-type fire tube boilers were coal fired by hand on shaking grates, much the same as most of us did in our domestic furnaces. Today, oil and gas have cut sharply into the coal-burning field for the small and medium sized boiler, and mechanical stokers have almost completely replaced hand firing. We will, therefore, discuss fuel for mechanical firing equipment only and outline a few of the principal factors governing its selection.

There are four main possibilities: to burn coal or coke, oil or gas, and the choice is usually made on a basis of cost and convenience. Of these, cost is by far the more important. Many boilers burn, annually, fuel costing between half to twice the initial value of the installation. It is obvious then, that a careful study of the cost of alternative fuels is more than warranted.

There are many things, some of them not too apparent, that affect the over-all cost of a fuel. Let us take coal and coke first and enumerate them:

(1) Initial investment for firing equipment including special furnace requirements.
(2) Initial investment for combustion controls.
(3) Initial investment for coal handling equipment.
(4) Initial investment for ash handling equipment.
(5) Initial investment for fly-ash collection equipment (if used).
(6) Initial investment for coal storage facilities.
(7) Cost of fuel per M.B.t.u., f.o.b. site.
(8) Cost of unloading.
(9) Cost of handling fuel from storage to boiler.
(10) Cost of handling ash from boiler to dump.
(11) Cost of boiler room staff wages.
(12) Cost of maintenance (all equipment).
(13) Boiler efficiency.

This is a formidable list of costs but, if approached systematically in the planning stage, they are not as difficult to determine as one might think. Some of them, however, deserve special mention:

The initial cost of the coal and ash handling equipment may, in a small heating plant, cost only a few dollars and consist merely of a couple of shovels and a wheelbarrow. In a larger plant they may amount to many thousands of dollars and consist of such items as track hopper, bucket elevators, storage bins, conveyors, pneumatic ash handling systems, etc. Whether such labour-saving devices are warranted or not depends largely on the amount of coal to be handled daily.

Consider the fly-ash collection equipment. In general, this is not needed by the owner for his own purposes, but is a requirement demanded by the smoke-abatement laws of most large urban centres when certain types of coal firing equipment are used.

The last item listed, boiler efficiency, enters into the balance sheet when comparing coal costs with those of oil or gas. This is due to the fact that it is virtually impossible to burn out a coal completely. There are, therefore, what we call "unburned" losses in our heat balance figures which do not apply when burning oil or gas and help weigh the efficiency figures against coal.

A corresponding list of cost factors for oil or gas firing would be as follows:

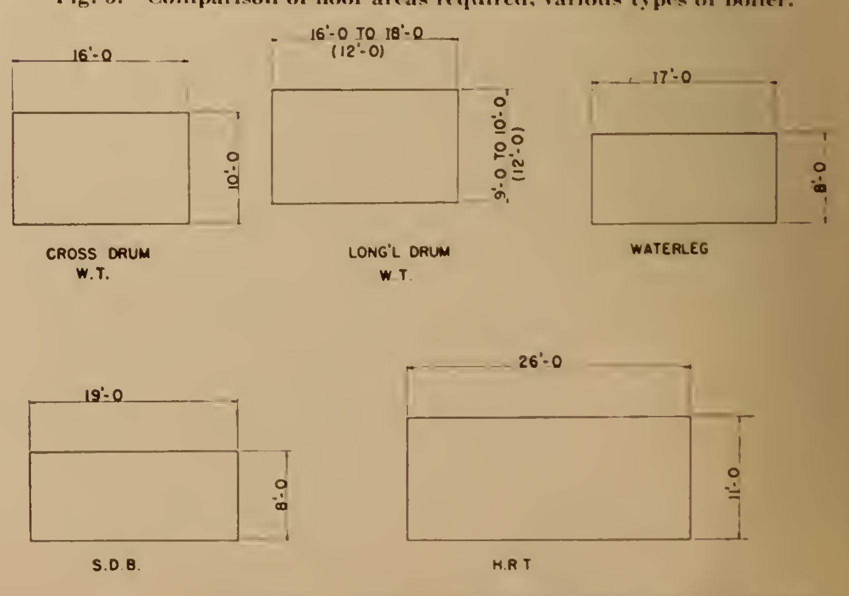
(1) Initial cost of burners.
(2) Initial cost of combustion controls.
(3) Initial cost of safety devices.
(4) Initial cost of oil heating and pumping equipment.
(5) Initial cost of oil or gas piping, valves, etc.
(6) Initial cost of oil storage facilities.
(7) Initial cost of oil unloading facilities.
(8) Cost of power for heating and pumping oil.
(9) Cost of fuel per M.B.t.u., f.o.b. site.
(10) Cost of unloading (other than power).
(11) Cost of boiler room staff wages.
(12) Cost of maintenance (all equipment).
(13) Boiler efficiency.

Certain of the above items will stand elaboration:

Item (3), safety devices—add perhaps 10 per cent to the initial cost of an oil or gas burner installation. They are, however, considered to be a "must" for burners in small automatically controlled self starting jobs. You will find them on your own oil burning domestic furnace. On larger jobs, with modulating controls—but not self starting—they are being used more and more, largely as a protection against human errors in operation and not so much to protect against mechanical failure. More and more the insurance companies are insisting on such devices before they will agree to insure.

Item (4) to (8) inclusive, having to do with the storage, heating, and transfer of oil are a common source of under-estimate. The storage and transfer facilities are

Fig. 5. Comparison of floor areas required, various types of boiler.



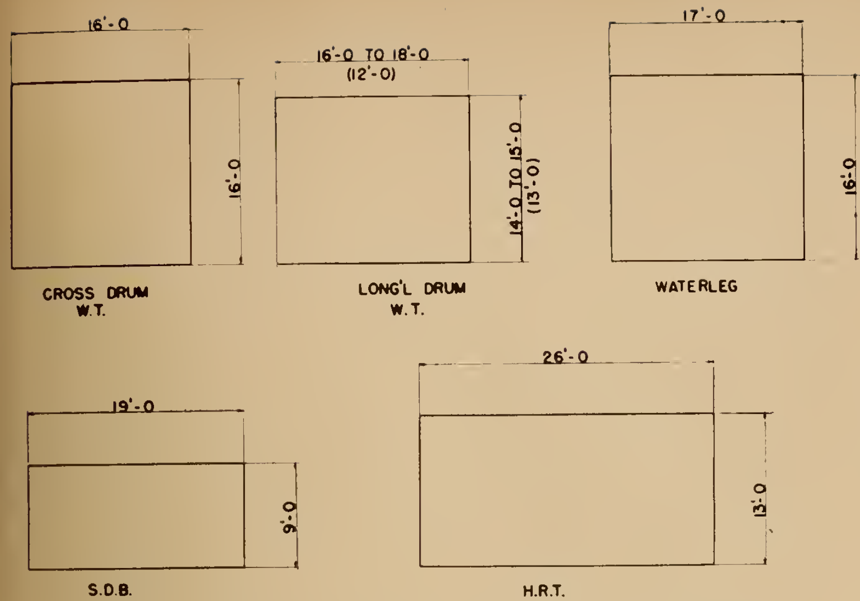


Fig. 6. Comparison of heights required, various types of boiler.

strictly controlled by the fire underwriters and, in these days of high plumbing and material costs, may form a surprisingly large percentage of the total cost—even exceeding the cost of corresponding equipment for coal.

Item (11), boiler room wages, usually shows a substantial saving over a coal-burning job, even if the latter is fully mechanized.

Item (12), maintenance costs, will usually be considerably less with oil or gas as a fuel than with coal. Stoker grates have a tough job to perform, but any stoker manufacturer can predict fairly accurately what the maintenance cost per ton of coal burned per year will be. The same goes for pulverizers. On the other hand, the burner tips and gas rings of oil or gas burners are exposed to severe conditions also, but are comparatively inexpensive to replace. Other components of the system such as pumps, heaters, valves, etc., operate under good conditions, and their mechanical deterioration can be kept very low by preventive maintenance.

This has been a brief summary of the main cost factors affecting the choice of fuels. We will now proceed to what we call the "convenience" factor.

It is apparent that this convenience factor is all in favour of oil or gas and against the use of coal. Many jobs have been installed with liquid or gaseous fuels, even when the economics were strongly in favour of solid fuel.

In the first place, it may not be convenient to allocate the space for coal storage when underground oil tanks offer so little obstruction. Secondly, some types of industry tend to make show places out of their boiler rooms, and this can more easily be done and maintained in the relatively dust-free atmosphere of an oil or gas fired job. Thirdly, it is not difficult to obtain operators who can operate an oil fired plant efficiently, but good stoker or pulverizer operators are more difficult to find. Fourth, there are numerous plants where cleanliness is essential to preserve the quality of the product.

These cannot tolerate coal dust, ash, or fly ash blowing about and will use oil or gas if it is at all feasible. Lastly, there is the very numerous group of small heating plants with unattended boilers operating entirely automatically except for cleaning and routine maintenance. For these, oil firing is not only a convenience, but may become a necessity if it is desired to keep operator attendance to a minimum.

Firing Equipment Selection

If the decision is made to burn coal (or coke) the type of stoker or pulverizer best suited for the job must be selected. The type chosen will depend principally on three factors as follows: (1) Is the coal caking or free-burning? (A caking coal is one which tends to fuse together and become impervious to air passage when heated.) (2) Capacity desired. (3) Rate and magnitude of load variations.

There are several types of stoker available, and each has its advantages and disadvantages.

The Single Retort Underfeed Stoker, as its name implies, introduces the coal under the fuel bed by means of a single screw or ram. The screw type, because it can deliver coal to one exit point only, has a limited capacity and is used mainly for small heating boiler jobs. The ram type employs a piston to force coal into a central trough, and auxiliary pushers to distribute it over the length of the trough. Capacities up to 40,000 p.p.h. can be obtained with the largest sizes available. Because of the constant motion of its fuel bed, the underfeed stoker can burn caking coals successfully. Any cakes that form are broken up immediately into fine enough particles to permit efficient air penetration. This type of stoker cannot be used where it is necessary to follow rapidly fluctuating load demands. It is, however, very simple to operate and is generally regarded as the "old reliable" of the small, steady load field.

The Multiple Retort Stoker was once extensively used in medium and high capacity plants. It has been largely supplanted now by the spreader and travelling grate stokers in the medium range, and by pulverizers in the high capacity range. Coal feed is effected by a parallel battery of rams feeding on to a stepped and rearward sloping grate. Secondary feeders nudge the coal down the slope toward the rear where the ash is either dumped or disposed of by mechanical means.

The Spreader Stoker (in its modern form) is a comparative newcomer in the stoker field but has already attained a large measure of popularity within its capacity range. Its principle is simple. Coal is fed by two or more variable speed feeders in parallel on to rotors which throw it backward onto a grate. The coarse particles are thrown furthest, the finer particles less far, and the very fine particles and dust burn in suspension. By proper proportioning of the small and large particles, a thin, even, fuel bed can be maintained. Almost any kind of coal can be burned so long as sizing is right. Rapid load fluctuations can be followed without difficulty. Since there is a practical limit to the distance the coal particles can be thrown evenly (12 to

13 ft.), the higher capacities must be attained by widening the boiler and increasing the number of feeder and rotor units proportionately.

There are two methods of cleaning the fire. The first is by means of longitudinally zoned dumping grates, each zone corresponding to one feeder and rotor unit. One unit is dumped at a time and, during that time, both capacity and efficiency suffer. For this reason, a minimum of three zones is often specified for small boilers in order to reduce the percentage of outage during the cleaning period. When the boiler capacity gets up around the 40 or 50 thousand p.p.h. mark, the chore of dumping the multiple zones in sequence becomes too onerous, and recourse is had to the continuous discharge travelling grate. Unlike the conventional travelling grate, this one travels from rear to front. This principle gives the larger particles, which were thrown furthest back, time to burn out before being carried over into the ash pit. Spreader stokers of this type are being used regularly up to 125,000 p.p.h. and, in a few cases, even higher. In this respect they now overlap what used to be considered the exclusive range of pulverizer firing.

There are four important features, however, of spreader stoker firing about which we should warn the prospective user. First, it is essential that the furnace be designed to give plenty of length of travel for the particles in suspension to burn out before they encounter the first pass of boiler tubes. Secondly, it is necessary to keep the furnace temperature down to prevent softening of the fly ash with resultant fouling of the first pass tubes. These two requirements add to the boiler dimensions as compared with one designed for underfeed stoker firing and this, of course, is reflected in the cost. The third warning is that the spreader does not function well at low loads. About 25 per cent of full capacity is generally agreed to be the practical minimum. This limitation will often rule out the spreader unless the boiler units are made small enough to permit one of them carrying the minimum plant load without the fuel bed becoming too thin and spotty. The fourth warning is that the spreader stoker is one of the worst offenders when it comes to emitting objectionable fly-ash and cinders. As a result, dust collectors are required by law in conjunction with spreaders in most urban centres. Even where by-laws do not demand dust collectors at present, there will likely be such a requirement some day, and the wise purchaser will leave space somewhere between his boiler and stack for one to be installed in the future.

It is worthy of note here that most boilers have some place in their gas passes where the larger particles are trapped. A fair percentage of these particles will be found to be unburned carbon. Consequently, for reasons of efficiency, it is standard practice with spreader installations to return these cinders to the furnace via an auxiliary air operated cinder return system.

The Travelling Grate Stoker has a wide range of capacity extending from about 15,000 p.p.h. of steam up to 250,000 p.p.h. There are two limitations to the use of this type of stoker other than its economic capacity range. It cannot follow rapidly fluctuating loads with best efficiency, and it cannot efficiently burn caking or semi-caking coals.

In principle, the grate is an endless belt conveyor whose top surface travels from the front toward the rear of the boiler. Coal is fed on to the grate through a guillotine-type gate from a hopper at the front of the boiler. The amount of opening of the gate regulates the fuel bed depth, and the burning rate is regulated by the rate of travel of the grate. Air is fed under the grate through transverse zoning chambers which permit the burning rate to be varied from front to rear. To obtain best results and minimize the likelihood

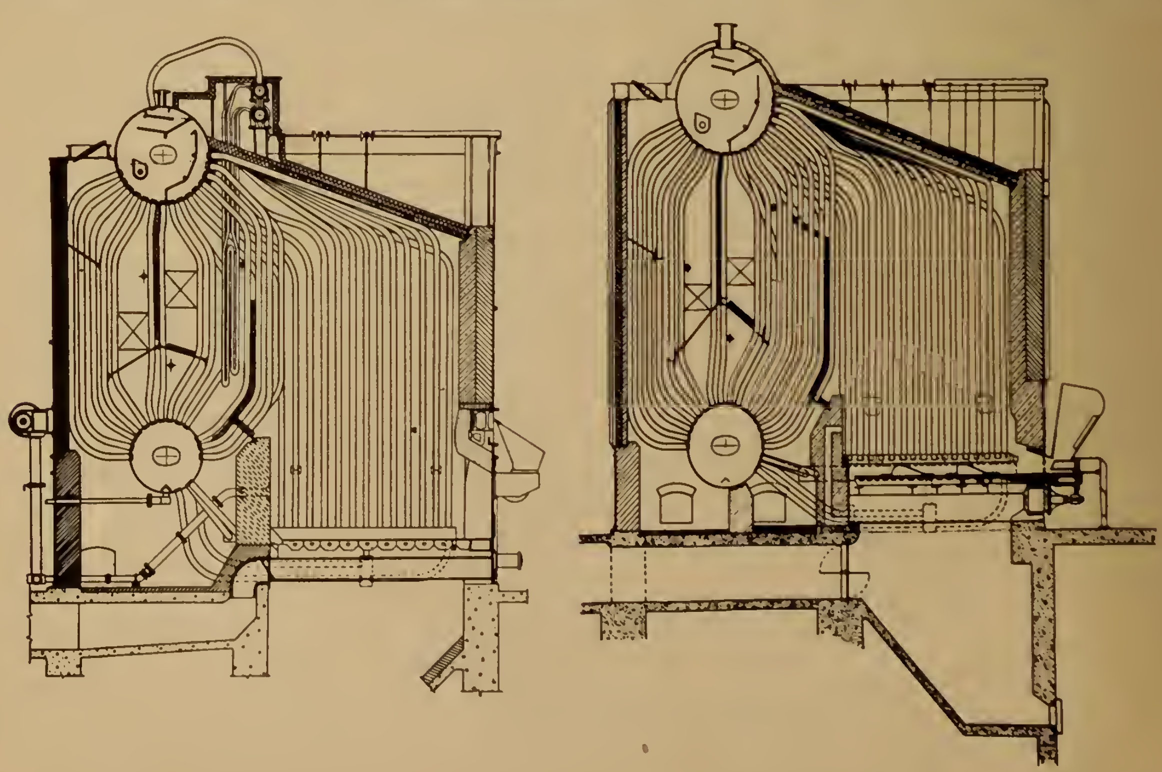

Fig. 7. Water tube boilers, cross drum type, dumping grate spreader and underfeed stokers.

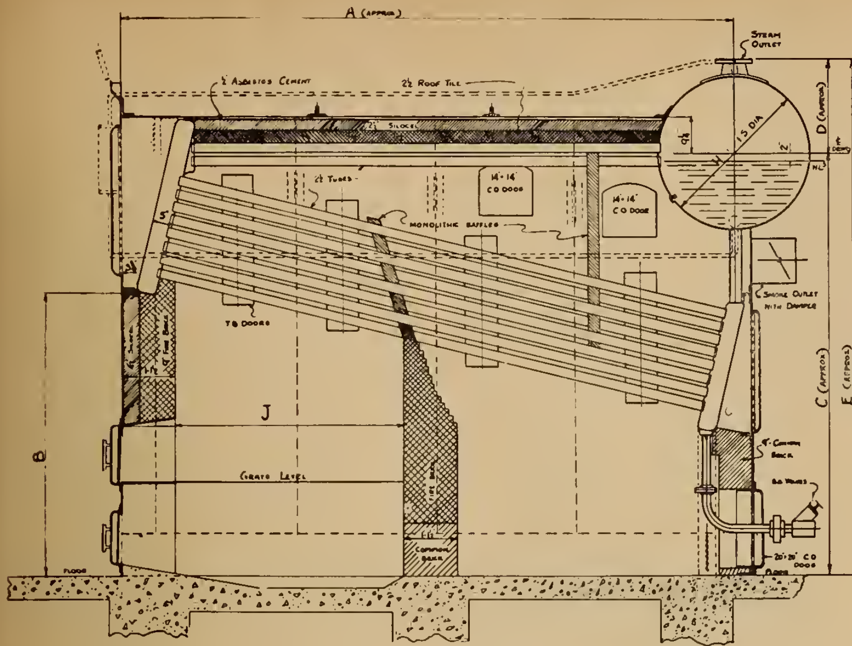

Fig. 8. Water tube boiler, cross drum straight tube, hand fired.

of the fire going out, it is customary to do as much burning as possible in the zones nearest the gate. This gets the raw coal ignited as rapidly as possible and gives it time to be burned out in an even, orderly fashion before it is dumped as ash at the rear of the furnace. It has been found that an overhanging arch over the first zone greatly assists in getting the raw coal ignited. With some fuels, notably coke breeze, a long rear arch is desirable to ensure relatively complete combustion. These arches, and the general design of the furnace for this type of stoker, make for a more expensive boiler than would be required for the same capacity were a spreader or underfeed to be used. In spite of this added cost, where the capacity desired exceeds the upper limit of the underfeed, and other considerations rule out the spreader or pulverizer, the travelling grate is frequently the only solution.

For the guidance of a prospective purchaser, it is worthy of note that there are two sub-types of travelling grate. The less expensive type is known in the trade as the chain grate. With this sub-type, the grate surface is made up of the chain links which are threaded on to long pins extending the width of the stoker. Special links at each side engage the drive sprockets. The principal disadvantage of this sub-type is that to replace a grate element, the stoker chain pins must be pulled and then reinstalled after the links are replaced — a time-consuming operation.

The other sub-type is known as the travelling grate—somewhat to the confusion of the uninitiate. A more accurate designation would be the "bar and key" grate. This grate differs from the chain grate in that the grate elements (keys) do not form part of the chain proper and hence can be renewed readily and with little loss of time. Since the chain elements are not at the firing surface, a much higher degree of mechanical perfection can be attained in their design, and this is reflected in lower maintenance costs and less outage time. Furthermore, by varying the width of the grate elements and the proportions of the air slots between them, finely divided fuels can be burned without excessive sifting of fuel or ash through the grate. This characteristic can be attained on the chain grate also, when new, but as the chain wears, the spacing between links increases and the advantage is eventually lost.

We can sum up the relative usefulness of the two sub-types of grate by saying that the travelling grate has a higher first cost than the chain grate, but is usually chosen in preference to the latter where the load demand requires a minimum of outage time and fine sifting fuel is to be used.

Pulverizers

Let us now touch briefly on the burning of pulverized coal. To be very elementary, we can say that pulverized coal firing consists of reducing the coal particle size to a point where, if blown by air carrier into a furnace, it will burn in suspension.

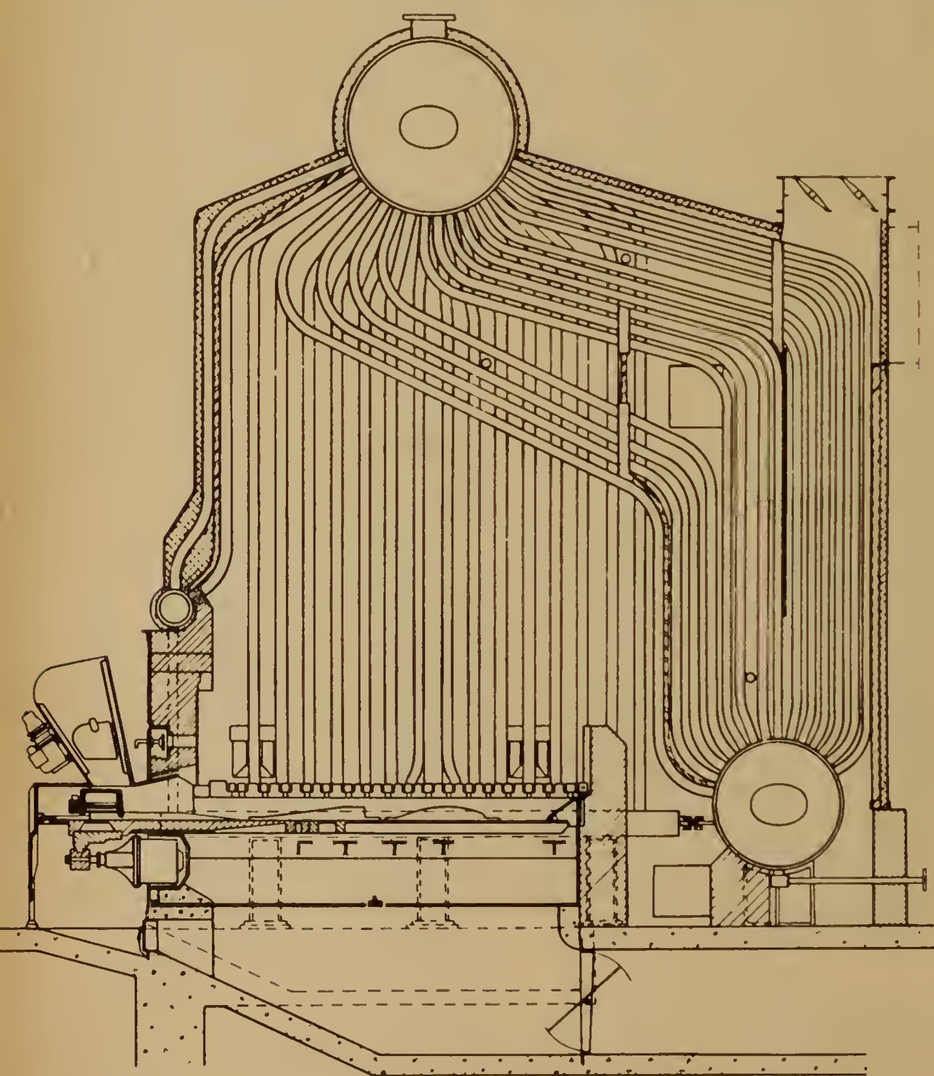
The two principal components of any pulverized fuel firing system are the pulverizer and the burner. There are many varieties of burner in use, and it is not proposed to go into their relative merits here. It should be noted, however, that pulverized coal firing is the only method of burning coal which permits easy conversion of the boiler furnace to oil or gas. In fact, there are many installations where combination coal-oil burners are installed and both fuels are used as the economics of fuel cost changes.

As for the major element of the system, the pulverizer, there are three main types: the ball mill, the impact-attrition mill, and the roll-race or ball-race mill. The ball mill consists of a rotating drum containing a number of hardened balls. Coal is introduced into the drum and is pulverized by the tumbling action of the balls and the coal itself. The impact-attrition mill consists of a series of hammers or lugs attached to a rapidly rotating rotor in a closed housing. The hammers break up the larger particles and, by windage and attrition, these produce the finer particles. The roll-race and ball-race mills consist of rollers or balls confined in a race with the coal, which is crushed and pulverized as the ring or race rotates. In all these types, the finer particles are carried away from the grinding elements by an air stream, passed through a classifier which rejects the coarser of these and allows the real fines to proceed to the burner and hence to the furnace.

All of these types have their advantages and disadvantages, and all will do a good job if the conditions are right for their type. For example, the ball mill and the impact-attrition mills have a large power to production ratio if operated at fractional capacity, while the roll-race and ball-race types are unduly expensive in first cost for small capacity installations. There are other factors which must be considered in choosing the most suitable type of pulverizers, such as moisture content of coal, and length and frequency of shut-down time for replacement of grinding elements.

The designer of a pulverizer fired unit should, for satisfactory operation, satisfy himself that five basic conditions are going to be fulfilled. First, the minimum load must be such that the pulverizer can handle it without losing ignition. The use of a pilot oil flame to stabilize ignition at low loads is frequently used to avoid such difficulties. The use of two or more pulverizers per boiler would have the same effect. For this reason and to provide part load capacity in the event of temporary pulverizer failure, it has become standard practice to install two or more units per boiler in the load range of 60 or 75 thousand p.p.h. steam and up. Second, the boiler furnace must be so designed as to have a maximum temperature below the ash-softening temperature of the coal. If this is not done and if the flame travel is not adequate, slagging will be sure to occur. The common method of minimizing slagging in a furnace, other than making it of adequate size and shape, is to have the furnace wall tubes practically touching, thus presenting completely water-cooled surfaces. Some boiler manufacturers use a wider wall tube spacing with fins attached to the tubes to fill in the gaps. With these arrangements, the wall refractory maintenance is practically nil. Furthermore, the water-wall contour is such that any slag formed cannot get keyed on and will usually drop off when it gets heavy enough, or when the boiler cools off during a shut-down. Third, the coal available should have a reasonably good grindability and not too low an ash fusion temperature. It should also be properly sized for the type of pulverizer to be used. The pulverizer manufacturer will always specify the coal sizing limits for his product and it is frequently found economical in large installations to buy over-sized coal and install crushing equipment to reduce it to the required size. Fourth, the fly-ash emission from a pulverized coal fired boiler is very high and, as with the spreader stoker, most urban centres require dust collection equipment to be installed. Fifth, the intelligence and ability of the operating staff probably needs to be higher to fire pulverized coal than for any other type of firing. For this reason, the small plant which may not by law require a class one operator and can least afford to pay extra money for a first class man, frequently encounters more operational difficulties than the large one.

Fig. 9. Water tube boiler, cross drum, type E underfeed stoker.



Oil and Gas Burning Equipment, in common with coal burning devices, is available in several types. For burning gas, there are the gas ring burner and the inspirating burner. Which to use will depend on the gas pressure available, the noise level tolerated, and the individual preference of the purchaser.

For oil burning, there are four principal types: *(a)* the spinning cup, which introduces a fine spray of oil via the centrifugal action of a highly-polished spinning cone. These burners have medium to low capacity and are used principally with heating boilers; *(b)* steam atomizing burners, which use medium pressure steam for atomizing through a gun-type burner element, and have a wide range of capacity. These cannot be used for water or low-pressure steam boilers unless medium-pressure steam is available from some other source for atomizing; *(c)* mechanical atomizing burners, which atomize the oil by pumping it at high pressure through a gun-type burner element; *(d)* the steam-assisted mechanical atomizing burner which uses steam for atomizing at partial capacity and a combination of steam and mechanical atomizing at higher loads. By this means, the low turn-down ratio of steam atomizing is combined advantageously with the economy and efficiency of mechanical atomizing at high loads. How the oil is heated and pumped, and how the combustion air is handled for each type, is too long a story to be told here.

Heat Recovery Equipment

Heat recovery equipment will now be discussed briefly. When used in conjunction with boilers, heat recovery can be defined as the extraction of heat from the flue gases after they leave the boiler. The purpose, of course, is to reduce the heat loss up the stack and hence improve the overall efficiency of the unit. There are two methods of doing this. One is by transferring heat from the flue gas to the feedwater in an *economizer,* and the other is to transfer heat from the flue gas to the combustion air in an *air heater* or *air preheater* as it is sometimes called. Both these devices are simply a special form of heat exchanger. These methods of heat recovery are seldom used together, except in the high pressure power plant field and in conjunction with some types of marine boiler, both of which are beyond the scope of this paper. There are several types of economizer and air heater in common use, but space will not permit their description here. The discussion will therefore be limited to the factors deciding whether heat recovery will be used and, if so, which type, economizer or air heater, is best suited for the job.

Whether or not to use heat recovery equipment is usually strictly a matter of economics. It is common to improve efficiency 4 to 5 per cent with an air heater, and $4\frac{1}{2}$ to $6\frac{1}{2}$ per cent with an economizer, the limitations usually being: the minimum flue gas temperature that can be attained without gas condensation and resultant corrosion or fouling up of the unit; or maximum water temperature that can be attained in the economizer without danger of steaming; or maximum preheated air temperature permissible for reasons of grate maintenance and coal slagging on the grate.

If the annual fuel bill is known, it is a simple matter to calculate the gross savings that can be reasonably expected when heat recovery equipment is used. Against these savings must be balanced the amortized cost of the heat recovery equipment, its maintenance, the additional cost of draught fan and power needed to overcome the draft losses through the equipment and the cost of the additional space needed. Even if the economics of the case do not warrant it, air heaters will usually be installed in conjunction with pulverizers, to improve the combustion and dry the coal.

If it is decided to install heat recovery equipment, the next step is to choose between an economizer and an air heater. In general, for steam pressures up to 200 or 250 p.s.i., the air heater is a better investment than the economizer while, above that, the conomizer begins to show the best returns. The reason for this lies basically in the fact that the higher the operating pressure, the higher will be the temperature of the saturated steam in the boiler, and the higher will be the gas outlet temperature. This means that more heat can be extracted from the gas before its dewpoint is reached. This larger amount of available heat may exceed that needed by the air heater to bring the combustion air temperature up to the permissible limit, particularly for stoker operation. Consequently, with an air heater the flue gas temperature cannot, in a high pressure boiler, be lowered to the optimum point, and the best efficiency cannot be reached. On the other hand, as the boiler pressure increases, the temperature of the feed-water can also be increased and, as a result, the economizer, in heating the feedwater, can make use of the optimum amount of heat from the flue gases and hence produce the optimum efficiency.

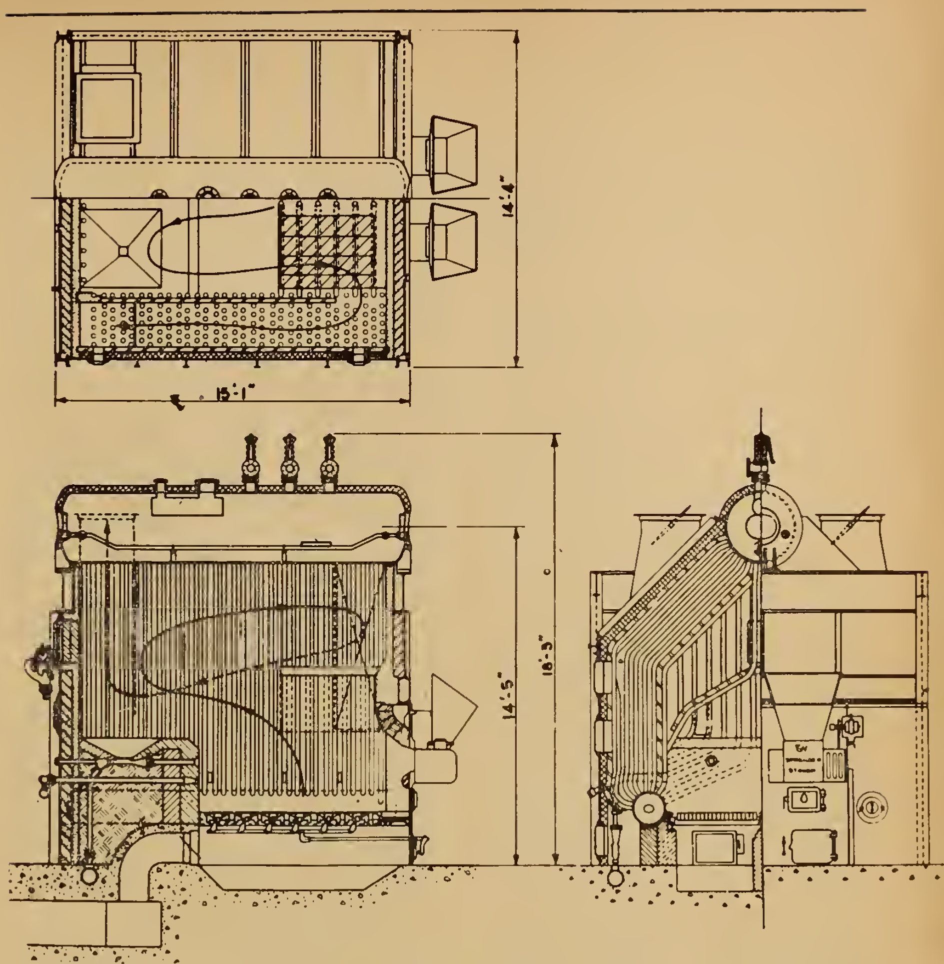


Fig. 10. Water tube boiler, longitudinal drums, dumping grate spreader.

In practice, the fields of application of the economizer and air heater are not so simply defined. For example, it will be found that an economizer will cost more than an air heater for the same pick-up. Against this is the fact that an air heater is likely to have cold spots, particularly at partial load, where condensation is likely to occur. It is therefore considered unwise to reduce the average gas temperature as low with an air heater as with an economizer. This is particularly true with oil firing where sulphur compounds are found in varying amounts in the flue gas. These compounds tend to condense and form hard insoluble deposits at temperatures around 300° F. and may require strong-arm methods for removal. To overcome these operating difficulties, air recirculation, air by-pass, or steam heater at the air entrance can be used to advantage. The critical gas temperature for various loads can then soon be determined and avoided by an operating procedure which will give best efficiency without danger of slagging.

Soot Blowers

The question of fouling heating surfaces leads naturally to the subject to soot blowers. Soot blowers may use either air or steam as the blowing medium and be installed in air heaters, economizers, and boilers of all types. When air is used, the blowing cycle is usually continuous and the operation completely automatic. This type is units as the cost is too high for normally used only on large boiler cconomic use in small boilers. Steam blowers, on the other hand, are relatively inexpensive. They are usually arranged for hand or semi-automatic operation once per shift or when rising flue gas temperatures indicate the need for blowing.

Whether or not to install soot blowers depends largely on the construction of the boiler and the load characteristics. Even a small fire-tube boiler, if it cannot be shut down for brush cleaning without interrupting important plant functions, should have soot blowers installed. Practically all water-tube boilers need to be on the line for long periods at a time and in addition have relatively inaccessible heating surfaces. Consequently, they normally require soot blowers. An exception is often made to this rule in the case of gas-fired boilers and occasionally where spreader stokers are installed. In the latter case, the scouring action of the cinders is said by some to keep the heating surfaces clean, but this has not been generally substantiated.

Fans and Chimneys

This paper would not be complete without the subject of draught fans and chimneys being dealt with. Draught fans for boilers fall into two categories.

Forced draught fans (or forced air fans) supply the combustion air under pressure to the burners or under the stoker grate. They are, in general, required when conditions are as follows: (*a*) when an air heater is used with the resultant relatively high air pressure loss; (*b*) when a stoker is used with its high fuel bed resistance; (*c*) with gas or oil burners of medium to high capacity where the fan pressure can create better air-fuel mixture by increasing turbulence and hence increase combustion rate and shorten the flame; (*d*) in "package" boilers where only a rudimentary chimney is supplied. These boilers usually operate under pressure from the forced draught fan and hence require to be gas-tight so that the products of combustion can be forced through the boiler (without leakage into the boiler room) and thence up the chimney.

Induced draught fans, on the other hand, are placed after the boiler and serve to draw off the products of combustion and send them up the chimney. They are essential under the following conditions: (*a*) where air heaters or economizers are installed; (*b*) where there is no adequate chimney and the boiler is not pressure fired; (*c*) where there is no adequate chimney and there is no forced draught fan.

The question of what constitutes an adequate chimney is not always clearly understood. As is well known, the "chimney effect" of hot gases in a smokestack creates a small reduction in pressure at the base of the stack which is continued through the breeching to the boiler. This reduction in pressure, or draught, is required to carry off the products of combustion and in doing so to overcome the draught losses through the boiler. In addition, with a natural draught oil burner, it may have the job of drawing in sufficient combustion air to operate the burner without smoke. The combined requirements may easily be more than the existing or projected stack height can handle and only trouble can ensue if either the stack height or diameter is inadequate.

It should be borne in mind by the prospective purchaser that just because someone of his acquaintance is "getting by" with a 50 or 60 foot stack does not mean that he also can do so. The draught loss through any given combination of burner, boiler, breeching and stack will vary as the square of the boiler rating. His friend may be operating his boiler at 100 per cent rating, whereas he may need to operate at 150 per cent, thereby requiring a stack two and a quarter times as high.

Other Auxiliaries

It should be noted that there are several other important auxiliaries which the designer must include in his thinking, even if he may not include them all in the specified equipment. A brief list of the more important of these would be:

(*a*) *Feedwater Supply*—required by Code to be in duplicate. If two pumps are used, at least one of them must be steam driven.

(*b*) *Feedwater Treatment*—Consult the experts.

(*c*) *Automatic Combustion Controls*—Highly desirable with rapidly fluctuating loads and essential for unattended boilers.

(*d*) *Indicating and Recording Instruments*, such as steam and airflow recorders, temperature gauges, draught gauges, aid the operator in attaining best efficiency, but may not be economically justified unless substantial quantities of fuel are to be burned yearly.

(*e*) *Automatic Feedwater Regulators*—Essential for unattended boilers and highly desirable for use when loads fluctuate rapidly or boiler water content is relatively small, as in watertube boilers.

(*f*) *Safety Devices* — including flame failure warning and shut-off, air-flow and gas-flow failure fuel cut-off switches. Essential in some form with unattended boilers, and usually specified in conjunction with oil and gas firing in all sizes of boilers.

PHOTOELASTICITY

. . . for Design Improvement

I. W. Smith,

Associate Professor of Mechanical Engineering,
University of Toronto.

Engineering design involves the calculation of stresses by means of recognized formulae. Occasionally a simple formula such as P/A or M/S does not give the correct value of stress, and in other cases the conditions may be complicated to the extent that no formula is available for stress computation. In situations such as these photoelastic stress analysis may provide the answer, and it is the purpose of this paper to outline something of its scope and application. Figure 1 is the fringe pattern for a short column, loaded in compression, and having a transverse hole 25.2 per cent of the width. Whereas the average stress from P/A is 830 p.s.i. on the reduced section, the 4.7th order fringe at the edge of the hole shows the maximum stress at this section to be 1950 p.s.i. or 2.35 times the average. The photoelastic method has been invaluable in the determination of stress concentration factors.

The photoelastic method for stress analysis is not new. In 1853 a gelatin model was used to investigate torsional shear[1]. A polariscope using glass plates to obtain a wider field was described in 1912 by Coker and Thompson[3]. Photoelastic tests in the plastic range were made in 1923 by Filon and Jessop[4]. A series of papers by Z. Tuzi was published in Japan in the late twenties, reporting work on three-dimensional stress problems, the stress freezing technique, and dynamic stress studies[5,6]. Credit should be given to these men, and others of their times, for the progress that was made in spite of relatively insensitive model materials, polariscopes of restricted size, and a limited background of proven techniques.

The introduction of Polaroid, making possible polariscopes with larger fields, and the development of improved model materials, have greatly expanded the use of photoelasticity since 1930. Many excellent books on the subject are now available [7,8,9,10,11,12] and there have been numerous technical papers. References 13 to 34 indicate the wide field of application for the photoelastic method and are typical of many more problems that have been successfully solved but never published. Figures 2 and 3 are fringe patterns for spur gear teeth showing stresses for one and two pairs of teeth in contact. References 35 to 37 indicate that photoelasticity has been used for twenty years in the study of gear tooth stresses.

Although most of the development of the photoelasticity method has been done in universities many private companies now own and operate polariscopes and are using the technique to analyze stresses for design improvement. A brief summary of the basic principles, together with the latest advances in technique and the difficulties encountered, will serve to show where the photoelastic approach may be used to advantage.

Photoelastic stress analysis may provide an answer to stress calculations where these cannot readily be solved by mathematical formulae. The paper outlines the scope and application of photoelastic techniques.

Plane Stress Analysis

To analyze the stresses in a proposed structure an accurately scaled model made of suitable transparent material is used. The model is placed in a beam of polarized light and loaded, in a manner similar to that of the prototype, in a plane perpendicular to the path of light. Strain, induced in the model by the applied load produces temporary birefringence. The entering ray of light, represented as a vector oriented by the plane of polarization, is resolved into components in the directions of the two principal stresses, p and q, at that point. The components travel through the model at different velocities and when recombining on emergence may be in phase, to give a resultant having the original orientation, or antiphased to produce a resultant that represents a 90 degree rotation, or may have a resultant at some intermediate angle. A second polarizer, known as the analyzer, is placed in the light beam beyond the model, either with its axis in line with the first polarizer (forming a "parallel" or "light field" polariscope) or 90 degrees to it ("crossed" or "dark field" polariscope).

The amount by which the emerging vector has been rotated depends on model thickness, material sensitivity, the wavelength of the light, and the algebraic difference of p and q. Rotation of the resultant is indicated by the intensity of light passing through the analyzer. In the crossed polariscope no light is passed in the unstressed regions (hence the term dark field) but as the resultant becomes rotated toward the axis of the analyzer, with increasing load, the light intensity increases at the viewing station. A further increase of load rotates the vector beyond the 90 degree position, until it is again perpendicular to the analyzer axis and the field is again dark. This cycle is known as one retardation and the effect will continue into higher orders as more load is applied. If n is the number of retardations, d the model thickness, and C a constant

Read at the 69th Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, May 1955.

Fig. 1. Fringe pattern for short column, loaded in compression, with transverse hole

for the material sensitivity and the wavelength used, then

$$p - q = n.C/d$$

The value of C is obtained by calibration, using a sample of model material and a known load. The relation between load and retardation number is usually linear up to 10 to 15 retardations.

The variation of $p - q$ throughout the model appears as a pattern of dark and light bands known as fringes and the retardation order is designated by the fringe number. In the light field polariscope the fringes are bright, Fig. 1: in the crossed polariscope the fringes are dark, Fig. 2 and 3. The fringe number at a particular point may be determined when the model is in the polariscope by counting retardations as the load is applied, or on a photograph by counting lines from a point where the fringe order is known, such as the zero fringe at the upper left or right corners of Fig. 1.

When the plane of polarization is in the direction of a principal stress the component perpendicular to it has zero magnitude and hence there can be no retardation effect regardless of how much load is applied. In a model, the points having principal stresses in a given direction will connect into lines known as isoclinics. By rotating the polarizer and analyser, the isoclinics for various stress directions are obtained and these may be used to draw stress trajectories or "flow lines". To make the isoclinics clearly visible, white light is used so that the isoclinic stands out as a black line (in the crossed polariscope) against a coloured fringe pattern.

The coloured fringe pattern results because white light contains all visible wavelengths and the retardation number is affected by wavelength. Above the third order, the coloured bands merge and become indistinct so that monochromatic light, usually from a sodium or mercury vapour lamp, must be used for higher orders. To remove the confusion of superimposed isoclinics, quarter-wave plates are placed between the polarizer and analyzer to produce (and then eliminate) circularly polarized light. Since the directions of principal stresses are not recognized by this light, no isoclinics appear. Figure 4 shows a complete polariscope using a "point" source of light and collimator to provide parallel light through the model. To circumvent the problems of obtaining parallel light over a large area the newer installations utilize a diffused light source, which may be a set of fluorescent tubes closely spaced. The polarizer, analyzer, quarter wave plate and diffused light mat-

Fig. 2. Fringe pattern for spur gear teeth: one pair of teeth in contact.

Fig. 3. Fringe pattern for spur gear teeth: two pairs of teeth in contact.

erials, for a 12 inch working area, may be purchased for about $100. To obtain sharp definition throughout the thickness of the model photographs of the fringe pattern are made with a long focal length camera, in some cases a distance of 15 feet between the model and the film, for a 1:1 magnification.

The maximum shear stress at any point is given by $\frac{1}{2}(p-q)$, so that the fringe number can be used to find this stress throughout the model. Components of shear can also be found from $\frac{1}{2}(p-q)\sin 2\theta$ when θ is obtained from the isoclinic. Since failure in a ductile material, under steady load, may start as a shear failure, the photoelastic method gives a direct indication of likely trouble spots.

Maximum tension and compression stresses are not indicated directly by the fringe pattern except at free boundaries, where one of the principal stresses (normal to the boundary) is zero. Since the stress causing failure is likely to be at the surface, no information beyond that given by the fringe pattern is usually required. In fact, where the peak stress can be expressed as a ratio relative to a known stress at some other point, it is not even necessary to calibrate the model material or measure the load that produced the fringe pattern. For example, in the crane hook of Fig. 5 the fringe pattern shows the maximum stress at the inside edge to be four times the stress in the shank and this would be true for any stress intensity within the elastic limit and for any prototype material. It can be shown that the *distribution* of stress within the model is identical with that in the prototype if the shape and load patterns are similar and if the elastic limit is not exceeded. It is also desirable that the optical limit of the model material, i.e. the fringe number for which linearity with stress ceases, be not exceeded. Local excesses of yield or optical limit, say where concentrated loads are applied, may be tolerated without disturbing the general pattern of stress (St. Venant's principle). However, when excessive distortion of the model, due to the low modulus of elasticity possessed by most of the model materials, results in a changed load pattern the stress distributions are no longer comparable with those of the prototype.

When stresses inside the boundary are desired there are several solution methods. although none of these is entirely convenient. If a pattern for $p+q$ could be obtained easily, this, with the fringe pattern for $p-q$ would enable the p and q stresses to be readily determined. Vol. 2 of reference 9 shows how isopachic diagrams for $p+q$ may be obtained experimentally. The Southwell relaxation method[38] is a mathematical means, usually requiring much computation time, in which $p+q$ may be obtained from boundary values found by the photoelastic method. Measurement of the change in model thickness as the load is applied will give $p+q$ but it is a delicate measurement requiring extreme accuracy, and usually can be done for only one point at a time. It is possible under certain special conditions to obtain p and q from photoelastic data, using methods given in Vol. 1 of reference 9. A newer method, developed by Dr. Shelson[39] combines the fringe pattern of the conventional polariscope with those obtained by the scattered light technique, but it is usually confined to the frozen stress models to be described later.

Edge Stress

Accurate determination of the fringe number at a free boundary involves difficulties. In the first place stresses may exist in the model before any load is applied. The materials supplied for photoelastic model-making are usually free of initial stress but if initial stresses do exist they may be determined and suitable compensation made in the assessment of the final fringe pattern. Some materi-

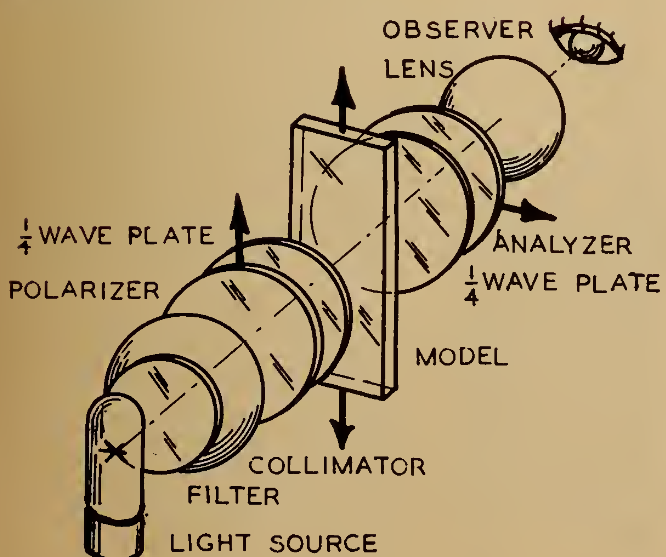

Fig. 5. Fringe pattern in crane hook.

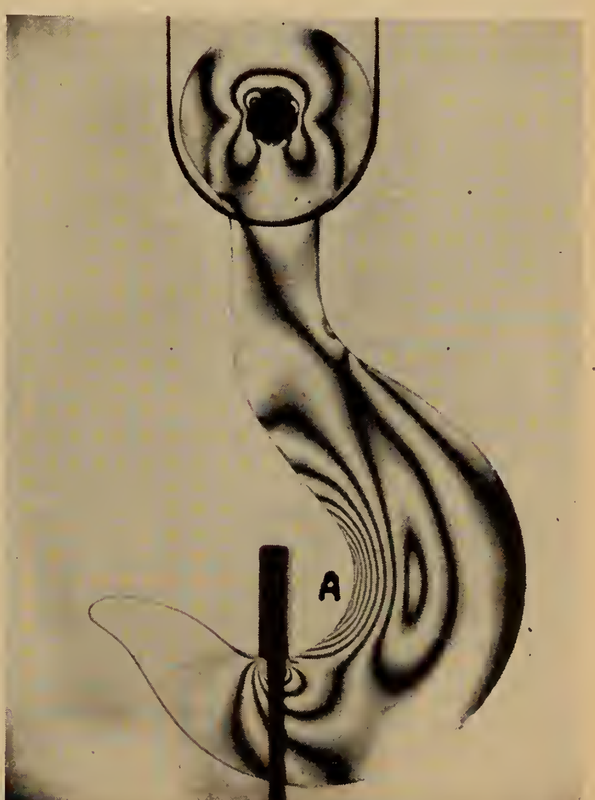

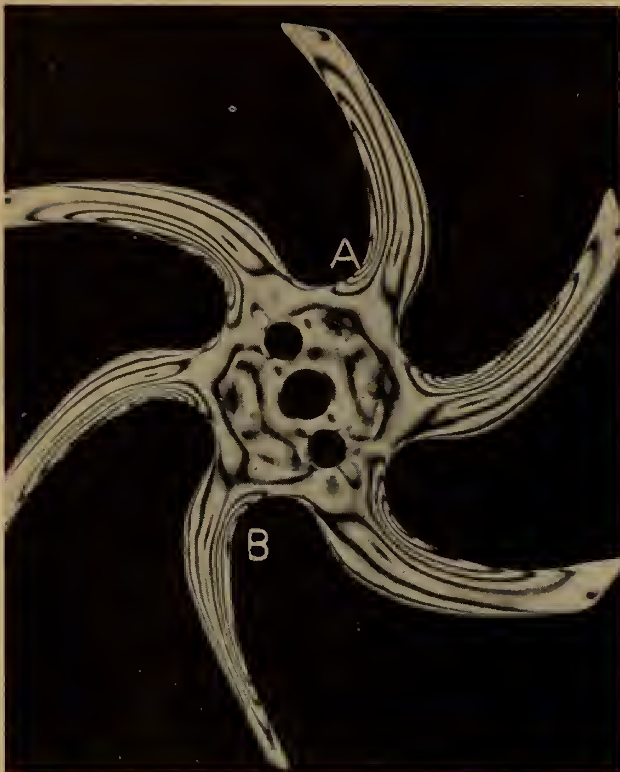

Fig. 6. Fringe pattern for pump impeller.

als permit removal of initial stresses by thermal annealing, although complete removal is somewhat difficult.

Edge stresses may be introduced during machining, particularly if heat is generated because of a dull tool, inadequate cutting clearance, or excessive depth of cut. Models for plane stress problems are usually cut from plastic sheets 3/16 or ¼ inch thick. A modern aid for this work is the Chapman profiler[48]. A high speed tungsten carbide multi-tooth cutter is guided by a follower pin in contact with a ⅛-inch thick metal template, of the correct shape and size, attached by adhesive tape to the plastic being cut. The model can be rough-cut to within 1/16 inch of the template, using a high speed jig saw, leaving only light cuts for the profiler. The presence of edge stress due to machining is evidenced by a disturbance of the fringe pattern. At point A in Fig. 5 the waviness of the fringes close to the edge shows that an uneven machining stress exists. Figure 2 shows the compression fringes in the A region and the tension fringes at B altered at the boundary to indicate the superposition of a tension edge stress. When small holes are required in a model it is usually necessary to have an accurate determination of stress at the edge of the hole, as in Fig. 1. Sharp drills with clean cutting edges will produce stress-free holes, particularly if the drill is submerged in a coolant while cutting.

The second cause of edge stress is an expansion or shrinkage of the machined edges of the model due to absorption or evaporation. This effect is usually uniform throughout the boundary and progresses with time. By using the model soon after it is made the extent of the error is limited. Figure 6 shows a compression edge stress at A and B, superimposed on the tension due to bending and tending to lower the fringe number at the surface.

Creep

Most of the plastics used in photoelastic work exhibit creep at room temperature. At any given point in the model the full strain is not developed the instant that load is applied so that the optical sensitivity appears to increase with time under a steady load. To obtain accurate stress values in a material that creeps, time calibration curves, as in Fig. 7, must be determined and applied to model work by noting the time lapse between initial load application and recording of the fringe pattern. Creep does not affect isoclinic values since these remain the same for all loads.

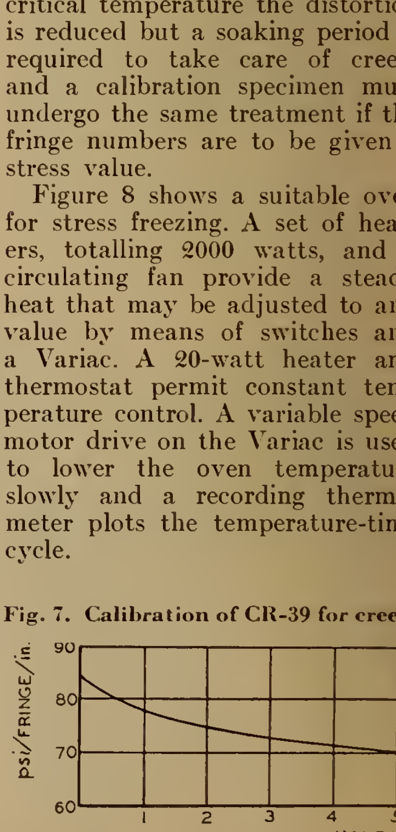
Stress Freezing

Some photoelastic materials will permit a thermal treatment that locks in the stresses, and hence the fringe pattern, after the loads have been removed. The model is heated to 80 to 90 per cent of its critical temperature during a two-hour period, the loads are applied and after about a half hour of "soaking" at constant temperature the model is slowly cooled to room temperature in about twelve hours. The di-phase materials used for this purpose may be visualized as having a fine elastic grid-work or lattice filled with a wax-like plastic that softens with increased temperature and becomes liquid at the critical temperature. The behaviour is fully elastic at the critical temperature but the modulus of elasticity is greatly lowered and hence the optical sensitivity is increased. As the material is cooled, under load, the plastic part stiffens and holds the grid work in the strained position, even when the model is cut into pieces.

If the model is heated to the critical temperature no soaking time is required because there is no longer any creep. However, the distortion is so great that unless the loads are very light the shape of the model may no longer represent that of the prototype. By using 80 to 90 per cent of the critical temperature the distortion is reduced but a soaking period is required to take care of creep, and a calibration specimen must undergo the same treatment if the fringe numbers are to be given a stress value.

Figure 8 shows a suitable oven for stress freezing. A set of heaters, totalling 2000 watts, and a circulating fan provide a steady heat that may be adjusted to any value by means of switches and a Variac. A 20-watt heater and thermostat permit constant temperature control. A variable speed motor drive on the Variac is used to lower the oven temperature slowly and a recording thermometer plots the temperature-time cycle.

Fig. 7. Calibration of CR-39 for creep.



The fringe pattern for the pump impeller shown in Fig. 6 was obtained by rotating the model at 3200 r.p.m. while the temperature was brought up to 210° F., held for half an hour, and then lowered over a 15-hour period. The photograph of the fringes was made in a conventional polariscope, and shows the largest stress to be tension at the inside fillet. Several blade shapes were included in the one model and it is interesting to note that the thinner blade at B shows one less fringe than the thick blade at A.

When dynamic stresses have "fixed" values, as in the rotating impeller, the stress freezing technique is suitable for stress evaluation but it is of no use for fluctuating stresses. In one of the impeller models that was tested the blades vibrated during rotation and the areas in which there were fluctuating stresses showed no distinct pattern. For problems of this kind and for stresses due to impact, a very strong light source of short duration is required. Figure 9 shows the Model 1534-A Polariscope[64] in which the Strobolume is used as a light source. With this equipment fringe patterns of a beam vibrating at 30 c.p.s. may be obtained, as described in references 40 and 41.

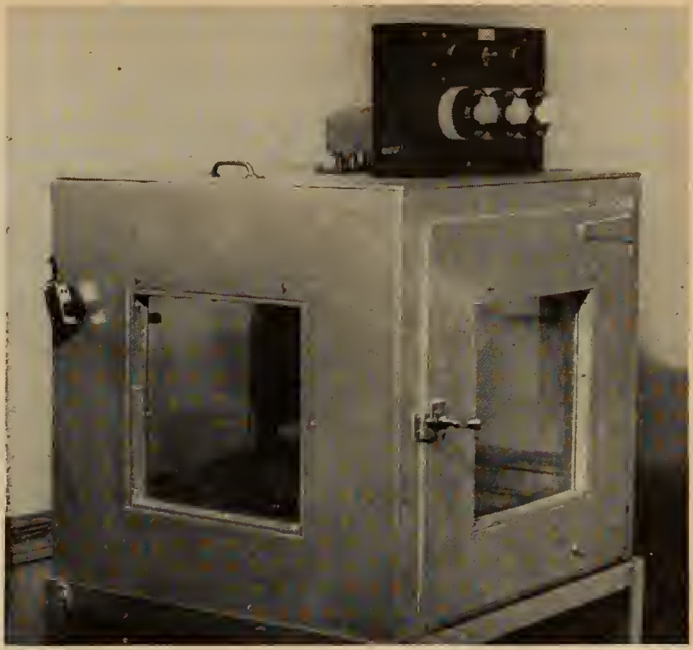


Fig. 8. Oven suitable for stress freezing. Constant temperature control is incorporated.

Materials

For plane stress models, CR-39 plastic[65] is most convenient. It is supplied in sheets of various thicknesses, 3/16 and ¼ inch being most useful, with optically polished surfaces. Although it cannot be annealed, it is usually free of stress when supplied and if machined carefully a stress-free model is obtained. Account must be taken of creep and time edge stress.

Celluloid, Lucite, and Plexiglas, although readily available and low in cost, are too insensitive optically for use as photoelastic models. This is illustrated in Fig. 5, where the model is made of CR-39 but the loading link at the top is Lucite of thickness equal to that of the model. No fringes appear in the loading link but those in the eye of the hook are readily visible.

BT-61-893 was the designation[66] of a material developed by another company for photoelastic work but it is now known as Catalin 61-893. It is supplied in sheets up to 1⅛ inch thick and is readily machined. The faces of a sheet are rough-sawn and it is necessary either to polish a model to optical clarity or coat it with an oil, of the same refractive index, while viewing the fringes. Catalin 61-893 can be annealed and is suitable for stress freezing, with a critical temperature of 230° F., but it develops severe time edge stress as can be seen in Fig. 6.

Other materials, such as Catalin 800, Marblette, Marco Resin, and Castolite may be used. For problems in which the body force (weight) is large relative to any externally applied load, such as in the study of earth dams and underground tunnels, gelatin is used. References 43 to 47 discuss materials.

Polariscopes

There are a number of commercial polariscopes available, ranging in price from $600 to $5000. References 41 and 48 to 51 list some sources of supply for polariscopes and one deluxe "home made" model.

The optics for a polariscope are usually purchased although the means for rotating the polaroids by remote control might be constructed by the user. The loading frame should be arranged for controlled application of load by a remote means so that the fringe build-up can be watched. There should also be an arrangement for bringing any point on a loaded model to the optical axis of the polariscope, preferably by controls at the viewing station.

The loading frame for the polariscope used in the Department of Mechanical Engineering at the University of Toronto has a screw thread arrangement giving coarse adjustment for tension, compression, and bending loads, a short stroke hydraulic piston for actual (remote) load application, and a strain gauge dynamometer system that measures only the load applied to the model. It permits a total force of 750 lb. with scale divisions of ½ lb. The loading frame (and model) can be moved horizontally and vertically, by handwheels located at the viewing station, for positioning of the model in the field.

Three Dimensional Stress Analysis

When the loads applied to a flat model are in the plane of the model the significant stresses will also be in that plane, although perpendicular stresses will exist. If the model is thin relative to its general dimensions the principal stresses will remain constant along the path of the light and the fringe pattern will be a true representation of the state of stress. However, if the model has excessive thickness, or if the loads do not lie in one plane, the value of $p-q$ may change along the light path and only an average value is indicated in the fringe pattern. Furthermore, with three dimensional loading the directions of the principal stress planes will vary throughout the body.

On a plane of symmetry in a body the principal stresses must lie in the plane and perpendicular to it. Hence, if this plane is isol-

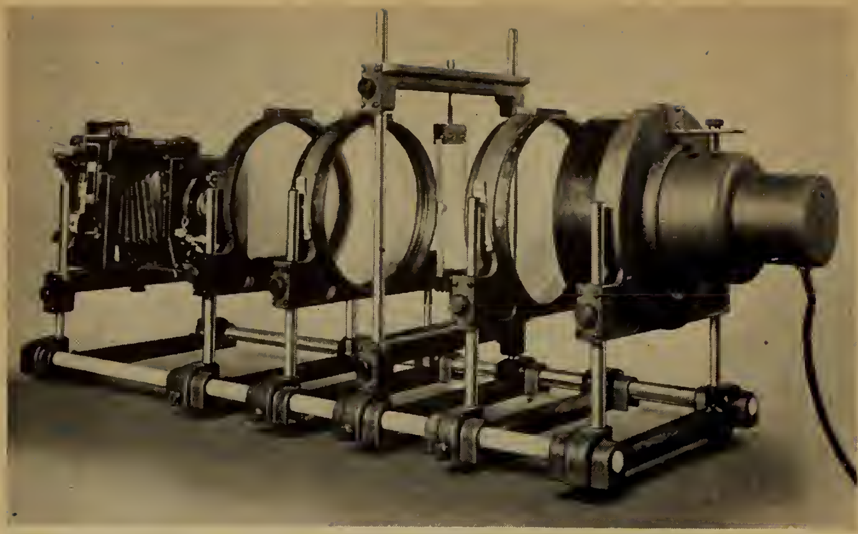

Fig. 9. Polariscope using the Strobolume as light source. Fringe patterns of a beam vibrating at 30 c.p.s. may be obtained. *(Photo.: General Radio Co.)*

ated, it can be examined in a conventional polariscope with the assurance that the observed fringes represent the differences of true principal stresses — those in the plane of symmetry. The principal stresses normal to the plane will not affect the fringe formation and some other approach is required to determine them.

At the surface of a body where no external load is applied one of the principal stresses is zero and the other two are in the surface plane. Again, if this plane could be isolated and examined in the conventional way, the principal stresses would be obtained.

One technique for examining the stresses in a plane using the conventional polariscope is to "freeze" the stresses as described previously and then saw the plane, as a slice, from the model. If the usual machining care is taken to prevent the introduction of machining stress, the frozen stresses will be unchanged by the slicing. A compromise must be made on the thickness of slice taken, since the fringe orders are reduced when the slice is made thinner, so as more nearly to approach uniform conditions in the perpendicular direction. If reduced forces are used to control distortion during stress freezing the highest fringe order in the slice may be only one or two.

A superior material[67] for the stress freezing technique is known as Fosterite. It has a high optical sensitivity, a lack of time edge stress, and is available in cylinders up to 6 inches diameter. The critical temperature is 194° F. so that a minimum freezing temperature of 160° F. is suitable. The University of Toronto oven, which measures 2 x 2 x 2 feet, requires about 200 watts for this temperature. The properties of Fosterite are outlined in references 51 and 52 and summarized in Table I.

Figure 10 shows a Fosterite model in the oven after stress freezing. The model consists of a hub and a flange, joined by a conical web section. With the flange securely bolted, a couple was applied to the hub in the form of horizontal forces acting through wires attached to the hub, passing over ball bearing pulleys and to which weights were attached. Because of the high coefficient of expansion for Fosterite (200×10^{-6} in./in./°C.) the flange was bolted to a Fosterite ring that was supported on thin steel rods to permit free radial movement of the ring. A Fosterite disc bolted to the jig and given the stress freezing cycle showed no stress induced by thermal effects.

The load applied to this model was too high and excessive distortion resulted. A slice from the plane of symmetry, Fig. 11*a*, shows a fringe order of 19 at the outside web fillet. In subsequent tests the load was reduced to keep the maximum fringe number below 10. Figure 11*b* is the same slice photographed 16 months later, showing the lack of time edge stress and no change in the fringe orders.

The slices were carefully sawed from the model and then faced in a lathe, using light cuts with the slice attached to the face plate by double adhesive. No polishing was done, but the slice was placed in a plate glass tank filled with oil of the same refractive index for viewing. In subsequent tests in this project the conical web was pierced with small holes and special techniques were used to obtain the stresses adjacent to

Fig. 10. Fosterite model (hub and flange joined by a conical web section) in the oven after stress freezing.

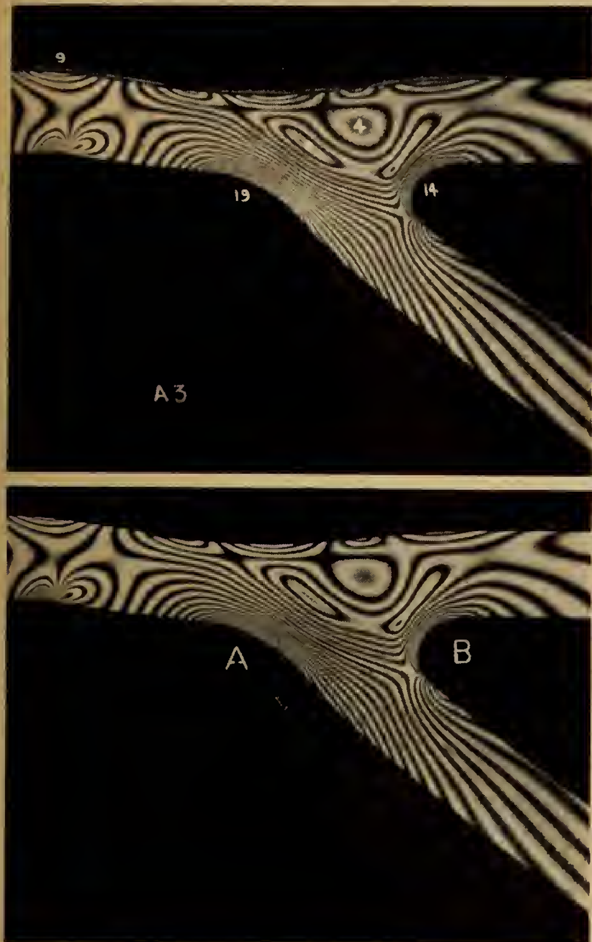

Fig. 11 (left). Slice from the plane of symmetry of the model shown in Fig. 10 showing excessive distortion; (*a*) above, original photograph; (*b*) same slice photographed 16 months later.

Fig. 12 (below). Two Fosterite models used in an analysis of stresses in thick-walled tubes.

path of light and a series of fringes may be observed indicating stress intensity not by fringe order but by fringe spacing. For each retardation the stress intensity is obtained from the fringe spacing d and material constant C as follows:

$$p-q = C/d$$

As the value of $p-q$ increases, the fringe spacing d decreases.

To prevent reflection and refraction at the model boundary it is submerged in a mixture of Halowax and Bayol, compounded to give the same index of refraction as the model material. A high intensity monochromatic light source is used with a polarizer, and a 0.010-inch slit provides the sheet of light. As the intensity of the scattered light is very low a completely darkened room must be used and a photographic exposure

them, but the maximum stress occurred at the hub fillet.

Scattered Light Technique

The problem of examining stresses on a plane can in some cases be handled by the scattered light technique in which a sheet of light is passed through the model instead of actually slicing it[54,55,56]. The light excites the particles of the plastic model so that they become secondary sources of light, of greatly reduced intensity, and may be viewed in a direction perpendicular to the beam. The effect is strongest where the light enters the model and diminishes along its path, particularly after passing through a region of high stress. Using a sheet of plane polarized light, preferably set at 45 degrees from the planes of principal stress, interference due to birefringence takes place along the

of 10 minutes is required with Super Pancro-Press Type B film. Measurement of fringe spacing must be accurately done and for this purpose the University of Toronto Photoelastic Laboratory has a microphotometer that measures light intensity on a spot 0.003-inch diameter. As the photographic film of the fringe pattern is moved with micrometer precision past the eye of the photometer a meter shows the exact centre of the dark fringe. The phototube is so sensitive that it must not be exposed to the bright part of the fringe pattern.

Figure 12 shows two of the Fosterite models used in an analysis of stresses in thick-walled tubes, subjected to axial load and internal pressure, with and without transverse holes. The study was made in connection with the gas

Table I. Properties of Materials Used for Models.

Material	Temp. °F.	Sensitivity p.s.i. per fringe	E p.s.i.	Poisson's Ratio	Creep	Time edge stress
CR-39	Room	75–90	295,000	0.41	medium	small
Catalin 800	Room	45–50	187,000	0.40		medium
	176	1.6	1,500			
BT-61-893	Room	84	630,000	0.36		large
	230	3.2	1,150	0.50		large

tube of an automatic shell ejector[57]. Figure 13 shows the model (A) in the loading frame ready for stress freezing; B is the frame for applying axial load through hook C and attached weight, D is the connection for internal pressure, and E the springs that hold the flange of the model against the bottom plate. A rubber membrane arrangement prevented loss of the hydraulic oil through the perforations, while offering no appreciable restraint on the internal pressure. Figure 14 shows the model in the scattered light polariscope. The letters indicate the high intensity mercury vapour lamp at A, a filter at B, collimating lens at C, polarizer at D, plate glass tank (before filling with Halowax mixture) at E, metal slit at F, and the model in its special holder at G. Fringe patterns were photographed from approximately the same point used to take Fig. 14.

Figure 15a is a scattered light fringe pattern for a transverse plane cutting through the unperforated tube shown at the left in Fig. 12. The tube has not been cut apart in any way, but it does not show in Fig. 15a because it is illuminated only on the transverse plane, the light entering from the left. The pattern frozen in the model resulted from internal pressure and axial load. The fringe *spacing* along the horizontal diameter represents the difference between the axial stress and the tangential stress. An increase in

Fig. 14. Model in scattered light polariscope. A, mercury vapour lamp; B, filter; C, collimator; D, polarizer; E, plate glass tank; F, metal slit; G, model in special holder.

stress intensity toward the inside of the tube is plainly visible. By using other optical sections the three stresses, axial, radial, and tangential, may be found. Figure 15b is a transverse section that was taken tangent to one side of the perforations. Although the holes are not visible in the photograph their effect on the fringe pattern may be clearly seen.

Oblique Incidence

When examining a slice, or a plane stress model, in the transmission polariscope care is usually taken to have all rays in the beam of light perpendicular to the face of the slice. However, for determination of stresses at a given point it is possible to rotate the slice about one of the principal stresses at that point and obtain a new fringe value[58,59]. The method is more difficult and in some cases not applicable for slices that are not from a plane of symmetry, but may be used for boundary stresses, particularly when the directions of principal stresses are known before slicing[60].

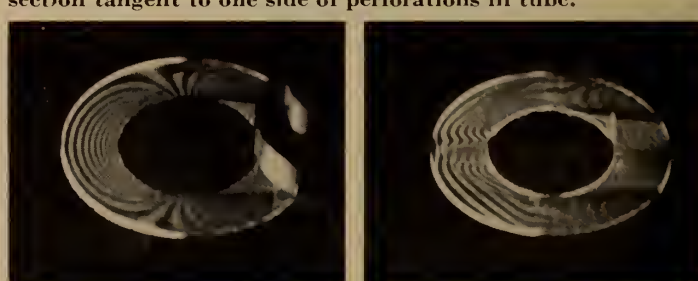
Conclusion

A number of photoelastic techniques have been described briefly and it may be necessary in a complicated stress problem to use a combination of these together with information from the applications of stress coat or strain gauges to a metal model. With careful work and straightforward techniques an accuracy within 5 per cent may be obtained but under questionable conditions the error might be 30 per cent[61]. However, in the latter case it frequently happens that there might be no alternative approach to the stress problem and the photoelastic method is infinitely better than none.

In plane stress work there is no effect on the similarity of stress distribution between model and prototype arising from differences in Poisson's ratio. In three dimensional work, however, these differences have a definite, although usually unknown, effect. In the stress freezing technique the plastics attain a ratio of 0.5 which is significantly different from that of metals, so that attempts have been made to develop three-dimensional room - temperature procedures[62]. However, in the discussion by V. M. Hickson of reference 61, it is pointed out that errors caused by differences in Poisson's ratio are not as significant in the maximum principal stress as in the lesser ones, and that some interpolation might be done between models made of materials having different values of the ratio if the effect became important.

Fortunately many problems can be treated with sufficient accuracy using CR-39 plastic in a transmission polariscope and the speed of this method makes it attractive. In the problem of the gas tube for the automatic ejector it was desirable to have the maximum amount of perforation, for gas discharge, without increasing stress concentration unduly. For this study the tube was considered as a flat plate,

Fig. 15. (a) Left, scattered light fringe pattern for transverse plane through unperforated tube. (b) Pattern for transverse section tangent to one side of perforations in tube.



loaded in compression, with various arrangements of holes in-line and staggered[63]. Figure 16 shows a plate carrying a vertical compression load while Fig. 17 and 18 are enlargements of the in-line and staggered arrangements.

The results of this investigation showed the stress concentration factor for the in-line arrangement remained at about 1.65 as the ratio of hole area to net area increased (closer hole spacing) while the factor for the staggered arrangement rapidly increased with increase of area ratio beyond 0.30.

In the measurement of loads, dynamometer rings are frequently used, with strain gauges cemented on the inside and outside of a metal ring. Since the strain gauge measures the average strain over the area to which it is applied, it is of interest to know the stress gradient along the external and internal surfaces of the ring and if the stress changes sign. The inside and outside gauges are usually connected into opposite arms of a Wheatstone bridge, so that the ratio of average stresses should be known. When the dynamometer ring is small, say two inches outside diameter, it is necessary to know whether a more expensive short gauge should be used or the conventional A-11. Accurate calculation of these stresses is quite tedious but the polariscope provides a very convenient method.

Sometimes stresses exist that are unsuspected until failures begin to appear. For example, there is a surface tension stress adjacent to a large compression contact stress. This stress was the cause of fatigue failures in railroad axles where the car wheels were shrunk to the shaft, until a combination of redesign and artificially induced surface compression stress eliminated the trouble. The tension stress was demonstrated photoelastically by a frozen stress model in reference 39, but it is also shown in Fig. 19, using a plane compression load on CR-39. The 1.8 order fringe at A represents a tension stress of 790 p.s.i. developed by the (average) 2140 p.s.i. compression stress at the contacting surface.

Many stress problems remain that cannot be solved by the photoelastic method; some of these may never attain solution, others await the ingenuity of the photoelastician to devise new or improved techniques. From the examples included in this paper and those given in the bibliography it is evident that in many instances photoelasticity can be of great assistance to the design engineer and that the day is not far off when the polariscope will be a necessary tool, not a luxury.

A Complete Sanitation Program for Metropolitan Toronto

L. B. Allan, M.E.I.C.
Commissioner of Works,
Municipality of Metropolitan Toronto.

Following the establishment of a metropolitan form of government in the Greater Toronto area a master plan was developed to provide adequate water and drainage facilities throughout this area of rapid growth.

In recent years industrial and residential expansion in the metropolitan Toronto area has been spectacular, perhaps as rapid as any city in North America. Since the war, the population of Toronto and its twelve surrounding municipalities has shown an intense growth — from 900,000 to over 1,250,000. Of this increase, very little has occurred within the city proper, but the population of some of the suburban municipalities has more than doubled. For instance, the population of the township of North York increased from 38,000 in 1948 to over 130,000 in March, 1955. The growth in population of the suburban municipalities shows no sign of abating.

Coincident with the rapid expansion of the Toronto area has come a tremendous demand for services of all types, which was one of the compelling reasons necessitating the establishment of a metropolitan form of government in the Greater Toronto area. Paramount in the service requirements was a demand for sewage disposal facilities which it had been demonstrated could not be provided by the individual efforts of the separate municipalities or by reliance upon the process of mutual assistance and cooperation.

The city of Toronto, for example, supplied sewage treatment facilities for the village of Forest Hill and the town of Leaside, and accepted some sanitary drainage from the townships of North York, York and East York, all of whom paid trunk sewer and outlet charges for the accommodation provided. The township of Etobicoke had agreements with the town of Weston, the village of Long Branch, and the Union Sewerage Commission (Mimico and New Toronto) for treatment of sanitary drainage. With the tremendous increase in population in the townships of Etobicoke, Scarborough and North York, shortage of water and sewerage accommodation in these municipalities was particularly severe. At this time the city and the municipalities through agreements endeavoured to give sewer and water accommodation within their ability to cope with the situation.

The problems presented by the above-mentioned conditions, among others, finally became acute and required an immediate remedy. Realizing the problem the city made application to the Ontario Municipal Board for amalgamation of the twelve adjoining suburban municipalities and itself. After a complete and exhaustive investigation of existing conditions the Ontario Municipal Board, in a report signed by its chairman, Lorne Cumming, and its vice-chairman, W. J. Moore, placed its findings and recommendations before the Government of Ontario. These recommendations were used by the Provincial Government as the basis of "Bill 80", which, after receiving Royal assent on April 2, 1953, became "The Municipality of Metropolitan Toronto Act."

The local municipalities which together constitute the new municipality of metropolitan Toronto are shown in Fig. 1 and listed in Table I.

The Municipality of Metropolitan Toronto Act provided that on and after January 1, 1954, responsibility for all sewage treatment within the metropolitan area rested with the new metropolitan corporation, and no member municipality would be permitted after that date to operate, plan, or own any sewage treatment works.

To enable the new corporation to meet its obligations under the act, it additionally provided that, on the date mentioned, all rights and titles to sewage treatment works, sewage pumping stations, and trunk sewers owned by area municipalities or boards thereof, and designated by by-law of the metropolitan council, were to be transferred to the municipality of metropolitan Toronto, which, along with the physical structures, assumed all outstanding debt, and all rights or obligations imparted by existing agreements, easements, etc.

One of the first steps taken by the new administration was the engagement of a firm of consulting engineers to present recommendations for a master plan to provide the much needed water and drainage facilities throughout the metropolitan area, in as orderly a fashion as possible, and in a manner that would keep the works program within the financial ability of the metropolitan corporation. On January 30, 1954, the firm of Gore and Storrie presented its report to the metropolitan works committee, which forwarded it to the metropolitan council, embodying a priority list for the works as recommended by the commissioner of works.

Existing System

Most of the existing sewers in the metropolitan area are of the

Read at the 69th Annual General and Professional Meeting of The Engineering Institute of Canada, Toronto, May 1955.

combined type, in which the sanitary and industrial wastes and surface water are collected and carried away together in the same sewers. The construction of sewers of sufficient capacity to carry the combined storm and sanitary flow to a single point of disposal is not economically feasible and, consequently, the usual practice is to convey an amount equal to 2½ times the normal dry weather flow to the sewage treatment plant, and to discharge the remainder of the flow to nearby watercourses or lakes.

In metropolitan Toronto there are many watercourses into which storm flow may be discharged without nuisance, but many of them are so small that the overflow from a combined sewer system would be objectionable because of pollution carried into the streams during such overflow periods. Accordingly, metropolitan Toronto has adopted the policy that in the future all sewers in the area will be separate, i.e., sanitary sewage is carried in one set of sewers and storm water runoff in another. Coupled with the resulting improvement in stream conditions will be the saving in the size of sewage treatment plant facilities, with the elimination of the extra 150 per cent load delivered to the plants by combined sewers designed to intercept 2½-times dry weather flow.

Table I. Municipalities Constituting Metropolitan Toronto

Municipality	Area Acres	Area Sq. Miles	Population March, 1955
City of Toronto	22,287	34.82	682,415
Township of York	5,050	7.89	106,695
Township of East York	3,747	5.85	68,812
Township of North York	44,588	69.65	130,766
Township of Scarborough	45,012	70.33	95,706
Township of Etobicoke	27,312	42.67	83,169

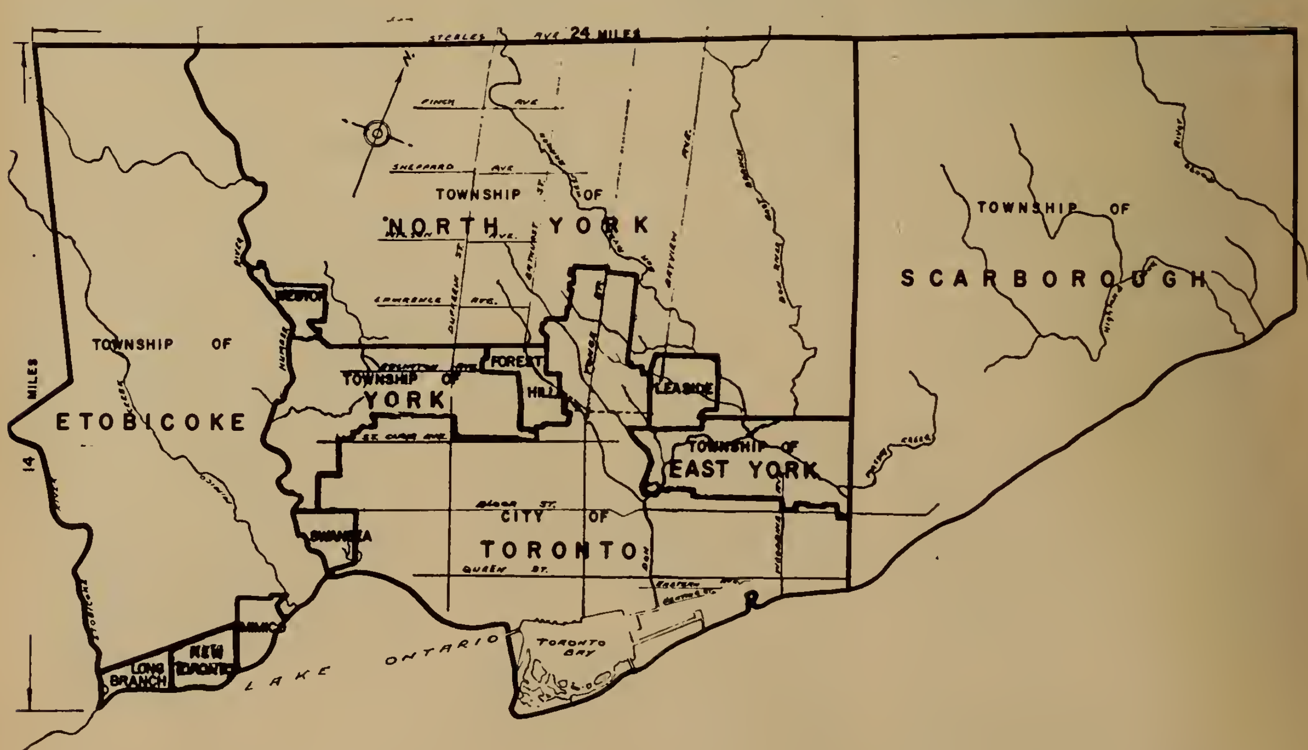
Town of Mimico	500	.78	12,383
Town of Leaside	1,126	1.75	16,873
Town of Weston	622	.97	8,569
Village of Forest Hill	739	1.15	18,664
Village of Swansea	682	1.06	8,718
Village of Long Branch	750	1.17	9,263
Totals	153,074	239.11	1,251,840

Prior to formation of the metropolitan corporation, proper engineering design of sewer systems was, in many cases, not possible because of artificial municipal boundaries. Where joint services were required, neighbouring municipalities often could not find a basis for determination of responsibility; down-stream communities, whose treatment facilities already were inadequate or overloaded, were obliged to refuse sanitary drainage from their up-stream neighbours and sewers in areas which provided natural outlets for storm drainage from up-stream communities were inadequate to serve the neighbour, so that some up-stream areas bordering heavily developed sections down-stream became virtually impossible to drain from an economic standpoint. In short, no long-range view was possible and the end result is the existence of a non-integrated system; sewers in one municipality draining large areas toward another municipality, and into which they logically should continue to flow, instead are intercepted by pumping stations, or a series of pumping stations, which pump the flow back, often by long and complicated systems, to a sewage treatment plant upstream. In many cases the plant effluent then flows back in an open stream often through the municipality which originally refused to accept the sewage. This condition cannot be corrected immediately but will gradually be improved with the construction of a metropolitan sys-

Fig. 1. Municipal boundaries of Metropolitan Toronto.



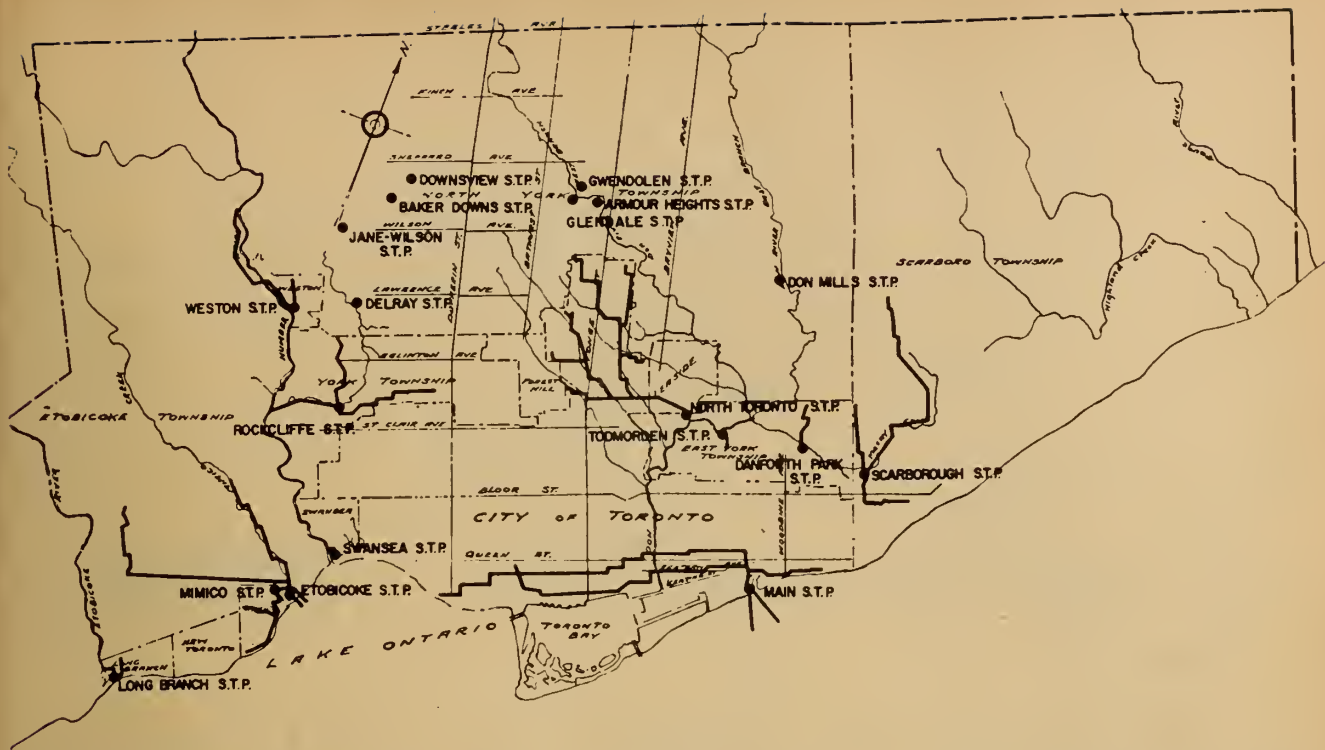


Fig. 2. Existing trunk sewers and sewage treatment plants.

tem designed to serve all areas with equal and adequate facilities.

Existing Sewage Treatment Plants

There are nineteen sewage treatment plants within the borders of metropolitan Toronto, as indicated in Fig. 2. A list of these plants is given in Table II.

The foregoing plants, with the exception of the R.C.A.F. plant at Downsview, and the Don Mills plant, were assumed by Metropolitan Toronto By-Law No. 36 on January 1, 1954, as authorized by the Municipality of Metropolitan Toronto Act. The other two plants were not assumed as they were not owned by an area municipality at the time the by-law was passed.

All of the above-mentioned treatment plants, with the exception of Weston, are of the activated-sludge type, the latter being a bio-filtration installation. The main plant, at the moment, provides primary sewage treatment only, with the second stage, i.e., installation of aeration tanks, secondary settling tanks, etc., at present under design.

Sewage may be broadly defined as "water-carried wastes", and its character depends upon the relative amount of water and the composition of wastes. Wastes from residential and commercial areas do not vary a great deal in composition or in quantity per capita. Wastes from industrial establishments, however, may vary a great deal.

Sewage treatment consists essentially of the removal of the wastes from the sewage so that its water content, which is used as the carrier of the wastes, can be safely discharged into the receiving waters. There are numerous processes involved in the treatment of sewage, and the degree of treatment to be accomplished depends upon the processes or the combination of processes utilized. Primary treatment consists of the removal of the heavier solids from the sewage, usually by means of screening, settling of grit, and sedimentation. Secondary treatment consists of the removal of the finer solids and colloidal matter and is generally accomplished by means of a bacteriological process involving oxidation and sedimentation. Treatment plants of the primary type remove 50 to 55 per cent of the suspended solids and about 35 per cent of the biochemical oxygen demand. Secondary treatment plants can accomplish reductions of 90 per cent or more.

In addition to the treatment of the sewage to provide a good effluent for discharge into the lake or stream, provision must be made for the disposal of the wastes as they are removed from the sewage. The first step is usually anaerobic digestion in heated tanks which reduces the solids by 45 to

Table II. Sewage Treatment Plants in Metropolitan Toronto

Name of Plant	Capacity (M.g.d.)	Constructed by	Location

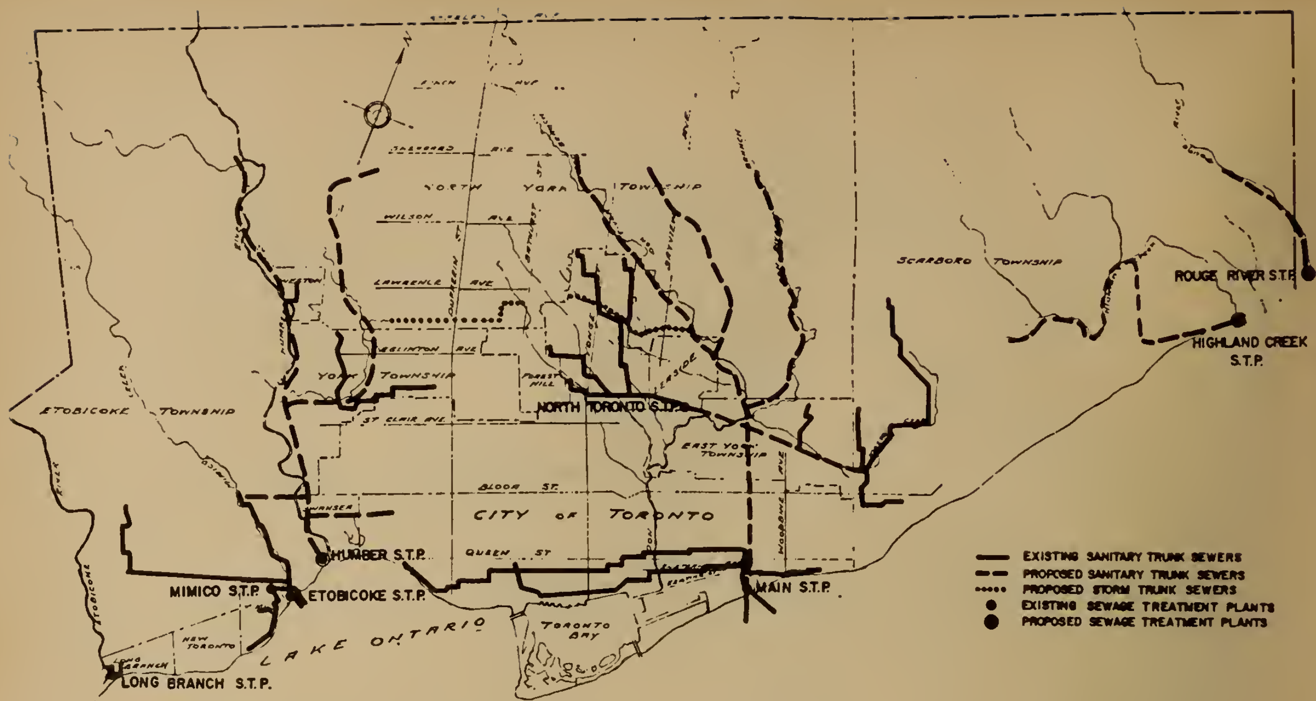

Fig. 3. Ultimate trunk sewers and sewage treatment plants.

50 per cent. The digested sludge can then be dewatered on vacuum filters, heat dried and disposed of as a fertilizer, or burned.

A treatment plant with secondary treatment to serve a population of one million persons will produce daily about 2,500 tons of raw sludge, 1,250 tons of digested sludge, 500 tons of sludge as dewatered on vacuum filters, 135 tons if heat dried, or, if burned, 25 tons of ash. It is quite apparent that the volume of wet sludge, even if digested, is great and if not hauled to farms and deposited on the land, requires that drying or incineration facilities be provided. The main sewage treatment plant at Ashbridge's Bay has facilities for either burning or heat drying the sludge.

The provision of complete treatment of the sewage to remove 95 per cent or more of the suspended solids and biochemical oxygen demand, together with chlorination of the effluent is planned for the main treatment plants to serve the metropolitan area.

The construction of eight treatment plants in the township of North York, as listed in Table II, scattered as they are over an area approximately double that of the city of Toronto, has served a useful purpose, but does not constitute a permanent solution for the disposal of sewage in that area of metropolitan Toronto. These plants have been constructed with a minimum of expense, on the understanding that eventually they would be abandoned and the sewage conveyed to adequate plants near the shore of Lake Ontario. In all cases, they are located in the river valleys, which will enable them to be taken out of service when sanitary intercepter sewers are installed in those valleys. The reason for the construction of numerous small plants was the pressure of development over a wide area. Some of them were installed and paid for by land subdividers since they were less objectionable and less expensive than individual septic tanks, which would have been the alternative in an unsewered area.

Sewage Treatment in the Future

The main sewage treatment plant at Ashbridge's Bay, which provides only primary treatment at present, was constructed with the approval of the Ontario Department of Health, which body directed that the installation of secondary treatment facilities must be commenced within four years of the time the primary plant was completed. Consulting engineers have now been engaged by metropolitan Toronto to prepare plans for the immediate construction of this second stage, and extension of the sea wall protecting the site from Lake Ontario is presently underway at an estimated cost of $200,000.

The main plant will be enlarged eventually to serve a population of one million persons, with a dry-weather flow capacity of some 120 million gallons per day. This plant will serve the entire Don River watershed within the metropolitan Toronto limits, except for a small portion of the flow which will continue to be treated at the North Toronto sewage treatment plant.

To serve residents in the Humber River and Mimico Creek watersheds, construction of a sewage treatment plant near the mouth of the Humber River has been recommended.

This plant will finally receive sewage from the village of Swan-

Table III. Current Authorized Sewage Treatment Projects.

Plant	Estimated Cost	Work to Start
Main Plant	$26,000,000	1954
Humber Plant	14,000,000	1954
Highland Creek Plant	12,000,000	1954
Mimico Plant (Addition)	300,000	1954
Rockcliffe Plant (Temporary Addition)	175,000	1954
Weston Plant (Temporary Addition)	125,000	1954
Long Branch Plant	1,000,000	1955
North Toronto Plant (Vacuum Drying)	400,000	1955
Etobicoke Plant (Addition)	1,000,000	1955
TOTAL	$55,000,000	

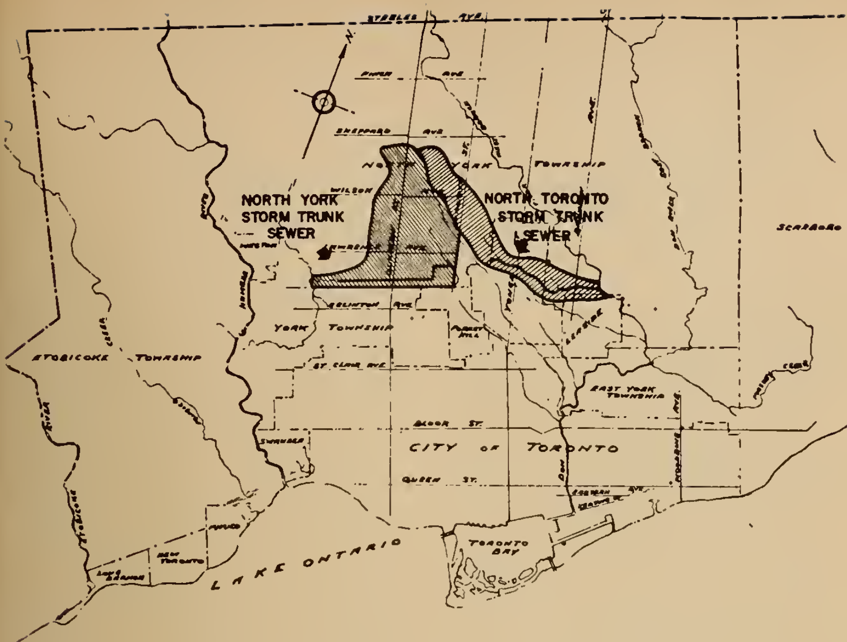

Fig. 4. Storm trunk sewer construction.

sea, the township of York, that part of the township of North York west of a height of land in the vicinity of Dufferin Street, the greater part of the township of Etobicoke, and a section of the westerly part of the city of Toronto, presently draining to the main plant at Ashbridge's Bay. Ultimately, it is expected that the plant will have a capacity of 87.5 million gallons per day, and serve a population of 800,000.

The North Toronto plant will be continued in operation, with its present overload relieved by construction of a sewer link to the interceptor leading to the main plant. Modern sludge handling equipment will be installed to relieve a serious situation developing at present with regard to disposal of sludge.

A third major plant will be constructed at the mouth of the Highland Creek, at the easterly end of the township of Scarborough. It will ultimately serve an area of some 23,000 acres, including the land assembly area at Malvern. Construction of this plant is now underway, with the initial unit designed to provide complete treatment for four million gallons of sewage per day. It is expected that its capacity will have to be doubled in a very short time, and that further enlargements will be made as development of its drainage area proceeds.

A further plant at the mouth of the Rouge River may be constructed at some date in the future, to serve Pickering township, to the east of Scarborough, and a small part of metropolitan Toronto.

The following plants will remain in service for a number of years, with possibly some expansion of facilities: Etobicoke, Glendale, Weston, Mimico, and Rockcliffe.

The Long Branch plant is severely overloaded, and consideration is being given to its improvement or its abandonment, and construction of an entirely new plant, probably in conjunction with the township of Toronto, which adjoins metropolitan Toronto on the west, to serve the lower Etobicoke Creek valley.

Table III outlines current sewage treatment projects, as authorized and given priority by the Metropolitan Toronto Council.

Table IV. Extensions to Trunk Sewers.

Sewer	Estimated Cost	Work to Start
Highland Creek Trunk	$ 7,000,000	1954
Black Creek Trunk	1,400,000	1954
Humber River Trunk	2,800,000	1954
Coxwell Trunk	2,800,000	1954
Humber Valley Trunk	500,000	1954
Etobicoke Trunk	1,250,000	1956
Massey Creek Trunk	740,000	1957
West Branch Don River Trunk	2,100,000	1956
Don River Trunk	510,000	1959
Wilket Creek Trunk	900,000	1956
High Park Trunk	450,000	1960
East Branch Don River Trunk	2,526,000	1956
TOTAL	$22,976,000	

Metropolitan Trunk Sewer System

On July 1, 1954, metropolitan Toronto, under by-law No. 144, assumed control of trunk sewers indicated on Fig. 2, asserting powers vested in it by the Municipality of Metropolitan Toronto Act. As may be seen from the plan, most sewers which drained sewage from a neighbouring municipality were assumed by the metropolitan corporation, in an attempt to eliminate one difficulty which past experience had indicated would stifle development. Other major interceptors were assumed on the basis of the area served by the sewer. Because of the combination of sanitary and combined systems in the area, as pointed out earlier in this paper, it was not possible simply to classify every sewer above a certain diameter as a trunk sewer. Careful consideration was given to this problem before the decision was reached as to which sewers would be classified as metropolitan trunks, and consultations were held with the municipal engineers of each of the area municipalities.

Plans for the extension of the trunk system are now well advanced, and in some instances, construction is under way. Figure 3 illustrates the proposed interceptor sewer extensions, which will, in the main, follow the river valleys.

Table IV lists the various projects and their value.

The Highland Creek trunk is at present nearing completion, having been designed by the township of Scarborough, engineering department, and checked by the metropolitan works department. It is expected to extend from the new plant at the mouth of Highland Creek to Brimley Road and Lawrence Avenue, early in 1956.

The Black Creek trunk, which extends from our Rockcliffe sewage treatment plant to our Baker Downs sewage treatment plant, along the valley of Black Creek, is now well advanced in the planning stage. Preliminary surveys are complete, soil boring work has been carried out, and will be further extended in the near future. Construction will be well advanced by the end of 1956.

The Humber River trunk sewer, extending from the river mouth to a point near Lambton golf course will be started early in 1956.

The Coxwell trunk extending from the main plant at Ashbridge's Bay northerly to the Don River in East York has been turned over for design to consulting engineers. Soil investigations are currently in progress for this 96-inch diameter sewer, which is proposed to be constructed in tunnel, at depths up to 160 feet below surface level. Experts in soil mechanics have been engaged to interpret the findings of the drilling contractor, in order to advise the proper structural design, and to predict the method of tunnelling most likely to be found necessary. Tenders are to be invited shortly.

The Humber Valley trunk, authorized for 1954 commencement, is now completed, and extends sanitary drainage facilities some 1½ miles northerly along the Humber River from a point south of Summerlea golf course. Temporarily, sewage from the area served by this sewer will be treated at our Weston sewage treatment plant.

The Etobicoke trunk is a northerly extension of the Humber River trunk, and will extend from Lambton golf course to a point north of the town of Weston.

The next four projects in the list, the Massey Creek, the West Don River, the Don River and the Wilket Creek trunks, as well as the East Don River trunk, form the Don River drainage system, radiating out from the northern terminus of the Coxwell trunk sewer. Their design and construction will follow commencement of the Coxwell trunk, which provides their outlet and a connection with the main sewage treatment plant. The East Don trunk, however, has been advanced to 1955. In a recent decision, the metropolitan council refused to permit further development of small sewage treatment plants proposed by subdividers, and proposed instead the immediate installation of the permanent trunk sewer. This interceptor will provide a drainage outlet for 15,000 acres in the township of North York.

The High Park trunk is designed to intercept flow from the northwest section of the city of Toronto, and may drain an area of approximately 2,500 acres. Its construction is set for the future, after preliminary development of the Humber plant.

Storm Drainage

As authorized by metropolitan council, storm projects are:

Project	Estimated Cost	Work to Start
Open Creek Channel...	$1,000,000	1954
North Toronto Trunk..	1,100,000	1954
North York Trunk.....	2,000,000	1954

As yet, the metropolitan corporation has not assumed any storm sewers as such, preferring to give the matter careful study before making a decision. Because of their purpose, storm sewers tend to be larger, and more costly, than sanitary trunks. Therefore, metropolitan Toronto will try to keep all sizeable watercourses open within the newly expanding areas, to avoid capital cost of construction of these large sewers at the present time. However, two major storm drainage projects are included in metropolitan Toronto's works program. Areas drained are outlined on Fig. 4. Both sewers are urgently required to permit development of a considerable area of the township of North York.

The North Toronto storm trunk will remove storm water from the North Toronto combined sewer system, and thus relieve the North Toronto sewage treatment plant. Several creeks are to be intercepted at the point where they enter the present North Toronto system and be diverted along a former creek bed by open channel and by piping where necessary. It is hoped to make it an attractive feature of the city of Toronto's parks system by the use of proper landscaping. Work is now under way on this project. The removal of creek water from the North Toronto trunk system will create capacity in those sewers for draining sanitary sewage from a large area of North York.

The North York storm trunk will intercept a number of creeks at present flowing from North York into York township, the village of Forest Hill, and the city of Toronto, and discharge the flow to Black Creek, a tributary of the Humber River. Major relief will be given to overloaded sewers in York township and Forest Hill by this project. Three contracts have already been awarded on this work.

Another function which was given to metropolitan Toronto under the act was the supervision of design, construction and maintenance of all works draining to metropolitan watercourses, trunk sewers, or sewage treatment plants. As a result, during the period since January 1, 1954, all thirteen area municipalities have submitted plans of proposed drainage works to the metropolitan administration for approval of design and financing. The chief advantage is the establishment of uniformity throughout the area in sewer design, as well as an overall control of expenditure which maintains metropolitan Toronto's splendid financial position. Construction standards have been left to the area municipalities to enforce, for a large inspection staff would be required to oversee all works in the area and in all cases the various municipalities have well trained and experienced personnel.

Associated with the foregoing, all new land subdivisions are reviewed for the metropolitan Toronto planning board and a report made about availability of sanitary drainage and treatment facilities. Recommendations and comment are also made on surface drainage requirements.

In the field of industrial waste, regular inspection of abattoirs, tanneries, refineries, soap works, etc., are made.

In conclusion, a brief summation of the points brought out by this paper might be in order. We have seen that the Toronto area is one of the fastest expanding districts in North America; that the rapid expansion is creating tremendous difficulties in many fields of public services, particularly water supply, drainage and sewage treatment, and transportation. Because the city of Toronto and its suburbs were experiencing difficulty in finding the way to provide the area with the services it needed, the municipality of metropolitan Toronto came into being.

Metropolitan Toronto at once engaged competent experts to set out a master plan for the provision of the services, with the financial resources of the entire area now available to back the debenture debt which must be assumed to pay for them.

(*Continued on page 36*)

Radar Echoes from the Aurora and the use of Doppler Techniques

A. G. McNamara,
National Research Council,
Radio and Engineering Division.

The history of radio reflections from aurora is quite young. In Norway in 1940, Harang first observed unusual echoes at times of aurora using a frequency of 40 Mc/s. These "aurora echoes" occurred at frequencies at which normal ionospheric echoes could no longer be obtained, i.e. in the VHF range, from 30 Mc/s. to several hundred megacycles.

World war II saw the advent of high-power VHF radar, and after the war some of this equipment became available for research purposes. Since then, auroral radar studies have been pursued strongly in Canada, Norway, and the United States and in England. At Saskatoon, where visual studies have been carried on for many years, radar observations of aurora were begun by Currie, Forsyth and Vawter in 1948.

The Aurora

Canada is very well situated for auroral observations as may be seen by referring to the map (Fig. 1). The auroral zone is the region in which the visible auroral occurrence is most frequent. This zone is a roughly circular annulus of about 23° radius centred at the geomagnetic pole. The geomagnetic pole, which is defined by the main part of the earth's external magnetic field, is not coincident with the magnetic dip pole, but is actually situated near Thule in Greenland. The magnetic control of auroral occurrence arises because the high speed particles which enter the atmosphere to produce the aurora, are charged particles and hence are constrained to follow certain paths.

The high-speed primary particles strike the air molecules during their passage through the atmosphere and excite and ionize them. The visible light which is emitted is called the aurora. The lower edge of auroral arcs and bands are remarkably constant in height — some 94 per cent of all auroras lie between 90 and 130 km. above the earth, the most frequent height being 108 km. (100 km. = 62 miles.)

The ionized particles within the aurora are mainly positive ions of oxygen and nitrogen and (negative) electrons. The index of refraction of a medium is modified by the presence of free charged particles. This effect can be very pronounced at radio frequencies with the charge densities encountered in the ionosphere. The index of refraction (in the absence of an external magnetic field) is given by

$$n = \sqrt{1 - \frac{Ne^2}{\pi m f^2}} \quad \ldots\ldots\ldots (1)$$

where e = the electric charge of the ion.
m = the mass of the ion.
f = the frequency of the electromagnetic wave.
N = the number density of the ions.

From equation 1 it is apparent that the deviation from free-space propagation is inversely proportional to the mass of the ions present. Hence, since the positive ions are of the order of 30,000 times the mass of the electrons, the interaction with the electromagnetic wave will be due almost entirely to the free electrons.

Actually the reflection process is complicated by further considerations such as the size of the electron cloud relative to the wave length employed, the density of the cloud, the density gradient within the cloud, the geometrical shape of the cloud, and its orientation with respect to the transmitter and the receiver.

The author discusses the theories of radio reflection from the aurora, which has been studied extensively by radar and Doppler techniques only in very recent years. It is concluded that auroral radar observations can provide information not only about the aurora itself, but also about the physics of the upper atmosphere and radio propagation in the ionosphere.

A critical reflection process, similar to that which occurs at normal ionospheric layers, has been supported by Currie and Forsyth to account for auroral echoes. If the electron density becomes sufficiently high to reduce the refractive index, n, to zero or to negative values, then the wave cannot penetrate the ionized region and total reflection occurs. This is called the critical electron density and its value may be found from equation 1. The condition is that

$$\frac{Ne^2}{\pi mf^2} \geqslant 1 \ldots\ldots\ldots\ldots\ldots\ldots (2)$$

or, the limiting critical density is

$$N_c = \frac{\pi mf^2}{e^2} = 1.24 \times 10^{-8} f^2 \ldots . (3)$$

If this reflection process is assumed to be valid, the reflection of 106 Mc/s. waves implies an electron density of 1.4×10^8 electrons/cm^3., at least within small volumes of the aurora. This value may be compared with the normal maximum electron density of the E-layer which is of the order of 10^5 electrons/cm^3.

The first VHF radar equipment operated at Saskatoon produced 50-kilowatt 35-microsecond pulses at 106 Mc/s. with a highly directional antenna. Later, a similar radar on 56 Mc/s. was added to permit dual frequency operation. More recently, a 196 Mc/s. set and a 91 Mc/s. Doppler radar have also been employed.

In Ottawa several years ago, during the course of the National Research Council's meteor radar program, auroral echoes were observed several times with the 200-kw. meteor radar operating at 33 Mc/s.

Figure 2 shows the observed distribution of echoes obtained at Saskatoon, corrected to take account of the variation of auroral occurrence with position. The presence of the maxima and minima are due largely to the lobe structure of the radar beam. Superimposed is a curve representing the theoretical distribution (for a height of reflection of 105 km.) which would be expected. In azimuth, the maximum echo occurrence is centered at geomagnetic north.

A vitally important observational fact is indicated in Fig. 2. Echoes cannot be obtained, even from the most intense auroras, when they are at high angles of elevation from the radar station. With the VHF radars at Saskatoon, echoes have never been obtained from aurora at elevation angles greater than about 18 or 20 degrees. This strong "attenuation" effect is clearly shown in Fig. 2 by the deficiency of echoes in the second lobe.

Figure 3 gives a graphical description of the echo geometry, showing how echoes are obtained at ranges of 350 to 1150 km. Angle-of-arrival experiments at Saskatoon have shown that the reflecting regions lie in a thin layer of very constant height at about 105 km. This height agrees closely with the lower border of most visible auroral forms. The orientation of the main part of the earth's field (the dipole field) is also shown. It is along these lines of magnetic force that the incoming primary high speed charged particles travel.

Fig. 1. Canada is well situated for auroral observations, as indicated by this map, which shows the auroral zone, in which visible auroral occurrence is most frequent. The relative positions of the geomagnetic, magnetic dip, and geographic poles are also shown.

At present there are three entirely different theories of the reflection process which attempt to explain the absence of echoes at high angles. These may be described as (1) the ground scatter theory, (2) the coherent scatter theory, and (3) the absorption theory. Harang, in Norway, has proposed that a forward reflection occurs to the ground via sporadic E-type clouds of ionization which are associated with auroral disturbances. The radiation strikes the ground and some of it is scattered back over the same path to the transmitter. In a manner analogous to oblique ionospheric reflection at lower frequencies, the ionized clouds will only reflect waves of a given frequency when the product of the critical frequency of the cloud and the secant of the angle of incidence on the lower surface of the horizontally stratified cloud is equal to or greater than the frequency of the wave employed. By the angle-of-arrival measurements at Saskatoon, we have shown that

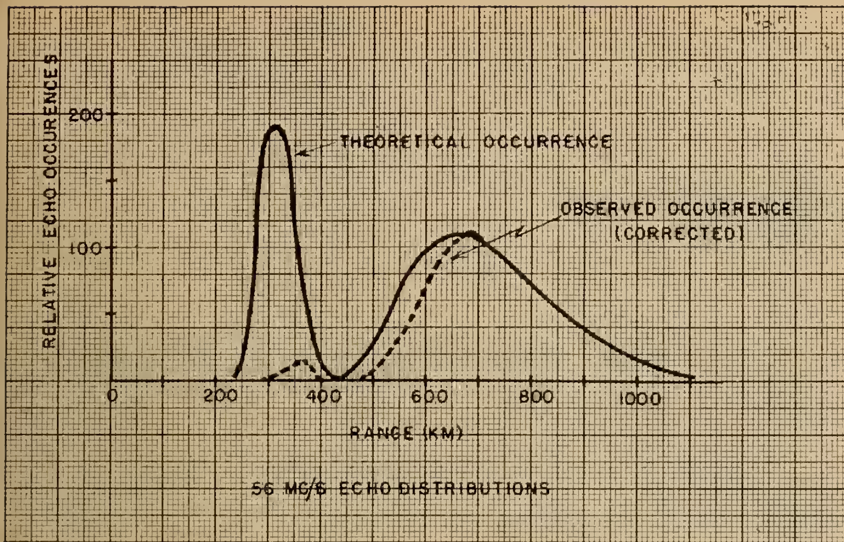

Fig. 2. Observed distribution of radar echoes obtained at Saskatoon.

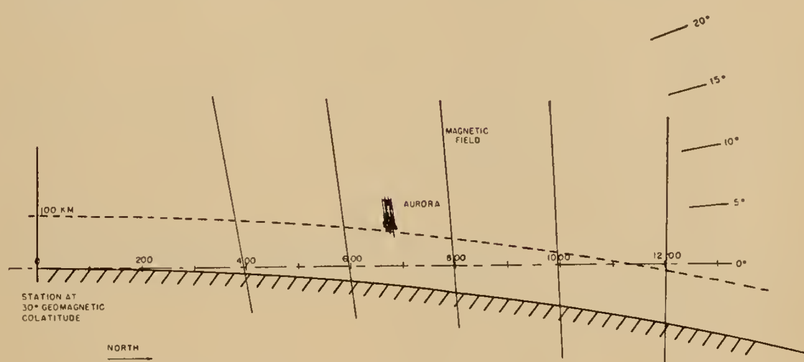

Fig. 3. The geometry of auroral radar reflections.

the echoes observed at Saskatoon do not arise by such a process, but rather are the result of direct reflections from ionospheric regions.

The other two reflection processes involve direct reflection. The coherent scatter theory of Moore and Booker assumes that the auroral ionization is in the form of long trails oriented along the lines of the magnetic field. Furthermore it is assumed that the ionization density is less than the critical value. When the radiation is incident normally upon these trails, the reflected signal is enormously enhanced by virtue of coherent re-radiation by all the electrons in the trail. This perpendicularity condition can only be satisfied in certain regions northward of the radar station.

The absorption theory, proposed by Forsyth and Currie, postulates that a strongly absorbing region must exist below each reflecting centre, and that the re-radiation pattern of the electron clouds is omnidirectional. At low angles of elevation, the radio waves can pass above the absorbing region and meet the reflecting cloud. At higher angles, the waves must pass through the absorbing region and are lost.

At present the observational evidence seems inadequate to exclude one or the other of the latter two theories.

Doppler Techniques

A new line of radio investigation of auroral reflections has been employed within the past few years. This is based upon the use of Doppler radar techniques. With this type of apparatus, a signal is transmitted whose frequency and phase are accurately controlled by a continuously-running precision crystal oscillator. The returning echo signal is mixed with this reference frequency in the receiver. If the two differ in frequency, their beat note emerges from the receiver as an audio frequency note which is the Doppler shift. If the frequency shift of the transmitted radiation is produced by a moving target, the Doppler beat is related to the radial velocity component of the target by

$$f_D = \frac{2v}{\lambda} \quad \ldots\ldots\ldots\ldots\ldots\ldots (4)$$

where λ is the radio frequency wavelength.

In the apparatus employed, $\lambda =$ 3.31 metres (90.7 Mc/s.) and hence

$$v = 1.65\ f_D \quad \text{metres/sec.} \ldots\ldots (5)$$

This radar was actually a "double-Doppler" radar in which two coherent detectors are supplied with two reference signals phased at 90 degrees. The phase relation of the resulting two audio output signals indicates the direction of motion of the target, i.e., whether the Doppler shift is positive or negative.

To record and analyze the signals returned from the aurora, a spectrum analyzer was designed to display the spectrum of the echoes in a form suitable for rapid recording. A sideband separator circuit differentiates between the positive and negative Doppler components and directs them toward their respective bank of five tuned audio circuits. The centre frequencies of the five tuned amplifiers in each bank are staggered uniformly across the audio passband. The outputs of the tuned amplifiers are rectified and applied to individual milliammeters which are photographed simultaneously by a single-frame electrically-operated camera. The meter readings are used to plot graphs showing the spectra of the signals.

The spectra obtained exhibit two types of frequency shift. Firstly, the transmitted spectral line is broadened, more or less symmetrically, to widths of from fifty to perhaps several hundred cycles. The widths may be correlated with theoretical deductions about turbulence, target duration, or expansion and collapse of ionized surfaces under the action of diffusion and recombination. Secondly, *en masse* shifts of the spectrum are observed which can be correlated with the movements of the entire auroral formation.

Conclusion

In conclusion, it may be stated that auroral radar observations can provide not only information about the occurrence, structure, and origin of aurora, but also about the physics of the upper atmosphere and radio propagation in the ionosphere. √

DISCUSSION

. . . of Technical Papers

The Tide and the Crisis

By G. E. Hall, President, University of Western Ontario, London, Ont.
***The Engineering Journal*, December 1955 issue, page 1671**

K. F. Tupper, M.E.I.C.[1]

Dr. Hall has pointed out very clearly the situation which will arise in just a few years' time. He has also referred to the various ways in which the situation may be met, which are three in number.

The first way is by exclusion. We can keep the would-be university students out. This can be done by raising admission standards, by setting admission quotas, by raising tuition fees, or by some combination of these methods. I share Dr. Hall's emphatically stated opinion that excluding students is not an acceptable solution.

The second way is by dilution. We can revert again to the position which prevailed between 1945 and 1950 when universities had too many students and not enough teachers. This way is also not an acceptable one. When I was a student at the University of Toronto the ratio of students to professors in the faculty of applied science and engineering was about 23:1. For many years during that period the ratio was near this value. During the period of post-war veteran "bulge" the ratio of students to professors rose beyond 100:1. At that time we had the almost ridiculous situation that students were receiving lectures in classes of 1100 using Convocation Hall as a lecture room. I submit that that was a poor way to carry on university teaching. We were forced to do it with the veterans, but it will not do as a way of meeting the situation which lies ahead.

The third way is by expansion. We can augment and expand our institutions of higher education. I do hope that this will be the chosen course. I also hope that we will recognize the necessity of increasing the number of such institutions. I am convinced that there is a size beyond which a university should not grow. Some of our universities may already have reached this size. While quotas restricting the number of students in an institution may be bad for society they may be good from the point of view of the institution. If I am right, even in part, then we must give every encouragement to the establishment of new colleges and to the growth of the smaller ones which have been started in recent years.

I was interested in Dr. Hall's suggestion that there might be more direct support of universities by industry. I think it is essential that universities should receive their financial support from as many sources as possible. Only in this way will it be possible for them to maintain the freedom which is essential for their healthy existence. I express the hope that the support of universities will not fall by default wholly into the hands of government. There is a real danger of this, in which case higher education would become another branch of the civil service. Universities need income from fees, they need bequests, they need gifts from industry and from living individuals.

Photoelasticity for Design Improvement

by

I. W. Smith, Associate Professor of Mechanical Engineering, University of Toronto.

***The Engineering Journal*, January 1956 issue, page 15.**

T. R. Loudon, M.E.I.C.[1]

May I congratulate Prof. Smith on his very clear and concise description of the photoelastic method. This method is an excellent addition to ordinary stress calculations. There are many cases of stress concentrations which can only be solved by photoelastic analysis.

I have used this method for the past thirty-two years and I have always wondered why it is not used more by manufacturers. My own conclusion is that those who insist upon giving the impression that the method entails some deep mathematical solutions are to blame for creating the wrong impression.

Any engineer who has a good university training can operate the method quite easily.

Dr. W. Shelson, M.E.I.C.[2]

The fundamental stress-optic laws were established just over a century ago by Neumann, Maxwell and Wertheim, but the application of this remarkably effective aid to structural analysis has not yet attained the widespread use that is its due. Thus, in presenting this illuminating and comprehensive review of photoelastic stress analysis, Professor Smith

[1] Engineering, The De Havilland Aircraft of Canada Limited, Toronto.

[2] Hydro-Electric Power Commission of Ontario, Toronto.

has made an important contribution towards the wider acceptance of this technique by underscoring both its usefulness and flexibility.

Any reader of this paper will undoubtedly realize from the many photoelastic methods and techniques described that this field is not one that can be easily mastered. What may not be as evident is that a knowledge of photoelasticity alone is an entirely inadequate basis for the solution of the structural problems confronting the designer. The competent photoelastician must have, in addition to photoelastic "know-how", a thorough grounding in the mathematical theory of elasticity, strength of materials including theories of failure, physical and geometrical optics, and a modicum of chemistry relative to plastics. Above all, photoelastician must be aware of conventional mechanical and structural design, and keenly cognizant of the complexity of the designer's task. Perhaps, the relatively slow application in industry of photoelastic analysis has, to a considerable extent, been the result of a lack of engineers with the necessary training for this demanding work.

I would like to make some specific comments on matters dealt with in this paper. Professor Smith notes that initial stresses may exist in the model before any load is applied, and that these initial stresses may be determined and the final fringe pattern adjusted accordingly. It will be realized that simple algebraic subtraction of fringe orders may lead to inaccuracies unless the directions of the stresses prior to and after loading are identical. It is likely too that part of the initial fringe pattern is not due to stresses, but is the result of inhomogeneities in the material. This may account for the incomplete effectiveness of annealing procedures in removing the initial fringe pattern.

The paper refers also to the use of photoelastic stress analysis in vibratory and impact studies. In view of the present limited knowledge of the precise significance of the fringe pattern under dynamic conditions, the use of photoelastic analysis in such cases would appear to be inadvisable except for research purposes.

Most engineers are probably unaware of the use of photoelasticity in three-dimensional problems, and this paper clearly reveals the essential features of this fascinating development. The difficulties in obtaining similitude when Poisson's ratio is one-half are well brought out. The comment by Hickson in reference (61), mentioned by the author, that "the errors caused by differences in Poisson's ratio are not as significant in the maximum principal stress as in the lesser ones" does not much simplify the problem of determining accurately the maximum principal stress since this stress is not obtainable independently of the lesser stresses. Thus, the general use of three-dimensional photoelasticity must remain for some time on a qualitative or comparative basis in design and as an elegant check on theoretical analysis.

R. M. Sachs[3]

Professor Smith's paper is a lucid summary of the field of photoelastic stress analysis and should be a great help in familiarizing designers with the benefits which can be realized from the use of this method.

In the field of design with which I am most familiar, that of aircraft gas turbines, competition for low weight is vigorous. There are constant pressures to reduce factors of safety on all mechanical parts. For the designer to be able to accede to these pressures, a more precise knowledge of stress levels encountered during operation is necessary. We feel that photoelastic method of stress analysis is one very valuable tool which is contributing to that knowledge. For many items, such as fabricated structures, frames, and shells, structure tests to failure with the use of strain gauges and stress coat are thought to give more relevant design information than photoelastic stress analysis could. The reason is that the loads involved in these members are usually very large and infrequently applied, and the criteria of failure are excessive yield or complete collapse. In these structures, local regions of high stress are usually permissible due to the ductility of the material used, allowing a redistribution of stress in a more even manner, until finally excessive yield or collapse occurs.

Generally speaking we feel that photoelastic stress analysis is unlikely to give much relevant information to a designer of a composite structure which is intended to be stressed in the plastic range under the design limit load.

Some of the most critical parts in a gas turbine engine are the blades, discs, and shafting. These parts are frequently subjected to fluctuating loads for long periods of time. It is here that we derive the greatest help from the photoelastic methods of stress analysis. The stress concentration factors illustrated by fringe patterns in pictures of photoelastic tests are very significant for parts loaded in this manner. An example of a detail which is extremely important and requires careful attention to prevent fatigue failures is the root fixing which provides a mechanical connection between the turbines or compressor blade and the disc. This connection must withstand very high steady tensile loads due to centrifugal forces and at the same time must resist fluctuating loads due to the uneven gas forces loading the blade itself. In most cases where we have witnessed a root fixing failure, it has been due to fatigue caused by the fluctuating loads rather than a direct failure due to the steady loads. For help in this particular problem we have referred to the results of work carried out by R. B. Heywood (Ref. — "Tensile Fillet Stresses in Loaded Projections" by R. B. Heywood, Institute of Mechanical Engineers, Applied Mechanics Proceeding 1948, Vol-

DISCUSSION

The editor invites discussion of papers appearing in the *Journal*.

Readers may contribute to this section by sending appropriate comments to the *Journal* office.

[3] Design Analysis, Orenda Engines Ltd., Toronto.

ume 159, page 384). It is interesting to note that Dr. Heywood's analysis and the empirical formulae resulting, depend mainly upon photoelastic stress analysis.

Professor Smith's bibliography attests to the volume of published data, based upon this method of analysis, which is available to assist the designer. Despite the wealth of information available, many machine elements being designed employ profiles, combinations of holes, fillets, steps etc. which cannot be analysed adequately using existing data. It is therefore certain that an increasing number of engineering organizations will be setting up photoelastic stress analysis facilities of their own.

The Author

Since he was among the first to use photoelasticity for stress determination, having a pair of Nicol prisms long before Polaroid was available, it was a great privilege to have Professor Loudon present at the meeting and to hear his comments. The author shares the view that by dispelling some of the mystery, photoelasticity should gain wider use. There are of course many difficulties, some of which at the present state of the art seem nearly insuperable. Dr. Shelson has introduced a note of caution by mentioning two of the problems. While the presence of initial stresses (or other optical disturbances) in a model is usually shrugged off by writers, the photoelastician is loath to place full dependence on the results of using such a model. Since the time of writing the original paper, the manufacture and sale of Fosterite has been discontinued and it has become necessary for those doing stress freezing to cast their own materials. Probably the most favoured of these is the epoxy resin, such as Bakelite ERL 2774 or Araldite 6020, solidified with phthalic anhydride, and given a heat treating cycle that is supposed to leave an optically clear (though amber coloured) casting. Blame for residual stress and other casting defects can no longer be directed toward the material supplier, but it is perhaps preferable to have these under direct control.

Dr. Shelson also points out that dynamic stress work must be handled with care. For example room temperature creep, which is an irritation when working with static stresses, becomes an affliction when dealing with rapidly fluctuating stress. It is also very difficult to induce the required vibratory stress in a model (for example the second mode torsional in a cantilever) without departing from similarity to the prototype, and it is still more difficult to "see" photoelastically the stresses that are developed. But this is a reason for enticing more people into the fold of photoelasticity, for its progress must inevitably be slow if there are only a few with the patience to pursue and overtake the problems.

As a stress analyst confronted with many widely varied problems, Mr. Sachs' comments are valuable. It is true that photoelasticity is only one form of experimental stress analysis and that it cannot be expected to solve everything. The low modulus of elasticity of the model materials results in large deformations, particularly in a "stringy" type of structure, and these may invalidate the method. On the other hand new cementing and casting techniques make possible a model complexity not hitherto achieved and it is to be hoped that greater versatility will bring photoelasticity out of the research laboratory into the design laboratory. Even when similarity between the model and the prototype cannot be obtained completely, some information, if interpreted correctly by the analyst, is preferable to a complete lack of applicable information.

A Complete Sanitation Program for Metropolitan Toronto

L. B. Allan

(continued from page 30)

We have examined at some length the many difficulties, and the plans which are now envisaged in order to overcome them, in relation to sanitary and storm drainage and sewage treatment over the entire metropolitan Toronto area.

That a tremendous job faces us, no one can deny. Our program involves a capital expenditure of some eighty million dollars in the next twenty years. Within five years, we hope to have trunk sewers and sewage treatment available at any point inside our boundaries. After the basic service is available, it can then be expanded and improved, so that metropolitan Toronto will rank with the finest communities in the world in the field of drainage and sewage treatment, as it already does in so many other respects. √

Erratum. — The author of the paper "The Possibility of Complete Solar Heating of Canadian Buildings" (Nov. 1955 issue, p. 1501) was inadvertently quoted without reference to his membership in the Engineering Institute of Canada. Apologies to Prof. F. C. Hooper, M.E.I.C.

ABSTRACTS . . .

OF RECENTLY PUBLISHED ENGINEERING LITERATURE

BIG LOOPS IN SUBMARINE CABLE LINES SOLVE PROBLEM CAUSED BY DEEP MUD

Engineering News-Record, June 2, 1955, p. 48.

A mile-wide bay with a bottom of soft, deep mud presented an unusual problem to builders of a communications link between the big Naval Air Station at Corpus Christi, Texas, and a new radio transmitting center across Oso Bay, in which soft silt had an average depth of 110 ft. with pockets believed to be as deep as 300 to 400 ft.

The local electric company had learned that poles would not stand up for any length of time in this mud. Hence the builders of the new communications link decided to use submarine cables. However, submarine cables of sufficient strength to meet the conditions found at this crossing would weigh 10 lb. per foot of length, which meant that they would sink slowly in the soft mud.

How deep the cables would sink or how long it would take them to reach a state of equilibrium could not be determined accurately. To meet this situation, it was decided that the cables should be laid across the bay bottom in looped lines of sufficient length to provide for settlement of the cables to the bottom of the soft mud. Using the best available information as to the depth of the mud, a tentative final profile was computed and then the length of the loops required to lay that length across the bay was increased about 60 percent to reduce strain on the cable should settlement be rapid at any one point along the cable line.

Finally, 60 ft. was added to the length of the cable to permit a reserve length of 30 ft. to be coiled in a big anchor manhole at each end of the submarine line.

Use of this reserve is not anticipated, but that arrangement has the advantage of simplifying the task of adding to the length of the submarine cable should periodic inspection of the manholes indicate that the computed amount of settlement was in error.

RUBBER CONVEYOR BELTS

R. W. Parris, *Rubber Developments,* v. 7, n. 4, Winter 1954, pp. 98/104.

Hundreds of miles of rubber conveyor belting are in operation giving efficient service and conveying annually millions of tons of materials and products at a very low cost. Rubber conveyor belts are made in a wide variety of types for conveying almost every kind of conveyable material.

In the majority of applications, the working life of the belt is governed by its degree of resistance to abrasion.

A rubber conveyor belt consists of a fabric interior, to provide the necessary strength, and a covering of rubber which serves the dual purpose of resisting abrasion and protecting the fabric from moisture. In some belts the fabric is treated to make it resistant to mildew, while recently chemically-treated cellulosic yarn of greatly enhanced strength has been used for the construction of belts. Where the maximum possible strength is required, the belt is reinforced with steel cord.

Some Special Types

For conveyance of products and materials up or down steep inclines, special types of belt are available. For packages, the belt has a gripping surface formed of numerous small isolated blocks or fingers. For lumpy or granular materials, cleats are provided on a smooth-faced belt. The cleats may be of metal or of rubber.

A rubber-coated steel band conveyor belt has been developed in Sweden. A belt which can shed water from the material being handled or can retain the water, according to requirements, is formed with moulded rubber ridges, ⅛ in. high in its surface. The incline of the belt and the angle of the belt idlers are adjusted according to whether the water is to be shed or retained.

A belt conveyor of novel construction, termed the cable belt conveyor, has recently been introduced. The belt itself is not subjected to driving pull, this being taken by two steel ropes, one at each side of the belt. The ropes are supported by pulleys mounted on ball-bearings and set at approximately 18 ft. centres. Spring steel straps are moulded in the belt at approximately 2½ ft. centres and project at each side of the belt for a few inches. At each of the projecting edges of the belt a shoe with rubber inserts is fitted so that it slides on the strap for a limited distance.

An entirely different type of belt conveyor, known as the *Zipper* closed-belt conveyor-elevator, is in effect a moving pipe line. It consists of: (a) a flat endless base-belt similar to the conventional rubber and fabric conveyor belt; (b) Flexible rubber side-walls hinged to the shoulders of the base-plate; and (c) interlocking rubber teeth moulded on the outer edges of the side walls. Immediately after material has been fed on the belt, the side walls are automatically closed around the material and the teeth interlocked. Rubber fins at the base of the teeth seal the belt and keep material from sifting out. The belt is automatically opened for unloading.

Idlers

Conveyor belts are supported on idlers, each idler consisting of one or more idler rollers mounted in a supporting bracket which is fixed to a base plate. For troughed belts the idler unit has three or five rollers so mounted that the belt forms a trough shape. Idler rollers are designed to retain lubricant and to rotate easily, thereby minimizing both belt tension and wear on the driving surface of the belt.

When abrasive or corrosive materials are being handled it is advantageous to provide rubber-covered idler rollers. Impact idlers are used at loading and transfer points to minimize wear on the belt. Where impact is very severe, as when logs or large heavy lumps of material are dropped on the belt, pneumatic tyres may be used to form the idlers.

A recent development is the hammock idler. The hammock idler consists essentially of a rubber tube which is flexed according to the load on the belt and allows the belt to assume its own shape of trough. As the extent of troughing necessary will depend upon the load being carried, the idler incorporates means for adjustment to meet these requirements. The use of the hammock idler reduces spillage as any tendency for the load to be nearer one edge of the belt is quickly corrected. The rubber tube is resistant to both abrasion and to continued flexing. Any impact which occurs when the loaded belt traverses the idler is readily absorbed by the rubber, but this type of idler is not intended for heavy impact duty at loading points.

The life of rubber conveyor belting will be prolonged by correct installation, frequent inspection and immediate correction of faults or repair of damage. The loading point of a conveyor receives most abrasion and nearly all the impact, and the life of the conveyor is therefore largely governed by the wear it receives at this point. To minimize this wear the material being handled should pass from the chute to the belt at the same speed and direction of travel as the belt and with a minimum amount of impact. Belt repair outfits are available and also portable vulcanisers for effecting belt repairs and for making vulcanised belt joints.

LATEST IN BUTT-WELDING . . . LONG RAILS BY FLASH PROCESS

Railway Age, v. 138, n. 23, June 6, 1955, pp. 26/29.

At Albuquerque, N.M., a new chapter is being written in the history of continuous rail. There the Santa Fe is taking short ones (39 ft.) and fashioning them into long ones (about 1,440 ft.) by the Matisa-Schlatter flash butt-welding technique. The set-up at Albuquerque, represents the first use of this process in the United States.

Mobility Was Problem

Welding of continuous rail in Europe is done at so-called *depot* or permanent set-ups. This practice is not generally considered practical here because of the greater distances the long rails would have to be transported. Development of the Matisa-Schlatter process is the outcome of many months of intensive effort to adapt the Swiss version of the electric-flash method for use in this country, and especially to develop equipment of the required mobility.

As now perfected the equipment is permanently housed in three specially designed steel box cars. These cars contain:

(1) The plant used for generating the necessary electrical power for the welding process, and such additional power as is required to operate the various motors and lighting facilities required during operation.

(2) The welding unit, an air compressor and a water-cooling unit for cooling the welding electrodes.

(3) The grinding machines and a winch for moving the welded rail.

Arrangement at Albuquerque

The welding equipment is arranged on two tracks at Albuquerque. The welding and grinding cars are on one track and the power car is spotted on a second track directly opposite the welding car. The production line begins at a rail-feeding ramp at the rear end of the welding car and extends through the welding and grinding cars to a portable building which houses equipment for testing the welds.

Portable platforms at car-floor height, with access stairs to the ground level, are provided between the cars, between the grinder car and the inspection building, and completely around the rail-feeding ramp. These platforms provide easy access to any point on the welding line.

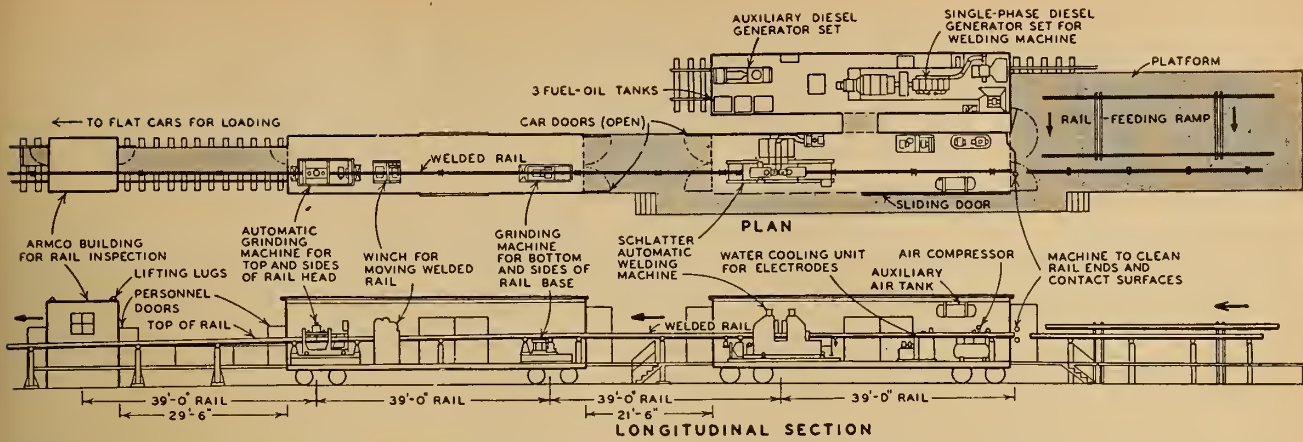
The preparation, welding, finishing and testing of the joints is carried out at six stations located along the length of the welding line. These stations are equally spaced so that each operation may be carried on simultaneously with all the others, thus insuring assembly line production.

The usual practice on the Santa Fe is to weld the rails into lengths about 1,440 ft. (37 rails) long. As the lengths come from the production line they are loaded directly on a string of 31 flat cars. On each car the rails are supported on a single specially designed assembly of 12 roller-bearing rollers mounted on a common shaft, thus accommodating 12 strings of welded rail. The draft gears of each car are blocked to prevent slack action in the train. Two trains have been provided so that one may be loaded while the other is transporting the rail to the unloading site.

Production and Personnel

The welding line is operated in two shifts with the expectation that full production, when reached, will approximate 180 welds per day. Eleven men are required for each shift, including the foreman and all personnel necessary to handle the rail.

Only full-length No. 1 and No. 2 rails are being welded on the Santa Fe. All rail sent to the welding line is blanked at both ends except that a limited number are drilled at one end only for use as end rails of the strings.



LAYOUT of production line at Albuquerque. As indicated by heavy arrows rail flows through the various fabricating and testing operations to its final discharge in 1,440-ft lengths for loading on strings of flat cars.

COMMUNICATION . . . WHERE DO WE GO FROM HERE?

Vannevar Bush, *Electrical Engineering,* v. 74, n. 5, May, 1955, pp. 367/369.

Today there are diverse and complex means for communication. You are not interested in having me recite a catalogue of them. Nor have I any intention of lifting your spirits with a rhapsody on the wonders of modern communication. In fact, I think some of those wonders are still rather crude.

The simplest form of communication is between individuals, and the principal instruments — in addition to direct speech — are the telephone, the transmitted message, and the letter. We take just pride in our telephone system. Some people can now make calls all over the country merely by turning a dial; and more will soon be able to do so, without human intervention, and without human error except their own.

The sounds heard over the telephone bear a surprisingly close resemblance to those of the human voice, close enough in fact to satisfy any reasonable demands. What else is there to do? Well, the telephone is still, on occasion, a nuisance, breaking in on our hours of rest, work, or contemplation in a most peremptory manner. There may be ways, aside from having competent secretaries, by which conversations could be carried on when both participants, rather than just one, want to talk. Certainly there are more effective ways than those employed today of carrying on a conference of several persons. The only difference between a conference around a table, and one over a telephone is the absence of gestures and facial expressions.

Correspondence

Billions of letters are being written. This process is still extremely crude. To write the letter an individual talks to a stenographer or a machine, and what has been said is reproduced, often none too precisely, by a girl who pushes keys on a typewriter. This process can be shortened by talking to a machine and mailing a disk or tape, to talk back on a distant machine, but this does not readily produce a convenient record.

When a letter is mailed, a half dozen persons have to read the address and toss it into its appropriate compartment. This is utterly archaic. It is quite possible to read addresses photoelectrically, if they are in proper code, and to render all sorting automatic. The great bulk of the mail could be thus handled.

The second principal form of communication is from one to many, or from a small group to a large audience. It is usually unidirectional. The greatest instrumentation here is the printed word. Much progress is being made in printing. Better methods of printing can confidently be expected as well as better methods of distributing what is printed.

Entertainment is a form of communication. It is fortunate that entertainment and advertising have made possible the enormous growth of radio and television. Together with the press and magazines, these media are producing an informed electorate and a united public opinion throughout the country beyond anything that was possible without them.

The progress of civilization in peace time depends not only on current thoughts and findings, but on the skill and facility with which we create, store, interchange, consult, and utilize the whole record of collective past experiences. Enormous strides are being made in the development of methods for creating a record of what is learned—in printed words, by photography, or on a magnetic tape. Also, strides are being made in developing means for the transmission of ideas from one to another or from a central point to great audiences. But in one exceedingly important phase of the whole problem, little progress indeed is being made. This is the phase of finding in the record the information needed.

Libraries

Libraries are filled to overflowing and their growth is exponential. Yet in this vast and ever-increasing store of information particular items are still sought by horse and buggy methods. We are being smothered in our own product. While the work of thousands of men, full of significance and timeliness to others, is recorded with great care, a large and increasing fraction of this work is, for all essential purposes, lost simply because it is not known how to find a pertinent item of information.

The problem is not essentially one of techniques. It is rather one of deciding who is to do the job of clearing up the confusion and under what auspices. There are many good techniques available. Recently I participated in a study of how mechanization could be applied to the problem of searching in the Patent Office, where millions of items need to be scanned for equivalents of the combination presented in patent applications. There are several ways in which items can be scanned at the rate of 1,000 a second, selected in accordance with a complex code, and reproduced automatically.

But to code the scientific literature or legal documents or any other part of the mounting records and thus to place them under the control of machinery responsive to our will is a stupendous undertaking. Worse than that, it is everyone's business and the assigned responsibility of no one group in particular. The whole art of data handling is improving every day, and it would be a mistake to freeze upon a single system prematurely. So it probably would not be wise to plunge in at once and undertake a comprehensive and extensive program for, to use an example, the entire bulk of scientific literature. The time has most certainly arrived when special sections of the record can be subjected to mechanization with genuine benefit to those who use them.

Communication is the lifeblood of democracy. An informed and intelligent electorate is our bulwark against political chaos. Education of the people is dependent on the means of communication that are available. In its simplest form, a teacher talking to a group of pupils, communication is an essential element. But in the more complicated processes by which the citizens of democracy become informed, the problem of communication is more involved and extensive. Today there are intricate and powerful means for the interchange of thought among the entire population. On the skill and wisdom with which these means are employed depend the stability and prosperity of our republic.

IMPORTANCE OF KNOW-HOW IN CHEMICAL DEVELOPMENT

Industrial & Engineering Chemistry. v. 47, n. 5, May, 1955, pp. 982/984..

The cost of industrial research has been increasing at a staggering rate. For many years the chemical industry classification provided the largest segment of industrial research. However, in the last few years, the chemical industries now provide little more than 10% of the total or approximately $300,000,000 per year. Research expenditure has been made possible by a rapid increase in the number of scientists and engineers employed.

Almost as significant as the increase in research workers is the greatly increased cost per professional scientist or engineer; the annual average cost of a professional in industry has increased from $6,300 in 1927 to $21,500 in 1952.

The unit cost of a research worker, however, does not completely explain the increases noted. A number of forces have combined to increase the complexity of research projects over the past years.

It is obviously impossible to compare identical projects, but some typical examples give some indication of the changes at Shell's Emeryville Research Center. As shown in Table I, in the period 1933-38 pilot plant developments averaged 14 man-years, but in the period 1944-48 this had increased to 50 man-years per project. And when one examines figures that include not only the pilot plant development but also the research prior to it and the engineering effort that followed, the total manpower utilized per project increased from 55 man-years in the period 1928-38 to 160 man-years in the period 1946-53.

Table I
CHEMICAL PROJECT
MANPOWER REQUIREMENTS

Period	No. Projects	Man-Years Project
Pilot Plant Investigations		
1933-38	16	14
1944-48	11	50
Commercial Projects		
1928-38	24	55
1939-45	13	125
1946-53	26	160

One of the reasons for increased research expenditure is the increased demand for chemical products. Since the cost of chemical research has averaged approximately 3% of sales for a number of years, this increased production would alone account for much of the increase in research expenditure.

No one in this field need be told that during the period of expansion, competition has increased materially. The few companies engaged in petrochemical manufacturing in 1931 have been joined by many others, until at the present time there are approximately 140 individual companies operating 300 plants. This rivalry has made it necessary for management to establish with certainty that capital expenditures will be made only for processes that are economically superior. This has led to a great increase in the use of process engineering evaluations, necessitating more detailed development and engineering efforts.

The rapidly increasing cost of construction also must be considered and every effort made to design plants requiring a minimum of capital investment consistent with reasonable manufacturing costs. Perhaps the most reliable index of construction costs is that provided by the *Engineering News Record.* This figure shows that the cost of construction has more than doubled since the beginning of 1946.

With this background, showing the influence of rapidly increasing markets, greater competition, and inflationary forces on research and development expenditures, there is a real incentive for research and development management to minimize expense by utilization of any available knowledge bearing on a specific problem. Among the sources of data available are the chemical literature. If chemical industry would exchange more information through increased publication, duplication of research and development effort could be materially reduced. When one considers the total expenditure in this field of $300,000,000 annually, even a small fraction shared would represent a real saving to everyone. Disclosures in the patent literature also provide knowledge which can be used effectively.

The most important source of information on which to base process development is the utilization of one's own research and development know-how on related processes. This source is obviously available in proportion to the extent of prior experience in the field involved, whether it applies to exploratory or bench scale research, pilot plant investigation, process design, or commercial operating experience.

Notes of the Institute and Other Societies, Comments and Correspondence, Elections and Transfers

Overseas Look for Canadians

Promotion of increased Canadian participation in foreign development works has been sponsored by the Canadian Manufacturers' Association, the Engineering Institute of Canada and the Canadian Construction Association.

Reason for the joint action of these three national organizations was the feeling that the opportunities which these projects present for Canadian manufacturers of capital goods can be improved in two ways: first, by improving and speeding up the channels of information in order that Canadian suppliers may be fully aware of potential requirements at the earliest possible stage; and, secondly, by promoting increased interest and activity in such projects on the part of Canadian engineering consultants, contractors, management specialists and technicians.

The joint liaison committee is headed by Hugh Crombie, m.e.i.c., vice-president and treasurer, Dominion Engineering Works, Montreal, who will represent the C.M.A.; B. A. Culpeper, m.e.i.c., manager and chief engineer, C. D. Howe Company, Montreal, who will act for the Engineering Institute; and C. G. Kingsmill, m.e.i.c., assistant to the president and director of Angus Robertson Limited, Montreal, who will represent the Canadian Construction Association.

Through this committee arrangements are being made for the collection and exchange of information regarding foreign undertakings in which Canadian engineers, contractors and manufacturers would be interested. The services of the Department of Trade and Commerce at Ottawa will also be utilized in this undertaking.

C.M.A. members who have overseas affiliations have been asked to report, on a continuing basis, on foreign developments and, with the co-operation of the other two sponsors, manufacturers will be kept abreast of important overseas contracts entered into by Canadian engineers and contractors.

This move should also be, in the long run, of value to Canadian manufacturers interested in consumer goods export. Experience has shown that Canadian exports of capital goods and technical services have a tendency to stimulate the foreign market for all sorts of other Canadian products which may be used in association with the products concerned.

Engineers' Joint Committee Formed

The civil engineers of Toronto have a concerted program of technical meetings this year, through the efforts of a committee representing Toronto members of the Institution of Civil Engineers (Britain), the American Society of Civil Engineers and the Engineering Institute of Canada.

On October 18, 1955, the first in a series of joint meetings of direct civil engineering interest was held. The inaugural paper was presented by Charles Hershfield, m.e.i.c., before a large audience in the McLennan Building of the University of Toronto. His subject was "One Cycle Moment Distribution for Structural Analysis".

The next meeting is scheduled for February 9, 1956, when a paper on "Waterworks and Fluid Mechanics" will be presented by Dr. Grant Huber in Room 103 of the School of Nursing of the University of Toronto. Professor Huber will discuss what effects fluid mechanics has, or should have, on our practical treatment of waterworks design. Specific reference will be made to the waterworks problems of Metropolitan Toronto.

The schedule includes also a tentative meeting on March 8, with a paper prepared by the Ontario Hydro structural research department; and one on April 12, at which the results of the N.R.C.

Cover Picture

The cover picture illustrates the installation of a 4-ft. diameter parabolic antenna reflector as part of an airborne profile recording system. Capable of measuring ground elevation on profiles to plus or minus 10 feet, it may also be used to measure terrain clearances from 1000 to 25,000 feet as a radar altimeter. The unit compensates for minor deviations of the aircraft from chosen barometric flying height so that the record obtained indicates the terrain contour along the flight line. Simultaneous ground position photography is featured.

Cobourg Beam tests will be presented by the Department of Building Research, N.R.C.

The joint civil engineering section came into being during the fall of 1955, the plan having been proposed in March to the sister societies by Harold Fealdman, M.E.I.C., on behalf of the executive of the Institute's Toronto Branch. The Institution of Civil Engineers had given its approval and offered financial assistance in May. Co-operation with ASCE was worked out later and in December agreement and financial support was announced by the Society.

Mr. Fealdman was appointed chairman of the committee. The secretary is B. Hardcastle, M.E.I.C. (c/o McColl-Frontenac Oil Company Limited, 8 Spadina Road, Toronto, Ont.) Their work in the interest of co-operative technical activity has been rewarding, and they volunteer to provide further information to anyone interested.

Ten Years of Aircraft Design and Production

When the second world war was over, Canada found itself with a great many new industries on its hands. In many instances the industries were not previously natural to this country but had been developed because of the exigencies of war conditions. One of these appeared to be the aircraft industry.

At the war's end most Canadians would have said there was no future in Canada for the aircraft industry and yet we now find it one of our most important industrial efforts. This has been a wonderful thing for Canada, not only from the point of view of employment for Canadians, but from the point of view of national defence.

Conspicuous in the group of companies that have been operating in Canada since the war's end is A. V. Roe (Canada) Limited. On December 1, 1955, they celebrated their tenth anniversary. This company has been unique not only in the field of aircraft manufacture but in the aero engine as well.

Back in 1945 Sir Roy Dobson and his associates representing the Hawker Siddeley group purchased the Crown owned Victory Aircraft plant at Malton, where Lancasters had been made during the war. The company's operations were very small in the beginning and certainly did not need a plant of this size. However, it was fortunate that the arrangements were made on such a generous scale because before long every inch of floor space was in demand.

In the beginning the company had 300 employees—today it has 22,000. It now consists of four separate companies with nine manufacturing and engineering establishments covering a total floor space of five and a half million square feet.

The companies controlled by Avro are Avro Aircraft Limited, Canadian Car and Foundry Company Limited, Canadian Steel Improvement Limited, and Orenda Engines Limited.

The list of products which are now manufactured includes four types of aircraft, two gas turbine aero engines, aircraft repair, overhaul and modification, aircraft ground handling equipment, mobile training systems for the R.C.A.F., guided missiles research, precision forgings and castings for aircraft, aero engines, consumer products, textile and wire and cable industries, light alloy products, heavy steel castings, railway equipment of all kinds for Canada and export to 26 foreign countries, railway track layouts, steel fabrication, electric street cars, electric trackless trolleys, gasoline and diesel powered buses, mining cars and equipment and machine shop products.

The company has many distinguished achievements in the field of aircraft design and manufacture. First of all there was the Jetliner, which came within a few days of being the first jet propelled airliner in the world. It was an excellent machine and made a first-class showing. Unfortunately, it now seems it was abandoned in order to devote more time and attention to fighting machines.

Next, the company turned its attention to an all-weather fighter, which was required for the defence of Canada. This became the CF-100. An engine as well as a plane had to be designed. However, in the beginning the CF-100 got into the air powered by Rolls-Royce engines. It was the height of wisdom to test the new plane with proven engines rather than that a new plane and new engines should be tested together.

The history of the Orenda is a story in itself. Looking back it seems almost impossible that such a modern engine could have been built so successfully the first time the team made a try at it. Today all the CF-100's are powered with the Orenda and as well it is used as the power unit in the F-86, which is being built by Canadair in Montreal.

To do justice to what this company has accomplished would take a book at least the size of this *Journal*. This short article is not intended to be a history, but simply an acknowledgment of what this group of intrepid workers has accomplished and a tribute to them.

Here's hoping that in the next ten years the company may set up another record that will compare well with that which they have made in the last ten years.

Conference on Human Problems of Industrial Communities

The Right Hon. C. D. Howe, Minister of Trade and Commerce, has been appointed chairman of a committee to assist in selecting 30 Canadians to attend the Duke of Edinburgh's study conference on the Human Problems of Industrial Communities in the British Commonwealth and Empire.

This conference, which will take place at Oxford, England, from July 9 to July 27, 1956, will provide an opportunity for people from all parts of the Commonwealth to study the practical working of industry in the United Kingdom and to discuss their common problems and how they are being tackled. The total membership of the conference will comprise 280 men and women broadly between the ages of 25 and 45 who are engaged in the managerial, technical and labour-operative roles of industry. They will be selected from among those who now hold, or are likely to hold, positions of responsibility, and who are taking an active interest in the life of their community. The industries from which members of the conference will be drawn include manufacturing, mining, transportation and distribution.

The Canadian selection committee, of which Mr. Howe is chairman, will consist of representatives of both management and labour. The vice-chairmen of the committee are Claude Jodoin, president, Trades and Labour Congress, Ottawa, and W. S. Kirkpatrick, vice-president, Consolidated Mining and Smelting Company of Canada Limited, Montreal. In reviewing applications for membership in the conference, the committee will try to ensure that all industries and regions in Canada are represented in the group which will go to Oxford. Secretary of the Canadian Committee is A. W. A. Lane, Room A-157, No. 1 Temporary Building, Ottawa.

The Duke of Edinburgh has said: "I cannot emphasize too strongly that this is a study conference not for research workers but for young people actually engaged in industry. Its main value will not lie in the report of the speeches and discussions. Its value will depend upon what the members make of what they see and hear. Its value will lie in the ability of the members to describe their points of view and experience for the benefit of others and their ability to distinguish what is likely to be useful in their own special cases. Ultimately it is hoped that the members will be able to extend their influence in their own countries and industries to the end that industrial enterprises are so organized that they form an integral part of a happy and healthy community."

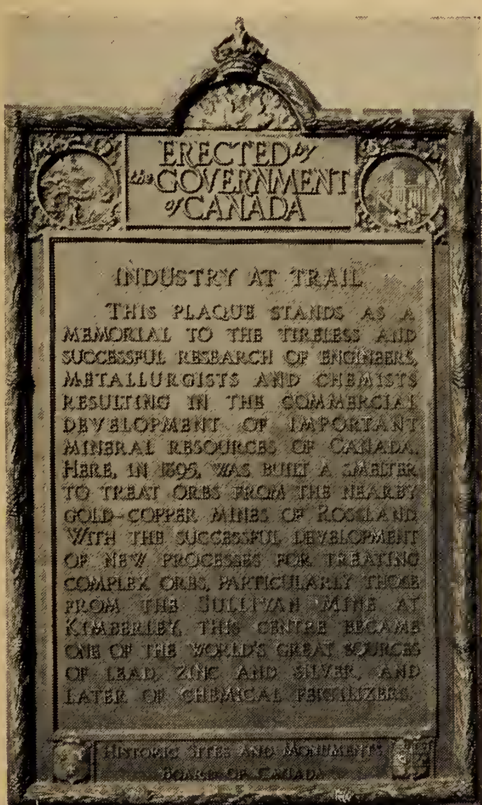
The Monument at Trail

A monument to "Industry at Trail," marking the "—tireless and successful research of engineers, metallurgists and chemists—" has been erected by the Historic Sites and Monuments Board of Canada. The plaque was unveiled by Dr. W. N. Sage, professor emeritus of history at the University of British Columbia, and B.C. representative on the Historic Sites and Monuments Board, at a ceremony held at Trail on November 19, 1955. The unveiling program was arranged by a local committee which included representatives of the district branches of the C.I.M.M., the C.I.C. and the E.I.C.

The monument is a mark of recognition afforded by the Federal Government to pioneer research and its practical application in the field of natural resource development in the Kootenays. It is the first monument ever dedicated to a modern industry by the Historic Sites and Monuments Board of Canada.

The members of the Kootenay Branch, who provided the *Journal* with this story and photographs, are particularly gratified to note specific mention on the plaque of the work of engineers. They also note with satisfaction, as did more than one official speaker at the ceremony, that the industry chosen as the first to be marked for significant research and development progress is one representing Canadian processing of domestic raw materials, with native energy resources, through to refined metals and finished chemical products. Most significant, perhaps, is the inherent recognition that the most important resource of all is trained manpower — and the recognition of the importance to Canada of men highly skilled in the physical sciences and engineering.

The erection of this unique monument, and the inscription on its plaque, should be sources of pride and justifiable satisfaction to every Institute member and Canadian engineer.



St. Lawrence Seaway and Power Project

The *Journal* reviews the news and progress of the St. Lawrence project.

Progress by Ontario Hydro

Total earth moving for Ontario Hydro's section of the St. Lawrence power project to the end of November amounted to some 6,100,000 cubic yards, indicating the progress that has been made. This includes excavation on the powerhouse site, dyke work, cofferdams, railway and highway relocation, and other phases of work.

During November the first section of the relocated No. 2 highway was opened to traffic. This 7.2-mile stretch from Cornwall to Moulinette area will divert traffic away from the construction work in the powerhouse and administration areas. A further layer of asphalt pavement will be laid next spring.

Interesting advances have been made in the construction of the new St. Lawrence transformer station. Most of the ground work has been done; the ducts are in place, while footings and foundations now are ready for equipment and structures. Some of the steel was being erected by the month end.

Cofferdam encloses excavations for power houses.

Good progress had been made on the diversion canal being constructed by C. A. Pitts General Contractor Ltd. Additional equipment had been moved to the site and with the diversion of traffic from the former No. 2 highway, a speed-up in the tempo of operations had resulted. Because of the diversion canal, a second length of access tunnels had been necessary to pass under this waterway, which will parallel the present Cornwall canal. Excavation for these tunnels had been completed; the concrete anchor pad for the steel tunnel liners has been poured, and the liners were in place by the end of November.

At the powerhouse site, excavation had been proceeding normally despite adverse weather conditions. An estimated total of more than 800,000 cubic yards of excavated material had been hauled away to the disposal area. More holes were drilled in the powerhouse area and these were grouted, using over 23,000 bags of cement for a total of some 85,000 bags to date.

Meanwhile, on the Cornwall dyke, work continued on stripping of borrow in section 2. The haul roads had been prepared and excavating the clay crossing in section 3 had started.

During November, channel improvement work progressed favourably. Removal of the western end section of Spencer Island pier to an elevation of 220.0 was completed in the Chimney Island sector. Pile driving for the bridge in the causeway to Spencer Island also was completed. A total of more than 230,000 cubic yards had been excavated to date.

Similar progress has been made on the Galops Island work, where shovels continued excavating in the main cut. Dewatering of the first excavation bay was completed and the cofferdam was increased in this area. Total excavation to the end of the month in the Galops Island area amounted to over 1,000,000 cubic yards and clearing of the island was virtually completed.

Rehabilitation work continued with little interruption at Iroquois during November despite inclement weather. A total of 55 houses had been moved to the new town site by the month end. There was much progress in laying sewers, water mains and other facilities in the new town site.

Meanwhile, at Mille Roches about 40 houses had been surveyed during the month in preparation for the development of town site No. 2. Necessary tree clearing was started and surveys completed for access roads to cross the railway at Mille Roches and Moulinette to the site of the new town.

In general, the progress of the work was outstanding during November, with some 35 major supply and construction contracts in progress. There were some 2,700 persons employed on Ontario Hydro's part of the project.

Progress by NYSPA

Progress during November was highlighted by two major achievements. On the 11th the first concrete was placed in Iroquois dam, and during the month the steel superstructure of the Barnhart bridge, connecting the island and the mainland, was completed. In addition, the total excavation quantities for all construction contracts now exceeds six and one-half million cubic yards out of a total estimated fifty million cubic yards.

In the powerhouse area, excavation was continued. More than 100,000 sacks of cement had been used in foundation consolidation and as a seal for rock excavation. While placing of embankment for the south forebay dyke had been discontinued for the winter, suitable material is being stockpiled for construction in the spring. On the river side of the main powerhouse cofferdam, steel sheet pile baffles were being reinforced to provide added protection from ice damage.

At Long Sault dam, as blocks of concrete rise in the right abutment end, and begin to define the shape of the structure, rock was being removed at the other end of the excavated area. In cut "F" excavation was accelerated as more than one and one-quarter million cubic yards of earth had been moved to date.

In addition to the placing of concrete at Iroquois dam, the driving of steel cofferdam cells progressed and earth excavation yardage reached the million mark. At the Massena intake, more than a half million cubic yards of earth had been excavated as construction of the dyke progressed.

Placing of concrete on the Barnhart bridge substructure was completed and construction of the access road and railroad on Barnhart Island was being pushed through in order to be ready to receive traffic when the bridge is opened. Steel girders now span the Grass River between abutments of the Grass River bridge, and preparations are in progress for placing concrete on the highway over the bridge.

Channel improvement excavation continued. At Red Mills Point, work progressed in spite of high water, built up by strong winds, overtopping the cofferdams. About 1,600 feet of cofferdams had been constructed in the Galop Island south channel in preparation for extensive under water excavation. A 12-cubic-yard dredge arrived and started work in the Chimney Island area.

With some 52 major supply and construction contracts in progress, production of engineering drawings and specifications continued on schedule. Specifications for channel improvements in the Sparrowhawk Point - Toussaint's Island area and emergency diesel generators were completed and issued during the month. Inspection and expediting of major items of essential equipment and materials continued to receive the priority demanded by the accelerated construction schedule. At end of November some 3,200 persons were employed on the work.

Progress by SLSA

As of November 25, on a total of 22 contracts valued at approximately $50 million awarded to date by the St. Lawrence Seaway Authority, and covering services by consulting engineers, the work completed stands at approximately 15 per cent of the total value of contracts awarded.

As winter begins to set in and the closing of navigation is announced, the 10 dredges working in Lake St. Louis and Lake St. Francis all summer and fall cease operations where they have been deepening the future channel to 27 feet. Cofferdamming in the Laprairie basin will be restricted because of the usual winter ice jam and rise of water levels. Excavation sites not clear of water cannot be worked.

Most of the work goes on, however, as winter conditions present no serious problems in the heavy earth cuts at Iroquois and Côte Ste. Catherine. Rock excavation of the overland channel at Côte Ste. Catherine and between Jacques Cartier and Victoria bridges proceeds as usual. Enlargement to piers of the Jacques Cartier bridge is carried on. About 75 per cent of the labour involved in building the navigation channel will continue working throughout the winter.

Below the Jacques Cartier bridge, where entry to the future channel will be made from Montreal harbour, Miron et Frères, Ltée. have a mile-long contract to excavate 2,000,000 cubic yards of material, of which 500,000 cubic yards are rock. Completion is called for by November 30, 1957. Excavation on this contract as of October 31 was 22 per cent completed. Considerable cofferdamming had been finished, and part of the site dewatered. Dyke construction was also progressing satisfactorily.

Atlas Construction Company had completed the water intake for the municipalities of Longueuil and Jacques Cartier. On their contract for enlargement of Piers 1 to 11 of the Jacques Cartier bridge, grouting around several of the piers was proceeding, along with work in the vicinity of Pier No. 11 in preparation for the enlargement. Work must be completed by September 30, 1956. Later, the southerly end and approaches to the bridge must be raised permanently.

On the MacNamara-Pigott-Peacock-McQuigge contract up-river from Jacques Cartier bridge towards Victoria bridge, for excavation of 1½ miles of seaway channel and dyke, due for completion by June 30, 1957, cofferdams were complete and the entire contract area dewatered. Excavation was about five per cent ahead of schedule, with about 43 per cent of the 3 million yards total removed. The dyke had been built to within five feet of finished grade throughout its length; riprap had been placed to within five feet of grade.

Tenders for the St. Lambert lock, to be built at the south shore end of Victoria bridge, were received December 20. Completion was called for August 31, 1958. This work will extend nearly a mile and will require removal of some 2,400,000 cubic yards of material. Also required will be some 400,000 yards of concrete.

The most easterly of the two channel and dyke contracts for some seven miles of channel and dyke in the Laprairie basin, to carry vessels past the Lachine Rapids, is with the Walsh-Canadian Construction Company Limited. It calls for excavation of 3.8 miles of channel and the requisite dyke, as well as construction of a turning basin for ships and the extension of the water intake for St. Lambert. Excavation required will be some 2,000,000 cubic yards of rock and nearly 5,000,000 cubic yards of common excavation, for completion by December 15, 1957.

On this contract cofferdams have been completed, a section of the channel has been dewatered, and rock excavation commenced during October. Temporary pumping facilities are now supplying water to St. Lambert. The contractor has laid 360 feet of 36-inch concrete pipe for the permanent water intake.

Adjoining this contract on the west and south is a like one, 3 miles, in length. Due for completion by August 31, 1958 it involves excavation of some 1,200,000 cubic yards of rock and some 2,500,000 cubic yards of common material. Contractor is Northern Construction Company and J. W. Stewart Limited of Vancouver. The contractor had completed some cofferdamming and about ¼ mile of channel had been dewatered. Channel excavation had been commenced and work was completed on a temporary water intake to serve Laprairie.

The work for the Côte Ste. Catherine lock and approaches was awarded to Canamont Construction Limited and Canit Construction Limited, for completion by July 31, 1958. It extends a distance of 2 miles and in addition to the lock it includes excavation of a navigation channel and dykes which form the approaches to the lock. It also includes the excavation of a turning basin downstream, regulating works for the upper reach of the canal and a reservoir pool upstream of the lock.

Common excavation required here will amount to some 2,800,000 cubic yards, rock excavation to some 1,653,500 cubic yards. Concrete work will call for some 1,750,000 bags of cement. Some 3 per cent of the material had been removed by end of October, and progress had been made in the placing and rolling of fill and raising of cofferdam.

Construction of ¾ of a mile of the overland channel along the south shore from the Côte Ste. Catherine lock towards the Indian village of Caughnawaga, is being carried out by Miron et Frères, Ltée., for completion by November 30, 1956. This contract includes some 340,000 yards of common excavation, 490,000 yards of shale and 800,000 yards of limestone, plus the laying of 100,000 cubic yards of rock cushion on each side of the channel. The contractor here had completed the north and south cofferdams for the lock, and had removed most of the earth and shale and 40 per cent of the rock.

The last contract awarded by the authority to Northern Construction Company and J. W. Steward Ltd. at a price of $4,877,700 adjoins this one, and proceeds further overland to the Honore Mercier bridge. This excavation, some 2.8 miles in extent, will involve 2½ miles of dyke. It includes 4,600,000 cubic yards of earth and 2,900,000 cubic yards of rock, as well as cofferdams and unwatering. Work is to be completed by August 31, 1958.

Lake Channels Dredged

For dredging the seaway channel in Lake St. Louis, Marine Industries Limited have a contract for the removal of 3,800,000 cubic yards of overburden and 100,000 cubic yards of solid rock. This firm was also awarded a contract for dredging 600,000 cubic yards of sand, silt and clay from the channel at Lancaster Bar in St. Francis.

At the western approach to the Beauharnois canal, in Lake St. Francis, McNamara Construction Company Ltd. has a contract for dredging 1,100,000 cubic yards of sand, silt and clay from the Seaway channel. Canadian Dredge and Dock Company, Ltd. is the contractor to dredge 2,700,000 cubic yards of overburden from the channel from Fraser Point to Cornwall in Lake St. Francis. Two of the dredging contracts are ahead of schedule. The other two are progressing satisfactorily. About 30 per cent of the total material has been removed.

International Section

Across Iroquois Point, Pentagon Construction Company Limited and Iroquois Constructors Limited were jointly awarded a contract to construct a canal and lock. This installation will serve to carry vessels past the Iroquois control dam which will control the level of Lake Ontario. About 1 1/3 miles in length, the contract requires excavation of about 4,500,000 cubic yards of material, mostly heavy glacial till.

Approximately 26 per cent of the excavation on this contract had been completed to the end of October. Previously cofferdams had to be built at the upstream end. Work was proceeding on the erection of a concrete mixing plant and equipment repair shops had been provided.

Of some 8,300,000 cubic yards of material to be removed under dredging contracts awarded, at least 2,000,000 cubic yards or some 24 per cent, have been removed already this season, and navigation on the seaway does not begin until the opening of the navigation season of 1959.

A number of excavation contracts were not awarded until late in the summer and fall yet nearly 5,000,000 cubic yards of material had been removed on lock and channel and dyke contracts, most of which had to be unwatered first. This is some 14 per cent of the total yardage to be removed under such contracts already awarded, (but upon some of which, recently awarded, no work had yet commenced) of some 35,000,000.

The Authority has established a special lookout platform at Iroquois Point, from which may be seen the machines at work in the cut for the Iroquois lock and approaches. The work at Montreal may be easily surveyed from St. Helen's Island, from the Jacques Cartier bridge, and Victoria bridge or from the riverside drive which passes through St. Lambert.

The Authority has conducted several official tours over the works for Canadian, United States and foreign governmental representatives and for the press. It has likewise supplied the services of its officers as guides to a number of independent tours which various educational and business groups have arranged with the Authority.

Changes in Soulanges Section

It has been decided to construct separate single locks at the lower end of the Beauharnois canal, instead of the twin-flight locks contemplated under plans developed some years ago. Provision, however, will be made for the twinning of these locks in the future should the need arise.

Although the normal difference in water level between Lake St. Louis and Lake St. Francis is about 84 feet, variations in the water levels require that the locks each be designed for a maximum lift of 47 feet; otherwise, the lock dimensions will comply with the standards adopted elsewhere. To avoid interference with the flow of traffic on Highway No. 3, a two-lane tunnel will be built under the upper end of the lower lock in place of the movable bridge originally planned. This change will result in an increase in cost of about $1,100,000.

Additional facilities for which the overall first cost has been estimated at $37,320,000, will include the installation of movable spans in three existing bridges, two of which are combined highway and railway bridges and the third a railway bridge.

SLSA Hydraulic Laboratory

It is announced that Neyrpic Canada Ltd. of Montreal has been awarded a contract for the construction and verification of hydraulic models of Montreal harbour and of the Lachine rapids, and for various test programs on the models.

Two river models have already been built in the N.R.C. laboratories at Ottawa, the first to permit of an exact appraisal of the effect of the Gut dam at the head of the Galops rapids, the second for detailed studies of the most effective and economic methods required for channel improvements north and south of Cornwall Island.

The purpose of the models now proposed is to provide means for studies of the Lachine section in a manner similar to those made by the Authority and by Ontario Hydro in the international rapids section, and in regard to the Niagara development where such tests have all resulted in great economies in construction.

The Authority will construct a hydraulics laboratory building at Ville La Salle, in which the models are to be built and operated. Lalonde and Valois, consulting engineers, have been retained to prepare plans and to supervise the construction. The hydraulics laboratory and the studies and reports emanating therefrom will be under the control of a Lachine models committee, of which two members will be appointed by SLSA and two members by the model testing organization.

The Lachine rapids reach model will reproduce a nine mile section of the river from Dorval Island to below Heron Island, with a fall varying from 30 to 34 feet. The Montreal harbour model will represent the section of the river from a point ¾ of a mile above Victoria bridge to a point off Longueuil, 1½ miles below Jacques Cartier bridge.

Three contracts for enlargement of Welland canal locks were awarded by the St. Lawrence Seaway Authority on December 6 as follows: McNamara Construction Co., $359,755; Swansea Construction Company, Ltd., $698,260; and Aiken and MacLachlan, Ltd., for $104,000.

Progress by SLSDC

On the American side of the river, SLSDC has three major contracts under way on the 10-mile Sault canal, with its Robinson Bay and Grass River locks, and two dredging contracts further upstream.

At the far upstream end of the work a cross-island channel is being cut through by "The Gentleman", a huge 650 ton dragline from the Kentucky coal fields, with a 14 yard bucket on an 85 foot boom. Here the Badgett Mine Stripping Corporation has a contract for digging 3.9 million yards at a bid price of $1,372,800, less than half the Government's estimate.

Further downstream where the channel location leaves the river and cuts across-country, a Kiewit-Morrison Knudsen Joint Venture group has a contract for moving 12.5 million cubic yards of channel excavation at a price of $6,452,540. This is a dragline operation and is now well started. Two dredging contracts, for 3 million yards of earth on the Cornwall Island section and some 60,000 yards of rock in the 1000-Island section complete the work in hand on channel excavation.

Excavation for Grass River lock, a 2,500,000-yard earth excavation job, 80 feet to rock, is being carried out by the Dutcher Construction Co. at a price of $2,197,843. This lock location was moved 500 feet in planning, into a difficult marine clay material to avoid a dangerous fault line. In spite of the difficulties encountered in dewatering and in handling the sticky material the contractor has more than half completed the work and hopes to meet the February 1956 completion date.

The contract for excavation for the Robinson Bay lock further upstream, involving 2,600,000 cubic yards of earth material, was originally awarded to the Jack and Jim Maser Corp. at $990,900. After half completing the contract, the Masers defaulted in September, and it is now being finished by the Tecon Corporation of Dallas, Texas. Completion is called for early in 1956.

Awards of contracts for construction of the two locks are yet to be made. The whole project will be pushed to completion over the 1956 and 1957 construction seasons, in order that limited 14 ft. draft navigation may be possible by July 1958 at which time the old 14 foot Cornwall canal on the Canadian side is closed. As of December 1 employment stood at some 450.

Canadian Seaway Authority officials visited Washington, D.C., December 8 and 9 for meetings with the Saint Lawrence Seaway Development Corporation for further discussions on the Polly's Gut bridge and allied matters in the international rapids section. Discussions regarding tolls were carried on between the two tolls committees, United States and Canadian, which are studying this subject and

London Meetings

President R. E. Heartz and the general secretary visited Britain in October and took this opportunity to entertain overseas members of the Institute, at headquarters of the Institution of Mechanical Engineers. Below left. Old friends at the E.I.C. reception: Sir David Pye, past-president, I. Mech. E., Dr. Heartz, Allan Quartermain, and Sir John Hacking, past-presidents of I.C.E.; Brian Robbins, secretary of I. Mech. E.

reporting from time to time thereon.

Canal Redesigned

The Canadian and United States governments have announced agreement with a scheme of the International Joint Commission for toning down extremes of high and low water in Lake Ontario. It is a plan for protecting perennially-threatened shore areas in the Montreal district by redesigning part of the St. Lawrence seaway canal there.

External Affairs Minister Pearson has made public a letter approving the I.J.C. plan. "Arrangements now have been made," he said, "for the redesign of a portion of the new 27-foot canal in the vicinity of Montreal, which will allow a flow of 40,000 cubic feet per second to be bypassed from Lake St. Louis to Laprairie basin through the canal during the non-navigation season.

"This will not only provide more favourable ice-forming conditions in the narrows between Lake St. Louis and Laprairie basin . . . but should also be of benefit to upstream interests on the St. Lawrence River and Lake Ontario."

Thirty-five Years Ago

Comment on the *JOURNAL* of January 1921

The *Journal* started off for 1921 with an issue in January somewhat plumper than most of its predecessors. A large part of the increase was in the advertising pages, where several new names may be noted, including some still with us.

I am told that the *Journal's* uprise in advertising was because it had acquired a full-time solicitor, S. A. Neilson, M.E.I.C., now on the staff of the faculty of engineering of McGill University.

Not all of our 1921 advertising patrons have lasted out the years, e.g., Armstrong-Whitworth, Ltd., which offered a great array of products ranging from brass rod to diesel engines. Its plant was in Longueuil, across the river from Montreal, and was probably the first in Canada to use pulverized coal as a metallurgical fuel.

The company's managing director was the late M. J. Butler, M.E.I.C., a choleric Irishman. I well remember riding over the Victoria Bridge with him long before it was widened, in his Armstrong-Siddeley car, a vehicle as long and unwieldy as many a small truck. Half-way across we met a farmer with a load of hay. No amount of squeezing and jockeying would allow us to pass, so Mr. Butler gave his chauffeur $20, he bought the hay and the farmer pitched it over the rail into the St. Lawrence. We passed.

Annual Meeting Papers

The technical papers in this *Journal* were all preprints of some to be presented at the *Institute's* annual meeting to be held in Toronto in February. The first was a design of a sewage disposal plant for a seaside city, by C. J. Yorath, A.M.E.I.C.; the *Journal* had not yet adopted the practice of identifying authors by their professional connections. The paper dealt with an hypothetical city and conditions, but the design was worked out in considerable detail, some of the computations being given in extenso.

J. C. Keith, A.M.E.I.C., followed with a paper on "Cost-plus Contracts". I wonder if this is the J. Clarke Keith for whom the Ontario Hydro's steam generating station in Windsor is named? I was surprised to learn that cost-plus contracts were quite novel in 1921, one of the earliest in America dating back only to 1907, according to Mr. Keith. Admitting that there are disadvantages in the cost-plus system, the author made out a pretty good case in its favour, citing a sewer contract where the final expenditure under cost-plus was about 20 per cent less than the lowest lump sum tender received.

Then one of our few chemical engineering members, L. E. Allen, M.E.I.C., discussed "Hydrated Lime". He pointed out that our chemical industry used more than one-half of our production and that the rest went mostly into civil engineering works as a constituent of mortar and plaster and as an additive to concrete, as a plasticizer and waterproofer. He wrote of the water-cement ratio as being "now well established as governing the strength of concrete" and strongly advocated the use of up to 10 per cent of hydrated lime in concrete to allow of the reduction of this ratio without loss of concrete strength or of work ability. We still use some hydrated lime in concrete, but not as much as Mr. Allen thought we were going to.

James Milne, M.E.I.C., had a paper in this *Journal* on the Toronto filtration plant, comparing the operation of the 1912 slow-sand filters with that of the 1917 drifting-sand filters. Both gave a perfectly satisfactory water, but the cost per million gallons of water filtered was higher for the latter than for the former. At any rate, when Toronto built a new filtration plant not many years ago, it did not use the drifting sand type.

Mr. Milne's paper was followed by one by E. A. Ryan, A.M.E.I.C., on the heating and ventilation of paper-machine rooms, with a long discussion by E. A. Briner, M.A.S.M.E. The two together gave an excellent picture of the state of the art then; I doubt if it has changed much in thirty-five years.

Personalities

The rest of the editorial matter deals with plans for the forthcoming annual meeting, a special nomination of H. G. Acres, M.E.I.C., for the post of vice-president—and a plea to the government to appoint an engineer to the Railway Commission.

Among the personals, I find that A. G. L. McNaughton, A.M.E.I.C., was on his way to England for a year's visit and that R. L. Weldon, JR.E.I.C., had just become mechanical engineer for the Three Rivers Pulp & Paper Co. The first is, of course, Gen. A. G. L. McNaughton, now chairman of the Canadian Section of the International Joint Commission and Mr. Weldon is president of the Bathurst Power and Paper Company.

One member is announced as having set up as a contractor in Toronto, in which business he "expects to continue . . . for some years to come". Don't they all?

The late J. M. R. Fairbairn, M.E.I.C., was the incoming president, so his portrait appeared in the *Journal*, a determined looking young man, but without the imperial bearing so characteristic of him in later life.

The Battlefields Memorial Commission, of which Col. R. W. Leonard, M.E.I.C., was a member, announced a design competition for the monuments it proposed to build at St. Julien, Courcelette, Vimy Ridge, Passchendaele, Hospital Wood, Dury Cross Road and Bourdon Wood, all points where Canadian troops helped to win Allied victories in the late war.

The Branches

Life in the branches seemed to be going along about as usual. Metering of a selected area in Halifax had cut water consumption down by about 65 per cent, but it was complained that building laws and plumbing regulations were hard to enforce on account of civic politics."

The Ontario Provincial Division was still trying to get an engineers' licensing act passed in that province and after a good bit of apparently acrid discussion, authorized its committee on the matter to use all legitimate means to forward such legislation. The Vancouver Branch was concerned because it was rumoured that "certain powerful interests propose . . . to endeavour to have certain amendments enacted, eliminating the compulsory clauses of the Engineering Profession Act."

The *Institute* was growing; there were an even hundred applications for membership published in this *Journal* and 17 for transfer.

Engineering Careers in Canada

On page 89 of this issue readers will find the first of three articles that will appear in the *Journal* covering the role of the engineer in the Canadian armed forces. Our purpose in publishing them is twofold, first, to inform readers of what the members of our profession are doing in the defence of Canada, and second, to help the services in their search for new technical personnel. It was our intention to run these stories according to established custom with the navy coming first. However, to save time, and with proper apologies to the sailors, they will appear in the order they are being received from Ottawa.

It is proposed to continue with a further series of articles on similar lines about careers in various fields of Canadian industry.

Annual Meeting of R.C.E.M.E Corps Association

The R.C.E.M.E. Corps Association held its tenth annual general meeting and dinner at the R. C. E. M. E. School, Barriefield, Ontario on October 22 last.

The president, Lieut.-Col. A. G. Edward of Montreal, was reelected for a second term, while the honorary secretary-treasurer, Lieut.-Col. LeSueur Brodie of Toronto was also re-elected. Lieut.-Col. J. K. Bradford of Toronto was elected first vice-president.

Guest speaker at the annual dinner was T. W. Eadie, M.E.I.C., of Montreal, president of the Bell Telephone Company of Canada Limited. A special feature of the dinner was the presentation to Gen. The Hon. A. G. L. McNaughton, M.E.I.C., honorary colonel commandant of the Corps of the Canada Decoration with two clasps, by Col. J. R. Dunlop, M.E.I.C., director of the Corps.

Delegates who attended the meeting and dinner were Lieut.-Col. E. D. Gray-Donald, M.E.I.C., chairman, Quebec Command chapter; Maj. O. B. Berringer, M.E.I.C., chairman, Eastern Command chapter; and Maj. L. Raisbeck representing Western Command chapter. Besides those mentioned above the following unit officers were present: Col. C. W. Jones, M.E.I.C., commanding the R. C. E. M. E. School, Barriefield; Lieut.-Col. L. Martin, M.E.I.C., commanding 3 Technical Regiment, Montreal; Lieut.-Col. L. M. Harding, commanding 4 Technical Regiment, Toronto; Maj. A. Anderson, 5 Technical Regiment, Hamilton; and Maj. O. Dunn, 6 Technical Regiment, Windsor.

R.C.E.M.E. Corps Association Meeting

Elections and Transfers

At the meeting of Council held at headquarters, on Friday, December 16th, 1955, a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

Members:

J. S. Arczynski, *Toronto*
W. L. Gross, *Montreal*
A. Mackie, *Toronto*
J. W. L. Monaghan, *Toronto*
E. M. Monteith, *Toronto*
J. E. Sutton, *Victoria*
E. I. Wigdor, *Montreal*
S. Wood, *Ottawa*

Juniors:

J. B. Laurie, *Montreal*
B. P. Nicholls, *Montreal*
J. R. Wells, *St. John's*

Transferred from the class of Junior to that of Member:

P. J. Boivin, *Kenogami, Que.*
N. E. Duncan, *Montreal*
G. Ewing-Chow, *Georgetown, B.G.*
J. L. Gariepy, *Sorel*
W. S. Jones, *Houston, Texas*
W. C. Leith, *Montreal*
M. H. Margles, *Toronto*
J. H. C. Massie, *Toronto*
A. R. D. Robertson, *Victoria*
G. C. Robinson, *Saint John*
T. E. Smith, *London*

The following Students were admitted:

McGill University

J. Achtman	A. Lipes
G. J. Akamoto	R. G. Lubelsky
R. J. Allore	L. J. Luyks
H. L. Atkinson	C. J. E. MacKay
G. Banks	P. G. Mackay
F. Barna	H. A. Macpherson
R. G. Begley	A. A. McAlear
R. E. Belair	J. G. M. McKirdy
P. R. Belanger	R. K. McNamee
G. Bellefleur	V. de P. Marceau
D. Bohonos	D. M. Martin
G. Boulais	S. R. Mester
J. E. Buchan	A. Miroshnichenko
I. A. Burla	W. G. Montgomery
J. R. G. Collard	D. R. Morrier
H. C. Clowes	W. H. Moulton
G. T. Connery	F. S. E. Murphy
C. H. Cormier	J. Mushka
T. A. Crooks	F. S. Nemet

Loyola College

R. K. Cox	S. M. Perrotta

Lakehead Technical Institute

G. W. Brown	R. T. S. Nash

Mount Allison University

G. W. Hannah

Graduates

L. Richard, B.Eng. (Mech.) 1955, Toronto.
K. E. Newbold, B.A.Sc. (Engrg. Physics) 1955, Toronto.
J. M. Neal, B.A. Sc. (Engrg Physics) 1955, Toronto.
J. D. Crickmore M.Sc. (Mining) Stanford 1955.

Applications through Associations:

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members:

R. F. Andretsch	K. G. Clarke

Junior to Member:

W. D. Usher	J. Steudel

SASKATCHEWAN

Members:

L. S. Earp	B. C. Palmer
F. A. Kidd	D. R. Rowe
J. H. Lapp	P. R. Wilson
R. L. McPherson	

Students:

H. R. Akehurst	J. J. Lipsett
D. Bartkiw	R. L. Mackenzie
D. W. Bishop	J. W. MacNeill
S. T. Bramwell	F. D. McCarthy
S. S. Brkich	J. M. McNeil
M. Cherney	A. W. Millard
E. W. Chornomydz	L. C. Miller
J. I. Daniels	F. W. A. Mosienko
S. I. Deckert	M. M. Muth
M. J. Demetrick	G. T. Narfason
G. C. M. Derbowka	G. G. Popoff
E. J. Dueck	W. A. Posehn
J. A. A. Field	V. A. G. Rein
D. G. Fisher	V. L. Ryhorski
T. B. Fletcher	R. Schindelka
F. W. Fossey	H. Schmidt
D. M. Galbraith	K. G. Schoenroth
F. K. Gerbrandt	W. J. Serne
T. P. Gilchrist	A. C. Shuster
R. W. Gillanders	R. O. Sochaski
W. H. Glaister	J. R. Stoffel
A. A. Gorkoff	G. R. Straub
H. M. Hleck	J. A. Thom
E. A. Hodgins	K. H. Thompson
L. A. Kaeding	M. B. Todd
H. J. King	L. E. Torfason
J. S. King	J. L. Townsend
B. W. Kischuk	S. S. Turek
G. Kobelak	S. D. Walker
P. Kozicki	D. J. Walsh
Paul Kozicki	M. W. Weddige
R. B. J. Kroeker	E. G. E. Wurts
G. E. Laliberte	T. Yoshida
D. L. Lawrysyn	

Junior to Member:

J. T. Dokken	K. J. MacRae
R. M. Heaton	

MANITOBA

Junior:

W. Naumko

NOVA SCOTIA

Members:

D. R. Downing	J. C. Eaton

Junior to Member:

A. M. Macdonald	D. E. Rudolph

Correction

In the December 1955 issue of the *Journal*, page 1693, under "Elections and Transfers"—Council Meeting of November 19, 1955, through a clerical error Mr. J. E. Wright, Toronto, was shown as a Member, whereas he was elected a Junior.

NEWS OF THE ASSOCIATIONS & CORPORATION

Information received through co-operation with the provincial organizations

Ontario

News of the Members

H. W. Tate of Toronto has been promoted from executive vice-president to president of De Leuw, Cather and Company of Canada, Ltd. at a recent meeting of the company which is associated with De Leuw, Cather and Company of Chicago.

De Leuw, Cather and Company of Canada Ltd., located at 52 St. Clair Avenue East, Toronto, was formed early in 1954 and at present employs nine professional engineers. Prior to joining this firm of consultants, Mr. Tate was assistant general manager of the Toronto Transportation Commission with which he had been associated for many years.

Norman A. Grandfield is now manager of the Public Utilities Commission of Brantford, Ont. A graduate in electrical engineering of Queen's University, Mr. Grandfield was formerly manager of the Public Utilities Commission of the City of Galt.

Donald H. MacDonald is on the engineering staff of H. G. Acres and Co. Ltd., of Niagara Falls, Ont.

Fred H. Edwards, formerly with the Canadian Westinghouse Company in Hamilton, is now assistant professor of electrical engineering at the University of Massachusetts, Amherst, Mass.

Professor Edwards graduated in electrical engineering from the University of British Columbia in 1949 and joined Westinghouse at that time. While with the Canadian Westinghouse he undertook post-graduate work and received a master's degree in electrical engineering from the Nova Scotia Technical College. He was appointed to the staff of the University of Massachusetts early this fall.

John W. Emerson is now engaged in the private consulting practice of John Emerson and Associates with Cleveland office at 1277 Ramona Avenue, Lakewood, Ohio.

Mr. Emerson graduated in engineering from the University of Toronto in 1930 and two years later obtained his master's degree. Before moving to the United States several years ago he was with John Inglis Company in Toronto

Robert B. Jennings, who was formerly claims and contract engineer with the Trans-Canada Highway division, Department of Public Works, is now associated with the Department of Planning and Works of the City of Ottawa

Dr. W. C. Winegard and **Dr. J. W. Rutter,** of the Department of Metallurgy of the University of Toronto, took part in a recent Canadian symposium on melting, diffusion and related topics. The meeting was held in Ottawa, under the auspices of the low temperature and solid state physics group of the National Research Council, to bring together scientists from Canadian research institutions and universities interested in various aspects of the problems of melting and the liquid state.

T. N. McLenaghan, of the Abitibi Power and Paper Company, Ltd., has been transferred from the Fort William division, where he was control superintendent, to the Iroquois Falls division of the company as assistant to the mill manager.

Dusan Lazarevich and Associates, Toronto consulting engineers, have moved to new offices at 244 Dupont Street, Toronto. We are informed by **D. P. Lazarevich** that the new phone number is WAlnut 10-6631.

Brian A. Tucker, of Canadian Westinghouse Co. Ltd., has been moved from Hamilton where he was employed as contract administrator, to Montreal, where he is senior technical representative of Westinghouse in one of the plants of Canadair, Ltd.

C. A. Dunham Co. Appointment

Announcement has been made by **A. J. Dickey**, president of C. A. Dunham Co. Ltd., of the election of **Richard M. Mitchell** as executive vice-president and assistant general manager of the company.

A graduate in engineering of Queen's University and also of the Harvard School of Business Administration, Mr. Mitchell has been actively connected with the heating and air conditioning industry for the past seven years. During the Second World War he served with the Royal Canadian Engineers, retiring with the rank of lieutenant-colonel.

H. C. Schwegler is now associated with the Dominion Electric Manufacturing Co. Ltd., of 60 Leslie Street, Toronto. He was formerly engaged in sales engineering with D. M. Fraser Ltd., of Toronto.

A. J. Vale has resigned from the employment of H. G. Acres and Co. Ltd., of Niagara Falls, Ont., to join the Atomic Energy of Canada Ltd., Deep River, Ont., as a design electrical engineer.

Heads National Carbon

The appointment of **John S. Dewar** as president of The National Carbon Company, a division of Union Carbide Canada Ltd., Toronto, was announced recently.

Mr. Dewar is a graduate in chemical engineering of Queen's University, and has been with National Carbon since 1943.

Lt. Col. R. H. Milne, of Toronto, has recently completed his tenure of command of the 2nd Field Engineer Regiment, R.C.E., whose headquarters are in Fort York Armouries, Toronto. Succeeding him in commanding the Regiment is **Lt. Col. A. G. Keith,** M.R.I.C.A., who is associated with A. D. Margison and Associates Ltd., of Toronto.

Colonel Milne graduated in civil engineering from the University of Toronto in 1941 and saw extensive service during the Second World War. He joined the 2nd Field Engineers Regiment shortly after return from overseas and was given command in 1952. He is chief engineer of the Department of Buildings for the City of Toronto.

W. E. Ewens has announced the opening of a consulting engineering practice in transit planning and traffic engineering. His offices are located at 462 Morrison Road, Oakville, Ont. Services offered in the transit field include long range and immediate planning, route studies, costs and all forms of transit research, particularly as related to smaller transit properties. Traffic services include all phases of traffic engineering, surveys and consultations.

Mr. Ewens is a graduate in civil engineering of the University of Toronto, and was with the Toronto Transportation Commission, as research engineer. He is a director of the Canadian Section of the Institute of Traffic Engineers.

Geoffrey C. Winkler has resigned his position as methods engineer at the Ford Motor Co. of Canada Ltd., Windsor, Ont., to accept a position as industrial-mechanical engineer with ACF Electronics, a division of American Car and Foundry Industries Inc., in Alexandria, Va.

Alberta

E.S.S. Plans Busy Year

Hugh Atkins, president of the Engineering Students' Society, when interviewed stated that they now have a membership of 670 students. This excellent percentage of the total student class speaks well for the membership campaign of the E.S.S.

Roy Mutter, secretary of the E.S.S., stated that a full program of monthly meetings was planned as well as many special events. The annual smoker, which has already been held, was extremely successful this year, with everyone on his best behavior.

First on the list of special events will be the annual Engineers-Nurses dance, a charitable undertaking, the proceeds from which go to the World University Service. In January the annual Engineers' Ball and Queen Contest will be held. This is the highlight of the E.S.S. program. Atkins stated that the Queens this year would be the most beautiful ever and that the model engineering displays would be the most outstanding to date.

In February and March the regular meetings will feature papers presented in the Webb Memorial Student Paper Competition. This competition, which is held in honour of the late Professor Webb, offers prizes of $25.00, $15.00 and $10.00 for the best papers presented to the E.S.S. during the regular term.

Finally, to complete the year, the annual Engineers' Banquet will be held in March.

Our interview with Hugh Atkins and Roy Mutter was too short to cover sports and other activities in which the engineers take part, but from what was learned it appeared that E.S.S. is, if anything, bigger and better than many readers will remember from their university days.

(Reprinted from *The Alberta Professional Engineer*, Nov. 1955.)

British Columbia

Annual Meeting in Victoria

Three hundred members and engineers-in-training affiliated with the Association of Professional Engineers of B.C. attended the two-day convention and annual meeting in the Empress Hotel, Victoria, on December 2 and 3. It was the first time the meeting had been held away from Vancouver since the Association was formed in 1920, and approximately 50 per cent of those present came from outside Victoria. Also in attendance were representatives of four other provincial Associations of Professional Engineers: E. W. Christian and A. E. McDonald, from Alberta; R. Bing-Wo, Saskatchewan; W. J. Patton, Manitoba; and Col. T. M. Medland, executive director of the Ontario Association.

Discussing their new duties are some of the members of the 1956 Council of the Association of Professional Engineers of British Columbia at the Association's annual convention held at the Empress Hotel, Victoria, on December 2 and 3. Left to right: W. O. Richmond, vice-president; J. E. Liersch, president; M. A. Thomas, all of Vancouver, and A. J. Saunders, Victoria.

C. D. Howe Addresses Luncheon

The Rt. Hon. C. D. Howe, Minister of Trade and Commerce, addressed an overflow audience at the annual luncheon on December 3. Mr. Howe said preliminary surveys of investment plans indicate that capital expenditure by governments and business in 1956 will be at least as high and probably higher than for the current year, and that this prospective expansion is not limited to any one area but seems to extend from coast to coast. He went on further to say that building activities during 1956 were more likely to be limited by shortage of materials than by a shortage of available capital. He warned, however, that there is no room for complacency, and advised that we have not yet been completely successful in mastering the problem of combining stability with progress.

J. E. Liersch Is New President

J. E. Liersch, vice-president of the Powell River Company, a forest engineer, was installed as president of the Association. He succeeds Dr. H. C. Gunning, dean of the Faculty of Applied Science at the University of British Columbia, who will serve another year on Council as past president. Elected as members of Council for 1956 were Professor W. O. Richmond, vice-president; A. C. Buckland, F. A. Lazenby, R. R. McNaughton, A. J. Saunders, and M. A. Thomas. Four additional members of Council will be appointed by the British Columbia Government.

Awards

At the annual awards luncheon on Friday, December 2, the Association Gold Medal was presented to F. S. Death, as the student in the 1955 graduating class at the University of British Columbia whose undergraduate record was considered by the Faculty to be most outstanding.

The Letson Memorial Prize, donated in memory of his father by Major-General H. F. G. Letson, C.B.E., M.C., E.D., for the best report or thesis submitted in support of an application for registration as a mechanical engineer, was awarded *in absentia* to N. L. Williams for his report "The Comparison Tower Concept for Predicting Cooling Tower Performance". Mr. Williams is at present on loan from the B.C. Electric Co. to the Chalk River development.

The Association Book Prizes of $25.00 value, which are annually awarded to engineering undergraduates in 3rd year Applied Science, will be presented during the president's visit to the campus next spring. Winners are: R. A. Sterne, chemical; J. J. F. Loewen, civil; W. N. Junas, electrical; K. H. Darke, geological; and E. Hay, mechanical.

The Ingledow Prizes, donated by T. Ingledow, for general proficiency in each year of engineering at the university, went to: W. R. Rasmussen; T. F. Somerville; J. J. F. Loewen; and L. G. Maranda.

Life Membership medallions were presented to: G. M. Irwin, Victoria; G. P. Sharpe, Salmon Arm; and W. Jamieson, Westview.

The president then called upon those about to receive certificates of registration and reminded them that they were publicly entering upon the privileges and responsibilities of a great profession; that they were bound by the same code of ethics as all professional engineers and that they must preserve the tradition of the profession faithfully as their most cherished possession. Certificates were then presented to the following: W. R. Cheriton, Vancouver; E. I. Dery, D. Logan, and D. G. Sutherland, all of Victoria; P. H. H. Hookings, and J. A. Procunier, of Vancouver; B. R. MacFarlane, of Port Alberni; H. M. Thurgood, of Campbell River; and Z. Wolski, of Westview.

In a special ceremony at Jubilee Hospital, Dr. Gunning, accompanied by Mr. Liersch and Registrar J. A. Merchant, presented a certificate of registration to A. C. Packard, who had been stricken with polio and was unable to attend the luncheon.

In addition to two days of business sessions there was a full program of social events, including two morning coffee parties and a Friday evening banquet for the 70 ladies who accompanied their husbands to the convention. For the men there was the annual stag party

(*Continued on page 106*)

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Frederick William Cowie, M.E.I.C., retired chief engineer of Montreal harbour, died in Montreal on October 30, 1955.

Mr. Cowie was born in Caledonia, Ont., on March 27, 1863. He received his education at Woodstock College and graduated from McGill University in 1886 with a B.A.Sc. degree in civil engineering. While at Woodstock College he studied special courses in mathematics and astronomy and spent his summer vacations as assistant in charge of the Astronomical Observatory there, and also worked on the survey of the Niagara Falls Park Commission. Upon his graduation from McGill he was employed as assistant engineer with the Montreal Harbour Commission, working on the St Lawrence ship channel.

In 1908, Mr. Cowie was one of a group of engineers who made extensive surveys of the principal harbours of Europe and the United Kingdom. This knowledge was put to use by Mr. Cowie during the first world war when he was sent as a consultant to Halifax where harbour expansion was underway. He was also responsible for planning the steady flow of grain shipments out of Halifax and Montreal at that time.

Mr. Cowie retired as chief engineer of the Montreal Harbour in 1926, having attained that position in 1907. After his retirement he was actively engaged as a consultant on major harbours including those at Norfolk, Va., Boston, Mass., and Havana, Cuba.

In 1914, Mr. Cowie received the Telford Medal of the Institution of Civil Engineers for a paper entitled "Transportation Problems in Canada and Montreal Harbour." More recently, he compiled the book, "Tales of the St. Lawrence," which is a series of incidents and stories connected with the River.

He was a member of the American Society of Civil Engineers. Mr. Cowie joined the Engineering Institute in 1887 as an Associate Member and transferred to Member in 1898. He attained life membership in 1933.

George A. Kydd, M.E.I.C., retired civil engineer in Ottawa, Ont., died suddenly in Kentville, N.S., on October 25, 1955.

Mr. Kydd was born in Montreal on November 20, 1883, and attended Montreal public and high schools. He graduated from McGill University in 1905 with a B.Sc. degree in civil engineering.

Upon graduation he joined the Grand Trunk Railway as assistant engineer in charge of construction of a grain elevator in Midland, Ont., and then was also with the National Transcontinental Railway in New Brunswick for a time, and with the Canadian Pacific Railway. In 1913 he joined the Department of Railways and Canals and was engaged on work on the Trent Canal in Campbellford, Ont. In 1924 he became divisional engineer on the Welland Canal, and then in 1932, resident engineer on Hudson Bay Terminals for the Department of Transport in Churchill, Man., subsequently coming to Ottawa as district engineer. He retired from the Board of Transport Commission in 1953.

Mr. Kydd joined the Engineering Institute in 1902 as a Student, transferred to Junior in 1911, to Associate Member in 1914, and to Member in 1940. He attained life membership in 1947.

Hector Somerville Philips, M.E.I.C., president of Philips and Roberts, consulting engineers of Hamilton, Ont., died suddenly of a heart attack in Port Colborne, Ont., on October 20, 1955.

Mr. Philips was born in Airdrie, Scotland, on November 20, 1882, and was educated at Wigan High School, Lancashire, England, and at Heriot-Watt College in Edinburgh.

Mr. Philips was employed as assistant engineer on various waterworks in Scotland before coming to Toronto in 1911 as draughtsman with the City of Toronto working on the design of sewerage and sewage disposal works, and then as engineer on sewage design. In 1915 he joined the staff of Professor E. B. Phelps, consulting sanitary engineer of the International Joint Commission in connection with the pollution of boundary waters, and the following year became designing engineer for Canada Nitro Products Company Ltd. in Toronto, in which capacity he supervised the design of a sharpnel loading plant. From 1916 to 1919 he held a commission as a lieutenant in the Royal Canadian Engineers.

In May, 1920, Mr. Philips was named engineer-in-charge of sewer design for the City of London, Ont., and the following year was named to the similar position with the City of Hamilton, Ont., subsequently becoming designing engineer. After twenty-three years service, in 1944, Mr. Philips retired from this position to establish the firm of Philips and Roberts, consulting engineers in Hamilton. At the time of his death he was president of this company.

Mr. Philips joined the Engineering Institute in 1915 as an Associate Member and transferred to Member in 1922. He attained life membership in 1951.

Charles H. Pinhey, M.E.I.C., construction engineer, died in Ottawa on November 6, 1955.

Mr. Pinhey was born in Ottawa on March 20, 1867, and was educated at Ottawa Collegiate Institute (now Lisgar Collegiate). He graduated from the School of Practical Science, Toronto, in civil engineering in 1887. The following year he passed examinations for Ontario Land Surveyor, and in 1889, for Dominion Land Surveyor. He was employed by the Department of Railways and Canals as rodman, leveller, and surveyor on the Soulanges Canal from 1889 to 1896, and for the next five years, as engineer for Manning & Macdonald, also working on the Soulanges Canal. He also spent some time as engineer on construction of a wharf at Three Rivers, Que., and then subsequently retired from active engineering practice to manage his personal property.

Mr. Pinhey joined the Engineering Institute in 1887 as a Student, transferred to Associate Member in 1894, and to Member in 1940. He attained life membership in 1947.

William O. Marble, M.E.I.C., partner in the engineering firm of Hodgson, King and Marble in Vancouver, B.C., died on August 27, 1955 in Vancouver.

Born in Hampstead, New Hampshire, he received his general education in Haverhill, Mass., and then studied engineering under private tutors. He spent five years as a draughtsman and resident engineer with the city engineer's office at Haverhill, Mass., and then in 1900, eight years on the engineering staff of Purdy Henderson, New York, working on the design of structural steel. Mr. Marble was then transferred to Boston by the company and was in charge of their engineering office in that city. From 1909 to 1917 he was western manager of Purdy Henderson (Canada) with headquarters in Vancouver, B.C.

In 1917 Mr. Marble entered into partnership with Hodgson and King as consulting engineers in Vancouver.

He was a member of the Association of Professional Engineers of British Columbia, and served on the board of examiners of the structural branch of that association.

Mr. Marble joined the Engineering Institute in 1919 as a Member, and attained life membership in 1950.

Alfred E. Hopper, M.E.I.C., retired steamship inspector, died in Ottawa on November 13, 1955.

Born in Darlington, England on July 20, 1870, Mr. Hopper received his general education there. He spent six and a half years as an engineering apprentice with the North Eastern Railway Company in Darlington before coming to Canada in 1891 and joining the Grand Trunk Railway Company in Montreal. The following year Mr. Hopper became an engineer on a ship and travelled extensively for several years.

In 1910 he was named steamship inspector at Vancouver, B.C. Mr. Hopper came to Ottawa in 1919 as principal inspector of boilers and machinery with the Department of Marine and Fisheries. He retired from government service in 1950.

Mr. Hopper became a Member of the Engineering Institute in 1923 and attained life membership in 1953.

Personals

News of the Personal Activities of Members of the Institute

H. S. Short, M.E.I.C., recently retired from his position as contract engineer of the Ontario division of Dominion Bridge Company Ltd. He will continue to be associated with the company as consultant, sales and contracting.

Mr. Short has spent 50 years in the structural steel industry. He began his career as a draughtsman with the Canada Foundry Company in 1906. In 1912 he became draughtsman checker with the Hunter Structural Steel Company and then in 1915 began his long association with Dominion Bridge, progressing through the positions of draughtsman, assistant chief draughtsman, sales engineer for Northern Ontario and Quebec, and, for the past 13 years, as contract engineer.

Mr. Short is a director of the Sault Structural Steel Company and a director and past-president of the Canadian Institute of Steel Construction. He is also a member of the Association of Professional Engineers of Ontario.

H. S. Short, M.E.I.C.

R. T. Harland, M.E.I.C.

MacKenzie McMurray, M.E.I.C., has been appointed sales manager in charge of sales and contracting by Dominion Bridge Company Ltd., Ontario division. He was formerly production manager with the company.

Mr. McMurray graduated in 1939 from the University of Toronto in metallurgical engineering and spent the following year at the University as a demonstrator in mining engineering.

In 1940 he joined the staff of Dominion Bridge's Toronto branch and spent the next five years as metallurgist and chief inspector at the Sorauren Avenue plant, then engaged in the production of munitions. He occupied a number of positions in the company's Toronto and Lachine, Que., plants until 1949 when he was appointed welding engineer at Toronto, a position he held until 1953 when he became production manager at that plant.

In 1954 Mr. McMurray received the degree of master of commerce from the University of Toronto. He is a member of the Association of Professinal Engineers of Ontario, of the American Society of Metals, and of the Canadian Welding Society.

He is a member of council of the Engineering Institute, and a past-chairman of the Toronto Branch.

M. McMurray, M.E.I.C.

M. D. Young, M.E.I.C.

Hydro Officials Promoted

The City of Winnipeg Hydro Electric System announces the appointment of **R. T. Harland,** M.E.I.C., as chief engineer and **M. D. Young,** M.E.I.C., as assistant chief engineer. Mr. Harland succeeds **D. C. Bryden,** M.E.I.C., who is now the utility's assistant general manager.

Mr. Harland graduated from the University of Manitoba with a B.Sc. degree in electrical engineering in 1938. In 1941 he received his M.Sc. degree from the Massachusetts Institute of Technology. He joined the staff of the Winnipeg Hydro in 1941, but from 1942 until the end of the war, served with the R.C.A.F. Returning to the Hydro in 1945, he became assistant principal engineer in 1948, and in 1952, principal engineer in charge of design.

M. D. Young, the new assistant chief engineer, graduated from the University of Manitoba in 1925 with a bachelor's degree in electrical engineering.

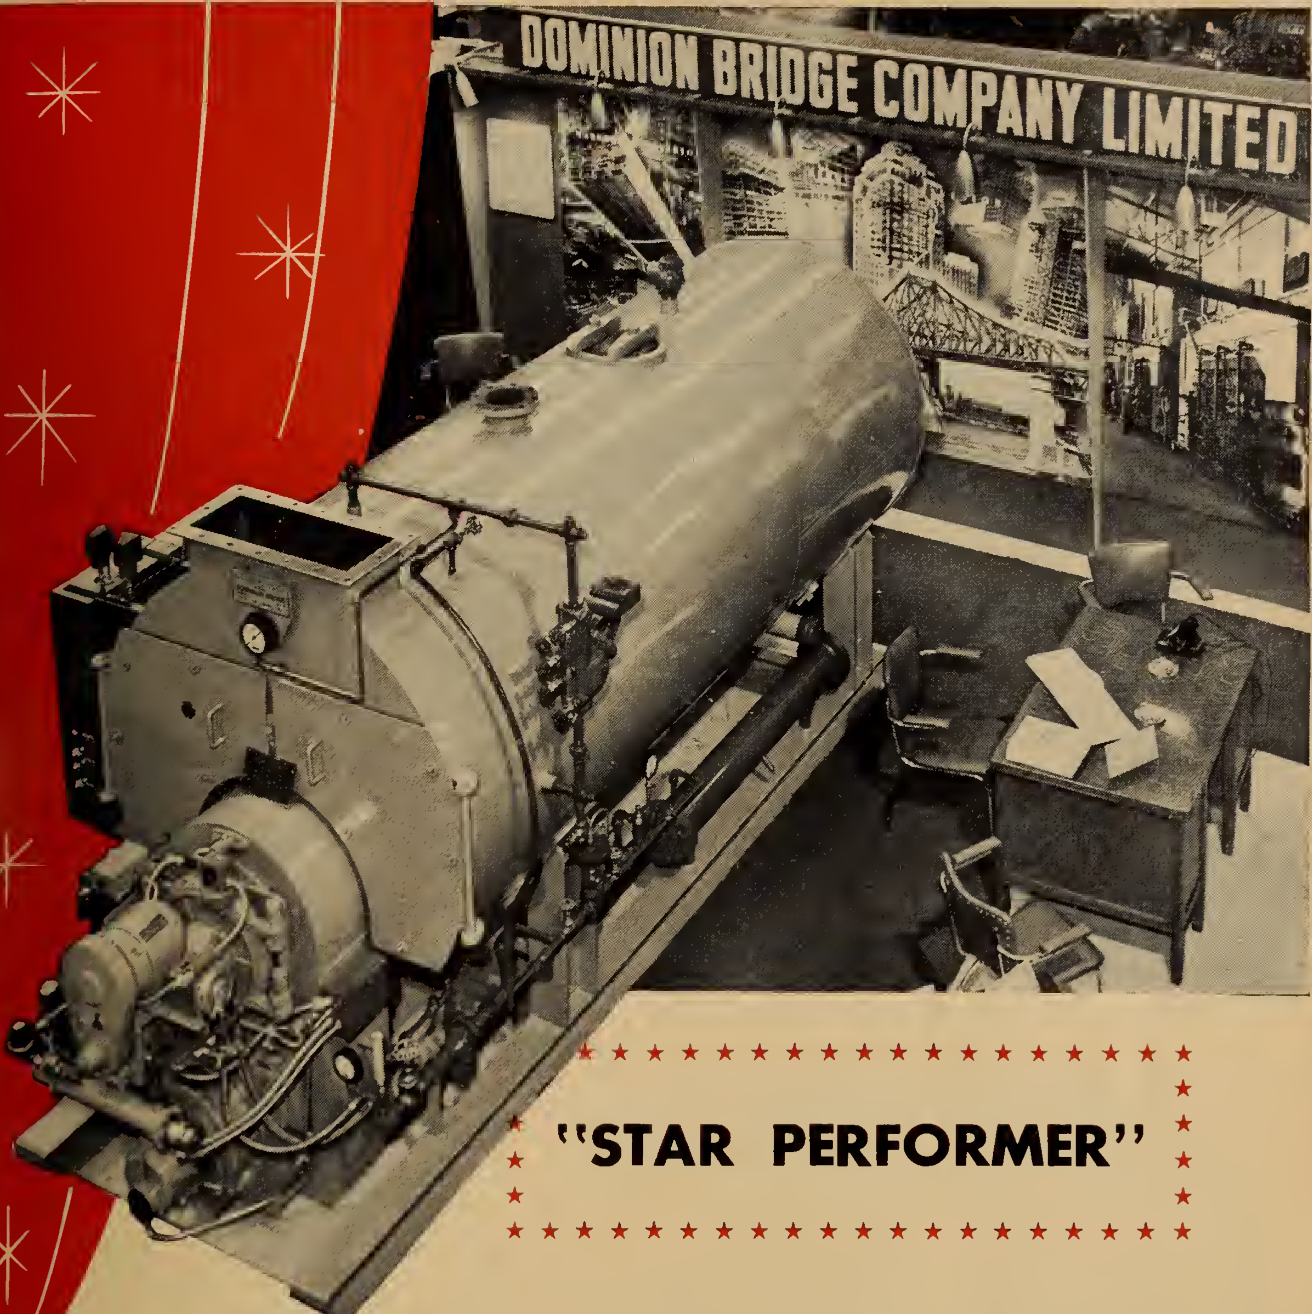
He joined the staff of Winnipeg Hydro in 1926 and has progressed through the positions of distribution engineer in 1930, assistant superintendent of distribution in 1938, assistant general superintendent in 1943 to general superintendent in charge of distribution in 1946.

Both Mr. Young and Mr. Harland are members of the Association of Professional Engineers of Manitoba and the Manitoba Electrical Association.

William O. Horwood, M.E.I.C., is now assistant to the president of International Equipment Company Ltd. at their head office in Montreal. Mr. Horwood was formerly branch manager of Lyman Tube and Bearings Ltd. in Toronto.

A mechanical engineering graduate of McGill University, class of 1937, he had joined Lyman Tube and Bearings Ltd. in 1945 and has also been eastern sales manager of that company's tubing and railway division.

J. H. Smith, M.E.I.C., vice-president and general manager of Canadian General Electric Company Ltd., who was recent-



"STAR PERFORMER"

No prima donna, the Star of *this* show is built for continuous day in and day out performance and is winning applause from heating engineers across the country!

Differing from other package boilers, it can be supplied with any proven type of firing equipment to suit individual conditions.

The user has the advantage of a generator "tailored" to his needs which offers the best local service facilities.

Full responsibility for the complete unit is taken by Dominion Bridge Company.

Hundreds of these boilers, already installed, have been proven in service.

ly transferred to Montreal to head the company's appliance division, is now in Peterborough, Ont., where he will hold the corresponding position in the apparatus division.

James Lundie, M.E.I.C., has been appointed district engineer of the Canadian Pacific Railway's New Brunswick district, with headquarters in Saint John. For the past two years Mr. Lundie has been locating engineer for the C.P.R. at Hemlo, Ont., where he built the recently opened Manitouwadge sub-division.

Mr. Lundie has been with the C.P.R. since his graduation in civil engineering from the University of Saskatchewan in 1930.

In 1939 he was appointed bridge and building master at Regina, and from 1944 to 1950 served as division engineer at Schreiber, Ont., Woodstock, Ont., and London, Ont. He was then appointed assistant district engineer at Toronto, a post he held until taking on the Manitouwadge project.

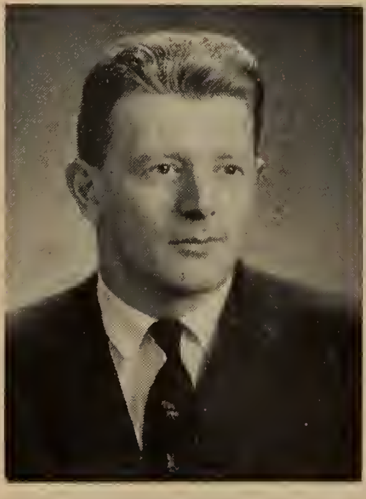
D. L. Dickson, M.E.I.C., has been named vice-president of the Eastern Electrical Supply Company in Montreal. He joined the company earlier this year as sales engineer.

A graduate of the College of Technology in Belfast, Mr. Dickson has also been electrical assistant with the Electric Tamper & Equipment Company in Montreal.

D. C. MacCallum, M.E.I.C., president of Racey, MacCallum and Associates Ltd., announces the appointment of **George L. Houghton,** M.E.I.C., as executive engineer in charge of the Toronto division of the company, and **R. Murray Campbell,** M.E.I.C., as executive engineer in charge of the Montreal division.

Mr. Houghton was previously assistant to the vice-president, Toronto division and Mr. Campbell was previously assistant to the president (technical).

Lionel Swift, M.E.I.C., has been appointed assistant general manager for Canadian Hoosier Engineering Company Ltd. in Montreal.



G. L. Houghton, M.E.I.C.

Lionel Swift, M.E.I.C.

Mr. Swift is a native of Shawinigan Falls, Que., where he received his early schooling and where he worked for some years before starting his studies at McGill University. He graduated in electrical engineering in 1934 and then spent the following two years on the Shawinigan Water and Power Company's training course. He worked in the generating and transmission department until 1945 when he was transferred to the Quebec Power Company.

With Quebec Power he successively occupied the positions of superintendent of the engineering department, superintendent of the electricity division, and finally, general superintendent of operations.

He is a member of the Corporation of Professional Engineers of Quebec, and of the American Institute of Electrical Engineers. He was also assistant professor in the electrical department of Laval University.

F. M. Kraus, M.E.I.C., has now established his own consulting engineering business in Montreal. He was previously with the Stadler Hurter Company in Montreal as structural design engineer.

Mr. Kraus received his doctor of engineering degree from Politecnico Di Turin in Italy in 1947.

R. M. Campbell, M.E.I.C.

W. A. Bentley, M.E.I.C.

William A. Bentley, M.E.I.C., has been named contract engineer for the Ontario division of Dominion Bridge Company Ltd.

Mr. Bentley received his education at Central Technical School and the University of Toronto. He spent a year with the Solway Process Company in Syracuse, N.Y., and then returned to Toronto in 1927 to join the staff of the McGregor-McIntyre Iron Works. After that company was taken over by Dominion Bridge in 1928 he served in various capacities until 1941 when he was appointed resident engineer of the Sorauren Avenue munitions plant. From 1946 he has been sales engineer in charge of mining sales, and in 1951 and 1952 he was on loan to the steel division of the Department of Defence as chief of the fabricating section.

Lt. Col. J. L. Dery, M.E.I.C., has joined Franki Compressed Pile Company of Canada Ltd. and will take charge of the new branch office to be opened in Ottawa. He was formerly with Pentagon Construction Ltd. in Montreal.

A graduate of the Royal Military College of Canada in 1934, Mr. Dery was in the Montreal district office of the Department of Public Works of Canada from 1934 to 1946. He served overseas during the Second World War with the R.C.A.

He has also been associated with Labrador Construction Ltd. and with Key Construction Limited in Montreal prior to joining Pentagon Construction in 1952.

Dr. W. C. Gussow, M.E.I.C., was recently honoured by the American Association of Petroleum Geologists. He was named distinguished lecturer and spent the month of November travelling extensively through the United States lecturing on "Problems of Oil Migration". While in Los Angeles he was the keynote speaker of the Association's annual regional meeting.

Dr. Gussow who practices as a consulting geologist in Calgary Alta. has travelled and worked in 18 different countries. He holds his B.Sc. and M.Sc. degrees from Queen's University in geology and mineralogy and before entering private practice was employed as chief geologist for the Shell Oil Company of Canada.

• *Personals*

R. N. Fournier, M.E.I.C., has been named manager of the mid-west district of the wholesale department of Canadian General Electric Company Ltd. in Winnipeg, Man.

A graduate in engineering physics from the University of Saskatchewan, Mr. Fournier joined C.G.E. in 1937. He served during the Second World War with the R.C.N.V.R. and returned to C.G.E. in 1945 as manager of the supply division in Halifax, N.S. Since 1952 he has been manager of the Maritime district of the wholesale department with headquarters also in Halifax.

J. G. Malus, M.E.I.C., has taken a position as structural engineer with H. A. Simon Limited, consulting engineer, in Vancouver, B.C.

Mr. Malus was formerly in Regina, Sask., with the Canadian Pacific Railway. He graduated in 1952 from the University of Manitoba in civil engineering and joined the C.P.R. as transitman in the division engineer's office.

Wm. A. Arsenault, M.E.I.C., is now associated with Fraser-Brace Engineering Company Ltd. in Montreal.

Mr. Arsenault was previously employed as resident engineer with the Rankin Newfoundland Company at St. Lawrence, Nfld.

A graduate of Nova Scotia Technical College in 1937, he has also been resident engineer with the Nova Scotia Department of Highways at Amherst, N.S.

R. N. Fournier, M.E.I.C.

D. R. C. Morris, M.E.I.C., has been transferred to Beauharnois, Que., by the Aluminum Company of Canada. His position will be superintendent of the mechanical and electrical division. He was previously in Shawinigan Falls, Que., for the company as electrical superintendent of their plant there.

Mr. Morris graduated from McGill University in 1947 in electrical engineering.

W. G. Enouy, M.E.I.C., has been appointed manager of the new Ottawa district sales office of Robertson-Irwin Ltd. of Hamilton, Ont. He was formerly manager of the Montreal branch of the company.

Mr. Enouy graduated in 1927 from the University of Toronto and immediately joined the H. H. Robertson Company in Toronto. He was transferred in 1936 to Montreal as district manager and then recalled to Toronto in 1946, moving to Hamilton with the transfer of the company headquarters to that city. With the amalgamation

of H. H. Robertson Company and Thomas Irwin & Son Limited as Robertson-Irwin Limited, Mr. Enouy assumed the duties of sales manager of the Robertson division, becoming subsequently general sales manager of promotion and development.

W. A. Ker, M.E.I.C., has been transferred to Victoria, B.C., by the Department of Lands and Forests, his new position is that of deputy comptroller of water rights and chief of the operations division. Mr. Ker was previously in Kelowna, B.C., with the Water Rights Branch of the British Columbia Government.

Mr. Ker is a civil engineering graduate of the University of British Columbia.

H. H. Todgham, M.E.I.C., and **C. W. Case,** JR.E.I.C., have formed a partnership as consulting civil engineers in Chatham, Ont. This new firm will offer consulting services in land surveying, drainage, structural design, and general municipal engineering.

Mr. Todgham was formerly a partner in the firm of Brisco and Todgham, Chatham, Ont., and has been in consulting practice with C. G. R. Armstrong in Windsor, Ont. He graduated from the University of Toronto in 1946 with a B.A.Sc. degree in civil engineering.

H. H. Todgham, M.E.I.C.

C. W. Case, Jr. E.I.C.

Mr. Case was deputy city engineer for the City of Chatham, having been appointed assistant city engineer after his graduation in 1950 from the University of Toronto.

C. H. Vatcher, M.E.I.C., has joined Salem Engineering Limited in Toronto as a sales engineer. Prior to this new position he was with Dominion Cutout Company Ltd. and Dominion Carbon Brush Company Ltd., also in Toronto.

A 1939 graduate of the University of Toronto, Mr. Vatcher has been with Canadian National Carbon Company Ltd., both in Vancouver and Toronto, and with the Toronto office of English Electric Company of Canada Ltd.

During the Second World War he

• *Personals*

served with the engineering branch of the R.C.N.V.R.

Donald C. Rotherham, M.E.I.C., has joined S.W. Explorations, C.M.&S. Company, in Trail, B.C.

A graduate in geology from the University of Saskatchewan, Mr. Rotherham was previously associated with Dee Explorations Limited in Saskatoon, Sask., as a geologist.

A. C. Findlay, M.E.I.C., is now with the engineering department of the head office of the Dupont Company of Canada in Montreal, and is engaged in project work for the company. Previously he was with Standard Brands Limited in Montreal as plant engineer.

Mr. Findlay graduated in mechanical engineering from McGill University in 1942. After a year with Steel Company of Canada Ltd., he joined the R.C.A.F. and served for two years as a flying officer. Upon his release from the service he became associated with Canadian Vickers Limited in Montreal, and then joined Standard Brands Limited in 1947 as project engineer.

A. J. Lewis, M.E.I.C.

A. J. Lewis, M.E.I.C., was recently appointed sales application engineer of the Scintilla Division of the Bendix Aviation Corporation, Toronto, and will assist Canadian airframe and related equipment manufacturers with electrical connector requirements and applications.

Brigadier D. A. G. Waldock, M.E.I.C., has been named chief superintendent of the Canadian Armament Research and Development Establishment at Valcartier, Que. He was previously director of Army Development at Army Headquarters in Ottawa.

Brigadier Waldock enlisted in the Royal Corps of Signals in 1939, was commissioned in 1940 and attained the rank of lieutenant-colonel in 1945. He was commissioned in the Royal Canadian Artillery in 1946 as a major and in 1952 he was promoted to the rank of colonel as commanding officer at Valcartier.

Early in 1955 he was named director of Armament Development at Army Headquarters, and in November was transferred to the Defence Research Board as chief superintendent.

Colonel C. R. Boehm, M.E.I.C., will relinquish command of Canadian Armament Development and Experimental Establishment and his appointment as deputy chief superintendent of the Canadian Armament Research and Development Establishment on being transferred to Defence Research Board headquarters as director of liaison. Col. Boehm will coordinate scientific liaison between D.R.B. headquarters and the defence research members on the Canadian Joint staffs in London and Washington.

A 1929 graduate of the University of Toronto, Col. Boehm was employed prior to the war as mining engineer in northern Ontario and Quebec. He was commissioned in the R.C.O.C. at the beginning of the war, transferring to the R.C.E.M.E. upon its formation. He served overseas with both corps for over five years.

In April, 1946 Colonel Boehm was promoted to his present rank and became deputy director of mechanical engineering at Army Headquarters, subsequently becoming director in 1948. Five years later he was appointed to London, England, as deputy Army member, Canadian Joint Staff, after

"Here's where the **TORRINGTON NEEDLE BEARING** *gets its high load capacity"*

The radial load capacity of an anti-friction bearing depends, in the final analysis, on the number of lines or points of contact made by the bearing surfaces in the load zone. This is where the Torrington Needle Bearing really shines.

With its full complement of precision-ground rollers, the Needle Bearing gives many more lines of contact than other types of anti-friction bearings. Thus for a given size, the Needle Bearing has a *greater* radial load capacity than other bearings.

What does this do for your product? The Needle Bearing can give you the benefits of its high-capacity performance for little more than the cost of a plain bearing; it can help you reduce the size and weight of surrounding members without sacrificing shaft strength, thickness or rigidity.

For twenty years, our Engineering Department has helped designers and manufacturers throughout industry to adapt the unique advantages of the Needle Bearing to their products. Let us help you make the Needle Bearing "standard equipment" in yours.

THE TORRINGTON COMPANY, LTD.
925 Millwood Road • Toronto 17, Ont.

TORRINGTON NEEDLE BEARINGS
Give you these benefits

- low coefficient of starting and running friction
- full complement of rollers
- unequalled radial load capacity
- low unit cost
- long service life
- compactness and light weight
- runs directly on hardened shafts
- permits use of larger and stiffer shafts

District Offices and Distributors in Principal Cities of United States and Canada

attending the National Defence College at Kingston, Ont.

Early in 1955 he was named deputy chief superintendent of the Canadian Armament Research and Development Establishment at Valcartier, Que., and at the same time he was commanding officer of the Canadian Armament Design and Experimental Establishment. the Army unit integrated with the Defence Research Board research station at Valcartier.

J. S. Busby, JR.E.I.C., assistant division engineer of the Coçhrane division of the Canadian National Railways, is the new secretary-treasurer of the North Eastern Ontario Branch of the Engineering Institute.

Mr. Busby served with the R.C.N.V.R. during the Second World War and then received his civil engineering degree from the University of New Brunswick in 1948.

That year he joined the Montreal Engineering Company as assistant purchasing agent, and then in 1950 first became associated with the C.N.R. as instrumentman in the Laurentian division. In 1952 Mr. Busby was junior assistant engineer in the Cochrane division and then assistant engineer in 1953 in the same division. He was appointed assistant division engineer in June, 1955.

He is a member of the Corporation of Professional Engineers of Quebec.

Mr. Busby joined the Engineering Institute as a Student in 1946, transferring to Junior in 1950.

Claude Senneville, JR.E.I.C., is now with the firm of Deschamps and Belanger, engineers and contractors of Montreal. He has recently returned from Europe where he was with Defence Construction (1951) Limited as area engineer in eastern France.

Mr. Senneville is a 1947 graduate of Ecole Polytechnique in civil engineering.

Christian R. deLannoy, JR.E.I.C., has been transferred by the Aluminum Company of Canada to Kitimat, B.C. He was previously in Isle Maligne, Que., as trainee with the company.

Mr. deLannoy received his B.Sc. degree from the Catholic University of Louvain in 1947, and his M.Sc. degree in 1950.

Kenneth H. Cram, JR.E.I.C., was recently appointed an assistant professor in the chemical engineering department of the University of Kansas. He was formerly with the chemical and metallurgical division of General Electric in Pittsfield, Mass.

Mr. Cram graduated in 1947 from McGill University with a bachelor's degree in chemical engineering and then spent three years with the Aluminum Company in Arvida, Que. Then he entered the graduate school at Princeton University and obtained a Ph.D degree in chemical engineering.

Harvey N. Burrows, JR.E.I.C., has been transferred by Canada Cement Company Ltd. to Fort Whyte, Man., as plant engineer. He previously held the same position in Montreal East, Que., for the company, and has also been plant engineer at the company's Port Colborne, Ont., plant.

Mr. Burrows graduated in 1947 from the University of Saskatchewan with a B.Eng. degree in ceramics, and has also been employed by Canadian Gypsum Company Ltd. at Hagersville, Ont.

Captain D. C. H. Francis, JR.E.I.C., has been posted to the School of Military Engineering of the British Army as an Exchange instructor at Chatham, Kent, England.

Captain Francis graduated in 1949 from the University of Saskatchewan with a B.Sc. degree in civil engineering. He joined the R.C.E. upon graduation and was stationed at the R.C.S. M.E., Chilliwack, B.C.

W. F. Allen, JR.E.I.C., is now project engineer with the Consolidated Toronto Development Corporation. He was formerly in Windsor, Ont., as a design engineer with the Ford Motor Company of Canada.

Mr. Allen is a 1949 graduate of Cambridge University in mechanical engineering, and has also been with the Department of Highways at Hamilton, Ont., as estimating engineer.

John T. Sinclair, JR.E.I.C., has been transferred to Toronto from Sarnia, Ont., by Imperial Oil Limited.

Mr. Sinclair graduated in 1949 from the University of Toronto with a B.A.Sc. degree in chemical engineering.

A. D. R. Robertson, JR.E.I.C., is with the Water Rights Branch of the Department of Lands and Forests of the British Columbia Government at Victoria, B.C., as hydraulic engineer.

A 1949 civil engineering graduate of the University of British Columbia, Mr. Robertson has also been connected with British Columbia Forest Service as project engineer, and with B.C. International Engineering Company Ltd. as design engineer in Vancouver.

Donald W. Gordon, JR.E.I.C., is now with the Bridge and Tank Company in Hamilton, Ont. He was formerly connected with Vulcan Iron Works Ltd. in Winnipeg, Man.

Mr. Gordon, who graduated in 1950 from the University of British Columbia in mechanical engineering, has also been with the tank department of the Toronto Iron Works.

William M. Kruse, JR.E.I.C., is now employed as a zone engineer with the mechanical department of Imperial Oil Limited at their Sarnia, Ont. refinery. He was field engineer with the Steel Company of Canada in Hamilton, Ont.

Mr. Kruse received his B.A.Sc. degree in civil engineering from the University of Toronto in 1950.

J. D. Dunn, JR.E.I.C., has joined Canadian Splint and Lumber Corporation, Ltd., as plant engineer in Pembroke, Ont. He was previously plant engineer at Nobel, Ont. for A. V. Roe of Canada Ltd.

Mr. Dunn graduated from Nova Scotia Technical College in 1951 with a

60 M.W. Turbo-generator installed in a British power station.

Four turbo-blowers (duty of each blower 80,000 cubic feet of free air per minute delivered at 30 lbs. per square inch pressure.)

Two 36 M.V.A. generator transformers and two 5,000 K.V.A. station transformers.

• *Personals*

bachelor's degree in mechanical engineering.

Douglas R. Wilson, Jr.E.I.C., has been appointed town engineer of Georgetown, Ont. He formerly held the same position at Greenfield Park, Que.

A civil engineering graduate of McGill University, class of 1951, Mr. Wilson spent some time on the divisional staff of Canadian National Railways and then joined H. W. Lea, consulting engineer of Montreal for two years.

In 1953 he was associated with Shell Oil of Canada as construction engineer with their Montreal East refinery and then in 1954 became town engineer of Greenfield Park.

Mr. Wilson served during the Second World War with the R.C.N.

Jean Louis Desautels, Jr.E.I.C., is presently employed as resident engineer with Defense Construction (1951) Limited, stationed at No. 2 (F) Wing, R.C.A.F., in Grostenquin (Moselle), France.

Mr. Desautels graduated with honours from the University of Toronto in 1951 with a B.A.Sc. degree in mechanical engineering, and has been with the Canadian International Paper Company at Three Rivers, Que.

W. E. Erlebach, Jr.E.I.C., has returned to Canada after receiving his Ph.D. degree at Cambridge University on an Athlone Fellowship, and is employed as an assistant research officer by Atomic Energy of Canada Ltd. at Chalk River, Ont.

Mr. Erlebach graduated from the University of British Columbia in chemical engineering receiving his B.A.Sc. degree in 1951 and his M.A.Sc. degree in 1953.

W. H. Loney, Jr.E.I.C., has been named plant engineer with Hobart Manufacturing Company Ltd. in Owen Sound, Ont. He was previously production engineer for the company.

Mr. Loney graduated in 1951 from the University of Toronto in mechanical engineering.

H. B. McLenaghan, Jr.E.I.C., is now in Fort Garry, Man., with Malcom Construction of Winnipeg, employed as an estimator. He was formerly with Structural Engineering Services in Calgary, Alta. as a structural engineer.

Mr. McLenaghan graduated in 1952 in civil engineering from the University of Manitoba and has also been associated with J. A. Lamb, consulting engineer in Calgary, and with the Central Mortgage and Housing Corporation as assistant resident engineer, also in Calgary.

R. Bryan Erb, Jr.E.I.C., has returned from a two year post-graduate course in England studying aerodynamics, and is now with Avro Aircraft Limited at Malton, Ont., as an aerodynamicist.

Mr. Erb graduated in 1952 from the University of Alberta in civil engineering.

Grant M. Locke, Jr.E.I.C., is now employed as design engineer in the atomic division of the Canadian General Electric Company in Peterborough, Ont.

Mr. Locke graduated from the University of New Brunswick in 1952 in civil engineering, and has recently been in Pittsburgh, Penn., with the Pittsburgh Des Moines Steel Company.

Jean Favron, Jr.E.I.C., is now with the aircraft design department of Canadair Limited, Montreal, as a designer. He recently returned from England, where he spent two years on an Athlone Fellowship.

He graduated in 1952 from Ecole Polytechnique with a B.A.Sc. degree in mechanical and electrical engineering, and then was employed as a mechanical design engineer with Canadian Industries Limited in Brownsburg, Que.

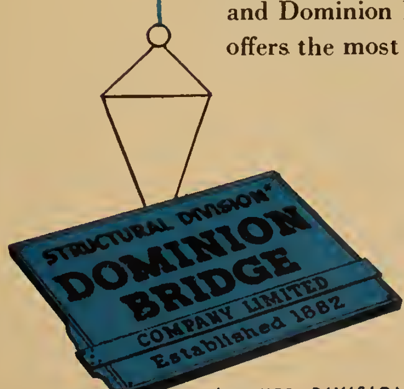
William M. Chisholm, Jr.E.I.C., is now on the staff of the Ottawa Hydro-Electric Commission as junior distribution engineer.

A 1952 graduate of Nova Scotia Technical College in electrical engineering, Mr. Chisholm has previously been with the International Nickel Company of Canada at Copper Cliff, Ont., and at Levack Mine.

Robert A. Newey, Jr.E.I.C., has now joined the staff of Dominion Engineering Company Ltd. in Montreal.

Mr. Newey is a mechanical engineering graduate of the University of Manitoba, class of 1953.

He has been in England, where he was an engineering student apprentice with C. A. Parsons & Company Ltd., in Newcastle on Tyne.



STRUCTURAL DIVISION*
DOMINION BRIDGE
COMPANY LIMITED

• Personals

J. Glenn Allan, Jr.E.I.C., is now with Canadian National Railways, and is employed as junior assistant engineer in the Belleville division office, Belleville, Ont.

Mr. Allan graduated in 1953 from Queen's University in civil engineering and then joined the Department of Highways of Ontario in Toronto.

Sydney Narvey, S.E.I.C., has been named senior engineer with Canadian Kodak Company Ltd., working on the design and installation of the plant air conditioning systems. He was formerly chief engineer with Engineering Industries Company Ltd. in Toronto.

Mr. Narvey graduated from North Carolina State College in 1953 with a B.Sc. degree, and spent some time as sales engineer with the refrigeration and air conditioning division of John Inglis Company Ltd. in Vancouver, B.C.

Zoltan D. Simo, S.E.I.C., is now employed as mechanical superintendent with Canada Packers at Edmonton, Alta. He graduated last year from the University of Saskatchewan with a B.Sc. degree in mechanical engineering.

Raymond Dumas, S.E.I.C., who graduated last year from Laval University with a B.A.Sc. degree in civil engineering and has recently been in Munich, Germany, studying prestressed concrete, is now in Labrieville, Que., with Concrete Repairs and Waterproofing Company Ltd.

F. R. Scrase, S.E.I.C., has been transferred by Canadian National Railways from Belleville, Ont., to Stratford, Ont., working in the division engineer's office. He graduated this year from the University of Manitoba with a B.Sc. degree in civil engineering.

Myron Flett, S.E.I.C., who graduated this year from Nova Scotia Technical College with a bachelor's degree in mechanical engineering, is now working with the firm of R. M. Way & Company Ltd., consulting engineers in Toronto.

Leonard R. Walker, S.E.I.C., is now an engineering trainee at Canadair Limited in Montreal. He is a 1955 graduate of the University of Manitoba in mechanical engineering.

F. D. McIntosh, S.E.I.C., has joined the Department of National Defence, armaments branch in Ottawa, Ont., as methods engineer for inspecting services. He received his B.A.Sc. degree this year from the University of Toronto in engineering and business.

William Brownlee, S.E.I.C., who graduated this fall from McGill University with a bachelor's degree in mechanical engineering, is now working with Rolls-Royce Limited in Montreal.

A. H. Abbott, S.E.I.C., has joined the Department of Highways and Public Works of Nova Scotia as a structural engineer in Halifax, N.S.

Mr. Abbott graduated from the University of New Brunswick this year in civil engineering.

M. M. Krpan, S.E.I.C., an electrical engineering graduate of the University of Alberta, class of 1955, is now employed by the Hydro-Electric Power Commission of Ontario in Toronto.

Activities of the Forty-seven Branches of the Institute

and

abstracts of papers presented at their meetings

Belleville

J. A. Grant, M.E.I.C.,
Secretary-Treasurer

General Meeting

The Belleville Branch of the Engineering Institute of Canada held its second meeting of the 1955-56 season on November 14, 1955, at the Masonic Temple. Approximately 20 members and guests attended.

C. L. Curry, assistant chief supervisor of field maintenance at the Maitland Works of Dupont of Canada spoke on "Instrumentation in a Continuous Process Plant". His talk was illustrated by lantern slides and was found very instructive to his audience.

The speaker was introduced by B. H. Downman and thanked by C. E. Meyers.

Brockville

Engineers and Guests Tour R.C.A. Victor Plant

The Brockville Branch members and their families, approximately 75 people, spent an informative morning on October 15 visiting the R.C.A. Victor Co. Ltd. in Prescott, Ont.

The tour was conducted through the five major production lines, each 350 ft. long, by the R.C.A. staff members.

The visitors were shown the printed circuit which is a special feature or advancement this year. The production of printed circuits are subassembled on their own sections and then moved to the main assembly line where they are added to the main chassis.

W. V. Heyden on behalf of A. M. Patience, plant manager, welcomed the visitors in the cafeteria, giving them some interesting statistics.

1000 T.V. Sets a Day

Other factors or production figures of Canada's biggest radio and television factory can be visualized by considering the enormous scheduling and planning problems.

Approximately 20 tubes for each 1,000 sets means 20,000 tubes per day; 300 electrical and 200 mechanical components per set, equals 500,000 components a day; for every five workers, there are two inspectors to check for the quality of the product.

Each component is already counted and tested some way or other before it enters the factory. This close inspection and quality control follows the sets on their route through the whole production cycle until they are shipped.

Chairman Fred Walsh, on behalf of the members and their families, thanked the R.C.A. Victor people for their conducted tour and the lunch.

Principles of Investment

R. D. Steers, educated at Loyola College and an associate of the R. D. Steers investment firm, was speaker at the Junior Member meeting held at the Manitonna Hotel on November 3.

Mr. Steers subject was "Principles of Investment".

The speaker stressed the point that "one should consider stocks as a part of his investment program, as part of his planning for the future as a means of putting his surplus funds to work, but not as a detour into gambling." He continued by saying that "the investor should realize that there is no royal road to riches, but that one should expect a reasonable income on his money plus a slow steady growth in values."

One of the best investments, Mr. Steers stated is Canada Savings Bonds. They are negotiable and have an attractive interest rate.

The speaker was introduced by W Simmons and thanked by T. Reade.

Eastern Townships

J.-P. Champagne, Jr.E.I.C.,
Secretary-Treasurer

G. Lorne Wiggs Is Guest Speaker

The eastern Townships Branch held a joint meeting with the Corporation of Professional Engineers of the Province of Quebec on Friday, November 11. G. Lorne Wiggs, Corporation president, was the guest speaker.

Mr. Wiggs said he was very happy to be in Sherbrooke in that he counts himself a resident since he spends his summers near one of Sherbrooke's "suburbs" — Magog. The Corporation has had a successful year, he said, in that it has brought its total membership up to 5,300, and has seen the completion of its new Montreal headquarters.

Corporation's Work Is Described

The demand for qualified engineers is still increasing, he said, as can be seen by the metropolitan newspaper ads for engineers to serve in Ottawa, Hamilton, Vancouver, Cleveland, etc. He admitted that the Quebec engineer does not quite, as yet, partake of the same privileges as engineers of other provinces; his role in the planning of a public building is second to that of the architect. However, the Corporation is working hard to enhance the prestige of the profession, he said, by keeping a strict surveillance over the use of the title of engineer; by insisting that public bodies hire engineers rather than other professionals when, due to the nature of the work, it can be performed as well, or better, by an engineer. Mr. Wiggs pointed out that more and more Quebec firms are employing engineers directly to design the electrical, mechanical and structural works of their projects rather than em-

ploying them indirectly through architects. A number of others, he said, are employing engineers as project managers to direct and control both architects and consulting engineers who prepare the plans and specifications for their projects.

Executive Changes

During the meeting two important changes in the executive of the local groups were announced. Jacques Lemieux was appointed chairman of the Eastern Townships Branch of the Engineering Institute to succeed Walter Sutherland who had resigned this office because of his frequent absence from Sherbrooke. Gaston Massé was elected regional representative of the Corporation of Professional Engineers. He succeeds George Dick whose term of office had expired.

At the E.I.C.-C.P.E.Q. joint meeting held in Sherbrooke on November 11. Front row, left to right, R. D. Mawhood, vice-chairman; J. Lemieux, chairman; G. Lorne Wiggs, C.P.E.Q. president; Dr. A. Crépeau, honorary chairman; and G. M. Dick, honorary chairman. Back row, left to right, J. P. Champagne, secretary; R. Painchaud, G. L. Côté, Léo Roy, Rev. Brother Léandre, G. Massé, and Pierre Bournival.

Panel Discussion on Traffic

The November meeting of the Fredericton Branch was held on the 21st of the month at Colwell's Inn, with about 40 members present.

Professor H. W. McFarlane, chairman of the Fredericton Branch, presided. Following a short business meeting, a panel discussion took place concerning the traffic problem in this city.

Members of the panel were Bill Barrett, city engineer, C. E. Weyman, alderman, B. Barker, chief of police, and John Evans, chairman of the Junior Chamber of Commerce. Professor McFarlane acted as chairman.

Problems and Improvements

The panel opened the discussion stating the various problems which exist in this city, such as blind crossings, heavy

Number three of a series . . . . ADVANTAGES OF RAYMOND CONCRETE PILES*

*uniform bearing capacity

THE COMPLETE FLEXIBILITY of Raymond Concrete Piles as to length permits all piles to be driven to a uniform resistance regardless of variations in depths of bearing soils. Raymond Piles are available in an endless variety of lengths through combining step-taper sections of different lengths or joining step-taper sections with pipe or wood lower sections. Because the piles are cast-in-place, time is saved (and cost reduced) by eliminating the driving of test piles to predetermine lengths, as well as eliminating the delay due to casting and curing of precast piles.

RAYMOND STEP-TAPER PILES, AVAILABLE IN SUITABLE LENGTHS, ARE DRIVEN TO UNIFORM RESISTANCE AND BEARING CAPACITY REGARDLESS OF SOIL CONDITIONS.

traffic on certain streets, etc. The panel indicated what had been done to date in the way of improvement in speeding up traffic, in control lighting, as well as other aids.

Then the members questioned the panel and several interesting opinions and suggestions were forthcoming.

Commission Proposed

In concluding, Professor McFarlane said that a commission of responsible and technical men, well qualified in traffic problems should be set up to study the existing regulations, keeping in mind the growth of the city and the passing through of the Trans-Canada Highway.

After the meeting a lunch was served.

Civil Defence Is Discussed By Brig. Todd

At the November dinner meeting in the Wentwork Arms Hotel the guest speaker for the evening was Brigadier P. A. S. Todd who discussed the subject of civil defence in Hamilton. Brigadier Todd, general manager of the Hamilton Transit Company and co-ordinator of civil defence for the Hamilton area, was introduced by D. Annan.

Brigadier Todd, who commanded the artillery of the Third Division during the second World War, stressed the duty of the Civil Defence organization to present its plans to citizens in view of the seriousness of any panic. Unfortunately Civil Defence is a misnomer, he said, in that the organization does not defend but goes into operation after a disaster has taken place.

Disasters

The types of disaster which may take place are a natural disaster, which is unlikely, due to Hamilton's geographical situation; a commercial disaster, which may take place at any time; or a hostile act in time of war. Consideration of the weapons in use must be given when planning for a possible hostile act. With the advent of A and H bombs, wardens have been felt unnecessary due to the fact that the whole city may be destroyed at once. Coventry, for example gave up the idea of civil defence in 1950. Hamilton decided to disband her wardens also.

Immediate Evacuation Impractical

This is the general opinion in Canada. The immediate evacuation of Hamilton upon the warning of an air attack, for instance, is impractical. Hamilton is in line with large eastern American industrial centres; near Lake Ontario which is easily recognized; and is in a vulnerable position should bombs miss their original targets. It has been estimated that with the aid of detection stations 2,300 miles north of Hamilton, and with planes flying at the rate of 700 miles per hour, the city would be permitted about three hours' warning only. It would be impossible to move 225,000 people out in so little time. It would involve the separation of families and the lack of food and shelter. Without shelter they would be exposed to radiation, and lacking medical attention.

Air Supremacy Essential

Several years ago it was realized that wars can be fought only with arms and supplies. Factories could not be deserted. The greatest defence, therefore, was air supremacy.

The uranium bomb, which is 140 times less expensive than the H bomb, and whose radiation extends 7,000 square miles, has influenced the civil defence plans developed in Hamilton.

It has been estimated that there are only 200 cities essential to war production. These could be destroyed with a minimum of 2,000 aircraft during approximately four to five days. Under these circumstances, factories mean nothing. For this reason, Civil Defence is considering evacuation before a war even starts.

Commercial Disaster

Of course, a commercial disaster can take place at any time. The work of

• Branch News

Civil Defence is that of co-ordinating existing services such as the fire and police departments, city engineering and the hospitals. Possibilities for commercial disaster are likely to increase with the development of Hamilton's harbour. Should such a disaster occur, Hamilton can make use of the services of neighbouring cities.

The Hamilton General Hospital is now equipped to handle 500 accident cases in four hours. By arrangement with the Bell Telephone Company the hospital can obtain 40 main lines. These were previously limited to four. In case of disaster, lists of necessary supplies to be ordered from many sources in Canada have already been prepared.

During the question period which followed Brigadier Todd's address, it was pointed out that the funds for Civil Defence in Hamilton are obtained from the municipalities (25%), from the Province of Ontario (25%) and from the federal government (50%).

J. L. Fair, M.E.I.C., *Branch News Editor*

Seaway Discussed by J. R. Montague

J. R. Montague, director of engineering of the Hydro-Electric Power Commission of Ontario, addressed the November meeting of the Branch. His topic was "Technical Aspects of the St. Lawrence Seaway" which was illustrated with slides showing some of the construction activities.

In spite of the immensity of the project and the many new problems to be solved, he said, it is expected that cost per kilowatt will not exceed that of other recent developments. Mr. Montague called attention to the impact of the Seaway on the economy of the St. Lawrence valley and the large investment involved in completing the power and navigation features of the project.

Relocation Work Described

A novel feature of the construction that was illustrated was the moving of houses on the large and rapid scale required to relocate the residential and industrial areas to be covered by the final water levels.

Light refreshments and a social hour were enjoyed after the meeting.

Montreal

G. M. Boissonneault, M.E.I.C., *Secretary-Treasurer*

M. Benoit, M.E.I.C., *Publicity Chairman*

Automation, Automatons and Men

On October 25 the Management Section of the Montreal Branch sponsored a meeting at which Dr. J. J. Brown of Aluminium Limited spoke on advanced methods of automatically operated assembly line production. The meeting chairman was George M. Foster of the Northern Electric Company.

The speaker gave an excellent treatment of the subject. Dr. Brown first defined automation and automatism. He favoured automation and declared that its incoming in industry was inevitable. Automation will lower production costs and reduce the number of workers. It will affect non-skilled labour and repairmen, but will develop a more diversified field of products which should absorb the surplus of workers. A long discussion followed from the large group present.

The vote of thanks was extended by J. Gray of the Northern Electric Company.

The Problem of Stream Pollution

On November 17 the Chemical Section of the Montreal Branch sponsored a panel discussion on stream pollution. The panel speakers were introduced by Chairman K. B. Owens, chemical sales engineer for Monsanto (Canada) Ltd.

Dr. L. Piché

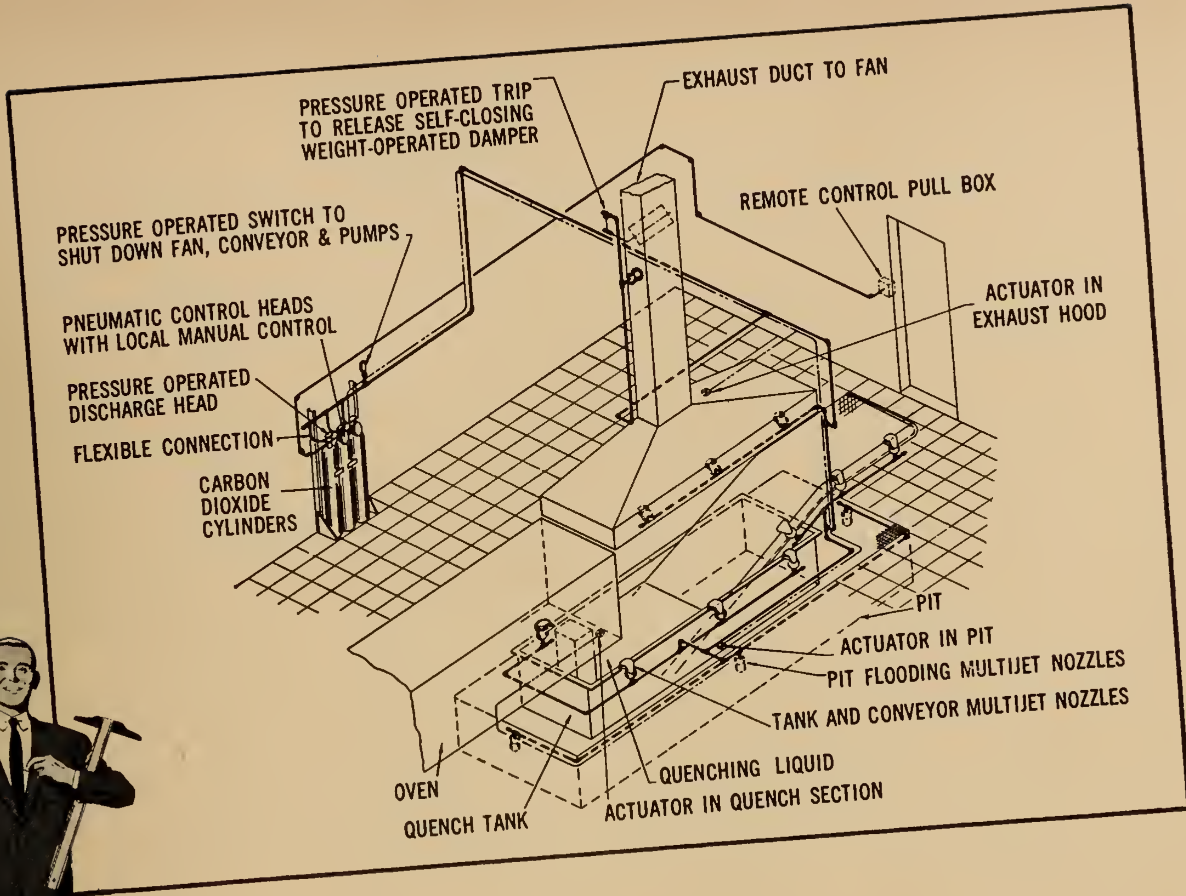
The first speaker was Dr. L. Piché, director, Department of Chemistry, University of Montreal. A comprehensive account was given of the causes of stream pollution and of the various methods used to indicate the type and degree of pollution, a necessary matter since these factors must be known before any concerted drive to clear the stream can be undertaken. In a more detailed coverage of the Ottawa River, charts and graphs indicated the location and degree of pollution present in the river below Ottawa. Emphasizing these points, Dr. Piché described both the Lower Ottawa and the North River at Montreal as "open sewers" in parts of their courses. It was very clearly demonstrated that both municipal and industrial sources were prime factors in the deterioration of water quality.

H. Clare

H. Clare, technical superintendent, Imperial Oil Company, outlined the methods by which the petroleum industry is attempting to reduce or eliminate the sources of stream pollution inherent in refining processes. Refineries handle millions of gallons of water per day and the problem of releasing these waters in the state received is one of varied mechanical or chemical treatment. The treatment plants required, while extensive and expensive, are part of the industry's obligation to the public. As well, a Pollution Control Committee, set up in 1943, co-operates with provincial governments in surveys which concern the industry.

D. Jones

D. Jones, speaking for the Canadian Pulp and Paper Association, covered the problem as related to that industry. Pollution causes are partly chemical, partly mechanical, and the industry is attempting by better processing methods to use more of its presently wasted materials. Much time and money is being expended in efforts to reduce pollution, but it was suggested that government and industry should co-operate in overall stream assessment, and that rather than restrict the industry



HAZARDS LIKE QUENCH TANKS... NEED THIS SPECIAL FIRE PROTECTION!

IN THE PLAN ABOVE, you see a typical Kidde fire extinguishing system installation for the protection of one of industry's most dangerous fire hazards. However, *all* Kidde quench tank installations are not exactly like this one, since Kidde treats each quench tank as a *special* hazard which requires *special* fire protection!

Using safe, efficient carbon dioxide, Kidde systems snuff flames quickly, cleanly. The CO_2 leaves no mess to harm machinery or equipment, will not even damage work-in-process. And, thanks to patented Kidde rate-of-temperature-rise detectors, Kidde systems remain on guard 24 hours a day, completely independent of outside power sources.

Kidde systems use no clumsy mechanical triggering methods, have no falling weights. Pneumatic or Electrical Control Heads insure instant and complete CO_2 discharge. The moving parts of a Kidde system are self-enclosed for safety, need no replacement after a fire, have easy-to-read visual indicators which show at a glance if system is "set" or "released." What's more, special Directional Valves on the Kidde system let you protect more than one hazard from the same cylinder bank, giving you the most versatile protection on the market today!

Without obligating yourself in any way, let the Kidde man analyze the fire hazards in your plant. Then let him show you our recommendations. For more information, write Kidde today.

Walter Kidde & Company of Canada, Ltd., Montreal—Toronto

Kidde

unduly, controlled pollution of certain river areas might be the answer in some cases.

D. Kirkbride

D. Kirkbride, development manager, Canadian Industries Limited, covered the development of pollution control by governments. Legislation and increasing industrialization go hand in hand. England began as early as 1814, and both the U.K. and the U.S.A. have steadily increased the range of pollution controls, with Canada beginning to feel the same need. It was emphasized that increasing problems make present legislation inadequate and new laws must be passed to enable industry and government to handle the problem in co-operation.

The small crowd made up for its lack of numbers in a spirited and lengthy discussion period lasting almost to midnight.

H. R. Stokes-Rees of Hydro Technic Ltd., thanked the speakers for the wide coverage of the subject. Meeting arrangements were by L. A. Phillips.

Linoleum Manufacture

On Tuesday, October 11, O. R. Brumell, spoke on "Linoleum Manufacture" to a highly interested audience. Marc Benoit introduced the speaker.

After a brief history on the manufacture of linoleum, Mr. Brumell entered into detail of modern methods used to produce the material.

He explained the differences in the types of backing, discussed their relative merits and described fully such parts of the process as printing, drying, etc.

A study on the economic outlook concluded his talk. A lively and instructive period of pertinent questions followed, all ably answered by Mr. Brumell. W. D. Kerr thanked the speaker.

Ottawa

R. F. Legget, M.E.I.C.,
Secretary-Treasurer

Carl B. Crawford, Jr.E.I.C.,
Branch News Editor

Colour Television

Ricardo Muniz, manager of the television-radio division of Canadian Westinghouse Company Ltd., was guest speaker at a luncheon meeting of the Ottawa Branch on November 10. In his talk Mr. Muniz suggested that the future of the T.V. industry lies in colour telecasting. A recent survey indicated that three out of four persons would buy colour T.V. sets if the price were reasonable and programs were available. The price of a 21-inch console set is now about $800. Colour picture tubes cost about five times as much as the equivalent black and white tubes. At the present time there does not appear to be much chance of lowering these prices.

First T.V. Colour Station April, 1956

Mr. Muniz said that the first coast to coast colour T.V. program in the United States was a showing of the "Tournament of Roses" from Pasadena on January 1, 1954. There are at the present time 100,000 channel miles installed for colour T.V. broadcasting. In the U.S. there are about 40 hours per month of colour T.V. programs and this is to be increased to 80 hours per month. In Canada some colour T.V. receiving sets are in use in the Toronto area receiving programs from the U.S. The first all-colour T.V. station is expected to begin operation on April 1, 1956, in Chicago. In Canada, the C.B.C. is delaying any commitments in the field of colour television until demand is sufficient to warrant entering this field.

Development of Colour T.V. Traced

The speaker traced the development of colour television, pointing out that the first development was an entirely new electronic system which would make black and white sets obsolete. For obvious reasons this was not a suitable system and later the development of a system compatible with the black and white system was achieved. Preliminary studies in this development were made in basic physiology of the human eye. Mr. Muniz outlined the basic electronics of television, including the complications of colour television. He pointed out that the number of tubes for colour television would have to be increased from 20 to 28.

Change-over May Be Rapid

There are now about 700,000 television sets in Canada for receiving black and white programs. Most of these sets have 17 inch screens or larger, indicating that much of the early development of television was missed in Canada. In addition to the growing demand for colour T.V., manufacturers are anxious to open up the market for colour television. With the rapid development to maturity of colour television, the speaker thought that the change-over from black and white would be a rather rapid process.

The speaker was introduced by W. B. Pennock, vice-chairman of the Branch, and he was thanked by R. E. Hayes, past chairman of the Branch.

Hon. Robert Winters Is Guest Speaker

The Hon. Robert H. Winters, Minister of Public Works, was guest speaker at the second evening dinner meeting of the Ottawa Branch to be held this season. Mr. Winters, in tracing the history of Trans-Canada highway developments, compared the highway with the building of the first Trans-Canada railway. He recalled that the last attempt to build a Trans-Canada highway was begun in 1930 to alleviate unemployment but that this effort was held up by World War II.

Trans-Canada Highway

Following the war, with an even greater need for a continuous highway link, the federal government, in 1948, invited the provincial governments to discuss ways and means of building a Trans-Canada highway. It was agreed that costs would be shared equally between the provincial and the federal government. Standards of construction were agreed upon. These included a minimum right of way of 100 feet, a minimum pavement width of 22 feet with a 10 foot shoulder, a minimum sight distance of 600 feet and a design axle loading of 18,000 lb. It was agreed that the route should in general cover the shortest distance across the country. Many difficulties, including the Korean war, combined to delay construction until it was evident that the completion date of December, 1956 would not be met. At the present time only about one-third of the highway is completed to the agreed standards. Recently, in consultation with the provinces, the original agreement was extended for another five years subject to parliamentary approval. In order to close the gaps where no highway exists, the Federal Government agreed to contribute 90 per cent of the cost on 10 per cent of the highway mileage in each province. Other construction costs are to remain on a 50/50 basis.

Mr. Winters pointed out some of the special difficulties existing in each province. He said that Ontario had the longest stretch of Trans-Canada highway and also the longest gap where no highway exists. British Columbia had some of the most difficult terrain to cross where costs would exceed one million dollars per mile.

Costs

In reply to questions Mr. Winters said that the 1948 cost estimate of $300 million was now thought to be only about half of the final cost, not including the cost of property. He stated that toll charges would not be made on any parts of the highway to which Federal Government contributions were made.

Mr. Winters was introduced by R. F. Legget, chairman of the Ottawa Branch, and the appreciation of the Branch was extended by K. M. Cameron, a former chairman of the Branch.

Newfoundland

C. W. Henry,
Secretary-Treasurer

Engineers' Wives Club Report

During the year 1954-55 the Engineers' Wives Association, St. John's Branch held six meetings. Our membership now numbers 41 and approximately 20 to 25 members attend our monthly meetings.

The social high-light of our season was, no doubt, the Halloween Dance held at the Chateau on October 29.

To add to our meetings we were fortunate in having on two occasions guest speakers, Miss E. Mallard, head mistress of Bishop Spencer College, and the Hon. R. F. Sparkes, Speaker in the Newfoundland House of Assembly. Mrs. Halme kindly showed coloured movies featuring some of the highlights of her stay in Bolivia at our January meeting, and at our March meeting Mrs. C. W. Henry showed coloured slides which were taken in Venezuela.

Our members continue to show quite an interest in child welfare, and brought many articles of children's clothing, both used and newly knitted. Their contributions were greatly appreciated by the Child Welfare Association.

The Bridge Tournament inaugurated during the previous year, was held again this season. Mr. and Mrs. Grant Jack were winners of the tournament and Mr. and Mrs. Clarence Knight were second.

Unfortunately, we were forced to discontinue the collection of used magazines for the Sanatorium owing to the fact that there were not enough members free to attend to the distribution of them at the hospital.

Our financial status this year was such that we were able to offer a prize of $25.00 to the Engineering Faculty at Memorial University and at the suggestion of Prof. S. J. Carew, this was awarded for Drawing I and was won by Arthur Knight of St. John's.

We continued during the season, to send congratulations to members who had new babies, "Get Well" cards to those who were ill, and messages of sympathy to any who were bereaved.

We also continued the practice of providing refreshments both for our own meetings and for those of the Engineering Institute, Newfoundland Branch.

Presidential Tour

On Friday, Sept. 23, Dr. R. E. Heartz, president of the Engineering Institute of Canada with Mrs. Heartz arrived in St. John's on the presidential tour. They were accompanied by Dr. L. Austin Wright, the general secretary of the Institute and the honorary treasurer E. V. Gage and Mrs. Gage. On Friday morning Mrs. Heartz and Mrs. Gage were guests of honour at a coffee party given by the Engineers' Wives Association at the home of Mrs. V. A. Ainsworth, 10 Forest Road; on Saturday, a luncheon was held in their honour at Bally Haly Golf Club. Preceding the luncheon, Mrs. Clarence Knight on behalf of the Association, presented Mrs. Heartz with a beautiful draw-string bag made by the Jubilee Guild, as a souvenir of her visit to St. John's. In thanking the Association, Mrs. Heartz said how happy she was to have had the opportunity of coming to St. John's and meeting the members of the Wives Club.

On Friday evening the Engineering Institute held a dinner at the Old Colony Club in honour of the distinguished visitors. The members of the Wives Club joined their husbands for the occasion. The dinner was preceded by a reception and followed by dancing at the Club. The presidential party left by plane for Halifax on Saturday, September 24.

BOOK REVIEW

Diesel engine principles and practice. C. C Pounder, ed. Toronto, British Book Service, 1955. Various paging, illus., $14.45.

All types of diesel engine from those for tractors to those for marine engines are covered in this volume which was compiled under the editorship of Mr. C. C. Pounder who has been responsible for the machinery designs for over a thousand vessels.

Each of the twenty-six chapters is written by an expert, and each is complete in itself, although each fits into the general scheme of the work.

The first chapters deal with the theory of compression-ignition engines, fuels, scavenge and exhaust systems, transmission gears, governors, bearings, etc. The middle section of seven chapters discusses the various types of engine, whilst the last chapters are devoted to vibration, testing and maintenance.

This is a very comprehensive work which should be in every technical library and which will be most useful to both practising engineers and students. There are many illustrations and diagrams, a detailed index, and bibliographies are found at the ends of most chapters. This is both a text book and a work of reference. S.C.

BOOK NOTES*

Prepared by the Library

The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

Abstracts of the literature on semiconducting and luminescent materials and their applications, 1954 issue. Battelle Memorial Institute. New York, Wiley, 1955. 200 pp., $5.00.

This compilation of abstracted articles is the second issue and contains over 750 items, taken from various journals and, where possible, from oral papers. Both foreign and American abstracts are included and an attempt has been made to give the most important experimental results or conclusions.

The articles are grouped under the following subjects: germanium, silicon, carbon, boron, and other semiconductors, selenium, and tellurium, selenides and tellurides, intermetalics, oxides, sulfides, halides, organics, fluorescence and phosphorescence, and theory. There are subject and author indices.

Aerodynamics: selected topics in the light of their historical development. Theodore Von Kàrmàn. Ithaca, Cornell University press, 1954. 203 pp., illus., $4.75 (U.S.).

The history of man's efforts to fly has often been spectacular but the behind-the-scenes contributions of engineers and physicists are sometimes overlooked. This book is an account of aerodynamics since Newton's time and particularly during the last fifty years.

The problems of lift, drag, skin friction, stability, aero-elasticity and supersonic aerodynamics are all discussed and reveal the manner in which engineers have met and overcome seemingly unsurmountable obstacles. An interesting aspect of the book is the account of the difficulties which must be met before space travel will become a reality.

The author has been closely connected with the field of aerodynamics, so that his writing has authority as well as high literary quality.

American aviation world-wide directory, v. 16, No. 2, 1955-56. Washington, American aviation publications, 1955. 794 pp., $7.50 U.S.).

The main part of this directory naturally covers aviation companies and officials in the United States, but Canada, Europe, Central and South America, Africa, Australasia and Asia are also represented.

The book is divided into sections covering certificated, intrastate and irregular U.S. air carriers, indirect air carriers, air taxi operators, holders of U.S. foreign air carriers permits, U.S offices of foreign air carriers and air carriers in foreign countries.

The information given on each company includes the address, names of executive officials and managers and a description of the equipment operated by the company.

There are also buyers' guides, and lists of aircraft manufacturers in the countries covered.

Analysis of symmetric cylindrical shells. John McNamee. Ottawa, United Kingdom Information Office, 1955. 84 pp., 12/6.

The lectures which form the text of this book were originally given at Liverpool University and in it the author outlines the theory of thin cylindrical shells for those who are not familiar with the subject. He has also attempted to carry the analysis to the point where it can be used to determine numerical values of the stresses in shell roofs.

In the three lectures unfamiliar mathematical techniques have been avoided if possible. The first deals with elementary analysis and concludes with a short historical account of the theory. In the second chapter matrix analysis is explained while the last is devoted to computations.

***An annotated bibliography on noise, its measurement, effects and control.** Pittsburgh. Industrial hygiene foundation of America, 1955. 364 pp., $7.50 (U.S.).

Over 2,000 references are arranged chronologically under subject subdivision of four major sections: noise measurement, effects of noise, measurement of hearing loss, and noise reduction and control. Most of the references are from the period 1927 to 1953 and include foreign titles as well as English. Representative articles are annotated or abstracted, and subject and author indexes are included.

Basic mathematics for science and engineering. P. G. Andres, H. J. Miser and Haim Reingold. New York, Wiley, 1955. 846 pp., $6.75.

This textbook could serve equally well as an introduction to the mathematics needed for science and engineering courses and as a refresher manual for practising scientists and engineers. It is a revision of an earlier volume published in 1944 under the title "Basic mathematics for engineers".

Topics from algebra, trigonometry, analytic geometry and introductory calculus are dealt with and the material in each chapter is placed in its mathematical and scientific setting. Mathematical principles are illustrated with engineering applications and a great number of exercises are included.

Some of the more useful features are the early explanation of the slide rule, the stress placed on graphical methods, the sections on trigonometric functions, vectors, and the Doolittle method of solving simultaneous linear equations.

Design in British industry. Michael Farr. Toronto, Macmillan, 1955. 332 pp., 87 plates, $11.75.

Because the author condemns a great deal of contemporary British design in industry, with frequent comments on American design as well, this book will be both interesting and controversial. In this survey he includes not only those who conceive and design the pro-

Hold it! Is it good enough for CRANE VALVES?

WHAT YOU SEE here is routine procedure on raw materials coming to Crane. There's no unloading of any incoming carload until the Crane Quality Control Lab gives an unqualified O.K.

The extra care that Crane gives to raw materials, and similarly to every step in manufacturing, pays off in better valves to you. You can be sure that Crane stands for quality that results in lower cost in the long run.

There's another reason why thrifty buyers prefer Crane valves. They know they're investing in better piping performance as well as protecting against untimely and excessive maintenance. A very important consideration in these days of high costs. And undoubtedly the main reason why industry keeps using more Crane valves than any other make.

For complete information—see your Crane No. 53 Valves and Fittings Catalogue—or get in touch with your Crane Representative, Crane Branch, Wholesaler, or

CRANE LIMITED

General Office: 1170 Beaver Hall Square, Montreal

7 Canadian Factories • 26 Canadian Branches

CRANE VALVES • FITTINGS • PIPING
PLUMBING • HEATING

NATION-WIDE SERVICE THROUGH BRANCHES, WHOLESALERS and PLUMBING AND HEATING CONTRACTORS

• Library Notes

ducts, but also those who manufacture, market, buy and use them.

The first part of the book deals with specific products such as furniture, metalwork, jewellery, appliances, pottery, and cars. It also discusses the place of the craftsman in industry and includes chapters on consultant designers, the retail trade and art schools. The publicity and propaganda used by design organization form the subject of the second section. The last two sections will create the greatest interest, and arguments, for in them Mr. Farr discusses such questions as design standards and mass production, the taste of the public, snob appeal, etc., and makes many pointed suggestions for improvement in the whole field of industry.

Dichtungen im Stahlwasserbau. C. F. Kollbrunner and Lothar Streuli. Zurich, Leemann, 1955. 34 pp., diagrs.

The subject matter of this German book on seals for steel watertight structures is divided into seven sections Following the introduction various types of seals are described. Within this section the authors deal with the mounting of packings relative to water pressure, the accessibility of packing at low water level, resilience of packing elements, material for packing and static and moving seals. Two chapters are devoted to older and modern sealing systems, followed by one on mountings. The last part of the book discusses guideways of locks compared to types of seals and measuring water to ascertain the water loss by weirs.

***Electric power stations. Vol. II,** 4th ed. T. H. Carr. Toronto, British Book Service, 1955. 832 pp., diagrs., $12.85.

This second volume of a two-volume treatise on the design, construction, and operation of electric power stations deals especially with the electrical side of the subject—alternators, transformers, reactors, switchgear, cabling, and protective equipment. Three chapters deal with hydro-electric, diesel-electric, and gas turbine plants, and there is a chapter on wind, atomic, and other power plants. Also covered are lubricating, indulating, and fuel oils; auxiliaries; station organization; and costs.

***Gear design and production.** Reginald Trautschold. Columbia, Conn., Columbia graphs, 1955. 204 pp., $4.50 (U.S.).

A restatement of basic principles accompanied by proofs of rules and formulas for critical computations. Each of the various standard classes of gears —spur, bevel, spiral, etc.—are taken up separately, and chapters on methods of production, materials, and inspection are included.

***Hawley's technical speller.** G. G. Hawley and A. W. Hawley, comps New York, Reinhold, 1955. 146 pp., $2.95 (U.S.).

This book contains over 8,000 technical words selected from the vocabularies of chemistry, physics, electronics, biology, medicine, engineering, and other fields of science and technology. Recommended word divisions are indicated. A separate list gives the correct prepositions for use after certain words.

Industrial management, 5th ed. W. R. Spriegel and R. H. Lansburgh. New York, Wiley, 1955. Various pagings, illus., $6.75.

In this edition much of the material has been rewritten and rearranged for better use in study and reference. There are new chapters on job evaluation and statistical quality control.

As in previous editions both theory and practice in management are discussed, with policies and principles forming a background for methods of putting them into successful operation. The book is divided into nine sections, beginning with a history of the managerial movement and going on to organization structure, problems concerning the product, the plant and equipment, motion and time study, wages and basic relations between employers and employees, buying, selling and cost controls, material and production control, and finally, personnel administration and management.

The text is generally geared to the point of view of the medium-sized plant with frequent references made to the large and small enterprise. Examples and illustrations have been chosen from a diverse group of industries.

Industrial power systems handbook. Donald Beeman, ed. Toronto, McGraw-Hill, 1955. 971 pp., diagrs., $15.50.

Because of the vast amount of commercial and industrial building going on today this book will answer a wide demand for an authoritative aid to designing electric power distribution systems. The editor has contributed helpful data from General Electric Company experience and the sixteen specialists cover all major phases of power system design.

The first part of the book contains technical information while the latter part is devoted to economic or system design information. There are chapters on short circuit calculations and protective devices, methods of voltage regulation and on system and equipment grounding. Various angles of economy are discussed, ranging from the cycles and economies of methods of generating by-product power from waste fuel or process steam, to cost load and cost estimating data for systems and commonly used equipment components.

One interesting section describes methods of modernizing and expanding existing power systems and suggests ways of applying modern power principles to commercial and office buildings, with many examples and case histories of such power system practices.

Many of the application data are in condensed tabular and curve form to aid in the practical solution of problems.

Introduction to TV servicing. H. L. Swaluw and J. Van Der Woerd. Eindhoven, Philips, 1955. 264 pp., illus., $5.50.

Although this manual refers to the European 625-line system, the theory, description of the TV receivers and the service information which it contains may be applied to the American 525-line system.

To make full use of this book radio service technicians should have a sound knowledge of circuit fundamentals. There is a theoretical introduction before the practical problems are presented and in it we find a short explanation of the scanning system, the working of the picture tube and the waveform of the TV signal. Several chapters then describe a modern TV receiver with separate sound channel and a section is devoted to intercarrier sound and the turret tuner with cascode amplifier.

The larger part of the book describes measuring instruments and the tracing of faults in the defective receiver. The illustrations include a series of photographs of screen pictures as they appear on incorrectly adjusted or faulty receivers.

Municipal organization in Canada. T. J. Plunkett. Montreal, Canadian federation of mayors and municipalities, 1955. 157 pp.

While this book was not written especially for the engineering profession it is, nevertheless, a valuable addition to an engineering library. Many administrators, sales engineers, contractors, etc., must deal with municipal government bodies and this up-to-date volume on local governments in Canada will greatly assist them.

The means by which municipal government is carried out differs greatly from province to province as well as between municipalities in the same province. The author has analyzed these different forms and discusses the various systems used to administer local community services.

Following a general chapter on the purpose and elements of municipal government Mr. Plunkett describes the council committee system, the council-manager system, the council-city commissioner system and the board of control plan. He also discusses the problems of these bodies.

The appendices form a valuable addition to the main text, describing the forms of government in the main cities of Canada. These are followed by municipal organization charts of the same cities.

Principles of farm machinery. Roy Bainer, R. A. Kepner and E. L. Barger. New York, Wiley, 1955. 571 pp., illus., $8.75.

In an attempt to present the subject of farm machinery from the engineering viewpoint the authors have included a minimum amount of descriptive material. Their book is intended for agricultural engineering students with a previous knowledge of static mechanics, who are also familiar with the common types of farm machinery. General discussions of materials, power transmission, economics, and hydraulic controls are included.

Where possible, machines for a particular practice such as planting, are treated on the basis of the unit operations performed by the functional elements of the machine.

Among the specific types of machinery discussed are those employed for earth-moving, soil tillage, crop planting and cultivation, application of fertilizers, hay harvesting, seed cleaning and harvesting, corn picking, spraying and dusting, and farm transport.

• Library Notes

***Principles of nuclear reactor engineering.** Samuel Glasstone. Toronto, Van Nostrand, 1955. 861 pp., illus., $8.75.

This is a broad, over-all review of fundamental scientific principles, prepared for engineers who wish to know something of the impact of nuclear energy on their professional activities. It may also serve as a text for senior and graduate students. The separate chapters cover essentials of nuclear physics, reactor theory, instrumentation and control, fuels and materials, and various associated problems of reactor design. A number of existing reactors are briefly described in the last chapter.

Principles of technical electricity, 2nd ed. M. Nelkon. London, Blackie, 1955. 250 pp., illus. 10/6.

Written for students, this is a general presentation of the fundamental principles of electricity with reference to its technical applications.

The book deals with two main topics: d.c. and a.c. theory. In the former section are described the heating, chemical, and magnetic effects of current, electrical measurements and instruments, and the principles of condensers. The a.c. circuit theory deals with series and parallel circuits of coils, condensers and resistors and applications of this theory to typical radio circuits is stressed.

In this second edition an appendix has been added on the M.K.S. system of units and some changes have been made in the main text.

***Problems and control of air pollution; proceedings of the First International Congress on air pollution.** F. S. Mallette, ed. New York, Reinhold, 1955. 272 pp., $7.50 (U.S.).

These proceedings papers, presented by experts from seven countries, provide new and authoritative information on a wide range of subjects of interest to engineers, municipal officials, management, and others concerned with reducing or eliminating air contamination. Two papers review the British smog problem and public relations aspect of air pollution control; the remaining twenty-three cover specific topics relating to gaps in available knowledge, current research findings, the treatment and recovery of sulfur dioxide, and experiences abroad. Bibliographies accompany many of the papers.

***Proceedings of the American power conference, volume XVII, 1955.** Chicago, Illinois institute of technology, 1955. 722 pp., $6.00 (U.S.).

As in previous years the papers in these proceedings emphasize the practical rather than the theoretical view and range from the technical to the economic and social aspects of power generation, transmission, and distributions. Grouped by sessions — general interest, nuclear energy, mechanical, water technology, and electrical — the individual papers deal with such subjects as scientific manpower, sodium graphite reactor power plants, power plant stacks under wind loading, small gas turbines, the St. Lawrence Seaway, computing devices, and many others.

Productivity measurement, v. I: Concepts. European productivity agency. Toronto, Ryerson, 1955. 143 pp., $1.00.

The first volume of this work discusses the various concepts of productivity measurement. Their practical application will be the subject of the two volumes to follow.

In this volume each of the contributions is an attempt to define the meaning of productivity and the problems involved in the measurement of production are discussed at length. The role of official statistics in measuring productivity is the subject of one chapter while another deals with the correlation between productivity, efficiency and wages.

The appendices contain studies by experts on the relationship between the ideas of "labour productivity" and "integrated labour" and on the possibility of making international comparisons in terms of man-hour purchasing power.

Review of current research and directory of member institutions, 1955. New York, American society for engineering education. Engineering college research council. 1955. 352 pp., $2.00 (U.S.).

Although none of the 105 engineering schools included in this review is in Canada it will, nevertheless, be of value

• Library Notes

and interest to faculty members and students of the universities in this country.

The institutions are listed alphabetically and under each there is information on the names of responsible administrative officers, policies governing research projects and contracts, personnel engaged in research activities, annual expenditures and sources of income for research, as well as the 5,000 entries of research project subjects.

Single-enterprise communities in Canada. Queen's university. Institute of local government. Ottawa, Central mortgage and housing corporation, 1953. 312 pp.

This is a "first of its kind" and extremely interesting report on Canadian communities established by government or industrial concerns. The rapid expansion in our northland and in other previously unsettled sections of the country has focused attention on living conditions which exist in these communities, especially as they might differ from the general situation.

The report describes the founding of single - enterprise communities, their local government, town planning, company housing, recreation, community institutions, utilities and services, and social problems. The final chapter contains a series of conclusions and recommendations.

An appendix lists these communities, giving the names of each townsite, founder, economic activity, population, year established, number of company-owned housing units and the percentage of these in relation to total housing, and type of local retail outlet, whether operated by the company or by independent enterprise.

Symposium on sinter. London, Iron and steel institute, 1955. 200 pp., illus., 37/-. (Special report No. 53.)

The seventeen papers contained in this report describe the process of sintering and reveal the extent of industrial research which has been directed toward increasing the productivity of sinter plants. The last three papers, published since the Symposium was held in 1953, discuss the practice of sintering.

The papers dealing with the physics and chemistry of sintering include discussions of the mechanism of reduction of iron oxides, the softening of iron ores at high temperatures, and radiographic studies of the process of sintering iron ores.

The next seven papers describe the production of sinter in terms of permeability of sinter beds, permeability tests on blast-furnace raw materials, faster sintering of ironstone, rating of sinter plants for economic output, and ironmaking from high-sinter burdens.

Theory of machines. W. G. Green. London, Blackie , 1955. 1,034 pp., diagrs., 40/-.

This is primarily a textbook and contains many worked examples. The author's aim has been to preserve a logical sequence throughout the seventeen chapters of the book. These begin with the kinematics and kinetics of a particle then go on to treat rigid bodies and the kinematics of machines. There are sections on the direct-acting engine mechanism, the balancing of machines, governors, valves, friction and lubrication, brakes and dynamometers and the motion of vehicles, higher pairing, cams and cam motions, vibrations of mechanical systems and motion in three dimensions.

World airline record, 5th edition, 1955. Chicago, Roadcap, 1955. 500 pp., illus., $17.50 (U.S.).

This edition has been expanded to include discussion of 269 regularly scheduled airlines which, it is claimed, represents 100% coverage of the world. Additional space has been given to explanations of individual airline problems and route maps have been brought up-to-date.

The book is arranged alphabetically by continent then by country. The data for each airline is arranged under systematic headings including route map, history and development, management, traffic analysis, seasonal chart, income account and historical statistical summary. An effort has been made to present comparable statistical data for all airlines although the difficulties of doing so, especially in the field of financial accounts, is apparent.

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Concrete

The durability of concrete under frost action. E. G. Swenson. (Canada. NRC. Div. of bldg. res. Tech. pa. 26) 25 cents.

ENGINEERING CAREERS

The Royal Canadian Air Force

Today, more than ever, engineering services play a prominent and essential part in the efficiency of a modern air force. The highly complex nature of aircraft and their ancillary equipment demands a wide range of technical knowledge and skill.

Canada as a nation emerged from the second world war in a leading position in aviation. Within her borders she had built vast facilities to accommodate the British Commonwealth Air Training Plan, and in military operations on both coasts and overseas, the RCAF made a remarkable contribution to victory and established an enviable record of achievement. In the five years following 1939, the RCAF expanded from a peacetime nucleus of some 4,000 personnel and a few aircraft to a wartime force of nearly 250,000 personnel and several thousand aircraft.

All this was made possible because of the teamwork that was developed between the scientist and the engineer who conceived and designed the fighting equipment, the employer and factory-worker who manufactured it, and the aircrew and groundcrew who maintained and operated it effectively against the enemy. The part played by the service and civilian engineers through all stages, from drafting board to active operation was vital.

In the RCAF today, the engineer, or technical officer as he is known, plays an even more prominent and increasingly important role in the design, development, testing, modification, construction, and utilization of Air Force facilities and equipment.

The primary responsibility of the RCAF is air defence, and, therefore, a large proportion of its resources are devoted to this task. To meet this responsibility Canada has built up her CF 100 all-weather-fighter-interceptor squadrons and her vast network of early warning radar units. These squadrons and radar units form the backbone of the RCAF's Air Defence Command.

To the North Atlantic Treaty Organization, the RCAF contributes an air division in Europe of 12 F86 fighter-interceptor squadrons, their equipment and personnel and land-based maritime aircraft for the protection of coastal and sea-lane communications. NATO aircrew training, air transport, search and rescue, survival training, air photographic and tactical air operations are other active and important roles of the RCAF. With the advent of new operational concepts and techniques, it is obvious that today's RCAF must keep at least one step ahead of any potential enemy. This can only be done if the force is provided with the finest and most advanced equipment available. The responsibility of the service engineer in making this equipment available when it is needed is paramount to the whole Air Force effort.

THE ENGINEERING BRANCHES

Engineers in the RCAF are grouped in the aeronautical, armament, construction, telecommunications, mobile equipment and photography branches. Nearly 1,500 technical officers are required to man these branches. This number will probably increase as further technological advances are made.

To qualify for entry into one of the engineering branches of the RCAF, an applicant must hold a degree from a recognized University in pure or applied science. Once he is enrolled he is given specialized training to adapt him to the specific requirements of the branch in which he wishes to serve. However, professional knowledge alone is not enough since in the Air Force the engineer must also possess qualifications of leadership and management so that he is able to supervise and handle men as expertly as he can materiel. During his career he will be required to fill a staff engineer position at a Command or Headquarters level and to take charge of men and equipment in the field.

Each of the engineering branches maintains its identity, but all are part of a closely knit team whose function is to discharge the Air Force's responsibility as efficiently and effectively as possible. A discussion of each branch's specific task and responsibility follows.

Aeronautical Engineering

Officers of the Aeronautical Engineering Branch of the RCAF participate in the formulation of policy and plans pertaining to the maintenance of service aircraft and associated equipment. Their responsibilities include the drafting of designs and specifications, the conducting of tests and development programmes, the supervising of engineering aspects of production, quality control and technical training. Duties also include the managing of aircraft maintenance organizations which involve responsibility for the servicing, inspection, repair, modification, preservation and service evaluation of aircraft and associated equipment.

Armament

The Armament Branch of the RCAF is responsible for the procurement, installation and maintenance of the airborne and ground armament systems which give the RCAF its striking and defensive power. Officers of this branch participate in policy and programme formulation with regard to the maintenance of armament equipment, armament sections and units and the operation of armament training facilities. Their duties include the preparing of equipment designs and specifications, estimating requirements, advising on the development and use of armament equipment, service trials and testing, quality control and technical training. Duties concerning the management of armament organizations involve technical and supervisory responsibility for the inspection, servicing, fault analysis, repair, modification, storage, demolition, salvage, re-conditioning and preservation testing and development of armament equipment.

Armament equipment consists of such weapon systems as guided missiles, homing torpedoes, drone targets and their guidance and control mechanisms, launching equipment and test equipment; explosive stores, electrical and mechanical fuses; pyrotechnic compositions and components; special weapons (atomic, biological and chemical) and flame warfare agents; guns and unguided rockets, turrets and launching gear; armament range facilities which include telemetering equipment, photo theodolites, electronic-optical analyzers, timing systems and calibrators; aircraft fire control systems and weapon directing radar devices.

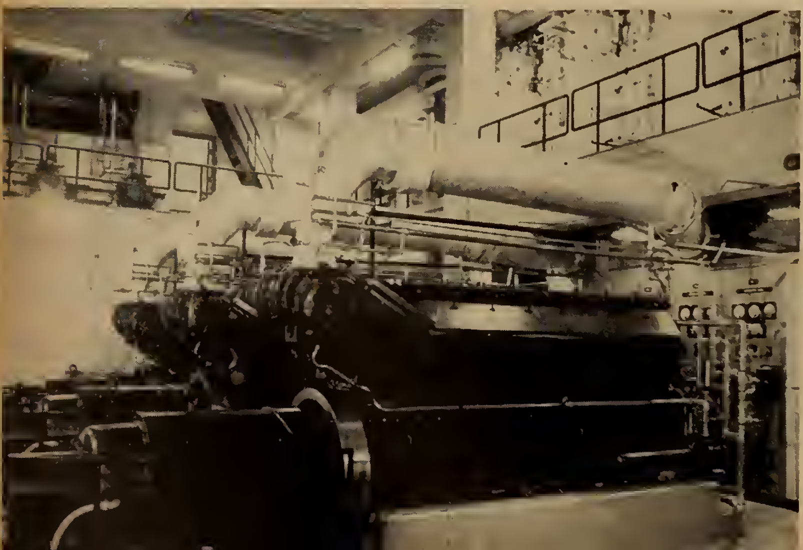
An R.C.A.F snowblower keeping an aircraft parking area clear at R.C.A.F. Detachment Resolute Bay, Cornwallis Island, N.W.T.; the responsibility of the mobile equipment engineer. (*National Defence Photo*)

Construction Engineering

The duties of officers of this branch cover a wide scope of activities in construction, and the operation and maintenance of structures and facilities. Officers of this branch participate in the formulation of construction and maintenance policies, programmes and procedures, prepare construction specifications, standards and estimates of costs, exercise administrative control of construction and maintenance funds and material, recommend acquisition and disposal of Air Force real property, maintain liaison with agencies involved in Air Force construction projects and inspect completed projects as a basis for acceptance, control fire-fighting, fire prevention and aircraft crash rescue services, provide trade training and manage Air Force construction projects and unit construction engineering sections.

This branch has two specialties: (*a*) Construction and Maintenance; and (*b*) Fire Protection.

Entry requirement for the Construction and Maintenance specialty of this branch is a Bachelor's degree in pure or applied science. For the Fire Protection division, senior matriculation, the equivalent or higher, combined with five years' experience (full-time duty) in fire prevention activities in either a municipal, industrial or other recognized fire prevention organization is needed for entry.



Diesel power plant at an R.C.A.F. radar station, providing heat and power for the operations centre, is part of the equipment under the construction engineering branch. (*National Defence Photo*)

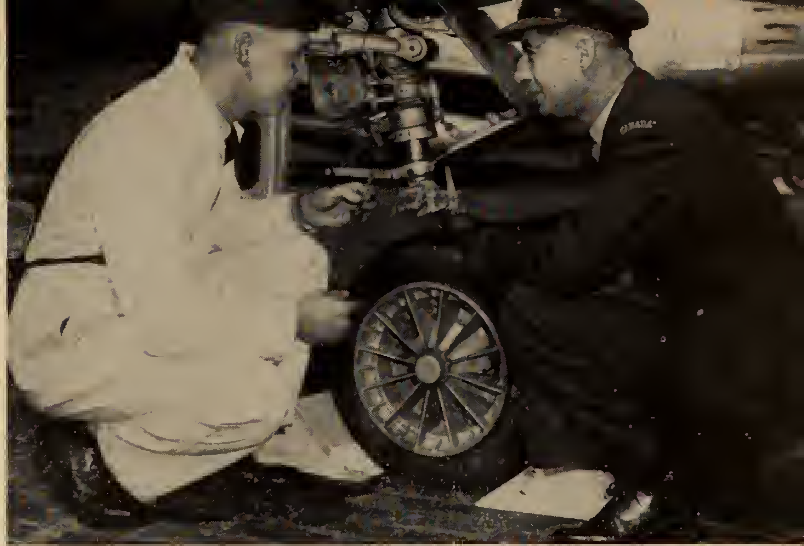
Mobile Equipment Engineering

This branch is responsible for the operation and maintenance of mobile land and marine craft, and the administration of RCAF road transport services. Officers of this branch advise on equipment selection and employment, prepare specifications and cost estimates for equipment procurement and maintenance, conduct accident prevention studies and give technical advice in accident investigations involving mobile equipment, and provide technical training. They are also responsible for the management of unit mobile equipment organizations which involves the administration of road transport services and the inspection, repair, modification, salvage, reconditioning and preservation of mobile equipment and marine craft.

Telecommunications

The Telecommunications Branch of the RCAF involves the installation and maintenance of RCAF telecommunications equipment and the operation of surface communication facilities. Officers of this branch participate in the functions of policy and programme formulation, preparation of equipment specifications, estimation of requirements, advising on the use and development of telecommunications facilities, design and development, provision of trade training and management of telecommunications organizations. It involves immediate supervisory and technical responsibility for the operation of service communication facilities as well as the installation, servicing, inspection, modification, salvaging and preservation of communications and radar equipment.

Officers may be employed in assignments for which special qualifications are required. Included in these are: Radar (Ground Search), Communications Operation, Electronic Counter-Measures.



An aeronautical engineer discusses a maintenance point with an aero-engine technician beside the nose wheel of an R.C.A.F. F86 Sabrejet at Volkel, Holland, before the Fifth International Air Show, Ypenburg.
(National Defence Photo)

Photography

Duties of the Photography Branch cover the installation, operation and maintenance of RCAF photographic equipment. Officers of this branch participate in planning air photography operations, formulate photography policies, programmes and procedures, prepare specifications and standards for photographic procedures and equipment and provide technical training. They also assume responsibility for still and moving picture photography, photographic production, materiel maintenance and the test and development of photographic processes and material.

CONDITIONS OF ENTRY

An engineering graduate, interested in an Air Force career, may apply at any of the 22 RCAF Recruiting Units across Canada or write directly to Air Force Headquarters, Ottawa. Successful candidates are posted to Officers' School at London, Ontario, for a nine-week course of basic officer training. Upon graduation from this course they are commissioned in the rank of Pilot Officer. The first year is devoted to specialized training after which the officer is promoted to the rank of Flying Officer. The RCAF may supplement basic professional qualifications by sending the officer for special courses in the United States or United Kingdom and post-graduate courses are arranged at universities in the United States and Canada. Many officers have attained a Master's degree in various sciences and some have obtained their Ph.D.

The maintenance, servicing and repair of such complicated equipment as this jet flight-simulator is the joint responsibility of the aeronautical engineering officer and the telecommunications officer. *(National Defence Photo)*

Undergraduates

The University Reserve Training Plan (URTP) allows selected undergraduates to be enrolled for training with the RCAF during their university years. In this way, as Flight Cadets, they receive training in the form of two-hour-a-week lectures during the academic year and officer training, engineering training, and employment at an RCAF station during the summer months. Upon graduation they may join the Reserve or enter the Regular Force as Flying Officers.

University undergraduates may also apply for subsidization through their four years of college under the Regular Officers' Training Plan (ROTP). Under this plan, students receive their lodging, books and tuition fees and an allowance of $55 per month. These cadets may attend one of the Canadian service colleges or a Canadian university. In the latter case, an additional allowance of $65 per month is granted in lieu of lodging. Uniforms are issued free of charge.

The ROTP cadet may also be granted a subsidization for a further year of study after graduation from the service college so that he may obtain his degree. On graduation, he is granted a permanent commission as a Flying Officer in the RCAF branch in which he has received his training. He has also the option of release after three years' service.

CAREER OPPORTUNITIES

Once the officer in the Regular Force has completed his basic training and other training courses, he will normally be posted to a unit in the field. The aim at this time is to permit him to consolidate and apply the extensive training undertaken at the University and in the RCAF. He may be charged with the supervision of many men and much complex equipment, including aircraft. Within his own sphere of responsibility he has great scope for exercising his personal initiative and ingenuity. He learns to be part of a highly effective team, including aircrew, groundcrew, and specialist personnel.

In the RCAF there is such a wide variety of employment for the engineer, that during his career he will be called upon to exercise his abilities in many areas. The manner in which he applies himself and handles his subordinates determines his rate of promotion. As he gains experience, he progresses to more responsible positions and receives recognition in accordance with his demonstrated ability.

MONTHLY RATES OF PAY

Monthly rates of pay are shown in the accompanying table.

An officer also receives an allowance of $375 for his uniform when he first enters the RCAF. He will receive substantial pension benefits, free medical and dental care and a $5,000 insurance policy for $2.00 per month as well as other fringe benefits.

Monthly Rates of Pay

Rank	Basic Pay	After 3 Years in Rank	After 6 Years in Rank	After 9 Years in Rank	*Marriage Allowance	†Subsistence Allowance (S) Single (M) Married	Total
Pilot Officer or Flight Cadet	$185	....	....	....	....	$65 (S)	$250
					$40	$91 (M)	$316

					$40	(M)	$864
Air Commodore	$827	....	....	....	....	(S)	$980
					$40	(M)	$1020

* An officer eligible for marriage allowance receives $40 per month if living off the unit and $30 per month if occupying Government married quarters.

† Subsistence allowance is provided when rations and quarters are not available.

FUTURE OUTLOOK

As Canadian military aviation continues its rapid progress, the need for greater numbers of highly qualified engineers increases. According to Secretary of Defence Wilson, "half of the scientists and engineers [in the United States] work directly or indirectly for the defense effort." Although a similar statement cannot yet be made for Canada, RCAF experience alone underlines the growing need for engineers that is developing throughout the Department of National Defence.

Each of the technical branches of the RCAF has its own requirements and areas of responsibility, but they are interdependent. Each officer becomes a specialist in his own branch but he is expected to have a working knowledge of the activities of other branches and an appreciation of their problems. Only in this way can the branches work together as an effective team. Policy planning demands co-ordination within the branch and with those concerned in other branches. The planning must be integrated with specifications of aircraft design and development of new and better weapons and modern electronic devices to be installed in the aircraft. Management of projects involved in the construction of runways, hangars, control towers and personnel housing is closely allied with the operations of the Mobile Equipment Engineering Branch which provides the tractors, bull-dozers, cranes and trucks as well as general transportation vehicles. There must be a constant interchange of ideas between the officers of these various branches. Only by this close integration can an effective fighting system be developed and the maintenance of that system be kept at peak operating efficiency.

A primary factor of modern military superiority is technology. At this time when aviation is on the threshold of vertical flight, atomic powered aircraft and space travel, the scope for engineers in the service is particularly challenging.

A career in the RCAF is interesting and rewarding for a graduate engineer. Apart from its professional advantages, there is the personal satisfaction of service with a team designed for the maintenance of peace and the security of the people of Canada.

Bus. and Ind. Briefs

New Epoxy Manufacturing Company.—The Bate Chemical Corporation, Ltd., Toronto, Ont., and Houghton Laboratories, Inc., Olean, N.Y., have formed a joint company in Canada to manufacture and market Hysol products, which consist of epoxy electrical insulating materials, adhesives and tooling compounds. G. H. Clifford Smith of Bate Chemical Corp., Ltd., is president of the new Canadian company to be known as Hysol (Canada) Ltd., and Russell H. W. Smith, an electrical engineer of Toronto, is sales manager. Offices of Hysol (Canada) Ltd., are at 184 Laird Drive, Leaside, Toronto 17, Ont.

●

German Industries Fair.—The 1956 German Industries Fair covering industrial and consumer goods is to be held at Hanover from April 29 to May 8. Mechanical and electrical engineering industries are prominent among the exhibitors, according to a comprehensive brochure which is available, together with all other information on the Fair, from the Canadian representative, The Trimont Corporation Ltd., 1170 Drummond St., P.O. Box 25, Montreal, Que.

●

Avro Anniversary.—A. V. Roe Canada Limited recently celebrated their 10th Anniversary. The winter, 1955, issue of *Jet Age* attractively presents the story, written by Scott Young, of the achievements of the company during these ten years.

●

Refrigeration Show.—The 2nd Canadian Refrigeration and Air-Conditioning Show, will be held in the Coliseum in Toronto, on February 1, 2 and 3. Sponsored by the Canadian Refrigeration Manufacturers Association, this all-industry show contains over half a mile of exhibits displaying the latest developments in the fields of refrigeration and air-conditioning, plus the finest equipment for commercial, industrial and domestic application. During the first two days (Feb. 1 and 2) admission is by ticket only. The show will be open to the public on the final day. Businessmen desiring to attend the show are asked to write for free tickets to: Sec'y-Manager, 2nd Canadian Refrigeration and Air Conditioning Show, Room 1209, 137 Wellington St., West, Toronto, Ontario.

●

Canadian Contributions to Geophysics.—Roy L. Adams is to supervise production engineering on the type T609 auroral recorder, one of Canada's contributions to the International Geophysical Year which starts in 1957. This was made known by J. M. Bridgman, managing director of PSC Applied Research Limited in announcing Mr. Adams' appointment as production coordinator of the Toronto company. The auroral recorder, which measures the light intensity of the Aurora Borealis was developed by a group under Dr. Donald Hunten at the University of Saskatchewan with the aid of the National Research Council and the Defence Research Board. PSC Applied Research Limited has been given a contract by the Canadian Government to build the first unit.

The company also announce that their Canadian-developed and produced magnetometer has been used to discover more than one hundred million tons of good quality ilmenite in South West Norway. This valuable ore is used in the making of jet engines, paints and other products. The find has been christened the Tellnes deposit.

Publications

Industrial or trade publications received recently cover many fields of interest to engineers. For copies of those mentioned below, please apply to the issuing company (mentioning *The Engineering Journal*).

Bathurst Packaging Handbook.—A comprehensive, illustrated loose-leaf book covering many aspects of packaging, such as design, construction, testing, freight regulations. Bathurst Power & Paper Co. Ltd., Container Division, Sun Life Building, Montreal 2, Que.

●

Barometric Condensers.—A bulletin, Form 9012-A, describing barometric condensers of the disc-flow and ejector-jet types. Canadian Ingersoll-Rand Co. Ltd., 620 Cathcart St., Montreal, Que.

●

Rock Bolts.—Brochure describing types and applications of rock bolts. The Steel Company of Canada Ltd., Hamilton, Ont.

●

Liquid Level Transmitter.—Bulletin 13-22, describing closed tank liquid level measurement and control with Type 13 LA d/p cell liquid level transmitter. (The Foxboro Company.) Peacock Brothers, P.O. Box 1040, Montreal, Que.

Safeguarding Construction.—Well illustrated booklet describing the inspection of construction from site to finished project as part of the services offered by the company. (Publication No. 102.) The Warnock Hersey Co. Ltd., 128 Elmslie St., Montreal 32, Que.

●

Diamond Anniversary. — Illustrated booklet marking 75th anniversary and describing services of J. T. Donald & Co. Ltd., 1181 Guy St., Montreal, Que.

●

Bishop Signs.—Catalogue No. 60, summarizing metal letter and allied product data. H. B. Tompkins & Son, 733 Versailles St., Montreal, Que.

●

Carboloy Blanks and Tools.—Catalogue SBT-17 covers grades, styles, and specifications of "throw-away" insert blanks; new pricing information on Carboloy standard tools and blanks is given in bulletins 54CT and SBT-7B. Carboloy Section, Canadian General Electric Co. Ltd., 1025 Lansdowne Ave., Toronto, Ont.

●

Power Generation Equipment.—Publication No. 2404 deals with large steam turbines; No. P-2560 deals with large generators used with the turbines, also details of other equipment. (The General Electric Company Ltd., of England.) Fraser & Chalmers of Canada Ltd., 1411 Crescent Street, Montreal 25, Que.

●

Shellcast Brochure.—Esco Shellcast Brochure No. 205 covers the shell-moulding process, showing some of its applications and advantages. Esco Limited, 146 East 1st Ave., Vancouver 10, B.C., or 2480 Dufferin St., Toronto, Ont.

News of the Associations and Corporation

(*Continued from page 52*)

on Friday night, and the convention culminated with the annual dinner dance which overflowed the Empress ballroom on Saturday.

Engineers in the News

Charles Bentall, chairman of the board of directors of the Dominion Construction Co. Ltd., recently announced the appointment of **H. C. Bentall** as president and **R. G. Bentall** as vice-president of the Dominion Construction Co. Ltd., Bentall Construction Co. Ltd., and their associated companies.

D. D. Morris has been appointed to the newly-created position of assistant to the general manager of the Consolidated Mining and Smelting Company. He had served as administrative assistant since January, 1954, and had previously been manager of the research and development division.

J. M. Bezer has opened new Calgary offices for Eric Ackland and Associates Ltd., from which he will handle mechanical and electrical lines throughout southern Alberta. Mr. Bezer is a 1950 mechanical graduate of the University of British Columbia.

M. J. Shelley, a University of British Columbia civil graduate of 1955 has won the first Engineering News Record Fellowship for graduate study in the field of public works engineering and administration. The award was based partly on a paper on the design and operation characteristics of the City of Vernon's sewage treatment plant.

Mr. Shelley worked this summer under **F. G. deWolf,** city engineer of Vernon, and has now returned to the University of British Columbia to take his master's degree.

R. N. Gordon, division engineer with the Department of Fisheries in Ottawa, has been transferred to Vancouver where he will continue his work with the Department. Mr. Gordon is a graduate of the University of British Columbia and had previously been with the Department of Fisheries in Vancouver from 1949 to 1954.

D. A. Pirttinen has resigned from the process department of Foundation of Canada Engineering Corp. Ltd., Toronto, and is now associated as project engineer with Catalytic of Canada Construction Co. Ltd., of Sarnia.

J. M. Fitzsimmons has accepted a position with H. A. Simons Ltd. He was previously employed by Canadian Forest Products at Port Mellon.

A. R. M. Stewart has accepted a position with Sandwell and Co. Ltd. in Vancouver. He was previously plant engineer at Powell River and was with the Powell River Company for the past 15 years.

R. G. Foxall has joined Northern Construction and J. W. Stewart Ltd. and will be engaged on work in connection with the expansion program of the Powell River Company. He was with Canadian Forest Products at Port Mellon.

J. H. Eastman has been transferred from Canadian Exploration Ltd., Salmo, B.C., to Pato Consolidated Gold Dredging Ltd., Barranquilla, Colombia, S. America, where he expects to stay for at least two years.

G. H. MacKay, formerly with the Department of Public Works of Canada in New Westminster is now in Winnipeg working for the P.F.R.A.

J. R. Wallis, who recently obtained his master's degree in forest engineering from Oregon State College, has accepted a position teaching at the Montana State University School of Forestry.

J. Moroney is now with Dawson, Wade and Macco engaged in hydro work in the Upper Campbell Lake district. Mr. Moroney was previously assistant to the municipal engineer of Esquimalt.

L. Dotto has accepted a position with the Canadian Western Lumber Co. at New Westminster. He had previously been with H. A. Simons Ltd.

D. J. Turland, of the apparatus division of Canadian General Electric Co. Ltd., has been transferred from Vancouver to Trail where he will be apparatus sales engineer for that district.

R. H. Ferguson has accepted a position with H. A. Simons Ltd. He was previously with Vancouver Iron Works Ltd.

W. T. Harrower, of Dominion Bridge Co. Ltd., was recently elected chairman of the Vancouver chapter of the Canadian Welding Society.

D. I. Cameron is now with the B.C. Electric Co. Ltd. as a protection test engineer. He had been employed by Barvic Engineering Ltd.

R. H. Elfstrom was recently re-elected president of the Greater Vancouver Health League. Mr. Elfstrom is supervisor of industrial safety for B.C. Electric Co. Ltd.

H. Matthews was recently appointed chief engineer of the Victoria Machinery Depot Co. Mr. Matthews had been chief engineer and plant manager of Vancouver Iron Works Ltd. and Vancouver Engineering Works Ltd. and had been employed by that firm since 1928.

H. T. Ramsden has been appointed to the position of district engineer, Water Resources Division, Department of Northern Affairs and National Resources. He is a native of British Columbia and a graduate of the University of British Columbia.

Mr. Ramsden served with the R.C.E. Corps during the late war, and returned to service with the Water Resources Division, where he has held the post of assistant district engineer for six years. He succeeds **W. C. Warren,** the retiring district engineer.

D. C. Gough has accepted a position with Swan, Wooster and Partners, as resident engineer on the Kelowna bridge. He will leave his former position of construction engineer with the Pacific Great Eastern Railway at the beginning of the year.

D. C. Codville, who has been with Giant Yellowknife, recently accepted a position with Northern Construction Co. and J. W. Stewart Ltd., and will be engaged in work on the removal of Ripple Rock.

J. A. Wallace, formerly with Mobil Oil of Canada Ltd. in Canada and more recently district geologist for that company in Edmonton, has been transferred to the head office of the parent company, Socony Mobil Oil Company, Inc., at 26 Broadway, New York 4. In his new assignment, Mr. Wallace will be concerned with the company's Canadian operations.

D. A. Duguid has accepted a position with Bumstead-Woolford Ltd. of Vancouver and Seattle and will take over his new duties in Vancouver at the first of the New Year. Mr. Duguid was previously in the marketing division of the Imperial Oil Company.

Cyril Jones will officially retire from his position as city engineer at Victoria at the end of December.

A. R. Luck has left his position with the electric department of the Vancouver City Hall to join the staff of Canadian Westinghouse Co. Ltd. in Vancouver.

E. A. Bianco, a '52 civil graduate of the University of British Columbia, is now attending Stanford University at Stanford, California. He is working towards his master's degree in engineering administration.

T. L. Horsley has accepted a position with Granby Mining, Smelting and Power Company at Copper Mountain, B.C. He was previously with Taiga Mines.

J. W. Lee has been promoted to the position of senior geologist with Kaiser Aluminum and Chemical Corp. He has been in Jamaica with the Kaiser Bauxite Company.

D. H. Rutherford of Stone and Webster Engineering Corp. has been transferred from Concrete, Washington, to Seattle.

C. H. Morrison, a '55 mechanical graduate of the University of British Columbia, has taken a position with A. L. Swanson and Co. in Vancouver. He was previously with the B.C. Power Commission in Victoria.

W. C. Sellens has left the traffic engineering department of the B.C. Telephone Company to take a position with the engineering branch of the marketing department of the Imperial Oil Company in Vancouver.

G. R. Hilchey has accepted the position of mine engineer at Canadian Refractories Ltd., at Kilmar, Que. He was previously at the Levack Mine in Ontario.

R. T. Lisset, formerly with Vancouver Iron Works Ltd., is now on the engineering staff of H. A. Simons Ltd.

SWITCHING . . .

of Shunt Capacitors and Reactors

Some of the more troublesome problems associated with the application of shunt capacitors and reactors to high-voltage lines are indicated in this paper, which deals mainly with the question of switching.

G. W. Clayton,
Apparatus Division,
Canadian General Electric Company Limited,
Peterborough, Ont.

The year 1954 has been called the Diamond Jubilee of Light. The development of the first practical light bulb required that power be made available to both residential and industrial areas. During the past 75 years, the demand for power has been increasing at a phenomenal rate. In order to meet this demand, electric utilities have been forced to transmit more power, greater distances than ever before. This continual battle between the supply and demand of electrical energy has not been confined to kilowatts alone. Increased transmission distances and heavy line loadings coupled with the increased motor load of the industrial and residential consumer has increased the demand for both leading and lagging kilovars.

For many years, power companies were able to supply the necessary system kilovars from available generation. In fact, quite a few of the smaller utilities still supply their entire kilovar requirements in this manner. However, most companies are rapidly realizing that, generally, it is neither practical nor economical to transmit kilovars any great distance. Reduced line and transformer capacity, generator instability, field heating and decreased generator kilowatt capacity have shown that it is better practice to install kilovar sources as close to the load as possible. In order to accomplish this, a large number of utilities are installing synchronous condensers, shunt capacitors and reactors at the load end of their transmission, sub-transmission and distribution lines.

Presented to the Winnipeg Branch of The Engineering Institute of Canada, 2 December 1954.

The installation of these devices on power systems has presented some unique problems. It is the purpose of this paper to point out a few of the more troublesome problems associated with the application of shunt capacitors and reactors to high voltage lines. Possibly, one of the most pertinent problems today is the question of capacitor and reactor switching. Because of this, I have decided to devote most of this paper to the switching question.

General

Many electric utilities have found that repetitive capacitor switching has produced severe transient system disturbances and caused extensive damage to switching devices. The difficulties involved in capacitor switching can be resolved into two separate problems. The first problem deals with the high momentary duty imposed on the switching device by the high inrush currents produced when a capacitor bank is first energized. The second problem concerns the production of overvoltages due to repetitive restriking in the switching device when a capacitor bank is being de-energized.

As will be pointed out later, the switching of a shunt reactor will not produce the effects just mentioned.

Causes of Inrush Currents

In order to fully appreciate the difficulties associated with capacitor and reactor switching, it is necessary that a few of the concepts underlying the production of inrush currents, be reviewed.

Figures 1A and 1B show, respectively, the equivalent circuit of a shunt reactor and capacitor bank which have been connected to a predominately inductive (i.e., resistance neglected) power system. The waveshape of the inrush current for switch closures at various points on the voltage wave, is also shown.

For a start let us consider the magnitude of the inrush current that is likely to occur when a shunt reactor is initially energized. From Fig. 1B, it can be seen that closing the switch at a voltage zero will result in an asymmetrical inrush current whose magnitude is twice normal. On the other hand, closing the switch at a voltage peak will produce a current inrush whose maximum transient value is equal to the final steady state value. In other words, switch closure at a voltage peak will produce a symmetrical inrush current. The reason that the current inrush is in one case symmetrical and in the other case asymmetrical can be attributed to the fact that it is essential that the current lag the voltage by 90 degrees. Therefore, closing the switch at a voltage zero necessitates that the inrush current wave be offset in order that the requirement mentioned above be satisfied. Of course, if the switch is closed at a voltage peak, the inrush current to the reactor can obtain the required phase angle displacement without any offset.

Now, let us consider the magnitude of the inrush current that is likely to occur when a capacitor bank is energized (Fig. 1A). If the switch is closed at a voltage peak, the ensuing voltage "shock" will initiate a transient oscillation, the magnitude and frequency of

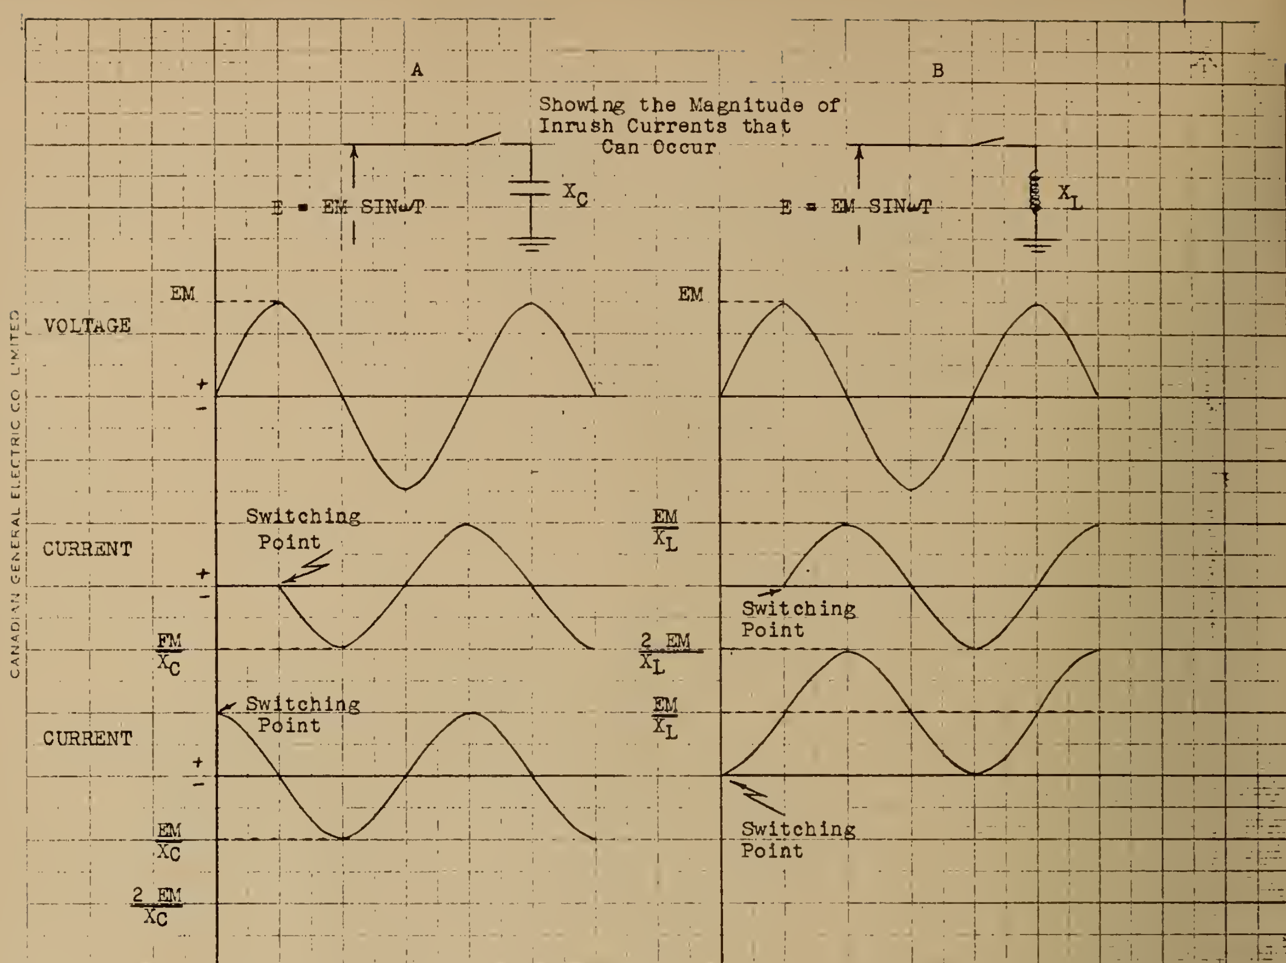

Fig. 1. Showing the magnitude of inrush currents that can occur.

which will be proportional to $\sqrt{\frac{X_C}{X_L}}$. Since the capacitor bank X_C is usually much larger than the system reactance X_L, both the magnitude and frequency of the inrush current will be high. However, if the switch is closed at a voltage zero, the magnitude of the transient component of the inrush current equals the fundamental frequency component. This indicates that even in the best case, the current inrush to a capacitor bank will be twice normal. For switch closures at points intermediate on the voltage wave, the magnitude of the inrush current will depend on the instantaneous value of voltage at the instant of switch closure and the ratio of $\sqrt{\frac{X_C}{X_L}}$.

From the above discussion, it can be seen that the magnitude of the inrush current to a capacitor bank can theoretically be equal to any value between the limits of twice normal and infinity. However, the magnitude of the inrush current to a shunt reactor will be, in the worst case, only twice normal, which leads to the conclusion that capacitor switching presents a more severe duty to the switching device than does reactor switching.

Effect of Resistance on Inrush Currents

Resistance in the lines leading to the reactor or capacitor bank will effect the inrush current in two ways. Firstly, it will reduce slightly the magnitude of the inrush current and secondly, resistance will determine the rate at which the initial value of inrush current decays to the normal current rating of the bank (Fig. 2). However, since we are normally interested in the current magnitude during the first quarter cycle and since resistance does not affect this magnitude appreciably, it is normal to neglect its effect completely. The reason for considering the first quarter cycle only, is that the momentary ratings of circuit breakers are based on the maximum value of current that can occur during this period.

Energizing a Single Capacitor or Reactor Bank

The circuits that have been considered so far have illustrated the fundamental concepts underlying the production of inrush currents. However, it would be of interest to consider the magnitude of inrush

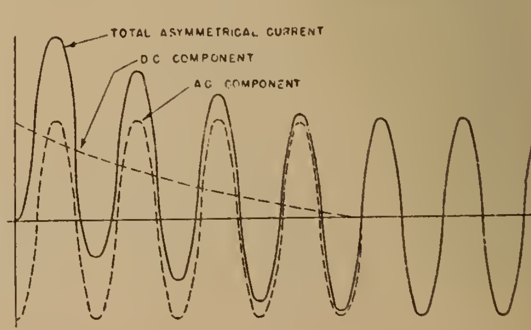

Fig. 2. Oscillogram showing decay of d.c. component and effect of asymmetry of current.

current that can occur in a practical power system. For reasons explained previously, all resistance will be neglected.

With the above thought in mind, let us consider what value of inrush currents can be expected when:

(1) A 13.8 kv. 5400 kvar. capacitor bank is energized.

(2) A 13.8 kv. 5400 kvar. shunt reactor is energized.

In both cases, it will be assumed that the system has an available short circuit capacity of 250 mva.

Case (1)

Figure 3 shows the system diagram and inrush current for the case where a 5400 kvar. 13.8 kv. capacitor bank is being energized. From the curves it can be seen that the inrush current is composed of two components. One component is the normal frequency (60 cps) current to the bank, while the second is the high frequency (410 cps) transient current. The magnitude of the normal fundamental frequency current is approximately 250 amperes and is given by $Em/(X_C - X_L)$. The magnitude of the transient component is 1580 amp. and can be found by multiplying the fundamental component by the ratio $\sqrt{\frac{X_C}{X_L}}$. The total inrush current is the sum of the two component waves and in this particular example will reach a maximum of 1830 amp. It is this total value of inrush current that determines the severity of the duty on the switching device. For this reason, it is customary to consider the maximum value of inrush current that is likely to occur. The curves shown in Fig. 3 have been prepared for the condition where the voltage is a maximum at the instant of switch closure and consequently, the inrush current is likely to be a maximum, depending on the ratio $\sqrt{\frac{X_C}{X_L}}$.

It was stated previously that the normal frequency current is 250 amp. However, the full load current of a 5400 kvar. 13.8 kv. capacitor bank is 226 amp. The difference in the two currents is due to the fact that the terminal voltage of the bank is unregulated. Thus, when the bank is first energized, the terminal voltage increases and the bank draws more than normal current. In order to prevent excessive voltage at the terminals of the bank, it is customary to regulate the terminal voltage by using multistep capacitor switching initiated by voltage control.

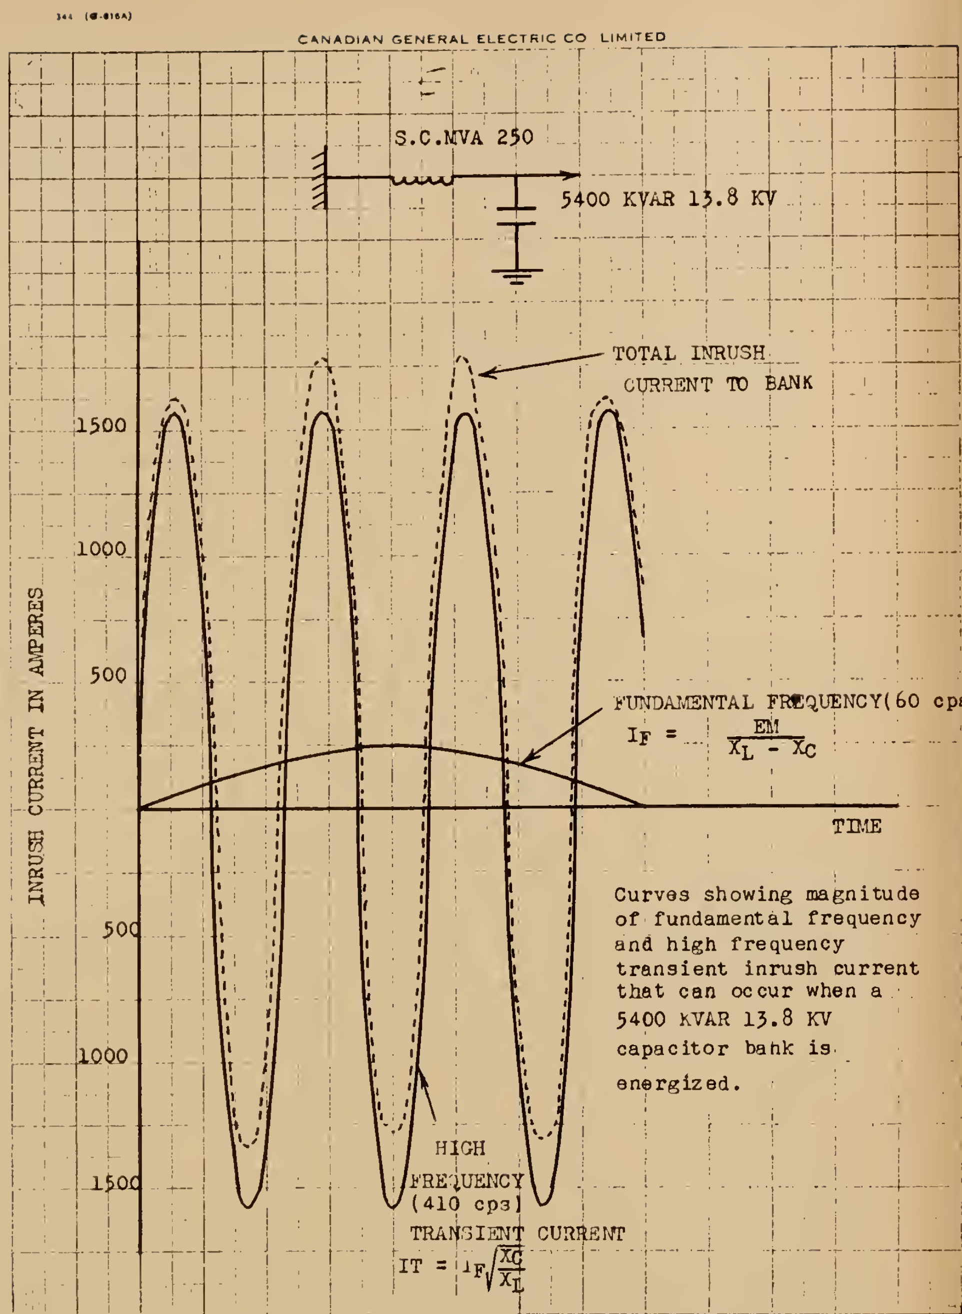

Fig. 3. Curves showing magnitude of fundamental frequency and high-frequency transient inrush current that can occur when a 5400 kvar. 13.8 kv. capacitor bank is energized.

The equation from which these inrush currents can be calculated is quite simple and will give the maximum value that is to be expected when switching a single bank. Figure 4 shows this equation and the type of circuit to which it can be applied. If the equation is expressed in per unit, using as base quantities the line to neutral mva., kv., X and I of the bank in question, it is possible to obtain a universal curve which will give the value of inrush current for a given system reactance. Figure 5 shows such a curve. It should be noted that the curve swings sharply upward at $X_L = 1.0$ p.u. This is, of course, the resonant point. It should also be noticed that it is impossible to limit the inrush current to less than four times normal unless the current limiting reactor is made exceptionally large. That is, the ohmic value of the reactor must be larger than that of the bank.

Case (2)

This next case investigates the

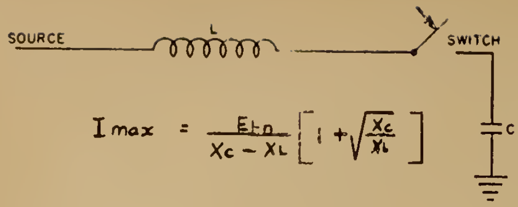

Fig. 4. Circuit diagram representing a capacitor being energized through an inductance.

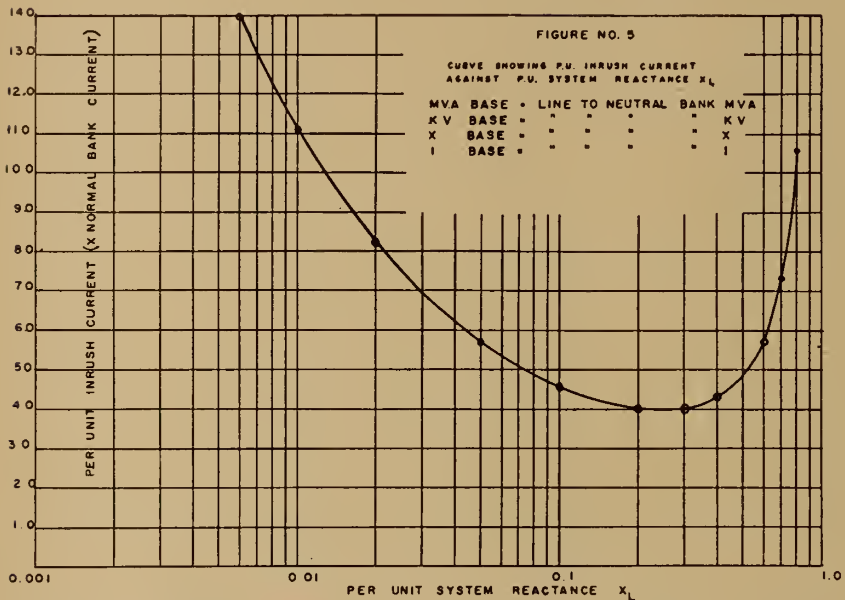
Fig. 5 (below). Curve of p.u. inrush current against p.u. system reactance X_L.



magnitude of inrush currents associated with switching a 5400 kvar. 13.8 kv. shunt reactor. Actually, this phenomenon has already been discussed under the heading Causes of Inrush Currents. Figure 1B illustrates the maximum magnitude of inrush current that can occur. It can readily be seen from this figure that the worst case will only produce a twice normal inrush, (500 amp.) at the fundamental frequency. This confirms the previously drawn conclusion that energizing a shunt reactor does not impose a very great duty on the switching device. If the switching device has an interrupting rating, then no trouble should be experienced, since the inrush current will be considerably less than the fault current at the same location.

There have been a few isolated cases where the switching of a shunt reactor has proved troublesome. This difficulty has been attributed to rapid rates of rise of recovery voltage causing restriking in the switching device. Normally, this condition can be remedied by using a circuit breaker rather than a load break switch as the controlling device.

Energizing Parallel Banks of Capacitors

The inrush current associated with multistep switching is invariably higher than the inrush current to a single bank. This statement becomes fairly obvious if we consider the circuit of Fig. 6. In the circuit shown, the inductance between parallel banks will be very low compared to the system if the banks are close-coupled physically. Consequently, the majority of the inrush current will come from the two parallel banks rather than from the system. Since we are primarily interested in the maximum inrush current that is likely to occur, it is assumed that the energized banks are charged to a maximum at the instant the switch energizing the last bank is closed. Since the inductance between the banks is small, the inrush current will be correspondingly high.

The maximum value of inrush current to be expected when switching parallel banks can be calculated from the equation shown in Fig. 6. The values of C_t and L_t are, respectively, the equivalent capacitance in microfarads and the equivalent inductance in microhenries of the circuit in question.

By way of comparison, it would be interesting to note how much the inrush will increase if a 5400 kvar. 13.8 kv. bank is energized in parallel with two other 5400 kvar. banks. Using the equation of Fig. 6, the inrush current is found to be 20,600 amp. at 5820 cps. It can be seen that this value of current is more than 11 times the value of inrush current for a single bank and the frequency of oscillation is more than 14 times greater than the frequency associated with the energizing of a single bank.

Although the equations themselves are relatively easy to use, it is sometimes difficult to determine accurately the inductance between the parallel banks. A good rule of thumb is to neglect the inductance of the capacitor leads and buswork and to use 0.5 microhenries per foot as the inductance of open conductor runs, including the length through the circuit breakers. This figure will give a value of inductance which is low, thus the calculated inrush current will be high and on the conservative side.

It should be noted that the formulae previously mentioned are based on the energization of an uncharged bank. If the bank happens to be charged at the instant the switch is closed, it is possible that the inrush current will be much higher than calculated. This can be attributed to the difference between the system voltage and the voltage trapped on the capacitor bank being, at a maximum, twice the normal system voltage. Consequently, at the instant of

$$C_t = \frac{(C_1 + C_2)(C_3)}{(C_1 + C_2 + C_3)}$$

$$L_t = \frac{(L_1)(L_2)}{L_1 + L_2} + L_3$$

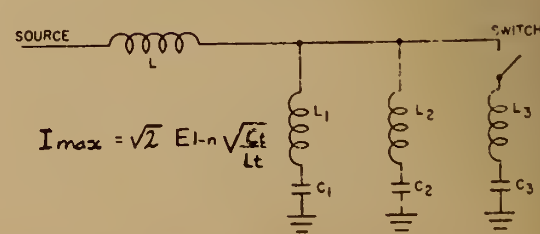


Fig. 6. Circuit diagram representing the energizing of the third step of a multi-step capacitor bank.

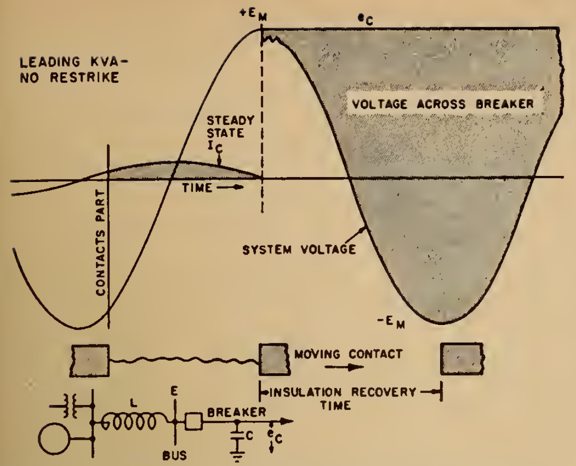

Fig. 7. Diagram representing voltage across contacts of breaker when interrupting capacitive current with no restriking.

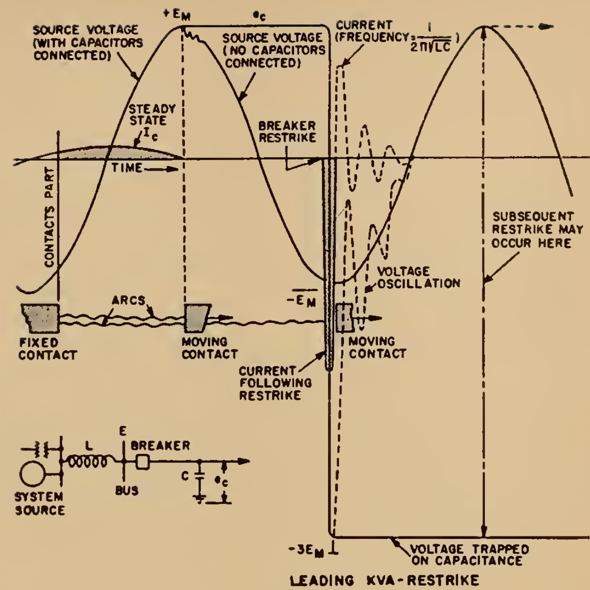

Fig. 8 (right). Diagram representing restrike in a breaker when interrupting capacitive current.

switch closure, the voltage imposed across the bank will be twice normal and the inrush current will also be twice normal. For this reason, it is best to have the bank de-energized for 30 seconds before attempting a reclosure. Likewise, the time delay of the automatic controls that are used to initiate the switching should be set for at least 30 seconds. This time delay will allow the internal resistor in each unit to discharge the capacitor to a relatively low voltage.

Transient Voltages

So far, we have been concerned with the inrush currents associated with energizing either single or parallel banks of capacitors. Before discussing the effect of the inrush currents on switching devices, it might be of interest to study briefly the transient overvoltages that can occur when a bank of capacitors is being de-energized.

Figure 7 illustrates the voltage across the contacts of a breaker when interrupting capacitive current with no restrike. The contacts part at some point during the voltage and current wave. The shaded part of the current wave represents arcing current. At the first current zero, the arc will be extinguished, and the voltage will be a maximum. The capacitor bank will be left charged at the instantaneous value of system voltage. At the instant of current zero the system voltage will drop slightly since the voltage rise due to the capacitor bank is no longer present. There will be a few small oscillations as the system voltage recovers to the no-load value. In the next half cycle the system voltage will go negative and the total voltage stress across the breaker contacts will be twice normal system voltage. If the rate of build-up of dielectric strength across the breaker contacts is sufficiently rapid, then no restrike will occur and the circuit can be considered cleared.

On the other hand, the dielectric strength across the contacts may not build up fast enough to prevent a breaker restrike. If such a restrike should occur when the source voltage is a maximum in the negative direction as shown in Fig. 8, a high frequency equalizing current is then established due to the reversal of potential on the capacitor. The frequency of the current is determined by the capacitance and inductance of the circuit and may be of the order of 1,000 to 10,000 cycles. This oscillating current would pass through many current zeros if it were not that the breaker usually interrupts this current at an early current zero.

The high frequency voltage associated with the high frequency current has the same frequency as the current but bears a phase relation to the current of 90°. Thus, if the high frequency current is interrupted at first current zero, the high frequency voltage, which is at a maximum, is trapped on the capacitor. This voltage may be as high as three times normal crest depending upon the instant at which restrike occurs.

A half cycle following the first restrike, the voltage across the open breaker is four times normal crest depending upon the instant at which restrike occurs. Should a second restrike occur at this point, the voltage on the capacitor may be theoretically as high as five times normal crest. However, extensive field tests have seldom shown overvoltages due to restriking that exceed three times normal value. This would indicate that cumulative build up due to restriking is rarely encountered in practice.

Figure 9 illustrates the type of random restriking that can be obtained when a large bank of capacitors or long high voltage line is being de-energized. The maximum value of overvoltage that occurred in this particular test did not exceed three times normal crest. The voltage trapped on the line after the breaker finally cleared does not exceed $1\frac{1}{2}$ times the normal crest value. It is apparent that if restriking is not limited, the voltage stresses may cause failure of the capacitors and other apparatus such as lightning arresters and transformers.

Effect of Inrush Currents and Restriking on Switching Devices

Having studied the theory behind inrush currents and restriking, it would follow logically if we were to determine how these phenomena affect the operation of switching devices. The stress imposed on any piece of electrical apparatus by high transient currents is mechanical rather than thermal. The inrush currents associated with capacitor switching are of such short duration that the thermal capabilities of the switching device are not severely stressed. However, the electromechanical forces on the switching

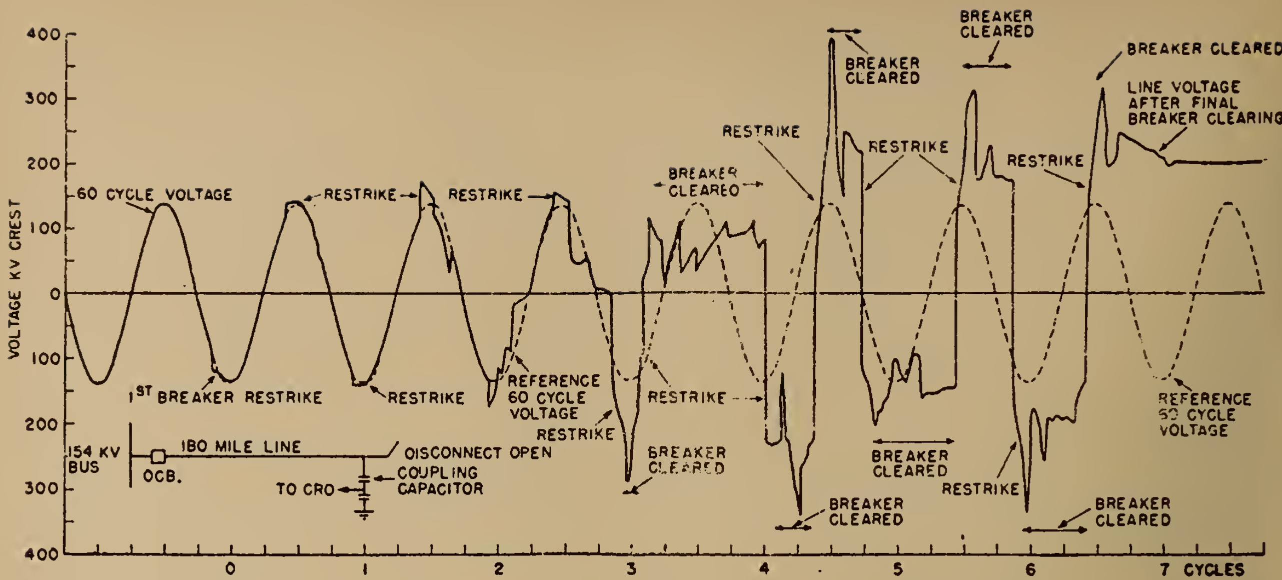

Fig. 9. **Oscillogram from interruption of charging current of 180 miles of 154-kv. overhead transmission line, showing random restriking of circuit breaker having interrupters unmodified for capacitive switching.**

device will vary with the square of the current. Consequently, if the inrush currents are high the mechanical forces on the switching device may be large enough to cause mechanical failure. Restrikes, on the other hand, may burn the contacts of the switching device and produce large overvoltages that might damage other apparatus.

How to Select a Switching Device

From the previous discussion, it can be seen that the switching device should be selected carefully if it is to perform satisfactorily. All switching devices have standard ratings as far as voltage, continuous current carrying capacity, interrupting capacity etc., are concerned. When selecting a switching device for duty with capacitor banks, each of the following ratings should be examined to insure that the device will be operating within its design limits.

(a) Voltage Rating.—The voltage rating of the switching device must be equal to or greater than the maximum operating voltage of the circuit to which the switch is connected.

(b) Continuous Current Rating.—The continuous current rating of the switch should be at least 135 per cent of the capacitor bank current in accordance with Nema standards. This margin is necessary since the capacitor current may exceed the name-plate value because of manufacturing tolerances of the individual units and because of the possibility of overvoltages and harmonic current flow.

(c) Interrupting Rating.—If the switching device is used as a means of short circuit protection in addition to its duty as a capacitor switch, it must have an interrupting rating adequate to handle short circuits occurring on the bank side of the switch. Even if the switch is not used for short circuit protection, it must be able to interrupt normal capacitor current without excessive overvoltages due to restriking. If the switching device has no interrupting rating, fault protection must be provided by backup breakers or fuses.

(d) Momentary Rating. — The switching device must be capable of withstanding the momentary duty due to fault current. In addition, the device must have a momentary rating greater than the maximum inrush current to the capacitor bank.

(e) Frequency of Operation.—The mechanical and electrical design of the switching device must be capable of withstanding repetitive operations.

Table I. Oil Switch Characteristics and Capacitor Switching Capabilities

Type	Rated Volts	Rated Amp.	Phase	Moment Amp Asym.	BIL Kv	Contact Life (No. of Operations)	Max 3-phase Capacitor Banks to be Switched: Volts	Kvar.
NR	15,000	200	1	9,000	95	6,000 at rating	2,400	600
							4,160 delta	1,080
							4,160 grd Y	1,080
							4,800	1,215
							7,200	1,845
							12,470	3,240
							13,800	3,555
B-1	15,000	150	3	40,000*	95	45,000 at 100 amp. 20,000 at rating	2,400	450
							4,160 delta	800
							4,160 grd Y	800
							4,800	900
							7,200	1,350
							12,470	2,400
							13,800	2,700

*40,000 amp. asym. applies only to 60-cycle currents. High-frequency inrush currents should not exceed 10,000 amp.

Capacitor Switching Capabilities of Load Break Switches and Circuit Breakers

Another point of interest deals with the amount of capacitor kvar. that can be handled by various types of switching devices. Table I shows the capacitor switching capabilities of two typical load break devices. It should be noticed that the B-1 switch has been derated to 10,000 amp. momentary when high frequency currents are being considered. It should also be noticed that none of these switches has an interrupting rating other than the nominal current rating. Hence, short circuit protection should be

Table IIA. Maximum Single-bank Three-phase KVAR to be Switched with Magneblast Breakers

Rated Circuit Voltage	Breaker Continuous Rating 1200 Amp.	2000 Amp.
2,400	3,700	6,200
4,160	6,400*	10,700
4,800	7,400	12,300
7,200	11,100	18,500
12,470	19,200	32,000
13,800	21,500	35,400

Table IIB. Maximum Single-bank Three-phase KVAR to be switched with Outdoor Breakers

Breaker Rating Kv	Single-bank Three-phase Kvar
14.4	30,000
23	30,000
34.5	30,000
46.0	22,000
69.0 – 1,500 mva	30,000
69.0 – 2,500 mva	30,000
69.0 – 3,500 mva	30,000
115.0 – 3,500 mva	50,000
138.0 – 5,000 mva	50,000
138.0 – 10,000 mva	50,000
161 – 5,000 mva	50,000
230 – 5,000 mva	50,000
230 – 10,000 mva	50,000

provided by backup breakers or fuses. Both switches will interrupt their rated capacitor current at rated voltage without restrikes.

Table IIA shows the amount of three-phase single-bank kvar. that can be switched with magneblast breakers. The interruption principle of the magneblast breaker is such that it is particularly suitable for switching capacitor banks. That is, the lengthening of the arc in the arc chutes tends to bring the current more in phase with the voltage thus reducing the possibility of restrike.

Table IIB will give some idea of the three-phase single-bank kvar. that can be switched by a large high voltage outdoor oil breaker. In order to switch successfully the amount of kvar. shown, it is necessary that the breaker be equipped with either an impulse or resistor type of interruptor. The principle of interruption of both devices is quite different although one does as good a job as the other.

On high values of fault current, the impulse interruptor relies on a self-generated oil blast to extinguish the arc. Under light current duty and reduced gas pressures, the spring-actuated impulse piston assists arc extinction by forcing cool oil across the arc.

On the other hand, the interruptor equipped with resistors achieves successful interruption by reducing the rate of rise of recovery voltages and equalizing the potential stress across the interruptor. The resistor also permits the capacitor bank to discharge into the system, thereby lowering the magnitude of the voltage trapped on the bank. These two features, combined with reduction of the phase angle between the voltage and current, decrease the possibility of restrike.

The values of capacitor kvar. shown in Tables IIA and IIB are standards which have been set by the electrical manufacturers. In general, most manufacturer's breakers can switch considerably more kvar. than the table would indicate.

Summary of Capacitor Switching Phenomena

The previous section illustrated the amount of capacitive kvar. that can be switched in a single step by various load break switches and circuit breakers. As mentioned previously, these values are conservative. The only way in which the performance of a switching device can be predicted accurately, is by actual field and laboratory tests. Such tests have enabled the following observations and conclusions to be drawn.

(1) The switching of shunt reactors does not present any problem since the maximum inrush current that is likely to occur is only twice normal. In general, the duty on a circuit breaker is much less when switching shunt reactors than when clearing a three-phase fault located on the reactor side of the breaker.

(2) Circuit breakers that are not designed for capacitor switching service may produce random restriking. This restriking will cause overvoltages which may damage the capacitor units, lightning arresters and other connected electrical apparatus.

(3) If a bank of capacitors is switched in parallel with a second bank of energized capacitors, the inrush current will be greater and the transient voltages less than if the energized capacitance were not present.

(4) By using properly designed shunting resistors across the breaker contacts, it is possible to reduce markedly the magnitude of the transient voltages and currents that are likely to occur if the switching device should restrike.

(5) A second effective means of controlling restriking is mechanically to force the dielectric between the parting contacts of the switching device. Since this principle is independent of the arc energy, low values of leading current can be interrupted successfully.

Although it is possible to design and build a restrike-free circuit breaker, it is felt that the economics involved would be prohibitive. This is especially apparent when it is realized that the maximum transient overvoltages, occurring from one restrike, will not usually be of sufficient magnitude to cause any damage to the system. Furthermore, on energizing an uncharged capacitor bank, it is possible to obtain twice normal crest line to ground voltage. Consequently, there is little point in attempting to limit the voltage due to restriking to less than twice normal crest. Because of this, it has been proposed that the following criteria should apply when determining the capabilities of circuit breakers for capacitor switching service.

(a) The transient voltages to ground resulting from possible restrikes when switching capacitor banks should not exceed twice normal line to neutral crest voltage.

(b) It should be demonstrated that the circuit breaker is so designed that not more than one restrike per phase will occur when interrupting capacitive current.

(c) The circuit breaker should be capable of successfully opening and closing the maximum transient currents as determined by (a) or (b) providing these currents do not exceed the momentary rating of the circuit breaker. √

Is Effective TOWN PLANNING Possible?

S. D. Lash, M.E.I.C.

Head of the Department of Civil Engineering,
Queen's University,
Kingston, Ont.

When I speak of town planning I mean a *process* aimed at creating the best possible urban environment with the available resources. It follows therefore that town planning is concerned particularly with health and safety, economic opportunity and efficiency, aesthetic and cultural satisfactions. I wish to consider whether such planning is in fact possible within the framework of democratic government. I am primarily concerned with planning as applied to existing towns for I am sure that all will concede that new towns such as Kitimat cannot come into existence without most careful planning.

Town Planning and Civil Engineering

Although planning activities of one kind or another are as old as cities themselves, the sort of planning that we are doing today is largely based upon the experience of the past fifty years. Most practical town planners have been trained either as architects, land surveyors or civil engineers and relatively few have had much university training in planning. There is necessarily a very close relation between civil engineering and urban planning and it is not surprising therefore to find that many of the most significant contributions to planning have been made by civil engineers. I believe that this will continue to be true.

Presented to the Kingston Branch of The Engineering Institute of Canada, April 19th, 1955.

At the same time it is important that we appreciate the differences between town planning and engineering design. We are all familiar with the latter and it may be illustrated by the following simplified example.

Suppose that an engineer is asked to design a bridge. He first surveys the site in order to determine the span and the foundation conditions. He then finds out what loads the bridge must support and how wide it must be in order to carry the traffic. With this basic information he can prepare alternative designs and estimate their costs. One of these designs is selected, working drawings are prepared and the bridge is built in accordance with the drawings. Our engineer can have the satisfaction of visiting the site and seeing his ideas take concrete form.

His colleague the town planner has a very much more difficult task. To begin with, the objectives of planning are seldom defined. The planner can survey the site but he cannot determine the size of the structure—he can only guess at what it may become. Most cities seem to feel that growth is all important—if only Kingston could be like Toronto all would be well—or would it? Chambers of Commerce believe that industry is all important—machines to make more machines. The planner is not so sure, perhaps because he has looked more critically at some of our large industrial cities.

Our engineer was dealing primarily with things; our planner is mostly concerned with people, and people are much more complex than things. Our engineer has learned effective techniques of design and construction. We say he has the know-how; but our planner is working in a field where technique is still in a rudimentary stage. The planner may draw up excellent plans but he is usually unable to do much about their realization. This will be the task of others. And finally even if the plans are followed it is unlikely that the planner will live to see their completion. Rome was not built in a day.

The Ineffectiveness of Planning

When we consider these differences we are not surprised to find that, so far, planning in Ontario and elsewhere has been relatively ineffective. If we study the matter a little further we will find additional reasons for ineffectiveness. These may be summarized as follows:

(a) lack of public understanding concerning the objectives and procedures of planning,

(b) uncertainty concerning the proper place of planning in the structure of local government,

(c) unsatisfactory administrative procedures,

(d) lack of properly trained personnel especially senior men,

(e) lack of money,

(f) vagueness of planning proposals.

Is town planning, particularly as it is concerned with health and safety, economic opportunity and efficiency, and aesthetic and cultural satisfactions, possible within the framework of democratic government? Dr. Lash considers that it is, but only if it has clearly defined objectives that are approached rationally.

Planning Objectives

May I examine these in a little more detail and at the same time suggest some remedies. Firstly, in this matter of objectives. I believe that town planning should have the following specific aims:

(i) The proper planning of town extensions.

(ii) The preservation of vitality in existing urban areas and especially in the central areas.

(iii) The improvement of means of communication.

(iv) The expression and encouragement of civic spirit.

The proper planning of town extensions involves the selection of land to be developed, the control of land use, the location of streets, the location of parks, schools and other public or semi-public uses of land.

The preservation of vitality in existing urban areas involves slum clearance, the reconditioning of obsolete properties, the remedying of deficiencies in open space, the creation of amenity, the improvement of traffic conditions including the development of off-street parking, the development of centres or precincts for specific purposes.

The improvement of communications involves the planning of by-pass or internal relief roads, road widening, the improvement of intersections, control over parking, control over the kinds of vehicles permitted on roads, traffic control devices, mass transportation facilities, the location of air, rail, and bus terminals.

The expression and encouragement of civic spirit is a rather intangible aim but it is of paramount importance. In 1915 Patrick Geddes wrote "the true town plan, the only one worth having, is the outcome and flower of the whole civilization of a community of an age". A more recent writer has said "Cities have personalities and characters as men have and the planner must try to catch the personality and character of the place he is planning before he can begin to formulate his plans". Nearly all successful town planning schemes in the past have commanded public support because of their visual appeal. Town planning will always be more of an art than a science. One of its primary aims must be the revival of the lost art of civic design.

The preceding summary of planning objectives may sound too ambitious and certainly not all these activities are likely to be carried on at one time and place. Nevertheless, all are practical and in fact all are being done successfully in various parts of the western world.

Planning and Local Government

May I consider next the place of planning in the structure of local government I believe that wherever possible the planning agency should be an integral part of local government. At the same time it must not be associated too closely with any particular department. It is the function of a planning agency to discover the public interest, to balance conflicting claims on the public purse and to co-ordinate development, both public and private, so as to produce a harmonious result. To do this effectively requires that the planning agency be very close to the normal machinery of local government but that it have a vitality and continuity of its own. Two systems have worked well—in one the planning agency is itself an independent department, in the other it forms part of the staff of the mayor or chief executive. What has not worked well is the North American system of a semi-independent planning board or commission. Planning boards may be useful if they function only as advisory committees on policy but they cannot deal effectively with the implementation of planning policy.

Size of a Planning Area

The size of a planning area is a matter of fundamental importance. It has become usual in North America to regard planning as being primarily a municipal concern. Unfortunately the municipality as presently constituted is seldom a suitable administrative planning unit. Either it is too small in terms of total population or it is too small geographically. Effective planning requires the planning staff consisting of a leader of high calibre assisted by a technical staff competent in a wide range of different fields. These might consist for example of a civil engineer, an architect, a sociologist and a real estate specialist. Obviously a small municipality cannot afford a planning staff of this size and it follows therefore that small municipalities should be grouped together for planning purposes. As a rough guide it is suggested that the population of a planning area should not be less than from 75,000-100,000 but further studies of this problem are clearly needed.

Many towns in Canada are overspilling their municipal boundaries with the consequence that there is often a multiplicity of government within a single urban area. The remedy is obvious but difficult to achieve — to extend municipal boundaries so as to include all existing and potential urban land. Where two or more towns are tending to coalesce, a single municipality should be formed. In many places this has been done with great success but little has been accomplished in Ontario except the creation of Metropolitan Toronto. It would seem that planning cannot wait for local government reform. In Ontario we are stuck with a municipal act of the horse and buggy era and there seems little chance of replacing it with more modern legislation. An interim solution is to form joint planning authorities such for example as the Kingston Area Planning Board. But experience has shown that such bodies are relatively ineffective and this is particularly true when they are supplemented by a number of subsidiary planning boards. Planning is accomplished not by setting up a large number of planning agencies, but by giving adequate authority to appropriate agencies. Effective planning therefore requires the establishment of regional planning authorities. This has already been done to a limited extent in Alberta and British Columbia. I have no time to discuss in detail the organization of such a planning system, but one feature should be mentioned. I would expect a regional planning authority to delegate some of its powers to local municipalities within its jurisdiction and thus retain local interest and experience.

May I remind you that I started out by describing planning as a process. This process consists essentially of three steps which are repeated cyclically—survey or the collection of information, the preparation of plans, and the control of development in accordance with approved plans. The approval, rejection or modification of plans must be the responsibility of elected governments.

We are fortunate that in Canada the general pattern of planning has been that of local action subject to approval at the provincial level. This is basically sound. In large measure this must be a local responsibility but there are circumstances in which local approval or disapproval may be irrelevant or unimportant in comparison with the wider interests of the public. Thus it should not be within the competence of a local municipality to prevent the extension of a much needed limited-access road. In such circumstances approval by the provincial Minister of Planning should be all that is required.

Appeals

It should be possible for all parties affected by local planning decisions, whether they be private citizens, or corporate bodies, to appeal such decisions to a level higher than that of purely local government. Such appeals should be decided by the Minister of Planning usually on the basis of evidence given at a local inquiry.

May I return for a moment to the subject of public relations. Experience shows that the public will support planning provided they understand its basic aims and are convinced that they are being dealt with in a fair manner. They are opposed to pernickety regulations and they are quite properly indignant when planning machinery causes lengthy delays to legitimate development. In the early stages of development of planning systems public participation is of great importance. It often provides the drive required to get the machinery established and working and it is a good method of educating both politicians and the public. However the public participation is likely to dwindle once an effective system has been established. Planning then tends to be accepted as a necessary feature of democratic government.

Compensation

Any effective planning system must come to grips sooner or later with the problem of compensation if it is to receive continued public support. There are really two questions—firstly, in what circumstances are property owners entitled to compensation if the value of their property is depreciated by planning action, secondly, in what circumstances should land be acquired for planning purposes and how much should be paid for it. All countries that take planning seriously have given a great deal of thought to these matters but I can find little evidence of even any thought in Canada. Unfortunately nobody seems to have arrived at any solutions of general acceptability. My own views are briefly as follows.

Compensation should be paid whenever planning actions cause undue loss or hardship to a property owner but it should not be paid where the loss is of a speculative nature. This is a much less radical point of view than that expressed by the Supreme Court of New Jersey in 1938 when they stated "the public welfare is of prime importance; and the correlative restrictions upon individual rights—either of person or of property are incidents of the social order, considered a negligible loss compared with the resultant advantages to the community as a whole". In my opinion a farmer should not be paid compensation if he is prevented from selling lots along the highway provided it is clearly in the public interest to prohibit such development. The value of his farm as a farm is not lessened by such a prohibition, what he loses is the possibility of an unearned increment of value and to lose this is not a hardship.

On the other hand a man who has bought a parcel of land from the same farmer for the purpose of building a service station and then discovers that this use is not permitted might be entitled to compensation. To obtain compensation he would have to show that at the time he bought it there was no reason to anticipate any objection to its use for a service station and that he had paid a price well in excess of its value as agricultural land. Whilst the difficulties of administering such a system may appear insuperable, in practice I believe it can be made to work and the difficulties diminish as planning becomes more effective. But the system will not work if the municipality has to pay the bill. The costs must be met to a very large extent by provincial government grants.

Public Acquisition

Many difficult problems of compensation can be avoided altogether by public acquisition of land and I am strongly of the opinion that this is a good thing, not because I am a doctrinaire socialist, for I am not, but because it solves so many planning problems. In support of this view I would like to read three quotations; the first two are by distinguished European planners, the third is from a recent judgment by the United States Supreme Court.

S. E. Rasmussen, "Towns and Buildings", Liverpool, 1951. — "A survey of town-planning will show that there have been well-planned cities since the earliest times but only in places where all the land was in one hand, whether a state, a town or a private landlord. But from the moment in which the ownership of the land is shared by many small landlords with all their egoistic interests, total planning and control of development are almost impossible".

H. Bernoulli, "Die Stadt und ihr Boden," Zurich, 1949.—"Where a radical solution by a single stroke proves impossible, the community should keep to the following rules: The community should never sell any of the land held by it. The community buys private land whenever possible. The community allows land held by it to be used for private enterprise by granting building rights. Repurchase of land, whether carried through in a day or in the course of years should however never be regarded as an end in itself, but as an indispensable stepping stone: it forms a first elementary basis upon which the city of the future can be built and a constant organic regeneration made possible".

United States Supreme Court, November 1954. — The judgment by the Supreme Court concerned the right of the District of Columbia Redevelopment Land Agency to acquire by compulsory purchase a small department store located in a blighted area which it is proposed to redevelop. "If those who govern the District of Columbia decide that the Nation's Capital should be beautiful as well as sanitary, there is nothing in the Fifth Amendment that stands in the way".

It is becoming increasingly evident that public acquisition of land is often an essential first step to effective planning. There are no fundamental difficulties in doing this for town extensions—though those who have followed the attempts to establish a land assembly project in Kingston will agree that there may be practical difficulties—but there are fundamental difficulties in acquiring land for redevelopment within existing urban areas. These difficulties arise from the very high values of land that are characteristic of large cities. These high land values are caused essentially by congestion or over-development and since planning actions aim at relieving this congestion there is frequently a loss in land value. In a recent redevelopment project in New York it cost $9,000,000 to acquire a site of 10.6 acres which it is estimated will have a value of only $3,000,000 when redeveloped. Few cities can afford much redevelopment at such a price even though the Federal government may absorb two-thirds of the cost as it is prepared to do under the U.S. Housing Act of 1954. I have no solution of this problem but I do know that it can be avoided if the central areas of cities remain in public or quasi-public ownership.

On the question of the price that should be paid for land acquired by compulsory procedures I am of the opinion that this should be the fair market value. If the price is less than this it is unfair to the owner and if it is more it is unfair to the public.

Thus I believe that an effective planning system requires the wide use of powers of acquisition of land by agreement or by compulsory purchase plus a readiness to pay compensation in special circumstances. Actions of this kind will cost money and it helps very little to say that good planning will save money in the long run. In the meantime we should be prepared to spend money in order to see that the right kind of development occurs in the right places at the right time. The experience of other countries, notably the United States and Great Britain, indicates that most of this money must come from central governments.

Next may I say a few words about the planners. They are a pretty motley crew and effective planning is only possible if there are well trained planners. In a recent report Professor Adams of M.I.T. has recommended that the university training for a planner should consist of three years of general education followed by three years of studies in the field of planning. In Canada today most people who have pursued any formal studies in planning have taken a one year course following graduation in some allied field and relatively few have done even that.

"Effective town planning is possible, but only if it has clearly defined objectives and only if we are prepared to proceed in a rational way . . ."

Much of the good planning that has been done in Canada during the post-war years has been done by immigrants who have brought with them a considerable breadth of knowledge and experience. If planning is to become effective it must acquire the status of a profession. This means that not only must there be adequate training for those wishing to enter this profession but also there must be continuing programs of advanced study and research. Many strange things are being done today in the name of planning and the growth of technical knowledge is slow. May I give one example—a slum area is to be cleared and redeveloped for housing. What density should be adopted in the new site —20 persons to the acre or 200 persons to the acre? What percentage of the land should be covered with buildings? How much land should be reserved for schools, shops and other ancillary uses? Some valuable studies have been made on these points by the British Ministry of Housing and Local Government but in spite of these the answer is basically that we do not know and we know comparatively little about the principles that should guide us in seeking answers.

In no field is the need for research greater than in the matter of transportation facilities. The average American citizen believes that he has a natural right to be able to drive in his own automobile to within a few feet of his destination and to leave it there until he is ready to use it again. It is becoming clearer each day that this is a physical impossibility in a city of considerable size and yet immense sums of money are cheerfully being spent on improving those facilities that cause congestion. As Lewis Mumford has recently pointed out our thinking about these problems is largely superficial. Much research is needed to discover the kinds of towns that are best suited to the age of the automobile. The very few experiments that have already been made in this field have paid off most handsomely.

Any extended discussion of planning technique would obviously be inappropriate in a paper of this kind but I would like to mention just one feature which I believe to be of basic importance to effective planning. I refer to the price tag. As engineers, we are always conscious of the importance of dollars and cents. Planners should be equally conscious but too frequently the public is asked to approve or disapprove of planning proposals without being told how much they will cost. It is not surprising that many planning schemes are gathering dust on the top shelf.

We are now in a position to answer the question posed in my title. Effective town planning is possible but only if it has clearly defined objectives and only if we are prepared to proceed in a rational way towards those objectives. This involves a recognition of the place of the planning function in democratic government, sound administrative procedures, properly qualified technical personnel and a willingness to spend money on preventing mistakes. Having said this, may I add that in my judgment planning should be compulsory in all areas where any substantial amount of development is taking place for it is only in this way that we have any chance of building the kind of cities in which we and our children will want to live. √

to November or December. The duration and intensity of this period of non-replenishment of ground water increases as we move in a southwesterly direction in the region.

It is easily seen from Fig. 4 why the farmers are becoming interested in irrigation with lake water. At Harrow, for instance from Fig. 3, it can be seen that there is a total moisture deficiency of 6.8 inches of rainfall during a period lasting from the last week of June to the first of October. National Research Council experiments have proved that calculations of the amount of irrigation water needed, based on these moisture deficiency calculations, are quite reliable and if excess water is used in irrigation above the calculated need, ponding will result.

It is evident that the water which moves laterally through ground water aquifers to be intercepted and carried away by a surface stream, or any water removed by pumping during the summer and fall months, represents a lowering of the water tables because there is no replenishment from above during this period. This lowering of the table is merely seasonal unless the pumpage represents more inches of water on the recharge area than will fall as rain following the time when the soil moisture has been replaced in November or December until the need again exceeds the rainfall in May or April.

Ground water levels rise during the period of recharge to reach a maximum elevation in the spring. A program of observing the fluctuations in the elevation of the ground water table was started in 1946 by the Ontario Department of Mines. Figure 5 shows hydrographs of water levels obtained from observation wells at Forest and London between 1946 and 1950.

There are about 22 wells in the region now under observation by the Department of Mines, but none, according to the information available, in the counties of Essex, Elgin, Huron, Bruce, Grey, Dufferin, Brant, Norfolk, Wentworth and Lincoln. It is very desirable that additional observation wells be established to enable the tabulation of this important information in all areas dependent on ground water. Several municipalities conduct their own level

Fig. 2. Map of bedrock geology (courtesy Ont. Research Foundation).

recording program and there may be some wells under observation in the counties listed by local authorities. It might be remarked in passing that once the opportunity for making a hydrological measurement has gone by nothing can be done to fill the gap in the statistical data. Increasing emphasis is being placed on statistical analysis of such data as experience accumulates proof of its value in forecasting future conditions. It is equally true of surface water resources as well as of ground water that a continuing study should be set up to capture irreplaceable data which would prove so valuable in future studies.

In the absence of information regarding the history of water table elevations it is very difficult and often impossible to know whether an aquifer is being overpumped. Evidence that wells have had to be deepened is not a reliable indication. As pumpage increases the drawdown will increase and result in a general lowering of the table so that where water once reached a shallow dug well it may no longer do so with higher pumpages from the aquifer. However, recharge may still be adequate to balance pumping plus the discharge to streams from the aquifer. The discharge to surface streams from the aquifer would be reduced in this case because of the lower hydraulic head available.

There are some areas where overpumping has occurred in the region. One known example is at Dresden where screens were placed at about 133 feet below surface. Now the water level is down to 133 feet below surface and air is entering the pumps. In this case it has been necessary to use the water of the Sydenham River.

Well drillers have been required to report to the Department of Mines on each new well drilled since 1946. Much valuable information has now been published in two reports of the Department, the latest being Bulletin 145, published in 1953, which records that in the three year period from 1948 to 1950 nearly 4,000 wells were drilled in the region, 23.7 per cent were in overburden and 66.6 per cent were in bedrock. About 4 per cent were not indicated and 5.8 per cent were abandoned or dry. Fresh water was reported in three-quarters of the wells. There are probably around 100,000 wells in total in the region divided about evenly between dug and drilled wells. It is interesting to note that in replying to a questionnaire asking their opinion as to the adequacy of farm water supplies, County Agricultural Representatives nearly all expressed themselves as satisfied with the supply.

except for short periods during the year. Haldimand County reported satisfactory quantity but unsatisfactory quality. The eastern part of Brant County was also classed as poor in this regard. Waterloo County was classified as fair in this questionnaire survey.

Use of Ground Water

Figure 6 shows some of the municipalities dependent, at least partially, on ground water supplies. There are about 70 indicated and there are at least 114 more communities, some very small, which are also ground water users. Table I shows that there are nearly 447,000 people living in these 184 communities and that there are nearly 640,000 more living on farms. Thus there are about 1,086,000 people dependent upon ground water supplies or about 60.5 per cent of the total population of the region. When the large populations of Hamilton and Windsor are excluded the percentage of the remainder using ground water rises to 75 per cent. If the rate of consumption of water by the farm population is assumed to be 30 gallons per capita per day (g.c.d.) the total consumption would be about 66.9 millions of gallons per day (M.g.d.). This is an average rate of 61.6 g.c.d. The rate for those living in the 184 communities averages 107 g.c.d. It will be noted from Table I that six counties are over 90 per cent dependent on ground water supplies. The rate of consumption

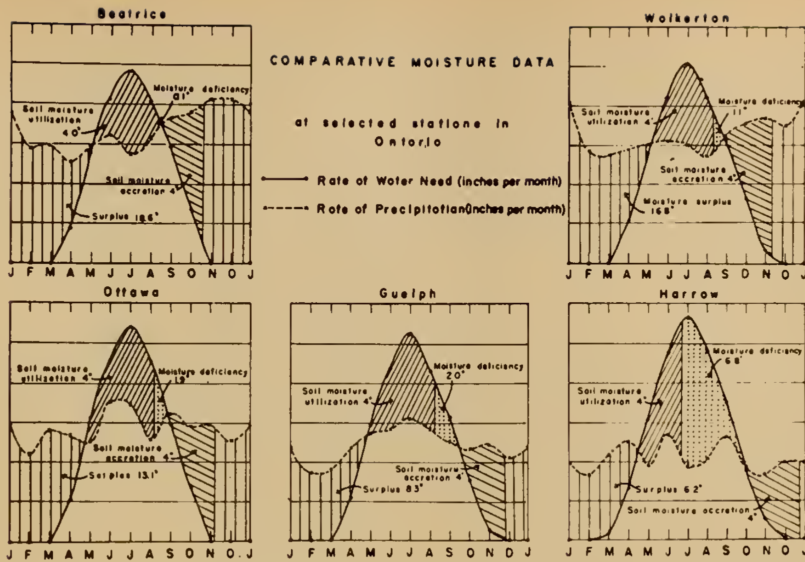

Fig. 3. Comparative moisture data (courtesy Ont. Research Foundation).

in farm areas at 30 g.c.d. does not include any water used for stock or irrigation.

Difficulties With Underground Supplies

Several municipalities in the region are experiencing difficulty in finding enough water. Frequently there is a fairly adequate supply but the quality is poor. The main cities which are concerned about getting enough water are London and Kitchener-Waterloo.

In each case there is a surface supply available. The water of the north branch of the Thames is of satisfactory quality and the use of the water impounded behind the Fanshawe Dam was envisaged by the designers of the dam. The 1953 report of the consultants on London's water supply recommended the installation of a treatment plant to treat this water.

Kitchener - Waterloo, on the Grand River, are reluctant to use this water which is polluted by upstream municipalities. Both the Thames and the Grand have waters of greater hardness than might be expected of surface supplies due to the limestone common in their watersheds.

Some of these problems are shown on Fig. 6. Among communities having quantity problems could be listed London, Kitchener, Waterloo, Aylmer, Dresden, Stratford, Leamington. The ground waters are generally hard. Cayuga has one of the hardest waters, 1900 p.p.m. (parts per million). A desirable limit is around 100 p.p.m., but 150 p.p.m. is not very hard. However, most of the communities shown on Fig. 6 have waters much harder than this. The London supply has a hardness of around 300 p.p.m. and Kitchener's supply is about 350 p.p.m.

Future Growth and Water Consumption

The principal areas of future growth for centres dependent on ground water are expected to be around London (population now 98,700), Kitchener-Waterloo (now 69,700), Guelph (now 31,000), Galt (now 22,200), St. Thomas (now 19,200), Woodstock (now 16,900) and many others. These are all manufacturing or commercial centres and are expected to continue their recent rapid devel-

opment. However, there is the danger that an unsatisfactory water supply might prove a limiting factor because so many industries require ample supplies of water and often have fairly stringent quality requirements for their process water. Cooling water for industry and for some types of air conditioning is becoming very important and it is likely that considerable water will be used in the future for irrigation if water is made available.

It is also expected that the rate of consumption will increase on a *per capita* basis from all causes. In the United States, the President's Materials Policy Commission estimated that between 1950 and 1975 the growth in water production would be 50 per cent for municipal supply, 170 per cent for industrial, and 25 per cent for irrigation. The *per capita* rate is expected to increase from the 1950 figure of 140 g.c.d. to 155 g.c.d. in 1975. According to the December, 1953 issue of "Willing Water" from which these figures are quoted, this can be interpreted to mean that the average city can expect a growth in population and consumer rate of use that will require it to provide 142 per cent of today's supply for tomorrow's city on an average day and possibly 235 per cent of the average 1950 day on a peak day in 1975.

These estimates are probably quite conservative for much of southwestern Ontario. A report made in 1953 for the Metropolitan Area of London indicates a 25 year rate of growth of about 59 per cent. The daily *per capita* rate of water consumption is expected to increase from the 1953 value of 98 g.c.d. to a value in 1974 of 125 g.c.d. Consumption is expected to rise from about 12.5 M.g.d. in 1953 to 22.5 M.g.d. on an average day in 1974, which is an increase of 80 per cent in 21 years. The city is entirely metered. London is the commercial and educational centre of the region and probably reflects the growth of the rest of the region. It is likely therefore, that greatly increased demands for water can be expected from the most of south western Ontario.

In London's case the consultants found that there was no evidence of overpumping since ground water levels seemed to reflect rainfall and river flows. This was shown on the hydrographs for London in Fig. 5. They concluded that the gravel deposits in which the wells are located could be expected to supply an additional 15 M.g.d. However, the report warned that while ground water reservoir would probably meet average day demands for some time to come it would not be adequate during protracted periods of low rainfall and hot weather. At these periods the demand is higher than usual and ground water levels are declining temporarily.

Possible Solutions

London has two ways of obtaining increased water supply over and above the 15 M.g.d. mentioned above. One is by water spreading in an attempt to increase the quantity available as ground water. Another way is to treat the water impounded at the Fanshawe reservoir and pipe it to the city. Both have been recom-

mended and water spreading has already been started.

Kitchener has found four good wells about five miles out of the city. A continuous exploration program has been necessary to meet increasing demands for water despite very effective conservation measures to discourage waste.

Water spreading has also been practised at Catfish Creek in an attempt to improve the water supply for Aylmer.

The 1950 report of the Select Committee of the Ontario Legislature on Conservation made a recommendation that "a detailed survey should be made to ascertain the feasibility and costs of piping water from the Great Lakes system to be distributed as a public utility for the benefit of participating municipalities." A committee has been set up to carry out this recommended study. Such a system would ensure adequate supplies to this very important part of the Province and it seems very desirable to make a thorough study now to determine the merits of the proposal.

The 98-mile aqueduct at Winnipeg is an example from Canadian practice of a long pipeline to supply a city. A more modern example is the pipeline built in Michigan between 1946 and 1948 to serve the cities of Saginaw and Midland with water taken from Lake Huron. Before the new system was put into operation in 1948 the two cities obtained their raw water supply from the Saginaw River system.

The cities of Saginaw and Midland have populations of about 98,000 and 17,000 respectively. The total length of pipe is 78 miles. The pipe is of prestressed reinforced concrete manufactured in 16-foot lengths and hauled by truck to the site.

The common supply from the intake to the junction pumping station and reservoir is a 48-inch diameter pipe 48 miles long; this cost $20.91 per foot to supply and lay. From this junction pumping station the line branches into two 36-inch lines having a combined length of 27 miles. The junction is about equi-distant from the two cities. The 36-inch line cost $15.39 per foot to supply and lay. The total cost exceeded $10,000,000. This cost included a 2-mile long 66-inch diameter steel intake and crib, a 70 M.g.d. pumping station at the intake end, the 78-mile pipeline, another 70 M.g.d. pumping station and a five-million gallon reservoir at the junction point, plus blow-off connections, air valves, access manholes, line valves, and river crossings. Present capacity of the line is 43 M.g.d. The greatest difference in elevation over the 48 miles of 48-inch pipe is 30 feet, and over the 78 miles does not exceed 80 feet. Comparative studies led to the selection of a 48-inch pipe designed for a 300-foot head for the main line and 36-inch pipe for a 300-foot head for the branches. Most of the head results from friction losses in the pipe. The pipelines generally follow the contours of the ground with an average cover of three to four feet. The line uses county road right-of-ways for about 25 miles and state highway right-of-ways for about 40 miles. It was not found necessary to expropriate any property forcibly. Rights-of-way across numerous pieces of privately-owned land were purchased by agreement on price with the owners.

Small communities along the line have the privilege of connecting to outlets provided for them and service connections were provided for in front of all homes and business establishments along the highways. At the end of 1954 there were over 600 such connections, 200 of which are on the 48-inch line. The raw Lake Huron water contains about 5 grains or about 86 p.p.m. hardness. The water is chlorinated at the Whitestone station at the intake end of the line and is conditioned in the existing plants in Saginaw and Midland. Even though the water may be in the pipe for 24 hours or more before reaching the customer there is very little change in its temperature.

This is quite a different problem from that facing pipeline planners in southwestern Ontario. The main difference is that there is a high lift required to reach many of the inland cities. Lakes Huron and Erie have elevations of about 580 and 572 ft. respectively. The elevation at Kitchener-Waterloo is about 1,100 feet, at Stratford nearly 1,200 feet. Galt, Preston and Woodstock are around the 1,000-foot contour and London is around 800 feet. Static lifts, therefore, are quite high ranging from around 225 for London to over 500 feet for some of the cities on the high ground in the interior of the peninsula.

There will probably be much discussion of the relative merits of treating the water at the source or of treating it in local treatment plants. Water treated before it enters the pipeline would make it possible to service consumers along the right-of-way through pressure reducing valves. A single plant would be more economical than a number of small plants. On the other hand, a single large plant is more vulnerable to damage, accidental or due to enemy action, than a large number of well dispersed small plants would be. Also in the event of a breakdown in the raw water supply due to either mechanical breakdown or contamination of the lake water by some weapon releasing radioactivity the small local plants could treat local supplies until the emergency had passed. An additional advantage of pumping raw water might be the saving in treatment costs for water not used for human consumption. This might apply to water for many industrial purposes and for irrigation.

The question of reliability of supply is a prime consideration and perhaps at a later stage a system of pipes will be in service linking the two lakes so that the main centres can receive water from either lake. In the event of a break in one main line it would then be possible to obtain enough water from the single line to serve during the emergency. Numerous reservoirs would also provide protection against interruption of supply.

Conclusion

In conclusion it may be said that there is a critical situation as regards ground water supply in the region. Problems exist in regard to both the quantity and the quality of the water. There is no evidence of overpumping except in very small areas. Many important cities whose welfare is a matter of vital concern to the province as a whole are dependent on supplies which at best are uncertain. Because of the poor quality of the ground water in many cases it does not seem advisable to look for a long term solution to the problem in terms of ground water.

The appointment of a provincial committee to study means of distributing lake water to the inland cities is a welcome development.

It is to be hoped that existing legislation in the western states, applicable to the use of ground water, will be reviewed to determine whether or not changes are needed in our own legislation to obtain the best use of ground water resources. If the pipeline plan does become a reality there may be a tendency on the part of the public to take less interest in stream sanitation. A program of public education on the value of clean streams will help to prevent this attitude arising.

Careful consideration should also be given to the benefits to be derived from the use of multiple purpose storage reservoirs at strategic positions along our inland watercourses. These would increase the elevation of the water table and conserve water by reducing excess run-off. They would also have many conservation and recreational advantages which do not enter into the ground water problem except in so far as they represent competing interests in the facilities provided by the reservoir.

I would like to express my grateful acknowledgement to the many people who have supplied information for this paper. The diagrams dealing with moisture relationships and the physiography of the region were supplied by L. G. Chapman of the Ontario Research Foundation. Dr. A. E. Berry and G. M. Galinbert of the Department of Health for Ontario were most kind in supplying advice and data. Much of the data on water use and quality came from the records of the Water Resources Survey of Ontario which was carried out by the Department of Health. A. K. Watt of the Department of Mines was most helpful personally and considerable use was made of his published work including the diagram of water level fluctuations at Forest and London. James F. MacLaren Associates very kindly aided in the production of some of the diagrams and in the typing.

THE DESIGN OF

COMPRESSED BEAMS

The paper presents a method of design for compressed beams; that is, beam-columns. The author's solution is based on a rigorous theoretical analysis and has been confirmed by tests. Intended for plastic design, the solution is also applicable to conventional elastic design.

D.T. Wright

Department of Civil Engineering,
Queen's University,
Kingston, Ont.

Conventional methods of designing steel skeletons for buildings are based upon elastic theory. These methods, or rather the philosophy behind them, evolved before the nature of steel as a structural material was fully understood. Although materials such as cast iron are brittle and must be designed to behave elastically, structural steel is ductile — it can deform without either fracturing or losing strength. This quality sets steel apart from most other materials, and provides a basis for more realistic design methods.

The work of the Steel Structures Research Committee[1] some 20 years ago showed conclusively that real stresses in steel skeletons bear virtually no resemblance to stresses predicted by elastic theory. If, as the elastic theory postulates, a structure failed when the elastic limit was reached anywhere in it, then virtually every structure standing can be said to have failed. That steel structures do not really fail, or collapse, depends upon the ability of mild steel to yield, to suffer large deformation past the elastic limit with no decrease in strength.

The simple plastic theory of structures which has been developed in Cambridge by Professor Baker and his associates attempts to provide a rational basis for the design of steel frames. The theory is based upon a consideration of the actual mechanics of failure of structures made of ductile material[2, 3]. The design methods derived by the plastic theory are different from conventional design methods in that they are based upon conditions of collapse rather than on the attainment of stresses equal to the elastic limit. That is, plastic theory applies a safety factor on load to prevent collapse, whereas elastic theory applies a safety factor on stress to prevent yielding. The significance of the difference is that for complex structures, loads considerably greater than those required to produce local yielding are required to cause undesirable deformations and collapse. Conventional elastic design neglects an appreciable part of the strength of redundant structures. However, the most important advantage offered by plastic theory is that it is realistic. Whereas stresses predicted by elastic theory are different generally from those measured in real structures, collapse loads predicted by the plastic theory give an accurate estimate of failure conditions.

In its present state of development the plastic theory provides for the analysis and design of flexural members and structures made up of flexural members. Compression members have also been studied, but general methods for their design are not yet available.

In fact, very few structural members are subjected to either pure flexure or pure compression. In building frames, most members are subjected to some combination of flexure, shear and axial load. Shear effects on beams have been determined[4]. The present work is concerned with the effects of axial compressive forces on flexural members.

Because of space limitations only an outline of the work can be presented. What follows is a discussion of conventional design methods for beam-columns, an outline of the plastic theory analyses, and a proposed design method which can be used either for conventional design, or for plastic design.

Elastic Analysis and Design

Members subjected to combined flexure and axial compression are known as beam-columns. Such members are common in most structures particularly so, perhaps, in rigid frames where the elimination of trussing induces moments in members. The design of beam-columns is customarily based on approximate formulae because of the difficulty of exact analyses. To be complete an analysis of beam-columns must take into account three effects: the axial load, the bending due to the transverse load, and the bending due to the eccentricity of the deflected member from the line of the axial compression. It is this last which introduces most of the difficulty.

Maximum stresses in members subjected to combined loading may be determined by means of the familiar formula

$$f = \frac{P}{A} + \frac{M}{S} \quad \text{..............} (1)$$

where f is the stress, P the axial load, A the cross-sectional area, M the bending moment, and S the section modulus. Equation (1) leads to correct values of maximum stress only if M is taken as the total moment

$$M = M_W + P\delta \quad \text{...........} (2)$$

where M_W is the moment due to the transverse load, W, and δ is the deflection. The deflection depends upon the magnitude and arrangement of the transverse load as well as upon the magnitude of the axial load, the moment of inertia of the section, and the length of the member. No simple way of determining δ is available. For a few cases formulas are known and have been tabulated[5], but because of complexity these are not often used. Only in the design of aircraft structures are accurate stress analyses generally made for beam-columns.

For ordinary structural design a simpler approach is required. Most standard specifications and building codes in Canada, Britain and the United States suggest that beam-

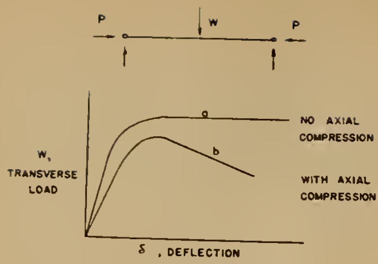

Fig. 1 (left). The behaviour of a compressed beam.

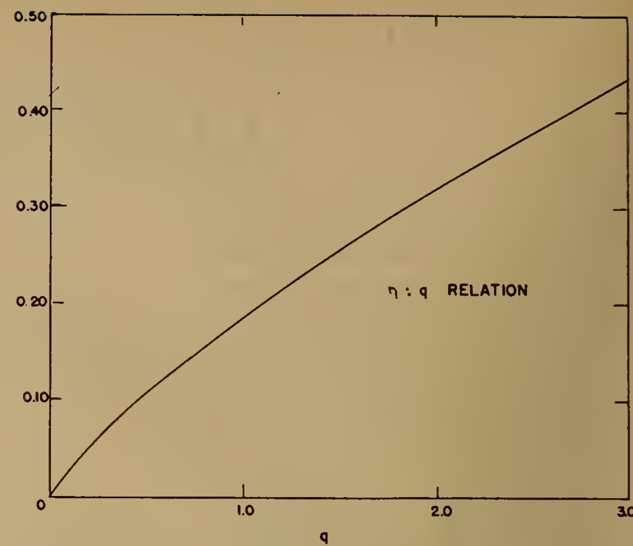

Fig. 2. Relation between η and q for a simply-supported beam of rectangular cross-section carrying a uniformly distributed transverse load (see equation 7).

columns be proportioned to meet the condition

$$\frac{f_a}{F_a} + \frac{f_b}{F_b} \ngtr 1 \quad \ldots\ldots\ldots\ldots (3)$$

where f_a and f_b are the simple axial and bending stresses in the member, and F_a and F_b are the permissible column and beam stresses. Equation (3) is generally known as the "interaction" formula although in fact it only expresses an interpolation between the conditions

$$\frac{f_a}{F_a} \ngtr 1 \quad \ldots\ldots\ldots\ldots (4)$$

and

$$\frac{f_b}{F_b} \ngtr 1 \quad \ldots\ldots\ldots\ldots (5)$$

according to which simple beams and columns are designed. As equation (3) is ordinarily used, interacting effects are actually *neglected.* The value of f_b is taken as M_W/S and the flexural stress due to the additional moment $P\delta$ (see equation 2) is not considered. Further, no account is taken of whether the axis of bending for M_W coincides with the axis about which column instability is expected. That is, in equation (3), F_a is always determined from the maximum slenderness ratio of the member even though this may not be the same axis as that about which the transverse load causes bending. Consider a member subjected to an axial load; surely deflections will be greater and failure nearer at hand if a bending stress f_b is applied about the column's "weak" axis than if it is applied about the column's "strong" axis. Yet the method of equation (3) does not distinguish between these cases.

The most important virtue of equation (3) is that it provides a smooth interpolation between the simpler cases of pure compression and pure flexure (equations 4 and 5). This alone does not appear to be reason enough for its acceptance. Neither is the fact that the formula has been used extensively and has not led to failures. The factors of safety provided by standard specifications both by specified working loads and specified maximum stresses are large enough to prevent failures even when design methods are grossly inaccurate. The most desirable criterion for a design method is that it provide a truly uniform factor of safety. It is obvious that equation (3) does not meet this requirement.

Plastic Analysis

Just as an accurate elastic analysis of beam-columns is found to be complex so plastic theory analyses are also found to be complex. For convenience the problem can be divided into two parts, depending on whether beam or column action is dominant. The present discussion is concerned only with the strength of compressed beams, where axial loads are small enough that beam behaviour defines the mode of failure.

The effect of axial compression on a beam made of an ideally plastic material is shown in Fig. 1. The upper curve, (a), is for a beam with no axial load: as the transverse load, W, increases the central deflection increases, proportionately at first up to W_y, the yield load, and then more rapidly as yielding increases. When the fully plastic load, W_p, is reached deflections increase indefinitely. This is characteristic of the flexural behaviour of any beam under any arrangement of transverse load, provided that lateral instability is prevented. The lower curve, (b), indicates the effect of a constant axial compression on the behaviour of a beam. As the transverse load increases elastic deflections are somewhat larger than in the previous instance, but the same pattern is repeated until a point is reached in the partially plastic state where the rate of increase in moment due to the increasing eccentricity of the beam from the axis of the compression load is greater than the rate of increase in bending resistance offered by increased deflection. At this point the beam becomes unstable and is said to have buckled. The maximum transverse load carried by a compressed beam is called the critical load, W_{cr}.

To determine critical loads it is necessary to study beam deflections in order to find the critical deflection, Y_{cr}, and the extent of yielding corresponding to Y_{cr}. For the cases which have been studied it was found most convenient to express the result, W_{cr}, in terms of W_p, the load that a beam could carry in the absence of axial compression. All the results obtained so far have been in the form

$$\frac{W_p - W_{cr}}{W_p} = \eta + \left(\frac{f_a}{f_y}\right)^2 \quad \ldots (6)$$

where f_a is the average axial stress (as in equation 3), f_y is the lower yield stress, and η is a function depending upon the particular details of beam section and transverse load arrangement.

Values of η have been determined for beams of rectangular- and I-section, for uniformly distributed and concentrated transverse loads, and for simple and restrained ends. In each case a general expression for deflection was first found by integrating curvature functions, then critical deflections were solved. The results are in the form of power series which though cumbersome are reasonably accurate. Certain minor simplifying assumptions made in the analyses have been shown to have no serious effect on accuracy by means of both separate special analyses and experimental verifications.

The solution for a typical case — a simply supported beam of rectangular cross-section carrying a uniformly distributed transverse load — is outlined in the appendix. The result for this case is

$$\eta = -0.0504\, q \log q + 0.170 q + 0.0161\, q^{3/2} + 0.0006\, q^2 \quad \ldots (7)$$

where

$$q = \frac{f_a}{E}\left(\frac{l}{r}\right)^2 \quad \ldots\ldots\ldots\ldots (8)$$

and E is Young's modulus, l the length, and r the radius of gyration about the axis of bending. From equation (7) it is seen that η is a function of a single parameter, q, which in one term expresses all the significant variables. It should be noted that

$$q = \left(\frac{f_a}{f_e}\right) \quad \ldots\ldots\ldots\ldots (9)$$

where f_e is the Euler stress.

For other cases involving beams of rectangular section expressions similar to (7) were found. For beams of I-section, however, two additional variables expressing shape characteristics entered the expressions for η. The effect of two extra variables on expressions already more complicated than (7) would appear to render the solutions useless because of excessive complexity. Fortunately, the first of these shape factors was found to be virtually constant for standard rolled sections, and the second shape factor, though having a marked effect on critical deflections, had an insignificant effect on the η:q relation. For all problems of practical interest then, critical loads could be expressed as in equation (6), with η as a function of only the one variable, q.

Figure 2 shows the η:q relation corresponding to equation (7). Similar curves were obtained for each case studied. Although useful in this form, simpler presentations are preferable for design. It was found that the η:q relation could be approximated with reasonable accuracy as

$$\eta = 0.19\, q^{3/4} \quad \ldots\ldots\ldots\ldots (10)$$

for all the cases studied. Using equation (10) it is possible to rewrite equation (6) as

$$\frac{W_p - W_{cr}}{W_p} = 0.19 \left\{ \frac{f_a}{E} \left(\frac{l}{r}\right)^2 \right\}^{3/4} + \left(\frac{f_a}{f_y}\right)^2 \quad \ldots\ldots\ldots\ldots (11)$$

Because of the approximations introduced by using equation (10) rather than the accurate η:q formulae, equation (11) is not exact. The errors are small however, and the advantage gained by having a single expression for the effect of axial loads on beam strength is important. It should be noted that equation (11) is in terms of ultimate and critical loads rather than working loads.

As a check some 16 tests were performed on beams of rectangular- and I-section. Figure 3 shows the testing frame that was used for the purpose. Loads were applied by hydraulic jacks and measured by standard load capsules. The variables included axial compression, slenderness ratio, and end fixity. As control, eight other beams were tested with zero axial load. The results verified the analyses satisfactorily. Of the 16 test beams, three suffered failure due to lack of lateral restraint, and three more exhibited strain hardening which tended to obscure critical load peaks. For the remainder the maximum difference between predicted and measured values of W_{cr} was 6 per cent, and the standard deviation for all the tests was 3 per cent.

Fig. 3. Test arrangement.

Design

As it stands, equation (11) is suitable for use in design by the plastic method where structures are proportioned so that collapse is about to occur when loads reach values equal to the product of load factor and working load. Equation (11) may also be applied to conventional "elastic" design, even though it is based on failure conditions rather than on elastic stress analysis. It may be noted that such common structural components as columns and riveted joints are designed not on the basis of exact elastic analysis but rather on the basis of simple average stresses with specified limits based on interpretations of ultimate load tests.

The factor of safety against collapse which is provided by conventional elastic beam design is

$$\frac{f_y}{f_b} \times \frac{Z}{S} = \frac{33}{20} \times 1.15 = 1.90$$

where f_y is the yield stress, f_b the allowable bending stress, and Z and S are plastic and elastic section moduli respectively. If a factor of safety of 2 is applied to equation (11), the result will provide greater safety than is ordinarily provided by simple beams. Using

$$\frac{W}{W_p} = \frac{S\, f_b}{Z\, f_y}$$

and a load factor of 2, equation (11) in design form is

$$\frac{f_b}{F_b} + \left(\frac{f_a}{F}\right)^2 + 0.30\left(\frac{f_a}{E}\frac{l^2}{r^2}\right)^{3/4} \not> 1 \quad \ldots (12)$$

where F is the permissible axial stress F_a corresponding to zero slenderness ratio, and the other terms are as have been defined previously. In the last term the slender-

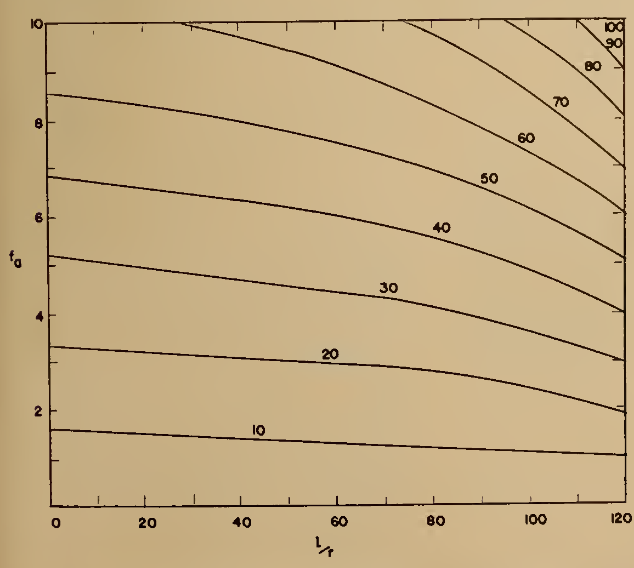

Fig. 4. Graphical solution of equation (3) showing percentage reduction in beam strength in terms of axial stress (f_a in ksi.) and slenderness ratio (l/r).

ness ratio, l/r, must be calculated for the axis about which flexure occurs due to the transverse load.

It is of interest to compare equation (3) with equation (12). Figs. 4 and 5 show the effects of axial stress and slenderness ratio on beam strength according to the two equations. For Fig. 4 the values of F_a have been taken from the AISC column formula. The lines in the figures are contours of effect: for instance, at any point along the line marked 30, the beam strength has been reduced by 30 per cent — that is, the permissible flexural stress, f_b, is 70 per cent of F_b. Comparing Figs. 4 and 5 it may be seen that equation (3) is much less sensitive to slenderness ratio than to axial stress; this is in contrast with the effect of equation (12). For values of l/r less than about 70, the true factor of safety using equation (3) and the AISC column formula is greater than 2. (For $l/r=20$ and $f_a=10$ ksi, the true factor of safety against collapse is 2.30). But for l/r greater than 70 conventional design becomes unsafe. (For $l/r=120$ and $f_a=8$ ksi, the factor of safety is 1.50.)

Although equation (12) appears much more formidable than equation (3), it should be noted that for (3), F_a must first be calculated from the slenderness ratio according to the applicable column formula whereas no such extra step is necessary with (12). Considering this there would seem to be little extra effort involved in using (12) rather than (3). Time may also be saved by using graphical solutions in the form of Figs. 4 and 5.

Limitations

Equation (12) is intended to apply to only a part of the beam-column problem. For axial stresses greater than about 12 ksi equation (12) becomes inaccurate. The present work is not applicable either to cases where transverse load causes flexure about one axis and failure occurs by buckling or twisting about the other axis, as for instance due to lateral instability.

Acknowledgments

The work described in this paper was carried out by the author at the Engineering Laboratory, Cambridge University, under the direction of Professor J. F. Baker and Dr. M. R. Horne. The work was supported by the British Welding Research Association and the author held an Athlone Fellowship at the time.

Appendix

Consider a simply supported beam of rectangular cross-section, breadth b and depth $2d$ with a span of length $2l$ subjected to a uniformly distributed transverse load w and an axial load $P=2\,pbd$, where p is the average axial stress. Taking coordinate axes such that the origin is at midspan on the axis of the undeflected beam, the moment can be written as

$$M = \frac{wl^2}{2}\left(1-\frac{x^2}{l^2}\right)+P\delta \quad \ldots (a)$$

where δ is the deflection. If δ is assumed to have a parabolic form (the actual form is not important, only the magnitude of the central deflection is important), (a) can be rewritten as

$$M=r^2M_p\left(1-\frac{x^2}{l^2}\right) \quad \ldots\ldots (b)$$

where r is a parameter defined as

$$r^2=\left(\frac{wl^2}{2}+Py_o\right)/M_p \quad \ldots (c)$$

and y_o is the central deflection. As the critical load, W_{cr}, is approached the central portion of the beam will have suffered some yielding, but the ends will still be elastic. In the elastic region ($x_1 \leqslant x \leqslant l$), noting that $I=2bd^3/3$ and $M_p=bd^2f_y$, the curvature is

$$\frac{d^2y}{dx^2}=-\frac{M}{EI}=-\frac{3f_yr^2}{2Ed}\left(1-\frac{x^2}{l^2}\right) \quad . (d)$$

In the partially plastic region ($o \leqslant x \leqslant x_1$), where the depth of the elastic core is $2t$, the moment of resistance is

$$M=M_p\left(1-\frac{t^2}{3d^2}\right) \quad \ldots\ldots (e)$$

for small values of p, and the curvature is

$$\frac{d^2y}{dx^2}=-\frac{f_y}{Et}=$$

$$-\frac{f_y}{\sqrt{3}\,Ed}\cdot\frac{1}{\sqrt{1-r^2+\frac{r^2x^2}{l^2}}} \quad (f)$$

Integrating (d) and (f) gives the central deflection

$$y_o=\frac{f_yl^2}{Ed}\left\{\frac{1}{\sqrt{3}\,r}\sinh^{-1}\frac{\sqrt{r^2-2/3}}{\sqrt{1-r^2}}+\right.$$

$$\frac{\sqrt{1-r^2}}{\sqrt{3}\,r^2}-\frac{\sqrt{r^2-2/3}}{3r}(3r^2+1)$$

$$\left.+r^2-\frac{1}{2r^2}\right\} \quad \ldots\ldots\ldots\ldots (g)$$

in terms of the parameter r. Differentiating equation (c) and noting that $dw=0$ when $W=W_{cr}$ gives

$$\frac{dy_o}{dr}=\frac{2M_p}{P}r \quad \ldots\ldots\ldots\ldots (h)$$

Expanding equations (g) and (h) in powers of $(1-r^2)$ permits r_{cr} to be determined in terms of q (see equation 8)

$$r^2_{cr}=1-0.0481q-0.0089q^{3/2}+0.0079q^2 \quad \ldots (j)$$

The reduction in strength is

$$\left(1-r^2_{cr}+\frac{Py_{ocr}}{M_p}\right) \quad \ldots\ldots\ldots (k)$$

Using (j) and (k) the expression given as equation (7) is found.

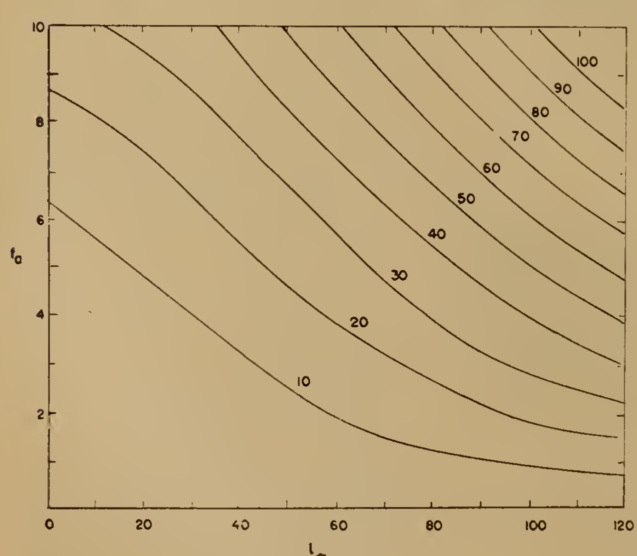

Fig. 5. Graphical solution of equation (12) showing percentage reduction in beam strength in terms of axial stress (f_a in ksi.) and slenderness ratio (l/r).

The Professional School in the University

C. T. Bissell,
Vice-President,
University of Toronto.

> **Dr. Bissell was the dinner speaker at the 23rd annual meeting of the Engineers' Council for Professional Development, held in Toronto in October 1955. A somewhat condensed version of his remarks is presented here. This we think will be of interest to all engineers, but particularly to those not long out of college or who have recent graduates under their direction.**

I bid welcome to our American guests with the sense of gratitude that those of us in university work feel towards American universities for the unquestioning generosity that they have always extended both to our students and to the members of our staffs. Between Canadian and American universities there is no problem of communication. There is such an unimpeded interchange between them that no danger of misunderstanding from ignorance ever arises. Many Canadian university teachers were trained in American graduate schools, and some have taught in American universities before returning to their native country. I think of Cornell as my second alma mater, and I take pride in her this evening, for I gather that she is not totally without distinction in the field of engineering. With the development of our own graduate schools, we are attracting an increasing number of students from American universities, so that the academic traffic between the two countries will soon be more evenly balanced. In one respect the balance has already been redressed, since a good many of your engineering graduates are coming to us for 'postgraduate work' of a remunerative variety in Canadian industry, in the oil fields of the west and in the immense mining development to the north.

The Engineers Council for Professional Development is, as I see it, a synthesis and concentration of the work of eight influential professional engineering bodies. It constitutes a formidable witness to the powers of intelligent organization that inhere in your profession. I doubt if any profession has so many professional societies, all firmly established and some, by the standards of this continent, ancient and venerable. The aims of the Engineers Council, as set out in your charter, are not narrowly directed towards the preservation of status and the circumscribing of the profession with rigid rules and regulations. The Council 'looks before and after, although it does not pine for what is not'.

You are concerned with the young man who is about to make his choice of a career—with placing before him a clear and yet imaginative picture of the role of the engineer as he leaves university and enters upon his work. You represent engineering bodies concerned about engineering bodies. Rightly, you are intensely interested in the educational bodies that train the engineering bodies—I mean the universities—since in Canada and in the United States the university is the custodian of professional training for the engineer. I am sure I speak for all universities when I say that we welcome your interest and your support. You represent in your council a healthy union of the theoretician and the practitioner. We can learn much from those who in the daily discharge of their duties see the product of a university course in action, and observe him as he is tested by practical problems and by the mysterious dynamics of human situations.

Yet I think that I am also speaking for the universities when I observe that it would be a pity if the centre of educational thought were to shift from the universities themselves to any outside body, no matter how reputable and wise that body might be. The final decision about university policy must be made within the university, by men and women who have devoted their lives to education and who are in a position to see the ramifications throughout the whole university of a policy shift in one of its parts. Most of you here will be aware of one difference in attitude between Canadian and American universities with respect to the ordering of professional education. We are suspicious of the value of the system of accrediting by outside organizations. In most cases there can be no doubt of the wisdom of those who carry out the accrediting of universities, and it is not the bodies concerned with accrediting that we would challenge. It is rather the implications of the system for the university. A university worthy of the name is an organic whole in which the various faculties and schools have vital interrelationships. If two or three of these faculties are subject to a system of accrediting, then they are subject to external pressure that may well disturb the welfare of the whole. As some of you will know, this has been a serious problem for some American universities, where accrediting agencies have attempted to prescribe the curricula and to scrutinize appointments to the staff under the threat of academic excommunication.

Since the university is an organic whole, no one faculty should be sharply marked off from another. Any tendency towards fragmentation, no less common in universities than in other areas of contemporary society, must be resisted. I think we can resist it in the university by constant emphasis upon the aims of higher education common to all departments and divisions, in other words, on the fundamental unity of knowledge. It is unfortunate that there should be such a marked distinction drawn between professional and liberal education . . . 'professional' is not an evil word. All higher education is professional in the sense that it seeks to combine certain general qualities of mind and heart with the mastery of a specific area of knowledge. That area of knowledge, of course, varies from faculty to faculty. But whether it involves a knowledge of the scansion of Greek verse or of the principles of hydraulics, it is still a specialized area of knowledge.

Professionalism

Professionalism has a long and honoured history in the development of the university. There are those who say that professional schools have no place in a university; that their expensive instruction saps the strength of the institution and that their aim of practical proficiency contributes little to the welfare of higher learning. Anyone who speaks in this way betrays a lamentable ignorance of the history and development of higher education. Training for the learned professions has been a responsibility of universities since the twelfth century. Bologna's law school, the medical centre at Salerno and the theological schools of Paris wielded a remarkable influence throughout the later mediaeval period. The professional schools, however, leaned heavily on the faculties of arts. There was established in those early days a primacy of the studies in arts that has been a continuing feature of higher education. In theology, for example, the mediaeval universities related the life of the spirit to that of the intellect and produced the great philosophers of the period. In the same way, the practice of medicine was ennobled by its marriage to liberal education and the medical profession thus attained its status as a learned and respected group. Professionalism in the early universities always involved the close interrelation betwen specialized knowledge and general qualities of mind.

Two Conditions

With this general proposition in mind, I would suggest two conditions that professional schools should try to meet. The first is that they must never lose sight of the importance of the general qualities of mind that should be common to all faculties—incisiveness of expression, powers of organization and of logical thought and willingness to reserve conclusions until the facts are all in, and their correlatives on the side of character — tolerance, humility and empathy. Now it is possible, I think, for these qualities to be developed in the teaching of any subject up to a point. You have all had experience of the vast gap that exists between the methods of two instructors in the same subject, where one is enmeshed in details that seem to have no relation outside of themselves, and the other is exhilarated—and exhilarating—by keeping before him broad relationships and ultimate goals.

The distinction is not between two types of mind, but between two ways in which each person's mind should be used, depending upon the subject-matter he is considering. To learn and to apply the 'law of things,' a man needs what Pascal called *l'esprit géométrique;* to learn and to apply the 'law of men', he needs *l'esprit de finesse.* Problems which are susceptible of systematic treatment, that is, the measurement of mass, or space, or time and the classification and interpretation of results, call on us to use *l'esprit géométrique.* On the other hand, the subtler facets of experience, which cannot be handled with the same rigour and confidence, must be examined in *l'esprit de finesse.* In university work, the subjects which develop in student's *l'esprit de finesse* are the humanities and work in the social sciences. For a number of reasons, the problem of relating specialized knowledge to general qualities of mind is particularly acute on the North American continent.

In all of the reports on engineering education that I have read recently, there is unanimous agreement that the humanities and social sciences should occupy an important place in the curriculum of an engineering student. As I recall, there was agreement that this element should constitute one-fifth of the curriculum; and the mathematical neatness of that conclusion prompts me to pay further tribute to the genius for organization displayed by your profession: twenty percent liberalizing yeast should be adequate to leaven the engineering loaf. Here at the University of Toronto—and I gather the practice is fairly common—we meet this need for general education by including in the curriculum during the four years of professional education a number of courses in the humanities and social sciences. There are some doubts in my mind as to whether this technique of diffusion is really the best way to meet the problem of general education. If courses in the humanities and in the social sciences are squeezed into a day that is otherwise solid with labs and lectures in professional courses, they must of necessity assume a secondary position in the students' mind.

Meeting the Difficulty

There are two possible ways of meeting the difficulty. The first way is one with which many of you are familiar, namely, a pre-engineering year or two, which, in addition to giving instruction in the humanities and social sciences, emphasizes the basic natural sciences. The argument against this is, of course, that the needs of the country for engineers are so urgent that it is uneconomical and wasteful to extend their period of training beyond what is absolutely necessary. The argument in favour of this procedure is that it does give the student the benefit of more continuous exposure to the humanities and to the social sciences, and, although involving a longer undergraduate course, produces professional men who are alive to their responsibilities as thinking members of society.

The second possible approach is one which may sound Utopian and impractical, but which could be given a trial. In brief, it involves bringing graduates in engineering back to the university for a concentrated course in the humanities and social sciences after they have had a few years' experience in the profession. It would, of course, be impossible to make this compulsory, so that my suggestion really applies only to those who have manifested leadership in their calling. My suggestion is not entirely a theoretical one, since it has actually been tried at one American university, though the course was not restricted to the engineering profession. Some of you may have read about it a year ago in *Harper's Magazine*. An Institute of Humanistic Studies was set up at the university for young executives in a large American corporation. Given the trends in modern business, I suspect that the majority of them were engineers. They were subjected for ten months to an intensive course in the humanities, under a curriculum that made unflinching demands upon their powers of concentration and assimilation. Judging by the comments of some of the graduates of this Institute, the course did not induce imaginative flights of impractical speculation. It seems to have contributed to a surprising degree toward the maturing of these men, and certainly towards their efficiency as executives.

One man wrote: "I have been much more efficient in organizing the relevant facts and placing alternative courses of action in sharp focus. Although I now see more angles and am less sure that any particular decision is the right one, I am aided in making it by the realization that there is probably no one right solution to many problems. I am now much less upset, and more able to learn, by mistakes."

I said earlier that there were two conditions that professional schools should try to meet, the first being the interrelation between specialized knowledge and general qualities of mind. The second condition is one that your various committees have also discussed, reaching conclusions that most educational thinkers would endorse. Professional education must emphasize the 'know why' as opposed to the 'know how'; it must be concerned with fundamental principles and not merely with the application of those principles. Although this concept is, I think, generally accepted, we have a tendency in our curricula not to apply it; instruction proceeds with melancholy clock-like precision from one class to another throughout the teaching day. It is easy for administrators, especially if they have been trained in an arts faculty where teaching hours are only a small portion of the day, to make these critical comments. Still I am convinced that unless a professional student has the time in which to absorb, and to reflect upon, basic principles, he cannot emerge either as an intelligent citizen or as a good professional worker.

Discussions of the philosophy of professional education must today be made in the light of the 'painful reassessment' of university policy consequent upon the vast increase in numbers that we all face. Recently there has been great publicity given to what should not be designated a 'bulge' in enrolment—a bulge has an end, as well as a beginning and a middle—but which should more properly be called the reaching of a new plateau. Most of you are familiar with the American statistics which indicate that the present university population of two and a half million may reach five million by 1965. The Canadian statistics are less overwhelming, but none the less challenging. It is estimated that the present percentage of persons of college age who go to college—7.2 per cent—will rise within the next ten years to 9, 10 or 11 per cent; and that this trend, combined with the increasing population, will give us a university population of from 110,600 to 135,200 instead of the present 65,600.

"The melancholy predictions . . . that we would be flooded with engineers have been confounded by the facts of our industrial development."

Our problem is not simply a problem of finding the money for the necessary expansion; it is also a problem of re-examining our human resources so as to make sure that the sums spent on education are spent on those people who are capable of using it to best advantage. Engineering faculties will have to face this problem perhaps sooner than any other faculties in the universities. Is it not our responsibility to examine more critically than we have the different kinds of education that may be necessary for the training of engineers?

In Canada and in the United States we have made engineering education almost entirely a university concern. In Europe and in Great Britain there has been a distinction between engineering training in the universities and engineering training in the technological institutes. I am aware that there is an ambiguity in the use of the designation 'institute of technology', and that some of these institutes are in their own right great universities.

The kind of technological institute to which I refer is one which does not concentrate on general principles, but rather on the application of general principles to particular situations. Is there not a likelihood that many of the students who now find their way into universities should be encouraged to go to such institutes? In this way we may salvage something of the waste which occurs in the first year of our engineering courses as a result of the student's inability to cope with the basic theoretical disciplines. We shall ensure that our universities are concerned with their proper task—the training of keen minds in fundamental principles. And we shall be making a discerning contribution to the problem of 'numbers' and the university. This setting up of two different kinds of institutions for training engineers can be done without suggesting that one is necessarily inferior to the other. We should endorse a recent report on technology in British universities: "The difference between the two types of institution is not in status or grade but in kind."

Of one thing we are sure: there is no possibility in the foreseeable future that the supply of engineers will exceed the needs of this country and of the United States. The melancholy predictions made during the early postwar years that we would be flooded with engineers have been confounded by the facts of our industrial development. The engineering profession has never before occupied a position of such power and influence. It is all the more incumbent upon it to respond adequately to its responsibilities. √

DISCUSSION

of Technical Papers

The Helicopter and the Engineer

by
W. H. D. Hanchet, M.E.I.C., Doman-Fleet Helicopters,
Fort Erie, Ont.
The Engineering Journal, December 1955 issue, page 1643.

T. J. Burgess[1]

In discussing Mr. Hanchet's paper "The Helicopter and the Engineer" I shall present my views as a representative of the Ontario Hydro which as you are aware is an operator of helicopters for transmission line patrol.

With vast sources of hydro-electric energy available to the Province of Ontario, it was only natural that high voltage transmission networks would eventually extend across the province linking the distant sources of generation with power loads in the industrial south of the province. Likewise the rich mining areas and extensive pulp, paper and timber industries extending from one boundary to the other across our extensive northland caused long distance power transmission lines to spread from Hydro developments to wherever industry led.

The Ontario Hydro today has some 8,000 miles of high voltage (115 and 230-kv.) transmission lines. Much of this transmission is over rough and isolated country, and because of its primary importance to the huge power pools of the province requires ever careful inspection and preventive maintenance. The early methods of power line patrol soon proved time consuming and costly, and something more efficient was required. We had some experience with conventional aircraft for this type of inspection and while these had their place, some vehicle of slower motion for more detailed and careful inspection was desirable.

The helicopter was tried on an experimental charter basis during the fall of 1948 and the winter of 1949, and the results appeared promising. In June 1949 we purchased a three place helicopter and commenced power line patrol in a modest manner. Immediate results were gratifying. With slow patrol speeds of 40 to 45 miles per hour, very careful inspection of towers, insulators and conductors could be made, and soon we were locating minor defects hitherto missed on ground patrol. I remember the search for many months by ground patrol over 60 miles of 115-kv. steel tower line from one of our northern plants to explain interruptions every time a heavy wind blew. Conductor loops, dead-ends and clamps were minutely inspected by walking patrol and no explanation found. The first patrol by the new helicopter explained the mystery. Over a long ravine a strand of aluminum cable had broken at the end of a compression joint and had unravelled to such extent that it could touch the adjacent conductor every time the wind blew in the right direction. This small strand of conductor wire could not be seen by walking patrol because the inspector stopped at the last tower and walked around the ravine. I cite this case simply to illustrate the minute imperfections in a high voltage transmission line that may cause trouble and can be readily located from slow-moving aircraft flying at conductor level. I should point out that helicopters like other aircraft are subject to weather conditions for flying and there are times when we have to resort to foot patrol.

Our experience with helicopters on line patrol was excellent from the start, but many problems of operation and maintenance peculiar to the helicopter had to be learned and overcome as we went along. Experienced pilots were scarce so that we selected men with many hours of fixed wing time and had them specially trained in helicopter flight at the Manufacturer's School. Likewise experienced air engineers had to be selected and given helicopter training also at the Manufacturer's Training School. As Mr. Hanchet pointed out, the field of helicopter operations is most certainly one for the professional and there is no place in it for the novice. Our observers, too, have been selected from experienced line maintenance foremen and supervisors. We thus have an experienced team in all patrol flights capable of handling the immediate inspection as well as any power line emergency that may and does arise from time to time.

Spare parts and an adequate maintenance base were early realized as essentials of the highest order. Gasolene caches spread over our patrol routes were also found to be a necessity to extend the machine's range and provide for emergencies. Notwithstanding these problems, our results continued to be excellent so that we gradually expanded the helicopter patrol fleet to a second and a third machine in 1950, a fourth in 1951 and fifth in 1952 to arrive at our present complement of 5 helicopters.

I should like to point out most emphatically that the helicopter is a delicate mechanism to maintain. We have found from experience that rigid and meticulous maintenance is the secret of safe operation. The Department of Transport rigidly controls the licensing of helicopter pilots, air engineers and machines, and rightly so. The manufacturers rigidly specify the frequency of inspections and overhauls. In our kind of operation, for safety reasons, we find it desirable to extend our maintenance over

[1] Hydro Electric Power Commission of Ontario, Toronto.

and beyond the minimums specified.

With the brief outline I have given, I feel that it must be fundamentally apparent that the operation of the helicopter should be thoroughly understood and its capabilities and limits realized before entering seriously into its use. It has no peer in the slow-flying field and its ability to hover for another look and get in and out of inaccessible places is unbeatable by any other type of aircraft. At low level contour flying, 90 to 100 feet above the ground, it is in a class by itself and many are the experiences our pilots have had in riding safely through heavy winds of 45 miles per hour and sometimes greater. If the weather does "close in", the crew can always land and wait it out.

For the Commission's vast network of transmission lines, many of which are over rugged country, the helicopter has proved itself vastly superior to any other method of inspection coverage in shorter time. Its efficiency in this field has to us been quite adequately demonstrated. It has speeded up maintenance when emergencies occur in inaccessible locations. It has also adapted itself to other services associated with the service security of high voltage transmission lines, such as right-of-way spraying and transporting of men and material, whether on construction or maintenance. The helicopters have also been used in Hydro for surveys and preliminary engineering studies and by outside organizations on loan during national emergencies and rescue.

J. D. Hunter[2]

Mr. Hanchet has outlined clearly the role played by the helicopter in the development of our Canadian northland, and how this comparatively new vehicle has enabled our engineers to accomplish modern day miracles in the construction field, with a substantial saving in time and manpower.

The paper has been fairly presented. Shortcomings of the present day helicopter have not been overlooked, and we are aware of the comparatively high operating cost and limited range of this aircraft. Design engineers are fully aware of the requirement to increase operational efficiency and I am confident that the basic factors affecting this requirement will be adequately met in the very near future. Significant progress has been made in component simplification which will increase efficiency and reduce hourly operating costs. The introduction of new structural materials will permit the saving of many pounds of parasitic weight, allow more economical production and reduce daily maintenance. These factors will increase the service life without loss of functional efficiency and play a great part in adding considerably higher pay load to the helicopter.

It is well to remember that the helicopter available today has been developed to military specifications and therefore cannot be expected to embody all the specific characteristics that are desired from a commercial operator's standpoint. We can say, however, that the military and civil requirements are becoming more closely connected, and this liaison in design specification is bound to benefit both users and the industry as a whole.

Mr. Hanchet has dealt briefly with many varied uses of the helicopter in transporting men and supplies to the sites of some of the greatest engineering projects in the north. We have heard how feats have been accomplished in a fraction of the time and with considerably less effort than we would have thought humanly possible a few short years ago. Engineers are in a good position to evaluate this new type of vehicle, and to put it to work in many new fields of exploration and development. The whole history of aviation is a story of continual progress and improvement, as are the techniques in the engineering practices, throughout Canada today.

Rapid advances are being made in helicopter design and I am confident that by continued faith in the transportation team of airplane and helicopter, Canada will lead the world in engineering development, far beyond the scope of our fondest dreams today.

The Author

Since I am indebted to Mr. Burgess and Mr. Hunter for information used in my paper, it would be surprising if I disagreed with any aspect of their discussions. Indeed I am certain their remarks on both usefulness and limitations are endorsed by all the operators in the country.

To us in the newly-formed Canadian helicopter manufacturing industry the challenge to "simplicate and add less weight" is a major one, and gives entirely new meaning to "The Helicopter and the Engineer". I am grateful that Mr. Burgess and Mr. Hunter referred to this challenge directly or indirectly, and can assure them that it is being resolutely met.

The Influence of Tropical and Sub-tropical Factors in the Design of Hydro-Electric Plants

by

J. K. Sexton, M.E.I.C., Chief Civil Engineer,
Montreal Engineering Co. Ltd., Montreal.

The Engineering Journal, October, 1955 issue, page 1363.

A. O. H. Neilson, M.E.I.C.[3]

I read with interest the paper on "The Influence of Tropical and Sub-Tropical Factors in the Design of Hydro-Electric Plants".

Cherrapunji is no longer considered the wettest place in the world. This doubtful honour has now been passed to the small village of Mawsynram in the same area. In the nine months ending September 30, 1954, Mawsynram had 17.5 metres of rain, whereas Cherrapunji only had 16.2.

A number of points occurred to me while reading the paper; although they are not perhaps strictly within the terms of reference, they have some bearing on the subject in general.

Hydro-electric stations in the tropics are frequently sited at considerable distances from the source of supply of their equipment. While this may not directly affect their design, it has a considerable influence upon their construction, and hence upon their cost. For instance, the size of the pieces of equipment is often limited by the handling capacity of the local transport system.

Cement also has sometimes to be brought from abroad. Where a local supply is available, the cement may be of a particular

[3] Project Engineer, Aluminum Company of Canada, General Engineering Department, Montreal.

type, in which case it may be economically desirable to ensure that the criteria used in the design of the concrete structures are such that it may be used.

Another point is that hydro-electric development in tropical countries is not infrequently carried out in under-developed, and consequently relatively poor parts of the world. Although the main design is seldom affected by this, the desire of the client for especially strict economy must always be borne in mind.

A further possible reason for the neglect of the buttress type dam, and of other relatively complicated types, is that usually a higher standard of workmanship is required for such a structure. A consistently high standard of workmanship throughout the job is a difficult thing to achieve in the tropics.

Mr. Sexton mentions that trouble is sometimes caused by small animals. Large ones can be a nuisance too; an over-inquisitive hippopotamus had to be chased out of the main building of the Owen Falls Power Station in Uganda, the very night that the first alternator went on load.

Electrical Equipment in Large Transport Aircraft

by

Clayton Glenn, Engineering Department, Trans-Canada Air Lines, Montreal
***The Engineering Journal*, September 1955, page 1189.**

Elsie G. MacGill, M.E.I.C.[4]

Mr. Glenn mentioned using a small auxiliary gas turbine for generating electrical power for the aircraft on the ground. What about using such a unit for developing electrical power in flight?

He mentioned that electrical power is only one of several power sources. I think when considering it we should keep in mind that electrical failure is usually complete, and rarely is partial, as may be the case in hydraulic failure. Also that damage to an electrical system sometimes has serious secondary effects, like fire.

For anti-icing, using compressed air off the jet engine, or tapping the inter-stage turbine for hot gas and passing the gas through a heat exchanger would seem a more natural source of heat supply, and moreover control of this hot air would be easy over a wide range of flight conditions. Would Mr. Glenn mention the chief arguments offsetting this?

Capt. J. Deane, M.E.I.C.[5]

Mr. Glenn stated that except inside the pressure cabin, 110-volt direct current equipment constitutes a serious problem at high altitudes. I would like to ask what happens if failure of a blower causes loss of pressure in the cabin?

D. C. R. Miller, M.E.I.C.[6]

Has any consideration been given in aircraft wiring, particularly having regard to the miles of wiring in large aircraft, to the possibilities of weight saving through reducing conductor diameters, operating conductors hotter and utilizing the high temperature insulating materials now available? I have in mind the Navy reduced-diameter cable program which has been able to effect considerable savings in space and weight requirement for power and communication cables on ships and the fact that with materials now available it is possible to operate at temperatures up to 200°C continuously. The weight and space savings aspects would be expected to be of much more value on aircraft than on ships.

The Author

Mr. Miller's question pertains to the possibility of increasing the rated conductor temperature of aircraft wire from 100° to 200°C.

Consideration was given several years ago to increasing the continuous copper rating from 100°C to 125° or 150°C, but no mention has been made of 200°C as far as we know. Most of the airframe manufacturers adhere to a set of standards prepared by themselves known as the Air Industries Association Aircraft Electrical Standards, the current issue of which limits conductors to a continuous temperature of 100°C. If up-rating the wire were to produce large weight saving benefits in aircraft they are now producing, then you can rest assured that the airframe manufacturers would pursue this field.

In the low voltage d-c systems used in current large transports, only a small percentage of the wiring would be affected by increasing the allowable temperature limit. Most of the wiring size is limited by mechanical strength, it having been found that No. 20 gauge is about the lightest gauge which will stand up to the strain of pulling through conduits and normal handling. Nearly all of the remaining wiring falling into the above categories could be reduced in size by increasing the allowable conductor temperature. On fighter aircraft, however, where runs are shorter and where voltage drop may not be a factor, there may be some weight advantage by doing so.

Our experience has indicated that the only conductors in the aircraft which are limited by current carrying capacity are the generator and battery feeders. Increasing the copper temperature from 100°C to 200°C for the generator cables would not appear desirable from our point of view since 200°C is approaching the autogeneous ignition temperature of some of our fuels, and these cables invariably pass through areas where there is the possibility of exposure to free fuel. Naturally, we would be concerned about any potential hazard.

The Navy may be able to get away with running their copper at 200°C, but conditions in a surface vessel are much different from those in an airplane, where cables are subjected to higher vibration frequencies and much different ambient air temperature and pressure conditions. If the airframe manufacturers can prove to our satisfaction that an increase in the maximum continuous copper temperature of aircraft cable is justified and introduces no additional hazards, then we would be foolish not to accept their recommendation.

In Answer to Miss MacGill

With respect to using the small auxiliary gas turbine for producing electrical power in flight, I can see several basic objections. First, for large civil transport aircraft we would require several sources of electrical power, so that if one source fails, we can draw

[4] Consulting Engineer (Aeronautical), Toronto.

[5] Assistant chief, Naval Technical Service, Naval Headquarters, Ottawa.

[6] General Manager, Dow Corning Silicones Limited, Toronto, Ontario.

from another. With the small auxiliary turbine drive, it would require, therefore, duplication or preferably triplication. This would increase the weight of the airplane and add to the overhaul cost, since maintaining these auxiliary turbines is no small cost item.

Another important factor is that which I mentioned in my paper, that of fuel consumption. These small gas turbines are notorious for their high fuel consumption, the currently produced units consuming about twice the fuel per unit of work than the engines used for propelling the airplane. This would show up as high operating costs and perhaps a loss of airplane range, if the airplane were already critical.

Fire hazard is another factor. These auxiliary engines would be no less of a fire hazard than the main engines and it may not be convenient to hang them externally. The non-pressurized rear fuselage seems to be the only spot left in the current transport designs for such an installation, it is doubtful if the airlines would accept the additional hazard in this area.

With respect to using engine bleed for anti-icing, I feel that there is more to ice elimination than providing a source of heat at the leading edges of the wings and tails. The run-back and refreezing of free water constitutes a major hazard in these high speed airplanes and tests seem to indicate that unless the surfaces are elevated to a very high degree, all the water will not vaporize to steam. Run-back can be practically eliminated with cyclic de-icing systems, which allows the ice to form and then supply just enough heat to break it loose. The cyclic control of hot gases to the wing, and the concentration of heat, is much more difficult to accomplish than the cyclic control of electric elements. Hot air bleed from the engines is the preferred method today, but I feel that in time, the electrical method will come into its own.

In Answer to Capt. J. Deane

When stating that 110 volt d-c. would constitute a certain hazard at high altitude, except in pressurized areas, I hope I did not imply that airplanes would have 110 volt d.-c. inside the cabin and some other voltage in the non-pressurized area. Naturally one basic system would be used throughout the whole airplane.

In any event, if it were possible to have all the electrical equipment in the pressurized fuselage and if that voltage were 110 volt d.-c., there would be no major high altitude problem since the loss of cabin pressure would necessitate dropping to a lower altitude due to the effect on passengers and crew.

Is Effective Town Planning Possible?

S. D. Lash, M.E.I.C., Head, Department of Civil Engineering, Queen's University, Kingston, Ont.

***The Engineering Journal*, February 1956 issue, page 116.**

A. E. K. Bunnell, M.E.I.C.[7]

Since Professor Lash's paper was originally presented to the Kingston Branch of the Institute I presume that he was speaking primarily of town planning in the Province of Ontario. In any case, my remarks will be based on the situation in Ontario since that is the province of which I have the most intimate personal knowledge.

Professor Lash's approach to planning is that of an engineer and perhaps because my primary training and experience have been in the engineering field, I may be expected to react in much the same manner. Whatever the reason, I find myself in substantial agreement with most of his statements and I consider his paper to be a valuable contribution to the current consideration of this most important subject. There are several matters, however, on which I should like to comment.

First of all, I am pleased to find that Professor Lash recognizes the significant differences between engineering and planning in that planning encompasses the broader field including in greater measure the social and economic aspects of a situation as well as the physical. It is primarily concerned with people and the policies and physical plant required in each community to most adequately serve their needs. It also must have regard to the future and a broader than purely local concept and must therefore have regard to many variables and consequently does not permit of an absolute solution as do most engineering problems.

As Professor Lash states, planning is primarily a function of local government, i.e., of local municipalities and combinations of local municipalities, and its effectiveness will depend to a great extent on its relationship to the local implementing authority. In view of the vital policy-making role of the planning agency it would not seem possible for it to be a normal department of the local government which is constrained to carry out dutifully the policies of the council rather than to initiate new ones. Nor does it seem that it should be denied the benefit of free consultation directly with all elements of the community. Further, it should have a maximum of continuity in its operation in order to study and develop policies over a period of time. Because of these factors, in Ontario where the term of office of elected councils is generally only one year, we have been constrained to operate local planning under the direction of planning boards, the members of which hold office for three years, appointed by the municipal council but consisting for the most part of public spirited citizens not members of council. While Professor Lash suggests that this type of organization does not work well and we are aware of many of its shortcomings, much effective planning is being accomplished under it and, short of a complete reorganization of our municipal institutions in Ontario, no more effective planning organization appears possible.

The organization for town planning has been established in most of the larger urban communities in Ontario. There are now well over two hundred planning boards functioning in areas containing more than three-quarters of the total population of the Province. One of the limiting features of their operation is the dearth of adequately trained and experienced technical staff to serve them. Four universities in Canada are providing a one year post-graduate course in planning which is providing some opportunity for special academic training in this

[7] Consultant to the Ontario Department of Planning and Development, Toronto.

field. The enrolment in these courses is increasing and a great many people in this and associated fields have taken short courses at M.I.T., and our own universities to supplement their knowledge of planning. It will, however, be some time before we have from these sources and elsewhere sufficient fully competent and experienced technical planners to adequately serve the various planning boards now functioning in Ontario.

In support of Professor Lash's suggestion that land in central areas of our cities might be held in public or quasi-public ownership and only building rights granted to private agencies, there is the experience of Stamford University near San Francisco. Stamford has developed for urban and suburban purposes a large part of 9000 acres (with which it was endowed and which by the terms of the endowment it cannot sell) on the basis of long leases, the fee in the land remaining in the University. Also, in the redevelopment proposed recently for a large area in central Toronto, one scheme proposed that the land would be acquired by the city and the redevelopment carried out by private companies on the basis of building rights or a lease for a definite term with the fee remaining in the municipality. There are other successful examples which would indicate the desirability of giving serious consideration to the continuation of this form of land tenure whenever land is acquired by a municipality for redevelopment or other public purpose.

Planning in Ontario under The Planing Act, 1955, is permissive and it is doubtful that compulsory planning is likely to receive public support in this Province. Regardless of the desirability of planning, it is not likely to be competently done or effectively implemented until it has the support and co-operation of at least a goodly number of the local citizens and councillors.

With this possible exception I can agree fully with Professor Lash's conclusions.

In Ontario we have tried to achieve as nearly as possible the conditions indicated as being essential to success. In view of the various difficulties pointed out in Professor Lash's paper and these notes, it is gratifying to be able to report the very great general interest in planning in Ontario and the quite substantial progress that has been made in overcoming these obstacles and obtaining a moderate measure of success. With greater public acceptance, more experience as to procedures, more experienced planning personnel and greater appropriations, we will come nearer to Professor Lash's ideal and, we hope, achieve a correspondingly fuller realization of the tremendous benefits planning can bring to Ontario.

G. Sutton Brown[8]

In commenting on a paper as comprehensive and as excellent as that of Dr. Lash, it is perhaps best to confine oneself to one or two points. The writer states that the objectives of planning are seldom defined, that the planner is mainly concerned with people as compared to things so that his task is made that much more difficult since people do not conform to formulae, that planning technique is still in a rudimentary stage, and that a planner is usually unable to do much about the realization of his plans. For these reasons, he is not surprised to find that so far planning in Ontario and elsewhere has been relatively ineffective.

To state that planning has been relatively ineffective does not do justice to some of the very fine developments which have taken place in recent years, or are being carried out at the moment. To take just one example alone, it is indeed encouraging to find a new town such as Kitimat in British Columbia being designed and developed as a comprehensive entity in accordance with a master plan prepared by some of the most eminent consultants on the continent and being executed under suitable control. This is but one instance, and there are many others, although, perhaps, we would find more reason for congratulation on work being carried out in Europe. I think what Dr. Lash means is that the planning process today has not nearly reached its enormous potential for bringing about major improvements in the efficiency of our urban areas and in our environment.

One of the reasons, as stated by Dr. Lash, is that planning, as we know it today, is in its infancy. Dr. Lash indicates that it is largely based upon experience of the past 50 years. I would suggest that planning, as we understand it today, is based almost entirely in the experience of the post-war years and certainly does not go back beyond 1930. It is not surprising, therefore, to find that techniques are still comparatively crude. It is perhaps significant that today we talk so much about the qualifications and training of planners, since we realize that we are still so deficient in the necessary skills required for practising in this most complex profession.

One of the reasons for relative failure has been the lack of defining our objectives and keeping these objectives within limits. It is now realized that plans of civic development and improvement should be limited to a period of time of say 20 to 25 years. Plans must be related to the financial and other resources of the area concerned. It has come to be realized that grandiose plans which have no possibility of realization cause more harm than good.

Modern planning techniques are now becoming sufficiently advanced to predict with some degree of accuracy the needs of an area for approximately 20 years ahead, assuming no world disturbances such as war intervene. Similarly, it is not too difficult to obtain some idea of the financial resources which a particular municipality or group of municipalities will command. The planner's task is to co-ordinate these two and translate them into a planned program of work. Increasingly, the preparation of integrated programs of capital expenditure are becoming the planner's responsibility and these programs to a considerable degree constitute a town plan or devlopment plan for a particular area.

It becomes necessary to understand these changes in technique because I would wish to endorse strongly Dr. Lash's recommendation that the planning agency should be an integral part of local government. It is perhaps our first concern to see that our administrative arrangements for planning are adequate for the tasks to be undertaken. √

This discussion of S. D. Lash's paper will be concluded in the March issue.

[8] Director of Planning, City Panning Department, Vancouver, B.C.

ABSTRACTS . . .

OF RECENTLY PUBLISHED ENGINEERING LITERATURE

TECHNICAL WRITING

Bulletin of the Institute of Engineers (*India*), v. 4, n. 7, August 1955, p. 1.

Vitruvius, who probably lived between the time of the death of Julius Caesar and the Battle of Actinium, said in his treatise, that an architect should be a good writer also, because an architect is to commit to writing his observations and experiences in order to assist his memory. But he was modest enough to inscribe in the preface, "I beseech you, O Caesar, and those who read this my work, to pardon and overlook grammatical errors; for I write neither as an accomplished philosopher, an eloquent rhetorician, nor an expert grammarian, but as an architect."

Technical writing of any merit or value is admittedly not easy. No writing is easy for that matter. At one time or another most of us try our hand at writing. The toddler's first step should be just to put himself down and write. Whatever the subject, a minimum of vocabulary is called for, and he soon becomes aware of its limitations. But if the brain is alert for new words and for old words in new contexts, slowly and with patience, the lack of skill in the selection of words ought to disappear. And while the engineer may not—indeed is not likely to blossom out into a litterateur of rare ability, he might at least attain that working knowledge to enable him to translate his experiences into interesting words.

The engineer who wants to get ahead finds that a considerable amount of his time is being devoted to writing, for his own benefit to begin with and then for other engineers and for less technical readers. If the writing is not effective and forceful, and if it does not mean what the writer intends, readers who may be specialists in their fields will have little confidence in the authority of the article or its significance. Neither employer nor employee will be persuaded or convinced.

If pursued in the right way, technical writing—as any other writing—can be an interesting pastime. The twin performance—the execution of the work and its expression in words—ought to run parallel, or in close sequence, to enable the author to maintain regularity, uniformity, precision and balance—qualities which, according to Matthew Arnold, should characterise any piece of good writing. In this are, or should be, combined science and art, the one rationalising and the other embellishing, making the organization and presentation of the whole work fascinating.

It is necessary to plan any piece of technical writing. Ideas have to be arranged. The article must start with facts known to the reader and lead to less known fields. A definite attitude towards the reader is necessary — an opinion of how much he is likely to know, and how much he is capable of taking in. A certain workmanlike ability, if not facility, can come fairly quickly if three basic rules are observed. First, simplicity of expression. Second, the writer must mean what he says. Third, the writing must have a head, a body and a tail—a clear announcement of the purpose, a logical development of the subject, and a brief summary, repeating the main points of the article with deductions, if any.

A last word. After the article is written out, the writer should, in every instance, try to edit his written words. And then he will appreciate too the hard task before an editor, that is, an editor who takes his work seriously—for not all editors of technical journals do this. He should check for grammatical correctness, examine his vocabulary, and eliminate verbosity—see if he cannot substitute 'The meter was read' for 'The reading of the meter was taken'.

Unfortunately, the lack of attention paid to training in technical writing in the universities has left the young engineer unconscious of the importance of his written words. He is not made aware that words are necessary to explain his works. He takes pride in his deeds but is not embarrassed at his lack of elementary literary skill.

There is a demand everywhere today for the engineer-writer who can effectively describe technical products and processes not only to the other technical men but also to the layman.

If the engineer approaches his writing as a challenge to his judgment, knowledge and accuracy as well as literary skill, articles will be better and better written.

AIRCRAFT RUNWAY DRYING MACHINE

The Engineer, v. 200, n. 5201, Sept. 30, 1955, pp. 485/86.

Pools of water on aircraft runways are a source of danger to aircraft landing at high speeds, and for this reason a machine for drying runways of aerodromes after rain storms has been developed and built.

The machine consists essentially of a fabricated steel frame mounted on four pneumatic wheels at the rear and three similar wheels on a castor head at the front. It is 13 ft. long overall by 6 ft. 4 in. wide and 3 ft. 10 in. high and is designed for towing by a tractor. Mounted on the frame is a totally enclosed steel tank of 400 gallons capacity, and there is a separate power compartment at the front.

In the power compartment a 3

h.p. engine drives a suction fan to create a vacuum in the tank. Depending from the rear of the tank is a squeegee, which is spring loaded into close contact with the surface of the runway, and runs across the full width of the machine. A slot above the rubbing surface along the front of the squeegee opens into a duct leading into the tank, so that as the machine moves along the water pushed up in front of the squeegee is sucked up into the tank. When the water in the tank reaches a pre-determined level it actuates a cut-out switch to stop the engine and prevents excess liquid being drawn into the fan compartment. Baffle plates are fitted in the tank to prevent water surge as the machine is drawn along.

When it is required to move the machine over dry patches on the runway or take it away after drying is completed a lever at the side is operated to raise the squeegee clear of the ground. The makers state that the machine is capable of removing water at a rate of 100 gallons a minute from a runway under normal conditions.

CANADA'S FUTURE BRIGHT FOR NUCLEAR POWER

Electrical Digest, v. 24, n. 8, August 1955, pp. 42/44.

By 1980 nuclear power plants may account for as much as 10 to 15 per cent of the total electrical generating capacity in Canada. Although by that year water power will still be the principal source of electrical energy in this country, thermal generation will have risen from negligible proportions of a few years ago to at least 30 per cent of the installed capacity.

A third to a half of this thermal generation will be by nuclear plants in spite of the fact that Canada has an abundance of coal that can be strip-mined in certain regions, and large reserves of petroleum and natural gas. Costs of conventionally produced electrical power are expected to rise despite significant improvements in long-distance transmission and further advances in the efficiency of central electric stations burning conventional fuels.

The most attractive feature of nuclear power is low fuel costs. They may be such as to make the economics of future atomic energy plants resemble more closely those of Canada's existing hydro-electric installations rather than those of steam plants burning coal or petroleum.

Nuclear energy will not be competitive anywhere in Canada until its price has fallen below 8 mills ($0.008) per kilowatt-hour. At 7 mills ($0.007), it might be able to compete with hydroelectric or with coal-fired steam power but demands for nuclear power at this price would be limited. The highly-developed power-consuming region of Southern Ontario, where imported coal will soon be the only alternative to hydro, could absorb large blocks of power at 6 mills ($0.006) without creating even a temporary surplus of generating capacity. Various engineering and economic studies under way at Chalk River suggest that nuclear plants capable of such performance will be under construction within the next 10 years.

The average annual rate of growth of total demand for electrical power in Canada is now about six per cent per year. Consumption could be expected to increase threefold to four-fold or more during the next 25 years. Domestic supplies of oil and natural gas are emerging as deterrents to the use of electrical power for steam-generating and other heating purposes. Furthermore, if inexpensive nuclear power becomes available in from 20 to 30 years time, a large part of Canada's established demand for new increase in power would disappear, for there would arise the tendency to locate certain heavy power-using industries, such as the refining of aluminum, close to the principal industrial markets of the world. On the other hand, Canada's increasing population seems likely to be forced to increase its productivity and thus use an increasing amount of power. While the annual rate of growth of consumption may, therefore, decline from its present level of six per cent to about four and a half per cent in the 1970's, annual installations varying between one million and two million kilowatts will still be required throughout the 1960's and 1970's.

The need for heavy water for Canada's nuclear plants will be several times the nation's present production capacity. What would be a sizeable segment of the country's chemical industrial may therefore have to be created simply to satisfy this large and rapidly expanding demand for a new material.

Production of natural uranium for domestic consumption, apparently, would have to run into tens of millions of dollars a year. Even if new methods are discovered for the manufacture of heavy water at appreciably lower costs, the expenditures might reach an annual level of from $40 million to $50 million twenty-five years from now. Outstripping these expenditures would be the outlays on generating plant, machinery and equipment—capital investments that might reach into the $100 million-a-year category by 1980.

JOB TITLES: HOW STEEL CLEANED HOUSE

The Iron Age, v. 176, n. 12, September, 1955, p. 71.

Main purpose of the handbook was to isolate all similar, but not necessarily identical jobs based on the predominant function of the job regardless of the job classification.

Because of the manner in which job titles had been applied over the years, it became a burdensome task to gather information for grievances and to compile and correlate data for establishing job classifications. In the past it had been the custom for the foremen to apply titles of their choosing.

This resulted in a conglomeration of titles for jobs performing the same work within or between plants, divisions and departments. As a result, an attempt at standardization was made in 1947. This initial effort was far from successful; the actual number of titles increased rather than decreased.

In 1951 the industry's cooperative Wage Bureau established The Standard Title and Code Committee to set up a standardized system for salaried, clerical and technical jobs. Successful in this effort, the committee reviewed all production and maintenance (hourly paid) jobs in 1952 and in January 1953 the present handbook was established.

SCIENCE AND THE SCIENTIST

The Engineer, v. 200, n. 5197, September 2, 1955, pp. 323/24.

Science is simply the record, enshrined in the literature, of the system of knowledge and of the conceptions correlating parts of that system.

It is fundamental that such knowledge cannot be based on dogma or authority of any kind, nor on any intuition or revelation, unless indeed it be of the Book of Nature that lies open before our eyes. It is inherent in the philosophy that the record may be imperfect and the conceptions erroneous; the potential fallibility of our science is not only acknowledged but insisted upon.

Where the material can be directly apprehended by our senses, there can be little doubt as to the validity of the record, though it may need some adjustment of errors of observation and of the value of any magnitude that is involved. The uncertainties are then largely concentrated on the conceptions and generalisations which have been based on the ascertained facts.

Justification of scientific theory has been obtained by the success of predictions and by the unanticipated convergence of more than one line of approach. In all the cases the degree of coincidence becomes so great as to carry conviction that we have been vouchsafed, if not the whole truth, at least something very closely related to it.

There is no philosophical line of demarcation that separates one branch of learning from another though the demeanour of many so-called humanists suggests that they perceive one. It is opportune to add another voice of protest against the often repeated assertion, that "culture" is the preserve of students of some particular branches of knowledge, and is denied to others. What is meant by "culture"? If it is the ability to think clearly and to express thoughts in language, what evidence is there that physical and biological scientists lack these qualities?

Before straying too far from actual science I would like to say something about the use of speculation, which should always arise from some correlation which was hitherto unknown or unnoticed, or the significance of which has been underestimated, or thought to have been underestimated. In the early stages it may be discouraging to study the literature; one can always find reasons there for believing that a new idea is not worth pursuing, or for that matter for saving oneself the trouble of doing an experiment. Later, having worked up an internal, self-generated pressure of enthusiasm, it is obligatory to face the hard facts already on record. Then, instead of weakly accepting a rebuff we shall at least put up some fight with "but on the other hand it might be that -----."

An important aspect of science is its universality, and its fully international character only rendered possible by the axiomatic freedom it enjoys from authority and dogma. The brotherhood of scientists is a reality. It is fortunately not unique; there is a similar fraternity among sportsmen, musicians, chess-players, and other categories of enthusiasts, not encumbered by the so-called ideologies.

WATER-ACTIVATED BATTERIES

The Times Review of Industry, September 1955, p. 39.

One of the most interesting advances in storage batteries is the recent utilization of a novel electro-chemical principle in the design of cell units for "one shot" and emergency applications. Such a battery had to be small, light and unfailingly reliable even after years of idleness in all climatic conditions—a requirement which ruled out the use of dry batteries. The new water-activated units achieved this combination of virtues so successfully that they have now been developed for many other related applications. A typical example from the new range of water-activated cells consists of special dry-charged plates of cuprous chloride designed to suit the particular application—which remain completely inert while protected from moisture by sealing tape or some similar means. In an emergency, the tape is ripped off and as soon as the plates come into contact with either salt or fresh water, the battery is energized. Once begun, the discharge then continues until the capacity is exhausted. A battery of this type has outstanding advantages for "one shot" emergency applications. It can be used for high discharge rates for relatively short periods, or for low-rate work over longer periods and has in either instance an outstanding high performance for its weight and volume. Protected from moisture, it remains completely inert under widely varying temperatures and humidities for an unlimited period. A number of water-activated batteries of different sizes and capacities has been developed, most of them employing cuprous chloride and magnesium electrodes.

BRASS-POWDER STRUCTURAL PARTS IN PRODUCT ENGINEERING

Mechanical Engineering, v. 77, n. 9, Sept. 1955, pp. 762/65.

The domestic production of metal parts from powder is not new. Practically all metals can be made into powders, but those most widely used for powder metallurgy today are iron, copper (largely mixed with tin to produce bronze), and brass. Brass was a late starter in the field of powder metallurgy and, consequently, the qualities of this powder for the pressing and sintering of structural parts are not so well known as those of some of the more firmly established metals.

It was not long ago that the production of satisfactory brass-powder parts was considered to be extremely difficult, and few fabricators were willing to tackle the problem. The production procedures have now developed, however, to a point where the majority of fabricators can turn out excellent brass-powder parts, and consequently their fields of application are rapidly expanding.

The fact that a considerable number of new brass-powder ordnance parts are now specified is a further indication that this method of production has become firmly established.

Parts Well-suited to Production:

1. Cylindrical, rectangular, or irregular shapes which are relative-

ly thick (up to 1 in.) and which, in general, do not involve large variations in cross-sectional dimensions and do not have a length-to-diameter ratio exceeding 2½ to 1.

2. Parts with surface indents or projections on tops or bottoms.

3. Parts with simple flanges or projections at one end.

4. Parts with splines, gear teeth, or knurling.

5. Parts with holes, counterbores, slots, or keyways.

It is good practice in designing brass-powder structural parts to avoid the following:

1. Narrow or deep splines.

2. Feather edges.

3. Sharp corners at the junction of the flange and body on flanged parts and other stepped designs.

Brass is exceeded only by the iron-copper alloys from the standpoint of tensile-strength, under comparable production conditions, and brass has much better elongation than the other commercial metals. It might be said that, when compacted and sintered under well-controlled conditions, brass-powder parts are generally comparable in physical and mechanical properties to brass castings. As related to wrought brass, the strength, hardness, and wear resistance of powder parts are more nearly equal to those of dead-soft annealed brass than to those of cold-worked stock. But the properties of parts made from wrought brass may be approached by re-pressing.

As an example of successful application of brass-powder structural parts, consider one which is never far from our finger tips— the dial mechanism of the latest telephone handsets. Three parts perform the important function of controlling the rotational speed of the dial and these vital parts are made from brass powder. They are the matching governor weights and the drive bar, in which close control of both weight and dimensional tolerances are imperative to efficient performance.

The powder-metallurgy process was easily the lowest-cost method of producing these parts. Although the shapes require relatively complicated tooling substantial savings over any alternative method result, because secondary operations are not needed to produce finished parts. Production rates of 1000 per hour per set of tools make for further economies.

CONSUMABLE-ELECTRODE INERT-ARC SPOT WELDING

The Welding Journal, v. 34, n. 9, September 1955, pp. 839/45.

Spot welding with an inert-gas-shielded arc is not a new concept. Spot welding, which utilizes a non-consumable tungsten electrode with inert-gas shielding has proved an extremely valuable production tool. However, it does have limitations. For one thing, it is limited as to the thickness of materials which can be joined. Another limitation is that it can be applied only to clean surfaces. Furthermore, this process adds no filler metal. Consequently, gaps or poor fit-up results in sinks or cavities.

Consumable-electrode inert-arc spot welding has been developed in order to overcome these shortcomings. Basically, the mechanics of this process are the same as those of the consumable-electrode inert-arc welding process, itself. In both, an arc shielded with inert gas is established between the weldment and a consumable filler wire. Here, however, most of the similarity ends. For in the spot-welding process, the ignition and extinction of the arc must be more precisely controlled. Usually the arc current density and voltages used are higher than those in the conventional process. The weld puddle develops and solidifies rapidly. Intense local heat develops instantly; but as the arc exists only briefly, the total heat input is rapidly quenched by the surrounding metal.

Present Limitations

At present, the consumable-electrode inert-arc spot-welding process can be used on carbon steel, stainless steel and copper-bearing alloys. Aluminum is omitted from this list due to some difficulty in obtaining consistency in starting. It is extremely important that starting consistency be obtained if uniformly good results are to be expected. the consumable-electrode spot-welding process can be used on metals up to about ⅛-in. thick in the downhand position. On thicknesses of ⅛ in. or thicker, it is necessary to plug weld.

The fit-up of the materials being welded does not constitute the problem it does in the tungsten electrode welding process. This is because filler metal added in the consumable-electrode spot-welding process can bridge the gap between the pieces. In fact, in many cases, it has been found that higher shear strength occurs with the consumable-electrode process when a slight gap exists. This is probably due to the ease with which the filler metal can flow over the lower plate and thereby effect a larger interface nugget. When larger interface nuggets cannot be obtained with the consumable-electrode process without burning through the lower plate, multiple cycling has been found useful.

Comparison to Other Processes

Generally, consumable-electrode inert-arc spot welding must be regarded as a supplement to other existing spot, plug and stud welding methods. The tungsten-electrode spot-welding process is still to be preferred on very thin materials, where it is cheaper and does not have the buildup or button which occurs with the consumable-electrode process as a rule. However, consumable-electrode spot welding does have advantages in that fit-up is not a problem and in that it can be used over a very wide range of thicknesses.

Manual plug welding may still be preferred in some cases where the plug is extremely large or where it is necessary to get a high degree of manipulation of the puddle in order to eliminate cold shuts or slagging. The consumable-electrode process may supplant some applications in which stud welding is now used. For tack welding, consumable-electrode spot welding offers an extremely valuable tool.

Consumable - electrode inert-arc spot welding can be applied easily and quickly to a variety of production problems. The process is now being used in all positions on carbon, stainless and galvanized steels as well as on copper-bearing alloys.

Its future growth will follow three major paths: First, it will serve more and more as a useful supplement to older methods of spot, plug and tack welding. Second, its inherent quality-control properties will help to make it an adjunct to automation-production operations. Finally, it will very possibly find use in applications which cannot be adequately handled by any other presently known welding method.

Month To Month

Notes of the Institute and Other Societies, Comments and Correspondence, Elections and Transfers

No Engineers Required

Members of the Institute may have noticed that within the personnel of the Royal Commission on Canada's Economic Prospects there is no engineer. They may have noticed also that the terms of reference for the Commission include a study of the "future developments in natural gas, power . . . the need for more roads, hospitals, schools and universities, a survey of Canada's energy resources and raw materials".

The Council of the Institute also observed this incongruity and instructed the general secretary to draw it to the attention of the Prime Minister, with the suggestion that the work of the Commission would be expedited and increased in value if the Commission were strengthened by the addition of an engineer experienced in such matters. Such a letter was written, but the Prime Minister replied that in his opinion the Commission was already competent to handle the situation satisfactorily.

In his own words Mr. St. Laurent said "the Government endeavoured to choose persons with as comprehensive experience as possible in Canada's development in all areas. . . . It is confidently expected that those who were selected have the qualifications for making a thorough survey of the nation's prospects." Also he stated that one of the commissioners was an engineer.

The Commission is composed of an accountant, three lawyers and a forester. (In Quebec a graduate in forestry from Laval may call himself a forest engineer, but graduation from such a course does not meet the requirements for registration under the engineers act.) One might be excused for wondering how they acquired a "comprehensive experience" in such things as natural gas, power, roads, and raw materials and the energy resources of the country.

The gentlemen of the Commission all enjoy an excellent status. No one would criticize them personally. It is more than likely that they too are puzzled to find that they are supposed to study and report on things so foreign to their experience.

In order to get this thing into proper perspective, suppose the Commission had been established to study and report on the rewriting of the North America Act or the Criminal Code. Is it possible that the government would have appointed a commission consisting of an accountant, a medical doctor and three engineers? And if they had, what would the lawyers and the press have said about it? There is no need to ask.

Or suppose the subject to be studied included the medical care of indigents, or the mentally ill or the study of contagious diseases, would the government have made up a commission of an architect, an engineer and three lawyers? How would the medical doctors and the press have received such a commission? Here again there is no need to ask. Nevertheless the case under discussion has much in common with these hypothetical cases.

Engineers in Engineering Work

It is apparent that there is still much to be done to impress some influential people with the fact that engineers are the ones best qualified to do engineering work. No one would want to belittle the other learned professions. On the contrary it is probably a compliment to them to suggest that they are so well informed, so expert in their own fields that they should not be expected to know anything about some other field which is equally specialized.

It is hoped that in spite of the handicap, the Commission may make a useful report on these subjects, which in the minds of many are the most important of all matters included in the terms of reference.

Library Regulations Changed

Recently Council has approved several changes in the regulations for the Institute library. These changes were submitted by the Library and House Committee at the request of the librarian.

Some of the changes are quite important and all are intended to make the use of the library more simple. Principal among them is the abolition of the $5.00 deposit, which has been required up to now, and the reduction in the penalty for overdue books from 25c to 10c a day.

Here are the regulations as they stand now with the changes incorporated in them:

1. *Hours:* Monday to Friday—
   9 a.m.-5 p.m.
   Saturdays—
   9 a.m.-12 noon
2. Two books, periodicals or pamphlets (or more at the discretion of the librarian) may be borrowed at one time.
3. The loan period is two weeks, but this may be extended, on application, for a further two weeks if the material is not in demand. Out-of-town members may add mailing time.
4. A fine of ten (10) cents a day will be charged on overdue books.
5. Requests for a book must be made in person, by telephone, or by letter, and members are personally responsible for items charged out in their names.
6. No charge is made for the library service and the cost of sending books by mail will be paid by the Institute, but the cost of returning books must be borne by the member.
7. Short subject bibliographies are compiled on request. When placing these requests, please give as much detail and background information as possible.
8. Any book or pamphlet may be ordered through the library, as may subscriptions to periodicals of other engineering societies. *Please make no payments in advance.*
9. Non-members may consult the library, but may not borrow material. Please address all requests to *The Library.*

The Engineering Institute of Canada has one of the finest engineering libraries in North America. It is staffed by a group of four competent people, including professional librarians.

Members outside of Montreal are reminded that the library is just as much for their use as for those living within the city. The same services can be given to non-resident members through the mail as can be given direct to those close to Headquarters. Now that the $5.00 deposit has been abolished, the facilities are even more readily available by mail than they were in the past.

It is believed the library can give to Canadian engineers a better service than they can obtain elsewhere. To those who have not used it previously it is suggested that the solution of many of their problems may lie in the use of this service.

"HELP WANTED"

Due to the retirement this summer of Colonel H. G. Thompson the Institute is seeking an assistant general secretary to be located at Headquarters in Montreal. The position carries excellent prospects for development on a permanent basis.

Applicants should have ability and experience in meeting people, in public speaking, and in writing. Personality is important. Experience in organizing, in conducting meetings and in office routine is essential. Experience in editing can be used to good advantage.

Membership in the Institute is not essential but naturally a preference will be given to members. Persons who have been active in Institute affairs will also have an advantage.

Age requirement is not fixed rigidly but applicants should be over thirty-five and under fifty.

This is a good opening for a person who is ambitious and energetic. Please mail applications with full particulars of education and employment experience to:

The General Secretary
The Engineering Institute of Canada
2050 Mansfield Street, Montreal

Custodian for Memorial

At the November meeting of Council held in Winnipeg, Council agreed that the Ottawa Branch be asked to act as custodians of the recently unveiled monument to Colonel By. A letter has been received recently addressed to the Council in which the Management Committee of the branch have agreed to accept this responsibility.

It is an important thing to have someone or some organization take a special interest in the maintenance of a memorial. Very often such things are erected amidst great enthusiasm and then within a surprisingly short time they are forgotten and neglected. It is the hope of Council that by making this the special responsibility of the Ottawa Branch such a fate will not await Colonel By and his fountain.

Of course the Institute is fortunate in having the Federal District Commission so vitally interested in the memorial. It was erected on F.D.C. territory and in a location selected by them. The task of the Ottawa Branch as custodians will be minimized by virtue of the assistance and the interest of the Commission; nevertheless it is nice to have the double assurance which has now come from the Ottawa executive.

Branch Scholarship

A short time ago word was received from the Vancouver Island Branch that they had awarded their first annual scholarship amounting to $100.00. It has been awarded to Howard A. Grant of Duncan, B.C., who is now a first year student at the University of British Columbia.

It is rather an unusual thing to find an annual scholarship of this amount being given by so small a branch. The funds were not raised specially but were taken from the branch's regular revenue.

The basis upon which the award is made is left to the committee on prizes and scholarships at Victoria College. The only stipulation is that the recipient must be an outstanding student and be proceeding into an engineering course at an approved university. The branch has been informed that the committee has made the selection, not only on the basis of scholarship but as well on character, leadership, conscientiousness and potential in his chosen profession.

Here is a real contribution towards the development of the profession. If other branches are interested in following this good example, there is no doubt but that the executive of the Vancouver Island branch would be very glad to pass on the full details of their thinking and of their experience.

Ontario Association Officers

Merritt W. Hotchkin, Kirkland Lake mining executive is the president of the Association of Professional Engineers of Ontario, succeeding John R. Montague, M.E.I.C., of Toronto.

As chief executive officer of the Association, Mr. Hotchkin, with the new council, will guide the body's policy-making throughout the present year affecting the more than 14,000 members in the province. The new president, well-known in Canadian and U.S. mining circles, is engineer-in-charge, outside exploration, for Wright-Hargreaves Mines Ltd.

Also named to the executive were John H. Fox, M.E.I.C., general sales manager, Minneapolis-Honeywell Regulator Co. Ltd., Toronto, as first vice-president, and C. T. Carson, vice-president and producing manager, Hiram Walker & Sons Ltd., Walkerville.

Serving on council during the year will be two representatives from each of the five branches of engineering. They are:

Civil Branch: Tullis N. Carter, M.E.I.C., Toronto vice-president and general manager, Carter Construction Co., and Joseph H. Irvine, M.E.I.C., Ottawa, of James F. MacLaren Associates;

Chemical and Metallurgical Branch: Gordon W. Ames, M.E.I.C., Sarnia, senior design engineer, Polymer Corp. Ltd., and Patrick E. Cavanagh, director, engineering and metallurgy, Ontario Research Foundation, Toronto;

Electrical Branch: John W. Holmes, design engineer, Canadian General Electric Co. Ltd., Peterborough, and John H. Waghorne, engineer-in-charge, electrical research dept., Ontario Hydro-electric Power Commission;

Mechanical, Aeronautical and Industrial Branch: John H. Ross, M.E.I.C., Toronto, consulting engineer; and William D. Sheldon, Jr., M.E.I.C., president and chief engineer, Sheldons Engineering Ltd., Galt;

Mining Branch: M. S. Fotheringham, M.E.I.C., president and general manager, Steep Rock Iron Mines Ltd., Steep Rock, Ont., and Charles P. Jenney, chief geologist, The American Metal Co. Ltd., Toronto.

The Association's permanent officers are: T. M. Medland, executive director; Murray Muir, secretary-treasurer and registrar, and T. C. Keefer, M.E.I.C., field secretary.

The new president of the Association of Professional Engineers of Ontario, M. W. Hotchkin (right), with three prominent members. From left, they are: John H. Fox, M.E.I.C., Toronto; Richard L. Hearn, M.E.I.C., who was awarded the Association's highest honour, the Professional Engineers' Medal; and James A. Vance, M.E.I.C., Woodstock, Ont.

Two 335-foot transmission towers at Cornwall, Ont., are associated with facilities which will provide interconnection between Canadian and U.S. powerhouses of the St. Lawrence power project.

St. Lawrence Seaway and Power Project

The *Engineering Journal* reviews the progress of the St. Lawrence Project.

Progress by Ontario Hydro

At the end of December, track laying operations had commenced on the relocated section of the CNR double track line which will skirt the flooded area. This eventual 40-mile stretch of track will take the railway line around the headpond area from Iroquois to Cornwall.

Meanwhile significant progress had been made in various sections of the railway relocation project. More than half the grading had been completed, while installation of culverts was well advanced and ditching operations also had been progressing favourably.

Commencement of the track laying operations for the railway line significantly coincided with work on the relocation of No. 2 highway. The highway work had been completed for 7.2 miles between Cornwall and Moulinette area, and the main stream of through traffic had been routed away from the work area. This had aided construction work in general in the vicinity of the power house and the administration area.

Building operations at the St. Lawrence transformer station had been impressive in the past few weeks. The various structures and buildings were taking shape and the whole area showed rapid development. The 115-kv. area which will largely be taking over the function of the Cornwall transformer station was well advanced. The Cornwall transformer station presently is distributing power to the immediate district and that station will be dismantled soon to make way for the new diversion canal.

At the new St. Lawrence transformer station, about 70 per cent of the total first stage work had been completed by Hydro's own forces. In the 115-kv. area of that station, more than 80 per cent of the work had been finished. The relay building was ready for service and two 25,000-kva. transformers had been installed. Most of the bus work had been completed.

Other important installations were being erected for full-scale building operations in connection with Hydro's half of the power dam and power house. The main section of the concrete batching plant had been erected. This plant will provide concrete for the power dam and it is expected that the concrete plant will be in operation in February.

Meantime, excavation on the powerhouse site and also grouting operations were continuing favourably. The liners for diversion canal access tunnels were in place, part of the aggregate conveyors were installed, the main part of the concrete batch plant had been erected, with excavation down to rock in the wingwall and U-abutment areas. Traffic in the Cornwall canal had been suspended for the winter, permitting the continuous use of access bridge at Lock 19.

Rehabilitation work extended over a wide area during December. At townsite No. 1, lot staking and surveys progressed favourably. In townsite No. 2, surveying of power lines and water intake lines was carried out, as well as the transferring of Bell Telephone cable and local traffic lines.

In the meantime, some twenty homes were moved into new Iroquois during December for a total of over seventy homes relocated. Work on building basements also progressed favourably and was well ahead of the moving schedule. At the same time, the footings for the shopping centre were constructed. Work continued on grading and gravelling roads and sidewalks in new Iroquois.

Work on channel improvements had been concentrated in the Galops Island sector. It is estimated that the quantity of material removed to the end of the year from the main cut was about 1,500,000 cubic yards.

Extremely cold weather and the holiday season slowed progress of the project work somewhat during the month of December. The work force was approximately 2,550 persons.

Progress by NYSPA

Another milestone in the construction of the power project was passed with the opening of the Barnhart Island bridge to traffic on December 15, 1955. This was followed by the start of removal operations of the temporary pontoon bridge from Hawkins Point to Barnhart Island. Excavation quantities for all construction contracts exceeded nine million cubic yards.

At year end, in the powerhouse area, excavation continued, and more than 130,000 sacks of cement had been used here for consolidation and cutoff grouting. The access railroad had been completed on Barnhart Island, with the access highway opened to traffic. Driving of piling for the baffles on the river side of cofferdam C1 was completed and the cells were being filled.

At Long Sault dam, concrete placement continued until December 16, and was then closed down for the season, with 31,000 cubic yards in place. Construction plant operations continued as the third upstream gantry crane was being erected. Excavation for the south wing dike was resumed. In Cut "F" excavation continued to progress rapidly, as approximately two million cubic yards had been moved to date.

At Iroquois dam, excavation for the south abutment of the dam structure at Rockway Point continued. Driving of piling for cofferdam cells and construction of dikes were in progress. Placing of concrete in the dam continued, but at a slower rate due to cold weather. 5000 cubic yards were placed to date. At Massena intake, excavation for Stage 1 construction continued as material was hauled to controlled stockpile for the dike.

Channel improvement excavation continued, with the excavation at Red Mills nearly completed. Channel excavation by dredge at Chimney Island was discontinued for the winter on December 16, 1955.

Placing of concrete on the Barnhart bridge was nearly completed and traffic was allowed passage over the bridge as noted above. Riveting for the Grass River bridge was complete. Nearly all structures for the Long Sault canal construction power line had been completed and half the conductors had been strung.

Preparation of engineering drawings and specifications continued on schedule. Specifications were completed and issued during the month for insulated wire and cable and the fixed hoists for Massena intake. On land acquisition, right of entry had been 85 per cent obtained. Reservoir clearing had been commenced.

Extremely cold weather and the holiday season retarded work in December. The work force during the month averaged 3040 persons.

Reforestation and Parks

In an illustrated booklet published in December by the New York State Power Authority, Robert Moses, chairman, has outlined the Authority's policy on reforestation and landscaping areas adjacent to the works, in part as follows:

"In the construction of large works such as the Seaway, there is a tendency to postpone, minimize and even forget serious consideration of final improvements such as trimming, reforesting, landscaping, recreation, esthetics in the broad sense. . . . There will be no such neglect on the St. Lawrence The beauty of the river and its benefits beyond commerce, industry and utilities must be preserved and enhanced. . . .

"We shall not forget reforestation of huge dykes and spoil areas, topsoiling and landscaping of roads, water front and parks, attractions for visitors, recreation facilities for local people as well as visitors, promotion of high standards of zoning and protection against eyesores. . . . Obviously some of this cannot be done until the spoil areas, dykes, dams and powerhouse are almost completed. . . .

"The land acquisition procedures for seaway and power involve the co-operation of various State agencies. . . . Also involved are the International Joint Commission, International Joint Board of Engineers, International Joint Board of Control, Bureau of Customs, Immigration and Naturalization Service and others. . . . It is perhaps the largest co-operative venture of this kind ever attempted.

"Certain problems, some of which are annual and others of a non-recurring type, are bound to follow. There is no mystery as to our policy. We have made it quite clear that we do not propose to assume the normal operating expenses of the local communities. . .

Architect's model, showing part of the Canadian section of the St. Lawrence power house. The building will span some 3,300 feet between Barnhart Island and the Canadian mainland, and will be built by Ontario Hydro and the Power Authority of the State of New York.

As to some of the more permanent improvements requiring large capital outlays, such as the badly needed sewage disposal plant in Massena, we can be of considerable help. . . .

"The Authority reiterates that its objective is not only to generate low cost power and to help build the new seaway, but to conserve the natural beauty of this magnificent river and to promote the healthy development of the entire frontage for industry, residence and recreation.

"The spoil areas . . . subsequently will be seeded and portions reforested with native pine and spruce in carefully studied arrangements so as ultimately to produce naturalistic effects. Hardwoods, which will reseed naturally, will be allowed to develop with the evergreens so as to create a native forest cover. . . . The result will be that of a strip of natural woodland and open meadow areas along pleasantly curving dykes that form the margin of the waterfront.

"The Federal Power Commission license provides for public access to the power pool for recreation. To meet this provision, the Authority is planning to provide access to the pool, including boat launching ramps at reasonable intervals. . . . A waterfront park is being planned for the village of Waddington, that will include a playground and open areas for general park use. . . .

"The Authority will develop an area now known as Wilson Hill and situated about halfway between Massena and Waddington, where many buildings may be relocated. The Wilson Hill area will become an island when the water level of the river is raised. . . . Access will be provided by the construction of a causeway. . . .

"In the meantime a permanent beach, nearer Massena and reached via Martin Road, will be constructed and will be ready for use in 1959. . . . This beach, which lies outside of the town of Massena, will be leased to the town for a nominal sum to cover the cost of maintenance and operation. It is assumed that there will be no problem in reaching an agreement to insure satisfactory standards of operation and maintenance. . . .

"The design of the St. Lawrence State Park has been progressed with particular emphasis upon the use of the lake. . . . A permanent park headquarters, overlook shelters and concession stands, and camping and picknicking areas, including the necessary related structures, will be constructed as a part of the project. . . .

"The power house will include exhibition rooms, an auditorium, a penthouse, and a promenade overlooking the lake. Ample visual and audible aids will be employed to demonstrate the operation of the project. An attractive approach drive with automobile parking for visitors will be provided. Overlooks incorporated in the park are being situated to show off the principal features of the power project. . . .

"The main highway that leads to Canada from Route 37 to the Polly's Gut bridge will be taken over by the State after completion of construction and maintained as a state highway. . . . The Authority has authorized the acquisition of easements for 1,000 feet each side of the highway to protect against the construction of advertising signs and bill boards. . . .

"It has been apparent to the Authority and to some of the bordering municipalities that a power project of this magnitude will require the adoption of local regulatory measures to insure the orderly expansion of the communities affected. . . . The Authority does not wish to interfere in any municipality's efforts to establish regulatory measures but is prepared to lend technical and advisory assistance through its staff and consultants to any of the towns or villages in the planning and zoning of their communities.

"We have indicated three possible areas between Massena and Ogdensburg where industrial plants and other commercial developments could locate advantageously. These areas are desirable because of low cost power, convenient railroad facilities and frontage on the seaway. Substantial acreages could easily be assembled by industry interested in locating on the St. Lawrence. . . .

Progress by SLSA

A contract for construction of St. Lambert lock and approaches in the Lachine section of the seaway has been awarded to McNamara Construction Company Limited, Pigott Construction Company Limited and Peacock and McQuigge Limited, all of Toronto, in joint venture. The successful bid, lowest of five tendered, amounted to $7,399,472. The work is to be completed by August 31, 1958. This contract is the twenty-eighth to be awarded by the St. Lawrence Seaway Authority and brings the total value of these contracts to approximately $57 million.

This lock is one of two locks to be built in the Lachine section, the other being the Côte Ste. Catherine lock, on which construction began last fall. To be built at the south shore end of the Victoria bridge, the St. Lambert lock will be the most easterly lock of the seaway. SLSA is to build five locks. The other two will be built by SLSDC in the international section.

The bulk of the work on the St. Lambert lock contract extends some 5,000 feet. It consists of construction of the lock, together with the excavation of the navigation channel and construction of the concrete walls which form the entrances to the lock. The contract also includes 48-inch water supply intake pipe for the city of St. Lambert and the CNR, with connection to existing intake works. Quantities involved include excavation of some 2,400,000 cubic yards of material and some 405,000 cubic yards of concrete.

Key Construction Limited and Deschamps & Belanger Ltée., both of Montreal, in joint venture, have been awarded a contract for a building to house hydraulic models at Ville LaSalle (St. Patrick Street) near Montreal. Value of the contract is $572,492. Construction of the building must be completed by the middle of May, this year.

On December 6, 1955, it was announced that Neyrpic Canada Ltd. of Montreal had been awarded a contract for the construction and verification of hydraulic models of Montreal harbour and of the Lachine rapids and for various test programs to be conducted on these hydraulic models. The building will house the models built and operated by Neyrpic Canada Ltd. This building will be 267 feet long by 115 feet wide. Specifications for its construction include steel structure, concrete work, prestressed concrete slab and also some asphalt flooring and all electrical, heating and ventilating systems.

Officials of the St. Lawrence Seaway Authority visited the Panama Canal Zone, as guests of the secretary of the Army of the United

States and the Saint Lawrence Seaway Development Corporation. The purpose of the trip was to observe the procedures of handling cargo ships and the collection of tolls through the Panama Canal.

They met at Washington, D.C., with the United States seaway party, headed by Lewis G. Castle, SLSDC administrator, and journeyed by air together, leaving Washington, January 18 for the Panama Canal Zone and returning to Ottawa January 23.

Progress by SLSDC

Low bid on a contract for the Robinson Bay lock was submitted January 10 to the Buffalo District, US Corps of Engineers, construction agent for SLSDC, by a joint venture Morrison Knudson-Walsh-Perini group, at a price of $20,172,451, the lowest of six bids.

The lock will be located about three miles east of Massena, being the furthest upstream of two locks on the Long Sault canal, the 10 mile channel south of the Long Sault rapids, the biggest man-made ditch on the seaway.

The structure will be of the concrete gravity type 860 feet long, 80 feet wide, and will have a 49 foot lift. The walls will be from 105 to 115 feet high. Approach walls will be ¾ of a mile in length. It is the first major SLSDC construction project, most contracts already awarded having been for excavation projects. Completion is called for in May 1958.

Ogdensburg Bridge

In an exchange of correspondence late in December respecting the subject of the Ogdensburg bridge, Lewis G. Castle SLSDC administrator stated in a letter to Hon. Robert Moses, NYSPA chairman, that he felt the bridge may become an eventuality, but the timing of its construction may have to be delayed until a later date when traffic count can be more accurately determined, and thus possibly provide a larger revenue bond issue to furnish funds for a larger percentage of construction cost.

The suggestion of a highway over the Iroquois control dam, he added, did not appear a good alternative, because of the 25 mile distance to be travelled between Ogdensburg and Prescott. Moreover, it would involve building two bridges in the Iroquois lock and a similar installation at Point Rockway, should the United States at some time in the future build a parallel lock at that location. He questioned if the Canadian Seaway Authority would consent to the bridge installation.

In his reply to Mr. Castle, the Hon. Robert Moses, commenting that the two authorities were in substantial agreement regarding the Ogdensburg bridge, pointed out SLSDC and NYSPA have a limited scope of activities defined by law, license and bond indentures. They were not directed or even authorized to take on or expedite the construction of the Ogdensburg bridge.

Other Seaway News

After receiving final submission on the issue of excluding British ships from trade between Canadian ports on January 11, the Royal Commission on Coastal Shipping adjourned to write its report to the Federal Government. There was no indication of when this might be completed.

General manager W. J. Fisher of the Canadian Shipowners Association, representing operators of Canadian owned deep-sea ships, proposed a middle course between extremes of opinion ranging from free British access to coastal trade, to outright exclusion of all but Canadian-built and owned ships.

He suggested that on inland waters the all-Canadian coastal trade be limited to ships owned in Canada but registered anywhere in the Commonwealth. Exclusion of British shipping, he said, would give Canadian shipping a monopoly through which it could well price itself out of the market, and thus be self-defeating. For the assistance of shipyards he suggested federal sponsorship of a shipbuilding program for ocean going ships.

Vice-president Arthur Simard of Marine Industries called for restriction of trade to Canadian built and owned vessels as a means of helping Canada's shipping and shipyards. Elimination of the coastal privileges now given British ships would ensure survival of Canada's shipbuilding industry.

Partial Lachine Development

It is reported Hydro-Québec is studying alternatives to the original idea of a single stage development for the full 1,200,000-hp potential of Lachine power immediately below Victoria bridge, which involves difficult problems respecting transportation arteries across the river.

One possible alternative being considered is a two stage development, with the first stage a dam and power house at Heron Island in the Lachine rapids and opposite Côte St. Catherine. This first stage would develop the larger half of the available power in the Lachine section, leaving the remainder to be built at a later date below the Laprairie Basin. Construction at Heron Island might also provide a means of controlling the level of Lake St. Louis if and when necessary.

Air view of excavation on overland navigation channel near Cote St. Catherine. Heron Island at Lachine Rapids, in background, is probable location for upstream of two future power developments by Hydro-Quebec.

Newsletter for Branch Members

Recently headquarters has received a copy of a newsletter issued to their members by the executive of the Belleville Branch. It seems such an excellent idea that it is now being passed on to other branches in the hope that they too may find it of interest and value.

The letter comes on two pages and is in letter press form. However, a mimeographed letter might be equally acceptable if it should be more convenient to other branches to print it that way.

Among other things the letter tells of the proposed program for the following season and gives the names of the members of the executive committee. It then goes on to talk about prizes available to members and also devotes considerable space to talking about the professional development course. Incidentally, the Belleville Branch has made an excellent showing in these P.D. courses.

Reference is made to the Canadian Committee on Counselling in Engineering and Science and the representative of that committee in the Belleville Branch. It suggests that any persons who desire counselling in these matters should get in touch with the representative.

The letter concludes with the request that members will not hesitate to send in their comments on the letter and on the branch activities. The executive hopes that through the contacts made by the newsletter, members will be encouraged to take a closer interest in branch affairs.

The executive of the Belleville Branch is to be congratulated on this enterprising effort.

Joint Boiler Meeting, Montreal, June

Some of our readers may remember that a meeting of the ASME Boiler Code Committee was held in Toronto in the spring of 1952. This year they are coming to Canada again, but this time for an even larger and more important gathering. Once each year the National Board of Boiler and Pressure Vessel Inspectors of the United States meets jointly with the ASME Boiler Code Committee in a centre other than New York. For 1956 this meeting will be held in Montreal.

Arrangements have been made on behalf of C. O. Myers, secretary-treasurer of the National Board for the meetings to be held at the Windsor Hotel, Montreal, on June 19, 20, 21, 22 and it is hoped that as many Canadians as possible will plan to attend.

Provision is being made for an open panel discussion dealing with all sections of the Boiler Code, on Wednesday, June 20, and a similar panel discussion dealing with welding repairs on the afternoon of Thursday, June 21. On Thursday morning it is planned to hold meetings of two or three of the Boiler Code subcommittees while the National Board holds its regular meeting in camera. Finally there will be a meeting of the main committee of the ASME Boiler and Pressure Vessel Code on Friday morning and afternoon.

A. LaBissonniere

Large Machinery Trailer

This machinery trailer, made in Woodstock, Ont., and weighing 78,500 pounds, is believed to be the largest ever built in Canada. The payload capacity is 220,000 pounds. For more details please refer to the December 1955 *Engineering Journal*, Page 1745.

The program is expected to include a number of social events such as receptions, luncheons, and a dinner dance as well as special

H. G. Thompson, M.E.I.C.

attractions for the ladies who will be particularly welcome.

Special arrangements are in the hands of Alfred LaBissonniere of Montreal, chief inspector of pressure vessels for the Province of Quebec and a member of the executive of the National Board, assisted by the executive assistant secretary of the Engineering Institute of Canada, H. G. Thompson, and a strong local committee including: A. M. Bain, M.E.I.C.; J. Bajada; K. H. Barnard; E. H. Brooke, M.E.I.C.; H. E. G. Dupuy, M.E.I.C.; H. M. Esdaile, M.E.I.C.; I. P. Fitzgerald; P. W. Gooch, M.E.I.C.; H. C. Hood, M.E.I.C.; J. D. Hood; G. N. Martin, M.E.I.C.; T. L. Noel; and M. D. Phillips.

January Journals Needed

The supply of January 1956 *Journals* is low, and there are requirements that have not been filled.

It would relieve the situation if readers who do not file or bind *The Engineering Journal*, would return copies of that issue to Headquarters.

Fraser River Dredging

A new dredge will be used by the Department of Public Works in the dredging operation on the Fraser River Delta, B.C., which has been a continuous necessity for many years.

Designed and constructed by Messrs. Yarrows Limited, Victoria, B.C., this is a non-propelled, heavy duty, hydraulic pipe line dredge, of the following dimensions: length overall, 150 ft.; breadth moulded, 40 ft.; depth moulded, 10 ft. 6 in.; draft, midship section, 6 ft. It is designed for dredging to a maximum depth of 45 ft.

The rigidly constructed steel suction ladder installed in the forward end of the hull contains a 24-in.-dia. suction pipe; and mounted on it is the cutter with drive shaft and bearings, driven by a 250-hp. electric motor.

At the after end is a structure for raising and lowering the "spuds" in guides, these being of tubular welded steel construction 30-in. dia. and 69 ft. long.

A 20-in. pipe on the port side and a 20-in. pipe line on pontoons discharge the spoil beyond the banks of the river. Silt, sand, clay and gravel can be handled through the system to a terminal height of 10 ft. above water level; the capacity of the diesel driven pump is 13,500 gal. per min. of spoil at 1.2 specific gravity, velocity 14 ft. per sec.

Progress of the dredge in operation is by means of wire rope haulage on each side of the suction ladder pivotting alternatively on a stern spud. As the dredge cutter moves through the silt, a swinging action is set up and the dredge advances "walking" from side to side by alternate raising and lowering of the spuds to the river bottom.

The dredge master conducts operations from the control room by electric and pneumatic controls.

Fraser River dredge.

Elections and Transfers

At the meeting of Council held at the University Club, on Friday, January 27, 1956, a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

Members:

I. R. Booth, *Montreal*
F. E. Burke, *Montreal*
J. B. Clarke, *Winnipeg*
R. E. Claudi, *Montreal*
H. J. K. Darling, *Calgary*
M. K. Douglass, *Vancouver*
H. P. Horlock, *Hamilton*
A. V. Johnston, *Montreal*
R. C. Keene, *Toronto*
J. W. Martin, *Mill Haven*
J. E. Nelligan, *Montreal*
G. Parrott, *Guelph*
M. Price, *Ottawa*
J. G. A. Stevenson, *North Bay*
D. C. Turner, *Cardinal*

Juniors:

K. D. Adams, *Calgary*
P. B. Franz, *Temiskaming*
H. J. Leutheusser, *Toronto*
K. MacKay, *Ft. William*
C. A. McCurdy, *Hamilton*
I. C. Martin, *Kitchener*
E. Noussan, *Montreal*
E. G. Phillip, *Kitchener*
J. M. Sargent, *Brockville*
H. W. Watson, *Moncton*

Transferred from the class of Junior to that of Member:

A. Baracos, *Winnipeg*
H. W. Beckett, *Salmo, B.C.*
C. W. Case, *Chatham*
C. B. Cooper, *Pointe Claire*
D. Danylkiw, *Montreal*
G. J. Foley, *Winnipeg*
R. F. MacKenzie, *Toronto*
H. D. McLellan, *Kitimat, B.C.*
C. H. Miller, *Toronto*
L. E. Rodway, *Calgary*
H. I. Thomas, *Edmonton*
J. Wartena, *London*

Transferred from the class of Student to that of Junior:

S. Narvey, *Toronto*
L. C. White, *Toronto*

The following Students were admitted:

University of British Columbia

L. T. Assimes — N. Malychuk
W. G. Botel — J. S. Mawdsley
N. P. Brooks — T. R. Meadowcroft
A. D. Bradshaw — R. Metzker
J. W. Carlyle — M. M. McKenzie
R. S. Charlton — J. A. McLean
C. Clark — E. Ounpuu
D. M. Davidson — W. E. Rusk
C. A. Day — S. Saimoto
G. G. Dempster — J. G. Sanderson
D. P. Dodge — R. A. Savage
A. D. Drummond — F. G. Schrack
J. H. Duerksen — W. J. Solonecki
H. A. Featherstone — J. R. Stanhope
R. M. Giegerich — J. G. Steeves
A. S. Haldeman — G. E. Taylor
J. D. Hankinson — B. A. Tweddle
D. G. Hay — G. A. Tzvetcoff
H. M. Hayward — J. Walsh
J. Jezioranski — J. A. Watson
R. G. Keech — J. W. Wedler
A. J. Kempe — O. R. Widholm
A. Kuhn — R. K. Wiltse
H. O. Lacy — E. V. Zydyk

University of Toronto

A. C. Emmott — G. J. Oliver
T. R. Fountain — A. G. Sale
R. B. McArthur — B. C. Wray
R. R. McCuaig

Queen's University

J. A. Barber — D. E. Srigley
G. F. O'Hara — K. Van Dalen
W. T. Patterson — J. D. West

Dalhousie University

W. G. Roberts

Ecole Polytechnique

G. Belanger

Nova Scotia Technical College

A. E. Creelman — E. C. J. J. O'Brien
J. D. Hodd — C. J. Scott
J. M. Marcinov — K. E. Tingley

University of New Brunswick

J. R. Holyoke — R. E. Platts
R. E. Ketch — J. A. Swim
F. E. Kimball

Mount Allison University

R. S. Butler — D. M. Watt
G. E. Frampton

McGill University

E. A. Asistores, Jr. — D. M. Palko

University of Alberta

J. S. Bereznicki

Loyola College

A. D. Greciano

Graduates

H. B. Fleming, B.A.Sc., (Chem.), Queen's, 1955.
K. Meipoom, B.Sc. (Civil), Toronto, 1955.
J. M. Tannenbaum, B.A.Sc., (Civil), Toronto, 1955.

Applications through Associations:

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members:

A. C. Dalrymple — L. R. Lauer
E. V. Hunt — R. E. Morton

Junior:

G. A. McNeill

Junior to Member:

R. N. Dalby — J. H. Keating

SASKATCHEWAN

Members:

E. Amendolagine — J. H. Heather
R. E. Anderson — G. J. McLeod
A. C. Cluff — H. van Hees
E. E. Erling — W. G. Wegenast

Students:

S. G. Bruskiewich — E. E. Lepine
L. B. Crawford — J. Martin
C. Fedosiewich — B.W. Mickleborough
G. F. Furse — J. R. Moar
R. M. Halyk — E. N. Parsons
H. M. Hill — E. C. Sherwin
D. M. J. Kent — E. A. Stumborg
M. H. Kuervers — R. B. Thompson

Junior to Member:

J. L. Campbell — R. C. Strayer
K. J. Newbert — D. C. Taylor

MANITOBA

Member:

J. Conrad

NOVA SCOTIA

Members:

J. H. Evans — H. Rounsefell
G. H. Lilly

Junior to Member:

K. R. Langille — J. E. Peters

News of Other Societies

American Society of Mechanical Engineers (29 West 39th St., New York, N.Y.). . . . The 1956 spring meeting will be held at the Multnomah Hotel in Portland, Oregon, March 18 to 21.

The full program, with 16 technical sessions of importance has been arranged. Several will be devoted to various phases of the wood industries. Also, there will be three sessions dealing with nuclear engineering, while other subjects on the program include material handling in airplane manufacture, power, fuels, gas turbines and material processing.

E.I.C. members will be welcome to attend without payment of a registration fee. Full particulars may be obtained from E.I.C. or ASME headquarters.

•

Canadian Electrical Association (Tramways Bldg., Montreal 1). . . . Divisions in the Western Zone will hold meetings at the Macdonald Hotel, Edmonton, March 19-21.

•

Canadian Institute of Timber Construction (150 Wellington St., Ottawa 4). . . . The 1956 annual meeting will be held on March 27-29, at the Royal York Hotel, Toronto.

The Chemical Institute of Canada (18 Rideau Street, Ottawa 2). . . . Schedule of meetings is as follows: February 23, conference of Protective Coatings Division, at the Royal York Hotel. Toronto; February 24, conference of Protective Coatings Division, Ritz-Carlton Hotel, Montreal; March 5-7, conference of Chemical Engineering Division, Guildwood Inn, Sarnia; May 28-30, annual conference and exhibition, Sheraton-Mount Royal Hotel, Montreal.

•

Cleveland Engineering Society (2136 East 19th St., Cleveland 15). . . . Design for Profit is the theme of the annual machine design conference, March 5, 1956.

•

Prospectors and Developers Association . . . Atomic Energy of Canada Limited will have an exhibit at the annual meeting of this association. Royal York Hotel, Toronto, March 5 and 6, 1956.

This exhibit will be open to the general public and staff members of A.E.C.L., Ontario Hydro, Canadian General Electric will explain exhibit material and discuss atomic energy developments and atomic power.

Thirty-five Years Ago

Comment on the *JOURNAL* of February 1921

Are we getting mature, is it a reflection of our changed corporate personality, have we less of which to be proud, or why is it that the official literature of the *Institute* is now a lot less colourful than it used to be? Take, for example, the reports for 1920 of Council and of its various committees as published in the *Journal* for February, 1921.

Council thought it "particularly gratifying to report the splendid professional meetings held during the past year", while the Committee on Policy lauded Council for having "established precedents which make the *Institute* one of the most progressive and practical professional engineering bodies in the English-speaking world. . . . In its support . . . of fundamentally important matters . . . the *Institute* gives place to no other comparable organization. . . . Progressive and often pioneer action . . . has been taken by the *Institute* . . ."

All of these statements may be quite true, but I doubt if any of us would express them as positively or in quite as flamboyant language today. By 1921 the *Institute* had proved to itself that it was a really important organization and it made no bones of saying so publicly. I think we are just as useful and important today as we were then—certainly we do a good deal more for our members—but we hesitate to make claims involving even a tinge of boastfulness.

A Report of Activities

Financially, the *Institute* wound up 1920 with a surplus of about $6,100, most of which was contributed by the *Journal*, whose advertising revenue had reached about $28,000. Some of this increase came through branch solicitations; the branches were being given a commission on any advertising they might sell. This was a bonanza to some of them; one collected $390 in a few months, almost enough to pay all its expenses for a year.

Our membership stood at 4,173, including 124 applications pending. It had grown by 836 during 1920, or by about 26 per cent. which must be a near record, if not a record. Almost every branch had an enthusiastic membership committee, actively engaged in rounding up all unattached engineers in its territory.

This large increase in membership brought the *Institute* face to face with problems of finance. More income had to be found if it were to continue to give its members the services they had been getting, let alone expand and improve. So a proposal to raise fees was submitted to the Toronto annual meeting, where it was soundly rejected. This action seems to have been taken only by those present at the meeting; there is no hint that absent members had any opportunity to vote by letter ballot.

There were 23 donations to the library during 1920, most of them pamphlets, including one entitled "Righteousness vs. Religion". Perhaps the author, one of our members, thought his fellows in need of redemption. I wonder if we still have the pamphlet and if it were ever circulated at all.

Six Technical Subjects Treated

The principal technical paper in this issue was "Mechanical and Electrical Equipment of the Toronto Union Station", by W. J. Armstrong, A.M.E.I.C., then associated with Ross & Macdonald, the architects of the building. Mr. Armstrong's detailed description showed that there was nothing very novel in most of the design. There was one noticeable feature, however. Steam for heating was purchased and the condensate did not have to be returned, so it was used for the domestic hot water supply, requiring only a little heating to bring it to the required temperature.

The whole east wing of the building was occupied by Postal Station A and was especially designed for that purpose. Here a complete system of conveyors for handling mail was installed, as well as galleries for the inspectors. Each inspector was to carry a portable telephone, which he could plug in at any of 40 stations to communicate with any other inspector on duty or to put through an external call. There was not much chance for a clerk to steal a letter with these bloodhounds watching him.

T. Linsey Crossley, A.M.E.I.C., had a paper on the Canadian pulp and paper industry in this *Journal*, which I found interesting. It was not very technical and would probably not appeal to a pulp and paper man, but to an outsider it gave a lot of information that he should have welcomed. Mr. Crossley was one of those rather rare engineers who can write well and with a touch of subtle humour. Did you know that our first paper was made at St. Andrews, Que., in 1803? And did you know that Mr. Crooks won a prize of £100 offered by Upper Canada for the first paper made in that province, beating John Eastwood and Colin Skinner by a few days only? With its statistics brought up to date, this paper would serve well as a general description of the Canadian pulp and paper industry today.

One can't say as much for "Present Day Illumination Standards", by G. C. Cousins. Artificial lighting in 1920 and in 1955 have little in common. We use equipment and methods undreamed of then, although our objectives are still much the same.

Mr. Cousins' paper was followed by "Municipal Engineering", by R. O. Wynne-Roberts, M.E.I.C. His contention was that the municipal engineer did not get the recognition to which he was entitled and he attempted to prove his case through historical references, backed up by a smattering of recent statistics. I must say that I was not much impressed by this paper, which I doubt if we would publish today.

In 1921 the activated sludge process of sewage treatment was new on this continent, though Houston, Tex., had a 15 million gallon plant and Milwaukee, Wis., was building a larger one. It was but natural, then, that the *Journal* should publish a paper on this topic by G. C. Nasmith. Some of Mr. Nasmith's tentative predictions have proved wide of the mark. For dewatering sludge he gave pressing little future, which turned out to be true, but he also thought centrifuging likely to become the standard method, which it has not. Apparently, vacuum filters had not then been considered: now they are the most commonly used apparatus.

In a well-written paper, Frank Barber, A.M.E.I.C., took issue with the *Institute's* standard specifications for concrete and reinforced concrete. While detailed with respect to design, he thought them much too loose in their clauses covering construction methods and materials; there was too much use of "if practicable", "approved", "as ordered by the engineer" and similar phrases. He believed it quite practicable to write much more precise clauses covering the construction side of concrete work, which would yet be fair to the contractor, and illustrated his points by copious quotations from his own specifications for bridge forms and centering.

Another paper on concrete was "On the Economics of Building Design", by J. M. Oxley, A.M.E.I.C. Though it occupied only seven pages in the *Journal*, it must have represented an immense amount of work, for it derived costs per square foot of floor for a selected type of concrete warehouse or factory of any number of stories from one to eight. Only the structural elements were considered; the costs of heating, plumbing, lighting, elevators, etc., would have to be added. Of course, the actual figures given are of little use today, but they might still be used for rough estimates if corrected by the application of the proper index numbers.

Perhaps I appreciate this paper more than most readers did, for I once had to make similar calculations for another type of structure. I ended with reams of calculations, but you could put the final results on a couple of sheets of paper.

A thumbnail biography of J. M. R. Fairbairn, M.E.I.C., the incoming president of the *Institute,* was given in this *Journal.* Jack Fairbairn was everything this note says he was and more, but I am willing to wager that the fulsome adjectives the writer dredged out of his subconscious embarrassed Jack. In fact, I think the whole note in rather poor taste.

Institute Business

Most of this *Journal's* editorial section was given over to a condensed account of the business transacted at the Toronto annual meeting in January, 1921. Nothing startling occurred, except, as I have already said, a proposal to increase membership fees was flatly rejected.

For the first time in several months a few letters from members were published. One described a simple method of binding the magazine into yearly volumes, another pleaded for a more responsible status for Juniors and the third attempted to explain the meaning of "subordinate engineer", as used in the proposed Ontario licensing act, not too successfully.

Branch news was pretty humdrum, though the Niagara Peninsula members were a little suspicious of the licensing act drawn up by the provincial section and refused to endorse it until some of their questions were answered.

Closing this *Journal,* there is only one question I want to have answered, "How did the *Institute* increase its income?" For that, I suspect I shall have to wait some months.

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Allan Keay Grimmer, M.E.I.C., mayor of Temiskaming, Ont., died in Temiskaming on January 1, 1956. Mr. Grimmer had been the mayor for 32 years.

Born in St. Andrews, N.B., on June 4, 1882, Mr. Grimmer received his B.A. degree from the University of New Brunswick in 1905, and his M.Sc. degree in 1907. During the summers of his university courses he was employed as rodman and instrumentman with the C.P.R. western Ontario surveys, and as resident engineer with York and Carlton Railway. After graduation he was city engineer at Fredericton, N.B., for three years before going to the University of Manitoba as assistant professor of civil engineering for one year.

From 1910 to 1915 Mr. Grimmer was city engineer at Medicine Hat, Alta., after which he returned to Fredericton to work as a consulting engineer. He designed and built the mechanical filtration plant for Woodstock, N.B., and other engineering works in the province. In 1918 he was employed on the reconstruction of Halifax after the explosion. Later he supervised the construction of a seaplane base in Sydney, N.S.

Mr. Grimmer went to Temiskaming in 1919 as town department engineer, later becoming town department manager for the Riordan Company, and its successor, Canadian International Paper Company Ltd. He retired as town department manager in 1952, but was retained as consultant by the company. Mr. Grimmer was in charge of the complete development of Temiskaming, incorporating modern installations of water, sewers, automatic telephone system, etc. He also supervised the construction of the Townsite of Thorne, Ont. He was chairman of all Victory Loan campaigns and of the ration board during World War II, and was regional chairman of the Canadian Federation of Mayors and Municipalities.

A. K. Grimmer, M.E.I.C.

He was a member of the American Water Works Association, the International City Managers Association, the Association of Professional Engineers of Ontario, and of the Corporation of Professional Engineers of Quebec.

Mr. Grimmer joined the Engineering Institute in 1910 as Associate Member and transferred to Member in 1920. He attained life membership in 1947, and served on the Council of the Institute in 1953.

Rupert Henry Vaughan, M.E.I.C., retired Department of Public Works engineer, died on November 3, 1955, at Oliver, B.C.

Mr. Vaughan was born in Sydney, Gloucester, England, on May 5, 1883, and received his general education at Tonbridge School, Kent, England. He studied engineering privately at Stony Stratford, Glasgow, and at Paisley, and then worked as a junior draughtsman at Arrol-Johnstone Motor Works at Paisley, and at Lanchester Motor Works in Birmingham.

Mr. Vaughan came to Canada in 1908 and joined the Esquimalt and Nanaimo Railway in British Columbia, working as rodman, leveller, and transitman, until 1915, when he went overseas with the British Expeditionary Force and served as a lieutenant. At the end of the war he returned to the railroad as assistant engineer of maintenance of way. In 1922 he joined the engineering staff of the Ocean Falls Pulp and Paper Company in B.C. and remained with them until 1933. From 1933 to 1937, Mr. Vaughan was in charge of relief camps in the Fraser Valley of British Columbia, and then joined the British Columbia Department of Public Works. as resident engineer at Duncan, B.C. He remained with the Department of Public Works until his retirement in August. 1955.

He became an Associate Member of the Engineering Institute in 1921 and transferred to Member in 1940. Mr. Vaughan attained life membership in the Institute in 1952.

LeRoy Brown, M.E.I.C., president and general manager of L. R. Brown & Company Ltd. in Sault Ste. Marie, Ont., died on September 10, 1955, in Sault Ste. Marie.

Born at Delhi, Ont., on August 23, 1891, Mr. Brown received his B.A.Sc. degree from the University of Toronto in 1915. After graduation until 1921 he worked in various capacities with the Toronto Chemical Company, the Algoma Steel Corporation, Dominion Tar and Chemical Company, and with the Newfoundland Power and Paper Company at Cornerbrook, Nfld.

Mr. Brown was city engineer of Sault Ste. Marie from 1921 to 1926. From that time on he was engaged in private construction work, and since 1934, under the name of L. R. Brown and Company Ltd.

He joined the Engineering Institute as a Student in 1914, transferred to Associate Member in 1917 and to Member in 1940. Mr. Brown was an active member of the Sault Ste. Marie Branch of the Institute, having served as a councillor in 1948 and 1950.

Henri A. Gibeault, M.E.I.C., former director of Public Works for the City of Montreal, died on November 5, 1955, at his home in Montreal.

Born in Montreal on April 1, 1885, Mr. Gibeault graduated from the College de Montreal and received his civil engineering degree from the Rensselaer Polytechnic Institute in 1908. Following graduation he was named associate professor in civil engineering at Villanova College in Philadelphia. Returning to Canada in 1914, Mr. Gibeault became assistant engineer of municipal improvements for the town of St. Lambert, Que. In 1920 he was appointed to the position of chief examiner of the Montreal Municipal Service Commission.

Two years later he joined the Montreal Public Works Department as assistant to the director, becoming assistant director in 1930, and also assistant chief engineer for the city in 1937. In 1942 Mr. Gibeault became director of the Public Works Department, the position he held until his retirement last year. His services were retained, however, by the city after his retirement, as consultant in connection with the St. Lawrence Seaway.

Mr. Gibeault was a member of the Canadian Institute of Sewage and Sanitation, the American Public Works Association, and the Corporation of Professional Engineers of Quebec.

He became an Associate Member of the Engineering Institute in 1915 and transferred to Member in 1940. Mr. Gibeault had attained life membership in the Institute in 1951.

Walter A. Rush, C.B.E.I., M.E.I.C., former controller of radio for the Department of Transport, died in Ottawa on September 27, 1954.

Mr. Rush was born in London, England, on April 25, 1880. He graduated from Faraday House in London, receiving honours in technical and theoretical courses in electrical standardization testing and training. He received his early experience with British electrical firms, among them the Bristol Corporation Electric Light and Power Works.

In 1905, Mr. Rush came to Canada and joined the Marconi Wireless Telegraph Company of Canada and was engaged on the construction and operation of radio stations on the east coast. He was engineer in charge of the Cape Race station in Newfoundland in 1911. He joined the Department of Naval Services in 1912 as chief inspector of the wireless service, and when radio came under the Department of Marine and Fisheries in 1922 he was named division superintendent of radio telegraph services. In 1936 the newly-formed Department of Transport named him controller of radio for the air services branch.

Mr. Rush represented Canada at numerous international conferences on radio from the North American Radio Communications Conference in Ottawa in 1929, and the International Radio Consulting Committee at The Hague the same year, to the Commonwealth Communications Council meeting in London and the Third Inter-American Telecommunications Conference in Rio de Janeiro in 1945.

During both world wars Mr. Rush was engaged on setting up coastal radio detection stations for locating German submarines and intercepting their short wave messages. During the second world war he developed the intricate radio system needed to support the expanded R.C.A.F. and the British Commonwealth Air Training Plan and the Ferry Command.

Mr. Rush was credited with many substantial contributions to the development of radio, radio communications and its adaptation to radar in Canada. He retired nine years ago after 34 years with the federal government.

He was a Fellow of the Institute of Radio Engineers, and served as vice-president of that organization in 1942. He also received a medal in 1946 from the Professional Institute of Civil Engineers of Canada, and that same year was awarded his C.B.E.

Mr. Rush became an Associate Member of the Engineering Institute in 1921, and a Member in 1940. He attained life membership in the Institute in 1951.

Alan MacKenzie James, M.E.I.C., lands and rights engineer and rural electrification engineer with the Nova Scotia Power Commission, died on October 16, 1955, at his home in Halifax, N.S.

Mr. James was born at Halifax on November 8, 1890. He received his B.Sc. degree from Dalhousie University and then studied mining engineering at Nova Scotia Technical College. From 1915 to 1919 he was on active service with the Canadian Field Artillery in France and England.

Returning to Canada, Mr. James was employed for a time as manager of Dunbrack Lead Silver Mine at Musquodoboit, N.B., and then in 1920 he joined the Nova Scotia Power Commission as engineer on field surveys, subsequently becoming rural electrification and land and rights engineer with the commission at Halifax.

Mr. James became a Member of the Engineering Institute in 1940.

Henry Morton Lake, M.E.I.C., special engineer with Algoma Steel Corporation Ltd. in Sault Ste. Marie, Ont., died on October 26, 1955 in Sault Ste. Marie.

Mr. Lake was born in Toronto on July 18, 1890, and received his general education in Willesdon, London, England. While working as machinist and fitter with the Grand Trunk Railway at Lindsay, Ont., he followed engineering studies through International Correspondance Schools. In 1910 he was employed as a draughtsman with Algoma Steel Corporation Ltd. During the first world war Mr. Lake was in business for himself working on structural steel design and fabrication.

At the end of the war he rejoined Algoma Steel as assistant chief draughtsman, and in 1925 became chief draughtsman and assistant chief engineer for the company, a position he held until 1954. Mr. Lake was then named special engineer for the company, the position he held until his death.

Mr. Lake became a Member of the Engineering Institute in 1944.

Harry Stanley Rimmington, M.E.I.C., bridge engineer for the Canadian National Railways at Winnipeg, died on October 24, 1955 in Winnipeg, Man.

He was born in Toronto on December 7, 1890, and received his early education there at Harbord Collegiate. Entering the University of Manitoba in 1907, he graduated in the first engineering class of that university in 1911, receiving a degree of bachelor of civil engineering.

Upon graduation Mr. Rimmington began his 45 years of continuous service with the bridge department of the Canadian National Railways. He progressed through positions of assistant engineer, designing engineer, assistant bridge engineer, and in 1945, was named bridge engineer for the western region of the C.N.R.

Mr. Rimmington was a member of the American Railway Engineering Association, and of the Association of Professional Engineers of Manitoba, having been president of the latter organization in 1944.

He became a Member of the Engineering Institute in 1952.

Ontario

Merritt W. Hotchkin Elected President

Nearly a half century of active participation in most of the western hemisphere's mining fields has done nothing to dull the lustre and challenge of such a vocation in the eyes of Merritt Windes Hotchkin, newly-elected president of the 14,000-member Association of Professional Engineers of Ontario.

M. W. Hotchkin

Mr. Hotchkin, a resident of Kirkland Lake, Ontario, assumed the Association's highest office in January, succeeding John R. Montague, of Toronto.

In his career as prospector, mining engineer and geologist, he has worked in many of the active mining areas of Canada and the United States.

He is currently associated with Wright-Hargreaves Mines Ltd., as engineer-in-charge of outside exploration.

Born in Chicago, the son of a medical doctor, Mr. Hotchkin plunged into the practical end of mining even before he graduated from Michigan School of Mining and Technology, class of 1908. For one and a half years prior to graduation, he worked in the mining and milling industry in western United States and Alaska.

After receiving his B.S. degree in mining, he spent the first three years prospecting the Gowganda and Porcupine areas with an associate and discovered in Porcupine what he described as "an economic deposit of gold ore", that is currently producing.

His find was sold to copper king F. Augustus Heinzie and with part of the proceeds, he bought control of a group of mining claims in the Kirkland Lake district, now known as Sylvanite Gold Mines Ltd.

Shortly afterwards, he began engineering work at the Tough Oakes Gold Mines Ltd., owned by the late Sir Harry Oakes and associates; and soon was its manager. However, production ceased shortly after the outbreak of World War I when the rich surface vein systems were cut off by extensive north and south faulting in the rock.

During the war, Mr. Hotchkin worked for the British Imperial Munitions Board under the late Sir Henry Flavelle, in Ottawa, and was in charge of molybdenite production, a metal used in the hardening of steel for airplane crank shafts and for making armor-piercing shells. In 1917 he was awarded the degree E.M. (Engineer of Mines) for accomplishment in the mining industry.

Following World War I, he returned to his mining engineering career, carrying out base metals exploration for himself throughout Canada, certain states in the United States and Mexico.

Then in 1929, when the base metal industry had reached its peak and began to decline, he joined forces with two friends in a small exploration company. Mr. Hotchkin's job was to find a gold mine for the company.

He recommended the Tough Oakes mine, despite discouraging reports from engineers and geologists. Unable to raise funds for exploration work, in Canada, he went to New York and interested the American Smelting and Refining Company in its potential. One year later, after exhaustive examination and detailed underground geological mapping, Mr. Hotchkin located the faulted portion of the high grade ore body, which turned out to be one of the richest gold veins found in Canada. Between 1932 and 1953 when it was closed down, Toburn Gold Mines Ltd., with Mr. Hotchkin as general manager, produced some $15,000,000.

In addition to being general manager of Toburn he was assigned the duties of vice-president and managing director of Asarco Exploration Company of Canada Ltd., a wholly owned subsidiary of the American Smelting and Refining Company of New York.

Following his retirement from Toburn in 1953, he returned to his "first love"—exploration work, and became associated with the Wright-Hargreaves Mines as engineer in charge of outside exploration, a position he currently occupies.

Married, with two married children, Merritt Hotchkin lives with his wife in Kirkland Lake. He is an active sportsman, with curling and golf his chief pastimes. He has been active in northern Ontario baseball and hockey association work and civic affairs and is also vice-president of the Canadian Seniors Golf Association (for golfers over 55).

He is also one of the few men to be an honorary life member of the Canadian Legion, an honour bestowed upon him in 1947 for his active interest in that organization.

In addition to his affiliation with the A.P.E.O. since 1937, he is a past president of the Ontario Mining Association, a member of the American Institute of Mining and Metallurgical Engineers and a past vice-president of the Canadian Institute of Mining and Metallurgy and also a Fellow of the Geological Association of Canada. He is also a 32nd Degree Mason, a Knight Templar and a member of Rameses Shrine.

News of Members

R. F. Legget, of Ottawa, director of the Division of Building Research of the National Research Council, attended the recent annual meeting of the Geological Society of America in New Orleans and spoke on the Division's permafrost research work taking place at Uranium City, Sask.

Department Heads Are Named

Relative to the recently established electric products department of Linde Air Products Company, a division of Union Carbide of Canada Ltd., several appointments have been announced. These include the appointment of **F. Gordon Murphy**, as general manager of the new department and of **John W. Ross**, as operations manager of the new electric products department.

Mr. Murphy, a mechanical engineering graduate of the University of Toronto, has been with Linde Air Products Company and its predecessor, Dominion

Oxygen Company, for the past ten years and for the past two years has been central district manager. Mr. Ross, also a Toronto graduate in mechanical engineering, has likewise been with the organization for ten years and for the last year has been manager of engineering services.

A. S. Robertson Retires

After 41 years of service with the Hydro-Electric Power Commission of Ontario, **A. S. Robertson,** of Niagara Falls, Ont., has retired from his position as manager of the Niagara Region.

A 1914 graduate in electrical engineering of the University of Toronto, Mr. Robertson joined Hydro the same year. For many years he has been recognized as an authority on operations, generation and plant design and has held the position of manager of the Niagara Region since 1948. One highlight of his Hydro career was his work in connection with the construction of the Queenston-Chippawa development, now known as the Sir Adam Beck Niagara Generating Station No. 1, and at one time the largest hydro-electric plant in the world.

G. Ashley Hutchinson has been appointed executive vice-president and director of Eddy Match Company Ltd. in Pembroke, Ont.

Mr. Hutchinson, a native of Ottawa, served as a navigation officer with the R.C.A.F. during World War II. He is a graduate mechanical engineer of Queen's University, Kingston, and of the management training course of the University of Western Ontario, London. He joined Eddy Match Co. Ltd., during 1955 as executive assistant to the president of that company.

M. C. Hart is now associated with Filtro Electric Limited, 5 Parnell Avenue, Toronto 13, in the capacity of plant superintendent. Prior to accepting this new position, Mr. Hart, who graduated in mechanical engineering from the University of Toronto in 1949, was plant engineer of the Scarborough plant of Link-Belt Limited.

P. Guy Money has been appointed general manager of Aceromex Atlas S.A., Ayuntamiento 158, Mexico 1, D.F. This company is the exclusive representative and distributor of Atlas Steels Ltd., of Welland, Ont.

H. L. Coons has announced that the name of the firm of engineering consultants, King Coons, Ltd., has been changed to Herbert L. Coons and Associates Limited, with offices at 194 Bloor Street West, Toronto.

Lester W. Childs is president of Cummins Diesel Michigan Inc., 3601 Gratiot Avenue, Michigan. **J. S. L. Shales** is vice-president of the company which handles the sales and service of Cummins diesel engines in the southern peninsula of Michigan and the northwest counties of Ohio.

K. C. Mohun is with Iroquois Constructors Ltd., at Cornwall, Ont., as cost engineer.

James E. Twiss has moved from Copper Cliff to Toronto where he is assistant chief electrical engineer of the R. M. Way and Company, Ltd., of 696 Yonge Street, Toronto. Mr. Twiss was formerly assistant to the electrical superintendent of The International Nickel Company Ltd., in Copper Cliff, Ont.

W. A. Jackson has resigned the position of vice-president of Gaswell Construction Ltd., Kirkland Lake, and as of the first of this year accepted the post of general superintendent of North Shore Construction Co. Ltd., in Quebec.

W. H. Martin, of Hamilton, Ont., has established a consulting service through Martin Engineering Inc., of Montreal and Toronto, and Martin Industrial Sales, Ltd., of Hamilton, in vibration analysis and source detection in balancing of rotating components on industrial machinery and equipment. He is also engaged in the training in the use of the IRD vibration analyzer, an electronic instrument designed by the International Research and Development Corporation of Columbus, Ohio, for whom Mr. Martin has been recently appointed as Canadian representative.

Allan M. Luce, of the Department of Transport, has been transferred from the Welland Canals Branch to Ottawa where he is operating engineer at the Department's Canal Services Headquarters.

Mr. Luce graduated from Queen's in 1948 and shortly after joined the Department.

Raymond J. Neals has moved to Toronto from La Tuque, Que. and is in the technical service department of Electric Reduction of Canada Ltd., 321 Davenport Road, Toronto. Mr. Neale is technical service engineer in the pulp and paper section.

Robert A. Wilbur, president of Ajax Engineers Ltd., has announced that the company's offices have been moved from Howland Avenue, Toronto, to 260 Merton Street. Mr. Wilbur is also president of Marley Canadian Ltd.

George Forrester is employed in the manufacturing engineering department of Ford Motor of Canada Ltd., at Oakville, Ont., and is now living in Port Credit. Mr. Forrester was previously in the methods engineering department of Lever Bros. Ltd., Toronto.

James W. Speight has joined the staff of P.S.C. Applied Research Ltd., of Toronto, after many years with the research division of the Hydro-Electric Power Commission of Ontario in Toronto.

G. L. Reist, of St. Catharines, Ont., has accepted the position as chief supervisor, Chatham area, of the frequency standardization division of Canadian Comstock Co. Ltd. His new headquarters will be in Chatham.

Prior to the move Mr. Reist was with Sterling Electric Co. Ltd., of St. Catharines.

Lieut. Col. G. W. Thompson has been reposted from Army Headquarters, Ottawa, where he was assistant director, in charge of plans and training, of the Directorate of Electrical and Mechanical Engineering, to Ortona Barracks, Oakville, Ont., where he is Central Command electrical and mechanical engineer.

W. David Hargraft has left the chemical division of the Shell Oil Co. of Canada Ltd., and is now engaged in industrial sales with Gypsum Lime and Alabastine Ltd., 50 Maitland Street, Toronto.

J. J. Marta, of Canadian Liquid Air Co. Ltd., has been transferred from Vancouver, B.C. to the Toronto offices of the company.

H. A. Mitchell is now located in Buffalo, N.Y. and is with the production control department of The Rudolph Wurlitzer Co., North Tonawanda, N.Y. Mr. Mitchell was earlier with Fleet Manufacturing Ltd., of Fort Erie, Ont.

Reginald S. Gray, formerly an assistant engineer in the electrical department of the Toronto Transportation Commission, has accepted the appointment of electrical engineer with H. H. Angus and Associates Ltd., consulting engineers, Toronto.

British Columbia

Engineers in the News

H. W. Poole has been appointed superintendent of the Sullivan Concentrator, Kimberley, according to an announcement by **W. G. Jewitt,** assistant general manager of mines of the Consolidated Mining and Smelting Company. In his new position, Mr. Poole will assume part of the duties previously carried out by **A. C. Robertson,** who, as Cominco's superintendent of concentration, continues to have overall responsibility for all of the company's mills and concentrators.

H. L. Fritz is manager and vice-president for the industrial electrical contracting firm, The Tide Company (B.C.) Ltd., which has established headquarters at the Annacis Island industrial development in New Westminster. Mr. Fritz, registered as an engineer both in Canada and the United States, was formerly with the parent company of the new concern, the Tide Company of Tacoma, Washington. Prior to that, he was the district engineer for the City of Tacoma.

M. D. E. Robinson has been appointed manager of engineering service in the western district of Linde Air Products Company, a division of Union Carbide Canada Ltd. Mr. Robinson will be located in Vancouver.

E. G. Taylor has been appointed an associate on the staff of R. J. Cave and Associates. Mr. Taylor, who heads the municipal and civil engineering department of the firm, was until recently with the Directorate of Works (Army), Department of National Defence, Ottawa.

H. M. Anderson formerly with the B.C. Forest Service, has accepted a position with the Interior Spruce Mills at Prince George.

A. W. Holloway, of Crown Zellerbach Canada Ltd., has been loaned to the Pulp and Paper Industrial Relations Board to make a special survey. He will leave Ocean Falls to reside temporarily in Vancouver while on the project.

P. Knight has accepted a position with Phillips, Barrat and Partners. He was previously employed by the B.C. Engineering Company.

E. L. McPherson, previously of the B.C. Electric Company, has accepted a position in the electrical engineering department of H. A. Simons Ltd.

Personals

News of the Personal Activities of Members of the Institutes

Joseph M. Breen, M.E.I.C., president and general manager of Canada Cement Company Ltd., was recently appointed a director of Du Pont of Canada Securities Ltd. and its operating company, Du Pont Company of Canada Ltd.

A native of Toronto, Mr. Breen is also a director of the Montreal Trust Company, Canadian Refractories Ltd., and the North American Life Assurance Company.

Beginning with Canada Cement in 1922 after his graduation from the University of Toronto, he served as technical engineer from 1922 to 1934 when he was appointed chief of the company's technical staff in Montreal. He became assistant general manager in 1947, executive vice-president and general manager and a director the following year, and then president and general manager in 1949.

F. Gordon Murphy, M.E.I.C., has been appointed general manager of the newly organized electric products department of Linde Air Products Company, division of Union Carbide Canada Ltd., in Toronto.

Mr. Murphy graduated from the University of Toronto in 1940 with a B.A.Sc. degree in mechanical engineering and has been on the staff of Linde Air Products and its predecessor for the past ten years. He has held a number of positions in the field in both the Ontario and Quebec areas and for the past two years has been central district manager.

F. G. Murphy, M.E.I.C.

He is a member of the American Society for Metals, the Canadian Welding Society, and the Society of Automotive Engineers.

John W. Ross, M.E.I.C., has been appointed operations manager of this newly formed electric products department of Linde Air Products Company.

He graduated from the University of Toronto in 1941 with a B.A.Sc. degree in mechanical engineering and has held various supervisory positions with Linde Air Products for the past ten years, acting in the capacity of manager of engineering service for the past year.

John W. Ross, M.E.I.C.

Mr. Ross is a member of the American Society of Metals and of the Association of Professional Engineers of Ontario.

Dean Adrien Pouliot, M.E.I.C., head of the faculty of science at Laval University, has been appointed vice-chairman of the Canadian Broadcasting Corporation board of governors. He has been a member of the board since 1939.

A well-known lecturer, Dean Pouliot holds an honorary degree of doctor of applied science from Laval University, an honorary doctorate of laws from the University of Montreal, and the Grande Medaille d'Honneur des Ingenieurs—Docteurs de France from the University of Ottawa.

J. M. Breen, M.E.I.C.

He is a member of La Societe Mathematique de France, American Mathematical Society, and the Canadian Institute of Mining and Metallurgy, among others. He served as vice-president of the Corporation of Professional Engineers of Quebec in 1950.

Dr. Thomas H. Hogg, M.E.I.C., a past-president of the Engineering Institute, has been elected a director of Philips Electrical Company Ltd. An internationally known consulting engineer, Dr. Hogg is also a director of John Inglis Company, Chartered Trust Company, Anglo Canadian Wire Rope Company, British Newfoundland Corporation, and English Electric Company, among others.

From 1913 to 1947 Dr. Hogg served with the Hydro-Electric Power Commission of Ontario, starting his career as assistant engineer and finally becoming, in 1937, chairman and chief engineer of the Commission. He retired from the Commission in 1947 and since then has been actively engaged as a consultant to the Federal Government on hydraulic matters and western water problems. He has also been on the Senate of the Uni-

• Personals

versity of Toronto for many years, having graduated from that university in 1908 with a degree of B.A.Sc. His professional degree of C.E. was won in 1912, and the degree of D.Eng. (honoris causa) in 1927.

Dr. Hogg, who joined the Engineering Institute in 1904, served as president of the Institute in 1940. He received the Sir John Kennedy Medal of the Institute in 1948, and also attained life membership in the Institute that year.

E. D. Gray-Donald, M.E.I.C., vice-president, personnel and public relations, of the Shawinigan Water and Power Company in Montreal, has been elected chairman of the Montreal Branch of the Engineering Institute. He is also vice-president and director of the Quebec Power Company in Quebec City.

Born at Amoy, China, he came to Western Canada at an early age, and was educated at Collegiate School, Victoria, B.C. In 1915 he went to Great Britain and completed his schooling at George Watson's College, Edinburgh. Subsequently he worked at Vickers Ltd., in London, and after the war spent two years in Palestine on general engineering work, returning to Canada in 1921.

He attended McGill University and graduated in 1926 with a B.Sc. degree in electrical engineering. After postgraduate work at Laval University he received the degree of M.ès. Sc. in 1934.

In June, 1926 Mr. Gray-Donald joined the Shawinigan Water and Power Company and followed its apprenticeship course, being transferred to the Quebec Power Company in 1927. He filled successively the positions of assistant superintendent and superintendent of the power division; assistant general superintendent, and from 1937 to 1942, general superintendent of the Quebec Power Company and the Quebec Railway, Light & Power Company. He was then appointed chief engineer of both companies in 1942, and then vice-president and chief engineer of the Shawinigan Water and Power Company in 1950. He was appointed to his present position in 1954.

Mr. Gray-Donald is a member of the Institution of Electrical Engineers

E. D. Gray-Donald, M.E.I.C.

J. Macé, M.E.I.C.

(Great Britain), the American Institute of Electrical Engineers, the Society of Automotive Engineers, the Canadian Electrical Association, and the Corporation of Professional Engineers of Quebec.

He is very active in the affairs of the Institute, having served on the Council in 1942, 1948 and 1953. He was chairman of the Quebec Branch of the Engineering Institute in 1944. He first joined the Institute in 1922 as a Student.

Major-General N. E. Rodger, C.B.E., C.D., M.E.I.C., has assumed the appointment of vice-chief of general staff at Army Headquarters in Ottawa. He was formerly general officer commanding Prairie Command at Winnipeg, Man.

Maj.-Gen. Rodger is a graduate of the Royal Military College and of McGill University. He was appointed to a commission to the R.C.E. in 1928 and in 1939 held the rank of major. From December 1941 until September 1942, with the rank of lieutenant-colonel, he was personal assistant to **General A. G. L. McNaughton,** M.E.I.C. Subsequently he became brigadier general staff, 2nd Canadian Corps, in which capacity he served until the end of the war. After the war he was appointed to the Canadian Army Staff at Washington, D.C. Major-General Rodger was quartermaster general of the Canadian Army for five years and then in 1951 attended a senior officers' course in England prior to his appointment at Winnipeg.

J. M. Macé, M.E.I.C., has been appointed assistant district sales manager (eastern) with Northern Electric Company Ltd. in Montreal. He was previously manager of wire and cable sales, eastern district, for the company.

Mr. Macé graduated from McGill University in 1935 with a bachelor's degree in electrical engineering. He joined Northern Electric in 1936 in the power apparatus sales department.

During the war he was named sales engineer for marine power and degaussing equipment. In 1946 he was transferred to the rural electrification department and was made manager at Quebec City the following year. He was named manager of rural electrification and power company sales for the eastern district in 1950, and then became manager of wire and cable sales the following year.

Mr. Macé is a member of the Corporation of Professional Engineers of Quebec, and of the American Institute of Electrical Engineers.

Andrew G. Watt, M.E.I.C., has been appointed vice-president and general manager of the structural steel division and of the warehouse division of Consolidated Steel Corporation Limited in Saint John, N.B. He was previously

A. G. Watt, M.E.I.C.

general manager for the Corporation.

A native of Scotland Mr. Watt came to Canada in 1927 and joined Canadian Vickers Limited in Montreal as structural draughtsman. In 1929 he went to Saint John, N.B., where he was chief draughtsman with Saint John Drydock and Shipbuilding Company Ltd. for eleven years and personnel manager for two years.

Mr. Watt joined Foundation Maritime Limited in 1942 at Pictou, N.S., as personnel manager; and he was industrial relations and personnel director of Fergusson Industries of Pictou from 1943 to 1945, when he returned to Saint John Drydock and Shipbuilding Company Ltd. as chief draughtsman of the structural steel division, becoming assistant chief engineer in 1950. He joined the Consolidated Steel Corporation in 1954.

Mr. Watt is an active member of the Saint John Branch of the Institute and was chairman of the Branch in 1953. He was elected to serve on the Council of the Institute last year.

W. H. Price, M.E.I.C., has been appointed assistant general manager of Mid-Western Industrial Gas Ltd. in Edmonton, Alta.

A 1949 graduate in chemical engineering from the University of Alberta, Mr. Price joined Mid-Western in 1952 and has progressed from the position of field engineer to chief engineer, the position he held at the time of his new appointment.

Mr. Price has previously been with The Petroleum and Natural Gas Conservation Board.

Jacques Lemieux, M.E.I.C., consulting engineer and partner in the firm Cote, Lemieux, Carignan & Bourque in Sherbrooke, Que., is the new chairman of the Eastern Townships Branch of the Engineering Institute.

Mr. Lemieux received his general education at St. Charles Seminary in Sherbrooke, Que., and then graduated from Ecole Polytechnique in 1944 with a B.A.Sc. degree in mechanical and electrical engineering.

• Personals

Upon graduation he joined the Department of Public Works working on bridge construction in Quebec province. In 1945 Mr. Lemieux became a partner in the firm of Crépeau, Coté and Lemieux in Sherbrooke, and in 1952 he became a member of the firm of Coté, Lemieux, Carignan & Bourque, professional engineers and Quebec land surveyors, also located in Sherbrooke, Que.

Mr. Lemieux joined the Engineering Institute as a Student in 1941, transferred to Junior in 1946, and to Member in 1951. In 1951 he was also one of the charter members of the Eastern Townships Branch of the Institute.

J. Lemieux, M.E.I.C.

K. E. Bentley, M.E.I.C.

Kenneth E. Bentley, M.E.I.C., a senior engineer in the engineering division of Imperial Oil Limited, manufacturing department, has been elected chairman of the Sarnia Branch of the Engineering Institute of Canada.

Born in Billtown, Nova Scotia, he attended Acadia University and later Nova Scotia Technical College where he graduated in civil engineering in 1934.

Mr. Bentley has been with Imperial Oil Limited since graduation, working in various capacities at their Halifax Refinery, until 1949 when he transferred to Sarnia. Presently, he is project coordinator in connection with the rebuilding and modernization of Halifax Refinery.

Paul M. Smith, M.E.I.C., has now joined the St. Lawrence Seaway Authority as division engineer in Beauharnois, Que. He was previously with William R. Souter & Associates, Hamilton, Ont. architects, and was employed as superintendent of the plant extension to the Chrysler Corporation of Canada in Windsor, Ont.

Mr. Smith graduated in 1942 from Ecole Polytechnique in civil engineering and has also been associated with Surveyer, Nenniger & Chenevert, consulting engineers in Montreal. He has also spent some time in India as construction engineer of the Kande Ela Reservoir Scheme at Nuwara, Eliya, and on other irrigation projects.

Fred L. Doty, M.E.I.C., branch manager of the wholesale department of Canadian General Electric Company Ltd. at Saint John, N.B., has been elected chairman of the Saint John Branch of the Engineering Institute.

Mr. Doty graduated in 1942 from the University of Toronto with a B.A.Sc. degree in electrical engineering. He

joined the General Electric test course at Peterborough, Ont., immediately following his graduation and then spent four years in the commercial department of the head office. He was transferred to Saint John as apparatus sales engineer for two years, and then to Montreal in the same capacity for three years. He returned to Saint John in 1952 as branch manager of the wholesale department.

He became a Member of the Engineering Institute in 1952.

C. V. Davies, M.E.I.C., has been appointed erection engineer for Canadian Bridge Company Ltd. at Walkerville, Ont.

Mr. Davies graduated from Queen's University in 1947 with a civil engineering degree, and then joined Canadian Bridge as a draughtsman. He was named assistant erection engineer in 1950.

He is a member of the American Welding Society, and the Association of Professional Engineers of Ontario.

Morris Katz, M.E.I.C., who is chairman of the Canadian section of the Technical Advisory Board on Air Pollution, has also accepted an appointment as consultant on atmospheric pollution for the Department of National Health & Welfare in Ottawa.

Mr. Katz is a graduate of McGill University, having received his B.Sc. degree in 1926, his M.Sc. degree in 1927 and his Ph.D. degree in 1929. He joined the National Research Council in Ottawa in 1930 as a research chemist.

J. B. Delage, M.E.I.C., has joined the Department of Public Works of Canada as senior engineer, Quebec district. He has previously been with the Department of National Defence in Quebec City, Montreal and Chilliwack, B.C.

Rowland H. Stokes-Rees, Affil.E.I.C., who is a director of the Rubenstein Brothers Company, is now also president of Hydrotechnic Limited, which is also in Montreal.

Mr. Stokes-Rees has previously been vice-president of the Kaiser engineers division of Henry J. Kaiser Company (Canada) Ltd., Montreal.

Donald G. Dunbar, M.E.I.C., is now in Vancouver, B.C. with Crippen Wright Engineering Ltd. He was formerly in New York with the electrical engineering division of the American Gas & Electric Service Corporation.

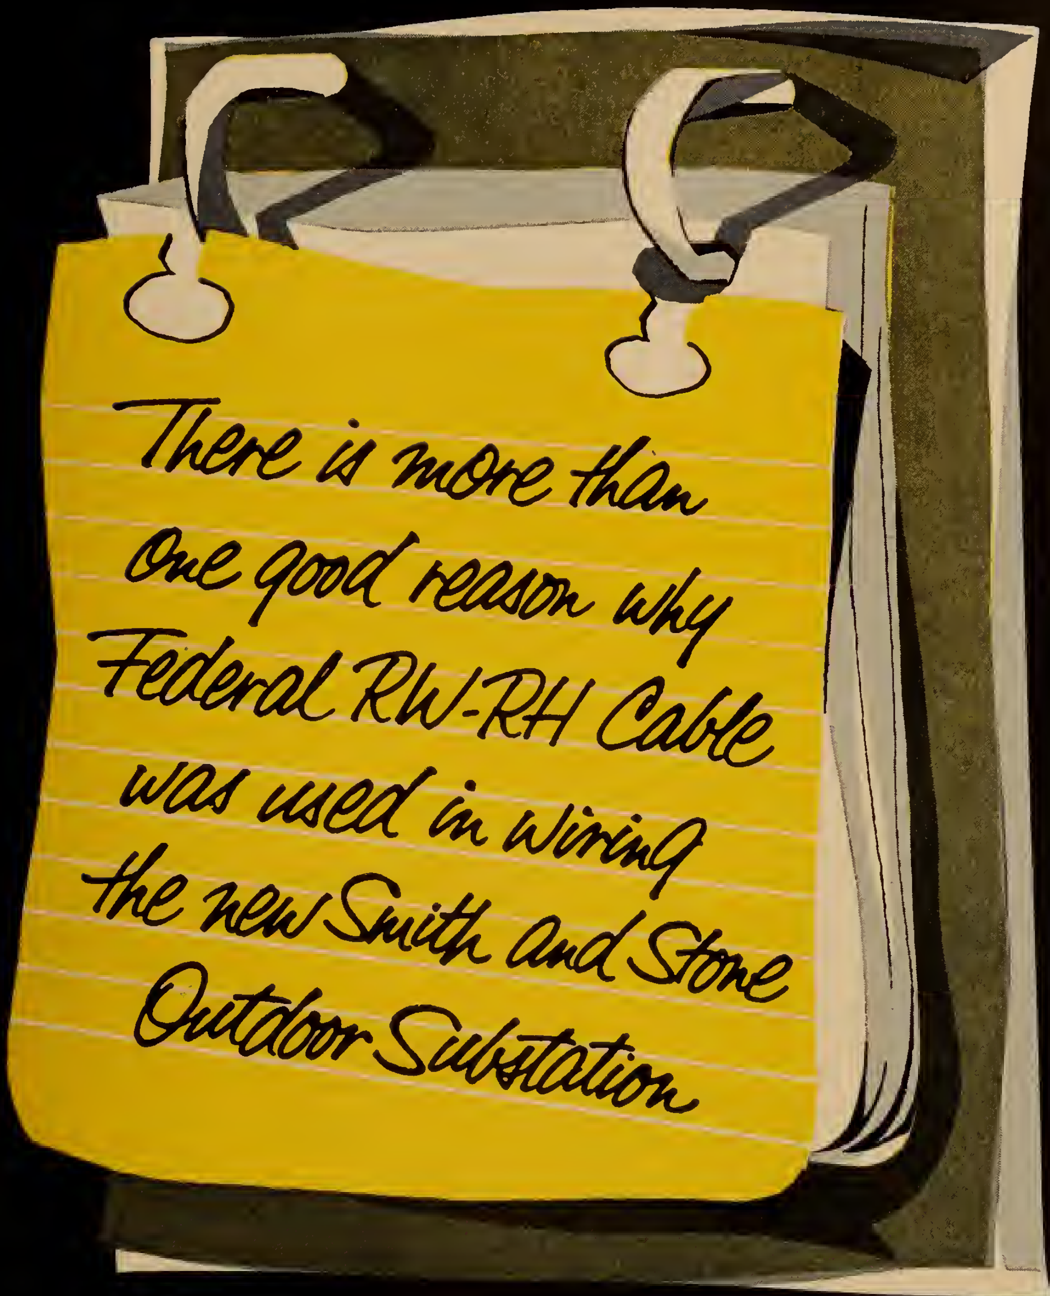
A 1949 civil engineering graduate of the University of British Columbia, Mr. Dunbar has previously been in Vancouver with International Engineering working on the design of the Kemano-Kitimat transmission lines for the Aluminum Company of Canada.

R. A. Shier, M.E.I.C., has been named assistant chief engineer with the Board of Transport Commission in Ottawa, Ont.

Mr. Shier, a civil engineering graduate of Queen's University, was formerly in Calgary, Alta. with the Board of Railway Commissioners as district engineer. He has also been division engineer with the Canadian National Railway at Belleville, Ont.

Fred Doty, M.E.I.C.

H. Matthews, M.E.I.C., has been named chief engineer of Victoria Machinery Depot Company Ltd. in Victoria, B.C. He has been chief engineer and plant manager of Vancouver Iron Works Ltd. and Vancouver Engineering Works Ltd. prior to this new appointment. He had been with these companies since 1928.



The Wire . . . Federal 500,000 CM Type RW 60^{C}—RH 75^{C}

The Purpose . . . To carry low voltage power (1350 KVA) from the new outdoor substation underground into the new Smith and Stone Plastics Plant.

The Reasons: Federal RW Cable has moisture resistant qualities that more than meet CSA requirements for underground wiring.

FEDERAL Wire and Cable Company Limited

GUELPH, ONTARIO

• *Personals*

T. H. Dobbin, M.E.I.C., commissioner of works for the City of Sarnia, Ont., has been elected secretary-treasurer of the Sarnia Branch of the Engineering Institute.

A native of Rothesay, N.B., Mr. Dobbin gained early experience working in building construction and land surveying prior to the Second World War. During the war he served six years with the R.C.E. From 1945 to 1949 he was employed as assistant city engineer at Fredericton, N.B., and also in 1949 he graduated from the University of New Brunswick with a degree in civil engineering.

Then Mr. Dobbin joined H. G. Acres and Company at Niagara Falls, Ont. and at Pine Falls, Man. In 1950 he was appointed assistant director of works for the City of Saint John, N.B., and then in 1952, became commissioner of works at Sarnia.

Mr. Dobbin joined the Institute as a Student in 1947 and then transferred to Member in 1950.

E. G. DeWolf, M.E.I.C., is with the Canadian Gypsum Company at Windsor, N.S., having previously been in Sarnia, Ont. with Sifto Salt Limited as works manager.

Mr. DeWolf graduated from Nova Scotia Technical College in 1944 with a bachelor's degree in engineering. He was with Maritime Industries Limited at Amherst, N.S. as assistant plant superintendent in 1949, and then joined the Prairie Salt Company, a division of the Dominion Tar & Chemical Company at Unity, Sask., as manager. He went to Sarnia in 1954 to join the Dominion Salt Company.

R. P. Charbonnier, M.E.I.C., is now scientific officer with the Department of Mines and Technical Surveys, fuels division, at Edmonton, Alta. He was previously with the same department at Calgary, Alta., working on research in coal preparation.

D. R. Brown, M.E.I.C., has moved to the United States and is working as a design engineer with the Mobay Chemical Company in Affton, Missouri. He was previously in Maitland, Ont. with Dupont of Canada as a senior engineering assistant.

Mr. Brown graduated in 1944 from McGill University with a B.Eng. degree. After serving with the R.C.N.V.R. until 1946 he joined Canadair Limited in Montreal. He returned to McGill in 1947 as lecturer in the department of mechanical engineering and obtained his M.Eng. degree in 1951. That year he joined C.I.L. in Montreal, transferring to Maitland, Ont. in 1953.

T. H. Dobbin, M.E.I.C.

Brian J. Palmer, M.E.I.C., is now with the Dow Chemical Company at Sarnia, Ont. as project engineer.

Mr. Palmer was previously assistant chief of staff with the U.S. civil service attached to the directorate of installations at the Pepperrell Air Force Base at St. John's, Nfld.

Raymond Saarits, M.E.I.C., has joined the St. Lawrence Seaway Authority in Montreal as assistant engineer. He has been with the Dominion Department of Agriculture as design engineer with P.F.R.A. in Regina, Sask.

SILAVENT FANS

Design 4

- ***Higher static efficiencies.***
- ***Lower noise levels.***
- ***Improved performance and appearance.***

APPLICATIONS — Designed primarily as a high efficiency ventilating fan, the DESIGN 4 also has ratings that fit the requirements of high pressure systems, forced draft applications in power plants and is frequently used as an industrial fan.

SIZES AND CAPACITIES — The Silavent fan is built in all standard Fan Association sizes from 12¼″ diameter to 108¾″ diameter with capacity ratings from less than 1000 cfm up to 500,000 cfm.

PERFORMANCE—The DESIGN 4 fan has the characteristic non-overloading horsepower curve of a fan with backwardly inclined blades. High static efficiencies over a wide range result in low noise levels and assure the quietest possible operation for the rating selected.

This fan can help you solve your air handling problems.

Write today for the complete information.

New 72 Page Catalogue Available

Complete ratings for Class I and Class II construction; dimension tables for all sizes and arrangements; fan weights for the selection of vibration isolators, and technical information on ducts and fittings for ventilating systems.

Architects, Consulting Engineers, Contractors, and Industrialists are invited to write for Silavent Catalogue #342.

Robert T. Bailey, M.E.I.C., has been named assistant to the city engineer at St. Catharines, Ont. He was previously city engineer at Welland, Ont., having gone to Welland in 1951 as assistant city engineer.

Mr. Bailey graduated in 1948 from Queen's University with a B.Sc. degree in civil engineering, and has also been with Margison & Babcock in Toronto, and village engineer at Crystal Beach, Ont.

Fred K. Stone, M.E.I.C., has joined the South Saskatchewan Pipeline Company at Swift Current, Sask. He was previously in Whitehorse, Yukon Territories, with Canol Pipeline Company.

R. M. Heaton, Jr.E.I.C., has accepted a position as assistant electrical design engineer with the light and power department of the City of Regina, Sask. He was formerly with the Schlumberger Well Surveying Corporation, also in Regina.

Mr. Heaton is a graduate of the Institution of Electrical Engineers of Great Britain and has been with Canadian Westinghouse Company Ltd. and with H. G. Acres & Company in Great Falls, Manitoba.

G. M. Boissoneault, Jr.E.I.C., who is with the hydraulic resources department of the Shawinigan Water and Power Company in Montreal, is the new secretary-treasurer of the Montreal Branch of the Engineering Institute.

He is a native of Rainy River, Ont., and received his general education at Calgary, Alta. He attended the Provincial Institute of Technology and Art in Calgary and then in 1942 joined the R.C.N. After the war he entered McGill University and graduated in 1949 with a bachelor of engineering degree in electrical engineering. The following year he studied business administration at the University of Western Ontario.

Mr. Boissoneault joined Shawinigan Water and Power as a staff development trainee in 1949 and was appointed to the system operating division of the generation and transmission department in 1950. He was transferred to the hydraulic resources department last year.

He joined the Engineering Institute as a Student in 1948, and transferred to Junior in 1951.

H. T. Blake, Jr.E.I.C., has joined C. O. Monat & Company Ltd. in Montreal.

Mr. Blake graduated from McGill University in 1949 in mechanical engineering and has been with Rochester & Pittsburgh Coal Company (Canada) Ltd. in Montreal since that time.

D. L. Aker, Jr.E.I.C., has rejoined the Aluminum Company of Canada at Arvida, Que., having completed his Athlone Fellowship. He is supervisor of electrical maintenance at the Arvida plant.

Mr. Aker graduated from the University of Manitoba in electrical engineering in 1949 and then joined McKinnon Industries Limited in St. Catharines, Ont. He went to the Aluminum Company in 1952 and was in the electrical maintenance department at Kingston, Ont., prior to receiving his Fellowship in 1953.

D. G. B. Anderson, Jr.E.I.C., has joined the Long Manufacturing Company in Oakville, Ont., as works manager. He was formerly assistant manager of the service department of the Toronto Hydro-Electric System.

Mr. Anderson graduated in 1950 from the University of Toronto and has been project engineer at Valleyfield, Que., for Defence Industries Limited, and with Lever Brothers Limited in Toronto.

T. B. Lounsbury, Jr.E.I.C., has been appointed manager of meter, instrument and relay sales for the Canadian Westinghouse Company's industrial products division at Hamilton, Ont.

A 1950 honour graduate in electrical engineering from McGill University, and a graduate of the university's management and business administration course, Mr. Lounsbury joined Westinghouse in 1950 as a student engineer. Until his recent appointment he was attached to the apparatus sales department in Montreal.

J. G. G. Hamel, Jr.E.I.C., is now with the engineering department of the Wayagamack division of Consolidated Paper Corporation Ltd. at Three Rivers, Que. He was formerly with Canadian Johns-Manville at Asbestos, Que.

Mr. Hamel graduated in 1950 from McGill University in civil engineering and has previously been with the Foundation Company in Ottawa as field engineer and with Harold Doran as

G. M. Boissonneault, Jr. E.I.C.

T. B. Lounsbury, Jr. E.I.C.

WHAT'S NEW IN PRODUCTION METHODS?
What's better, faster-working,
more economical, more accurate?
What's the shape of things to come
in production engineering?
For all the answers, come to the . . .

INTERNATIONAL MACHINE TOOL EXHIBITION 1956

Olympia - London - England June 22—July 6
(Sundays excepted)

Here, under one vast roof, for close study and comparison at first-hand, the Machine Tool Trades Association (of Great Britain) will present an extensive show of the most modern machine tools and allied equipment from the world's leading makers—British, European, American.

This show will surpass in information value a whole library of catalogues, a mile of correspondence. You can see the machines themselves at work in actual production. You can discuss with the world's best informed experts your own production problems and plans.

The huge range of exhibits includes machine tools, engineers' small tools, gauges and measuring equipment, testing equipment, presses and power hammers, heat-treatment plant, woodworking machinery.

This will be Europe's outstanding engineering display of 1956. Be there! Be *sure* to be there! Note the dates and make your plans *now!*

Organized by The Machine Tool Trades Association (of Great Britain),
Victoria House, Southampton Row, London, W.C.1, England.

assistant resident engineer at Lac St. Jean, Que.

Roderick R. MacKenzie, Jr.E.I.C., was recently appointed to the position of assistant engineer, maintenance of way, central region of Canadian National Railways, with headquarters in Toronto. He was previously division engineer with the C.N.R. at New Glasgow, N.S.

Mr. MacKenzie is a civil engineering graduate of the University of New Brunswick, class of 1945. He began his career with the C.N.R. with summer work in 1941 and 1942. In June 1945 he was instrumentman with the Campbellton division, subsequently becoming assistant division engineer at Campbellton in 1948. He became division engineer at New Glasgow in 1952.

J. C. Smith, Jr.E.I.C., has been transferred from the Three Rivers, Que., mill of the Canadian International Paper Company to the Dalhousie, N.B., mill of the New Brunswick International Paper Company as assistant plant manager.

Mr. Smith graduated in 1947 from Queen's University in mechanical engineering and joined N.B. International Paper at Dalhousie that same year. He went to Three Rivers in 1953 as mill engineer for Canadian International Paper.

A. M. White, Jr.E.I.C., is now with the Vancouver office of Racey, MacCallum & Associates Ltd. He was formerly maintenance superintendent of the sulphate and nitrate plants of Consolidated Mining and Smelting Company Ltd. at Trail, B.C.

Mr. White graduated from the University of British Columbia in 1948 with a B.A.Sc. degree in mechanical engineering.

C. Gordon Lindsay, Jr.E.I.C., recently joined the staff of Atlantic Bridge Company Ltd. in Halifax, N.S. He was previously attached to the U.S. Corps of Engineers at the Ernest Harmon Air Force Base in Stephenville, Nfld.

A 1948 civil engineering graduate of McGill University, Mr. Lindsay was first associated with the concrete design department of the Shawinigan Engineering Company in Montreal before going to Newfoundland in 1952.

Paul R. Brown, Jr.E.I.C., has joined the staff of Reliance Electric & Engineering (Canada) Ltd. as transformer engineer in Welland, Ont.

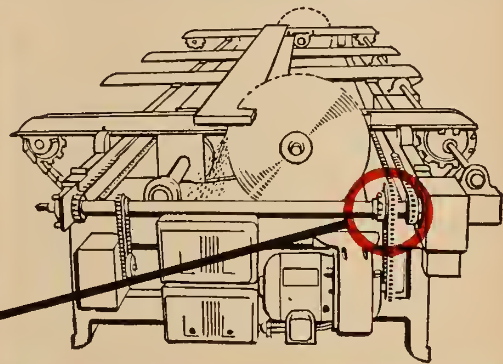
Mr. Brown is an electrical engineering graduate of Nova Scotia Technical College, 1948, and has been with the Canadian Westinghouse Company in Hamilton, Ont., as electrical engineer in the engineering department of the company. He joined Westinghouse immediately after his graduation.

Brian B. Hanson, Jr.E.I.C., is now employed as city electrician for the City of Moncton, N.B.

A 1950 electrical engineering graduate of the University of New Brunswick, Mr. Hanson has been with the Canadian National Railways in Moncton as circuit designer in the signal department.

Norman G. Brown, Jr.E.I.C., has joined the staff of Dutton-Williams Brothers Limited in South Edmonton, Alta.

MORSE TORQUE LIMITER PROTECTS MOTOR AND REDUCER FROM DEAD-STOP OF DRIVEN UNIT!



Morse Torque Limiter and sprocket act as slip clutch on Model 55 Automatic Electric Shift Trimmer made by The Wheland Company, Chattanooga. Arbors are shifted at 120 fpm, instantly stopped and locked into place. Torque Limiter on jackshaft is set so sprocket slips when motor torque (38 ft.-lbs.) is exceeded. Absorbs inertia of 1-hp, 155-rpm gearmotor; reduces shock on drive unit when driven shaft is stopped.

Typical application shows how you can safeguard drive units and eliminate shear pins

Check these advantages of Morse Torque Limiters

- √ Eliminate downtime
- √ Torque-sensitive and fully adjustable
- √ Completely automatic and dependable
- √ Resume operation automatically
- √ Compact, standard sizes

In this Wheland Electric Shift Trimmer, two 200-pound saw arbors are automatically moved into position at 120 feet per minute . . . then stopped dead and locked into place.

The tremendous shock transmitted to the drive mechanism when the arbors are stopped, is safely dissipated by a Morse Torque Limiter used as a slip clutch between the driving and driven units. In addition, it prevents motor inertia from building up torque in the drive.

Versatile Morse Torque Limiters can safely control many of the shock-load problems present in your machine operations.

These simple devices are dependably sensitive and easily adjusted to desired torque limits. When overload or jam-up is cleared, they automatically resume operation, eliminating downtime or dismantling necessary with shear pins.

Send for Free Catalog

A full line of Torque Limiters is stocked by your Morse Distributor. For free catalog, or power transmission engineering help, see him or write today.

Mr. Brown graduated from the University of British Columbia in 1950 with a B.A.Sc. degree in mechanical engineering and joined John H. Ross & Company Ltd. in 1951 as sales engineer in Edmonton. In 1952 he was appointed manager of the Calgary branch of the company and then returned to Edmonton in 1953 as sales manager.

Charles Yoshida, JR.E.I.C., who received his M.A.Sc. degree in chemical engineering from the University of Toronto this fall, has joined Canadian Wallpaper Manufacturers Ltd. in Toronto.

Mr. Yoshida graduated in 1951 from McGill University with a B.Eng. degree in chemical engineering, and then joined the Wayagamack division of Consolidated Paper Corporation at Three Rivers, Que.

He is a past secretary-treasurer of the Saint Maurice Valley Branch of the Engineering Institute.

A. M. Garlicki, JR.E.I.C., has joined the engineering staff of Timberland Machines Ltd. in Woodstock, Ont., as mechanical engineer.

Mr. Garlicki is a 1951 mechanical engineering graduate of the Polish University in London, England. He has been with Babcock-Wilcox & Goldie-McCulloch Ltd. in Galt, Ont., as project engineer since 1952.

Richard C. Sircom, JR.E.I.C., is now engaged in underwater physics research work with the Naval Research Establishment in Dartmouth, N.S. He was formerly in Peterborough, Ont., with Canadian General Electric as switchgear design engineer in the apparatus department.

Mr. Sircom graduated in 1951 from Nova Scotia Technical College with a B.Sc. degree in electrical engineering and then joined the Canadian General Electric's test course.

K. A. Millions, JR.E.I.C., is now resident materials engineer with the Trans-Canada Highway division of the Department of Public Works at Banff, Alta. He was formerly resident highway engineer with the Alberta Department of Highways in Edmonton.

A 1951 civil engineering graduate of the University of Alberta, Mr. Millions was with the R.C.A.F. as flying officer in the Air Division at Headquarters in France after his graduation.

Lt. (L) G. A. Kastner, JR.E.I.C., of the Royal Canadian Navy, has been appointed electrical officer at H.M.C.S. Algonquin, an operational unit of the Royal Canadian Navy at Halifax, N.S. He was previously at Navy Headquarters in Ottawa as section head, underwater detection engineering in the electrical engineer-in-chief's division.

Lieutenant Kastner is a 1952 graduate of the University of New Brunswick in electrical engineering.

J. K. Maitland, JR.E.I.C., has joined the staff of Haddin, Davis & Brown Limited in Edmonton, Alta. He has been in Brandon, Man., on the staff at City Hall.

Mr. Maitland graduated in 1952 from the University of Manitoba in civil engineering, and has also been with Underwood, McLellan & Associates Ltd. in Saskatoon, Sask.

Marc Brunet, JR.E.I.C., has been transferred by the harbours and rivers engineering branch of the Department of Public Works from Rivière du Loup, Que., to Quebec City.

Mr. Brunet graduated in 1952 from Laval University with a B.A.Sc. degree in civil engineering and joined the Department of Public Works as a civil engineer in Quebec City after graduation.

Ronald G. Foxall, JR.E.I.C., is now employed as resident engineer at Powell River, B.C., for the Northern Construction Company.

Mr. Foxall graduated from the University of British Columbia in 1952 in civil engineering, and then joined Canadian National Railways as a trainee in Montreal with the research and development department. In 1954 he became associated with Canadian Forest Products Limited in Port Mellon, B.C., as plant engineer.

J. A. Harding, JR.E.I.C., is now with Ontario-Minnesota Pulp and Paper Company Ltd. in Kenora, Ont. He was formerly in Hamilton, Ont., with Canadian Westinghouse Company Ltd., having joined that company upon his graduation in 1953 from the University of Manitoba with a B.Sc. degree in mechanical engineering.

D. D. Young, JR.E.I.C., who recently returned from England where he spent two years on an Athlone Fellowship, has joined the mechanical development

• Personals

department of the ammunition and explosives division of C.I.L. as a project engineer in Brownsburg, Que.

Mr. Young graduated in 1953 from the University of Manitoba with a B.Sc. degree in mechanical engineering.

Edmund H. McIntyre, JR.E.I.C., has returned from England where he spent two years on an Athlone Fellowship, and is now with Canadian Refractories Limited in Montreal. While in England he was with the metallurgical staff of Steel, Peech and Tozar, a branch of the United Steel Companies.

Mr. McIntyre graduated in 1953 from McGill University with a bachelor's degree in metallurgical engineering.

W. J. Lund, JR.E.I.C., has joined Westminster Iron Works Ltd. as a mechanical engineer in New Westminster, B.C. He was previously with the Harmac Pulp division of MacMillan and Bloedel Ltd. in Nanaimo, B.C., having joined that organization in 1953.

Mr. Lund graduated from the University of British Columbia in 1953 with a B.A.Sc. degree in mechanical engineering.

R. A. J. Arsenault, JR.E.I.C., has returned to Canada following a two year period spent in England on an Athlone Fellowship, and is employed by Marine Industries Limited at Sorel, Que., as assistant superintendent of machine shop and machinery installation and repairs.

A 1953 electrical and mechanical engineering graduate of Ecole Polytechnique, Mr. Arsenault spent the first year of his fellowship studying at the Royal Technical College in Glasgow and received a postgraduate diploma in power engineering. The following year he was with Fairfield Shipbuilding and Engineering Company Ltd., also at Glasgow.

Fernand Demers, S.E.I.C., a 1955 graduate of Nova Scotia Technical College in civil engineering, has joined Perini Quebec Inc., general contractors in Montreal.

Earl Misfeldt, S.E.I.C., has joined the Department of Mineral Resources of the Province of Saskatchewan at Lloydminster.

He graduated in 1955 from the University of Saskatchewan in civil engineering.

Eric Christman, S.E.I.C., a mechanical engineering graduate of McGill University, class of 1955, is now with the control department of the Anglo Canadian Pulp and Paper Mills in Quebec City.

John J. Sled, S.E.I.C., has joined H. A. Simon Limited at Port Alberni, B.C.

He graduated last spring from the University of Saskatchewan in civil engineering and then worked with Haddin, Davis & Brown in Edmonton, Alta.

J. Gaetan Trudeau, S.E.I.C., is presently employed as field engineer with the west district, water and sewerage division of the Department of Public Works of Montreal.

Mr. Trudeau graduated in 1955 from Ecole Polytechnique with a B.A.Sc. degree in civil engineering.

Belleville

J. A. Grant, M.E.I.C.,
Secretary-Treasurer

J. L. Colter Guest Speaker

The Belleville Branch of the Engineering Institute of Canada held its third meeting of the 1955-56 season on December 12, 1955, at the Masonic Temple. Approximately 30 members and guests attended. J. L. Colter of the Canadian National Railways spoke on the "Applications of Electronics in the Toronto Stock Exchange". He explained the processes involved in implementing and recording financial transactions in the Toronto Stock Exchange.

Mr. Colter was introduced by A. Argue and thanked by John Ross.

A supplementary film entitled "Immediate Action", supplied by the Toronto Stock Exchange, was shown.

Central British Columbia

H. D. DeBeck, Jr.E.I.C.,
Secretary-Treasurer

President Attends General Meeting

The annual general meeting of the Branch was held at the Plaza Hotel in Kamloops on November 28, 1955 with 41 present, including members, wives and guests.

Vice-Chairman A. F. Joplin was in the chair and welcomed to the meeting the president of the Institute, Dr. R. E. Heartz and Mrs. Heartz, and the general secretary, Dr. L. Austin Wright. The chairman then called on W. J. M. Owen to introduce Dr. Heartz, who addressed the meeting on the subject of the shortage of engineers and possible means of meeting the problem.

The chairman then thanked Dr. Heartz and introduced Dr. L. Austin Wright who spoke on the business of the Institute, touching briefly on the subject of confederation and the film "Leonardo da Vinci".

Dr. Wright also drew the attention of the meeting to the fact that the 1957 meeting of the Institute will be in Banff.

1956 Branch Officers

The election of branch officers for 1956 was then held with results as follows: chairman, A. F. Joplin; vice-chairman, R. G. Harris; committeemen, A. C. Dimock, E. R. Gayfer, and M. A. Thompson.

Owing to the visit of the president the presentation of annual reports and other business was deferred until the first meeting of 1956.

Executive Meeting

A meeting of the executive was held at the Plaza Hotel in Kamloops on November 28, 1955. The meeting convened at 9.20 p.m. with Mr. Joplin in the chair. Others present were Messrs. Harris, Thompson, Wade, Zirul and DeBeck.

Two applications for membership as Branch affiliates were approved, and a nomination for the presidency of the Institute was endorsed. R. L. Bigg was appointed member of the Nominating Committee. In addition to financial business, it was moved by Mr. Harris and seconded by Mr. Wade that the secretary contact Mr. Dimock in Vernon to arrange a meeting there for February 17, and that an executive meeting also be arranged for that date.

Buffet Supper and Film

The December meeting of the Cornwall Branch was held at the Cornwall Golf and Country Club on Friday, December 9, 1955. A buffet supper was served, followed by the showing of the film on the life and work of Leonardo da Vinci.

Invitations were extended to members and their wives of the local branches of the Association of Professional Engineers, the Chemical Institute of Canada, the Architects and the Medical Association. Approximately one hundred members and guests attended one of the most successful meetings of the year.

Supper Meeting

On December 15, 1955, the Fredericton Branch held a supper meeting at the cafeteria of the Memorial Students Centre of the University of New Brunswick. Special guests for the evening were the wives of the members.

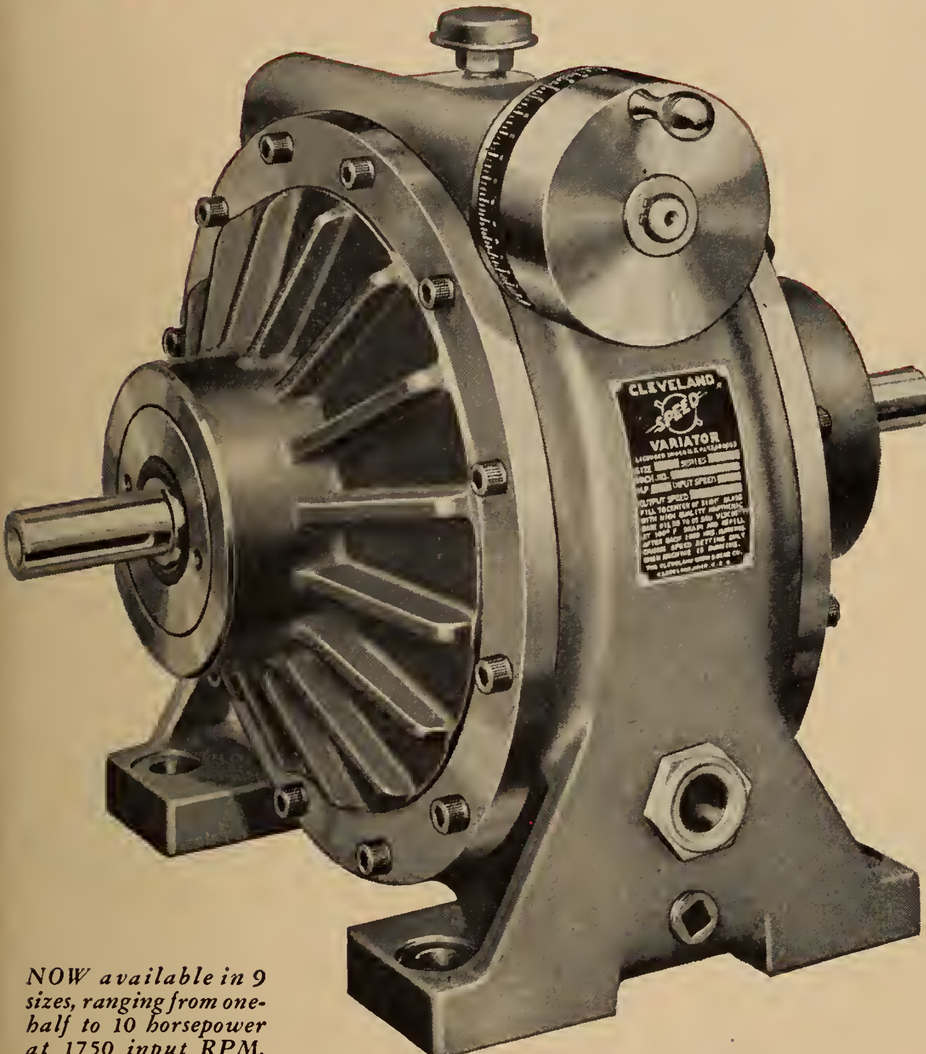
"Leonardo da Vinci"

After the supper, a preview showing of "Leonardo da Vinci", a documentary film exclusively owned in Canada by

Members of the executive of the Halifax Branch. Left to right, seated, J. J. Kinley, R. D. T. Wickwire, vice-chairman, G. A. Cunningham, chairman, W. D. Pippy, secretary-treasurer, W. A. Devereaux, past-chairman; standing, Professor B. N. Cain, Professor B. F. Vail, J. D. Kline, P. M. Lane, E. C. Parsons and O. K. Smith. Others elected to the executive are R. F. McAlpine, G. H. Dunphy and John Powers.

HERE IT IS

Cleveland Speed Variator



NOW available in 9 sizes, ranging from one-half to 10 horsepower at 1750 input RPM.

INFINITELY variable, stepless speeds within a 9:1 range (from ⅓ to 3 times the input speed).

Smooth, instant change of speed by simple manual adjustment or by remote control devices, either manual or power operated.

Operating efficiencies—75% to 90%.

Coaxial input and output shafts, rotating in same direction, either clock-wise or counter clock-wise.

Ample bearing support for both input and output shafts to carry overhung pulleys.

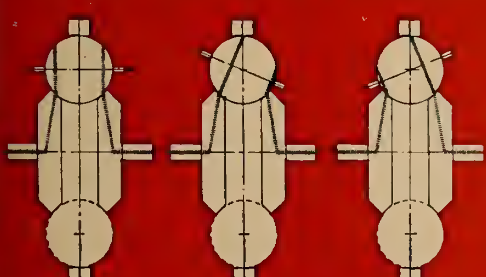
Compact and inherently quiet and smooth running, due to simple construction.

Minimum maintenance and long life, due to absence of belts and other complicated linkage.

Performance proved by prolonged tests in the laboratory and field operation.

These are the outstanding advantages of the Cleveland Speed Variator. It is now ready for service. Immediately applicable to a wide variety of machines and equipment where a dependable variable speed drive is required. For detailed description and specifications, write for Bulletin K-200 Peacock Brothers Limited, P.O Box 1040, Montreal 3, Que.

HOW THE CLEVELAND SPEED VARIATOR WORKS



Power is transmitted from input shaft to output shaft through alloy steel driving balls which are in pressure contact with discs attached to the two shafts.

Relative speeds of the shafts are adjusted by changing the positioning of axles on which the balls rotate (see diagrams, left, and cutaway view, right).

Officers for 1956

The Halifax Branch of Engineering Institute of Canada reports a year of exceptional activity. Election results were announced at the annual meeting and officers named for the Branch. Those chosen were: G. A. Cunningham, chairman; R. D. T. Wickwire, vice-chairman; and W. D. Pippy, secretary-treasurer. Other members of the executive include O. K. Smith, R. F. McAlpine, G. H. Dunphy, J. D. Kline, P. M. Lane and Prof. B. F. Vail, Halifax; E. C. Parsons, Windsor; Prof. B. N. Cain, Wolfeville; J. J. Kinley and J. W. Powers, Lunenburg.

The retiring chairman, W. A. Devereaux, reported on a highly successful year in which membership of the Branch rose above the five hundred mark. Meetings held during the year were highly diversified to meet the needs of the many technical divisions represented by the engineering profession in the Halifax area. In addition to subjects of general engineering interest, topics have been chosen which are related to marine, naval and military problems.

The newly-elected chairman, G. A. Cunningham, assured the members that meetings of general interest as well as topics of a specialized engineering nature would form a part of the 1956 program. New developments in the fields of electronics and nuclear energy will be included in the program. When he asked members to put forward their ideas regarding future meetings, a spirited discussion brought forth a wide variety of suggestions and a wealth of constructive comments for the guidance of the new executive.

The Committee chairmen appointed were: F. H. Tremain, publicity and news editor; G. H. Dunphy, Public Relations; M. L. Baker, Student Guidance; W. J. Philips, Professional Development; G. F. Vail, Student Activities; and J. D. Kline, By-laws.

Branch News Editor

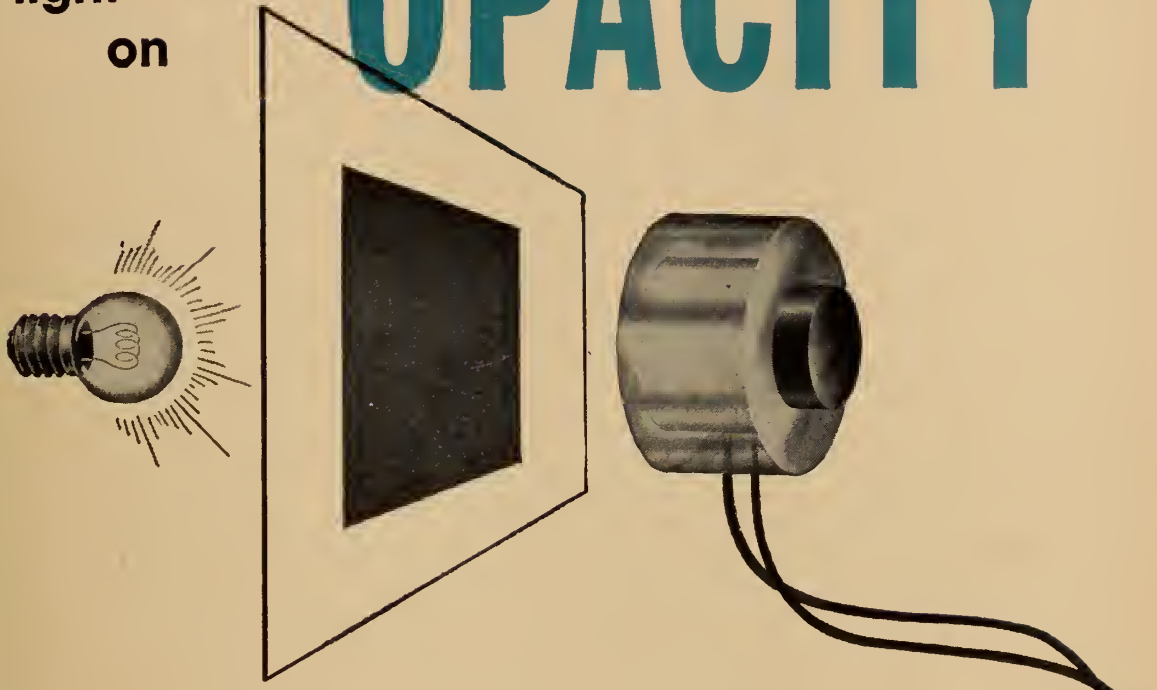
"Trans-Canada Micro-wave Radio Relay Systems" was the subject of J. B Leworthy's talk at the December meeting of the Hamilton Branch. A 1937 electrical engineering graduate of the University of Toronto, Mr. Leworthy now heads the division of the Bell Telephone Company of Canada concerned with micro-wave radio relay systems, mobile two-way communication and television facilities.

Micro-wave Radio Relay System

Mr. Leworthy was introduced to the Branch members by H. Seeley. In discussing the new system now under construction from Sydney to Vancouver, Mr. Leworthy said that the project is one of the significant achievements to be undertaken by Canadian engineers since the war. The Trans-Canada telephone system provides circuits from coast to coast by means of seven different companies. Since 1945 circuit mileage has been increased five times. With the need for long distance dialling and for television service, these companies are now in the process of providing a micro-wave radio relay system which is due for completion in 1956.

Outlining the basic principles of the

A new light on OPACITY



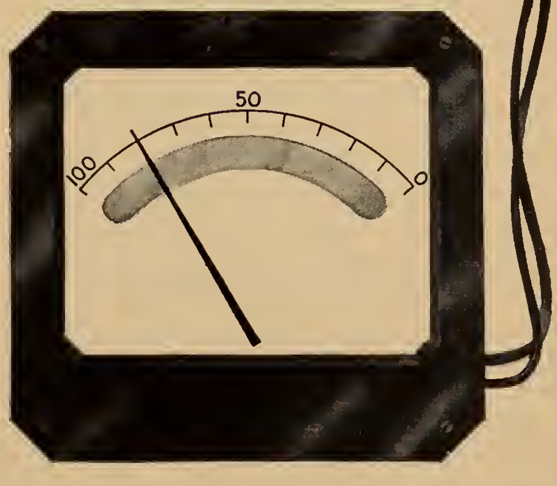
insures sharp reproduction from your TURQUOISE tracings

READ HOW, for the first time in pencil history, Eagle's laboratory measures the opacity of a pencil line with scientific accuracy. Three precision instruments are involved:

(1) Our two-ton "Pencil Sharpener" gives the test pencil a cylindrical point (as shown at left) of fixed diameter, accurate to .0001".

(2) In our Automatic Shading Machine, the pencil deposits graphite as a square of parallel strokes under uniform pressure on the paper.

(3) A Microammeter, connected to a sensitive light cell, first measures the light blocked by the chart paper, and then measures the *opacity of the graphite deposit alone* to a fraction of one percent!



Such exact measurement of every TURQUOISE degree enables us to develop and maintain maximum opacity . . . the quality that gives you perfect prints from TURQUOISE pencil tracings.

PROVE IT IN THE PRINT with a free TURQUOISE sample.
Just write us, naming this magazine and the grade you prefer. Made in Canada

system, Mr. Leworthy described some of the engineering aspects of the project which requires the services of practically every branch of the profession.

The TD2 system which works on a 3700 to 4200 kc./s. frequency with a 3 in. wave-length requires that 135 repeater stations be constructed every 30 miles to offset the curvature of the earth. Sixty-five of these stations, over a distance of 1,800 miles, are being built by the Bell Telephone Company. There are, in addition, 25 towers for spur lines.

In the selection of a route, determining factors are the availability of power, the existence of land and telephone lines, as well as transportation and communication services. Topographical maps have been made of certain areas; others have been revised to show unmapped obstructions, as in the case of British Columbia. Even in the prairie region 100-foot hills are not uncommon.

Each site is tested by means of a 200-foot portable tower and mobile radio equipment. The construction of the permanent towers, averaging 225 ft. and weighing approximately 40 tons, to provide a negligible twist under high winds, is usually done by contractors, as well as work on roads and clearing of the property.

The stations are pre-fabricated buildings approximately 36 by 21 ft. Each station is equipped with auxiliary power to ensure dependability. In addition, there is a wave guide system from antenna to radio building, in readiness for the complex switching equipment required in long distance customer dialing.

Automatic "Watch Dog"

Each tower is equipped with an automatic "watch dog", by means of which men on duty are constantly supplied with information on the fuel level, temperature, radio equipment performance, and auxiliary power supply. The "watchdog" can answer 40 questions required by maintenance men; it can also perform certain functions, such as the switching-on of auxiliary power. At each relay station repeated checks are made to make sure that signals are clear.

The path of a typical television broadcast is as follows: The broadcast studio camera converts the view into electrical impulses which are sent by telephone to the main telephone building of a major city where a frequency modulation system changes the frequency and amplitude. The signals are then transmitted through the relay stations to another major city where they are again modulated for receiver use.

At the conclusion of his talk Mr. Leworthy displayed some new inventions of the Bell Telephone Company among which were a pocket transmitter, and samples of cable and tubes used in trans-Atlantic telephone calls.

A question period followed the address. F. E. Milne, Branch chairman, thanked Mr. Leworthy on behalf of the members.

Publicity Chairman

Automatic Computers

Tuesday, November 29, 1955, at the Mansfield St. headquarters of the Engineering Institute, Montreal Branch members were given the opportunity to enlarge their views on a modern tool for management represented by the family of "Automatic Computers".

The speaker, Walter Smuck, applied science representative for International Business Machines (I.B.M.), did a good job of conveying the basic principles of operation and application of these complex machines which now render possible the almost impossible of yesterday.

After a brief historical approach to the problem, Mr. Smuck described the different types of available machines plus the auxiliary equipment required. In few words, one starts with the basic punch card where the information is permanently recorded (or a magnetic tape recorder having a considerable larger capacity), and in a matter of seconds or a split second in some cases, these machines start producing results pertinent to material inventory, material routing to strategic warehouses, payroll, bookkeeping, and solutions of complex technical problems, etc. Every

In Price Purchasing

THE DOWN PAYMENT

MIGHT BE THE ONLY EASY ONE

The purchase of water meters involves more important economic factors than price alone. Actually, the bid price is only your down payment . . . and it could well be the only easy payment.

Any instrument loses its accuracy as it wears. After a few years . . . maybe only a few months . . . an improperly selected meter begins to lose revenue. In time, you'll also have high repair costs . . . or costly scrap-and-replace programs.

Avoid these high costs with Trident meters. Tridents retain accuracy longer . . . derive maximum revenue longer. Most important, you avoid high costs of obsolescence and repair. The most modern Trident parts fit the oldest Tridents you have. You actually modernize as you repair . . . with Trident.

When you consider all these economic factors you will quickly see why Trident meters earn more and cost less. Ask your neighbor . . . or ask us to supply verified evidence.

neptune

one present must have felt some sort of relief when Mr. Smuck, who said that a single one of these machines could replace thousands of office workers, also added that the machine still required at least one man to do the initial and final thinking.

Prior to the question period, a coloured film was shown depicting different types of automatic computers, classifiers, automatic punch card machines, etc.

Machines are Self-checking

One interesting point to remember, is the fact that information can be sent directly to the machines from various long distance sources; also, all the machines are self-checking and any error will stop and hold everything.

One last point of general interest is that machines can be built to suit special specific requests or problems. In all events, the manufacturer remains the sole owner of the machines. These machines are then rented on a monthly basis and the necessary skilled personnel is supplied by the manufacturer.

G. H. Hoganson, of Canadian National Railways and chairman of the Management Section of the Program Committee, expressed a vote of thanks to Mr. Smuck and the meeting chairman, Leo. Roy of the Quebec Hydro-Electric Company, declared the meeting over.

The meeting was arranged by D. Danylkiw of the Bell Telephone Company.

Montreal Electrical Section

Chairman

Marconi Company Is Host

On Monday evening, November 14, 1955, the Canadian Marconi Company received 123 guests consisting of members of the Engineering Institute of Canada, American Institute of Electrical Engineers, and the Institute of Radio Engineers Montreal branches. The visitors were greeted by the president, S. M. Finlayson, and were then conducted on a 3½-hour tour of Marconi.

In the Marconi building they were shown such items in production as marine radar, 20 kw. communication transmitters, mobile FM communication sets, marine radiotelephone, quartz crystals, photocells, radios, television receivers, and radio relay equipment.

The guests were then taken to the McEachran Avenue premises by bus to see through the aviation, radio relay and research departments where new equipment and components are under development.

The tour ended with light refreshments in the company cafeteria.

Winnipeg Electrical Section

G. L. MacDonald, M.E.I.C.,
News Editor

D. H. McKeough is Speaker

On November 3, 1955, the Electrical Section of the Winnipeg Branch was addressed by D. H. McKeough, Switchgear Engineering Division, Canadian Westinghouse Company. The subject of his address was, "The Jetaire Air Blast Circuit Breaker".

Mr. McKeough traced the development of high voltage circuit breakers from the earliest attempt at a high power breaker built for the new Niagara Falls power development about 1895. This was a plain air break breaker powered by an air operated mechanism. The early oil circuit breakers also used a simple break under oil and development was hampered by the lack of testing laboratories, and because the nature of arc interruption under oil was not understood. It was supposed that insulating oil made an effective arc quenching agent because of its high dielectric strength, that is, the oil supply flowed between the contacts and stopped the arc from flowing. About 1929, design engineers began to realize that the arc was always encased in a bubble of gas, and that the flow of gas formed from the thermal breakdown of oil was the effective agent. The interrupting ratings of oil breakers rapidly increased

and arcing times diminished. At the same time, the new large testing stations were able to demonstrate the operation of these breakers.

Development of high voltage breakers on the North American continent, up to the present, has been largely concentrated on the development of high voltage dead-tank oil breakers which are being used up to the highest voltages and interrupting capacities. A different trend developed on the European continent where part of the effort was directed to the development of oil poor breakers and air blast breakers.

First Air Blast Breakers

The first commercial air blast breaker was built by a German firm in 1929, and by the end of the war, most British and continental manufacturers were building high voltage air blast breakers. This European trend appears to be due in part to the relatively high material costs and low labour costs prevailing in that area. The porcelain clad air blast breaker with its minimum content of steel and copper has had an advantage, whereas on this continent, the relatively high wage rates and low material costs have favoured the design of the bulk oil circuit breaker.

The modern high voltage breakers fall into three broad classes: (a) dead-tank bulk oil breakers, (b) porcelain clad oil poor breakers, (c) porcelain clad air blast breakers. The first two use insulating oil as an interrupting fluid while the third uses compressed gas. One fundamental difference between these two methods is that the oil interrupter is a 'suicide type' interrupter in that the arc generates the gas pressure for its own extinction so that the interrupting effect is a function of the current flowing. In the air blast breaker, the gas is stored at some arbitrary pressure and the interrupting effect is independent of the size of the arc. Consequently, the oil breakers tend to show some tendency towards long arcing times at low currents, particularly with low power factor switching unless the oil flow is aided by mechanical pumps or some such device. They also tend to have trouble with capacitive currents where successive restrikes can build up dangerous overvoltages in the system and discharges within the breaker can damage interrupters from the mechanical forces involved unless provided with special switching resistors for this service. Air blast breakers tend to have an excessive interrupting effort for very low currents, in the order of 50 amps or less, and may force the natural current zero. Under certain circumstances, the current chopping also may lead to switching surges which may be a hazard unless proper provisions are made in the form of surge diverters.

Porcelain Clad Air Blast Breakers

In the porcelain clad air blast breaker field, a great diversity of ideas is evidenced by the different designs available. One thing in common to all is that all use axial blast interrupters as opposed to the cross blast principle. The nominal service voltage impressed across each interrupter varies from 30 kv. to 110 kv. Some breakers have their interrupters stacked vertically, one above the other; others mount them on a slant at the top of wyes; while still others mount them horizontally at the top of tees. Most manufacturers build the disconnect switch into the breaker structure to isolate one side of the breaker when it opens because the interrupting gaps remain open only while the blast valves are held open and the disconnect must open during this time. These disconnects, or sequential isolators as they are sometimes called, are usually exposed to the weather and use different devices such as pneumatic hammers or the exhaust blast to lessen the hazard of their becoming locked shut due to icing.

Jetaire Circuit Breaker

A fourth distinctive type of high voltage breaker, which may be called a dead-tank air blast breaker, has been developed by the Canadian Westinghouse Company and has been christened the 'Jetaire' circuit breaker. Mr. McKeough showed a slide of a 115 kv. or 138 kv. design 'Jetaire' circuit breaker being assembled in the shop. The same design principles apply to 69 kv. and up, as the same interrupters, blast valves, control valves and so on are used at all voltages so that all parts will be interchangeable. At the voltage mentioned, the breaker is a three tank breaker and structurally is very similar to a bulk oil breaker. The interrupters are mounted inside the tanks, two per pole. They are arranged in series electrically and in parallel pneumatically so that the arc energy from one cannot affect the air flow from the other. The top section of the tanks are registered pressure vessels and hold air at 250 p.s.i. The blast valves extend through the bottom of the vessel into the skirt which is made weather tight by gasketed louvres and a blast valve is mounted at the lower end of each blast tube. The current is brought in and out of the tanks through conventional terminal bushings. Ring-type current transformers are mounted on the top of the breaker. The high pressure air in the tanks is used to (a) provide the interrupting medium, (b) store energy for operating the breaker, (c) increase the voltage level between live parts and ground.

Sparkover and Creepage Strength

At the start of this development, it was found that little was published regarding the sparkover and creepage strength in high pressure air in the ranges of voltage and distances in question. A test tank was built to take a 138 kv. bushing and pressures up to 300 p.s.i. and tested for breakdown voltages of different shapes of electrodes at different gaps of up to 8 in., both for 60 cycle and impulse. Several hundred of these tests were carried out under a variety of conditions and led to the following conclusions; (a) for any given arrangement the results were very consistent and therefore reliable; (b) high pressure air was at least as good an insulating medium as insulating oil.

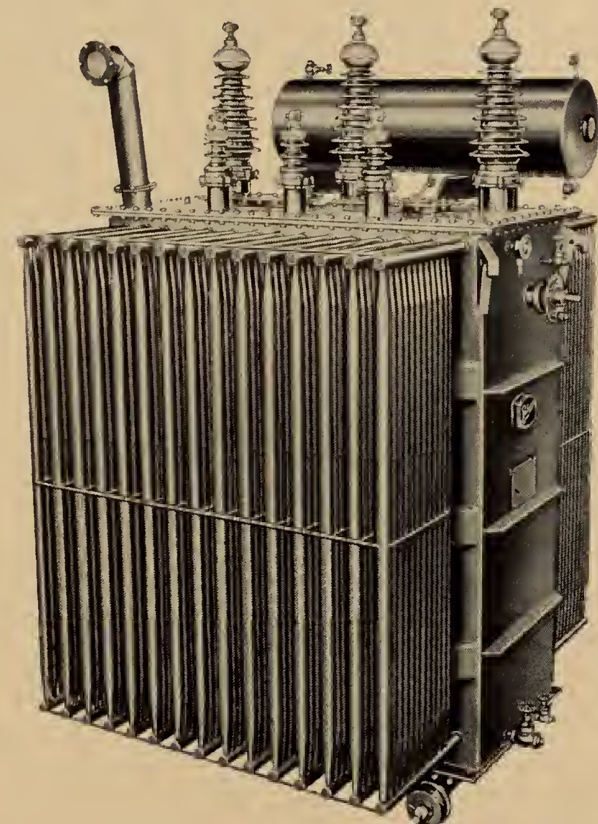
A single pole prototype breaker was then built for a 138 kv., 5,000 mva.

There's EXTRA VALUE in Packard Standardized Power Transformers

When you purchase a Packard "Standardized" power transformer, you get the traditional Packard over-load qualities as well as light weight, low sound level and low losses. You also get shorter delivery periods since all components are kept in stock.

In addition to the requirements of CSA specification C88 these are some of the EXTRA VALUE features in Packard's standardized design which mean easier installation—less maintenance—longer life

- *Light weight for easier handling.*
- *Four-way 'ski-tip' ventilated base with ample jack-pockets and a means for attaching towing cables. Designed to accommodate wheels, if required.*
- *Easily read instruments and accessories are all conveniently located at one end.*
- *Filter press connections at both top and bottom of tank as well as in conservator tank.*
- *Tap changer handle comes out end of tank wall for safe operation—can be arranged for ground level operation if required.*
- *Trouble free control and fan wiring in aluminum sheathed or neoprene jacketed cable.*
- *Fans have individual weatherproof plug and socket connections for easy removal.*
- *Durable 'alkyd-base' paint finish 'flow-coated' for complete coverage.*



Available in ratings up to 10,000 kva., 69 kv., type ONS or ONP

rating and tested both for mechanical operating and interrupting.

Jetaire Features

The following features distinguish the 'Jetaire' breaker from previous breaker designs: Structurally the breaker is much more rugged and compact than porcelain clad air blast breakers.

The interrupter is placed directly in the high pressure air so that full tank pressure is available at the contacts even before they separate. This makes for a very efficient interrupter with short arcing times.

The only moving parts are the interrupter contacts, blast valve stem, control valve stem and auxiliary switch operator.

All moving parts are enclosed in dust-proof compartments.

Since the blast valves are mounted at the exhaust of the breaker, no atmospheric moisture can condense on the insides of the blast tubes.

Up to twelve ring type current transformers may be used, two per bushing. Potential devices also may be added simply.

The relatively large tanks serve as additional air storage for the user without adding separate tanks. This means that at least four separate close-open operations are available above lock-out air pressure without any assistance from the air supply system.

The 'Jetaire' breaker uses much less ground area than any porcelain clad air blast breaker and considerably less than bulk oil breakers of the same rating.

The ground shock is negligible during interruptions. This permits a considerable saving in foundation design.

The load current is carried on separate surfaces from the arcing surfaces. This combined with the short arcing times of ½ to ¾ cycles assures long contact life.

Contacts may be removed and inspected on any pole in less than 20 minutes.

The elimination of the sequential isolator simplifies the breaker both structurally and from an operating standpoint.

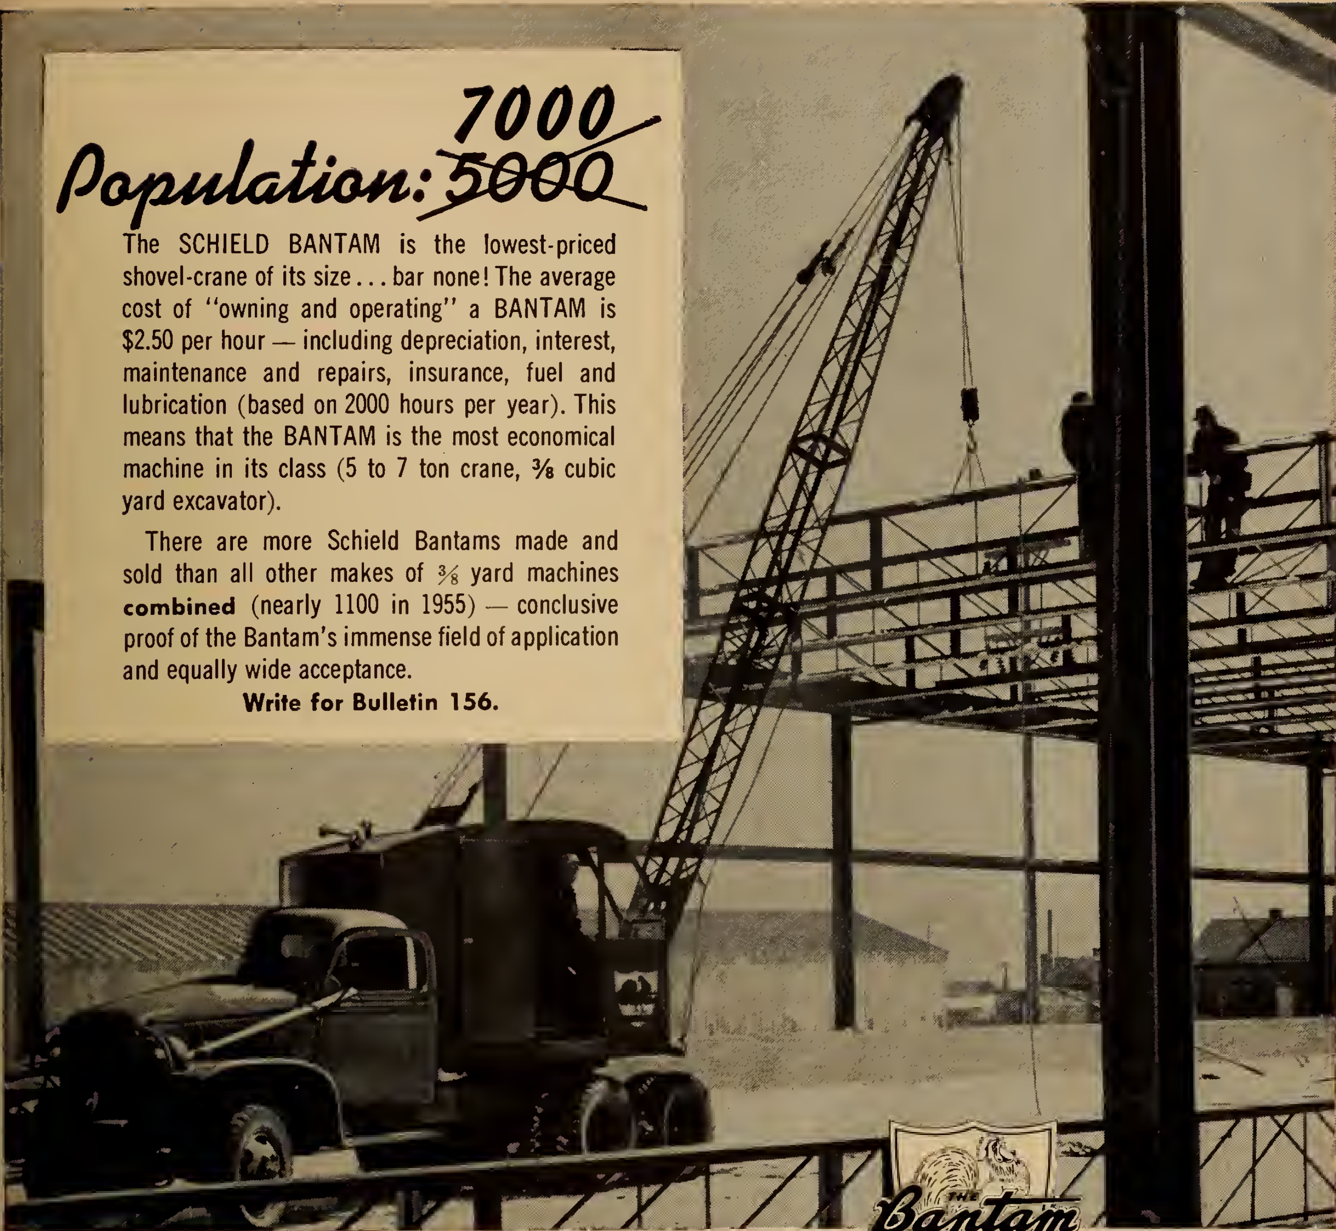
The breaker may be shipped on rails as a completely assembled unit.

Annual Dinner and Dance

On November 18, over two hundred engineers and their ladies gathered at the Marlborough Hotel for the annual dinner and dance of the Winnipeg Electrical Section. This dinner and dance is now a well known and popular social event in Winnipeg engineering circles, and it was further enlivened this year by a visit from the president, Dr. R. E. Heartz and Mrs. Heartz, accompanied by Dr. L. Austin Wright.

Life Membership Presented

An event of special interest was the presentation of a Life Membership in the Engineering Institute to Dr. E. P. Fetherstonhaugh by the president, Dr. Heartz. Dr. Wright gave the address of presentation and paid tribute to Dr. Fetherstonhaugh as an engineer, an educator and as a citizen.



Population: ~~5000~~ 7000

The SCHIELD BANTAM is the lowest-priced shovel-crane of its size . . . bar none! The average cost of "owning and operating" a BANTAM is $2.50 per hour — including depreciation, interest, maintenance and repairs, insurance, fuel and lubrication (based on 2000 hours per year). This means that the BANTAM is the most economical machine in its class (5 to 7 ton crane, ⅜ cubic yard excavator).

There are more Schield Bantams made and sold than all other makes of ⅜ yard machines **combined** (nearly 1100 in 1955) — conclusive proof of the Bantam's immense field of application and equally wide acceptance.

Write for Bulletin 156.

BOOK REVIEW

My mother the judge. Elsie Gregory MacGill. Toronto, Ryerson, 1955. 248 pp., $4.50.

Elsie MacGill's lively and loving biography of her remarkable mother is at once a work of a considerable historical interest, dealing, as it does, with early Upper Canadian days and graphically depicting the fight for and growth of social legislation on the West Coast.

Born to an old family of considerable influence and standing in Hamilton. Judge MacGill had an established and conventional background which was surely an unusual starting point for such an extraordinary and variegated career. It is not surprising that the daughter of such a mother should herself be Canada's outstanding woman aeronautical engineer.

One of the first women graduates of Toronto's Trinity College, Judge MacGill received her degree in 1890. She began her career as a "budding journalist" turning out, as her daughter relates, "political, social and historical pieces" for American and Canadian publications notably the American magazine "Cosmopolitan".

John Brisbane Walker, editor of that publication, hit upon, at that time, the most unusual idea of sending Judge MacGill to Japan to report on the new constitutional government then arising out of the upheaval of 1868.

Before sailing on this mission, Judge MacGill made an extended tour of the western settlements then in the throes of boom and expansion. Here she met and married her first husband, Dr. Flesher.

After her return from her successful trip to Japan, she went with him first to California and later to Minnesota.

Following his untimely death in 1901, she returned to Canada, eventually marrying an old Toronto acquaintance, lawyer James MacGill. Together they settled in Vancouver, where two daughters were born.

Mrs. MacGill soon turned her enormous energies into work for improvement and reform in that growing community. Women's suffrage, penal conditions, juvenile delinquency and the care of needy women and children all had her ardent attention.

Her objectives in the improvement of social conditions were met with bitter opposition which she cheerfully and courageously weathered with growing support for her programs.

Her efforts on behalf of juveniles culminated in her nomination as judge of the Juvenile Court in Vancouver in 1917. In this "first" in the Province of British Columbia and possibly in Canada, she again made history.

Numerous social reforms and legislation stemming therefrom all bear the imprint of this remarkable woman.

Her daughter's charming and intimate biography makes of her life story a great human and interesting documentary.

Constance G. Short, LL.B.

BOOK NOTES*

Prepared by the Library
The Engineering Institute of Canada

*Review provided through the courtesy of the Engineering Societies Library in New York.

Analyse quantitative minérale, 3e éd. Gaston Charlot et Denise Bézier. Paris, Masson, 1955. 823 pp., 7000 fr.

While this edition has been completely revised it still remains a practical guide for the analytical chemist and metallurgist, rather than a theoretical text.

The book is again divided into two sections. The first deals with the various methods used in analytical chemistry to study the phenomena of solutions, precipitations, etc. The different types of reactions which can be produced are also studied.

The larger half of the book covers the properties of the elements, arranged in alphabetical order.

This edition contains new information on spectrophotometry and electrochemical methods of analysis.

Architectural engineering. Editors of Architectural Record. New York, Dodge, 1955. 494 pp., illus., $11.50 (U.S.).

The editors of the well-known "Architectural Record" have gathered together articles by specialists on the newest developments in the field of architectural engineering. Each section is supplemented by plans, diagrams and photographs.

The reader will find cost-cutting methods, new uses for old and new materials, new structural systems and new mechanical and electrical equipment. The book is divided into six large sections covering all details of building design and construction. The first section on the building shell includes studies of roofs, floors and prefabrication; the next chapter deals with environmental control including interesting data on panel heating, thermal insulation, acoustics, etc. The next two sections discuss such utilities as vertical transportation and materials handling equipment, and site planning. The information on many new materials in the next section will be very useful, while the last chapter goes into special problems connected with structural safety, fire and explosion protection, and planning for atomic energy.

In addition to such specific information the book attempts to establish common ground between the architect and engineer by outlining basic principles, and demonstrating their applications.

Basic electrotechnics, 2nd ed. B. L. Goodlet. Toronto, Macmillan, 1955. 277 pp., diagrs., $4.10.

The present edition has not been changed to a great extent but does contain a new chapter on transient phenomena and additional material on the three-phase system. It is intended, as was the first edition, to be a textbook for students in electrical engineering, and covers basic electromagnetic theory.

There is a condensed account of steady and alternating current theory, electrostatic fields, condensers and dielectrics, and electrodynamics. There are also chapters on the calculation of magnetic fields, Maxwell's equations and electromagnetic waves, and generators, motors, transformers, and some other apparatus are briefly described. Rationalized m.k.s. units are used throughout the book.

The Beama catalogue, 3rd ed., 1955-56. London, Iliffe, 1955. 1034 pp., illus.

In this third edition of the well-known buyers' guide to the products and services of the electrical industry in Great Britain, the information has been brought completely up to date. There are again a large number of valuable illustrations and, for the reader's convenience, each section is printed in a distinctive second colour.

The products of member firms are displayed in three sections: electrical power plant; electrical equipment in industry, transport and communications; domestic and commercial electrical appliances, lighting, accessories and installation material.

In addition there is a five language glossary of technical terms, a classified buyers' guide using more than 1,200 headings, and a trade directory giving addresses of domestic and overseas branches and agents.

"Nobody knows de trouble I've seen"

HOW MANY times has a glove like this on the hand of a maintenance worker gripped a wrench to repair a valve in your plant? How many of those times could have been avoided if the valves had been better ones from the start? The big advantage of quality valves like Crane is in the performance they deliver *with less maintenance.* Just one repair job can, and often does, cost many times the difference in price between a "bargain" valve and a Crane quality valve.

So today as you seek ever more intently for ways to cut costs, look for the kind of valve dependability that cuts down your piping upkeep. Buy better for lower ultimate cost. That's *always* real thrift. It's the reason why so many Crane valves and fittings are going into service today.

For complete information on Crane quality valves to meet your particular requirements, ask your Crane Branch, or write

Boundary layer theory. Hermann Schlichting. Toronto, McGraw-Hill, 1955. 535 pp., diagrs., $18.00.

Although the boundary layer theory is an important part of modern fluid dynamics, this is the first book to treat the subject exclusively. It first appeared in the German language in 1951 and included material which had been classified as secret during the war.

The book is written especially for engineers and for students of mechanical engineering and machine design and the emphasis is on basic physical ideas rather than on mathematical details.

The main purpose of the text is to present the mathematical and physical background of the problems involved in the motion of viscous fluids. The first section discusses the basic equations of the boundary layer theory as they are derived from the Navier-Stokes equations of motion. The second part contains the theory of laminar boundary layers, and includes the theory of thermal boundary layers. The third section covers the phenomenon of transition from laminar to turbulent flow, while the last section is devoted to turbulent flows.

Some examples and results of experiments are given to provide a clear insight into the phenomena and because they constitute the foundation of the semi-empirical theory.

The common sense of the exact sciences. W. K. Clifford. New York, Dover, c. 1946. 249 pp., pa. $1.60 (U.S.).

Another in the series of cheap editions of classical scientific works published by Dover, this has been a general reader's guide to modern scientific and mathematical thought for seventy years, covering such topics as number, space, quantity, position and motion.

*__La construction des tunnels, galeries et souterrains.__ Georges Bardout and Pierre Berny. Paris, Eyrolles, 1954. 287 pp., illus., 3400 fr.

A comprehensive treatment of tunnel construction covering planning, excavation methods, timbering, blasting, shield and compressed air operations, sintering of caissons, etc. Separate chapters are devoted to the description of equipment, to the necessary calculations, and to the evaluation of costs. Some notable tunnels are briefly described and a group of detailed diagrams of typical projects is appended.

*__Constructional steelwork.__ Oscar Faber. Toronto, British Book Service, 1955. 368 pp., illus., $8.50.

Based on British Standard 449/1948, this book discusses the design of beams, girders, columns, fasteners, and connections for steel frame buildings of the normal office or apartment type. The design of small and large roof trusses and of workshops with traveling cranes is also treated, and chapters are included on elementary design principles, materials and properties, specifications, and working stresses. Fully worked out examples are included.

Cours d'électrotechnique: 1. partie—Théories générales, 3e éd. Edgar Gillon. Montreal, Fomac, 1955. 288 pp., diagrs., $10.20.

This is a general introduction to electrical engineering theory and differs from previous editions by the inclusion of Giorgi units.

The six chapters of the book discuss electrostatics, electrical circuits, dielectrics, magnetic circuits, the theory of alternating currents and methods of measuring electrical units.

Engineering students would find this a useful background text in the field of electricity.

Les dislocations et la croissance des cristaux. Willy Dekeyser et Severin Amelinckx. Paris, Masson, 1955. 184 pp., diagrs., 2000 fr.

This book discusses the theory, advanced by Frank in 1949, of the helical growth of crystals at the supersaturation point. The authors also describe methods of observing this phenomena and cover the subject of dislocations of crystals. Because these latter are closely connected to the properties of solids, this work will not only interest crystallographers and mineralogists but also metallurgists and physicists.

Electrical year book, 1956. Manchester, Emmott, 1955. 360 pp., illus., tables, 3/6.

The 1956 Electrical year book has a new section giving a concise account of electronic fundamentals and methods, illustrating these by reference to the more appropriate of the new applications. In the section on electric lighting new material has been included on the quick-start fluorescent lamp.

Eléments de mécanique quantique. Ph. Pluvinage. Paris, Masson, 1955. 547 pp., 4600 fr.

Some of the most recent theories and discoveries connected with quantum mechanics have been covered in this new book. It presents not only the theory of the subject but also the practical applications resulting from this theory. The author's purpose in writing his book was to assist students and practising scientists and engineers to become familiar with this branch of physics.

There are three large divisions in the book, following the basic concepts of atomic physics. The first of these discusses the particle in movement on an axis, and includes Schrodinger's equation and Heisenberg's theory. The next section on the particle in space includes detailed treatment of such phenomena as spin and the Zeeman effect. In the last part of the book the general principles of the systems of particles are outlined.

First congress of the Fédération Internationale de la Précontrainte, London, 1953. London, Cement and concrete association, 1955. 255 pp., 50/-.

The present volume contains the general reports in English, French and German on the three main topics discussed at the technical session of the Congress, and the discussion on these topics in English.

The topics considered are: The influence of abnormal temperatures on prestressed concrete construction; The design of statically determinate beams and slabs in prestressed concrete, based on ultimate load; Statically indeterminate structures in the elastic and plastic states. The general reporters and members of the discussion groups include such famous names in the field of prestressed concrete as Magnel, Guyon, Hill, Dardanelli, Lazard and many others.

Frontier to space. Eric Burgess. Toronto, British Book Service, 1955. 174 pp., illus., $3.60.

The author of this interesting book has attempted to gather together in-

• Library Notes

formation and data on the long-range rocket which had previously appeared only in technical papers and reports. As in his other book, **Rocket Propulsion.** Mr. Burgess forecasts space travel and the fascinating discoveries which the advance of rocket propulsion are making possible. Most of his book could be read by persons with little scientific training but the references will make it valuable to the serious student.

The first part of the book describes the short history of long range rockets and the experiments which are being constantly carried out and which will eventually lead to the artificial satellite and the probe missile. Other chapters discuss the ionosphere, solar radiation, cosmic rays and the debris of space, and the region beyond the exosphere.

Frontiers of astronomy. Fred Hoyle. Toronto, British Book Service, 1955. 360 pp., illus., $5.00.

Mr. Hoyle is well known for two other books written in the same popular style as the present work: **The nature of the universe** and **A decade of decision.** In **Frontiers of astronomy** he reveals himself both as an authority in this particular branch of science and as an experienced writer. The book is based on studies he made at Mount Palomar Observatory in California and much of the material has not previously been presented in popular form.

Atomic and nuclear physics are discussed in two of the early chapters as well as the applications of physics to astronomy. These are followed by chapters on the earth, moon, sun, planets and various types of stars. The author then proceeds to a broader description of star systems like the Milky Way and includes the origin of galaxies and the birth of stars. The interesting new subject of radio astronomy is also considered.

The last three chapters are devoted to modern theories of the Universe and to future unsolved problems in astronomy.

Fuel: solid, liquid and gaseous, 5th ed. J. S. S. Brame and J. G. King. Toronto, Macmillan, 1955. 551 pp., illus., $8.50.

The first edition of Fuel appeared in 1914 and, as there had been no revision since 1935, this edition has been almost completely rewritten. The book is intended to be a broad introduction to fuel technology but is limited to the properties of fuels and their methods of application. The details of processes of production or utilization of fuels are not included.

The different types of fuel discussed are wood and peat, coal and coke, oil fuels, gaseous fuels and water gas. Many advances in fuel technology are described including the widespread use of pulverized coal, the conversion of coal to oil by hydrogenation or synthesis, and new methods of petroleum refining such as catalyst-cracking.

The last three chapters deal with fuel analysis, determination of calorific value and economy in fuel usage.

*__Gas turbines and jet propulsion,__ 6th ed. G. G. Smith. London, Iliffe, Toronto, British Book Service, 1955. 412 pp., illus., $6.00.

Concerned mainly with airplane engines, this book covers basic principles, thrust and performance, the relative efficiency of jets and airscrews, components, combustion, metallurgical problems, testing, and maintenance. It also contains descriptions of current American, British, Canadian and European gas turbines, a chapter on ramjets, pulsejets, and rockets, and brief discussions of gas turbines for automobiles, locomotives, ships, and for various industrial applications.

*__Instruments for measurement and control.__ W. G. Holzbock. New York, Reinhold, 1955. 371 pp., illus., $10.00 (U.S.).

Nine chapters of this book are devoted to descriptions of the operational characteristics and, in many cases, the structural details, of instruments commonly used in industrial plants for measuring temperature, humidity, pressure, flow, and other process variables. Five chapters deal with various control devices—electric, pneumatic, hydraulic, etc. — and the last chapter briefly summarizes recent trends in the use of centralized control systems.

Machine translation of languages. W. N. Locke and A. D. Booth, eds. New York, Wiley, 1955. 243 pp., $6.00.

One of the greatest problems in the world today is the language barrier which prevents understanding and tolerance among nations. In recent years there has been an effort to enlist the aid of machines in overcoming this barrier. This collection of fourteen essays surveys the progress that has been made since 1949 when Warren Weaver, with his **Translation,** started linguists and engineers thinking on this subject.

After an historical introduction the book covers such topics as the design of an automatic Russian-English technical dictionary, a preliminary study of Russian, some problems of the "Word," speech input, storage devices, the Georgetown University-I.B.M. experiment in mechanical translation, the mechanical determination of meaning, model English, syntax and recent experiments.

Most of the authors are specialists in the field of languages and mathematics and their essays will provoke much thought among engineers and other readers.

Matter and light: the new physics. L. De Broglie. New York, Dover, c. 1939. 300 pp., pa. $1.60 (U.S.).

The author, recipient of the 1927 Nobel Prize for Physics, here presents several of his studies of contemporary physics, written so that those with no mathematical training can understand the greater part of the work. Topics covered include matter and electricity, light and radiation, wave mechanics and quantum physics.

Mécanique, 5e éd. G. Bruhat, A. Foch, rev. Paris, Masson, 1955. 724 pp., 3000 fr. (Cours de physique générale).

This general textbook on mechanics gives full coverage to the various topics usually associated with the subject. It is presented in seven general sections which are subdivided into detailed chapters.

The first section deals with statics, including a basic discussion of vectorial calculus, kinematics and the theory of work. In the second section the subject of dynamics is covered in its different aspects. The third part is shorter but is devoted to a subject not always included in this type of book: metrology. The measurement of time and the theory of vibrations are explained next, followed by a section on fluid mechanics. The last two sections contain a great deal of new material on the discussions of vibrations in fluids and solids.

The book contains many equations and, as well as being a text for uni-

• Library Notes

versity students, it would serve as a "refresher" course for graduate physicists and engineers.

Mechanical world year book, 1956. Manchester, Emmott, 1955. 360 pp., illus., tables, 4/6.

A feature of this edition is a new section on gas turbines. Now that experience in gas turbine design has been accumulated and become more widespread, a more advanced account of current practice is required, therefore, a concise section on design procedure has been included. This presents data and detailed methods for use in dealing with the principal components.

Additional or revised material appears in the sections or tables on materials, power plants, limits and fits, keys, cutting speeds and feeds.

National directory of the Canadian pulp and paper industries, 1955. Gardenvale, National business publications, 1955. 501 pp., $4.50.

This publication is similar to previous editions, and includes the latest available statistics of the industry. At the beginning there is a general description of the pulp and paper industry, the paper box and bag industry, the roofing paper industry, the forest resources of Canada, etc. The directory then lists pulp and paper mills by provinces and towns, followed by tables showing the number of mills by type, the number of grinders, machines and digesters by kinds, location, and capacity. Other sections cover converters of paper, distributors, and merchants and trade commissioners connected with the pulp and paper industry.

Nuclear physics. Irving Kaplan. Cambridge, Addison-Wesley, 1955. 609 pp., diagrs., $8.50 (U.S.).

With nuclear physics entering the field of industrial engineering there is a great need for engineers and scientists with a working knowledge of the subject. This book attempts to provide an understanding of the atomic and nuclear bases necessary for the solution of problems involving reactors, etc. The reader needs no previous training in atomic or nuclear physics although a general background in physics and calculus is assumed.

The first seven chapters deal with the foundations of nuclear physics and cover such subjects as radioactivity, X-rays, atomic structure, atomic spectra, and relativity. The next section discusses the physics of the nucleus, while the last five chapters are devoted to special applications and subjects, including neutron physics and nuclear fission.

The petroleum refinery engineer's handbook, 2nd ed. J. F. Strachan. Toronto, British Book Service, 1955. 168 pp., diagrs., $8.50.

The main purpose of this book is to correlate inspection procedures, methods, recording and equipment used in oil refining plants. Since the first edition appeared in 1947, under the title **Practical inspection of oil refinery equipment,** new inspection methods, using electrical and electronic methods, have been introduced and are discussed in this edition.

The book is divided into five chapters. The first deals with the organization and personnel of the plant inspection department; the second with inspection procedure, and the third with corrosion and protection of oil equipment. The last two sections discuss calculations and formulae used by the inspector, and the principles of general safety in a refinery.

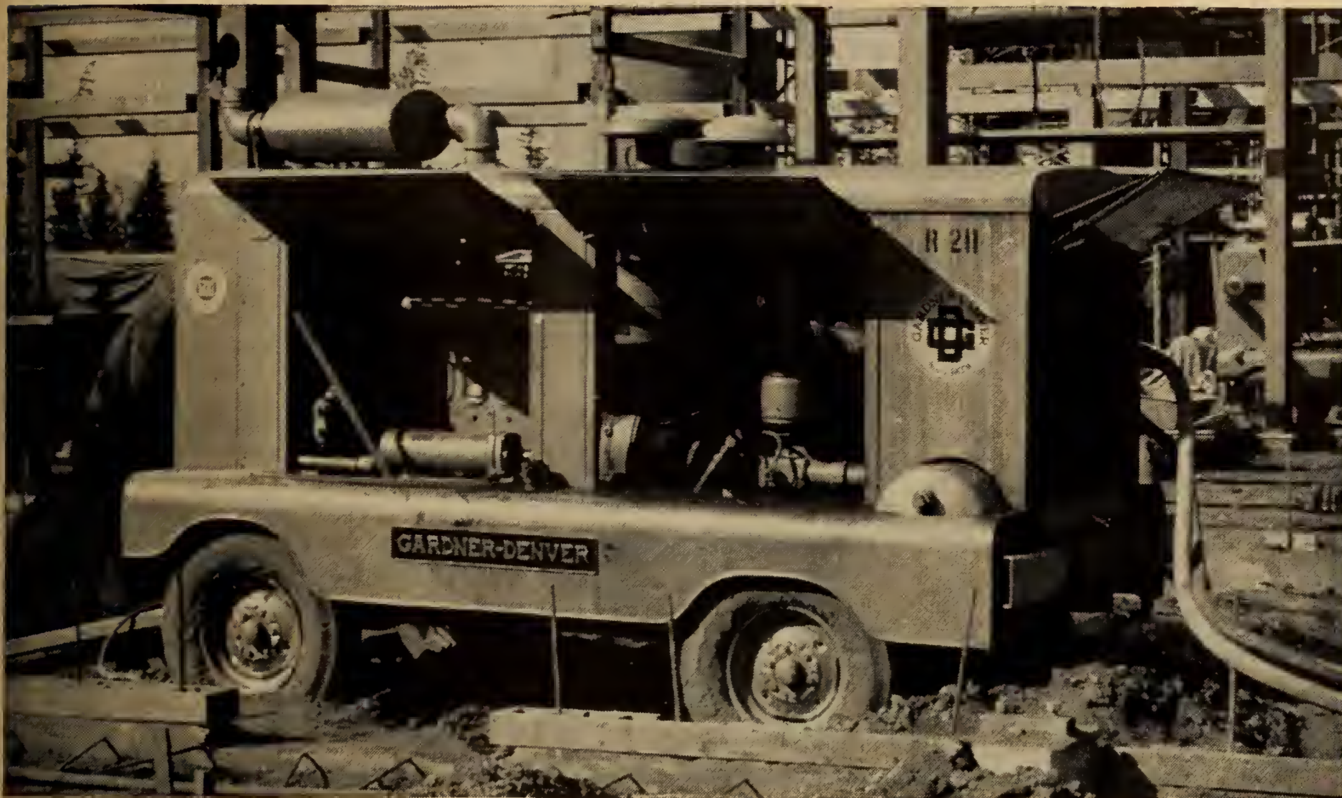
Physique atomique. Marcel Rouault. Paris, Colin, 1955. 220 pp., diagrs.

The many branches of atomic physics are discussed in this little textbook. Beginning with a chapter on the granular structure of matter and the constituents of the atom, it goes on to describe the theories of quanta and photons, Bohr's theory and wave mechanics. There is a chapter covering the electronic structure of atoms and the emission of spectral rays. The last chapter deals with the complex atoms and touches on such subjects as spin, X-rays and the theory of absorption.

***Research reactors.** United States atomic energy commission. Toronto, McGraw-Hill, 1955. 442 pp., illus., $7.80.

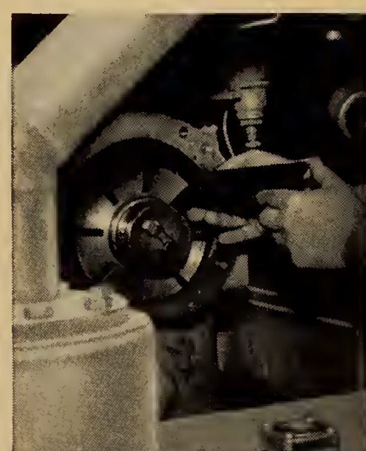
This book gives descriptions of three types of light-water-moderated reactors (pool, solution, and materials-testing), and of three other types: hydro-carbon-moderated; heavy-water-moderated, and

Gardner-Denver . . . Serving the World's Basic Industries



More reliable on the job . . . new Gardner-Denver Water-Cooled Rotary 600

Here's a work-horse weather can't faze; automatic water-cooling keeps compressor and engine operating at their most efficient temperature. Water circulation system warms up compressor oil, assures full lubrication as soon as compressor is engaged, offers you extra safe starts.



Extra Easy to Inspect!

Preventive maintenance is a matter of minutes . . . handled by your regular compressor mechanic . . . right on the spot.

Special inspection covers give quick and easy access to all vital compressor parts. And it's just one of the many advances pioneered by Gardner-Denver to make sure the new Rotary 600 gives you the air you need when you need it!

GARDNER - DENVER

THE QUALITY LEADER IN COMPRESSORS, PUMPS, ROCK DRILLS AND AIR TOOLS FOR CONSTRUCTION, MINING, PETROLEUM AND GENERAL INDUSTRY

Gardner-Denver Company (Canada), Ltd.; 14 Curity Ave., Toronto 16, Ont. Factory: Brantford, Ontario. Branch Offices: Montreal, Que., Kirkland Lake, Ont.; Vancouver, B.C.; Nelson, B.C.; Sydney, N.S., Edmonton, Alta.

• Library Notes

graphite-moderated. Information given for each type includes general design features, core design and fuel handling, cooling system (where applicable), control and instrumentation, shielding, experimental facilities, and operating characteristics. The book was prepared originally for the International Conference on the Peaceful Uses of Atomic Energy.

Spectrochemical abstracts, v. 4, 1946-1951. E. H. S. van Someren and F. Lachman. London, Hilger and Watts, 1955. 179 pp., 30/-.

The eight hundred abstracts presented in this volume cover the years 1946-1951. The main arrangement is by subject, and there are complete author and subject indices. Some of the topics under which the material is grouped in-
been made to select for inclusion papers
clude the various substances analyzed—biological materials, gases, minerals, etc.—apparatus, methods and source theory.

Many of the abstracts are taken from other compilations, and an attempt has
which not only give the results of spectrochemical analysis, but also contribute to the development of the subject.

Ultrasonic engineering. A. E. Crawford. Toronto, Butterworth, 1955. 344 pp., illus., $8.00.

Although the study of ultrasonics has been generally left to the physicist, recent discoveries on the applications and effects of ultrasonic waves have led to a much greater interest in the subject among industrial engineers. While this book has devoted some space to the basic theory and generation of ultrasonic waves, the larger part deals with their use in such processes as metal coating and cleaning.

The first two theoretical chapters discuss the characteristics and measurement of ultrasonic waves, and the nature of cavitation. The section on generation is divided into four chapters, covering piezoelectric and magnetostriction transducers, jet generators and electromagnetic transducers. Besides the practical applications mentioned above the author describes the use of ultrasonics in such processes as precipitation and agglomeration, emulsification and dispersion, as well as their applications in the fields of chemistry, metallurgy, biology and medicine. The last chapter discusses ultrasonic instruments and control gear.

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Air pollution

The effects, measurement and control of the atmospheric pollution due to combustion—a review and a bibliography. P. C. G. Isaac. (Durham. University. Dept. of civil eng. Bull. No. 3.)

Automobiles

Facts and figures of the automobile industry, 1955. Motor vehicle license fees, 1955 (Canadian automobile chamber of commerce).

Education

List of students registered in the graduate schools of Canadian universities in science, engineering and medical sciences, 1955-1956. (Canada. NRC Div. of admin. Personnel br.)

Labour supply

Adjustments to labor shortages. R. A. Lester. (Princeton Univ. Industrial relations section.)

Metals refining

Refining antimony by electrodeposition and by distillation. R .R. Rogers and R. A. Campbell. (Canada. Dept. of mines and technical surveys. Mines branch. Tech. pa. No. 11.)

Miscellaneous

A decade of progress: The Quebec hydro-electric commission, 1944-1955.

The first tool engineer. R. B. Douglas. American society of tool engineers.

For Greece a tear: The story of the Greek War Relief Fund of Canada. Florence Macdonald. (Fredericton, Brunswick press.)

Radio and television engineering

Color television receiver practices. Hazeltine corp. laboratories staff. (Rider pub. No. 162) $4.50 (U.S.) pa.; $6.00 (U.S.) cloth.

Crystal oscillators. Alexander Schure, ed. (Rider cat. No. 166-4) $1.25 (U.S.).

Frequency modulation. Alexander Schure, ed. (Rider cat. No. 166-3) 90c (U.S.).

Rider's specialized HI-FI AM-FM tuner manual (Rider pub. No. 7001, v. 1) $3.50 (U.S.).

ENGINEERING CAREERS

The Royal Canadian Army

With the constant threat of military aggression facing the western nations, Canadians have thought it wise to join with other free countries in a compact for mutual protection from foreign domination.

To protect our home soil from possible invasion and to fulfil our other obligations to the United Nations and NATO, the armed services of Canada have been increased from their token strengths of the 1930's and now are strong fighting forces equipped with the best of modern arms. Today there are close to 50,000 men in Canada's Regular Army. Canadian troops are serving in Europe, and the army has provided troops in such places as Korea and Indo-China. There are military missions in the Middle East, India and Pakistan, and military staffs at embassies in various capitals.

The peacetime task of the Regular Army is mainly one of preparedness. The army must keep itself fit so that it can fight effectively in times of war. Study, training, planning and research are its principal occupations. The advent of nuclear weapons has worked great changes in the nature of war, but it has not made armies obsolete. Victory in a new war would go, not to the side that relied on the new weapons alone, but to the side that integrated them most effectively with conventional arms and used *every* weapon most efficiently. It is still true in any war that only the soldier can seize ground and hold it. Moreover, Korea showed that only the soldier can fight small wars fought with conventional weapons.

Increased application of scientific and technical discoveries to the arts of war has altered most of the concepts of military strategy. To develop, test, service and repair the many new weapons and machines needed for defence, the army operates design establishments, proving grounds, training schools, repair depots and maintenance units. All of these give the engineer opportunities not easily matched by civilian industry. While an engineer in civilian life may be compelled to limit his talents to a narrow field of endeavour, there is wide scope for the engineer in the army.

Thus there are fine opportunities for young university men with brains, initiative and a sense of purpose. There are openings for every special talent that the engineering profession develops. The army uses every engineering skill and technique.

The life of the engineer in the army is one of study, teaching and of leadership in the service of Canada. It is a life which provides variety in employment, experience and travel. Advancement is based on ability. Clever engineers can go to the very top. In the army you will find no end of challenge for your ability. The following are some of the fields in which military engineers are indispensable: architectural design, radiation control, radar, design and development of vehicles, weapons, electrical and telecommunication equipment, development of guided missiles, map making, photogrammetry, Shoran plotting, and many others.

THE ENGINEERING CORPS

In the Regular Army there are three corps which employ professional engineers. These are: The Corps of Royal Canadian Engineers, The Royal Canadian Corps of Signals, and the Corps of Royal Canadian Electrical and Mechanical Engineers. Here is a brief outline of their vital work:

The Corps of Royal Canadian Engineers

The RCE is one of the largest and most varied technical arms of the army's combat forces. It provides vital engineer work that permits the troops to live, move and fight. Airfields must be levelled, harbour facilities built, railways and roads constructed, water and sewage systems installed, light and power provided, rivers bridged, obstacles demolished—this list scratches the surface.

In peacetime the RCE plans construction, repairs army properties, supervises building projects, maintains the Northwest Highway System and develops architectural design. To win battles, commanders must have the best of maps. It is the responsibility of the RCE to supply them. The Army Survey Establishment is the second largest topographical agency in Canada. It uses electronic instruments, helicopters and a wealth of the latest scientific equipment — a really up-to-date organization.

Everyone knows the splendid work done by the RCE during floods, fires and hurricanes. Providing aid to the stricken populace in times of disaster is another task of soldiers who wear the iron ring.

The Royal Canadian Corps of Signals

Without efficient up-to-date communications a modern army would be in a state of chaos. Radio, telephone, land line and cable systems are all essential to speed information to and from commanders both in the field and in permanent locations. The Royal Canadian Corps of Signals provides this communication network.

The Signal Officer plans and supervises the setting up and operation of mobile radio stations, the design and installation of line communication systems using equipment which must be portable yet thoroughly reliable. The army's permanent communication system in Canada uses modern radio teletype, tape relay and local telephone services. Much study is also being done in the fields of microwave radio relay, antennae systems, and in suppression of radio interference.

An important pioneer communication network installed and operated by this corps is the Northwest Territories and Yukon radio system. This system carries on a fine public service, providing many of the isolated communities with their only outside contact.

The Corps of Royal Canadian Electrical and Mechanical Engineers

The modern army is highly mechanized and uses a great variety of electrical, electronic and mechanical tools and weapons. The secret of its successful operation lies, of course, in the skill and speed with which the Electrical and Mechanical Engineers keep all the machines working. There is nothing so useless as a gun that will not fire accurately or a tank that breaks down at a crucial moment of combat. To keep all equipment in first class working condition, the Army has men who are thoroughly trained in electrical, optical and mechanical precision work.

The Royal Canadian Electrical and Mechanical Engineers are the repairmen of the army. In both their own shops and with units of other corps, their motor, tank and gun mechanics, electronic and instrument repairmen, machinists, welders, electricians, and other tradesmen, do every kind of repair on all types of army equipment—from tanks to watches and from field cookers to radar sets. Directing these skilled workers requires top engineering know-how.

DESIGN AND DEVELOPMENT ESTABLISHMENTS

Discoveries made during recent years in such fields as nuclear physics, electronics and new substances compel the Canadian Army to exercise and encourage the highest initiative in the design and development of new equipment. To do this the Regular Army operates five Design and Development Directorates which are responsible for progress in the fields of armament, vehicles, signal stores, engineer equipment, and general stores and clothing.

Some of the best scientific talent in universities and industry is working with the armed forces in matters of defence. But the importance of all new technical discoveries from a military point of view can only be fully assessed by engineers who are trained directly in military operations. The army engineer working in the design and development fields plays a valuable role in collaboration with civilian scientists and technicians engaged in defence projects.

Army development project engineers keep in close contact with advances in technology by liaison with such organizations and firms as: Canadian Arsenals, Limited; The National Research Council; Atomic Energy of Canada, Limited; Canadian Industries, Limited; The Aluminum Company of Canada; The Steel Company of Canada; Massey-Harris-Ferguson; Sorel Industries, Limited; General Electric; Northern Electric; and Westinghouse.

There is a great deal of analytical thinking to be done, and the professional engineer in the army has ample opportunity to exercise his imagination.

TRAINING

Engineering graduates with COTC training are appointed to the Regular Army in the rank of Lieutenant. Those without COTC training are enrolled as Second Lieutenants and take a short course which is the equivalent of COTC training. On the successful completion of this course they are promoted to Lieutenant.

A tri-service training scheme which will appeal to engineering undergraduates is the Regular Officer Training Plan (ROTP). The ROTP makes it possible for university students to complete their studies at government expense. The financial benefits to undergraduates who join the army under ROTP amount to approximately $1,700 a year in pay, subsistence, tuition, books and other academic fees. Most Canadian universities provide courses which are acceptable for subsidization under ROTP.

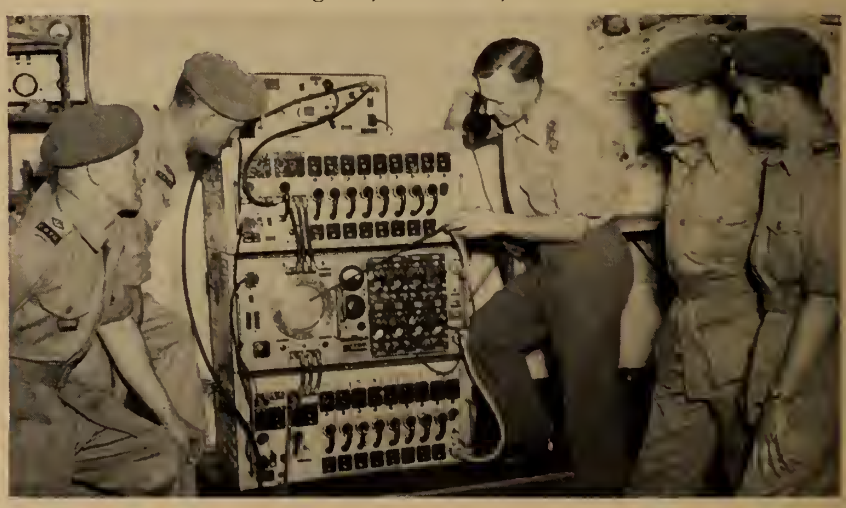
On completion of his initial training, the new Lieutenant is posted to a unit of his corps where he takes a technical course designed to gear his university education to service engineering problems. His next posting is to a unit where he undertakes regimental duty. This is a most important phase of his practical training. It is during this period that he develops qualities of leadership and man-management by training and administering troops. It is his job to mould his NCOs and men into an efficient, well disciplined and enthusiastic team.

During this phase he also carries on his studies, is taught and coached by his superior officers to prepare for promotion and greater responsibility. He is given a variety of duties over a comparatively short period of time.

As their careers develop, selected officers are often sent for advanced training in other countries, particularly to the U.S.A. and U.K. For officers desiring to raise their educational standards, the army sponsors a number of post-graduate courses at universities in Canada, the U.S.A. and U.K. These courses lead to Masters degrees in such fields as automotive engineering, chemistry, biochemistry, communications engineering, soils, sanitary and structural engineering.

When the professional engineer eventually leaves the army, the

Lecture on radiocommunications being given at the Royal Canadian School of Signals, Barriefield, Ont.



knowledge and experience gained in the service will greatly improve his opportunities in business.

PAY AND PROMOTION

A comparison between army and industrial salaries shows that 55 per cent of professional engineers do not reach the amount of pay and allowances which engineers in the army receive. Moreover, the average salary of engineers employed in industry does not surpass that of their Army counterparts except in the middle thirteen years of their employment.

Promotion is based on individual merit, qualifying time in rank, and seniority. A survey taken since the end of the second world war shows that on the average the new officer may look forward to four years as a Lieutenant, five years as a Captain, and seven years as a Major. At that rank both the army and civilian engineering fields show the same pattern for future promotion; as in all worthwhile careers, the highest positions and salaries go to the men who show executive ability in addition to their technical skill. It might be of interest to know that a number of graduate engineers have attained the rank of Major-General in the Army, including S. F. Clark, H. F. H. Hertzberg, H. Kennedy, W. H. S. Macklin, W. J. Megill, N. E. Rodger, C. Vokes, G. Walsh, H. A. Young; M. A. Pope became a Lieutenant-General.

Candidates who are enrolled as Second Lieutenants receive pay and allowance of $250 a month. On successful completion of their short course they are promoted to Lieutenant with pay and allowance of $319 for unmarried officers, or $380 for those who are married.

Army Officers also receive special allowances under various circumstances. These include risk allowance, foreign service allowance, and northern allowance. All army personnel receive complete medical and dental care free of charge. The new officer is given $375 as an incoming clothing allowance to buy military uniforms.

The duty of an army officer in wartime is a strenuous occupation. It is a task for young men, and as a part of keeping itself in fighting trim the army must be able to retire officers when they are too old for effective military service. One result of this is that most officers retiring are still young enough to continue their careers as engineers in industry.

Donjek bridging project on the Northwest Highway System.

The Defence Services Pension Act provides for the payment of a pension to army officers on completion of a full term Army career. In addition, there is an act that ensures a pension to the officer or his dependents in case of injury or death which arises out of or is directly concerned with military service.

MARRIAGE ALLOWANCES POSTINGS AND LEAVE

There is plenty of room for an enjoyable family life for the army man. When an officer is transferred, his family and belongings are nearly always moved with him at public expense. The married officer who has completed his introductory training and is at least 23 years of age will receive a marriage allowance of $40 a month.

Of course the army cannot supply all military personnel with married quarters. But it is a fact that military authorities are doing their best to accommodate as many people as possible with the facilities available at the moment and that they try to speed up their programme for more such buildings. In the case of the Second Canadian Infantry Brigade, the Government sends English and French teachers from Canada to make sure that the children of our soldiers in Germany receive the same education as those in Canada. In short we may say that in peacetime the Army is doing extremely well in this regard and that few civilian enterprises can boast of similar achievements.

Postings are usually for three years' duration. Wherever he goes the officer lives in a social environment that is friendly and rewarding. Sometimes new postings look uninviting, but often turn out to be surprisingly pleasant. Postings to out-of-the-way stations are frequently filled by volunteers, but the army considers such postings as part of the normal duty of every Army man.

The army officer must frequently work on week ends or in the evenings, because his work is involved with matters that cannot be put aside and with the lives and welfare of other men entrusted to his care by the Queen's Commission. But the army recognizes that holidays are important for morale. All army personnel normally get 30 days annual holiday, and in some cases travelling time up to 8 days may be allowed. Leave is also granted under special circumstances, such as for convalescence, after a foreign posting, or for compassionate reasons.

SELECTION

Selection of army officer candidates is rigorous and any new officer can be proud of his acceptance. Candidates undergo a thorough examination for suitability, and successful applications are forwarded to the officer selection committee at Army Headquarters for further screening. The physical requirements are high, and a complete medical inspection must be passed. But the energetic young engineering students or graduates who have a liking for the challenge and responsibility of service life usually possess the qualities from which fine officers are made. In brief, the army offers them an excellent opportunity for good comradeship, excellent training and a chance to do their part in the defence of Canada. √

Employment Service

THIS SERVICE is operated for the benefit of members of The Engineering Institute of Canada and for industrial and other organizations employing technically trained men—without charge to either party. It would be appreciated if employers would make the fullest use of these facilities to list their requirements—existing or estimated.

NOTICES appearing in the SITUATIONS WANTED column will be discontinued after three insertions. They will be reinstated, on request, after a lapse of one month.

REPLIES to advertisements should be addressed to File No. 000, Employment Service, The Engineering Institute of Canada, 2050 Mansfield Street.

INTERVIEWS with the Institute Employment Service, 2050 Mansfield Street, Montreal—Telephone PLateau 5078—may be arranged by appointment.

SITUATIONS WANTED

EXECUTIVE ENGINEER, M.E.I.C., P. Eng. (Quebec) B.Sc. Queens with electrical and mechanical background and strong management and administrative experience desires change and seeks a senior and challenging appointment where his abilities can be fully used. Married with three children and speaks and writes French. Full details of past experience and positions will be furnished to serious inquirers upon request. File No. 937-W.

GRADUATE ENGINEER, M.E.I.C., P. Eng. (Que.) McGill, substantial background manufacturing operations, plant organization and administration. Plant and project engineering. Layout, methods studies, standard costs, production control, material handling. Some sales. Age: mid-forties. Available reasonable notice. Seeks opening as production executive or assistant. Plant engineer or sales. Resume on request. File No. 1186-W.

CHEMICAL ENGINEER, B.Sc., (Ch.E.) M.E.I.C., M.A.I.Ch.E., 43, married, Canadian and U.S. resident; equal knowledge of English and German, Experience: 9 years research and development in fuel technology, 5 years process and project engineer in petroleum refinery engineering. Desires assignment in Germany, Austria or Holland as process, project, or sales engineer in the field of petroleum refinery engineering. Presently employed. Available on one month notice minimum. File No. 1314-W.

MECHANICAL ENGINEER — sound technical and executive background gained through 18 years of practical engineering experience. B.Sc. and M.E., M.E.I.C., A.S.M.E., P.Eng. Ontario, Canadian. Age 40, married. If a future with scope for advancement exists in your organization for an engineer with this background, please contact File No. 2745-W.

MECHANICAL ENGINEER, Jr.E.I.C., P.Eng. (Ont.), N.S.T.C. graduate 1950, 27 years old, single. Two years pulp and paper mill design and layout, one year diesel locomotive maintenance, 18 months railway car building and heavy repair. Desires responsible position where qualifications and experience can be utilized. Available on reasonable notice to present employer. File No. 3271-W.

ADMINISTRATIVE ENGINEER AND PHYSICIST available on part time short term, or retainer basis. Already has a satisfied clientele and now wishes to expand operations. Total of 26 years experience in small and large firm management, testing, instructing, reporting, co-ordinating and service selling. At present, specializes in working for companies requiring extra assistance for short periods at reasonable rates. Where necessary, the following qualifications and affiliations can be cited: B.Eng., M.Sc., M.E.I.C., Soc. Sigma XI, C.A.P., P.E.Q. Security risks previously approved. File No. 3322-W.

ENGINEER, PRESENTLY EMPLOYED, is looking for an interesting and challenging supervisory position in construction or an allied industry. Experience in practically all phases of light and heavy construction with owner and contractor. Experience includes supervision in field and office, evening courses on industrial management as well as field and design work on civil and mechanical engineering projects. Married, age 35, B.Sc. in civil engineering at U.N.B. 1949, P.Eng., M.E.I.C. Will supply summary of experience on request. File No. 3386-W.

ELECTRICAL ENGINEER, B.Eng., McGill 1950, P.Eng., Jr.E.I.C., C.G.E. Test Course, desires responsible position with development or managerial prospects. Experience includes design and construction of industrial power and lighting systems, power factor correction, frequency conversion, system control, air conditioning, resistance welding, material movement and various fabrication processes and plant engineering work (4 years). Polyphase induction motor (½ to 600HP) design, application and test experience (2 years). Overseas World War II five years. Married with three children. Now in Hamilton area but will consider any location. Available on reasonable notice. File No. 3859-W.

MUNICIPAL ENGINEER, JrE.I.C., P.Eng. (Ont.), Queen's (civil) 1949, age 33, single, with 6½ years municipal experience including 2½ years as Town Engineer in Ontario town of 8000 population, seeks an opening in municipal or allied field with future and responsibility. Available in 1956 on one month's notice to present employer. Anywhere in Canada. File No. 4012-W.

CIVIL ENGINEER, M.E.I.C., P.Eng. (N.S.) A.M.I.C.E., (Britain), age 34, married with family. Seeks responsible appointment with consultant, municipal authority, or well established contractor, preferably in Nova Scotia or New Brunswick. Experience in Britain included 8 years with municipal authorities, mainly designing and supervising highways, sewers and buildings. 2½ years with consulting civil engineer in Canada, designing large sewerage and water distribution schemes. Used to writing specifications, taking-off quantities, and preparing reports and estimates. Good administrative experience. Available on one month's notice to present employer. File No. 4157-W.

ELECTRICAL ENGINEER, Jr.E.I.C., McGill 1951, P.Eng., experienced in industrial maintenance, consulting engineering and construction. Desires responsible position in one of these fields where qualifications and experience may be fully utilized. Location not important. Available on one month's notice. File No. 4202-W.

ELECTRICAL ENGINEER, B.Eng. (Hons.), M.A.Sc., M.E.I.C., P.Eng., age 37, married and presently completing tenth year as a professor of electrical engineering. Most of teaching has been on advanced level with emphasis on power. Broad general experience in construction, public utility engineering and as a naval officer. Has done considerable consulting work of a general nature. Seeks appointment conducive to personal and professional growth. File No. 4402-W.

TO CONSTRUCTION FIRMS AND CONSULTANTS located in Montreal area: Civil engineer, Jr.E.I.C., seeks a partial position to work during evenings and Saturdays in concrete design, reinforcing details, supervision of contract and in estimating costs. Additional information obtained by phone or sent on request. File No. 4477-W.

MECHANICAL ENGINEER, M.E.I.C., P.Eng. (Ont.), single, aged 29. 5 years apprenticeship, 8 years combined machine design, project engineering, estimating, tendering and sales in medium/heavy engineering. Presently employed but desires a more responsible position principally interested in administrative design and project engineering. References available. Location preference, Toronto or surrounding cities. File No. 4796-W.

MECHANICAL ENGINEER, Jr.E.L.C., 1952 B.Eng., married, age 34. Completed training course with large manufacturer of electrical equipment. Presently employed; experience includes cost reduction and product improvement work as manufacturing engineer on switchgear equipment, induction and synchronous motors. Varied experience in sales and field engineering. Capable public speaker. Desires sales or product engineers' position demanding initiative and with opportunity for advancement. Preferred location in Ontario or Maritime Provinces. File No. 4820-W.

PROFESSIONAL ENGINEER, B.A.Sc. Electrical 1953, S.E.I.C., 27 years old, married, two children. Fluently bilingual, 2½ years extensive design and supervision work with consulting engineering firm. Other diversified experience as resident engineer on construction project. Capable of dealing with people at any levels. Would consider position where initiative, ability and productivity is needed and which offers challenge and advancement. Location preferred: Eastern Ontario or Quebec. File No. 4830-W.

CHEMICAL ENGINEER, Jr.E.I.C., B.Eng., McGill, 1952, A.I.Ch.E., Jr.E.I.C., C.I.C., P.Eng., age 28, married, desires a more responsible position. Experience in development work in chemical plant and paper mill. Also administrative experience as production supervisor in a chemical plant. Presently employed in Quebec, however would consider employment anywhere in production supervision or development. File No. 4832-W.

CREATIVE ENGINEER, supervisory and management background in chemical and process metallurgy fields, and with sound engineering understanding. B.A.Sc. (Toronto), M.Sc. (Queen's), and A.H.I. business course. M.E.I.C., age 34. Can contribute in plant management, operational analysis or technical administration. File No. 4833-W.

HYDRAULIC ENGINEER, M.E.I.C., Junior member A.S.C.E., graduate B.Sc. (C.E.) Man. 1948, M.Sc. Utah State 1955. Married, 31, two children, returning to Canada desires employment in hydraulic design or related fields. 6½ years experience in drainage, irrigation and highways. File No. 4834-W.

GRADUATE ENGINEER, economist, accountant, 33, experience in construction, cost and production control, management, Government, and commerce in the Far East, requires senior executive or advisory appointment in Ontario, Quebec or foreign. File No. 4835-W.

Applications of High Alumina Cement

P. H. Harris,
Director,
Lafarge Aluminous Cement Company Ltd.,
London, England.

This paper indicates the main characteristics and uses of high alumina cement and outlines its origin and qualities.

During the last few years, there has been an increasing use of high alumina cement in Canada. This material is also known as aluminous or calcium aluminate cement.

It is not a special type of Portland cement, but is of the hydraulic type, and the concreting techniques employed are in general very similar to those employed with Portland cement. It must not be forgotten, however, that high alumina cement is a completely different chemical substance; briefly, the principal cementing constituent of high alumina cement is mono-calcium aluminate, whereas in Portland cement, it is di- or tri-calcium silicate. This fact has an important bearing on the physical properties of the two cements. Typical analyses given in Table I show the essentially different chemical make-up of the two types of cements.

The raw materials and manufacturing methods employed make high alumina cement considerably more expensive than Portland cement, and therefore its use is normally only justified in situations where one or other of its four main characteristics are necessary or desirable. In brief, these four main characteristics are:

(1) Great rapidity of hardening following a normal setting time.

(2) Resistance to many chemical agents that attack ordinary cements.

(3) Ability to provide a "refractory concrete" which will withstand white heat.

(4) In low atmospheric temperatures, the concrete will harden normally without the application of external heat.

High alumina cement was evolved at the beginning of this century. Although the first traceable patent was taken out in 1888[1], this, like other early patents[2], only covered the calcium aluminates as additives to a variety of materials including Portland cement, plaster, etc.; apparently, these early patentors did not realize the significance of calcium aluminate as a cement on its own. The first workers to realize this significance were the Société J. & A. Pavin de Lafarge, who patented a manufacturing process for high alumina cement in France (1908)[3] and England (1909)[4]. This process essentially consisted of melting bauxite and lime in a water-jacketed blast furnace, the resultant clinker being ground to cement fineness. The cement was known as Ciment Fondu[5] which means literally "melted cement".

The experimental work that led to this material's production was carried out in order to produce a cement that would be completely immune from sulphates whether found in the ground or in sea water. Extensive full scale trials during world war I showed that it was, in fact, immune from these conditions, and Ciment Fondu was first marketed in France in 1918.

During the 1920's the commercial sale of high alumina cements commenced in England (Ciment Fondu, 1923) and the United States (Lumnite, 1924). Although high alumina cement was first marketed for its sulphate resisting properties, it was soon discovered that it had rather remarkable rapid-hardening characteristics. These rapid hardening qualities were soon utilized in industry and they are worth mentioning.

The only existing standard specification for high alumina cement, British Standard Specification 915-1947, calls for the following physical properties:

Compression — on 1:3 vibrated mortar cubes:

24 hours: over 6000 p.s.i.
72 " " 7000 p.s.i.

Setting time (Vicat):

Initial: From 2 to 6 hours.
Final: Less than 2 hours after initial.

Soundness (Le Chatelier): Expansion not greater than 1 mm.

Some recent test results[6] obtained from 12 in. standard compression cylinders give an idea of the strength curves to be expected from various mixes. Forty-eight cylinders were tested, all of which were cured in a fog room at 65°F. from the time of casting to that

Table I. Analyses of Cements

	High Alumina		Portland	
	A	B	A	B
Insoluble	0.11	0.52		
SiO_2	3.6	9.5	23.84	21.2
FeO	6.4	4.6		
Fe_2O_3	10.4	4.4	2.12	7.11
Al_2O_3 and TiO_2	41.4	41.2	3.96	2.64
CaO	36.9	38.5	64.96	63.04
MgO	1.0	0.89	1.2	1.05
SO_3	0.03	0.21	1.31	1.6
Other impurities to 100%	—	—		

of testing. Tables II and III give the results of these tests.

The compressive strength figures largely speak for themselves, but it is also interesting to note that samples were taken for six and twelve hour strengths. A typical 1:2:4 concrete (mix 3, Table II) gave the following results:

6 hours: 1440 and 1350 p.s.i.

12 hours: 5120 and 5110 p.s.i.

These figures show the remarkably high strengths of high alumina cement concretes at very early ages and, furthermore, that even weak mixes have strengths of structural grade. It should be noted, however, that these weak mixes will be porous and therefore not suitable for every application.

It will be seen from Table III that the hardening of high alumina cement is virtually complete 24 hours after casting, and the heat release during this period, due to the intensity of the chemical reaction, is enough to protect the concrete against damage in temperatures many degrees below freezing point. As the chemical action reaches its height 10-14 hours after casting, the period of time over which frost penetration can occur is comparatively short.

(2) In warm weather, when aggregates are exposed to direct sunlight, it is also a good idea to wet down aggregate piles in order to keep the placing temperature of the concrete within reasonable limits.

Following these two simple rules should ensure good grade concrete in the field, but, should the reader be in any doubt, the manufacturers should be consulted.

If the ultimate strengths inherent in this type of concrete are required, it is not normally recommended that structural high alumina concrete is poured when atmospheric temperatures above 85°F. are expected during the pouring and hardening period; this is due to the difficulty of effectively cooling any mass of concrete, but the season when such sustained temperatures are experienced is comparatively short, and this should not represent any real inconvenience to the user.

Chemical Resistance

High alumina cement concrete has an extensive use when resistance to a wide variety of aggressive chemicals is required. The resistance of this type of concrete to the influences that can affect Portland cement is probably due not only to the absence of highly reactive free lime, but also to the gelatinous aluminous hydrate formed during the hydration of the calcium aluminate. In practice, this means that high alumina cement can be used in contact with pure water, very dilute acids, sulphates and certain organic compounds. Whereas high alumina cement cannot be regarded as an acid proof cement, concrete made with it is resistant, and in many cases immune, to attack from the various acidic industrial wastes which readily attack Portland cement.

One of the chief applications of high alumina cement is for floors which are subject to spillage of aggressive liquids. In situations where attack is likely to be at the limit of the concrete, high alumina cement can be used for mortar joints to impervious tiles, but under the majority of circumstances an ordinary stone and sand concrete is sufficient, providing, of course, that the aggregate is equally immune from attack.

A full survey of the chemical resistance of the high alumina cements has already been published[7] and any reader requiring information about a specific problem is advised to consult it. It is unfortunately, not within the scope of this article to deal with all cases as these are numerous, but the list below will give some idea of the types of plant in which high alumina concrete has been used successfully:

Fertilizer Plants: Resistance to dilute sulphuric acids and sulphates.

Gas Producing: Resistance to gas scrubbing liquors.

Tanneries: Resistance to tan liquors (but not chrome tan).

Food Products: Resistance to fats, sugars, etc.

Breweries and Distilleries: Resistance to dilute organic acids.

Meat Packing: Resistance to oils, fats, and organic acids.

Sugar Refineries: Resistance to sugar, molasses, etc.

Candy and Chocolate: Resistance to cocoa butter, fats and sugar.

Dairies and Milk Products: Resistance to lactic acid and cream fats.

Ice Cream Plants: Resistance to lactic acid and cream fats.

Plastics Industry: Resistance to phenol and formaldehyde.

When considering the use of high alumina cement for any of these purposes, it should be borne in mind that it is attacked by caustic alkali solutions.

Refractory Use

In recent years, the refractory use of high alumina cement has gained predominance in Canada and the United States and the terms "refractory concrete" and "insulating concrete" are now in common usage, as meaning a mixture of high alumina cement and crushed refractory or refractory insulating aggregates. The wide acceptance of these materials has been largely due to their cheapness of installation and mainten-

Table II. Test Results

Mix	Nom. proportions	Water/ cement	Slump in.	Comp. factor	Workability
1	1:2:4	0.35	0	0.73	very low
2	"	0.45	0	0.81	very low
3	"	0.55	1	0.87	low
4	"	0.65	8	1.00	high
5	"	0.75	—	1.00	high
6	1:3:6	0.82	4	0.98	high
7	1:4:8	0.90	1¾	0.90	medium

This rapidity of hardening and the heat evolution associated with it has a close effect on the ultimate strength of the concrete. It can readily be seen that the higher the atmospheric temperature at the time of placing, the higher the starting temperature of the concrete constituents, and therefore, the higher the ultimate internal temperature of the concrete during the hardening period.

(1) For this reason high alumina cement manufacturers recommend that all high alumina cement concrete should be cured with cold water during the period from final set to, say, 24-hours after placing. This curing helps to keep the internal temperature down and thus ensures good grade concrete.

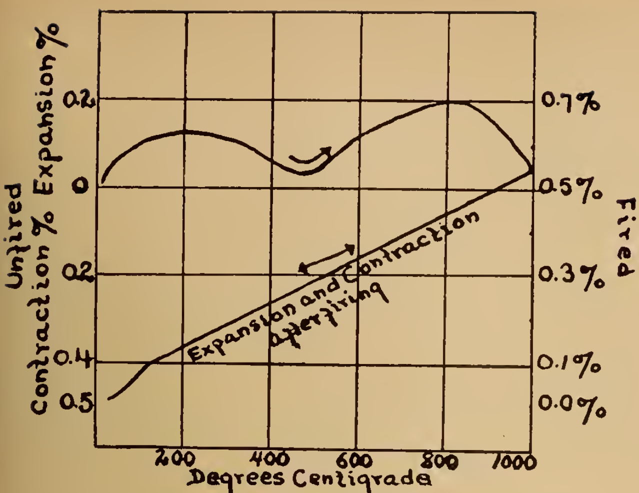

Fig. 1. Expansion and contraction characteristics of refractory fire-brick concrete.

ance, and their effectiveness as low and medium temperature refractories.

In order to satisfy the demand for these concretes, a large industry has grown up which specializes in manufacturing "ready to use" dry refractory and insulating concrete mixes. These mixes only need the addition of water, and are normally designed for specific purposes; they provide the user with a practically foolproof method of making these concretes. These dry mixes are known generally as castable refractories.

The placing techniques used with refractory concrete are generally the same as those used with structural concrete; many methods are open to the user, including concrete cast in place, Guniting, pre-cast concrete sections and units. There are, however, three general points which must be remembered.

(1) Reinforcing steel should not be used in positions where it is likely to reach a temperature of over, say, 600°F; or, if this is impracticable, then arrangements should be made to use high-temperature steel and artificially to break the bond between the steel and concrete, either by applying a thick coating of pitch to the steel or by wrapping it in several thicknesses of building paper.

(2) Manufacturers of dry mix castable refractories, usually specify the amount of water to be used in their mixes, but should the user contemplate mixing and placing his own home-made refractory concrete, it must be remembered that the majority of the aggregates employed are porous and should be pre-soaked in order to cut down any suction of water needed to hydrate the cement.

(3) The expansion characteristics of refractory concrete are different from other refractories, and can be best illustrated by a simple graph as shown in Fig. 1.

As a general rule, it can be said that a given volume of refractory concrete will be the same size at 1800°F., as when first cast.

Although the manufacturers of high alumina cements recommend that the same curing procedure is carried out with refractory concrete as formerly outlined, the concrete can still be put into service 24 hours after casting, although care has to be taken during the first heating owing to the excess water being driven off the concrete.

When the user contemplates placing large masses of refractory concrete, such as furnace foundations and large underground flues, he will find it cheaper and more practicable to crush and grade his own scrap material and make his own refractory concrete on site. Any type of alumino-silicate fire-brick is suitable for this purpose, but silica brick should not be employed owing to its expansion characteristics at comparatively low temperatures. Special bricks, such as sillimanite, chrome, magnesite, silicon carbide, etc., can be used, and they will largely reflect their own particular characteristics in the concrete. A simple table is given below which shows the various aggregates which can be used in each temperature range:

Temperature service up to 1800°F.

Suitable aggregates:

2nd quality crushed fire clay brick.

Crushed insulating fire clay brick.

Expanded shale materials.

Calcined diatomaceous earth.

Olivine, trap rock, emery (2000°F.).

Perlite, vermiculite, pumice.

Temperature service 1800° to 2400°F.

Suitable aggregates:

Crushed fire clay brick—first quality or high heat duty brick.

Crushed pottery saggers.

Calcined clays.

Selected crushed insulating fire clay brick.

Temperatures over 2400°F.

Chromite

Fused alumina

Sillimanite

Dead burned magnesite

The advantages of carrying concrete construction techniques into the refractories industry are obvious and therefore, require no comment here except to say that the simplification and adaptation of design is almost limitless. Refractory concrete does, however, have other properties which will be of particular interest to the refractories user.

(a) It appears that some non-ferrous metals (e.g. aluminum) do not wet refractory concrete and, therefore, it is easy to clear melting furnaces between charges; furthermore, in the case of pure metals, pick-up from refractories is drastically reduced.

(b) The cellular structure of refractory concrete gives it a truly remarkable resistance to the spalling action of wide and rapid fluctuations of temperature. As an example of this, a cube of concrete

Table IV. Comparison of Insulating and Refractory Concretes

Insulating Concrete	Refractory Concrete
Made with High Alumina cement and crushed refractory insulating brick or lightweight aggregate.	Made with High Alumina cement and crushed refractory firebrick.
Only suitable in general for hot face temperatures up to 2000°F. (with certain special lightweight aggregates it can be used up to 2400°F.)	Suitable for hot face temperatures up to 2400°F. (with certain special refractory grogs it can be used up to 2800°F.
Lightweight (30-80 lb. per cu. ft.). Comparable to insulating brick construction.	Heavier than insulating concrete (110-120 lb. per cu. ft.) although somewhat lighter than firebrick construction.
Low thermal conductivity (somewhat higher than that of insulating brick used.)	Higher thermal conductivity than insulating concrete (although considerably lower than that of firebrick.)
Lower strength than refractory concrete (but higher than insulating brick used.)	Comparatively high strength.

at white heat can be immersed in cold water without any spalling or distortion taking place.

(c) Refractory and insulating concrete can be cast integrally without fear of subsequent separation in service. This property would be of some value to the user requiring thermal efficiency, but having hot face temperatures beyond the range normally covered by the insulating aggregates.

The strength of refractory concrete in service depends on the ceramic bond formed between the cement and the fine aggregate particles, and since a higher proportion of cement gives a ceramic bond at lower temperatures, it is generally advantageous to use fairly rich mixes when operating temperatures are not likely to exceed 1800-2000°F. Conversely, if operating temperatures of over 2400°F. are expected, then weaker mixes should be used. Variations within this range are almost limitless and, therefore, a general rule can be stated that the lower the cement, the lower the ultimate strength, but the higher the refractoriness, and vice versa.

In order to give practical expression to this rule, the following mixes will cover the majority of cases met with. Aggregates should be reasonably well graded from maximum size to dust, the maximum size being determined by the maximum thickness of section envisaged.

Mix "A"

For use in sections of, say, six inches or over. If very thick sections are anticipated, the maximum aggregate can be raised to 1½ in., and in such cases four to six volumes of aggregate (1½ in. down to dust) to one volume of cement should be used.

Coarse firebrick ¾ in.-⅛ in.—3 vol.

Fine firebrick ⅛ in. to dust—2 vol.

H. A. cement—1 vol.

Mix "B"

For use in sections from 2 in.-6 in. in thickness.

Medium firebrick ⅜ in.-⅛ in.—2 vol.

Fine firebrick ⅛ in. to dust—2 vol.

H. A. cement—1 vol.

Mix "C"

For use in thicknesses thinner than 2 in., or for patching.

Fine firebrick ⅛ in. to dust—2½ vol.

H. A. cement—1 vol.

The above mixes are for use in the temperature range between 1800°F. and 2400°F., but if temperatures at the upper end of this range are expected the cement content of the mixes can be reduced with advantage, as this type of concrete is approaching its service limit.

If service in temperatures above 2400°F. is required, then there are several courses open to the prospective user.

(1) The use of a weak mix (6-8 vol. of aggregate to one of cement) using as aggregate an alumino-silicate brick of over 40 per cent alumina content.

(2) The use of a mix incorporating a highly refractory aggregate such as sillimanite, fused alumina, silicon carbide, etc.

(3) The use of a proprietary high-temperature castable refractory.

Insulating Concretes

When greater heat insulation is required from the concrete, a refractory insulating aggregate should be employed, and in order to prevent any confusion between refractory and insulating concrete the main general differences are shown in Table IV.

Although all these differences do not necessarily apply when special insulating aggregates are used, the table does illustrate the essential differences between the concretes.

Insulating concrete will usually give a lower compressive strength than refractory concrete, both before and after the concrete is heated, and its strength is more or less proportional to the unit weight of the concrete. Aggregates of the Haydite type are an exception to this rule, and will give strengths comparable to refractory concrete, i.e., about 3000 p.s.i. cold strength.

The thermal conductivity factor (K factor) of the various concretes made with insulating aggregates vary within fairly wide limits and, therefore, the pertinent details of each group is given in Table V.

Combinations of the above aggregates can be used in order to produce concrete of relatively high insulation with greater strength. √

Table V. Thermal Conductivity of Concretes

Aggregate	Conductivity (K) Btu/hr./sq. ft./°F./in. (at 1500°F.)	Concrete wt. per cu. ft. lb.	Service limit °F.
Firebrick	7.5	120	2500
Ins. firebrick	2.5 - 3.5	60/70	2400
Haydite	3.0 - 3.5	90	2000
Diatomaceous earth	2.7	60	1800
Vermiculite	1.5 - 2.0	30/40	2000

Strain Gauge Analysis

Applied to the Design of Construction Equipment

H. A. Spencer, M.E.I.C.
Mechanical Engineer,
Research Council of Alberta,
Edmonton, Alta.

and

E. H. Brennan, M.E.I.C.
Chief Engineer,
Barber Machinery Limited,
Calgary, Alta.

Electrical strain gauges are being used to analyse difficult designs when solutions cannot readily be found by conventional methods. Strain gauge analysis offers a new and valuable approach for the designer, particularly in the manufacture of construction equipment—a field in which arbitrary methods have often been used in the past.

For fairly simple structures, when loading conditions are known or can be estimated, the pattern of stress may be calculated. Where shock loads are indeterminate, it is customary to use a "load factor". However, for some complex applications, a designer may be at a loss to estimate an appropriate load factor, since each component of a structure may be subjected to different kinds of shock. In such cases, tedious and difficult calculations may be required.

Frequently it is difficult to trace the distribution and magnitude of the stresses through an intricately braced structure. For example, an overhead loader has a wide range of attitudes in which the components may be stressed, and it may be impossible to calculate the position of maximum stress for each component.

Confronted with such difficult problems, a designer resorts to his mechanical judgment to proportion his design. Invariably, the tendency to "play it safe" results in "overdesign" of the structure. Even so, when the first test models are built, failures may occur. These are remedied, generally, by reinforcement of the member at the point of failure instead of through a redesign to improve the distribution of the stresses. Such design methods do produce a saleable machine since it is not likely to fail in service. Overdesign, however, imposes two disadvantages on the manufacturer of construction equipment:

(1) Material is wasted, thereby increasing the cost of the product.

(2) The "payload" is decreased, as each additional pound incorporated in the equipment represents a decrease of one pound in payload capacity.

Since the construction contractor is interested primarily in the payload per dollar of investment, any increase in the payload capacity will increase equipment sales.

Conservative designs may never fail in service, but may not be economically competitive. Less conservative designs cost less to produce, but they may be dangerous to operate and breakdowns may occur frequently. Hence, a correct design is most important, and involves knowing the magnitude of stresses which actually occur so that an appropriate design load factor may be selected to anticipate sudden shocks.

Overhead Loader-Dozer

The "Malo" overhead loader and bulldozer[1] was built first in 1947 to fit a "crawler" tractor. From the illustrations of an early model (Fig. 1) and a current model (Fig. 2), one may see the structural changes which have been developed.

The primary design was engineered as thoroughly as possible, using the meagre information which was available to the designers, who corrected for the few failures that occurred by the simple expedient of stiffening and enlarging those components which required greater strength.

Eight years of experience with this overhead loader had proved that the machine performed its function well and did not fail under operating conditions. However, the management thought that the machine's efficiency could be improved and manufacturing costs reduced by redesign of some of the components to accommodate the actual stresses applied. To accomplish this purpose it was decided to conduct a strain gauge analysis of the unit under loaded conditions to determine:

(1) The actual stress distribution through those parts which seemed stronger than necessary.

(2) An accurate load factor as an aid to future design work.

(3) A stress pattern from which actual loads on components (such as bearings, bolts, pins and welds) could be calculated.

(4) The upper stress range in known critical sections.

Test Equipment and Procedure

Two amplifiers ("Brush" model BL-310), attached to one dual-pen magnetic oscillograph (Brush model BL-222), were set up to record strains. Baldwin SR-4 strain gauges, with a gauge factor of approximately 2.0, were used; these were of the usual felt and paper type to be applied with nitrocellulose cement. The overhead loader-dozer was mounted on an International TD-9 crawler tractor.

Fig. 1. First model of the overhead loader-dozer, built in 1947.

Fig. 2. Current model of the overhead loader-dozer.

of rail embedded in the concrete floor in front of the testing area and the tractor, with load in place, was driven forward at normal speed to apply a push to the barrier.

Each day, before testing, the Brush strain analyzer was warmed up for 30 minutes and left on for the duration of the tests. Gauges, which had been cemented into place, were soldered to lead wires before each test. The leads were attached firmly to each machine component so that, as it moved, there would be no pull on the connections. Before each test the gauges were calibrated in position at "no load". Since only a two-pen instrument was available, testing was limited to two gauge points at a time. Dummy gauges were set as near to the tractor as

Test Preparation

The following strain gauge positions were selected:

(1) The highest stress points as determined by mathematical analysis.

(2) The high and low stress points which, in the designers' judgment, required analysis.

(3) Positions known to have failed occasionally during heavy service.

In addition to these positions on the loader, several gauge points were selected on the tractor itself, to determine the effect of severe overhead loader action.

The selected points were buffed clean and the strain gauges applied with their axes parallel to the highest expected stresses in each component (see Fig. 3).

The rated capacity of this overhead loader-dozer for the TD-9 tractor is about 1½ cubic yards. Since this yardage of wet gravel weighs approximately 4,200 pounds, a number of pieces of solid steel shafting totalling this amount were fastened securely to the inside of the bucket. The load was placed so that its centre of gravity coincided, as nearly as possible, with the centre of gravity of a normal gravel load in order to simulate actual working conditions.

Since a fixed load would provide stresses greater than normal, it served as a fair test for the loader. However, the loaded bucket was not moved to the "unload" position for two reasons: (i) unrealistic impact loads would have resulted since, normally, in the unload position, the load is loose; (ii) a fixed load of 4,200 pounds in the unload position might create a hazardous condition of unbalance.

Simple methods were used to approximate the loader's working conditions. To simulate the effects of loading, unloading, and travelling over rough ground, a chock was placed under one track. This provided sufficient height to raise that track completely off the concrete floor, at an angle such as to support most of the weight on the front idler. By abrupt clutch and hydraulic applications the tractor and loader were made to rock and pitch violently, thus providing the stresses which occur when travelling over rough or uneven surfaces. To simulate pushing into a gravel pile or the normal impact of bulldozing through trees and rocks, a steel barrier was welded to a piece possible to equalize temperatures, and all testing was done indoors in the large heated shop.

Notes were written directly on the graph paper as it moved past the recording needles in order to correlate strain with the position and action of the loader. When check runs seemed advisable they were performed immediately.

As most stresses were very low, a maximum sensitivity of 10 micro-inches per inch per graduation was used for most of the tests. When stresses were of greater magnitude, the sensitivity was reduced to 20, 50, or 100 micro-inches per inch. For rapid stress fluctuations, repeat runs were made at higher tape speed so as to record the stresses more accurately. Maximum stresses within the range of 18,000-22,000 p.s.i. were assumed to be satisfactory.

Stress was calculated during the test by the formula:

$$S = Ee$$

where S = stress, p.s.i.
E = Young's modulus, 30×10^6 p.s.i.
e = unit elongation, inches/inch

Test Procedure Outline

Each test of two gauge points was run through in the following sequence:

(A) Bucket movement with tractor on level floor:

(1) Digging.

(2) Steady lifting to overhead position.

(3) Steady lowering to floor.

(4) Jerky lifting to overhead position.

(5) Jerky lowering to floor.

(6) Dropping bucket freely from 5°, catching it just before it struck the floor.

(B) Bucket movement with one track on the chock: repeating the operations shown in (A).

(C) A "loaded push" against a solid barrier.

Test Procedure Details

To simulate rough "digging", the bucket was pushed down until the front of the tractor was raised off the floor; then, while in this position, hydraulic pressure was rapidly applied and released.

The steady "lifting" and "lowering" tests were performed to obtain design data for the "steady state" stress condition through the complete range of load travel.

The jerky "lifting" and "lowering" tests were performed to establish a normal "load factor" for rough operation and to determine the highest stresses which could be expected under these conditions.

The "dropping and catching" operation was achieved by allowing the load to drop freely from 5°, and then catching it just before the bucket struck the floor. This involved a free drop of approximately three feet and represented an extreme action which should never occur in practice. It imposed the severest stresses on most components, and should represent the maximum stresses which would occur under operating conditions.

The "loaded push" test was carried out only when determining stresses on the yoke and mounting bar, since it soon became apparent that all the forces were carried directly through the yoke to the track frame of the tractor. This test, which involved a full throttle run at the barrier, produced impact forces severe enough to break the barrier and its braces.

Fig. 3. Typical attachments of strain gauges to components.

Results and Application

From the graphs (Fig. 4) maximum stresses were calculated. Analysis of these figures gave the following interesting results.

(A) *Component Parts*

(1) The back section of the pickup arm, which had been enlarged to accommodate eccentric loads, was found to be much too strong as the maximum tensile stress was 8,400 p.s.i. This component currently is being redesigned.

(2) The cylinder saddle casting, which carries the hydraulic cylinder trunnion and the pickup arm fulcrum bearing, also had been made strong to accommodate eccentric loads. Since the maximum stress was 11,000 p.s.i. on this component, it also is being redesigned.

(3) The yoke section was found to be of good design and no suggestions for improvement were necessary. The maximum stress at the outside front corner was 22,500 p.s.i., which occurred during a loaded push at the barrier. This was in agreement with previous engineering calculations.

(4) The outside support plate, which fastens the hydraulic cylinder saddle to the tractor frame, was found to be slightly overweight since its maximum stress was 10,500 p.s.i. The inside support plate was considered to be well designed since its maximum stress was 19,500 p.s.i. In addition to redesigning these plates for more equal distribution of the load, consideration will be given to replacing them by flat bars so that more open space will be available for cleaning the track rollers.

The Friction of Ice
and Its Economic Significance

C. D. Niven,

National Research Council,
Division of Physics,
Ottawa, Ont.

The low friction of ice is such commonplace knowledge that until recently scientists have paid little attention to the explanation of this strange phenomenon. Ice however is unique among common substances in so far as several of its physical properties are concerned—to cite one other of these, it expands on freezing. Reynolds, the great pioneer of hydrodynamic lubrication, saw that there might be some connection between these two properties: if freezing causes expansion then pressure must tend to cause melting and this suggested to Reynolds that the pressure of a skate or sleigh runner on ice would tend to form a film of water and therefore ice might supply its own lubricant. It was quite difficult to prove or disprove that theory and so unfortunately it came to be accepted by knowledgeable people; thereby the stimulus for the investigation of the real problem was removed. If the phenomenon was commonplace, the explanation was reckoned to be self-evident to anyone who knew why an iceberg floated.

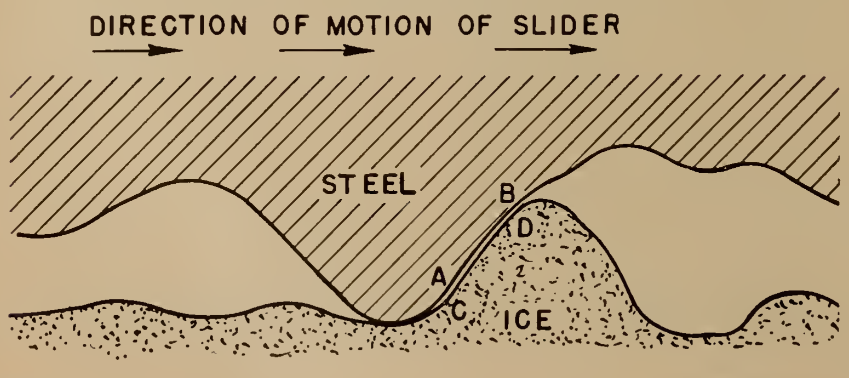
As the ideas of Hardy on adhesion of molecules became woven into the theory of friction, Bowden saw that all was not well with the accepted explanation because the pressure which would be required looked too high, and he favoured the idea that if water were present to supply the lubricant then it was generated by heat, not by pressure. Around this time the problem took on a new significance, because the aeroplane had become a regular means of transportation and skis were required for landing on snowcovered lakes. Among the first in this field of investigation was Klein[3] who supported the heating rather than the pressure-melting theory, be cause of course loadings per unit-area are comparatively small on skis. More recently, however, McConica[4] of the American Ski Company while definitely opposing the pressure-melting theory has cast doubts even on the correctness of the heating theory and has been led to conclude that "lubrication was effected . . . by a fluid film of adsorbed vapour". Clearly the explanation is not as simple as Reynolds' suggestion had implied: a real understanding of the problem can in fact only be reached by considering molecular or at any rate microscopic phenomena.

Before discussing the friction of an exceptional material like ice, it is perhaps not out of place to mention some of the modern ideas on the friction of normal substances. Thanks to the work of Bowden[1] and others, information on the friction between unlubricated surfaces is fairly extensive at the present day. If solid surfaces be closely examined it will be found that they are not nearly as smooth as one imagines. As one writer has expressed it, the surface appears like a mountain range in miniature. Thus when one surface rests on another, one miniature mountain range turned upside down is resting on another miniature mountain range. Only the highest of the peaks therefore make contact. Although some scientists have endeavoured to explain friction by the interlocking of these peaks, the majority of authorities on the subject believe friction is caused by the adhesion of these peaks or "asperities". Bowden and his collaborators have contributed some very convincing evidence to show that the adhesion theory is correct.

Bowden and Ridler[2] have shown that high instantaneous temperatures can be generated when one substance slides over another. Thus constantan sliding on steel can generate instantaneous temperatures up to 1000°C. If a metal with a much lower melting point be substituted for constantan then the maximum temperature that can be observed is the melting point of that metal. Since there is high temperature and high pressure at the tips of the asperities in contact with the other surface it is reasonable to expect that welding will take place. That such a supposition is correct has been amply proved. Bowden has published photographs which show that one metal can actually pull microscopic chunks out of the other metal. It has also been shown that just as oxide or other contamination tends to prevent a sound weld, so they reduce friction as a general rule between metals.

Returning now to the problem of ice friction, one can assume in the first place that heat is generated at the asperities on the surfaces of the slider and of the ice. There can be no doubt about this because it requires work to move a slider over ice which is perfectly

Fig. 1. Diagrammatic representation of two asperities coming in contact with one another.



level: this is more obvious at colder temperatures. From the observation described above referring to temperatures developed by the friction of a low melting point metal, it is safe to assume that in the case of ice the maximum asperity temperature which can be reached on slider or ice surface is 32° F. Therefore the heat developed is either absorbed as latent heat used in melting some of the asperity on the ice surface or else it is carried away by conduction to the main body of either surface and eventually lost to the atmosphere.

Much interest has centred for long around the debatable point as to whether water was present or not under a slider on ice. Actually such a discussion is quite irrelevant unless one wants to bolster up the old hydrodynamic lubrication theory. Experimental evidence indicates that there is no continuous layer of water under the slider except at temperatures over 32° F. McConica goes as far as to point out that if water be present as a fluid, increase of speed would cause increase of friction, while observation shows that friction decreases on dry ice with increase of speed. This subtle argument gives a definite reason for supposing that water is not present below 32° F. as a fluid layer. On the other hand it is to be expected that there be a softening of the asperities on the ice with actual melting in some cases. One may also expect that in those cases in which melting occurs, some asperities will melt considerably more than others. This can be surmised from the record which Bowden has published, demonstrating that 1000° C. and other high temperatures are reached only occasionally when constantan slides on steel.

If attention be now concentrated upon those asperities which do melt, it is easily seen that the possibility of making a weld between ice and slider depends to a considerable extent on whether water wets the slider or not. The importance of one substance "wetting" the other substance if a satisfactory weld is to be obtained is illustrated in the every-day technique of tinning before soldering. It is to be expected then that those substances which are not easily wet by water will show a lower friction than those which are. At low temperatures this is amply demonstrated by the much lower friction of materials like Bakelite and Teflon which do not wet easily as compared to clean steel which does wet easily. Lightly loaded steel has in fact very bad sliding qualities on ice at low temperature. Such facts as these indicate that much the same processes are at work when a slider slides on ice as when metal slides on metal—asperities are heated; asperities then start to weld together or "adhere"—a force which is called the frictional force is required to break these welds by shearing.

There is, however, one thing which has not been taken into consideration. When two asperities meet there is a sudden increase in pressure along the surfaces (AB and CD in Fig. 1). Heat is developed as AB attempts to slide up CD and CD down AB because the molecules in the asperity are compressed as the asperity is forced to shear. In normal substances increase of pressure tends to facilitate solidification but in the case of ice it tends to retard solidification. So it is to be expected that the increase in pressure along the AB-CD interface operates against the increase in temperature in the case of a normal substance, but that in the case of ice both increases cooperate in tending to melt the asperity, so that if a weld is to be formed conduction must carry away the heat sufficiently quickly to cause freezing.

The low friction of ice is well known, but the reasons for this phenomenon are not so well established. The author discusses current theories and the possibility of economical transportation in northern areas.

Such reasoning would lead one to expect, firstly, a reduction of ice friction with high loading or high speed because the pressure along the AB-CD interface is increased; and secondly, an increase of ice friction when the ambient temperature is low because then the conduction of heat away from the asperities is high.

The Economic Significance

Reduction of friction with increase of load implies a definite violation of Amontons' Law (frictional force proportional to load). The writer had the privilege of discussing the problem with Mr. W. E. Wakefield of the Forest Products Laboratories, Ottawa, who had observed this reduction in friction at high loading during some tests carried out with actual sleighs: Mr. Wakefield at that time made the rather remarkable statement that after a certain load was put on a sleigh the drag increased but little by additional loading. The statement sounded so much like getting something for nothing that the writer thought it warranted verification under controlled laboratory conditions. If the statement were really true it added an exceedingly important item to the data that had to be explained apart from its economic implication.

Figure 2 shows some data obtained on a turntable and indicates that the statement is correct. Drag appears to be practically constant when the load per unit area of apparent contact is high enough. Presumably, after enough pressure is available along AB-CD (Fig. 1) completely to liquidate the asperity, the load over and above what was needed to supply

(*Continued on page 230*)

A PILE LOAD TEST

D. F. Coates, M.E.I.C.,
Assistant Professor, Department of Civil Engineering, McGill University, Montreal, Que.

A brief account is given of a pile load test which brought up many of the theoretical and practical questions that often arise in piling work. In addition, some interesting light was thrown on the behaviour of the soils encountered.

A pile load test was performed which brought up many of the theoretical and practical questions that often arise on any piling job. In addition, some interesting light was thrown on the behaviour of the soils encountered. As most piling problems must still be solved empirically, a brief account of this test is presented.

The test pile was a steel-encased concrete cast-in-place pile. The base diameter was 11 in., the diameter increasing in 1-in. steps every 8 ft. The pile was 45 ft. long, thus the diameter at the top was 16 in.; 3000 lb. of concrete was used inside the No. 12 gauge shell. The test pile was the first pile driven of a group of four.

All piles on this job were driven by a single-acting steam hammer weighing 6200 lb. with a drop of 3 ft. Eighty per cent efficiency was assumed for the hammer, thus giving a blow of 15,000 ft.-lb. of energy. The hammer blows were transferred through a driving head, containing a hardwood cushion, to a 48 ft. mandrel, weighing 10,000 lb., inserted in each shell. All piles were driven to a resistance of 6 blows/inch for a penetration of 1 foot. No driving resistance record was retained of the test pile (it being selected after the driving), but the records of two adjacent piles, *A* and *B* (see Fig. 2 and 3) are shown.

During the driving of the other three piles in the group, the base of the test pile heaved up 2 in. The upheaval of the shells generally occurred during the driving of the last 3 ft. to 6 ft. of the adjacent piles. The test pile was not retapped as the results of the load test were to be used in determining the retapping policy. The spacing of the four piles was 3 ft. centre to centre in one direction and 4 ft. 6 in. in the other direction.

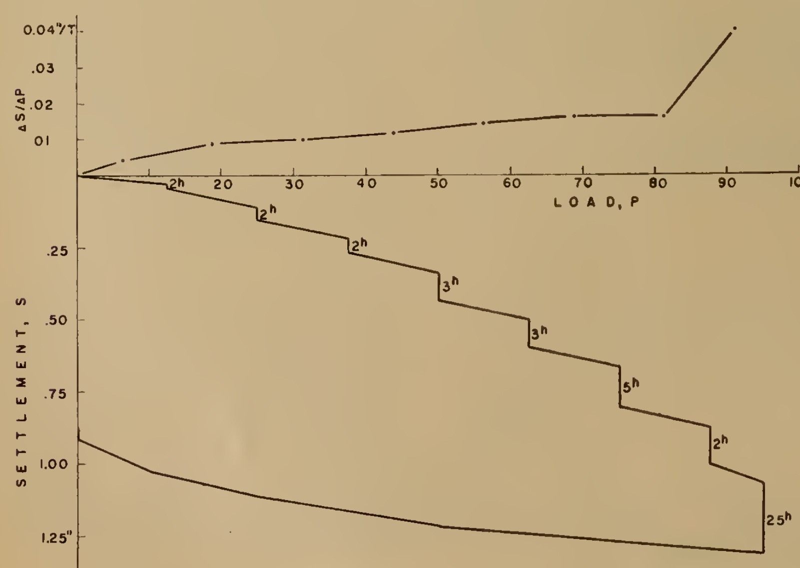
Soil Profile

The building site was in the St. Lawrence lowland region. The principal soils in this area are glacial till, post-glacial marine and lacustrine clays (Leda clays), and alluvium.

Three borings were made on the building site some distance from the test pile (see Fig. 4). These showed that for 25 ft. below the datum (the level of the fill at the time of the borings) there were strata of organic and non-organic, soft to firm clay (Fig. 4). The average unconfined compression strength of five tests on samples between 6 ft. and 20 ft. depths was 0.5 tsf. From 25 ft. down to bedrock there was glacial till of varying amounts of silt, sand and gravel, and of varying relative densities from loose to very dense. The bedrock varied from 57 ft. to 64 ft. below the datum. The average D_{10} of the till was of the order of 0.006 mm. (with practically no particles smaller than 0.003 mm.), and the uniformity coefficient varied between 20 and 50. Some of the maximum particle sizes taken in the standard spoon sampler (2 in. *OD*, 1.5 in. *ID*) were ⅜ in. in *TB*-1 at 45 ft, 1½ in. in *TB*-1 at 50 ft., 1 in. in *TB*-2 at 40 ft., and ⅛ in. in *TB*-3 at 50 ft. (Fig. 4). These indicate that the high penetration resistances found at these points were probably due in only one case to the interference of stones. (The resistance is to a standard 2 in. *OD* sampler driver by a 140 lb. hammer dropping 30 in.).

The ground water level at this time was 3 ft. below the datum.

Fig. 1. Load test settlement curves (time, in hours, of load duration also shown).



Load Test

The load test was run 10 days after the pile had been driven. The pile was loaded in increments of 12½ tons up to 87½ tons (Fig. 1) by jacking against the pile driver. The maximum test load was 95 tons. Each load increment was maintained until the rate of settlement was less than 0.01 in. per hour. The maximum load of 95 tons was applied for 25 hours.

By plotting the increase in settlement per unit increase in load against the total load (Fig. 1) a curve was produced that indicated that failure took place between 87½ and 95 tons (failure being accepted as the point at which the settlement becomes disproportionate with increase in load). This type of curve makes the point of failure more distinct than a normal load-settlement curve.

The permanent or net settlement of the pile after the load had been removed was 0.87 in. The maximum settlement of the pile head under 95 tons was 1.32 in. The elastic deformation of the pile assuming only point resistance would have been about 0.26 in. (the confining effect of the steel casing is insignificant with regard to this deformation). Thus the elastic deformation of the soil would have been 0.19 in. In view of the previous upheaval of the shell of 2 in. it is possible that the ultimate capacity of the pile was actually greater than 95 tons.

Retapping

Owing to the upheaval of a large number of the pile shells, the retapping of most of these piles was carried out after the shells had been filled with concrete. The *predominant* pattern of this retapping showed penetration resistances from five to nine blows per inch for depths twice the distance of upheaval — with no sharp decreases or increases. As the retapping was done with the top 12 ft. of the mandrel sitting on the concrete pile, this indicated a similar, if somewhat lower, penetration resistance to that obtained in the original driving. From this, two conclusions could be drawn: the surface friction had not increased or "set" appreciably between driving and retapping (two weeks to a month), and the 1 in. to 2 in. of upheaval did not produce a void under the pile, i.e. it had not been produced by water pressure alone unless the surface friction had increased and supplied the resistance to driving until the bottom of the void had been reached under the pile (the exact compensating effects of these two mechanisms required to produce the retapping record seems improbable). Thus upheaval would seem to have occurred as a result of the compression and shear strain in the soil produced by the adjacent piles.

Besides the above behaviour on retapping a few piles showed very little resistance and were driven down several feet. Presumably the original driving resistance of six blows/inch here had been supplied largely by the water not being able to flow away from the pile during driving. Eventually the excess hydrostatic pressure would have been dissipated and the piles driven farther through soft till.

This explanation brings up an interesting paradox concerning till. Recent experience (both personal and of others) has indicated that till can sometimes be both medium soft and dense (dry density of the order of 125 pcf). One of the properties that may be used for identification is that this till seldom contains many particles greater than ¼ in. Resistance to the standard penetration test may not provide the necessary clue due to the effect of pore water below the water table. A few of the soil samples from this job indicated that some of the till fitted this description. Unfortunately, it is not known if this soil occurred where the piles disappeared on retapping, although it seems a likely explanation.

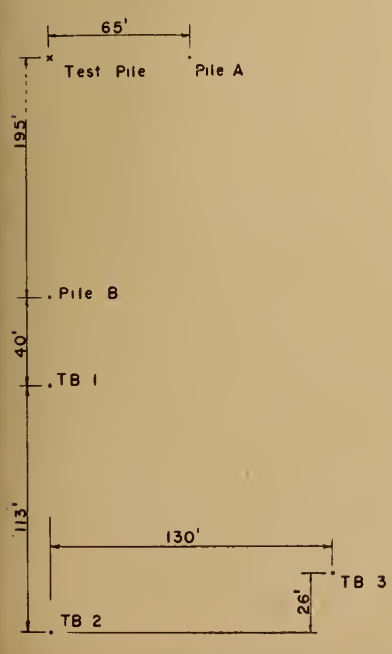


Fig. 2. Location of test pile in relation to piles A and B, and test borings 1, 2 and 3.

Pile Capacity

The pile capacity can be calculated for the driving resistance from the Hiley formula. The energy of the hammer blow was considered to be 15,000 ft.-lb. If the coefficient of restitution of the hammer on the driving head is assumed to be 0.25 and the temporary compression of the ground, pile, etc. is assumed to be 0.3 in. (from ref. [1]), the ultimate capacity of the pile is calculated as 115 tons. This is about 27 per cent higher than that indicated by the load test. Moreover, the same figure would be obtained by this calculation for the piles that were retapped several feet.

According to Meyerhof[2] the ultimate bearing capacity of piles in sands and gravels can be calculated from

$$Q_f = \gamma\ ADN/2$$

where γ is the effective soil density,
A the area of the toe,

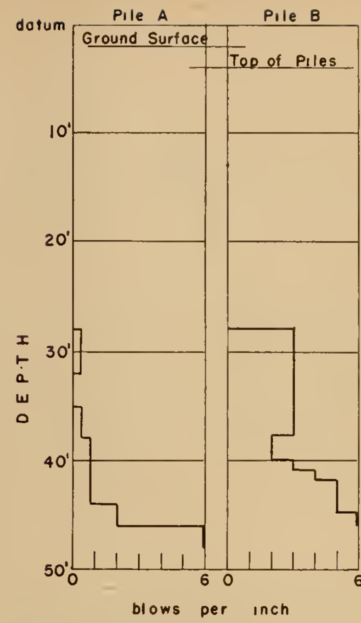

Fig. 3. Driving resistance record of piles A and B.

D the depth of toe below the sand surface, and
N the bearing capacity factor.

For a compact well-graded sand N is 960; for a loose well-graded sand N is 240. Thus for this dense silt, sand, and gravel till the ultimate pile capacity using N of 960 is calculated as 330 tons. Using an N of 240 the ultimate pile capacity is calculated to be 83 tons.

Alternatively, Meyerhof's expression for clays might be used.

$$Q_f = 9\ cA + c_a F$$

where c is the cohesion of the soil at the toe,
c_a is the average adhesion along the pile shaft, and
F is the embedded surface area of the shaft.

Thus if the average adhesion is assumed to be made up of 40 per cent of the cohesion of the clay (the possible thixotropic regain of the Leda clay in 10 days) and 1000 psf. (ref. [3]) for the till, c_a is 590 psf. If the cohesion of the till is also assumed to be 1000 psf. then the pile capacity is calculated as 50 tons. If the cohesion of the till were 2000 psf. (which has been obtained in some quick tests in similar tills) the pile capacity would be calculated as 53 tons. However, this calculation does not seem applicable as it does not take into account the frictional properties of the till (the drained ϕ usually being above 30°, although the undrained ϕ varying between 0 and 40°).

Using Terzaghi's bearing capacity formula[3], and assuming the angle of internal friction of the till to be 35°, the cohesion of the till to be 600 psf., the adhesion-friction of the till

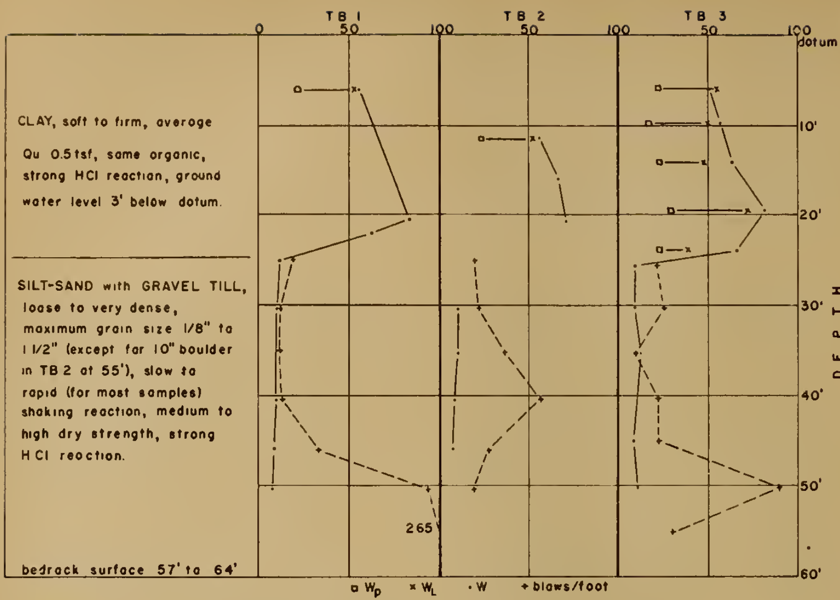

Fig. 4. Soil data from three test borings.

to be 800 psf., and the adhesion of the clay to be 200 psf., then the ultimate load is calculated as 97 tons. The close agreement of this calculated ultimate capacity with the load test value, in view of the many assumptions, is to a large extent coincidental; however, the assumed strength values are those that are considered to be most probable for the dense till.

It can be seen from this record that although soil theories might help, the practical problem of determining pile capacities for a large number of piles on one job has not yet been solved. Furthermore, the variation of the engineering properties of glacial tills needs to be better understood.

THE FRICTION OF ICE

C. D. Niven

(*continued from page 227*)

that pressure gets over "free": the obstacle in the path simply no longer exists. The liquidated asperity has nonetheless still to freeze again. Figure 2 shows that the drag in "zero" temperatures is about five times what it is just below "freezing".

The fact that ice in moderate Canadian winter temperatures provides a means of getting something for nothing by way of trans portation seems to offer great commercial possibilities and scope for engineering ingenuity in that immense tract of very sparsely populated country in Northern Canada lying between James Bay and the Yukon.

STRAIN GAUGE ANALYSIS

H. A. Spencer, M.E.I.C. and E. H. Brennan, M.E.I.C.

(*continued from page 225*)

(B) *Load Factor*

Through comparison of the "steady load" and "suddenly applied load" conditions for all the components, a maximum "load factor" of 1.9 was obtained. This factor should prove useful in all future design work for tractor-mounted equipment.

(C) *Stress Pattern*

A comparison of the stresses imposed on the components while the tractor was on the level floor with those while one track was on the chock indicated few differences. In no instance was the stress greater when one track was on the chock. This indicated conclusively that the method used in mounting the overhead loader, which retains the full track oscillation of a standard tractor, is superior to other mounting methods which, under oscillation, may apply twisting stresses to both loader and tractor.

Strain gauges, attached to the tractor at critical points, showed that the greatest stresses on the tractor occurred during the "digging" operation, and corresponded in severity and location to that occurring during normal bulldozing. Thus, the manufacturer was supported in his contention that the loader applies no greater stresses on the tractor than those produced by a bulldozer. Actually, the maximum stresses found were quite normal for this tractor.

(D) *Critical Section Examination*

Two points on the loader had given occasional trouble under very severe conditions. Stresses found at these points were 28,500 p.s.i. and 26,300 p.s.i. At one of the points a reinforcing band was welded over the section and, on further tests, the corresponding stress was found to be 18,000 p.s.i. This band was incorporated into the design. The other point also was redesigned to provide a similar normal stress figure under load.

Strain gauge analysis is useful when applied to the design of construction equipment since it provides a continuous record during a practical test. Designers at Barber Machinery Limited, in co-operation with the Research Council of Alberta, applied the method and obtained information readily and at reasonable cost. The construction industry should find this testing technique of considerable aid in solving design problems.

The authors wish to express their appreciation to Dr. George Ford, of the Civil Engineering Department, University of Alberta, for his assistance with the project.

AUTOMATION TO DATE

R. W. Bolz,
Editor, Automation Magazine,
Cleveland, Ohio.

As part of the Centennial of Michigan State University, the School of Engineering organized a symposium on automation, of which this was the introductory paper. Automation, with its influence in such fields as economics, quality, and labour, is of interest to the engineer, who plays a major part in its development. This paper is presented as an appropriate contribution to the subject.

Today automation brings both a challenge and an opportunity for engineering. Few developments have ever evolved that offered so great a potential for elevating the status of the engineer and improving his position in all industries. Success in the field of automation will rest to a large extent on the ability of engineers to utilize the principles of automation wisely: by seeking to reduce costs of operations, improve product quality, and effect better distribution of products to help attain a gradually increasing standard of living.

And this can be attained. We see automation evolving as a natural and highly satisfactory answer to many of the problems which have arisen in the past decade. Under a rising living standard, with a continuously increasing educational level, the stage arrives at which choice and desire become effective. Brute labour jobs cannot be filled, and machines must be created to do these jobs.

Developing simultaneously are other factors of importance, among which is our rising population with its changing ratio of age groups and a fast rising market demand. To fill this demand for good products, automation has been gradually evolving as a logical solution. No amount of labour, were it plentiful, would suffice in many present-day instances. The modern light bulb is an excellent example: whereas one plant with 230 employees produces 1,200,000,000 bulbs per year on continuous automatic equipment, 1927 methods and machinery would require 75,000 men to produce this quantity. The economics are self-evident.

What is Automation?

Many have talked of automation and have given their individual interpretation of its character. To the layman the result has resembled to a striking degree the age-old fable of the eight blind men and the elephant. Each blind man gives an accurate picture of what he feels it to be and is positive he is right. The fable ends, "and they fell to quarrelling among themselves," (Engineers, of course, are not subject to such error!)

Stepping back for an objective view of the whole, we can more readily perceive the basic character of automation as it is today.

Although new in name, automation basically involves the application of principles which have evolved steadily over a long period of years. It is not confined to transfer machines or materials handling; it is not merely the application of electronic control, instruments, computers and feedback. Accomplishment of really economic automation requires a combination of equipment, machines and controls. Defined in broad terms it is—manufacturing, processing or performing of services as automatically as economics permit or demand.

In the achievement of automation, groups or sequences of operations, along with mechanisms, machines and control devices, are brought into a single system to produce continuous or cyclic operation. Wherever two or more automatic operations are tied together with overriding automatic controls to create a self-feeding, a self-initiating, and self-checking process; an automated system is created. Material, data or pieces can be introduced into the system manually and automatically and the processing steps carried out without manual intervention to completion. Generally, almost any process can be automated. It is possible to automate a single operation, a sequence of operations, a whole department or a plant.

Automation can be segregated into several types. It is possible to create an automatic batch or a continuous system. One process, for instance, may be more economically carried out in batches while another is most economical when operated continuously. Process characteristics, as well as economics, dictate the best method. Likewise, metal-working in job-shop operations may require batch-type arrangement, owing to continuous change, while mass-production operations are more economically carried out on a continuous basis.

Secondly, automation systems

may be set up with end-control or in-process control. With the end-control, processing is completed before testing, checking, or gauging is done. This is suitable with many processes and feasible with others. However, where precision output is necessary, in-process control is desirable for economic reasons. Material being processed is under continuous control: metal parts, for instance, are gauged in the machine and correction or size control is accomplished during the operation. Chemical and similar processing operations are held under continuous sensing and measuring instrument control, and necessary corrections are fed back to the equipment continuously.

Automation of plant operations may range from lines of automatic equipment, such as presses which are automatically fed and cycled continuously, to complete manufacturing facilities where components are fed, sorted, oriented, assembled, and tested automatically. Where job-lot operations are involved, flexible automatic control of standard machines is sought in order to achieve the economic results desired.

Process Industries

In such areas as chemical and petroleum processing, flow of component materials is continuous from step to step under instrument control to final desired end products and byproducts. Automatic instruments maintain preset temperatures, pressures, or flow, and record and control specific portions of the processing cycle. Materials may be weighed, fed, conveyed, and dispensed by automatic devices. Completed products may be fed directly to automatic bagging, packaging, canning, bottling, or other equipment and then to storage.

In the food procesing field, automatic machines again are linked together to produce an automated line. Food processing, like many modern chemical and metallurgical processes, defies manual control owing to speeds, pressures, loads, and accuracy of measurement because of sanitary and critical processing conditions. Automatic control devices monitor the conditions, flow or movement of the product continuously as preset. Processing may be continuous and untouched by hand throughout to the final packaging and cartoning stages. Here, owing to necessity, economic processing has been achieved. Today, necessity is leading to similar achievements in other areas.

Distribution

An area in which automation today is rising to meet a critical need is in merchandising and distribution. Here the delays and problems of distributing products are being overcome through the use of automatic machines designed to handle, store, unload, and load for shipment. Laborious handling of goods, both in-plant and in warehousing, is carried out automatically with systems of machines and handling devices. Conveyors of belt, chain, plate, roller, screw, and overhead-rail types automatically deposit, retrieve and carry products under control of limit switches, photoelectric cells and numerous other devices to dispatch them as needed. Central push-button control panels permit selection, coordination and dispatching as desired. Stores are resorting to use of automatic devices to stimulate sales, speed handling of goods, increase customer service, and keep close control over inventories.

Metalworking

In metalworking today, automation ranges from simple units all the way to complete plants. Through automation the big problem of handling between operations is eliminated almost entirely with accompanying cost savings. In this regard there are two approaches: (1) handling can be mechanized; (2) handling can be eliminated. Machining, stamping, heat treating, washing, degreasing, plating and finishing operations, as well as assembly of complete units, is being done.

With the achievement of practical tape devices, numerous machines can be controlled. Not only can a coded tape be used to reproduce information in complete form, but such a tape can also be used to control other kinds of equipment. Today many machines can be so controlled. Machine tools are in use which follow instructions punched into a tape or recorded by similar coding marks on a photographic film or magnetic tape.

Milling machines automatically carry out a series of machining operations by this means. Complex machines grouped into a single unit read a tape to drill specific sequences and sizes of holes, select a suitable rivet from automatic feeders, place the rivet, buck it properly, and drive the rivet under precisely controlled conditions. As requirements change or design is modified, a new tape and fixtures adapt the equipment as necessary. Used in aircraft manufacture where design changes are frequent, such automation offers improved quality as well as flexibility and speed of production.

Automation and Mass Production

You may well ask: What is the difference between automation and ordinary mass production as we know it? First, automation should not be confused with ordinary mass-production techniques. Mass production, as developed from the original ideas of Eli Whitney, comprises the basic approach and science of manufacturing, without individual fitting, large quantities of products from groups of components produced in mass. The primary feature of mass production revolves about the dimensional standardization of components to permit interchangeability in assembly. Note however, manufacture may be entirely by hand methods from start to finish. Mass production techniques, though, constituted a major step in creating the possibility of providing large quantities of complex products with superior quality and uniformity at lower cost in time and money. But, today, hand methods often fail to fulfil the requirements because of economics, market demand, speed, labour and other factors. The solution is the succeeding step in the manufacturing picture—automation.

In this picture the design of products has a strong influence. Real economy in mass manufacture of products has been closely associated with good design for production, but failure to ensure the best design features has seldom denied satisfactory results. Actually, it has even been possible to defy good design criteria and depend on the skill of the men along the lines to supply the necessary correction factors. Not so in automation. Mere mass production techniques must be superseded by modern production design for automatic manufacture. Although there are instances where production of components and assemblies has been automated without design change, in most cases significant savings await ingenious design modification.

This is also true of automatic assembly. To attempt to assemble automatically without consideration of design modification for suitability would parallel the attempt to mass produce without regard to the technique of interchangeability. Today, with automation, simplicity in product design is the byword. With some designs, even arduous labor and large expenditures may not provide the desired economic result. The much publicized "Project Tinkertoy" bears this out. After thorough economic studies were completed it was found out that semi-automatic methods offered the most effective result, not complete automation.

In this analysis of the project it was found that the electronic amplifier of simplified modular design reduced manufacturing cost 38.5 per cent over conventional piecemeal design. This method consists in hand-assembling the simplified machine-produced components. Fully mechanized production of the same modular design reduced cost 44 per cent with roughly the same output per hour. However, seven of the process steps proved to be lower in cost with the hand method. When substituted in the otherwise mechanized procedure, the combination offered the lowest total cost per unit.

Significant factors in the project were that $665,000 was required to create the all-automatic facility and $82,000 the semi-manual. Little savings would accrue from increase in size of either facility. Limitations on the output, and hence economics, of the mechanized production installation were found to centre around equipment cyclic rates, machine delay time, reject percentage, equipment costs, numbers and skills of operators and equipment maintenance. This example merely indicates that automation is not a panacea. As always, a neat overall compromise in both design and production provides the best final result.

Overriding considerations in basic design detail which must be brought into play for automation can also, and often do, contribute direct additional benefits. Typical cases on record show that the constant drive toward suitability for automation procedures and for simplicity result in much superior products from standpoints of performance, uniformity, stability, service life and maintenance. The overall economic results not often recognized constitute an advance worthy of note in any management planning.

Another field that assumes key importance in automation is statistical quality control. Although desirable in ordinary mass production, it is not always used nor is it an absolute necessity. Common methods of gauging, after manufacture without machine control, are still commonplace and still largely suitable. To permit economic automatic assembly or automatic production of separate pieces, in-process continuous gauging to eliminate scrap and off-size is desirable and often necessary. Though not commonly recognized, feeding, chuting, orienting, and assembling operations in automation fail most often because of nonconformity of parts.

"When automation develops in industry, what happens to labour? Is it displaced? . . . The answer, of course, is No."

Through automatic size and uniformity control of parts being produced, production of bad pieces is eliminated. Of little economic importance in production for hand assembly where scrap can be detected by the assembler, in-process gauging before continuous production assembly operations is important. Extremely small irregularities can easily jam intricate devices. Hence, some crude operations may often be impractical to automate.

Here, again, design for economical automatic production assumes critical importance. Individual pieces can be designed for maximum facility in the reproduction process; in the gauging procedures; in the handling, chuting, orienting, and feeding steps; and in the actual assembly arrangement.

Where granular and fluid materials are processed, the same holds true: the quality of the product produced is dependent on the control of the ingredients. Manual control usually results in high rate of loss and wide variations. Quality can be improved and maintained by automatic control of ingredients. Cost is largely reduced by eliminating scrap and re-run and attaining faster output. In many cases, scrap reduction and quality control alone account for significant savings. In one instance, by replacing hand inspection test with an accurate automatic test, not subject to operator variations, apparent scrap was reduced almost 50 per cent. In another instance, automatic metering and weigh feeding of ingredients eliminated millions of pounds of re-run. Cost savings are worthy of real concern, but in many of these cases actual losses fail to appear as such or are accepted as a necessary evil associated with the particular product.

This then is the area of feedback. Regardless of the level of automation, information can be fed back through the control system more or less to "ride herd" on the accuracy of the job being done. Gauges and measuring devices can monitor processing operations to hold pre-set values or vary values as desired; mechanical controls can maintain pre-set or sequences of steps as needed. They can also shut down the process in event of trouble. In other cases the actual procedure itself forms the feedback loop (if it cannot be completed the operation stops) or even an operator at the final controls can form the feedback loop.

The main purpose is quality or accuracy.

Information and Data Handling

An important segment today in automation is the problem of information and data handling. This has grown to enormous proportions in all areas of commercial and industrial enterprise. Automation in this field is being actively developed as a solution. Profitable operations may hinge closely about immediate and accurate information concerning markets, production, and sales. And with increasing markets there is need to tie such information directly to plant operations. Processing and storing of data for operations is already being done with automatic machines. Original information recorded on an automatic typewriter which creates a continuous coded punched tape forms the basis from which subsequent operations can be automatically carried out. Address stencils, order sheets, work sheets, cost sheets, accounting data, shop orders, bill of materials, and numerous other data can readily be produced from an original punched tape. Punched cards likewise can form the basic means for subsequent operations. Speed, accuracy, and space savings are important advantages gained. Data available on punched tape or cards can be transmitted by teletype to outlying plants where a similar tape produced serves as the master data source.

Automation and Labour

When automation develops in an industry, what happens to labour? Is it displaced? Is the ultimate the workerless plant as so often predicted?

The answer of course, is no. Labour-saving devices actually create new jobs. A study of the employment of production workers since the turn of the century reveals an unchanging trend in employment — upward — directly tied in with an upward rate of mechanization.

Most automatic plants today help employ more people than before automation. Whereas automation can often reduce direct plant labour, this is not effective net reduction. High-grade maintenance labour must be added to care for the complicated equipment. The old-fashioned factory electrician is no longer adequate. Needless to say, automatic machines are not foolproof. They require many more skilled technicians for control and maintenance; much more advance planning and research is needed preceding their operations; and many more sales and service industry personnel must be added in the distribution end of the vastly increased end-product market.

Engineers and Management

Automation creates a greatly increased demand for engineers. Not only does the product or service to be automatically processed require better and more competent preliminary design, but so also does the equipment. Improved design for production is a must for economic reasons and for suitability to automatic processing. Greatly increased engineering time is inescapable in the design of automatic systems. Today, the engineering time and cost is paramount, the actual equipment construction cost becomes insignificant in comparison. The use of more widespread automation places a high priority on the supply of competently trained engineers and engineering technicians. Future rate of advance will be closely associated with their availability and the development of techniques and know-how. Demand for engineers in 1954 increased 45 per cent, and actually led the field by a wide margin. This demand, based on actual jobs opened, was mainly for electricals and mechanicals, followed by design specialists.

Along with increased engineering staff is engineering activity; automation requires a much closer co-ordination of top management and engineering. Successful application of automation principles necessitates full appreciation of all factors involved.

So many cases of real achievement on record, which stemmed from altogether unrelated causes, emphasize the need for careful management study of the over-all problem. To expect automation to develop "upward" from plant and engineering sources alone, may fail to produce the full potential.

Many automation programs being instituted today are set up so as to be sparked by management and fully controlled, since the effective climate for automatic operations includes many areas of the enterprise outside the sphere of engineering. Thorough search of management can often reveal the presence, absence or adaptability of factors necessary for realization of automation benefits.

In studying the character of automation, the need for special management consideration and organization becomes apparent. From the functional engineering standpoint, the basic technology of automation is horizontal across an array of vertical specialized areas. There is the need to correlate all the specialized knowledge of machine design; electrical, hydraulic and pneumatic controls; handling; sensing and measuring; instrumentation; drives; power, etc., to effect a complete system. Few engineers are well versed in all the necessary areas.

In addition, modern automation systems involve the interrelation of know-how and experience from many specialized areas of industry. Chemical processing, materials handling, packaging, food processing, metal-working, paper making, heating, textile processing and other specialized areas of manufacture must often be drawn upon to evolve the complete integrated system. Also, practical solutions to production problems known in one area of industry can often supply the answer to unrelated problems in another industry developing continuous systems. Innumerable cases of this nature have come to light in recent years.

The net result is a real need for organization to bring together a widely diversified group capable of engineering successful systems. Only through management's recognition of this problem can the desired results be attained.

Once the full perspective and high potentials of automation become apparent, proper application in suitable degree can result in real advance. The necessary engineering skill and knowledge can be developed and the needed practical elements of automation are available. The question today is not will there be automation, but how much and how soon?

Highway Problems in Ontario

W. J. Fulton,
Director of Planning,
Ontario Department of Highways,
Toronto, Ont.

The paper describes the reasoning followed by the engineers of the Ontario Department of Highways in deciding the number and location of limited access routes to be built in that province in the next few years. It may serve to dispel the too widespread idea that most provincial highways are built for political expediency.

In Ontario there are now approximately 74,000 miles of roads, exclusive of some 8,000 miles of streets in cities and towns. In "Old Ontario"—that part of the province which is divided into counties—there are 56,000 miles of this total. The 56,000 miles in Old Ontario, originated in two ways: trails which afterward developed into roads were here when the white man arrived and after his arrival he built roads to facilitate the movement of troops, to open new trade routes, to promote mining and lumbering and to replace those surveyed road allowances which he found impossible to follow.

These constitute less than 6 per cent of the total. The remaining 94 per cent of the 56,000 miles is the by-product of subdividing Ontario into townships. In laying out these townships, it was considered desirable for the lots to be rectangular in shape. The roads arbitrarily following these boundaries encounter obstacles which might easily have been avoided. They are subject to correction jogs in the township surveys and they vary radically in direction from one township to another.

But the fact that these roads were fitted together without any plan and without considering topography is not nearly so important as the fact that Ontario authorities found themselves confronted with a system of highways greatly in excess of the needs of the population so far as mileage went, but along which development had taken place, and with a popular demand that these roads remain where they were to serve this development and to encourage further growth.

The primary purpose of this great mileage of roads was to furnish access to land, but this was not their exclusive function, because very early we find that a limited mileage was separated from the 56,000 miles originally administered by the townships and placed under the jurisdiction of the counties. This was in 1874 and it marked the beginning of the county road system. Almost all roads were still unimproved then and of necessity all road travel was of short range.

With the advent of the automobile a road construction program began and some years of unsystematic building followed, until finally the builders awakened to the hopelessness of ever joining the disconnected roads these years had produced. Then they began to realize the need for classifying the road network and of giving priority to the improvement of portions of the greatest potential use. This resulted in 1916 in the designation of what was then known as the "Provincial Highway System." The roads selected as provincial highways were the most important ones in the 56,000 mile system.

The chief problem of the engineer then was road surfaces. New surfaces were generally placed on the old dirt road without change in location or with only slight revisions. Steep grades and sharp curves were accepted to keep costs down and were not inconsistent with the requirements of slow moving traffic. Engineers and the authorities were concerned with getting the motorist out of the mud. This was a generally wise and useful policy for the time. Its mistakes lay in its acceptance and fixation of obsolescent road alignment and in its failure to anticipate the need for rights-of-way of greater width than those theretofore considered ample.

These were pardonable mistakes. When they were made high-speed motor vehicles were generally unforeseen and probably unforeseeable. The standard of alignment required today would have then been considered fantastic. The great increase in vehicle registration and in traffic volume was anticipated too late, but, even if it had been foreseen earlier, lack of the necessary legal and popular sanctions would have prevented the forehanded acquisition of the wider rights-of-way and the introduction and enforcement of regulations required by widened and controlled-access highways.

Our most important highways were the ones which suffered most because of these mistakes. The explanation of this paradox is that

Read at a meeting of The Engineering Institute of Canada, Ottawa Branch, April 1955.

these roads, in recognition of their prime importance, were among the earliest to be durably improved. Structurally, many of their improvements are still embarassingly sound, but in location, in traffic capacity, and in lack of most of the features of modern design that make possible the safe operation of vehicles at high speeds, they are lamentably obsolescent.

This was realized during the 1930's when the department attempted to meet the situation by developing No. 2 highway into a four-lane road in its present location from Windsor to the Quebec boundary. Work was undertaken on four sections of this road and the right-of-way was widened at considerable cost in moving buildings. Two east-bound and two west-bound lanes were built, separated by a median strip 20 to 30 feet wide. Although the new construction was a definite improvement, inability to control development along the widened right-of-way allowed these roads to deteriorate, so that they are now simply side streets with a thirty-mile speed limit.

A repetition of experiences of this kind indicated that we were approaching the end of the last stage of the pioneer period of road construction, so far as our main trunk roads were concerned, and that an important feature of any new modern highway would be control of access. It was apparent, of course, that the majority of roads would still give access to land and would permit the owners of abutting property to develop their holdings with unlimited right of entry into the highway. However, a small mileage of trunk roads, incorporating control of access, would have to be built to divert as much traffic as possible from these general purpose roads.

The first road of this new type built in Ontario was the Queen Elizabeth Way. It had just been completed when world war II began and normal highway improvement ceased. As a consequence the mileage of road no longer adequate for the traffic carried, and difficult to maintain in service, grew through the war years, so that, when peace was declared, a serious reconstruction problem confronted the province.

Before undertaking the program of this work it was essential that a better understanding of the traffic trends and the travel habits of the motorist be obtained so that former mistakes in planning, location and design might not be repeated. For instance, it had been widely accepted that adequate accommodation for the King's Highway traffic would necessitate the construction of by-pass routes around the cities. In the absence of statistics, it was believed that a large part of the traffic on the roads approaching the cities was "through traffic", i.e., traffic bound to points beyond the city and it was thought that this traffic should be accommodated by routing it around, rather than through, the city. Such routing was also believed desirable from the standpoint of the city, since its streets would then be relieved of a substantial volume of traffic.

Table I. Traffic Capacity - Vehicles per Day

	Annual average daily traffic capacity	
	2-lane	4-lane
Passenger vehicles only	5,750	19,250
90% passenger, 10% comm.	5,200	17,500
80% passenger, 20% comm.	4,800	16,050

To test this belief and to ascertain what volume of traffic such by-pass routes would serve studies were undertaken, and it was found that for a large city the destination of 95 per cent of the traffic on its approach roads was the city itself and only 5 per cent wanted to by-pass. For smaller cities, the by-pass traffic increases, i.e., it is inversely proportional to the population.

We knew that all highway traffic is a composition of long range and short range movement, but, until recent studies disclosed the facts, we did not know the relative percentages of these two movements; about 85 per cent of all trips are of less than 20 miles and only about 2 per cent are of more than 100 miles. Traffic is predominantly short range movement.

Also, as might be expected, it was found that the cities were most important as the origin and the destination of traffic. Analyzing the traffic on the King's Highway, it was found that about 50 per cent had *both* its origin and destination in the cities, an additional 37 per cent had its origin *or* its destination in the city, while only 13 per cent of the traffic on our highways has both its origin and destination in rural areas. From these origin-destination, or "OD" surveys as they are called, we derive a great deal of information.

To make an OD survey a road block is set up on the highway that will effectively stop all vehicles, but at the same time allow any vehicle that should not be stopped to get through (e.g., ambulances, police cars, etc.). The interviewers endeavour to question as many as they can of the drivers of vehicles passing the station in a 16-hour period. The questions are not intended to be personal and, if the driver cooperates, the time spent asking and answering the questions does not require more than 20 seconds.

These data are sorted mechanically. When the results are compiled they give us, among other information, "desire lines", which in effect are straight lines joining the major origins and destinations. These lines are then plotted on a map of the area, their weights being in direct proportion to the number of people with the same desire.

By using these desire lines we can indicate the location of the highway which would best provide the greatest service. We can also predict, approximately at any rate, the volume of traffic which will use the highways when it is built and determine where we will require traffic interchanges, what width of roadway is necessary and the like.

We have also made studies on highway speeds and have found that on the King's Highway only a scattered few travel faster than 60 miles per hour. The studies afford no justification for the design of highways to accommodate speeds in excess of 70 miles per hour under any conditions.

Studies also indicated that to permit the desired clearances of commercial vehicles, a 24-foot pavement is required on our major roads and that obstacles within six feet of the edge of a traffic lane influence the position of traffic in that lane to some extent.

Another study was made on a highway three miles east of a bridge. Here 76 per cent of the traffic was in its own lane, 15 per cent in the passing lane and 9 per cent was straddling. However, on the bridge, only 18 per cent was in its own lane, 21 per cent in the passing lane, 51 per cent straddled the centre line of the west bound lane and 10 per cent was half on the west bound lane and half on the east bound lane. This was because cars veered away from the bridge hand rail.

We also made some studies of the hill-climbing abilities of commercial vehicles and found that they will slow up traffic on hills unless grades are reduced to 3 per cent or less, or engine power is more than doubled, or gross vehicle weights are reduced excessively. Except on the highest type of highway, where 3 per cent grades may perhaps be easily obtainable, any combination of these three conditions to obtain a safe and efficient flow of traffic would be costly to all interests involved and are practically impossible of attainment in the foreseeable future.

Tables I and II give the department's standards for estimated traffic capacity and for sight distances.

Table II. Sight Distances - Feet.

Design speed, m.p.h.	Stopping 2-, 3-, and 4-lane roads	Passing 2-lane roads Desirable	Passing 2-lane roads Absolute	Passing 3-lane roads Desirable	Passing 3-lane roads Absolute
30	200	600	500		
40	275	1100	900		
50	350	1600	1400	1100	900
60	475	2300	2100	1500	1300
70	600	3200	2900	2000	1800

The studies I have mentioned and others similar to them have been responsible for the development of improved highway standards and have had a considerable influence on the reconstruction program of the department.

The Highway Improvement Act was amended in 1939 to permit the Minister of Highways to designate a King's Highway as a divided highway. This name was later changed to "controlled access highway," a term more nearly descriptive of its character. This amendment gave the Minister power to set up regulations prohibiting or regulating the opening into controlled access highways of private roads and entrances, to prohibit or to regulate the use of this type of highway by any class of vehicle and to prohibit or to regulate the erection of buildings or other structures upon intersecting roads within 600 feet of their intersection with the controlled access highway. Upon approval of the Ontario Municipal Board, it gave the department power to close any county, township or other road which intersected a controlled access highway.

From the operation of the Queen Elizabeth Way the department engineers learned much, which knowledge was incorporated into the design when the department built the next controlled access highway from Toronto to Barrie.

Up to now our chief problem has been to decide the characteristic features of the type of road to be built. This having been determined by our experience with the Queen Elizabeth Way and the Toronto-Barrie roads, the problem now is where to locate this additional mileage so that it will do the most good, keeping in mind the fact that this type of road costs from three to eight times as much per mile as an ordinary highway, and that our objective is to build a more serviceable, rather than a more extensive, highway system.

Just to get the picture in perspective we may arbitrarily divide Ontario into three parts; the southwestern, the southeastern and the northern sections. In the southwestern section there is 68 per cent of the province's population in only 5 per cent of its area; in the southeastern section there is 17 per cent of the population in 3½ per cent of its area and in the northern section there is 15 per cent of the population in 91½ per cent of its area.

There is 74 per cent of the motor vehicle registration in the southwestern section, 16 per cent in the southeastern section and only 10 per cent in the northern section, so it is obvious that any controlled access highways that may be built will almost certainly be in the southwestern and southeastern sections.

Traffic flow charts show that our most heavily travelled road is No. 2 highway from the Quebec boundary to Windsor, except for No. 11 north of Toronto and No. 2 and 8 from Toronto to Niagara Falls, which are now supplemented by controlled access highways.

It has already been established that the practical working capacity of a two-lane road is 5,200 vehicles per day, composed of 90 per cent passenger cars and 10 per cent commercial vehicles.

Checking the daily traffic volume on No. 2, we find that many sections of this highway are carrying traffic in excess of its practical working capacity, so that some relief is necessary now. When we estimate the increase in traffic volume in the next few years, it is evident that this highway will be unable to carry its future load efficiently.

To obtain further information as to where improvements on No. 2 should be made an origin-destination survey was carried out. During the three summers while this survey was in operation, 378,770 drivers were stopped and interviewed on the highways between Windsor and the Quebec boundary. When the information from the interviewers was processed, we were able to plot the major desire lines of travel. These desire lines were combined to represent the general path of the majority of the highway users.

This path was then laid down on existing maps and the routes were photographed from the air. The photographs were vertical, taken with sufficient overlap both in the direction of flight and at right angles to the line of flight, to enable them to be used in stereo pairs. Viewing these stereo pairs, one can study the topography of the ground and so lay down on the pictures a line which not only fits the topography of the country well, but which also approximates as nearly as possible the major desire lines.

From the pictures a map on a scale of 400 feet to the inch is prepared which shows all the cultural detail. From information obtained from registry offices and township assessors' books, real estate boundaries can be plotted on this map, which covers a width of about a mile on each side of the projected line.

The line which was laid down on the photographs is then transferred to this strip map and a survey party, guided by the pictures and the plan, establishes this line, or lines if there are alternatives, on the ground.

DISCUSSION

of Technical Papers

Is Effective Town Planning Possible?

S. D. Lash, M.E.I.C., Head of the Department of Civil Engineering, Queen's University, Kingston, Ont.

The Engineering Journal, February 1956 issue page 116.

J. D. Lee, M.E.I.C.[1]

Dr. Lash is to be complimented on his thought provoking paper on a very difficult subject. There is no doubt that if planners and the public could agree upon the detailed objectives of planning there would be greater opportunity for an effective process of planning being developed soon.

While running a risk of being dubbed "know-it-alls" or worse by the general public, planners must agree upon *detailed* objectives and processes if planning is ever to have a semblance of a rational and scientific professional enterprise.

As a basis for argument let us state certain detailed objectives and then see how they may be achieved.

1. Assume that all urbanization is planned to occur in groups called towns or super-neighbourhoods which will support a senior secondary school. Such an area might occupy 1,500 acres of land and be separated from its adjacent neighbourhood by a "green belt" used to carry feeder lines of utilities and a limited access arterial highway.

2. The super - neighbourhood groups would be separated into neighbourhoods which would support primary schools. They might occupy 150 acres and be separated by a 160 ft. right of way supporting a main roadway of the limited access type, and service roads. The street system layout in neighbourhoods would encourage traffic to use the main roadways which would be in the separation zones.

4. Within the exterior framework of neighbourhoods areas could be allocated for major shopping centres, for general business activities, for major recreational facilities and so forth.

5. Groups of super-neighbourhoods (again not rigid as to exact size or shape) could be fitted to the topography and major communication and utility systems to form metropolitan areas.

The process of development envisaged above can be worked out within our present framework of legislation and municipal organization but it requires super-planners, super-aldermen and a little sheer magic to get from the nice plans to actuality. Experience has shown that the development of the type which fixes the character of the future municipality occurs in our townships. The townships and villages do not have a sufficiently complex municipal structure either elected or appointed to achieve the end results of planning, even if they thought they had the resources to carry out the processes of planning.

It is evident that good planning can be best achieved where a large area is involved, and in which the pattern of land use and development can be fixed several years before the pressure of local development is felt. There seems to be at least one way to achieve this without making serious changes in present legislation or political structure:

(a) Recognize that county councils should be elected and that there should be no separated municipalities.

(b) Unify leadership in our provincial government through the departments of planning and of highways and with the aid of a grant system induce responsibility on the local level to promote planning in advance of need *and* a continuing project of land acquisition to promote the securing of public land for green belts between neighbourhoods, for schools, for major parks and for a major street system. The price of such land would be fixed by its use as agricultural land and not by hope for what Professor Lash so aptly calls an "unearned increment of value."

It is my belief that public recognition of the need for compensation to individuals whose rights are affected by planning activities is already here. The history of most cities records the fact that the municipality always gets the worst of any bargaining in land transactions and so forth. This makes councils loath to establish mechanisms on a general base for making compensation payments a prerogative of the city hall staff. It is to be expected that the practice will become well established in the redevelopment of existing cities, and will be avoided by proper planning in the new.

I wish to take exception to Dr. Lash's comment that planning has been relatively ineffective. Rather let us say that a mis-choice of political division within our provinces has made it something we did without. Our troubles are so fundamental that until recently there has been no planning, and unless we divorce the primary control from the strictly local government it will never be successful. A well known rule of business is that responsibility and authority go together. Let us then give our county units both, "un-separate" our so called separated towns and cities (in regard to planning at least), embody all of the potential adjacent urban land in the single county unit and forget regionalism as a trade name for the process.

---

[1] J. D. Lee and Company Limited, Consulting Engineers, Kingston, Ont.

C. E. Campeau, M.E.I.C.[2]

One of the main reasons why town planning has encountered so many difficulties up to now in its acceptance by the public at large is probably the fact that too much insistence has been put on its aesthetic aspects. Scientific rules and norms have been neglected as secondary, although no artist has ever been found who had not mastered first the science on which his art is fundamentally dependent. Efforts should be made by all planners to intensify research on basic requirements and on scientific approaches to the solution of standard problems. As soon as the science of town planning is well established, then and then only will the art of town planning become more easily accepted and applied. There is an urgent need for all universities and practitioners of town planning to develop the scientific basis of town planning.

It would be ridiculous to limit the role of town planning to the "revival of the lost art of civic design". Town planning is primarily concerned about people so that the sites on which they live be provided with the facilities required for their physical and spiritual betterment. There is no mysticism, but only crude reality, in measuring the dimensions and qualities of such facilities in the light of well established social desires.

There is a very important field which has been neglected by our Canadian planners, namely capital expenditure programming. Without an effective program of capital expenditures, official planning has not much meaning. Most of the American cities have now introduced, within their administrative procedure, the obligation for the town planning organism to prepare a capital budget program for three to five years. Such a program has to be approved by the city council and the budget of the current fiscal year has to include 1/3 or 1/5, as the case may be, of the total amount of the approved capital expenditures program. This procedure should be investigated very thoroughly by our Canadian planners since, in its absence, no major planning objectives can be easily attained.

There is a great need everywhere of streamlining legislation in accord with our modern conceptions of town, metropolitan and regional planning. It would be very useful for our town planners to study the existing laws more carefully so as to find ways and means of implementing their plans under existing conditions. However, there is no doubt that effective town planning requires the establishment of scientific standards, recognized by an adequate legislation. Such a legislation should be conceived according to local needs and customs, if it is to be successful.

The role of education cannot be overlooked. Professional associations have to be supplemented by amateur groups, whose role is too often minimized. Planners should never forget that planning is for the people, who should be convinced that they need planning.

[2] Director of the City Planning Department, City of Montreal.

• • •

W. C. Miller, M.E.I.C.[3]

I discuss Dr. Lash's paper for the most part from the point of view of planning in the smaller city of 40,000 population and under. The problem in the smaller city must be handled in a manner that differs considerably from the techniques used in larger metropolitan centres. In the smaller units we have more compact arrangements which have a very close application to the interests of almost every citizen. In larger cities there is a tendency for the average citizen to think only of those measures that have a particular application to his own section of the city.

There is a current tendency toward divorcing planning from the agency in which it has been carried on for many years, and the setting up of another agency or board. The city's most important elective body, the council, with the final responsibility, has been, over the years, deprived of many functions for which it should be the co-ordinating group, and is forced to work in an atmosphere of competing commissions, boards, etc., each concerned with its own problems and frequently responsive to very few efforts at coordination. The tendency is a product of the sedulously cultivated theme that all public service is "ipso facto," inefficient, and all privately directed enterprises are the reverse. According to this philosophy, therefore, we should set up quasi business bodies to administer the various parts of the city's work. We have public utilities commissions, industrial boards, boards of health, hospital commissions, recreation commissions, boards of education, etc., all requiring the council's financial backing, all directing parts of the municipal business structure, and with little or no coordination with the council or with the other boards.

Now, councils will generally look upon the planning board as "just another board," even if it is supposed to be purely advisory. It will provide another opportunity for council itself to stop consideration of larger policies with respect to the city's growth, and in the end neglect them altogether, and make decisions that should rightfully be dealt with first by the board, because it is not kept in close touch with the various studies being made. Council ought to be close to these things constantly, so that it may be always reminded of the effect of a current problem on the city's development.

The work of the planning board is almost entirely concerned with that part of the engineer's work which has been frequently called "functional design." This functional design, particularly in the smaller cities, must always precede the technical design, if the latter is to be effective. I am not sure that I agree with Dr. Lash's description of the role of the municipal engineer in his example of the bridge. It has been my own experience that the municipal engineer is first concerned with the bridge location and its function as a traffic-carrying feature. The functional design has always preceded the technical considerations, which, important as they are, are a secondary detail. The careful preliminary studies of location, of grade, approaches, the effect on traffic, etc., are all an integral part of the bridge design.

The same thing will apply equally to the design of roads, their width, their location, channelization of difficult intersections, and many other similar details which must be studied before the type of the pavement is established. Similarly, the municipal engineer must foresee the most likely loca-

[3] City Engineer, St. Thomas, Ont.

tion of future developments in his city, and plan trunk sewers and watermains accordingly.

This functional design merges into what is now considered as "planning" by the professional planner. The municipal engineer who is content to start only at the level of technical design is only doing part of the job that should be expected of him. He has to be at once an idealist and a practical realist. His determination of most of these basic data and their presentation to his council in an intelligible way is most important if his council is to establish its policies adequately. In a smaller city, this planning function is most effective, in my opinion, when it is a recognized part of the engineering function. It is one part of what we have formerly called engineering economies, and may usually best be done by the municipal engineer who has been well described as civil engineering's 'general practitioner'.

This argument will at once be eountered with the question "What municipal engineer has the time to devote to this kind of planning?" This is perhaps fair criticism, but it also points up the simple solution of the addition to the staff of a junior engineer, who may devote his time to many of the details, enabling the chief to indulge in the valuable occupation of municipal strategy. Such a procedure would also be less burdensome to the budget, and the coordination with the operating departments would be complete.

It should not be assumed that because there is no planning board there is no planning being done. Planning may be carried on in a very close relationship with the other municipal functions and it will give the Council the feeling of being a part of it. Someone has said, concerning methods of administration of cities, that "self-government is to be preferred to good government". So with planning. It must keep closely in step with council and keep council in close step with planning.

Dr. Lash shows in his paper that he is familiar with the frustrations of the planner, and is well acquainted with the reasons therefor. However, in the matter of planning in the older existing city, the planner must always be satisfied with approaches only to the solutions that the planning authority believes in. The only part of the municipality where the maximum application of planning in principles would be found, is in those areas where a new city is being created from unimproved farm land. Here all of the rules may have the maximum of application. In the older parts of the municipality, especially in the smaller city, there is simply not the money available for large schemes of civic improvement. Any official who has been through the process where a development involved acquisition of land, will know the frustrating effects of compulsory land acquisition. When these cases go to court or arbitration, one is shocked at the free rein of imagination given and accepted as evidence in the proceedings.

On the outskirts of the municipality, or in the "fringe areas" there has usually been a lot of uncontrolled development across the town limits, where the suburban areas are looked upon by a predominantly rural council as mere "assessment." Later, when the rural council finds that this added assessment is becoming an obligation for additional fire and police protection, more school rooms, urban style refuse collection, sewers, storm drains, etc., the pressure is placed on the urban area to annex, after that area has been ruined by uncontrolled development, and when it requires expensive redevelopment which the rural area is unwilling to undertake because of the expense involved.

Definition of Town Planning

In most papers on town planning, a thesis is built up on the basis of the definitions that we use. A very simple definition of town planning is simply "organized municipal foresight." If we do consistently practise this foresight, we approach in the established smaller city, even though we never actually achieve it, better "health, safety, economic opportunity and efficiency, aesthetic and cultural satisfactions" and all of the other considerations that must be studied as to their place in the growth of the city and the welfare of its inhabitants. The municipal engineer who does not consider the social problems related to his work is only practising the technical half of his profession. He is neglecting that "trusteeship" that Dean Young always tried to impress on student engineers in his school, as being the distinguishing feature of the "professional" engineer. Professor Hardy Cross, in his delightful little book on engineering philosophy "Engineers and Ivory Towers", is constantly referring to his theme that engineering, too, is more of an art than a science.

Professor Lash does well to emphasize that one of the greatest single problems of effective municipal planning is the question of municipal boundaries. The remedy must usually be solved on political levels and the solution of the troublesome problems of annexations must always be based, not on the effect of the proposed annexation on the general economic structure of either the gaining or losing municipality, but on the question of the greatest good for the persons in the area concerned.

Now, after expressing an almost complete disagreement with the modern concept of the way effective planning should be carried out, and after considering Dr. Lash's thesis as to how effective planning can be, let me apply my own principle and say that planning as it is presently carried out is an approach only to effective procedures. Dr. Lash has set forth some of the difficulties and the problems, and with his philosophy no one would seriously disagree. If we continue to realize that perfect planning will only be done under an autocracy, and that in the English-speaking world at least, this will never replace our modern concepts of democracy, and if we realize that we are striving toward a goal which we will never reach, but where every nearer approach to that goal is an improvement, then, I think, we may appreciate that town planning, ineffective as it may be in its larger concept, does produce further satisfactions for both the "planned-for" and the planner. In that steady improvement we may see a real accomplishment and not frustration.

• • •

Eric W. Thrift[4]

At the outset, in answer to Dr. Lash's question "Is Effective Town Planning Possible?" I think briefly the answer is yes, a little better than he would lead us to believe in his article.

---

[4] Director, Metropolitan Planning Commission of Greater Winnipeg.

There may be many interpretations of what constitutes success in planning and while the article appears to deal largely with the implementation of public and private works, this is really only one aspect of the successful application of planning. It is, in fact, the physical expression of a broader plan which also involves sociological, legal and economic questions about which the people of any community have ideas and opinions that must be respected. In order to respect these opinions, of course, the civic administration and the planning function in that administration must know and understand them. We should be careful that in a desire for perfection in the physical application of our plans we do not tend to involve ourselves in political conditions of which we would not approve. We do not want to see physical perfection of our communities at the expense of political freedom. Competent civic officials including planners understand that in the operation of democracy there must be a good deal of unavoidable compromise. There can be no one authority that knows all the answers.

To return to the text of Dr. Lash's article, in the section dealing with town planning and civil engineering, there is argument that most of those in planning practice in Canada are inadequately trained academically. I should like to suggest however, that unless we were able to get a complete review of the training of those in planning practice in Canada it would be difficult to substantiate that many of these people have not had adequate planning training. In carrying on with this section he compares engineering design and town planning. While they may be compared for the purpose of gaining the understanding of the engineer, I think what is more important is the relationship between the design and execution of an important public work such as a bridge, and the sound planning of the community in which it is located. The relationship may be created by the fact that the bridge is the implementation of part of an overall plan worked out for the community and many of the initial decisions with respect to location, connections and many other aspects of basic requirements of that bridge are tied up in the planning function of the local government.

Turning now to the discussion of objectives, certainly the planner's objectives are not as neatly expressed by formulae and statistics as the engineer's when he sets out to design a particular structure to meet a particular specified need, but the planner must have objectives or he is no more good than any other person who doesn't really know where he is going or why. His objectives are a little more difficult to define because as Dr. Lash says, 'he deals with people rather than things'. In fact, he deals with both and the broad relationships between them. In this respect the relative values that people put on certain aspects of their community development are important to the planner and he must know as well as he can what these relative values are. These are some of the things that help him to determine with more precision what his objectives are for the particular community with which he is working.

Because the planner's objectives appear to be less clearly defined than those of the engineer, Dr. Lash points out that the planner, therefore, has much more difficulty in having any part in the realization of the plans which he helps to prepare. Many planners, however, have played extremely effective parts in implementing plans which they have had a hand in preparing. The implementation of these plans or ideas, of course, does not always involve public works or construction projects. For example, the planner considers implementation to include better use of vacant land, the management of city owned property, control of damaging land use, improvement of circulation, more economical development of industrial areas or residential areas, improved recreational facilities, removal of blight or slums and sound redevelopment and so on and on. All these may be regarded as examples of the effective results of a planner's work.

In the short section on "The Ineffectiveness of Planning" Dr. Lash makes what appears to me to be a rather all inclusive statement and I am afraid I'm not prepared to agree with it completely. A great deal has been accomplished through planning, not always in terms of major construction that we can gaze upon in admiration, but in terms of gradually improving methods for meeting problems more effectively as they develop and of getting better and better understanding of the aspects of our community life and economics. This will in turn, of course, affect what we do with physical improvements and construction.

The reasons given for the ineffectiveness of planning are not unalterable conditions. They are common problems for which solutions are being found in different ways in different places. He is quite right in stating that his reasons have had a detrimental effect on planning operations in various communities throughout Canada. There undoubtedly is room for improvement in all of these respects, but the need for improvement varies in degree and extent depending upon the locality and its particular problems.

Dr. Lash provides us with a set of objectives which are quite clear and fairly comprehensive. He explains briefly the work involved in reaching each of the several objectives.

With reference to civic design, I think it is hardly a lost art but perhaps one that is not as much exercised in many parts of Canada as it could be.

Planning and Local Government

Turning now to the relationship between planning and local government there are a number of extremely sound ideas expressed here and I think most practising planners working with local government would confirm his convictions. However, I think the wide breech between the planning operation in many towns and cities in Canada and the local government is narrowing and in many places it is disappearing altogether.

At the same time it seems to me that we might use some caution in summarily condemning the use of planning commissions and boards. They have been and in many places continue to be a vital element in the planning process. The kind of change of relationship which Dr. Lash suggests is probably better if it is carried out in an evolutionary way rather than revolutionary way. Local planning agencies must often build confidence in their operations. This confidence has been gained in many places in Canada but very often planning commissions have been instrumental in gaining it.

In the discussion of the size of planning areas, I think the need for a larger planning area is quite evident and again the points made are unquestionably valid. Perhaps, however, we find some conflict with the previous suggestion that the planning function be integrated as part of local government.

Creating larger planning areas will not solve the problem alone. We need jurisdictions of a governmental character with a wider area under their supervision and with which the regional planning function can be integrated in the manner that Dr. Lash suggests. This has in a measure been achieved in the metropolitan area of Toronto and perhaps this is really the only place where we can see this in operation at present. While this is a technique to aim at I do however believe that there are a number of jurisdictions in Canada in which planning is being handled on a metropolitan or regional basis but which do not, at the present time, have a parallel level of government. Success such as has been achieved has been due to the fact that the local governments, their planning boards and their planning technicians have approached their common task with a good deal of interest and goodwill and certainly with an intent to cooperate wholeheartedly.

In going on to discuss the possible relationships between a wider regional planning authority and local government, Dr. Lash expresses the opinion that the municipal act in Ontario will continue to be a handicap in this connection and suggests a regional planning authority which might "delegate some of its powers to local municipalities within its jurisdiction".

It seems to me that a planning authority is not a government and it therefore has no authority to delegate powers, because it has none except those which may be delegated to it from local government or from the provincial government. Dr. Lash mentions the Alberta legislation and experience, with its provisions for regional planning authorities. Success in their application is due in part, it seems to me, to the fact that the local governments still exercise a good deal of their own authority and the regional planning body only has such power as the local government may be prepared to assign to it. Dr. Lash points out, however, and this point is extremely important, that "The approval or the rejection or modification of plans must be the responsibility of local government". I don't think we can avoid this, and we would be unwise to try.

In discussing appeals, his statement is quite brief and it seems to me too all inclusive about a subject which can be quite complicated and difficult. Again, brevity may be due to the fact that this was an address given within a limited time.

Dr. Lash makes a brief reference to public relations which again seems hardly adequate in such an article as this. I suspect that the Community Planning Association of Canada with its various branches throughout Canada would have a good deal to say on this subject. There is also the aspect of public relations that has to do with the acceptable application of planning. Even though there may be a thoroughly effective planning operation in being in a community, sometimes good public relations are required in order to make sure that this aspect of the relationship between government and people continues to be understood. The planning commissions, moreover, have also had an important part to play in this connection in many North American cities. We cannot ignore their value in this respect.

In discussing compensation with which is coupled betterment, Dr. Lash points out that this is a broad and difficult field and further that its administration may appear insuperable. The British in using it apparently found that in fact it was insuperable because it has been abandoned in the face of the administrative difficulties. The fact that it seemed to fly in the face of what may be considered common human nature may also have contributed to its abandonment. As Dr. Lash says at the beginning of his article, it is people we must deal with, and we must consider carefully the view they take of the handling of the property they own and the values they attach to it.

Dr. Lash states the case for compensation and betterment rather simply and it would, therefore, appear to call for a rather simple solution, but it appears to me anyway, that there are too many unstated factors.

Dr. Lash makes use of a provision for caring for the costs of compensation and property acquisition which is common to many other difficult aspects of local government particularly where cost is involved. He suggests that the costs of such operations should be the responsibility of the provincial government. I think provincial government officers would confirm that this is commonly an apparently easy way out of a municipal financial difficulty. It seems to me that this touches a much more fundamental problem, that of the relationships among federal, provincial and municipal governments and their relative responsibilities and resources. Since this is a subject about which volumes could be written alone one cannot enter into a long discourse on that subject here.

Toward the end of the article Dr. Lash deals with planners and I think he couldn't expect to make the statement that present planners are 'a pretty motley crew', without being challenged by some.

No one would argue with the statement that we need adequate educational and training standards, but it seems to me to be doubtful wisdom to put all of the current planners in Canada, particularly, the home-grown ones into the limbo of the half-trained with doubtful abilities. Many of those in the field today in Canada are quite competent people.

I am always afraid of the word "compulsory". It seems to me that if a planner or the planning function of any community is doing a good job and is capable of pointing out the validity of its recommendations and ideas, that is part of its responsibility. If it does not and cannot do so then it is the responsibility of the community and its government to get a planning operation that can and will. If the people of our communities are convinced that they want good, sound communities as pleasant places to live and to work in economical and comfortable circumstances it should be up to them to decide that they want it so, and no official, it seems to me, should have the power to push it down their throats. He can help them establish their standards and goals, point out the consequences of various kinds of action, legislative or otherwise, and when the community's decisions are made, help to maintain standards and labor toward the achievement of its goals.

E. G. Faludi, M.E.I.C.[5]

Dr. Lash's statement that planning is a process aimed at creating the best possible urban environment with the available resources and that town planning is concerned particularly with health and safety, economic opportunity and efficiency, and with aesthetic and cultural satisfaction, will be met with wide agreement.

In addition, planning means the application of wisdom of organizing and regulating the relations between people and people, people and nature, people and the machine.

Planners are not just designers nor beautifiers. They closely resemble efficiency experts. They study carefully the social and economic problems of a community before they recommend physical improvements. As Dr. Lash says, it is important that we appreciate the differences between town planning and engineering design.

Planning is a process of compromises rather than an instrument of doctrinaire philosophy or a weapon of personal ambition.

It is an astonishing fact that in a century dominated by the idea of efficiency, the uneconomic organization of our cities has caused so little concern. Partially built up areas and ribbon development which causes cities to spread out in all directions, result in inefficient and uneconomical servicing.

The reasons for ineffective planning given by Dr. Lash may be augmented as follows:

(1) lack of public understanding concerning the objectives and procedures of planning

(2) political interference with regard to the proper place of planning within the structure of municipal government

(3) unsatisfactory administrative procedure.

(4) lack of trained personnel, especially senior men

(5) lack of money.

In addition, the increase in urban population and the increase in the number of automobiles on our city streets present significant problems to the planners.

The automobile, invented as a means of locomotion, has become a means of congestion. A bedroom takes up 80 - 100 sq. ft. and the space that need be provided for parking a car is three times this amount. Car parking space is required at home and on the street in a city centre. City centres are congested, have some narrow streets, traffic snarls and insufficient parking areas.

The population of Canada in 1975 is estimated to be 25,000,000. We will have twice the present population to accommodate in our cities and it is necessary to prepare for this.

The specific objectives in urban planning have been discussed by Dr. Lash and these may be summarized to include:

(1) cleaning out and redeveloping slums and blighted areas

(2) reserving land for parks

(3) planning industrial and residential areas with iron clad by-laws to ensure that they will be so used

(4) controlling haphazard fringe development by regulations

(5) widening streets and constructing traffic arteries capable of handling tomorrow's traffic as well as today's

(6) providing additional and up-to-date commercial airports.

The basis of sound national planning is regional planning. Nature has divided the land into regions according to climate and resources. No single community within such areas can plan its own improvements if it concentrates on its own legal territory and ignores the regional peculiarities that so vitally affect its welfare.

Regional planning areas should be established on the basis of economic, social and geographic factors, not just on a basis of population density and economic feasibility as Dr. Lash suggests.

Research is essential to effective planning. We can build for the future when we understand exactly the problems we have to deal with, the conditions we have to meet, and the materials available.

Legislation to control development and to ensure that the plans will be put into operation is also an essential.

Effective town planning can only be achieved with the cooperation of the common man. Opposition to planning is mainly the result of misunderstanding. It is only fair that people should know what is being planned, why it is needed and how it will answer the need. Plans must be explained and discussed openly if the necessary co-operation from the citizen is to be had.

[5] Managing director, Town Planning Consultants Limited, Toronto.

HIGHWAY PROBLEMS IN ONTARIO

W. J. Fulton

(*continued from page 237*)

Considerable care is taken to adjust the line so as to do as little property damage as possible. All necessary topographic and soils surveys are made to obtain the information for designing the road and the structures and for preparing the estimates, etc.

As a result of its incorporating the most modern of highway design standards, a controlled access highway, such as is proposed for No. 2, will permit the motorist to benefit economically from a saving in time, from a saving in fuel consumption, from a saving in vehicular wear and tear, and from a reduction in personal injury and property damage accidents.

The mileage of fully controlled access highway built, being constructed, or proposed to be built in Ontario is 672. Because it has been established that cities and metropolitan areas include the sources and destinations of much the larger part of the heavy flow of traffic that moves over the highways of the province, this system of controlled access highways, within the limit of the mileage adopted, connects as many as possible of these cities and metropolitan areas.

It is believed that this mileage of controlled access highways will serve a larger proportion of the total highway traffic of the province than it is possible to attract to any other system of the same extent. As an example, it may be noted that No. 2 highway is in the centre of a band 20 miles wide, within which live 3,000,000 people, or 66 per cent of the population of the province, holding about 70 per cent of the motor vehicle registrations. It is estimated that, although the proposed system of controlled access highways represents less than one per cent of the mileage of the entire highway and street system of Ontario, it will serve more than 15 per cent of the total traffic in the province. ✓

ABSTRACTS . . .

OF RECENTLY PUBLISHED ENGINEERING LITERATURE

THINKING AHEAD

An Editorial, *Harvard Business Review*, November/December 1955.

Automation necessitates extensive planning operations within the plant if costly mistakes are to be avoided. But the new mechanization also poses considerable questions in other fields. In the area of industrial relations for instance, will it lead to more jobs or, as many fear, fewer jobs? Will it create a need for more skill in the work force, as generally assumed, or less? Will it increase maintenance costs? Again, what significance will automation have in the field of small business? Will the effects be as severe as many writers have anticipated?

In 12 out of 13 of the plants studied, the number of people employed is higher than it was prior to automation. Many changes in materials, processes, and product design produce as much displacement as automation, or more. More often than not, the machine had assumed most of the skill requirements of the job and the production systems required less skilled labor than before. Automation seemed to lower training requirements for the *majority* of the workers.

Automation has one notable impact on the character of the maintenance force: the new skills demanded of plant electricians. Indeed, it seems we need a new class of plant electricians, "Electronic technicians." Yet there are definite indications that *maintenance costs in some kinds of plants will actually drop under automation*, because automation has reduced the total amount of machinery in the factory.

To a certain extent, the very logic of automation will operate in favor of small business's survival. *In general*, automation reduces production flexibility — thus automation may well prove a blessing to the small business man who is fast on his production and sales feet. But he will have to make his living by producing the fastest or the finest.

Although there are many production advantages as a reward, automation means much more worry for management. The question for management is, therefore, "shall we buy this much trouble; and if so shall we buy it *now?* Shall we pioneer . . . or shall we wait till it is perfected a bit more? As one topnotch manufacturing research man points out: "The firm that rushes into this thing blindly is going to lose its shirt. The firm that doesn't go in at all is going to lose its market."

• • •

GLASS COATINGS PROMISE LONG LIFE FOR STEEL STACKS

Power Engineering, v. 59, n. 8, August 1955, p. 63.

Glass-lined smokestacks have been on test for nearly two years and are just now being marketed. Such stacks are made of a mild steel with two coats of fused glass. A 20-month test recently completed showed a loss of surface gloss to be the only effect of exposure to a highly corrosive flue gas for this full period.

It is not claimed by the developers of these stacks that they will last forever, merely that they will last much longer than steel stacks without glass protection. Specifically, a life of 25 years (as compared with 10 to 12 years) is forecast, and is considered conservative.

There is more to be considered than length of service, however. Corrosion protection of this calibre permits the elimination of that extra margin of steel provided in unlined stacks expressly to allow for corrosion. Where plate thicknesses of $\frac{1}{4}$ in. are required for structural reasons, it is customary to allow another $\frac{1}{8}$-in. of steel which can be eaten away before the stack becomes unsafe.

Many steel stacks subjected to corrosive duty are lined with brick, and the steel plates must be heavy enough to support the brick as well as their own weight. Compare the weight of five inches of brick in a conventional lining with the 0.012-in. (±0.002-in.) coat of glass. It should be obvious that weight savings of this magnitude will affect the requirements for foundations and for structural steel supports, where stacks are mounted on boilers or buildings.

It might appear that this would be pertinent only where the reduced structural requirements could be accommodated in new designs. It presents another possibility, however; stack replacements with the lighter stacks can be taller than the conventional stacks they replace, without increasing the investments in supports. Plants faced with ultimatums from air pollution groups could make good use of this characteristic to discharge their gases higher, possibly going to a smaller-diameter stack with higher velocities at the same time. The smaller stack diameter would, of course, permit an even greater increase in height if proper guying is practiced.

This leads us to another consideration. How high can a glass-coated stack be made before its own weight leads to base loading to such an extent that the glass fails? What about the natural sway of the stack? Would this cause glass failure?

Tests conducted on this type material indicate that glass failure occurs after the deformation stress of the metal is reached. Since any structural use of metal calls for stresses well below those at deformation, we have reason to believe that the exercise of elementary design practice is all that is required to avoid such stress-failures of the glass coat. The glass, in other words, is tough.

Glass-coated steel can be drilled and cut much as other steel. Should some small boy try out his new rifle on the stack, it is possible to flame-cut out the affected area and bolt on a coated patch. Holes may be drilled also for attaching ladders and other hardware. Special bolts with glass-coated heads extend the protection of glass throughout the stack and could be used to patch holes small enough to be covered by their heads.

Until research devises some way for welding sections together without damaging the glass, stacks will be supplied in flanged sections and will be bolted together. High-temperature plastic coatings protect the exposed parts of fasteners, such as the bolt threads, from atmospheric corrosion.

Selection of a class-coated stack would mean paying about 50 per cent more than for a conventional unlined stack, but conservative estimates predict a 100 per cent increase in life.

• • •

CANADA IS VITAL

Engineering, v. 180, Dec. 1955, pp. 842

British manufacturers have tended to neglect the Canadian market for long enough. While British exports to Canada have recovered from the low levels reached in 1955, they represent only 8 per cent of the goods entering Canada from abroad, compared with the pre-war share of 20 per cent (and a post-war high of 11 per cent). During the first ten months of 1955 our exports to Canada remained the same as in the corresponding period of last year, despite a 9 per cent rise in the Canadian gross national product. Meanwhile, Continental competitors have been stepping in, and the United States has also increased its share. Yet Canada says that it wants to "Buy British"—and not necessarily from any feeling of sentiment. It is in their own interest to develop their export markets and the United Kingdom is Canada's second largest customer. There are large markets for all types of capital goods—particularly machinery and equipment for the big new mining developments, and naturally the demand for consumer goods is rising consequently. Why then has Britain lost ground in the Canadian market?

It has been suggested that United Kingdom manufacturers are unable to offer short delivery dates due to rising investment demand at home and in other countries. The proximity of the United States is quoted as offering lower transport costs and hence lower prices, even though British manufacturers have been assured that they have nothing to fear in this direction, since United Kingdom prices are often as much as 25 per cent less than their competitors. Such excuses, however, cannot explain German success. The real answer probably lies in a remark made by Mr. Marc Boyer, a member of the recent mission to Britain from the Canadian metal mining industry. "You cannot sell in Canada from a desk in the United Kingdom. You must be on the ground over there." Mr. Boyer condemned the apparent lack of aggressive selling and recommended British manufacturers to appoint their own representatives and selling organizations in Canada, the warehousing of stocks for immediate dispatch, and the establishment of assembly plants. Certainly, the majority of British concerns who have penetrated the Canadian market on any scale have found the experiment rewarding. Another recent suggestion was that companies should co-operate to reduce the expense, share the risk, and by this means present a wider and more attractive range of goods and thereby secure better representation in Canada, as has been done over the St. Lawrence project.

Opportunities there certainly are. In 1955 the amount spent on construction work on new houses is said to be 200 million dollars. Output of base metal (copper, nickel and zinc) this year is estimated to be 12 per cent above the total in 1954, while output of aluminum is increasing steadily. A most significant indicator is electric power. The gross generating capacity of electricity stations is planned to reach 16.6 million kw. in 1958 compared with 13.1 million in 1954. These are signs not only of boom but of long-term expansion.

DOWN COME ALUMINUM CASTING COSTS

W. G. Patton, *Iron Age*, v. 176, n. 26, December 29, 1955, pp. 61

A simplified method now makes practical the production of large, comparatively short run aluminum castings in permanent molds. Castings up to 70 lb. have already been made and it is apparent that castings weighing 100 lb. can be produced by this method at competitive prices. Castings weighing only a few ounces have also been produced by this method at rates as high as 6000 per day.

Successful use of the process centres around a unique, low cost casting machine. It has many features of a diecasting machine except that metal is hand poured instead of being injected at high velocity into the molds.

Another important difference is the use of gray alloy iron molds that are precision cast to required tolerances. Except for minor polishing or touch up, and machining of the parting line, molds are used as cast. The comparatively low cost of molds is a major reason why this new process can compete with gray or malleable iron casting, or diecasting, for many applications.

While the process is particularly suitable for medium and long-run large castings, the production of comparatively large runs of small production castings is possible. Tooling for small parts, may be simplified by making a single master part and using this single part as a pattern to produce all other cavities in the mold. As many as 20 or even 30 parts can be included in a single permanent mold.

CAN'T BE DONE? . . . THEY'RE SLUICING ASH UPHILL

Power, v. 99, n. 9B, Mid-September 1955, p. 68.

When Interstate Power decided to add another boiler and turbine-generator, they also decided to do something about the ash-disposal system—mainly because new boiler needed space taken by the boiler-room sluice pit. That's when one of the operators came up with his payoff idea: "Forget about the first sluice pit, pumps, discharge lines and clinker grinders. Just plain sluice it right into the second pit." Initial reaction: not practical . . . would take too much power.

But the chief engineer, trying to prove the point, set up a test section of the sluice pit, borrowed hose from the local fire department to feed flushing nozzles. Hoisting test-section discharge with locomotive crane to a 15% rise, he turned on nozzle-flushing water, duplicating sluice conditions. The test rig worked. It picked up water, ash, cinders and hurled them far over a 20-ft. pile of cinders.

The uphill sluice line went in. High-pressure water-injection nozzles, at eight points along the 110-ft. inclined sluice, flush ash uphill, into an outside pit. Locomotive crane piles ash alongside the pit. Local contractors, using ash for fill or other purposes, haul it away.

Since modernizing, maintenance costs have been a meager $50—for one sluice liner, two nozzles and installation labor.

AEROFALL MILL FINDS INCREASING APPLICATION

Mining Engineering, v. 7, n. 9, pp. 842/845, September, 1955.

The basic feature of the Aerofall mill is continuous dry crushing and grinding of ore upon ore, combined with classification of the ground material by passing air through the mill at a controlled rate.

Combinations of these ideas — dry grinding, autogenous crushing, and large diameter mills — have been attempted before but the results were inconclusive. In some cases development was interrupted, in others success came only in specialized applications. In the face of this background the first Aerofall mill installations represented considerable engineering courage. The designer was putting all his eggs into one basket, into a unit that promised to both crush and grind.

Changes in ore character and in moisture content have been problems in autogenous mill design. It is stated that the Aerofall mill can tolerate up to 4 per cent moisture without effect upon capacity or product. With heating apparatus for the air intake, the mill has reportedly ground ore up to 12 per cent moisture. Flexibility as to feed make-up is also supplied, if necessary, by adding a ball charge of up to 2.5 per cent of total mill volume. With such a charge ball consumption figures range less than 0.05 lb. per ton.

History of the Design

Aerofall mill development had its beginning in the late 1930's. Despite the depression which was then almost at its worst, so far as the base metals industry was concerned, the management of Consolidated Mining & Smelting Co. of Canada started a comprehensive program of research for the purpose of testing various theories of comminution. The objective was to improve performance of the then existing mill equipment. During this program, which was interrupted by the onset of World War II, much was learned about the nature of comminution which formed the basis for new theoretical approaches to the problem.

Serious development work on the Aerofall mill was begun following World War II at the Canadian Bureau of Mines in Ottawa. The mill used in this work was 5 ft. diam. and capable of reducing 10-in. feed to as fine as 75 pct-325 mesh.

First commercial installation was at a gold mine in northern Canada. The plant operated only a very short time because it was found there was insufficient ore to maintain production. However, much valuable data was obtained so that correlation between the test and commercial units could be started.

Other commercial units followed, and in 1950 the largest unit constructed to date, a 17-ft. mill was built for a large asbestos producer. This unit went into operation in 1951 and gave fairly complete information on correlation of capacities of the various size units. Many of the problems in air handling and mill control were solved from this installation.

After this installation other commercial units were gradually built, installed, and put into operation. The diverse materials handled by these installations created new problems, but the Aerofall mill is now handling nearly every type of ore, and under widely varying conditions.

GUN KILLS OR FEEDS TREES

Paper Trade Journal, v. 139, n. 39, September 26, 1955, p. 80.

The development of a new and efficient method of injecting substances into trees, their roots, or the soil, utilizing a gun with gunpowder or other propellant in a cartridge, has been announced. Main implement of the process is a gun, similar mechanically and in operation to a shotgun, but equipped at its muzzle end with a combination metal and resilient shield.

In outward appearance the cartridge used is similar to the ordinary shotgun shell, although somewhat longer. The cartridge contains in addition to the firing or priming cap, gunpowder or propellant, a primary charge of tree poison which usually is in particle or powder form. The primary charge may also contain insecticide, preservative, stain, seasoning agent, or debarking chemical. The forward end of the cartridge is a slug or projectile which may be hollow. The hollow projectile in addition may be filled with a secondary tree poison or a combination of other substances already mentioned for the primary charge.

To operate, the gun is held against a tree or the ground and fired. The projectile punches a hole in the bark allowing the poison charge and expanding gases to enter. The explosive force lifts the bark and distributes the poison over an area of two square feet or more. Following the charge, the bark collapses substantially to its original position, leaving the poison in intimate contact with the cambium, phloem, and zylem cells, which is absorbed into the circulatory system of the tree, killing it.

Many different substances may be injected into a tree this way, with a single shot. The advantage of this process is that when harvest time approaches, the dead, peeled, seasoned and otherwise conditioned trees are cut down with several of the usual mill operations already completed, partly by nature.

FRETTING CORROSION

The Chartered Mechanical Engineer, v. 2, n. 7, Sept. 1955, pp. 334/35.

Since fretting corrosion was first noticed in 1911 it has continued to excite interest, largely because of its association with fatigue failure. It is defined as the particular kind of damage which occurs when two surfaces in contact experience slight periodic relative movement of a few micro-inches. It can occur under very diverse circumstances, but it is encountered most commonly where a hub or bearing housing is press-fitted on to a loaded rotating shaft, and in riveted assemblies which are subjected to vibration. The removal of material from the surface can lead to loss of fit of the two components, or if the debris cannot escape, it may cause seizure in a case where they are occasionally required to move.

Particle Size

The particle size of the debris estimated in the electron microscope of Cornelius (1944) and Wright (1952-53) is of the order of a few hundred angstroms. On mild steel in air it has a characteristic red colour and X-ray diffraction has shown that it is α-Fe_2O_3. On aluminium it is black and consists of particles of aluminium coated with a transparent film of alumina.

Influencing Factors

The most important of the factors that influence fretting corrosion is the relative movement or 'slip' between the mating surfaces. The surrounding temperature also influcnces the amount of damage. It increases as the temperature falls, rising sharply at 0 deg. C. This rise has been attributed to the freezing of adsorbed films of water (present on the metal surface and on the debris particles) which act as a lubricant, but there is a possibility that it is connected with the transition from ductile to brittle fracture of steel in this temperature region.

The composition of the atmosphere has some effect on the amount of damage and on the chemical composition of the debris. In pure nitrogen the damage on mild steel is very much less and the debris is metallic iron. If the supply of oxygen is restricted by the presence of a lubricant, the debris is black and consists of γ-Fe_2O_3 or Fe_3O_4. An increase in the humidity leads to a decrease in the amount of damage. At very low humidities the debris is black but is α-Fe_2O_3. The influence of the humidity may be to provide a lubricant film of water to alter the composition of the debris with the formation of a hydrated and less abrasive oxide.

Possible Mechanisms

Three possible mechanisms for fretting corrosion have been suggested:

(1) the removal of metal from the surfaces in a finely divided form by a mechanical grinding action, or by the formation of cold welds at the points of intimate metallic contact which are subsequently ruptured with tearing of the surfaces.

(2) The removal of metal particles which are subsequently oxidized to an abrasive powder which continues the action.

(3) Oxidation of the metal, which, in the absence of mechanical action, soon becomes very slow, but which will be maintained indefinitely if the oxide film is continually being removed, exposing fresh metal, probably in a highly deformed state.

Preventive Methods

The numerous methods which have been applied, most of them successfully, to the prevention of fretting corrosion, may be divided conveniently into five groups.

(1) Prevention of relative motion.

(2) Reduction of the coefficient of friction.

(3) Increase of abrasion resistance.

(4) Exclusion of the atmosphere.

(5) Increase of the distance of separation.

Fretting corrosion is a condition in which a large number of factors play a part. Before a particular remedy is tried, a detailed analysis should be made of the conditions producing the damage, so that an enlightened selection of the most effective cure can be made.

Annual General and
of The Engineering
In association with The American
Sheraton-Mount Royal Hotel

PROGRAM*

Industrial Power Distribution:

J. R. Auld, M.E.I.C., Supervising Engineer, Power Services, Du Pont Company of Canada Limited.

General Design of the St. Lawrence Seaway — Montreal Area:

D. M. Ripley, Jr. E.I.C., Senior Assistant Engineer, Hydraulics, St. Lawrence Seaway Authority.

Application of Welded Design to Hydraulic Turbine and Valve Manufacture:

J. G. Warnock, Head, Hydraulic Department, English Electric Company, Limited, St. Catharines, Ont.

A Rapid and Accurate Method for Calculating the Transient Temperature in Composite Slab:

W. F. Campbell, M.E.I.C., Division of Mechanical Engineering, National Research Council.

The Growth and Development of Large Electric Power Systems:

W. R. Way, M.E.I.C., Vice-President and Chief Engineer, Shawinigan Water and Power Company Limited.

The Use of Hydraulic Models in the St. Lawrence Seaway Design:

Duncan McIntyre, Senior Assistant Engineer, Hydraulics, St. Lawrence Seaway Authority.

- Thirty outstanding papers
- Two panel discussions
- Special tours of the St. Lawrence Seaway (26 May)
- Special ladies' program
- Advance registration forms will be mailed early in April

The Kaplan Turbine in Canada:

G. D. Johnson, Mem. ASME, Chief Hydraulic Engineer, S. Morgan Smith Company, York, Pa.

Lateral Rigidity of Building Frames:

J. L. de Stein, M.E.I.C., Associate Professor, Department of Civil Engineering, McGill University.

Cross Suspension System, Kemano-Kitimat Transmission Line:

H. B. White, M.E.I.C., Power Transmission Engineer, Aluminum Company of Canada Limited.

Experimental Work on Coal Burning Gas Turbines:

D. L. Mordell, M.E.I.C., Chairman and Professor Department of Mechanical Engineering, McGill University.

The Mechanical Design Features of the St. Lawrence Power Project:

Otto Holden, M.E.I.C., Chief Engineer and P. Pemberton-Piggott, Asst. Mechanical Engineer, Generation Department, Hydro Electric Power Commission of Ontario.

Bersimis Power Development:

F. P. Rousseau, M.E.I.C., Chief Engineer, Power Development Division, Quebec Hydro Electric Commission.

Air Pollution Control Problems:

E. A. Allcut, M.E.I.C., Head, Department of Mechanical Engineering, University of Toronto.

The Metal Bonding of Aircraft Assemblies:

J. J. Waller, Chief Materials and Process Engineer, Canadair Limited.

*Subject to minor changes.

Professional Meeting
Institute of Canada
Society of Mechanical Engineers
Montreal, 23-24-25 May, 1956

PROGRAM*

The Trans-Canada Radio Relay Telephone System:

A. J. Groleau, M.E.I.C., Area Chief Engineer, The Bell Telephone Company of Canada Limited.

How the Mackinac Bridge was Designed for Aerodynamic Stability:

D. B. Steinman, M.E.I.C., Consulting Engineer, New York, N.Y.

Current Developments in Air Pollution in the United States:

L. C. McCabe, President, Resources Research Incorporated, Washington, D.C.

The Challenge of Progress:

R. C. Sebold, Vice-President, Engineering, Convair Division, General Dynamics Corporation, San Diego, Cal.

Co-Operative Research in the British Electrical Industry:

Jerzy Miedzinski, A.M. I.E.E., The Electrical Research Association, Greenford, England.

Survey of the Hamilton River:

E. N. Webb, M.E.I.C., Consulting Hydro Electrical Engineer, British Newfoundland Corporation Limited.

The Control of Air Pollution in England:

S. G. G. Wilkinson, Ministry of Housing and Local Government, London, England.

Automation, Men, and Machines:

J. J. Brown, Consulting Engineer.

The Canadian Atomic Power Program:

I. N. MacKay, M.E.I.C., Manager, Engineering Civilian Atomic Power Department, Canadian General Electric Company Limited.

High Speed Photography in Chemical Engineering:

A. I. Johnson, Professor, Department Chemical Engineering, University of Toronto.

*Subject to minor changes.

Automating the Engineer's Task:

Josef Kates, President, K.C.S. Data Control Limited.

Modern Alloys for Industrial Use Above 1200 Deg. F.:

J. P. Ogilvie, M.E.I.C., Shawinigan Chemicals Limited.

Mechanical Design and Equipment of Labatt Brewery, Montreal:

R. E. J. Layton, M.E.I.C., Chief Mechanical Engineer, T. Pringle and Sons Limited.

Moving-Bed Processes:

E. H. Lebeis, Catalytic Construction Company, Philadelphia, Pa.

Long Range Planning in an Atomic Age—Management Panel Discussion:

Chairman, L. F. Urwick, C.I.Mech.E., Management Consultant.

Mass Transportation in Cities—A Traffic Panel Discussion:

Chairman, George S. Mooney, Director of St. Lawrence Municipal Bureau.

Special Lecture:

Production Engineering Research in Britain:

D. F. Galloway, M.I.Mech.E., Director, Production Engineering, Research Association, Melton-Mowbray, England.

Chairman: J. W. Barker, Mem. ASME, President, American Society of Mechanical Engineers.

SPECIAL VISIT

On Thursday afternoon, 24 May, there will be an exceptionally interesting visit to the Canadair plant, at Cartierville, where open house will be held for inspection of aircraft and production facilities. An air show, in which the R.C.A.F. will also take part, will highlight the occasion.

Report of Council

FOR THE YEAR

1955

Together with Committee and Branch Reports

In Times like these it is to be expected that any organization will show from year to year an increase in activities and an improvement in finances. So it is with the Institute again for 1955.

The "vital statistics" shown herein, indicate a substantial increase in membership, the total being for the first time in excess of 16,000. The strength of the Institute financially has been increased substantially by a great number of transfers to senior classifications. The loss of members by death is still a substantial figure, but this is not surprising in view of the large membership, and the increasing years of the society.

It is surprising to see the number of new applications that are required to offset the losses through resignations, removals and deaths. It is surprising too to see the number who are leaving Canada to take up residence elsewhere. Many of these are senior men who have retired and are moving to a more equitable climate. In the light of these things it is hoped the branches will continue and even expand their efforts towards getting new members.

The Institute has had a good year—perhaps the best in its history, but these results are but a spur to greater achievements in 1956.

BRANCH VISITS

The president, like his predecessor, Dr. D. M. Stephens, did not plan to visit every branch. However as it worked out he did visit 36 out 47, which is substantially more than the 50 per cent basis upon which presidents are now supposed to be working.

On top of this he attended three meetings of American societies, at Boston, New York, and Chicago, and the annual meeting of Engineers' Council for Professional Development at Toronto. In October he flew to England at the invitation of the Institution of Mechanical Engineers to attend an international conference on power.

The office of president has required Dr. Heartz to be away from Montreal for approximately 120 days. Also there were many days, which although spent in Montreal, were spent on Institute business. A rough estimate of the distance covered by Dr. and Mrs. Heartz would be twenty-five thousand miles Truly the post of president of the Institute is no sinecure. It is perhaps the greatest tribute received by the Institute, that a member is willing to make such sacrifices in the interest of the society.

CONFEDERATION

This subject continued to be one of the most interesting before the Institute and the membership. Considerable progress was made by each committee, and at a meeting of both committees. Negotiations and discussions are still being pursued actively, and the farther these go, the more encouraging the picture becomes. It is hoped that shortly an informative report can be made that will indicate specifically the progress that has been made. It is not possible to make an interim report inasmuch as no decisions can be final until all or nearly all points are settled.

However it is clear that real progress has been made, and that the road to confederation has been traversed for a great portion of its length and over many of its rough spots.

PROPAGANDA

During the year a new pamphlet was issued and distributed for the attention of students. It is called "So you're going to be an Engineer". It told of the advantages there were in the Institute for students and young engineers.

Another membership pamphlet was prepared during the year. but it was not ready in time to go to the printers by the end of the year. It will be distributed early in 1956. Its contents are in the form of twenty-five answers to the question — "Why should I belong to the Institute?" It is hoped this publication will meet the need so often expressed by branch officers, for background material useful in recruiting new members.

TECHNICAL ACTIVITIES

Much thought has been given to expanding the amount of technical material brought to the attention of members. Council has before it, proposals for setting up groups at the branch and at the national level, who will give leadership in a program of activities that will enlarge substantially the technical content of branch and Institute programs.

Such a development is now needed because of the great increase in highly technical matters in several fields such as electronics, nucleonics and aeronautics.

It is expected that the proposed action will result in an increase in the number of branches with technical divisions. Already some branches are canvassing their members to see if and how they would like to set up one or more such divisions. Council looks upon this development as being of vital importance and has authorized the addition of a department at Headquarters to assist the branches in proceeding along these lines. It is likely the year 1956 will see a lot accomplished in this field.

FILMS

The reception given the film Leonardo da Vinci would seem to suggest that branches would welcome more material of this kind. Since the Fall programs of the branches have been underway, all four copies of Leonardo have been almost continuously "on the road".

Many branches have arranged to have the film shown to audiences other than their own, such as universities, high schools, libraries, service clubs, women's clubs, church groups, boys' clubs and so on. As the main purpose in purchasing the film was to give the public some idea of the origin of engineering, thereby increasing their appreciation of the profession, it is gratifying to see such a broad distribution being made.

LIFE MEMBERS

The number of Members now free of dues, because of their long membership, totals 640 as of the end of 1955. These "seniors" have an organization of their own through which they raise a substantial amount of money each year to do things for the Institute. Already they have helped materially in sharing the cost of the Leonardo da Vinci film. The group in the Montreal area meet together from time to time to renew old friendships and to discuss ways and means of helping the Institute.

REPORTS

Most of the activities of the Institute are covered by the annual reports of committees and departments of Headquarters, which are an important part of this overall report. Members are urged to read them as they are one of the best means of acquiring a good knowledge of what the Institute has accomplished in 1955.

REPORT OF THE FIELD SECRETARY

During the year the field secretary has met the executives and special committees of the following branches: Brockville, Calgary, Edmonton, Hamilton, Huronia, Kingston, Kitchener, Kootenay, Lakehead, London, Nipissing and Upper Ottawa, Niagara Peninsula, North Eastern Ontario, Port Hope, Saskatchewan, Sault Ste. Marie, Sudbury, Toronto, Vancouver, Victoria, Whitehorse and Winnipeg; and orphan groups at: Brandon and Flin Flon (Manitoba), Prince Albert and Saskatoon (Saskatchewan), Medicine Hat (Alberta), Kitimat, Ocean Falls, Port Alberni, Prince George and Prince Rupert (British Columbia) and in Ontario: Barrie, Collingwood, Gravenhurst, Huntsville, Marathon, Meaford, Midland, Nobel, Owen Sound, Penetang, Red Rock, Temiskaming and Terrace Bay.

The field office was in touch with the nine Professional Development Courses operated during 1955, at the following branches: Belleville, Halifax, Hamilton, Kootenay, Saguenay, Saskatoon, Ottawa, Toronto and Winnipeg. In April, 28 representatives from six branches who were interested in Professional Development Courses in Ontario, met in Toronto and discussed plans for the coming season. The success of all courses depends upon the efforts of a few enthusiastic young men such as these. Total enrolment across Canada was close to 500, and the expense to the Institute was nil. The costs have been met by small fees from the members enrolled, donations from the branches concerned, and the personal generosity of a member of the Toronto branch.

In employment the field office has a record of 142 assisted during 1955, and we advised at least another 20 or 30 men whose names we did not list. We did not keep any record of numerous calls from employers. During the last three months of the year we did not have as many requests from newcomers to Canada, due to less immigration and to more positions being advertised in the daily papers.

This office has been impressed with the desire of many university students to meet informally with older men to talk over such matters as choice of openings after graduation and their future careers generally. Such requests seem to favour first a meeting with one or two engineers who have graduated within the last five years, after which they sometimes ask for another meeting with an older man. Groups should not be larger than a dozen, so that there is every opportunity for individuals to ask questions of the visitor. It is recommended that this form of counselling be considered by all branches in university towns where this is not already being done.

I take this opportunity of thanking the officers and executives of the branches for the warm welcome and hospitality which I have received.

L. F. Grant, hon. m.e.i.c.,
Field Secretary

ROLL OF THE INSTITUTE

The membership of all classifications now totals 16,070. New names added for the year amount to 1,272, but deaths, resignations and removals amounted to 473, making a net gain of 799.

During the year 1,195 candidates were elected. These were classified as follows: Members 253, Juniors 90, Students 850, Affiliates 2. Seventy-seven reinstatements were effected. Life Membership was conferred on eighty-three members under By-law 26.

Transfers from one grade to another were as follows: Junior to Member 286; Student to Member 3, Student to Junior 543, a total of 832.

Removals from the Roll

There have been removed from the roll during the year by resignation and for non-payment of fees: Members 164, Juniors 180, Students 43, Affiliates 2, a total of 389.

Deceased Members

During the year the deaths of 84 members of the Institute (including five Honorary Members) have been reported as follows:

Honorary Members

Allan, John Andrew
Grant, Alexander Joseph
Hungerford, Samuel James
Sexton, Frederic Henry
Wallace, Robert Charles

Members

Anglin, Douglas Gould
Balfour, Reginald Herbert
Beer, Alfred Netlam
Bissett, James Randolph

REPORTS OF COMMITTEES

Admissions Committee

During 1955 the committee held eight meetings and examined 1,544 cases. These consisted of:

Applications for Admission ..	258
Applications for Transfer	238
Applications through Professional Associations:	
(a) Admissions	204
(b) Transfers	69
Student Applications	760
Special Cases	15
	1,544

In the report of Council will be found the number of members admitted to each class during the year.

E. D. Gray-Donald, M.E.I.C.,
Chairman

Canadian Chamber of Commerce

The undersigned, your representative on the Executive Council of the Canadian Chamber of Commerce for several years, wishes (prior to impending retirement from that post) to make several observations in addition to the usual report of the Executive Council's activities.

Your representative has learned during the past few years that, despite the tremendous growth of the Canadian Chamber of Commerce movement in this country, a considerable number of our engineers, particularly the younger ones, are unaware of the structure of the Chamber and its broad objectives. As Canada grows, the Chamber of Commerce grows, making its vigorous contribution to community, provincial and national progress. Canada being, in truth, an engineers' country and a country in which engineering activity continues apace, no engineer can ignore the work that is being carried on by the Chamber, indeed it is very much to his personal interest that he be well aware of it; the Chamber needs his support and, on analysis, it must be admitted that the engineers need the Chamber's support.

What is the Canadian Chamber of Commerce? It is the national federation of more than 730 Boards of Trade and Chambers of Commerce in all ten provinces, the Yukon and the North West Territories. The objectives of the Canadian Chamber include the stimulation and maintenance of a vigorous Canadian national sentiment; the promotion and co-operation among Boards of Trade and Chambers of Commerce, increasing their efficiency and extending their usefulness to all provinces; the development and presentation of an informal public opinion and the securing thereby of effective action by the national government upon questions relating to economic and public welfare; the support and development of the Canadian system of representative government; the preservation and further improvement of Canada's economic system, based upon private initiative and individual enterprise; and, finally, the maintenance of fair relations among labour, management and capital.

From the above it can be seen that this non-sectarian and politically non-partisan movement consists of a vast army of volunteers working together unselfishly for the general good. Because of this cellular structure it is equipped to present to governments at all levels the views and opinions of Canadians on all subjects affecting the economic and public welfare. Its record of achievement on the local, provincial and national levels merits the support of all engineers, indeed, all citizens who are interested in Canadian progress and development. It should be a matter of considerable satisfaction to engineers that many of the senior members of the profession are deeply interested in the movement generally, and actually from year to year are members of the Executive Council.

The activities of the Executive Council during the past year have, as in previous years, been widespread and have reached into all of the important phases of our national economy. Particular concern has been evinced about the effects of high taxes and government spending and it is in this field that the Chamber over the past year did an outstanding job. The Chamber continued to urge the kind of tax system which will encourage individual thrift and incentive and which will afford industry an opportunity to grow. Well in advance of "budget night" a Chamber delegation spent some time with Ministers of Finance and National Revenue presenting a set of public finance and taxation guide tests following weeks of documentation and careful study by a committee of experts. The brief strongly urged the government within the limits of its expenditure requirements to ease the heavy burden of taxation in those areas which would be most conducive to personal and corporate incentives.

Administration of the method of collection of sales tax is a matter of concern to the whole business community and it is interesting to note that the government recently set up a small committee of experts to review this question. This is also in line with a Chamber recommendation.

The Chamber also welcomes the setting up of an Estimates Committee to review estimates of government departments in advance of their being considered by Parliament.

Canada's biggest customer today is the United States and the Canadian Chamber is conscious of the fact that dependence on any one country for a major part of foreign sales is dangerous. Consequently, the Chamber feels that some effort should be made to keep Canadian exports in better balance between our two major customers, the U.S. and the U.K. This is one of the reasons behind the Canada and U.K. Committee, which held a meeting last June in England. Top Canadian and U.K. businessmen discussed such widely varying influences on trade between the two countries as convertibility, capital investment flow and imperial preferences.

Another important part of the work to increase selling opportunities abroad was a June meeting in Montreal with a group of Mexican business men. This was a follow-up of the Chamber Trade Mission to Mexico last year. Then, too, five directors of the Chamber participated in the bi-annual congress of the International Chamber of Commerce in Tokyo last May.

The Canadian economy is so dependent upon foreign trade and the engineering activity of this country is so bound up in the production of materials for export and the construction of plants in which these materials are produced, that such activities of the Chamber, as above described, should be a matter of vital interest to every engineer.

This report is the last of a series of yearly reports to be made by this representative. It has been a high privilege as well as a great pleasure and honour to have represented the Engineering Institute of Canada in the Councils of the Canadian Chamber.

Board of Examiners

The Council of the Institute elected eight Members and three Juniors during the year 1955, subject to examination and while most of these were referred to their respective provincial bodies, the Board of Examiners after a careful review recommended the admission of two Members on the basis of oral examinations.

The Board also examined the curricula and examination standards of ten well known engineering schools in countries outside of Canada. All of these were found acceptable by our standards and recommendations were submitted to Council for their names to be added to the list of engineering schools recognized by Council.

J. L. de Stein, M.E.I.C.,
Chairman

Life Members' Committee

At the end of 1955 there were 640 Life Members. Of these 574 reside in Canada, 19 in the Commonwealth, 44 in the United States and three in foreign countries.

During the year 27 members died.

A "Life Members' Night" was held in February at headquarters. Light refreshments were served from 5.30 p.m. to 7.00, after which the film "Leonardo da Vinci" was shown. This film was purchased by voluntary contributions of the Life Members. A total of 60 were present. Consideration is being given to having another "Night" in March, 1956.

Voluntary contributions were continued, starting in September. At the end of the year the fund had been increased by $1,392. This money is to be used to establish an engineering film library. These films will be sent to branches as requested. Life Members will be notified of purchases as made.

J. A. Freeland, M.E.I.C.,
Secretary

Committee on Professional Interests

The main problem that this Committee dealt with during the year 1955-56 was that of unionization of engineers. No overall meetings of the Committee were held, but considerable correspondence was exchanged between the members and one meeting was held wherein as many members as possible, principally from Montreal, attended. The Committee does not feel that any particular report concerning the unionization of engineers can be drawn up at this time, but nevertheless it feels that a very careful and close watch on developments affecting the establishment of unions among engineers in Canada must be maintained. Your Committee has followed the literature published in various American journals and technical publications and in the newspapers concerning the developments in unionization of engineers in the United States. At the moment, there does not seem to be any great trend towards the unionization of engineers in Canada.

Late in the year, this Committee was requested to advise Council concerning the desirability of the presentation of a brief to the Royal Commission on the Economic Prospects of Canada. The Committee recommended to Council that the Engineering Institute of Canada should prepare a brief, but that the scope of the brief should be limited to the shortage of engineers in the profession.

E. B. Jubien, M.E.I.C.,
Chairman

Committee on the Training and Welfare of the Young Engineer

The formation and operation of Professional Development Courses for Junior members of the Institute continued during the year. Courses are presently active in the following Branches—Belleville, Halifax, Hamilton, Kootenay (Trail), London, Ottawa, Saguenay (Arvida), Saskatchewan (Saskatoon), Toronto and Winnipeg. Discussions relative to the setting up of further courses have been held in Kingston, Montreal, Niagara, Nipissing and Upper Ottawa, Orillia-Huronia.

Copies of the Minutes of the Third Annual Conference of Professional Development Courses held at Toronto on April 23, 1955, together with reports from the courses which operated during the 1954-55 season, were mailed last spring to all Branch secretaries with a letter of transmittal from Colonel Grant, field secretary. We hope the many copies thus distributed have been circulated among Junior members for the reports reveal the enthusiasm of young engineering graduates for the types of Professional Development Courses initiated in Canada during the past four years by Colonel Grant, immediate past-president of Engineers' Council for Professional Development, who has organized the whole of this work assisted by his secretary, Mrs. Lillian Robertson. We thank them heartily.

Committee members have collaborated in policy discussions during the year, however no recommendations for changes or additions were proposed. The committee's purpose is to continue to sponsor the formation of Professional Development Courses and Branch executives will be urged to approve the setting up of courses by Junior members in their respective communities on the pattern of the published reports mentioned above.

The following members resigned from the committee during the year: J. Benoit, J. N. Finlayson, R. DeL. French, and A. Jackson. We wish to record our sincere thanks for their loyal support during many years.

J. F. Muir was appointed a new member of the committee.

George B. Moxon, M.E.I.C.,
Chairman

Employment Service

To quote from last year's report "In general 1954 has been noteworthy, not only for the activity in the last few months, but also the promising outlook at the year end for 1955", the promising outlook was predicted correctly. The department listed approximately 550 vacancies, although only 125 known placements were made. Graduates were required in all branches of engineering. With the limited supply of candidates seeking a change of employment, the department was forced to depend on its advertising facilities for possible applications and with more prosperous employment conditions existing in The United Kingdom, employers were not able to count on this source of supply as in former years. The bulk of vacancies required the engineer with one to five years' experience. Although many listings did require senior engineers. Noteworthy was the increasing demand for civils for every type of construction project.

The department acknowledged 2,229 letters. However the greatest volume of correspondence received was in answer to the "Wanted Section". Some applicants were contacted by 30 or 40 employers over a period of one to two months.

Throughout the year the Employment Bulletin served its intended purpose. It brought to 1,600 employers and employees up-to-date employment information. However it should be noted that a number of applications received for vacancies were returned or readdressed to similar jobs, because the one applied for had been filled. The pages appearing in *The Engineering Journal* are printed directly from the employment bulletin and in most cases notification of the position being filled was received too late to delete it from the classified section. All information concerning new vacancies listed was also made available monthly to our Toronto Office.

As a result of the contact made with the department, a number of undergraduates found interesting summer employment. The bulk of vacancies received were from organizations located in Eastern Canada, therefore it was difficult to make successful contacts for young students not easily available for interview. The service will be maintained during 1956.

The department canvassed 1,000 employers of engineers in December 1955 to obtain, if possible, more precise information. To date approximately 400 have reported 550 unfilled jobs in 1955 due to a lack of available personnel. They hired 2,008 engineers in 1955, and anticipated hiring 2,922 engineers in 1956; of this number 1,395 will be recent graduates.

The shortage of engineering manpower continues with unfilled vacancies from 1955, augmented by new listings and anticipated needs for 1956.

(Miss) A. Summers,
Employment Service

Committee on Prairie Water Problems

Some 141,000 acres of additional land have been brought under irrigation on the St. Mary's Milk River project through the combined efforts of the Prairie Farm Rehabilitation Administration of the Federal Department of Agriculture and the Province of Alberta. The P.F.R.A. has continued its program of reconstruction, repair, and extension of the Bow River system, extending still further the acreage under irrigation.

The members of your Committee have been keeping in touch with the situation, but in view of the progress being made, and as no problems arose in which your Committee could be helpful, no meeting was held during 1955.

G. A. Gaherty, M.E.I.C.,
Chairman

Canadian Standards Association

The expectation voiced in the closing paragraphs of the 1954 Report has certainly been fulfilled during the year now coming to a close. 1955 has been a successful and busy year. A great many new standards have been published, several under the general heading of the Canadian Electrical Code, and others concerning a wide variety of subjects, such as plywood boxes, solid rivets, regulations for the inspection of boilers and pressure vessels, plastic floor tiles, etc. In addition to the standards actually published, there are a very large number under consideration and in various stages of development, so that at the moment. 11 are in the hands of the Technical Council, which under the new constitution, is the final authority for revision and approval previous to publication. There are 17 proposed standards which have reached the sectional committees, having been fully developed in working committees, and there are 12 others at present in the hands of the working committees and over 100 more in various preliminary stages ready for classification and for consideration by either specification committees or by those making the policy of the Association, that is to say, the board of directors and their executive committees.

There are at least ten new specifications that have been authorized by the Board and are at present being processed through the proper routine, and these cover such diverse subjects as venetian blinds, atmospheric pollution control, names for the pesticides, a brazing code, the marking and grading of lumber, linoleum products, both in sheet and tile form, identification systems for motor vehicle lighting, and so forth. The list, while not complete, will serve to emphasize the wide variety of subjects to which the Association now gives its careful attention.

This last year has been an election year for the Association's officers under the new constitution, and also for the managing boards of the subsidiary divisions of the Association, namely, that dealing with approvals and that dealing with welding. Our new president is J. S. Cameron, M.E.I.C., of the Northern Electric Company, Montreal, and the vice-presidents are Dr. J. M. Thompson, M.E.I.C., of Ferranti Electric Company, Limited, of Toronto, and R. S. Eadie, M.E.I.C., vice-president of the Dominion Bridge Company, Montreal.

One noteworthy event of the year has been the award to James C. Morrow, M.B.E., past-president of the Association for many years, by the American Standards Association in recognition of his service in the general field of industrial standardization. The Association has increased its activities during the year in the international field, both as a member body of the International Standards Organization, and as the Canadian unit in the International Electrotechnical Commission. Increased interest has been taken in the technical committees of these bodies, so that the Canadian Standards Association will be all the more widely recognized.

During the 12 months period, the board of directors have met five times, but the various working or specification committees have held a very large number of sessions at which the real production work has been carried out. Other committees, such as the sectional committees and the Technical Council, have provided their services by review and criticism, and finally by voting as to the acceptability of the drafts and their readiness for publication.

The new approvals laboratories outside of Toronto, which were opened in 1954, have settled down to business and have been fully occupied during the year in all the various branches. The new facilities and the additional equipment are appreciated by all concerned.

The general financial situation of the Association is very satisfactory, the head office and each of the subsidiary divisions having been operated successfully from every point of view. It can be truly stated that the Association continues to serve usefully, both Canadian industry and the general public in the matter of testing, certificating and specification, with a view to achieving maximum safety in the installation and use of all electrical equipment and devices, as well as other systems and materials, methods and conveniences which lend themselves to the general policy of simplification and economy through standardization.

P. L. Pratley, M.E.I.C.,
Institute Representative

Library Report 1955

Once again there has been a general increase in most phases of the library's activities. Over 6,000 people made use of the library facilities during the year. All enquiries, especially those received in the mail, are handled as quickly as possible, but members are asked to give as much information as they can when placing requests so as to avoid delay.

Some 3,000 items were circulated outside the library, and 5,000 used in the reading room. Many libraries in the Montreal area made use of our facilities, borrowing almost 700 items. Requests were also received from many parts of Canada and the United States.

The library continues to order books for members, and to place subscriptions for publications of other engineering societies. In all, over 500 orders were filled.

During the year 357 books having a value of $2,600 were received for review, and 64 were purchased. Members of the library staff wrote 257 reviews for inclusion in the Library Notes section of *The Engineering Journal*, while the remainder were provided by the Engineering Societies Library in New York. Short reviews of Canadian, British and United States standards were also published. The library contains a complete set of Canadian standards, which may be purchased through the library.

The library now receives regularly over 500 periodicals in engineering and allied fields, many coming in exchange for *The Engineering Journal*. The value of material received on exchange now totals nearly $1,000.

In December it was decided by Council that various changes would be made in the library regulations to take effect January 1, 1956. The most important of these was the abolition of the $5.00 deposit which had previously been required before books could be borrowed from the library. In addition, members now are required to pay return postage charges only, and not both ways as previously. It is hoped that these changes will render use of the library easier for all concerned, and that more members will make use of the unique facilities which are provided for their convenience.

(Miss) Shirley Courtis,
Librarian

Library and House Committee

Your Library and House Committee met once during the year, on December 13, 1955. It reviewed present library regulations covering the loan of books and periodicals to members. As a result of its deliberations, the Committee recommended to Council new library regulations, with the expectation if Council saw fit these might be adopted at the beginning of 1956.

F. L. Lawton, M.E.I.C.,
Chairman

Papers Committee

Working in co-operatioan with the headquarters staff this Committee has the specific purpose of arranging for suitable papers for presentation at the seventieth annual general and professional meeting of the Institute to be held in Montreal in May, 1956.

Members of the Institute were advised by Council in the November, 1955 issue of *The Engineering Journal* that the Committee would welcome worthwhile papers for consideration in the annual meeting program. In addition to these, the Committee also considered proposals by members of the Committee, and by the headquarters staff who are in close contact during the year with authors and who are conversant with topics specially in demand.

Since the 1956 annual meeting is scheduled to take place in Montreal, it was felt that a fair proportion of the papers should be of particular interest to members in the Quebec area. Some valuable suggestions in this connection were presented by the Toronto member, W. H. Paterson.

The Committee met four times between November 2, 1955 and January 18, 1956, making its report to Council on January 20, 1956. In this report a program of 33 papers and two panel discussions was recommended. The recommendation was approved by Council at its Montreal meeting on January 27, 1956.

This year the Committee succeeded in arranging the program earlier than in previous years so that manuscripts could be made available to headquarters staff in sufficient time to facilitate arrangements for discussion, and for publication.

W. H. Gauvin, M.E.I.C.,
Chairman

Publications Committee

The year 1955 was the thirty-seventh of publication of *The Engineering Journal*. Over 202,000 copies were printed and the average monthly circulation was 16,497, the highest comparable figures to date.

Reading material totalled 1,261 pages, a monthly average of 105, and technical papers occupied 476 pages, an average of 40 a month.

The ratio of technical and other editorial material to advertising space increased to 54:46, contrary to the usual prevalence of a minority of editorial matter in most Canadian technical publications.

The 75 technical papers published dealt with some 36 different subjects or fields of industry. A further analysis shows the following divisions.

	No. of Papers	Number[1] %	Pages[2] %
Chemical	8	10.7	9.4
Civil	22	29.3	25.3
Electrical	10	13.3	13.2
Mechanical	12	16.0	24.4
Mining	2	2.7	4.5
Miscellaneous	21	28.0	23.2

(1) Per cent of total papers.
(2) Per cent, by length, of total pages.

The committee extend their thanks and appreciation to all authors, correspondents, and advertisers.

The interest shown in the technical papers is reflected in the total of 25,200 reprints ordered, an increase over the previous year of over 18 per cent.

The policy of building an adequate reserve of technical papers has been continued, and articles on subjects of particular topical interest will be commissioned as necessary to maintain a wide editorial coverage.

Many papers were read during the year on various aspects of nuclear energy, and your Publications Committee recommended a policy of covering this subject, particularly the production of power from nuclear energy, by a logical series of papers that should follow the major developments in the field without undue repetition.

The increase in general reading material is partly due to the introduction, in January, of a regular monthly section on the progress of the St. Lawrence Seaway and Power Project. Abstracts of engineering literature were also continued, and 65 abstracts (60 pages) were published. It is proposed to widen the scope of these abstracts still further by careful selection and control of length.

In June the editorial staff was augmented by the appointment of P. C. Bell as technical editor.

The findings of the sub-committee formed to study the advisability of publishing transactions are being correlated at headquarters and will be presented as soon as the work is complete.

The factors involved in the publication of a membership directory will be the subject of a separate report by a special committee of Council appointed to investigate this subject.

Results of the readership survey, which was carried out over a twelve-month period, were gratifying and showed a 43 per cent return. This survey is to be extended for one additional year to obtain a broader comparative coverage.

In common with most Canadian publishers, the gross cost of publication increased slightly over that of the previous year. The average cost was 90.6 cents per copy or $10.87 per year per subscriber.

Five meetings were held during the year by your committee. All were well attended by its members and by headquarters staff.

G. N. Martin, M.E.I.C.
Chairman

Legislation Committee

No matters concerning legislation came to the attention of the committee during the year, and as a result it has nothing to report.

Jacques Benoit, M.E.I.C.,
Chairman

Membership Committee

This Committee reports to Council that it has not, as yet, found any new ways of increasing the membership that are more suitable than those presently employed. The suggested methods advanced by the Committee do not seem practical under present conditions and nothing new has come to its attention.

H. R. Sills, M.E.I.C.,
Chairman

Ontario Division

The Ontario Division held one general meeting in 1955 at the Prince George Hotel in Toronto on May 13. The 23 members present represented eight branches in Ontario.

The chairman, Dr. A. E. Berry of Toronto, briefly addressed the meeting outlining the functions of the Ontario Division, and stating that the main purpose of the meeting was to review the scope of activities and the future plan of operation.

In the general discussion which followed, the consensus of opinion was that, while there were no matters requiring active attention at the time, it was considered advisable to maintain the Ontario Division in its present form. The view was expressed that there should be available an organization to represent the Ontario branches in matters requiring collective action.

At this meeting it was moved by W. H. Paterson and seconded by S. Sillitoe that the present officers continue in office: Dr. A. E. Berry, chairman, G. R. Henderson, Sarnia, vice-chairman; Major General G. R. Turner, Ottawa, treasurer; and G. H. Rogers, Toronto, secretary.

G. H. Rogers, M.E.I.C.,
Secretary.

Finance Committee

This report refers only to the highlights of the financial situation of the Institute as the details are covered in the Treasurer's report. It is pleasing to note that revenues for the year were $496,820.34 and expenditures $488,875.34, giving a surplus of $7,944.89, which is sightly greater than the surplus in 1954.

A comparison of the financial position of the Institute at the end of 1955 with 1954 must take into account that a directory was issued in 1954 which increased revenues for that year by $23,428.84 and also increased expenditures by $44,961.81.

Additions were made to our reserve funds of approximately the same amount as in the previous year.

The cash in hand of the Institute builds up during the early months of the year due to incoming fees. The Committee has put these temporary surplus funds to work by investing them in short term interest-bearing debentures. Any surplus funds for reserve have been invested as promptly as possible. This policy has resulted in an increase in our revenue from investments. All investments have been carefully reviewed by the Finance Committee after recommendations made to it by an Investment Sub-Committee.

Meetings have been held regularly to deal with financial matters and such other Institute affairs as are referred to them.

The Committee wishes to express its appreciation of the assistance of the General Secretary, the Chief Accountant and other members of the staff for their constant help in dealing with this phase of the Institute's activities.

R. L. Dunsmore, M.E.I.C.
Chairman

Treasurer's Report

It is a pleasure for your Treasurer to report that the finances of the Engineering Institute at the close of the fiscal year 1955 were in an excellent condition. Although the budgetted expense of operations was overrun slightly, the increase of revenue far exceeded this amount.

After paying all running expenses and setting aside all budgetted reserves, a surplus of about $8,000.00 is shown.

During the year there was added to the investment portfolio an amount of $54,716.50 consisting of high grade government and industrial bonds. This brings the total of our investments up to $192,375.80. An amount of $25,000.00 was also placed on call loan with the National Trust Company which is shown in our statement as Cash in Bank.

E. V. Gage, M.E.I.C.,
Treasurer.

The annual comparative statements of revenue and expenditure, and of assets and liabilities, are presented on the following pages.

Comparative Statement of

AUDITORS' CERTIFICATE

We have examined the statement of assets and liabilities of The Engineering Institute of Canada as of December 31, 1955 and the statement of revenue and expenditure for the year ended on that date and have obtained all the information and explanations we have required. Our examination included a general review of the accounting procedures and such tests of accounting records and other supporting evidence as we considered necessary in the circumstances.

In our opinion the above statement of assets and liabilities and accompanying statement of revenue and expenditure are properly drawn up so as to exhibit a true and correct view of the state of the affairs of the Institute at December 31, 1955 and the results of its operations for the year ended on that date, according to the best of our information and the explanations given to us and as shown by the books of the Institute.

PEAT, MARWICK, MITCHELL & CO.,
Chartered Accountants.

Montreal, Quebec, January 30, 1956.

THE ENGINEERING INSTITUTE OF CANADA

Vice-Chair., G. R. HENDERSON
Treasurer, G. R. TURNER
Secretary, G. H. ROGERS

Reports from the Branches

For Membership and Financial Statements see pages 266-268

Belleville

During 1955 eight meetings were held, the minutes of which have been filed. Included among the eight meetings was the dinner arranged on the occasion of the President's visit to Belleville. During his visit, Dr. Stephens spoke on "Canada's Development and Handling of Resources". Among the subjects covered by the papers given during the year were "Instrumentation", "The Application of Electronics in the Toronto Stock Exchange", "Engineering Standards", "Pipe Organs", "Investments" and "Mineral Resources of Hastings County".

The October meeting took the form of a plant tour of the Canada Cement Company operations at Point Anne.

The second half of a Professional Development Course in business administration, consisting of a further 20 lectures sponsored by the Belleville Branch in co-operation with Queen's University, was held during the fall and winter of 1955. Approximately 50 people were enrolled in the course and attendance ran above 90 per cent on the average indicating its popularity.

The Branch sponsored a $25.00 prize to be given to the Grade XIII student at the Belleville Collegiate Institute and Vocational School who plans to take an engineering course and who had the highest standing in English, Algebra, Trigonometry, Geometry, Physics and Chemistry. This prize was won by Gary Hall and was presented by C. H. Lusk at the Commencement Exercises at the Collegiate on October 28.

Border Cities

Meetings were quite varied during the past year. Field trips were the most popular and therefore the best attended. Branch members toured the CKLW T.V. Station in January, and in February welcomed the president of the Institute on his visit in Chatham. Dr. A. E. Berry, sanitary engineer, was guest speaker at a dinner meeting in March; and R. N. Scott spoke on "The Port of Windsor and the St. Lawrence Seaway" at a dinner meeting in April. The last meeting before the summer months was a field trip through the Ford Motor Co. of Canada Ltd. engine plant.

In the fall the meetings began with a tour in September of the Canadian Rock Salt plant. This was followed by the annual dinner dance in October, and the showing of the Leonardo da Vinci film in November. The annual meeting took place in December.

The Ladies Auxiliary, with a membership of 94, has had a very successful year. The interest groups have progressed favourably and are accomplishing the goal of promoting friendship among members.

The Border Cities Branch has had active representation this year on the Senate of Assumption University, as well as on the Educational Council of Windsor. New representatives have been appointed to both of these offices.

Brockville

Nine meetings were held by the Brockville Branch during the year, including the annual meeting on December 8 1955.

On December 7, 1954, the annual meeting of the Branch was held in Prescott. The guest speaker on that occasion was Col. L. F. Grant, field secretary of the Institute.

The January, 1955 meeting took place at Phillips Electrical Co. Ltd. Dr. G. M. Mahoney of Montreal spoke on the place which psychology holds in industry. At the February meeting Dr. W. M. Campbell, director of the chemical engineering branch of Atomic Energy of Canada Ltd. discussed "The Chemical Factors in Atomic Power".

On March 10 Judge D. E. Lewis addressed the Branch members in Brockville on the subject "Town Planning"; and on April 19, R. W. Foster-Pegg of McGill University spoke to the Branch in Prescott on "Solid Fuel Turbines". At the May meeting in Brockville W. D. Sinclair of the paint and varnish division of Canadian Industries Limited discussed "Effective Use of Colour in the Home"; while at the September meeting Ian McNab of General Motors, Oshawa, addressed the meeting at the Maitland Works on "The Car of Tomorrow".

On October 15 Branch members and their families made a tour of the R.C.A. Victor radio and television plant in Prescott; and on December 1 they attended a showing of the "Leonardo da Vinci" film at the Maitland Works.

Calgary

The year 1955 was a very active one for the Branch. Eight evening meetings were held during the year, including a joint meeting with the Chemical Institute of Canada, and a joint dinner meeting with the Association of Professional Engineers of Alberta.

The annual smoker was held in the fall. As usual, this was a very informal get-together and was an excellent way to start the fall meetings rolling.

For the final meeting of the year the Branch was honoured by the visit of the presidential party, Dr. R. E. Heartz, Mrs. Heartz, and Dr. L. Austin Wright.

The annual "Slide Rule Soirée" was held again in February and was once again a tremendous success with about 330 in attendance. This annual dance has become one of the highlights of the activities with the members and their wives pooling their talents to put on a lively and amusing floor show.

The regular Monday luncheon meetings were as successful as ever with both interest and attendance at a high peak.

Cape Breton

During 1955 seven gatherings were held, four of which were regular dinner meetings in the Isle Royale Hotel in Sydney, N.S. The average attendance at the regular dinner meetings was approximately 35.

Highlighting the year's activities was the ladies' night on the occasion of the visit to the Branch in September of the president, Dr. R. E. Heartz. Accompanying the president were Mrs. Heartz, and the general secretary, Dr. L. Austin Wright. Unfortunately Dr. Heartz had to leave the meeting early to make flight connections.

In April the Branch was invited to a display performance by the local Reserve Army Engineers Corps, and was afterwards entertained in the officers' mess.

The annual lobster party was held in June and attended by 48 members and guests. Although the occasion was marred by poor weather, those who attended enjoyed themselves immensely and were grateful to the chairman, M. R. Campbell, for the use of his summer home.

At the first regular dinner meeting in March members heard an informative lecture on "T.V. Transmission and Reception" by R. J. Norton, chief engineer of T.V. station CJCB in Sydney, N.S.; while at the May meeting J. Russell, chief mechanical engineer of the Dominion Coal Company spoke on "The Dosco Downdraft Furnace". In November Mr. Hynes of E. W. Playford Limited, Montreal, addressed the Branch on "Industrial Applications of Electrical Heating". At the last meeting of the year H. N. Bacon spoke on "Segregation in Large Forging Ingots".

Central British Columbia

The Central British Columbia Branch covers the south central portion of British Columbia. Since the economy of the area is chiefly based on the primary industries such as agriculture, logging and mining, a large proportion of the Branch membership is engaged in fields of engineering connected with these industries.

There are four main centres of population within the area actively served by the Branch: Kamloops, Vernon, Kelowna and Penticton, and Branch meetings are rotated among these centres. The Branch also takes in a large area in north central British Columbia, but members in this area are not able to attend Branch meetings and are classed as non-resident members.

During 1955 five general meetings and four executive meetings were held with an average attendance at general meetings of betwen 25 and 30. All the meetings were dinner meetings and were held jointly with the Central British Columbia Branch of the British Columbia Engineering Society. In addition to Branch business, the meetings usually featured the presentation of a talk or film.

Cornwall

An attempt was made to diversify the type of meetings this past year. Meetings arranged included one luncheon meeting, a ladies' night, two buffet suppers, and full dinner meetings. Generally, this arrangement proved satisfactory with an average attendance of approximately 40 per cent of the total membership.

The membership of the Cornwall Branch has increased to 81 from the 1954 level of 53. This increase has been brought about mainly by the influx of engineers on the hydro development and by an increase in the number of Branch Affiliates.

High school students, expressing an interest in engineering as a profession, were permitted to accompany practising engineers on the job for one day to see for themselves what sort of work engineers do. Following this, special arrangements were made with the Hydro-Electric Power Commission for a tour of the power development site.

A committee has been established which has set up a bursary for high school students about to enter university. This is called the Colonel Magwood Bursary, and the administrating committee consists of D. Giles, T. Hawkes, W. Nesbit, and the Branch chairman. It is hoped that the first presentation of the bursary will be made in 1956.

The Cornwall Branch was invited to assist the Township of Cornwall in reconciling the many differences of opinion which arose from the necessity of relocating Highway 401 and the C.N.R. through-line. The Branch was able to make some contribution toward clarifying the situation.

Corner Brook

The year 1955 has not been a very active one for the Corner Brook Branch. Only one business meeting was held and that was not too well attended. We had one technical meeting when a paper on "Surveys of Power Potentials in Labrador" was presented by the late Eric Hinton, M.E.I.C. The meeting was well attended and thoroughly enjoyed by all present.

It is with regret that we have to record the death of Eric Hinton, one of the founders and the first chairman of this Branch. He was a great engineer, a fine citizen and a beloved friend.

On September 21, 1955 the Branch was honoured by a visit of the president, Dr. R. E. Heartz. Dr. Heartz was accompanied by his wife and the general secretary, Dr. Wright. Some 45 members, their wives and guests attended a dinner meeting at which Dr. Heartz was guest speaker. After the dinner the members and guests enjoyed a period of dancing. The visit was thoroughly enjoyed by all.

This Branch looks forward to a more active year in 1956.

Eastern Townships

The Eastern Townships Branch held eight meetings during the year 1955. The first meeting in January took the form of a tour to the St. Lawrence Corporation in East Angus in which 35 members participated. At the February meeting A. T. Roblin of Imperial Oil Co. Ltd. addressed a meeting of 40 on "The Future of the Oil Industry in Canada"; while at the March dinner meeting which was attended by 50 members Leo Roy of Hydro Quebec spoke on the Bersimis power development.

Two films were shown at the April meeting attended by 25 members. Both films, supplied by Canadian Ingersoll-Rand Co. Ltd. and International Harvester Co. Ltd. depicted engineering activities on the Kitimat project. The annual meeting took the form of a ladies' night which took place at Hovey Manor in North Hatley. Over 100 persons were present.

In October 30 members made a tour of the Lake Asbestos Corporation at Black Lake; and in November Lorne Wiggs, president of the Corporation of Professional Engineers of Quebec, addressed a joint dinner meeting of members of the Corporation and the Institute. Sixty-five were present on this occasion. At the December meeting 120 members and their ladies attended the showing of the "Leonardo da Vinci" film.

Edmonton

The Edmonton Branch held 14 activities during the year of 1955. These activities consisted of eight dinner meetings, three evening meetings at the University of Alberta and one plant tour; the average attendance of these twelve activities was 82. The two annual highlights of the year again took the form of the annual picnic where there were over 300 in attendance and the annual dance which had an attendance of 358.

Fredericton

Eight general meetings were held during the year. In February a joint dance was held with the University Student Engineering Society. In October a joint meeting was arranged with the Maine Section of the A.S.C.E. and was held at Loring Air Base, Limestone, Maine. Although a general meeting with the E.I.C. President was not possible, he did arrange to address the Student Society and have luncheon with the Branch Executive.

Total membership has increased during the past year.

Halifax

During the year several local speakers presented papers on subjects or projects of special interest in this area. There is room for some highly technical papers offering information helpful to engineers in local industry.

Meetings this year were held at various places throughout the city, rather than at a hotel exclusively. This variety in meeting places appeals to the membership.

There have been some resignations and a few removals due to non-payment of dues. Engineers in the Armed Services are increasing in number due to the greater technical nature of defence work. A closer liaison between these engineers and the Branch will doubtless stimulate interest in Branch membership.

A committee to establish by-laws or regulations to aid the Executive in carrying out its duties was formed. This committee, consisting of four members, was to submit its recommendations to the membership before the next annual meeting.

The year ended with finances in a good state. A budget was prepared during the year to serve as a guide in spending. Income was augmented by a surplus from the dance in honour of the president's visit.

The Engineers' Wives Association is well established. It is of great assistance in the social activities of the Branch which serve to maintain a high level of general interest among the members.

During the year a joint conference was held with some members of the Council of the Association of Professional Engineers in connection with public relations and publicity for the engineering profession in this area. This resulted in the formation of a committee under the chairmanship of R. F. McAlpine.

It is hoped that Confederation which is being given a good deal of study will come into being very soon. Fortunately, we have few, if any, differences to work out in this area with the Association.

Thanks are extended by the Branch to the various members of the Executive Committee for their fine co-operation this year, and particularly to executive members from out of town who attended most of the meetings. Special mention must be made of the work of the secretary-treasurer, W. D. Pippy, who revised the Branch files and methods to provide a better service for the members, and to the Branch news editor, F. H. Tremain, who handled all newspaper reporting and items for the Engineering Journal. The work of the various committees and their chairmen, and their assistance to the Branch and especially the Executive, is appreciated, as well as the help of the councillors and members who served with the Executive in an ex-officio capacity.

During the year 1955 the Professional Development Committee, in co-operation with St. Mary's University, sponsored a course in "Effective Public Speaking".

This course, which comprised a series of 12 lectures commencing on January 11 and concluding on March 29, had a total registration of 27 members. Although it was felt by the Committee that the type of course offered would prove to be quite popular with the members, average attendance throughout was approximately 70 per cent. However, this figure is partially offset by the fact that the weather on several lecture nights was extremely inclement, plus the additional reason that the particular work of some of the registrants from time to time required their absence from the city.

In summing up the Professional Development Course for 1955 there is every justification in stating that the course offered an excellent lecturer with first-class material which was presented with a good understanding of the group's immediate and future requirements.

Although it is realized that there are perhaps good reasons why the Branch should conduct its Professional Development Courses entirely as an E.I.C. membership group, it is felt at this time that there is too much to lose. Three or four years' experience in Professional Development work has indicated that by a large margin the courses most asked for are those covered by the broad subject of "Business Management". In our very first year of operation, when a series of lectures was held covering a variety of subjects, lectures dealing with Finance, Investment, etc., commanded the greatest interest by a wide margin.

For these reasons it is felt that by associating the Professional Development Course this year with St. Mary's the Branch may take advantage of the excellent opportunity afforded in their series, "Background for Investment". It is to be pointed out that some of the lecturers for this series will be men from other Canadian cities who would not normally be available to the Branch as an independent group.

Hamilton

During 1955 records show that Branch membership has increased slightly from 465 at December 31, 1954, to 474 at December 31, 1955. There was an increase in the Junior classification, but it is partially offset by decreases in Student and Member classifications.

Six meetings and a plant tour were held during the year and were well attended, with the exception of the November dinner meeting. It appears that Hamilton Branch dinner meetings other than the annual dinner meeting will not be successful either financially, technically, or socially, because of small attendance.

The Engineers' Ball held in October was again well attended and was financially successful in that the Branch almost broke even on it.

Seven committees deserve special mention this year: The Students' and Juniors' Papers Competition Committee was successful in providing an interesting Students and Juniors Night, with four contestants. The Ball Committee is to be congratulated for a very successful social function enjoyed by 186 couples. The Budget Committee produced a forecast which regulated spending and produced a surplus for the year's activities. The Professional Development Program Committee produced a very successful program attended by many Students, Juniors and Members, as well as by A.P.E.O. Members.

The Program Committee which arranged a very interesting and varied program of meetings and a field trip are to be congratulated for its work. The Technical Sections Committee is to be congratulated for its work in gathering information on the various Technical Sections operating in other Branches and for its work in preparing a questionnaire. The Attendance Committee is to be congratulated for reviving the Telephone Squad and obtaining attendance estimates for meetings. The Branch News Editor is to be congratulated for the excellent press, radio and T.V. coverage he has been successful in providing for the meetings.

The passing of H. S. Phillips and E. P. Muntz is here recorded with regret.

Kitchener

Membership in the Kitchener Branch has increased by ten per cent. Field trips create the most interest, along with good general technical papers on current engineering topics, such as the St. Lawrence Seaway project. The pattern of meetings has been fairly well established, and it is felt that this pattern will be adhered to for some time to come. Attendance at the general meetings has been quite gratifying, and if meetings continue to be of interest, attendance may be expected. Social functions have been quite successful.

Kitchener Branch members are keenly interested in the prospect of unification with the Association of Professional Engineers of Ontario and hope that it may be accomplished during 1956.

Kingston

The major activity for 1955 was a drive to enroll Queen's students in the Institute. This drive took the form of meetings with representatives of student societies, and also the writing and mailing of the pamphlet, "So You Want To Be An Engineer". As a result of this drive 94 Student Members were enrolled.

In addition, eight monthly meetings were held, the highlights being the annual general meeting in June and a joint dinner meeting with the Chemical Institute of Canada and the Kingston Metallurgical Society. Meetings were held at the R.C.E.M.E. School, The Royal Military College, and Queen's.

Kootenay

The 1955 activities of the Branch were highlighted by two plant tours; one through the Kaiser Aluminum Plants at Spokane, Washington; and the other, through the Canadian Pacific Railway Diesel Shops at Nelson, B.C.

The tour in Spokane started at 10 a.m. on April 16, 1955, at the Trentwood Rolling Mill Cafeteria where the members were welcomed by Marvin L. Lee, works manager, and shown a film "Take a Look at Tomorrow". The remaining part of the morning was spent in touring the rolling mill. At noon the members were guests of Kaiser Aluminum at a Luncheon in the Trentwood Cafeteria. After lunch, immediately leaving by car for the Mead Reduction Plant, members were again met by officials of Kaiser Aluminum, who conducted them through this part of their operations.

The members journeyed to Nelson by car, and were met at the C.P.R. station by George Fyke, divisional engineer, Canadian Pacific Railways, and W. S. Jackson, Nelson representative on the Branch Executive. The tour took in the various departments of the shops, and two of the huge diesel locomotives, which happened to be in the shops for routine maintenance checks. The tour was followed by dinner in the Round-Up Room at the Bus Depot, a short business meeting, and a talk by G. Fyke on the economic and engineering aspects of switching the Kettle Valley line from steam locomotive to diesel operation.

In addition to the above tours, a total of six regular dinner meetings, including one business meeting, and seven Executive meetings were held during the year.

The business meeting was a new venture, but judging by the attendance and interest shown, it will probably be a regular feature for the Branch, as it emphasized again that the members are vitally interested in the affairs of the Institute.

An advanced Professional Development Course was sponsored by the Branch for the first time. The course was a follow-up to earlier Professional Development Courses, and consisted of five meetings starting in October. Each meeting was devoted to a study of a case history in human relations, and proved very popular with those taking part.

While the Branch had a full and varied program, the members were, however, disappointed in not having a presidential visit this year, as it always seemed a fitting event to end a successful year.

Lakehead

During 1955 seven general meetings were held. The topics of addresses given covered a variety of subjects including the "Lakehead College of Arts and Science", "Cast Iron Pressure Pipe", and "The Influence of American Capital in Canada" and "Malting Processes". Two other meetings were cancelled due to weather conditions and will be held during 1956.

Professional Development Courses are still in the planning stage; however, they are due to start in the early part of 1956. Also group technical meetings in the electrical field are due to start in 1956 on a trial basis.

The Student Guidance Committee continued with programs similar to past years by giving papers and holding discussion periods with the High School students and the University students at the Lakehead Technical Institute.

Lethbridge

The Lethbridge Branch held during 1955 five regular meetings at which the average attendance was 40; two special meetings with an average attendance of 87; one field tour attended by 50; and six executive meetings with an average attendance of seven.

The year was highlighted by a joint meeting with the Montana Section of the American Society of Civil Engineers, and by a field trip to Calgary Power Limited Bearspaw Dam, a hydro-electric development near Calgary, and to the Imperial Oil Company's refinery at Calgary.

In April some 20 members of the Montana Section of A.S.C.E. from Great Falls, Billings, Helena, Missoula, and Tiber Dam, Montana, joined the Lethbridge Branch for a joint dinner meeting and ladies' night. Following the meeting a dance was held and the total attendance of 108 made it the largest Engineering Institute meeting held in Lethbridge in recent years at least. The following day the Montana engineers and members of the Branch visited St. Mary's Dam, a large irrigation reservoir and dam near Lethbridge which was constructed under P.F.R.A.

In September a number of the members and their wives visited two separate developments at Calgary. In the morning Calgary Power Limited conducted a tour of its hydro-electric generating station at Bearspaw which is at present the only large hydro development on the prairies of Southern Alberta. Following a luncheon provided by Calgary Power Limited, Imperial Oil Limited conducted a tour of its Calgary refinery. During both the April and September events the Branch was favoured by good weather.

A ladies' night was held in December. The attendance of 65 members and their wives during this busy season indicated the continuing popularity of these social, as well as cultural events.

Branch membership was reduced by some 11 members during 1955, due mainly to the transfer of P.F.R.A. personnel upon completion of certain projects in the Lethbridge district.

Lethbridge Branch meetings were all dinner meetings. Community singing and some special musical entertainment were provided at each meeting in addition to the main program. Mr. and Mrs. George Brown, who have been providing dinner music and accompaniment for the meetings for some 30 years, were again able to favour the Branch with their presence at every meeting during 1955.

Lower St. Lawrence

The Branch held three Executive meetings and four general meetings during the year.

On September 12 and 13 the President and Mrs. R. E. Heartz met the engineers of the Branch at two different meetings, one held at Seven Islands and one at Rimouski. Mr. and Mrs. Dunsmore, J. Martineau and the General Secretary accompanied the President to the meeting held at Rimouski. Mr. McLaren from Quebec City, our former president and Mrs. McLaren attended the meeting also. Refreshments were served at the Hotel St-Louis, followed by a banquet and a dance.

On November 29, the Branch members attended a presentation of four films loaned to the Branch by Georges Demers, M.E.I.C. These films were leased to Mr. Demers by "La Société des ingénieurs civils de France".

Moncton

During the year, a total of seven meetings, including the annual meeting, was held. On January 17, a paper on "Industrial Instruments" was read by Gordon Frey. "Civil Defence" was the subject of an address on March 21, given by Daniel Billing, co-ordinator of Civil Defence for the Moncton area.

Nomination of Branch officers took place at the meeting of April 18, and the annual meeting was held on May 16. M. E. Endicott spoke on "Oil Well Exploration in Albert County" on September 26. President R. E. Heartz and Mrs. Heartz and the general secretary, Dr. L. Austin Wright, were entertained by the Branch Executive and their wives on the evening of September 28.

"A survey of the Moncton Water Supply" was the subject of an address by William Godfrey on October 31. The final meeting of the year was held on November 21, and took the form of a mixed "Oyster Frolic". At this meeting the Leonardo Da Vinci film was shown.

Montreal

Program activity of the Montreal Branch has been held at a high level throughout the past year. Technical sections developed of recent years have maintained their vigour and individuality. Some 43 meetings have been held under the sponsorship of the various technical sections. The traditional program of Thursday night meetings devoted to the presentation of papers of broad interest was also maintained. Nineteen meetings of this nature were held.

The policy of maintaining close relations with Sister Societies by joint program activity with the corresponding Technical Section of the Program Committee was followed throughout the year. In addition E. R. Smallhorn was appointed by the Executive to represent the Branch on the local committee of the American Concrete Institute charged with the responsibility of arranging a regional meeting of that society in Montreal during 1956.

Branch membership now stands at 4,265, an increase of 116 over the previous year. This increase in membership is most gratifying. The Executive has been aware for some time, however, of a fall off in student enrolment and steps are being taken to offset it.

A consultatory panel for undergraduate engineers was established. The membership of this panel is made up of senior men in the engineering community who have indicated their willingness to provide advice and guidance on a private interview basis to those undergraduates who desire it. Approved procedures for judging undergraduate prizes and awards have been developed.

Three forums were held for high school graduating classes—one in English and two in French. A total of more than 600 students attended these meetings. In addition, career symposia speakers for Lower Canada College and Lachine High School were arranged.

Assistance was afforded the Junior Section with their efforts to formalize their by-laws. The task has now been completed. The status of Ex-officio member of the Branch Executive has been extended to the chairman of the Junior Section, thereby establishing him as a voting member. One of the changes in the organization will be an increase in the number of Councillors from six to fifteen. This step is being taken with a view to providing more assistance in the organization of its many activities.

During the year a new method of handling publicity was organized. Observation of results achieved lead to the view that the use of a retained publicity man, as had been done in 1955, should not be continued. The new form of activity for the Publicity Committee consists of achieving direct contact with most of the local newspapers and of writing the press communiques themselves.

The continued growth of the Branch and increasing complexity of its activities have made it apparent that the practice of holding Executive meetings between the close of the business day and dinner do not provide sufficient time to deal with the agenda. The Executive now has dinner together once a month followed by a full evening meeting. The results have been most gratifying. Attendance has improved, full discussion leading to prompt decision has been made possible, and in consequence, pending items have been reduced to a minimum.

The Entertainment Committee, under the chairmanship of Leo Scharry, has continued its usual excellent and efficient work. Two hundred and seventeen guests attended the Annual Dinner Dance. The Oyster Party, held this year under the joint sponsorship of the Senior and Junior Sections, was a huge success. A pre-Christmas reception for the more than 100 members of the many committees of the Montreal Branch was given by the chairman of the Branch. The Entertainment Committee provided refreshments and food for several meetings of the Technical Sections throughout the year as well.

Nipissing and Upper Ottawa Branch

During the year 1955, the Nipissing and Upper Ottawa Branch held seven business meetings and two plant visits.

In May a tour was made of the R.C.A.F. Depot at North Bay, where the members were shown what Canada has in the way of air defence, the CF-100 fighter. In October the Branch paid a visit to the newly completed Otto Holden Generating Station (La Cave) at Mattawa. For those who are not employed by the Ontario Hydro it was very interesting and instructional.

The only other meeting worthy of note was the Students' Night. In March the Branch invited as guests the district high school students who indicated that they were potential engineers. During the evening several speakers outlined the various aspects of engineering and helped those students with their decision. It was felt that this should be an annual Branch affair.

The Branch is looking forward to a good year in 1956. There are prospective members in view. Meetings are becoming of considerable value to the members.

Niagara Peninsula

During the year eight general meetings were held. In January at the evening meeting in Niagara Falls, Charles Eder of General Motors, Oshawa, presented two films, "Look of Things", depicting the styling and designing of automobiles, and "Sand and Flame", illustrating the manufacture of glass. Mr. Eder discussed these films and other aspects of automotive design.

The March meeting took the form of a dinner meeting in Niagara Falls. The guest speaker was Jasper H. Ings who showed colour films taken during the time he was in Pakistan for H. G. Acres and Co. Ltd. In April the members were conducted on a tour through Horton Steel Works Ltd. in Fort Erie. After dinner they enjoyed an illustrated talk by C. A. McDonald. Interesting points of design with regard to flat bottom tanks, overhead tanks, and pressure vessels were discussed.

A dinner meeting was arranged in May in Niagara Falls. This was the annual meeting and Ladies' Night at which Mrs. Hazel Hardstone of T. Eaton Co. Ltd. spoke of the history and manufacture of chinaware. She brought with her a wide selection of china to illustrate the various types available throughout the world. In September an evening tour was arranged through the plant of Provincial Engineering Ltd. in Niagara Falls. Fabrication and hot dip galvanizing of steel transmission towers, T.V. towers and sub-stations were in progress. D. A. Barnum afterwards discussed the various aspects of the design and manufacture of the above products.

The October meeting took the form of a tour through the Port Colborne plant of Canada Cement Co. Ltd. After dinner in the plant cafeteria members were able to discuss points of interest with J. B. Hanly, plant manager, and with representatives from the technical sales division. A joint dinner meeting with the Niagara Chapter of the Association of Professional Engineers of Ontario was held in St. Catharines in November. A panel, including eight members of the Planning Board of the City of St. Catharines Planning Area, discussed various phases of town planning.

A joint meeting of the Hamilton, Kitchener, and Niagara Peninsula Branches was arranged at Hamilton to meet the president of the Institute on February 25. The Niagara branches of the Association of Professional Engineers and the Engineering Institute sponsored their second annual Engineers' Ball on October 7. It was a successful event.

Northern New Brunswick

The year 1955 can be expressed as successful for the Northern New Brunswick Branch. A total of eight meetings were held, five general and three executive with an average attendance of about 50 per cent. Membership, however, has shown a drop from a total of 71 to a total of 64, although it is believed that nearly 100 per cent of the eligible engineers in the area belong to the Engineering Institute.

The first general meeting of the year was held in Campbellton on March 11. Two speakers were heard during the evening, both Members of this Branch. The first was A. R. Bonnell, whose paper was entitled "Some Problems of Highway Design in the Province of New Brunswick". Following a discussion period, the second speaker, J. O. Flower, spoke on "The Care and Breeding of Tropical Fish"; this topic was also followed by an informative discussion.

The next meeting was held in Bathurst on April 29. At the conclusion of a short business meeting the members then joined invited guests at the showing of the film, "Leonardo da Vinci".

The Annual Meeting of the Branch, a "Ladies' Night", was held at Kent Lodge in Bathurst during the evening of June 11. This was a dinner meeting with a brief business session including the installation of new officers. The guest speaker, A. M. Glendenning, mine superintendent of Brunswick Mining and Smelting Corporation Limited, gave a detailed description of his Company's operations and future plans in the Bathurst area. A dance followed the dinner to complete a very pleasant evening.

Branch activities resumed in the fall with the occasion of the visit to the Branch of the Institute president, Dr. R. E. Heartz, and the general secretary, Dr. L. Austin Wright. This also was a dinner meeting and a "Ladies' Night" which was concluded by a dance.

The final meeting of the year included an interesting tour of parts of the R.C.A.F. Station at Chatham on November 4. Permission for the members to visit the Station was kindly given by Group Captain M. E. Pollard, the Commanding Officer. Following the tour those attending gathered at the local Golf and Country Club for a general meeting.

Due to the distances between centres encompassed by this Branch and also due to the difficulties encountered in travelling during the winter months few activities beyond Branch meetings were attempted this past year. Interest in the Institute remains high, and it is expected that 1956 will be another successful year.

North Eastern Ontario

Four Branch meetings were held in the year. In January Mr. Swindon of Inter-County Gas Line, and Mr. Woods, of Conversion Surveys Limited, spoke to the group in Kapuskasing on the problem of distributing natural gas.

A special meeting was held in May to hear a report from Councillor C. W. Boast on the progress toward Confederation.

Mr. Fowler, an electrical engineer with extensive experience in India, spoke to a Branch meeting in Iroquois Falls on his experiences abroad.

The annual Branch meeting was held in Iroquois Falls on October 8, 1955. A. M. Lount, a consultant in pre-stressed reinforced concrete design, spoke to the group on the place of pre-stressed concrete and its advantages. Prior to the meeting the large ice area, using pre-stressed concrete members, was inspected.

The Western Section (Smooth Rock Falls, Cochrane, Kapuskasing) had a particularly active Professional Development Group. Courses included invention and public speaking. The latter course is continuing. Western Section meetings presented a talk on statistics by R. H. Stafford, and a discussion of the principles and application of fluid drives in industry. Of timely interest locally was a paper, "Method of Increasing Rainfall by the Use of Silver Iodide in Ground Generators", by B. A. Powers.

A membership spread out over many miles, and relative remoteness from a source of speakers qualified to talk on subjects of interest to the members as a whole, remain the two major problems besetting the Branch.

Ottawa

In reporting upon the work of the Branch during 1955, the Management Committee must first record, with unusual regret, the passing of the Secretary of the Branch, Gordon A. Sutherland on December 5. The year took also a heavy toll of more senior members including past-Chairman J. L. Rannie (1924), and R. W. Boyle (1935).

The Branch has had an active year of operation, having held 14 reasonably well attended meetings. With its total membership now approaching 1,000, the

(1) Includes general printing, meeting notices, postage, telegraph, telephone and stationery.
(2) Includes rental of rooms, lanterns, operators, lantern slides and other expenses.
(3) Includes dinners, entertainments, social functions, and so forth.
(4) Includes speakers, councillors or branch officers.

Branch cannot regard with complete satisfaction the ratio of average attendance at meetings to total membership.

Recent steady development in the pattern of meetings continued, aided by advice received from a personal telephone canvass of members by the Management Committee. One luncheon meeting (following the long established tradition of such meetings), and one evening meeting each month appear to meet general wishes. The experiment of having the evening meetings as dinner meetings at the Assembly Hall is considered by the Committee to warrant further trial, despite initial financial loss, in view of the many favourable comments from members.

The interests of out-of-town members of the Branch received further attention during the year, under the guidance of the vice-chairman. An informal meeting was held with members in Hawkesbury, to mutual pleasure, on February 28. It was found that this was the first such E.I.C. meeting to have been held there for at least 20 years. A field trip to Hawkesbury followed later in the year.

The Management Committee has continued to follow with sympathetic interest and financial support the steady development of the Junior Section of the Branch. They commend the work of these younger members of the profession to those more senior. The chairman of the Junior Section accompanied the president of the Institute on his official visits to the University of Ottawa and to Carleton College, both speaking on these occasions to the student bodies.

Completion of the memorial to Colonel By, first suggested at the annual Branch meeting of 1954 by Major W. S. Lawson, was an important event in the Branch year. The memorial was unveiled in appropriate ceremonies on October 5 last which were well publicized at the time. The president of the Institute, Dr. R. E. Heartz (accompanied by the general secretary, Dr. L. A. Wright) kindly arranged to pay his official visit to the Branch in order to preside over these ceremonies, in keeping with the adoption of the memorial as a project of the Institute as a whole. The absence of the chairman of the Colonel By Memorial Committee, Dr. J. J. Green, was generally regretted.

Following suggestions from earlier annual meetings, co-operation with other engineering and allied societies in the Ottawa area was fostered during the year. Concrete evidence of this is the monthly Calendar of Scientific and Engineering Meetings now being published by the National Research Council on behalf of all such local societies, as part of an effort to co-ordinate meeting times and dates.

The support of the Branch was given to the Community Planning Association of Canada, in its move to establish a local group. S. G. Frost was asked to represent the Branch for this purpose.

The Management Committee has followed with close attention reports given to them upon the meetings of the Council of the Institute by the Councillors of the Branch. Ten meetings of the Council were held during 1955 (five in Montreal, two in Toronto and in Hamilton, Charlottetown and Winnipeg). Seventeen individual attendances were made by Branch councillors at these meetings. This is a notable record since total attendance of members of Council was only 172 for the ten meetings. This represented a considerable personal effort on the part of Ottawa Branch councillors. The Branch is greatly indebted to them.

B. G. Ballard continued his service to the Institute as vice-president. Because of his transfer to Washington, Dr. J. J. Green had to resign as one of the councillors; T. Foulkes was appointed to serve for this unexpired term and kindly agreed to this further service as a councillor. W. G. Pennock was appointed to the Papers Committee of the Institute.

The movement towards Confederation has been followed with most careful attention throughout the year by the Management Committee. The Branch is fortunate in having one of its members, T. Foulkes, as a member of the small Confederation Committee of the Institute. It is greatly to be hoped that this vitally important development moves steadily towards fruition during 1956.

Prince Edward Island

For the year 1955 nine meetings were held, five of which were dinner meetings with various types of programs. Except for one, these meetings were well attended. The poor attendance for the one meeting was due to travelling conditions.

During the year the principal matter under consideration was the establishment of a Provincial Association of Professional Engineers and considerable work was carried out in this regard relative to by-laws, procedure and the setting up of the necessary machinery in compliance with the legislation passed at the last sitting of the Provincial Legislature. For the first time a representative of this Province was requested to attend the Dominion Council of Professional Engineers which meeting was held at St. John's, Newfoundland. This Branch went on record as being very appreciative of the invitation tendered by Dominion Council and has profited much by the information gained in setting up their own Association of Professional Engineers.

The annual picnic was held as usual at the north shore and was the source of much amusement and pleasure. All who were in the province attended and a good time was had by the engineers, their wives, and children. A few of the more adventurous spirits took advantage of the opportunity to go swimming and returned just in time to consume in ample quantity the various forms of refreshments offered.

This Branch was indeed honoured in the annual visit of the president this year. The visit of Dr. Richard Heartz, M.E.I.C. a native of this Province, took place on September 16 with an almost one hundred per cent attendance of local members and a very considerable representation of Council members from other Provinces. Dr. Heartz gave a very enlightening and interesting talk on the need for more highly qualified engineers. This meeting took the form of our regular annual meeting and the ladies were in attendance.

The fall meetings centred around considerable discussion on how this Branch could best organize and set up complete co-ordination and joint meetings with the Association of Professional Engineers presently being constituted in this Province. As such a large amount of work has been done in this regard, at our recent meetings, there was little opportunity for the entertainment committee to provide programs. However, a very excellent picture illustrating the development of Kitimat was shown and thoroughly appreciated by all.

Peterborough

The Peterborough Branch held seven technical meetings during the 1955 season. In covering a variety of topics, the Branch was most fortunate in obtaining excellent speakers. The average meeting attendance was 43.

The social highlight of the season was the annual meeting in January which honoured the ladies of the Branch at a supper meeting and dance.

The summer outing was held at the summer home of D. A. Drynan at Stony Lake. The afternoon of sports was supplemented by entertainment as daring members tried their skill at water skiing.

The Branch extended a cash prize to students in each of the three city collegiates. These were merit awards to boys in subjects which included English and Science. It was felt that this token would serve to bring the Institute and the engineering profession before the student body and indicate those subjects vital to the profession.

Québec

Le Comité exécutif a tenu sept séances avec une assistance moyenne de huit pour disposer des opérations régulières de la section et étudier les questions d'intérêt local ou national pour l'Institut.

Au cours de l'année écoulée, le Comité exécutif a rétabli le Bal annuel de la section et celui-ci a eu lieu le 21 janvier 1955, au Château Frontenac. Il a remporté un franc succès; près de 300 personnes y assistaient et une atmosphère de franche gaieté et de courtoisie a existé durant la réception.

En février, le Comité exécutif a reçu officiellement le Docteur H. H. Burness et M. Hickle, d'Angleterre, venus au Canada pour présider au choix des boursiers Athlone à Laval.

Le Comité exécutif a eu au cours de l'année une communication du Conseil de l'Institut avisant que le terme de membres "Junior" de l'Institut a été porté à neuf ans au lieu de sept ans, sans frais de transfert, ou de huit à dix ans avec frais de transfert.

Le Comité exécutif a pris l'initiative de préparer et de présenter une requête au sept "grands wardens" de Sons of Martha pour obtenir l'établissement d'un camp à Québec. Sept members de notre section ont signé ladite requête et nous espérons obtenir une réponse favorable bientôt. Cela nous permettrait de tenir régulièrement, une ou deux fois l'an, la cérémonie d'initiation à Québec, sans recourir aux "Wardens" de Montréal.

Le Comité exécutif a obtenu de nouveau, cette année, un octroi de $1,000 du ministère provincial du Bien-Etre Social et de la Jeunesse afin de permettre la poursuite des cours avancés ou de perfectionnement en structure. Le Comité se permet de souligner ici l'empressement avec lequel le ministre Jean-Paul Sauvé a accueilli notre demande et se propose de souligner la précieuse collaboration de l'Honorable Sauvé plus tard.

Le programme des réunions générales, cette année, a été le suivant: 21 janvier, assemblée annuelle de la section et bal annuel de la section; 30 janvier, réception conjointe avec les Anciens de Polytechnique en l'honneur de MM. Ludger Gagnon et Henri Béique; 10-17 février, visite individuelle d'un entrepôt de A. Deslauriers et Fils avec charpente de bois lamellée; 10 mars, conférence de M. Henri Audet, ingénieur régional pour Québec de Radio-Canada sur la "Télévision au Canada". Les membres de la section de Québec de l'A.I.E.E., de l'I.R.E. et de la C.I.F. sont nos invités; 23 mars, représentation de films sur la fabrication de l'acier et conférence par M. Robert David, de C.I.S.C. sur la "Protection des bâtisses contre l'incendie et son influence sur les taux d'assurance" et "l'Insonorisation des bâtisses"; 26 mars, jitney mixte de curling pour architectes et ingénieurs et partie contestée entre les as du curling dans chacune des professions; 14 avril, conférence: "Vapeur Barrier" et "The Magic Marble", par M. K. D. Hutchison et R. M. McMay, de Fiberglass Canada Ltd.; 26 avril, les membres de E.I.C. sont les invités de l'American Society of Metals, section de Québec, à une conférence de M. L. D. Richardson de Eutectic Welding Alloys Corporation sur "New Welding Developments". Un film sur la soudure est également projeté; 17 août, tournoi de golf de la Construction organisé cette année par les ingénieurs de l'E.I.C., section de Québec; 12 septembre, tournoi annuel de golf de la section de Québec au Royal Quebec Golf Club; 17 octobre, ouverture des Cours de perfectionnement en structure; 22 novembre, présentation de films; 24-27 novembre, retraite fermée à Villa Manrèse pour Ingénieurs Professionnels et Ingénieurs forestiers; et 30 novembre, banquet aux huîtres aux Voûtes Talon.

Le Comité exécutif déplore la perte d'un membre distingué en la personne de M. Paul Joncas, ingénieur conseil et professeur à Laval. M. Joncas était reconnu par son intégrité et sa compétence.

Le Comité exécutif se plait à souligner les charges importantes que certains membres de notre section ont remplies dans différentes organisations professionnelles, politiques, publiques ou charitables de Québec. M. G. E. Sarault, président du Comité des paroisses pour la campagne 1955 de la Fédération des Oeuvres de Québec. Il a été choisi président général de la Campagne 1956. M. Guillaume Piette, président du Comité des noms réservés pour la Campagne 1955 de la Fédération des Oeuvres de Québec. M. Piette a également été élu président de l'Association Conservatrice du district de Québec. Il est représentant de la région de Québec à la Corporation des Ingénieurs. M. Georges Demers, président du Dominion Council of Professional Engineers pour l'année 1955. C'est le premier canadien-français à occuper cette charge.

Un nombre important de membres de notre section ont apporté une contribution active dans la campagne 1955 de la Fédération des Oeuvres de Québec au niveau des paroisses. Plusieurs également ont grandement contribué au succès du Carnaval d'Hiver de Québec 1955 et continuent cette contribution dans l'organisation du Carnaval 1956.

A ceux de nos membres qui ont obtenu des promotions au cours de l'année, nos plus sincères félicitations.

Votre Comité a tenu à souligner de façon particulière la participation de M. André Bertrand, membre étudiant de notre section, aux Olympiques d'hiver, division du ski, à Cortina, Italie. Un souvenir lui fut remis au cours du banquet aux huîtres, le 30 novembre. Le même soir, votre Comité a signalé les dix années de M. Roger Desjardins comme secrétaire de la section de Québec et un témoignage tangible lui fut également remis à cette occasion.

Saint John

During the year six dinner meetings and three Professional Development meetings were held affording members the opportunity of hearing interesting talks on a wide variety of subjects.

The joint dinner with the Association of Professional Engineers of the Province of New Brunswick was held on January 27 at which time Brig. J. R. B. Jones spoke on "The Military Engineer".

The "Ladies' Night" dinner meeting was held on March 24 when the special speaker was T. Rogerson of Simpson-Sears Ltd. The subject of his talk was "The Background and Approach to the Opening of a Modern Simpson-Sears Store in Saint John".

On April 19 Dr. I. R. Tait, vice-president of the Engineering Institute presented a talk on "Plastics"; and on May 10 B. W. Fleiger spoke on the spruce budworm spraying operation in New Brunswick.

A mixed dinner meeting was held in honour of the president, Dr. R. E. Heartz, on September 29. His talk emphasized the need for more engineers in Canada.

The annual meeting and election of officers took place December 13.

Professional Development Programs were held on March 10, October 25 and November 22, the subjects being "Mortgages Pertaining to Industry and Housing", "Why Do I Work", and "Industrial Relations and You". There was no definite enrolment for these courses but the average attendance was 23.

On February 23 a plant visit was made to Atlantic Sugar Refineries Ltd. and on October 13 members were conducted on a tour through the plants of Automatic Sprinkler Co., Ltd. and Eastward Industries Ltd.

Saguenay

Close co-operation between the Saguenay Branch and the local chapter of the Corporation of Professional Engineers of Quebec was continued during 1955, and the membership expressed their approval of this by again electing a joint executive.

Activities included two technical meetings, with refreshments served at the conclusion, one field trip to a modern bakery, two social evenings or dances and the annual meeting. The Junior Section was active and sponsored one technical meeting, a film night, and was responsible as well for the Professional Development activities in the region. These took the form of study groups which met every two weeks; eight members participated in a course on principles of investment, while seven followed a chemical engineering refresher course.

The Membership Committee was quite active and although a number of new members were obtained, a slight decline in Branch membership occurred due to transfers out of the region.

St. Maurice Valley

During the year the Branch continued to operate under a system whereby meetings of both the executive and membership were held alternately in Shawinigan Falls and Three Rivers. Notices of meetings were sent to all members of the Branch so that they had the opportunity of attending meetings in either centre. In all, seven events took place in Shawinigan Falls and five events in Three Rivers.

The program during 1955 included talks of an educational nature such as "Management Responsibilities", "I.B.M.'s Electronic Computing Machines", "Stocks and Bonds and Investment Principles", "Hamilton River Power Possibilities", "The Plant Publication", "The Erection of the Halifax-Dartmouth Suspension Bridge", and an address by Dr. L. A. Wright on the E.I.C.'s services to its members.

One program night consisted of films on "Stock Exchange Operation", "Development of the Jet Engine", "Fishing and the Atom". The last meeting of the year consisted of the showing of the film "Leonardo da Vinci".

The annual dinner meeting was held in Shawinigan Falls on May 4 and the guest speaker dealt with the topic "Recent Developments in the Metallurgical Industry in Canada".

During the month of June a dance was held in Three Rivers at the Radisson Canoe Club. The other event during the summer months consisted of a golf tournament and buffet dinner held jointly with the A.I.E.E. and the C.P.E.Q. in the Three Rivers district.

Sarnia

Membership in the Sarnia Branch is 165, a decrease of three from the 1954 total. Eleven meetings were held during 1955, the average attendance for dinner meetings being 50, while that for other meetings being 30.

The Branch held a dinner meeting at the Colonial Hotel on January 27 at which Dr. G. A. Sinclair of Imperial Oil Limited spoke on "The Contribution of Industrial Medicine to Industry". On February 24 members of the Sarnia, London and Border Cities Branch held a joint meeting in Chatham honouring the visit of the president, Dr. D. M. Stephens, who spoke on "Confederation". At the March dinner meeting at the Colonial Hotel the members heard J. J. Legate speak on "Building a Better Sarnia".

The Sarnia branch of the Chemical Institute of Canada organized a joint meeting with the members of the Engineering Institute in April; while the Junior members of the Branch organized a visit to Detroit and a tour of the Edison plant in May. In June Sarnia Branch members attended the Eighth Annual Convention of the Michigan Society, organized by the Port Huron Branch.

J. E. MacLaren of J. F. MacLaren and Associates addressed a dinner meeting at the Colonial Hotel on "Water and Sewer Problems as Related to City of Sarnia" on September 22; and the Institute film "Leonardo da Vinci" was shown to members at the Sarnia Collegiate Auditorium on October 13.

E. G. deWolfe of the Sifto Salt Company addressed a joint meeting of the Sarnia Branch and the Chemical Institute of Canada at the Vendome Hotel in October. His subject was "Mining and Manufacture of Salt". On November 22 Dr. P. L. Pratley, consulting engineer, spoke to a Branch dinner meeting at the Vendome Hotel on "Bridge Design and Construction".

The year's activities were concluded by the annual business meeting held at the Colonial Hotel. At this meeting the election of 1955-56 officers took place, and reports by the chairmen of the various committees were presented.

Saskatchewan

Eight Executive meetings and the annual meeting were held during the year for the transaction of Branch business.

Professor A. H. Douglas was appointed to the Institute Nominating Committee in January, representing the Saskatchewan Branch for 1955.

Col. L. F. Grant, field secretary, visited Branch Sections at Saskatoon, Prince Albert, and Regina. He was main speaker at the annual dinner in Regina on February 18.

At the annual meeting, the president of the Student Engineering Society recommended that W. E. Wickenden's "A Professional Guide for Junior Engineers" be presented to students entering the College of Engineering. The Executive approved of presenting each graduate student with a copy of the guide, at an appropriate time in the spring, and with a suitable talk by a senior practicing engineer.

John E. Campbell, engineering student at the University of Saskatchewan, attended the Student's Conference in Toronto, May 9 to 14, representing the University of Saskatchewan.

Professor J. B. Mantle, was nominated E.I.C. Councillor representing this Zone.

The E.I.C. Prize was awarded to Donald Grant Fisher for 1955 at the University of Saskatchewan.

The president of the Institute, Dr. R. E. Heartz, and general secretary, Dr. L. Austin Wright, were present at the November Executive meeting where they reported, among other things, that a new department was being set up at headquarters to promote the formation of technical sections; that the Institute was participating in the activities of he Canadian Committee on Engineers and Scientists on the matter of guidance work and the shortage of engineers.

Sault Ste. Marie

The annual meeting for 1954 was not held until January, 1955, and that for 1955 was held in December of the same year when the officers for 1956 were elected. The new slate is composed of younger members and it is hoped that the Branch will continue to thrive under them.

Every assistance was rendered by the executive committee but special mention should be made of Mr. Tooley, as secretary, and Mr. Snell who was in charge of the papers. The papers were extremely interesting and varied, and did much to increase the attendance over past years.

The visit from Colonel Grant was, as usual, interesting and informative, and was enjoyed by all. In addition to the annual meetings, there were six regular meetings. Walter Mulfler of Algoma Steel explained the operation and products of the new bar and strip and the cold mills at Algoma. Capt. Jackson of the U.S.A.F. Station at Kinross, Michigan, described the work of turbo-jet planes in the Northern Defence Scheme and a representative of the jet manufacturer told about the design and operation of the engine. H. D. Ellis of the Mackinac Bridge Authority described construction detail of the deep water piers to carry the new bridge across the Strait of Mackinac. Some extremely interesting and clever photographs were shown in connection with this talk. W. A. Sweetman of Fairbanks-Morse talked on abrasives, their design, construction and uses. K. M. Clarke of Algoma Steel described the many details in the planning, to produce steel products, from the making of iron to the finished shape. G. M. Stevens, general manager of Algom Uranium Mines, spoke on rock structure and the extent of the uranium ore field in the Quirke Lake area (Blind River). The average attendance for the above meetings was 22.

In May the Institute's film on Leonardo da Vinci was presented in the Sault Armoury theatre and was much appreciated by the 147 citizens and members who attended. A small profit was sent to Headquarters to assist in the purchase of other films.

This year the president held a combined meeting of the Northern Ontario branches and Sudbury which was attended by three members of the Sault Ste. Marie Branch who were inspired by Dr. Stephens' remarks.

Sudbury

The Sudbury Branch held eight meetings during 1955 which included a visit from the president of the Institute, Dr. D. M. Stephens, and Mrs. Stephens, and Dr. L. Austin Wright, general secretary, on February 28. Members of the Branch took part in an interesting tour of the Western Properties of the Falconbridge Nickel Mines, and attended six technical meetings.

The varied technical papers included "Air Conditioning" presented by B. E. Judges of The Trane Company on January 6; "Servo-Mechanism" by W. G. Wright of the Canadian General Electric Company on February 3; "Recent Developments in the Petroleum Industry" by G. L. Green of the Imperial Oil Company on March 24; "Rural Electrification" by J. E. Twiss of the electrical engineering department of the International Nickel Company on March 24; "Principles and Practice of Management Control" by B. A. C. Hills, president of Urwick Currie Ltd. on November 3; and "Public Water Supply in Relation to the Municipal Engineer and the Medical Officer of Health" on December 6.

The annual meeting was held on April 25. At this meeting officers for 1955-56 were elected and reports presented by the chairmen of the various committees and by the Branch councillor, E. R. Eaton.

Average attendance at the meetings was 42 per cent of the Branch membership.

Twelve executive meetings were held to conduct the program for the year, at one of which Col. L. F. Grant, Institute field secretary, held a discussion.

The Professional Development Course comprised four lectures on the following subjects: House and Household Insurance, How Civil Liberties Die, Mental Health in Industry, and Municipal Engineering in Expanding Communities. Attendance for the course of lectures was approximately 15 per cent of the resident members.

Toronto

The Toronto Branch enjoyed many outstanding meetings during the year. The first general meeting was Students' Night during which the panel discussion was used with excellent results. In February Sir Claude Gibb presented his paper "Investigation into the Failure of Two 100 Mw. Turbo-Generators" before an audience of approximately 700. Sir Claude flew from England to present his paper in Canada. The Toronto Branch was honoured to be host on this occasion. The visit of the president, Dr. D. M. Stephens, in February was the occasion of an enjoyable meeting and social evening for the Branch executive and their ladies.

Three papers presented in March were "The Engineer and Industrial Management" by Charles R. Armstrong, assistant vice-president, employee relations, for the Bell Telephone Company of Canada; "Engineering and Political Aspects of the Abadan Refinery" by John Fulcher, chief mechanical engineer, design division, Directorate of Works (Army); and "Leadership with Engineers" by C. A. Morrison, vice-president of Canadian General Electric Company Limited. Mr. Morrison's paper was presented to a joint dinner meeting of the Toronto Branch and A.I.E.E. in Hart House. At the meeting prior to the Annual and Professional Meeting of the Institute, Dr. J. Kates presented a paper and demonstration on "Computing Machines".

Highlighting the Toronto Branch activities was the Sixty-ninth Annual and Professional Meeting of the Institute which took place in Toronto. The program of this meeting has been well described in the *Engineering Journal*.

After the summer months members of the Branch made a tour of the Maclean-Hunter Publishing Company plant in Willowdale, after which they were entertained to lunch by the company in the spacious cafeteria.

During October two papers were presented. The first was that on "Models", which was ably given and demonstrated by Dr. L. E. Jones; the second was "The Coal Burning Gas Turbine" by Dr. D. L. Mordell. Interest in Dr. Mordell's paper was clearly indicated during the question period which followed.

J. G. Lucas addressed a meeting in November on the subject "Paint—An Engineering Material" which evoked considerable interest. Later in the month a panel consisting of H. R. Burton, W. E. P. Duncan, W. J. Fulton, J. R. Walker, and John Chisholm, with H. W Tate as moderator, discussed "Toronto's Traffic Problems".

The final meeting of the year was held jointly with the Royal Canadian Institute in Convocation Hall, University of Toronto, in December. At this meeting Dr. Hueler spoke on "The Development of Colour Television" and demonstrated a colour T.V. transmission.

Further attempts were made to convene meetings at 6.30 rather than 8.15. These were successful. It is planned that as many early meetings as possible should be held, consistent, of course, with the equipment requirements of the speaker.

The Toronto Branch also sponsored Professional Development Courses. Two courses are now in progress, with an enrolment of about 70 in Group I, and six in Group II. About 20 weekly meetings are held for each group, two or three being joint meetings. In general, Group I has preferred topics unrelated to engineering and business such as public speaking, insurance, anthropology, sports, current events, etc., while Group II prefers to concentrate on business topics stressing case studies, making full use of group discussion. An outstanding joint meeting was one addressed by Assistant Commissioner J. B. McClellan of the R.C.M.P. on "Communism Inside Canada". There were many guests present including members from the Hamilton Branch who are sponsoring a very successful Professional Development program there.

Vancouver Island

The Branch held six technical meetings during the year, all of which were joint meetings with the Victoria Branch of the B.C. Engineering Society.

The first meeting of the fall season was in the form of a field trip to the Harmac Pulp Plant at Nanaimo. This was also a joint affair; and a luncheon with the "up-island" Members was held at Nanaimo.

On the occasion of the field secretary's visit a Smoker was held at the Pacific Club which proved to be a very successful evening.

The highlight of the year was the visit of the president, Dr. R. E. Heartz, and the general secretary, Dr. L. Austin Wright, who were entertained to dinner at the Princess Mary Restaurant Vessel.

There were five Branch executive meetings during the year.

Winnipeg

During 1955 the Branch held six meetings (including the annual general meeting) and the members participated in three plant visits. The total number in attendance at the meetings was 504, or an average of 56 per meeting.

In addition to this the Branch was favoured with visits from two presidents of the Engineering Institute. Dr Stephens was here in the spring of 1955 and in the fall of that year Dr. Heartz and Mrs. Heartz and Dr. Wright paid a visit. It was impossible to arrange a Branch meeting when Dr. Heartz was in Winnipeg because the length of his stay did not permit time to send out a general notice to the members. However, he had an interesting meeting with the Management Committee and he addressed the student section of the Branch at the university. The Electrical Section was very happy to have him as a guest at the annual dance.

The Civil Section held seven general meetings and two plant visits. The average attendance at these was 35. The Section has an enrolment of 235, which is about the same number as the aggregate attendance at the section's meetings. The officers of the Section hope for a higher average attendance at their meetings in 1956, and they are of the opinion that the total attendance in that year may be as high as 360.

The Electrical Section held eight meetings during the year (including the annual dance) and the average attendance at the meetings was 65. The Section has 181 members on its mailing list. The total attendance at the meetings was 516 and its officers anticipate approximately a total attendance of 700 in 1956.

The Brandon Section held eight general meetings during the year, one of which took the form of the annual dance, which was held in May. The Section Executive also held eight meetings during the year. The Brandon Section has an enrolment of approximately 40 and the average attendance at the meetings, exclusive of the annual dance, was 22.

The Brandon Section experienced a little difficulty in the matter of Executive operation during the year, for the reason that many of the Branch officers were transferred by the companies with whom they were employed. Nearly a full new slate of officers was required to take over, but despite this change in executive management during the year the section made satisfactory progress.

Care is taken to see that there is no overlapping in the matter of papers given at the Branch and at the Section meetings. Each of the Sections has a papers chairman and he maintains very close contact with the general papers chairman of the Branch, and by this method of co-operation, duplication is, to a great extent, eliminated. At the same time every precaution is taken to allocate papers dealing with the purely technical side of engineering to the Sections and those of a general nature and of particular interest to the public are arranged for Branch meetings.

Yukon

Six meetings of the Yukon Branch were held during the year. In January a National Carbon Company film was shown. During that same meeting a motion that the Yukon Branch of the Engineering Institute sponsor a Yukon Professional Engineers' Association was carried. In March a Yukon Professional Engineering Ordinance was passed by the Territorial Council in session, and later in the year the by-laws were passed. The matter is now under the provisional direction of the Engineering Institute executive.

At two meetings members heard interesting addresses by guest speakers. The first, in April, was a talk by T. Main who spoke on the Whitehorse Utilities project concerned with providing sewer and water facilities for Whitehorse. In June, Dr. Hans Froberg, consulting engineer with the Teck Exploration Company in Toronto, told of his impressions and experiences in Costa Rica.

The Branch was fortunate in having two visits from members of national headquarters. In March Col. L. F. Grant, field secretary, visited Whitehorse and addressed a meeting of the members. On November 25 the Branch was privileged to welcome the president, Dr. R. E. Heartz, and Mrs. Heartz, and Dr. L. Austin Wright, general secretary. On this occasion a dinner meeting of the members, associates and their ladies was held.

During the summer the members arranged an enjoyable trip on the sternwheeler *Tutshi* to Ben-My-Chree, an historic beauty spot situated at the head of Tagish Lake, one of the sources of the Yukon River.

The Maritime Professional Meeting

St. Andrews by the Sea, N.B.

September 5, 6, 7, 1956

Month To Month

Notes of the Institute and Other Societies, Comments and Correspondence, Elections and Transfers

The Seventieth Annual General and Professional Meeting

To be held jointly with ASME

This year our annual general and professional meeting will be held at the Sheraton-Mount Royal Hotel, Montreal, on May 23, 24, and 25 and as an added feature will be arranged in association with the American Society of Mechanical Engineers. Actually there will be not only some technical papers presented under the auspices of ASME Technical Divisions but several papers by members of the British Institutions from Great Britain as well.

Transportation

As usual, special reduced convention fares will be available for rail travel in Canada and the necessary certificate will be sent to all members requesting it at time of registration. Members are requested to make their own travel arrangements through local ticket agents.

Hotel Accommodation

The Sheraton - Mount Royal Hotel will be headquarters for the meeting and ample room accommodation for all members and their wives will be available there.

Advance Registration

Hotel reservation and advance registration cards will be mailed with advance copies of the meeting program, early in April. Room allotments will be made in the order of the receipt of reservation cards at Institute Headquarters. It is expected that all social functions will be fully attended, therefore members are urged to order tickets for dinners, etc., on their advance registration cards. Otherwise reservations cannot be guaranteed.

Annual Banquet and Ball

The meeting will end as usual with the annual banquet and ball to be held on Friday evening May 25.

Ladies Events

All events such as dinners and technical meetings will be open to the ladies. In addition, a number of special social events will be provided.

Special Features

On Thursday afternoon, May 24, all those attending the meeting are invited to visit the plant of Canadair Limited at nearby Cartierville, Que., following which a special air show and refreshments will be provided. Arrangements are being made likewise for special visits to the Montreal section of the St. Lawrence Seaway development, as well as the International Section of the joint Seaway and Power Development at Cornwall, Ont., on Saturday, May 26 for any who may be interested.

General

Some thirty technical papers as well as two panel discussions have been arranged for. There will also be some special entertainment features and particulars of these will be found in the advance program.

Muriel's Room

To members and their wives who have attended annual meetings in recent years, the hospitality dispensed by our Canadian industries through the E.I.C. hostess "Muriel" is well and favourably known. It is anticipated that her hospitality this year at our Montreal meeting will be in no way lacking.

Consulting Engineers Association

The annual banquet of the Association of Consulting Engineers will be held in the Sheraton-Mount Royal Hotel at 6.30 p.m. on Thursday evening May 24. More complete details will be announced separately.

Opportunities for Future Engineers

University of Sherbrooke

Ten years ago, before the foundation of the University of Sherbrooke, the School of Engineering came into existence through an extension of courses offered by the local Superior School conducted by the Brothers of the Sacred Heart.

In 1945, with the approval of the school board, the faculty of the Superior School, wishing to offer students an opportunity for further study in engineering, organized an extra year of study to meet university entrance requirements. Upon the completion of this last year the students were directed either to Laval, to Polytechnic School in Montreal, or to McGill University.

In September 1951 a first year course in engineering was inaugurated with quarters in the Superior School. This move was made possible through an understanding with and cooperation of the Sherbrooke Catholic School Board. Three years later, in September 1954, following the foundation of the University of Sherbrooke in May 1954, a second year engineering course was also introduced.

Turning Point

The ever increasing enrolment during the past five years created a classroom shortage. Larger facilities were needed. This problem was solved in January when Premier Duplessis announced that a $750,000 grant would be voted by his government for the erection of a school of engineering affiliated with the University of Sherbrooke.

Functioning

At present, the Sherbrooke School of Engineering has three classes in operation: an undergraduate, a first, and a second year engineering, already totalling 135 students.

The undergraduate course offers students a general training which prepares them to enter engineering or other specialized fields. A high school diploma is the minimum requirement for this undergraduate course. The curriculum includes philosophy, languages, mathematics, bookkeeping, economics, sciences, history and geography.

The following are the subjects offered in the first two years of engineering:

First year: algebra, calculus, chemistry, mechanical drawing, analytic geometry, applied mathematics, physics, bookkeeping, trigonometry.

Second year: algebra, surveying, calculus, chemistry, engineering drawing principles, analytic geometry, descriptive geometry, mechanics and physics.

It is essential that the student master the general principles underlying scientific work before commencing professional subjects. and greater importance is given to the study of all mathematics. particularly calculus and analytical geometry.

At the end of the second year. students are required to attend a two-week surveying project. A comprehensive training in surveying is added to this background.

Projects

Next fall, the faculty will be ready to begin a third year of engineering. Accommodations will be found outside the Superior School building. Subjects offered in the third year are designed to emphasize the fundamental principles of mechanics, strength of materials, design of structures, and hydro-dynamics, while at the same time affording an opportunity of applying these principles to practical problems in the field of civil engineering.

The New Building

The School of Engineering, first building to be erected on the Sherbrooke University Campus, will stand on a recently purchased property of five hundred acres on St. Catherine Road, just outside the Sherbrooke city limits and near the Montreal highway.

The school project consists of a modern two storey brick building, three hundred by two hundred feet, an area of forty thousand square feet. The new school will provide space for ten classrooms and lecture halls, a library, a drafting-room, a cafeteria, an auditorium, laboratories for physics, chemistry, mineralogy, hydraulics, electricity, strength of materials, and offices for general administration. The cost of the building will be about $600,000. Construction is scheduled to start early in April and it should be ready for occupation in January 1957.

This new School of Engineering. affiliated with the University of Sherbrooke, is under the direction of three members of the Institute: Dr. Armand C. Crepeau, M.E.I.C., dean of the Faculty of Science; Gaetan J. Côté, M.E.I.C., director of the School; Jacques Lemieux, M.E.I.C., chairman of the Eastern Townships Branch of the Institute and assistant-director of the School.

Plastic Design of Steel Structures

Recent years have seen the development of ultimate or plastic strength design methods for steel structures. Work on the basic theory was pursued initially in Europe and later in Great Britain and the United States, and the results published in a wide variety of periodicals.

A stage has been reached where plastic design methods are applicable — with advantage — to practical problems. These methods are being used in Great Britain under the provisions of the British Standard, The Use of Structural Steel in Building. The American Institute of Steel Construction is interested and a revision of the AISC code is anticipated. Under the new National Building Code of Canada, the use of plastic design methods would be permissible.

Because the methods used in plastic design are novel, and because information on the subject is so widely scattered in engineering literature, it has appeared necessary to introduce the subject in special short courses, where the advantage of first-hand presentation is obtained. The first course of this sort in North America was intended for educators, and was held at Lehigh University in September of 1955. It is now proposed to hold a similar short course in Canada, intended for practising structural engineers. In this course, emphasis will be placed on plastic methods of design, and it is expected that an intensive course of a week's duration will enable a designer, already experienced in elastic methods, to assess the opportunities offered by these new methods.

The course will be given jointly by The Royal Military College of Canada and Queen's University, assisted by the Canadian Institute of Steel Construction, during the period May 28 to June 1, in Kingston. It will include formal lectures, discussion periods and laboratory demonstrations. Methods for the plastic analysis and design of steel structures will be developed, and actual design examples will be worked to illustrate the theory. The laboratory demonstrations will consist of tests to destruction of real structural members and frames.

Because of the space requirements in lecture rooms and laboratories, the numbers attending the course must, unfortunately, be limited. Applications will be accepted up to this limit until May 1. No tuition will be charged for the course; however, there will be a $10 registration fee.

For application forms and further information, please write: Prof. J. W. Dolphin, Plastic Design of Steel Structures, Royal Military College, Kingston, Ont.

Canadians in Britain

In December a group of 1955 Athlone Fellows visited the Stanton Ironworks Company Limited near Nottingham, England. At present in postgraduate courses at the Imperial College of Science and Technology, London, the six Canadians were guests of the Company for the two-day visit. In the group are, left to right: L. Soderman (Manitoba, 1953), J. Campbell, S.E.I.C. (Nova Scotia, 1955), A. Bjornsson, Jr.E.I.C. (Manitoba, 1954), D. Shields, S.E.I.C. (Saskatchewan, 1955), K. Peaker, S.E.I.C. (Manitoba, 1955), and P. Langeman, S.E.I.C. (Saskatchewan, 1955).

Anniversary Clock

Last year the University of New Brunswick at Fredericton celebrated the one hundredth anniversary of the beginning of the first course in engineering ever given at a Canadian university. At that time the Institute in recognition of the university's achievement presented a clock.

Recently the opening of the new building for student activities has provided a suitable place for the clock to be located. It now sits on the mantel shelf in the common room of the students' union.

Through the courtesy of Dean E. O. Turner the Institute was able to get a photograph recently and *The Engineering Journal* is pleased to show it herewith.

The inscription reads as follows: "Presented to the University of New Brunswick by The Engineering Institute of Canada on the occasion of The Centennial of Engineering Instruction, February 15, 1854-1954."

At Whitehorse the Yukon Branch is host to the President on November 25. Left to right: Mrs. Kenneth Baker, Brigadier J. Meusier, Mrs. Heartz, John Phelps, Mrs. Phelps, Dr. Heartz, Mrs. Meusier, and Dr. L. Austin Wright, general secretary.

The President attends a dinner meeting of the Sault Ste. Marie Branch on February 8. Left to right: Mrs. H. M. Lang, E. C. Luke, assistant general secretary, Mrs. G. L. Brown, Dr. Heartz, Mr. Brown, chairman, Mrs. Heartz, Alderman H. M. Lang, and Mrs. D. C. Holgate.

K. E. Bentley, Sarnia Branch chairman, V. A. McKillop, president-elect, Dr. R. E. Heartz, president, and E. C. Luke, assistant general secretary, get together before the executive meeting begins in Sarnia.

At the Sault Ste. Marie Collegiate Dr. Heartz discussed the opportunities available to the Canadian engineer at a student assembly. Lower left: W. W. Fraser, principal; Catherine Nasi, vice-president, Student Council; Dr. Heartz; Mickey Contini, president, Student Council; W. D. Adams, of Algoma Steel Corporation, and E. C. Luke, assistant general secretary of the Institute. Below: G. L. Brown talks to Dr. Heartz, with W. D. Adams, and D. C. Holgate, general manager of Sault Structural Steel Company.

President R. E. Heartz and Mrs. Heartz are entertained at a reception at the home of the president-elect V. A. McKillop and Mrs. McKillop in London. Left to right, Mr. McKillop, Mrs. Heartz, Mrs. McKillop and Dr. Heartz.

St. Lawrence Seaway and Power Project

The *Engineering Journal* reviews the progress of the St. Lawrence project.

Full scale operations commenced on the construction of new townsite No. 2 during January. The sewer and water-main contractor moved on to the site the middle of the month, and already had made outstanding progress in laying of sewers and water mains. Nearly 150 houses had been measured preparatory to moving to the townsite and for construction of new basements. Power and telephone lines were being installed in the new town and an access highway was being built to the townsite.

Meanwhile for townsite No. 1, numbering of houses had been completed in the original hamlets, staking of lots had been completed in the new townsite in preparation for moving operations. At Iroquois some 85 houses had been transported to the new town. Work was in progress for the new pumping station and installation of the intake was progressing rapidly.

Normal winter weather favoured construction operations throughout January and significant progress was made. The total work force was approximately 2,700 persons. Excavation for all project operations had reached 7.51 million cubic yards of material removed.

Progress by Ontario Hydro

Indicative of the important progress in the power-house area excavation, some 100,000 cubic yards of earth and 1,800 cubic yards of rock were removed during January. Rock excavation for the U-abutment base at the north end, where that structure will be tied into the dike, was started early in the month. Earth excavation was mainly in the south end of the power-house area, most of the earth removal in the north section having been completed.

Drilling and grouting operations also continued in the grout curtain area of the power-house. At month end virtually all the estimated 475 holes had been drilled, while some 445 holes had been filled with grout using about 170,000 sacks of cement.

Installation of equipment at the batch plant had been completed. The new 10-ft. dia. access tunnel had been completed, ready for the installation of the final section of the aggregate conveyor. Work on form panels for the U-abutment was well advanced, and work on construction of draft tube forms had been started.

Important progress was made in the Cornwall dike closure structure excavation. About 60 per cent of all the excavation had been completed in that area. In dike construction, stripping of the marine clay crossing in section 3 progressed well. Excavation was carried out by dragline and with caterpillar scrapers, pusher loaded, despite the extensive frost in the ground. Some stripping of the clay crossing in section 2 also was carried out by the contractor.

Extensive stripping operations were carried out at the aggregate quarry during the month. This will result in increased production of clean aggregate, and already heating equipment had been installed to thaw stockpiles.

At the St. Lawrence transformer station, installation of equipment was right on schedule. Hydro's construction division expects to meet the in-service date of April 1, 1956.

Ditching operations and placing of granular fill for the roadbed proceeded well on the Canadian National Railway relocation. A total of 24 miles of the entire contract in the three sections had been finished to sub-grade elevation, while a total of some 9½ miles had sub-ballast on it.

In channel excavation work in the Galop Island contract, an estimated total of approximately 1,600,000 cubic yards of material had been excavated at month end. During the month, four shovels were working in the main cut, but seepage around the shovels was giving some trouble.

Progress by NYSPA

During January, Barnhart Island was linked to the mainland by rail. The first trainload of equipment for the power-house crossed Barnhart bridge on January 19. Removal of the floating bridge was completed with the dismantling of cable towers. For the entire project more than ten and a quarter million cubic yards of excavation had been removed.

Due to lack of snow, frost penetration was deeper than usual, requiring blasting to allow excavation of frozen earth throughout the project. Construction plants were being built up during this period to enable all construction operations to proceed in accordance with the accelerated schedule during the coming season.

With most of the rock foundation of the power-house exposed, drilling and grouting operations were continuing, as nearly 150,000 cubic feet of grout had been pumped into the rock for consolidation and cut-off grouting. More than a million yards of common excavation had been removed from the power-house area. The delivery of construction material by railroad started on January 19. Placing of rock fill in the baffles on the upstream side of cofferdam C-1 had progressed to 75 per cent of completion.

Long Sault dam concrete pouring had been suspended for the winter as other essential activities progressed. A quarry was opened in the unwatered channel between Sheek and Barnhart Islands to supply rock for construction of a revetment along the embankment of Cornwall canal beside the rapids. Cut "F" was taking shape as excavation operations continued. On Barnhart Island, clearing crews were working along the locations of the north earth wing dike, Barnhart Island road and the left abutment of Long Sault dam.

Iroquois dam guide towers were set as pouring of concrete continued. Earth cofferdams were enclosing off-shore areas which were being unwatered and excavated. Steel cofferdam cells were being driven for the stage 1 construction.

Channel excavation at Red Mills Point had reached the clean-up stage with the remaining upstream cofferdams being removed. The south Galop channel was being excavated in the area between the islands and mainland. Cofferdams linked these islands to the mainland and the enclosed 150 acres of channel had been unwatered.

A contract was awarded on January 5 for 11,839,000 cubic yards of channel improvement work at Sparrowhawk Point of Toussaints Island. At Massena intake shovels were excavating for the structure about 30 feet below the water level of the canal.

Specifications were issued during the month for intake gate hoists for Barnhart Island power plant, 440-volt motor control centres and the electrical work at Barnhart Island power plant. The work of inspection and expediting of major equipment increased to meet the demands of the schedule. The work force totalled some 2,400 persons.

NYSPA Annual Report

In the absence of official press releases this month on progress by the St. Lawrence Seaway Development Corporation and the St. Lawrence Seaway Authority (Canada), the annual report of the New York State Power Authority, issued February 13, 1956, where it refers to the progress by the two Seaway Authorities, is quoted in part as follows:

"Barring unforeseen calamity, the St. Lawrence project will be completed on schedule in spite of severe winter and ice conditions, exacting requirements as to the maintenance of navigation, river levels and flows, insufficient labour market and housing for labour, shortage of strategic materials, numerous administrative and supervisory agencies, and conflicting laws, regulations and procedures involving two countries on national, state, provincial and local levels. We can report that the project is on schedule and that the first power will be generated in September 1958.

"The two seaway authorities are responsible for constructing the locks around the dams. These locks must be ready when the pool is raised because the old Canadian fourteen foot canal will be flooded out and discontinued. The United States St. Lawrence Seaway Development Corporation, with the Corps of Engineers as its agent, is building the Long Sault canal, including the Robinson Bay and Grass River locks. The Canadian St. Lawrence Seaway Authority is constructing the canal at Iroquois with one lock. These agencies are working very closely with Ontario Hydro and the Power Authority.

"We aim to leave the St. Lawrence area as beautiful as we found it and more accessible. Throughout the country, hydroelectric developments have been a magnet for tourists. We have combined visitor, park and recreation programs. Facilities provided pursuant to these programs will add to the benefits which will accrue to the North Country strictly from the power and seaway features of the project.

"Entering the second construction season, the Long Sault canal, under construction by the United States St. Lawrence Seaway Development Corporation, was well under way. During 1955, approximately eight million dollars was paid out for work, principally excavation, embankments and dike construction.

"Looking ahead to the 1956 schedule, the Corporation forecasts that thirty-five per cent of the work will be accomplished at an estimated cost of thirty million

Long Sault Dam. The south channel is covered with ice and construction in the dam area lies dormant until spring.

dollars, with substantial construction proceeding on the Long Sault and Grass River locks including bridges and other incidental improvements.

"The Corporation has scheduled completion of its work in time to provide for navigation for ships of 14-foot draft by July, 1958. This corresponds with the power schedule. Full scale 27-foot navigation is scheduled for the spring of 1959.

"The Canadian Seaway Authority has proceeded rapidly with the construction of the Iroquois canal, including locks for navigation around the Iroquois dam. Completion of the Canadian work has been scheduled for October 31, 1957."

Channel Improvement Before U.S. Senate

A $109 million federal appropriation to improve Great Lakes channels, already passed by Congress, is now up for U.S. Senate approval. A favourable vote is expected. The Great Lakes-St. Lawrence Association, strongest promoter of the plan, claims annual savings to the commerce in ore, grain and stone resulting from increased channel depths will exceed $280 millions over a 50 year period. The distance saved will be about 175 miles. Work will not be undertaken for a year or two.

In detail, $40½ million is earmarked for widening and deepening the St. Mary's River channels; $2¼ million for deepening the channels between Mackinac and Round Islands and at Poe Reef; $18.2 million for improving existing channels by widening and deepening and removing shoals at nine different locations in the Detroit River. Alternate and supplementary proposals would boost the total by a further $7 million. These include a six mile canal through Canada's Walpole Island in the St. Clair River.

An army engineer's report made 30 years ago on a possible canal to join Lake Michigan and Lake Erie is again up for consideration by Indiana Chambers of Commerce. The project, turned down as impractical in the "twenties," would have made use of the St. Joseph channel for part of the way across lower Michigan, thus allowing vessels to pass from Lake Michigan to Lake Erie and vice versa without sailing through Lake Huron.

Though the original scheme, to accommodate vessels with an 8 ft. draft, was turned down as costing more than the estimated benefits that would accrue from it, opening up of the Seaway might enhance the usefulness of such a project. The cost today would of course be considerably greater, built to a 27 ft. draft.

Shipping on the Seaway

Subsidy for U.S. Lakers

The U.S. Maritime Administration has made American ship operators on the Great Lakes eligible for government subsidies by declaring the ocean route between American lake ports and western Europe "essential" to U.S. trade and economy.

This opens the way for U.S. ship operators to apply to the Federal Maritime Board for an operating-differential subsidy of $750 per day for each, which in total is expected to cost the government some $8 million annually. Current increased shipping operations have made it necessary to consider and determine its essentiality under the law, well in advance of the 1959 scheduled opening of the seaway. However the subsidies will be immediately effective for small vessels of 14 ft. draft plying existing Canadian canals.

Under the program subsidized U.S. vessels may pick up and discharge cargo at any Canadian ports on the Lakes or between Windsor, Ontario, and Sept Isles in the Gulf, but not at Halifax or Saint John. Vessels plying the route could not stop and turn around at any Canadian port without completing the full round trip to or from Europe. When business warrants, similar subsidy programs will probably also be announced from U.S. Lake ports to the Caribbean, British West Indies, the Mediterranean and the West Coast of Africa.

This will provide stiff competition for Canadian vessels plying the same route. John Paterson, president of the Dominion Marine Association, speaking at the association's nineteenth annual joint convention with the Lake Carriers Association in January, stated the DMA stand on inland waterway competition by foreign ships had already been expressed before the Coastal Shipping Commission. Briefly, DMA asked that foreign flag ships, including British vessels, should be barred from carrying on trade between Canadian coastal ports along the seaway route.

At present foreign ships are restricted in trading along U.S. coastal waters and between U.S. ports along the inland waterway. In Canada there are no such restrictions, and DMA has been pressing for restrictive legislation.

General Manager J. W. Fisher of the Canadian Shipowners Association comments that "U.S. subsidies mean the seaway will become a beautiful highway for everybody but Canadians, though Canada put up the money for it." No Canadian vessels now operate between Lake ports and Europe, and U.S. ships carry only a small part of the trade, Fisher stated. But Canadian ships have considerable trade into U.S. ports carrying pulp, paper, lumber, ore and other commodities. American ships without full loads would now be able to undercut Canadian vessels in this trade, he observed.

New Trade Route Will Influence All Canada

"Prodigious resources of hydro-electric power will be produced in conjunction with enhancement of other resources," predicted President Lionel Chevrier of the St. Lawrence Seaway Authority, addressing members of the Montreal Geographical Society, at the University of Montreal recently." On the Seaway, wheat coming down will meet iron ore being shipped upstream to Great Lakes industrial centres. In making possible this transportation of iron ore and competitive freight traffic conditions for its carriage, the seaway will create a market capable of absorbing an annual production of 10 million tons. We know mining circles foresee already the sale of 20 million tons per year, double the present annual objective."

Stressing the prospects for development of the steel industry, the speaker pointed out this industry could benefit at the same time from the hydro-electric power made available, lower freight rates, an abundant labour force, proximity to conversion industries and to markets.

Thus the steel industry would directly feed the whole metals industry, thereby aiding the whole of heavy industry and the chemical industry including manufacturing of dyes, pharmaceutical products, synthetic fibres, etc. "Such is the promise which the seaway opens to us, which we must take every step to encourage," he declared.

Speaking of water levels in the Lachine Section, he continued: "The works undertaken by the Ontario Hydro will make a decided change in water level, but in the international section alone. It is precisely to protect the interests of those downstream from the international section that the control dam at Iroquois has been set up, the object of which is to protect downstream interests, particularly those in the metropolitan area. There will exist, none the less, variations of water level caused by nature, variations originating at the head of the lakes. But floods will be no greater and no less because of the works in progress."

He further pointed out that a favourable element would be the development of hydro-electric energy in the Lachine section. Another favourable element is the ice-breakers now at work between Montreal and Sorel and performing very useful work. They can reduce flooding markedly if the channel is freed from ice during the winter months.

Great Lakes Another 'Mediterranean'?

CNR Vice-President S. W. Fairweather, addressing the Canadian Fruit Wholesalers Association in February, predicted the seaway would create another "Mediterranean," greater by far than the economic empires that have grown up in the United States after linking up raw materials in various parts of that nation. The combination of tremendous resources and cheap power in the St. Lawrence river and gulf would produce an industrial empire which can hardly be envisaged.

He classed the ports of the world as either industrial ports which thrive on sea transportation for organizing materials of production, or liner ports engaged in general distribution of the world's goods to and from their hinterland. The Great Lakes lie right in the hinterland of the two main liner ports of the continent, he pointed out, namely New York and Montreal. Great Lakes ports would become industrial ports, not liner ports.

Other Seaway News

Manicouagan First, Lachine Power Later

Premier Duplessis of Quebec reiterated in the legislature February 10 that his government intends to complete development of power on the Bersimis and Manicouagan Rivers on the north shore of the lower St. Lawrence before harnessing the Lachine rapids. The Manicouagan is now only partly developed, has a power potential of two million horsepower, and may even exceed the giant Bersimis in capacity. Legislation would be introduced concerning it.

Referring to the Mercier bridge at Lachine, he indicated there was near agreement between federal and provincial authorities on the solution to problems connected with it. The lift span had now been abandoned in favour of a plan calling for a 4 per cent elevation of the south approach to the bridge, with divided one way traffic lanes, and costing an estimated $7 million.

Federal authorities, he stated, had outlined a tunnel project for passing under the Beauharnois canal between Melocheville and Beauharnois. Including approaches the proposed four lane tunnel would be some 3,000 feet in length.

Montreal Harbour

Montreal Harbour will get improvements costing more than $12 million in 1956. Extension of grain handling facilities tops the list of some 30 projects, which includes:

Galop Island, south channel. Looking upstream at the area, encircled by haul roads, which has been unwatered and is being excavated. The upper road follows cofferdams which were built between islands.

extension to wharves 58 and 61, $1,500,000; wharves 50 to 53, $1,950,000; Sutherland pier, $400,000; Laurier pier, $400,000. Another $2,419,000 will be spent on grain elevators. A further $990,000 is earmarked for widening Jacques Cartier bridge roadway and for altering the bridge approaches.

Lake Levels

Engineers will be able to control the level of Lake Ontario by 1958 to almost completely eliminate seasonal floods. General A. G. L. McNaughton, head of the Canadian Section, International Joint Commission, said controls being built as part of the seaway would make it possible to keep water levels within safe tolerances.

Trucking

Municipal Seaway Bureau Director George Mooney of Montreal told the Quebec Trucking Association in January that it was unlikely the seaway would make major inroads into the volume and established pattern of truck haulage. "It could, however, have a disturbing effect on certain long distance commodity shipments such as automobiles, and durable goods, especially those shipped from central Canada to eastern Canada or the west."

"However, if the seaway presented stepped up competition for the trucking industry, it will also provide a new volume of traffic for truckers. Development of new areas such as Ungava will create new demand for rail and trucking services. For five months of the year, water haul is stopped, and some shippers will prefer consistently available facilities," he said.

Land Values

Farmers whose land lies in the path of the seaway power project have established a scale of land values for bargaining with Ontario Hydro. A petition is being circulated amongst the farmers on Sheek Island listing the values, to be forwarded to Premier Leslie Frost to circumvent the 'horse-trading methods' being used by Hydro's land agents. Slash and woodland is listed for $50 an acre plus value of fuel or growing timber; pasture land is valued at $50-$150 an acre; unplowed land free of trees $100, and tillable land $150 an acre.

CCA Annual Meeting at Winnipeg

The 38th annual convention of the Canadian Construction Association was held at the Royal Alexandra Hotel in Winnipeg, January 15-18, 1956. Delegates were welcomed by His Worship Mayor George Sharp. Following secretaries' seminars for builders exchange representatives on Saturday, January 14, Sunday was devoted to registrations, a management committee meeting and a reception by President W. G. Malcom.

Committee Reports

The first general session was opened on Monday with presentation of committee reports. Chairman Roy Foss of the Apprenticeship Committee, noting that volume had roughly doubled since 1945, pointed out the increase in the labour force had been brought about by a large influx of workers of varying degrees of skill from other countries and of large numbers of Canadians from other vocations. Yet the number of apprentices trained in 1955 would only be about equal to the number trained in 1954.

Recalling the president's statement last September that the number of trade apprentices should be at least doubled, he emphasized it was necessary to bring in boys interested in learning trades and willing to practice these trades after leaving training centres.

Building Committee

With the growth of both the industry and of its national association had come strong feelings that the CCA should erect its own office building.

Past President Bob Drummond, AFFIL.E.I.C., chairman of the Building Committee, recalled the opening ceremonies held on October 17 and 18 last year. Welcomes had been extended to those present, including ten past presidents, special guests and representatives of all firms who had played a sizable part in executing the project, by President Malcom and Her Worship Mayor Charlotte Whitton. The guest speaker, the Rt. Hon. C. D. Howe, HON.M.E.I.C., had unveiled a plaque marking the occasion.

Construction Equipment Committee

Chairman H. R. Montgomery, M.E.I.C., expressed his committee's view that current practices of permitting equipment to be imported on a proportionate basis of 1/60 tariff per month on temporary six month importation, and of second-hand vehicles upon payment of full tariffs and sales taxes levied on assessed value at time of importation, were on balance detrimental to the interests of the construction industry.

Contractor Relations Committee

Chairman R. F. Legget, M.E.I.C., reported that four meetings of the committee had been held, and many informal discussions throughout the year. It was clear to the committee that serious problems still remain in the field of contractor relations, although real improvement in some directions during the year was noted and welcomed; that a number of developments (such as the Toronto bid depository scheme) were beginning to yield results of interest and probably of value.

Accordingly, the committee recommended that it be continued throughout 1956 in order to continue its studies with a view to submitting periodic reports to the Management Committee and a full report to the annual meeting of the Association in January 1957.

C.C.A. Housing Report

Referring to the fact that over 125,000 dwelling units were completed last year, with a record 80,000 carryover into 1956, Chairman V. L. Leigh emphasized the minute number of Canadians with incomes less than $3,600 who finance the purchase of $5,000 or more.

His committee hoped, he said, that the 90 per cent loan provision would be expanded past the present limit and that new appraisal values would correspond closely with actual cost. It was most desirable that loan applications continue to be assessed on their individual merits and that loans be granted in those cases where the 23 per cent ratio may be safely exceeded. Open end mortgages were also recommended, to permit small homes to be enlarged at the same mortgage rate. NHA mortgages should be made available to cover purchase of existing houses, thereby enabling "trade-ins" at reduced rates.

Labour Relations

On a national basis, 1955 hourly earnings of construction workers

The Canadian Construction Association's leaders for 1956: left to right: W. G. Malcom, Winnipeg, immediate past-president, T. N. Carter, M.E.I.C., Toronto, vice-president; A. Turner Bone, M.E.I.C., Montreal, president, and H. J. Ball, Kitchener, vice-president.

had risen about 3 per cent, the same as for 1954, which meant a gain in "real" wages, reported Chairman Allan C. Ross, M.E.I.C. Higher volume had resulted in more employment, contract settlements had been achieved with more harmony and the number of work stoppages had been reduced.

It would appear that the National Joint Conference Board could be usefully reconvened to give consideration to industry trends, jurisdictional problems and apprenticeship, he said. Now that the TLC had agreed to amalgamation with the CCL it might be that it would also be agreeable to sit down with the Catholic Syndicates (CCCL) from Quebec Province.

During 1955 amendments to the Unemployment Insurance Act had been made which seemed not out of line with changed conditions.

Legislation Committee

Chairman J. Hastie Holden, M.E.I.C., pointed out that as a national organization the CCA was most concerned with federal legislation, but also submits the industry's views to the provincial and municipal governments where necessary. He recommended that builder's exchanges, provincial road builders and general contractors associations affiliated with the CCA should consider the merits of annual submissions to their provincial cabinets.

With increased opportunities for bidding on overseas construction projects, Canadian contractors were finding they were handicapped in arranging credit for foreign work by lack of insurance to cover risk of non-payment by the owner. Such protection under the Export Credit Insurance Act had been advocated by the CCA management committee last September he said, but would require amendments to the act. A resolution advocating this was before the convention for consideration.

Membership Committee

Lorne Bain, chairman, told the meeting the new membership category system, whereby each firm's classification is based on its previous year's volume, was now fully established and working successfully. The fee structure remained unchanged at the 1946 level. A breakdown of present CCA membership was as follows:

General Contractors	339
Road Builders	65
Trade Contractors	251
Manufacturers and Suppliers	341
Affiliates	33
Allied Professions and Services	38
Total	1,067

Research and Education Committee

Chairman J. D. Allan recorded awards of prizes for the 1955 CCA construction thesis competition. Announcement was also made of a $2,000 annual fellowship by the CCA for post-graduate study in construction.

Publicity Committee

Chairman W. S. Sparrow reminded delegates that the CCA's first major publicity effort was at the 1955 annual meeting in Quebec City. Complete publicity arrangements had been handled by the association itself. This departure had been a complete success and so again this year convention publicity was being handled by the CCA staff.

Sales Tax Committee

Chairman G. A. Burnett recalled that the CCA had made detailed representations over a number of years that present exemptions to the federal sales tax be expanded to cover the remaining materials still subject to the tax. A more detailed submission had been made to Finance Minister Walter Harris following his appointment.

In subsequent submissions to the Department of Finance sales tax committee, changes were advocated. The committee felt that the Association should continue to press strongly for the extension of sales tax exemption to include all construction materials.

Standard Practices Committee

Chairman E. V. Gage, M.E.I.C., told the meeting that his committee's main achievement for 1955 had been completion of a lengthy revision of the standard cost-plus-fixed or -percentage fee contract form. The English form had been published jointly with the RAIC in July and a French translation had followed in January 1956. Engineers' versions of both the revised lump sum and cost-plus-fee contract was soon to be available. With these major forms revised, his committee was turning to revisions of the standard form of sub-contracts and form of construction tender.

The final draft of the "suggested guide to bidding procedure", developed by the CCA-RAIC-EIC joint committee on tendering practices in June 1953, had now been returned by the RAIC with deletions. An early meeting with the RAIC had been suggested for discussion.

Joint meetings had been held by the committee with officials of Defence Construction Limited and the Department of Public Works, at which problems were discussed fully and frankly, particularly the expediting of clean-up work on DCL projects. Later, meetings were arranged in a dozen cities between DCL officials and local builders exchange officials to discuss tendering and contract procedures.

CCA Office Reports

S. D. C. (Don) Chutter, whose appointment as general manager of the association had been confirmed last April, then outlined the activities of the CCA headquarters staff at "Construction House" in Ottawa during the past year.

Reviewing costs, he presented statistics showing that residential and non-residential basic construction costs had moved upwards about 2 per cent in 1955 after a year of relative stability, according to CMHC indexes. Both material prices and wage rates had advanced in 1955. Prices of non-residential building materials increased in almost every month up to November, the latest month for which the DBS indexes were available. Residential building materials prices rose throughout the first three quarters of 1955 but held firm in October and November. Average wage rates for construction workers in 1955 were about 2 to 3 per cent higher than the previous year compared to increases of 1 to 2 per cent in average building material prices.

President's Address

CCA President W. G. Malcom of Winnipeg, addressing delegates at the first day's luncheon session, remarked 1955 had been the first year any CCA president had been able to report the completion of over $5 billion of construction in the year just ended. Prospects for the 1956 volume would equal and probably exceed the 1955 total, with some 30 per cent of it in Western Canada, he said, though the total would possibly be limited by shortages of materials such as steel, rather than by shortages of investment capital.

The industry's post war operations had served to act as one of the most powerful stabilizing influences for our overall economy, giving $2 billions of purchasing power to over half a million Canadians, while spending of $3 billions for materials and equipment meant employment and pay cheques to an even greater number employed in manufacturing, transportation and merchandizing operations, he said. So much of the Canadian economy relied on the construction program that a sizable reduction in it would not only affect adversely the industry itself but also our general economy.

Legislation affecting taxation, depreciation, credit and interest rates, as well as policies concerning immigration and trade, might well influence the construction of even a greater volume of privately financed projects than is represented by our public works programs, he observed. Privately financed work amounted to over three quarters of total volume, and it was vital that governments give prime attention to encouraging a business climate that in turn would encourage individuals and organizations to invest in and build for the future.

The industry itself could also help, he pointed out, by maintaining costs at levels that would encourage investment, by increasing the current rate of production of materials and equipment, by a stepped up training program for tradesmen and engineers, by development of new techniques, materials, and labour saving devices, and by continuing to expand the length of the construction year by increased wintertime work.

Guest Speaker at Annual Banquet

The Hon. Milton F. Gregg, Federal Minister of Labour, the guest speaker at the annual dinner, pointed out that expenditures on construction accounted for a growing share of the national income, from 15 per cent in 1947 to 17 per cent in 1950 and to almost 20 per cent last year. This meant Canadians were willing to invest more and more heavily in their nation's future.

Workers had shared in the industry's prosperity, he stated, average weekly earnings had recorded a sharp rise in recent years, from $41.98 in September, 1950, to $63.35 in September, 1955, a gain of 50 per cent. Compared with this the gain for nine leading non-farm industries had been 38 per cent.

Industrial disputes, he declared, were seldom the major cause of lost work and income in industry. Seasonal unemployment by far overshadowed disputes as a cause of lost working time.

A cabinet directive to all federal departments and agencies last summer had instructed them to do all possible to create a maximum of winter employment. Steps designed to increase winter work had also been taken by many provincial governments across Canada. Efforts in this direction were not entirely focused on the construction industry. Educational efforts through posters and radio and articles in the press were being undertaken on a broad national scale this winter.

CPA President's Address

Tuesday sessions were devoted to sectional meetings of general and trade contractors, manufacturers and suppliers and road builders. The guest speaker at the second luncheon was Vernon Taylor, manager, Western Canada Regional Production Department, Imperial Oil Ltd., representing the board of governors of the Canadian Petroleum Association.

Outlining the spectacular oil and gas developments since the discovery at Leduc in 1947, he observed that in 1945, oil had supplied only some 30 per cent of Canada's energy requirements while today it enjoyed close to 49 per cent of the market. In 1945 natural gas had supplied only 3 per cent of the demand for energy, while today it enjoyed a 5 per cent share. In the next five years the gas share should be about 7½ per cent, or an increase of 50 per cent.

The provision of adequate outlets for gas, he predicted, would act as a stimulus to the oil industry which had, as it were, to fly on one wing due to the absence of an economic market for natural gas. By 1960 oil reserves, presently estimated at some 3 billion barrels, should be approaching 5 billion barrels. By that time the oil potential or maximum efficient rate of production could be in excess of a million barrels daily.

The second dinner meeting was addressed by the Very Rev. John Burton Thomas, D.D., Rector of St. John's Anglican Church, Winnipeg, Dean of the Diocese of Rupertsland and immediate past president of the Winnipeg Rotary Club.

Closing Day

With the issue to members of a statement of CCA policy was included a list of 13 draft resolutions approved for discussion by the Management Committee at its December meeting.

At the Wednesday luncheon the election and installation of officers for the ensuing year took place. Alan Turner Bone, M.E.I.C., of Montreal, was elected president, with T. N. Carter, M.E.I.C., of Toronto, and H. J. Ball of Kitchener as national vice-presidents. Following a joint meeting of 1955 and 1956 executive committees a reception and buffet dinner were held, ending with a "Western Jamboree."

Thirty-five Years Ago

Comment on the *JOURNAL* of March 1921

The farewell addresses of our retiring presidents have followed pretty much of a pattern, tinged a little by the personality of the author. Each speaker has felt that there were perforce certain topics with which he must deal—membership, finances, the continuing struggle for greater public recognition of the engineer as a professional man, more adequate salaries, engineering education—and the results have sometimes been pretty humdrum. And almost every retiring president has tried his hand at a little prophecy, with all the rewards prophets are said to receive.

But once in a while the Institute has been lucky enough to have for its president a member who was not only distinguished in the profession, but who was also widely informed in other fields. Such a man was R. A. Ross, whose presidential address is published in the *Journal* of March, 1921.

I knew Ross pretty well, because I worked intimately with him during his term of office. He had a keen engineering mind and his professional advice was sought by many. But he was also a fair Latin scholar and had a good command of at least three modern languages. His reports were models of accuracy and brevity, though I could never agree wholly with one of his axioms, "Never tell a client any more than you have to." He had an interest in the fine arts, but I do not recall that he practised any of them, even in an amateur way.

President R. A Ross

From such a man one might expect a presidential address somewhat out of the ordinary and that is exactly what we got. I wish the *Journal* had room to reprint it in full here, but since that is not possible, we shall have to be content with some excerpts.

He got his hearers into an amiable frame of mind by saying, "When . . . the president lays down his office, divests himself of his robes, his staff and his mitre, leaving his . . . blessing and his portrait behind in the Valhalla of the Institute . . . the occasion demands a swan song, the usual chorus from the audience being, 'How long, O Lord, how long'?"

He thought that engineers ought to apply "pressure of whatever kind most appeals to the politician" to secure appointments to public bodies where their training and experience were most needed. Further, he said, "One engineer . . . applying himself to . . . (public) problems will be of more service to the profession in determining its status than ninety and nine who devote themselves to purely technical matters."

He pleaded for some integrated organization which would bring together all from "the pure dreamer without practical sense," through the "speculative researcher," the "industrial researcher" and the "engineer" to the "industrialist." He was decidedly of the opinion that such a group should develop a class consciousness, because "no profession ever emerged until it had become self conscious and organized itself on a caste system and no profession ever will."

Mr. Ross thought we ought to angle for more associates and affiliates. I wonder if he hadn't something there. "Thus, we can draw to our side those industrial leaders . . . who loom largest in the public view. . . . We need the researchers who will someday rend the atom . . . and develop means for transforming atomic energy into commercial power . . ." Prophecy speaks here; remember that these words were written in early 1921.

"Those about to be born salute you. Have we not a house prepared for them with accommodation for all?" With this paraphrase of a familiar quotation Mr. Ross concluded one of the best and most thoughful presidential addresses we have ever had.

Toronto Annual Meeting

Of course, the presidential address did not fill the *Journal*. It had a running account of the Toronto annual meeting; compressed biographies of the new officers and chairman of committees.

Radio Then

Though not entirely prophetic, an address delivered to the Hamilton Branch was partly so. The vice-president of the International Radio Telegraph Co. spoke on "Progress and Achievements in Radio Engineering," saying that his company was broadcasting from Pittsburgh "concerts, news items and weather and market reports." This service . . . is . . . by radio telephone, so . . . knowledge of the Morse code is not required. . . . Musical selections are sometimes specially rendered for this service. . . . Every Sunday evening the . . . services of a church . . . are sent out. These have been listened to as far away as Texas, Maine and Ontario. . . . The day has already arrived when . . . (a) country household . . . can listen . . . to what is going on in the city, and it is easy to foresee the time when houses will have, beside a gramophone for entertainment, wireless telephone for both news and entertainment."

Highways and Harbours

There were two technical papers in this *Journal*: "Construction of the Toronto-Hamilton Highway," by H. S. Van Scoyoc, A.M.E.I.C., and "Toronto Harbour Improvements," by E. L. Cousins, A.M.E.I.C. Both projects had been much delayed by wartime restrictions, but the one was now completed and the other well on its way.

The Toronto-Hamilton highway was conceived partly as an unemployment relief measure. It was the first long stretch of concrete road in this country, and, it appears only the second example of concrete paving of any kind, some having been previously laid in Sarnia, Ont. Construction methods were crude by today's standards, but the results were nevertheless excellent. Compressive strengths at 28 days of concrete mixed more or less by rule of thumb ranged from 2700 to 4500 lb. per sq. in., if we omit one set of samples which were obviously too sloppy, not at all bad for those days.

The Toronto Harbour Commission was almost as much concerned with the reclamation of the lands within its jurisdiction as it was in the improvement of navigation and wharfage facilities, so a good part of Mr. Cousins' paper described the filling operations of an ultimate 1900 acres. Not all of this had been finished in 1920, but about 270 acres had been leased to industrial firms by that time and they had spent some $8 million in its development. Work has continued since 1920, so that now Toronto is perhaps as well prepared for the advent of the Seaway as any lake city.

Elections and Transfers

At the meeting of Council held at the Empress Hotel, Peterborough, Ontario, on Saturday, February 25th, 1956, a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

Members:

R. O. Beauchemin, *Montreal*
G. S. Grimmer, *St. Andrews*
L. J. Macdonald, *Montreal*
A. J. McLaren, *Kenogami*
H. Meier, *Toronto*
C. G. Miller, *Montreal*
C. M. Mitchell, *Calgary*
K. M. Oddson, *Winnipeg*
F. D. Ross, *Toronto*
R. F. Swain, *Halifax*
W. A. Webster, *Collingwood*

Juniors:

L. C. Laferriere, *Montreal*
A. Rozanski, *Hamilton*
H. W. Siemens, *Arvida*
J. R. Soy, *Shawinigan*
B. J. Swain, *Montreal*

Transferred from the class of Junior to that of Member:

F. D. Butler, *Corner Brook*
R. E. Crysler, *London*
W. L. Dodson, *Sydney*
G. B. Dowdell, *Toronto*
E. L. Fytche, *Rio, Brazil*
O. I. Johnson, *Trail*
J. D. Lambert, *Montreal*
R. E. J. Layton, *Montreal*
R. G. Meek, *Montreal*
B. F. Reimer, *Trail*
R. Westwood, *Chalk River*
A. G. Wilson, *Ottawa*

Transferred from the class of Student to that of Junior:

G. L. Genest, *Ottawa*
D. M. McLaurin, *Hamilton*
R. M. Moore, *Trenton*
K. D. Tuddenham, *Halifax*

The following Students were admitted:

University of Toronto

D. R. Baker — W. S. Melinyszyn
K. J. C. Harries — R. Olech
T. T. Heike — W. S. Pick
E. J. Levy — K. A. Selby
O. V. Martini — J. Waggott

Nova Scotia Technical College

L. R. Baril — F. R. MacMichael
I. P. Campbell — J. C. Maurais

University of New Brunswick

D. H. Baker — R. M. Nason
G. M. McDonald

University of Alberta

D. M. Mawdsley — L. J. Schneider
E. O. Olsen — R. D. Steed

University of Manitoba

W. Anhang — G. Manchur
M. P. Enders — T. D. Rooke

Dalhousie University

P. F. Adams — P. A. Ehler
D. H. W. Dibblee — R. G. Hill

Queen's University

G. W. Bracken — G. W. Browne

McGill University

K. C. MacKenzie

Mount Allison University

L. D. Johnston

Carleton College

G. N. Fulford

Graduates

M. Bloch, B.Sc. Civil, Manitoba, 1955
J. W. S. Marshall, B.Sc. Elect., Queen's, 1955
L. Marzec, B.Sc. Engrg. Physics, Queen's, 1955
L. P. Mendes, B.A.Sc. Civil, Laval, 1955
L. Itiniant, Student, A.P.E. of Ontario
L. A. J. Lalonde, Student, A.P.E. of Ontario

Applications through Associations:

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections have become effective:

ALBERTA

Members:

A. J. Arens — E. J. Burge
R. A. Vair

Junior:

G. D. Langereis

Extending Winter Work

As the result of a meeting in July, 1955, sponsored by the Department of Labour, an independent joint committee was set up under the chairmanship of Raymond Brunet, O.B.E., president of the Canadian Construction Association, to spearhead on a national level efforts across the country to increase the volume of winter-time construction work and so to reduce seasonal unemployment.

Represented on the committee are the Canadian Construction Association, Canadian Manufacturers Association, the Royal Architectural Institute of Canada, the Labour Congresses, National House Builders' Association, Canadian Chamber of Commerce, and the Engineering Institute of Canada. The National Research Council is also taking part in the project.

W. B. Pennock, M.E.I.C., has accepted the invitation of the Engineering Institute to be their representative on the committee.

News of Other Societies

Fifth World Power Conference (Canadian Committee, Room 500, 150 Wellington St., Ottawa 4, Ont.) . . . Vienna, June 17 - 23, 1956. The theme of the conference is "World Energy Resources in the Light of Recent Technical and Economic Developments". Main divisions of the program are as follows: I—The State and Development of Power Production and Utilization in Individual Countries; II—The Preparation and Conversion of Fuels; III—Utilization of Primary Sources of Energy; IV—Purification of Waste Water and Waste Gas in the Production and Use of Energy; V—International Collaboration in the Production and Use of Energy.

The General Program is now available, giving complete information about technical sessions, tours, and travel. The program contains instructions for participants, and forms which must be returned to the National Committee in the participant's country. The membership fee of 1,200 Austrian Schillings is to be submitted with "Form A — Application for Participation" to the National Comittee. "Form C — Travel and Hotel Accommodation" must reach a Cook/Wagon-Lits Travel Office not later than April 30, 1956.

For further information, programs and forms, please contact the Canadian Committee.

●

Institution of Electrical Engineers (Savoy Place, London W.C. 2). . . . a convention on Electrical Equipment of Aircraft is announced for May 2-4, 1956 in London. Twenty papers to be presented.

American Society of Tool Engineers (10700 Puritan, Detroit 38). . . . Invites papers to be presented to the 25th anniversary annual convention, April 1957. ASTE membership is not required, and papers will be accepted for consideration until May 1, 1956. Outlines of proposed papers, with information about authors should be sent to L. S. Fletcher, program director of ASTE. . . . The 1956 annual convention will be in Chicago, March 19-23.

●

The American Concrete Institute will hold its 1956 regional meeting in Montreal, October 24-25, in the Mount Royal Hotel. . . . E.I.C. members may attend on the same basis as A.C.I. members. . . . Suggestions for papers are invited and information can be obtained from M. F. Macnaughton, c/o Mount Royal Paving and Supplies Ltd., P.O. Box 2000, Rosemount, Montreal.

●

Canadian Technical Asphalt Association (1166 West Pender St., Vancouver 1). . . . D. T. Willis of the Provincial Department of Highways was named the first president of the new Association in October.

●

Operation Research Society of Toronto. . . . Growing Canadian interest in industrial operations research has led to the formation of this Society by Toronto industry, university, and research organizations. Officers are: president, Dr. Peter Sandiford; vice-president, Dr. Josef Kates; and secretary-treasurer, Eric Sorensen.

Information received through co-operation with the provincial organizations

Ontario

Brief on Canada's Economic Prospects

A recommendation that the facilities of Canadian engineering schools be expanded by almost double their present size to accommodate the growing trend in engineering student enrolment has been made by the 14,000-member Association of Professional Engineers of Ontario.

In its 2,500-word brief to the Royal Commission on Canada's economic prospects, the Association suggests that such an expansion program should begin immediately and continue for the next five years. It estimates the cost at $60 millions. At the same time, the A.P.E.O. also calls for $10 millions for providing additional research and laboratory equipment in the engineering schools to meet the increased enrolment.

The brief also recommends that a study be taken at once to seek ways and means of improving the position of engineering staffs with consideration being given to the following: staff salaries and loads; recruitment of senior staff; funds to permit graduate study in engineering schools of other countries by junior staff; introduction of some form of attractive tax deduction to encourage more liberal support of engineering schools by industry; expansion of senior technical schools facilities; that industry be urged to accord professional recognition to engineering staff.

According to the brief, the proportion of professional engineers to the total working force in Ontario in 1955 is 1 to 145. Ten years ago, it was 1 to 368. The brief forecasts that by 1965, the proportion will have been reduced to 1 to 100.

The increase in proportion is due in part says the brief, to the increasing complexity of technology in industry, and a very serious present shortage of professional engineers in the Public Service at all levels. This shortage is said to be the result of government's unwillingness to align its salary rates with those paid by industry.

"We feel that Canada is much more urgently in need of the highest level of technological manpower than most other countries. This is due to the fact that 25 per cent of our annual production is exported. In many lines of manufacture we cannot compete in the world market on the basis of labour costs and therefore must resort to other devices . . . such as excellence of engineering in design, production and invention. That Canada is capable of such technological pioneering is evidenced by our contributions in atomic fission and jet plane development.

In its reference to professional recognition, the Association's brief points out that it is essential that employers of professional engineers give greater consideration to this condition. The Association adds that it is in the best interest of industry and the country's economy that the professional engineer subscribe to his one loyalty—his professional body. It points out that there is some tendency on the part of engineers employed in large numbers by individual companies to lean towards unionization in order to secure adequate consideration by employers of salaries and working conditions. It further recommends that government at all levels should be leading the way in ensuring that professional recognition is accorded members of the profession in the Public Service.

R. L. Hearn Receives Highest Honour

Ontario Hydro Chairman Richard L. Hearn has received the highest honour accorded an engineer by the Association of Professional Engineers of Ontario.

The coveted Professional Engineers' Medal, struck in 1946, and awarded to only four persons since that time, was presented to Dr. Hearn on January 28 during the Association's annual luncheon meeting in Toronto. More than 1,000 members of the Association from all parts of Ontario as well as representatives from other provinces and the United States attending the meeting.

The Engineers' Medal was awarded Dr. Hearn, not only for his contribution to Canadian engineering as a hydraulics authority but for his more recent prominence in the realm of atomic energy. He has been instrumental in making available considerable information on atomic energy for peaceful uses to Canadian industry and also in encouraging industrial enterprises to develop their own reactors.

The actual wording of the illuminated citation which accompanied the award read: "The Professional Engineers' Medal presented by the Association of Professional Engineers of Ontario for outstanding achievement by one of its members is awarded to Richard Lankaster Hearn, B.A.Sc., D.Eng., P.Eng., Chairman of the Hydro-Electric Power

The Professional Engineers' Medal is awarded to Dr. Richard L. Hearn, right, chairman of the Ontario Hydro, by Dr. G. R. Lord, left, for his outstanding achievements in the sphere of hydro-electrical engineering and for his contribution to the welfare of mankind in furthering the application of nuclear fission in peacetime uses.

Commission of Ontario for his distinguished accomplishments in the sphere of hydro-electrical engineering and for his contribution to the welfare of mankind in furthering the application of nuclear fission in peacetime uses."

The four previous recipients of the medal are Rt. Hon. C. D. Howe, Dr. C. R. Young, Gen. A. G. L. McNaughton and Dr. J. B. Tyrrell.

Recognized internationally as one of Canada's most eminent professional engineers, Dr. Hearn has been associated with many of Ontario Hydro's major undertakings since joining the Commission more than 40 years ago. As its chief executive he has played a leading role in Hydro's unprecedented power expansion program embracing major hydro-electric projects and Canada's largest steam generating installation. Latterly, he has applied his wide experience to studies of the future possibilities of producing electrical energy from atomic power.

Gold Medal Award

The Association of Professional Engineers of Ontario presented its Gold Medal award to the two engineering students graduating with the highest standing from University of Toronto and Queen's University at its annual luncheon meeting on January 28 in Toronto.

The two recipients were I. M. Duck, Kingston, of Queen's University, who is now associated with the University of British Columbia; and M. T. Grisaru, Toronto, of U. of T., who is now taking post-graduate studies at Princeton, N.J.

The awards, presented annually, also include $50 in cash to be used by the winners in the purchase of text books.

The Association also provides a $450 university entrance scholarship which is awarded alternately at University of Toronto and at Queen's to the student with the highest academic standing entering the Faculty of Applied Science. In addition, the Association grants 18 annual scholarships to University of Toronto and Queen's students in first, second and third year of $100, $75 and $50 respectively.

News of Members

Francis C. Kresz, of Toronto, has been named honorary president of the recently formed Club of Hungarian Engineers. **Michael Vegh,** also of Toronto, is the acting president of the Club.

Andrew S. Zakrzewski is president of Pneuma-Serve Ltd., of 42 Queen Elizabeth Boulevard, Toronto 14.

The Company, which has recently been organized, is licensed by Taymouth Industries of Toronto to manufacture and distribute Pneuma-Service Screw Feeding devices in Canada. Mr. Zakrzewski states that his company intends to specialize in the field of automation as well as the development and manufacture of special machines.

Frank W. Roberts, the assistant supervisor of the Hillcrest Shops of the Toronto Transportation Commission, is the author of a recent paper "The Electrical Equipment of the Toronto Subway Cars" which appeared in the Proceedings of the Institution of Electrical Engineers of October, 1955. The paper won for Mr. Roberts the IEE Oversea Premium.

Mr. Roberts graduated from the University of London in 1939 and was with the traction division of Crompton Parkinson until 1952 when he joined Bepco and six months later came to Canada. He left Bepco Canada in 1954 to join the Toronto Transportation Commission. His paper, referred to above, was first presented at a joint meeting of IEE and EIC members in Toronto in October, 1954.

John R. Baker has been appointed assistant manager of the central district at Toronto of the Linde Air Products Company Division of Union Carbide Canada Ltd.

Mr. Baker graduated in mechanical engineering from the University of Toronto in 1949 and has been with the company since that time.

Dr. Joseph Kates, of KCS Data Controls Ltd., has been appointed vice-president of the recently formed Operations Research Society of Toronto. The president of this organization is **Dr. Peter Sandiford** of Ontario Hydro, and **Eric Sorensen** of the British American Oil Co. Ltd. is secretary-treasurer.

The new society is governed by a committee representative of industry, universities, and research organizations. Industrial operations research is defined as "the objective analysis of factual information in order to develop relationships which so define a situation that alternate courses of action may be visualized and their consequences forecast in a manner capable of verification in practice."

Several members of the Toronto Society have presented technical papers before the recent annual meeting of the Operations Research Society of America, at Ottawa, early in the new year. This was the American Society's first meeting in Canada.

George F. Knight, assistant general manager of the Consumers' Gas Company of Toronto since 1952, has resigned because of other business plans.

Mr. Knight, associated with Consumers' Gas for 13 years, was responsible for all the company's outside operations, including the transmission of natural gas from the Niagara frontier, expansion of facilities and other planning and of Toronto distribution and service. He was on the board of directors from 1951 until 1954.

A graduate of Manchester College of Technology in England, George F. Knight began his career in engineering and in the manufactured gas industry in that country. He later went to the United States where he supervised construction and maintenance of boiler plants, material handling equipment, chemical plant equipment and gas production plants, including the big Station "A" plant of Consumers' Gas—closed down after arrival of natural gas early last year.

He joined Consumers' Gas in 1942 as engineer in charge of construction and maintenance, and became general superintendent of works in 1946, in charge of all the company's manufacturing facilities.

Col. H. C. Craig has recently retired from the Department of Northern Affairs and National Resources, Ottawa, and is now living in Cobourg, Ont. An engineering graduate of Queen's University, Kingston, he has been engaged in engineering and administration work of federal departments for many years. During the First Great War he was an officer in the Royal Air Force overseas and in command of repair parts and depots for aircraft and transport equipment. For a period following that war he was director of equipment for the Dominion Air Board. Latterly Col. Craig has been financial advisor in the Department from which he has just retired.

D. W. Knowles is chief engineer, gas turbines, government and industrial products division of Studebaker-Packard Corporation, Detroit 32, Mich.

Mr. Knowles, who obtained his degree in engineering at the University of Toronto in 1942, was formerly with the Continental Aviation and Engineering Corporation, also of Detroit.

George F. Martin, of Union Carbide Canada Ltd., has been transferred from Welland, Ont., to Toronto where he is assistant to the manager of purchasing. Prior to this change Mr. Martin was assistant to the superintendent of the electro-metallurgical division in Welland.

Donald R. Steele has left Philco Corporation of Canada Ltd., to join the Minneapolis-Honeywell Regulator Co. Ltd., aeronautical division, Toronto, as a field service engineer. Prior to undertaking his duties he is attending a course of instruction in the Minneapolis plant of the company.

Ferdinand De Maio has joined the development and engineering department of the Canadian Liquid Air Company Ltd., Toronto. Mr. De Maio was formerly employed by Steel Company of Canada Ltd., in Hamilton, Ont.

J. Charles Honey, of Canadian Johns-Manville Co. Ltd., calls attention to the fact that the company's new office and warehouse is located at 565 Lakeshore Road East, Port Credit, Ont.

Clarence W. Johnson, of Windsor, Ont., has been named president of Canadian Sirocco Company Ltd. Current with this announcement is that of the appointment of **Richard R. Noyes,** as vice-president of sales.

Mr. Johnson, who is an engineering graduate of the University of Wisconsin, joined Canadian Sirocco in 1932 as a district manager and during the following five years was sales engineer for American Blower Corporation, the parent company. In 1944 he was made vice-president of the Canadian organization.

Mr. Noyes, a University of Toronto graduate, joined the company in 1936 immediately following graduation. He served as a sales engineer and then as district manager in the Montreal area until his appointment as sales manager in 1952.

P. E. Kent, formerly fire prevention engineer with the Ontario Fire Marshall's office, is with the Canadian Standards Association, Weston, Ont., in the capacity of a test engineer.

Manitoba

Annual Dinner Meeting

The annual meeting of the Association of Professional Engineers of Manitoba was held in the Marlborough Hotel on the evening of January 19. The meeting was preceded by a dinner attended by a large body of the membership as well as the following guests: C. N. Blankstein, president of the Manitoba Association of Architects; J. A. Merchant, registrar of the Association of Professional Engineers of British Columbia; E. J. Durnin, president-elect of the Association of Professional Engineers of Saskatchewan, and T. M. Medland, executive director of the Association of Professional Engineers of Ontario. After dinner the gentlemen from the other provinces made some very interesting comments on their own Associations.

Internal Public Relations

Mr. Merchant discussed public relations as practised by the B.C. Association. Some of the highlights of their program included what he called "internal public relations"; the forming of Toastmaster Clubs in Vancouver, Victoria and Nelson, and a system of awarding certificates to the young engineers qualifying for membership in the Association at a public gathering about twice a year. He felt that these events would stimulate interest and pride of the members in their Association and that publicity was only of secondary importance. He stressed building from within as the best means of achieving good public relations.

Trade Unionism

Mr. Durnin of the Association of Professional Engineers of Saskatchewan gave an interesting talk on the effect of trade unionism on engineers in that province, particularly in regard to the provincial government. It was pointed out that engineers as well as members of other professions, were required by law to be members of trade unions. At present the Saskatchewan Association is making every effort to persuade the government to enact legislation which will eliminate this practice.

Salary Schedules

T. M. Medland, executive director of the Ontario Association of Professional Engineers discussed Ontario's pioneering in the field of salary schedules. It was generally felt by those present at the meeting that the obtaining of a reasonable salary schedule was a very difficult and arduous task, and that Mr. Medland and those who assisted him in this project were to be congratulated for their efforts and the satisfactory results.

After the speeches the meeting adjourned and was reconvened later by the president who presented his annual report to the Association. The highlight of the president's report was the formation of a full time office with a permanent secretary to assist C. S. Landon in his multitudinous duties. The membership had indicated previously by secret ballot their willingness to have such an office set up and the president was applauded for his efforts.

Following this message, the reports of the committee chairmen on Public Relations, Consulting Engineering, Social Functions, Examination Requirements, and the Advisory Committee were heard. There was some lively discussion and some disagreement of the work done by the committees, but generally it was felt that they had rendered good service.

J. Hoogstraten Is New President

The scrutineers' report was then given and a list of the elected Council members for 1956 was read. After a short recess, the Council then elected by secret ballot the officers, as follows: president, J. Hoogstraten, professor of engineering at the University of Manitoba; vice-president, N. Bubbis, director of the Greater Winnipeg Water District; secretary, C. S. Landon. Council Members are G. W. Moule, contract engineer, City of Winnipeg Hydro-Electric System; W. L. Wardrop, consulting engineer; D. M. Stephens, chairman and general manager of the Manitoba Hydro-Electric Board; L. A. Bateman, general superintendent of production, City of Winnipeg Hydro-Electric System.

The meeting adjourned at 10.30 p.m.

Former deputy minister of Manitoba's Public Works Department, M. A. Lyons, left, was honoured in Toronto with a life membership in the Manitoba Association of Professional Engineers. He served as its first president when it was established in 1920. Now a resident of Toronto, Mr. Lyons is the first to be so honoured by the Manitoba Association. Presentation was made by Georges Demers, Quebec, president of the Dominion Council, during the annual meeting of the Association of Professional Engineers of Ontario.

British Columbia

Engineers in the News

J. W. Birch has resigned his position with Hopkins Exploration Consultants and is now employed in the engineering department of Algom Uranium at Quirke Lake Mine, Algoma Mills, Ont.

Mark Robinson, previously of the B.C. Engineering Company, is now with Alaska Pine and Cellulose Ltd. He expects to work in the Vancouver office for a few months before going to Port Alice as assistant resident engineer.

N. E. Cooke, who recently received his Sc.D. degree in chemical engineering from the Massachusetts Institute of Technology, has accepted a position with Canadian Industries Ltd., in Montreal.

Robert M. Martin recently retired from his position with the Indian Affairs Branch, Department of Resources and Development.

J. C. Garnett, has been appointed city engineer of Victoria. He had been assistant city engineer and, recently, acting city engineer during the illness of his predecessor, **Cyril Jones.**

D. J. Baker, a graduate of the University of British Columbia, civil class of 1949, was recently in Vancouver for a short visit. He is with Lockwood, Kessler and Bartlett, Inc., and has been working in Colombia for the past few years.

J. C. Bowling, formerly a design engineer with the B.C. Engineering Company, is now with the Dominion Construction Company at Port Alberni.

G. J. Gill, has accepted a position with the Foundation Engineering Company in Vancouver. He was formerly with the Department of Public Works of Canada.

F. Leipert has left the firm of Gardner and Thornton to accept a position with the B.C. Engineering Company.

R. G. Urquhart is now working as a field engineer for H. A. Simons Ltd. at Port Alberni. He was previously with the B.C. Electric construction department at Lillooet.

W. B. Gale of the B.C. Power Commission was recently transferred from Williams Lake to the head office in Victoria, where he will take up the position of assistant to the superintendent of power districts.

J. P. Sullivan has left the employ of H. A. Simons Ltd. and taken a position with **D. W. Thomson.**

A. W. S. Stuckey is now with Foundation Engineering Co. Ltd. in Vancouver. He had previously been with R. N. Hardy and Associates Ltd. in Edmonton.

R. N. McLellan has moved his recently established consulting practice to 1166 W. Pender St. Mr. McLellan specializes in aerial tramways, cableways, light suspension bridges and general wire rope engineering applications.

S. P. Fox is now with the Canadian Institute of Timber Construction at Ottawa. He had previously been working in Toronto.

J. E. Schoevaars has accepted a position with H. A. Simons Ltd. He was previously with the Wieser Lock Company of Canada.

D. J. Baker, formerly with Lockwood, Kessler and Bartlett, Inc., in Colombia, S.A., has accepted a position with B.C. Concrete Co. Ltd. in Vancouver.

W. E. Kenny, of the B.C. Power Commission, was recently promoted from maintenance engineer to operations engineer, and will move from Nanaimo to Victoria to take up his new duties.

Charles Bentall recently assumed the duties of campaign chairman for the B.C. Heart Foundation. Mr. Bentall is a member of the board of directors and has played a leading role in the establishment of the organization.

S. D. Cavers is now research engineer with the B.C. Research Council at the University of British Columbia. He was formerly with the department of chemistry at the University of Saskatchewan.

G. W. C. Lake, until recently municipal engineer of the District of Richmond, has accepted a position with Canadian British Associates in New Westminster.

E. B. Jakeman, a 1955 civil engineering graduate of University of British Columbia, is now working for Mobil Oil of Canada at Drayton, Alta.

W. Hemerling has accepted a position with Foundation of Canada Engineering Corporation Ltd. in Vancouver. He was previously on the design staff of the B.C. Engineering Company.

W. S. Jackson, of the water rights branch, Department of Lands and Forests, has been promoted from assistant hydraulic engineer to assistant district engineer.

F. E. Rutquist has left Wells, B.C., where he was mill superintendent with the Cariboo Gold Quartz Mine, and is now living in Calgary. He is plant manager with the Alberta Ytong Manufacturing Company, makers of light-weight cellular building blocks.

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Norman Keith Cameron, M.E.I.C., partner of the firm Cameron and Phin, contractors in Welland, Ont., died on December 24, 1955.

Mr. Cameron was born in Strathroy, Ont., on January 7, 1883, and received his education at the Royal Military College in Kingston, Ont. His early experience was gained with the Transcontinental Railway and with the Hydro-Electric Commission of Ontario, working on transmission lines in Ontario. In 1907 he was with Larkin and Sangster, contractors, engaged on the Trent Canal. He also worked on the Welland Ship Canal from 1913 to 1915. During the First World War Mr. Cameron served overseas with the Canadian Expeditionary Force. At the end of the war he returned to Canada and spent some time working on the Cornwall Canal at Cornwall, Ont., until 1921 when he went to New Brunswick and was in charge of concrete work for the Saint John Dry Dock and Shipbuilding Company. In 1928 Mr. Cameron went into partnership and formed the firm of Cameron and Phin, contractors, in Welland, Ont.

He joined the Engineering Institute in 1922 as an Associate Member and transferred to Member in 1940. Mr. Cameron attained Life membership in 1954.

Edmund J. Bolger, M.E.I.C., who was recently with the Cartier Construction Company on the Bersimis River Project at Forestville, Que., died on October 19, 1955.

Mr. Bolger was born in Belleville, Ont., on March 24, 1886. He attended Queen's University for two years studying civil engineering and then in 1916 enlisted in the Royal Canadian Engineers. He saw service overseas and retired from the Army with the rank of major following the end of the war.

Prior to attending Queen's University, Mr. Bolger was with the Transcontinental Railway as resident engineer and locating engineer at La Tuque, Que.

In 1924 he was with Hollinger Consolidated Gold Mines Ltd. at Timmins, Ont. Mr. Bolger subsequently spent many years in Northern Ontario engaged in the mining industry. He became mine manager in 1943 for Eldorado Mining and Refining Ltd. at Port Radium in the Northwest Territories, and in 1947 came to Ottawa as assistant to the president for the company. In 1953 he became associated with the Cartier Construction Company on the Bersimis project.

Mr. Bolger joined the Engineering Institute in 1904 as a Student. He transferred to Junior in 1911, Associate Member in 1915, and to Member in 1940. He attained Life membership in 1950.

Jean Paul Boucher, JR.E.I.C., director and general manager of St. Denis Construction of Ville Jacques-Cartier, Que., died on August 24, 1955, in Montreal, following an explosion which occurred during an inspection tour of work completed by the company in Longueuil, Que.

Mr. Boucher was born in Sorel, Que., on October 22, 1918, and received his general education there, and in St. Hyacinthe, Que. He graduated from Ecole Polytechnique in 1946 with a B.A.Sc. degree in civil engineering. He spent some time as instrumentman with Marine Industries Limited at Sorel during vacations from his university courses.

Immediately following his graduation he joined J. A. Lalonde and Company Ltd., consulting engineers in Montreal, as field engineer. He remained with this company until 1953 when he became associated with St. Denis Construction as general manager and director.

Mr. Boucher joined the Engineering Institute as a Student in 1942 and transferred to Junior in 1948.

John Alexander Reid, M.E.I.C., mining engineer, died on December 28, 1955, at his home in Toronto.

Born in Halifax, N.S., on October 23, 1877, Mr. Reid graduated from Queen's University in 1902 with a B.Sc. degree in chemistry and mineralogy. He gained general experience in gold mining from 1903 to 1908 in Nova Scotia, British Columbia and Mexico. For the next few years after that he was engaged in field exploration work in the Cobalt, Ont., area.

Then he became associated with the late Dr. P. A. Coleman in preparing the first Sudbury mining map, which later became famous over the world for its detailed geological information. After lecturing for a year at Queen's University, Mr. Reid returned to Cobalt, Ont. in 1916, where he remained for eight years as geologist and mine manager for the O'Brien Mine. From 1924 to 1934 he travelled extensively covering mining fields in Western Canada and South and Central America. In 1934 he went into private practice as a consultant. He wrote a number of technical papers on his work in Northern Ontario during the next few years.

Mr. Reid was a member of the Walker Mineralogical Club, the Society of Economic Geologists, the Geological Association of Canada, and the Association of Professional Engineers of Ontario.

He joined the Engineering Institute as a Member in 1919 and attained Life membership in 1949.

Correction

In the February issue the Journal published the biography of the late Henri A. Gibeau, of Montreal, a former director of public works for the City of Montreal.

In error, the name was given as Henri A. Gibeault. The editors regret this mistake in its treatment of the biography of a senior and respected Member.

Personals

News of the Personal Activities of Members of the Institute

Dr. O. M. Solandt, HON.M.E.I.C., who was chairman of the Defence Research Board, has been appointed assistant vice-president, research and development, of the Canadian National Railway. The appointment is effective March 1.

Born in Winnipeg in 1909, he received his early education there and in Toronto, and obtained a B.A. degree from the University of Toronto in 1931. Following two years of post-graduate work in the department of physiology, he received an M.A. degree. In 1936 he took his doctorate with honours under Dr. C. H. Best. A year of research at Cambridge University, internship at Toronto General Hospital, and further post-graduate work at the London Hospital, England, preceded his appointment to the teaching staff of the department of physiology at Cambridge, where he was subsequently named a Fellow of Trinity Hall.

Following the outbreak of the war he directed the South-West London Blood Supply Depot until 1941. He founded the Medical Research Council's Physiological Laboratory at the Armoured Fighting Vehicle School at Bovington and became engrossed in research on the physiological problems of tank personnel. In 1942 he established the operational research group, which investigated important tank gunnery problems, and in May, 1944 he was named superintendent of the Army Operational Research Group. He had already joined the Canadian Army in February, and in May was appointed acting colonel.

In 1945 he was chosen to direct the operational division of the South East Asia Command as scientific advisor to Admiral Lord Louis Mountbatten, but the war ended before he could assume this post. Instead he went to Hiroshima and Nagasaki with a joint military mission to evaluate the effects of the first atomic bombs.

Dr. Solandt returned to Canada in 1946 to join the Department of National Defence in Ottawa and take on the job of forming a permanent defence research organization for Canada. He became the first chairman of the Defence Research Board in 1947 and a scientific member of the chiefs of staff committee and defence council.

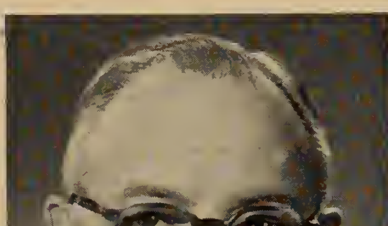
J. T. Dyment, M.E.I.C., director of engineering for Trans-Canada Air Lines, has been elected vice-president in charge of activities concerned with air transportation, for the Society of Automotive Engineers, Inc.

Mr. Dyment will head the thirty-nine member Air Transport Activity Committee. He has also been a member since 1945, and one-time chairman of the technical committee of the International Air Transport Association.

He has been associated with Canadian aviation from the time of his graduation from the University of Toronto, and since 1938 has been with Trans-Canada Air Lines. In 1943 he was chairman of the Winnipeg Branch.

Francis G. Ferrabee, M.E.I.C., president of Canadian Ingersoll-Rand Company Ltd., has been elected a director of the Ingersoll-Rand Company in New York. Mr. Ferrabee has been associated with Ingersoll-Rand since 1924, in Canada and the United States.

Mr. Ferrabee is president of the Machinery and Equipment Manufacturers' Association of Canada, a past-director of the Canadian Industrial Preparedness Association, a past-president of the Montreal Board of Trade, a member of the Canadian Institute of Mining and Metallurgy, and of the Institute of Administration.



F. G. Ferrabee, M.E.I.C.

Rear Admiral (E) John G. Knowlton, R.C.N. (Ret), M.E.I.C., has been elected president of Bogue Electric of Canada Ltd. at Gloucester, Ont. His offices will be at the company's new plant at Gloucester near Ottawa, headquarters for the production of motors and generators, power supplies, communications systems and electronic components.

Rear Admiral Knowlton had completed 37 years of service upon his retirement from the Navy. Since 1947 he has been chief of naval technical services and member of the Naval Board in Ottawa. In this capacity he directed the greatest peacetime ship-building program in the history of the Canadian Navy.

Rear Admiral (E) J. G. Knowlton, M.E.I.C.

In 1945 Rear Admiral Knowlton was awarded the O.B.E. for his World War II activities as engineer superintendent of H.M.C. dockyard at Halifax. He directed the build-up of the dockyard from a small prewar base to its present position of importance as a huge repair and operating base.

S. Logan Kerr, M.E.I.C., president of the consulting engineering firm of S. Logan Kerr & Company Inc. in Philadelphia, was recently cited by the University of Pennsylvania as one of the twenty-three alumni of its engineering school whose professional achievement, contributions to the public welfare and service to their alma mater has been recognized.

Voted by the engineering faculties, these "Centennial Citations" were conferred at the engineering alumni's annual dinner and meeting at the university a short time ago.

• *Personals*

T. A. I. C. Taylor, M.E.I.C., has been named president of the firm of Patterson Electric (Eastern) Limited, Montreal.

A 1936 graduate of the University of Alberta with a degree in electrical engineering, he was for a time with the Saguenay Power Company Ltd. at Arvida, Que., and in 1938 was transferred to the Aluminum Company of Canada Ltd., becoming electrical maintenance engineer. He remained with the company until 1942 and rejoined it in 1946 in the position of project engineer, after four years service with the R.C.E.

Later, in 1950, Mr. Taylor joined Patterson Electric. He was at that time general manager and chief engineer.

F. S. Jones, M.E.I.C., has retired from the Department of Transport after 40 years of government service. He was chief engineer of the St. Lawrence Ship Channel branch of the department, having attained that position in 1942.

He joined the Department of Transport in 1916 following his graduation from the University of New Brunswick. During the First World War he served overseas with the Royal Canadian Engineers and received the Military Cross. In 1946 he was awarded an M.B.E.

Gatineau Power Personnel

Claude Glidden, M.E.I.C., has recently retired from active service with the Gatineau Power Company, Ottawa. He has held the position of chief engineer for twenty years.

Mr. Glidden studied at McGill University, receiving a B.Sc. degree in electrical engineering and in 1922 an M.Sc. degree in mechanical engineering. He was a demonstrator in McGill electrical

R.C. Silver, M.E.I.C.

engineering department for two years, working between terms as resident engineer on a hydro electric plant for Beaubien Busfield and Company Ltd., consulting engineers, at St. Alban's, Que. In 1925 he joined the department of Railways and Canals, St. Lawrence Waterways. He became an electrical engineer with Canadian Hydro Electric Corporation, in 1926, and later, in 1930, joined the Gatineau Power Company in the same capacity. He was appointed chief engineer in 1935, and in 1951 received the additional appointment of vice-president.

Rupert F. Howard, M.E.I.C., has recently retired from his position as purchasing agent for Gatineau Power Company in Ottawa. He will continue to be associated with the company as consultant.

Mr. Howard began his career in the construction department of the Westinghouse Electrical and Manufacturing Company and worked for a time in Pittsburgh, completing the two and a half year student course offered by the company at that time. In 1907 he was transferred to the Canadian Westinghouse Company at Montreal as assistant engineer, having charge of all engineering work for the company from Ottawa to the maritime provinces.

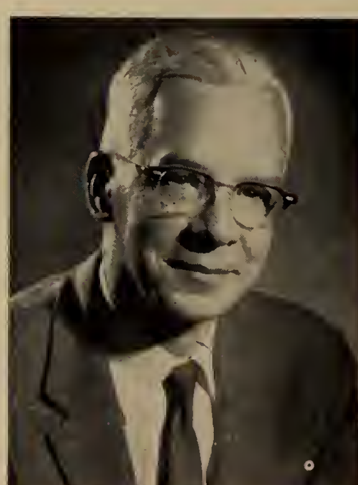
He subsequently assumed charge of the company's work at the city of Winnipeg hydro-electric plant and in 1917 was attached to the Winnipeg office as commercial engineer. Later he resigned to accept the position of chief engineer of the British American Nickel Corporation at Ottawa. He remained there until 1921 when he became connected with Messrs. Kerry and Chace Limited, consulting engineers, Toronto, as assistant in connection with investigating and reporting on the proposed electrification of the Temiskaming and Northern Ontario Railway. In 1922 he entered private practice, but gave this up in 1927 to join Gatineau Power Company and was appointed manager of power sales, then purchasing agent, with headquarters in Ottawa.

Mr. Howard is a graduate of McGill University.

Ralph C. Silver, M.E.I.C., will be assistant chief engineer of the Gatineau Power Company. He was formerly system planning engineer with the company.

Mr. Silver graduated from McGill University with a B.Sc. degree in 1927 and obtained his M.Sc. degree in 1929. From 1927 to 1929 he was demonstrator in the university's electrical laboratory. He first became associated with Gatineau Power in 1929.

He is a member of the Association of Professional Engineers of Ontario, the Canadian Electrical Association, and of the American Institute of Electrical Engineers, having served as a past chairman of the Ottawa section of the latter organization.



A. J. Chabot, M.E.I.C.

Arthur J. Chabot, M.E.I.C., has been appointed chief engineer of the Gatineau Power Company. He joined the company in 1928.

Mr. Chabot graduated with honours from McGill University in 1925 with a B.Sc. degree in electrical engineering, and was awarded the British Association Medal. Then he followed the three year advanced course in engineering with the General Electric Company, in Schenectady, N.Y., at the completion of which he joined Gatineau Power as electrical engineer.

He is a past chairman of the Ottawa section of the American Institute of Electrical Engineers, and a member of the Corporation of Professional Engineers of Quebec, and of the Canadian Electrical Association.

J. A. Michaud, M.E.I.C.

J. A. Michaud, M.E.I.C., has been elected vice-president in charge of woodlands for Consolidated Paper Corporation Limited, Grand'mere, Que. He was formerly general woods manager of the corporation, and has been with Consolidated Paper and its affiliates for 35 years.

Mr. Michaud is president of the St. Maurice River Boom & Driving Company, with which he has been associated since 1920; a director of the Quebec Forest Industries Association, the woodlands section of the Canadian Pulp & Paper Association, and of several forest protective associations.

A. G. Tanner, M.E.I.C., has accepted a position with Angus Robertson Ltd., and is assistant construction engineer on the Warsak Hydro-Electric Development in Pakistan, intending to reside in that country for 2 or 3 years.

A civil engineering graduate of the University of British Columbia, class of 1947, he was previously design engineer with the Shawinigan Engineering Company in Montreal.

F. R. Charles, M.E.I.C., has been named chief of the patents section of the National Research Council of Canada in Ottawa. Mr. Charles has been with N.R.C. since 1946.

Got a lifting problem?..

then get this handbook!..*

If you have an *industrial* lifting problem, you will find our new Crane Handbook invaluable.

In it you will find information on the classification and selection of electric overhead cranes for various services; features of construction; runway design data and many other items.

• Personals

He is a mechanical engineering graduate of the University of Toronto and a law graduate of Osgoode Hall. During the Second World War he served as flight lieutenant with the R.C.A.F.

Mr. Charles is a member of the Patent Institute of Canada and of the Canadian Aeronautical Institute.

G. L. Brown, M.E.I.C., has been elected chairman of the Sault Ste. Marie Branch of the Engineering Institute.

He is assistant manager of L. R. Brown and Company Ltd., general contractors, Sault Ste. Marie. He has been carrying on as acting manager of the company since the death of his father and has been associated with the company since his graduation from the University of Toronto in civil engineering in 1945.

Mr. Brown was first a field engineer on construction work of various types, and was appointed assistant manager of the company in 1950.

E. K. Lewis, M.E.I.C., of Imperial Oil Limited, has been transferred from the Ioco refinery in British Columbia to the Edmonton refinery, and is with the manufacturing department.

With Imperial Oil since 1934, Mr. Lewis has been at Dartmouth, N.S., and in the engineering and development section of the company at Sarnia, Ont. In 1946 he was production manager of the Polymer Corporation and two years later became superintendent of the Imperial Oil Refinery at Montreal. He went to Winnipeg in 1951 as superintendent of the manufacturing department and was then transferred to Ioco the following year.

Mr. Lewis graduated in 1930 from Nova Scotia Technical College.

Ivan M. Wallace, M.E.I.C., has recently joined the consulting engineering firm of C. C. Parker and Associates of Hamilton, Ont., and will have general supervision of their western Ontario operations.

Since 1946 Mr. Wallace has been designing engineer and contract manager with the London Steel Construction Company Ltd. of London, Ont., and was previously with the Canadian Bridge Company Ltd., of Walkerville, Ont.

I. M. Wallace, M.E.I.C.

J. S. Johnston, M.E.I.C.

Linde Air Products Appointments

J. Stuart Johnston, M.E.I.C., has been transferred from Winnipeg to Vancouver as manager of the western district of Linde Air Products Company, division of Union Carbide Canada Ltd. He was previously district manager in Winnipeg.

Mr. Johnston has been connected with Linde Air Products Company since his graduation in 1940 from McGill University. He was in Montreal in 1947 as manager of the process service for the district.

Peter R. Maitland, M.E.I.C., has been appointed assistant manager of Western district with headquarters at Edmonton, Alta., for Linde Air Products Company. He has been sales engineer for the company in Vancouver, B.C.

He graduated in 1950 from the University of British Columbia in mechanical engineering, and has also been chief designer of the engineering department of Barber Machinery Limited in Calgary, Alta.

John F. Short, M.E.I.C., has been transferred by the Linde Air Products Company to Montreal as manager of engineering service for the Eastern district. He was previously service engineer in Toronto for the company.

Mr. Short graduated in 1949 from Queen's University in mechanical engineering and immediately became a sales engineer with the company. He was appointed service representative in Toronto later that same year.

Norman E. Duncan, M.E.I.C., is now in Cleveland, Ohio, with Arthur G. McKee and Co., where he is employed as project engineer on industrial buildings.

He was formerly with Aluminum of Canada in Montreal as a structural design engineer, and is a 1948 graduate of the University of Edinburgh with a B.Sc. degree in civil engineering.

Philip H. Morgan, M.E.I.C., is in Peshawar, West Pakistan, in the capacity of project manager for the H. G. Acres and Co. Ltd.

Mr. Morgan was previously British West Indies project manager with Sprostans Ltd. in Shooters Hill, Jamaica and in 1954 became construction consultant with Aluminum Laboratories in Montreal.

P. R. Maitland, M.E.I.C.

J. F. Short, M.E.I.C.

B. C. Palmer, M.E.I.C., has accepted a position with Mid-Canada Defence Line, in northern Saskatchewan, at LaRonge, Sask.

Mr. Palmer, who graduated from Ohio State Agricultural College in 1948, with an engineering degree has previously been engaged in hydraulic and structural design with Prairie Farm Rehabilitation Administration, Regina, Sask.

K. L. Broe, M.E.I.C., has been appointed manager of the apparatus sales division of the Canadian General Electric Company, in Calgary. He has formerly been with the company in Trail, B.C. He graduated in electrical engineering from the University of British Columbia in 1946.

W. B. Peterkin, M.E.I.C., has been named manager of Canadian Cutler-Hammer Limited in Toronto.

An electrical engineering graduate of the University of Manitoba, Mr. Peterkin was formerly district manager at Winnipeg, Man., for Amalgamated Electric Corporation Ltd. of Toronto.

R. S. Lockeberg, M.E.I.C., has moved to Ottawa and is with R. L. Crain Limited. He was formerly in Montreal on the staff of B. W. Deane & Company.

A 1947 mechanical engineering graduate of Queen's University, he has also been with Canadian Ingersoll-Rand Company Ltd. in Montreal.

• Personals

E. Jack Prince, M.E.I.C., of Dominion Iron & Steel Limited, has been elected chairman of the Cape Breton Branch of the Engineering Institute.

Mr. Prince was born in Leeds, England, and received his education at Brigg Grammar School, Scunthorpe Technical College, and Sheffield University, where he was admitted as associate in ferrous metallurgy in 1933.

Previous to joining the staff of Dominion Steel & Coal Corporation in Sydney, N.S., as research engineer in 1947, he occupied positions in various British steelworks as steelworks chemist, electric furnaceman, melting shop shift manager, assistant melting shop manager, and works metallurgist. Since 1953 he has been assistant superintendent of openhearth and electric furnaces in Sydney.

He is a Fellow of the British Institution of Metallurgists, a member of the British Iron and Steel Institute, and a member of the Association of Professional Engineers of Nova Scotia.

Mr. Prince joined the Engineering Institute in 1948 as a Member. He has been vice-chairman of the Cape Breton Branch in 1950, and secretary-treasurer in 1953, and has served on the Branch Committee since 1949.

E. J. Prince, M.E.I.C.

George F. Knight, M.E.I.C., has resigned as assistant general manager of the Consumer Gas Company of Toronto. Mr. Knight has been with the Consumers' Gas Company for 13 years, and was responsible for all the company's outside operations, including the transmission of natural gas from the Niagara Frontier, expansion of facilities and of Toronto distribution and service. He was on the board of directors of the company from 1951 to 1954.

A graduate of Manchester College of Technology in England, he began his career in engineering and in the manufactured gas industry in that country.

G. F. Knight, M.E.I.C.

Mr. Knight joined the Consumers' Gas Company in 1942 as engineer-in-charge of construction and maintenance, and became general superintendent of works in 1946. He was named assistant general manager in 1952.

He is a member of the Institution of Gas Engineers of Great Britain, the American Gas Association, and is a member of the board of directors of the Canadian Gas Association.

M. Couse, M.E.I.C., is chief engineer of the Scarboro branch office of Proctor, Redfern & Laughlin, consulting engineers of Toronto.

A 1950 civil engineering graduate of the University of New Brunswick, Mr. Crouse joined the company in 1952 as resident engineer.

• Personals

L. P. Bonneau, M.E.I.C., professor in the mechanical engineering department of Laval University, has been elected as the new chairman of the Quebec Branch of the Engineering Institute.

Professor Bonneau was born in St. Francois, Que., and completed his early education there. He graduated from Laval University in 1942 with a B.A.Sc. degree. He spent the next six years on the staff of the Canadian Johns-Manville Company as assistant engineer. In 1944 he was engineer, working on layouts for underground mining, crushing plants, and hoisting plants for the company.

He returned to Laval University in 1947 as lecturer in thermodynamics and applied mechanics. In 1951 he also acted as assistant secretary for the faculty of science and in 1954, was named full professor of thermodynamics and director of the mechanical engineering department.

Professor Bonneau is a member of the board of examiners of the Corporation of Professional Engineers of Quebec, and a member of the young engineers committee of that organization. He is on the committee of revision of the syllabus of examinations of the Dominion Council of Professional Engineers. He is also a member of the Canadian Institute of Mining and Metallurgy, the American Society for Metals, and of the American Society of Mechanical Engineers.

L. P. Bonneau, M.E.I.C

He joined the Engineering Institute in 1945 as a Member and has been active on the executive of the Quebec Branch for a number of years.

Andrew S. Zakrzewski, M.E.I.C., recently announced the formation of a new company, Pneuma-Serve Limited, in Toronto, of which he is president. This new company will specialize in the field of automation as well as the development and manufacture of special machines.

Mr. Zakrzewski was formerly with Taymouth Industries Limited in Toronto.

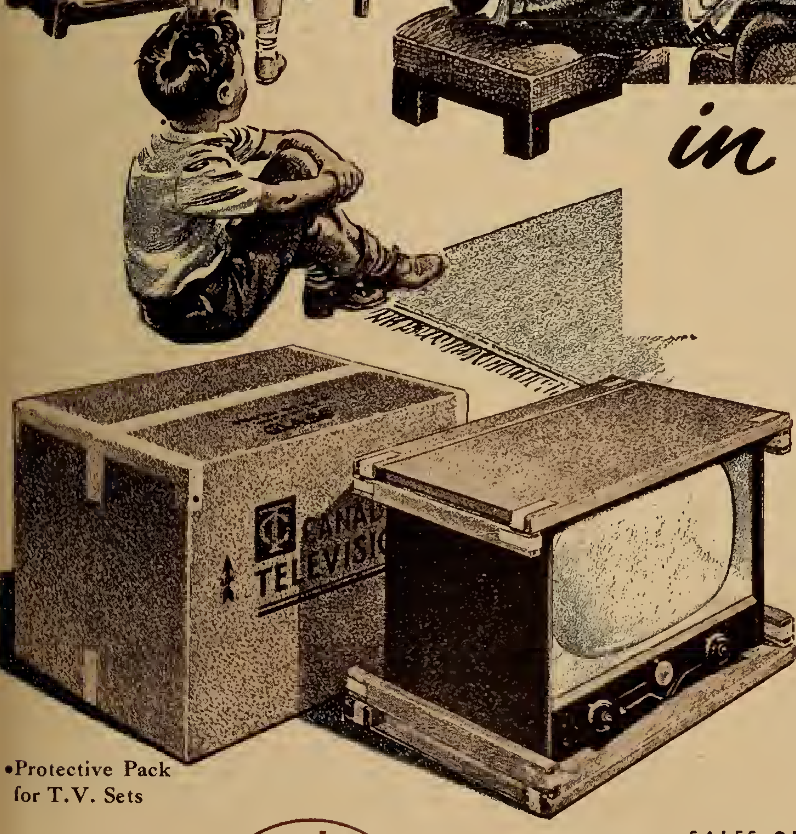
J. C. Pratt, M.E.I.C., is now in the research department of McCulloch Motors Corporation in Los Angeles, California, working as development engineer.

A 1942 electrical engineering graduate of the University of Manitoba, Mr. Pratt has been with the National Research Council in Ottawa, and at Winnipeg as the Manitoba representative of the Technical Information Service for N.R.C.

C. Sidney Dutton, M.E.I.C., has accepted a position as design engineer with Proctor, Redfern and Laughlin, consulting engineers of Toronto. He was formerly field engineer for Infilco (Canada) Ltd. in the Ontario territory.

Mr. Dutton graduated in 1939 from the Victoria University of Manchester with honours in civil engineering. Previous to being associated with Infilco (Canada) Ltd. he served as a design engineer on sanitary engineering projects in Britain and the United States.

SHIP ANYTHING···ANYWHERE···



in BATHURST CONTAINERS

TELEVISION sets are among the great variety of manufactured articles which can be safely and speedily shipped in Bathurst Containers.

Attractive in appearance, strong and durable, Bathurst Containers are easy to handle . . . hard to damage. Also, they are laboratory tested at every stage of manufacture . . . from forest to finished package.

Today, Bathurst offers you a complete line of corrugated containers and wirebound boxes. Whatever your shipping needs may be, Bathurst can meet them. Consult us about your packaging problems.

W. G. Mitchell, M.E.I.C., chief draughtsman with Canadian Bridge Company Limited in Walkerville, Ont., is the new chairman of the Border Cities Branch of the Engineering Institute.

W. G. Mitchell, M.E.I.C.

Born and educated in Ireland, Mr. Mitchell received bachelor degrees in engineering and arts from Trinity College, Dublin, Ireland, in 1925. After several years in the London offices of Dorman Long and Company, he came to Canada in 1929 and joined Dominion Bridge as a draughtsman. He has held the position of chief draughtsman for the company in Walkerville, Ont., for a number of years.

He is a member of the Association of Professional Engineers of Ontario, and became a Member of the Engineering Institute in 1941.

T. W. H. Stoddart, M.E.I.C., has joined the staff of Philips Canadian Industrial Development Company Ltd. in Toronto. Prior to this new position he was manager of the commercial research department of Rogers Majestic Electronics Ltd. in Toronto.

Mr. Stoddart graduated from the University of Toronto in 1941 and has also been with the Exide Battery Company and with Northern Electric Company Ltd. in Montreal as development engineer.

T. O. Whillans, M.E.I.C., is presently on retiring leave from his position as assistant commissioner of patents with the Patent and Copyright Office of the Secretary of State Department.

He joined the patent office in 1921 as an assistant patent examiner and has held progressively higher positions since that time.

Mr. Whillans graduated from Queen's University with a B.Sc. degree in mechanical engineering in 1917.

V. F. Murzo, M.E.I.C., has joined the staff of P. G. Gauthier, consulting engineer and Quebec land surveyor in Montreal as a civil engineer.

Mr. Murzo, who is a civil engineering graduate of the University of Belgrade, was formerly with Angus Robertson Limited of Montreal, working as civil engineer on the Bersimis project.

• *Personals*

N. E. Hudak, Jr.E.I.C., has joined Amalgamated Electric Corporation Limited in Toronto. He was formerly design engineer with Canadian Westinghouse Company Ltd. in the metalclad switchgear department in Hamilton.

Mr. Hudak graduated in 1948 from the University of British Columbia with a B.A.Sc. degree in electrical engineering. He was awarded the British Columbia Telephone Company Limited scholarship and returned to the University of British Columbia for post-graduate studies. He received his M.A.Sc. degree in 1951 and that year joined Canadian Westinghouse on a graduate engineer training course.

In 1953 Mr. Hudak was awarded the John Galbraith Prize of the Engineering Institute for his paper "Locations of Faults in Power Cables by Fault Generated Surges".

Lucien Jean, Jr.E.I.C., is now employed as an electrical engineer with Shawinigan Water and Power Company, at St. Therese, Que. He is a 1954 graduate of Ecole Polytechnique in electrical engineering.

R. B . Kerr, Jr.E.I.C., has joined Cooper-Bessemer of Canada Ltd., in Edmonton. He was formerly with Canadian Westinghouse Company Ltd. in Edmonton as sales engineer.

Mr. Kerr graduated in 1948 from the University of Saskatchewan with a B.Sc. degree in electrical engineering, and then joined the engineering apprentice course at Westinghouse in Hamilton, Ont.

He was secretary-treasurer of the Edmonton Branch of the Institute in 1954.

A. J. McInroy, Jr.E.I.C.

Andrew J. McInroy, Jr.E.I.C., has been appointed to the sales engineering staff of Martin Engineering Incorporated in Montreal. The announcement was made by **Lt. Colonel L. Martin,** M.E.I.C., president of the company.

Mr. McInroy received his B.Eng. degree from McGill University in 1954 in electrical engineering. Upon graduation he joined the staff of the Shell Oil Company and was employed as junior geophysicist in the exploration division at Edmonton, Alta.

He has been on the training course program of Martin Engineering up to

• *Personals*

his present appointment, and has just recently returned from a visit to the American manufacturing plants represented by Martin Engineering in Canada.

A. G. MacDonald, JR.E.I.C., has joined the staff of Wirtanen Electric Company Ltd. in Edmonton, Alta., as electrical engineer.

Mr. McDonald graduated from McGill University in 1953 in electrical engineering and has also been associated with Harrington Tool and Die Company Ltd. in Lachine, Que.

R. S. Shephard, JR.E.I.C., is now design engineer in the central engineering office of Fraser Companies Ltd. at Edmunston, N.B.

Mr. Shephard, who has returned after spending two years in England on an Athlone fellowship, graduated from the University of New Brunswick in 1953 with a B.Sc. degree in civil engineering.

F/O D. A. Walker, JR.E.I.C., has been transferred by the R.C.A.F. to Claresholm, Alta., from Lethbridge, Alta.

F/O Walker, who has been with the R.C.A.F. for some time, is a 1951 graduate in mining engineering from McGill University.

L. H. Mensforth, JR.E.I.C., has been transferred to the civilian atomic power department engineering laboratory of the Canadian General Electric Company in Peterborough, Ont. Mr. Mensforth was previously with the fractional motors facilities engineering of the same unit.

He graduated in 1952 with a B.Sc. degree in mechanical engineering from the University of Manitoba.

E. Madsen, JR.E.I.C., has been named assistant supervisor in the testing and communications section of B.C. Electric Company Ltd. in Vancouver, B.C. He was formerly service engineer with Canadian Westinghouse Company Ltd., also in Vancouver.

Mr. Madsen graduated in 1949 from the University of Alberta in electrical engineering and immediately joined Canadian Westinghouse as an apprentice engineer in Hamilton, Ont. He was transferred to Vancouver in 1952 to the service department becoming service engineer in 1953.

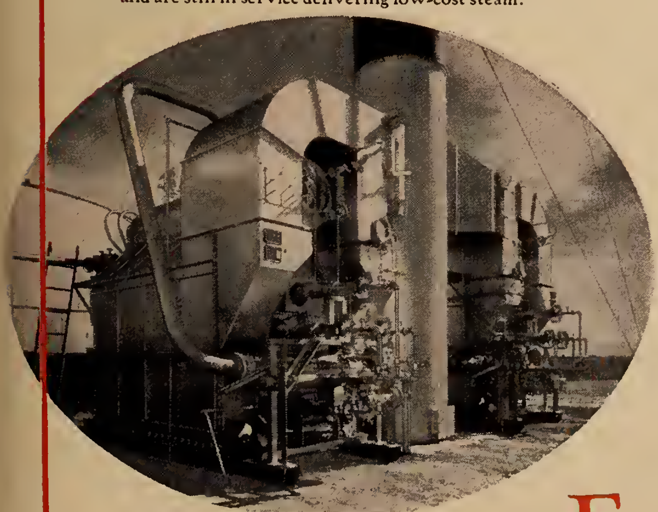
Gilles Brochu, JR.E.I.C., has accepted a position with the firm of Piette, Audy and Lepinay, consulting engineers, in Quebec City.

Mr. Brochu obtained his B.A.Sc. degree in civil engineering at Laval University in 1954. He has recently worked with the drainage service, Department of Agriculture, Quebec City, Que.

Stanley A. Herzog, JR.E.I.C., has accepted a position with the Petroleum and Natural Gas Conservation Board of Alberta, situated at Camrose, Alberta.

Mr. Herzog received his B.Sc. degree in petroleum engineering from the University of Alberta in 1952. Recently he has been associated with the firm of Black, Sivalls and Bryson Limited, Edmonton, Alta.

New Series AG-100 Packaged Steam Generator



• *Personals*

C. A. Marteinson, Jr.E.I.C., has been transferred to Calgary from Winnipeg by E. H. Price Limited. He is employed as a sales engineer and will be in charge of the Calgary office of the firm.

Mr. Marteinson graduated in mechanical engineering from the University of Manitoba in 1950 and has been service engineer with Superheater Company Ltd. in Winnipeg, Man., and with the Combustion Engineering Corporation as sales and service engineer in Montreal.

Jacques Perreault, Jr.E.I.C., is now city engineer for the City of St. Lambert, Que. He was previously construction supervisor at the Beloeil works of Canadian Industries Limited at McMasterville, Que.

He graduated in 1952 from Ecole Polytechnique with an engineering degree.

Charles S. Walker, Jr.E.I.C., has joined Sandwell and Company Ltd., pulp and paper mill consulting engineers at Vancouver, B.C. He was formerly with Canadian General Electric Company Ltd. at Peterborough, Ont.

Mr. Walker graduated in 1951 from the University of British Columbia with a B.A.Sc. degree in electrical engineering, received his master's degree in business administration from Stanford University in 1953.

W. B. Dodd, Jr.E.I.C., has returned to Canada after completing his Athlone Fellowship, and is now with the hydraulic division of Dominion Engineering Works in Lachine, Que. While in England he was employed as a graduate apprentice with British Thomson Houston Company Ltd. in Rugby. He also spent a year in Switzerland working in the turbo-supercharger section of Brown-Boveri's turbine division.

Mr. Dodd graduated in 1951 with a mechanical engineering degree from the University of Toronto, and spent some time with Canadian Industries Limited at Brownsburg, Que., before going overseas.

George Skoryna, Jr.E.I.C., has been named industrial engineer with Ford Motor Co. of Canada at Windsor, Ont.

Mr. Skoryna came to Canada from the Institute of Technology in Vienna where he received a diploma in engineering in 1943, later graduating with an M.Eng. degree from the Nova Scotia Technical College, Halifax, N.S. He has since been associated with the firm of Surveyer, Nenniger and Chenevert, in Montreal.

M. Poupard, Jr.E.I.C., has returned to the staff of Ecole Polytechnique as instructor in the mechanical engineering department, following two years spent in England on an Athlone Fellowship. While in England Mr. Poupard was employed by the Brush Group Organization, spending some time with Petters Company Ltd., Bryce Berger Company Ltd., National Gas & Oil Engines Company Ltd., and with Brush Electrical Company Ltd. He also spent some time at the University of Sheffield studying courses in mechanical vibrations and in plasticity of metals.

Mr. Poupard graduated in 1953 from Ecole Polytechnique with a B.A.Sc. degree and remained on the staff as assistant professor prior to going to England two years ago.

Robert Theriault, Jr.E.I.C., has joined the staff of the Aluminum Company of Canada at Isle Maligne, Que.

Mr. Theriault, who received a bachelor's degree in civil engineering from the Ecole Polytechnique, Montreal in 1951, has been with the rehabilitation and design department of Canadian Arsenals Ltd., Valleyfield, Que.

K. C. Read, Jr.E.I.C., has moved from Montreal to Deep River, Ont., where he is employed with Atomic Energy of Canada Ltd. on a building construction project.

Mr. Read is a graduate of McGill University, class of 1954, where he received a degree in mechanical engineering.

P. A. Preville, Jr.E.I.C., is employed as port engineer with Clarke Steamship Co. Ltd., in Montreal.

Mr. Preville graduated from McGill University in 1954 with a bachelor's degree in mechanical engineering.

George W. Newman, Jr.E.I.C., is currently employed as a plant engineer with the firm of Bulloch's Limited, Winnipeg.

Mr. Newman graduated from the University of Manitoba in 1954 with a degree in mechanical engineering.

W. A. Webber, Jr.E.I.C., has joined the radio engineering department of Canadian National Telegraphs in Toronto, Ont. He was formerly with the sales department of Rogers Majestic Electronics Ltd., also in Toronto.

Mr. Webber graduated in 1954 from the University of Manitoba with a B.Sc. degree in electrical engineering.

E. D. Blix, Jr.E.I.C., has joined the Aluminum Company of Canada Ltd. at Kemano, B.C. He was formerly with the electrical laboratory of Northern Electric Company Ltd. in Lachine, Que.

Mr. Blix graduated in 1954 from the University of Leeds with a B.Sc. degree in electrical engineering.

B. C. Kaulback, Jr.E.I.C., has accepted a position as mechanical engineer, with the Lunenburg Foundry and Engineering Company of Lunenburg, Nova Scotia.

A 1950 engineering graduate from McGill University, Mr. Kaulback has previously served as assistant to the division manager, ammunition department, Canadian Industries Limited, Montreal.

G. I. Fekete, Jr.E.I.C., has been transferred to Montreal from Brownsburg, Que., by Canadian Industries Limited For the past year and a half he held the post of production and process engineering assistant. He now takes on head office duties as assistant project engineer, engineering department.

Mr. Fekete obtained his mechanical engineering degree at McGill University in 1954.

P. M. Evjen, S.E.I.C., a civil engineering graduate of the University of Alberta in 1955, is now employed by the Alberta Department of Highways, at Stony Plain, Alta., as resident highway engineer.

J. C. Clark, Jr.E.I.C., is now employed as manufacturing engineer with the electronics division of Canadian Westinghouse Company Ltd. in Hamilton, Ont.

J. C. Clark, Jr. E.I.C.

Mr. Clark received his engineering degree from the University of Saskatchewan in 1951 and then joined the Robinson Machine & Supply Company in Calgary, Alta. In 1953 he was awarded an Athlone Fellowship spending the following two years in England.

Maurice L. Desjardins, Jr.E.I.C., is employed by the Quemont Construction Inc., Montreal, as the assistant to the chief engineer, buildings division.

Mr. Desjardins graduated in 1954 with a degree in civil engineering, from the Ecole Polytechnique, Montreal.

Richard F. Dee, Jr.E.I.C., is at present employed with the Ontario Hydro as a junior engineer on an engineering program. He is temporarily working in the rehabilitation and relocation schemes of the St. Lawrence Seaway Project.

Mr. Dee, a 1954 graduate in civil engineering, received his degree from the University of New Brunswick.

K. J. Fallis, Jr.E.I.C., has joined the staff of the Manitoba Hydro Electric Board as resident engineer of the Brandon generating station, Brandon.

Mr. Fallis graduated in civil engineering from the University of Manitoba in 1949 and has been associated with the Winnipeg Electric Company, Winnipeg, Man.

James S. MacDonald, Jr.E.I.C., is employed as an engineer with the Bell Telephone Company of Canada Ltd. in Montreal. He was formerly in Sydney N.S. with Dominion Coal Company Ltd

Mr. MacDonald graduated in 1950 from Nova Scotia Technical College with a bachelor's degree in mechanical engineering and has also been with Canadian Vickers Limited in Montreal as industrial engineer.

Armand Couture, Jr.E.I.C., is now employed by the Foundation Engineering Corporation of Canada in Montreal.

Formerly with the National Harbour Board in Ottawa, Ont., Mr. Couture is a civil engineering graduate of Laval University, class of 1953.

Wm. J. Roy, Jr.E.I.C., has rejoined the engineering department of the City of Lethbridge, Alta. He was town engineer at Fort MacLeod, Alta.

Mr. Roy graduated in civil engineering from the University of British Columbia in 1951, and in 1953 was with the

engineering department of the City of Lethbridge, prior to going to Fort MacLeod.

I. Thomassen, Jr.E.I.C., is now employed as a structural engineer with H. A. Simons Limited in Vancouver, B.C. He was previously with the Hydro-Electric Power Commission of Ontario in Toronto.

Mr. Thomassen graduated in 1954 from the University of Manitoba in civil engineering.

Z. E. Wasarab, Jr.E.I.C., has accepted a position as product development engineer with Clayburn Company Limited in Abbotsford, B.C.

Mr. Wasarab, who graduated in mechanical engineering from the University of Saskatchewan in 1954, was previously with Northern Electric Company Ltd. in Montreal.

Gordon S. Roy, Jr.E.I.C., has moved to the United States and is with the Consumers Power Company in Jackson, Michigan, as assistant distribution engineer.

Mr. Roy graduated from Nova Scotia Technical College in electrical engineering, class of 1954. Recently he was with the engineering staff of the Shawinigan Water & Power Company in Three Rivers, Que.

Pierre Brillon, S.E.I.C., who graduated in 1955 from the Ecole Polytechnique with a B.A.Sc. degree in electrical and mechanical engineering is now with Hydro-Quebec at Labrieville, Que.

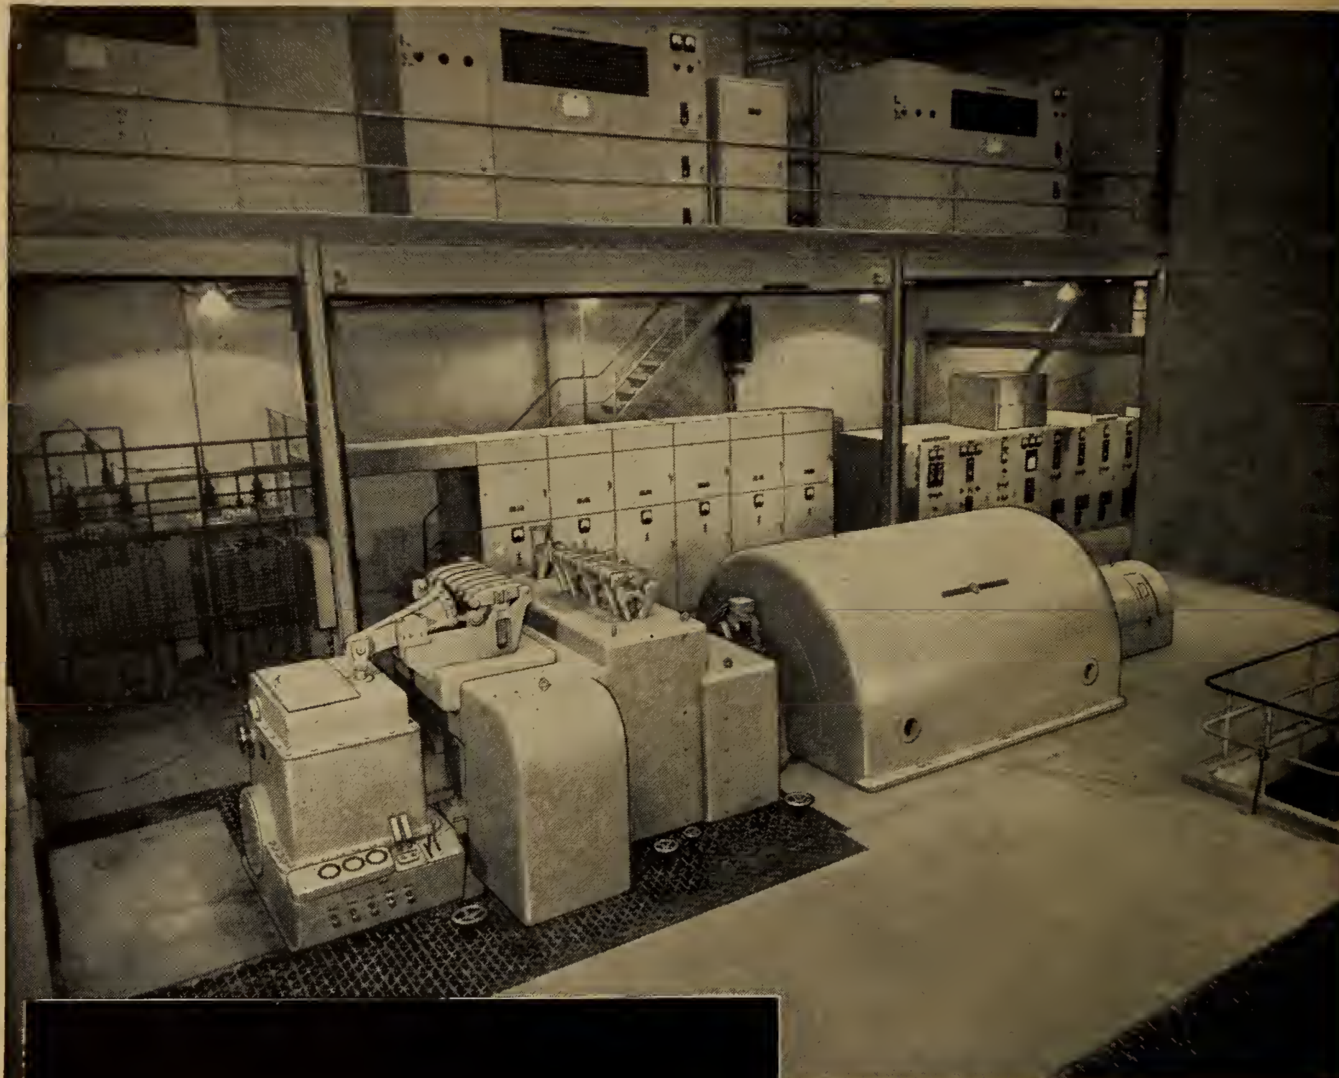
J. T. McManus, S.E.I.C., is presently employed as a petroleum development officer with the Saskatchewan Department of Mineral Resources, Swift Current, Sask.

He is a 1955 graduate from the University of Saskatchewan School of Engineering.

D. W. Tutt, S.E.I.C., who graduated in 1955 from the University of Toronto with a B.A.Sc. degree in civil engineering is employed with Mobil Oil of Canada Limited, Drayton Valley, Alta.

Francis M. Yamada, S.E.I.C., has been transferred to the Sao Paulo Light and Power Company Ltd., from the Rio de Janeiro Tramways, Light and Power Company Ltd. Both of these utilities are among the operating companies of the Brazilian Traction, Light and Power Company Ltd., of Toronto, Ont.

A 1955 graduate of the University of Toronto, with a B.A.Sc. degree in engineering, Mr. Yamada went immediately to Brazil. Prior to graduation he was associated with the Stone and Webster Engineering Corporation for two and a half years as office engineer and acting resident engineer during the construction and preliminary operation of the Richard L. Hearn Generating Station, in Toronto, Ont. He has also been with the Fletcher Manufacturing Co. Ltd., formerly of Toronto, Ont., as a mechanical design draftsman.



General Electric Steam Turbine Generator and Plant Switchgear, Transformers and Control at the Saint John Mill of Irving Pulp & Paper Ltd. Turbine is rated 12,500 KW at 3600 RPM and 6,900 volts. Single Automatic Extraction, non-condensing — installed in 1955

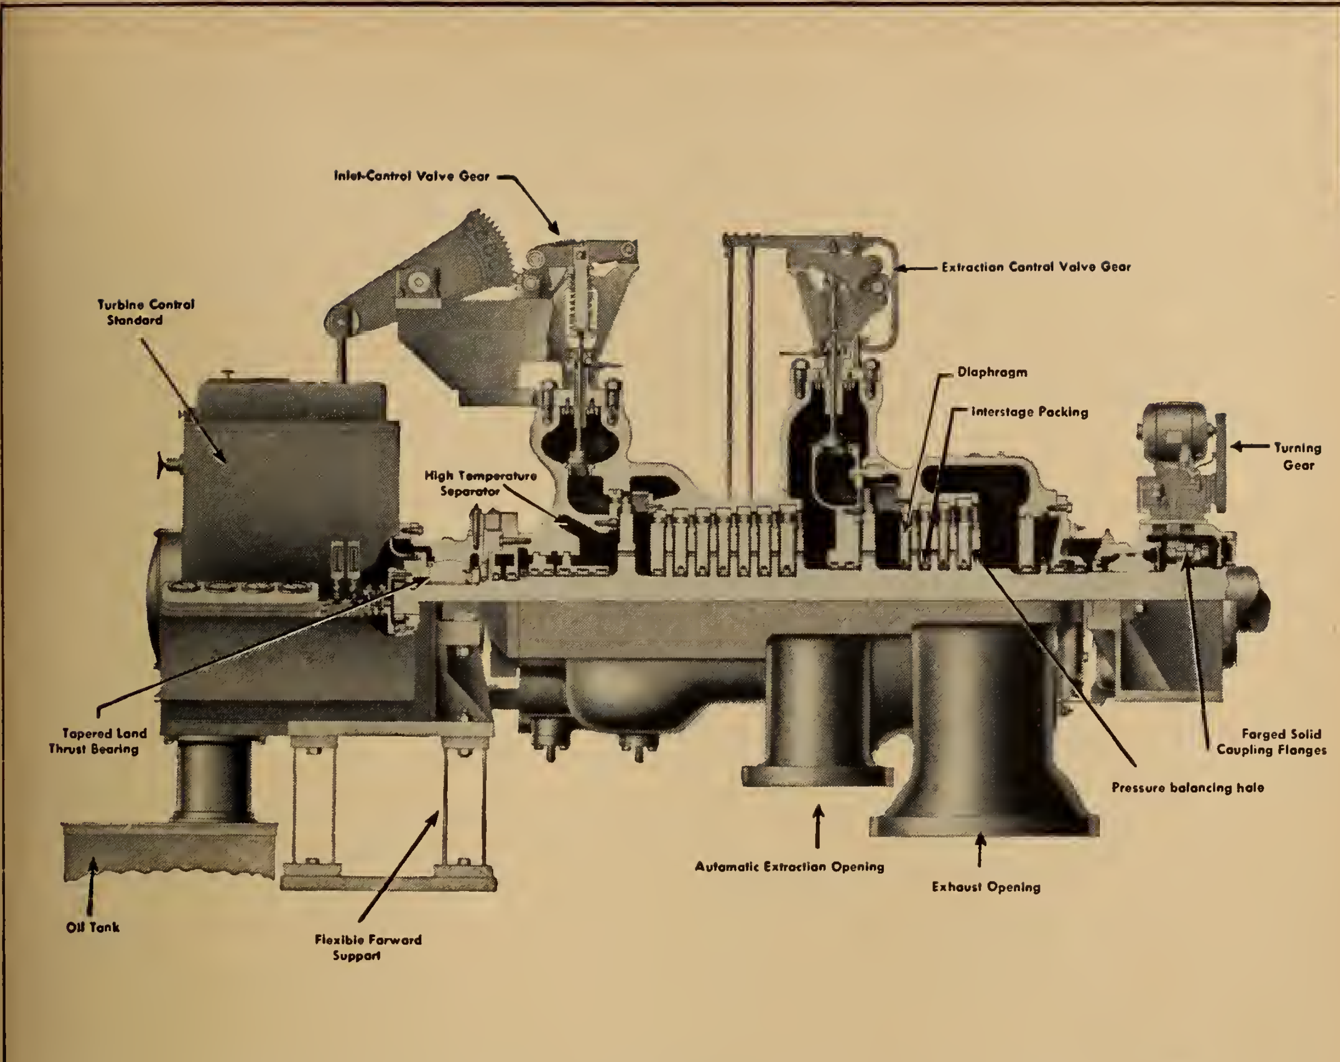
G-E Turbine at Irving Pulp and Paper Limited lowers operating costs

TO KEEP operating costs to a minimum, the Irving Pulp and Paper Limited of Saint John, New Brunswick, has chosen a G-E Steam Turbine Generator for its new plant — thereby lowering operating costs. In addition to the Turbine Generator, Canadian General Electric also supplied Switchgear, Transformers, and Control Equipment for the plant.

The Single Automatic Extraction, Non-condensing Turbine used is rated at 12,500 KW at 3600 RPM and 6,900 volts. It takes steam at

APPARATUS

CANADIAN GENERAL



Sectional view of General Electric single automatic-extraction, non-condensing steam turbine. High pressure steam passing through turbine produces economical by-product power — with steam extracted and exhausted at lower pressures for plant processes.

850 psig, 825°F., automatically extracts at 140 psig and exhausts at 40 psig for plant process uses.

G-E single or double automatic extraction units in other plants throughout Canada are continually providing economical by-product power and process steam.

This Turbine Generator installation at the Irving Pulp and Paper plant is another example of the manner in which C-G-E works with pulp and paper companies to increase production and lower operating costs. In fact . . . C-G-E supplies 75% of all Turbines for the Pulp and Paper Industry.

Canadian General Electric leads the field in supplying Turbine Generators for Canadian industry — leads too in engineering techniques . . . continually devising new and better methods to keep plant operating costs at the lowest possible level.

For further information, write to: Apparatus Department, Canadian General Electric Co. Ltd., 212 King St. West, Toronto, Canada.

W. M. Hogg Discusses Power Project

A general meeting of the Belleville Branch was held on January 16, 1956, the fourth meeting of the 1955-56 season. Approximately 60 members and guests attended.

Mr. W. M. Hogg of the Hydro Electric Power Commission of Ontario spoke on the St. Lawrence Power Project. Mr. Hogg's talk was accompanied by coloured photographic slides of the project in various stages of construction.

The speaker was introduced by E. G. Gurnett and thanked by Mr. J. A. Grant.

Brockville

K. R. Bullock, Jr.E.I.C.,
Secretary-Treasurer

Joint Meeting With C.I.C.

The Brockville Branch held a joint dinner meeting with the Brockville-Prescott section of the Chemical Institute of Canada, on January 17, at the Manitonna Hotel in Brockville. Sixty members heard William Hogg, field project engineer of the H.E.P.C. of Ontario speak on the St. Lawrence Power Development.

Wm. Hogg Guest Speaker

The many phases of the project were discussed and the progress and difficulties encountered were reported upon. His talk was illustrated with coloured slides showing scenes of recent construction. Mr. Hogg's subject was of considerable interest to his audience many of whom are involved with the changes being made in the St. Lawrence River.

Mr. Hogg was introduced by D. A. S. Laing and thanked by F. F. Walsh, past chairman.

J. S. Waddington is Speaker

On Tuesday evening, February 14 at the cafeteria of Phillips Electric, J. S. Waddington of that company described the fabrication and installation of the 13.2 kv. power transmission line to Pelee Island from the mainland. Films and slides were used to illustrate the presentation.

Approximately 11 miles of 13.2 kv. single conductor 1/0 submarine cable (ground return) were manufactured in two lengths and shipped by railway on spools to the area. Here the cable was transferred to a barge and while in the process of rewinding on the barge, the two lengths were spliced. Laying of the cable involved the hazards of weather and of crossing a busy ship channel.

Mr. Waddington discussed the methods of manufacturing and testing. In conclusion he commented on the recent failure of the cable due to ice formations and described the efforts being made by the owner, H.E.P.C. of Ontario, to resume services to Pelee Island.

Mr. Waddington was introduced by R. H. Wallace and thanked by George Fowler.

Branch News Editor

Annual General Meeting

The annual general meeting of the Branch was held at the Cornwall Golf and Country Club, on Monday, January 30, 1955, dinner being served at 7.00 p.m.

Reports were given by the secretary-treasurer, L. Snelgrove, and the chairmen of the program and entertainment committees. A report on student guidance was given by W. Nesbitt, who suggested that ways and means should be sought to present more information and advice to potential engineering students at an earlier age, stressing the advantage of a general course in the high school rather than a technical course for those wanting to become engineering graduates. The meeting was later thrown open for general discussion of this topic, and members indicated their keen interest in the subject by discussing the problems involved at some length.

Branch Bursary

The Branch is sponsoring a bursary for award annually to a student of engineering from the Cornwall district tenable for one year, and made possible from funds subscribed by local industries. Drummond Giles, chairman of the Bursary Committee gave his report, and was able to tell the meeting that funds had been assured for this purpose and further details would be announced later.

The chairman, Jack Morris, announced to the meeting that the president would be visiting the Cornwall Branch on Wednesday, February 22, and that a dinner and dance had been arranged for the occasion to which the Brockville Branch members and their ladies had been invited.

P. Nasmyth, chairman of the nominating committee, announced the election of two members to the executive, Vic Harrison and Dave Burnham.

Radioactive Isotopes

At the January meeting of the Hamilton Branch Dr. P. J. Stewart, director of radiography for Isotope Products Limited, described the nature and manufacfacture of radioactive isotopes.

Radioactive isotopes, he said, are produced by irradiation in nuclear reactors, of which Canada has one of the most powerful in existence. The irradiated materials look the same as the normal element or compound, but contain active isotopes which emit characteristic radiations of which the most significiant are called beta (electrons) and gama (short-wave electromagnetic radiation, comparable with X-rays). Breakdown of some radioactive elements produces other active isotopes—another source of radioactive material.

Radiation emitted is characteristic of the element and a wide range of gamma wavelengths is available. The life of an active isotope is also characteristic and varies from seconds to years; the half-life (time for half of the active material to decay) of cobalt 60 is five years, that of radio-sodium 13 hours.

Industrial Uses

Industry makes the widest use of the radiation from radioactive isotopes for gauging materials and for radiography. Thickness gauges are based on the variation of absorption of beta-radiation by different materials or thicknesses of material. Applications include measurement and control of paper, rubber, and metal sheet thickness; coating thickness; and profile. Densities of fluid and solid phases in process industries may also be measured.

Gamma radiation is widely used to obtain radiographs of castings, structural materials, welded vessels and pipelines Exposure time is relatively long, but isotope sources are more convenient than X-ray equipment for use in confined spaces, greater penetration is obtainable, complete vessels may be radiographed at one exposure, and constant energy radiation gives sharp pictures.

Joint Annual Banquet

One of the highlights of engineering activity in the Halifax area is the joint annual banquet of the Halifax Branch of the Institute and the Association of Professional Engineers of Nova Scotia.

Under the capable direction of Committee Chairman W. T. Windeler, the banquet, held on January 31 this year, was an outstanding success. Included in the list of distinguished guests were Premier Henry Hicks, Lieut. Gov. Alistair Fraser, and representatives of many organizations with interests in the engineering field.

Comdr. F. W. H. Bradley Guest Speaker

The principal speaker of the evening was Commander F. W. H. Bradley, Comdr. Air, Shearwater Naval Base, who described the role of aviation in naval strategy, tracing developments from earliest pioneering to the recent adoption of Banshee Jet aircraft by naval units.

Co-Chairmen G. A. Cunningham, representing the Institute, and C. N. Murray of the Association, remarked on the close and happy relationship which has existed between these bodies at all times. Seating capacity was taxed to the utmost by 300 engineers from all parts of Nova Scotia who joined in the festivities.

Among the guests at the annual banquet of the Halifax Branch and the Association of Professional Engineers of Nova Scotia were the Lieutenant Governor and the Premier of Nova Scotia. Chatting with the co-chairman of the meeting, they are, left to right: Premier Hicks, C. N. Murray of Sydney, Lieutenant Governor Fraser, and G. A. Cunningham of Halifax.

The President's Visit

January 24 marked the president's visit to the Hamilton and Kitchener Branches, as well as the annual meeting of the Kitchener Branch.

Dr. and Mrs. Heartz, accompanied by the assistant general secretary, E. C. Luke, met at luncheon in the Walper House, Kitchener, with members of the executives of the branches and some of their wives. During the afternoon the president conferred with executive members on Institute affairs, rejoining the ladies at a five o'clock reception.

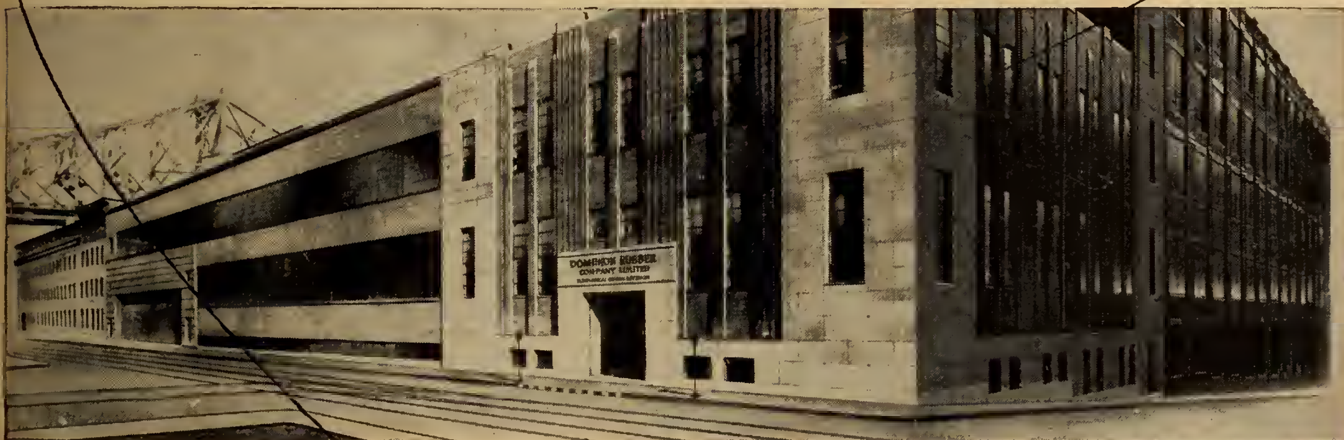
Dinner was held at the Kress hotel

Canada's pioneer rubber producer chooses

BRISTOL CONTROLS

Precision instruments for Industry



THE choice of Bristol automatic controls by the Dominion Rubber Company Ltd. is a significant one. Not only was Dominion the founder of the rubber industry in Canada but today it is one of Canada's most important producers of rubber and plastic products. In keeping with its more than a century of leadership, Dominion insists on the highest standards of precision control over this vital vulcanizing process. Naturally, we are proud that Bristol instruments are used on this crucial job.

The same qualities of accuracy and rugged dependability that recommend Bristol Instruments to Dominion Rubber, have made them the choice of the leaders in every field of industry.

If you have a problem related to instrument control engineering, involving recording, measuring or controlling, get in touch with us—we will be pleased to make a specific survey, report and estimate.

One of the colourful episodes in Dominion Rubber's long history was the land office business it did manufacturing rubber boots for the Klondyke Gold Rush miners. It's a far cry from the equipment of those days to the immense vulcanizer in the Mechanical Goods Division, Montreal. The largest in Montreal, it is typical of the plant's advanced equipment. In the foreground are some of the Bristol instruments which automatically control its operation.

Product reliability has always been stressed at the Dominion Rubber Company. Bristol instruments do their part by precisely controlling and adjusting temperatures and pressures according to a predetermined time schedule. To the left are Bristol diaphragm-operated control valves.

in nearby Preston with about 85 members representing the two branches. Due to the illness of the retiring chairman, L. J. R. Sanders, a past chairman, W. R. Roberts, presided. A. J. Girdwood, another past chairman, introduced the president.

Dr. Heartz delivered a pointed and challenging address on the requirements for training engineers to meet the growing needs of Canada and the responsibility of the profession in making possible the achievement of the new objectives. He emphasized the need for more graduates, more competent graduates, and the importance of filling the gap between the secondary schools and the universities.

". . . Increasing the engineering student body, reducing the number of failures, and improving the quality of the graduate, all highly desirable, is a complex problem which has some of its roots, I fear, at high school level, or possibly even earlier," he said.

"While the universities have done an excellent job, often under trying conditions, it seems the time has come for them to modify their programs to suit existing and probable future demands. . . . As engineering knowledge spreads further and deeper, and life becomes increasingly complex," he added, "there is an urgent need for more engineers who, in virtue of their basic training, will be qualified to solve not only the problems of today, but be in a position to handle the new ones tomorrow.

"We cannot expect the universities to carry out their monumental task without our moral and financial support. We must think more about the universities and we must increase our contributions substantially, and convince others to do likewise, if we are to carry our full share of responsibility," Dr. Heartz said.

Following the address the assistant general secretary, E. C. Luke, gave an interesting account of Institute affairs for the past year. Mr. Roberts introduced the new executive and the incoming chairman, W. R. Runge, spoke briefly.

December Dinner Meeting

Kitchener Branch members and friends joined with the Kitchener-Waterloo chapter of the Canadian Welding Society and the Grand Valley chapter of the American Society of Tool Engineers for a dinner meeting at the P.U.C. Restaurant in Kitchener.

Harry Thomasson, manager of the mechanical and metallurgical section of the Canadian Westinghouse Research and Development Laboratory, addressed the meeting. The speaker showed his usual intense, almost infectious, interest in this industrial art and science as well as his great "knowledge of familiarity." Special reference was made to metallurgical problems associated with the highly alloyed steels common in the manufacture of tools and certain non-ferrous alloys in use today. Mr. Thomasson also discussed the role of pre-welding and post-welding heat treatments in coping with some of the problems he described. A spirited discussion followed.

Mr. Thomasson rounded out the evening with a presentation of some outstanding 3-D colour slides of flowers.

E. A. Olafson is Speaker

E. A. Olafson, engineer in charge of drainage, P.F.R.A., Vauxhall, Alta., was the featured speaker at the regular January meeting of the branch. Mr. Olafson has recently returned from a two-year assignment under the United Nations Food and Agricultural Organization in India, and during the assignment he visited irrigation and drainage projects in Holland and Egypt.

In his address Mr. Olafson presented a brief review of the political history of

• Branch News

Pakistan. Pakistan was formed in 1947 of two widely separated areas containing peoples of predominantly Moslem faith. East Pakistan, in the extreme East of India is a very wet area, with an exceptionally high annual rainfall. West Pakistan is a dry area, with large desert sections and with some 20 million acres under irrigation. The irrigation projects, started by the British engineers some 30 years ago, dwarf irrigation achievements in Canada. The very flat country, however, makes storage of water, except in the mountain region, almost impossible, and the system has no water storage. Water tables have risen so much that some 800,000 acres of irrigable land have been almost ruined due to salinity of the soil. It was in the phase of land drainage that Mr. Olafson received his assignment.

Irrigation in Pakistan

The only practicable method of land drainage devised to date is by a system of wells and the lack of electricity is a great deterrent to the success of the operation. Almost all work is performed by primitive methods. Mr. Olafson stated that machinery cannot be used by the Pakistanis with any measure of success due to their almost complete lack of experience with machinery and equipment. Wells are dug by hand and electricity provides the power for pumping where possible.

Due partially to political difficulties, the F.A.O. drainage project has now been abandoned. Education and training and stable political leadership are badly needed, as is electric power and industrialization in this predominantly agricultural country.

British Engineering Praised

Mr. Olafson expressed praise for the British engineering and accomplishments in the field of irrigation in Pakistan. He stated that at present wheat is grown in winter, and that two or three crops can be harvested annually. Recent low rainfall has caused non-productivity and famine, however the speaker expressed confidence in the eventual success and ability of Pakistan to provide food for its population and for export.

West Pakistan has some 2,400 miles of main irrigation canals. Water is carefully controlled to minimize silting of the canals since dredging on a system of this size is virtually impossible.

Following his address, Mr. Olafson showed a short film on Pakistan, and colour slides he had taken covering pertinent projects and places of interest in Pakistan, Egypt, Palestine and Holland. Mrs. Olafson and their four small children accompanied Mr. Olafson during this interesting, if only partially rewarding assignment.

Walt Thomson introduced Mr. Olafson, and Charlie Moore expressed the thanks of the membership present for his very interesting and educational address.

Mr. and Mrs. Geo. Brown provided dinner music and accompaniment for community singing led by George Brown.

Novelty vocal numbers were presented by very charming and talented young Miss Dolores O'Connell, who was accompanied at the piano by her father.

R. A. Thrall is Speaker

Alberta has a large percentage of the world's known reserves of coal, tremendous petroleum and timber resources; however, these are only a small part of the important resources of this province, according to R. A. Thrall, guest speaker at the Lethbridge Branch regular dinner meeting held February 11.

In his talk, Mr. Thrall, a prominent Lethbridge business man, manager of the McIntyre Ranching Company, the Summit Lime Works, and Mountain Minerals, listed resources roughly into two main classifications, human and physical. The physical resources may be further broken down into three main classifications. First, those which do not diminish with use such as air and scenery. Second, there are the recurring resources such as rain, grass and other crops, and livestock. Under the third sub-classification come the disappearing resources such as petroleum, mined minerals and timber. Whereas timber does recur the time for this to take place is so long that it may be classified as

• Branch News

non-recurring for practical considerations.

Alberta's Resources

When we consider the clear pure air of this province we take too much for granted. Industrialization on a large scale can cause smog conditions such as found in Los Angeles and London.

Water is a resource which is often in short supply. Mr. Thrall noted that it costs about 5c per ton to purify salt water, and Lethbridge water is sold for from 5c to 12c per ton. A prominent oceanographer Professor Isaacs has estimated that Antarctic icebergs weighing 1,000 million tons, could be towed and floated with the aid of the Humbolt stream to Los Angeles for approximately one million dollars, or one tenth cent per ton. Such an iceberg containing only pure water would be worth 10 million dollars at 1c per ton.

Referring to Western Canadian and local engineering, the speaker suggested that water conservation projects such as the South Saskatchewan river irrigation scheme should be proceeded with as soon as practicable in order to conserve this practical resource. Water uncontrolled can cause havoc, and Mr. Thrall suggested that the gas turbine-generator for Lethbridge might be installed away from the steam plant and out of the river valley in order to achieve protection from floods.

At the home of J. L. Armstrong and Mrs. Armstrong in Nobel, Ont., engineers were entertained to a buffet supper and an Ontario Hydro-Electric Power Commission film on December 1. Front row, left to right: P. G. White, W. Ayers, J. C. Conrath and R. A. Nutt. Second row: P. A. Ross-Ross, C. Fry, J. L. Armstrong, F. Alport, E. P. Guloien, and M. L. Rooney. Back row: C. A. Margison, H. R. Montgomery, R. Harper, Col. L. F. Grant, A. Rowbotham, and J. A. Chant.

Livestock and Minerals

Wherever good livestock are in evidence, good civilization is in evidence also. Lethbridge used to be in the midst of one of the world's finest grass areas, and grass and consequently livestock are very important resources of this province.

Alberta stood third among the provinces in 1955 in mineral production, largely because of petroleum which pro-

Roto-King Pumps are manufactured only by Viking Pump Company, Cedar Falls, Iowa, U.S.A.

THROUGH ERROR, our advertisement for Roto-King pumps in a recent issue of this magazine showed illustrations upon which the word "Viking" appeared. "Viking", in Canada, is the registered trade mark of Viking Pump Company, Ltd. of Windsor, Ontario, Canada, and our use of that mark in Canada was unauthorized. We regret this error. In the United States the "Viking" mark has been owned and the pump manufactured since 1911 by the original Viking Pump Company of Cedar Falls, Iowa, U.S.A.

Our November ad announced Roto-King pumps. "Roto-King" in Canada is the registered trade mark of Viking Pump Company, Cedar Falls, Iowa, U.S.A. which has no connection whatever with the Canadian company.

Viking Pump Company, Cedar Falls, Iowa, U.S.A. is the world's largest, exclusive manufacturer of positive displacement rotary pumps. It originated the "gear-within-a-gear" principle in 1911, and has been continuously engaged in the manufacture of a full line of positive displacement rotary pumps embracing that principle ever since.

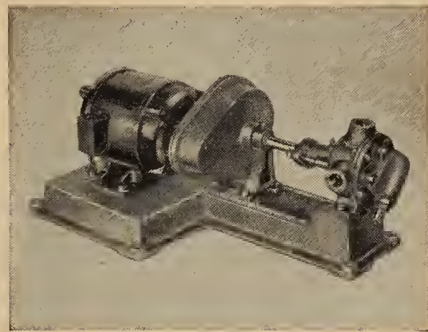
Its pumps have been sold throughout the U.S.A. since 1911 and in most nations of the world under its trade mark "Viking", but are marketed in Canada under the trade mark "Roto-King".

Strict quality control,

including iron and brass castings from its own foundries, a large engineering and research staff constantly seeking improvements,

and modern manufacturing methods utilizing the latest developments in metal working,

combine to make the products of Viking Pump Company, Cedar Falls, Iowa, U.S.A. the standard against which its competitors' products are measured the world over.



General purpose pump mounted gear drive unit.

vided the highest dollar value of any of Canada's mineral resources. Other minerals in order of value were copper, nickel, gold, zinc, iron ore, asbestos, coal and lead.

The Mountain Minerals plant in Lethbridge processes barytes, pyophyllites, talc, volcanic ash. Barytes which weighs 300 lbs. per cu. ft. is used for "heavy mud" for oil well drilling.

The human resource must be improved if other resources complemented by nuclear energy are to be used to the benefit of mankind. Mr. Thrall stated he looks to the future with the greatest of confidence.

C. S. Clendening introduced Mr. Thrall, and the thanks of those present was expressed by C. E. Little.

Musical entertainment was provided by Brown's Orchestra who supplied dinner music and accompaniment for community singing ably led by Bob Lawrence, George Brown, and Ron Jones. The "Serenaders" favoured the meeting with several barber shop quartet numbers, and encores.

Montreal Junior Section

John Mikulec,
Secretary-Treasurer
Yvan Montcalm, Jr.E.I.C.,
Publicity Chairman

Annual Meeting

The annual meeting of the Junior Section, Montreal Branch, took place on January 16 at headquarters. It was the scene of an election which resulted in the appointment of four new directors, namely, Messrs. Jim Coke, Simon Marcotte, Robert Walker and G. Vermette.

G. L. McLean Elected Chairman

New Chairman G. L. McLean told the members in attendance that every effort would be made to arrange a program that would differ from that of other years and urged all young engineers to participate in the activities of the Institute.

Executive Members

Other members of the executive are: Jacques Soucy, vice-chairman; John Mikulec, secretary-treasurer. Heading committees and working groups are: André Bérard, Steve Bloomer, Jean Blouin, William Broughton, William Cameron, Jean Dubuc, Gaetan Ducharme (ex-officio), Maurice Joubert, Yvan Montcalm, Yves Rousseau and Ron Somers.

Four Speakers at Dinner Meeting

A dinner meeting of the Nipissing and Upper Ottawa Branch was held on Wednesday, January 11, at the Windsor Hotel in Sturgeon Falls. Members were present from Temiskaming, North Bay, and Sturgeon Falls, with several guests from the Sudbury Branch. The meeting was conducted by Chairman R. Prescott of Temiskaming.

J. S. Cooper

After dinner four brief papers were presented. Mr. Prescott first introduced J. S. Cooper of North Bay, assistant chief engineer of the Ontario Northland Railway who served during World War II as engineering officer with the Royal Navy and the Royal Canadian Navy. With the aid of drawings Mr. Cooper described the engine room and auxiliary equipment of large battleships and destroyers. *H.M.S. Queen Elizabeth* was constructed, he said, with four boiler rooms and four engine rooms, each separated from the other by heavy bulkheads with a valve system by means of which any engine room could be connected to any boiler room in case of damage. The ship carried 3,300 tons of oil not only for her own use but also for refuelling of smaller vessels at sea. He gave a brief description of auxiliary equipment for lubrication, water and fuel pumps, the closed system for feed water, air compressors for torpedo discharging and all important provisions for fire and damage control.

L. Wilson

The second speaker, L. Wilson, township engineer for Neelon and Garson, was introduced by Ted Powell, consulting engineer from Sudbury. His topic was "Problems in a Typical Mining Community." He outlined the problems of a residential community adjacent to a community with one large central industry. The residential area is not self-supporting from local taxes. Education development and maintenance costs are high. Debts tend to pile up and it becomes difficult to sell debentures. To minimize the above, he said, development must be carried out in a sane manner. Subdivisions have come to realize that they must provide many initial services. Without presenting a final solution Mr. Wilson discussed the alternatives of amalgamation, annexation, and the more favoured creation of a metropolitan area which would provide assistance from assessment of the neighbouring industries.

M. Felix

M. Felix, mechanical engineer with Canadian International Paper Company, Temiskaming, was then introduced by the chairman. His subject was "Problems of Industrial Documentation." He emphasized the need in industry for a logical and simple system for locating desired information in libraries, periodicals and other sources. Libraries are usually remote, he said. Circulation of many periodicals through a plant is an expensive and inefficient method of distributing information. The long time required results in a loss of novelty. It was felt that someone conversant with company operations should be assigned the job of circulating bulletins on available material. This information should be indexed and classified. A big problem, of course, is the classification suggested. Use of the decimal system was suggested.

E. Heslop

The final speaker of the evening was Elliot Heslop, assistant manager of the Sturgeon Falls division of the Abitibi Pulp and Paper Company, who was introduced by Frank Clark. His topic was "Dimensions of Materials Used in Paper-Making." Mr. Heslop first emphasized the difficulty in forming a clear mental comparison of dimensions of very small particles when stated in microns, and also the tendency to assume erroneously that very small particles are perfect spheres or perfect cylinders.

Illustrations depicted on a highly magnified view of a section of paper-making screen gave a clear picture of the sizes and shapes of various hard and soft wood fibres, clay filler particles and micro organisms, etc., and of how they interlock and adhere to each other to form paper. The effect of the irregularities of these particles and of the screen itself in producing a rough surface on the paper was discussed and also the means adopted to smooth the paper by means of clay filler paste and rolling to provide a surface suitable for the printing of coloured pictures.

The meeting was then briefly addressed by W. S. Black, chairman of the Sudbury Branch. P. Rebin of Sturgeon Falls expressed the appreciation of the group to all of the speakers and the meeting was adjourned on the motion of J. W. Millar.

Saint John

D. I. Higgins, jr.e.i.c.,

Branch News Editor

The annual meeting of the Saint John Branch was held on Tuesday, December 13, 1955, in the Admiral Beatty Hotel.

Officers for the coming year were elected with F. G. Doty, chairman; J. J. Donahue, vice-chairman; D. R. Higgins, secretary-treasurer; H. N. Day, councillor, and J. B. Eldric Jr., councillor.

Minutes of the last annual meeting, reports of the Executive, and a report of the councillor, A. G. Watt, were presented at this meeting.

A total of 108 members were listed for the year 1955.

At the close of the business meeting two films were shown, a documentary of the life of Leonardo da Vinci, and another entitled, "See How They Fly".

"The Microwave Story" by D. G. Black

The regular monthly meeting of the Sudbury Branch was held at the Granite Club on Thursday, January 12, 1956.

"The Microwave Story" and its connection with long distance transmission of television programs and long distance calls, was the subject of an interesting lecture given to 34 members and guests by D. G. Black, Bell Telephone Company representative.

4,300-Mile Network

The Canadian Broadcasting Corporation, early in 1955, awarded a contract to the Trans-Canada Telephone System to carry network television programs across the country. In order to meet the C.B.C. contract and at the same time provide increased long distance facilities, the system is now building a 4,300-mile microwave radio-relay network stretching from the Atlantic to the Pacific.

At the present time, microwave links Toronto, Ottawa, Montreal and Quebec City, with a Toronto-Buffalo link to carry television programs to and from the United States. According to present schedules, the Toronto-Winnipeg section will be in operation by the fall of 1956. Regina and Calgary will be added by early 1957. The Quebec-Saint John-Sydney section is expected to be in service by the middle of 1957 and the Calgary-Vancouver chain by early 1958. In addition there will be spur lines built to a number of cities including Sault Ste. Marie, Sudbury, Timmins, Saskatoon and Edmonton.

Television Principles Illustrated

Mr. Black in his presentation used miniature microwave equipment to illustrate some of the characteristics of radio relay and with the aid of a "Nipkow Disc" explained the evolution of basic television principles. A short film also very effectively illustrated the long distance aspect of microwave.

"The completion of the microwave project will mark one of the most significant advances in Canadian Communication," Mr. Black said.

A discussion period followed in which several of the members and guests from the Bell Telephone Company participated.

Students' Night

On February 9 the annual Students' Night was held in Hart House. The successful event was under the direction

Institute members from Hawkesbury, Ont., and Brownsburg, Que., met together on January 19 at the Bridge Inn in Hawkesbury. Front row, left to right: D. R. Crawford, L. T. Gaunt, S. V. Donvito, P. E. Wall, C. Brain, D. U. Findlay, J. K. Watson; middle row: E.E. Lang, W. G. Ivany, G. D. McKay, J. Defeyter, C. Dodd, Col. L. F. Grant, R. J. Child. G. Legault; back row: L. F. Camus, D. Young, J. S. Pringle, R. D. Christie, K. B. Bourne, H. J. Whiting, R. A. W. Bond, B. A. Watson.

of Ivan Widdiefield and Ross Norgrove of the Branch executive. About 150 were present to witness the able efforts of the student panel of experts who had volunteered to appear from the student body of the University of Toronto Faculty of Applied Science.

Quizmaster John Hall drew quick responses from the students on the panel and from the floor. Witty answers brought appreciative laughter and applause from the members present.

Panel of Practising Engineers

While the winners were being selected by the judge, Ross Norgrove, questions of the student panel were answered by another panel of experts, all practising engineers: Clare Carruthers, Bob Teagle and Dunc Whitson. Questions from the students centred principally on the profession of engineering and what it meant to the practising engineer. The expert panel of practising engineers received an attentive hearing. Students remarked afterwards on the statements of this panel, stating the simple lessons learned from them were much appreciated.

Prize Winners

Prize winners in the student panel were: first prize, Al Walden, fourth year chemical; second prize, A. J. Burgess, fourth year civil; third prize, N. Laughlen, fourth year aeronautical.

The Civil Club won the prize for having the greatest percentage of its members present. Various prizes of slide rules and data books were given to those who answered questions correctly from the floor.

Following the quiz program coffee and doughnuts were served in the Great Hall of Hart House. Members and students mingled and discussed student problems to their mutual benefit. Questions such as "Which job should I take?" and "Is it best to work for a large or a small engineering firm?" loom large in the students' minds. The older engineer in practice will realize that the students are asking such questions all the time, and an experienced engineer can help the student to feel at home and be part of the profession with his answers. Many students feel lost and can be orientated and helped to feel the fellowship of older engineers when their questions are answered, even if the answer is only a partial one.

Credit is due to Tony Webster, S.E.I.C., the Professional Relations representative of the Students' Engineering Society who helped to arrange publicity for the event.

Both students at the University and members present enjoyed themselves. All look forward to next year's Student Night with anticipation.

Winnipeg Electrical Section

G. L. MacDonald, M.E.I.C.,
News Editor

R. J. A. Behan is Guest Speaker

At the December meeting of the Electrical Section of the Winnipeg Branch, members heard a talk on testing of low voltage high rupturing capacity fuses by R. J. A. Behan, manager of the fusegear division of the English Electric Company of Canada, Limited.

• Branch News

Low Voltage H.R.C. Fuses

The high rupturing capacity fuse, Mr. Behan said, was developed to cope with higher fault levels and to maintain constant characteristics throughout the working life of the fuse. The latter characteristic was considered a most important feature of the device and tests were primarily to investigate the property of non-deterioration claimed for these fuses. The tests were detailed and also somewhat unique in that they were not of the so called accelerated aging type.

R. J. A. Behan of English Electric Company of Canada Ltd. and G. C. Cartwright of Railway and Power Engineering Corporation, Winnipeg.

Development of the hermetically sealed H.R.C. fuse began in England about 25 years ago, and fuses were available which had been in continuous service from 18 to 25 years, and some record was also available of loading and service conditions of these fuses.

Protective Devices

Protective devices are subject to a variety of conditions that may produce deterioration. They carry varying degrees of load currents, including overloads, and may be called on to withstand through fault currents of considerable magnitude. They may be exposed to extremes of ambient temperature and to innumerable cycles of expansion and contraction of the metal parts. They may also be subject to mechanical vibration of associated equipment, and to atmospheric contamination.

The principal components of the fuse are a ceramic body, pure silver elements, clean silica quartz, asbestos washers, and copper end caps and tags, the last two being electro-tinned. The fuse is hermetically sealed and the silver elements are solidly soldered to the end caps, and the end caps, in turn, soldered to the tags. Solid solder joints are used throughout, the object being to effect a perfect electrical contact without affecting the structure of the materials being joined together.

To provide a basis of comparison, a number of fuses were made up to exactly the same specification as the earlier types of fuses being tested, and old and new fuses were tested simultaneously when possible. Tests included visual examination of all inner and outer components, X-ray tests, X-ray difraction tests, photo-micrograph examination of fuse elements, measurement of resistance, temperature rise at full rated current, determination of minimum fusing current, and short circuit tests at various values of fault current.

Hermetic Sealing Effective

It was found that the hermetic sealing emained completely effective. The silver elements were as bright as when first placed in the fuse, and the quartz filler was completely unchanged. The elements were in their proper position and free from sagging or thinning as might be caused by mechanical or thermal stress. All solder joints were completely effective and cement joints as effective as when the fuse was new. Resistance tests showed that, in all cases, the fuse links were within the permitted tolerance of plus or minus 5 per cent. Temperature rise, measured at the top contact, top terminal and on the cable 12 in. from the top contact, was also within permitted tolerance. Short circuit tests were considered the most critical as the test imposes the maximum stress on the fuse link, both electrically and mechanically, and the criterion of success is that the fuse will interrupt the short circuit without bursting, or in any way damaging associated equipment. A study of the current limiting characteristic of the fuse was included in the short circuit test. Test results and oscillograms were shown by slides. The old fuses successfully interrupted short circuit test currents, and the oscillograms showed a remarkable degree of agreement between the old and new fuses, both as regards operating time and the shape of the prearcing and arcing curves. A point of interest on the oscillograms was the fact the arc voltage, in no case, exceeded the system voltage by more than a small margin.

President R. E. Heartz, right, presents the certificate of Life Membership in the Engineering Institute to Dr. E. P. Fetherstonhaugh, while Mrs. A. E. Macdonald looks on.

Test on Associated Equipment

A separate series of tests was carried out on associated equipment, including motor starters and fusible disconnect switches. Specification C22, No. 106, calls for a low voltage H.R.C. fuse to have an interrupting capacity of 100,000 R.M.S. asymmetrical amperes at 600 volts. It was desirable to know what would happen to associated equipment when the fuses were interrupting fault currents of this magnitude. Short circuit tests were carried out on standard combination magnetic starters, Sizes 1, 2, 3 and 4, fitted with high rupturing capacity fuses. Tests were made at 46,000, 66,000, and 80,000 symmetrical amperes. Three tests were made at each fault level on each starter with the fault applied to the closed starter, and a further three tests on each by closing the starter on the fault. Tests were satisfactory and all starters were suitable for use after the tests were made. A switch, of the service entrance type, rated 200 amps, 575 volt, 3 PST, was fitted with high rupturing capacity fuses and subjected to the same test. Again, three short circuit tests were made at each fault level, with the switch closed, and a further three tests at each fault level by closing the switch on the fault. A slight burning of the contacts was experienced and the switch was suitable for further use without replacement of any parts.

Helicopter Company Tour

Members of the Vancouver Branch spent an interesting morning as guests of Okanagan Helicopters Limited at Vancouver International Airport on Saturday, January 28, 1956.

The party was welcomed by A. Stringer, vice-president in charge of engineering, who gave a discussion on the history of the company and its future plans. This was followed by the showing of two films depicting the rise of helicopter transportation to its present position of importance in industrial development. In his talk, Mr. Stringer outlined the many problems and trials that faced the growing company and then went on to tell of current plans to extend operations into other areas and of plans for regular helicopter passenger service as soon as equipment becomes available.

Under the guidance of the pilots, individual groups then inspected some of the helicopters in the hangar and were shown the points of interest of the machines and the method of operation.

BOOK REVIEW

Industrial lubrication practice. P. D. Hobson. New York, Industrial Press, 1955. Various paging, illus., $8.00 (U.S.).

Directed primarily to plant lubrication overseers, this book will be of interest also to plant engineers, maintenance engineers and repair superintendents. The author concentrates on practice, machine design, operation, the lubrication systems and the conditions under which the lubricant must function. Text is accompanied by good diagrams, illustrations and views. The Appendix has useful charts covering blending; gravity, temperature and viscosity conversion, Viscosity Index chart, and a Glossary of Terms.

Generally speaking this text covers a wide range of applications in a thorough and very complete way. It should prove a good reference for those concerned with the lubrication and maintenance of machinery. The chapters covering Types of Lubricants and their Use is apt to create some misconceptions for those who are learning about lubricants. The term asphaltic is no longer considered synonomous with napthenic, and lubricating oils produced from napthenic stocks do not contain asphalt. In the section on lubricating greases the statement "Barium grease has no dropping point in the normal sense" is misleading and we rather suspect that the author was confusing Barium with Bentone. Also the statement that Calcium base greases are insoluble in water and may be used submerged in it, must be taken with reservations, since continuous exposure to water will result in fairly rapid break-up of the common types of Calcium base greases.

The contents of the chapter on Physical and Chemical Characteristics of Lubricants could have been more interesting by the use of illustrations of the test apparatus. The text is rather skimpy on the subject of viscosity and fails to bring out that the majority of oil companies use the Kinematic Viscosimeter and convert back to Saybolt Universal. In other chapters we feel that the book would benefit from some updating of material, particularly with regard to the comment on compression ratios of Four Stroke Gasoline Engines, and on the A.P.I. MM classification. Chapter 23 on Cutting Fluids is a very good chapter but needs some updating on new cutting oil types. In Chapter 25 no mention is made of solvent carrier type wire rope lubricants.

The major part of this work is very well done, with comprehensive coverage of the subject, good illustrations and good maintenance information.

John H. Whyte,
British-American Oil Co. Ltd.

BOOK NOTES

Prepared by the Library
The Engineering Institute of Canada

*Review provided through the courtesy of the Engineering Societies Library in New York.

Air industries and transport association of Canada reports, 1954-55. Quebec City, 1955. 132pp.

Following the general manager's report and the summary of the work done by different committees of the association, there is a section of statistics on labour trends in aviation, licensing, aircraft accidents, etc. This is followed by an outline of the activities of the members of the association and a directory of products and services. The last section lists the important personnel, and their positions, of the member companies.

Alloy series in physical metallurgy. M. C. Smith. New York, Harper, 1956. 338pp., $6.00 (U.S.).

This is the companion volume to the author's **Principles of physical metallurgy,** which is reviewed below, and presents the background for this book.

We find here a systematic discussion of the effects of composition and of heat treatment upon the structures and properties of metals and their alloys.

In detail, the chapters cover such subjects as the phase rule and its applications, constitutional diagrams, binary alloys, changes in solid alloys, alloys of iron and carbon, the cast irons, and ternary and higher alloys.

Basic television. Indianapolis, Sams, 1955. 304pp., illus., $5.00 (Practical training manual; television series, v.1).

This practical manual is divided into 24 lessons which include both theoretical and practical discussions of each subject, with emphasis upon modern commercial circuits. Topics covered are commercial cathode-ray oscilloscopes; AM and FM carrier waves; detectors; antenna; picture tubes; tuners, sweep circuits, I F amplifiers; sound and video systems; and others.

A separate section gives suggested shop jobs on a number of different projects so that students can practice the lessons in the manual.

Bibliography on machinery foundations; design, construction, vibration elimination. Engineering Societies Library. New York, The Library, 1955. 25pp., $2.00 (U.S.).

This revised list of annotated references to books and periodical articles, published from 1924 to 1955, covers the theory, design and construction of machinery foundations; certain specific problems such as heavy foundations on unstable soils; and vibration as related to foundations of hammers, oil engines, electrical machinery, turbines, steam engines, compressors, machine tools, pumps, presses, etc.

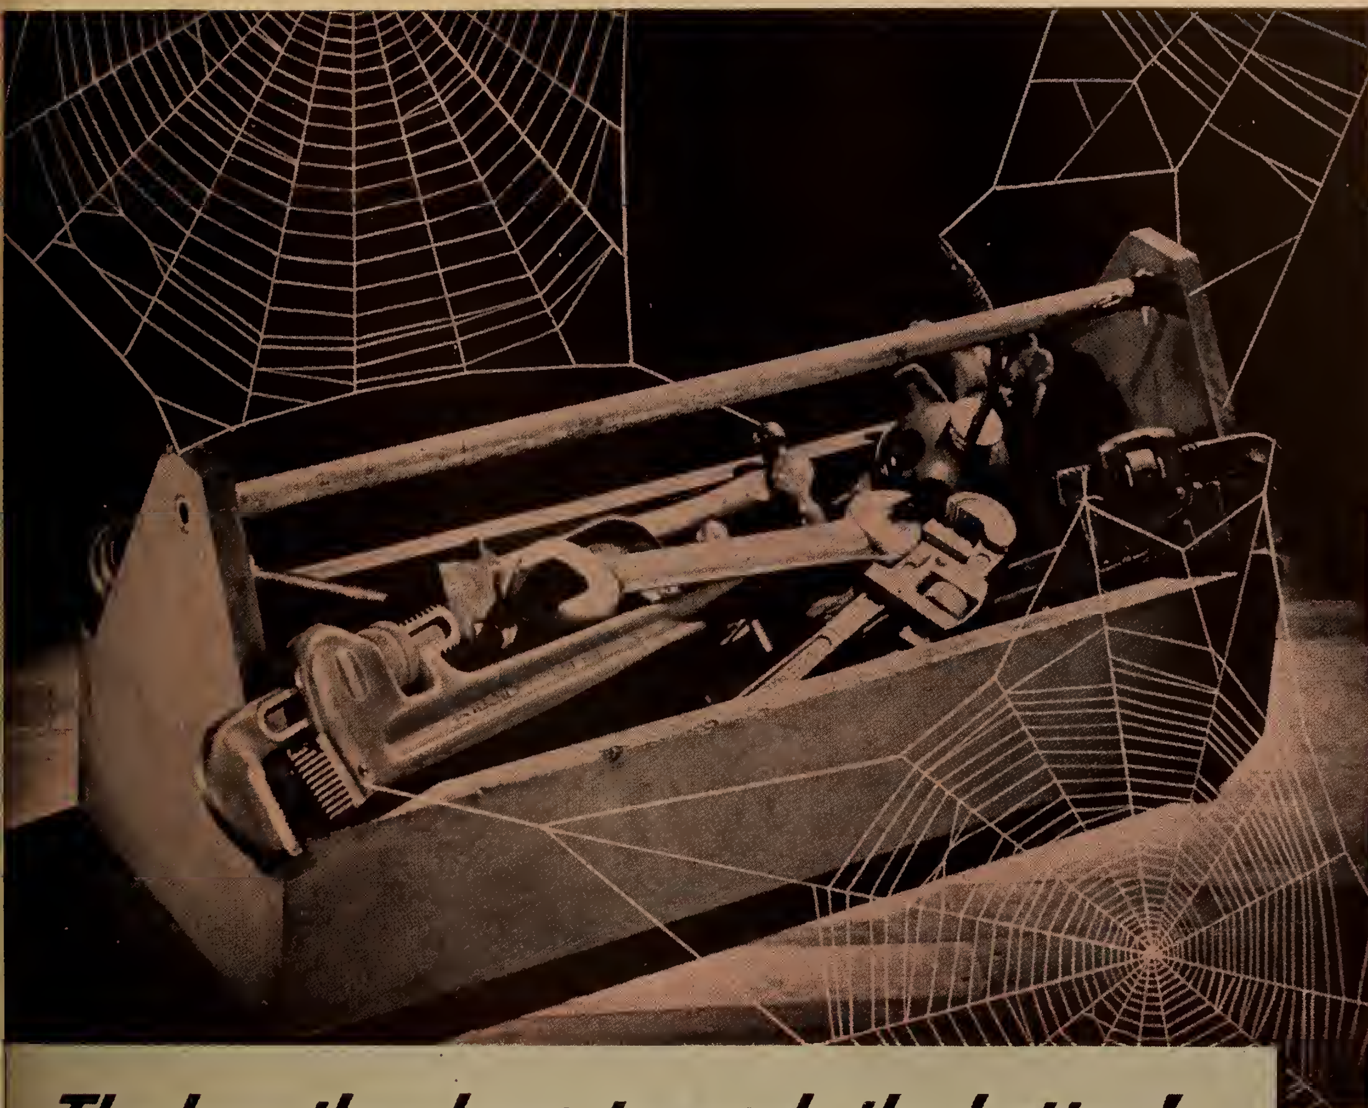
Compact heat exchangers: a summary of basic transfer and flow friction design data. W. M. Kays and A. L. London. Palo Alto, Calif., National press, 1955. 156pp., diagrs., $5.00 (U.S.).

The purpose of this volume, which first appeared as a technical report to the Office of Naval Research, is to make available the results of experimental and analytical work on compact heat-transfer surfaces. All the types in use today are dealt with, including tube banks, plate-fin surfaces, finned tube surfaces, screen and sphere matrix surfaces. Basic heat transfer and flow friction test data are presented for a total of 88 surface configurations.

Other chapters consider analytical solutions for abrupt contraction and expansion pressure-loss co-efficients, laminar-flow heat transfer in circular and rectangular tubes, and the effects of temperature-dependent field properties on heat transfer and flow friction. There is also a discussion of heat-exchanger performance theory, developed around the effectiveness versus number of heat-transfer units concept.

***Design of heating and ventilating systems.** F. W. Hutchinson. New York, Industrial Press, 1955. 308pp., diagrs., $7.00 (U.S.)

Intended to supplement rather than to replace standard texts in the field, this book emphasizes the elements of the system which require the rational application of engineering knowledge. Considerable space is allotted to the factors involved in determining loads — transmission losses, intermittent heating, ventilation, humidification, and losses from ducts, — and design procedures are given



The less they have to work, the better!...

HERE'S ONE PLACE where cobwebs would be strictly O.K.—on piping maintenance tools. For the less they have to work, the lower your maintenance costs. Excessive valve maintenance is serious simply because the average plant has so many valves. So it's sound economics and good business to buy quality and low maintenance rather than "bargains" and frequent maintenance.

Naturally, the thrifty buyer always chooses quality valves, and for biggest value he insists on Crane. There's no greater assurance of dependable, low-cost performance . . . and the Crane line provides such quality in valves for every need.

For complete information on the Crane Valves to meet your particular requirements, ask your Crane representative, or Crane Branch—or write

for panel and solar heating as well as for conventional systems. Full-page graphical solutions of important equations are included, along with basic data for solving many practical problems.

Dimensional motion times; development and application. H. C. Geppinger. New York, Wiley. 1955. 100pp., illus., $4.00.

This is the first broad survey of a new motion time system and it will interest many plant supervisors and managers. It describes concisely how to specify and record work details by motions and how to predetermine the necessary manual time of operations, and shows how to ensure uniformity of analysis context and measurement.

Familiarity with decimal equivalents and the ability to read blueprints are necessary for a better understanding of this technique. Complete examples of the application of the theory are included.

Electric melting and smelting practice. A. G. E. Robiette. London, Griffin. 1955. 347pp., illus., $7.20.

The author's **Electric melting practice,** published in 1935, was the basis for this new book, the scope of which is extended by the inclusion of a survey of smelting practice.

The book deals with the construction and operation of all the principle types of electric furnaces in use: arc furnaces for steel-making, for melting iron and for non-ferrous metals; normal frequency or channel-type induction furnaces; high-frequency or coreless induction furnaces; and resistor melting furnaces. The basic principles of operation, and the electro-chemistry of the different processes are explained with particular attention given to changes in design of plant due to increasing size and mechanization.

The electrical engineer's reference book. 7th ed. Toronto, British Book Service, 1954. Various paging, $14.00.

Arranged in thirty-two sections, this is a broad survey of modern standard practice and the most recent information on new developments in all branches of electrical engineering.

The 7th edition includes such new subsections as generators for steam and gas turbine drive; generators for hydroelectric plant; power station batteries; Diesel engine power plant; controlled expansion alloys: argon shielded welding.

Following the first section on basic electrophysical principles, there are twenty-seven sections describing standard practice in applied electricity. Another section, entitled "Progress", covers development, research, construction and design in all branches.

In addition to the technical sections, there are others dealing with education, electricity rules, regulations and supply data, periodicals and bibliographical references.

***Electronic and radio engineering,** 4th ed. F. E. Terman. Toronto, McGraw-Hill, 1955. 1078pp., diagrs., $15.00.

The change of title in this edition from the title, ***Radio Engineering,*** of the previous editions reflects the greater

emphasis on general techniques of electronics without regard to their use in radio systems. In manner of presentation and coverage the book remains the same: a summary in readily understandable terms of basic principles and techniques treated in three parts devoted to circuit elements and circuit theory, radio engineering and radio systems, and electronic fundamentals. Some material has been added to most of the chapters, and the chapters on microwave tubes and transistors are new.

L'électronique française. Paris, Syndicat des industries de matériel professionnel électronique et radioélectrique. 1955. 68 pp., illus.

This is a catalogue of electronic equipment produced by French manufacturers, with a description of each item in French and English.

FBI register of British manufacturers, 1956, 28th ed. London, Iliffe, 1955. 1110 pp., 42/-.

Listing the products and services of 7,000 British industrial firms, the Register also features French, German and Spanish glossaries, and an alphabetical directory of member firms of the Federation of British Industries.

The Financial Post survey of mines, 1956. Toronto, Financial Post, 1955. 376 pp., illus., $3.00.

1955 saw important developments in Canadian mining, especially in the production of uranium, copper and nickel. This new edition of the Financial Post survey of mines again includes statistical data on mineral production, price range of stocks and metals, and a large section, alphabetically arranged by provinces, on the principal milling plants in Canada. At the conclusion of the survey are a professional directory and maps of Canada's mineral areas.

The foreseeable future. George Thomson. Toronto, Macmillan, 1955. 166pp., $2.00.

A well-known scientist and winner of the Nobel Prize, who is concerned with nuclear physics, fuel research and scientific administration, writes of the changes which science could bring about in our world in a hundred years. He forecasts the exciting changes which might occur in the fields of energy and power, materials, transport and communications, meteorology, food and biology. The social consequences of such scientific advances are discussed and the last chapter is devoted to the new possibilities of artificial and natural thought, with the many problems which may arise.

Guidance. A. S. Locke. Toronto, Van Nostrand, 1955. 729 pp., diagrs., $13.50. (Principles of guided missile design, ed. by Grayson Merrill, v. 1).

This is one of several volumes which present the underlying principles of guided missile technology. In particular, it deals with those devices and techniques that are used to guide missiles.

The first two chapters describe the fundamental problems of missile guidance and earlier developments in the field. These are followed by chapters (each written by a specialist in that aspect of the subject) on terrestrial and celestial references, transmission of radio waves, emission, transmission and detection of the infra-red, basic mathematics, servo systems, measurements of missile motion, detection and information gathering, and target considerations.

There are also sections on launching missiles, economic considerations, missile guidance systems and bandwidth studies.

Illuminating engineering course. H. Zijl. Eindhoven, Philips, 1955. 241 pp., $4.50 (U.S.).

Many aspects of illumination are treated in the twenty-three chapters of this book which is more practical and utilitarian than artistic. The theoretical technical principles of lighting are covered, with a minimum of mathematics, and are related to the basic rules which govern visual perception and mental reaction.

Architects, works or production managers, as well as illuminating engineers, will find this book helpful. A large number of questions and examples are included.

Kinetic theory of liquids. J. Frenkel. New York, Dover, 1955, c. 1946. 488pp., $1.95 (U.S.)

This volume includes discussion of all types of arrangements of solids, thermal displacements of atoms, motion, interstitial atoms and ions, and transition between states of matter.

The mathematical analysis of electrical and optical wave-motion on the basis of Maxwell's equations. H. Bateman. New York, Dover, 1955, c. 1914. 159pp., $1.60 (U.S.).

This is a practical introduction to those developments in Maxwell's electromagnetic theory which are directly connected with the solution of the partial differential equation of wave-motion.

Modern physics. R. L. Sproull. New York, Wiley, 1956. 491 pp., diagrs., $7.75.

Those aspects of modern physics most productive of engineering applications form the subject of this analytical book. Crucial experiments are analyzed and the elementary theory underlying the properties of atoms, molecules, solids, and nuclei is based on this analysis.

The first two chapters discuss fundamental particles and their assembly, followed by a chapter on atomic physics which is divided into a study of the extranuclear structure of the atom and the study of nuclear physics.

The next three chapters are devoted to quantum mechanics and its applications. The author then turns to the development of molecular and solid-state physics before returning to the subject of nuclear physics. Included in this last chapter is a section on nuclear reactors and on applications for radioactive isotopes.

Mks units are used throughout the book but instructions are given for converting to cgs units. Other useful data and tables are found in the appendices.

The nature of cities. L. Hilberseimer. Chicago, Theobald, 1955. 286pp., illus., $8.75 (U.S.)

The origin, growth, and decline of cities is an important topic today and the value of this book is heightened by the high calibre of the illustrations. It discusses early settlements as well as modern cities and is divided into three sections.

The first part is a history of various types of cities and clearly illustrates how they reflect the social and cultural trends of the age. The second part deals with the geometric and organic planning of cities and includes notes on the architecture and landscaping of certain representative cities. The final section is concerned with the present day problems of cities e.g. the rapid growth of industry and mechanized transportation, traffic hazards, noise, air pollution, blight and slums. The possibilities of decentralization, replanning of old cities, and ruralizing cities are discussed.

The author has written extensively on art and architecture, housing and planning and is well known in both Europe and the United States.

Partial differential equations of mathematical physics, 2nd ed. A. G. Webster, ed. by S. J. Plimpton. New York, Dover, 1955, c. 1938. 440pp., $1.98 (U.S.).

This treatise covers the basic method, theory and application of partial differential equations, dealing with integral and elliptic equations, Cauchy's method and other topics.

Principles of physical metallurgy. M. C. Smith. New York, Harper, 1956. 417pp., $6.00 (U.S.).

This is the first of two volumes which present the theory of metal behaviour in an integrated and consistent manner.

The principles of physics and chemistry, as relating to the field of metallurgy, are outlined in the introductory chapters. These include descriptions of the atom, crystal structures, polymorphism, and crystal imperfections. The next chapters discuss the electrical and magnetic properties of metals, deformation, the effects of elevated temperature, and fracture.

The second volume in the series, **Alloy series in physical metallurgy,** begins where the present book ends.

Proceedings of the joint conference on combustion, sections 1-5, advance copies. Institution of mechanical engineers and the American society of mechanical engineers. Westminster, The institution, 1955. £2.5s (for the bound volume to be published later).

The first of the five sections deals with general questions of combustion—its chemistry and physics, scientific principles, and an appraisal of combustion research. The second section on boilers includes papers on the detection of flame failure, effect of fuel properties on firing methods and liquid-fuel firing. Among the papers on industrial furnaces are those on gas as a source of protective atmosphere, instrumentation of process tubular heaters, and oil burners for open-hearth furnaces. The fourth part of the proceedings deals with internal-combustion engines and discusses combustion in large diesel engines, in diesel engines with divided combustion chambers, in petrol engines, and in dual-fuel engines. The last section on gas turbines contains papers on coal-firing for the open-cycle gas turbine, combustion of residual fuel in gas turbines, and application of research to gas-turbine combustion problems.

Rotorcraft. R. N. Liptrot and J. D. Woods. Toronto, Butterworth, 1955. 161pp., illus., $6.50.

Here is a fairly comprehensive treat-

what's your PROBLEM?

Dusty Roads?

Ice Control?

Concrete Curing?

BRUNNER MOND

Calcium Chloride

is the answer!

IMPROVE GRAVEL ROAD MAINTENANCE, at no extra cost. Use Brunner Mond Calcium Chloride with binder soil to cut down hours of work for road gangs, save road metal and provide a smooth, hard, dustless surface that stands up longer with minimum maintenance.

GET BETTER ICE CONTROL. Abrasives treated with Brunner Mond Calcium Chloride bore right in. They cannot blow away, reducing labour and material costs and providing quicker, surer stops.

SPEED UP CONCRETE CURING. Brunner Mond Calcium Chloride produces a denser, tougher, more waterproof concrete, increases workability and permits a lower water-cement ratio. Brunner Mond Calcium Chloride speeds the set, cuts down protection time and minimizes freezing.

It pays to use Brunner Mond Calcium Chloride. Our engineers will be glad to talk to you about it.

BRUNNER, MOND CANADA SALES, LIMITED

"Less Cost — Greater Safety"

• Library Notes

ment of rotary wing aircraft, presented in a simple and practical manner. After a historical resume there is a chapter on definitions, nomenclature, and basic principles of rotor flight. A general description of the operation of the helicopter precedes more technical and detailed chapters on rotor aerodynamics, the articulated rotor, vibration and noise, and control and stability. The last two chapters discuss design study procedure and economics of the helicopter.

The appendices include specifications of numerous makes of rotorcraft, a bibliography, and names and addresses of manufacturers.

Strengthening management for the new technology. New York, American management association, 1955. 64pp., $1.75 (U.S.).

Three phases of the new development in management are here discussed: developing patterns in company organization, management development under changing conditions, and the impact of automation on these aspects of management.

A study of the September 1952 dust explosion at Port Arthur grain elevator no. 4A. A. R. Morse, Ottawa, National research council, Radio and electrical division, 1955. 158pp.

This study includes a review of other dust explosions as well as the one at Port Arthur, and also investigates the possibility of ignition of grain dust clouds by electrostatic or mechanical sparks. The report contains a bibliography, arranged chronologically and giving abstracts of articles.

The supervision of civil engineering construction. A. C. Twort, Toronto, Macmillan, 1955. 234pp., illus., $4.25.

The duties and responsibilities of the civil engineer who supervises construction of works on the site are here discussed. Young "resident engineers," as they are described in this book, will be helped by the practical information and advice offered by the author.

Part I of the book outlines the chief supervisory duties and powers, and responsibilities for organization and management, of the resident engineer. It also deals with the administrative and clerical work connected with the position.

Part II is more technical and describes the types of civil engineering work which are common to almost all contracts.

The last section includes specifications, bills of quantities and contract drawings.

Traffic engineering and control in the United States. Organisation for European economic co-operation. Toronto, Ryerson, 1955. 186pp., illus., $1.25.

This report was prepared by a group of road engineers, chiefs of police, town planners and representatives of road users, who visited the United States in 1954. A general review of American traffic conditions is followed by the conclusions, observations and recommendations of the group.

The main part of the report deals with such specific problems as highway administration and finance, road and street design, parking, traffic laws and control, and traffic safety education. The appendices include statistical tables on U.S. highways and a short note on the New Jersey turnpike.

Trigonometrical series. Antoni Zygmund. New York, Dover. 1955, c. 1935 329pp., $1.85 (U.S.).

The theory of trigonometrical series is covered in twelve chapters, half of which treat the Fourier series. The theorems of Hausdorff-Young and Riesz. Fejer, Cantor-Lebesgue, etc. are discussed. With a few exceptions, the book does not presuppose any special knowledge.

Vacuum valves in pulse techniques. P. A. Neeteson. Eindhoven, Philips. 1955. 170pp., 27/-.

In this book a method is developed to analyze networks containing vacuum tubes which are treated as non-linear elements. These new calculation methods could apply to the whole field of electronic pulse equipment such as computers, scalers, radar, television, telephony, etc.

The introductory chapters discuss the opening and closing of switches in networks and some principles of operational calculus, followed by a thorough study of the vacuum valve as a switch. This section is sub-divided into a treatment of the grid circuit and of the anode circuit, both for the triode and pentode.

In the last chapters, three important and widely used circuits, known as multivibrators, are described—these are the bistable, monostable and astable multivibrators. Throughout the book, the author presents experimental verification of the theories included.

Year book of the heating and ventilating industry, 1955. London Technitrade Journals. 1955. 379pp. 8/4.

While some of the sections in this year book, in particular those concerning the working agreements in Great Britain between employers and contractors, will be of little use to Canadian users, there are "feature" articles which will interest anyone in the heating and ventilating industry. These discuss fuel consumption, heating and ventilating on the farm, the selection and application of unit heaters, and panel heating. As in former editions, there is a buyers' guide, and lists of trade names, manufacturers' addresses, and trade associations.

STANDARD REVIEWED

A.S.T.M. standards, American society for testing materials, 1916 Race Street, Philadelphia 3, Pa.

A.S.T.M. standards on paper and paper products and shipping containers (with related information) September, 1955. $3.75 (U.S.).

A total of 101 designations are included in this publication. There are five new standards and ten others have been revised since the previous edition, published in 1953. There are seven appendices, four of which are new.

New standards cover Tentative specifications for electrical insulating paper—interlayer type; Tentative methods of test for tensile strength of paraffin wax; Tentative method of test for needle penetration of petroleum wax; Tentative method of test for package cushioning materials; Method of test for 45-deg., 0-deg. directional reflectance of opaque specimens by filter photometry.

A.S.T.M. standards on soaps and other detergents (with related information) September, 1955. $2.50 (U.S.).

This compilation containing specifications, methods of test, and definitions of terms for soap and other detergents has been substantially revised since the previous edition was published in March, 1952. Of the total of 42 specifications and tests, six are new and 12 have been revised. There are 17 specifications for soap and soap products, 9 for various alkaline detergents, and 15 methods of analysis covering soaps and detergents. Definitions applying to these materials are also included.

British standards, British standards institution, 2 Park Street, London, W.1. British standards are available from the Canadian standards association, National research building, Ottawa, Canada.

B.S. 2635: 1955—Drafting specifications based on limiting the number of defectives permitted in small samples, by B. P. Dudding. 2/6.

This standard is a contribution to the solution of problems of sampling for industrial specifications. It is intended to aid those concerned in the drafting and use of clauses in specifications based on a statistical analysis of the results of sampling, particularly with small samples. The chances of finding defectives in tests of small samples of consignments of different quality are discussed, and are illustrated by graphs for different sizes of samples and a wide range of percentage of defectives in the articles produced.

The information given in this standard can be applied to individual consignments of goods, for which no information other than that given by the particular sampling test is available; or better still, to the examination of successive consignments to provide information as to the general level of quality maintained by the producer.

B.S. 2640: 1955—Class II oxy-acetylene welding of steel pipelines and pipe assemblies for carrying fluids. 7/6.

This standard is one of the process standards in the comprehensive series for the welding of steel pipeline and tube assemblies. It covers the shop and site oxy-acetylene welding of the steel pipe and tube assemblies suitable for Class II conditions, in sizes up to 20 inches in diameter, and of a thickness not exceeding 7/16 inch. It refers to all types of butt joints, branches and sleeve welds, in addition to qualifying tests for welders.

The appendices give recommendations for the welding techniques, and the method of preparation for macro-etching.

B.S. 2S 99: 1955—80 ton, 2½ per cent nickel-chromium-molybdenum steel (high carbon) for aircraft. 2/-.

This revision of the standard has been prepared to make provision for heat treated parts.

Canadian standards, Canadian standards association, National research building, Ottawa, Canada.

C.S.A. C22.2 No. 24: 1955—Construction and test of temperature-indicating and -regulating equipment, 2nd ed. $1.75.

This specification applies to temperature-indicating and temperature-regulating equipment for potentials up to and including 600 volts between conductors. It applies to electrical control equipment for air-conditioning, heating, cooking, and refrigeration.

C.S.A. C22.2 No. 64: 1955—Construction and test of cooking and liquid-heating appliances (domestic and commercial types) 2nd ed. $1.00.

This specification applies to both portable and stationary cooking and liquid-heat appliances for potentials of 250 volts and less.

It covers toasters, waffle irons, hot-plates (table stoves), sandwich toasters, grills, coffee makers, kettles, chafing dishes, water-heaters, doughnut cookers, portable electric ranges (rangettes) and similar devices, but does not apply to stationary electric ranges, humidifiers, stills, sterilizers or industrial heating appliances.

It applies to cooking and liquid-heating appliances intended for general and commercial purposes, e.g. in homes, restaurants, and similar establishments

ENGINEERING CAREERS

The Royal Canadian Navy

The technical officer, with a solid background of education, training, and experience, is playing an ever increasing part in the moulding of the Royal Canadian Navy to meet the modern trends in sea warfare.

The recent advances in warship design and propulsion machinery and the mounting number of electronic devices and complicated weapons systems carried in fighting ships, have combined to broaden the role of the technical officer in all phases of naval operations.

Officers with engineering backgrounds today are serving in the navy's engineering, electrical, ordnance, constructor, and civil engineering branches.

With the exception of engineering, all of these branches are comparative newcomers to the naval scene, the electrical, ordnance, and civil engineering branches having been set up since the second world war. Each of these activities, however, has been part and parcel of naval operations for some time.

A brief description of the function of each of the technical branches follows.

Engineering Branch: The design, supervision of manufacture, evaluation, operation and maintenance of main and auxiliary prime movers in ships and aircraft and the associated ancillaries and auxiliaries, and the equipment which supplies the services for the ship, such as fresh water production and distribution, air conditioning and ventilation.

Electrical Branch: The design, supervision of manufacture, evaluation, operation and maintenance of electrical equipment, such as power generation and distribution, communications, radar and other detection and warning devices.

Ordnance Branch: The design, supervision of manufacture, evaluation and maintenance of armament in ships and aircraft.

Constructor Branch: The design of the ship as a whole, including its arrangement, structure, floatability, stability, strength, habitability and speed. The design, supervision of manufacture, evaluation and maintenance of the structure, and all fittings in the ship associated with seaworthiness and habitability.

Civil Engineering Branch: The design, construction and maintenance of the Navy's works and buildings.

ENTRY

It is possible for young men who qualify, to enter the Navy's technical branches through the Canadian Services Colleges at Royal Roads, Victoria, B.C., Collège Militaire Royal de St. Jean, P.Q., and Royal Military College, Kingston, Ont., through the Regular Officer's Training Plan (ROTP) at various Canadian universities. In addition, it is possible for an engineer with the required academic and professional background to enter any one of these branches of the service directly from civilian life.

Each technical branch requires the successful candidate to undergo further technical training in the application of mathematics and the physical sciences to the specific problems of design, construction and operation peculiar to each branch.

After completing his formal training, the officer is then employed at sea or ashore until he reaches the higher administrative levels, when his employment is entirely ashore.

The general pattern in the career of a young man with senior matriculation and entering each technical branch is noted below under respective branch headings.

Engineering Branch

(1) Canadian Services College as a cadet; two years.

(2) Sea service with Royal Navy as midshipman (E); eight months.

(3) Royal Naval Engineering College as midshipman (E) to undergo basic engineering training; two years.

(4) Sea training as sub-lieutenant (E); one year.

(5) Specialization course, Royal Naval Engineering College, to specialize as general engineer, ordnance engineer, or air engineer; one year.

Alternative: Direct entry from a background in the physical sciences with training as in (4) and (5) above.

On completion of this training, promotion to lieutenant (E) and employment in the engineering branch.

The general pattern of this employment will include two years at sea in an aircraft carrier as a watchkeeping and departmental officer, during which time the officer will be responsible for operating a main propulsion plant of up to 80,000 h.p., and maintenance of a section of the machinery, such as boilers, turbines, and auxiliary machinery. A firm understanding of the details and relationships in employing and training personnel of the branch is gained at this stage.

Following his initial service at sea, the officer will be employed ashore in a maintenance activity in the dockyard, in an overseeing activity in the naval ship construction program or in a design activity at headquarters — duration four years.

He then returns to sea as engineer officer of a ship, such as a destroyer, where he is in charge of all aspects of operation and maintenance of the ship's propulsion plant and associated ancillaries, involving a plant of 40,000 h.p., extensive refrigeration and air-conditioning equipment, diesel engines, evaporating plant capable of producing extensive pumping arrangements. During this period he directs a staff of some fifty technicians and semi-skilled men. The duration of this appointment is approximately two years, following which he returns ashore for two years, in a design, maintenance, manufacturing or training activity; or he may remain at sea as senior engineer of a large ship for two years.

If he has been appointed ashore, his next appointment normally will be to sea as engineer officer of a large ship, such as a carrier or cruiser for two years, or he may remain ashore in a senior administrative post in a maintenance, manufacturing or design activity; or in a liaison post, such as naval technical representative to the U.K., U.S.A., or other country where the navy has technical interests. He may be employed in intelligence, logistics, planning or training duties, where experience and judgment involving technical matters are required. This variety of duties with increasing administrative responsibility continues for the remainder of his career.

He may rise, by selection, to the navy's highest technical administrative position — that of Chief of Naval Technical Services, who is a member of the Naval Board with the rank of Rear-Admiral, is the head of all technical branches in the RCN, and is the senior RCN authority charged with the overall responsibility for the naval shipbuilding program.

Electrical Branch

(1) Canadian Services College as a cadet for four years, or ROTP for five years.

(2) From Canadian Services College, one further year in either electrical engineering, engineering physics, radio physics or mathematics and physics.

On completion of ROTP or college training:

Rear-Admiral (E) W. W. Porteous, O.B.E., C.D., Chief of Naval Technical Services.

(3) Training at sea for four months.

(4) Divisional training as an officer for two months.

(5) Electrical School for long naval electrical course, for one year.

On successful completion of this training he is promoted to the rank of lieutenant (L) in the electrical branch.

The general pattern of his employment will include appointments in which a wide knowledge of the responsibilities of the electrical branch can be obtained, including ship's electrical department for four months; dockyard for four months, and naval radio station for four months.

On completion of these appointments he will go to sea for two years and receive extensive experience in maintenance and supervision of fire control engineering, communication engineering and detection, including radar, Asdic and radio aids to navigation. On the other hand, he may remain ashore for practical experience in air electrics, including air radar and radio, or in electrical systems and electrical installations, including power generation and distribution. After such experience, the officer may be selected for further training in one of the preceding special categories.

Subsequent employment may be in a maintenance activity in the dockyard, in an overseeing activity in a naval ship construction program, or in a design activity at headquarters, usually for a period of four years. On the other hand, he may go to sea as electrical officer of a ship, such as a

During the construction and fitting of the aircraft carrier Bonaventure at Belfast, Northern Ireland, supervisory RCN personnel discuss machinery space arrangements with a representative of the shipbuilder. (National Defence Photo)

On the bridge of HMCS St. Laurent are Rear-Admiral J. G. Knowlton (left), who retired as Chief of Naval Technical Services in January 1956, Commander R. W. Timbrell, commanding officer, and Constructor-Captain F. Freeborn, Principal Naval Overseer, Montreal Area.

destroyer, where he is in charge of all aspects of supervision and maintenance of the ship's electrical system. During this period, normally two years, he directs a staff of 20 technicians and semi-skilled men.

Subsequent appointments, within his branch, parallel those of officers in the engineering branch, up to and including the appointment of Chief of Naval Technical Services.

Ordnance Branch

(1) Canadian Services College as a cadet for 4 years, followed by degree year at University or ROTP.

(2) Sea training for four months as a sub-lieutenant.

(3) Officers' divisional Course for 6 weeks.

(4) Long ordnance course in the Ordnance School for one year, or gunnery specialist course, Royal Naval Engineering College, for one year.

On completion of this training, promotion to ordnance lieutenant in the Ordnance branch.

The general pattern of the ordnance officer's appointment within his branch, parallels that in the above-mentioned technical branches, beginning with employment at sea in an aircraft carrier or cruiser as a department officer, or employment in ships such as destroyers as head of the Ordnance Department, during which period he is in charge of all aspects of supervision and maintenance of a ship's ordnance equipment. He directs a staff of 7 technicians and semi-skilled men. He usually spends less time at sea than fellow officers in the engineering branch. He too, may rise to the position of Chief of Naval Technical Services.

Constructor Branch

(1) Canadian Services College as a cadet for two years.

(2) Training as for Engineering branch which includes sea service as midshipman (E) Royal Naval Engineering College to undergo basic engineering training.

(3) Selection for training in Constructor branch.

(4) Practical and theoretical training in a Royal Navy dockyard for one year.

(4) Royal Naval College, Greenwich, for special training as naval constructor for two years.

Alternative method of entry:

(1) University under Regular Officers' Training Plan (ROTP) for four years.

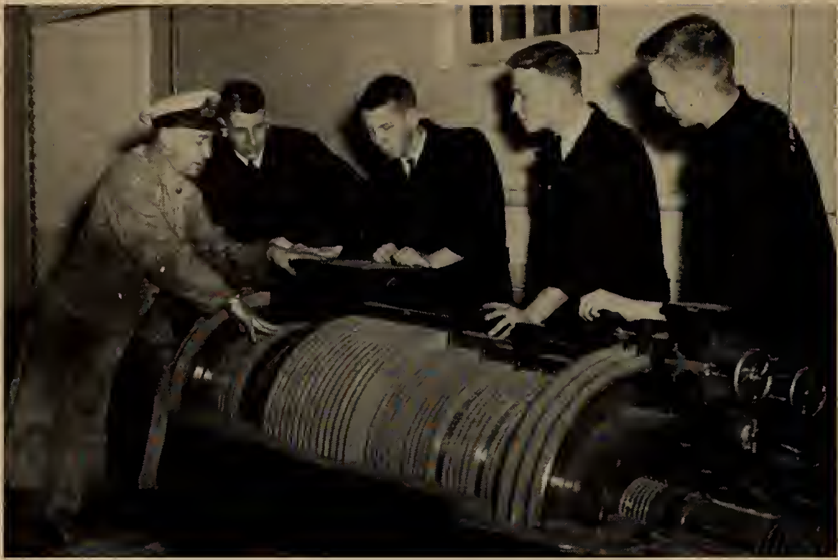
(2) By selection, further training in naval architecture in the Massachusetts Institute of Technology for two years. On completion of formal academic training, promotion to constructor lieutenant in the Constructor branch.

The general pattern of his employment will include a period of one year at sea in a large ship, during which time he will carry out duties involving the supervision of hull maintenance and repair.

Subsequent employment during the career of officers in this branch is most likely to be ashore where they will be involved in maintenance activities in the dockyard, in an overseeing activity in the naval ship construction program, in a design activity in headquarters.

As experience is gained, employment in senior administrative positions in a maintenance, manufacturing or design activity, employment in various liaison positions such as naval technical representative in the U.K., U.S.A., and other countries in which the navy has technical interests.

Naval cadets on board the cruiser Ontario undergo practical training in the ship's engine room during her training cruise to Australia and New Zealand.



Cadets at Royal Roads, one of the three Canadian Services Colleges, receive instruction on turbines.

This variety of duties, with increasing administrative responsibility, continues for the remainder of the career.

Officers of the constructor branch may rise by selection to the highest technical administrative position of Chief of the Naval Technical Staff.

Civil Engineering Branch

Entry from university with a degree in civil engineering or architecture, or equivalent professional qualifications recognized by E.I.C. or R.A.I.C.

Additional professional training is not given prior to employment in duties pertaining to design, construction, maintenance, repair and alteration of buildings and works and outside services.

HMCS St. Laurent, the Royal Canadian Navy's new anti-submarine destroyer escort, carries an engineer officer, two electrical officers, an ordnance officer, and a constructor officer.

The pattern of employment generally is in shore-based activities, during which experience is gained leading to increased responsibility.

GENERAL

The general pattern of requirement and employment of naval personnel with a background in the physical sciences is:

(1) Intelligence and personal qualities required for leadership.

(2) Provision of formal training in the physical sciences at government expense, or, alternatively, formal training attained by the individual through his own resources.

(3) Further formal training in the class-room and on the job in the application of the physical sciences to concrete problems of design, construction and operation.

(4) Employment at sea or ashore in general administrative and design duties related to the special requirements of a specific technical branch.

(5) Employment at sea or ashore in the higher levels of administration and maintenance duties related to the special requirements of a specific technical branch.

(6) (a) Employment ashore in the higher levels of administrative duties related to the co-ordination and administration of many or all technical activities in a dockyard, design, or ship construction activity; or

(b) In duties related to the co-ordination and administration of many functional related activities such as personnel, planning, intelligence, foreign liaison.

(7) Employment ashore in the highest levels of administrative duties related to the co-ordination and control of all technical functions within the navy.

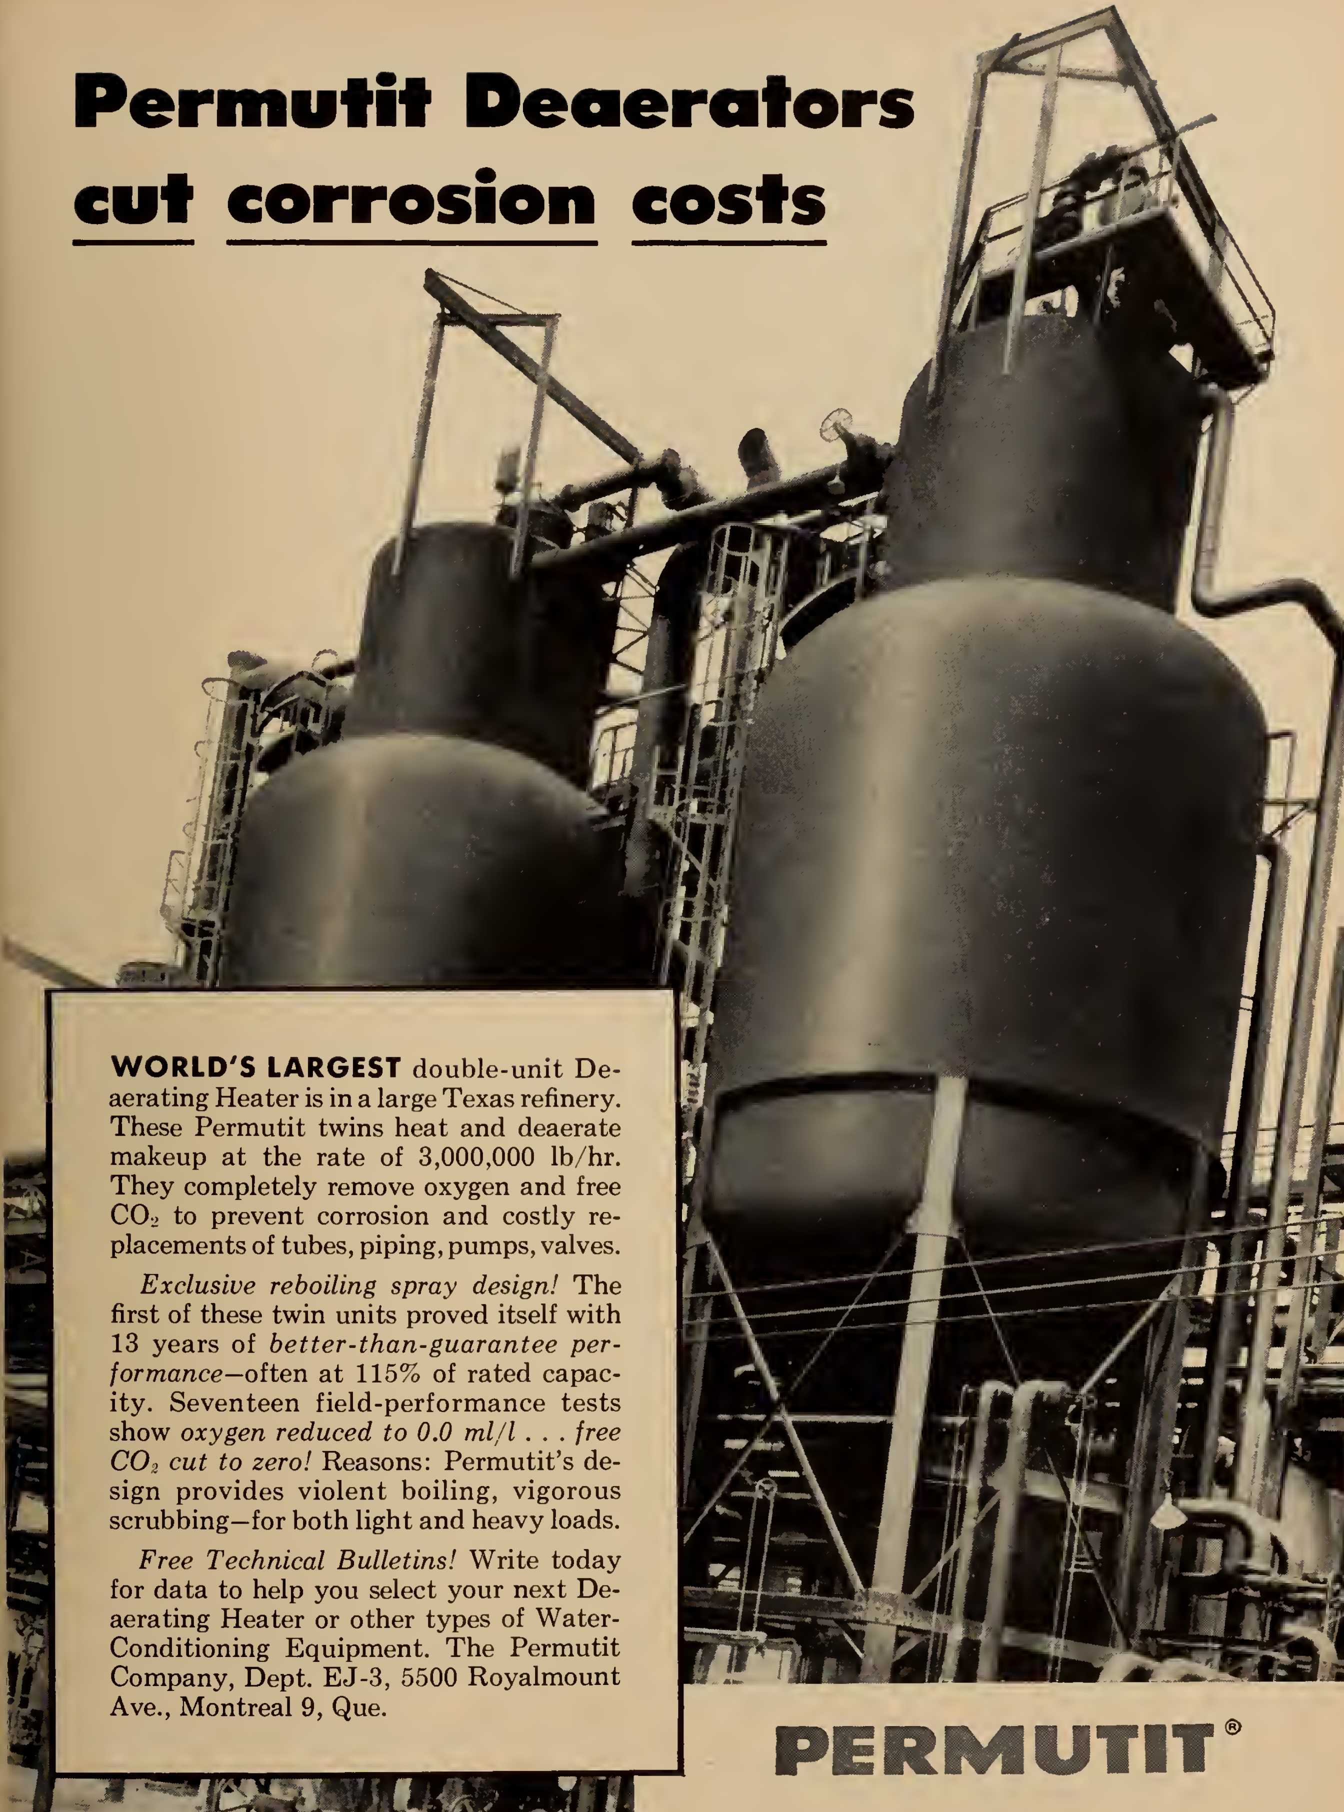
PAY SCALE

Some samples of the pay scale for naval officers are as follows:

A naval cadet receives each month a basic pay of $55 together with rations and quarters. A married lieutenant receives $290.00 basic pay, $110.00 subsistence allowance and $40.00 marriage allowance, for a total of $440.00 per month. A married commander receives approximately $7,500 annually, and rear-admiral about $14,000.

In addition, beginning in the rank of sub-lieutenant up to and including captain, progressive increases to the basic rate of pay for the rank held are given after three and six years in that rank.

Additional benefits for all naval personnel include free medical and dental care and pension benefits. ✓



Salt-Stabilized Roads

It was in 1928 that one of the first, if not the very first, modern efforts to stabilize roads with salt were made in Nova Scotia, near Canada's first rock salt mine at Malagash. Improvements were made in Canada during the '30's, but with the coming of the war in 1939, practically all efforts in this method of road construction were abandoned.

Although far from perfect, even these earliest Canadian results pointed the way to the development of today's efficient salt-stabilized roads.

Meanwhile, in the United States interest was maintained and the Canadian idea was studied and perfected. But efforts were somewhat sporadic until about 1950. Then engineers started turning to salt as a major means of meeting the rising construction and maintenance costs of farm-to-market roads and unimproved urban streets.

Use of salt to stabilize gravel, clay or other untreated earthen roads is on the increase in many sections of the country, according to the Salt Institute, as more and more engineers turn to this type of construction to build durable, low-maintenance, hard-surface secondary roads. In other instances it is a basic part of the construction of stronger subgrades and all-weather shoulders for already hard-surfaced roads.

ECONOMY

Economy is the principal advantage. Others are increased safety of vehicular traffic by eliminating dangerous loose gravel, or sand, and reduction of maintenance costs.

On the subject of economy, an untreated gravel or dirt road will lose one-half inch of the surface material each year due to the wheel throw-out, and deterioration effects of the elements, such as blow-away, erosion and frost heave. At an average cost of $2.00 per yard for gravel, loss of surface materials from a one-mile, 20-foot wide stretch amounts to $300 annually, with an equal amount needed for replacement, or a total cost of $600 to put the road back in its original condition. Salt compaction bonds loose material to prevent this loss.

On the average, based on costs in divergent sections, a road can be salt stabilized for $400 per mile per 20-foot width, which includes a base mat 4 inches in depth. Records kept on such roads over the period of the last three to five years showed the need of minimum maintenance on the original stabilized surfaces. A few roads date back to the early 1930's and are still in service.

The latter is considered an "experimental" road by the salt industry that first began work on stabilization 18 years ago, when they used from 16 to 18 tons of salt per mile. Today, with the added experience and know-how at their disposal, salt companies recommend on the average 1½ tons per mile per inch of compacted depth on a 20-foot width of road.

With Canada's increasing salt supply, the improvements of modern road-building equipment and methods, salt-stabilized roads seem the obvious answer to many roadbuilding headaches. This method should be of particular interest to the prairie Provinces and other less densely populated areas where paved roads are not feasible.

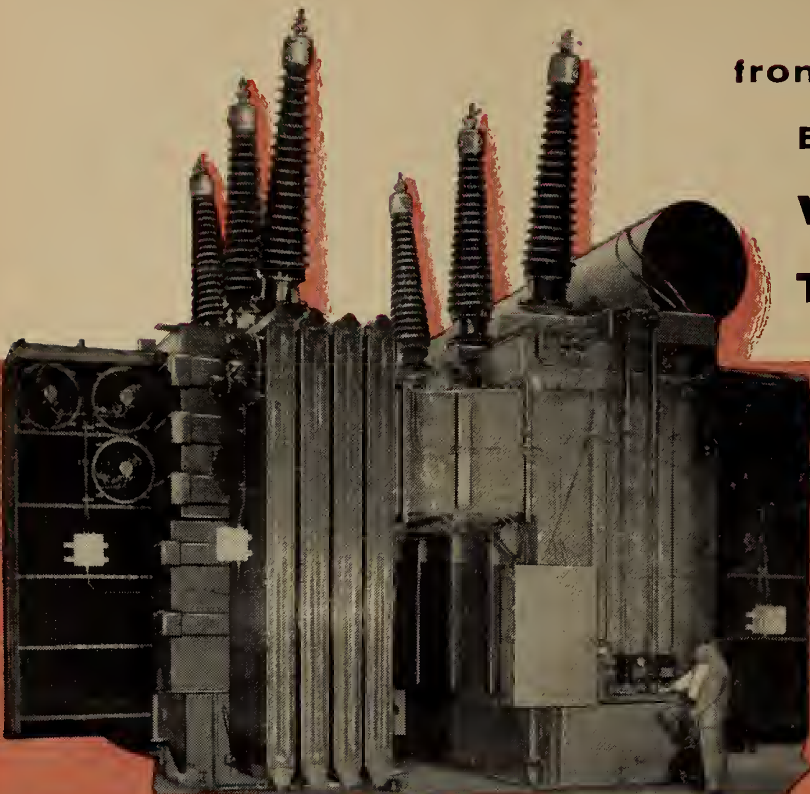
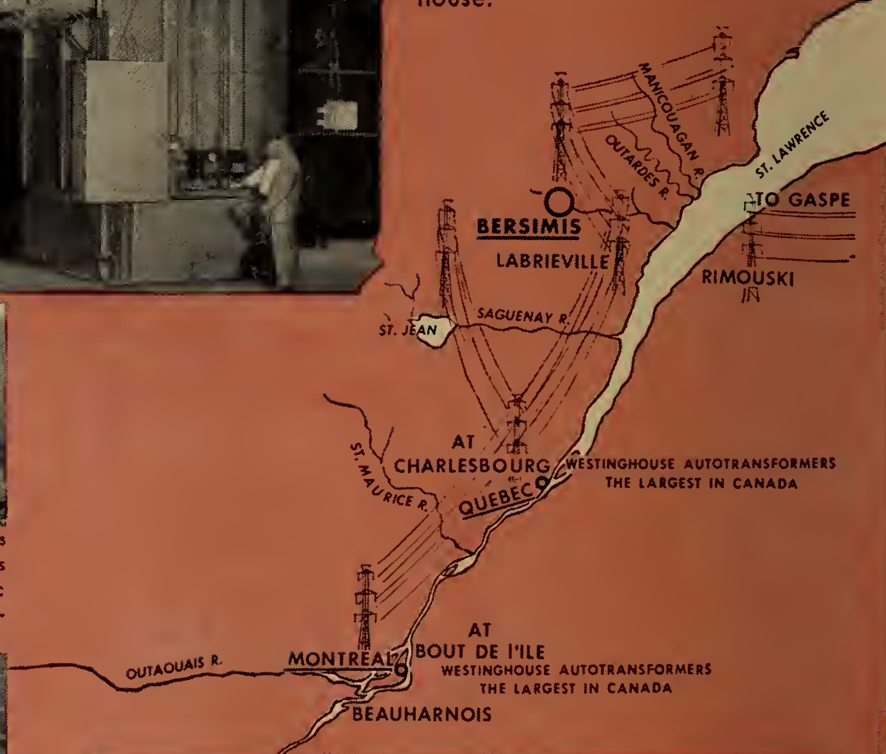
ALL THE POWER

from the giant Bersimis system is WESTINGHOUSE TRANSFORMED



Largest autotransformers with TCUL ever built in Canada, this is one of five supplied for the Bersimis system by Westinghouse.



Beneath the hills at right is the huge Bersimis generating station. Westinghouse transformers boost the voltage of the generated electric power for transmission over miles of countryside such as this.

The townsite of Labrieville.

One of the huge dams on the Bersimis system. These dams make possible a lake containing 350 billion cu. ft. of water.

From the underground generating station in Labrieville, townsite of Hydro-Québec's Bersimis River project and from the Lower Bersimis Generators will come 1,800,000 hp of electric energy. This power will travel over 400 miles of transmission lines to Quebec and Montreal.

Transformation of power on this system is accomplished by thirty-six Westinghouse power transformers, among them Canada's largest phase-shifting and autotransformers with TCUL* located at Charlesbourg and Bout de l'Ile to step down and shift voltage for the Shawinigan and Montreal systems.

Hydro-Québec has done a magnificent job. Westinghouse, a major supplier, congratulates the farsighted men who made Bersimis a reality.

Today, as in the past, it may be said of this, Canada's oldest land "Québec sont là!"

BERSIMIS-LAC CASSÉ

Hydro-Electric Power Development

F. Rousseau, M.E.I.C.
Chief Engineer,
Power Development Division,
Quebec Hydro-Electric Commission

Despite the author's reserve in regarding the Bersimis Power Development as ". . . just another power plant", there can be no doubt that it is, in fact, a major engineering achievement. The reasons for choosing the site, and a detailed account of the constructional work are given in this paper, which is to be presented at the forthcoming Annual Meeting of the Institute, May 1956.

The picture that forms a background to the title of this paper shows a view of the temporary power project and the rapids above which the main reservoir dam was constructed on the Bersimis River.
(Quebec Provincial Publicity Bureau—Photo Driscoll)

ALTHOUGH COMPETENT authority has qualified the Bersimis Power Development an outstanding engineering achievement, to engineers of the Quebec Hydro-Electric Commission it is just another power plant being added to a system to meet an ever-increasing demand for power.

A few details of background might be useful to provide a more complete perspective.

Hydro-Quebec took over the Montreal Light, Heat & Power Cons. and its subsidiary companies in 1944. The production capacity of the system at that time was 916,000 h.p. This capacity had been increased to 1,675,000 h.p. by 1954, mainly by adding the No. 2 plant to the existing Beauharnois installation. Quebec's rapid and steady industrial expansion, however, has developed a hunger for power which seems to grow in geometrical proportions. So much so, that the 1,200,000 h.p. expected by 1958 from the Bersimis plant will barely satisfy the demand.

Why did Hydro-Quebec decide in 1952 to give preference to Bersimis over such other power sites as the closer-at-hand sites of Lachine and Carillon or the No. 3 plant at Beauharnois?

The Lachine development could not have been started before the St. Lawrence Seaway project had been approved by the Canadian Government in 1952. Even had construction been started immediately, the additional production of 500,000 h.p. required for the Hydro-Quebec system by 1956 could not have been obtained from this particular development within the time allotted.

The Carillon development, with a firm capacity of 300,000 h.p., would have been inadequate. Moreover, Carillon will have its maximum usefulness in the future as a peak plant to firm up the Beauharnois and Lachine run-of-the-river plants.

Construction of the No. 3 plant at Beauharnois must coincide with completion of the Beauharnois Canal and, even at the present fast rate of dredging operations, the Canal could not be completed before 1960.

With its installed capacity of

1,200,000 h.p., at an estimated outlay of $190 per horsepower delivered in Montreal, Bersimis seemed to Hydro-Quebec authorities to be the proper answer to the immediate problem.

THE BERSIMIS RIVER

The Bersimis River discharges into the St. Lawrence on the North Shore at a distance approximately 190 miles below Quebec City. It flows in a southerly direction for 250 miles and its watershed is bounded on the west by the Saguenay River drainage basin and on the east by the Outardes River watershed. The total fall in the river is some 1,500 feet, with a drop of 1,225 feet in the 100 miles between Lake Pipmuacan, into which the Upper Bersimis flows, and the mouth of the river.

The most important potential head on the river—amounting to approximately 720 feet—is formed by a series of falls and rapids over a stretch of about 20 miles below Lac Cassé. Another drop of 370 feet is experienced in an adjoining 20-mile stretch of the river, ending downstream of the first falls and 45 miles from the river mouth. The river is narrow, has steep, rocky banks and provides favorable sites for power plants. With a surface area of 100 square miles, a drainage area of 4,500 square miles and high banks, Lake Pipmuacan provides the most favourable storage conditions.

The entire Bersimis watershed is rather mountainous and covered with spruce. It is unpopulated except for a very narrow strip along the shore of the St. Lawrence. Prior to construction of the power plant, activities in the area were limited to hunting, fish-

ing and the logging operations of pulp and paper companies.

HYDROLOGY, STORAGE AND POWER

Under the direction of H. M. Finlayson, the Shawinigan Water and Power Co. made a preliminary report in April, 1952, on 'The Hydrology and Power of the Bersimis River'. This report contained most of the information available at the time and showed the possibilities of power development at several sites.

Hydro-Quebec requested H. G. Acres & Co. Ltd. early in 1952 to design a power plant for completion by the Fall of 1956, utilizing all or the greater part of the natural drop of 720 feet below Lac Cassé.

No record of Bersimis water flow over a sufficient period of years was available to compute the regulation of this river with reasonable accuracy. Fortunately, a continuous record of daily discharges of the Outardes River had been kept since 1931 by the Quebec North Shore Paper Co. at its Outardes Falls development. Since the watershed of this river is adjacent and comparable to that of the Bersimis, it was considered that the unit run-off of the Outardes could be applied with sufficient accuracy to the Bersimis to determine its flow for regulation purposes.

The drainage areas of the two rivers were measured from maps charted by means of vertical photography done by the Federal Government. The mean monthly run-offs of the Outardes, derived from the period of record, were applied then to the drainage area of the Bersimis watershed under consideration. This procedure resulted in a hydrograph of the natural flow in the Bersimis River which would have occurred during the same period.

The drainage area at the outlet of Lac Cassé amounts to 5,010 square miles and a study of the hydrograph indicated that the mean monthly regulated flow of 9,250 c.f.s. can be maintained with 168 billion cubic feet of usable storage capacity.

Cost studies established that the most economical utilization of the river could be realized: (1) by building two rock-fill dams at the outlets of Lac Cassé to impound water at elevation 1,300; and (2) by tapping the storage by means of a 7.5-mile tunnel of section sufficient to carry the flow for maximum utilization of the river at 70 per cent load factor. This tunnel, driven across the bend formed by the river, would terminate at an underground powerhouse where tailwater could be maintained at approximately elevation 425.

Table I gives the pertinent statistics.

Table I. — Pertinent Statistics

Drainage area at Lac Cassé outlet	5,010	sq. mi.
Reservoir area	290	sq. mi.
Water surface elevation when full	1,300	
Maximum draw down	25	ft.
Gross storage	410	B.c.f.
Net storage (for regulation)	168	B.c.f.
Maximum gross head	875	ft.
Tailwater elevation	425 - 440'	
Tunnel intake: invert elevation	1,235	
Mean monthly regulated flow	9,250	c.f.s.
Design maximum total turbine discharge	15,000	c.f.s.
Installed capacity: 8 units at 150,000 h.p., 277 r.p.m.	1,200,000	h.p.
Peak primary output at 70% load factor	1,070,000	h.p.
Annual primary energy output	4,890,000,000	kwh.

DAMS AND DIVERSION

To impound storage water in Lac Cassé and Lake Pipmuacan at a water surface elevation of 1,300 feet, dams were found to be required not only on the Bersimis River — at the natural outlet of Lac Cassé — but also on the Desroches River, about 2,500 feet south of the Bersimis River dam and at the northwesterly end of Lake Pipmuacan.

The best location for a dam on the Bersimis was found to be at a distance of some 1,200 feet upstream from the Lac Cassé Falls. The Desroches flows north, in a direction almost at a right angle to the Bersimis, until it turns sharply eastward and is parallel to the Bersimis — with a distance of about 2,500 feet separating the two

graded from three to 10 inches, the intermediate one from one-half to three inches, and the last layer, on which the sloping core rests, is composed of sand.

The purpose of this filter is to prevent the clay core from infiltrating into the rock. The thickness of the clay core is 27 feet at the base of the dam and 15 feet at the top. The material is glacial till and was compacted in six-inch layers to the optimum density of 140 pounds per cubic foot. A reverse filter — one layer of sand and one of gravel graded from one-half to three inches — was placed up-

Soil investigations proved the material to be water-tight and of strength sufficient to carry the weight of the dam.

All unsuitable overburden and organic material were removed and, prior to placing the sluiced rock, a five-foot layer of sand was placed on the foundation, followed by another five-foot layer of gravel graded from one-half to three inches. The impervious core was keyed in a cut-off trench.

The dams were given a slight camber upstream to introduce axial compression in a core shaped in the form of an arch, thus de-

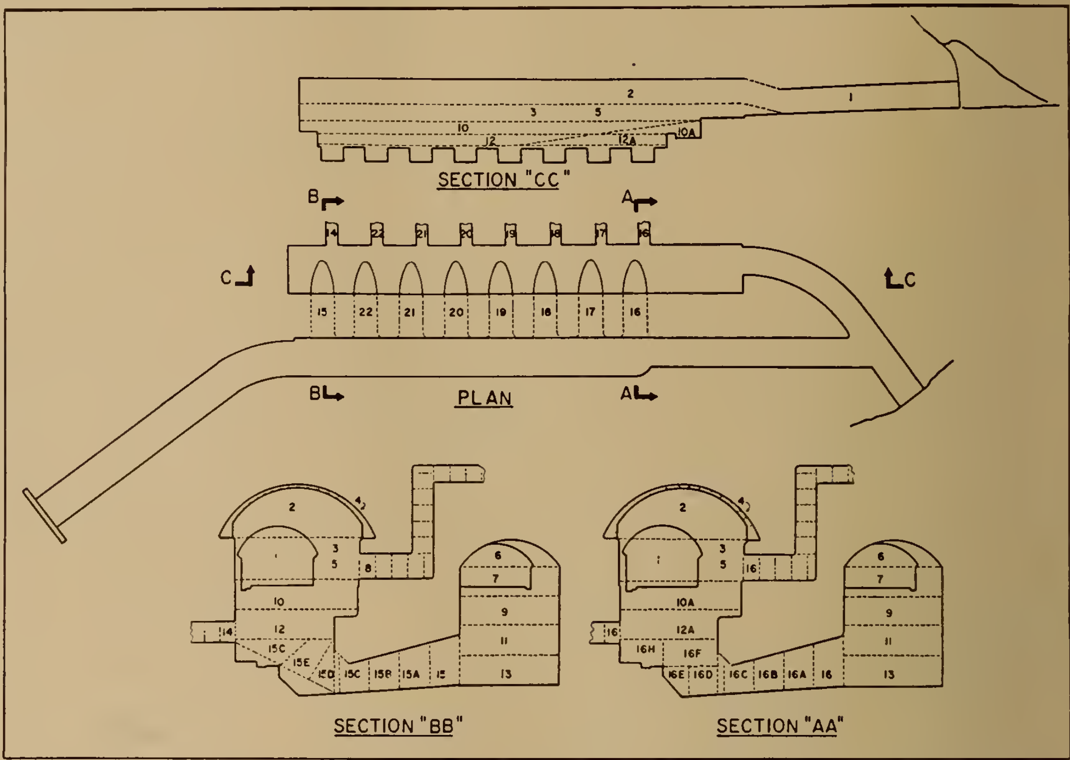

Fig. 3. Power house and tailrace excavation. Numbers indicate the sequence in which the excavation work was performed.

waterways. A suitable location for a dam was found almost in line with the Bersimis River dam.

The two dams at Lac Cassé, completed in November, 1955, are the rock-fill type with sloping clay core at top elevation 1,322. They are similar in every respect to the Kenney dam of the Kemano development. The main body of the dams was formed by dumping quarry-run rock into natural slopes. To reduce the amount of settling in the completed structure, the rock was sluiced thoroughly while being dumped. The quantity of water used for this operation equalled four times the volume of rock being sluiced.

On the upstream face, a filter of three seven-foot layers of graded material was placed. The layer in contact with the stone fill is gravel,

stream from the core. Finally, a rock-weighting zone, with an upstream slope of 1.0 vertical to 2.0 horizontal for the top 50 feet and 1.0 to 2.5 for the remaining height, was placed on the reverse filter.

The foundation below the core was cleaned carefully down to bedrock and grouted to a depth of 40 feet in stage grouting, this to develop an effective cut-off against leakage through the rock and to provide a good seal between core and rock.

Special consideration of dam design and construction was required for the north end of the Bersimis dam. Although bedrock outcrops at river level on the north bank, its surface dips steeply to the north beneath a deposit of glacial till more than 100 feet deep under the north abutment of the dam.

creasing the possibility of tension stresses.

The Bersimis dam is 2,200 feet long at the crest and 900 feet wide at its maximum height of 200 feet, while the Desroches dam is 1,305 feet long and 200 feet high. A fixed crest spillway 1,000 feet long was provided between the structures by the simple process of quarrying surplus rock from the mountain separating them. This rock was used for the dams.

Quantities involved in this phase of the work follow:

	cu. yd.
Sluiced rock	2,500,000
Rock in weighting zone	1,150,000
Filter material	950,000
Rolled clay	500,000
Total	5,100,000

Diversion of the river at the

Bersimis dam was achieved by means of a tunnel 39 feet wide, 36 feet high and 1,050 feet long. Driven 100 feet below the river bed, it terminates in an intake structure upstream from a rock-and-clay cofferdam across the river to a top elevation of 1,175 feet. The intake is provided with two closure gates 19 feet wide by 34 feet high and the tunnel will be closed eventually by a concrete plug below the clay core.

The diversion tunnel is supplemented by a diversion channel 80 feet wide and located on the south bank of the Bersimis. They were designed to prevent spring floods from overtopping the cofferdam, thus permitting preparation of the foundations of the dams during the 1953-54 winter and following spring. As soon as the receding waters permitted, the diversion channel was cofferdammed to allow materials to be placed in the dam the full width of the river.

The construction schedule calls for commissioning three units of 150,000 h.p. apiece by December 1, 1956. The minimum level of the storage at which the Bersimis plant can operate is elevation 1,270, this operating level requiring 242 billion cubic feet of dead storage at that elevation. To impound that much water it was necessary to close the gates of the intake structure of the diversion tunnel in the fall of 1955.

The diversion tunnel performs another very important function—feeding a temporary power plant erected for construction purposes at the Lac Cassé Falls, 1200 feet below the axis of the Bersimis dam. Since the intake gates have been closed, only the minimum flow required for operation of the temporary plant is being admitted into the tunnel—through a regulating valve in the intake structure.

Diversion of the Desroches River was very simple. With a watershed of 200 square miles, this river was diverted easily through a 40-foot square concrete culvert of 1,000-foot length built on the rock foundation across the dam.

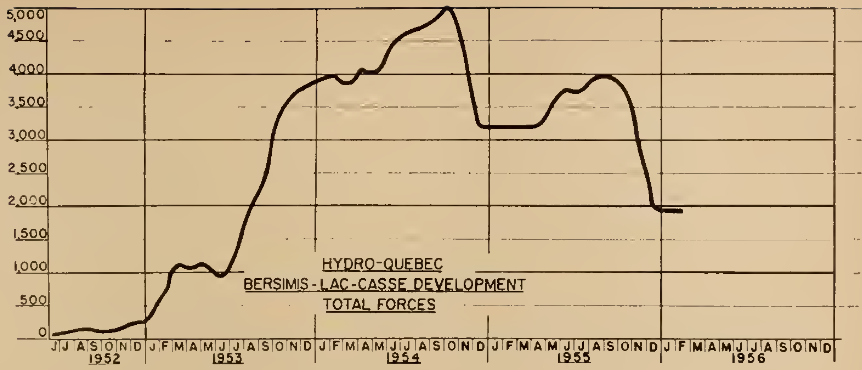

Fig. 4. Chart showing the fluctuation of labour employed on the project.

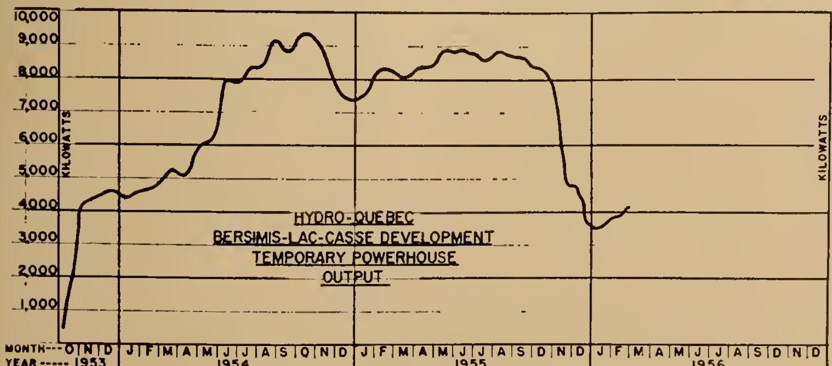
LAKE PAMOUSCACHIOU DAMS

To prevent water in the Lac Cassé reservoir spilling into the nearby Shipshaw and Peribonka watersheds, it was necessary to build cut-off dams at the western extremity of the reservoir. Suitable foundations for these dams not being available within the limits of the Bersimis watershed, agreement was reached with Price Brothers and Co. whereby two existing dams on their Lake Pamouscachiou reservoir were replaced by dams designed to raise the level of Lake Pamouscachiou by 20 feet.

Founded on rock, both dams are earth fill, with impervious roll fill core flanked by transition zones of pit-run gravel. Dam No. 1—at elevation 1,320—is at the outlet of the lake and has a concrete sluiceway 15 feet wide for river regulation and logging. Dam No. 2, on the western shore of the lake near its junction with Lake Shipshaw, is provided with two 12.5 by 12.5-foot submerged concrete sluices which can be used for diverting water into the Manouane River and thence to the Peribonka if, as and when available. Stop-logs at Dam No. 1 are operated by a 125-kva. diesel generator and gates at Dam No. 2 by a 75-kva diesel generator.

Fig. 5. Fluctuation of temporary power house output, kilowatts.



INTAKE AND POWER TUNNEL

The location of the intake was not a matter of choice. It was dictated by topography. The two dams back up water into the Desroches River for a considerable distance in the direction of the powerhouse. At a distance of 4.5 miles from the Bersimis dam, the river bed of the Desroches is at elevation 1,251 and its east bank, high and steep, provides an ideal site for the intake.

This concrete structure was designed for equal distribution of flow into eight openings of 16 by 30-foot dimensions at the trash racks. There are also intermediate piers especially shaped to provide a change in the direction of the flow of about 75° before it enters a chamber adjoining the tunnel. The velocity at peak flow will increase from four feet per second at the trash racks to 19 in the tunnel, with a corresponding head loss of less than two feet. A gate, 33 feet wide and 32 feet high, with sill at elevation 1,235, will be provided between the chamber and the tunnel. Elaborate model studies paid dividends in providing information which resulted in the design of a structure most economical in head losses.

Some 90,000 cubic yards of rock are being excavated from the bed of the Desroches River, approximately one mile from the intake, to provide a channel of sufficient cross-section at draw down.

The power tunnel is 7.5 miles long from its portal to the manifold of the powerhouse. An elaborate program of core drilling and boring was undertaken to determine the best layout in terms of quality of rock and rock cover. The rock in the general area comprises pre-Cambrian sedimentary gneisses, intruded by a graduated series of igneous rock. The sediments contain mainly quartzite, pegmatite and granite. Special attention was paid to the shear zones or ancient faults in the area and it was established that no trouble of any proportions could be anticipated from poor rock or water. In all respects, indications were that a tunnel could be driven through solid rock without much supporting being required and with sufficient rock cover.

The course of the tunnel varies very slightly from a straight line between the intake and the powerhouse. This deviation was necessary to provide enough rock cover or to shorten the length of the adits. The tunnel drains towards the powerhouse on a grade not exceeding 2 per cent, this grade limit being set to facilitate construction of the tunnel. The total drop in the tunnel is 445 feet. The minimum depth in feet of rock cover at any point of the tunnel was specified at not less than 50 per cent of the maximum pressure at that point.

The most economical section of the tunnel was set at the limit beyond which any gain in value of power, resulting from elimination of friction losses due to increase in the size of the tunnel, would no longer provide a fair return for the additional capital expended. Since the rock proved very solid and tough, it was thought that an unlined tunnel was the answer. Cost studies proved, however, that a lined tunnel would be less expensive than an unlined one for the same friction losses.

The lined tunnel was designed to carry a flow of 13,250 c.f.s. for a load factor of 70 per cent, using the Manning coefficient of friction n=0.0109. It has a horseshoe-shaped cross-section almost equivalent to a circle 31 feet in diameter. This horseshoe-shaped cross-section was chosen—in preference to the circular section—for construction reasons only: it permitted the swinging of the 1.5-cubic yard electric shovels working at the headings.

The thickness of the concrete lining was specified at 10 inches minimum. With the expected overbreak, however, this thickness averages more than 18 inches. Any void left between the lining and the rock at the crown was grouted at 10-foot intervals in two stages at 50 and 100 p.s.i. A different pattern of grouting with higher pressures was specified at the location of faults—to suit particular conditions. Approximately 2.5 bags of cement per lineal foot of tunnel were used for grouting.

SURGE TANK

Entirely hewn out of rock, the surge tank is located above the axis of the tunnel 60 feet upstream from the first penstock. In view of the importance of this structure, extensive design and model studies were carried out on different types of tank. Analysis showed that the restricted orifice-type of tank would be more economical than the differential type.

A 27-foot concrete-lined shaft rises 313 feet from the tunnel at elevation 822 to the bottom of the tank at elevation 1,135. The unlined tank is 85 feet in diameter and 365 feet high. It emerges into the open at the hill top at elevation 1,500 and is offset 45 feet from the axis of the surge shaft to make room for a rock trap at the bottom of the tank. A concrete rim at the top of the tank supports the roof.

It will be noted that the top of the rim is 200 feet above normal water elevation in the reservoir.

PENSTOCKS

The tunnel terminates at invert elevation 792 in a manifold 31 feet in diameter. The 12-foot concrete-lined penstocks of the eight turbines join the manifold at an angle of 50° from the horizontal and 60° in plan, dropping to scroll case level at elevation 422.

Model studies of the manifold were carried out with the view to maintaining equal distribution in all branches and eliminating head losses as much as possible.

The penstocks are field welded to 7 ft. 9 in. straight-flow valves weighing 160 tons apiece and inserted upstream from the scroll cases. Penstocks, valves and scroll cases will be subjected to a maximum pressure of 540 p.s.i. or the equivalent head of 1,240 feet.

The two-foot lining of the concrete penstocks and the two-foot concrete backing between the steel lining and bare rock were poured by means of pumpcrete machines. Pressure grouting — in stages up to a maximum of 300 p.s.i. and to a depth of 15 feet in the rock — was specified to fill any possible void and provide a water-tight curtain around the penstock. The penstocks are steel lined over a distance of 328 feet from the straight-flow valves. The diameter of the steel lining drops by stages from 10 to 9 feet and is finally reduced to 7 ft. 9 in. at the straight-flow valve. Thickness of the lining varies from 1 1/16 to 2 1/16 inches. The steel liners were delivered in 50-foot sections weighing approximately 50 tons. Field joints were welded electrically, stress relieved, and thoroughly X-rayed.

THE POWERHOUSE

Cost was the major factor on which was based the decision to

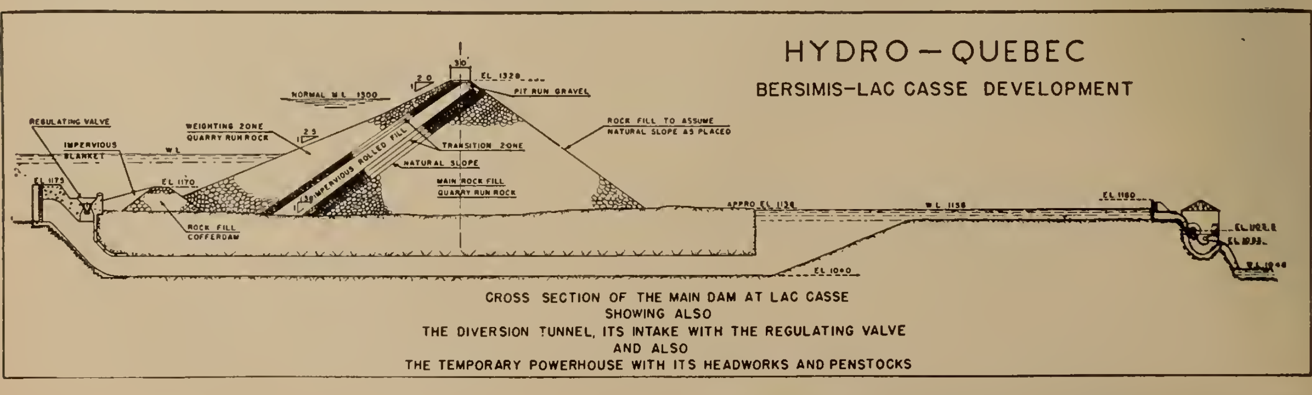


Fig. 6. Cross-section of the main dam at Lac Cassé, showing also the diversion tunnel, its intake with the regulating valve, and the temporary power house with its headworks and penstocks.

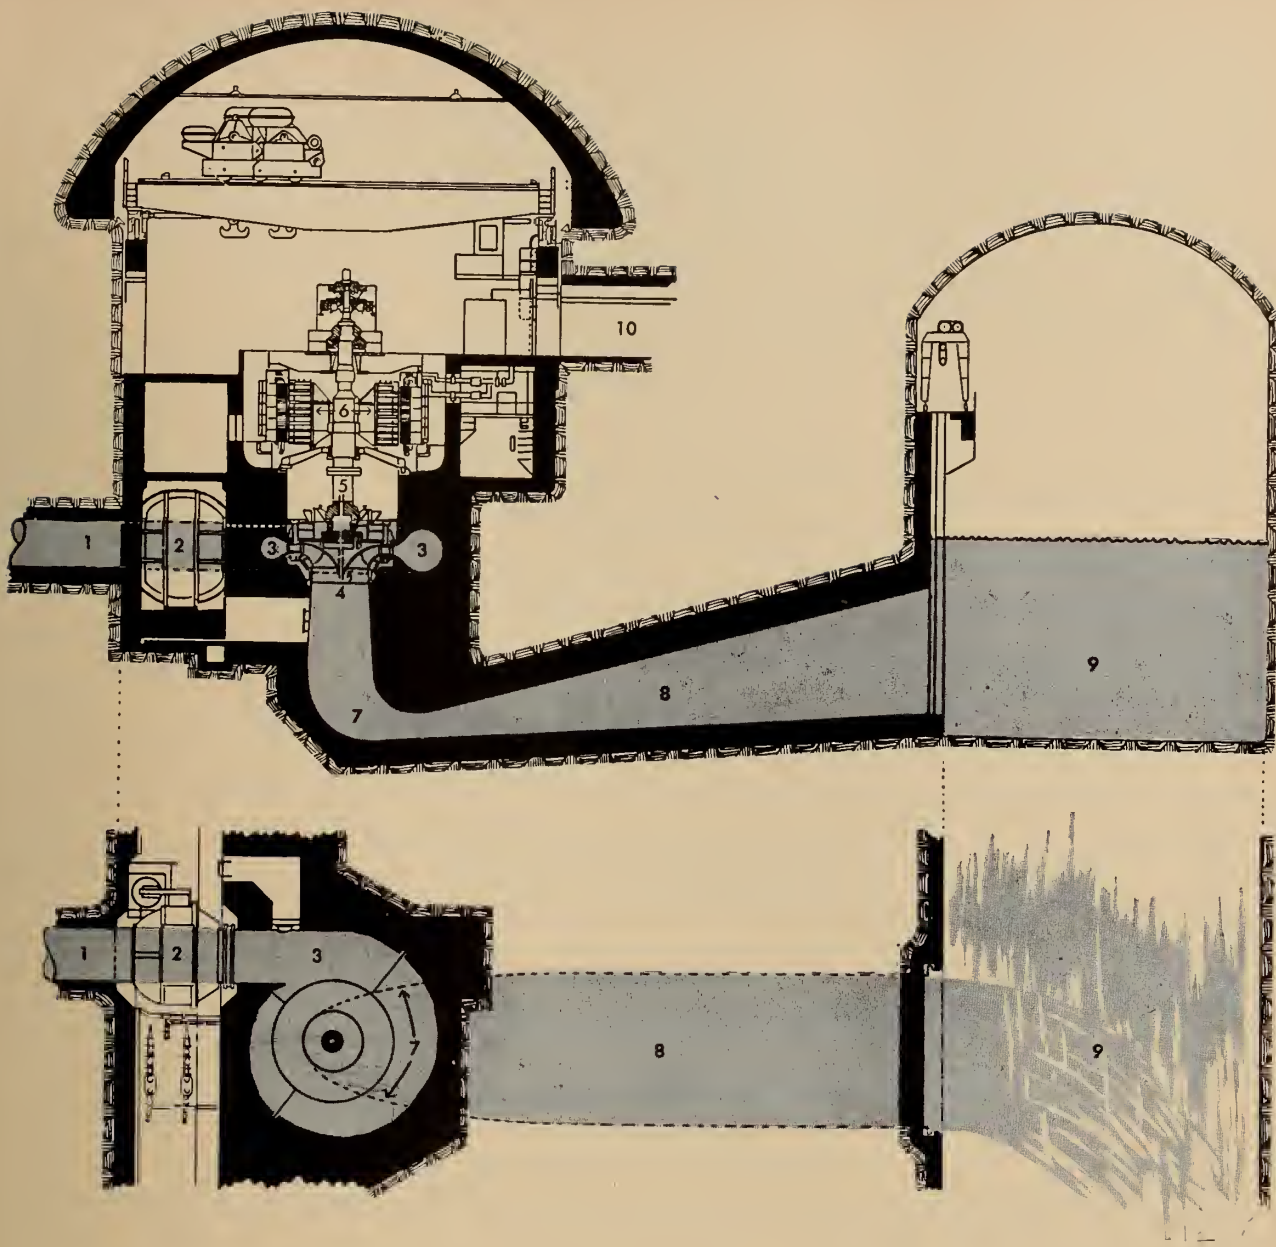

build an underground powerhouse. A towering mountain of rock, a few hundred feet from the river, provided the mass to resist the heavy surge pressures to which the penstocks will be subjected and eliminated the necessity of building expensive, wide-diameter penstocks in the open.

A cavern 565 feet long, 65 feet wide, and 80 feet high will house eight Francis turbines 55 feet apart. They are rated at 150,000 h.p. under a 785-foot head at 277 r.p.m. Each unit will drive a direct-connected, three-phase, 60-cycle, 13,800-volt generator rated at 138,000 kva. with 95 per cent power factor.

Each draught tube is connected to a tailrace chamber at atmospheric pressure. Parallel to the powerhouse, this chamber is 410 feet long, 47 feet wide and 75 feet high. A tailrace tunnel, 380 feet long, 47 feet wide and 65 feet high, will carry the discharge to the open tailrace.

Providing normal access to the powerhouse is an entrance tunnel 270 feet long, 36 feet wide and 30 feet high, sloping down from ground elevation 468 to the erection bay north of unit No. 1 at generator floor elevation 447. An eight-by-eight-foot emergency tunnel is located at the other end of the powerhouse, while another tunnel 20 feet wide and 11 feet high — between units No. 4 and No. 5—connects the powerhouse to the control building in the switchyard.

The powerhouse roof arch is concrete-lined and a suspended ceiling will hang from it.

A 400-ton bridge crane, supported by concrete girders and columns poured against the rock walls of the cavern, will handle the heavy equipment parts.

Each generator will be connected by leads through a bus tunnel — 8 by 9.5 feet — to three-phase transformers rated at 40,000 kva.

(10) Cable tunnels

13.8/301.4 kv. and located outside in the switchyard.

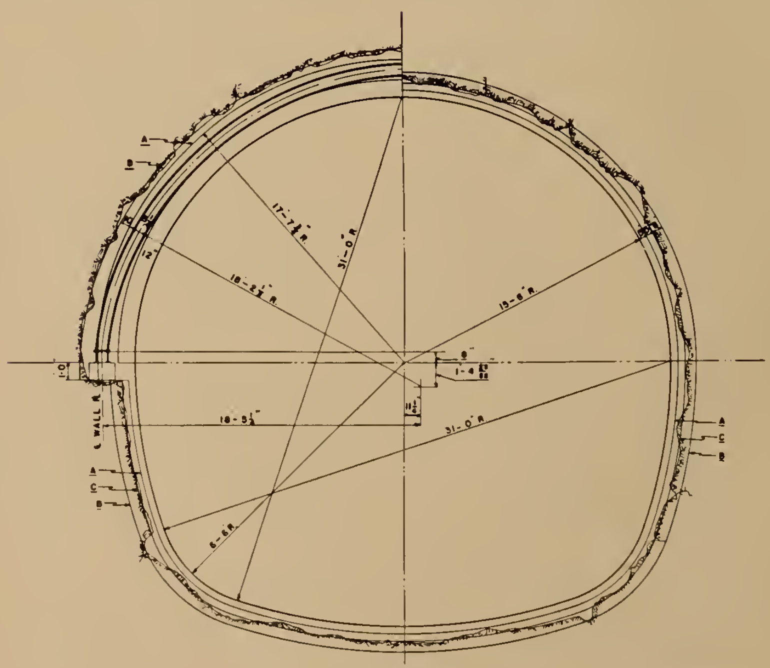
A ventilating tunnel using four blowers is located at the north end of the tailrace chamber. It will circulate from 72,000 to 282,000 c.f.m. of air into the cable passageway below the generator floor for distribution to the generation room at each unit. The air will be admitted directly to the generator room for ventilation alone or will be deflected through the generator when heat is required. A false ceiling, suspended from the roof arch, will house the return duct to the tailrace chamber where part of the air will be discharged or re-circulated. Blowers at the bus tunnels will also discharge a minimum 9,000 c.f.m. and, at the same time, carry away the heat generated by the busses.

The control building in the switchyard will house complete control equipment, instrumentation and necessary office space.

Power will be transmitted from the switchyard to Quebec City and Montreal by means of 300-kv. transmission lines.

Operating and maintenance personnel will be housed within walking distance of the switchyard in a small modern town — Labrieville — with church, school, stores, recreation and other facilities. The town, incidentally, was named after Bishop A. N. Labrie, Bishop of the Gulf of the St. Lawrence.

Fig. 9. Cross-section of tunnel.



ASPECTS OF CONSTRUCTION

The Commission decided early in 1952 to complete the Bersimis development for November 1, 1956. The only information available at that time was a preliminary report showing the possibility of power development and a few vague outlines of several schemes. A practically unknown region in the wilderness had to be explored, surveyed, mapped and from this information structures had to be located, designed and constructed —all in the space of four years.

The project, now nearing completion, offers some interesting constructional aspects.

The surveys were well under way by June, 1952, at the possible sites of the structures. In the same month — even before the location of these structures could be established definitely — work was started on the access road linking Forestville, the nearest St. Lawrence River port, and Labrieville. Surveys had provided sufficient information by August to establish the general scope and layout of the works, permitting Hydro-Québec engineers to draft a preliminary construction schedule.

CONSTRUCTION POWER

It was estimated that the power required for construction would be 12,000 h.p., of which 8,000 had to be available during the summer of 1953. An analysis indicated that approximately two million dollars could be saved if, instead of using

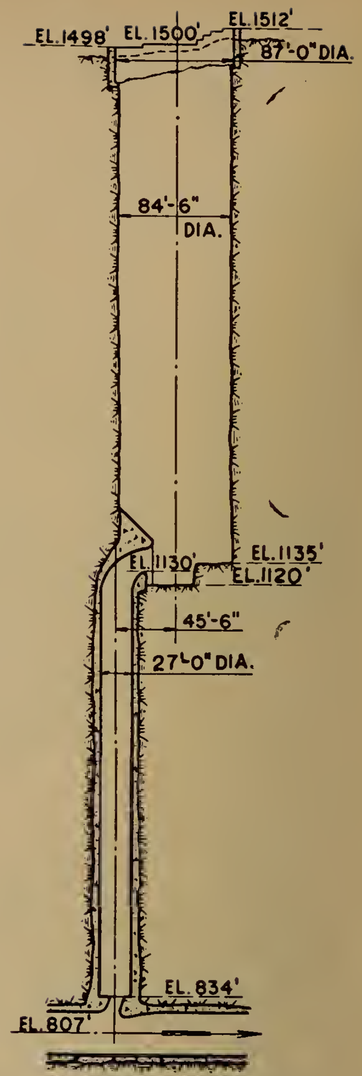


Fig. 8. Vertical section of surge shaft and tank.

diesel power, Hydro-Quebec were to install — at the Lac Cassé Falls — two units from the abandoned St. Timothée hydro-electric plant on the shore of Lake St. Louis near Montreal.

The two 40-year-old horizontal units were dug out of the concrete in September, 1952, transported by boat to Forestville and hauled by road to Lac Cassé during the winter following. The last 15 miles were over a hastily built snow road to assure delivery on time of the turbine and generators.

Erection of the powerhouse by the Hydro-Quebec Power Development Division began in November and continued through the 1952-53 winter. The plant was ready in July, 1953, and a 44-kv. transmission line more than 20 miles long was supplying power to the construction sites by the beginning of October. It is interesting to note that only 50 of the 90 feet of falls were used to conform to the designed head of the turbines. At time of peak, the plant was able to cope with a demand of almost 15,000 h.p.

BUILDING THE TWO DAMS

Construction of the rock-fill dams, diversion works and by-pass tunnel was the object of a separate contract. Most of the 1953 summer was used to build a complete camp set-up and construction plant. The cofferdams, diversion tunnel and intake were completed by the spring of 1954 and preparation of the foundation was well under way. Actual placement of loose rock, clay core and filter materials was started only in August, a month behind the original construction schedule.

To make up time, it was decided to extend the placement of clay into the freezing weather of late November, dissolving calcium chloride in the water used for sprinkling to obtain optimum moisture. Good weather before the spring flood of 1955 permitted the placement of clay to elevation 1,198, the Bersimis was prevented from overtopping the impervious core and the race against Nature was won. Work on the dams continued until completion in the fall of 1955.

The two steel gates of the intake were closed at the beginning of November, 1955, to permit impounding water to the operating level for 1956. The regulating valve, which allows sufficient water to pass to operate the temporary power plant, will discharge via the by-pass tunnel until November, 1956. With the Bersimis power plant in operation then, temporary power will be needed no longer. At that time a plug will be poured in the diversion tunnel under the clay core.

Fig. 10. South end of Lac Cassé dam under construction, showing monitor jets at work.

Due to the short time allowed to drive the diversion tunnel during the 1953-54 winter, mining had to proceed on two headings from a shaft sunk at mid course, offset 30 feet from the tunnel and connected to it by a cross-cut. The cross-cut was sealed by a concrete plug prior to the spring flood.

The rock for the two dams was blasted from a granite hill nearby. Drilling equipment comprised two quarry masters drilling six-inch holes and five nine-inch churn drills. It turned out, however, that this drilling equipment was not sufficient to keep pace with the placement of rock and it was necessary to have recourse to three 50,000-cubic yard coyote blasts. Seven shovels (one of five, two of 3.5, and four of 2.5 cubic yards) were used to load the quarry-run rock into 26 diesel trucks (14 of 35-ton and 12 of 22-ton) which took their loads to the dam sites for back-dumping. Monitors, with 150 p.s.i. jets discharging four times as much water as the volume of rock being placed, assisted compaction.

Fig. 11. Tunnel intake under construction.

Clay or, rather, glacial till was obtained from a pit located four miles from the dams. Loading and transportation were by means of shovels of ¾-cubic yard capacity and three- to five-ton trucks. Pneumatic and sheep foot rollers could not keep pace with the placement of clay in the narow strip. Accordingly, compaction to the optimum density of 140 pounds per cubic foot was realized by rolling loaded trucks back and forth. These vehicles were especially assigned to this process.

A screening plant was set up some three miles from the dams to produce 950,000 cubic yards of screened gravel in three sizes for the filter layers of the dams. Since the only suitable gravel deposits were located in areas to be flooded when the cofferdam was completed, the screening plant was designed to stock-pile at the one time all the material required for the two dams.

The rate per week of placing materials in the dams was 80,000 cubic yards for the rock, 15,000 to 20,000 for the clay, and 30,000 for the filter materials.

DRIVING THE TUNNEL

Due to the short time the construction schedule allowed to complete the tunnel, it was necessary to undertake its driving on six different headings. An analysis of cost proved that it would be cheaper—in this particular case—to drive the tunnel from adits instead of shafts. The cross-section of the adits was reckoned at a width of 32 feet and a height of 25 feet, sufficient to permit truck traffic in both directions, as well as installation of ventilation ducts, air, water and pump discharge lines. Maximum grade allowed for the adits was 8 per cent.

Three different contracts were let for construction of the 40,000-foot tunnel and excavation of the powerhouse. The first contract was for 16,000 feet of tunnel, the intake and an adit of 2,500-foot length, the second for 16,000 feet of tunnel plus an adit of 2,500 feet, and the third for 8,000 feet of tunnel, a 1,400-foot adit and excavation for the powerhouse, tailrace, penstocks and cable tunnels.

Included in each of the two first-mentioned contracts was the erection of camps and temporary buildings to house the work force, of repair shops and stores, compressor buildings, boiler rooms and all the necessary auxiliary structures required for the work. The third tunnel contractor made his headquarters at Labrieville, where most of these auxiliary functions were handled from a central set-up.

Work on the three adits began in July, 1953, and the entire tunnel, including 18-inch concrete lining, was completed in the fall of 1955—with the exception of 50,000 cubic yards of concrete in the invert which is scheduled to be placed early this spring. Worthy of note is the fact that the final break-through was made less than 18 months after the start of adit and tunnel excavation.

Two full headings were developed in opposite directions once the adits had been driven to the tunnel line. For the drilling of each face, 18 to 20 power-feed drifters of 3.5-inch were set on hydraulic booms for positioning. They were mounted at four different levels on a jumbo. Depending on the pattern and round chosen by the contractor, from 150 to 190 two-inch holes—varying in depth from 12 to 20 feet—were drilled on a face and loaded with approximately four pounds of dynamite per cubic yard of rock.

Fig. 12. General view of underground power house showing arch-roof, crane rails, beams, and columns. At centre, the supports for unit No. 2 scroll case.

Long-delay electric blasting caps were used in some 15 intervals varying from 100 milliseconds to one second each. Several types of blasting caps were tried, but it was found that only with the use of long-delay caps could a neat, compact pile of muck be left at the face after a blast for easy loading. Tungsten carbide bits were used for drilling, their average drilling life being 240 feet.

Electric shovels of 1.5-cubic yard design but equipped with 2-cubic yard buckets were used to load the blasted muck into 15-ton diesel trucks. Scrubbers were installed on the exhaust pipes of the trucks to reduce the fumes in the tunnel.

Compressed air plants, each comprising two 2,800 c.f.m. vertical electric compressors, were used to supply air to the drills at the first two adits. The air plant near the third adit contained three compressor units and was used to supply air to the powerhouse as well as the tunnel.

Ventilation of the tunnel was effected by means of 38 reversible axivane fans driven by 60-h.p. electric motors. The fans were set in series on 48-inch metallic ducts. The ventilating system was designed to move the air in the tunnel at a velocity of 50 feet per minute.

A total of 320 feet of non-telescopic metallic form work, set on a jumbo moving on a track, was used to line the arch of the entire tunnel with concrete. The arch was poured in sections varying from 80 to 160 feet and it was not long before six full cycles were attained in one week. From six to nine hours in a 24-hour cycle were allowed for placing concrete, 10 to 11 hours for the concrete setting, and the balance for lowering, moving and setting up the form work in its new location. Guns were used in the first two sections for placing concrete and pumpcrete placers were used in the third section. The sequence for concreting the lining made provision for the invert to be poured last — after the arch had been grouted — to

Fig. 13. General view of power house showing scroll cases No. 2 and 3 in position.

effect savings on the cleaning of the tunnel invert.

The tunnel rock was very good and driving became a matter of routine except for a total length of 2,000 feet of faults where steel supports were required. Serious water trouble was experienced at only one place — under a lake in the first section. Approximately 2,000 cubic yards of grout had to be forced into the rock from inside and outside the tunnel to keep the lake water from leaking into this particular heading.

A power load of 7,000 h.p. was required 24 hours a day, six days a week for the almost 2½ years it required to complete the tunnel.

Data pertaining to the construction of the tunnel are summarized in Table II.

Fig. 14. Drilling jumbo for tunnel excavation.

THE SURGE TANK

Excavation of a surge tank, 365 feet deep and 85 feet in diameter, and excavation of a shaft of 31-foot diameter, dropping another 313 feet from the bottom of the tank, presented a hazardous problem worth mentioning. A 10 by 12-foot pilot shaft was raised from the tunnel to ground level, a height of 678 feet. It followed a previously drilled hole of nine-inch diameter bored from the top. Timbering was removed and a muck-loading chute was set at the bottom of the shaft at tunnel-roof level. Tank and shaft were then slashed to full size by means of down hand drilling in steps from the top of the tank. All muck was passed down through the pilot raise to a loading pocket in the manifold, thence into 15-ton trucks for hauling to the spoil pile.

EXCAVATING THE POWERHOUSE AND TAILRACE

Excavation of the powerhouse cavern and the tailrace chamber with its tunnel was carried out in the simplest manner ever devised. The permanent access tunnel (36 feet wide and 30 feet high) to the powerhouse was driven full face to grade, using standard tunnel practice, from ground elevation 468 to about 50 feet from the entrance to the powerhouse. From this station, the grade was reversed and ended at the entrance to the powerhouse at elevation 470, flush with the shoulder intended to receive the thrust of the powerhouse concrete arch. From there on, the entire face between the roof and the haunches was driven the full length of the power-house. A large quantity of rock bolts was used to make the roof safe before the concrete arch could be poured.

The following method was used to preserve as neat faces as possible at the haunches.

First, a line of 20-foot holes, spaced at 12 inches, was drilled at the face of the two haunches. Then, the drilling of the rock mass between the two lines of holes was carried out the full width of the powerhouse to a depth of 18 feet by means of drifters. The rock was blasted in a herringbone pattern, using long-delay caps to minimize overbreak. The rock from these blasts was left in place over the whole area to support a 30-foot section of wooden arch form set on rails and blocked on the muck for pouring of the concrete arch. After the entire arch had been poured, mucking was resumed and the remaining solid rock was mined in 15-foot lifts down to grade. The rock below the powerhouse entrance, which could not be hauled out through the access tunnel, was taken out through the previously excavated south draught tube and discharge tunnel.

Another cavern (410 feet long, 47 feet wide and 75 feet high) still had to be excavated for the tailrace chamber. For this purpose, an access tunnel was driven, branching from the main entrance tunnel down to a few feet below the springing line of the chamber roof at the north end. The area of the arch was driven the full length of the chamber. Since the muck could be hauled out only through

Fig. 15. Tunnel form used for concrete lining.

Table II. — Tunnel Construction Data	
Total length of tunnel and adits	46,600 ft.
Total excavation, tunnel and adits	1,678,000 cu. yd.
Concrete lining, 18-inch thickness	5.9 cu. yd./ft.
Excavation per linear foot of tunnel	36 cu. yd.
Average weekly advance on two headings	244 ft.
Best weekly advance on two headings	404 ft.
Average overall weekly advance	732 ft.
Average overall round	13 to 14 ft.
Average Tunnel Excavation Cycle	
Loading dynamite, moving jumbo, blasting	1 hr. 25 min.
Ventilating smoke out	25 min.
Scaling, bulldozing, moving shovel in, mucking, moving jumbo in	7 hr. 20 min.
Drilling	3 hr. 40 min.
Total average cycle	12 hr. 50 min.

the north end at this stage, a ramp was developed down to close to the tailrace tunnel grade along the length of the chamber in the process of excavation. The triangular mass of rock left between the north end of the chamber and the tailrace tunnel was excavated then and the muck hauled out through the discharge tunnel.

The tailrace to the river is being dug in gravel by means of tractors, scrapers and shovels. A natural cofferdam of gravel is left at the junction with the river and will be removed later by means of draglines.

Penstocks

The upstream side of the powerhouse mucking was stopped at the level of the penstock invert while the driving of the eight 16-foot diameter penstocks themselves was carried out.

The horizontal section of these penstocks was driven full face from a jumbo mounting four drifters and mucked with rocker shovels loading into 15-ton trucks. The inclined section, at 50° angle, was mined by means of six-by-nine-foot pilot raises which were subsequently slashed to size by downhand breast drilling. A loading pocket was established at the elbow and muck chuted directly to the 15-ton trucks.

Cable Tunnels

Mucking on the downstream side of the tunnel was stopped at the level of the invert of the cable tunnels while their driving was completed. Drilling was carried out by two drifters mounted on booms, the whole placed on sleds moved by bulldozers. Muck was removed by rocker shovels which dumped their loads into the powerhouse muck pile.

CONCRETE AND AGGREGATE PLANT

Over 500,000 cubic yards of concrete will have been required before the Bersimis development is completed. Of this amount, 460,000 cubic yards have been placed already in various structures by six different contractors. For the sake of economy, it was decided to erect a central mixing plant in a gravel pit strategically located less than one mile from adit No. 2—to serve all the tunnel, powerhouse and town site contractors.

The standard automatic concrete plant with a 500-ton overhead bin is fed by a conveyor loading from a reclaiming tunnel under three different stockpiles of aggregate. Four tilting mixers, each of two-cubic yard capacity, discharge into a collecting hopper from which eight cubic yards of concrete are dumped into 15-ton diesel trucks. Except for the Lac Cassé job, all the concrete was mixed in this plant and transported in trucks with open bodies, some of it as far as six miles.

Due to the addition of a dispersing agent, there was practically no segregation at the points of delivery. Before being used in the concrete guns or the pumpcrete placers, the concrete was agitated in a standard re-mixer. The concrete was kept warm during winter transportation by passing the exhaust gases of the trucks through a jacket on their steel bodies. An average 5.5 bags of cement per cubic yard were used in the mixes to produce a concrete with compressive strength of well over 3,000 p.s.i.

Bulk cement was used in the central mixing plant. The cement was transported in a 2,700-ton boat to Forestville, unloaded by pumps into a wood-staved cement silo with a capacity of 25,000 barrels and then piped to a reloading silo. The cement was transported from this transfer silo in tank trucks whose 10-ton loads were dumped into a 50,000-barrel, wood-staved silo at the mixing plant. The silos, 60 and 80 feet in diameter, are equipped with air slides set in the concrete foundation slab to make cement flow to the discharge point.

The aggregate plant consisted of a 48-inch gyratory primary crusher, a 36-inch secondary cone crusher, vibrating screens, scrubbers, conveyors and stacking conveyors over the reclaiming tunnel. The aggregate plant feed was mostly gravel from a nearby esker. Since the esker was deficient in coarse material, it was found expedient to add tunnel muck to supplement the stone supply.

TRANSPORTATION

Over 250,000 tons of equipment, materials, supplies and foodstuffs have been transported already by boat to Forestville and it is estimated that shipments will amount to 50,000 tons during 1956. A 500-foot wharf was built at Forestville to handle cargoes, while a 50-ton derrick on the wharf handles the heavy equipment.

ORGANIZATION

Hydro-Quebec was quite surprised when contractors working on the project stated that the Commission was the general contractor for the Bersimis development. Upon retrospection, however, it was realized the contractors were not far from the truth.

Hydro-Quebec preferred to let the work to six different contractors instead of letting the entire development to a single contracting firm. The reason was twofold: to create more stimulation on the job and to benefit from the experience of a greater number of key men than a single organization could make available.

All equipment, materials, supplies and spare parts have been purchased by Hydro-Quebec. Construction stores, payrolls, accounting, cost accounting, transportation, distribution of construction power and the catering for the men are handled also by the Commission. Common use of all these services could not but result in appreciable savings. Hydro-Quebec feels there is ample justification for this method of handling a big assignment providing, of course, that the project can be handled and co-ordinated efficiently by the owner's organization. The contractors were relieved of some of the inherent worries of the trade and were therefore free to concentrate all their efforts on performance.

Very appreciable economy was realized by forming an equipment pool from which contractors could draw the equipment they required. Endeavour was made to arrange the construction schedule in such a way as to make continuous use of the equipment on any part of the job, equipment being shifted from one contractor to another. Standardization was achieved to a certain degree, resulting in a lesser variety of spare parts being kept in construction stores. Only new equipment was purchased and the job benefited from the best years of the equipment's lifetime. All this could be achieved only through Hydro-

Fig. 18. Tunnel concreting jumbo at portal before entering tunnel (total length including forms 440 feet).

Quebec owning the equipment.

At that period when the contractors were required to start the work, there was insufficient information about the project to have the work carried out on a unit price basis. Accordingly, the contracts were let on a cost-plus-fixed-fee basis. To effect maximum economy on that type of contract, it was decided to provide some incentive for efficiency by interesting the contractors financially in the resulting savings. For that purpose, target prices were established whenever possible and the contractors were entitled to a generous share of the difference between the actual cost and the cost set by the target prices. This is working well and helping to keep cost within the estimate.

The estimate was $150,000,000 for the entire project, excluding the transmission line. Up to now, 80 per cent of the work has been done and there is every reason to believe that the cost will not go over the original estimate.

The demand for power in the Province of Quebec keeps increasing continually in staggering proportions. In fact, all the power that can be generated at the Bersimis development will be absorbed within a few years. Is it not logical, therefore, to conclude that the construction of power plants will be a continuing process until all water power potential in this Province has been harnessed?

This paper has dealt with the general aspects of the Bersimis-Lac Cassé development. There are many interesting studies and phases of construction which deserve to be treated more thoroughly. Other engineers who have had much to do with the execution of such work will contribute papers or talks on specific problems when circumstances so arise.

Under the supervision of the Commission's technical staff, eight general contractors were engaged in the planning and construction of the overall Bersimis-Lac Cassé Development.

These were: H. G. Acres, consulting engineers; Atlas Construction Co. Limited, Cartier Construction Limited, and Perini (Quebec) Limited, excavation of tunnels and powerhouse, and concrete lining of tunnels; Angus Robertson Limited, construction of dams; Dufresne Engineering Limited, preparation of concrete and construction of powerhouse; Komo Construction Limited, construction of buildings and public utilities at Labrieville and of wharf at Forestville; Anglo-Canadian Pulp and Paper Mills Limited, construction of roads, supply of lumber, boat unloading at Forestville, and transportation of materials to job sites.

Air Pollution Control Problems

E. A. Allcut, M.E.I.C., Fellow ASME,

Professor and Head of the Department of Mechanical Engineering, University of Toronto.

During the past six hundred years, many sporadic attempts have been made to control the amounts and kinds of pollutants in the atmosphere (Fig. 1). In the earlier attempts, the problem was somewhat simpler because concentrations of industrial activity were fewer and smaller than they are now and also because the control was limited to visible impurities or "smoke". Since the beginning of the present century, the problem has increased in seriousness and complexity to such an extent that its very name has been changed from "smoke abatement" to "air pollution control". Its importance has been made manifest by the smog episodes in the Meuse Valley, Donora, and London respectively and by the continued and chronic condition of Los Angeles.

The word "control", however, implies a knowledge of what is to be controlled as, unless the contaminant can be identified and measured, the only criterion is opinion or judgment, which is a personal and variable factor. These considerations apply particularly to "odours" or "nuisances", which are frequently referred to in codes and by-laws, but can be defined only in terms of general consent or public opinion. For legal and testing purposes however, the definitions, measuring instruments, techniques and methods of control must be made specific and uniform. Unfortunately, these vary in different control areas so that, while valid comparisons can be made at different times in each individual area, to determine whether the degree of pollution is rising or falling, it is frequently impracticable to compare the results obtained in one area with those obtained simultaneously in another. This is obviously a very undesirable situation, which can only be rectified by agreement on an international basis. It is somewhat analogous to the confusion that existed with regard to the properties of steam before the International Steam Tables Conference of 1929, and calls for similar action before it is too late for useful action to be taken.

Air pollution has become a problem affecting whole communities and extending beyond the scope of purely short-term remedies or legislation. Lack of agreement on definitions and on techniques of measurement and control, have led to an unsatisfactory situation that can only be rectified by agreement on an international basis. Action to achieve this must be taken before it is too late. The paper is to be read at the Annual Meeting of the Institute, May 1956.

The difficulties encountered in practice may be divided roughly into three classes, as follows:

(1) Measuring devices and techniques.
(2) Surveys and identification of sources of pollution.
(3) Administration and control.

It is evident that some of the factors concerned can be included in more than one of these categories and that, therefore, the classification will be, and must be, arbitrary in some respects.

Measuring Devices and Techniques

The identification and, therefore, the control of any pollutant depends upon the specification implied by its name.

Definitions

Definition is thus the initial stage of control and the various definitions of smoke, fumes, and soot, illustrate the confusion that exists at this point.

Smoke is variously described as:

(a) Small gas and air borne particles consisting essentially of carbonaceous material in sufficent number to be observable.[1]

(*b*) A product of combustion . . . the particle size being generally less than 0.5 micron.[2] (1 micron=1/25,000 inch).

(*c*) The gaseous products of burning organic materials . . . when rendered visible by the presence of small particles of carbon which finally settle as soot.[3]

(*d*) The exhalations, whether visible or not resulting from oxidation or other chemical action and containing either liquid or solid particles less than 1/10 micron in mean diameter.[4]

Thus, smoke may be either solid, liquid, gaseous, or any combination thereof, it may or may not be visible or carbonaceous and it may or may not be defined in terms of particle size.

Fumes are defined as:

(*a*) Gases or vapours of such a character as to create an uncleanly, destructive, offensive or unhealthful condition.[1]

(*b*) A product of combustion, sublimation or condensation . . . with a particle size generally less than 1 micron.[3]

(*c*) Solid material suspended in a gas . . . formed by condensation from the gas phase.[3]

(*d*) Gaseous mixtures containing solid particles between approximately 1/10 and 1 micron in mean diameter. These may result from distillation, oxidation or other chemical reaction.[4]

Fumes, therefore, are variously defined according to particle size, what they are, how they are produced and the undesirable conditions they create.

Dust is always tacitly considered to be solid, but is described as follows by different authorities:

(*a*) Gas and air borne particles larger than 1 micron in mean diameter.[1,4]

(*b*) A product of mechanical disintegration with a particle size between 1 and 150 microns.[2]

(*c*) Finely powdered earth or waste materials. The median size of outdoor dust is 0.5 micron; industrial dust 1.5 micron.[3]

Here there is less confusion but the sizes cited are respectively minima, median and range.

These are but a few of the variations that might be quoted, but they are sufficient to illustrate the point that, if there are so many different starting points, what degree of uniformity or correlation is to be expected in the final results?

Sampling Procedures

Where there are a large number of variables, it is evidently necessary for the sampling procedure to be chosen carefully, so that the samples may be representative of the prevailing conditions, both in quality and quantity. The classical way of dealing with problems of this kind is by the application of statistical methods,[5, 17] but this is rarely possible in practice and therefore other and less accurate methods of approach must be used.

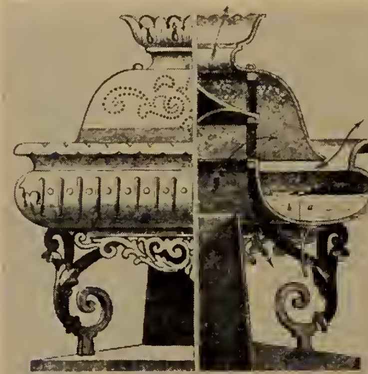

Fig. 1. Capping piece for chimneys to wash flue gases before entering the atmosphere (1869). (Courtesy "*Smokeless Air*").

The principal requirements for a practical air sampling equipment have been outlined as follows.[6]

(1) Must be capable of collecting a large number of samples without excessive labour requirements.

(2) Must be inexpensive enough to allow several instruments to be used simultaneously.

(3) Must be versatile enough to enable specific determinations to be made in the presence of various interfering compounds.

(4) The volume of samples must be large enough to provide a reasonable degree of sensitivity.

(5) Samples must be adaptable to rapid and accurate analysis.

(6) Time of sampling must be short enough (in some cases) to allow for changing weather conditions.

(7) Provisions must be made for relating concentrations with time.

(8) Must be adaptable (in some cases) to the determination of several different contaminants.

When these requirements have been met, there still remains the problem of suitably locating the sampling equipment, having regard to local variations in fluid velocity and, if pertinent, the general effect of environmental conditions. With regard to the time factor, recording instruments are desirable if they are available, but questions of initial cost, servicing, transferring and interpreting the data may, and often do, restrict their general use. On the other hand, where hourly variations occur (as in wind direction or velocity) an average sample taken over a lengthy period may be misleading. Nevertheless, comparisons are often made on the latter basis, but such comparisons should be made with care and discrimination—if they are made at all!

The importance of uniform design is indicated by the case of the collecting bowls or cans, which are widely used for measuring rates of dustfall. These bowls are of various shapes and sizes; the four examples shown in Fig. 2 being respectively 18 inches, 12 inches, 11 inches and 6 inches in diameter. From the solid materials collected on these small areas, the monthly deposit per square mile is calculated, on the assumption that the sample does not depart materially from the average, in spite of variations in local conditions and activities. Comparisons made at the University of Toronto [7] showed that, when duplicate equipment (Type A) was used in a single place, the average rates of deposit in the two bowls were 224.4 and 225.9 tons per square mile per annum respectively, a difference of less than 1 per cent. Comparisons between Types A and C, made under similar conditions over a period of three months, gave the figures shown in Table I.

Types A and C are employed constantly in two different cities and it is evident that, when these variations exist, no reliable comparisons of relative cleanliness can be made. Also, when dustfall readings are averaged over an area of (say) 50 square miles, valid comparisons with other areas are practically impossible, particularly as, in some cities, the sampling points are located mostly in the dirty areas while in others, they

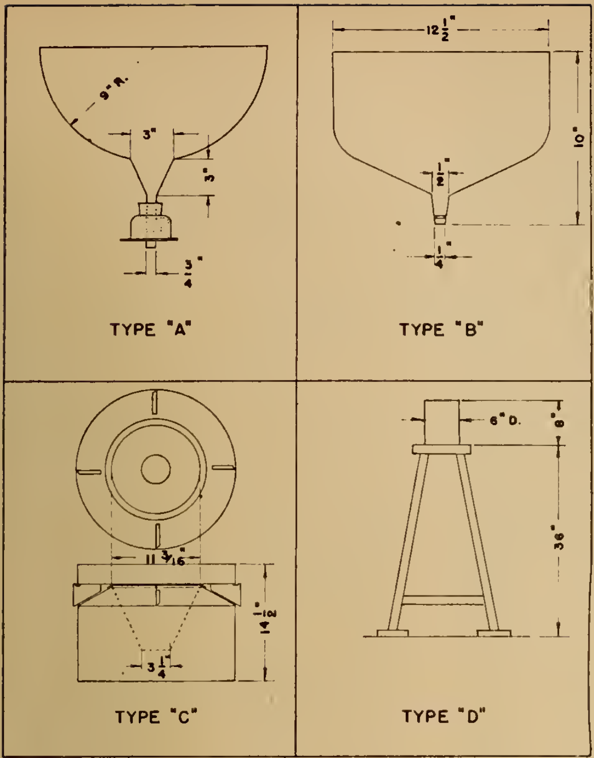

Fig. 2. Four types of gauge for measuring dustfall.

are distributed more uniformly. Yet, these kinds of comparison are demanded by the public and by their elected representatives, who provide the money to carry out the work and who want the results to be stated in terms that they can understand.

The above considerations relate to the sampling of gas-borne dust in the open air. Many (and perhaps most) of the codes and by-laws also limit the amount of dust that may be emitted from stacks and the following quotation indicates that there are some differences of opinion and practice regarding the maxima permissible. [8]

"Three major cities have a standard of 0.40 grains per cubic foot under standard conditions. Two cities report 0.30 grains per cubic foot. Two cities use 0.85 lb. per 1000 lb. of flue gases at approximately 12 per cent CO_2. One city allows 0.75 grains per cubic foot but not to exceed 0.20 grains of such a size as to be retained on a 325 U.S. standard sieve. One city specifies that there shall be 90 per cent removal of particulate matter at the 20 micron level. Still another city applies a rule of reason based on individual nuisance cases actually reported."

It is evident that, where such stipulations exits, [11] [12] it is possible to evade them without in any way reducing the amounts of dust entering the atmosphere, by diluting the effluent gases with air. In some instances, this situation may be met by prescribing the maximum emission of solid matter in pounds per hour [4] but, even so, it is necessary to determine the facts by using a standard sampling procedure such as that recommended by the A.S.M.E., [32] employing special sampling devices which are not usually available. It is also necessary, in practice, for the inspector or observer to have access to the premises which are under observation and for him to have sufficient scientific knowledge or training, so that the readings taken may be reasonably accurate (Fig. 3). This combination of conditions seldom exists in practice and it is doubtful, therefore, whether the inclusion of stack-loading requirements in civic codes is of any particular value. Similar criticisms may also be made regarding stipulations as to the efficiencies of the dust collecting appliances. These are meaningless, unless the size ranges of the dust particles are known.[2, 10]

Smoke densities are mostly based on the Ringelmann chart or its derivatives and the limitations of this method of measurement are so obvious and well known that they will not be repeated here.[9] Alternative appliances that may be used by an inspector in the field, such as the Umbrascope and Smokescope have been utilized in a few cities but, so far, have not been widely adopted.[11] Some clarification of this situation is urgently required, so that a single standard of comparison may be specified.

The amount of finely divided suspended matter in the atmosphere is important, not only because it affects cleanliness generally, but also because it controls visibility. The composition of these fine particles is frequently very different from that of the deposited matter ("dustfall"), as is evident in the following example taken from the Leicester survey.[5]

	Suspended Matter	Deposited Matter
	% by weight	
Tar	14	1
Other combustible matter	71	30
Ash	15	70 approx.)

This suggests that the finely divided material originated mostly from small (domestic) installations and the deposited matter from large (industrial) furnaces. The influence of suspended matter on visibility is illustrated by Fig. 4 and 5, which show the appearance of University Avenue, Toronto, on June 6th and August 24th, 1955, respectively. An A.I.S.I. automatic smoke sampler was used in Toronto to filter measured samples of air through a paper strip, which was moved to expose a fresh area for each two-hour period. The records obtained at two different stations in September 17th, 1955, are shown in Fig. 6. The results are expressed in "Coh" units, one of which is defined as that quantity of light scattering solids on the paper as will produce an optical density of 0.01 when measured by light transmission. The optical density is defined as log (incident light)/(transmitted light). On clear days readings of 1 - 1.5 Cohs are obtained, but on murky days they may increase to

Table I. Comparisons between types of dust collectors

	Type A	Type C	Ratio C/A
	Tons per square mile per month		
April 1955	36.1	65.0	1.80
May 1955	27.6	50.8	1.84
June 1955	22.8	50.5	2.21

6 or 12 Cohs. In the early part of 1955, the Toronto averages varied from 3.1 to 4.4 Cohs. These results are interesting and informative, as far as they go, but they are not directly comparable with results obtained in other places where different types of measuring apparatus are used [9] although attempts have been made in some instances to correlate the results obtained and to express them in terms of mass. The calibration curve given for this purpose in the Leicester report [5] (p. 9) is stated to represent "average conditions accurately to about 5 per cent, but may also have an unknown persistent error". In view of the importance of visibility, particularly in relation to aircraft operations, a greater degree of standardization and calibration in this field of measurement is evidently required.

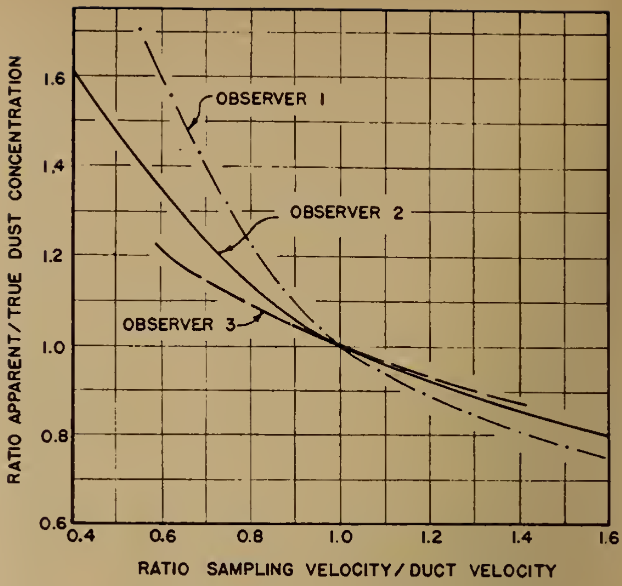

Fig. 3. Errors caused by differences of velocity when sampling dust laden gases.

One of the most important and potentially dangerous pollutants is sulphur dioxide and most surveys make some provision for measuring and recording the amount of SO_2 present in the atmosphere. Parker [13] states that "with highly efficient boiler installations achieving complete combustion and producing flue gas containing 12 to 15 per cent of carbon dioxide, the concentration of sulphur dioxide in the flue gas is ordinarily less than 0.1 per cent by volume. As the volume of flue gas produced for each (long) ton of coal burned is roughly equivalent to 360,000 cubic feet at ordinary temperature, the volume to be discharged every hour from a large boiler installation using (say) 2000 tons of coal a day is about 30 million cubic feet". The problem of removal, therefore, is one of bringing very large volumes of gas into effective contact with a solvent or reagent that will rapidly dissolve or react with sulphur dioxide to give a solution or product that is easily removable from the gas. This procedure is only possible in large installations and consequently, in practice, most of the sulphur dioxide produced enters the atmosphere where it is liable to affect health, vegetation and structures.[15]

Various standard chemical tests and kinds of apparatus are available for measuring SO_2 concentrations,[5, 9] but they are usually expensive or difficult to service in the field and therefore comprehensive records of this constituent are generally limited in practice to a few locations in any one area of jurisdiction. The lead peroxide instrument[14] is simple, cheap, is not unduly affected by external conditions and requires no ancillary services in the field. It would appear, therefore, that these instruments have considerable advantages for comprehensive surveys but, as far as can be ascertained, they are not widely used outside the United Kingdom. Certainly a simple, reliable, and cheap method of measuring small concentrations of sulphur dioxide in different locations is badly needed. A case in point is that of Toronto, where the SO_2 concentrations at a sampling station exceeded the desirable limit of 0.5 parts per million on 17 occasions between April 19th and July 28th, 1955, and on one occasion (May 2nd) the concentration reached 1.2 parts per million. If this situation is general, and is not peculiar to that location, it is a matter of some concern. The recording instrument used, however, is expensive and somewhat difficult to get, so that only one of them was available.

These are some of the principal difficulties met with in the day to day program of sampling and measurement which constitutes the basis of the control procedure. Obviously, the list is far from complete and it may be enlarged considerably when the disposal of

Fig. 4. University Avenue, Toronto —good visibility (1955).

Fig. 5. University Avenue, Toronto —bad visibility (1955).

radioactive waste matter becomes an acute problem.[16]

Surveys and Identification of Sources of Pollution

It is assumed that the general purpose of a survey is to determine systematically the condition of the air in different places at various times, so that the nature and extent of the air pollution problem may be determined for one or more of the following purposes[17]:

(a) To plan an abatement program for the whole or some part of the area concerned.

(b) To identify individual offenders and to determine the nature and extent of the offence.

(c) To check the performance of remedial or other equipment.

(d) To monitor processes for the purpose of preventing financial losses or to determine the possibilities of by-product recovery.

(e) To study the deleterious effects of various pollutants on plant and animal life.

It is evident that the nature and extent of the facilities required and the organization of the survey itself cannot be determined unless and until the objectives of the study have been clearly defined. For instance, if the problem is one of discovering whether or not a nuisance is being created, the circumstances of the case and the location of the offending plant are important factors.

"In considering what constitutes a nuisance, it should be realized that a nuisance in a residential area may not be considered a nuisance in an industrial area. The concept of restricted legal liability for nuisances in industrially zoned areas is gaining some acceptance in air pollution regulations. However, it is advisable to remember that the topography and meteorology of the country surrounding the industrial area, as well as the height of industrial stacks determines what air pollutants reach ground level in industrial, business and residential districts."[18]

Thus, in addition to the measurement of the amount and kind of pollutant that is being emitted from a chimney or other opening, it may be necessary to find out what happens to it afterwards. Calculations, wind tunnel experiments, and direct observation (Fig. 7, 8, 9) have been made

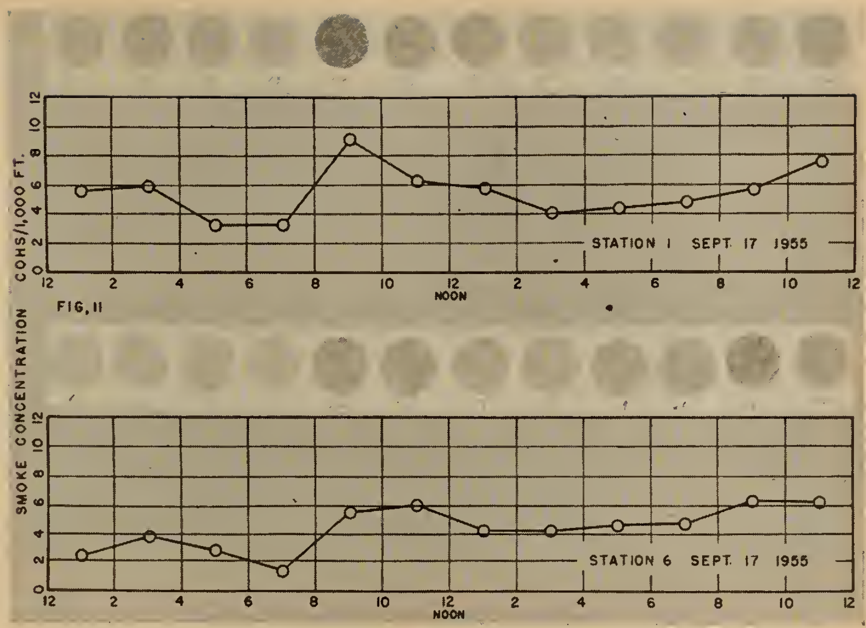

Fig. 6. Records from automatic smoke sampler, Toronto (1955).

to determine the paths taken by smoke plumes from chimneys in different circumstances and, in one recent investigation regarding the advantages of washing flue gases, the conclusions were[19]:

1. The loss of buoyancy resulting from washing the flue gases from a chimney destroys the advantage of removing SO_2 if the air turbulence is less than that corresponding to a wind speed of 15 miles per hour.[21]
2. The advantages of washing increase with wind speed and turbulence.
3. With a given volume rate of discharge there is a critical exit diameter for the stack, above which the maximum concentration of SO_2 is greater for the washed than for the unwashed gases. For chimneys higher than 100 feet, this effect is not important.
4. For unwashed gases and chimneys higher than 200 feet and with wind speeds of about 20 m.p.h. the maximum concentration of SO_2 on the ground will not exceed 1/1000 of the concentration at the chimney exit.
5. With increasing chimney heights the maximum concentration of SO_2 (at ground level) decreases and occurs further from the stack.
6. With washed gases the velocity of exit should be as high as possible.
7. The distribution of pollutants from a chimney is influenced by the contours of the surrounding country and by the arrangement of nearby buildings.

Mountain barriers and river valleys also are effective in restricting the volume of air into which waste effluent is discharged and variations of wind velocity and direction [22] will prevent a smoke plume from continually sweeping over the same area. Moreover, the presence of a heavy layer of smoke haze at the ground, particularly when it is thickened by fog into a "smog", resists the penetration of sunlight from above, thus preventing the heating of cold air in a valley. In this manner an accumulation of pollution may be built up, with fatal results.[15] In some instances, as at Trail, B.C., and Brookhaven, N.Y.,[20, 22] industrial operations are controlled by the prevailing meteorological conditions. In any event, atmospheric turbulence must be relied upon to remove most of the finer particles and this is a very complex problem containing many variables, which add to the difficulties of analysis and prediction.[22, 23] Its importance becomes manifest to the general public when temperature inversions occur on windless days.

The problems that arise and that call for solution in dealing with stationary plants are themselves sufficiently numerous and serious, but the rapidly increasing use of mechanical transport adds to their complexity and potential seriousness. The contributions of automotive vehicles to the Los Angeles problem are well known, if they are not entirely under-

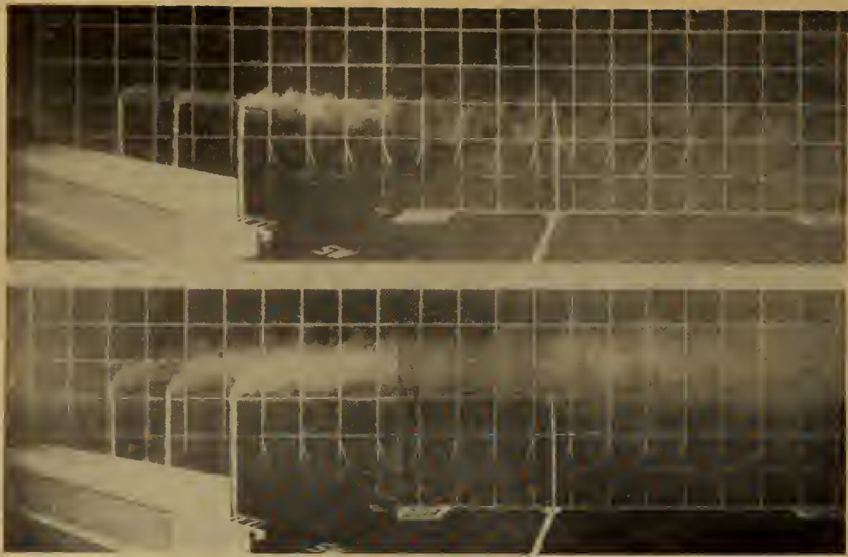

Fig. 7. Smoke plumes in wind tunnel tests (New York University).

stood, and Katz[23] comments on the general situation in the following terms:—

"The contributions to this problem from the general activities of the public must not be underrated. Thus, in a city where half a million automobiles, trucks and buses are operated, there may be consumed a daily total of one million gallons of gasoline and oil, releasing nearly one billion cubic feet of exhaust gases."

Gasoline engines, working on rich mixtures give off large volumes of carbon monoxide which is a very dangerous gas when present in sufficient concentrations[24, 15] and, in addition, diesel engines which are overloaded or poorly maintained emit large amounts of smoke at or about the breathing level. Diesel engines working on lean mixtures also produce aldehydes, which are smelly and irritating[21, 15] (Fig. 10) and may also produce dangerous oxides of nitrogen. The carbon dioxide produced is rarely harmful to health and some of the other gases may be removed, wholly or partly by washing or by catalysts,[25] but washing is difficult to apply in a moving vehicle and catalysts are not always effective at comparatively low exhaust temperatures. Most vehicles offend in one or more of these respects and, although the concentration of harmful pollutants from this source in cities rarely reaches dangerous levels,[24] it could become serious in periods when heavy traffic coincides with a prolonged temperature inversion. The difficulty in these cases is that of identifying the chief offenders and bringing them to book effectively.

In the case of locomotives and steamships the problem of air contamination is not that of identification but (in Canada) is almost entirely that of jurisdiction, because the local and provincial authorities have no legal control over these transportation agencies. This has caused many disputes and, after several conferences with railway officials, representations are now being made by several municipalities to the Board of Transport Commissioners, for the purpose of amending the regulations regarding smoke emission from steam locomotives and other pollution produced by diesel engines. The steamship problem is also bad, particularly in waterfront areas and in this case there seems to be no general agreement as to where the jurisdiction lies. When the St. Lawrence Waterway comes into operation with, presumably, a greater concentration of shipping and more diversification of ownership, this problem will probably become progressively worse.

Pollution caused by cupolas, metal processing plants, cement plants, and others is frequently difficult to check because, either the emission of dust and other pollutants is not concentrated in one or a few places, or cooling and washing facilities [8, 18, 26] are difficult to provide, and also because measurements are frequently impracticable. In such instances it is usual to take action under a general nuisance clause in the by-law.

Domestic incinerators, which have proved to be so troublesome in Los Angeles and other places are in a similar category. These have been dealt with recently in Toronto by the addition of a new clause to the by-law, which lays down regulations limiting the type and design of incinerators which may be installed. These approved designs are intended to promote complete combustion of garbage and are based on the experience of cities in the United States.[27] As the legislation has only been in operation for a few months, it is too early to say whether or not this procedure will be effective in reducing, to negligible proportions, pollution and odours from these sources.

The effectiveness of any program of air pollution control depends on the possibility of locating the offender. In some cases, as in isolated plants or where the products have distinctive charac-

Fig. 8 (left.) "Looping" smoke plume (Brookhaven National Laboratory).

Fig. 9 (right). "Fanning" smoke plume (Brookhaven National Laboratory).

teristics, this is a simple matter.

"Thus, if the offending stack is isolated, the dust is in big chunks, its colour is dark, a snow has freshly fallen and an inspector can get to the area before the snow melts, any air pollution control inspector can walk right to the offending stack and have little trouble in convincing plant management of their responsibility in the matter. Black fly-ash on white snow is impressive. On the other hand, if a suspected source of a justifiable complaint is buried deep in a maze of plants, several of which are potential sources, then the job calls for all the knowledge and skill the air pollution enforcement officer can muster." [28]

It is evident that, in most instances, the funds and staff available will not allow the provision of as many fixed sampling points as are necessary to arrive at a reasonably correct average for the area being surveyed. Special consideration, therefore, should be given to the following types of area.[22]

(1) Critical areas such as residential areas, gardens, parks.

(2) Areas of maximum air pollution complaints, to determine cause and justification.

(3) Areas of theoretical maximum and minimum concentrations of pollution.

(4) Areas delineated by special topographic features.

For the detection of individual offenders, directional sampling (Fig. 11-12) or, more appropriately, mobile sampling laboratories, may be added to obtain additional information from particular areas. Alternatively, spot checks using simple apparatus such as sticky paper or local observations on car surfaces, vegetation or snow are sometimes used to pin-point an offender or to provide supplementary evidence. When an exhaustive scientific survey can be made it is obviously desirable, but the procedure is lengthy and expensive. It is considered[5] that for ordinary purposes in Great Britain, five years is the probable ideal time in which to estimate the annual variation of pollution (Fig. 13). Few communities, however, are willing to wait that length of time for the information and the usual result is the adoption of some kind of compromise between the desirable and the practicable.

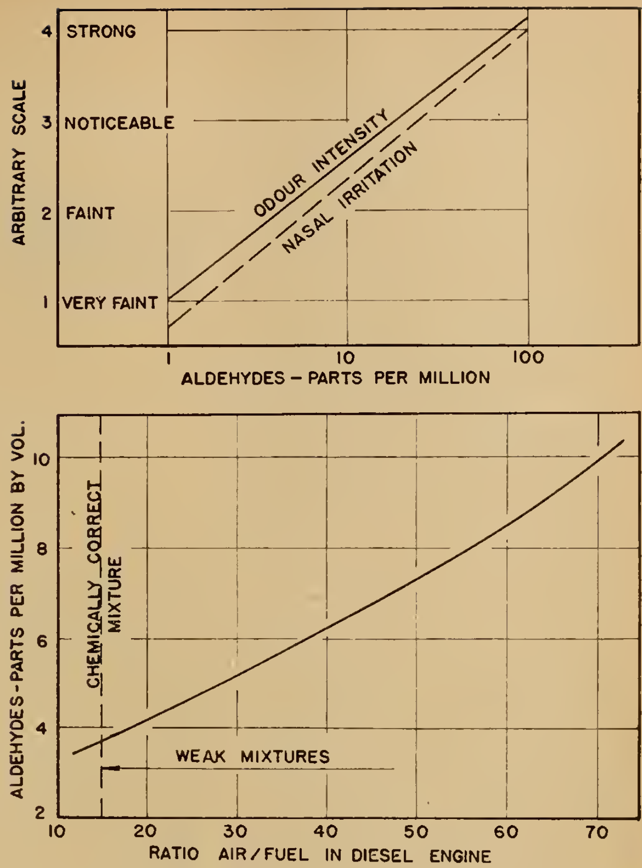

Fig. 10. Aldehydes in diesel engine exhaust gases.

Administration and Control

It has already been remarked that, although smoke is the most evident, it is not necessarily the most important factor in air pollution. Nevertheless many, and perhaps most of the local air pollution control procedures have been built round an existing organization which was designed originally for handling smoke abatement. The Committee on Atmospheric Pollution in Canada was appointed in 1949 to study these matters and to suggest standardized procedures that might be applied, with some local modifications in different parts of the Dominion. Among other things the report stated:[4]

"It is strongly recommended that the problem should be dealt with on a regional basis by means of appropriate control areas to be set up by the various provincial governments, because only those governments have the power to take such action. Cases where the control area must necessarily cross provincial boundaries could be dealt with by the two governments concerned."

Examples of this kind of problem on an international basis are the Windsor-Detroit[20] and Sarnia-Port Huron[21] areas. The recent transfer of the responsibility for air pollution control from the City of Toronto to the Metropolitan authority will give an opportunity of trying out this recommendation in an urban residential-industrial area of about 240 square miles. The government of Ontario has also set up a committee to study air pollution control on a provincial basis but, at the time of writing, that committee has not yet reported.

The controlling committees or boards are usually responsible to various municipal or governmental departments[29] such as Health, Works, Property or Planning but, in any event, they must be set up in such a manner that they are relatively free from political interference. However, as stated above, they are still dependent in some measure on politicians for the finances necessary to enable them to carry out their responsibilities. In this connection, the importance of good public relations must not be underestimated.[30] In the Toronto program the support of service clubs, civic and business organizations, the Council of Women, and other similar bodies has been enlisted by means of talks, illustrated by slides and exhibits. Also, the local press has given valuable publicity to these activities and this can be quite effective in influencing legislation, if the statements published are simple, correct and interesting.

"The average newspaper reader has little interest in a technical description of electrostatic precipitation or a detailed analysis of stack effluents. He, probably, is not more than casually interested in what is being done to abate air pollution on a national scale. What he does want to know in simple, easily understood language, is what *local* plants are doing to reduce the smoke and soot that dirty his house paint and blacken the family wash, and the fumes that offend his nostrils and blight the trees and gardens in his neighbourhood."[31]

The fundamental principle for reducing smoke and other pollution is quite simple—keep it from getting into the air. Many of the troubles are caused by incomplete combustion or by lack of facilities for cleaning or filtering plant effluents. In most instances this condition is met by a system of "installation" and "operating" permits, which certify that the plant is properly designed and constructed. This procedure, however, takes care of new construction only. Most of the difficult problems occur with old plants, where it is frequently claimed, with some reason, that the cost of providing the necessary remedial measures would put them out of business. In some instances, the pollution control staff can suggest ways of improving operations without excessive outlays.

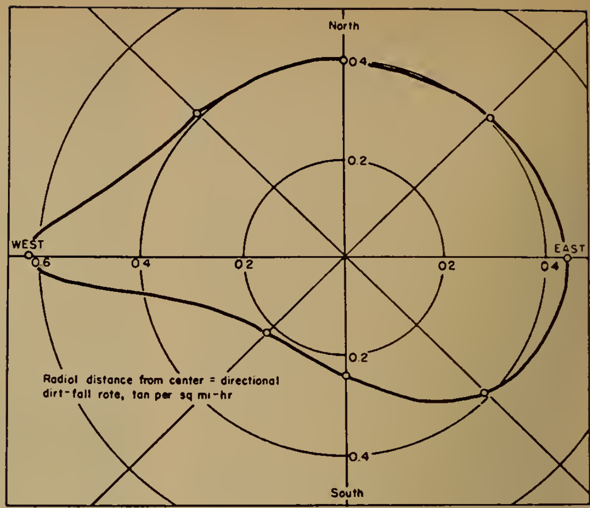

Fig. 12. Polar diagram from directional collector and wind-hour meter (Battelle Institute).

Sometimes, also, annual inspections of plants are made,[30] but generally the size of the staff available is too small to enable this to be done systematically. In fact, the number of inspectors that can be appointed and paid is insufficient in most cases to cover the prescribed area adequately. An attempt was made recently to improve this situation by requesting the police to report instances of flagrant and repeated violations of the law but, while collaboration was promised by them, very few reports were received. In practice, therefore, action must usually be based on information received from local residents.

The composition of the air pollution control board varies in different areas. In some municipalities, the members are chosen to be representatives of the various interests concerned, such as property, labour, chamber of commerce, and in others the composition is restricted to technical personnel such as chemists, engineers and medical men who have some specialized knowledge of the different aspects of air pollution. It would be useful to obtain some concensus of opinion regarding the relative advantages and disadvantages of these two kinds of composition.

Finally, the following principles may usefully be observed in adopting a policy.[15]

(*a*) Complete elimination of air pollution is not economically attainable and therefore a balance must be struck between the need for a decent living environment and the need for the economic support of local industries.

(*b*) The legislation must be enforceable and have the support of the community.

(*c*) The enforcement policy must be one of continual adjustment and education.

(*d*) Except in the case of definite hazards to health or safety, plants should not be closed down. The cooperation of industry generally must be sought and encouraged. Ar-

Fig. 11. Directional dustfall indicator (Battelle Institute)

The Battelle Memorial Institute points out that various difficulties of maintenance of the working parts of the collector have led recently to development work on a much more versatile system. This would employ motor-actuated covers for each jar and each jar could be set separately from all the others. All the covers would be controlled electrically from a central point. One advantage of this would be that the jars would be replaced by gas and aerosol samplers. The performance of the trial units has been encouraging.

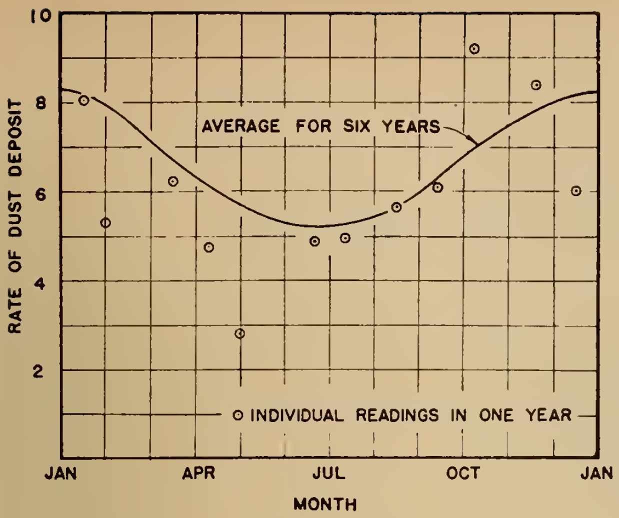

Fig. 13. Individual monthly dustfall readings compared with the average over a six-year period (Leicester Survey).

bitrary and stringent legal procedures cause irritation and result in non-cooperation.

(e) The program undertaken must be of the long range type and implemented with adequate funds and competent personnel. Results must not be expected too soon, as there is no prompt and universal cure. Each community constitutes a new and different problem which can only be solved by arduous and persistent effort.

Extending Winter Work

The joint committee formed to combat the problem of winter unemployment in the construction industry reported after its second meeting in March that there was less unemployment in the building trades this winter. The membership of this committee, in which the Institute has a representative, was described in last month's *Journal.*

Good results had been obtained from a concerted promotional campaign on the federal, provincial and local levels. It was agreed that the general public was now more aware of this problem which affects a large segment of the Canadian population. Last year about 125,000 construction workers were laid off by late February. The committee will carry out an extensive campaign this summer.

The Department of Trade and Commerce has forecast a phenomenal 19% increase in construction work over 1955 for a construction program totaling $6.2 billion. The forecast also indicates that limits on the availability of materials, manpower and investment might well prevent the accomplishment of a program of this size. Committee Chairman Raymond Brunet, O.B.E., Hull, Que., noted, "The industry expects there will be a shortage of certain materials this summer, especially of steel and cement. These shortages will tend to delay the commencement of the construction of larger structures until late fall deliveries and so increase the volume of work carried out during next winter".

Expansion in the

Pulp and Paper Industry

Recent Developments Undertaken by Canadian International Paper Company

W. T. Bennett, M.E.I.C.
Chief Engineer,
Canadian International Paper Company,
Montreal, Que.

The pulp and paper industry in Canada is in the midst of an extensive program of expansion and development. To illustrate the growth of the industry this paper, covering the activities of a leading organization in the field, is presented.

For many years Canadian International Paper Company has been a leading producer in Canada of newsprint, dissolving pulps for rayon, cellophane, acetate, staple fibre, etc., building boards, and hardwood plywoods. Last year the company entered the field of kraft pulp and started expanding into kraft paper and board for the first time through purchase of the Canadian assets of Brown Corporation on December 1, 1954. In this important transaction it acquired a kraft pulp mill in La Tuque, P.Q. and additional forest acreage in the St. Maurice Valley. This assured the company of adequate wood supply for the Three Rivers and La Tuque mills, and makes it possible to continue the pulpwood harvest according to best conservation practices.

Fig. 1. Before starting excavation for the sewer shown here it appeared that there was virgin soil in this area. Excavation revealed an old concrete Venturi flume used at some time to measure effluent.

La Tuque Mill

The La Tuque mill had a rated capacity of 550 tons per day of high grade bleached sulphate pulp. The forward planning was such that, with the completion of the deal with Brown Corporation, Canadian International Paper Company was able to start a $20,000,000 expansion program in the La Tuque mill. The mill's daily pulp capacity has been increased to 900 tons per day, the increment to be primarily unbleached kraft products, such as board for the manufacture of corrugated paper containers, and paper for kraft wrapping, bags, and so on. The project at La Tuque is the most spectacular part of the present expansion program, since it involves a major addition to a large existing plant and the installation of a 276-in. Beloit kraft board and paper machine, which is the widest machine yet installed in North

America for production of these grades and has a potential capacity, when it is required, of 1,000 tons per day. The project has been substantially completed within a period of approximately 15 months as the machine started production on March 15, 1956. The project also involves expansion of wood handling facilities, a 225,000-lb./hr. power boiler, a similar size recovery boiler, a new causticizing plant for lime burning, six additional digesters, a sextuple effect evaporator with a capacity to provide for the full 900-ton/day output, brown stock washers, and all the equipment associated with a board machine.

The design was carried out by Foundation of Canada Engineering Corporation Limited under the direction of Canadian International Paper Company personnel with additional technical assistance from the Southern Kraft Division of International Paper Company. Fenco were also responsible for adapting design information as used in the United States to Canadian conditions. The Foundation Company of Canada Limited were the general contractors.

The La Tuque mill was originally built close to the turn of the century and it has had many additions and alterations since the original construction. As is usual with an old mill, plans and specifications for the early construction are either scanty or non-existent and when new construction is involved, unexpected problems are often encountered as soon as excavation is started. This project was no exception with the result that even when excavation was started in what appeared to be virgin ground, old foundations, pieces of machinery, etc., which had been buried during previous alterations, had to be dug out. It was necessary to solve the problems of supporting new structures as excavation proceeded.

The mill is located on a well drained sand site and soil bearing values of 2 tons per square foot were used. In a few cases, involving temporary loadings, a 25 per cent increase in soil bearing value was assumed.

The new machine room is a building 943 feet long by 98 feet wide, plus an additional area on one side devoted to warehousing. In laying out this building it was found that the southwest corner projected over a 48-inch water main supplying both the mill and the town. Re-location of this main was not desirable, and it was therefore decided to leave it under the corner of the building. To protect the building foundations from being undermined in case of breakage of this main, it was encased in reinforced concrete designed to carry the full water pressure of 60 lb. per square inch. Since one of the building columns came directly above the main, it was necessary to span the main with a beam carrying the load to footings on either side of the main.

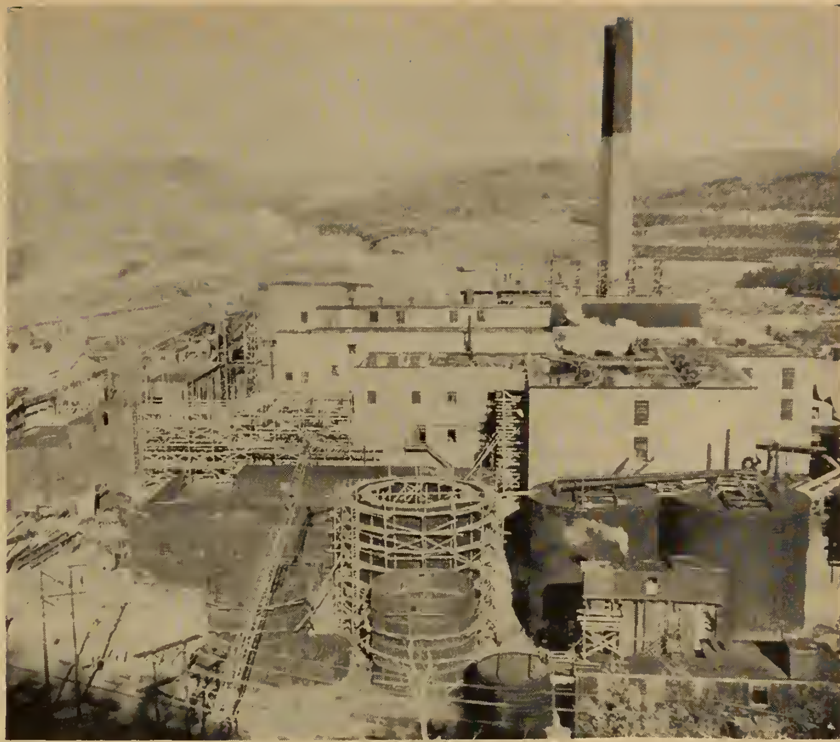

Fig. 2. Erection of a brown-stock washer and evaporator building together with some of the many tanks required in a pulp and paper mill.

The machine room was designed for extension to the west to take a second paper machine in the future. To provide for this the foundation wall on the west side was designed as the future machine beam on columns. The space between columns under the beam was closed with concrete panels designed so that they could be knocked out at a future date. Machine anchor bolts were placed in the beam, covered with grease, and buried in a concrete curb designed for future removal.

Roof trusses were designed for a future clear span of 132 feet. This provided clearance for two machines with a working aisle between them. Panel points of the trusses were arranged so that one came over the temporary west wall and the initially installed shortened trusses were supported on columns at the wall.

The paper warehouse building adjoins the machine room on the east side and was designed for a 600-lb.-per-square-foot live load on the storage floor, which was built on backfill at the same level as the machine floor. The basement wall of the machine room adjoining the warehouse had therefore to be designed as a retaining wall for the 18-foot height between machine floor and machine room basement floor. In order to economize on concrete in the section beside the machine opening, it was decided to design this retaining wall, the machine floor, machine room basement floor and the two rows of columns between the machine opening and the west wall as a rigid frame. This caused some difficulties during construction since it was decided to backfill and use the warehouse before sufficient information was available on the machine to pour the machine floor. This difficulty was overcome by tieing back the retaining wall to dead-men.

The hydrapulper was placed in a deep pit in the machine room basement and because no greater than a 30° slope was permitted between adjacent footings set at different levels, it was decided to enclose the excavation with sheeting which was left in place.

Because of the depth of the machine room basement, it was necessary to build a new 36 in. sewer to the river. This sewer was of reinforced concrete and was covered with up to 37 feet of sand backfill. After backfilling, an inspection showed that a great many of the lengths had cracked both in the invert and directly opposite. Investigation revealed that more lightly reinforced pipe than specified had been supplied. Because of the depth at which the pipe was buried, it was found to be more economical to line the concrete pipe with asphalt coated liner plate than to re-excavate and replace the concrete pipe. The liner plate was placed through two manholes and through an intermediate shaft sunk for the purpose. After the liner was in place the space between it and the concrete pipe was filled with grout placed under pressure.

Foundations for the brown stock washers presented a difficult problem because it was decided to locate the washers over the old machine room in which two machines had to be kept in operation. Columns were located so as not to interfere with the old machines. This required that the beams supporting the brown stock washers had to be framed into very heavy girders to carry the loads to the columns. The columns had to be brought down very close to an existing wall and footings had to be elongated in the direction of the wall so as not to interfere with the adjacent machine foundations. The existing wall had to be underpinned and carried on these new footings. Provision was made in the design to construct the new footings in short sections so that the wall could be underpinned.

The evaporator room is adjacent to the salt cake storage building in which 20 feet of salt cake had to be stored above ground level. When excavating for evaporator room footings, it was found that old pump pits, machinery foundations and a sewer existed well below the present ground level. In one location it was necessary to carry the evaporator footings to a depth of over 15 feet below ground level. Fortunately, it was possible to step up the footings in the direction of the salt cake storage buildings. A retaining wall was designed for the storage area with a toe extending under salt cake.

The location of the 16-in. main carrying 250 lb. steam at 500°F. between the boiler house and the machine room presented some difficulties since it was preferred not to follow the road. An examination of the site revealed that it would be very difficult to locate the line in and through the buildings. A route was therefore selected following the outside of the buildings. This route made it possible to support most of the line from the buildings and at the same time permitted giving it a grade for drainage. Following the building line also provided sufficient changes of direction to give flexibility for expansion.

Heating and ventilation of No. 3 recovery boiler room and No. 8 boiler room presented a problem since the intakes for the forced draught fans supplying the two boilers are located inside the boiler rooms. With a combined fan capacity of about 140,000 c.f.m. and a boiler room net volume of about 870,000 cubic feet, there would have been over six air changes per hour. This could have resulted in uncomfortable working conditions and possible freezing of pipe lines in the winter time. In addition neither of the air heaters was designed for minus 40° air intake, and air at this temperature would have been especially unfavourable for the No. 8 boiler air heater as low air temperature would have probably caused condensation on the tubes.

In the No. 3 recovery boiler house an air intake was located in the boiler house wall near the forced draught fan intake. Hand-operated dampers are provided so that the fresh air through the dampers can be tempered with warm air from the building to provide a suitable temperature for the steam coil air heater. In summer the air intake dampers could be closed and the doors and windows in the lower part of the building opened. This would provide ventilation of the building from the ground level up to the sixth floor where the fan is located.

In the No. 8 power boiler building a forced draught fan is located on the ground floor in the coolest furnace area. The intake opening is located about 70 feet higher

Fig. 3. Clearing the site for erection of a new building within an existing plant is a major undertaking as indicated by the steel erection shown in this view of the recovery boiler building during construction.

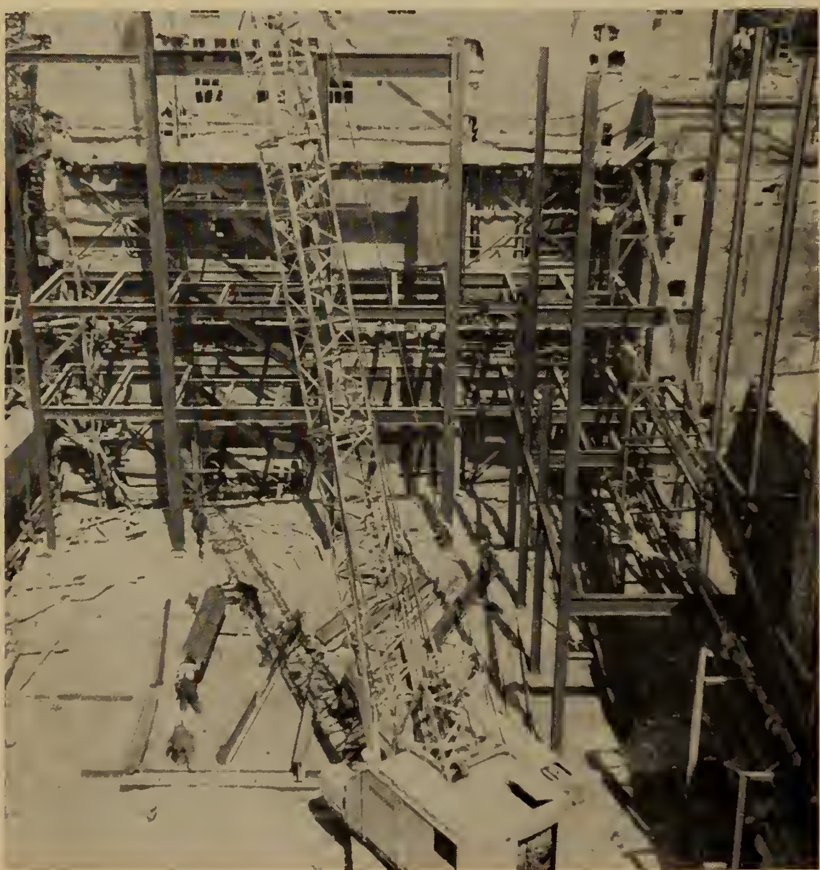

Fig. 4. New 250-ft. concrete brick-lined stack for the recovery furnace. Tanks connected with the caustic plant are seen under construction, and beyond this the lime kiln has been erected. The structural steel frame under the lime kiln is for a roof, to be installed, but no side walls will be provided despite temperatures reaching 50 deg. below zero. Heat radiated from the kiln, which never stops, keeps the ground dry under the roof.

and the entering air passes through a steam coil heater to bring it up to plus 40°F. in the winter time and is further heated by boiler radiation before reaching the forced draught fan inlet. Hand-operated dampers are provided in the intake. In the summer the forced draught fan will be supplied from adjacent doors and windows and the air intake opening will be used to ventilate the upper section of the boiler room.

The construction of such a project in the limited time between December 1954 and March 1956 is a highly creditable performance, especially in view of delays beyond the control of the construction organization, such as the strike in the United States of the company which had the contract to supply a major portion of the electrical equipment required. Particular credit should go to Mr. A. T. Jeffreys and to the electrical contractors, for working out many substitutions for unavailable electrical equipment and for completing the electrical installation within the required time.

Container Plants

A second development of major importance, closely related and complementary to La Tuque, was Canadian International Paper Company's entry into the corrugated shipping container business through the purchase of Hygrade Containers Limited. With this purchase the company acquired a modern corrugated shipping container plant in London, Ontario. C.I.P. has since built a new plant at Pointe-aux-Trembles at the eastern end of Montreal Island, involving an expenditure of $2,500,000; this new plant commenced production February 1, 1956. A third container plant in Toronto figures in future planning and a building site has been acquired; engineering for this plant is proceeding at the present time.

The plant at Pointe-aux-Trembles is built on a 33-acre lot with adequate space for future expansion and contains approximately 150,000 square feet in two main buildings: the manufacturing section 360 feet x 300 feet with all the bays 60 feet by 50 feet, and a warehouse building 360 feet by 90 feet and 50 feet high, equipped with a crane for handling the raw material for the plant. This is a typical light manufacturing building; however, soil conditions were out of the ordinary in that the maximum allowable bearing load was between 500 and 700 lb. per square foot. Even under this loading it was predicted that some settlement could be expected. To provide for stability of the structure, a total of sixty-eight 100-ton and one hundred and thirty-eight 50-ton Franki tube piles were driven to bed rock at the various column points. These piles had an average length of 85 feet. The outside foundation walls of the building were then designed as a beam to stand between the pile clusters and to support the masonry construction.

Linerboard and corrugating medium produced at La Tuque will be shipped in rolls to container manufacturing plants at Pointe-aux-Trembles, London and Toronto, where this product will be converted into all sizes and shapes of corrugated paper containers, designed to package the whole field from canned goods to refrigerators.

Newsprint Expansion

Although the emphasis during the past year has been on entry into the kraft manufacturing field, newsprint expansion has not been neglected. Canadian International Paper Company operates newsprint mills at Gatineau, P.Q., Three Rivers, P.Q., and through a subsidiary, New Brunswick International Paper Company, a third mill at Dalhousie, N.B. In the last ten years a speed-up program for expansion of newsprint capacity has cost more than $40,000,000. When this program was begun in 1946, the rated capacity of the three newsprint mills was 2,150 tons per day. When this program is completed by the end of this year, the rated capacity will be nearly 3,000 tons per day. Because the programs have been nearly continuous since the war, and often new programs are started prior to completion of existing ones, it is difficult to separate those which could be considered current expansion; however, the ones which are presently in progress or nearly completed at the various mills are as follows.

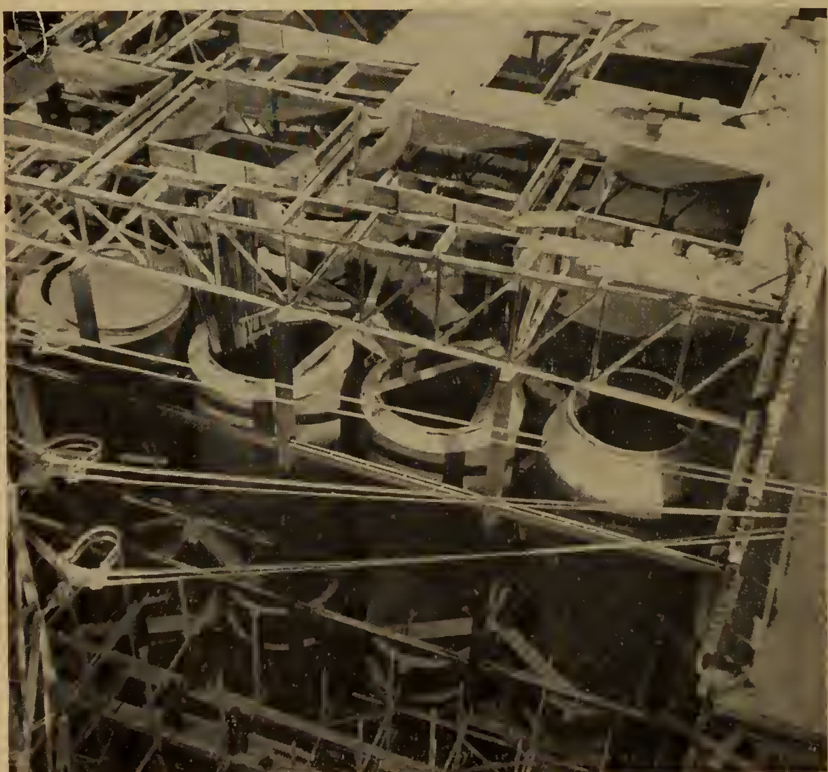
Fig. 5. Extension to the digester building to house six additional digesters. The chip bin had not yet been installed.

Gatineau Mill

At Gatineau in May 1954 the initial steps were taken to prepare for an increase in newsprint production from 911 to 1,024 tons per day. The whole program, which is to be completed by the end of 1956, involves an expenditure of $4,300,000 and provides for speeding up two of the four paper machines. The work also entails the necessary additions to the basic pulp producing units, including an additional digester for sulphite production and two lines of hydraulic grinders for groundwood production. Processing this extra pulp required the installation of additional screens, pumps, thickeners, washers, and other auxiliary equipment.

Major improvements on the two machines to be speeded up were designed to permit operating speed increases from 1600 to 1800 f.p.m. All improvements were designed for an ultimate speed of 2000 f.p.m. in case it was decided in future to expand production further. On the other two machines minor improvements were included to increase their speed from 1470 to 1600 f.p.m.

Fig. 6. To meet the time schedule, equipment had to be installed as construction of the building progressed. The size of the sextuple effect evaporator is indicated by the workmen on the scaffold (lower left). The hatches framed on the roof make provision for future installation of new internal tubes for the evaporators. Some of these tubes are shown before installation extending through the top of one of the evaporators.



The basic design of paper machines has changed very little over the years, but the speeding-up process has necessitated refinements and improvements in the design of the many components making up a machine, so as to make them mechanically and hydraulically safe for operation at higher speeds and increased tonnage rates. Consequently, it is not unusual to find most of the components of a machine progressively replaced with improved types over a period of a few years. At Gatineau the major improvements already installed or yet to be installed on the two lead machines include new head boxes, deculators, breast rolls, couches, heavy duty presses, additional dryers, amplidyne drives, mechanical drive improvements, dryer evacuation systems, calender improvements, new reels, dry end beaters, and new roll handling equipment. Even the winder design had to be changed, with a new machine being provided for a maximum operating speed of 6600 f.p.m. as compared with the original winder designed for 3000 f.p.m. maximum speed.

Three Rivers Mill

At Three Rivers mill three separate programs are currently underway or nearly completed. The first program, involving $1,700,000, is to be completed by the middle of 1956 and covers the speed-up of two machines, including No. 5 machine which although originally designed to operate at 1200 f.p.m. has established new world records by operating at high efficiency consistently for a whole year and at speeds in excess of 2100 f.p.m. Like the 4-minute mile in sport, this was an unheard of feat just a few years ago.

The major changes to accomplish this speed-up were new pressure head boxes and deaerating equipment, larger table rolls, new heavy duty press rolls of larger diameter permitting heavier loading, a vacuum transfer to take the sheet when it is weakest from the couch to the first press, increased drying capacity, increased vacuum pump capacity, improved condensate removal equipment in the dryer, improvements to the design of mechanical parts of the drive, and sectional electric amplidyne drives.

Fig. 8. Recovery furnace required a 10-storey extension to the existing building; here, the top drums have just been installed.

A second program involving $2,000,000 is scheduled for completion by the end of 1956 and provides for machine improvements on four paper machines. Again there are new pressure head boxes, centricleaners, improved dryer drainage, new press sections, drive improvements, and breaker stacks.

The third program, involving $2,300,000 and also scheduled for completion by the end of 1956, provides for speeding up one machine and includes a pressure head box, centricleaners, new press, breaker stack, calender stack, and an improved drive. This project also includes additional groundwood pulp-producing and electric power facilities.

As part of the above programs two additional lines of super grinders, each equipped with a 5000 h.p. synchronous motor, have been provided, and this is typical of the large demand for power involved in most paper mills' speed-up programs. Incidentally, the present consumption of power at the Three Rivers mill is approximately 100,000 h.p. The additional facilities provided for supply of electric power include a new 12,000 kva. primary transformer bank and two new 7500 kva. secondary banks.

With larger and heavier rolls in the presses and calenders necessitated by the higher speed, additional equipment had to be provided to maintain them so that it was necessary to provide a new roll grinder and a large double spindle lathe scheduled for delivery late this year.

Fig. 7. Looking up through the partially assembled water cooled walls of the 250,000-lb./hr. power boiler. Arrangement of the tubing to allow installation of a tangential type burner is shown at the centre of the picture.

Dalhousie Mill

The current expansion program at Dalhousie mill involves $6,250,000 and is scheduled for completion by the end of 1956. It provides for speeding up three paper machines and the actual project is divided into three parts, namely: machine changes and mill additions; power and steam; and shipping.

The mill was started up in 1930 with four machines which have a trim of 218 in. producing 32 lb. basis weight newsprint. The production at that time was around 550 tons per day running at 1000 f.p.m. At the present time up to January 1956, the same four machines are running at 1625 f.p.m. producing about 825 tons of news per day. This increase in production was accomplished by the addition of grinders and

Fig. 10. Looking down through the machine room, showing the sole plates being installed for the side frames of the paper machine. The basement floor had not yet been poured. Reinforcing steel projecting through the floor (foreground) is to take the drives for the various machine sections.

digesters and various changes and additions to the screening and pumping systems. Apart from power, one of the major engineering projects to surmount was the lack of fresh water. At present the mill consumes about 19,500 U.S. g.p.m. of fresh water per ton of newsprint produced, which compares with up to 50,000 g.p.m. per ton in other mills. This was made possible by a program of reclamation of water within the mill and re-use of water in the process. Water which was sewered when the mill started up, such as from the vacuum pumps, was reclaimed and used as dilution water for the digester blows in the sulphite mill.

Part of the speed-up program involves increasing the production of No. 2 paper machine 25 tons per day by increasing the speed to 1800 f.p.m. and this program is just about completed. In designing higher speed equipment for this machine, a 2000-f.p.m. ultimate objective was used. A grinder line was added and the refining system re-located from the east to the west end of the mill in order to make room for additional coarse screens and provide space for more refiners and still have all the refiners in one area for operating purposes. Additional fine screens were added in the screen room. A new roll grinder is now being installed to take care of the accelerated roll grinding schedule due to the increased speed of the machines. On the machine itself a pressure head box had been previously installed with a vacuum deculator for deaerating the stock.

Larger table rolls have been installed increasing the size from 11 in. diameter to 13 in. diameter for increased water removal. A 54 in. couch had previously been installed. Heavier press framing for the second press will be installed shortly. The granite press roll on the second press has been increased from 28 in. to 36 in. to improve water removal before the dryers. This was done previous to this program. Heavy duty rubber covered stainless iron suction press rolls were previously purchased for the second presses of all machines to accommodate the heavier granite rolls and increased nip pressures.

The drainage system of the dryers will be changed starting in March. This involves removal of the present stationary syphon pipes and steam joints and replacing them with revolving syphons and new steam joints. This will provide better dryer eva-

Fig. 9. General view of the new machine room nearing completion clearly shows the arrangement of the roof trusses with provision for their extension to house an additional paper machine.

Fig. 12. Paper machine dryers partly erected in the new machine room.

cuation at the higher speeds and improved drying with the same number of dryers.

The original drives were removed and new drives of the same make installed. The mechanical type of regulators with a master shaft controlling each section were removed, and the sections are now controlled by carbon pile regulators which are connected to the machine electrically. The motor horse powers were boosted to give control of load variations at high speeds.

A high-speed winder was installed in another building to act as spare until such time as another is received which will allow the installation of both new winders on the machines. The present winders were bought for 3000 f.p.m. The new winders are good for 6000 f.p.m. New 18 in. reel bars were purchased to prevent unbalance at high speeds and snap-offs at the winder.

A more recently approved part of the current program involves increasing the speed of Nos. 3 and 4 paper machines to 1800 f.p.m. This will increase the paper tonnage per day by around 50 tons and make the total mill production from the four machines about 900 tons. In designing new equipment to be installed on these machines, an ultimate speed of 2500 f.p.m. was used, although sufficient equipment is being bought at this time only to get the two machines to 1800 feet. The work is now being engineered and all heavy equipment is on order for 1956 delivery.

Fig. 11. View of one of the basement substations gives some idea of the large number of conduits needed for electric power supply and control of the paper machine.

In the sulphite mill a new digester, an additional knotter screen and an extension to the present set of coolers are being provided. In the groundwood mill a new grinder line and hydraulic system, sliver screen, primary fine screen, secondary fine screen, tailings refiner and drainer, and a decker are being installed. In the general category a new air compressor and an additional transformer bank will be required.

In order to reclaim more fresh water for use in the mill a water reclamation plant is contemplated. A decision on the type and make of machine has not been finalized, but it will be of a capacity of 2000 U.S. g.p.m. with the provision that in the future another 2000 can be added. The water reclaimed will be used for blow pit dilution in the sulphite mill and possibly for shower water on the filters in the screen room.

On paper machines 3 and 4, pressure head boxes and a deculator for deaerating the stock will be installed. The Fourdrinier will be lengthened 10 feet increasing the wire length from approximately 81 feet to 100 feet; 14 in. table rolls will replace the 11 in. rolls. Heavier press framing is required for the second press. The dryer drainage system will be converted from stationary to revolving syphons.

Amplidyne drives will replace the present drives. This involves extensive changes on the machines, entailing the removal and replacement of 11 drive motors and speed reducers on each machine. The prime mover in the basement is now a turbine with a reduction unit and generator on each machine. The new drive will have a synchronous motor in the basement coupled to multiple generators, one for each motor on the machine, and it will also be coupled to the reduction unit on the steam turbine. In this way the machine can be driven by the synchronous motor electrically, or it can work in conjunction with the steam turbine carrying any load the turbine cannot handle. Because of the shortage of electric power at this mill, it is necessary to run the steam turbine utilizing the exhaust steam as a supply for the dryers.

A jumbo reel is now being engineered for No. 4 paper machine which will allow rolls up to 60 in. diameter to be wound as against the present 42 in. This necessitates a new crane to handle the heavier rolls. A winder will be installed on No. 4 paper machine capable of 6000 f.p.m. winding. New heavier reel bars 18 in. diameter are also being ordered to accommodate this speed.

When the mill was constructed, power was obtained from the Gatineau Power Company at Grand Falls on the Saint John River. To supplement this power a 6000 kw. back pressure turbine was installed. There were four main boilers rated at 85,000 lb. per hour each which generated at 450 lb. pressure. The 6000 turbine exhausted at 125 lb. pressure and this steam was used for process. A 750 kw. generator was installed for a standby. As the capacity of the mill increased, additional electric power was required. Also, due to the tremendous variations in the power delivered from Grand Falls caused by there being insufficient storage of water to take care of dry periods, a 10,000 kva. condensing steam turbine and generator was installed in 1936. Again in 1954 a 5000 kw. condensing turbine was installed along with a 200,000-lb.-per-hour steam boiler.

At the present time when producing 825 tons of news per day, N.B.I.P. requires 57,000 kw. to run the mill. The average offering from Grand Falls is 33,000 kw. and the balance is made up by mill generation. This, however, does not take care of offerings from Grand Falls below 33,000 kw. At these times it is necessary to put purchased groundwood into the system, which having already been ground requires a relatively small amount of power to process. This operation is very costly, the cost of purchased groundwood being double the cost of mill-made groundwood. This condition is now being alleviated partially by a tie-in with the New Brunswick Electric Power Commission, which is just completing a transmission line from Chatham to Dalhousie along with associate transformers and switching. The Commission's feeders will also be connected into the 5000 turbine generator which will be able to feed back to them in case of an emergency. This power will help reduce outside purchases of groundwood pulp. This in turn means more wood will be used from the area which will increase employment in the region. It will also allow speeding up of the machines to meet present objectives without increasing power or steam generating equipment.

It is noteworthy that in the very near future the original design capacity of Dalhousie mill will be almost doubled with the four paper machines originally installed.

Dalhousie is a shipping port and approximately 60 per cent of the paper produced is loaded directly on ships, the balance going by rail. Up until the winter of 1955 the port was closed for five months of the year as the Baie de Chaleur was frozen over. In the winter of 1955 and 1956 the port was kept open by paper company tugs which break the ice and allow ships to come in during the winter. This was the first time in history the port was kept open. This winter, facilities were installed to pump bunker oil into oil-burning ships.

Conclusion

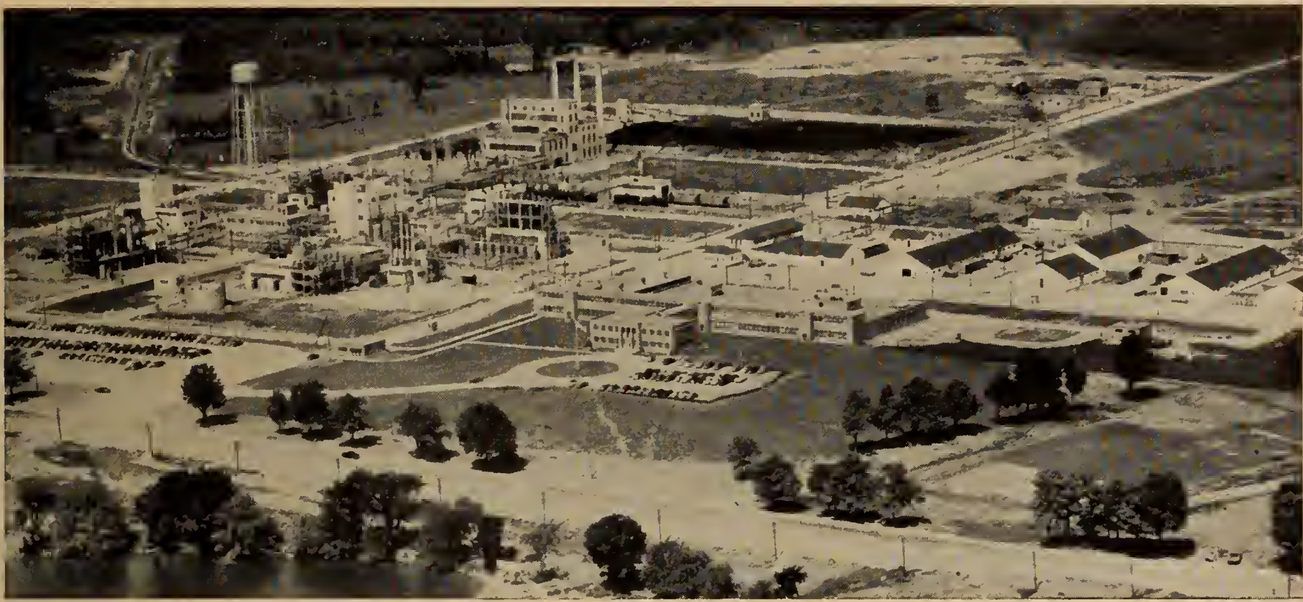
These are a few of the more important developments in Canadian International Paper Company. Together they are a part of a long-range plan to give increasing economic strength and stability to company operations, to provide more complete utilization of forest resources and greater diversification of the products made from these resources.

Seventieth

Annual General and Professional Meeting

Montreal, May 23-24-25, 1956

The advance program, published on pages 437-440, gives details of the registration requirements, the technical sessions, and associated functions and social events.



Industrial Power Distribution

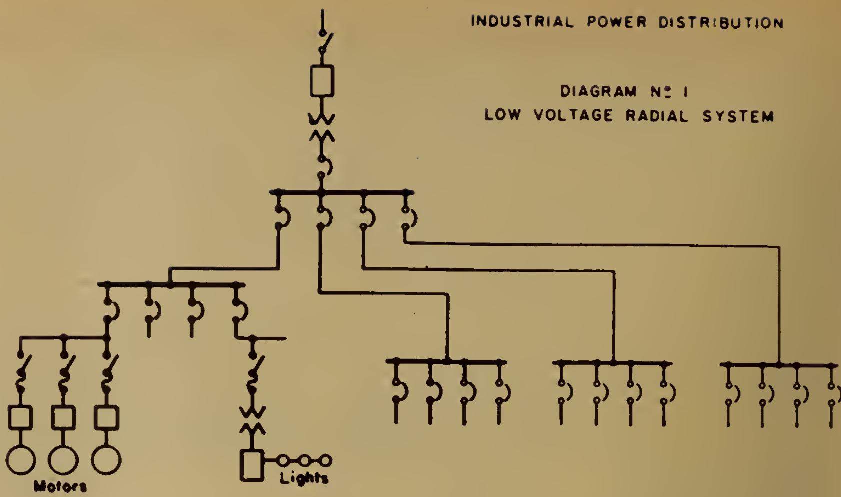
J. R. Auld, M.E.I.C.
Supervising Engineer,
Power Services,
Du Pont Company of Canada Limited

Industrial power distribution has developed only since the latter part of the nineteenth century. The author points out that engineering foresight and imagination are needed to fit a modern distribution system to the requirements of any specific job. After a general review, a particular case is discussed as an example, the installation being that made in a modern chemical plant of which a general view is seen above.

The subject of this paper is industrial power distribution, and in our modern world electricity is its secret weapon. This was not always so. Less than 150 years ago industrial power distribution did not rate even a half-hour talk. It consisted of a rough wooden shaft and wooden gears connecting a windmill to a millstone. About the middle of the 19th century the development of the steam engine brought a big change in industrial power distribution and, by the end of the century, mechanical power distribution reached its peak. Large and elaborate rope and belt drives were used to enable a large steam engine to drive a whole factory of textile machines. There are some large belt drives in use even today and I know a flour mill in Montreal that is still driven by a single motor and a continuous rope drive.

About 1875 electric lighting was first used in factories and the first industrial power distribution system of the kind we are going to consider was installed. Even in those simple days, engineers had their troubles with new designs. F. H. Ellis in a recent article[6] tells us that fires were caused by defective wiring in 21 of the first 63 factories insured by the Mill Mutual Insurance Companies. Mr. Ellis reviews the early progress of the set of rules for safe wiring now known as the National Electric Code. The first formal set of rules

A paper to be read at the 70th Annual General and Professional Meeting of The Engineering Institute of Canada, Montreal, May 1956.



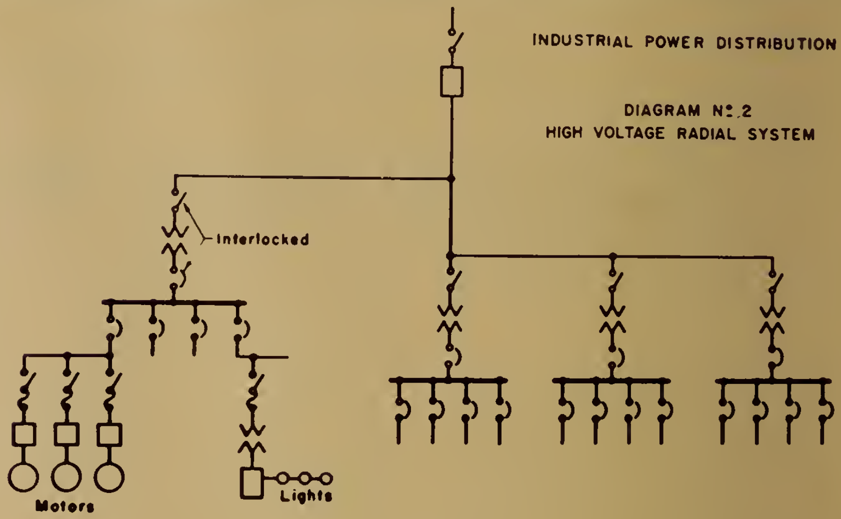


Fig. 1 (top). Low voltage radial system.
Fig. 2. High voltage radial system.

were published in 1893 and in 1896 the NEC first came into existence. Our own Canadian Electrical Code got many of its ideas from the NEC. From the article by Mr. Ellis it is easy to see why the fire insurance companies had so much to do with the first building wiring code.

FROM EARLY DAYS

It is interesting to recall that the first large scale electrical distribution system also dates back to the eighteen eighties. It was in December 1880 that the Edison Illuminating Company began installing the first 6 steam engine driven dynamos in their Pearl Street Station. At the same time they started laying 100,000 feet of cable under the New York City streets for the distribution of power.

Since 1880 tremendous changes have taken place in power generation and distribution, and electricity has been the principal means used for the purpose. This talk is about schemes for distributing electric power in industrial plants; not on wiring methods, but concentrating on systems in general and a special one in particular.

Until about the late nineteen-thirties the power distribution system in most industrial plants followed a fairly simple pattern. Power was usually distributed by radial feeders at the voltage at which it was used. In the larger plants an intermediate voltage was sometimes employed.

Just before the last war, when a great number of new industrial plants were being designed, studies were made which indicated that more economical distribution systems could be designed by using higher voltages. Since then much has been written on the subject of industrial power distribution.

About 1943 the A.I.E.E. committee on industrial power applications developed and published a very complete report[1]. Although many ideas and suggestions have been published since, the fundamentals outlined in the report are still the same. Many of the schemes suggested in the A.I.E.E. report and by other engineers have been used to a very limited extent because of their high cost, and I propose to review only six basic systems. After a general review, I will describe in more detail an actual system that only recently has been placed in service. This system has one or two special features which, I think, will be of some interest. In the single line diagrams used to illustrate the six basic schemes, all circuit breakers shown without isolating switches can be assumed to be of the draw-out type, although the draw-out symbols have been omitted for the sake of simplicity.

BASIC SYSTEMS

The first system to be considered is shown on Fig. 1. It is the familiar low voltage radial feeder system, the most economical for small plants with loads below about 1,500 kw. and which do not require twenty-four hour year-round electric service. For large plants the low voltage radial system, except in special circumstances, will cost more than some of the other types. Even in a large plant, however, it is simple to operate, and its maintenance cost is low. To make it possible to add future load the main sub-station must be designed with extra capacity, and this adds to the initial investment.

The second system, shown on Fig. 2, is also a radial system but a higher voltage is carried nearer the load and a number of unit sub-stations are used to step the voltage down to the level that is required for the plant motors. Where power can be obtained at voltages between 2,400 and 14,400 or even up to 26,000, the high voltage radial system is economical, its voltage regulation is good, and additions can be made readily as required. The high voltage radial system for large loads is considerably cheaper than the low voltage radial system, because the small size single high voltage cable costs much less than the large number of large low voltage cables required in the low voltage radial system, and also because the low voltage circuit breakers are cheaper because much lower interrupting capacity is required. The transformer cost in the low voltage radial system may be lower (if no future capacity is provided), but this is usually not enough to outweigh the other higher costs.

In the two systems already considered no provision is made for maintaining power service in the event of a failure of a main circuit breaker, transformer or cable. It is necessary to shut the power off completely to inspect or adjust the main circuit breakers or transformers. Provision for continuous electric service in a small plant operating on one or two shifts, and which is closed down on week-ends and perhaps also for a two-week vacation period is worth very little. In fact, a more complicated scheme, because it introduces more possibilities for accidents, would be less satisfactory than the radial type system in such a plant. However, in large plants and especially in plants with continuous processes in operation, it is necessary to consider the economics of providing means to service the electrical equipment and supply at all times at least some electric power.

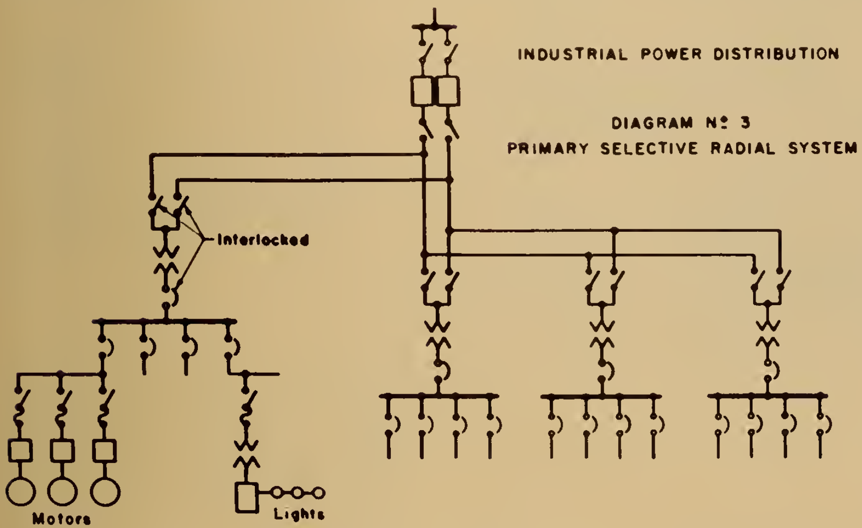
In the system shown on Fig. 3, called the primary selective radial system, additional equipment is installed in order to reduce the time that power service must be interrupted either due to faulty primary breakers or circuits or for their routine inspection and maintenance. The additional cost of this system can be checked with the possible production losses and as an insurance investment it may be worthwhile.

A variation of the primary selective radial system is shown on Fig. 4. In this scheme, secondary ties are provided to enable some load to be carried from one unit-sub-station to another in order to supply certain essential loads even if a unit-sub-station transformer has to be taken out of service. By using the tie circuits to carry some load under normal conditions, the extra cost of this scheme is often small and it can prove very useful some night at forty below zero when a ten-hour shutdown of such things as unit heaters, boiler auxiliaries, and so on would be very inconvenient.

The tie connections also overcome a feature of the system shown on Fig. 3 which is one of its weak points from a safety aspect. An objectional feature of the system on Fig. 3 is that an isolating disconnect switch may be closed in on a faulty transformer when its primary line is energized. The switch may be damaged and the operator hurt. To avoid this, both lines can of course be de-energized during the switching operation. However, if a low voltage tie connection is installed, a transformer can be checked by first energizing it from one of the other transformers through the low voltage circuit breakers. A faulty transformer will trip one of the low voltage breakers and warn the electrician not to try to re-energize the transformer by closing the isolating switch.

A more elaborate system is shown on Fig 5. This might be called the Lincoln or Cadillac system and it is designed to make it possible for the electrical maintenance engineer to go fishing, attend curling bonspiels and play golf. If any item of electrical distribution fails or needs to be inspected, a few switching operations will disconnect it from the system, and when the maintenance engineer returns he can repair it or replace it. This system also avoids those unpopular discussions that often take place between the maintenance department and the production department when a transformer or circuit breaker requires an overhaul.

The above advantages are not cheap. The initial cost may be 50 per cent more than the lowest cost radial system; the operating losses are higher; there is more equipment to maintain; and more care is



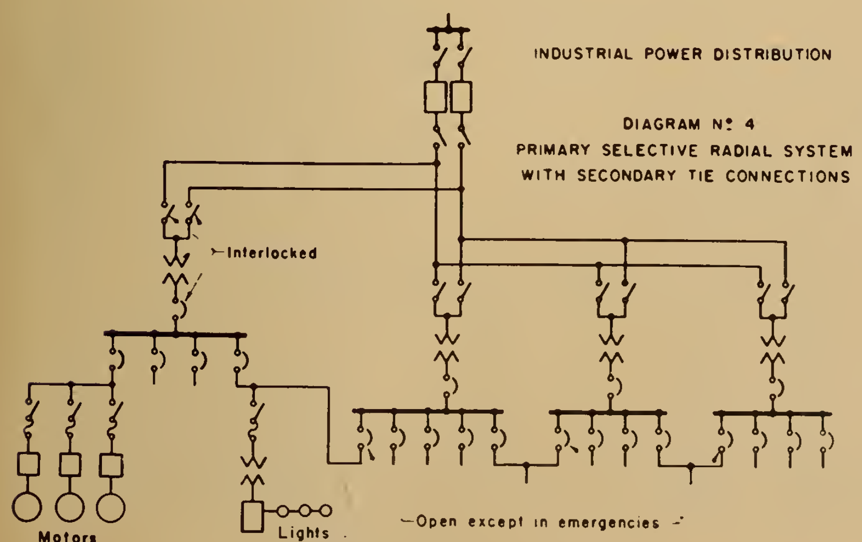


Fig. 3 (top). Primary selective radial system.

Fig. 4. Primary selective radial system with secondary tie connections.

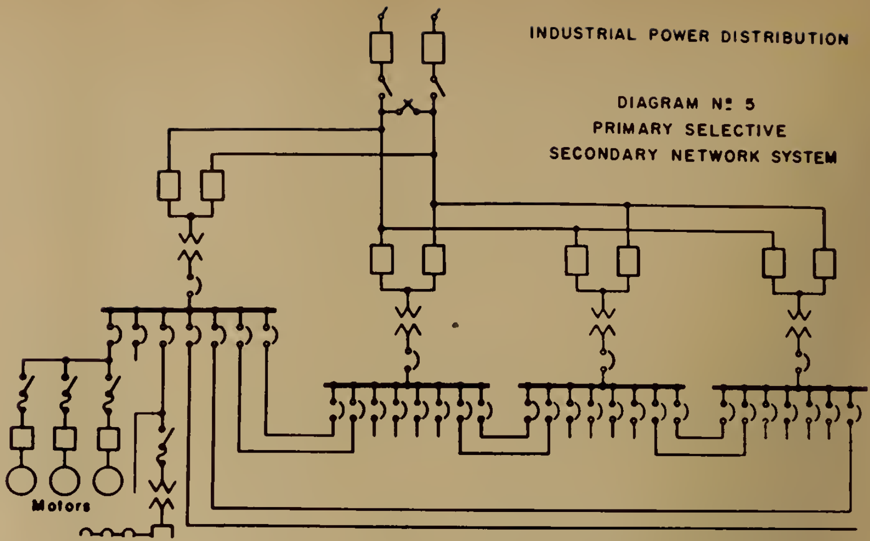
needed to avoid accidents to maintenance mechanics. In spite of this, the elaborate secondary selective system or some modification of it may be justified if power service outages are very expensive.

It is obvious to everyone that many variations of the five distribution systems are possible and many arguments have been put forward as to the merits and defects of the many alternatives. I can think of breakers *v.* fuses and disconnects; loop feeder *v.* radial feeders; double throw isolating switches *v.* two single-throw switches; overhead lines *v.* underground lines; interlocked armoured varnished cloth cable *v.* paper-insulated lead-covered cable in conduit; the frequency of 600 volt cable failures *v.* those of 4,000 v. or 15 kv. cable failures and so on.

There is one other really gold-plated distribution system, called the net-work. This system also has several variations and it is designed to give *de luxe* service. To be economically justified it should be backed up with an alternative source of power and be designed to supply a process that either is so simple that it requires practically no service or that has stand-by motors, lights and heaters, etc., and can be operated continuously.

Figure 6 shows a primary-selective spot network system designed to give uninterrupted service. Very few Canadian industrial plants require or can justify this type, which can cost from 60 to 75 per cent more than a radial system.

We will now take a brief look at an actual electrical distribution system which has been in service nearly three years. The system is



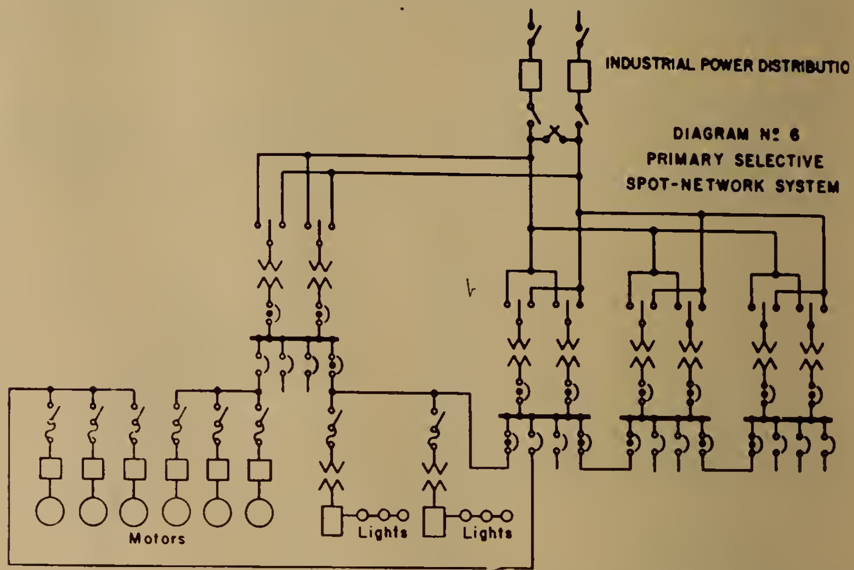


Fig. 5 (top). Primary selective secondary network system.

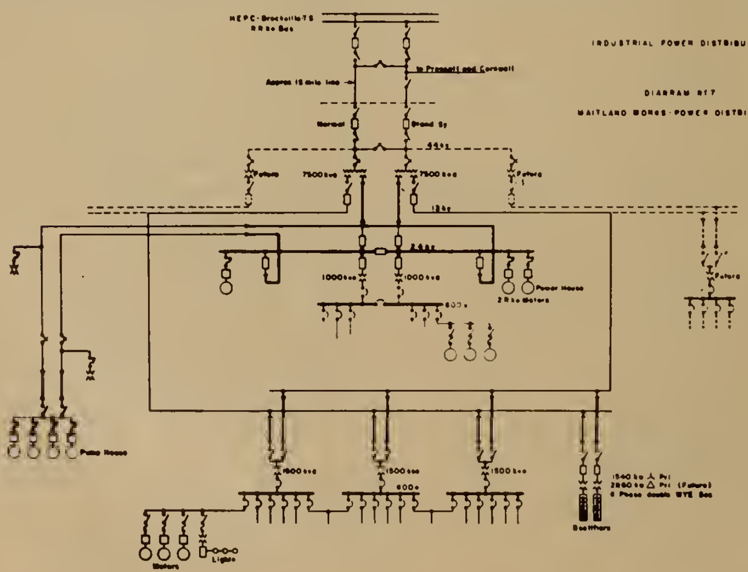
Fig. 6. Primary selective spot-network system.

Fig. 7 (below). Power distribution at the Maitland works.



operating at the Maitland nylon intermediates plant of the Du Pont Company of Canada Limited, between Brockville and Prescott along the St. Lawrence river.

The system was designed to take care of the present load of the plant and provide means for expansion so that loads up to four times the present load can be added. The plant site is a large one and the process is a continuous chemical operation with very elaborate automatic controls.

From the diagram of the Maitland works system, Fig. 7, the main features of the system are:

(1) Power is obtained from the HEPC at 44 kv.

(2) Two incoming lines have been provided; one is for emergency stand-by service.

(3) Four voltage systems are employed in the plant. Three-phase systems, using 13,000, 2,400, and 600 volts, are used for main distribu-

tion and motors. Lighting is obtained from 240/120 volt single-phase systems.

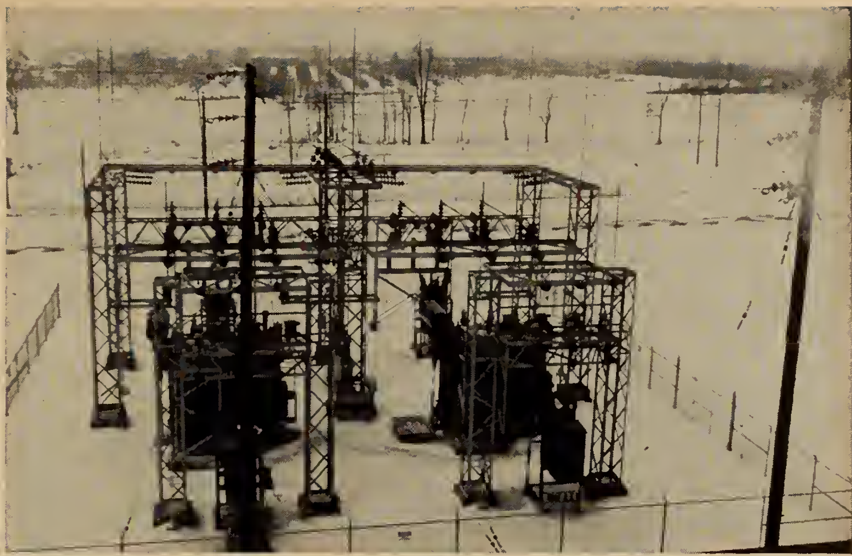
(4) The main transformers have double voltage secondaries. They are oil-immersed, self-cooled, rated 7,500 kva., and designed so that fans can be added to increase their rating to 10,000 kva. when required.

(5) The system is essentially a primary selective radial one, with some emergency cross connections at the 2,400 volt and 600 volt levels.

A cost comparison was made before any detail design was started between systems using different distribution voltages. It was found that a 13 kv. system would cost no more initially than any other lower voltage system, and that it would be much more economical when additional load was added. This choice proved a sound one because before the actual design was completed it was found necessary to take care of about 3,000 kw. more load than the early plans anticipated, and we are now planning on still other additions.

In the preliminary planning stage the system was laid out as a 13 kv. primary selective system, and unit sub-stations were to be used to supply 2,400 volt and 600 volt power where needed. When the actual loads and the building locations were known it was found possible to locate the main sub-station close to the power house. Several large 2,400 volt motors were to be located there. The pump house, where three large motors were to be installed, was close enough to the power house to make it feasible to supply 2,400 volt service directly from the power house. A comparison indicated that a considerable sum would be saved by eliminating 13/2.4 kv. unit substations at the pumphouse and power house and using, instead, double voltage secondaries in the main transformers. The 2,400 volt switchgear was somewhat more expensive due to the higher interrupting rating required but the elimination of transformers more than made up for this added cost. Double voltage secondaries in the main transformers in the ratings used, cost about 5 per cent more than standard units would cost.

A disadvantage of double voltage secondaries in the main transformers is that a future increase in plant load may have a ratio of 13 kv. to 2,400 volt load which is not the same as the capacity provided in the transformers. In other words, the 2,400 volt load



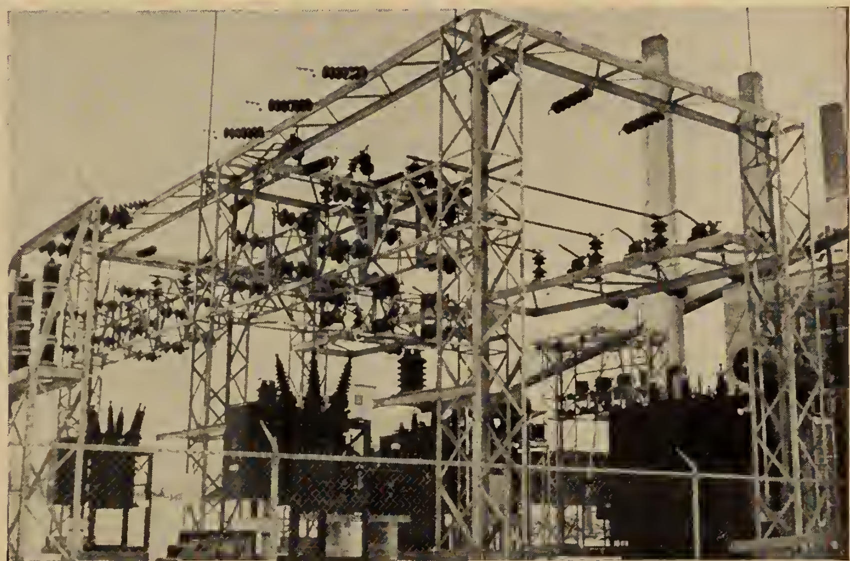


Fig. 8 (top). The main sub-station seen from the power house roof.

Fig. 9. Main sub-station from incoming line side.

Fig. 10 (below). Main control switchboard.

Fig. 11. Double ended 2400/600 volt unit sub-station in the power house.

at the powerhouse might grow so large that the 2,400 volt windings of the main transformers would be overloaded while considerable capacity existed in the 13 kv. windings. If this situation develops, it is planned to install a 13/2.4 kv. unit sub-station at the pumphouse, change the existing 2,400 volt lines that feed the pumphouse to operate at 13 kv., and thus transfer load from the main transformers 2,400 volt windings to the 13,000 volt windings. This same change may be required if a large increase in pumphouse load has to be made.

Due to the large area of the plant site, additional load may be added from time to time. To take care of this, three provisions were made. Main transformers somewhat larger than the estimated load were obtained; provision was made for adding fans to the main transformers to increase their rating to 10,000 kva.; large enough primary switching equipment was installed, and sufficient space was left, so that 2 additional 10,000 kva. main transformers can be added. These provisions increased the cost above the bare minimum required by about 8 per cent.

Fig. 12. 13-kv. poles and circuit.

Because of the importance of uninterrupted water, steam, and compressed air service, dual electric supply is provided for the pump house and power house.

To improve reliability, simplify maintenance, and make line work safer, the two 13 kv. circuits are on separate poles throughout the plant. The 2,400 volt circuits have also been kept separate as much as possible.

The two main 44 kv. circuits are also on separate poles for most of their length. The 44 kv. circuit now used for emergency service was installed before the plant was built to supply power for construction, and it has been retained.

I think it is clear from this brief review of an actual distribution system that the old adage "circumstances alter cases" is very true. Engineering foresight and imagination are needed to fit a distribution system to the requirements of any specific job. It is also evident that the six fundamental systems serve as a very good base on which to start the job and much time can be saved in using them for this purpose.

Figures 7 to 16 illustrate the actual installation at Maitland.

Fig. 13. Out-door unit sub-station, 13 kv./600 volt, 1500 kva.

COSTS

Since money is very important in all engineering work a paper of this sort would not be complete without some reference to costs. I will now give you some approximate unit cost figures for the system we have just been considering.

The approximately unit costs include equipment, foundations, ducts, cables, fences, etc., labour, construction overhead costs, and the cost of engineering.

(1) Main out-door sub-station 15,000 kva.: $ 14/kva. When required, fans can be added to the transformers; the sub-station rating will

be increased from 15,000 kva. to 20,000 kva. and the cost reduced to $11.50/kva.

(2) 2,400 volt switchgear including control relays for out-door circuit breakers: $ 12/kva.

(3) 2,000 kva. double ended 2,400/600 volt indoor substation: $ 25/kva.

(4) 1,500 kva. single ended 13 kv./600 volt outdoor substation: $ 23/kva.

(5) 13 kv. single circuit overhead lines: $ 5/ft. 13 kv. single circuit underground lines: $ 20/ft.

(6) Cost of complete distribution system not including wiring in the buildings: $ 50/kva.

(7) Cost of wiring in the buildings: $ 30/kva.

SELECTING A SYSTEM

I will conclude with a recipe for selecting an industrial power distribution system.

First. Obtain a list of the motors, heaters, and areas to be lighted, as early as possible. Even if the list is not exact or complete, estimated sizes can be used at first to fill in the unknowns.

Second. Estimate the expected kva. and kw. maximum demand load that will be required during the first, fifth, and tenth year.

Third. Make a plan of the plant showing the approximate location of the larger motors, the motor control centres or power distribution panels.

Fourth. Find out from the power company what voltage they will use to supply your load.

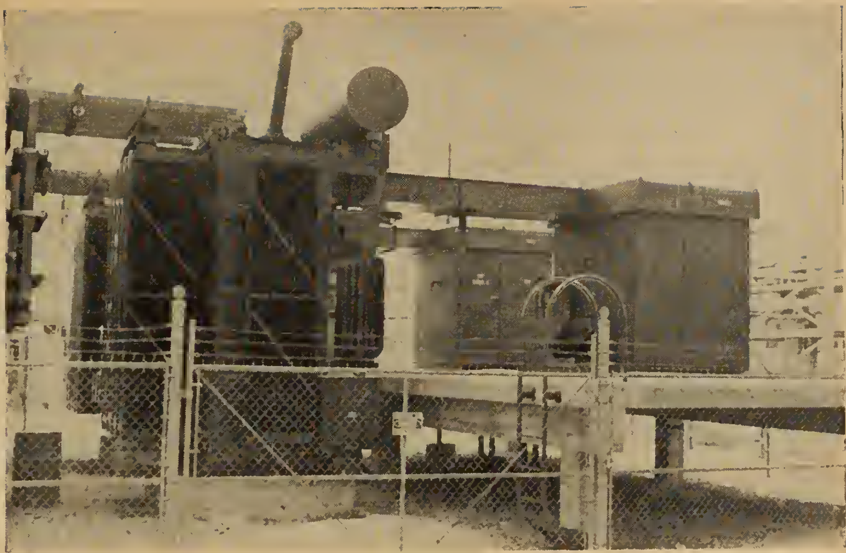

Fig. 14. Rectifier sub-station.

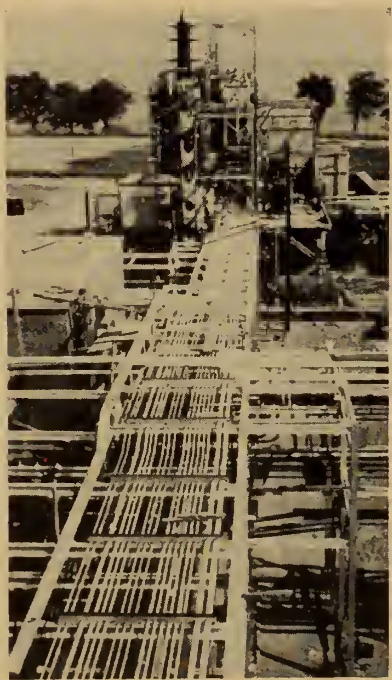

Fig. 15. Conduit on the pipe bridge.

Fig. 16. Motor control unit in one of the process buildings.

Fifth. Decide whether continuous power supply service is economically desirable. (You may have trouble with this one.)

Sixth. Draw two or three single line diagrams similar to Figures 1 to 6. One may be a low voltage radial feeder type, the second a high voltage radial feeder, the third one of the more elaborate types. The equipment ratings, the line sizes and lengths, and the future additions can be added to each diagram. With this information an approximate estimate of the present and future cost of each system can be made.

The estimates, together with a tabulation of the merits and disadvantages of each system, should make it possible to select an economical and satisfactory industrial power distribution system.

Construction of a

New Cement Plant at Edmonton

W. Rutherford, M.E.I.C.

The great construction programs that have developed in recent years in Canada have placed heavy demands on the cement industry, which has had to expand to meet the situation. This paper deals with the construction of the new cement plant of the Inland Cement Company Limited, at Edmonton, Alberta.

CEMENT IS produced by thoroughly mixing calcareous and argillaceous materials and burning the mixture to form a clinker of silicates and aluminates of lime. This clinker, when ground with no additions except gypsum, is known as Portland cement.

Calcareous materials usually occur as marble, limestone and chalk, whereas argillaceous materials occur as clay and shale, these forming the main sources of cement making materials.

This definition varies in detail for different countries, but in general principle remains as above. The use of the term "Portland" is not patented and refers only to the original description of the properties of concrete made from this cement, which was said to be equivalent to English Portland stone.

The first successful work on this subject was done by Vicat, in 1813, who made cement clinkers by burning mixtures of lime and clay. Subsequent researches have only confirmed his experiments with alterations in detail.

Apart from the general raw materials mentioned above there are a number of additives which are used. Iron oxide is added to the raw materials to act as a flux in theburning zone of the kiln and thus allow the combination of lime with silica and alumina at a lower temperature than it would without the addition of this material. Sand is also added to raw materials when they are deficient in silica.

Gypsum is added to the clinker when grinding it to cement as it has the property of fixing the setting time of the final cement to comply with standard specifications. Though there are other additives, the above are the most usual in cement manufacture.

Not all lime, silica and alumina bearing materials are suitable for cement manufacture because they contain impurities such as magnesia, phosphates etc. which would cause the cement to have unsound properties. The former impurity can be present in cement in quantities of about 3 per cent without harmful effect and, in the factory which is the subject of this paper, adequate controls are imposed to maintain the percentage below this value. Excessive sulphate in the raw materials or fuel must be avoided, because when burning takes place in the kiln the sulphate is broken down into sulphur dioxide and sulphur trioxide which form, on combination with water, hydrosulphurous and sulphuric acids respectively. These acids have a highly corrosive effect on the metal parts of the kiln back end equipment.

MANUFACTURING PROCESS

The limestone for the cement factory comes from a deposit outcropping in the Rocky Mountains near Cadomin, Alberta, adjacent to an existing railroad track. The quarry has been opened by extend-

Fig. 1. Site of the primary crusher at Cadomin (left) with formwork for loading bay. Right, secondary crusher under construction.

ing a bench from the crusher building, running north on the limestone deposit to form a face. This stone is blasted to bring down a large quantity of limestone at one time.

A bulldozer is used to push the broken rock down the bench into a gyratory crusher, which has a maximum capacity of 1400 tons per hour when crushing stone to 7½ inches and down, and a minimum capacity of 270 tons per hour when crushing to 4 inches and down. Fitted to this crusher is a hydraulic system known as a "hydroset" which functions in two ways, firstly to act as a cushion against the effects of any uncrushable material passing through the machine and, secondly, to raise or lower the crushing head when adjusting the size of the crushed stone to be delivered from the machine.

The hydroset system is built around a hydraulic accumulator which is provided with a neoprene membrane filled up on one side with nitrogen at 700 pounds per square inch and on the other side with oil. When a piece of tramp iron enters the crusher, the movement of the crushing head will cause the oil pressure to increase above the nitrogen pressure, so that oil will flow into the accumulator, compressing the nitrogen and give a cushioning effect to the shock on the crusher. After the tramp iron has passed through, the crushing head will return to its original position.

To vary the size of the crushed stone a separate oil pump has been provided, which either pumps oil into or from a hydraulic cylinder at the base of the crusher shaft, thus raising or lowering the shaft of the crushing head relative to the skirt of the crusher.

This crushed stone is dumped from the stone box of the crusher to an inclined troughed belt conveyor, which transports it to a loading bay alongside the railroad track where it is discharged into railcars.

No outside power supply is available at Cadomin and, therefore, a small power station has been installed in the basement of the crusher building. The equipment consists of a 350 kva. diesel generator set to carry the main electrical load when the crusher and inclined belt conveyor are in operation, and a 20 kva. diesel generator set to carry the electrical requirements of the auxiliary loads, such as heating, lighting and water supply.

An electrically driven overhead crane traverses the full length of the crusher building and is primarily installed to deal with the lifting of heavy crusher parts for maintenance. It is possible to lift any one of these crusher sections out and deposit it on the ground floor of the crusher building, as removable wooden panels have been provided over the crusher and sections of the upper concrete floors have also been provided with similar panels. This is done to avoid the over-stressing of suspended concrete floors by heavy loads.

All the equipment using fuel in this crushing plant has been designed for diesel oil, for which storage is provided in two above ground tanks on the south side of the crusher building. The oil fuel piping is arranged so that a rail tank car can be offloaded through two pumps on the lower floor of the loading bay. The pumps can deliver to the main storage tanks or, alternatively, to a high level service tank under the roof of the crusher building. Oil is distributed from this tank by gravity to all the equipment.

Sufficient water for cooling and domestic use is taken from a 40 feet deep water well, about 150 feet to the west of the railroad track, which on test delivered 75 gallons per minute. The McLeod River, which runs from south to north on the west side of the crushing plant, can supply additional water if required in the summer, but its utility in the winter is doubtful because of icing.

The cement plant requires about 500 tons of crushed limestone per day to maintain its normal output of cement and the crushing plant is capable of producing this amount of stone in a very short period of each day.

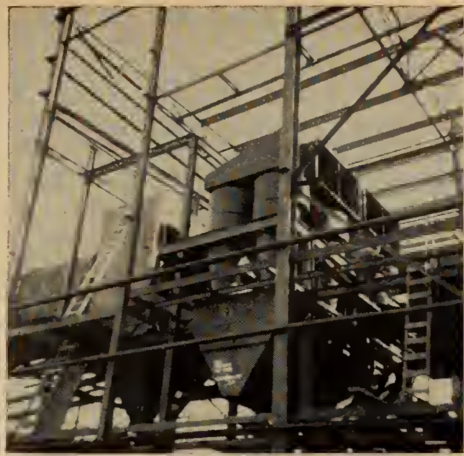

Fig. 2. Kiln dust cyclone collector (left); kiln chimney and slurry storage basin (right).

The reason for installing such a large capacity machine is to insure the cement plant against interruption of limestone supplies by inclement weather, or stoppage of rail transport. During the fall the crushed limestone storage bin will be filled completely to provide three months' reserve of stone and, if deliveries from Cadomin are stopped due to heavy falls of snow, the manufacture of cement may still proceed until communications are restored. When conditions return to normal the crusher will be worked to its full capacity for as many hours per day as are necessary, not only to supply 500 tons per day of crushed stone to keep the plant in operation, but also to fill up the depleted crushed limestone storage bin as soon as possible as an insurance against any other interruptions.

The railcars transporting the crushed limestone from Cadomin to the cement plant site are of the standard ore carrying type, with hopper bottom openings. These cars arrive at the cement plant sidings in Edmonton and are hauled to the feed track hopper of the secondary crusher at the south western part of the site.

This crushing section of the plant is built round a hammermill of the central feed reversible type, which is rotated clockwise or anti-clockwise usually for periods of 16 hours in each direction, to obtain the most satisfactory service from the machine.

The limestone cars discharge into the track hopper below rail level, which is provided with a chain curtain, vibrating feeder and stone box delivering to an inclined belt conveyor, which in turn feeds the hammermill. A d.c. magnet is installed at this conveyor head to remove tramp iron before the stone goes through the hammermill; incidentally, this machine has a conventional type tramp iron pocket provided to take care of any iron escaping the magnet.

This crusher is installed in a reinforced concrete pit covered in by a building. At ground level there is a bag filter type dust collector and induced draught fan, exhausting and cleaning the air discharged from the hammermill. On the first basement level the hammermill and electrical equipment are installed and, at the lower basement level, the crushed stone is discharged through a hopper to a belt conveyor system, which delivers to a crushed limestone bin in the storage hall, or direct to crushed limestone feed bins in the grinding area, using a standard belt tripper.

This crushing plant is also used for crushing rock gypsum and the only difference in operation is that the material passes straight through the tripper and along to the east end of the last conveyor, where it falls into the gypsum storage bin.

Clay, the other major raw material, is dug from the company's property at the cement plant site in Edmonton, and is trucked to a grabbing pit in the western gable end of the storage hall. A 10-ton travelling crane grabs this clay from the grabbing pit and deposits it in a storage bin. Other raw materials received at this grabbing pit are sand, ferrous compound, and additives for special cements, all of which are dealt with in the same way as for the clay.

The storage hall when full of material provides a reserve against breakdown, maintenance and other unforeseen events and allows the cement plant to operate continuously, providing these interruptions are not of too long a duration. The storage hall is 105 feet wide, 570 feet long and 68 feet high, and is divided into storage bins by reinforced concrete retaining walls averaging 25 feet in height, though in places these walls are increased to 42 feet in height. The travelling crane covers the whole length of this storage hall, moving raw materials and clinker from their storage bins to the feed hoppers over the grinding mills at a sufficient speed to keep these units in full operation. This crane is also used for trimming the raw materials within the storage bins when not feeding the hoppers, or in use at the grabbing pit on the western end of the storage hall.

The preparation of clay slurry is the next stage in the process and this is done in a clay washing section at the south western end of the storage hall. Clay is fed into a clay hopper by the storage hall crane, from whence it is dumped into a washmill.

The washmill consists of a rotating steel framework from which are hanging chains and heavy cast iron harrows, which thoroughly mix clay and water together until all the clay is broken down and finally suspended to form a slurry containing 50 per cent water. The washmill tank, constructed in reinforced concrete, is lined with granite blocks to protect the concrete from abrasion. Insoluble material, gravel and stones left at the bottom of the washmill tank after the suspension of the clay in water is raked out into a gravel pocket at the side of the washmill for disposal. Alongside this pocket a washwater pump is set up for cleaning out the tank.

The finished clay slurry is discharged from the washmill into a sump from whence it goes by pipeline to a suction header of the pumps under the slurry tanks. These pumps deliver this clay slurry to any one of the clay slurry tanks.

Fig. 3. Construction of the cement silos: left, excavating piles; right, sliding forms in position.

Fig. 4. During construction of the cement silos a mass pour of 650 cu. yd. was carried out.

Eight slurry tanks have been built in one block, all 69 feet in height, four being 17 feet diameter and the other four 24 feet diameter. The method of operating this storage is to reserve six of the tanks for slurries of different chemical compositions, one for use as a blending tank for finished slurry and one as a spare tank for cleaning and maintenance. This gives great flexibility in preparation of finished slurries of different chemical compositions required for burning various types of cement in the rotary kiln.

The slurries in these storage tanks must be agitated in order to maintain the finely divided raw material in suspension, and this agitation is effected by vertical compressed air lines in each of the tanks. Two rotary air compressors, each with a capacity of 336 cubic feet per minute, at 100 to 60 pounds per square inch, have been installed adjacent to the tanks delivering compressed air through air storage tanks to a distribution header under the slurry tanks. The individual air lines to the storage tanks and slurry blending basin are valved at this place which is convenient for operating the blowing of these tanks.

There is a piping reticulation arranged so that clay slurry made in the washmill can be pumped to the slurry tanks, or direct to the wet mills; the slurry can be transferred from one tank to another, or pumped to the two wet mills from any two slurry tanks; the slurry can be pumped from the wet mills to any of the slurry tanks, and cross-connections make it possible to pump these slurries from one tank to another or from any tank to the slurry storage basin or even to the kiln feed tank direct.

This complex piping system involves the use of nine slurry pumps and 100 rubber diaphragm slurry valves. The valves are specially designed for viscous fluids such as slurries and consist essentially of a rubber diaphragm which is pressed against a machined face on the bottom of the valve body when shut; when open the slurry passes between the flexible diaphragm and the valve body. This type of valve is eminently suitable for handling viscous fluids of this nature.

The pumps are specially designed to handle slurry and have a water connection for cleaning out the pumps after use. There is an easy adjustment on each pump for placing the impeller casing in the correct position to achieve the right clearance after wear takes place by passage of the slurry through the pumps. As an experiment three of the pumps have been rubber lined to ascertain whether the abrasive effect can be overcome or lessened.

As there are two slurry lines to and from the slurry mills it is possible to deliver and discharge slurries of different chemical composition before and after grinding.

Fig. 5. Lifting a section of the kiln, at the east end.

Crushed limestone, sand or ferrous oxide is placed in feed hoppers in the storage hall by the travelling crane. These materials are proportioned by automatic belt feeders which discharge to inclined belt conveyors feeding into the mills. Slurry or water is introduced at this place to the two mills.

The two slurry mills are identical two compartment attrition mills fitted with cast iron liners and carrying a heavy ball charge. Each mill is driven by a 900 h.p. 180 r.p.m. synchronous motor through a magnetic clutch and countershaft to a pinion which engages a spur wheel fixed to the mill shell which rotates at a speed of 18 r.p.m. The two mill motors and switchgear are completely shut off from the rest of the equipment in the millhouse, and a ventilating fan is installed to induce a positive air pressure in the motor room which prevents dust from entering and causing damage to the motor bearings and switchgear.

The slurry is discharged from the mills into concrete sumps and is pumped back to the storage tanks.

The next stage in the process consists of drawing off finished slurry and discharging it by gravity or pumping into the slurry storage basin on the north-western area of the cement plant. This basin is a cylindrical concrete tank with clay bottom, constructed below ground level, 70 feet in diameter and 18 feet deep. In this storage tank three to four days' kiln capacity of slurry is held and mixed to make it thoroughly homogeneous before feeding it to the kiln. An agitator is installed in this tank which uses a combination of air and mechanical agitation to mix thoroughly the finely divided raw materials suspended in water. A steel structure bridges the tank and carries a geared drive to which is fixed a hollow central vertical drive tube, guided at its lower end on an adjustable step bearing. Attached to the tube are blades raking the bottom of the tank which agitate settled raw material. At one position about halfway along each of the blade arms, air lift tubes are fixed vertically to scoop the solids off the tank bottom and raise them to the top surface of the tank, thus setting up a circulatory motion and agitating the slurry. Auxiliary air nozzles are spaced along the blade arms providing vertical air agitation over the complete tank bottom with each revolution of the agitator. The combination of mechanical and air agitation ensures that the contents of the tank are circulated continuously with no dead spaces. It is interesting to note that the nozzles on the blade arms contain circular discs of porous tile, which diffuse the air as it passes into the slurry, and also prevent the slurry flowing back into the air pipes when the air pressure is off.

Slurry, completely homogenized, is drawn off through a pumping pit alongside the storage basin and discharged to a ferris wheel slurry feeder above the feed end of the kiln.

The rotary kiln is one of the most important sections of the cement plant because it is in this furnace where the chemical change takes place, converting slurry to cement clinker. The kiln is a steel tubular shell 340 feet long and 11 feet diameter made from steel plate about 1 inch thick. This shell is supported on five water-cooled kiln bearings and has a slope of 1 in 32 from the feed end to the discharge end. The piers supporting this kiln are constructed in concrete, four of them being solid whilst the central drive pier is hollow to house the motor control centre for the electrical equipment of this section of the plant. This same pier carries the kiln drive mechanism and thrust bearing for the kiln. It is interesting to note that a stand-by gasoline motor normally disengaged from the kiln drive by a claw clutch is installed here in order to drive the kiln when a breakdown in power occurs. This emergency drive is necessary because the kiln would be seriously damaged by unequal temperature strains if allowed to remain stationary.

At the feed end of the kiln for a length of 56 feet a chain curtain is installed to lift the slurry where its moisture is removed by the exhaust gases.

The kiln is lined completely with material, which in the burning zone is a 70 per cent alumina firebrick, followed in turn by 40 per cent alumina firebrick, castable refractory and common red brick at the feed end. The care and maintenance of the firebrick lining of the kiln is of great importance in the efficient operation of the cement plant, because the high temperatures generated in the burning zone can cause fluxing of the firebrick, and it is usual practice to develop a protective coating of clinker. The kiln can then be run for a considerable period without renewal of the lining. As there is a minimum loss of production of two days for even partly relining the kiln, it can mean a loss of production of about 1,000 tons of cement and, therefore, the importance of protecting this lining cannot be too greatly stressed.

Natural gas with a low sulphur content and a calorific value of 980 B.t.u. per cubic foot is used for firing the kiln. A 15 p.s.i. gas supply to the kiln is provided with a control valve which shuts off the gas if the pressure in the line builds up above 17 p.s.i., thus providing a safety measure against overheating the kiln. The primary air for combustion is supplied in the normal manner by means of a blower and the secondary air comes from the cooler where it has already been preheated in cooling the clinker.

The clinker falls from the kiln into the throat of an air quenching cooler installed in a concrete pit below ground level. This cooler consists of an inclined grate with alternate rows of fixed and moving grate castings, which cause the clinker to move downwards to the end of the cooler in a bed of even thickness. The cooling is accomplished by passing air through the clinker bed on the grates and the principal condition to be observed is that the depth of the clinker bed on the grate and the fan pressure should be such as to cause the fan to operate at its correct static pressure. The use of a bed of insufficient thickness results in a small resistance to air flow, thus delivering a quantity of air in excess of the designed value which could overload the cooler vent stack. Because the clinker may vary in size, the temperature of the clinker may change, and the rate of delivery may vary, it is necessary to have bed speed control of the cooler. This is done by hooking up a thermal couple above the clinker bed with the variable speed drive on the cooler grates. Dampers are also installed on the cooler fan ducts to control the supply of air to the underside of the inclined grate.

Part of this preheated air passes upwards and into the kiln as secondary air, thus reducing the fuel consumption. Air which is in excess of kiln requirements is extracted through a dust collector by an induced draught fan and discharged through the cooler vent stack.

Exhaust gases from the kiln pass through a highly efficient dust collection plant, consisting successively of mechanical cyclones and electrostatic precipitators to an induced draught fan and kiln chimney. This is an elaborate and costly dust collection system which the company considered advisable to install in view of the proximity of the plant to the City of Edmonton. This equipment is arranged so that half the mechanical cyclones and half the electrostatic precipitators can be shut off for maintenance, whilst the exhaust gases pass through the other half of the dust collection plant. The dust is removed from the collecting electrodes by a mechanical rapping system and discharged into hoppers and carried to the south side of the kiln building by screw conveyors, where it is discharged into trucks for disposal.

A control panel for the kiln and cooler is located near the discharge end of the kiln on the firing platform in a convenient position for inspection by the kiln burner. The panel has ammeters indicating the operation of motor drives, temperature and gas analyses recorders for various points on the kiln, bed speed control of the cooler, and remote controls to operate dampers, fuel consumption, quantity of combustion air, slurry feed, and kiln speed. This control panel

Fig. 6. Construction of the slurry silos with sliding forms.

is set up to make immediate corrections to any one of these variables for correct operation of the kiln.

Clinker is normally discharged from the cooler at a temperature of 140° F. to an inclined grizzly where the smaller pieces pass through to two drag chain conveyors. Any oversize clinker on the grizzly is pushed into a clinker breaker of the hammermill type which breaks up these pieces and throws them back to the inclined grate for further cooling.

The clinker is then conveyed by the two drag chain conveyors and bucket elevators to the clinker bin in the storage hall.

One of these drag chain conveyors is reversible and can discharge to another bucket elevator and thence to a swivel conveyor on the northern exterior wall of the kiln building, in order to dump clinker outside if the clinker bin in the storage hall is completely filled. This outside store of clinker can be returned to the storage hall when space is again available by feeding it into a hopper at ground level to the other drag chain conveyor which feeds only toward the clinker bin. This system is now being moved to build the plant extension.

The next stage in the process is to abstract gypsum and clinker from the storage hall and place them in feed hoppers discharging into automatic belt feeders which proportion the materials being fed into the two cement mills. These cement mills are similar to the slurry mills, except that in this case the grinding is dry. The cement passes out of the south end of the mills and is discharged into screw conveyors, which in turn convey the ground cement through bucket elevators to air separators which apart from their primary function of grading the cement particles have an important function in cooling of the cement through continuous injection of cold air during grinding, thus lessening the possibility of dehydration of the gypsum which is the main cause of flash setting.

These separators receive the cement by gravity into a cone and rotating distributing plate hub, which gives the cement particles a centrifugal force outward through the hub ports to the lower distributing plate. The centrifugal force on these particles increases as they move farther from the centre of rotation until the edge of the plate is reached, at which point there is a separating zone. The larger particles are thrown further out, but as their centrifugal force decreases they begin to fall by gravity into a tailings cone, and are returned to the feed end of the mills for further grinding. The finer particles are retarded in their outward path due to their lower centrifugal force and are lifted by an ascending air current, induced by the main circulating fan, to the selective zone where the lighter particles are easily lifted by the ascending air, whereas the heavier particles have passed beyond the path of this air and settle out to join the other oversize material for regrinding in the mills.

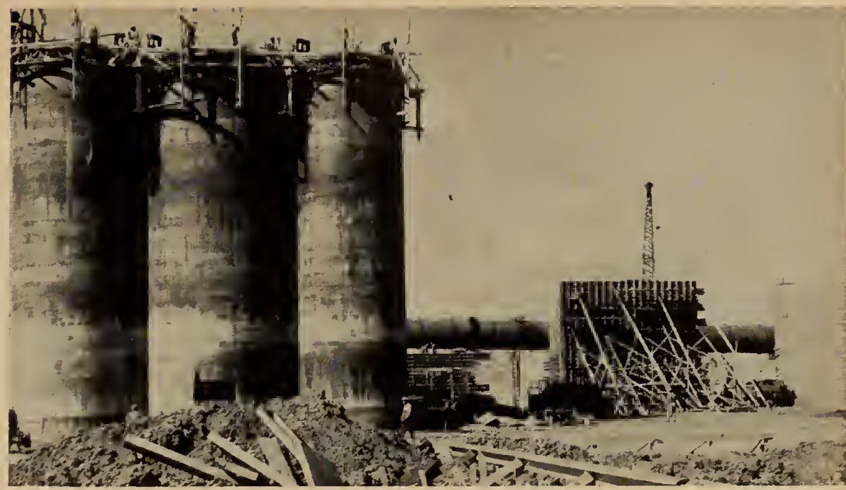

Fig. 7. Slurry silos and kiln looking north from the secondary crusher.

The dust generated in grinding is taken from the discharge end of the mills to two dust collectors and the cleansed air discharged to atmosphere, whilst collected cement dust is delivered by pipeline to the feed hoppers of the transport pumps. Each mill is completely separate with its own dust collector, air separator, pump and compressor, so that two types of cement can be ground at one time. The transport pumps are made from a short length of cast-steel screw conveyor rotating at high speed in a totally enclosed casing. The cement is fed into the casing at the inlet of the spiral and discharged into a pipeline at the remote end; when discharging it is thoroughly mixed with compressed air through a perforated ring and the aerated cement flows at 45 feet per second along a pipeline. A great advantage of this type of conveying is that there is no difficulty in transporting through a vertical line. The pipelines in this case are above ground from the millhouse until they come to the main road, where they cross in a covered concrete trench to the cement silos.

The cement silos are part of the storage and shipment section of the plant which is located in the south-east corner of the site. This section is adjacent to the railroad track to facilitate the loading of railcars, either in bulk or with bagged cement, and on the north side a large paved area in the shape of a circle is being provided for road transport either to load cement in bulk from under the silos or to receive bagged cement from the bagging plant. In this way the plant is completely flexible for delivery of cement to customers.

The two cement transport lines from the mills carry the cement to the roof in a space between the silos. At roof level the cement is piped to any one of the six silos. A dust collector with interconnecting piping to each silo is installed to remove the cement dust in the compressed air which is discharged to atmosphere from the cement silos.

There are six silos, each 113 feet high by 24 feet diameter so that a number of kinds of cement can be stored at one time.

Each of the six silos has three nozzles at the hopper bottom, one of which delivers to a telescopic chute beneath the silos for bulk loading of cement to road transport, the second delivers to air slide conveyors for bulk loading of railroad trucks and the third to air slide conveyors for delivering the cement to the bagging plant.

The air slide conveyor consists of a lower channel forming an air chamber and an upper channel for cement; the upper surface of the air channel is made from porous fabric and the air passing through the fabric fluidizes the cement above sufficiently to allow it to flow by gravity. As the fall required is about 8°, the loss in head required to install these conveyors is not excessive and, because an ordinary blower of low horsepower is required, the unit is economical in operation.

The bagging of cement takes place in a six storey building at the north side of the silos. The system adopted is to carry the cement in a bucket elevator to the top floor, where it passes through a screening screw conveyor to remove oversize particles from the cement. The cement is then discharged into a cement surge bin over a bagging machine where the paper bags are filled. The filled bags are then distributed to road or rail by bag slides, belt conveyors and chutes as necessary. In the top storey of this building a dust collector removes dust from the air before discharging it to the atmosphere. This latter section completes the description of the cement making machinery.

AUXILIARY SERVICES

A block of offices has been built, together with a separate modern laboratory complete with all necessary equipment to carry out tests on raw materials, cement clinker, etc., to standard specification.

A workshop and stores building with overhead cranes in each of the two bays has been built adjacent to the railroad sidings to accept mechanical and electrical stores, and at the same time provide working area for mechanical and electrical maintenance, with an oil store and carpenters shop.

A scale-house has been constructed adjacent to the main entrance of the plant with a track large enough to accommodate the largest prime-mover and trailer at present in use. This will be used for check weighing of trucks at entry and exit from the plant.

A standard water supply from the City of Edmonton has been installed, but because the water has a minimum pressure of 30 p.s.i., two centrifugal pumps have been installed on the supply line to boost the water pressure if required to the elevated storage tank at the top of the slurry silos. This storage tank has a capacity of 104,000 imperial gallons and forms a reserve of 75,000 gallons for fire protection, the remainder being made available for process water. These water pumps have a capacity of 800 gallons per minute against a head of 100 feet and can be used if required for boosting the fire line through a by-pass.

A natural gas supply to the cement plant is delivered at a pressure of approximately 200 pounds per square inch to a gas preparation room located near the east end of the kiln house. The gas is reduced in pressure, first to 75 p.s.i. where it is measured and, secondly, to 15 p.s.i. at which pressure it is delivered to the rotary kiln for burning clinker. A further reduction to 7 inches of water gauge is made for heating the factory buildings.

The electric supply to the cement factory is taken from the Calgary Power Company at 22,000 volts, which is transformed down

Fig. 8. The slurry mills after installation.

Fig. 9. Some of the foundation work: mill house (top) and wash-mill.

in their 6,000 kva. transformer and delivered to the cement company's main switchboard at 4160 volts.

Main transmission cables carry this 4160 volt power to four sub-stations, each of which has a 1,000 kva. transformer stepping down the power from 4160 volts to 550 volts. The grinding mill motors, two air compressor motors and a hammermill motor consume a large amount of power and they have been made for a 4160 volt 3-phase 60-cycle supply.

The general supply characteristics for other motors are 550 volt 3-phase 60-cycles, with the exception of a number of fractional horsepower motors for dampers, etc., which are on the 120/230 volt single-phase lighting circuits. A diesel generator set has been installed in the sub-station to provide emergency lighting in the event of breakdown of the normal power supply.

SPECIAL NOTES

In this cement factory clinker is manufactured by the wet process, but this is not the only method by which cement clinker can be made. Generally there are two main methods of manufacture, known respectively as the wet process and dry process. In the wet process the raw materials are broken down or crushed and mixed together with the addition of water and fired in the cement kiln as a slurry, whereas in the dry process the raw materials are crushed, dried if necessary, ground and mixed in the form of a dry powder and fired in the cement kiln in a dry state. The decision to adopt either process is an individual problem for each cement plant.

There are inherent advantages in adopting the wet process in this case; firstly there is no shortage of water which could limit the production of cement by the wet process, secondly it is easier to achieve a homogeneous mixture of limestone and clay in a finely suspended slurry than it is to achieve a dry mixture of the same materials and, thirdly, the additional fuel required to drive off moisture from the slurry in the kiln by the wet process is not so important when a cheap fuel such as natural gas is available, as in this case.

The limestone deposit is situated in Cadomin, 200 miles from the cement plant, though in many other cases in the past factories have been built adjacent to the limestone deposits to avoid freight charges on this raw material. There are advantages in siting this factory at Edmonton, because in Cadomin there is little or no skilled and semi-skilled labour available to operate the cement plant. Though coal is available at Cadomin it does not have the same homogeneous properties as natural gas, which as mentioned previously is readily available in Edmonton at a comparatively low cost.

The company in the initial stages propose to manufacture normal setting and oil-well cement, though naturally future manufacture will depend on customer requirements. The factory has been equipped with the idea of producing not only the two cements mentioned above, but also high early strength cement, masonry cement, and sulphate resistant cement.

CONSTRUCTION FEATURES

An investigation into the subsoil of the cement plant site at Edmonton was made in order to design correctly the heavy foundations necessary for this type of industrial plant.

The tests carried out showed that the upper fifteen feet of subsoil is a highly plastic clay of about 35 per cent moisture, with an unconfined compressive strength of approximately 1 ton per square foot. This layer of clay showed signs of numerous fissures due to repeated shrinkage and swelling of the soil brought about by soil moisture changes. This clay, because of the fissuring, is more than normally permeable.

Below this very plastic clay is a layer of silty clay at a depth of 16 to 22 feet, which has an extremely low compressive strength and contains about the same amount of moisture as the plastic clay above it.

Below the silty clay there is a layer of dense glacial till of considerable depth which has a moisture content of 15 to 20 per cent. This material consists of a clay containing sand, gravel, and stone pockets and has an unconfined compressive strength of at least $2\frac{1}{2}$ tons per square foot.

The first two clay layers have such a low bearing value that all the main structures for heavy equipment are founded on piles of the end bearing type, which terminate in the layer of dense glacial till. Furthermore, because of the high water content in the first two clay layers, all foundations were taken down at least 8 feet below ground level as a precaution against frost damage.

Piled foundations were constructed for the slurry silos, cement silos, kiln piers, storage hall, and mills; 1,048 caisson piles were driven, having an average pile length of 20 feet each. It is interesting to note that in a test on one of these piles on June 15, 1955, where a maximum load of 120 tons was imposed, a total deflection of the pile was 15/32 inch. The 120-ton load was maintained on the pile for 9 hours, during which time the pile settled a further 3/32 inch, and on removal of this load the pile recovered 7/32 inch, leaving a final settlement of

Fig. 10. Aerial view of the plant.

11/32 inch. This deflection was considered acceptable as the pile is rated for 90-ton loading only.

Approximately 20,000 cubic yards of concrete was required for the construction work and it was all supplied by ready-mix companies. The largest concrete pour was a 670 cubic yard reinforced concrete base for the cement silos, which was placed in about three hours.

The construction of the slurry and cement silos was done using sliding formwork raised by hydraulic jacks. Though this form of construction has been previously used elsewhere, there are a number of interesting features which are worth mentioning here. The first condition to be satisfied is that once the work has commenced it must be continuous until the completion of the silo walls. The preparation work must be made in advance so that all plant and material is available on the site before commencing the operation. Three shifts of workmen were allocated with a number of extra men to be called upon as reserves in case of illness. The actual locations of all holes, access doors, etc., were entered in a book kept on the sliding forms platform and pointed out by the engineer-in-charge to the foreman before each shift commenced, so that blockouts could be made for positioning when the sliding forms reached these locations.

The interior and exterior circular forms were held by yokes on which hydraulic jacks were mounted. The jacks were threaded on steel jack rods welded to the base dowels and the whole of the formwork hauled up on these rods. As the jacks had a stroke of 1¼ inch and pumping of the hydraulic fluid was done every 8 or 12 minutes, the formwork was raised 6 inches to 9 inches per hour on the jack rods.

Owing to slight inequalities in the stroke of individual jacks, there was a tendency for one side of the silo forms to gain on the other and this was continuously corrected by closing the needle valves controlling the flow to the jacks which were gaining. When the forms returned to a level position these needle valves were opened again. There was a tendency also for the silos to swing laterally, this being checked by plumbing to a fixed point on the base and correction was again made by operation of the needle valves as mentioned previously. The rate of jacking was checked on the jacking rods by an instrument man every hour, as this served not only as a check on the level of the formwork, but also on the rate of lift.

Due to shortage of water the curing of the slurry silo concrete was done by painting a plastic solution on the exterior concrete surface, but on the construction of the cement silos a plastic hose with water sprays was hung just below the bottom of the sliding forms to spray on the exposed concrete. This method proved very successful.

In forming the lower part of the cement silos a second circular concrete wall was necessary inside the silo to support the hopper bottoms, and this wall was constructed in a novel manner. The jacks were fixed above the top level of this inner wall and jack rods were threaded through them down to the basement and fixed to an inside sliding form. In this case the jacks were installed inverted so that the rods were hauled up through the jacks, instead of the standard method where the jacks climb up the jack rods. As the jack rods were hauled up, the concrete was placed in the forms in the normal way. This operation also proved very successful.

PLANT EXTENSION

In November, 1955 the company announced that the factory would be extended to double the output of cement. In the original design arrangements had been made for this event, so that adjustments were minor to the existing foundations and buildings. The necessary work involved in the driving of piled foundations has already been commenced.

The additional equipment includes a new travelling crane for the storage hall, a complete new kiln with auxiliary equipment, a new cement mill and a new cement storage bagging and shipment section. The other parts of the cement factory already have a sufficient capacity to handle the materials necessary for the increased output.

CONCLUSION

The work on the cement plant site in Edmonton started in April, 1955 and proceeded without interruption to meet the tight schedule imposed to bring this project to an early conclusion. The weather conditions during the summer of 1955 were ideal for the excavation and concrete work, but with the early commencement of cold weather the construction works were made extremely difficult. By the installation of temporary heating, and concreting with the addition of calcium chloride, the progress of this work was maintained. It was fortunate that this possibility was foreseen, so that a large proportion of the underground work such as sewers, water piping, gas piping, and cable ducts were completed early in the construction program.

The project was under the direction of the Company's consulting engineers, Cimenteries et Briqueteries Réunies of Belgium and their Canadian associates, Kemet of Montreal, who designed the process and supervised purchase of equipment, construction and starting up of the plant. The Company also retained special consultant services of Mr. Norman Edgar and Dr. Stanley of Edmonton. The detailed engineering drawings, specifications and construction management were made by Foundation of Canada Engineering Corporation, Montreal, in conjunction with R. M. Hardy & Associates, consulting engineers, Edmonton, who were also responsible for the original foundation investigation.

The main contractor was Burns & Dutton Concrete & Construction Company, of Calgary and Edmonton, who were responsible for the construction of all the cement process work at the factory site in Edmonton, including civil, mechanical and electrical work. The architects for the plant were Durnford, Bolton & Chadwick, Montreal and their Edmonton associates, K. C. Stanley & Company.

The organization of the professional associates in their particular spheres, together with the excellent collaboration between the contractors' staff and machinery suppliers has been largely responsible for the fast and efficient progress of this project.

The factory is the first venture in Canada of this Canadian company, whose intention it is to maintain production ahead of the foreseeable demand.

Engineering for a New Petroleum Refinery in Montreal

J. Alexander, M.E.I.C.
Refinery General Manager,
Canadian Petrofina Limited

E. Alzner, M.E.I.C.
Chief Estimator,
Industrial Engineering Division,
Canadian Vickers Limited

In September 1955, less than two years from the awarding of the project contracts, the Montreal refinery of Canadian Petrofina Limited went on stream. Although the main refining operations are based on standard practice, the design and construction of the plant presents several interesting engineering aspects, and its operation is exceptional in the degree and extent of automatic control and recording that are incorporated in the process layout.

The basis for design was Middle East crude, which has a high sulphur content (a "sour" crude). The present alternative feed-stock, Venezuelan crude, is also sour. Problems of corrosion and contamination by sulphur products were therefore involved.

The final selection of process units was largely governed by the aim of obtaining the maximum yield of saleable products of high quality and maintaining flexibility of operation to deal with variations in crude feed-stock. Present capacity is based on a throughput of 20,000 bbl./day of crude.

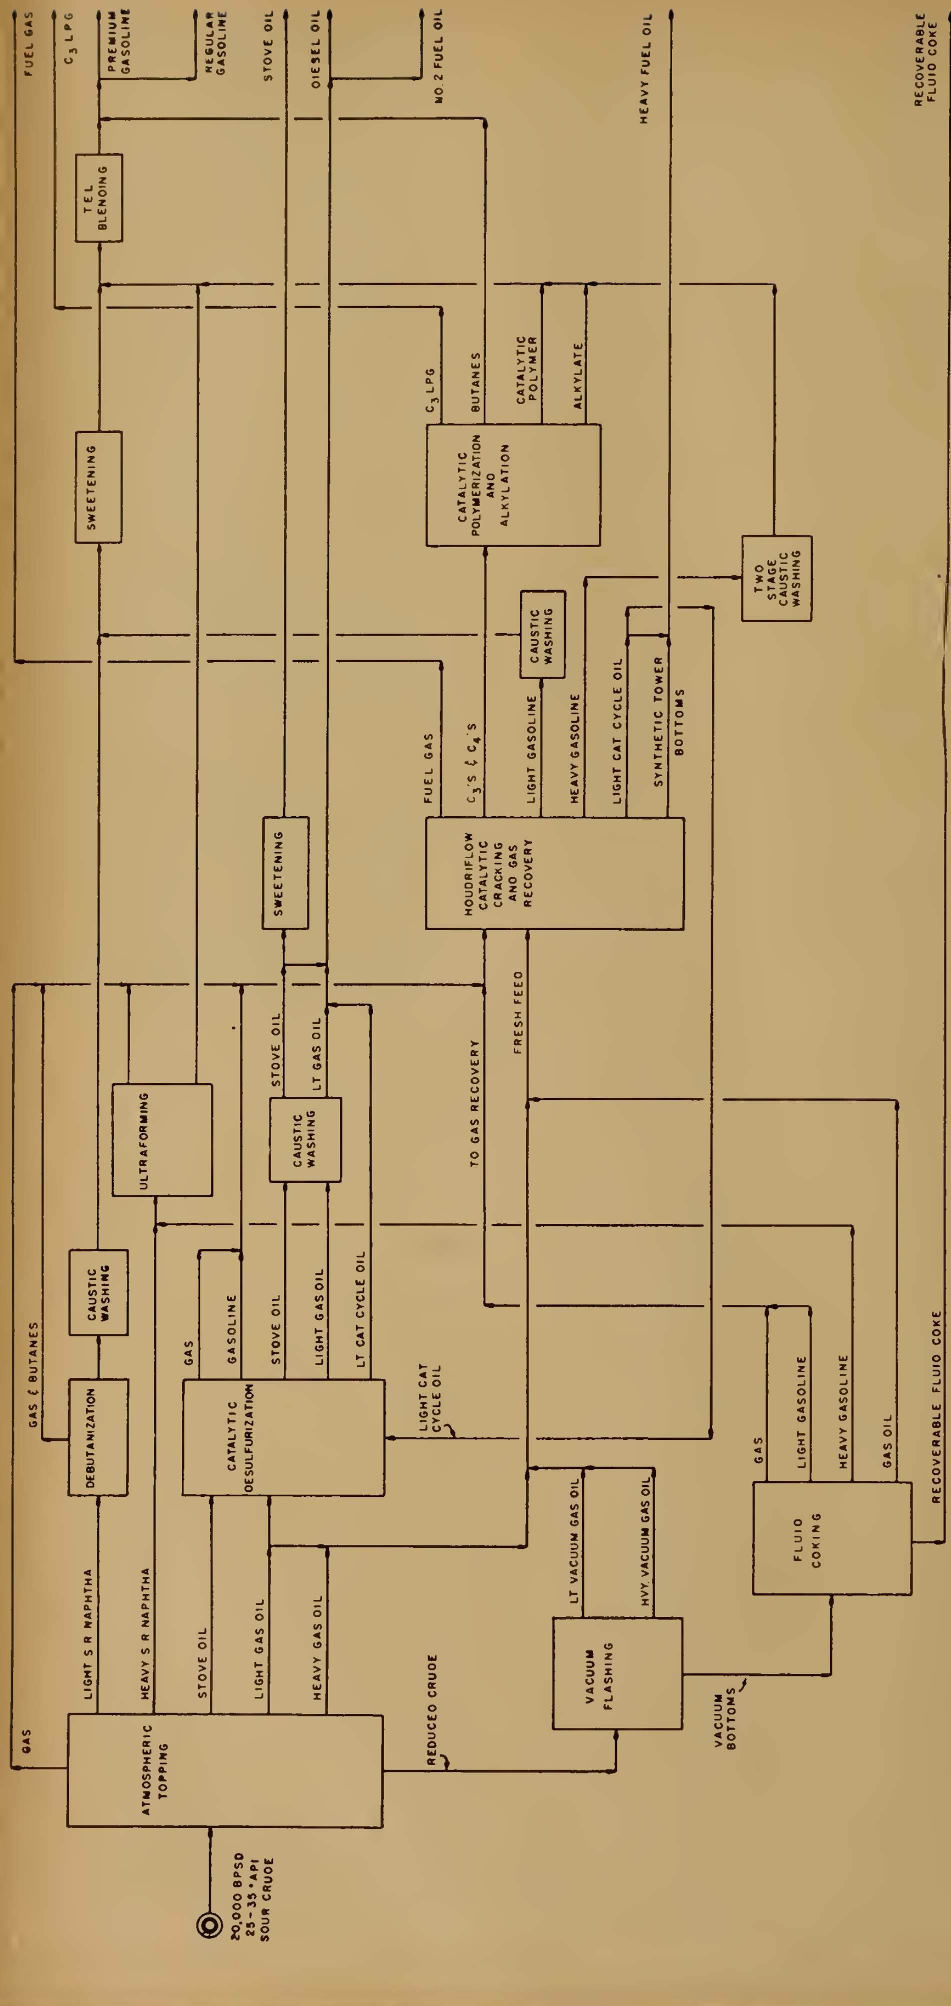
The newest of Canada's major industries, petroleum, has expanded vigorously in recent years. Bulk transportation, by tanker and pipeline, has made feasible the refining of petroleum in convenient marketing areas far from the original sources of crude. A recent addition to Canadian petroleum product capacity is the refinery of Canadian Petrofina Limited, at Pointe aux Trembles, Que., which not only incorporates the latest process and control techniques, but involves many interesting engineering problems.

Basically the process consists of fractionating the crude in a combined topping and vacuum distillation unit, from which the products require such further treatment as removal of sulphur, reforming of certain light fractions to increase octane rating, cracking of heavier fractions to obtain gasoline, and alkylation and polymerization of vapour fractions also to produce gasoline. A schematic flow diagram is shown in Fig. 1.

It is not proposed to discuss the refining process in detail, but rather to bring out the major engineering features of the refinery, including the offsite facilities. To exemplify the construction of the process units, the fabrication and field erection of the catalytic cracking unit will be discussed in greater detail, particularly as the size of this unit (nearly 300 ft. high) posed several interesting problems.

THE PROCESS AREA

The heart of the refinery is the process area, in which are grouped



the main process units indicated in Fig. 1; in area, however, it occupies only a small fraction of the total system. The whole process area was excavated and prepared at one time, although subsequent installation of units in the area was in the hands of two main contractors.

The main process vessels were pre-fabricated in the manufacturers' shops and (excepting the catalytic cracker, which is discussed in detail below) were transported to the site by rail and road and erected by mobile cranes.

To meet the corrosive conditions imposed by sour crudes, fairly extensive use is made of alloy steels, particularly in regions of high temperature and pressure operation.

The bottom section of the crude fractioning tower is clad with 11/13 chrome steel, the middle section of the tower is extra thick carbon steel, and the top three bubble trays are made of Monel. As a further precaution a proprietary material is added to the crude feedstock to give a surface plating effect within the vessel.

Chrome alloys are also used in such places as the furnace tubes on the catalytic reformers; inlet lines to the reformers operating above 600°-650°F. are chrome steel, but below this temperature range are usually of carbon steel.

Similarly, chrome alloys are used in the fluid coking unit for temperatures above 600°-650°F.

Hydrogen embrittlement of steel is liable to occur where hydrogen is present at high pressures and temperatures, and alloy steels are used in vessels under these conditions. The catalytic reforming reactors consist of a separate aluminized steel shroud within an external pressure vessel. Aluminizing is used in regions liable to attack by hydrogen sulphide (present in the reaction phase). The formation of iron sulphide must be avoided in the presence of certain catalysts, which would be adversely affected.

Welded fabrication was largely used throughout. Most of the alloy pipework was shop fabricated, but some of the carbon steel pipe was welded in the field.

Fig. 1. Schematic flow diagram of the 20,000 b.p.s.d. catalytic refinery.

CATALYTIC CRACKING UNIT

Supported by a huge concrete structure, which rests on a massive concrete block embedded in natural rock, the catalytic cracking unit has a main diameter of 24 feet and towers to an elevation of almost 300 feet — the tallest catalytic cracking unit ever built in Canada.

For the purpose of incorporating into a single unit all operations such as recirculation of the catalyst (which is in the form of small beads), the cracking reaction, regeneration of the catalyst by burning off the carbon deposit, and cooling of the catalyst, use is made of gravitational flow. This results in the immense height of the complex vessel.

The intricate internal components of this one-vessel arrangement consist of 12 heads pierced by thousands of catalyst distribution- and transfer-pipes, catalyst distribution screens, and a shell-piercing cooling coil system comprising over 700 pipes.

Some 75 various types of ferrous materials such as carbon steels, low alloy and austenitic steels were used to withstand possible operating temperature well over 1000°F.

In addition to the design complexity, the really great problem in furnishing this refinery unit was that of the field erection — carried out under the particularly severe winter conditions of 1954-55.

Sub-freezing temperatures, the deep snow and high winds of a typical Canadian winter, plus the transportation to the erection site of the shop fabricated assemblies weighing up to 85 tons — one of the largest trucking jobs ever undertaken within the city limits — made this task unusually difficult.

A job of this magnitude obviously has too many details to be included within the space of this paper. There are details of apparently minor importance which, however, when overlooked could result in a serious setback in the course of operations.

Careful and detailed planning was the secret and the key to the successful completion of this project.

The geographical relation of shop to field was opportune—both located in the East end of Montreal. The clearances for transport purposes from shop to field were relatively good, except for a few electric wires which could easily be raised or temporarily removed. It became evident that the most efficient way of handling this project would be to accommodate work as much as possible in the shop and make this project shop pre-assembled rather than field-erected, in the usual sense of the term. From these general considerations the pattern of overall planning began to take shape and continued until the finest detail was clearly laid down.

This pattern of planning may be outlined in its main points.

(1) A study of the vessel structure. This included the sectionalization into a number of sub-assemblies, with due consideration being given to the ensuing problems of shop fabrication, transportation to the site, and assembly at site.

(2) A study of shop-fabrication procedure for individual sections.

(3) A study of method of pre-fitting and pre-alignment of shop completed sections for the purpose of reducing to a minimum costly and difficult fitting operations in the field.

(4) An investigation into the various available means of transportation of the sub-assemblies from shop to the site.

(5) A study of the various lifting schemes, the corresponding equipment, and its availability.

(6) A study of the site (after selecting the most practical erecting equipment) to ensure proper location of the equipment, as well as deadmen, etc.; subsoil survey.

(7) A study of all welding procedures, including pre-heating operations, for both shop and field work.

(8) A study of field working conditions, with special emphasis on maximum accessibility of working area and, for efficient handling of vessel sections, arrangement of work platform, suitable location of welding generator station, propane gas pre-heating distribution system, office and service shacks.

(9) A study of safety precautions and regulations.

(10) A study of the problems presented by test requirement.

(11) Liaison with local weather offices.

Figures 3 to 9 illustrate some of the stages involved in the resultant construction and erection.

Shop Fabrication

The catalytic cracking unit was divided into 18 main sections. Each section was completely shop assembled with all internals, nozzles, etc. in place. The weight of each section varied from 35 tons up to 85 tons. Segments of the heads, up to 1-5/16 in. thick, were heated and shaped by pressing, and assembled by welding together in intricate jigs. The material specified for these heads was in the main chrome-moly steel which requires preheating the weld seams to 400°F. and this problem was solved by incorporating into the assembly jig a con-

Fig. 2. Crude tower, stripper, and furnace. Excavations and forms in foreground for coke unit. Control house at extreme right.

trolled propane gas heating system. This took the form of radially arranged pipes fitted with thousands of tiny burner tips. These pipes extended underneath the seams to be welded. This system was also capable of controlling the required post-heating of welds. Welders worked inside the head from rotating hammocks of asbestos. Temperature chalk was used to check the amount of preheating obtained.

The shop fabrication of the shell-piercing cooling coil system was a most difficult problem. Great skill and craftsmanship were required to comply with the specified close tolerances—uncommonly exacting in plate work. Some 1400 sleeves had to be fitted and welded into the 1½ in. thick shell casing. These sleeves had to be in perfect parallel alignment to each other. The task was also to place each sleeve on the one side of the circular section in perfect alignment with the corresponding sleeve on the opposite shell side. Finally each sleeve had to match with the corresponding holes in a series of flat beams located within the shell in transverse arrangement, which served as supports for the cooling coils. It was indeed gratifying to the boiler makers when cooling coils were introduced into the completed and erected section without the slightest difficulty.

A number of other sections had complicated internal components, such as internal decks pierced by hundreds of welded-in catalyst transfer pipes or other distribution systems oriented to a definite pattern with close tolerances. The alignment requirement of these internals was most severe in order to assure uniform distribution of the catalyst in its downward flow through the various superimposed process zones of the unit.

Much engineering and workmanship went into the so-called catalyst disengager, the top component of the cracking unit. This shop assembly (with the catalyst lift pipe stubs inserted in the withdrawn position for transportation and lift) measured 18 ft. 6 in. in diameter by 70 feet high, and weighed 85 tons. Its internals consisted of an intermediate deck and a series of bellow-type expansion joints into which the 9 catalyst pipes could expand. Needless to say, the transportation of this component, and its erection in a single lift to a height of over 300 feet on a severe winter day was an outstanding event. Though much heavier lifts have been handled in the past, it is extremely rare that a load of 85 tons is lifted to a height such as this.

Prealignment of Sections

All sections before shipment to the field were prefitted and then prealigned by means of transit survey. The relative position of sections one to each other with allowance for a 3/32 in. to ⅛ in. wide welding gap was predetermined and then in this position fixed by the attachment of angle-bolting bars spaced equally around the circumference of the adjoining sections. Fitted bolts were used for these bolting bars, to assure simulation of alignment at field assembly. Prealignment was not carried out only with the intent of reducing the costly field operations to a minimum — it was an absolute necessity from purely meteorological considerations. Sudden weather changes are characteristic for the Montreal area. Especially during the winter season wind speeds might change in a space of only two hours from a breeze to a storm. On account of the heights involved all operations at field were limited to a wind speed of 27 miles per hour. Experts of the Dominion Weather Bureau advised that a guaranteed forecast for stable weather conditions could not be given for a time longer than

Fig. 3. Part of the plate shop during the fabrication and assembly of the 18 main sections of the catalytic cracking unit. Weights of sections ranged from 35 tons to 85 tons.

Fig. 4. Large jigs were built for the assembly of the heads for the catalytic cracking unit. Welders worked from rotating asbestos hammocks inside the head. Seams were pre-heated by controlled propane burners, of which a closer view is seen in the left-hand picture.

one to two hours. It was, therefore, clear that sections would have to be raised, placed and secured against high winds within this available time limit. In view of these uncertain weather conditions, the shop prealignment program proved invaluable. The complete operation, including lifting and securing each section for welding, in no instance took longer than 45 minutes.

This ease of field assembly prevented a serious setback on the occasion of the second to last lift. Immediately after securing this particular section, the wind velocity increased to 45 miles per hour.

Transportation

Transportation of sections from shop to site was carried out during low traffic hours at night and early morning under police escort. Low bed trailers from 50 to 120 tons capacity were used which deposited the sections directly beneath the derrick.

Lifting Equipment

The unique features and principles incorporated in the main guy-wire derrick used for this erection job were of great interest.

After an extensive search for a lifting rig that could handle this work, a derrick was acquired from western Germany.

This derrick is of the Meccano-set type and can be assembled into a variety of forms to suit special job conditions. For the Petrofina project components were assembled into the form of a huge guy-wire derrick of an overall height of 427 feet. The cross section of the main column was 6 ft. 8 in. square; the guyed mast, 215

Fig. 5. The 1½-inch shell of the cracking unit had some 1400 sleeves fitted and welded to stringent tolerances, to accommodate cooling coils. Several complex welding jobs were involved in fabricating other internal components (such as the deck in the top picture) to close tolerances.

feet long, stood in a ball joint on a reinforced concrete block embedded in natural rock. The boom, 185 feet long, had a cross section of 3 ft. 4 in. square. Provision was made for heavy lifts on an eight-fall hook and a separate arrangement for light and fast lifts. The bullwheel, 33 feet in diameter, arranged at the base of the mast, carried on its platform all operational equipment, consisting of four electric winches, a special mechanism for swinging operation, and a control room for housing the electric controls, recorders and operating crew. The heavy lift system was hooked up to two 12.5 ton winches and the fast lift to a 7.5 ton winch. Movements of the hook for heavy lifts could be controlled to ⅛ in. accuracy. Ladders within the derrick structure with landing platforms every 28 feet lead from the base of the derrick to both tip of the mast and tip of boom for maintenance purposes.

The guywire system was hooked to a series of winches located on 4 deadmen, each a concrete block 20 feet square embedded 13 feet deep into natural rock. The winches served for the adjustment of the required prestress in the guywires. Such adjustments had to be carried out periodically and especially in cases of sudden temperature changes. The amount of prestress (10 tons) was checked by means of special hydraulic jacks.

Erection of the derrick was in itself a rigging job of considerable proportion. On the ground, preassembled sections of the structure were raised and set in place by means of an auxiliary creeping mast. The boom was a single-lift operation. Under most adverse weather conditions erection of the derrick was completed within 35 working days.

Derrick Placement

The selection of a suitable location for placement of a derrick of this size in the midst of a site, which in its final stage of erection would become a most crowded set-up (typical of refinery construction) was a matter of prime importance. Besides considerations of the most efficient handling in a certain sequence of all lifts at various reaches and corresponding load capacities of the derrick, further thought was given to locating the equipment (also the deadmen), so as not to cause an obstruction in the final phase of erection. It was later discovered. that a small deviation of a couple of feet only from the actual derrick location would have caused a considerable delay in the overall refinery erection schedule.

Welding Procedures

On account of the various types of materials involved, elaborate welding procedures had to be prepared. Welding operators had to be qualified involving numerous tests for various positions. Especially the welding of dissimilar materials, particularly of stainless steel clad, chrome-moly and chromium alloy steel to carbon steel called for special attention to technique and procedure. Preheating problems in field at sub-freezing temperatures were successfully solved by means of specially designed propane gas heaters. A total of over 10,000 feet of welding was completed without a single case of repair.

Some Notes on Field Erection

As already stated, shop-fabricated sections were hauled directly underneath the derrick. Heavier sections—weather conditions permitting—were lifted directly from the trailer and set into place. Lighter sections were unloaded on to the work platform secured together and welded while on the ground. This procedure kept the number of lifts as well as the number of high altitude welding operations to a minimum.

Scaffolds were fastened to the sections before lift. Rope ladders were mostly used from scaffold to scaffold. For work at higher altitudes crews were usually lifted in a specially designed cage by means of the derrick. Specially laid out tents of fireproof tarpaulin were fastened around the scaffold platforms at levels of the circumferential joints for protection of welders and the weld joint against the weather.

Routine checks of plumb of the vessel during assembly had to be carried out in cloudy weather, or before sunrise in days of fair weather, in order to assure uniform temperatures within the shell wall. The temperature differences, and consequently uneven expansion introduced in the shell wall through radiation from the sun, are of sufficient magnitude to cause deviations of nearly 5 in. from the true horizontal measured at the top of the vessel.

Safety Measures

Tight overalls, safety belts, and safety hats were worn throughout by the field crew. Loose parts and tools were removed from scaffolds and platforms as soon as these were not longer required. The job was carried through without a single accident.

Tests

The process vessel was built in conformance with the A.S.M.E. code for unfired pressure vessels. Gamma-ray examination of welds were periodically carried out and

Fig. 6. The catalyst disengager, 70 feet long and 18½ feet in diameter, presented a major transportation problem. This unit and other components were carried by low bed trailers (up to 120-ton capacity) and deposited below the lifting derrick.

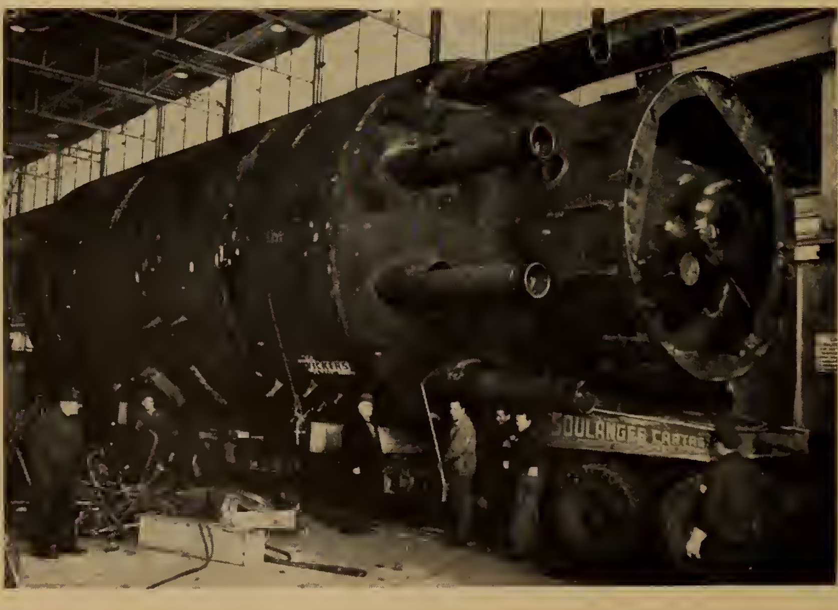


Fig. 7. The 85-ton catalyst disengager nearing the top of the cracking unit.

Fig. 8. The top unit of the catalytic cracker, the 85-ton catalyst disengager, is finally placed in position after a single lift of over 300 feet.

recorded in special log books. In general one or two shots per week on each welding operator's work served to keep a close control on weld quality. Welds in the reactor portion were fully X-rayed to assure highest quality of joint. These examinations, besides pneumatic, hydraulic, and hammer-tests, to which individual portions of the vessel were subjected, formed the basis for the final acceptance of the completed tower.

A notable operation in this connection was the hydraulic test in a single procedure of the regenerator portion, extending between elevation 37 feet and 107 feet. The required test pressure at elevation 107 feet of 17 lb./sq. inch meant—on account of the hydrostatic head—a pressure of 48 lb./sq. inch measured at the bottom head (24 feet diameter). This pressure introduced into the head stresses which at critical points came close to the yield strength of the material. The admissible deflection before yield was calculated, and measured under actual test as a safety precaution. At a total actual deflection of 11/16 inch calculations proved to be within an accuracy of -1/16 in.

Other safety measures for yield-observations were applied, such as white-washing the head at critical points. Pressure tests were carried out at near to freezing temperatures. Over one million gallons of preheated water had to be pumped into the vessel. Temperature recorders were arranged to measure the outside skin temperatures of the shell at different points during test.

Liaison with Local Weather Bureau

Arrangements were made with the weather bureau at Dorval for the supply of detailed weather information at short notice—especially with regard to changes in wind speeds. Such information was of vital importance for the safe disposition of all field operations. As already stated, all operations at height had to stop at wind speeds over 27 miles per hour. A number of precautionary measures had to be taken before wind speeds would increase to such values: The derrick had to be set into its resting position: the bottom had to be withdrawn to its steepest position pointing into the direction of the wind, the hook had to be lifted to its highest position, winches and various cables had to be secured and all crews had to descend from the derrick platform and the tower in safe time. In many instances there was not much time left. No heavy lift was started before assurances of stable weather conditions were obtained. It would be a serious omission to mention the invaluable services rendered by the weather bureau in this respect.

AUTOMATIC CONTROL

A feature of the refinery is the use of one central control room for all eight process units and the installation of a single automatic logger which covers the complete process plant and can record up to 480 operating variables.

All refinery units are coloured in accordance with a code used to identify different products; in general, dark colours for heavy products (coke, crude, etc.), and light colours for light materials (vapours, air, steam). This colour code is reproduced exactly on a graphic panel that lines the wall of the control room and depicts the entire refining process. The graphic panel incorporates all the operating and control instruments (of the "miniature" type) and uses symbols rather than words to simplify the operator's grasp of the presentation.

Purely informative instruments are grouped in consoles, which can be seen in the general view of the control room (Fig. 10).

Completion of the automatic logger will abolish the written operating log which is usually recorded by the operators, and is always subject to human error, especially during periods of emergency or rapid change. Data are received either on electronic or pneumatic instruments and are converted for use by the logger. For example flow (time-rate) data are continuously scanned and are converted by a computer to volumes.

At pre-set intervals the logger can automatically record up to 480 variables on an automatic typewriter. Punched tape storage and a tabulated digital log are produced simultaneously. A recording cycle is also started (and an alarm sounded) if conditions become abnormal, in which case any abnormal values are distinguished by being recorded in red. The operator may manually start a recording at any time he wishes.

The tabulated log is set out on prepared forms designed for operating requirements and colour coded for easy identification.

Eventually, feed-back from the recording instruments could be used to obtain automatic correc-

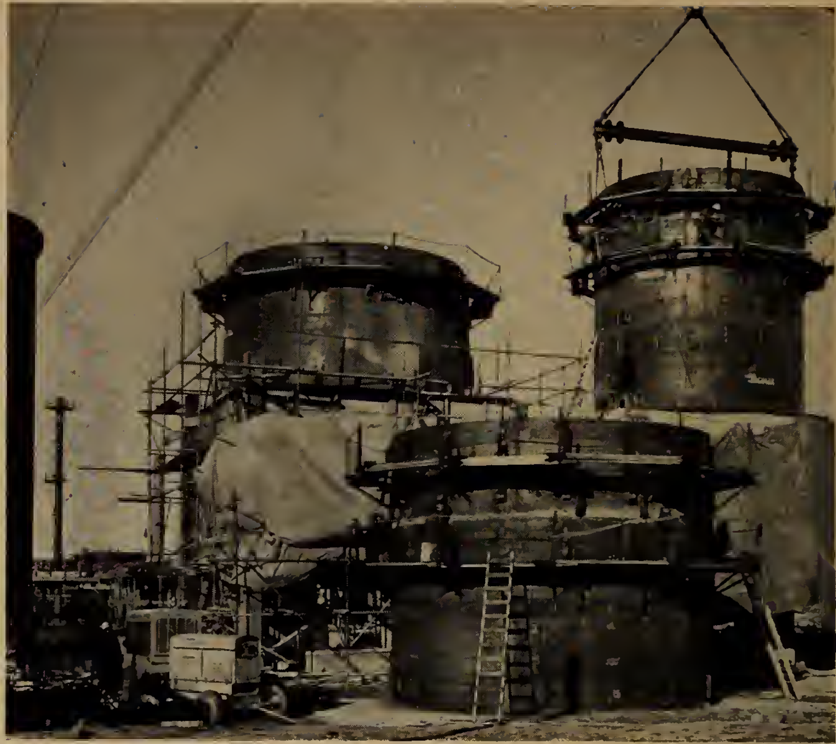

Fig. 9. After being transported to the site, some sections of the cracking unit were assembled on the ground and welded before being lifted into position. This reduced the number of lifts and minimized high altitude welding. Scaffolds were fastened to the sections before lift.

Fig. 10. Interior of the control house, showing the graphic panel, lining the walls, and the separate instrument consoles. The panel is coloured to correspond with a colour code that is followed on the actual refinery vessels and pipes.

tion of process conditions and to achieve almost fully automatic control.

Pneumatic control is used for nearly all processes except high-temperature measurement. Pneumatic lines, mostly of ¼-in. copper tubing, are laid between the control room and the process units as "multi-tubing" or multi-stranded tubes in units of 6, 12, 24, etc., made in the form of a cable and run in ducts in the same way as pipe or electrical conduit. This multi-tubing has previously been used only in one other Canadian refinery.

The panel board was entirely pre-fabricated by the manufacturer and shipped in sections to the control room. Despite the great complexity of the piping and wiring involved, no undue difficulty was experienced in assembling the complete panel and joining the sections.

A specific example of the automatic control provided is the time cycle for operation of the catalytic reformer. This unit includes four reaction vessels, of which three are operating while the fourth is cut out for regeneration; the vessels are cut out in turn, on a definite time cycle, by electrically-operated 6-in. positive shut-off valves. These valves are fully interlocked and are controlled automatically for correct operation and to avoid any possibility of introducing oxygen into the process, which produces a high proportion of hydrogen. The positions of the valves (open, mid-way, closed) are indicated by lights on the control panel.

Skin temperatures of high internal temperature insulated vessels, such as the reformer, are recorded as a check on their internal condition, defects in the insulation being shown up as excessively high skin temperatures.

SERVICES AND FACILITIES

Because of its cheapness, electric power is used primarily for driving compressors and other heavy equipment throughout the process, only essential services being spared by the use of steam-driven units.

The main supply from Hydro-Quebec is by two 12-kv. feeders to the main sub-station, where two 7500 kva. transformers, each dealing with half the plant load, convert the supply to 4160 v. This 4160 v. supply is distributed by individual circuit breakers to all process and off-site facilities. Further reduction to 550 v. is also made at off-site substations and at process units, and lighting is provided at 120 v. Supply is duplicated, with automatic switch-over in case of failure.

Some 200,000 lb. of steam an hour are required for full operation. Of this, most is provided by two 80,000 lb./hr. boilers fired by gas or fuel oil, and the remainder by process steam from the exothermic reaction in the catalytic cracker (some 40,000 lb./hr.).

Boiler feed water is pre-heated in process cooling exchangers to about 150°F.

Supply and make-up water are obtained from the St. Lawrence river via an intake flume. A closed recirculating water system is used, water from process units being passed through a 27,000-bbl. storage tank and cooling tower basin. The storage tank also acts as a fire-fighting water supply. Any oil contamination is removed by an API separator. Water from the cooling tower is circulated at 22,000 gal./min., for which 800 h.p. is required.

EFFLUENT

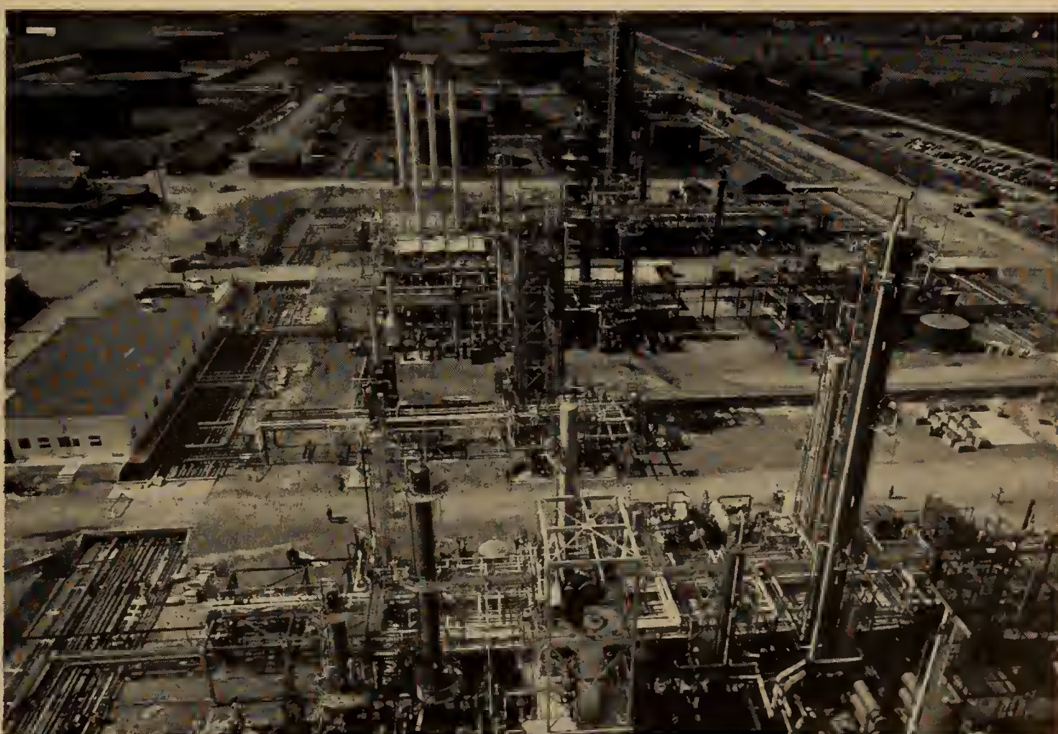
Since a closed water circuit is used, most of the effluent from the site comes from surface drainage. However, precautions have to be taken to avoid contamination from certain areas.

Where process acid is used, acid-proof paving is laid and any spillage is neutralized with caustic before dumping to sewers. Similarly, spent caustic is also neutralized.

The oily water sewer leads to an oil separator, which is in series with a holding basin provided with a surface skimmer; the holding basin also gathers some run-off from other areas.

Waste gases from process are passed to the flare and burnt.

Fig. 11. The central control house (left) serves all the process units, some of which are seen here. Alkylation and catalytic polymerization unit in foreground; hydrodesulphurization unit; ultraforming and acid treating; crude treatment units at far end of process area, beyond which are the crude tanks. Pipe runways are seen flanking the process area.



STORAGE AND MARKETING

Crude oil is brought in by tanker or by pipeline from Portland, Me., and stored in six 150,000 bbl. tanks which are provided with heating coils. Products are stored in a series of tanks with capacities of 150,000, 80,000 and 27,000 bbl.

Tanks for light products are interconnected and have vapour domes; the roofs of volatile product tanks are painted white to reduce radiant heating. Process rundown tanks for volatile ends are linked to a vapour sphere. Contrary to more common practice, tanks are painted with high quality materials and given an enamel finish. Despite the relatively high initial cost, it is anticipated that the resultant long paint life (5-7 years) will prove economical in the long term.

Provision is made for in-line blending of lead and colour into gasoline, so that, for example, a ship may be loaded directly from process tanks.

There are some 13,000 feet of rail siding, one of the longest commercial installations of its kind, extending along one side of the tank farm, with spurs for lubricating oil receipts and shipments, and spurs to process and other areas for receipts of such materials as catalyst, process acid and caustic, salt, T.E.L., and warehouse stores. Rails were laid on continuous columns bearing on rock some 2-3 ft. below the surface, and special clips were used for anchoring the rails.

Road tankers are supplied with products in a separate marketing area; products can be taken on at 550 gal./min. One man can control all deliveries from a central room in the tanker-supply area; the invoice for the delivery is printed automatically in this control room. Deliveries from storage are automatically remotely controlled.

Railbed and pavement in both the rail and road delivery areas may be heated in winter by subsurface pipes through which is circulated light oil preheated by steam in an exchanger.

GENERAL CONDITIONS

Excavating cost and time were high because of the prevailing rock base in the area. Some 120,000 yd. were removed, mostly by blasting, to prepare foundations, trenches, sewers (to a depth of 20 ft.) and even for line poles. The refinery is designed to meet earthquake conditions.

One of the main aspects to be considered was the cold winter weather encountered in Montreal. The heated pavement in delivery areas mentioned above is one result of these considerations. Particular attention had to be paid to insulation of process and steam lines and heating certain storage tanks; steam-tracing is widely used, but is replaced by electrical heating for some above-ground process lines.

The Houdriflow unit and the vapour recovery and desulphurization units were contracted to Lummus Company of Canada (with Canadian Vickers Limited fabricating and erecting the Houdriflow cracking unit); the Canadian Kellogg Company was responsible for the remaining process units and all the off-site facilities.

Fig. 12. Behind the tank car loading rack (lower picture) can be seen one of the vapour dome tanks. Delivery from storage to outlet is remotely controlled, both for rail shipments and at the road tank truck loading rack (top picture). Loading areas can be kept free from ice and snow by buried heating coils, carrying light oil heated by steam in an exchanger.

DISCUSSION

of Technical Papers

The Professional School in the University

by

Dr. C. T. Bissell, Vice-President, University of Toronto.

The Engineering Journal. February 1956 issue, page 131

R. M. Hardy, M.E.I.C.[1]

It was a privilege for me to have had the opportunity of hearing Dr. C. T. Bissell, vice-president of the University of Toronto, address the annual dinner of the Engineers' Council for Professional Development in Toronto in October 1955 on the subject "The Professional School in the University". One could not help but be impressed by his insight into the problems of professional education and the difficulties of imparting knowledge in specialized fields while attempting simultaneously to foster intellectual qualities of the mind. His remarks were addressed to a group who in general were well aware of the wide divergence of opinion on many of the points discussed, and were most conscious of the inherent difficulties in attempting to formulate policies providing a satisfactory compromise of such differing views. Dr. Bissell's comments were admirably provocative to this gathering, but it is unfortunate that the nature of the meeting did not permit discussion of the several most controversial points he brought forth.

In reprinting a condensed version of his remarks in the February 1956 issue of the "Journal" you comment editorially that it "will be of interest to all engineers, but particularly to those not long out of college". My concern is that many of this group will not be aware of the controversial nature of some of Dr. Bissell's comments, and that strong opposing opinions are held by many, both within and without the Universities.

If one goes back to the original reports of the committees whose studies led to the current practice of dispersing the general educational content throughout the curriculum, it will be found that the recommendations were arrived at only after very careful consideration of the relative merits of pre-engineering years. The practice in pre-medical and pre-dental education was available for evaluation. The decision in favour of dispersion throughout the professional course was arrived at, not so much because of a reluctance to extend the formal educational period, but rather because of the considered opinion that if courses in the humanities were to serve their best purpose, they were better integrated as closely as possible with the technical content of the professional curriculum.

Courses in the humanities and social sciences of a post graduate nature to be taken after a period of experience in professional work are an interesting possibility. However it is difficult to see how in fact they could become available to more than a very small percentage of engineering graduates. Therefore they could hardly be considered as an adequate substitute for a general educational program properly integrated into the formal curriculum of all engineering students.

Dr. Bissell also deals with the merits of technical institutes as a means of meeting the increasing requirements for technically trained personnel, and as an expedient for relieving the pressure on university facilities. While he acknowledges that professional education must emphasize the "know why" as opposed to the "know how", he also subscribes to the British concept that "The difference between the two types of institution is not in status or grade, but in kind". The technical institute is primarly concerned with the "know how". It is therefore difficult to conceive how these two conceptions can be compatible.

One, of course, may argue that the contribution of the "know hows" to the functioning of our economy is equal to and just as essential as that of the "know whys". But both cannot satisfy an acceptable definition of "professionalism". Moreover one can scarcely justify extending this equality to include factors of edu-

DISCUSSION

The editor invites discussion of papers appearing in the *Journal*.

Readers may contribute to this section by sending appropriate comments to the *Journal* office.

cational background and quality of mind. It is the confusion of thinking on this point that is responsible for the continual pressure on the professional organizations on this continent to recognize purely technical training as meeting the requirements of professional education.

Dr. Bissell undertook to speak for the universities in reserving to them the final decision in educational matters, and in expressing suspicion of the value of the system of accreditation of professional engineering curricula presently practised by our American friends. It is on these questions that I would take greatest issue with him.

Authority for Curricula

He sets forth the principle that, "The final decision about university policy must be made within the university, by men and women who have devoted their lives to education and who are in a position to see the ramifications throughout the whole university of a policy shift in one of its parts". One must certainly give Dr. Bissell credit for a statement that in its philosophical neatness is at least the equal of the "mathematical neatness" he ascribes to the conclusion of engineering educators that one-fifth of a curriculum should well be devoted to general educational courses. An intriguing picture is suggested of a group of dedicated university administrators thoroughly ensconced within their ivory tower, concerning themselves with the interrelationships of faculties and schools and serenely oblivious to external pressures, financial or otherwise—truly an academic paradise. Unfortunately, as a generalized conception of university administration, particularly amongst the provincially financed universities, it is a fact neither in theory nor practice.

The final authority in most university administrations is a board of governors and/or a senate, or their equivalent. In the case of provincial universities these bodies in turn, at least in financial matters, must conform to the policies of the current government of the province. Frequently the members of these governing bodies are men or women who are devoting their lives to education, but they also frequently are publicly minded, well-meaning and capable citizens frankly representative of specific economic, religious or political groups. Rarely are those who are devoting their lives to education more than a small minority, and even more rarely is a specific profession represented on these bodies.

It is seldom that any major change in curriculum or policy in regard to facilities or quality of teaching staff does not have its financial aspects. As an example, consider a proposal to add a course in English to a first year class of 350 students in a faculty of engineering at a provincial university of say 4,000 enrolment. It may require four new instructors in the department of English. It certainly has a disrupting effect on the existing interrelationships of faculties and schools, but unfortunately these may be largely irrelevant to the basic problem as to whether it is desirable to expose this group of students to the new course. However assuming these internal disturbing influences are finally reconciled the proposal must still run the gauntlet of a provincial legislature in competition with demands for increased funds for a host of purposes including roads, bridges, buildings, other areas of education, the sick, the mentally infirm and the penal institutions. If the democratic process functions as it should under these circumstances surely the final decision will be made on the basis of the general public benefit with its effects on the internal balance within the university very much of a secondary consideration. Again, if the democratic procedures are to properly function those with the final responsibility may be expected to need and to welcome reliable and informed opinion on the merits of a policy. Where better can these be forthcoming than from a professional body dealing with a subject of special concern to its welfare and dedicated to manage its affairs in the best public interest?

Dr. Bissell points out that professional education has been a responsibility of universities since mediaeval times. There are examples of universities coming into being as an outgrowth of training offered at a center by a particular professional group under its own responsibility. It is a moot point as to whether the universities can rightly claim more than trusteeship for professional education and for the body of specialized knowledge upon which the practice of a profession is based. One needs only to consider the national or provincial examinations in force in such fields as accountancy, surveying and medicine to appreciate that all professions do not grant complete trusteeship of educational requirements to the universities. A similar situation exists in some cases with facilities. The mere suggestion that a hospital used for medical instruction purposes no longer conforms to a certain minimum standard as rated by the medical profession rightly becomes a matter of grave public concern rather than a problem of the interrelationships between schools and faculties within the university.

Accreditation in Canada

No Canadian university has to date officially used the American accrediting system in rating their engineering curricula. However the boards of examiners of the various professional engineering associations do find it most helpful in assessing the educational qualifications of American trained engineers. As bitter a "pill" as it may be for a university administration to have to accept recommended curricula and certain minimum standards for facilities and academic staff or risk "academic ex-communication", it scarcely is more severe than to condemn in their ignorance a potential group of embryo professional engineers to a sub-standard educational background.

The engineering profession in Canada relies completely upon the universities for the standard of engineering education, but the universities have no inherent right to the responsibility. If one grants that they hold it in trust for the profession they surely should not be adverse to an accounting of their trusteeship, nor should they be adverse to accepting cooperation, well informed criticism, suggestions and recommendations from the profession. In my judgment the best interests of professional education in engineering will be best served by as close cooperation as possible between the universities and the engineering profession; and if they will be better served by accreditation, then let's have accreditation.

ABSTRACTS . . .

OF RECENTLY PUBLISHED ENGINEERING LITERATURE

DOES FULL MECHANIZATION PAY IN LOW-VOLUME PRODUCTION?

Joseph Cooper, *Iron Age*, v. 176. n. 26, December 29th, 1955, pp. 70

Standards people sometimes raise dubious eyebrows at the thought of applying automation techniques to any but mass production lines. Yet, this fully mechanized metal treating line fully paid for itself in a year, despite irregular production and low volume.

Results so encouraged a paper machinery manufacturer that the firm now phosphate coats many components previously painted. Money previously spent in shipping the material elsewhere to be surface treated is sufficient to pay the entire cost of the operation.

A side benefit showed up when the mechanized line proved so efficient that open production time became available. Lodding Engineering Corporation now phosphate-coats many other paper machinery parts that formerly were painted. In addition to cutting manufacturing costs, the coating provides added protection.

To realize the benefits of full automation, all heating tanks are designed with covers that lift during the loading cycle. Immersion time is controlled by accurate timers. Fluid is kept at a predetermined level by a float and solenoid-operated valves. No operator is needed once the process starts.

The automated line employs microswitches, timers, and solenoid valves to guide the material through its various cycles. A master push-button starts movement of the load over the first tank. There a microswitch stops it in the correct position. When the microswitch holding circuit for forward movement is broken by a timer, a contact is made simultaneously that starts downward motion.

The only other controls required are two solenoid valves to initiate flow of water in the rinse tank when the load stops directly over it. Water continues to flow until the unit is moved to the next tank.

Manual operation of the treating line is accomplished by means of push buttons. The buttons bypass the automation mechanism.

The entire installation costs considerably less than one year's bills for phosphating from the previous outside sources.

NUCLEAR ENERGY TODAY

L. N. Rowley and B. G. A. Skrotzki, *Power*, v. 99, n. 12, December 1955, pp. 73-101.

Nuclear plants are taking concrete form and will soon be feeding kwhr into major utility systems. Thus it seems a good time to see where this new energy source stands today and what the future holds.

This special report does just that. After a brief review of fundamentals it plunges directly into a roundup of developmental and commercial-scale nuclear projects—what the equipment looks like, what advantages are claimed for various designs, what problems remain.

This, then, is the nuclear-energy picture at year end 1955—as we move out of the laboratory and experimental phase into what might be called the "hardware" stage. From the experience gained with these plants, and with others just a gleam in some reactor designer's eye, will come the economically competitive nuclear plants of the future.

All the heat we use comes from converting solid matter to energy. The amount of matter that disappears as energy in our ordinary fires weighs so little that we never miss it. For instance, one pound of any kind of matter equals a total of 11.3 billion kwhr or 38.6 trillion Btu of energy.

This means that when we get 14,000 Btu from burning a pound of coal, less than one billionth of a pound of the coal disappears in converting to the heat produced. No wonder we never are aware of this process.

About 150 designs have been proposed for steam-generating power reactors. We will look at just a few to understand the basic principles. Thermal reactors use moderators to slow the high-speed neutrons to a level where they react more readily to fission U-235. Such reactors, fueled with natural uranium or uranium slightly enriched with U-235, must use moderators. On the other hand, fast reactors fueled mostly with U-235 need no moderators.

In addition to graphite, we can use heavy water as a moderator for natural uranium, or light water for enriched uranium. Thus, water can do double duty—act as (1) moderator and (2) as a coolant to carry heat out of the reactor core.

In a nuclear power plant, the reactor and its coolant circuit replaces the steam boiler of a conventional power plant. As you might suspect from the elementary circuits the nuclear reactor has auxiliaries like other main power equipment. The auxiliaries have familiar forms and parts — but some have radically new designs and jobs.

One of the striking features of nuclear power plants will be large tanks or containment vessels completely sealing the reactor and the coolant circuit. These guard against radioactive gases from a reactor or coolant-circuit accident spreading through the plant and vicinity.

Most of the reactors built and operated to date have been research or experimental units, designed to test nuclear effects on materials or to check the safety and performance of new reactor ideas. And new ideas keep coming along — consider the variety of materials available as fuels, moderators, and coolants, and the number of forms in which they can be used. With so many possibilities, it can be seen that the search for desirable power-reactor types would be a herculean task if each were investigated on a large scale.

The pressurized - water reactor fueled with slightly-enriched uranium uses light water as both moderator and coolant. This reactor may be classified as a thermal, heterogeneous type. The fuel elements and control rods making up the core mount in a pressure vessel. A pump circulates the water through the core and vessel to an external heat exchanger. These form a closed circuit.

Like the PWR's just covered, the boiling-water reactor also uses light water as coolant and moderator, with solid fuel elements. It differs from the pressurized-water reactor, however, in that steam is generated in the reactor vessel and goes directly to the turbine generator. There is thus only a single loop, no heat exchangers, and reactor pressure is essentially the same as steam pressure. This permits a higher thermal efficiency for a given reactor coolant temperature than with a PWR.

In the dual-cycle unit boiling is limited to a short upper section. At the core exit, per cent of steam by weight may be of the order of 3 per cent. The 600-psi steam formed in the reactor goes to steam-separator drums for moisture removal and then directly to the first turbine stage.

Now we come to a reactor type using graphite as moderator and liquid sodium as coolant. The liquid-metal system permits high temperatures without high pressures. It thus offers the possibility of steam-cycle efficiencies like those of modern conventional plants.

The nuclear "dream cycle" was described by Dr. L. R. Hafstad, former director of reactor development for AEC, as "a pot, a pump, and a pipe". The homogeneous reactor aims at this ideal of simplicity. As the name implies, fuel, coolant and moderator (if any) are combined in a solution, slurry, or metallic fluid.

It is certainly too early to say which of today's reactor types hold most promise for the future. Or even whether tomorrow's reactors may not stem from concepts not yet explored. One thing can be said with assurance, however: The years will be as exciting for power men as those when electricity was first coming into use. And they should be as fruitful of developments beneficial to all mankind.

• • •

A STUDY IN HIGHWAY FINANCING

R. A. Draper, *Roads and Engineering Construction,* December 1955, pp. 62.

The inescapable results of greatly expanded post-war roadbuilding programs are the many difficult questions of finance: what methods governments should use to pay for new and reconstructed roads and streets, and how the financial burden will be distributed among road users and the general public.

A recent study by the Canadian Tax Foundation, of Toronto, entitled "Taxes and Traffic," is the result of two years' work by the staff of the Foundation and does much to rectify these shortcomings. It takes a substantial stride in bringing into focus the elements of road fiscal problems.

Growth has now reached the point, "Taxes and Traffic" notes, "where the financing of roads, streets and highways now represents one of the major problems of local and provincial finance."

By levels of government, the provinces accounted for 68 per cent, municipal governments for almost 28 per cent, and the federal government for less than 4 per cent.

A great deal of the money required for highways, roads and streets has come from the road-user in the form of gasoline taxes, license and registration fees, etc.

In the years from 1930 to 1953 the federal government collected $1,770 million from the sale of motor vehicles and related products.

For the years 1930 to 1952 federal road expenditures totalled $175 million, some 10 per cent of estimated federal revenue during the same period.

Roads and streets are becoming "a progressively greater drain" on the budgets of the provinces and municipalities, "Taxes and Traffic" states. In the current year provincial net current and capital expenditures for roads, highways and bridges are estimated to account for 27.6 per cent of provincial budgets, ranging from 37.8 per cent in Alberta to 19.5 per cent and 19.7 per cent for Saskatchewan and British Columbia, respectively.

The Foundation sees no prospect of a let-up in the number of automotive vehicles coming onto the road.

A general lack of planning for future building of highways and streets is pointed out by the study.

"It is evident that a comprehensive statement of the future financial requirements for roads, streets and highways is not now available. This fact in itself is an indication of the lack of study in the past of the all-important implications of the subject."

Comprehensive studies, predicted upon present and estimated future traffic conditions, should be made to determine on a long-term basis, our total road and street needs. At least two approaches should be considered—the modernization and rebuilding of existing facilities to permit maximum use of our present plant, and the provision of new facilities to supplement and complement existing roads and streets.

Broad studies are necessary to establish the relative responsibilities of motor-vehicle users and other taxpayers towards the various classes of homogenious roads and streets.

Allocation of the motor-vehicle users' share of total outlays for roads and streets should be in accordance with principles that distribute costs to the various classes of vehicles on an economic basis.

The present basis of taxation of private, and public, motor carriers should be reconsidered.

A system of provincial aid for municipal road and street programs should be predicted on a basis which conforms closely to responsibility and need.

Responsibility should be assumed by provincial governments for street extensions of primary highways and other arterial city streets where the motor users' responsibilities substantially exceed 50 per cent of the total, with compensating adjustments to the other grants-in-aid for road and street purposes within the municipality.

There should be acceptance of responsibility for development of roads as a general charge on budgets.

The federal role in roads of national importance should be reexamined.

In most provinces increases in gasoline taxes or motor-vehicle licenses are warranted if the present relationship between user revenue and road and street outlays is valid for the future.

The adoption of the toll-road principle is justified for economically feasible projects if required roads cannot be financed in the usual manner and when not inconsistent with broader governmental action.

AIRBORNE GEOPHYSICS IN CANADA

Canadian Mining Journal, v. 76, n. 12, December 1955, pp. 43-48.

Like all new inventions, airborne geophysical instruments required dramatic demonstrations before their value was recognized. What Marmora and New Brunswick did for the airborne magnetometer in Canada, The International Nickel-American Metals find in New Brunswick did for airborne electromagnetic gear. The airborne scintillation counter is still awaiting its fulfillment. By putting all three of these devices in the same aircraft, their usefulness is compounded, and the shock of expense softened.

Obviously, the chief reason why airborne methods are particularly suited to Canada is because of the vast expanses over which ground transportation is archaically slow and expensive. Along with the study of aerial photographs and reconnaissance geological information from government maps, information is acquired without the necessity of showing one's hand by staking and attracting competition to the area.

The airborne magnetometer records the magnetic effects of the underlying rocks and is unaffected by overburden or water. Different types of rock have different magnetic effects and thus an aeromagnetic map can be regarded as a specialized type of geological map.

There is still room for considerable improvement in the use of the airborne magnetometer. If costs could be reduced and if lightweight instruments could be developed for use in small aircraft, more of the "tree-top" type of survey would be done to replace ground work. It is on the interpretational side, however, that there is most need for improvement. In the meantime, there is every reason to believe that the magnetometer will continue to be used as it is now — for assisting mapping and for prospecting for iron ore and magnetic pyrrhotite.

Many proponents of airborne geophysics have recently transferred their affections from the airborne magnetometer to the airborne E.M., not because they are dissatisfied with the performance of the airborne magnetometer but rather because they are dazzled by the successes airborne E.M. has had in its short history. Thus airborne E.M. and E.M. in general is considered to be a direct method for locating base metal deposits.

There is evidence already that airborne E.M. will also have possible uses as a means of obtaining geological information under overburden. The history of the airborne scintillation counter in Canada has been fairly well documented. On the whole it has been a disappointment in Canada, especially in the Canadian Shield. In the six years of use, only about fifteen uranium occurrences out of five thousand or more known in Canada were discovered with the airborne scintillation counter. None of these fifteen has proven economic.

With the decrease in costs which will follow the development of lighter-weight equipment, and with the advent of the helicopter, it is predicted that airborne geophysics will be used extensively for more detailed work in the future.

HOW TO RECAPTURE LOST PASSENGER MILES AT A PROFIT

Railway Age, v. 139, n 26, December 26, 1955, p. 23.

The most promising measure now in sight for restoring to the rails passenger-miles and passenger profits is to acquire passenger cars of new designs in the development of which the inhibitions of past practice are abandoned. The goals of the new design are (1) low first cost, (2) reduced operating and maintenance expense, and (3) higher average speeds without excessive top speeds.

In this issue appear the ideas and designs proposed by four railway equipment builders for meeting these objectives. All four emphasize the importance of keeping weight to a minimum — in order to reduce both first cost and operating costs. All four seek a low centre of gravity to permit high average speeds, without discomfort to passengers. In many other respects, the approaches of the four companies differ.

The four current developments for providing light-weight low cost, high-speed railway passenger trains are set forth in detail for critical appraisal. Two employ low-contour, articulated cars, with low centre of gravity, one with dollys under one end of the uncoupled cars. Another has lightweight low-centre-of-gravity cars each carried on two single-axle trucks, but the floor is at approximately conventional height. The fourth employs cars of refined structure, but the bodies are carried on conventional four-wheel trucks and they couple at standard height for interchange with conventional rolling stock. All achieve weights under 1,000 lb. per passenger seat, exclusive of motive power.

Among the trains' features are innovations in heating and air-conditioning equipment. The use of head-end power will have an opportunity for a good workout. The adaptability of air-ride suspension to railroad cars will also be determined. The popularity of several novel methods of dispensing food will be tested.

A year's service will probably be enough to indicate the all-important reaction of the traveling public to the quality of service which these trains can render. It will take longer to appraise fully the ultimate economics of ownership of the new equipment. But radical improvements in railroad passenger service are passing out of the stage of talk and are entering that of concrete experience.

WATER-LUBRICATED WOOD ROLLS BEVEL ALUMINUM

A. F. Schub, *Iron Age,* v. 176, n. 26, December 29, 1955, pp. 68

Valuable production time on a 10-stand progressive rolling machine has been saved by transferring a second aluminum forming operation to home-grown, two-stand equipment. A development of the Douglas Aircraft tool design department, the low-cost machine also eliminates a degreasing operation. Water-lubricated male rolls of laminated wood are used, which with only minor resurfacing, have formed more than a million aluminum aircraft parts to accurate contours.

Costs are reduced even further by conventional design of the two-stand machine, eliminating the need for special parts. Standard parts are used wherever possible to permit interchangeability with other forming machines, and to reduce maintenance. Machine downtime while wood rolls are redressed does not exist, for a duplicate set is built into the equipment.

A CONTROLLED EXPERIMENT IN CONFERENCE LEADERSHIP

William M. Fox, *Advanced Management,* v. 20, n. 12, December 1955, pp. 13

This article gives a report of the results of a controlled experimental study of positive and negative styles of conference leadership, involving four discussion groups and two conference leaders, who were trained in and used the different styles of leadership alternately. The findings indicate that the positive style led to greater satisfaction and acceptance of group solutions and was more effective in changing the attitudes of the participants.

One survey shows that the average executive devotes from one-fourth to one-half of his time to conferences. Yet surprisingly little is known about conference leadership. The typical author who writes in this area usually bases his "principles" upon feelings or hunches which he has derived from limited experience in leading discussions. Although some good practical points can be found in such literature, the general inadequacy of the approach is made clear by the lack of agreement among various authorities.

The value of this training approach is pointed up in the opinions expressed by the discussion leaders at the conclusion of the experiment. They admitted that though they had understood the conceptual distinctions between the two styles of leadership at the conclusion of their leader training, they had definitely doubted the value or utility of these distinctions; but that by the time of their last experimental meetings, as a result of their experience with the groups, the basic importance of the distinctions had become crystal clear.

HOW TO INSTALL PVC PLASTIC PIPE

Heating, Piping & Air Conditioning, v. 27, n. 12, December 1955, pp. 112-116.

Polyvinyl chloride plastic pipe, being rigid, can be installed overhead with pipe supports or underground. Fittings are attached by any of four methods: solvent cementing, threading, heat welding, and adhesives.

Rigid polyvinyl chloride plastic pipe is available in two types: normal impact and high impact. Installation procedures for the two are the same, with but a few exceptions.

The normal impact type, which can be used at temperatures up to 150 F. and at higher working pressures than can the high impact type, is also more resistant to chemicals. However, the high impact type, is recommended where rough handling during transportation and installation is expected and where the properties of the normal impact type are not critical.

In applications where underground installation is required, care should be exercised so that the pipe is not damaged in the laying operation. Ditches should be smooth and regular, so that the localized bending stresses are not imposed. The pipe should be laid below the frost line if water is to be conveyed, since the pipe may fail due to expansion of the water if it freezes. High impact PVC plastic pipe is best suited for most underground applications.

Flow charts are given to assist in the design of polyvinyl chloride plastic pipe lines. For a given flow rate or pressure drop, the most economical pipe size and schedule may be chosen through the use of these charts.

Tables are included for determining maximum operating pressure of PVC plastic type at any temperature, and for maximum allowable operating pressures for high impact type pipes.

VISIT THE ST. LAWRENCE SEAWAY DEVELOPMENT - SPECIAL TRIPS - SATURDAY, MAY 26th

For the benefit of those who are interested visits have been arranged to both the Montreal and International Sections of the Seaway development. Buses will leave the Sheraton-Mount Royal at 9.30 a.m. and will return as follows:

Montreal Section:	1.30 p.m.	Bus Fare — $1.00 per person
Cornwall Section:	7.00 p.m.	Bus Fare — $3.00 per person

Members taking the latter trip who do not wish to return to Montreal will be able to catch the west-bound express at Cornwall at 4.47 p.m. E.S.T.

ATTENTION - MEMBERS! - PLEASE NOTE

Prices for meals include gratuities and provincial tax. Tickets must be obtained in advance and refunds cannot be made less than three hours before any function.

Attendance at social functions will tax all available accommodation. Members are urged to indicate their ticket requirements by completing and mailing advance registration cards well before the meeting. Tickets not paid for will not be held for less than three hours before any function. To ensure admission to all social affairs send remittance for all tickets with advance registration whether from out of town or not!

REGISTRATION

Foyer - Convention Floor

3.00 p.m. to 6.00 p.m. — May 22nd
9.00 a.m. to 6.00 p.m. — May 23rd-25th
*Members $5.00
*Juniors $3.00 — Non-Members $6.00
Ladies, guests of the Institute, speakers, authors and students — complimentary.

*ASME and ARS members will be registered at E.I.C. Member rate.

"MURIEL'S ROOM"

The hospitality of "Muriel" will be extended, as usual, to all registered members, ladies and guests, thanks to the continued co-operation of Canadian industry.

Registration Badges Must Be Worn

All times are Eastern Daylight Saving.

*PROGRAM

Wednesday, May 23rd

9:00 a.m. REGISTRATION - FOYER

10:00 a.m. CHAMPLAIN ROOM

ANNUAL GENERAL MEETING

12:30 p.m. LUNCHEON

SHERATON HALL—
$2.75 per person
Chairman: E. D. Gray-Donald, Chairman, Montreal Branch
Speaker: Dr. R. E. Heartz, President, The Engineering Institute of Canada

2:00 p.m. BALL ROOM
INDUSTRIAL POWER DISTRIBUTION
J. R. Auld, M.E.I.C.,
Supervising Engineer, Power Services,
Du Pont Company of Canada Limited,
Montreal

CHAMPLAIN ROOM
GENERAL DESIGN OF THE ST. LAWRENCE SEAWAY — MONTREAL AREA
D. M. Ripley, Jr.E.I.C.,
Senior Assistant Engineer, Hydraulics,
St. Lawrence Seaway Authority,
Montreal

BRITTANY ROOM
APPLICATION OF WELDED DESIGN TO HYDRAULIC TURBINE AND VALVE MANUFACTURE
J. G. Warnock,
Head, Hydraulic Department,
English Electric Company Limited,
St. Catharines, Ont.

3:00 p.m. BALL ROOM
THE GROWTH AND DEVELOPMENT OF LARGE ELECTRIC POWER SYSTEMS
W. R. Way, M.E.I.C.,
Vice-President and Chief Engineer,
Shawinigan Water and Power Company Limited, Montreal

CHAMPLAIN ROOM
THE USE OF HYDRAULIC MODELS IN THE ST. LAWRENCE SEAWAY DESIGN
Duncan McIntyre,
Senior Assistant Engineer,
Hydraulics,
St. Lawrence Seaway Authority,
Montreal

BRITTANY ROOM
THE KAPLAN TURBINE IN CANADA
G. D. Johnson, Mem. ASME.,
Chief Hydraulic Engineer,
S. Morgan Smith Company,
York, Pa.

4:00 p.m. BALL ROOM
THE CROSS-ROPE SUSPENSION SYSTEM OF THE KEMANO-KITIMAT TRANSMISSION LINE
H. B. White, M.E.I.C.,
Power Transmission Engineer,
Aluminum Company of Canada Limited, Montreal

CHAMPLAIN ROOM
THE MECHANICAL DESIGN FEATURES OF THE ST. LAWRENCE POWER PROJECT
Otto Holden, M.E.I.C.,
Chief Engineer, and
P. Pemberton-Piggott,
Assistant Mechanical Engineer,
Generation Department,
Hydro Electric Power Commission of Ontario, Toronto

BRITTANY ROOM
LATERAL RIGIDITY OF BUILDING FRAMES
J. L. de Stein, M.E.I.C.,
Associate Professor, and
J. O. McCutcheon, M.E.I.C.,
Assistant Professor,
Department of Civil Engineering,
McGill University, Montreal

6:15 p.m. COMPLIMENTARY BUFFET SUPPER
Courtesy the City of Montreal
THE CHALET, MOUNT ROYAL

6:30 p.m. ADDRESS OF WELCOME
His Worship, Mayor Drapeau

7:00 p.m. REFRESHMENTS -
Courtesy of "MURIEL"

8:00 p.m. BUFFET SUPPER

Badges Must Be Worn

Buses will leave The Sheraton-Mount Royal Hotel for The Chalet at 5:45 p.m. and return at approximately 9.30 p.m. Bus tickets must be purchased in advance — Price $1.00 per person.

HOTEL ACCOMMODATION AND TRANSPORTATION

The Sheraton-Mount Royal is the headquarters hotel and all meetings and functions will take place there unless noted otherwise. All those planning to attend are urged to make requests for room reservations as early as possible. If desired accommodation is unavailable, delegates will be assigned to the next best that can be obtained. Unaccompanied delegates should indicate whether they will be prepared to share twin-bedded double rooms. It is most satisfactory of course if such sharing arrangements can be worked out in advance and indicated on the application for reservations.

All requests for convention reservations should be addressed to:—

THE GENERAL SECRETARY, THE ENGINEERING INSTITUTE OF CANADA,
2050 MANSFIELD STREET, MONTREAL 2, QUE.

Reduced convention fares have been authorized for rail travel in Canada. A special fare certificate will be mailed to you from headquarters if requested on your registration card. This entitles you and members of your family to round-trip tickets at one and one-half times the one-way fare plus twenty-five cents.

Trans-Canada Air Lines have special family and group rates. Your local T.C.A. agent will gladly supply details.

No matter how you travel, be sure to make your reservations now to avoid disappointment.

***Subject to minor changes.**

9:00 a.m. BALL ROOM
A RAPID ANALYTICAL METHOD FOR CALCULATING THE EARLY TRANSIENT TEMPERATURE IN A COMPOSITE SLAB
W. F. Campbell, M.E.I.C.,
Senior Research Officer,
Division of Mechanical Engineering,
National Research Council,
Ottawa.

CHAMPLAIN ROOM
BERSIMIS POWER DEVELOPMENT
F. P. Rousseau, M.E.I.C.,
Chief Engineer, Power Development Division,
Quebec Hydro Electric Commission,
Montreal

BRITTANY ROOM
AIR POLLUTION CONTROL PROBLEMS
E. A. Allcut, M.E.I.C.,
Head, Department of Mechanical Engineering, University of Toronto,
Toronto

SALON J
THE METAL BONDING OF AIRCRAFT ASSEMBLIES
J. J. Waller,
Chief Materials and Process Engineer,
Canadair Limited, Montreal

10:00 a.m. BALL ROOM
THE TRANS-CANADA RADIO RELAY TELEPHONE SYSTEM
A. J. Groleau, M.E.I.C.,
Area Chief Engineer,
Bell Telephone Company of Canada Limited, Montreal

CHAMPLAIN ROOM
SURVEY OF THE HAMILTON RIVER
E. N. Webb, M.E.I.C.,
Consulting Hydro Electrical Engineer,
British Newfoundland Corporation Limited, Montreal

BRITTANY ROOM
CURRENT DEVELOPMENTS IN AIR POLLUTION IN THE UNITED STATES
L. C. McCabe, President,
Resources Research Incorporated,
Washington, D.C.

SALON J
THE CHALLENGE OF PROGRESS
R. C. Sebold,
Vice-President, Engineering,
Convair Division,
General Dynamics Corporation,
San Diego, Cal.

11:00 a.m. BALL ROOM
CO-OPERATIVE RESEARCH IN THE BRITISH ELECTRICAL INDUSTRY
Jerzy Miedzinski, A.M.I.E.E.,
Development Engineer,
Department of National Defence,
Navy, Ottawa

CHAMPLAIN ROOM
MECHANICAL SERVICES IN A MODERN BREWERY
R. E. J. Layton, M.E.I.C.,
Chief Mechanical Engineer,
T. Pringle & Sons Limited,
Montreal

BRITTANY ROOM
THE CONTROL OF AIR POLLUTION IN ENGLAND
S. G. G. Wilkinson,
Ministry of Housing and Local Government, London, England.

SALON J
PROJECT VANGUARD — THE IGY EARTH SATELLITE
F. R. Furth, Rear Admiral,
United States Navy,
Naval Research Laboratory,
Washington, D.C.

1:45 p.m. CANADAIR VISIT AND AIR SHOW - Cartierville, P.Q.
Buses will leave The Sheraton-Mount Royal at 1:45 p.m. and return at approximately 6:00 p.m.
Bus tickets must be purchased in advance — Price $1.00 per person.
Badges Must Be Worn

6:45 p.m. ASSOCIATION OF CONSULTING ENGINEERS OF CANADA
ANNUAL DINNER
SHERATON HALL
Chairman: J. G. Chenevert, M.E.I.C.
Speaker:
(Tickets obtainable from Association or E.I.C. registration desk)

8:00 p.m. BRITTANY ROOM
JUNIOR PANEL DISCUSSION — WHAT CAN A YOUNG ENGINEER DO IN DEVELOPING PROFESSIONALLY?
Co-Chairmen: N. J. Viehmann, A.M., ASME, Jones and Lamson Machine Company, Springfield, Vt.
G. L. MacLean, Jr.E.I.C., Foundation Company of Canada Limited, Montreal

8:30 p.m. INFORMAL RECEPTION
E.I.C. HEADQUARTERS
2050 Mansfield Street

***LADIES' PROGRAM**
Morning coffee: 9:30 a.m. daily — Salon B
Wednesday, May 23rd, 11:00 a.m.
Montreal Museum of Fine Arts
Tour of Museum followed by lunch and Fashion Show by Doreen Day — $1.50 per person.
Friday, May 25th, 10:00 a.m. City Bus Tour and visit to Botanical Gardens — $1.75 per person.

9:00 a.m. BALL ROOM
AUTOMATION, MEN, AND MACHINES
J. J. Brown, Consulting Engineer, Montreal

CHAMPLAIN ROOM
A PROGRESS REPORT ON CANADIAN ATOMIC POWER
I. N. MacKay, M.E.I.C., Manager, Engineering Civilian Atomic Power Department, Canadian General Electric Company Limited, Peterborough, Ont.

BRITTANY ROOM
HIGH SPEED PHOTOGRAPHY IN CHEMICAL ENGINEERING
A. I. Johnson, Professor, Department of Chemical Engineering, University of Toronto, Toronto

10:00 a.m. BALL ROOM
AUTOMATING THE ENGINEER'S TASK
Josef Kates, President, K. C. S. Data Control Limited, Toronto

CHAMPLAIN ROOM
EXPERIMENTAL WORK ON COAL BURNING GAS TURBINES
D. L. Mordell, M.E.I.C., Chairman and Professor, Department of Mechanical Engineering, McGill University, Montreal

BRITTANY ROOM
MODERN ALLOYS FOR INDUSTRIAL USE ABOVE 1200 DEG. F.
J. P. Ogilvie, M.E.I.C., Shawinigan Chemicals Limited, Montreal

11:00 a.m. BALL ROOM
HOW THE MACKINAC BRIDGE WAS DESIGNED FOR AERODYNAMIC STABILITY
D. B. Steinman, M.E.I.C., Consulting Engineer, New York, N.Y.

CHAMPLAIN ROOM
200,000 KW REHEAT BOILER DESIGN FOR ONTARIO HYDRO COMMISSION
F. W. Cranston, Babcock-Wilcox & Goldie-McCulloch, Limited, Galt, Ont., and
M. G. Ireland, Assistant Contract Manager, Babcock & Wilcox Company, Barberton, Ohio

BRITTANY ROOM
MOVING-BED PROCESSES
E. H. Lebeis, Catalytic Construction Company, Philadelphia, Pa.

12:30 p.m. ASME LUNCHEON
SHERATON HALL —
$2.75 per person
Chairman: G. Ross Lord, Chairman, Ontario Section ASME.
Speaker: J. W. Barker, President, American Society of Mechanical Engineers.

2:00 p.m. BALL ROOM
LONG RANGE PLANNING IN AN ATOMIC AGE - MANAGEMENT PANEL DISCUSSION
Chairman: L. F. Urwick, C.I.Mech.E., Mem. ASME., Management Consultant, Urwick Currie Limited, Montreal

CHAMPLAIN ROOM
MASS TRANSPORTATION IN CITIES — A TRAFFIC PANEL DISCUSSION
Chairman: George S. Mooney, Director, St. Lawrence Municipal Bureau, Montreal.

3:30 p.m. CHAMPLAIN ROOM
Special Lecture
THE APPLICATION OF CENTRALIZED RESEARCH AND EDUCATIONAL SERVICES TO IMPROVE PRODUCTION ECONOMY
D. F. Galloway, M.I.Mech.E., Director, Production Engineering, Research Association, Melton-Mowbray, England.
Chairman: J. W. Barker, Mem.ASME., President, American Society of Mechanical Engineers

6:30 p.m. RECEPTION - CHAMPLAIN ROOM

7:15 p.m. THE ANNUAL BANQUET
$5.50 per person (including dance)
BALL ROOM
Chairman: Dr. R. E. Heartz, M.E.I.C., President of the Institute
Speaker: Dr. David L. Thomson, Vice-Principal and Dean of the Faculty of Graduate Studies, McGill University, Montreal
Presentation of Medals and Prizes and introduction of the new president, V. A. McKillop and new members of Council.

9:00 p.m. ANNUAL DANCE
CHAMPLAIN ROOM -
$2.50 per person (Dance only)
(Dress Optional)

9:00 p.m. RECEPTION
There will be an informal reception after the banquet when members and guests may meet the incoming and retiring presidents, distinguished guests, the Chairman of the Montreal Branch, and their wives.

PRINTED IN CANADA

Engineering Institute Brief to the Royal Commission on Canada's Economic Prospects

Institute Asks for a Complete Study of Needs for Engineering Education

Some time ago the president on Council's instruction appointed a small committee to prepare a brief for the Royal Commission on Canada's Economic Prospects. The committee consisted of E. B. Jubien, chief engineer of Dominion Textiles, R. F. Shaw, vice-president of the Foundation Company Limited and G. N. Martin of the Dominion Bridge Company, a councillor of the Institute and chairman of the Publication Committee.

The brief was presented to the Commission in Ottawa on March 8. It had been arranged that the presentation would be done by the president, accompanied by Mr. Martin and the general secretary. Unfortunately, the date selected corresponded with one of eastern Canada's worst blizzards, and the president was unable to get to the airport or the railway station in Montreal, hence the presentation was made by the general secretary.

The brief was introduced by some general observations and was backed up with four documents which amplified and emphasized the statements made in it.

The supporting documents were (1) a letter from Rt. Hon. C. D. Howe, HON.M.E.I.C., (2) an article by Dr. C. R. Young, HON.M.E.I.C., reprinted from the March 1944 *Engineering Journal* (which will be printed again in the *Journal* under instructions of Council) titled "The Desirability of Establishing Technical Institutes in Canada," (3) the article "The Tide and the Crisis" by Dr. G. E. Hall of the University of Western Ontario, which appeared in the December 1955 *Engineering Journal,* and (4) a paper by Rear Admiral Hyman G. Rickover of the U.S. Atomic Energy Commission titled "Engineering and Scientific Education", which appears in this issue of *The Engineering Journal.*

The brief and the introductory remarks follow.

Introduction

Mr. Chairman and Gentlemen:

Thank you for this opportunity to appear before your important body. The breadth of the field which you have been called upon to study is so great that one may well wonder just what he can do to help toward the accomplishment of your task.

Our story as told in our brief is a simple one, but we think it deals with the most important single element in the equation which you will have to find in order to solve the problems of "Canada's Economic Prospects". This element is manpower — trained manpower.

Our brief does not labour any point. We do not try to tell you how to solve the problem, but simply how to approach it. We have studied the problem too long to believe that the answer is an easy one, or that one person or group has the whole answer, but we do recommend that something sensible be started now so that we will not always be in our present confused state of mind. We feel that your Commission is the one to point the way with clarity and emphasis.

We have noticed that a great many briefs presented to you have emphasized the need of more engineers and scientists, and more well-trained technicians. Apparently most of those who have appeared before you are agreed on it. This has pleased us greatly and we hope it will give the Commission further encouragement to bring forward a far-reaching recommendation.

The Institute has been asked by some of the university authorities to undertake a study such as we are now recommending to the

The Introduction is continued on page 446. The Brief is on page 442.

The Royal Commission on Canada's Economic Prospects

Gentlemen:

1. The purpose of this presentation is to discuss with the Royal Commission, one of Canada's most serious shortages in resources. We refer to manpower, and in particular to one segment of it i.e. engineers, scientists and technicians.

2. The terms of reference of the Commission include more than one reference to a field in which engineers may be the most important element. It seems appropriate that in any study of "Canada's economic prospects," the supply of engineers and scientists should be considered. No other human element will be effective as the engineers in "the supply of raw material and energy resources," in extension "of productivity", and in meeting "the prospective requirements for industry".

3. It is not necessary for us to submit proof of the shortage of engineers, scientists and technicians. That is now a self evident fact, that can be denied by no one who is informed and who regards the situation objectively. However, the present and potential seriousness of the shortage, in terms of "Canada's economic prospects" does merit the presentation of some facts and some recommendations.

National Defence

4. The most important consideration is that of national defence. We do not wish to appear to be hysterical, but we are concerned about prospects for the future. Russia continues to be a threat, and the fear of that threat increases daily, with the rapidly increasing number of engineers and scientists being educated and trained there.

5. British scientists who visited Russia last summer turned in a startling report—by 1960 Russia would have between 2 and 3 million engineers and scientists, the quality of the training was high, and the top men were at least as good as the top men in the United Kingdom and the United States. In a single generation this nation has risen from the most lowly to the highest in these fields.

6. Why has Russia done all this? In order to excel! Just to what extent she wants to excel, it is hard to tell, but we can be sure she wants to excel in trade at least. Many people believe that she wishes to dominate the world. To do this she is building up the greatest army of technically trained persons that the world has ever known. She believes that such personnel are the means of reaching her objectives.

7. These tactics should both disturb and inspire us. If we are to realize our own destinies, we must not sit by quietly, while these developments take place before our eyes. We must join with others in preparation for the future. As far as we are concerned this means more engineers, more scientists and more technicians.

Natural Resources

8. Canada is blessed with the greatest gift of undeveloped natural resources of any nation in the world. The two things most essential to their development are money and men — technically trained men. Without these men the resources are without value. If the present shortage is allowed to continue, the full use of the resources is denied us. To develop Canada we must have more technically trained people.

Industry

9. It is hard to tell which section of Canada's activities is hardest hit by the shortage in technical manpower, but there can be no doubt that industry is indeed suffering. The Engineering Institute operates an employment service for its members and employers. This is an excellent medium through which to follow the nation's industrial development. We have more job vacancies and fewer applicants than ever before in our history. Even positions offering up to $25,000 a year are hard to fill. Right now we have one opening of $40,000 and we have not yet found the man for it.

10. The design and building of new plants and the extension of existing ones, is being delayed in many instances because of the shortage of design engineers. Consulting engineers have told us that they have had to decline invitations to design plants and industrial buildings, highways and bridges because they could not find additional engineers to enlarge their design staff. Most definitely, Canada's industrial development is being retarded by such shortages.

11. No one can tell exactly how many should be trained, but according to the now famous Sheffield report, in ten years' time the university population will have doubled. Assuming that the same proportion continue to enter the sciences, it is evident that the present facilities will be completely inadequate. The likelihood is that a greater proportion

will go in for science. What are we going to do about it?

Facilities of Education

12. More facilities and more staff will have to be provided. This includes universities, technical institutes and high schools. The staff problem will be the more difficult one to solve, but it must be solved. More people must be trained for teaching and all must be given a remuneration commensurate with their importance, and more nearly in line with that offered by industry for such services. Canada appears to be the only nation that pays its university teachers substantially less than they could obtain from other employers (see—Survey of National Research Council). Any further extension of such a policy will be ruinous to our future.

13. Up until a year or so ago, it was possible to get some real help in our difficulties, by employing European engineers, but this source is now dried up. We now face a situation where we will have to "grow our own". It becomes increasingly evident that a great effort has to be made in Canada by Canadians.

Finances

14. It is plain that more money must be made available for education in addition to the natural increase in the volume of fees. For engineering, fees pay only forty per cent of the cost. It is evident that the money must come from outside the university. It seems equally evident that a substantial portion of it must come from government. We believe the federal government has a real responsibility here.

The Cost

15. It is always interesting to know what a proposal adds up to in dollars and cents, but there is no way of which we are aware, whereby even approximate figures can be obtained for all of Canada that would include extensions to existing universities, the building of new institutions, additional equipment and new staff. However, it is not necessary now to have such figures. They can be developed when they are needed.

16. Plans should be made at least to double the present number of graduates. No matter what this costs it will be modest in terms of benefits derived. Today's expenditure for university education is lamentably small. We spend more on recreation than we do on education. We spend more than twice as much to keep a criminal in custody as we do to educate a free man at a university. Without a murmur we hand out more to take care of a mentally deficient person than we do to educate a mentally efficient one. We spend more than twice as much on carbonated beverages and about three times as much for alcoholic beverages as we do for a university student. Truly our sense of values is badly distorted. Isn't it time we did something about it?

17. It would be futile for the Institute to attempt to state before the Commission just how the situation should be met. To find the full sensible solution will require an exhaustive study by persons concerned with the answer, and competent to locate and evaluate evidence. There is much urgency about this matter, but enough time should be given to it to find the one best answer. This is no time for half measures or mistakes.

18. The Engineering Institute of Canada has considered the problem for several years. Discussions with university presidents, deans of engineering, faculty members and employers right across Canada, and in the United Kingdom and the United States as well, have given us an insight into the situation and have left us with a sense of urgency. This brief is not the place to go into details, but if at any time our knowledge of conditions and our opinions may be helpful to your Commission or to departments of the government, we shall be happy to collaborate.

Further Proof

19. Rather than lengthen this brief with arguments and proof, we are attaching some documents which give emphatic and colourful support to the things we have said. We are confident you will find them interesting and helpful. They are (a) a letter from the Right Hon. C. D. Howe, HON.M.E.I.C., Minister of Trade and Commerce and of Defence Production, (b) a paper by Dr. C. R. Young, HON.M.E.I.C., Dean Emeritus of the Faculty of Applied Science and Engineering, University of Toronto, and a past president of The Engineering Institute of Canada, (c) a paper by Dr. G. E. Hall, President and Vice-chancellor, the University of Western Ontario, (d) an address by Rear Admiral H. G. Rickover of the United States Atomic Energy Commission.

20. The problem of technical education is a complex one, the solution of which will require more money and more collaboration between government, educators and employers. As we have said we are not now attempting to present details although they are known to us. We feel that our proposal to the Commission should be clear and simple, and that details should be reviewed later.

21. Believing that a great share of the responsibility of meeting the problem belongs to the federal government, *we recommend with a sense of urgency that your Commission propose to the federal government, the creation of a body to study the problem immediately so that a realistic program may be developed with a minimum loss of time.*

R. E. Heartz, M.E.I.C.,
PRESIDENT

L. Austin Wright, M.E.I.C.,
GENERAL SECRETARY

The Engineering Institute of Canada

March, 1956

The Desirability of Establishing Technical Institutes in Canada

by

C. R. Young, M.E.I.C.

Dean of the Faculty of Applied Science and Engineering, University of Toronto

Past-President of the Engineering Institute of Canada

A memorandum submitted to the Council of The Engineering Institute of Canada on February 9th, 1944. Council approved the proposal and has since taken steps to initiate action through the provincial departments of education.

The Need for Technical Institutes

One of the present obligations of the educational authorities and institutions in this country is to direct their resources towards a speedy and sound re-establishment of men discharged from the forces or released from war industry. A forward-looking and realistic technical educational program ought to form an important part of the general scheme of rehabilitation. The faculties of engineering of the universities will, no doubt, do their share, but they are properly restricted to the professional field. It is therefore necessary that steps be taken under provincial auspices, but perhaps with federal support, to provide essential training to many men with technical aptitudes who either could not qualify for admission to a university or could not spend four more years of their lives in obtaining an education for a livelihood. Some plan should be devised whereby men without professional ambitions could have their needs satisfied in institutions giving a training above the ordinary vocational level but less advanced than that offered by the engineering colleges. Minimum qualifications for admission would naturally have to be less than complete university matriculation and might in some instances have to rest chiefly on personal capacity and interest, supplemented perhaps by assurances of future employability in technical pursuits.

Consideration of technical education in Canada clearly indicates a serious gap in it above the secondary school level and below that of the degree-granting engineering faculties and colleges. The universities, as the sole type of institution above the ordinary or vocational high school, cannot possibly serve adequately all of the needs of the country in the matter of advanced training of technical personnel and any attempt at doing so is bound to be unsatisfactory both to those seeking training and to the universities themselves. Experience in the United States, in Great Britain, and on the continent, has shown that the whole fabric of technical education is strengthened and marked public benefits realized from the establishment of an intermediate type of institution commonly designated as the "technical institute".

Employment of Technical Institute Graduates

It is of importance to note that in the United States renewed emphasis is now being placed on the work of the technical institutes. Much of the technical training to be made available for men discharged from the forces and released from war industry will be given by them. As an evidence of the growing activity expected in this field, eight technical institutes are projected for New York State, to be built as part of the post-war construction plan and turned over to the State for operation.

While the graduates of engineering colleges look to professional employment involving investigation of the scientific and economic features of undertakings and are concerned with devising what are often original methods of analysis, design, construction, manufacture, or operation, the graduates of technical institutes are for the most part concerned with repetitive activities associated with production, operating or maintenance procedures. Graduates from the latter type of institution constitute the "line" side of an organization, as contrasted with the "staff" side, which is generally recruited from the graduates of professional schools.

Technical institute graduates very often limit their interests to, and are trained for, particular industries. Their duties are normally of a supervisory character, but may include minor technical functions such as drafting, design of details, laboratory testing, inspection, construction in the field, or the technical aspects of sales work.

Careful studies made in the United States indicate that the technical institute graduates required by industry represent from 2.2 to 3.0 times the number of graduates required from the professional schools. These two groups are related in much the same way as are non-commissioned officers and commissioned officers in the army.

Types of Technical Institute Students

Technical institutes serve more effectively than the engineering colleges the following types of young men:

(1) Those who have had industrial experience and have already chosen a vocation upon which they wish to embark with the least possible loss of time.

Dr. C. R. Young, HON.M.E.I.C., is now Dean Emeritus of the Faculty of Applied Science and Engineering of the University of Toronto.

(2) Those who have passed the state of "book-mindedness" and whose mental learning processes centre on actual doing rather than on formal study.

(3) Those who, for financial or other reasons, cannot devote four years to preparation for remunerative employment.

(4) Those who, having practical rather than intellectual interest, have had to leave college before progressing very far.

(5) Those whose educational qualifications would not admit them to a university.

General Characteristics of Technical Institutes

While great diversity exists in the character and practices of the presently-operating technical institutes, they nevertheless exhibit certain well defined general characteristics. The courses offered are shorter and more practical than those available in the professional schools. While courses in the latter develop the specialized functions of research, analysis, design, and new production or operating procedures, the work of a technical institute is centered upon and seeks to rationalize the higher practical pursuits of industry. Students of the latter learn by doing rather than by studying and there is much less emphasis on independent study than in the universities. The mathematical and physical sciences are not taught as independent disciplines, but in intimate and very direct and practical connection with their technical applications.

The length of technical institute courses varies from one to four years, the most common being two years. Under favourable aspects, two years of intensive practical work with a sound grounding in the underlying sciences will result in a high employability of the graduate.

Three broad types of training are offered in technical institutes: — (1) generalized engineering courses, (2) technology of particular industries, (3) functional courses.

Experience has shown that there are innumerable positions in industry for the efficient occupancy of which a wide range of scientific or technical knowledge is not necessary. Many of these are conventionally classed as belonging to engineering and many open paths to posts of high responsibility in producing and operating organizations. The technical requirements of such positions can be adequately met by an intensive type of engineering training from which the more advanced scientific features are omitted. To meet this situation, so-called generalized engineering courses have been established in some of the technical institutes.

In the generalized engineering courses a strong effort is made to present basic science and technology that would be useful in any one of a variety of industries. Some of the subjects taught are mathematics, physics, chemistry, mechanics, engineering drawing, descriptive geometry, electricity, and materials of construction. To these there may appropriately be added industrial relations, sociology, industrial safety, and industrial law. The generalized engineering course in a technical institute parallels the engineering courses in the universities but represents an abridgment of them. The material is presented in a more practical form and in a manner not demanding of the student any marked attainments in mathematics or in theoretical science.

Many technical institutes offer courses in the technology of particular industries, often with a definitely local application. Some of the most successful of these institutions have grown out of the idea of service to one or more important local industries. An application of this principle in Canada might well be advantageous.

Some technical institutes offer what are called functional courses. These pertain to such activities as quantity surveying, textile designing, power plant management and operation, management, and general supervision.

The co-operative plan has been found particularly helpful in extending the usefulness of technical institute work. Under this, the student alternates between study in the institute and employment in industry. His experience and practical qualifications increase in parallel with his theoretical knowledge.

Although degrees cannot be granted on the completion of the typical short, practical courses offered by the technical institutes, it is highly essential that some form of certification should be adopted through which the graduate would be able to establish his qualifications. This has been admirably worked out in Great Britain. A scheme of examinations and credentials has been developed under the joint auspices of the English and Scottish Boards of Education and a group of professional institutions. *National Diplomas* are given for successful examinations following full-time day courses, and *National Certificates* for examinations following evening and part-time courses.

In order to guard against an effort by anyone to attain professional recognition without the prerequisite training, a clear understanding should be reached by those sponsoring technical institutes with the Provincial Associations of Professional Engineers respecting the attitude of the latter to applications for admission from technical institute graduates. Credentials obtained from a technical institute might be acceptable in lieu of part at least of the examinations required of non-graduates of professional schools for admission to the associations. The difference in required practical experience for the two types of graduates should be determined at the outset.

Relation of Technical Institutes to the Universities

Experience has shown that it is not practicable for a degree-granting engineering college itself to attempt parallel technical institute activities on the same campus, under the same administrative and teaching direction, and during the same operating hours. No experiment of this kind has so far succeeded. Under such circumstances, the technical institute is soon regarded as a salvage mechanism for failures, culls and misfits. Students in the short courses are not accorded the full privileges of regular students in campus activities and organizations. Unconsciously, but nevertheless almost inevitably, the staff comes to favour the longer course, to the very great prejudice of the technical institute work and to the detriment of the morale of the institution as a whole. No such undesirable situation exists if the technical institute has its own administration, its own instructors, its own quarters, and its own particular policies and ideals, freed of any invidious comparison with institutions giving professional courses.

From the point of view of the engineering faculty or college the superposition of aims and objectives is undesirable. The colleges must protect their standing with the professional societies and accrediting agencies. They must insure that industry places definite value on their credentials. One standard of admission, one general level of work, and one grade of credentials are essential. It is not practicable to arrange the curriculum of an engineering college in such a manner that attendance of one, two, or three years would constitute adequate and final educational preparation for different types of technical employment. Many years ago, the German technical universities attempted this plan and had to abandon it in favour of different types of schools for different callings.

Credits toward a University Course

Experience has shown that it is difficult to arrange automatic credits for students who complete technical institute courses and desire to enter engineering colleges with a view to obtaining professional training. The two types of programs are widely different. To obtain the greatest success, the methods of teaching should correspondingly differ.

A dominating principle in the technical institute work has been that the courses are of a "terminal" character. It consequently appears impracticable to admit graduates of technical institutes at any higher level than the first year, except in special cases. The difficulty arises in the fact that the so-called theoretical courses have by intention been made very different in content in the two institutions. In most cases, technical institute men have had neither the amount nor the type of mathematics that would serve as a prerequisite for the more advanced engineering subjects and for which the colleges will allow any considerable credit, however purposeful or useful the content or giving of the instruction has been. Graduates of the technical institutes would, on their part, often experience disappointment in being asked to start over again far down the line. They could scarcely escape a feeling of repetition, waste of time, discouragement, or even embarrassment.

While any regular plan of admission of technical institute graduates to advanced standing in the engineering courses appears to be impracticable, exceptional men, having higher educational qualifications than most technical institute students have, might be admitted to the professional schools above the first year. The possibility of this would prove highly attractive to young men thinking of entering a technical institute. Undoubtedly, it would be in the public interest for the universities, possibly in co-operation with the Department of Education for the province concerned, to arrange suitable "bridging" courses for facilitating such transfers.

Advantages of the Technical Institute Plan to the Universities

Due to the comparative absence of technical institutes in Canada the engineering colleges have, in effect, been forced to conduct two over-lapping types of training. Primarily, the courses offered are designed for men seeking professional qualifications and capable of acquiring them. At the same time, however, there are, in every engineering college, appreciable numbers of students who can hope to attain only a general education or a sub-professional status. Their capacity, or interest, does not enable them to keep pace with the majority of their classmates. As a result, they waste their time and in some measure, hamper the training of the better students. Actually, their own interests are ill-served and industry is by no means a gainer in the process. It must be admitted, too, that a very substantial part of the demand for technical personnel could be filled by technical institute graduates with a greater continuity of service and often with greater immediate satisfaction to the employer.

The concensus of opinion amongst persons long experienced in educational matters is that strictly professional education would be advanced, the engineering colleges would be greatly relieved, and their primary objectives brought nearer, if those students whose interests are practical and vocational rather than professional were to seek their training in an institution of the type of the technical institute.

Suggested Action

It is my belief that both education and industry would be notably served if, with the sponsorship of the provinces, a number of technical institutes were immediately established so as to be available for qualified demobilized men and displaced war workers as soon as they are free in substantial numbers.

Introduction to Brief to The Royal Commission

(Continued from page 441)

Commission. Some preliminary study had been done before the announcement was made of the appointment of this Commission. It was decided to withhold further action in the hope that the Commission would find that an adequate supply of engineers and scientists was inextricably and basically involved in any attempt to evaluate "Canada's Economic Prospects".

At the latest meeting of the Council of the Institute funds were voted to finance an engineering education conference, to which would be invited the deans of engineering and members of their staff. The preliminary arrangements are already under way and it is proposed to continue, inasmuch as the details of education itself are not likely to come within the terms of reference of the Commission, but the availability of funds to supply buildings, equipment and personnel would seem to be appropriate to your field of interest.

In this way the Institute hopes to have a part in planning the future of Canada. We feel it will be most advantageous to have the studies on engineering education completed in time to be integrated into this expansion program which should follow the report of the Commission.

The Institute's study of the subject and our facilities from coast to coast are at the service of your Commission, or any body that succeeds to your responsibilities. We are a national body with a strong sense of national responsibility in this matter. We have no personal "axe to grind". We just happen to believe that more properly trained people are going to be needed as time goes on, and that the only way to meet today's desperate situation and to attack tomorrow's, which will be even worse, is to do something about it now. We believe your Commission is the body to start it. We hope you will agree with us.

Engineering and Scientific Education

by

Rear Admiral Hyman G. Rickover, USN

Chief, Naval Reactors Branch, U.S. Atomic Energy Commission

and

Assistant Chief of the Bureau of Ships for Nuclear Propulsion

Head of the atomic-powered submarine projects, the Nautilus *and the* Seawolf

Address given to the Sixth Thomas Alva Edison Foundation Institute on "The Growing Shortage of Scientists and Engineers", November 21-22, 1955

For the last eight years my work has been in the field of nuclear power. In dealing with the problems involved in developing this new source of energy, I have found them to be but one facet of a much larger problem — how to provide the trained men and women to maintain the momentum of our rapidly expanding technical civilization. You are all aware that our explosive population growth has placed a tremendous strain on the resources — human and material — of our educational institutions. There are just not enough good teachers and schoolrooms to give each child the opportunity to develop his capabilities to the fullest.

I consider the present crisis in education as grave a problem as any that faces our country today. Unless it is dealt with promptly and effectively the machinery which sustains our level of material prosperity and political power will begin to slow down and we will be in danger of losing the cold war by default. Let me illustrate this with a few figures:

First, the United States has doubled its population in the past fifty years and is expected to double it again by the end of the century.

Second, with only seven per cent of the world's population and eight per cent of the land area, the United States is today responsible for more than half the world's production.

Third, to maintain our relative position in the world economy and to preserve our high standard of living, American industry must — ten years from now — produce forty per cent more than it does today.

The use of electric power, for example, is expected to quadruple in the next twenty-five years. Or take minerals and most mineral fuels: the United States has used up more of these in the last thirty years than the entire world did in all of history before 1914. A similar growth in consumption in the next thirty years cannot occur unless we make profound changes in technology.

Experiment or Perish

Our accelerated increase in production over the past century has been due to the efforts of but a small number of companies. Only one per cent of all the businesses in existence a hundred years ago are still alive today. And in a recent study by the Brookings Institution it was shown that only thirty-eight of the one hundred largest industrial companies existing in 1909 are still in business today. The companies which survived are those which have been willing to experiment, to take risks, to innovate, to break precedent. Their managements have anticipated and helped to bring about the very changes which caused their less astute or less courageous competitors to slip back. These companies hold their place in a world of change. The top is a slippery place.

The same holds true for nations; like industrial organizations, they will decline if they are not continually alert to the needs of the future. The law of life for industrial organizations and for nations is the same: "adapt or perish." The industrial, and hence the political power of nations is dependent in large part on their scientific and engineering professions, and these in turn depend on a continuous inflow of capable and well-trained individuals. In other words, a nation progresses or falls back in the race for survival to the degree that it succeeds or fails to afford each individual citizen the maximum opportunity for education and training.

An essential function of leadership, in the government of nations as in the management of industries, is to plan for the future. What we do today was largely determined for us by the vision and action of those who preceded us. Likewise, tomorrow's events will depend on what we plan and do today — on the wisdom we use in planning for the future. Perhaps the most insidious weakness a nation can have is the belief, fostered by propaganda of one kind or another, that it can do everything better than other people. We in this country are subjected to this kind of propaganda in various media — such as the slick advertisements of magazines — week upon week, month upon month. We overlook what we do not hear much about, especially if it is unpleasant.

Unpleasant Facts

One of the unpleasant facts which has but recently been mentioned is that in the field of scientific and engineering education our main competitor — Russia — is speedily passing us. According to the best estimates, the United States now has about 800,000 engineers and scientists — Russia 650,000. Disturbing as this is, it is insignificant as against the rate with which she is increasing her engineering and scientific talent compared with us. In 1954 she graduated more than 50,000 engineers and scientists; we graduated 23,000. Mr. Allen Dulles, the Director of our Central Intelligency Agency, has stated that between 1950 and 1960 Soviet Russia will have graduated 1,200,000 scientists and engineers, compared with 900,000 in the United States in our present program. Thus by 1960 it is estimated she will have more engineers and scientists than we; moreover, the rate of attrition in Russia is lower than ours because of lower age.

Some may argue that Russian engineers are not technically as well trained as ours. This is not the case. It is true that they are trained in engineering exclusively and at the cost of their general education. Further, their engineering training is confined to narrow specializations. This is so because the Soviet educational philosophy is based on the premise that the purpose of education is to train the individual for the particular purpose the state requires.

You know what kind of a job the Russians have done on jet engines, radar, long-range bombers, and atomic weapons. Their industrial production has quadrupled in the last fifteen years.

The Clear Trends

The Russian approach to education is a total approach. They are educating as many women as men, and women constitute one-half of the total in the professions. In contrast, in the United States this is but a fraction of one per cent. Can we continue to neglect so large a potential of trained personnel ?

While our mass production system will permit us, for the time being, to build more things faster than Russia, their engineers may soon, by their very numbers, invent better machines. In rate of progress they are, in fact, already ahead of us. We must not take for granted our present technological leadership.

There are some who believe that the United States is not even graduating enough trained people merely to sustain our present rate of technical expansion beyond the year 1970. What is certain is that unless the number of our scientists and engineers increases at an accelerated rate our economy will be in serious trouble for lack of technological nourishment, because our pool of graduate engineers is the source from which arise nearly all our technological advances from jet engines and nylon, to earth satellites, atomic power, and intercontinental missiles.

In light of these facts, the present Soviet peace offensive makes a great deal of sense to the Russians. Recently Mr. Khrushchev said: "We don't have to fight. Let us have peaceful competition and we will show you where the truth lies. . . . Victory is ours."

Can we in the United States permit this challenge to stand ?

Quality Imperative

America's present educational crisis is not only one of quantity — *i.e.*, not enough engineers and scientists being graduated each year — but also one of quality. And this is a serious matter, for in the contest with Russia we must depend on greater human quality, since we cannot match her manpower in numbers.

Our primary and secondary schools have recently come in for much criticism for not doing a good job. Actually, the average high school graduate of today is better trained than the one of seventy-five years ago — which should not surprise us since today's school year is twice as long as that of 1870; the proportion of teachers to pupils is greater; and — even taking into account the changed value of the dollar — we spend nine times as much per pupil today as we did in 1870. We have thus a situation where the child goes to school twice as long, costs us nine times as much to educate, but gets only a little better education than he was getting eighty-five years ago.

Unsatisfactory as this may be, the real issue is not whether the present-day pupil compares favorably with the pupil of 1870, but whether he is adequately trained for the demands of today's society. I submit that he is not.

I say this on the basis of study, intuition, and the experience I have gained from interviewing more than one thousand college graduates over the past ten years.

My experience in selecting people may have some relevance for other engineers because the design and development of nuclear power plants is extremely difficult. It encompasses the most advanced scientific and engineering concepts in physics, mathematics, chemistry, metallurgy, electrical engineering, electronics, and mechanical engineering. The problems we face in nuclear power plants are indicative of what all branches of engineering will soon have to face.

The single most important thing I have learned from these interviews is that all but a small number of the young college graduates lack proper motivation. Some of them consider their degree merely as a ticket to a job, and a pass for security. They use the college as a "service station".

This desire for security in terms of money, rather than in opportunity for self-improvement, is hard to understand in a society where security is so readily available.

Another important point that has been made clear to me in interviewing young graduates is that they know many facts — but they have not learned many principles. Principles are more important than facts and far more difficult to master. But once a principle is learned, it becomes a part of one, and is never lost. The facts we learn are soon forgotten and their meaning changes with time. A trained man knows how to answer questions. An educated man knows what questions are worth asking.

My concept of a good engineering course is one in which the student learns the principles of mathematics, of physics, of mechanics, of electricity, of metallurgy, and of chemistry. A thorough understanding of these leads easily to handling the facts associated with them.

I do not believe that "practical stuff" should be or can be properly taught in a university. The reason is easy to see. Nearly all college textbooks are several years behind current industrial practice. Furthermore, they are written by men who do not have the latest "practical" information, so that the texts are obsolete even while they are being written.

The employer who wants a "practical" engineering graduate is simply hiring a man who knows how to make the same mistakes that have been made in his plant for the past ten to fifteen years.

Whose Responsibility?

The failure in education is not the fault of the educators alone. It is the fault of all of us in not recognizing the impact of the Twentieth Century scientific revolution and taking the necessary measures in time.

I have tried to give you my view of the problems that face us in engineering education. What can we do about them ?

First, we must see to it that every young man and woman who is qualified obtains a college education. Today less than half of those capable of acquiring a college degree enter college. Sixty per cent of the best students graduating from high school do not go to college. This is a tremendous loss of talent amounting to 250,000 students each year. And nearly half of all those who do start college do not graduate. For every high school graduate who eventually earns a doctoral degree there are twenty-five others who have the intellectual ability to achieve that degree, but do not. We simply cannot afford a waste such as this.

Second, we must increase the funds for education. The United States is spending about two and a half per cent of the national income on education. In contrast we spend more than four per cent on recreation. We spend more money for comic books than for all textbooks used in our elementary and high schools. In 1951 the amount spent for advertising was $199 for every family in the United States, but the amount spent for primary and secondary education was $152 per household. This means that our national outlay for the education of citizens was substantially less than our expenditures for the education of consumers.

It may amuse you to know that in a recent year the United States home permanent wave industry budgeted for research into ways of improving the looks of human hair a sum amounting to two cents per United States (female) capita. The whole nation meanwhile was spending only three cents per capita for research into the distressing things that go on inside the human head.

How Much Are Teachers Worth?

Third, from what I read in the papers we seem to be more concerned with expenditures for school buildings than for spending money to obtain better teachers. Schools can be constructed in two years or less, but it takes four years to train an elementary or high school teacher, and seven to eight years to train a college professor. Our school buildings may be the best in the world, but can we say the same of our teachers ? I do not mean to imply that we should not have the best school buildings, but perhaps our children would be better off with fewer buildings but with the best teachers it is possible to obtain. We plan to spend twenty-five billion dollars in the next ten years on school buildings. What amount are we prepared to spend for assuring better teachers for these schools ?

The real question is, "Can we afford not to spend enough for such assurance ?"

This leads me to the question of the salaries we pay teachers. Compared to other professions there has been a considerable drop in their purchasing power, particularly for those at the highest professional levels. The deterioration at the top is so great that it has affected the attractiveness of the academic career as compared to other professions.

In any profession, and particularly in the teaching profession, there are dedicated people who will work under adverse conditions and at low pay. But we must not delude ourselves that the answer to our dilemma lies solely in dedicated people. There will never be enough of these. We are not entitled to educate our children on the philanthropy of our teachers. Whether we like it or not, in the culture which exists in the United States today the desirability of a given occupation is measured largely in terms of salary. As a rule the better people are attracted to the higher paying professions. This explains why the ablest young men and women are turning away from teaching even though numerous scholarships and fellowships are available. No such recruitment problem exists, for example, in medicine or in law. These have no lack of applicants; in fact many are turned away.

When the income of teachers rises to the point where it competes with other professions, it will attract the right kind of people.

Therefore, I submit that an immediate step in solving our educational problem is to increase salaries drastically. It little matters that some teachers will be overpaid. The low salaries paid for the past fifty years have served to attract to the teaching profession many who are not really qualified. It will profit us very little to spend millions of dollars on scholarships and then place the students under incompetent teachers. Increasing salaries is the surest way to attract more competent men and women over the long run. Further, when salaries are increased it will be possible to base advancement on performance, and not on the basis of time served.

Current Alternatives

Unless we quickly remedy the present treatment of our teaching and scholarly resources we will inevitably have morally and intellectually incompetent teaching staffs. Eventually the bright young man will sacrifice his desire to teach in favor of an adequate standard of comfort, decency, and security for his family. The movement away from teaching has actually begun and it looks as though it will continue at an increasingly rapid rate.

We all know of the nationwide shortage of elementary and high school teachers. What is not evident is the real meaning of this shortage, because very few classrooms are ever closed because a teacher is lost. What happens is that teaching standards are lowered or the class size is raised. Both of these accommodations are already taking place at a growing rate. When a teacher with the desired qualifications is not available, someone with lesser qualifications is hired. The teacher then becomes, in effect, a "baby sitter."

The result of this niggardly payment of our teachers — of those upon whom we depend to transmit our culture and our civilization — is to commit a fraud on our children. If the children were as astute as their elders supposedly are they would say: "I'm sorry, but I'm not ever going to be ten years old again. Can't you afford to give me good teachers now ?"

Lengthen School Year

Another thing we can do is to increase the length of the school year. The present school year is based on the requirements of an agricultural economy where the children had to help on the farm. True, the actual number of days at school now averages about 180 as compared with 90 days about 80 years ago. But, as you well know from your own experience, and from what your children tell you, many of these 180 days are wasted. With the great and geometric advance in knowledge since the turn of the century, can we afford to have our children devote less than half their available days to elementary schooling ? Students in Europe, including Russia, attend school six days a week instead of five, and their vacation period is about two-thirds of ours.

There is no longer a sufficient number of years left during youth to develop properly educated men and women. And we cannot keep them in school too long after they reach the age of twenty-two or twenty-three because it is then time for them to face the problems of the world. So it is to the earlier years that we must look for added learning. This problem has become particularly acute due to universal military training.

Many of you occupy responsible positions in industry, and you know that the great increase in our productive capacity comes from the optimum use of people and facilities. Some of the problems of education, particularly those concerned with administration, are susceptible of solution by the same methods we use in industry. Industry cannot operate effectively on a 180-day year. Why should we think our schools can ?

Increasing the length of the school year, say to 210 days, would be the equivalent of making two additional years available before college.

If to these two years we added better teaching, better school administration, and better use of school facilities, it is quite possible that by the time a young man reached the age of eighteen he could have completed the equivalent of the present day college course. This is not as farfetched as it may sound. Something close to this has been achieved in Europe.

Permit Rapid Individual Advance

Another important thing to be done is to make it possible for every gifted student to advance as rapidly as he is able to. It may be impossible for us to compete with Russia in the number of trained people but we must excel in the quality of our trained people. To accomplish this requires a drastic change in our attitude towards our primary and secondary schools — particularly our high schools. Up to World War I the high school was intended as a preparatory school for those who desired to continue on to college or university. The courses were organized on this basis and they did a pretty good job, considering the cultural and scientific climate of the time.

But the high school of today is no longer a place whose primary purpose is to prepare students for college. Instead, its purpose has proliferated into providing educational, occupational, civic, and cultural training for every child.

In this time of acute teacher shortage in our schools we might well consider relieving them of the problems which could just as well be taken care of in the home or by other activities. Under pressure from various groups, courses are being given whose educational value is questionable. Nearly half of our high schools offer little or no instruction in physics, chemistry, or in mathematics beyond introductory algebra. The percentage of high school pupils who today study scientific subjects is indicative of this:

	1900	*1950*
Physics	23	4
Chemistry	10	7
Algebra	52	27
Geometry	27	13

The high schools have been required to arrange the necessary curriculum to take care of the average boy or girl. For many children the school makes up for what they cannot obtain at home; and, in some cases, it takes the place of the home. The ones who suffer are the gifted children. Some parents, those who can afford to, send their children to private schools. Whether or not these are really better than our public schools is a moot question. Certainly it is not altogether desirable to have children, during their impressionable years, associate only with those who have the same economic background.

Two Kinds of Schools

A partial solution to the high school problem lies in setting up two different kinds of schools, one having higher standards than the other. There can be no valid objection to this because boys and girls with the necessary ability could go to the more difficult school. True democracy does not require of us that we hold back the qualified; it does require that we give each individual the opportunity to develop his talents to the fullest.

There is, however, a current of educational thought which is opposed to special treatment of gifted children. It is claimed that there are too many difficulties and injustices involved in recognizing ability at an early age, so that children of all abilities must be educated in a common manner. It is also claimed that educational grouping of this sort leads to or accentuates social stratification, and is, therefore, undemocratic.

Neither of these arguments will bear critical examination. If it is considered democratic to give special care to our retarded children, as we should and must, why should it not likewise be considered democratic to help our brightest children. There are many things which are pure gifts and which we cannot acquire even by the greatest application: they are endowments granted to us by God. Among these gifts are creative artistic talents, profound sensitivity to art, music or literature, philosophical power, and scientific or engineering intuition.

Every outstanding scientist or engineer is in his own way an artist. That is why he is able to reach out into the unknown and grasp a new truth which remains invisible to others.

This is the reason we must seek out and cultivate our gifted children, for it is from their ranks that creative ideas will come.

I have spoken of these major methods by which our educational potential can be improved: increasing the length of the school year together with better school administration; making sure that gifted children are afforded every opportunity; and obtaining enough good teachers.

Scale of Demands

Here are the unprecedented educational problems we now face: Elementary school enrollment has risen from 20 million in the 1940's to 29 million today, and is expected to reach 34 million in 1960. High school enrollment will increase from 7 million today to about 12 million in fifteen years. But the severest impact will be felt by the colleges and universities where the attendance will increase from about 2½ million today to between 5 and 7 million within the next ten to fifteen years.

To maintain the present pupil-teacher ratio the elementary and high schools will have to enlarge their teaching staffs by 500,000 in the next ten years; this is a greater increase than took place in the previous thirty-five years. But to achieve a net increase of 500,000, three times that many will have to be recruited to take care of those who leave to get married, to take other jobs, or to retire. And the colleges and universities will have to add more teachers in the next fifteen years than they have in all their previous history.

But faced with this formidable and unprecedented situation, we start with a present shortage of 140,000 qualified teachers. If the nation's schools are to be adequately staffed during the next ten years, more than half of the college graduates during that period will have to enter the teaching profession. But at present only one-fifth of the college graduates become teachers.

Public and Private Efforts

Our difficulty arises from the fact that we are not living in a static society, nor do we have a static population. We are faced with a national problem of the first magnitude and a major and over-riding effort by all of us is necessary — the federal government, the state and city governments, the schools, industry, and other private organizations. Because we have not been mindful of this situation does not mean that others have been equally unmindful. The meaning of what the Russians have been doing in education now becomes plain.

A partial solution and one which could be immediately effective is to enlist the aid of industry. Why cannot the scientists and the engineers from industry be given sabbatical leave to teach in our schools? The very shortage of college graduates and many of our educational problems have been created by the vastly increased requirements of industry. In 1900 the ratio of engineers to other workers was one in three hundred; today it is one in sixty — and in highly advanced industries it has already reached the figure of one for about every twenty workers.

Industry is today short more than 40,000 engineers and will require a minimum input of 30,000 for many years to come. The only serious attempt made by industry to solve this problem has been to offer considerably higher salaries to young college graduates. This has resulted in an unhealthy situation where the small number of graduates are being sought after by many organizations. Recently, at one college, the same 200 members of the graduating class were interviewed by representatives of nearly 500 companies. This is not recruitment; it is inflation. We have learned in the case of goods that inflation can only be solved by greater production; this is true of college graduates as well. There is danger to the young graduates in being sought after so avidly. Success is too easily achieved, and he gains it so quickly and so easily that he has had no time to learn the humility to handle success, or even to realize that he will need humility.

It is not farfetched to expect industry to help carry this social obligation. In present day America the business corporation is not a business device alone — it has become a social institution and has acquired the obligations inherent in this concept.

We have always recognized a duality in our schools: federal and local support; public and private support. Industrial support of schools fits into this duality.

It has also been characteristic of our people that when a social need arose which government was not able to take care of, groups of citizens have joined together to help.

Specific Recommendations

Specifically, I suggest that, at their own expense, industrial organizations make available their scientists and engineers for one-year periods to teach in our high schools, colleges, and universities. The cost of this will be more than repaid by the larger number and better trained students who will soon be available.

Another thing industry can do is to help finance education. This has already been started by some corporations in providing scholarships and other aid. I suggest that financial contributions to education rather than scholarships be made, but on a considerably larger scale than is presently the case, perhaps as a percentage of gross sales. These funds might be assigned for distribution to central groups of men not associated directly with industry or with the schools. This will eliminate any possibility of industry being accused of influencing education or the schools of being self-seeking.

The use of manpower and funds by industry in this manner could be considered as a legitimate operating expense required for the future good of the business.

Similar contributions by labor unions would also be appropriate.

There are a number of aspects connected with this proposal which I would like to discuss at greater length, but which time does not permit. There is the possibility of using the funds so contributed for the establishing, staffing, and operating of new schools. There is also the possibility that scientists and engineers of each community, as part of a definite company plan, could act as counselors for one or more high school students, devoting a part of their time to helping them to become interested and proficient in scientific and engineering subjects. They could also take over the leadership of the various after-school clubs in science, radio, mathematics, etc., thus relieving the teachers of this duty.

The United States, if it is to succeed in its role of world leadership, must produce citizens who have the wisdom, the vision, and the knowledge to grapple successfully with world problems; citizens who can see critically through conventional values and who are able to subject to principle and to reason all claims to power.

In the conditions of modern life the rule is absolute, the race which does not value trained intelligence is lost. It will matter little what other excellences our educational institutions possess if they neglect to recognize and to foster high ability wherever it is found.

The Choice Now

The task of ensuring that every youth in our land is helped to his highest intellectual growth is a formidable one. This task arises not alone from the military situation posed by Russia, but also from the realities of the rapidly spiralling scientific revolution. We are faced with a fateful challenge. The way we, today, meet it, will determine the future of our Country. We must not let it be said by future generations that we used our intellectual and moral capital without replacing it.

Only by an educational system strengthened, not only in its members and its organization, but in its sense of purpose can we hope to meet the obligations which today's events place upon us. And only if we meet them can we create in our society the kind of leadership without which we cannot hope to meet the responsibilities and the possibilities that our time has opened before us.

Month To Month

Notes of the Institute and Other Societies, Comments and Correspondence, Elections and Transfers

Increased Technical Activities

Report to be made at the Annual Meeting

For some time Council has been giving consideration to a proposal whereby the Institute's interest in technical papers and other activities will be increased materially. Over a long period of time F. L. Lawton, a councillor of the Institute, has been advocating this increased activity. He has presented a series of reports to Council the outcome of which it is expected will be a revised program.

For many years the Institute has made no special effort to develop highly technical activities within the branches or within the membership. This has been due to a number of causes principal among which was the fact that as the Institute was catering with equal emphasis to all branches of the profession it became more difficult to specialize in highly technical papers which would be related to one particular branch of the profession.

The second reason is that there have been fewer technical developments within the profession in Canada as compared to the United States or the United Kingdom. In Canada a great many of the industrial organizations are subsidiaries of organizations mostly in the United States but not infrequently in the United Kingdom. Naturally enough these organizations have done their research and development work in their parent plants rather than in their branch plants. In this way the technical aspects of the Canadian companies' activities have been greatly reduced and the opportunity for technical activities within the Institute have thereby been reduced.

Technical Development

Today, however, there are many changes coming over the profession. There are so many new divisions of it such as nucleonics, electronics, aeronautics, to mention only a few that even in Canada there is a great development in technical thinking. As a consequence of this there is an increasing interest in research and the theoretical aspects of engineering.

One must not overlook the excellent work done over the years by the technical divisions of the branches at Montreal and Winnipeg and later Toronto. It is the broad expansion of such activities in many branches and on a national basis that is now needed.

Mr. Lawton expects to present his final report at the annual meeting of Council in Montreal on May 22. It is expected that as an outcome of his recommendations the Institute will set up a new division whose purpose will be to promote activities within the technical field, on the part of our members. It is expected that the organization will finally find its way down to the branch level and that through the new arrangements, not only will branches have more technical papers on their program, but the annual meeting of the Institute itself will have access to a greater number of really technical manuscripts.

Members Will Participate

When the time comes to set up the new organization it is evident a great many members will need to be recruited to carry on the work. As soon as all arrangements are agreed to by Council the membership will be informed. This note is simply by way of indicating that something is underway and that shortly it is planned to present a detailed report of a far reaching nature.

Seventieth Annual General Meeting

Notice is hereby given, in accordance with the by-laws, that the annual general meeting of The Engineering Institute of Canada for 1956 will be convened at the Sheraton-Mount Royal Hotel, Montreal, at ten o'clock a.m., on Wednesday, May 23rd, 1956.

Competitive Bidding and Professional Conduct

Recently the American Society of Civil Engineers conducted a ballot which proposed a revision in their Code of Ethics. It is significant that the proposal was carried with a favourable ballot of 12,443 against an unfavourable ballot of 1,554.

The article in its former form read as follows: "It shall be considered unprofessional and inconsistent with honourable and dignified bearing for any member of the American Society of Civil Engineers:

> "4. To participate in competitive bidding on a price basis to secure a professional engagement".

The amendment which was approved by an overwhelming vote has changed the wording to read this way: "It shall be considered unprofessional and inconsistent with honourable and dignified bearing for any member of the American Society of Civil Engineers:

> "4. To invite proposals for the performance of engineering services or to state a price for such services in response to any such invitation, when there are reasonable grounds for belief that price will be the prime consideration in the selection of the engineer".

This is a subject which has been discussed many times by many engineers in different parts of Canada. This recent action of the members of the American Society of Civil Engineers doubtless will be found interesting to many Canadians.

Journal Changes Printer

Readers should be informed that effective with the July issue *The Engineering Journal* will be handled by a different printer. In addition to definite financial advantages resulting from a better price schedule, it is confidently expected that the date of publication, and mailing, will also be improved appreciably.

It would be more satisfactory to all concerned we are sure if the *Journal* came out by the 15th of each month instead of at the end of the calendar month as has been the case too often. Improved service, and lower cost, are the objectives of the change.

Work Outside of Canada

As has been reported before in *The Engineering Journal*, the Institute has been interested in securing information about engineering and construction projects which are taking place outside of Canada but which might be of interest to Canadians.

In the July 1955 issue of the *Journal* a report was made about a meeting held in Montreal at the time of the annual meeting of the Canadian Manufacturers Association. Since that time a certain amount of information has come to the joint committee and has been circulated to a group of individuals and firms who have expressed an interest.

Information about such projects continues to arrive and as far as the Institute is concerned the question now is to know which consulting engineering firms and which contracting firms are interested in knowing about this work to be done under the Colombo plan or in the Middle East. It is intended now to prepare a list of interested persons and to see that copies of the information go to them promptly.

As was reported before, a joint committee has been set up to distribute the information. The committee is made up of a representative of The Canadian Construction Association, The Canadian Manufacturers Association, and The Engineering Institute of Canada. There are many organizations that are interested in all three of these agencies. Therefore it becomes necessary when preparing a mailing list, to make certain that duplications are eliminated but that in one way or another everyone gets the information in which he is interested.

The purpose of publishing this notice is to bring to the attention of consulting engineers, and general contractors, the existence of information dealing with this type of project. If they are interested in seeing the details we would recommend that they send to the Headquarters of the Institute the name of the individual within their organization to whom such reports should be transmitted.

Where are Your Button and Certificate?

If you have had occasion to visit a medical doctor lately you could hardly have missed noticing several details of his surroundings. A well displayed sign near his entrance carried the title "Doctor", and in a place of importance inside you saw the framed certificate setting forth his professional status. Maybe there were several. He, and his colleagues, are proud of these insignia, and take for granted the prominent display of them. Why are so many engineers so different in this respect? And is it a good thing for us to thrust these tokens of professional achievement into a bottom drawer? We think not.

At many points on the President's tour this was a subject of discussion with members of the branch executives. These men were practically unanimous in their approval of the idea, at least in principle, that much can be done to stimulate interest in displaying E.I.C. certificates in engineering offices, and in wearing lapel buttons. But let's DO something about it! Where are yours?

We have found that quite a few members are actually unaware that certificates of membership and E.I.C. lapel buttons are available. Simply write to headquarters, 2050 Mansfield Street, Montreal 2. And look for the display of these items at the Annual Meeting in May. The cost is moderate —$1.25 for a certificate, and $2.00 to $7.00 for a button, depending on your grade of membership.

GZOWSKI and the Construction of The International Bridge between Fort Erie, Ont., and Buffalo, N.Y.

by W. E. Greening and Dr. Ludwik Zubkowski
Montreal, Que.

> **Canada is now old enough to have some engineering history, but much must have been lost for lack of a recorder and much is buried in official reports in inaccessible files and in books seldom seen. The authors of this paper have rescued some important incidents of Sir Casimir Gzowski's career from oblivion - Sir Casimir for whom our medal is named and who was a founder of the old Canadian Society of Civil Engineers and its president in 1889 and 1890.**
>
> **They read this paper at a meeting of the Institute of Slavic Studies.**

One of the most important engineering figures in Canada during the nineteenth century was the romantic Pole, Sir Casimir Gzowski. Of aristocratic origin he was exiled (in 1813) from his native land because of his participation in the revolt of the Polish patriots against Russian Czarist despotism and tyranny in 1831 and 1832. He landed in America as a penniless refugee, not knowing a single word of English, but eventually made his way to Canada, where he quickly rose to prominence in the engineering profession.

As Chief Engineer of Public Works in Upper Canada in the early eighteen forties, he was responsible for the construction of many highways, bridges, lighthouses and harbour works. Later, he entered the field of railway engineering and supervised the construction of part of the St. Lawrence & Atlantic Railway between Montreal and Portland, Me., the first line between Montreal and the Atlantic Coast. Later, he formed a construction firm, Gzowski, Macpherson & Co., which built the line of the Grand Trunk from Toronto, through Guelph and Sarnia to Detroit, Mich. He was also employed on several surveys by the Canadian Government which led to the improvement of the navigation channels and the canals on the St. Lawrence River between Lake Ontario and Quebec City.

He was one of the founders of the old Canadian Society of Civil Engineers, now The Engineering Institute of Canada, in 1887, served as its president in 1889 and 1890 and had a great deal to do with its early development and progress. The Gzowski medal, which is still given by the Institute annually for the best paper by a Canadian, on an engineering topic, commemorates his name.

One of Sir Casimir's most distinguished engineering exploits was the construction of the International Bridge across the Niagara River between Fort Erie, Ont., and Buffalo, N.Y., in the early eighteen seventies.

Ever since the beginning of the railway era, there had been discussion both in Canada and in the United States of the project of building a railway bridge across the Niagara River at this point, near the eastern end of Lake Erie. Several bridges had already been constructed across the river in the vicinity of Niagara Falls. The most celebrated of these was that erected by the well known German-American engineer, Augustus John Roebling, in the eighteen fifties. It was the object of great wonderment at the time because it was one of the first important bridges in North America to be suspended on wire cables. It afforded rail connection close to the Falls between Canada and the United States by linking the system of the Great Western Railway in Ontario with that of the New York Central in New York State. During the same period, another bridge had been constructed for road traffic further down the Niagara River at Lewiston, but it had been wrecked by a violent gale in 1861.

By the middle of the eighteen sixties, it was apparent that there was need for a more direct rail connection than that afforded by the suspension bridge at Niagara Falls, between the fast growing City of Buffalo and the section of the Ontario peninsula directly to the west, on the other side of the Niagara River. The construction of the Great Western Railroad between Detroit and Niagara Falls, through London and Hamilton, had already shown the convenience of the rail route across Ontario between Michigan and New York. Other railway companies became interested in giving the Great Western some competition in this area.

As early as 1858 a line was projected from Buffalo across the Niagara River to Lake Huron. This was the Buffalo, Brantford & Goderich. It was promoted by a group of capitalists in Brantford and some of the adjacent Ontario communities. It was planned to cross the Niagara River by bridge and then run westward through Brantford and Stratford, where it would make connections with the Grand Trunk, having its terminus at the Port of Goderich on Lake Huron. The men behind this scheme hoped that freight brought by steamer from the upper lakes would be transported by this line as a fast route from Goderich to Buffalo, where a connection would be made with American rail lines and with the Erie Canal.

Like so many other Canadian

railway ventures of this era, the Buffalo, Brantford & Goderich soon fell on evil days, became insolvent and was acquired by an English group, who changed its name to the Buffalo & Lake Huron. This company was able to complete the line between Fort Erie and Goderich, but lacked the large amount of capital necessary for spanning the Niagara River at this point. Eventually the Buffalo & Lake Huron was absorbed by the Grand Trunk, which possessed both the money and the initiative to make a start on the bridge.

The aim of the directors of the Grand Trunk in giving their support to the bridge project was an obvious one. By linking their own lines from Detroit and Sarnia with the Stratford, Fort Erie and International Bridge route, they would create a new fast route across southern Ontario from Detroit to Buffalo, which would rival the Great Western one from Detroit to Niagara Falls.

The Grand Trunk acquired control of the International Bridge Company, which had been chartered under the laws of the Province of Ontario and of the State of New York, and capital was raised in England for the enterprise. Since the undertaking was an international one, permission had to be obtained from the British Imperial authorities in London and an act of Congress had to be passed in Washington before work could be begun.

It was natural that the Grand Trunk should choose the engineering firm of Gzowski, Macpherson & Co., of Toronto, for the construction of this bridge. Casimir Gzowski was thoroughly familiar with the latest methods of bridge construction in Europe and North America. The structures which he had built on the Grand Trunk line between Toronto and Sarnia had received much praise because of the excellence of their design.

The plan for the project, as originally outlined by Gzowski in 1870 with expert advice, called for the construction of a simple truss, iron bridge on stone piers across the main channel of the Niagara River between Fort Erie and Squaw Island on the American side of the international boundary. A shorter span would take the rail line across Black Rock Harbour, which forms part of the Erie Canal, to Black Rock on the mainland of New York State. From there, a spur line would connect the bridge with the main line of the New York Central in Buffalo, a short distance to the south. Swing spans would be placed in the centre of the section across the Niagara River and in the section across Black Rock Harbour to allow the passage of boats. When completed, the bridge would thus give the Grand Trunk direct access into the centre of Buffalo and links there with the New York Central and with the other American lines converging at that point. It would be the first bridge built on piers across the Niagara River since the previous ones near Niagara Falls had been of the suspension type.

In undertaking this project, Gzowski was almost immediately confronted with some tough problems. The prospects were not very encouraging. People familiar with conditions in the Niagara River in the vicinity of Fort Erie and Black Rock declared that such an enterprise was impossible of achievement. Gzowski, in his own account of the construction of the bridge which was published in Toronto in 1873, recounts some of these obstacles and they were certainly enough to discourage the most stout hearted and determined individual.

The Niagara River was fifty feet deep in the centre at this point and the bottom was a treacherous one. The current was very swift and the depth of water was subject to sudden and completely unforeseeable fluctuations. A strong northeast wind from the New York shore could cause the level of the water to sink by nearly two feet in less than half a day. On the other hand, a strong southwest wind blowing up Lake Erie would raise the surface near Black Rock as much as five feet in as many hours. All these factors meant that the construction of the stone piers upon which the superstructure of the bridge would rest, in the centre of the river, would be a tricky and hazardous undertaking at the best.

Further difficulties were created by the ice conditions in the river, which made all construction activity impossible there during the winter months. At the end of the navigation season in the Great Lakes in early December, the centre of the river did not freeze over because of the swift current, but cakes of ice, sometimes twenty feet across, would float down the river from the ice fields opposite Buffalo at the end of Lake Erie. Later on, toward spring, there was the danger of large ice floes from other parts of the lake. Pessimists claimed that the pressure from these great masses of ice would destroy any stone piers in the centre of the river, no matter how strongly they might be based and built.

During the summer months huge rafts of logs passing down the river from Lake Erie to Tonawanda, N.Y., created an added hazard to the construction operations.

These alarming stories eventually reached the ears of the directors of the International Bridge Company and of the Grank Trunk in London. The latter sent an eminent engineer, a Captain Tyler, to Canada for the purpose of inquiring into the truth of these rumours. After examining Gzowski's plan for the bridge and making extensive investigations on the spot, he returned to London with the report that there was no cause for undue anxiety, and that the stone piers designed for the bridge would be strong enough to resist the force of the largest ice floes coming down from Lake Erie.

Work was begun on the bridge from the Canadian side of the river at Fort Erie in the early spring of 1870. Gzowski, of course, spent much time on the spot, personally supervising construction operations and working out engineering problems as they arose. But it is indicative of his great energy and capacity for work that, during some of this same period, he was also serving on an important commission the activities of which required much travel, and which had been appointed by the Federal Government to investigate the entire canal and waterway system of the new Dominion with a view toward its extension and improvement.

The superstructure of the bridge was of iron and was manufactured at the Phoenix Works in Pennsylvania. Iron was used for the fabri-

The authors of this article are preparing a complete biography of Sir Casimir Gzowski, which is to be published this year in book form.

cation of bridges during this period, as steel did not come into general use for this purpose until the end of the eighteen seventies, some years later. A Pratt truss design was selected because it had the advantages of being strong and at the same time comparatively light in weight. This latter was an important factor, since it cut down construction costs and Gzowski's budget, a million dollars, was a low one for an enterprise of this size and difficulty.

The stone piers on which the superstructure of the bridge was to rest in the section across the main channel of the Niagara River, were erected on caissons which were floated into position and sunk with the aid of cables and anchors. No very great difficulty was met in placing the first three piers in the section of the river which was closest to Fort Erie, since the bottom there was solid rock. By the spring of 1871 these structures and the stone abutments which were to carry the rail line out into the river from Fort Erie were completed.

The first real engineering headaches were met in sinking the foundation for Pier No. 4, which was near the centre of the river where the bottom was deepest and the current strongest and where fluctuations in the level of water were the most frequent. Early in May, 1871, when the caisson which was to be the foundation for this pier was lowered, one of the cables holding it parted. This threw such a strain on the remaining cables that the anchors began to draw and the caisson to sway violently from side to side. Finally it sank at a point below the line of the bridge. Before arrangements could be made to raise it, a violent wind storm carried part of it still farther down the river.

Gzowski then decided that no further effort should be made to obtain a base for this pier during 1871. Soundings in the area, made with the aid of divers, revealed the very unwelcome fact that the bottom of the river at this point consisted of layers of gravel interspersed with boulders and shale, which would have to be removed before the solid rock beneath could be reached. It was obvious that extensive dredging operations were necessary there. Gzowski finally decided to sink at this spot a large bottomless caisson inside of which excavation and dredging operations could be carried on in calm water. Divers worked at the bottom dislodging material which was brought to the surface with dredges. This was a difficult task, since the divers had to work in complete darkness with only their sense of touch to guide them. After much effort, the over-burden was completely removed and the inner watertight caisson on which the pier was to rest was lowered and secured.

In the summer of 1871 preparations were made for the sinking of the caisson for Pier No. 5. Here an even more serious mishap occurred. As we have said, at this period of the year large log rafts were floated down the river past the site of the bridge. An unusually big one came down the current from Lake Erie. It was about 3,000 feet long and most of the logs of which it was composed were more than 60 feet long. Through the carelessness of the crew operating the tug to which it was attached, this raft struck the caisson and there was an ear-splitting crash. The logs in the raft were twisted into all kinds of irregular positions. The stern of the raft swung into the main current of the river against the cables holding the caisson, which were thus exposed to a tremendous strain from the immense log structure. For a few moments the whole confused mass of caisson and raft remained stationary and then it began to move down river, dragging the anchors with it. The wreckage finally came ashore near the lower end of Squaw Island.

This accident was a grave one and involved much loss of time and additional expenditure of thousands of dollars. The caisson had to be towed back to Fort Erie and prepared for sinking a second time. When it was being placed in the centre of the river again, it swung around in the current and became completely unmanageable.

When fresh soundings were made, it was found that the bottom here was of the same treacherous type as that underlying the site of Pier No. 4, and the same type of excavation and caisson work was used again with similar success. Little difficulty was encountered in building the remainder of the piers in the Niagara River and in Black Rock Harbour which were erected on foundations of piles. In the meantime, work had begun on the installation of the iron superstructure, which was raised with the aid of pontoons.

First Locomotive Crosses Bridge

By the end of the summer of 1873 the sections of the bridge over the river and across Squaw Island and Black Rock Harbour were practically complete. The first locomotive went across the new bridge from Fort Erie to Black Rock on October 27, 1873, and the structure was officially opened to rail traffic at a ceremony which took place about a week later and at which high officials of the Grand Trunk were present. Mr. Bridges, the president of the company at this time, paid high tribute to the builder of the bridge, saying: "There is no other man in this country who could have carried on the work of this bridge or gone through the daily and hourly anxiety which it has entailed during the past four years, save Colonel Gzowski."

Indeed, it was a triumph of perseverance, skill and resourcefulness in the face of obstacles which would have completely defeated a man of lesser calibre. One notable fact was that the gloomy prophecies which had been made concerning the menace of the ice floes in the Niagara River to the foundations of the bridge proved to be utterly unfounded. The piers were so solidly constructed, out of such good quality stone, that they were in no way affected by the severe ice conditions during some of the winters which immediately followed the completion of the structure. Although the iron superstructure was replaced by a steel one at the beginning of the present century, the stone piers still remain as Gzowski built them more than eighty years ago.

The construction of this bridge was the subject of general acclaim in engineering circles both in North America and in Europe and its completion was recognized to be an outstanding feat even in this era of such epoch making accomplishments in the engineering field as the building of the Brooklyn Bridge and the Eads Bridge.

In addition to its importance as a feat of engineering, this bridge also had a good deal of significance in connection with the linking of the rail networks of Canada and the United States. It gave the Grand Trunk an entrance to Buffalo from which lines radiated south and east to New York, Philadelphia, Pittsburgh and other points. Shortly after the completion of the bridge, the Great Western, in order to compete with the Grand Trunk, built a short line from Glencoe, between Windsor and London, and across Ontario to the bridge. But what was more important still was the construction of another railroad across this region, the Canada Southern. Although the promoters of this road had no direct connection with the International Bridge Company, there is no doubt that their plans were powerfully affected by its completion. The route of the Canada Southern ran from Amherstburg on the Detroit River eastward through St. Thomas to Fort Erie and the bridge, with a side line to Niagara Falls. It provided a considerably shorter route between the Detroit River and Buffalo and the Niagara frontier than those of the Great Western or the Grand Trunk. At Amherstburg, it was connected by ferry across Lake Erie to Toledo, Ohio, where it had links with the Wabash system which ran southwestward to St. Louis and Kansas City. It thus provided the nucleus of a new east-west rail route.

These developments in Canada aroused the keen interest of the American railway king, Commodore Vanderbilt. He wanted to create for the New York Central a new route between Chicago and the Atlantic Seaboard. Within the next few years, he bought control of the Canada Southern and linked it at the western end with the Michigan Central, which ran between Chicago and Detroit, and at the International Bridge with his New York Central which ran eastward from Buffalo to New York. He now had a new fast line between Chicago and Buffalo, through Canada, around the north end of Lake Erie and across the International Bridge. The completion of the bridge therefore gave Buffalo important new rail links with the Province of Ontario and the State of Michigan to the west; with no fewer than three lines running westward from Buffalo to Sarnia and Detroit—the Canada Southern, the Great Western and the Grand Trunk. Other railways entering Buffalo from the south and the east, such as the Pennsylvania, the Erie and the Delaware, Lackawanna and Western also built lines to connect with the bridge. It still forms the most important rail link between Canada and the United States across the Niagara frontier.

The Good Things of Life and Engineering

There are many examples of persons complaining that the advance in engineering and science is retarding the development of the arts. Many engineers and scientists have sprung to the defence of the profession and have refuted such charges. Here is another excellent example, not only of a defence, but of an attack as well.

The European and United States Engineers' Conference (EUSEC) held its annual meeting at Copenhagen in September, 1955. On reading over the verbatim of this conference your editor's attention was called to a discussion in which some very cogent observations were made by Mr. J. Eccles who at that time was president of The Institution of Electrical Engineers. Believing that members of the Institute everywhere will support Mr. Eccles in his observations the *Journal* is herewith presenting two paragraphs from the verbatim.

"Mr. Eccles called attention to the importance of encouraging more young people to take up the engineering profession, saying that we are accused as scientists and as applied scientists of having no philosophy of life to offer in our work. Mr. Eccles continued, 'I think that this thing is being played up by the classical people who have themselves a classical education, and who are asking what kind of existence we are creating for the people of the world by mechanizing and creating robots and simply improving in some way the general standard of life and giving people no philosophy as to what life is all about. They feel that is the truth and they believe it, and think the best we can is to produce instruments of destruction.'

"Mr. Eccles continued, 'I myself feel that there may be truth in it, but I think that it is greatly exaggerated and considerably overstated and I should hope that we who are the representatives of the senior people in our respective professions who are old enough and mature enough to have ourselves formed some philosophy of life and the implications of the things we do, should be bold enough to state, if we believe it, that science and the applications of science provide probably the only way in which you can get a satisfying existence for the great majority of the people on this earth. In the past there has been a good life for a few people, and those people who study classics and developed philosophy are inclined to forget that the people they read of in ancient times were only one per cent of all the population, and that the others were slaves and helots; the philosophy that we bring to mankind is that we are extending the good things of this life to the great majority of the people, and that the average standard of living and the possibility of thought and expression for the ordinary man and woman is far more realized today through the invention of science and the application of science, than has ever been possible in this world up till now'."

Consulting Engineers Elect Officers

J. Georges Chenevert, M.E.I.C., of Montreal, was elected president of the Association of Consulting Engineers of Canada Inc., recently. Other officers elected were: vice-president, James MacLaren, M.E.I.C., Toronto; honorary secretary-treasurer, F. J. Friedman, M.E.I.C., Montreal. Other directors are: H. W. Lea, M.E.I.C., and J. G. Frost, M.E.I.C., of Montreal, Georges Demers, M.E.I.C., of Quebec City; C. D. Carruthers, M.E.I.C., of Toronto; past-presidents, E. A. Cross, M.E.I.C., Harry H. Angus, M.E.I.C., Toronto, and A. T. Hurter, M.E.I.C., of Montreal. Associate directors are Col. W. G. Swan, M.E.I.C., Vancouver, K. E. Whitman, M.E.I.C., of Halifax, and Roy A. McLellan, M.E.I.C., of Saskatoon.

Mr. Cross, the retiring president, reviewed the year's work, particularly the program planned in the field of public relations and publicity. The final phase of the annual meeting will be held in Montreal on Thursday, May 24, coincidental with the annual general meeting of the Engineering Institute of Canada. The annual meeting in 1957 will be held in Banff.

Great expansion was reported in the engineering field throughout Canada; natural resources were under a broad program of development in every province and the outlook for the coming year the brightest in history.

St. Lawrence power-house, Barnhart Island. Looking downstream at construction plant and power-house excavation, from U.S. side.

St. Lawrence Seaway and Power Project

The *Engineering Journal* reviews the progress of the St. Lawrence project.

Progress by Ontario Hydro

First concrete was placed on the main dam and power-house in February. Much preliminary work had preceded the concrete placing in the U-abutment section of the north end of the powerhouse excavation. Forms for the base pours were prepared and installed. Erection of the three gantry cranes for handling concrete placing proceeded on schedule.

Work of building the extensive conveyor system to take aggregates to the site of the concrete batching and mixing plant was completed. Assembly of the concrete plant was finished by mid-February, also the pipe system to convey cement under the present Cornwall canal and the diversion canal to the mixing plant silos were completed.

The trial run was made of all this equipment before concrete placing commenced. Several adjustments were made as the batching and mixing plant operations started. Output from the plant was limited at first because of these adjustments and the restricted area for placing the concrete. By the end of February, after ten days of curtailed plant operation, some 5,000 cubic yards of concrete had been placed on the power-house site.

As facilities for handling concrete increase, and the area for placing is enlarged, it is expected that about 2,000 cubic yards of concrete will be placed daily. Meanwhile, excavation was continued at an accelerated pace on the power-house site. The estimated total earth and rock removal by the end of the month amounted to 1,350,000 cubic yards.

In other areas of the project, significant progress was made. Almost 95 per cent of the excavation at the dike closure structure area of Cornwall canal diversion was completed. Installation of the concrete mixing plant for this sector was well advanced.

During the month, excavation continued at the western end of the cut in the Galop Island channel improvement contract. Some difficulty was experienced in hauling because of soft foundation conditions. Pumping was continued in the first excavation bay and the total excavation to date was estimated at nearly 2,000,000 cubic yards. On the Chimney Island contract, building of cribs proceeded on schedule.

At the St. Lawrence transformer station, work was pressed forward towards completion of the 115-kv. area. It was estimated that approximately 90 per cent of the work has been completed by the end of the month.

Preparations for first house moving to townsite No. 2 received further impetus during February as work started on the access road from Mille Roches. Already several hundred feet of sanitary sewer and water main had been laid at the new townsite and work was well advanced on the water intake pipe. Meanwhile at townsite No. 1 sewer and water line were being laid. Some 700 feet of water line and 2,000 feet of sewer pipe had been laid.

At Iroquois, 102 houses had been moved to the new townsite. Work continued on the water pumping station intake and was well advanced. At Morrisburg, house surveys continued. Crews were also carrying out basement surveys, soil investigation and lot surveys. Work continued on the water pumping station site. Total personnel on the work was 2,880.

Mixing Plant for Hydro Power-house

Approximately one million cubic yards of concrete will go into the Canadian power-house, with about the same into the U.S. structure. In terms of railway carloads, the combined concrete total for the two power-houses would make up a train that would stretch for about 1,000 miles, the distance from Cornwall to Fort William.

Concrete for the Ontario Hydro power-house will be produced in the large batching and mixing plant which stands on the north shore of the river. Four thousand tons of concrete on the average will be discharged every workday for the next two and a half years. The plant is completely automatic. Now owned and operated by Iroquois Constructors, before being brought to Cornwall this 200-yard-per-hour plant served Ontario Hydro's new Sir Adam Beck-Nia-

View of the power-house area where first placing of concrete took place in February shows preparation of the site.

gara No. 2 project at Chippawa for the intakes and for sections of the lining of the twin power tunnels.

This central mixing plant has many unique features. It provides fast, accurate, automatic weight batching; compensation for variations in sand and gravel moisture content; instantaneous mix changes with a mix selector; interlocking operations to prevent errors; centering of all controls on one control board, and complete, detailed records of every batch poured.

A rock quarry three miles north of the power-house site will supply three sizes of coarse aggregate and manufactured sand. Trucks will transport the material to hoppers at the north end of the tunnels under Cornwall canal, from where belts will convey them through the tunnels to stockpiles near the mixing plant. From there, conveyors will take the material to hoppers at the top of the batching and mixing plant as required.

Cement will be brought in by railway cars to a siding near No. 2 highway and unloaded into a surge silo. From there it will be blown in a six-inch steel pipe extending through the tunnel and up into two storage silos at the mixing plant. As required the cement is brought into the mixing plant by bucket conveyor.

From the mixing plant concrete is dumped on to conveyor belts and taken to a large hopper, where it is loaded in trucks equipped with special buckets or into buckets on narrow gauge railway cars hauled by small diesel engines. Cranes will lift the buckets and discharge the contents. Pouring operations will continue around the clock, with crews working in three eight-hour shifts. Completion of the power-house is scheduled for late summer in 1958.

Progress by N.Y.S.P.A.

February progress was highlighted by excavation at the structure sites, together with erection of the various contractors' construction plants preparatory to full scale concrete operations. More than twelve million cubic yards of excavation had been removed for the entire project by the end of the month.

The quarrying, hauling and placement of rock fill for Cornwall canal revetment was practically completed. This embankment will serve as a haul road to the Canadian end of cofferdam "E", as well as support for the canal when the river rapids are unwatered. Excavation for cut "F" is more than half completed. At Long Sault dam, excavation was started for the north earth wing dike and for the left abutment.

Placing of concrete at Iroquois dam continued, as over 15,000 cubic yards had been placed to the end of February in the east section of the dam and in the spillway apron. Excavation from the upstream unwatered areas continued along with driving of piles for the cofferdam cells.

In the powerhouse area, excavation, drilling and grouting of the foundation progressed, as erection of the contractor's construction plant continued. All work in connection with the construction of baffles on the water side of cofferdam "C-1" was completed early in the month.

At Massena intake, excavation, drilling and grouting continued concurrently with the erection of the contractor's construction plant. Progress was retarded due to saturated condition of the foundation area. The wet condition is considerably improved as a result of grouting and improved sumps to allow full scale excavation.

Work at the south Galop channel continued, as excavation passed the one and a half million cubic yard mark. Preliminary work was started in the Sparrowhawk-Toussaints channel area as equipment started arriving. Field office and shop buildings were being constructed. Work on the Barnhart Island bridge consisted of construction of sidewalk and installation of lighting conduits. Clearing operations progressed upstream from the Long Sault dam.

The Long Sault canal construction power line was practically completed and relocation of the Barnhart Island construction power line was progressing.

Specifications were issued during February for the construction of water facilities at the Massena lake intake, for the load centre unit substations and for the rehabilitation of the Massena-Taylorville transmission line. The production of drawings continued on schedule.

Total personnel on the job was 2,380.

NYSPA Opposes Public Service Act

On February 22 the Public Service Commission released a statement in connection with an act to amend the public authorities law, with respect to power produced and sold by NYSPA, in which admission was made that the bill is designed to transfer from the

Power Authority to the Commission the job of determining the geographical area in which St. Lawrence power is to be sold.

This statement expressed concern that unless the Commission regulates the rates at which Authority's power is sold, its distribution will "have to be confined to limited areas immediately adjacent to the production sites".

In a memorandum in opposition released February 27, Chairman Robert Moses of NYSPA replied that "The Authority is engaged in making arrangements with power companies, whereby the benefits of seaway power can be made available to consumers who also will receive power from other sources. Interconnection arrangements have already been worked out with respect to the contracts the Authority has made with Vermont, the City of Plattsburg and the Plattsburg Air Base.

"The proposed bill is not only unnecessary but clearly unconstitutional, because it would violate the pledge of the State contained in Section 1011 of the Public Authorities Law, and would impair the obligations of the contracts which the Authority has entered into with its bondholders and with those who have already agreed to purchase its power."

Progress by Canada's Seaway Authority

The seaway's most important contract from the point of view of navigation, and the last of the dredging contracts for the Lachine Section, is valued at $10,636,000, and was awarded on March 9 to Marine Industries Limited, Montreal. Canadian Dredge and Dock Company Limited, Toronto, had submitted a bid of $10,903,000.

The work comprises dredging of an area one mile below the Jacques Cartier bridge for the approach between the St. Lawrence ship channel and the seaway canal, and of an area two miles downstream to provide a turning area for vessels. Dredging is to commence within 10 days of the opening of the 1956 navigation season on April 16, and all work must be completed by August 31, 1958.

The amount of overburden to be dredged is some 3,200,000 cubic yards and the amount of solid rock is some 100,000 yards. Rehandling and shore disposal of material and towing material to the north shore of the harbour area amounts in all to some 3,000,000 cubic yards.

Award of this contract brings to some $72,000,000 the value of contracts awarded by the Seaway Authority to date. Dredging to be performed by the Authority calls for the removal of some 16,000000 cubic yards from the seaway channel, of which 700,000 cubic yards will be rock and some 15,300,000 will be over-burden, sand, silt, clay and other common material. Of this, the five dredging contracts now awarded require the removal of some 200,000 cubic yards of solid rock and some 12,000,000 cubic yards of common materials.

Three contracts have also been awarded for concrete aggregates for the locks to be constructed at St. Lambert and at Cote Ste. Catherine in the Lachine Section, and for the two locks to be built between Lake St. Louis and the Beauharnois power canal.

The contract for aggregates at Beauharnois, valued at $2,131,000 has been awarded to Canit Construction Limited. Two firms, Mount Royal Paving and Supplies Limited and Miron & Freres Ltee., submitted identical bids based on unit prices, for the supply of coarse aggregates for the St. Lambert lock and the Cote Ste. Catherine lock. The contract awarded to Miron & Freres Ltee. is valued at $1,113,000 and that awarded to Mount Royal Paving is valued at $1,099,000.

Tenders were called on February 29 for the first stage of construction of lower and upper Beauharnois locks and approaches thereto in the Soulanges section. What requires to be done is to complete the junction between the canal and Lake St. Louis by means of two single locks. This contract will provide the preliminary work prior to the construction of the locks.

The location of the work is at the entrance to the Beauharnois power canal on Lake St. Louis and adjacent to the power development at Melocheville. The work includes clearing of the site, excavation, rock grouting, cofferdams and unwatering, service roads and relocation of a portion of the New York Central railroad line. Work involved includes excavation of some 170,000 cubic yards of common material, and some 1,115,000 cubic yards of rock. Tenders were received up to March 27. The work is to be completed by October 31, 1956.

Officials of SLSA met at Washington with SLSDC administrator Lewis G. Castle, March 1 to 5, 1956, regarding progress of the work in the International Rapids section. Among items discussed were the Polley's Gut bridge; the

St. Lawrence power project. General view of power plant looking west from the Canadian side.

relocation of the highway and railway facilities on both sides of the international boundary; the dismantling of the south channel bridge and dredging north and south of Cornwall Island.

President Lionel Chevrier, accompanied by Vice-President Charles Gavsie and engineers of the Authority, visited the Niagara Peninsula on March 14, to view Authority contracts to enlarge the Welland ship canal and to observe how much work has been completed this winter while the canal was dewatered. The Welland canal will be reopened for navigation April 2. Under these contracts some 549,000 cubic yards of material must be excavated. The work is to be completed by June 30, 1958.

Iron Ore Forced the Seaway

President Lionel Chevrier of The St. Lawrence Seaway Authority, addressing the Canadian Institute of Mining and Metallurgy at Montreal on February 22, stated that "the mining industry — at least one important branch of it, the iron ore industry — can take credit for swinging the balance in favour of an immediate start on this great project." Combination of development of the Quebec-Labrador iron ore fields and worsening of the ore supply position of the steel industry in the Great Lakes area "made the seaway the obvious and necessary solution," he declared.

"The course of events since the start of construction of the seaway has greatly reinforced the position of those who believed it a strategic necessity for the steel industries of both Canada and the United States," Mr. Chevrier pointed out. Steel production had expanded to its greatest peace time level and consumption of iron ore had preceded it in the same direction. Indeed, this future movement is already being anticipated by the canaller-type vessels on the present canals, Mr. Chevrier revealed.

"From the reshipping point at Contrecoeur below Montreal, some 300,000 tons of Labrador ore moved up the St. Lawrence canals in 1954 — the first year of production at Knob Lake. In 1955 this traffic grew to 1,750,000 tons. When the seaway is ready, this movement is expected to reach 10,000,000 tons annually without considering possible future expansion", he said.

"While traffic in other mine products on the seaway does not approach the scale expected in the case of iron ore there is every reason to look for a considerable use of the seaway in the movement of these commodities so well adapted for bulk carriage by water," he continued. "Let us remember that the seaway is to be a two-way street connecting the two major Canadian industrial areas and consumer markets—Southern Ontario and Southern Quebec."

"The future developers of new mineral deposits and the future planners of industry will be able to count on a 2,000-mile waterway—from the Gulf to Western tip of Lake Superior. The availability of this route will doubtless often serve to convert marginal or sub-marginal prospects into economically justifiable undertakings."

Electric Smelting Possible At Iron Mines

"Cheap hydro power may permit electric smelting at the site of the Ungava iron ore developments in the forseeable future, but the prospect for steel production along the St. Lawrence is remote." This was the opinion expressed by W. H. Durrell, executive vice-president, Hollinger Hanna Ltd., management company for Iron Ore Company of Canada, when giving evidence before the Royal Commission on Canada's Economic Prospects at Montreal, February 22.

While research on electric smelting may make the process practical for low grade ore at mine sites, economics of steel production made it plain that any increase in Canada's steel making capacity must come from extension of existing facilities, he said.

Any new mill must have a capacity of two million tons yearly for economical construction, which means Canada would have to enter the steel export trade in competition with Germany, Britain and United States. Lack of coal along the St. Lawrence was another handicap, he pointed out, though ore boats might bring coal from the Great Lakes area on return trips.

Some 12 million tons of ore would be shipped during the 1956 season, continued Mr. Durrell, two million to Britain and Europe, two million to Hamilton and Lower Great Lake ports and eight million to U.S. Atlantic ports. The volume of ore that would be shipped through the seaway when completed would depend upon whether tolls to be established would per-

Professional Development Groups

The Toronto Branch has an active P.D. group (see above). At their January 10 meeting, this year, E. C. Luke of Headquarters, spoke on "The Impact of NATO on Europe". Committee members are E. M. Spencer, Jr.E.I.C., chairman; Lee Broderick, S.E.I.C., treasurer; E. J. Rice, Jr.E.I.C., and J. A. Gingrich, Jr.E.I.C.

Below: The Winnipeg P.D. Group photographed at their January 10 meeting.

Engineering students of the University of Saskatchewan study public speaking as a professional development course. Here, two fourth year mechanical engineering students participate: A. A. G. Swanson, speaking, and R. W. Gillanders.

Hamilton (below). Committee for the large Hamilton group, with registration totaling 147, consists of: G. T. Fenwick, secretary, W. H. Hohn, E. W. Hill, W. A. H. Filer, G. L. Schneider, R. de Young, J. A. Walsworth, K. Crean, K. W. Baker.

The Ottawa professional development meeting of January 11 in session. At right: H. E. Gladish; J. J. Deitrich, of the Association of Polish Engineers; Major J. Wendt, the speaker, chief of research and development for personnel selection in the Canadian Army; A. A. Swiderski, of the Polish Engineers; J. M. Pritchard.

The Belleville Branch has a P.D. course, with an enrolment of 40. On January 11, the speaker was Prof. J. L. McDougall, of Queen's University.

Saguenay Branch P.D. program includes a chemical refresher course. Six of the seven participants are shown here, at the meeting of January 11: D. Williamson, W. W. Robertson, sec.-treas., J. Jefferies, D. Monogan, M. Marhengi, H. Edwards.

The Saguenay course in public speaking has an enrolment of 11. In this group, photographed on January 10: G. B. Gilbert, chairman; J. K. Furlong, J. Kirkland, B. Benson. Other members are: R. V. Norman, H. J. Baker, T. Barwick, R. Langevin, E. Wiggans, B. Culton, and S. Wellein.

Other branches have professional development courses, photos of which were not available for this report.

Orchids from U.S.A.

The following letter from Harvey M. Kolesar, JR.E.I.C., came into Institute Headquarters some time ago but several months passed before we were able to get in touch with Mr. Kolesar to see if we had his permission to publish the letter in the *Journal*.

In this day and age when so many of us in Canada seem to think that all the best things come from countries outside of Canada it may be a bit of a surprise and relief to find that at least one Canadian engineer believes that on a comparative basis the Engineering Institute of Canada is not doing too badly in Canada. — Ed.

Dr. L. Austin Wright:

Your invitation to the reception at the Sheraton-Blackstone Hotel in Chicago, on Wednesday, November 16, is gratefully acknowledged, and I regret that I shall be unable to attend.

The Engineering Institute of Canada is rightfully included in the celebration, for their part in improving the standing of the engineering profession in Canada deserves considerable praise. It is unfortunate that there is not a similar organization in the United States to serve as a rallying point for all engineers, for it has been my observation that the prestige of engineering is certainly higher in Canada than it is in this part of the United States.

Harvey M. Kolesar, JR.E.I.C.,
Wheatridge, Colorado.

Thirty-five Years Ago

Comment on the *JOURNAL* of April 1921

The *Journal* for April, 1921, finally got around to announcing the results of a letter ballot on several proposals to amend the bylaws, including one that would have raised the fees. This one was defeated; as I wrote last month, the first report the *Journal* carried made it look as though it was defeated solely by the votes of those present at the Toronto meeting, but it seems that every corporate member had his chance to say "Yea" or "Nay". I couldn't imagine that it could have been otherwise, but I reported the matter just as the *Journal* did in March, 1921.

The principal technical paper in this April *Journal* was "Relay Protection Features of the Toronto Power Company's Transmission and Distribution System", by P. Ackerman. The schemes of protection described, some of which appear to have been novel for the times, were successful in reducing the outages in the company's system. As a general average, complete outage became very rare by 1920 and only six times during that year was more than 30 per cent of the load lost through line disturbance.

Mr. Ferdinand van Bruyssel, the organizer of the Belgo-Canadian Pulp & Paper Co., Ltd., in "The Pulp and Paper Industry of Canada" made some pretty caustic comments on Quebec's treatment of the companies. His major theses were that leases of timber lands ought to run for long periods, that they should require something in the way of reforestation and that each ought to carry with it the lease of a power site, all, it would seem, reasonable enough requests. He mollified the provincial government in advance, however, by saying that it was "recognized to be patriotic, progressive and wise, a combination of qualities one should not expect to find in a ministry elected under a system of universal suffrage, unattended as yet by any measure of proportional representation."

Under "Correspondence" there appeared an unusual letter from Lockwood, Greene & Co., of Boston, congratulating J. M. Oxley on his paper on the economics of building design, noted here last month. "(A) very excellent paper . . . one of the finest we have seen . . . We shall find this paper of very great value in checking our (own) results"; thus L.G. & Co., then perhaps the leading firm of industrial engineers and architects in the United States. This letter must have pleased Mr. Oxley.

Another correspondent quoted some of the propaganda of the Technical Alliance of New York. In effect, this organization claimed that all government and all industry ought to be run by engineers and technicians as they were the only people who really knew how. I believe this was the beginning of the cult of "Technocracy", which created quite a stir for a time. Where is it now? It is dead; it failed, largely, I think, because like most socialistic movements it did not recognize the most basic of human desires, the desire for personal advancement. This correspondent naively concludes his letter, "The foregoing . . . which I cannot quite follow in all its inferences, seems to me . . . provocative of thought . . ."

For some months the *Journal* had been running a column or two in each number of "Town Planning News and Comments". The contents of these columns can be succinctly summed up as composed of personals, accounts of numerous conferences and endless talk and little or no report of tangible results. Town planners have ever been good talkers.

In April, 1921, the *Journal* carried lists of engineering students at McGill and Queen's Universities who were looking for permanent or summer jobs. Most of the names mean little to us, but there is the occasional one of somebody who made a name for himself in the nation's affairs.

This *Journal* ran a brief biography of H. G. Acres, M.E.I.C., who had just been elected a vice-president on a special nomination against the candidate put up by the Institute's nominating committee. One gets the impression on reading this note that the writer was not too pleased with Mr. Acres' election. He served the Institute long and well and those who nominated him did us an excellent turn.

The Calgary Branch listened to a talk on the petroleum situation. The speaker estimated that United States production would cease about 1938. He thought that Alberta's chances of becoming a real producer were pretty slim and he gave its 1920 production as about 12,000 barrels. Geological exploration was too uncertain and cost too much, he said. Beside, geological exploration was quite unnecessary. Some years before one lucky Alberta oil man knew a squaw "quite intimately." She pointed out a place where oil was flowing in a great river under some land he owned. He sank a well, struck oil and there you are.

The Saint John Branch was interested in the paving of the streets of its city, about 70 per cent of which were then unsurfaced . . . "Granite blocks and asphalt are the best types of paving for use in Saint John." Where were the concrete people, to let such a statement pass without comment?

They had just finished the Toronto-Hamilton highway, which gave them something of which to be proud. Asphalt is still very much with us, but a street paved with granite block is a museum piece.

And so we may now put down this *Journal* in the hope that when we look into the one of May, 1921, we shall find something a little more exciting.

Elections and Transfers

At the meeting of Council held at the Chateau Laurier Hotel, Ottawa, Ontario, on Saturday, March 24th, 1956, a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

Members:

K. Bailes, *East Angus*
R. L. Booth, *Toronto*
L. G. Cazaly, *Toronto*
V. Davidovitch, *Montreal*
F. H. Davies, *Toronto*
T. J. Farrell, *Montreal*
G. Gelfreih, *Montreal*
J. F. Gniewosz, *Montreal*
M. G. G. Curr, *Toronto*
M. D. Head, *Copper Cliff*
A. Himsley, *Toronto*
S. C. Jones, *Owen Sound*
A. Kane-White, *Montreal*
J. Kates, *Toronto*

Members:

J. E. Bright	W. McCabe

Junior to Member:

E. P. Smith

NEWS OF THE ASSOCIATIONS & CORPORATION

Information received through co-operation with the provincial organizations

Quebec

Leo Roy, New President

Leo Roy, of Montreal, was elected president of the Corporation of Professional Engineers of Quebec at the 37th annual meeting of the group, held in Montreal.

Leo Roy

A graduate of Ecole Polytechnique and McGill University, Mr. Roy is chief engineer of auxiliary services at the Hydro-Quebec. He had previously been connected with the Shawinigan Water and Power Company and the Quebec Power Company.

Mr. Roy is vice-president of the Montreal Section of the Engineering Institute of Canada, a vice-president of the Electrical Club of Montreal, and a member of the Illuminating Engineering Society, the Canadian Gas Association, the American Institute of Electrical Engineers. He has also been active on the Engineers' Council for Professional Development.

The new Council of the Corporation of Professional Engineers for 1956 is as follows: president, Leo Roy; vice-president, R. A. Phillips; honorary secretary-treasurer, Guillaume Piette. Quebec district representatives are Robert Painchaud and O. S. Gislason, and Montreal district representatives are Yvon De Guise and Leopold Nadeau.

Ontario

Initial Meeting of Council

The inaugural meeting of the 1956 Council of the Association took place on January 26 and 27, President M. W. Hotchkin being in the chair. In opening the meeting Mr. Hotchkin specially welcomed the new members of Council, J. H. Irvine, Ottawa; D. S. Simmons of Toronto, J. W. Holmes, Peterborough; and Dr. C. P. Jenney, Toronto.

Reports submitted by committees included that of the Board of Examiners, under the chairmanship of Professor V. G. Smith. This report contained the recommendation that graduates of the course in chemical engineering at the University of Ottawa be given the same recognition as given graduates of similar courses of other Canadian universities. The recommendation was unanimously approved by Council.

The chairman of the Professional Status Committee, Gordon W. Ames, reported that during the latter part of the year recommendations of Council that courses be started to train technicians in heating, ventilating and plumbing; refrigeration and air conditioning; and structural draughting and design detailing had been transmitted to the Ontario Department of Education. He further reported that a reply had been received to the effect that steps had been taken to implement the first two courses and that the last-named, structural draughting and design detailing, is already operating at the Provincial Institute of Trades in Toronto.

Approval was given by Council to the awarding, in 1956, of nine scholarships each at the University of Toronto, and Queen's University, to undergraduates in the first, second and third years. Another award authorized was the Admission Scholarship which this year will be given to the top Grade 13 student entering engineering at the University of Toronto. This alternates between Toronto and Queen's. In addition to the above there is also the Association's Gold Medal which is awarded to a member of the graduating class in engineering at these two Universities for academic attainment.

The secretary-treasurer reported that as of December 31, 1955 the number of members enrolled totalled 14,027, a net increase of 1,024 members during 1955. During the year 90 members were added through transfer to the Association as against 72 who left Ontario to join other Associations.

Committees

Committees appointed for the year are as follows:

Executive: M. W. Hotchkin (Chairman); J. R. Montague; J. H. Fox; C. T. Carson; T. N. Carter; J. H. Waghorne; D. S. Simmons; J. H. Ross; G. B. Langford.

Legislation: G. B. Langford (Chairman); W. D. Sheldon; J. R. Cavanagh; F. R. Duncan; J. W. Holmes; J. H. Irvine.

Finance: J. H. Fox (Chairman); C. T. Carson.

Professional Status: G. W. Ames (Chairman); J. H. Waghorne; N. Fodor; D. L. Angus; A. DeMaio; O. D. Johnston; D. R. Yeomans.

Public Relations: P. E. Cavanagh (Chairman); W. J. Gilson; J. N. Milne; J. W. Carrington; C. F. Morrison; R. W. Harris; R. C. Poulter; R. G. Tredgett.

Practice and Ethics: J. F. MacLaren (Chairman); G. R. Lord; A. E. MacRae; E. A. Cross; M. S. Fotheringham; O. D. Johnston; N. A. Eager; C. W. Knight.

Board of Examiners: V. G. Smith (Chairman); W. L. Sagar; S. E. Wolfe; R. C. Wiren; C. K. Fraser; N. Fodor.

Appeal Board: A. W. Murdock (Chairman); G. B. Langford; J. W. Bain; W. J. Gilson; J. H. Fox.

House: G. R. Lord (Chairman); J. H. Brace; J. R. Mens; B. A. Hole.

Consulting Practice: J. H. Ross (Chairman); E. A. Cross; D. L. Angus; W. H. Bonus; R. A. Crysler; A. D. Margison; L. C. A. Walford.

Insurance: A. W. Murdock (Chairman).

Interviewing: R. C. Wiren (Chairman); K. R. Rybka; J. W. Bain; O. W. Ellis; N. Fodor.

Professional Engineers Medal: J. C. Keith; W. P. Dobson; O. W. Ellis; M. J. Aykroyd; L. F. Grant; E. V. Buchanan; H. G. Conn; A. E. MacRae; G. L. Macpherson.

Honour Science Graduates: G. P. Jenney (Chairman); G. L. Macpherson; V. S. Murray; W. G. McIntosh; W. P. Dobson.

Scholarship: G. R. Lord (Chairman); A. M. Doyle; W. W. Loucks; G. M. McHenry; K. C. Siddall.

Company Groups: J. H. Waghorne (Chairman); J. H. Fox (Vice-Chairman); G. W. Ames; (alternates: J. W. Holmes; V. S. Murray).

Over 400 Write Qualifying Tests

Some 360 hopeful applicants were busy writing examinations in March in a central-Toronto church hall that could qualify them to practise professional engineering in Ontario. Another 45 to 50 persons were writing the same type of examinations in other Ontario centres as well as in certain parts of Canada, including one Canadian serviceman stationed in Germany. The examinations began March 19.

A total of 62 different papers on the various branches of engineering constitute the examinations held annually by the Association of Professional Engineers of Ontario. Applicants must write a maximum 15 separate papers at university level and a thesis on the particular branch of engineering chosen.

The examinees comprise a number of skilled technicians who have not received an engineering degree from a university, but who have the background and experience to try for admittance to Association membership.

"Approximately two or three per cent of those admitted to membership stem from the examination-writing group," says J. M. Muir, Association secretary-treasurer. He adds that about 60 per cent are successful, a figure comparable to university examinations. The majority of candidates are over 30 years of age, and there is a significant sprinkling of new Canadians among them. Many of these have taken engineering in their native lands, but must pass additional examinations in order to qualify under Canadian standards.

The examinations are set by university professors and noted professional engineers.

This year marks the first time that a uniform syllabus of examinations is being used by the ten provincial registering bodies of the engineering profession.

News of Members

James M. Reed, has been appointed to the Ontario district sales staff of Ferranti Electric Ltd., Mount Dennis, Toronto, as a sales engineer.

A graduate in electrical engineering of the University of British Columbia, Mr. Reid was engaged in traffic control and street lighting and engineering and communication sales from 1951 until he joined Ferranti Electric in 1955.

G. W. Mitchell, fomerly sales engineer at the Toronto office of Canadian Westinghouse Co. Ltd., has been appointed sales engineer of the apparatus division at the Windsor, Ont., office of the company.

Ian L. Colquhoun of English Electric Co. Ltd., St. Catharines, Ont., has been made manager of circuit breaker engineering of the company; **James A. Hibbert,** manager of switchgear engineering; and **J. R. M. Szogyen,** assistant manager of rotating equipment engineering.

Leslie A. Shaver, of Canadian Westinghouse Co. Ltd., Hamilton, Ont., has been appointed to the new position of headquarters approvals engineer of the company.

Mr. Shaver has been with the organization for over 40 years and before receiving his new appointment was section engineer of marine and transport control. His new responsibilities will include co-ordination of all Westinghouse activities associated with the Canadian Standards Association.

R. C. McMordie has recently resigned from the engineering staff of the Hydro-Electric Power Commission of Ontario to assume the appointment of chief engineer of the British Columbia Power Commission. This new responsibility has entailed his move from Toronto to Victoria, B.C. (See "Personals.").

Charles A. Wakeham is now associated with H. G. Acres & Co. Ltd., of Niagara Falls, Ont., and recently arrived in Masanjore, India, where he will be located for several months during the construction of the power house at the Canada Dam.

Mr. Wakeham graduated in electrical engineering from the University of New Brunswick in 1928 and has had a wide professional experience in the electrical and industrial fields.

John R. Caswell retired some months ago as Algoma district engineer of the Canadian Pacific Railway. Mr. Caswell has since been devoting part of his time in engineering work with the Caswell Construction Co. Ltd. of Kirkland Lake, of which his brother is senior executive. The undertaking in which Mr. J. R. Caswell is engaged is in the Sault Ste. Marie area.

George W. Beecroft, of Toronto, is president of Propane Containers of Canada Ltd., Mimico, Ont. **John H. Becker** is vice-president and general manager and **James W. Thompson** is works manager.

This company is manufacturing a complete line of bulk tanks for propane gas and anhydrous ammonia, and also equipping tank trucks for bulk deliveries.

W. K. Redsell has been appointed inspector of mines at the Sudbury district. A graduate in mining engineering from the University of Toronto, Mr. Redsell has latterly been with Kerr Addison Gold Mines Ltd., at Virginiatown, Ont.

N. J. Ypes has advised of the change in firm name to Jackson, Ypes and Associates with offices at 5453A Yonge St., Willowdale, Ont. The partnership of Mr. Ypes and D. K. Jackson, M.R.A.I.C., started three years ago and has operated under the name of Jackson and Ypes until the recent change. Jackson, Ypes and Associates engage in consulting practice as engineers and architects.

New staff announcements have been made by Johnson Temperature Regulating Co. of Canada Ltd., Toronto, as follows: **W. L. Rootham,** who has been manager of the Toronto branch, becomes assistant sales manager with headquarters at the company's main office in Toronto. **Bruce Overend,** formerly engineer in charge of the London, Ont., branch, succeeds Mr. Rootham as Toronto manager. **Arthur P. Johnson,** of the Toronto branch, becomes engineer in charge at London, Ont. **T. M. Patterson** will supervise the assembly and manufacturing operations at the company's Toronto headquarters.

Kenneth E. Hunter has accepted the position of manager of the geophysics department of Hycon Aerial Surveys, 1020-1030 South Arroyo Parkway, Pasadena 2, California.

Mr. Hunter is a graduate in engineering physics of the University of Toronto and prior to joining Hycon Aerial Surveys was chief geophysicist of Tsumeb Corporation Ltd., of Tsumeb, South West Africa.

R. B. Sweet has moved from Sault Ste. Marie, Ont., to Windsor Mills, Que., where he is employed by the Canadian Paper Company as assistant mechanical superintendent. Prior to this change in work Mr. Sweet was with Algoma Steel Corporation Ltd. as a sales representative.

J. R. Baird has resigned his position of chief engineer of Trailmobile Canada Ltd., to assume the duties of a director and chief engineer of York Transport Equipment Ltd.

Mr. Baird will be in the United Kingdom for a period in connection with the establishment of a subsidiary company owned by York Transport Equipment Ltd. and his address will be York Trailer Co. Ltd., Cherry Lane, Liverpool, England.

A. J. G. Campbell, formerly combustion engineer of Imperial Oil Ltd., has been made field engineer of the National Warm Air Heating and Air Conditioning Association of Canada, with headquarters at 4195 Dundas St. West, Toronto 8.

His initial undertaking will be a trip across Canada during which he is scheduled to deliver a number of lectures on the latest requirements and developments in the warm air heating industry.

Ivan M. Wallace has joined the firm of consulting engineers, C. C. Parker and Associates, of Hamilton, Ont., and will have general supervision of their Western Ontario operations. His address in London is 232 William St. Mr. Wallace, who obtained his engineering education at the University of Toronto, has been chief engineer of the London Steel Construction Co. Ltd. for a number of years.

H. F. McEntire, chief engineer of Atlas Steels Ltd., Welland, Ont., has announced the promotion of **Thomas J. Nolan** to the position of assistant chief engineer, and of **Harry L. Brien** to the post of electrical engineer.

Mr. Nolan is a Toronto graduate of 1938 and first joined Atlas Steels in 1943 in connection with the company's extension program. In 1946 he was employed by H. G. Acres and Company in connection with power developments on the Pacific Coast and in 1947 he returned to Atlas where he has functioned as plant electrical engineer until his recent promotion.

Mr. Brien obtained his engineering degree at Queen's University in 1952, in which year he joined the company. In 1954 he was appointed engineer of the hot planetary mill and in 1955 was made general foreman of the stainless strip and tube department.

J. N. Milne has recently been appointed assistant manager of the Market Research Department of MacLaren Advertising Company Ltd., Toronto.

Mr. Milne obtained his degree in electrical engineering at Queen's University in 1935 and in that year joined the Canadian General Electric Company's test course. Remaining with the company until moving to the MacLaren Advertising Company last fall, he was engaged in the engineering and marketing areas of the C.G.E. activities. Seven of his 20 years with the organization were spent with the export subsidiary and for the past three years he was manager of marketing research.

British Columbia

Granted Life Membership

The Association of Professional Engineers of British Columbia announced on February 16 that the following engineers have been granted life membership in the Association: Col. W. G. Swan, Charles Brakenridge, Charles Bentall, F. J. Bartholomew, H. P. Archibald, C. T. Hamilton, F. B. Hardin, T. H. D. Lundy, W. G. McElhanney, J. S. Wilson, M. Y. Williams, W. W. Urquhart, S. J. Crocker, A. Cummings, G. H. Burnett, E. F. Carter and F. Bagshaw, all of Vancouver.

B. C. Affleck, Nelson; F. J. Donkin, Francois Lake; D. J. McCugan, New Westminster; C. D. MacKintosh, Victoria; G. J. Jackson, Victoria; E. I. W. Jardine, Victoria; G. H. Shepherd, Burquitlam; E. N. Horsey, Victoria; H. D. Dawson, Royal Oak; F. P. Burden, Prince George; and E. F. Cooke, Sechelt.

Engineers in the News

A. G. Tanner has sent word that he is now with Angus Robertson Ltd., as assistant construction engineer on the Warsak hydro-electric development in Pakistan. This work is being carried out under the terms of the Colombo Plan and Mr. Tanner expects to remain on the project for two to three years.

J. B. Bush, formerly at Nickel Plate, B.C., is now employed as a geologist with Granby Consolidated Mining Smelting and Power Co. Ltd. at Copper Mountain, B.C.

W. E. Erlebach, who was studying in England at Cambridge, is now back in Canada with the Atomic Energy Commission, Deep River, Ont.

B. Colloby has accepted a position with H. A. Simons Ltd. as assistant project engineer. He was previously with Alaska Pine and Cellulose Co. Ltd.

W. C. Rueger, who had previously been with Industrial Mill Services, has taken a position with John Laing and Son (Canada) Ltd.

W. R. Cheriton recently accepted a position in Edmonton with Wirtanen Electrical Co. Ltd., on industrial installations, maintenance and repairs. He had been employed by Hume and Rumble Ltd. in Vancouver.

H. J. Page was recently appointed assistant chief engineer of the Public Utilities Commission. Mr. Page is a 1949 electrical graduate of the University of British Columbia and has been in Vancouver as toll plant extension engineer at the B.C. Telephone Company.

G. S. Ortner has been appointed to the position of assistant manager of the personnel division of the Consolidated Mining and Smelting Company of Trail, B.C. Mr. Ortner, who has been with the company since his graduation as a chemical engineer in 1928, had recently been supervisor of methods studies.

Wm. Thornber of the B.C. Lumber Manufacturers' Association left for the United Kingdom at the end of March with Professor Fred Lasserre, director of the School of Architecture at the University of British Columbia. Mr. Lasserre will give a series of talks to architectural groups in 12 major cities. He will feature Pacific Coast housing designs and building methods in this program, which is sponsored jointly by the Department of Trade and Commerce and the B.C. Lumber Manufacturers' Association.

E. H. Parr, who has been with the Northern Construction Company and J. W. Stewart Ltd., and recently engaged in work on the Distant Early Warning Line, has accepted a position as project engineer with the newly formed B.C. company, Route Surveys and Engineering Ltd.

W. H. R. Gibney of the Consolidated Mining and Smelting Company, has been transferred from the Bluebell Mine at Riondel to the Sullivan Mine at Kimberley as section engineer.

V. N. Jacobson is now living in San Francisco and has accepted a position as structural engineer-designer with Sverdrup and Parcel Inc. Mr. Jacobson has been employed by Swan, Wooster and Partners for the past several years.

R. C. Wannop, formerly with F. W. Urry, is now with A. B. Sanderson and Co. Ltd. in their Vancouver office.

Knute Soros, until recently assistant city engineer of New Westminster, has taken a position with the B.C. Engineering Company in Vancouver. Mr. Soros had been with the City of New Westminster since his graduation from the University of British Columbia as a civil engineer in 1949.

H. J. Greenwood has accepted a position with Ventures as a geologist on their Lake Dufault property in Noranda, Que. Mr. Greenwood received his B.A.Sc. degree in geological engineering at the University of British Columbia in 1954, and has been working towards his master's degree.

J. B. Dyson has left the employ of the Department of Fisheries, Vancouver, and has taken a position with H. G. Acres and Co. Ltd. on the John Hart Power Development at Campbell River, B.C.

E. E. Olson, a 1952 civil engineering graduate of the University of British Columbia, is now studying for a M.B.A. degree at the Graduate School of Business Administration, University of California, Berkeley. He is on leave of absence from the Canadian National Railway's department of research and development at Montreal.

Bruce Tait has resigned his position with the bridge department of the Provincial Department of Highways, and has joined the Tidewater Contracting Company. He will continue to reside in Nanaimo.

I. D. Smith has accepted a position with the Linde Air Products Company at Tonawanda Laboratories, New York State. He will be leaving his position as associate research officer, Fraser River model, Department of Civil Engineering, University of British Columbia at the end of April. He also intends to study control engineering at the University of Buffalo.

L. A. Butterfield, previously with the eastern company of Ainsworth Electric, has accepted a position with Elworthy and Co. Ltd. of Vancouver.

D. H. Baker recently resigned his position with MacMillan and Bloedel Ltd. to become assistant manager of the new B.C. Forest Products Ltd. mill at Crofton.

J. H. Shumka, a 1950 chemical engineering graduate of the University of British Columbia, has been appointed technical supervisor, Harmac pulp division, MacMillan and Bloedel Ltd., the position left vacant by D. H. Baker.

Norman E. Cooke has recently joined the staff of Canadian Industries Ltd. in Montreal as a chemical engineering specialist. Dr. Cooke spent the past three and a half years at the Massachusetts Institute of Technology, where he recently completed work for his D.Sc. degree in chemical engineering. Prior to attending M.I.T., he served in Korea with the R.C.E. and, after graduation from the University of British Columbia (M.A.Sc., 1946), was employed by the Pacific Fisheries Experimental Station of the Fisheries Research Board in Vancouver.

J. A. Willcox is now with the Pacific Coast Pipe Co. Ltd. as a sales engineer. He was formerly with Lorado Uranium Mines Ltd. as property superintendent.

H. N. Halland has been appointed consultant to the Shawinigan Engineering Company in Montreal. Mr. Halland had been project engineer for the Greater Vancouver Water Board on the Cleveland dam.

A major shuffle in the Department of Highways has come up with several promotions for department engineers:

D. D. Godfrey, divisional engineer at Prince George since 1950, has been promoted to regional engineer of the Vancouver Island - Lower Mainland region. **R. S. Cunliffe,** divisional engineer at Prince Rupert, has been appointed regional engineer at Prince George. **M. C. Nesbitt,** district engineer at Fernie, has been appointed regional construction engineer at Prince George.

O. W. H. Roberts, divisional engineer at Pouce Coupe, has been promoted to regional maintenance engineer at Prince George.

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Charles Osborn Wood, M.E.I.C., retired civil engineer and Dominion Land Surveyor, and former resident of Ottawa, died on December 2, 1955, in Montreal.

Born in Elwood, near Ottawa, on October 8, 1868, he attended Lisgar Collegiate, Ottawa. His first engineering duty, in 1890, was as a rodman with a survey party for the Great North Western Railway in the Saskatoon and Battleford, Sask., areas.

C. A. Wood, M.E.I.C.

Back in Ontario the following year, he became, in turn, transit man, assistant in municipal drainage engineering, engineer of roads and bridges, and township engineer for the communities of Gloucester, Kenyon and Casselman, Ont. In 1901 he joined the late Andrew Bell and was engaged for the next few years on hydraulic engineering and flood investigations for the Dominion government. Some of the projects on which he was employed while working with Andrew Bell, were the Rouge River electric power house and dam at Table Rock Falls, Que., the electric power house at Almonti, and the bridge and dam over the Mississippi River at Almonti.

The occupation of Dominion Land Surveyor had been already well established in the family as Mr. Wood's father, Henry Osborne Wood and his grandfather, Leonard Wood, had previously held the title.

He became associated with the Ottawa firm, Keefer and McKay, around 1910 as a civil engineer, and remained with the firm until his retirement in 1949, both as an engineer and later as manager of the Keefer and McKay estates. He was, also, for many years engineer for the village of Rockcliffe, in Ottawa.

For many years Mr. Wood served with the old 43rd Regiment, Duke of Cornwall's Own Rifles, retiring with the rank of captain.

Mr. Wood joined the Institute as an Associate Member in 1904, transferred to Member in 1940, and attained Life membership in 1947.

Gustave C. Piché, M.E.I.C., noted forest authority, died in Montreal, on February 7, 1956. Mr. Piché was president of Titanium Products Corporation, vice-president of Hebecourt Corporation, and consulting forester with the James MacLaren Company Ltd., Birmingham, Que.

Born in Montreal, on December 3, 1879, he attended Mount St. Louis College, Ecole Polytechnique, Yale Forest School, Laval University, and l'Ecole des Eaux at Forets, in Nancy, France.

He obtained his master of forestry degree at Yale in 1907, and a master of arts at Laval in 1923. Emeritus Professor, he was granted by the same university his doctorate in science (honoris causa) in 1937.

Before entering the Ecole Polytechnique and Yale University he worked as a clerk for the Canadian Pacific Railway, 1897-1900, and as a clerk for the Belgo-Canadian Pulp and Paper Company until 1903.

Upon his return from Yale, he served as forest engineer from 1907 to 1909 for the provincial government. He was then named chief of the forest service, holding this position until 1936. During the second world war he undertook the task of deputy wood fuel controller for Quebec.

As a representative of the province on special missions to Europe, he travelled widely in France, Italy, Germany, Belgium and Sweden.

Mr. Piché was the founder of Laval University's forestry school, in Quebec City, and was the first director of the institution from 1910-19. He was the promoter and first general inspector of the Ecole de Papeterie in Three Rivers, Que., and the School of Forest Rangers. From 1931 to 1936 he was secretary-manager of the Timber Products Commission of the Province of Quebec.

He was a member of the principal European, American and Canadian forestry associations. He delivered many papers in Europe, the United States and Canada and was responsible for articles on forestry and wood utilization.

G. C. Piché, M.E.I.C.

Recognized as the Father of Forestry in Quebec, he was awarded the O.B.E. for meritorious service, the Jubilee Medal, and the rank of Officier du Mérite Agricole, by the French government. The Association of Forest Engineers of the Province of Quebec presented him with a diploma of honour, for meritorious services and made him a life member of the association in 1954.

Mr. Piché was a life member of the Association des Anciens du Mont St. Louis, the Société Forestière de Belgique, the Quebec Forest Association, and the alumni society of Yale.

He joined the Engineering Institute in 1913 as an Associate Member, transferred to Member in 1940 and attained Life membership in 1946.

Alfred Netlam Beer, M.E.I.C., who retired as engineer for the Canadian Pacific Railway's Laurentian division in 1944, died on December 3, 1955, in Montreal.

Born in Canterbury, England, on August 31, 1870, he was educated at the College of Preceptors, South Kensington, London. His early experience as engineering assistant was gained at the Borough water works of Richmond, Surrey, during the years 1892 to 1898 and in 1899 he was resident engineer of Woking Water and Gas Company, Surrey. In 1907 he transferred to a similar position with a company in Bristol.

Mr. Beer left England in 1912 and, coming to Canada, assumed the position of assistant city water works engineer,

• Obituaries

in Ottawa. In 1921 he joined the C.P.R. and remained with the company until his retirement from active engineering work in 1944.

He was a life member of the Corporation of Professional Engineers of Quebec, and of the Engineering Institute. He joined the Institute in 1915 as an Associate Member and became a Member in 1940.

Charles E. Herd, M.E.I.C., retired consulting engineer with the Dominion Engineering Company Limited, of Montreal, former resident of Ventnor, Ontario, died on January 9, 1956, in Brockville, Ont. He had been ill for only seven weeks, after enjoying four years of retirement.

Mr. Herd was born in Crewe, Cheshire, England, on July 12, 1875. Educated at Crewe Academy, and the Mechanics Institute, Horwich, England, he was apprenticed to the Lancashire and Yorkshire Railway Company at Horwich.

Coming to Canada in 1895 he worked as fitter and assistant to the chief draftsman with the Canadian Pacific Railways in Montreal. From 1899 to 1910 he was with the Laurie Engine Company and in a few years had direct charge of design, and of the preparation of estimates and specifications for Corliss engines and other machinery.

In 1910 he was assistant draftsman to Allis Chalmers Bullock on hydraulic turbines, and had charge of the mechanical design of electrical apparatus. He went in 1911 to the Dominion Safe and Vault Company at Farnham, Que., as chief engineer. In 1916 he transferred to the Montreal Ammunition Company as assistant chief draftsman.

He became associated with Dominion Bridge Company in their design and estimate department in 1917.

In 1920 he transferred to the Dominion Engineering Company of Montreal, and remained with the firm until his retirement in 1952, being employed as mechanical engineer in the hydraulic department. He was appointed a consulting engineer with the firm in 1949.

Mr. Herd joined the Engineering Institute in 1920 as an Associate Member and transferred to Member in 1940. He attained Life membership in 1950.

A. M. MacKenzie, M.E.I.C., former assistant vice-president in charge of labour relations for Bell Telephone Company of Canada, died on January 30, 1956 in Montreal, after forty-seven years of service with the organization. He had retired to private life only shortly before his death.

Mr. MacKenzie was born at Guelph, Ont., on June 13, 1891, and it was there that he began his telephone career in 1908. Two years later he entered the University of Toronto to study electrical engineering, working for the Bell Company during vacations. He graduated in 1914 and was sent back to Guelph as plant wire chief.

In 1916 he was transferred to the engineering department in Montreal. On leave of absence overseas, with the Royal Signal Corps, 1918-19, he served as a lieutenant, and on his return to Montreal was given the position of outside plant and transmission engineer, in which capacity he remained until 1927. He was then successively named division plant engineer, in Montreal, general plant supervisor of the Eastern Area; and general plant supervisor of personnel, Eastern Area.

Invested as a Commander of the Order of St. John of Jerusalem by Vis-

A. M. MacKenzie, M.E.I.C.

count Alexander, then Governor-General of Canada in June, 1947, he received the award for his deep interest in the St. John Ambulance Association. In recognition of his services as secretary of the Bell centre of the St. John Ambulance Association he was recently endowed with the Coronation Medal. He was president of the Montreal Personnel Association, 1951-52, and was among the Canadian delegates attending the Tenth Congress of the International Committee for Scientific Management in Brazil in 1953. Last fall he attended an executive meeting of the Committee in Norway. He was also associated with the work of the Canadian Management Council.

Mr. MacKenzie joined the Engineering Institute in 1921 as an Associate Member, transferred to Member in 1940.

Robert G. Watson, M.E.I.C., retired power superintendent for the City of Edmonton, died in Victoria, late in the summer of 1955.

Mr. Watson was born at Blackhurst Hill, Essex, England, on September 22, 1880. In 1896 he enrolled at the Robert Gordons Technical College of Aberdeen, Scotland, where he spent six years as a student, while at the same time being apprenticed to a company of Aberdeen engineers, foundrymen and boilermakers. In 1902 he passed the Board of Trade examinations as first class marine engineer.

His career began with the Houlder Brothers and Company Limited, shipowners in London, as first class engineer and with the Measham Colleries Limited, Leicestershire, England, where he was assistant mechanical superintendent of the Iron Ore Mine, at Wabana, Newfoundland. In 1924 he became the chief engineer of the St. John Dry Dock and Shipbuilding Company, which position he held until 1929.

Then came a period of four years association with R. A. Ross and Company as chief draftsman and later as design engineer. He worked in 1929-1932 as supervisor of all mechanical work on the building of the Beauharnois canal and power house. In 1933 Mr. Watson entered into private practice as a member of the Toronto firm, Watson and Ferguson, consulting engineers.

In 1937 he accepted the position of power superintendent with the city of Edmonton, where he remained until his retirement in 1946.

Mr. Watson joined the Institute in 1921 as Associate Member and became Member in 1940. He attained Life membership in 1952.

Dr. W. B. Ross, M.E.I.C., assistant registrar and assistant professor of mathematics at McGill, died on December 27, 1955, in Montreal, following a lengthy illness.

Born in Westmount, Que., on September 25, 1905, he had his preliminary education there and led the province upon matriculation in 1923. He entered McGill University with the Sidney Hodgson Scholarship that year, graduated with first class honours in mathematics and physics. He was a recipient of the Douglas Tutorial Bursary in Physics, for three years, the National Research Council Bursary in 1930, and the Studentship. In 1931 he gained a master of science degree and in 1933, the Ph.D. degree, in physics.

His engineering included survey work in Montreal and test and experimental work for the Canadian Marconi Company. During his post-graduate years he took part in research work being done on dielectric constants, the Heaviside and Appleton Layers, and on air flow and sound. In 1932 he was in charge of McGill's National Research Council party at Newfoundland, to investigate radio effects of Solar Eclipse.

Dr. Ross joined the staff of McGill University as lecturer in mathematics in 1932, was promoted to assistant professor in 1942, and assistant registrar in 1946. He also served for a number of years as university marshall and warden of Douglas Hall.

He joined the Engineering Institute as a Student in 1929, became an Associate Member in 1935 and transferred to Member in 1940.

Frank Young, M.E.I.C., assistant city engineer for the City of Saskatoon, died at his home on January 19, 1956, after a lengthy illness.

Mr. Young was born in Marclesfield, Cheshire, Eng., on September 6, 1891, and attended a technical school in that city. He came to Canada in 1911 and soon joined the surveying firm of Phillips, Stewart and Phillips, in Saskatoon, working on subdivision surveys, drainage projects, road surveys and municipal engineering. He remained with the firm for more than ten years.

In 1921 he accepted a position with the City of Saskatoon as field engineer on various types of municipal construction. He continued to serve the community until last July when ill health intervened, except for a period of five years war-time service with the Federal Department of Transport in work concerned with the development and paving of prairie airports. This led Mr. Young to recognition as an expert on asphalt paving. Named assistant city engineer in 1947, Mr. Young had served in all phases of the engineering department, and at the time of his death he had been with the city for thirty-four years.

He was member of the Association of Professional Engineers of Saskatchewan. He joined the Institute as an Associate Member in 1938, transferring to Member in 1940.

Alexander Stuart Donald, M.E.I.C., former chief highway engineer and deputy minister of public works, resident of Moncton, N.B., died at Shediac Cape, N.B., on September 25, 1955.

Born in Moncton in 1885, he was well known throughout the province for his many contributions to public life. During world war I he saw service overseas, was wounded in action and awarded the D.S.O. for gallantry. In the second conflict he was appointed chief airways engineer for the Eastern Air Command, under the Department of Transport. For outstanding work in this position, he was awarded the M.B.E., in the Dominion Day Honours, 1946.

He was appointed chief engineer for the Department of Highways and Public Works of N.B. in 1946, and subsequently became deputy minister of highways and public works for the province.

Mr. Donald, who retired in December, 1953, joined the Engineering Institute in 1942, and was elected chairman of the Moncton Branch in 1944. He has supported the work of the Institute in Moncton, and was a familiar figure at annnual meetings and at Maritime professional meetings.

J. D. MacMillan, M.E.I.C., died suddenly at his home in Beaupre, Quebec, on January 31, 1956.

Mr. MacMillan was born in Richardsville, N.B., on June 6, 1921, attended high school at Campbellton and, graduating in 1939, entered the University of New Brunswick. Four years later he obtained a B.Sc. degree in civil engineering. He immediately joined the Canadian Army on active service, receiving his R.C.E. commission that fall. He was later recommissioned in the R.C.I.C.

Discharged at the end of the war, he worked as instrumentman with the engineering division of Canadian National Railways in Quebec City, for a time, then in 1947 accepted a position with the Abitibi Power and Paper Company Ltd. After a few months in the Sault Ste. Marie, Ont., division he went to the engineering department in Beaupre, where he remained.

He joined the Engineering Institute as a Student in 1943, transferred to Junior in 1946, and Member in 1951. He was a member of the Canadian Pulp and Paper Association.

J. S. Wilson, M.E.I.C., retired president of Tyee Machinery Company Limited, died in Vancouver on February 21, 1956. He was chairman and founder of the company.

A Scot, Mr. Wilson was born in Glasgow on August 15, 1882. He received his mechanical engineering grounding in the Royal Technical College, Glasgow, and his early shop training in a Clydeside machine shop. He finished these studies in 1904 and in 1907 he moved to the United States where he established himself on the west coast, joining the staff of the Washington Iron Works. He remained there until 1915, when he transferred his services to the Willamette Iron and Steel Works, Portland, Oregon. Within two years he was appointed chief engineer. He also designed the company's first duplex loader and high lead yarder. In 1919 he was named managing director of the Canadian Willamette Company of Vancouver.

However, a few years later he resigned in order to establish his own logging machinery firm, opened early in 1922 and named Tyee Machinery Company. The firm was to supplv the equipment needs of the B.C. logging operator, which Mr. Wilson thought should be built locally. It served also as the local representative for other machinery firms supplying equipment essential to industry on the coast. An affiliate company is the Tyee Equipment Company. Mr. Wilson had been president and general manager until his retirement in 1955.

He was a member of the Association of Professional Engineers of British Columbia, and had been a member of the Institute since 1942.

W. Chester Smith, M.E.I.C., retired civil engineer and town planner, died on December 19, 1955, in Toronto.

He was born in Strathroy, Ontario, on October 3, 1886, and had his early education in London, Ont. He was an art school graduate in 1902, and received a first class teaching diploma in 1905. In 1912 he graduated from the University of Toronto with a B.A.Sc. degree. He qualified for the degree of civil engineer at the same university, in 1917.

Prior to this date he worked as assistant city engineer in Victoria, B.C., and with the government of British Columbia in the Water Rights Branch. He was chief engineer on the Sumas Reclamation project and was instrumental in the investigation and development of waterpower rights and irrigation for that province. Later, in 1919, he was, for a short time, consulting engineer in Vancouver.

He was also concerned at time with the development of the Mesabi Iron Range near Duluth.

In 1921 he went to Toronto to work as an engineer for the Toronto transportation commission.

Mr. Smith accepted the position of city engineer for the city of Oshawa, Ont., in 1922, and during eight years supervised the rebuilding of the city's road, water sewage and fire fighting systems and in general conditions conducive to industrial investment, and expansion and residential comfort.

Mr. Smith joined the Cooksville Company Limited, of Toronto in 1931 as chief engineer, taking a prominent part in the development and full utilization of light-weight building products. He remained with the firm until his retirement in 1952, due to failing health.

Well known in civil engineering circles in the United States and England, he was, from 1946 until 1950, a director of National Concrete Masonry Association. He was a member of the Corporation of Professional Engineers of Quebec. He joined the Engineering Institute in 1936 as a Member.

F. A. Brownie, M.E.I.C., president of Canadian Western Natural Gas Company Limited, and prominent in the province's gas utility industry, died on January 23, 1956, in Calgary.

Mr. Brownie was born in Montreal, on April 16, 1908. He received his public and high school education in Calgary as well as a first class teaching certificate from the Calgary normal school. In 1933 he graduated from the University of Alberta with a B.A. degree and a year later he received a B.Sc. degree in civil engineering.

F. A. Brownie, M.E.I.C.

As a student he had worked on townsite surveys for the Canadian Pacific Railway and on the construction of Glenmore Water Supply project of the city of Calgary.

On graduating, in 1934, he spent the summer as instrument man on a seismic survey for Dominion Gas Service Limited. Later that year he became an inspector in the assessments branch of the Department of Municipal Affairs in Edmonton.

• Obituaries

He joined Northwestern Utilities Limited in Edmonton in 1935 as an assistant engineer. In 1939 he went to Calgary to assume the position of assistant to the general manager of Canadian Western Natural Gas Company Limited. Named general manager of the company in 1948, he became president of the two gas companies a year later. In 1954 he assumed also the presidency of Canadian Utilities Limited.

Mr. Brownie was a director of the Alberta Gas Trunk Line Limited and head of Sturdie Propane Limited, Hugh Gas Limited, and New Fidelity Trust Company.

A tireless worker in his direction of the various companies under his leadership, he found time for community work as well, through the Calgary Chamber of Commerce and the Canadian Red Cross Society.

He was a past-president of the Canadian Gas Association, a past director of the American Gas Association and a past-president of the Association of Professional Engineers of Alberta.

He had been associated with the Engineering Institute since his student days, joining in 1932, and transferring to Junior in 1935, to Associate Member in 1938, and to Member in 1940.

Professor A. E. Flynn, M.E.I.C., dean and professor of mining engineering at the Nova Scotia Technical College, Halifax, died suddenly on February 28, 1956, in Halifax.

Professor Flynn was born in London, England, on October 29, 1890. He received his preparatory eduction in the United States, where the family were then established, but later returned to England for specialized training at Finsbury Technical College, London, 1906-08, and the Royal School of Mines for the next three years. In 1912 he had qualified for the degrees of A.R.S.M. and D.I.C.

He gained his early professional experience in England, Germany and Spain, but soon after completing his studies was attracted to the development at Cobalt, Ont. He came to Canada to take up work in Cobalt for the Nipissing Mining Company from 1912-1916. He designed and built the mining laboratory of the Haileybury School of Mines in which he was one of the first instructors in 1916-1918. After two years spent in mining pyrites at Goudreau, Ont., and a year with the Hardinge Company at York, Pennsylvania, in 1921, he was offered the chair of mining engineering at the Nova Scotia Technical College, where he remained permanently. In 1953 he was made Dean of Faculty.

His service to Nova Scotia was not confined to teaching. Acting as development engineer in the provincial Department of Natural Resources for five years, and in many other ways, notably by extensive research in the utilization of minerals, he played an important part in developing the mineral industry of the province. He contributed many invaluable papers and discussions on the subjects in which he was an authority. He was a member of the Nova Scotia Advisory Board of Mineral Development.

Professor Flynn joined the Engineering Institute in 1940. He worked with the Halifax Branch and filled the offices of chairman and representative on the Institute council, the latter in 1945.

His support was felt by several professional organizations. He was elected president of the Canadian Institute of Mining and Metallurgy in 1953. He had earlier served that Institute as vice-president for the Maritimes in 1941-1942, and a member of council in 1937-1939, and chairman of the coal division in 1948-1949.

Prof. A. E. Flynn, M.E.I.C.

He was president of the Mining Society of Nova Scotia in 1939; president of the Association of Professional Engineers of Nova Scotia in 1947. He held membership also in the American and British Institutes of Mining and Metallurgy.

Professor Flynn was awarded the Leonard Medal of the Engineering Institute in 1930.

G. A. Sutherland, M.E.I.C., executive assistant with the electrical engineering and radio branch of the National Research Council, Ottawa, died on December 5, 1955, in Ottawa.

Mr. Sutherland, who was born in Winnipeg, on October 31, 1913, received his education there and in 1934 was graduated from the University of Manitoba with a B.Sc. degree in electrical engineering. He joined the firm of Fetherstonhaugh and Company soon after, but in 1935 transferred to the position of technical instructor at the Chicago Institute of Diesel Engineering in Winnipeg for a two year term. He became a member of the staff of Kipp-Kelly Limited, in Winnipeg, as a designing engineer in 1937, and later gained experience with the Western Steel Products Corporation Limited.

In 1940 he received the appointment of administrative assistant to the director of the Division of Physics and Electrical Engineering, with National Research Council in Ottawa. He became administrative assistant to B. G. Ballard, M.E.I.C., officer in charge of the electrical engineering and radio branch of N.R.C., in 1946 and was named executive assistant in 1953.

Mr. Sutherland joined the Institute as a Junior in 1938 and became a Member in 1948. He was active in the Ottawa Branch and had been its secretary-treasurer for two years when his untimely death occurred.

D. A. Buhr, M.E.I.C., died on January 22, 1956, in Swift Current, Saskatchewan,, following a lengthy illness.

He was born at Langham, Sask., on March 29, 1925, and received his schooling there. In 1943 he first joined the Prairie Farm Rehabilitation Administration in Regina, to work as rodman in the summer months while a student of the University of Saskatchewan. He graduated in 1947 in civil engineering, after a period of active service with the R.C.N.V.R., during the final months of the war. Going on to the Utah State Agricultural College in Logan, Utah, he obtained a master's degree in civil engineering. About this time he was awarded an Aluminum Company of America fellowship to conduct research on aluminum sprinkler irrigation tubing and couplings.

In 1949, once again with P.F.R.A. in Regina, he was engineer in charge of construction and drainage investigations and since that time had been resident engineer with the organization.

Mr. Buhr was a member of the American Society of Civil Engineers. He joined the Engineering Institute in 1946, as a Student, transferred to Junior in 1948, and became a Member in 1951. He was a member of the Association of Professional Engineers of Saskatchewan.

John A. Linney, M.E.I.C., electrical engineer with the Canadian National Railways, died on November 11, 1955, in St. Lambert, Quebec.

Mr. Linney was born in North Battleford, Sask., on November 3, 1924. He received his general education in Edmonton, and graduated from the University of Alberta in 1946 with a B.Sc. degree in electrical engineering.

Prior to graduation he had had experience with Calgary Power Company at Calgary, during the summer of 1944. He was on duty with the R.C.N.V.R. during 1945.

His association with the railway company began in Montreal immediately upon graduation in 1946. Since that date he was employed by the architects department in the design and layout of all types of electrical distribution systems in buildings throughout the system.

In 1950 Mr. Linney was transferred to Edmonton to take over the supervision of the electrical installations in the Canadian National Railways' McDonald Hotel extension, in Edmonton.

He returned to the chief architects department in 1953.

Mr. Linney joined the Institute as a Student in 1946, became a Junior in 1948 and a Member in 1955.

President

OF

The Engineering Institute of Canada

1956

Vernon Archibald McKillop

For its next president the Institute has chosen Vernon Archibald McKillop, M.E.I.C., general manager of the London Public Utilities Commission and of the London Railway Commission.

Mr. McKillop is a native of West Lorne, Ont., where he was born on March 12, 1899. Proceeding through the local schools and the course in electrical engineering at the University of Toronto, he received the degree of B.Sc. in 1924. His education was interrupted by a term of service with the Army Service Corps.

Joining the Public Utilities Commission immediately after graduation from the university, he has never had any other employer. His advancement in rank and responsibility has been regular from the grade of assistant engineer to that of general manager, to which post he was appointed in 1952. His duties involve the distribution of electricity, bought from the Hydro-Electric Power Commission of Ontario, in a city of 100,000 people, the distribution of water and the search for additional underground supplies, the operation of an extensive park system and recreation program, and the management of the hundred-year-old, city-owned railway from London to Port Stanley on Lake Erie.

Mr. McKillop's association with the Institute began in 1926, when he was admitted to membership as a Junior; he became an Associate Member in 1929 and a Member in 1940. From 1940 to 1955 he sat on council as the representative of the London Branch and he was a trustee of the Bennett Educational Fund from 1948 to 1956.

Active in the affairs of the London Branch, he was its chairman in 1933.

During and after the late war, Mr. McKillop served as a volunteer advisor to the London Board of Education in dealing with both civilian students and veterans who showed an interest in engineering as a career. He is a member of the Association of Professional Engineers of Ontario, of the Canadian Section of the American Waterworks Association (chairman as of April 24, 1956), of the Kiwanis Club of London (president, 1953), and of the Association of Municipal Utilities (president, 1942).

Mrs. McKillop is the former Frances Horton, R.N., of St. Thomas, Ont. Married in 1925, the couple has two sons and a daughter.

Newly Elected Officers of the Institute

At the Annual Meeting, the president, three vice-presidents and twenty-six councillors will take office, and will serve with others whose terms of office continue. The complete list of Council will appear in the next issue of the *Engineering Journal*.

H. W. L. Doane, M.E.I.C., manager and director of Standard Paving Maritime Ltd. of Halifax, has been elected vice-president of the Institute, representing the Maritime Provinces for a two-year term.

Mr. Doane was born in Halifax and received his general education at the public and high schools there. After three years of study at Dalhousie University, he attended the Nova Scotia Technical College, graduating with a B.Sc. degree in civil engineering in 1913. He is also a qualified Nova Scotia Provincial Land Surveyor.

He served with the rank of major during World War I with the Canadian Artillery and with the Imperial Forces in Egypt, Palestine and France, and upon his return to Canada, formed the 9th Siege Battery.

In 1919 Mr. Doane was appointed assistant city engineer for Halifax, which position he occupied until 1928 when he became manager of Argyle Motor Services. Three years later he undertook the management of Standard Paving Maritime Ltd. of which he is now manager and director. During 1944-47 he was manager of the Halifax Utilities Commission.

Mr. Doane is a member of the Association of Professional Engineers of Nova Scotia and of the Canadian Legion.

He joined the Engineering Institute as an Associate Member in 1919, transferring to Member in 1923, and has shown an active interest in its affairs. He is a former chairman of the Halifax Branch and a former member of Council, representing the Branch, and, again, representing the Association of Professional Engineers of Nova Scotia.

H. W. L. Doane, M.E.I.C.

George M. Dick, M.E.I.C., chief engineer of Canadian Ingersoll-Rand Company Ltd., has been elected vice-president of the Institute to represent the Province of Quebec.

George M. Dick, M.E.I.C.

Mr. Dick was born in Stirling, Scotland, and received his general education there. He came to Canada in 1913, and after a short period spent in Western Canada, came to Sherbrooke and joined Canadian Ingersoll-Rand as an apprentice. During the First World War he was employed in the design of machinery for the manufacture of munitions.

He became a student at Bishops University in 1920 and then came to McGill University, where he graduated with honours in mechanical engineering in 1924. He was British Association Medallist and holder of the Babcock and Wilcox Scholarship. His summer essay was awarded the Engineering Institute competition prize and the Pulp and Paper Association prize. During the summer months of his university course he was with the Brompton Pulp and Paper Company in East Angus, Que.; with Babcock Wilcox and Goldie McCullough Ltd. in Galt Ont.; and with Canadian Ingersoll-Rand Company Ltd. at Sherbrooke.

Mr. Dick rejoined the permanent staff of Canadian Ingersoll-Rand after graduation as designing engineer on mine hoists. He became chief hoist engineer in 1937, and in that position pioneered the design of a considerable number of mine hoists used in Canada today.

During World War II he was also chief engineer of the Sherbrooke Pneumatic Tool Company, a subsidiary of Canadian Ingersoll-Rand, and was responsible for the design of much of the shell manufacturing equipment used by this company. Later he became technical assistant to the works manager, a position he held until 1945 when he was appointed manager of engineering with duties which embraced management of all phases of the company's engineering and technical activities, also the complete control of the company's purchasing program. Since 1952 Mr. Dick has been chief engineer of the company and has recently devoted his time principally to the development of new products, materials and processes.

He is a member of the American Society of Mechanical Engineers, the Technical Association of Pulp and Paper Industry of U.S.A., the Canadian Institute of Mining and Metallurgy, and the Canadian Pulp and Paper Association. He is a past regional representative for the Eastern Townships on the Council of the Corporation of Professional Engineers of Quebec.

Mr. Dick joined the Engineering Institute in 1922 as a Student, transferred to Associate Member in 1928, and to Member in 1940. He is a charter member of the Eastern Townships Branch of the Institute, and served as its first chairman. He has also been a member of the Institute's committee on Confederation.

H. R. Sills, M.E.I.C.

H. R. Sills, M.E.I.C., design engineer with the apparatus department of Canadian General Electric Company Ltd. in Peterborough, Ont., has been elected a vice-president of the Engineering Institute representing the Province of Ontario.

Mr. Sills has designed or been responsible for the design of generators for the majority of hydraulic generating stations in Canada, as well as a number of foreign countries. He has been with Canadian General Electric since his graduation in electrical engineering from Queen's University in 1921.

In 1922 he was assigned to design engineering with the AC group and has served the company in a supervisory capacity since 1945. Mr. Sills has a number of important inventions to his credit and has been granted patents on twenty of these inventions so far. His work and responsibility has also covered large synchronous motors for pulp grinding and pumping applications, and large outdoor hydrogen-cooled, and outdoor and indoor air-cooled synchronous condensers.

Last year he was made a fellow of the American Institute of Electrical Engineers, having been an active member of that organization since 1920. For some years he has been a member of the A.I.E.E. technical committee on rotating machinery, and a member of the synchronous machine sub-committee.

Mr. Sills has always taken an active part in the affairs of the Engineering Institute which he joined as a Student in 1921. He transferred to Associate Member in 1936, and to Member in 1940. From 1940 to 1945 he was a councillor of the Institute, ~~and since 1945 he has been chairman of the Membership Committee of the Institute.~~

J. Roderick Wallace, M.E.I.C., chief metallurgist of Dominion Iron and Steel Limited, has been elected a councillor of the Institute to represent the Cape Breton Branch for a two-year term.

Mr. Wallace was born in Westville, N.S., and received his early education in Westville and New Glasgow, N.S. He graduated from McGill University in 1940 with a bachelor of engineering degree in metallurgy.

J. Roderick Wallace, M.E.I.C.

He became associated with Dominion Iron and Steel during the summers of his university course, working at the Sydney steel plant as a labourer in the open hearth department in 1939. In 1940 he joined the permanent staff as open hearth observer. Three years later he was transferred to the coke oven department and in 1944 was named assistant superintendent of that department.

Mr. Wallace was appointed assistant director of research in 1946 and director of research and development in 1950. He became chief metallurgist of the company in Sydney last year.

He is a member of the Canadian Institute of Mining and Metallurgy, and of the Association of Professional Engineers of Nova Scotia.

Mr. Wallace is a past chairman of the Cape Breton Branch of the Institute, which he joined in 1949 as a Member.

O. Nelson Mann, M.E.I.C., executive manager of the Atlantic Provinces Economic Council, has been elected to represent the Halifax Branch of the Institute on Council for two years.

Mr. Mann was born in Sydney, N.S.,

O. Nelson Mann, M.E.I.C.

and attended the public and high schools there. In 1933 he received his engineering certificate from Acadia University, and two years later, his B.Eng. degree in mechanical engineering from the Nova Scotia Technical College.

After graduation he was employed successively by Dominion Steel and Coal Co. Ltd. in Sydney, Imperial Oil Limited in Dartmouth, N.S., the Eagle Pencil Company in Drummondville, Que., and Defence Industries Limited in Brownsburg, Que., Verdun, Que., and Montreal.

At the close of the war he was associated in the consulting field with J. D. Woods and Gordon, Ltd., and Stevenson Kellogg, Ltd., in the Toronto area. He also gained wide experience in the metal and textile industries.

In 1950 Mr. Mann returned to his native province of Nova Scotia to join the Nova Scotia Research Foundation. He subsequently entered the provincial Department of Trade and Industry, and last year was appointed to his present position as head of the Atlantic Provinces Economic Council.

He joined the Engineering Institute as a Student in 1936, transferring to Junior the following year, and to Member in 1947. In 1954 he was elected chairman of the Halifax Branch.

Donald J. MacNeil, M.E.I.C., head of the department of geology at St. Francis Xavier University, Antigonish, N.S., has been elected to represent the North Nova Scotia Branch on the Council of the Institute.

Dr. MacNeil was born in Sydney, N.S., and received his early education there. After working as engineering assistant in the planning bureau of the New York Edison Company from 1925 to 1928, he entered St. Francis Xavier University and graduated in 1930 with a B.Sc. degree, and then received his Ph.D. degree in geology from Princeton University in 1935.

Donald J. MacNeil, M.E.I.C.

He worked as a petroleum geologist for the Shell Oil Company in Oklahoma and Texas for four years thereafter, and then joined the Texas Company in Illinois and Alberta in the same capacity. He accepted his present position in 1946.

In addition to the teaching and consulting work that he carries on at Antigonish, Dr. MacNeil is lecturer in the department of geology and geophysics at the Massachusetts Institute of Technology, and is lecturer in engineering geology at Nova Scotia Technical College. He is a member of the Advisory Board on Mineral Development for the province of Nova Scotia; executive secretary of the Nova Scotia Centre for Geological Sciences; secretary of the Associate Committee on Coal for the Nova Scotia Research Foundation; a fellow of the Geological Society of America; and a member of the National Advisory Committee on Research in the Geological Sciences.

Dr. MacNeil is a past vice-president of the Canadian Institute of Mining and Metallurgy, a past president of the Mining Society of Nova Scotia, and a past president of the Association of Professional Engineers of Nova Scotia.

He became a Member of the Engineering Institute in 1943, and was a vice-president of the Institute in 1952.

M. F. Keith Leighton, M.E.I.C., has been elected a councillor of the Institute to represent the Moncton Branch.

Mr. Leighton is a past-chairman of the Moncton Branch and a member of Association of Professional Engineers of New Brunswick.

He is with the Canadian National Railways in Moncton, N.B., as structural engineer. In this capacity he is responsible for the inspection of steel bridges and timber trestles, the design of steel and timber bridges, and the design of such reinforced concrete structures as abutments, piers, and retaining walls.

Mr. Leighton was born in Moncton

and received his early education there. He graduated from the University of New Brunswick in 1949 with a B.Sc.

M. F. Keith Leighton, M.E.I.C.

degree in civil engineering. Previous to his graduation, from 1941 to 1943, Mr. Leighton was a member of the original crew which surveyed and laid out Goose Bay Airport in Labrador. During this time he held the positions of rodman, foreman, and inspector, and worked on various types of construction for the Department of Transport.

During the summers of the last two years of his university courses, he was employed as instrumentman with the New Brunswick Department of Highways working on highway diversion, and then, also as instrumentman with Canadian National Railways working with the terminal engineer at Cape Tormentine, N.B., where he was in charge of surveys, setting grades and taking soundings for dredging.

In 1949, after receiving his degree, Mr. Leighton was named structural engineer with the bridge department of the Canadian National Railways.

Mr. Leighton joined the Institute as a Student in 1947, transferred to Junior in 1951, and to Member in 1953.

Robert C. Eddy, M.E.I.C.

Robert C. Eddy, M.E.I.C., vice-president and director of George Eddy Company Ltd., has been elected to represent the Northern New Brunswick Branch of the Engineering Institute on Council.

Born at Bathurst, N.B., Mr. Eddy spent one year at the University of New Brunswick before proceeding to Queen's University, where he graduated in 1941 with a B.Sc. degree and medal. After graduation he undertook post-graduate work at the University of Michigan and at Queen's University, but interrupted these studies to join the Royal Canadian Engineers in 1942. He received the Military Cross while serving in Holland.

Upon his return to Canada after the war he was appointed lecturer in chemical engineering at Queen's University. Subsequently he entered the family business in Bathurst and is now vice-president and director of this company.

Mr. Eddy is also a director of Eddy Hardware Limited, Raworth and Mollins Limited, Bathurst Broadcasting Company Ltd., the Maritime Lumber Bureau, and the Canadian Forestry Association. He is presently serving as president of the Maritime Retail Lumber Dealers' Association.

He joined the Engineering Institute in 1941 as a Student, transferred to Junior in 1946, and later the same year, to Member. In 1953 he was active in establishing the Northern New Brunswick Branch of the Institute and served as its first chairman.

C. H. Boisvert, M.E.I.C., chief engineer of the Public Service Board, has been elected to serve for a two-year term as councillor representing the Quebec Branch of the Institute.

C. H. Boisvert, M.E.I.C.

Born in Montreal, Mr. Boisvert completed the scientific course offered by Mont Saint-Louis College there. He continued his training at Ecole Polytechnique, graduating in civil engineering in 1925. During the summer months of his university course he was engaged in general and topographical survey work.

Upon graduation he undertook the student training course offered by Shawinigan Water and Power Company, and in 1926 joined the engineering staff of the Public Service Board in Quebec, becoming chief engineer in 1931.

Mr. Boisvert is a member of the Corporation of Professional Engineers of Quebec.

He joined the Engineering Institute as a Junior in 1927, transferring to Associate Member in 1932, and to Member in 1940. He served as chairman of the Quebec Branch in 1946-47.

Roger Brais, M.E.I.C.

Roger Brais, M.E.I.C., head of the department of chemistry and chemical engineering of Ecole Polytechnique, has been elected by the Montreal Branch to serve as councillor for three years.

A Montrealer by birth, Professor Brais completed the scientific course at Mont-Saint-Louis College in 1929. In 1933 he received the degrees of civil engineer and bachelor of applied sciences from Ecole Polytechnique, and the following year the degree of chemical engineer from the same university. He followed special courses in physical chemistry in 1938 at the Massachusetts Institute of Technology with Professors E. B. Millard and G. Dietrichson. In 1942 he received his Ph.D. degree from McGill University, having majored in physical chemistry since 1939 under Dr. O. Maass.

Professor Brais began his engineering career in 1934 as a chemical engineer with the Quebec Department of Health, becoming in 1936 a consulting chemical engineer and chemist for the mining industry in Abitibi. Two years later he joined the staff of Ecole Polytechnique as assistant professor of chemistry, being named associate professor in 1944, and professor and head of the department of chemical engineering and chemistry in 1948.

Elected a fellow of the Chemical Institute of Canada in 1950, Professor Brais is also a member of the American Chemical Society, the Society of Chemical Industry, the National Association of Corrosion Engineers, the Chemical Society (London), and the Corporation of Professional Engineers of Quebec.

He joined the Engineering Institute as a Member in 1949. That same year he served as chairman of the chemical engineering section of the Program Committee, and in 1950 and 1951 as vice-chairman and chairman of this Committee. During 1952 and 1953 he was a member of the Publications Committee, and in 1954 and 1955, a member of the Executive Committee of the Montreal Branch. During 1955 he also served as chairman of the Admissions Committee of the Branch.

Clifford E. Frost, M.E.I.C., who is building and structures engineer in the special contracts department of the Bell

Telephone Company of Canada, is one of three members elected to represent the Montreal Branch for a three-year term on the Council of the Institute.

Clifford E. Frost, M.E.I.C.

Mr. Frost was born in Danville, Que. He attended Lachine High School and McGill University, graduating with a B.Sc. degree in civil engineering in 1931. Upon graduation he became assistant engineer with the National Harbours Board.

He began his association with the engineering department of the Bell Telephone Company of Canada in 1937 and has remained with the company since that date except for a period of service during World War II with the Royal Canadian Air Force. In 1949 he was appointed special duties engineer, and in 1951, construction contracts engineer for the eastern area. Two years later he became construction contract engineer of special projects, and in 1954 he was appointed to his present position.

Mr. Frost joined the Engineering Institute as an Associate Member in 1936, becoming a Member in 1940. He served as chairman of the Junior Section in 1937, and as chairman of the Branch in 1955.

H. A. Mullins, M.E.I.C., purchasing agent for equipment and construction materials with Du Pont Company of Canada Ltd., is one of three newly elected councillors who will represent the Montreal Branch of the Institute for a three-year term.

H. A. Mullins, M.E.I.C.

Mr. Mullins, born in Herschel, Sask., received his general education in Winnipeg public and high schools, and graduated from the University of Manitoba with a B.Sc. degree in electrical engineering in 1936.

Upon graduation he joined Kipp Kelly Limited in Winnipeg and spent a year on the development and testing of mechanical separating machinery. Moving to Toronto in 1937, he became associated with Eastern Power Devices and Maloney Electric Company. In 1938 he served as chief engineer with the Taylor Electric Manufacturing Company in London, Ont., and in 1940 joined Defence Industries Limited in Montreal as project engineer on the design and construction of munitions plants at Nobel, Winnipeg, Shawinigan Falls, and various locations in Canada. He was transferred to Canadian Industries Limited in 1945 and occupied successively the positions of assistant project engineer, project engineer and coordinating engineer on the design and construction of chemical, explosives, films, and synthetic fibres plants.

Since July, 1954 Mr. Mullins has been employed by Du Pont Company of Canada Ltd. in the purchasing and traffic department as purchasing agent for equipment and construction materials.

He joined the Engineering Institute as a Student in 1937, transferring to Junior in 1942, and to Member in 1947. Active in the affairs of the Montreal Branch since 1940, he has served as chairman of the Entertainment Committee, and as member of both the Branch executive and the Publication Committee.

John M. Hawkes, M.E.I.C., owner of Parisien Beverages in Cornwall, Ont., has been elected to represent the Cornwall Branch on the Council of the Engineering Institute for a two-year term.

John M. Hawkes, M.E.I.C.

He was born in Oshawa, Ont., and received his early schooling in Oshawa and at King's College. After attending Adelaide University in Australia from 1927 to 1928, he received his B.Sc. degree from Queen's University in 1932.

He worked during the summer of 1931 in the engineering department of General Motors in Oshawa, and after graduation worked as a draughtsman with General Motors in Oshawa, the Skinner Bumper Company in Oshawa, and then in 1935 with the Duplate Glass Company, also in Oshawa.

In 1936 Mr. Hawkes was named chief engineer and production manager of Pepsi-Cola Company of Canada Ltd. in Montreal, and was in charge of all buildings and equipment for the company, including the Outremont plant which was built in that year. He remained with Pepsi-Cola until 1945 when he became owner of Parisian Beverages in Cornwall.

He became a Member of the Engineering Institute in 1945 and has taken an active part in the activities of the Cornwall Branch, serving as its chairman in 1953.

Robert F. Legget, M.E.I.C., director of the division of building research of the National Research Council since 1947, has been elected Ottawa Branch representative on the Council of the Institute for two years.

Robert F. Legget, M.E.I.C.

Mr. Legget was born in Liverpool, England. He received his general education at Merchant Taylor's School in Great Crosby, afterwards attending the University of Liverpool where he obtained his B.E. degree with honours in 1925, and his M.E. degree in 1927.

In 1925 he became assistant engineer with C. S. Meik and Buchanan in Westminster, and four years later accepted the position of resident manager of Power Corporation of Canada Ltd. He remained with this company until 1932 when he joined Canadian Sheet Piling Co. Ltd. in Montreal.

Mr. Legget served as lecturer on the civil engineering staff of Queen's University in 1936. Within the next two years he was appointed assistant professor of civil engineering at the University of Toronto, becoming associate professor in 1943.

In 1945 Mr. Legget was named chairman of the Committee on Soil and Snow Mechanics, and in 1947 was appointed to his present position. He has served as consulting engineer on soil and foundation problems for the Toronto Transportation Commission, Steep Rock Mine, the Polymer Plant, the Shipshaw Development, and others.

Mr. Legget holds the J. P. Joule and

J. Forest Medals, the Miller Prize and Telford Premium of the Institute of Civil Engineers, and the Society's Premium of the Liverpool Engineering Society. He is a member of the Institution of Civil Engineers (London); the American Society of Civil Engineers, and the Association of Professional Engineers of Ontario. He is also an honorary fellow of the Royal Architectural Institute of Canada, and a fellow of the Geological Society of America.

Author of "Geology and Engineering" (1939), and joint author with C. P. Disney of "Modern Railroad Structure" (1949), Mr. Legget has also contributed numerous papers on engineering and research in soil mechanics.

He joined the Engineering Institute as a Junior in 1929, and transferred to Associate Member in 1931, and to Member in 1940. He has served as chairman of both the Toronto and Ottawa Branches of the Institute.

A. J. Bonney, M.E.I.C., plant engineer for the Quaker Oats Company of Canada Ltd. in Peterborough, Ont., has been elected to represent for a two-year term the Peterborough Branch on the Council of the Institute.

A native of Oshawa, Ont., Mr. Bonney attended Queen's University, graduating with a B.Sc. degree in mechanical engineering in 1935. He also holds the Ontario first class stationary engi-

A. J. Bonney, M.E.I.C.

neer's certificate which he received in 1943.

Mr. Bonney joined his present company in 1935. He transferred from the mechanical maintenance department to the electric power department in 1936, and the following year to the steam power department. Previous to his appointment as plant engineer, he occupied successively the positions of electrical superintendent and chief steam engineer.

He joined the Engineering Institute as a Student in 1935, transferring to Junior in 1940 and to Member in 1947. In 1951 he served as chairman of the Peterborough Branch.

M. W. Huggins, M.E.I.C., associate professor of civil engineering at the University of Toronto, has been elected to serve for three years as a councillor of the Institute, representing the Toronto Branch.

A native of Toronto, Mr. Huggins was educated at Parkdale Collegiate and the University of Toronto. He received his B.A.Sc. degree in 1932, and his M.A.Sc. degree the following year. During the summers of his university course he worked as rodman with the roadway department of the City of Toronto, and as field engineer with the Consumer Gas Company in Toronto.

In 1933 Mr. Huggins joined E. P. Muntz Limited in Dundee, Ont., and was engaged in research work on prestressed concrete and on formwork accessories. He became associated with the Vernon Construction Company in

M. W. Huggins, M.E.I.C.

1936 as engineer in charge of design and erection of forms and falsework at Oakville, Ont.

After a year with Dominion Bridge Company as detailer and designer in Toronto, Mr. Huggins began his teaching career with an appointment as lecturer in civil engineering at Queen's University. He joined the faculty of engineering at the University of Toronto in 1941. At present he is also a partner in the consulting firm of Morrison, Hershfield, Millman and Huggins in Toronto.

Mr. Huggins is a member of the Association of Professional Engineers of Ontario and is a past councillor of the Association.

Joining the Engineering Institute in 1935 as a Junior, Mr. Huggins transferred to Associate Member in 1939, and to Member in 1940. He was elected chairman of the Toronto Branch of the Institute in 1955.

Paul E. Buss, M.E.I.C., president of Spun Rock Wools Ltd. in Thorold, Ont., will serve his sixth consecutive two-year term as representative of the Niagara Peninsula Branch on the Council of the Institute in 1956-57.

Mr. Buss was born at Three Rivers, Michigan, and received his engineering education at the University of Michigan. After service with the United States Army Engineers in France, Mr. Buss joined the engineering staff of Provincial Paper Limited on the construction of the first sulphite plant at Port Arthur, Ont. He was next associated with Dominion Engineering Works, and then served for a number of years as plant engineer at the Thorold division of Provincial Paper Limited.

During 1932-33 Mr. Buss and his brothers made experiments in the development of a new process for the production of rock wool by the spinning

Paul E. Buss, M.E.I.C.

method. A direct outcome of these was the setting up of the firm Spun Rock Wools Ltd. in Thorold, of which Mr. Buss is president.

Mr. Buss joined the Institute as an Associate Member in 1927 and became a Member in 1940. Previous to his activities as councillor of the Niagara Peninsula Branch, he served as its secretary-treasurer in 1931, and as its chairman in 1935.

Wm. R. Roberts, M.E.I.C., vice-president of Wm. Roberts Electric Ltd. in Kitchener, has been named councillor of the Institute representing the Kitchener Branch for two years.

Mr. Roberts was born in Kitchener where he received his general education. He attended Queen's University, graduating with a B.Sc. degree in electrical engineering in 1945. Upon graduation he undertook the one-year test course offered by Canadian General Electric Co. Ltd., after which he was appointed superintendent of the Davenport transformer test.

In 1947 he became vice-president of Wm. Roberts Electric Ltd. and has been

70th Annual Meeting Program

pages 437 to 440

in charge of all engineering and estimating.

Mr. Roberts joined the Engineering Institute as a Student in 1945, transferring to Junior in 1947, and to Member in 1953. He served as chairman of the Kitchener Branch in 1953.

L. C. Sentance, M.E.I.C., manager of the manufacturing department of the electronics division of Canadian Westinghouse Company Ltd., has been elected to serve as councillor representing the Hamilton Branch of the Institute.

L. C. Sentance, M.E.I.C.

Born in Melville, Sask., he received his early education in Saskatchewan and afterwards his B.E. degree in mechanical engineering from the University of Saskatchewan in 1935, and his M.Sc. degree in 1937. During the summers of his university course he worked as a surveyor with the Water Development Committee, and during his post-graduate studies he was an instructor in mechanical engineering subjects at the university.

Mr. Sentance began his career with Canadian Westinghouse immediately after receiving his master's degree, by enrolling in the engineering apprenticeship course at Hamilton. On completion of this course he was attached to the general engineering staff as mechanical engineer. Transferred to the manufacturing methods division in 1944 as manufacturing engineer, he was appointed director of manufacturing methods the following year.

In 1947 he was named assistant manager of works for the company, and then in 1951, manager of the manufacturing department of the apparatus division. He was appointed to his present position in 1952.

He is a member of the American Society of Mechanical Engineers, and of the Association of Professional Engineers of Ontario, having served as a past-councillor of the mechanical branch of that organization.

Mr. Sentance joined the Engineering Institute in 1936 as a Student, and transferred to Member in 1942. He is a past-chairman of the Hamilton Branch of the Institute.

H. C. Bates, M.E.I.C., of the Trans-Canada Highway division of the Department of Resources and Development, has been elected to represent the Huronia Branch for two years on the Council of the Institute.

Toronto born, Mr. Bates received his general education in that city and at the Woodstock Boys College. He graduated in civil engineering from Queen's University in 1917, having gained experience during his undergraduate years on survey, dredging and dock construction work with the Toronto Harbour Commission.

Upon leaving Queen's he was associated with the Grand Trunk Railway and with the Ontario Hydro-Electric Commission. He joined the Bell Telephone Company of Canada in 1923 as assistant engineer and subsequently became district engineer on construction design and maintenance of the outside plant. After completing 11 years of service with the company, he was associated with the Department of Northern Development, Sutcliffe Engineering Company, A. B. Crealock, consulting engineer, and Fred A. Bell, Elgin county engineer and Ontario land surveyor. In 1940 he was appointed county engineer for Lanark, and later, for Perth.

After almost 20 years of road building experience, he joined the engineering staff of the Trans-Canada Highway in 1953. His headquarters are located in Orillia and his territory extends from Norwood to the French River.

Mr. Bates has been a member of the Association of Professional Engineers of Ontario since 1923.

H. C. Bates, M.E.I.C.

He joined the Engineering Institute while a student in 1916, and transferred to Junior in 1920 and to Member in 1942. A charter member of the Huronia Branch, Mr. Bates is an active member of the Executive Committee.

R. A. McGeachy, M.E.I.C., administrative assistant to the refinery manager of Imperial Oil Limited in Sarnia, has been elected councillor to represent the Sarnia Branch of the Institute.

Mr. McGeachy was born in Collingwood, Ont. After attending public and high schools in Sarnia, he was for a time in the ground school of the Royal Flying Corps. After two years of study with the Case School of Applied Science, he completed his course at the University of Michigan, graduating with a B.Sc. degree in 1923.

R. A. McGeachy, M.E.I.C.

He began his engineering career in the employ of the bridge department of Nickel Plate Railroad, and later served as contractor's engineer in Michigan and Ohio.

Mr. McGeachy joined his present firm as a draughtsman in Sarnia. Four years later he transferred to the mechanical department and was engaged in construction and maintenance. Granted leave of absence in 1940, he served overseas with the Royal Canadian Engineers until September, 1945. He was discharged with the rank of major and was later awarded the M.B.E.. Upon his return to the Sarnia refinery of Imperial Oil Limited, he was named zone engineer. In 1953 he was appointed to his present position.

Mr. McGeachy is a member of the Sarnia Township Planning Board and the Sarnia Suburban High School Board. He also takes an active interest in the work of the Scouts and Sarnia Sea Cadets.

He joined the Engineering Institute as a member in 1945 and served as secretary of the Sarnia Branch in 1954.

G. G. M. Eastwood, M.E.I.C., of the Spruce Falls Power and Paper Com-

G. G. M. Eastwood, M.E.I.C.

pany in Kapuskasing, has been elected to represent for two years the North Eastern Ontario Branch on the Council of the Institute.

A native of Cornwall, Ont., Mr. Eastwood received his general education at the Collegiate Institute there. He entered the University of Toronto in 1933, graduating with a B.A.Sc. degree four years later.

By 1939 he had completed the two-year apprenticeship course offered by Canadian Westinghouse Co. Ltd., and the following year served the company as electrical draughtsman on switchboard layout. In 1942 he was appointed technical liaison between the engineering and sales departments of the firm which at that time was handling important war orders. At the close of the war Mr. Eastwood joined Courtaulds (Canada) Ltd. in Cornwall as assistant to the chief engineer, and was subsequently named plant engineer. He became associated with his present company in Kapuskasing in 1951. In his position as instrument engineer he is responsible for consolidating instrumentation and for assisting in the company's modernization program.

Mr. Eastwood has taken an active interest in the affairs of the Institute. While in Cornwall he served in 1948 as secretary-treasurer, and in 1950 as chairman of the Branch. In 1952 he was elected chairman of the western section of the newly formed North Eastern Ontario Branch, becoming chairman of the Branch in 1954. He was also a member of the committee which set up the Professional Development course in public speaking. This group is still active in the western section of the Branch.

D. C. Holgate, M.E.I.C., manager of Sault Structural Steel Co. Ltd., is the newly elected councillor representing the Sault Ste. Marie Branch of the Institute for a two-year term.

D. C. Holgate, M.E.I.C.

Mr. Holgate was born in Montreal. After receiving his general education at the Sherbrooke High School, he attended Acadia University where he graduated with a B.A. degree in mathematics in 1935. In 1938 he was granted a B.Eng. degree in civil engineering by McGill University.

He then became associated with MacKinnon Steel Corp. Ltd. as structural steel draughtsman and designer in Sherbrooke, Que., and afterwards joined Dominion Bridge Co. Ltd. in Toronto in the same capacity, transferring in 1941 to the company's subsidiary, Sault Structural Steel Co. Ltd. From that time until 1947 he was engineer in charge of all design and drawing office work by the company, and also served as assistant to the manager in the co-ordination of drawing office work, and the fabrication and erection departments on all contracts undertaken by the company. Mr. Holgate was granted a two-year leave of absence in 1943-44 to serve with the Royal Canadian Air Force. He was appointed to his present position in February, 1954.

Mr. Holgate joined the Engineering Institute as a Junior in 1942 and became a Member in 1947. Active in the affairs of the Sault Ste. Marie Branch, he has served as secretary-treasurer, chairman, and councillor representing the branch.

R. T. Harland, M.E.I.C.

R. T. Harland, M.E.I.C., chief engineer of the Winnipeg Hydro-Electric System, will represent for two years the Winnipeg Branch on the Council of the Engineering Institute.

A native of Winnipeg, Mr. Harland attended St. John's College School and graduated from the University of Manitoba in 1938 with a B.Sc. degree in electrical engineering. After a brief period with the City of Winnipeg Hydro-Electric System he resigned in 1939 to study at the Massachusetts Institute of Technology where he obtained his master's degree in 1941. He returned afterwards to the Winnipeg Hydro.

Mr. Harland served with the R.C.A.F. from 1942 to 1945, and then returned to the Winnipeg Hydro as operating engineer. He was appointed assistant principal engineer in charge of design in 1948, and principal engineer in charge of design in 1952. He was named chief engineer in November, 1955.

He is a member of the Association of Professional Engineers of Manitoba, and of the Manitoba Electrical Association.

Mr. Harland joined the Engineering Institute in 1938 as a Student and transferred to Member in 1944. He is a past secretary-treasurer of the Winnipeg Branch.

J. B. Mantle, M.E.I.C.

J. B. Mantle, M.E.I.C., associate professor of mechanical engineering of the University of Saskatchewan, has been elected councillor for a two-year term, representing the Saskatchewan Branch of the Institute.

Professor Mantle was born in London, England. He received his general schooling at Paynton, Sask., and at City Park Collegiate, Saskatoon. In 1941 he graduated with a B.Sc. degree in mechanical engineering from the University of Saskatchewan, and in 1947 he received his M.Sc. degree in theoretical and applied mechanics from the University of Illinois.

He completed the Canadian General Electric Company test course in 1942 and that same year joined the Royal Canadian Air Force, serving until 1945 as aeronautical engineer.

Professor Mantle became an instructor at the University of Saskatchewan after the war. He was named assistant professor of mechanical engineering in 1947, and was appointed to his present position in 1953. During the summer months of recent years Professor Mantle has been employed as stress analysis consultant with the National Research Council, Dominion Engineering Co. Ltd., the Department of Agriculture, and other government groups.

He is a member of the Association of Professional Engineers of Saskatchewan, serving as secretary-treasurer of the Saskatoon Section during 1947-49, and as councillor for two consecutive terms during 1949-51. He is also a member of the Society for Experimental Stress Analysis. Commanding officer of the University of Saskatchewan Squadron, R.C.A.F. during 1949-54, he is at present technical officer of 23 Wing H.Q., R.C.A.F. (Aux.), with the rank of wing commander.

Professor Mantle joined the Engineering Institute as a Student in 1941, transferring to Junior in 1943, and to Member in 1946.

W. A. Smith, M.E.I.C., general mechanical superintendent of Burns and Co. Ltd., has been elected councillor of the Institute representing the Calgary Branch for two years.

Born in Belfast, Ireland, Mr. Smith attended Calgary schools and afterwards the University of Alberta from which he received his B.Sc. degree in civil engineering in 1933. He gained experience during his undergraduate years while working during the summers with the City of Calgary, Canadian National Railways, and the National Parks of Canada.

In 1934 he joined the draughting office staff of Dominion Bridge Co. Ltd. in Calgary where he was employed on

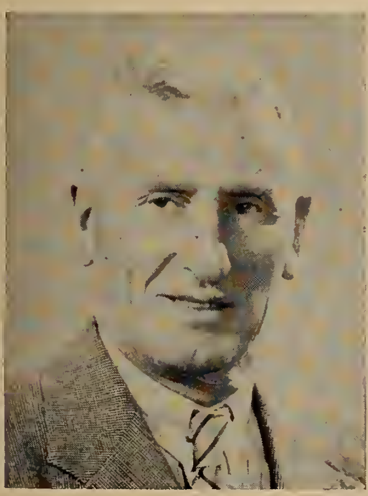
W. A. Smith, M.E.I.C.

structural steel assembly. The following year he became associated with the International Nickel Company of Canada in Sudbury, Ont., and was engaged successively in mucking, mine survey, ore reserves and underground construction work until 1937 when he joined Canadian Johns-Manville Co. Ltd. as sales engineer covering all mining districts in northern Ontario.

He was in the employ of John W. Fogg Ltd. in Timmins in 1939 and was engaged in sales, design, estimating and construction supervision for mine construction. In 1940 he was appointed superintendent of utilities for Burns and Co. Ltd. in Calgary, working on steam, refrigeration and plant construction, and in 1949 was appointed to his present position.

Mr. Smith joined the Engineering Institute as a Member in 1944. He was elected chairman of the Calgary Branch in 1950.

J. M. Campbell, M.E.I.C., has been re-elected to represent the Lethbridge



J. M. Campbell, M.E.I.C.

Branch on the Council of the Institute. Mr. Campbell retired from his position as division engineer with the Canadian Pacific Railway in 1952.

Born and educated at Dumfermline, Scotland, Mr. Campbell received his early training as an engineer in Scotland with the Fife County Council, as pupil to the road surveyor and master of works.

Coming to Canada in 1907 he joined the Canadian Pacific Railway at Souris, Man., as chainman and rodman. From 1910 to 1913 he was transitman at Souris and at Kenora, Ont., engaged on maintenance work, becoming resident engineer at Kenora in 1913, and then roadmaster from Winnipeg to Brandon, Man.

During the First World War he served overseas with the Canadian Railway Troops, and then returned to Canada in 1919 and rejoined the C.P.R. as roadmaster at Dryden, Ont. In 1920 he was named division engineer of the Portage division at Winnipeg, subsequently becoming division engineer at Kenora, Winnipeg, Moose Jaw, and Lethbridge, until his retirement.

Mr. Campbell joined the Engineering Institute in 1920 as Associate Member and transferred to Member in 1940. He was elected in 1954 to represent the Lethbridge Branch on Council.

H. L. Roblin, M.E.I.C., of Edmonton, Alta., has been elected councillor to represent the Edmonton Branch of the Engineering Institute. Mr. Roblin is a member of the consulting engineering firm of Stanley, Grimble, Roblin Limited in Edmonton.

A native of London, Ont., he received his early education there, and then graduated from the University of Toronto in 1913 with a B.A.Sc. degree.

H. L. Roblin, M.E.I.C.

During the First World War he served with the Canadian Expeditionary Forces and received the Military Cross.

In 1919 Mr. Roblin began his long association with the Canadian National Railway as resident engineer in Edmonton. He spent some time at Regina as roadmaster for the C.N.R. office there, and subsequently became division engineer at Edmonton. He retired from the company last September and then joined Stanley, Grimble, Roblin Limited.

During the Second World War he was in command of the 13th Field Company of the R.C.E. at Regina, retiring in 1945 with the permanent rank of major.

Mr. Roblin joined the Engineering Institute in 1919 as an Associate Member and transferred to Member in 1940. He attained Life membership last year and was also elected chairman of the Edmonton Branch of the Institute.

E. L. Hartley, M.E.I.C., general manager of Western Bridge and Steel Fabricators Ltd. in Vancouver, B.C., has been elected to represent the Vancouver Branch of the Engineering Institute on the Council for a two-year term.

Mr. Hartley was born in Liverpool, England, and graduated from the Liverpool Institute School in 1930, and then entered Queen's University, graduating in 1933 with a degree in civil engineering.

In 1934 he entered the properties department of Jas. Richardson and Sons, Ltd. in Winnipeg, Man. Two years later he joined W. G. Swan Engineering Company Ltd. in Vancouver. In 1937 he was appointed engineer in charge of construction of the Canada Packers Ltd. Vancouver plant, and also served as

E. L. Hartley, M.E.I.C.

assistant estimating engineer for the Western Bridge Company during this period. In 1938 he was associated with B.C. Appraisal Company Ltd., and with the Dominion Bridge Company during the construction of the Lions Gate Bridge.

At the beginning of World War II, Mr. Hartley joined the Royal Canadian Engineers as works officer in the Vancouver area. Subsequently he was promoted to the rank of captain in 1941 and served overseas until the end of the war. He was mentioned in despatches, named a Member of the British Empire, and awarded the E.D. for distinguished service. He was also named an officer of the Order of Orange Nassau by the Netherlands Government.

In 1945 Mr. Hartley, returned to Canada and joined Western Bridge and Steel Fabricators Ltd. in Vancouver as designing engineer, becoming contract engineer in 1947. He was named assistant general manager of the company in 1950 and general manager in 1955.

Mr. Hartley joined the Engineering Institute in 1933 as a Student, transferred to Junior in 1946, and to Member in 1947. He served as chairman of the Vancouver Branch of the Institute in 1953.

Personals

News of the Personal Activities of Members of the Institute

Dr. R. S. Jane, M.E.I.C.

Dr. R. S. Jane, M.E.I.C., has been elected president of Shawinigan Chemicals Ltd. He has been executive vice president of the company.

Dr. Jane graduated from the University of British Columbia in 1922 and was awarded a Ph.D. degree at McGill University in 1925. He attended the University of London on a Wembley scholarship for the following two years.

On his return to Canada in 1927, Dr. Jane was named chief chemist at Shawinigan Falls, Que., with Canada Carbide Company. When that company became the carbide division of Shawinigan Chemicals Ltd., a few months later, Dr. Jane took charge of plant research for the division. In 1936 he went to the Montreal head office, then in 1943 was transferred to Shawinigan Water and Power Company, heading, for the parent plant, the industrial research department, which was formed at that time. Three years later he returned to Shawinigan Chemicals Ltd., as director and vice-president in charge of research and development. The appointment as executive vice-president of the company was received in 1954.

He is also a director and vice-president of Canadian Resins and Chemicals Ltd., a director of B.A. Shawinigan Ltd., Montreal, and of Shawinigan Resins Corp., Springfield, Mass.

Dr. Jane has been active in the work of the Chemical Institute of Canada and was elected its president for 1952-53. He is a member of the Society of Chemical Industry and of other professional associations.

F. Y. Dorrance, M.E.I.C., technical advisor to the waterworks division of the Department of Public Works, for the city of Montreal, retired in February following a lengthy municipal career.

F. Y. Dorrance, M.E.I.C.

Mr. Dorrance was born in Troy, N.Y., and studied engineering at the Rensselaer Polytechnique Institute. As a young graduate he went to work for the City of Pittsburgh as a design and construction engineer, and later spent three years with a firm of consulting engineers.

With six years professional experience, he came to Montreal in 1912, where he was soon embarked upon the career that was to last 43 years. He was chiefly concerned, throughout his years of service, with the design and construction of water transmission lines and facilities, and he has been responsible for the recent enlargements of the Montreal filtration works. In 1935 he received the appointment of divisional engineer and in 1953 took office as consulting engineer on water supply.

A Life member of the American Water Works Association, he was in 1952 elected a trustee of the Canadian section of the Association. He was winner of the George B. Fuller award presented by the parent organization. He also holds Life membership in the American Society of Civil Engineers and is a Member of the Corporation of Professional Engineers of Quebec.

Dr. Dorrance joined the Institute as an Associate Member in 1915, transferred to Member in 1940 and attained Life membership in 1950.

P. L. Kuhring, M.E.I.C., has been promoted to chief engineer with the St. Lawrence Ship Channel.

Joining the Department of Marine in 1913, he was loaned to the River St. Lawrence Ship Channel as a junior engineer, and apart from three years spent overseas on military service, 1916-1919, he has spent his entire career in this field.

He is a member of the Professional

P. L. Kuhring, M.E.I.C.

• Personals

Institute of the Civil Service of Canada. In 1952 Mr. Kuhring was elected president of the Canadian Author's Association.

B. W. Pitfield, M.E.I.C., who is vice-president and general manager of Northwest Industries Ltd., has been appointed a member of the Board of Industrial Relations Department of Industries and Labour of the Alberta Government.

Mr. Pitfield is a past chairman of the Engineering Institute of Canada, Edmonton branch, and is presently a member of the Industrial Advisory Committee, Research Council of Alberta.

He was also a member of the Board of Governors, University of Alberta; president of the University Alumni Association; member of the Council of the Association of Professional Engineers for Alberta; and member of the Council of the Edmonton Chamber of Commerce.

As an executive of Northwest Industries Limited, Mr. Pitfield has had extensive experience in labour relations. He was formerly general superintendent of Northwest Utilities Limited, member of the Labour Management Committee of the Edmonton Chamber of Commerce, and chairman of the Chamber's Utility and Manufacturing Committees.

Mr. Pitfield graduated from the University of Alberta in 1934, obtaining a degree in civil engineering.

W. B. Pennock, M.E.I.C., has been elected chairman of the Ottawa Branch of the Institute.

Mr. Pennock was born in Ottawa and attended McGill University. He obtained a B.Sc. degree in 1915 and immediately joined the army, serving overseas with the Canadian Engineers, CEF. At the war's end he returned to Canada and for two years was District Vocational Officer in the Department of Soldier's Civil Re-establishment in London, Ont., and Toronto.

In 1920 he accepted a position with the Gray-Dort Motor Car Company as agent and field representative. Four years later he was named department manager with Canadian Fairbanks Morse Company Ltd., in Windsor, Ont., but in 1925 he set up a manufacturing agency and engineering contractor practice in Windsor, London and Hamilton. After ten years, he joined the Department of National Defence, Ottawa, as chief mechanical engineer. He later returned to his business as sales engineer, acting for a number of manufacturers.

The second world war called Mr. Pennock to further military service, and during the years 1940-45, he was in the Canadian Army, first as second in command of the engineer training centre, Petawawa, Ont., and latterly as C.R.E., 8th Canadian Division, in Western Canada, which appointment carried the rank of lieutenant colonel.

W. B. Pennock, M.E.I.C.

On discharge from the army he continued to operate his office as sales engineer until 1949 when Pennock Engineering Company was established in its present form, as consulting engineers, associated with Canadian-British Engineering Consultants, in Toronto, Halifax, and Vancouver.

Mr. Pennock's association with the Institute dates from 1919 when he was a Student Member. He became an Associate Member in 1936, transferred to Member in 1940.

J. H. Legate, M.E.I.C., superintendent of Canada Cement Company Limited, Plant No. 5, at Belleville, Ont., was promoted to manager in October last.

A. O. Drysdale, M.E.I.C., who has been assistant superintendent since 1951 was made superintendent.

A. O. Drysdale, M.E.I.C.

Mr. Legate has been associated with Canada Cement at Belleville since his graduation from the University of Toronto in 1921. He received his appointment as superintendent in 1924. He is a member of the Association of Professional Engineers of Ontario.

Mr. Drysdale graduated in mining engineering from McGill University in 1941. He worked for Canada Cement as plant engineer, but after five months joined the forces, serving overseas with the First Canadian Army. He was discharged as a major, in 1946. Returning to Canada, he resumed his career with Canada Cement Company Ltd., and became assistant superintendent of the Montreal East No. 1 plant, transferring, four years later to the plant in Belleville.

Mr. Drysdale is a member of the Association of Professional Engineers of Ontario, the Royal Canadian Electrical Mechanical Engineer Corps Association, and is a past chairman of the Belleville Branch of the Institute. He is serving this year as president of the Kiwanis Club and the Chamber of Commerce in Belleville.

R. H. Stokes-Rees, AFFIL. E.I.C., has been named president of Hydrotechnic Ltd., a company recently formed in Montreal as a water specialist organization, offering consulting and design services in association with Paul Pelletier, Consulting Engineers, and S.E.M. Prospecting Ltd.

Mr. Stokes-Rees was born and educated in England. He studied metallurgy and design, and later, following many years affiliation with the Royal Navy, came to Canada. He had served in such capacities as superintendent of armament design to the forces, and as a deputy in the British Admiralty Technical Mission to Canada, and in the submarine service.

In 1947 he was named general manager of the G. R. Marshal and Company Ltd., firm of engineering exporters, and the following year organized and was president of Stokes-Rees Corporation Ltd., (and Affiliates), hydro-electric suppliers and installers. He was appointed vice-president of the Kaiser Engineers Division of Henry J. Kaiser Co. (Can.) Ltd., Montreal, in 1953, and last year became associated with Rubenstein Bros. as a director.

Robert C. McMordie, M.E.I.C., the newly appointed chief engineer with the British Columbia Power Commission, Victoria, is a former senior project engineer of Ontario Hydro's generation department.

Graduating in 1930 from the University of Toronto, in civil engineering, he worked with the Ontario Hydro Electric Power Commission, first as a designing draftsman, then in 1934 as a structural design engineer. For a short time he was with Canadian Bridge Company Ltd., and Gordon L. Wallace, consulting engineer, in Toronto. In 1936 he joined the staff of H. G. Acres and Company Ltd., to work on the design of the Outardes Falls development, Que.

R. C. McMordie, M.E.I.C.

* **There's been a Revolution in Rubber**

Can POLYSAR Add New Values to Your Products?

Yes, Polysar certainly can, because ***there's been a revolution in rubber!** Now...with Polysar chemical rubbers and the help of Polymer's research chemists...you can have the material that will give your products a strong competitive advantage.

Whether rubber now enters into your products or not, it will pay you to investigate the possibilities of Polysar. You'll find—as have manufacturers in 40 countries—that Polysar can provide new product qualities and production economies.

Polymer Corporation Limited—makers of Polysar rubbers—has the largest industrial research and development division in Canada. Why not make full use of these facilities and learn how Polysar can add new values to *your* products?

Write to our Sales and Technical Service Division, Sarnia, Canada.

Here's why POLYSAR Rubber Is Used In Floor Tiling

Polysar SS-250 and Krylene NS—special purpose polymers—have made possible the rubber tiling illustrated—richer in colour, longer wearing, and more resilient underfoot.

Manufacturers specify the combination of Polysar SS-250 and Krylene NS because it is reliably uniform . . . has a lighter white colour for easier, more accurate colour control . . . is non-staining and non-discolouring . . . and possesses good processing characteristics.

Polysar rubbers have improved floor tiling—they can improve your products, too.

After further study at the University of Toronto, he obtained the degree, Civil Engineer, in 1940. He then renewed his affiliations with the Ontario Power Commission, serving successively as building engineer, program planning and control engineer, which latter appointment was made in 1953.

Mr. McMordie was among those elected in 1954, to the executive council of the Association of Professional Engineers of Ontario.

E. Frank Gillies, M.E.I.C., has been appointed by the Minnesota Mining and Manufacturing of Canada Limited as Supervisor, Reflective Products Group, for Eastern Canada.

A graduate in engineering from the University of Manitoba, Mr. Gillies has been with the company for the past four years. Prior to that time he was City Traffic Engineer for Winnipeg, Manitoba and Director of Manitoba Highway Safety Council for five years. Previously he had eight years experience with the International Nickel Company of Canada, Ltd.

Mr. Gillies is a member of the Association of Professional Engineers of the Province of Ontario, Canadian Institute of Traffic Engineers; Associate Member Institute of Traffic Engineers, (U.S.A.); Member Canadian Highway Safety Conference, and Engineering Committee, the Canadian Good Roads Association and the Ontario Good Roads Association.

E. F. Gillies, M.E.I.C.

William Aubrey Messenger, M.E.I.C., has been appointed vice-president of Barrett Company Ltd. In this capacity he will continue to direct the company's manufacturing operations at Montreal, Joliette, and Louisville; at Toronto, Winnipeg and Vancouver.

Mr. Messenger was formerly director of operations for the company, having been with them since 1940. He has also been superintendent of the Montreal plant of the company.

W. A. Messenger, M.E.I.C.

A McGill University graduate, Mr. Messenger worked in the construction and building material industries before joining the Barrett firm in 1940.

Dudley S. Young, M.E.I.C., has been appointed president and managing direc-

• Personals

tor of Powerlite Devices Ltd., Toronto. He was named vice-president of the company in 1949.

Mr. Young graduated in electrical engineering and later received an S.M. degree from the Massachusetts Institute of Technology.

Prior to that time he was associated for four years with Canada Wire and Cable Company Ltd., serving that firm for a period of sixteen years.

Active in professional affairs through the Canadian Electrical Manufacturers Association and the Canadian Transit Association, he has held offices in these, and in Manitoba and M.I.T. alumni groups.

W. T. N. Reeve, M.E.I.C., has been recalled by his firm, Sir Alexander Gibb and Partners, to their London, Eng., head office.

Mr. Reeve has recently spent some time in this country in connection with the firm's Toronto, Ont., interests.

He is a graduate of Cambridge University where he received an M.A. degree in mechanical sciences.

W. M. Walker, M.E.I.C., is with Atomic Energy of Canada Ltd., at Chalk River, Ont. He has been on loan for the past year from the B.C. Electric Company Ltd., in Vancouver, B.C., where he has been assistant system planning engineer.

A graduate of the University of British Columbia, he received a B.A.Sc. degree in electrical engineering in 1945, then worked with Imperial Oil Ltd., at Sarnia, Ont. Later, in 1947 he became industrial power engineer with the B.C. Electric Railway.

Baldur Sigurdson, M.E.I.C.

Baldur Sigurdson, M.E.I.C., has joined the staff of Mueller, Limited, of Sarnia, Ont., as Alberta sales representative, with residence in Calgary.

Formerly associated with Linde Air Products Company, Mr. Sigurdson is a 1949 graduate in mechanical engineering from McGill University.

J. B. Shallenberger, M.E.I.C.

John B. Shallenberger, M.E.I.C., has been elected president of the Albert Sheetz Corporation, in Hollywood, California.

In 1950 he was assistant to the president of Canadair Ltd. He has been associated in engineering and sales capacities with Douglas Aircraft Company Incorporated; General Dynamics Corporation, Aluminum Company of Canada, and Ford Motor Company.

He will retain the presidency of Shallway Corporation, Connellsville Manufacturing and Mine Supply Company, and Shallway International Corporation.

Once a part-time lecturer at McGill, Columbia, New York, and Stanford Universities, Mr. Shallenberger is a graduate of Stanford, the University of Munich, and the Harvard Graduate School of Business Administration. He was also associated with the Aluminum Company school of international business administration, in Geneva, Switzerland, as lecturer and director of case study research.

Commander P. F. Fairfull, M.E.I.C., has been elected chairman of the Vancouver Island Branch of the Institute.

A native of the British Isles, Cdr. Fairfull began his engineering career as an apprentice with William Simons and Company, Ltd., of Renfrew, Scotland, engineers and shipbuilders. He also studied naval architecture at the Technical College, Paisley, Scotland.

Established in this country in 1925, he accepted a position in Toronto, with Chapman and Oxley, architects and engineers. In the early thirties he went to work for the Toronto Star as building supervisor and engineer, but with the onset of the war, once more was connected with shipbuilding. He served as chief engineer for the Crown operated Toronto Shipbuilding Company, which firm he joined in 1941. In the Naval Service, two years later, he was appointed overseer of ship construction on the Great Lakes. He then became manager of the constructive department, H.M.C. Dockyard, Esquimalt, B.C., and was ultimately chosen as principal ship overseer for the west coast. He still holds the rank of constructor commander, R.C.N. (R).

In 1948 the Department of Public Works of Canada named him superintendent of the Esquimalt, B.C., graving dock.

Cdr. Fairfull has been active in the work at the Institute, and has served the Branch as Secretary-Treasurer.

Cdr. P. F. Fairfull, M.E.I.C.

L. A. W. Davis, M.E.I.C.

L. A. W. Davis, M.E.I.C., has joined the staff of Computing Devices of Canada, Ltd., of Ottawa, as technical administrator in the guided missile department.

Since August 1954, Mr. Davis has been associated with the Canadian Armament Research and Development Establishment of the Defence Research Board, at Valcartier, Que., as trials controller, (technical), on the Velvet Glove guided missile project.

STEEL PLATE PRODUCTS

T.I.W.

Storage Tanks for Petrofina

ONLY THE BEST WOULD DO . . .

Toronto Iron Works Ltd. are extremely proud of the role they have played in supplying storage tanks and fittings for the new Canadian Petrofina refinery near Montreal.

This new plant is one of the most remarkable installations of its kind ever built in Canada—it brings together a combination of vacuum distillation and fluid coking with 5 catalytic processes. This ultra modern plant is unique in the refinery field.

"Toronto Iron" have a special kind of leadership too . . . in the fabrication of steel plate, stainless steel, Monel, nickel, aluminum and alloys.

If you have a job you want done well — "Toronto Iron" is at your service.

THE TORONTO IRON WORKS LIMITED

ESTABLISHED 1907

TORONTO • MONTREAL

DESIGNERS • FABRICATORS • ERECTORS

Prior to this, Mr. Davis specialized in the development and trials of classified naval electrical installations in ships of the Royal Navy, the Royal Canadian Navy, and the Royal Australian Navy, serving with the Admiralty, and in the Naval Headquarters of Canada and Australia from 1940 to 1952. He was the electrical test engineer, from 1952 to 1954, for naval vessels at Canadian Vickers Ltd., in Montreal.

Mr. Davis was educated at Christ's College, London, England, at the London Polytechnic and the Melbourne Technical College, Melbourne, Australia. He became an Associate Member of the Institute of Electrical Engineers in 1951, and is also a member of the Association of Professional Engineers of the province of Ontario.

G. R. Doull, M.E.I.C., regional chief engineer with the Canadian National Railways at Moncton, N.B., has retired after long years of service.

Mr. Doull, a Nova Scotian, of New Glasgow, joined the C.N.R. engineering service in 1914. He worked as draftsman on the Halifax ocean terminals in 1916, and that same year was transferred to Moncton as assistant engineer where he remained until a 1921 assignment to the Toronto office of the engineer of standards. Later he was moved to Montreal as assistant engineer, but in 1943 returned to Moncton, being appointed bridge engineer for the Atlantic region in 1944.

Named principal assistant engineer in 1949, he became assistant chief engineer in 1952 and chief engineer the following year.

G. R. Doull, M.E.I.C.

D. W. Blair, M.E.I.C., has been appointed chief engineer with the Canadian National Railways, Atlantic Region, at Moncton, succeeding G. R. Doull, M.E.I.C.

Graduating from the University of New Brunswick in 1946 with a B.Sc. degree in civil engineering, Mr. Blair immediately joined the C.N.R. in the department of research and development in Montreal as a junior assistant engineer.

D. W. Blair, M.E.I.C.

In 1947 he worked as assistant engineer at Levis, Que., and later that year was named division engineer for the Laurentian division at Quebec City. Acting in the same capacity, in 1950, he worked at Montreal terminals and the St. Jerome division. He was named district engineer of the Southern Ontario district in 1953 with headquarters in Toronto, and two years later was transferred to Moncton.

C. N. Murray, M.E.I.C., general superintendent of the Dominion Steel and Coal

• Personals

Corporation, Sydney, N.S., has been elected president of the Association of Professional Engineers of Nova Scotia.

Born in Sydney and educated at Acadia University and the Nova Scotia Technical College, he graduated from the latter in 1935 with a degree in mechanical engineering. He joined Dominion Steel and Coal Company Ltd., as an instrument clerk in 1936 being appointed in 1943 superintendent of blast furnaces, and was subsequently named assistant to the general superintendent.

C. N. Murray, M.E.I.C.

Mr. Murray is a past-councillor of the Institute, and a past-chairman of the Cape Breton Branch of the Institute.

E. J. Durnin, M.E.I.C., construction engineer with the Saskatchewan Power Corporation, and 1956 president of the Association of Professional Engineers of Saskatchewan, has recently been elected chairman of the Saskatchewan Branch of the Institute.

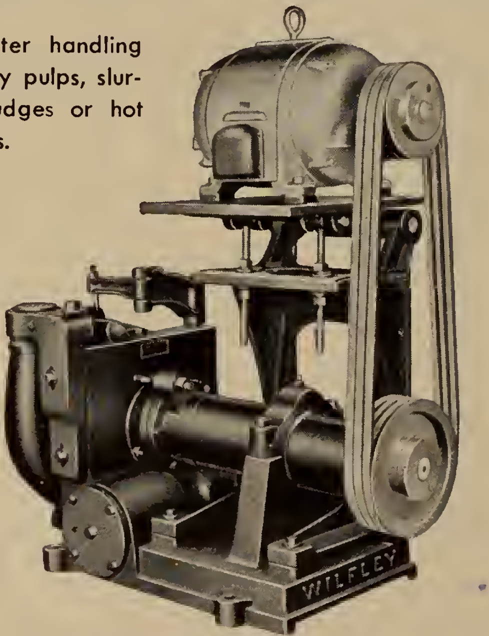
Born in Dauphin, Man., educated in Saskatchewan, he received a B.A. degree from that university in 1924, then joined the R.C.A.F. and spent the following three years as a pilot officer. In 1928 he qualified for a B.A.Sc. degree in electrical engineering at the University of Manitoba, and enrolled in an apprentice engineering course with the Canadian Westinghouse Company, in Hamilton, Ont., which he concluded in 1930.

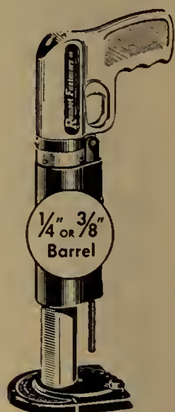
Returning to Saskatchewan, he accepted a position with the then Saskatchewan Power Commission, later known as the Saskatchewan Power Corporation, and became, successively, junior engineer, district superintendent, and commercial superintendent. At the onset of the second world war, in 1940, he joined the army and spent five years in Canada, Great Britain and Northwest Europe with the Corps of the Royal Canadian Engineers, retiring with the rank of major. In 1946 he resumed affiliations with the Power Corporation and was at once engineer in charge of

E. J. Durnin, M.E.I.C.

construction and transmission, distribution and substation projects, which position he has held to the present time.

He is a member of the Canadian Electrical Association. In 1948-49 he served as councillor with the Association of





"They're Roasting Rock -to help Canada Grow!"

EVERY DAY at the gigantic new Villeneuve Plant of the St. Lawrence Cement Co. near Quebec City, hundreds of tons of limestone, shale and other ingredients are quarried, crushed, cooked to clinker in a giant kiln, then pulverized and mixed with gypsum. The resulting product is cement, required for roads, bridges, hydro-electric developments, industrial, commercial, agricultural and residential construction.

This $13,000,000 cement plant, one of the most modern in the world, is equipped with crushers, grinding mills, screens, kilns, motors and controls supplied by Canadian Allis-Chalmers.

There's hardly an industry contributing to your better living today that isn't served at some point by Allis-Chalmers, one of the world's largest builders and suppliers of cement plant equipment. For further information, contact Canadian Allis-Chalmers Ltd., P.O. Box 37, Montreal, Quebec.

Professional Engineers of Saskatchewan; in 1955 became vice-president of the organization. He has served the Engineering Institute also, being elected a councillor in 1951.

J. J. Green, M.E.I.C., Defence Research Member of the Canadian Joint Staff, Department of National Defence, at Washington, D.C., has presented the Institute with a copy of the eleventh British Commonwealth and Empire Lecture which he gave before the Royal Aeronautical Society in London, England, in October, 1955. The subject of Dr. Green's lecture was "The Growth of Aeronautical Research in Canada During the Post-War Decade."

The British Commonwealth and Empire Lecture was started in 1945, with the intention that it should form the focus for the aeronautical problems of the Commonwealth and Empire.

Dr. Green was the first president of the Canadian Aeronautical Institute in 1954. His transfer to Washington in September, 1955 interrupted a term of service to the Engineering Institute as councillor representing the Ottawa Branch. He is a past-chairman of the Branch.

The Journal will carry an abstract of Dr. Green's R.Ae.S. lecture in an early issue.

Mr. F. E. Regan, M.E.I.C., has been appointed vice-president and assistant general manager of Bepco Canada Limited.

Mr. Regan has been with Bepco Canada Limited and its associated companies, since 1924. He was appointed

F. E. Regan, M.E.I.C.

Ontario manager in 1934, became a director of the company in 1949, and vice-president in 1952. His new duties have necessitated a move from Toronto to the head office in Montreal.

H. H. Moor, M.E.I.C., who has been transferred to Dartmouth, N.S., by Imperial Oil Ltd., as refinery manager of their Halifax refinery has held the position of superintendent of the Edmonton refinery for the past eight years.

A chemical engineering graduate of the University of Toronto with a M.A. Sc. degree, Mr. Moor joined Imperial Oil upon graduation in 1923, and for the next ten years held various junior positions in the company's laboratory and research departments. This experience was followed by two years in France as engineer in charge of a lubricating oil plant with Standard Franco-Americaine de Raffinage, at Pt. Jerome, France. Returning to Canada he was given the position of assistant to the chief research chemist with Imperial Oil, becoming, in 1942, technical assistant superintendent of the Sarnia refinery,

H. H. Moor, M.E.I.C.

and finally, in 1946, assistant superintendent. His appointment to Edmonton occurred a year later.

Mr. Moor is a past president of the Association of Professional Engineers of Alberta.

Lt. Cdr. (E) V. F. O'Connor, R.C.N., M.E.I.C., has been appointed senior engineer with H.M.C.S., Magnificent, Halifax, N.S.

Lt.-Cdr. O'Connor began his engineering career as engine room artificer with the R.C.N. in 1934, imediately after receiving a mechanical engineering degree from the Nova Scotia Technical College. He became chief engine room artificer in 1940, and two years later received an appointment as engineer officer in the engineering branch. In 1946 he served as a lieutenant with H.M.C.S. Scotian, based at Halifax, and in 1953 was posted at naval headquarters, Ottawa, as a Lieutenant Commander with the Department of National Defence.

Richard F. Andretsch, M.E.I.C., is with H. A. Simons in Vancouver, B.C., as structural designer.

Mr. Andretsch obtained an engineering diploma from the Institute of Technology in Graz, Austria, in 1951.

In Canada only a short time, he has been employed by D. R. Stanley and Associates Ltd., in Edmonton, Alta.

J. Steudel, M.E.I.C., has accepted a position as structural design engineer with Samborn, Steketee and Associates, in Toledo, Ohio.

Mr. Steudel graduated in 1950 from Munich Institute of Technology. In Canada since 1953, he has been in reinforced concrete design work, in the West, mainly with Dominion Construction Company Ltd., Edmonton.

S. W. Pappius, M.E.I.C.

B. J. McColl, M.E.I.C., is a consulting engineer in Strathmore, Que.

With Canadair in 1947, he was chief of the power plant section, (design office) in Montreal. Later, in 1948 he was given charge of the mechanization activities of the Woodlands section of the Canadian Pulp and Paper Association.

Mr. McColl is a mechanical engineering graduate of Queen's University.

Joseph J. Kelly, M.E.I.C., chairman of the Institute's Hamilton Branch has been named general manager of sales for Union Drawn Steel Company Ltd., in Hamilton.

Born and educated in Ontario, Mr. Kelly graduated from the University of Toronto in 1932, with a B.A.Sc. degree in electrical engineering. He immediately joined Lincoln Electric and was engaged in the development of arc welding and its application to industrial processes. Later he was named manager of the Hamilton district office, and a director in the company.

He is a member of the Association of Professional Engineers of Ontario and past national chairman of the Canadian Welding Society.

Gilbert Proulx, M.E.I.C., has been transferred from Saguenay Electric Company of Chicoutimi, Que., to the Aluminum Company of Canada Ltd., in Montreal, where he will hold the position of power operations engineer.

Employed for a short time by Dominion Bridge Company Ltd., Lachine, Que., following a 1941 graduation from Ecole Polytechnique, Mr. Proulx has been with Saguenay Electric Company since 1942. At that time assistant to the superintendent, he was named plant superintendent in 1946.

H. W. Carss, M.E.I.C., is with Bell Telephone Company of Canada, special contracts division, at Dawson Creek, B.C.

A 1945 graduate of the University of Saskatchewan in civil engineering, Mr. Carss was named city engineer, Swift Current, Sask., in 1946. More recently he has been associated with Poole Construction in Regina, Sask.

S. W. Pappius, M.E.I.C., has been appointed sales engineer with Canadian Vickers Ltd., in charge of the promotion and sale of hydro-electric equipment.

Attached to Canadian Vickers Ltd., engineering department since 1948, Mr. Pappius was originally employed by the company as design engineer. He transferred to standards engineer in 1952, participating in numerous projects within the hydro electric field.

He received his training in England during the war, in connection with the Royal Naval Engineering College and came to this country in 1948, serving briefly with the Canadian National Railway at Winnipeg, before joining Canadian Vickers.

H. F. Schmelz, M.E.I.C., consulting engineer, acting as works manager and chief engineer, since 1954, with Industrias Metalicas de Palmira, Palmira, Columbia, South America, has accepted a contract for an additional two years in his present capacity.

Mr. Schmelz organized the consulting firm of Engineering Associates in Montreal, in 1951, and later continued as an independent consulting engineer.

In 1953, living in the United States, he was associated with special engineering projects for the Channel Master Corporation of Ellenville, N.Y.

Prior to handling his own practice, he was in charge of the design and devel-

• Personals

opment division of Dominion Rubber Company, Montreal.

Mr. Schmelz is a graduate of the Technological Institute of Vienna, Austria.

Reginald Hugo, M.E.I.C., was appointed several months ago as western region bridge engineer with the Canadian National Railways, at Winnipeg, Man.

Mr. Hugo's career with the C.N.R. dates back to 1919 when, after service in the R.F.C. he was taken on the staff of the bridge engineer in the company's Winnipeg offices as draftsman. He was promoted to the position of designing engineer in 1924, assistant engineer in 1932, and in 1950 was named assistant bridge engineer. He graduated from the University of Manitoba in civil engineering.

He served on the council of the Association of Professional Engineers of the Province of Manitoba during the years 1951-1953.

G. M. Josephson, M.E.I.C., formerly secretary of the Amherst Branch of the Institute, has been named plant manager of Sifto Salt Ltd., in Sarnia, Ont.

Mr. Josephson started his engineering career with the Leckie Tannery in New Westminster, B.C., in 1946, then joined the Dominion Tar and Chemical Company Ltd., in 1949, at Goderich, Ont., later transferring to Amherst, N.S.

He is a 1946 graduate of the University of British Columbia in chemical engineering.

J. Devlin, M.E.I.C., has been transferred by McColl Frontenac Company Ltd., to Montreal, Que. Formerly with the company in Winnipeg, Toronto and Calgary, he had been assistant divisional manager of industrial sales since 1949.

Mr. Devlin joined the company in 1934 and was employed for a number of years as a lubricating engineer. He became manager of automotive and industrial lubrication in 1942.

Originally from Scotland, his first work in Canada was with Christie Brown and Company, Winnipeg in 1934. Prior to that time he held junior engineering positions with Cunard Steamship Company Ltd., and the P. and O. Steam Navigation Company, in England.

G. T. Hughes, M.E.I.C., has joined the firm of Ripley and Associates, in Vancouver. Professor Hughes was on the staff of the college of engineering, University of Saskatchewan, since receiving a M.Sc. degree in civil engineering from the University of Alberta in 1953. Most recently he was assistant professor in civil engineering.

P. J. Dowling, Jr.E.I.C., has been appointed divisional manager for Alberta and Saskatchewan for Franki Compressed Pile Company at Edmonton.

Mr. Dowling joined Franki Compressed Pile Company in Montreal in 1951 and was transferred to Toronto to become works manager in 1953. Awarded an Athlone Fellowship the following year, he devoted two years to advanced study in Great Britain.

He is a 1951 graduate of the University of Toronto, with a B.A.Sc. degree in civil engineering.

D. A. Slack, Jr.E.I.C., has been appointed division engineer for the Edmundston division of the Canadian National Railways Atlantic Region.

Mr. Slack entered the railway service in 1940 as a messenger in the communications department at Sackville, N.B. He enlisted with the R.C.A.F. in 1943 and at the conclusion of the war returned to the railway; whereupon he was granted leave of absence for purposes of study.

On graduating from the University of New Brunswick in 1950, with a B.Sc. degree in civil engineering, he was immediately employed as instrumentman with the C.N.R. at Edmunston.

R. C. Miller, Jr.E.I.C., formerly employed by Prudham Building Supplies Ltd., Edmonton, has joined Inland Cement Company Ltd., also of Edmonton.

Mr. Miller, a 1953 graduate of the University of Alberta, with a B.Sc. degree in civil engineering, has been associated with Alexander Construction Ltd., in Edmonton, as construction engineer, and the Calgary firm, Larwill Construction Company.

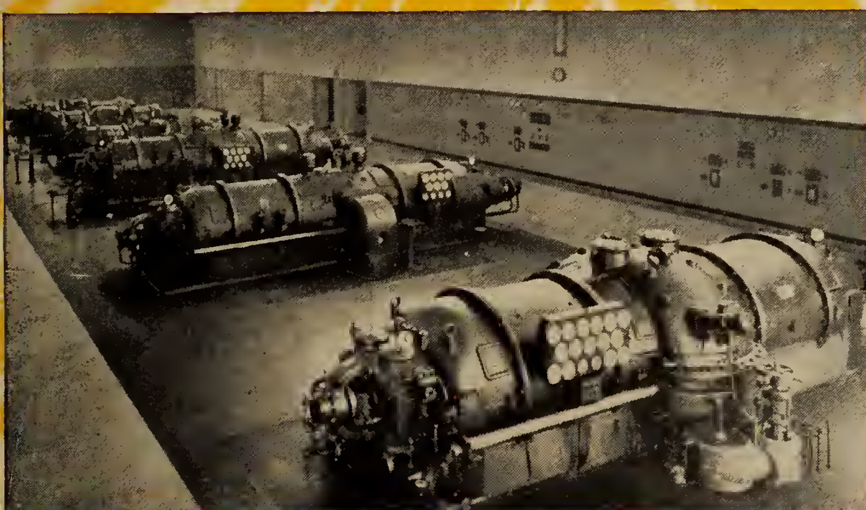
R. B. Sweet, Jr.E.I.C., has accepted a position with the Canada Paper Company, Windsor Mills, Que., as assistant mechanical superintendent.

Previously employed by Algoma Steel Corporation Ltd., in Sault Ste. Marie, Ont., he was, in turn, junior engineer, mechanical engineer, then project engineer and sales representative.

for low cost, reliable

POWER

SPECIFY **STAL** BACK PRESSURE TURBO GENERATORS



Power Station of Celulosa Argentina, S.A., Rosario, Argentina, with 5 STAL Back-Pressure Turbo-Generators and 1 STAL Condensing unit.

The utilization of the expansion of steam between boiler pressure and process steam pressure through STAL Back-Pressure Turbo Generators has provided many mills with a cheap and reliable source of power. The universally accepted ability of STAL Turbo Generators to outperform all others is indicated by the fact that they are now in use in 43 countries, including Canada.

STEAM GENERATING PLANTS WITH STAL TURBO GENERATORS HAVE THESE OUTSTANDING FEATURES

- Reliability in service with minimum attention
- Superior steam economy at all loads
- Small space required and accessible installation
- Low weight and cost of foundation
- Very quick starting time

STAL *Turbo Generators sold and serviced in Canada by*

• Personals

While in Sault Ste. Marie he served with 34 Tech Squadron R.C.E.M.E. Canadian Army Reserve, from 1950 to 1956, having transferred to supplementary reserve as a qualified captain, prior to departure from that city, January, 1956. He had previously held the rank of lieutenant.

Mr. Sweet is a member of the Association of Professional Engineers of Ontario. He graduated from the University of Saskatchewan in 1949.

Harry F. Burns, Jr.E.I.C., has received an appointment with the staff of A. D. Margison and Associates Ltd., of Toronto. He will head the traffic section of the firm's municipal department, now engaged jointly, with an American firm, on the design of the Metropolitan Toronto Expressway.

H. F. Burns, Jr.E.I.C.

On graduating in 1950 from the University of Manitoba, where he won the McKechnie memorial scholarship, Mr. Burns entered the Winnipeg city engineering department. Two years later he was named city traffic engineer. In the war he served with the Royal Canadian Navy on North Atlantic corvette convoy patrol.

He was elected president of the Canadian Section of the Institute of Traffic Engineers in 1955; and is a member of the Association of Professional Engineers of Manitoba.

John Daniels, Jr.E.I.C., has gone to Bolivia where he has accepted a position as distribution engineer in La Paz. He is with the Bolivian Power Company, a subsidiary of the International Power Company Ltd., of Montreal, Que.

With Bepco Canada Ltd., in Toronto, he was switchgear engineer in 1953, and has more recently been associated with ECC, Canada Ltd.

Lt. J. G. Forth, R.C.E., Jr.E.I.C., is now second-in-command of No. 1 Airborne Troop, Royal Canadian Engineers which is the engineering support for the airborne component of the Canadian Army. He is stationed at Calgary.

After graduating from the R.M.C. in 1952 he served a one year tour of duty

• *Personals*

with the twenty-third Field Squadron in Korea. In 1953 he attended the University of Toronto, where he obtained a B.A.Sc. degree in chemical engineering the following year. He has since been on the staff of the Royal Canadian School of Military Engineering at Camp Chilliwack, B.C.

Lt. Forth is a member of the Association of Professional Engineers of the Province of Ontario.

J. K. Wood, Jr.E.I.C., has accepted a position with Canadian Industries Limited, Montreal, as an assistant engineer.

Mr. Wood is a 1949 graduate of the University of Toronto, with a B.A. Sc. degree in chemical engineering. Later he worked with Canadian Kodak Co. Ltd., in Toronto. The past two years have been spent in England on an Athlone Fellowship.

H. C. L. Joe, Jr.E.I.C., has joined R. A. Hanright, consulting engineer, in St. Catharines, Ont., as an electrical engineer.

For the past seven and a half years he has been design engineer with the English Electric Company of Canada Ltd., St. Catharines, in their transformer, switchgear, motor and industrial control divisions.

Mr. Joe has represented the English Electric Company on the Canadian Electrical Manufacturer's Association industrial control technical committee for the past three years. He served as an executive member of the Niagara Peninsula Branch of the Institute for three years, one of which he was secretary-treasurer. He has also served twice on the committee for the annual joint E.I.C.-A.P.E.O. dance for Niagara Peninsula.

He is a graduate of the University of Toronto with a B.Sc. degree, class of '48.

E. H. Clayson, Jr.E.I.C., has accepted employment with B. F. Goodrich Chemical Company in Paducah, Kentucky.

Mr. Clayson joined the staff of Dominion Oilcloth and Linoleum Company in Montreal as development engineer in 1949 and the following year was named department head of the plasticizer and special resins unit, which position he held until his recent apointment.

He graduated from McGill University in 1949 with a B.Eng. degree in chemical engineering.

Stuart Lyon, Jr.E.I.C., is at Stilfontein, Transvaal, South Africa, working for John Laing and Son (S.A.) Pty. Ltd. of Johannesburg. He is engaged in road construction.

Mr. Lyon graduated from the University of Toronto with a B.A.Sc. degree in civil engineering, class of 1954.

D. A. McRae, Jr.E.I.C., now holds the position of vice-president and electrical engineer in charge of all electrical construction, with Cemco Inc., industrial designers and builders, Downey, California.

Quite recently, Mr. McRae has been associated with Adams Electrical Contractors, in California, and prior to that time worked with Dominion Steel and Coal Company, in Sydney, N.S.

He is a graduate of the University of Manitoba, class of 1948, with a B.Sc. degree in electrical engineering.

D. R. Francis, Jr.E.I.C., is with the Department of Mineral Resources, Regina, Sask.

He joined the department of geology, at the University of Saskatchewan in 1952, having gained a B.Eng. degree in geology in 1950, at that university.

Frank G. Oravec, Jr.E.I.C., is working with Atomic Energy of Canada Ltd. in Chalk River, Ont.

He graduated in 1952 from Queen's University in mechanical engineering, and was previously associated with Montreal Cottons Limited, a branch of Dominion Textile Company, in Valleyfield, Que., where he was employed in the standard department as an industrial engineer.

Captain J. F. Clarabut, Jr.E.I.C., is with the Canadian Army Staff College at Fort Frontenac in Kingston, Ont. He was formerly in Quebec City, Que., with the C.A.R.D.E.

Captain Clarabut graduated in mechanical engineering from the University of Toronto in 1950 and has been at Valcartier, Que., with the Canadian Armament and Research Establishment, and also spent some time in England at the Military College of Science at Shrivenham.

Dick Jamieson, Jr.E.I.C., is chief metallurgist with Trenton Steel Works Ltd., Trenton Industries Ltd., and the Eastern Car Company, at New Glasgow, N.S.

In 1954, Mr. Jamieson was a research fellow at the Ontario Research Foundation in Toronto, and had before that time been associated with the Dominion Steel and Coal Corporation in Sydney, N.S., as junior metallurgical engineer.

J. T. Denley, Jr.E.I.C., has joined the consulting engineering firm of H. A. Simons, Ltd., in Vancouver. He is a design engineer associated with the construction of pulp and paper mills.

A 1949 graduate of the University of Alberta, he was associated shortly after graduation, with Perforating Guns of Canada, Ltd., and as a logging engineer with the Oil and Gas Well Servicing Company, in Edmonton, Alta.

E. H. Clayson, Jr.E.I.C.

J. R. Dupuis, JR.E.I.C., has been transferred by the Aluminum Company of Canada to McKenzie, British Guiana, from Arvida, Que., where he served as electrical engineer. Mr. Dupuis is a 1950 graduate in electrical engineering from the University of New Brunswick.

R. R. Cheyne, JR.E.I.C., has been transferred by the Aluminum Company of Canada to British Guiana where he will fill the position of assistant mechanical superintendent of the Demerara Bauxite Co. Ltd., at Watooka, McKenzie, British Guiana.

He has, since graduating in mechanical engineering from the University of Saskatchewan, in 1949, been associated with Shawinigan Chemicals, at Shawinigan Falls, Que., General Steelwares Ltd., at London, Ont., and for the past five years has worked for Aluminum Company of Canada, recently at Arvida, Que.

E. R. Cleveland, JR.E.I.C., has joined the Department of Highways, bridge branch, in Edmonton, Alta., as resident engineer. He is a 1954 graduate of the University of Alberta, in civil engineering.

W. Edward Donahue, JR.E.I.C., has accepted a position with Intrusion Prepakt Ltd., of Toronto, at Kemano, B.C.

Mr. Donahue is a 1948 graduate of the University of New Brunswick in civil engineering and has previously been in London, Ont., with the Department of Public Works of Canada.

B. G. Butler, JR.E.I.C., is in Toronto with the harbours and rivers engineering branch of the Department of Public Works of Canada.

He graduated from the University of London in 1954 with a B.Sc. degree in engineering and has since then been employed as instrumentman with Canadian National Railways at Senneterre, Que., and was design engineer for hydraulic structures with H. G. Acres and Co. Ltd. of Niagara Falls, Ont.

Russell H. Smith, JR.E.I.C., was recently named sales manager of Hysol (Canada) Limited, Toronto, Canadian affiliate of Houghton Laboratories Inc. of Olean, N.Y. He was formerly chief sales engineer of Burndy Engineering in Toronto where he was in charge of salesmen, advertising and promotion.

Mr. Smith received his B.Sc. degree in electrical engineering from the University of Manitoba in 1947, and studied business administration at the University of Toronto. He has also spent some time with the Canada Cement Company in Montreal.

Paul F. Karrow, JR.E.I.C., is studying for a Ph.D. in pleistocene geology and soil mechanics at the University of Illinois. Mr. Karrow received a B.S. Sc. (Geol.) degree from Queen's University in 1954.

D. C. Patel, JR.E.I.C., who graduated in 1954 from the University of Nebraska with a degree in electrical engineering is working as a methods engineer for the firm of George Angus and Co. Ltd., Oil Seal Division, Newcastle upon Tyne, England.

Mr. Patel has for some time been engaged in post graduate study at the University of Durham.

George H. Milne, JR.E.I.C., has been appointed comptroller of Horton Steel Works Limited in Fort Erie, Ont. He joined the company three years ago and has been industrial engineer with the company prior to his present appointment.

Mr. Milne received a commerce degree from McGill University and then his bachelor's degree in mechanical engineering in 1953. He became a chartered accountant in 1954.

R. H. Smith, Jr.E.I.C.

He is a member of the Association of Professional Engineers of Ontario and of the Corporation of Professional Engineers of Quebec; a member of the American Society of Mechanical Engineers, and of the Institute of Chartered Accountants of Ontario and Quebec and the Dominion Institute.

R. P. Fillmore, JR.E.I.C., has been transferred from Ottawa to North Bay, Ont., with the Department of Public Works. Mr. Fillmore has been associated with the department since 1952 and was formerly with the forests and scientific services of the topographical survey, Department of Mines and Resources, Ottawa.

He is a 1949 graduate of the University of New Brunswick in civil engineering.

Rolland Marcotte, JR.E.I.C., is a project engineer with Hydro-Quebec, at Montreal. He was formerly in Longueuil, Que., with the Stowell Screw Co. Ltd., in the position of assistant to the chief engineer.

Mr. Marcotte is a 1951 graduate of the Ecole Polytechnique in civil engineering.

Arthur Denis, JR.E.I.C., is now with the Square 'D' Company Ltd., of Canada, Montreal, Que., as field engineer.

He received a degree in electrical and mechanical engineering in 1953 from the Ecole Polytechnique, Montreal.

C. M. Goodrich, S.E.I.C., is now with the Peace River Oil and Pipeline Company at Valleyview, Alta.

Mr. Goodrich graduated from the University of Saskatchewan last year with a B.Sc. degree in mechanical engineering, and then was employed as a mechanical engineer with Canadian Gulf Pipe Line Company, in Edmonton.

Gerald A. O'Brien, S.E.I.C., has accepted a position in Quebec City with North-eastern Paper Products Limited.

Since his graduation as a mechanical engineer from the University of New Brunswick, class of 1955, Mr. O'Brien has been active as a research engineer for Anglo-Newfoundland Development Co. Ltd., Grand Falls, Newfoundland.

Congratulations

to QUEBEC HYDRO

on the achievement

of BERSIMIS

The mighty Bersimis Development ranks with Kitimat, Kemano and the Seaway as achievements which have changed the face of Canada and promoted important benefits for millions of Canadians. The Quebec Hydro-Electric commission is to be commended for conceiving and implementing this broad undertaking.

We feel privileged to have supplied essential equipment for underground placing of vast quantities of concrete and, on the surface, pneumatic conveying equipment for the unloading, transfer and storage of vital bulk cement.

Activities of the Forty-seven Branches of the Institute and abstracts of papers presented at their meetings

Amherst

W. G. Miller, jr.e.i.c.
Secretary-Treasurer

General Meeting

The Amherst District Branch met February 17, 1956 in the Amherst Hotel for a dinner and general business meeting. The meeting was under the chairmanship of Charles Archibald. Reports were read from various committees and a full agenda of new business matters were dealt with.

Belleville

J. A. Grant, m.e.i.c.
Secretary-Treasurer

J. Rywak is Guest Speaker

The regular monthly general meeting of the Belleville Branch was held on March 12, 1956. This was the sixth meeting of the 1955-56 season and approximately 25 members and guests attended.

The speaker was J. Rywak who read a paper on "Automatic Digital Computers". Mr. Rywak has recently returned from a nine-month assignment on loan to Defence Research Board, Ottawa, where he was engaged in research work associated with the digital computer. Mr. Rywak's talk dealt with the distinguishing features of the various forms of automatic computation and with analysis of digital techniques.

The speaker was introduced by W. Benger and thanked by E. Flinn.

Refreshments were served at the close of the meeting.

President's Annual Visit

Wednesday, February 22, 1956, was the date of the president's annual visit to the Cornwall Branch. Dr. Heartz, accompanied by E. C. Luke, acting for Dr. Austin Wright, met with the Branch executive for an enjoyable luncheon and subsequent business session.

Dr. Heartz, Mr. Luke and members of the executive then proceeded to the main administration office of the Ontario Hydro's St. Lawrence power project. Gordon Mitchell, project director, after explaining details of the power project and the Longue Sault section of the St. Lawrence Seaway, conducted the group on a most interesting tour of the project. The group was also accompanied by W. M. Hogg, field project engineer.

Mrs. Heartz, accompanied by wives of the Branch executive, also enjoyed a separate post luncheon tour of part of the power project, including a visit to Hydro's newly constructed hospital.

Canada's Need for Engineers

In the evening, Dr. and Mrs. Heartz, Mr. and Mrs. Gordon Mitchell and Mr. and Mrs. Drummond Giles, attended a most enjoyable dinner dance at the Cornwall Golf and Country Club. Later, Dr. Heartz in addressing Branch members, stressed the present and growing need for more engineers to keep pace with Canada's expanding economy. He also emphasized the desirability of establishing more technical centres for training suitable assistants for engineers. These, he stated, were required in the ratio of about three technicians per engineer and would result in the more effective utilization of engineering skills. A further system of obtaining a relatively small percentage of more highly qualified graduates to meet with increasingly difficult technical problems was also advocated by President Heartz.

Dr. Heartz, who had been introduced by Drummond Giles, was thanked by Gordon Mitchell.

Joint Meeting at Officers' Mess

Brigadier J. R. B. Jones, officer commanding of the N.B. Military Area, was chairman at a joint meeting of the Military Engineers Association of Canada and the Fredericton Branch of the Engineering Institute of Canada, held in the Officers' Mess, N.B. Army Area Headquarters in Fredericton on February 20, 1956.

H. F. Peters, federal supervising engineer for Nova Scotia on the Trans-Canada Highway, addressed members of the Halifax Branch at their December meeting on the progress and the problems encountered in highway construction. Seated by Mr. Peters (insert) is W. A. Deveraeux, chairman of the Branch.

Congratulations

TO THE HYDRO-QUEBEC AND THE CONTRACTORS WHO ARE BRINGING THE BERSIMIS PROJECT TO COMPLETION

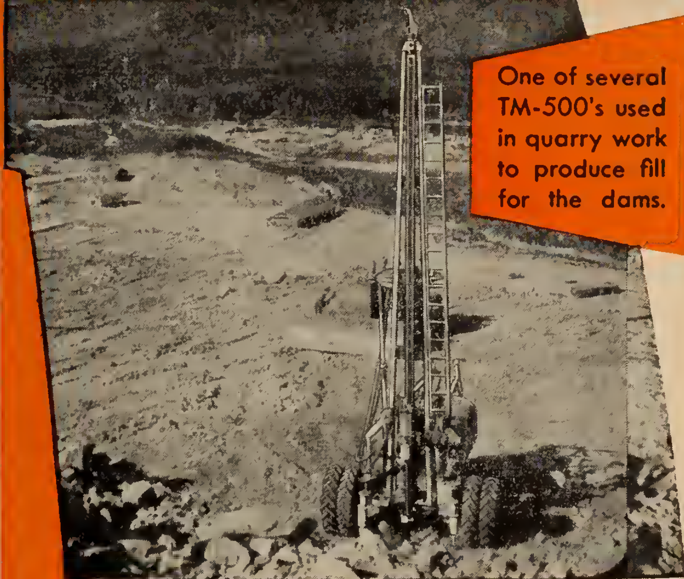
The Engineers of Hydro-Quebec, together with the Engineers of Atlas Construction Co. Ltd., Angus Robertson Limited, Cartier Construction Ltd., Dufresne Construction Co. Ltd., Komo Construction Co. Ltd., and B. Perini & Sons (Canada) Ltd. have co-operated in a modern miracle in Quebec's north country.

JOY equipment has been employed in all phases of this huge project, and has again demonstrated its rugged strength and versatility.

For the construction of the dams, TM-500 tractor-mounted Blast Hole Drills were used for quarrying fill. In the 8.5 miles of tunnel which had to be driven, the TM-500 Drill jumbo-mounted was used for burn cuts, and LBM-47 Airleg Drills and SLB-47 Stopers were also used. JOY AF-111 Hoists were used on turn plates, to turn the trucks carrying the muck from the face. Tunnel and jumbo lighting was sectionalized with JOY String-A-Lite installations. Electrical power distribution throughout the tunnel was sectionalized with JOY Connectors, and maintained with cable vulcanizers, and the entire tunnel system was ventilated with JOY Axivane Fans.

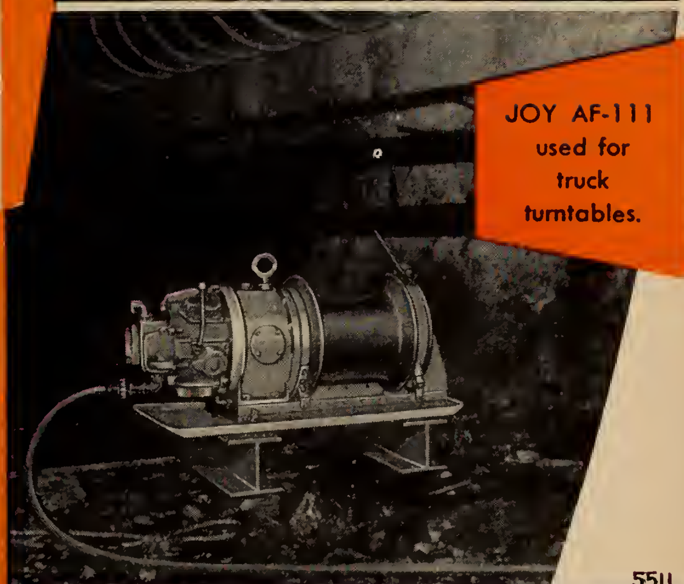
For any project, large or small, JOY Construction equipment pays dividends in time and money saved.

Consult your nearest JOY Office for full information.



One of several TM-500's used in quarry work to produce fill for the dams.

JOY LBM-47 air leg drilling at tunnel adit.



JOY AF-111 used for truck turntables.

JOY Series 1000 AXIVANE FAN standard for tunnel ventilation.

The meeting began with the presentation of the "Royal Canadian Engineers Book of Remembrance" to the Engineering Department of the University of New Brunswick. The book, which contains the names of all the members of the Royal Canadian Engineers who were killed in the Second World War, was presented by Major Garnett, chairman of the Military Engineers Association of Canada to Major Gillespie of University of New Brunswick.

Brigadier Jones next presented Officer Commanding L. D. Richards with a military scholarship. This scholarship is presented to a worthy senior student and a member of the C.O.T.C. or R.O.T.P. at each university in Canada.

G. L. Wiggs Describes Gagetown Heating

Professor H. MacFarlane next introduced G. Lorne Wiggs, senior member of the firm of Wiggs, Walford, Frost and Lindsay, and president of the Corporation of Professional Engineers of Quebec. Mr. Wiggs is one of the leading authorities in North America in radiant heating and cooling, air conditioning and high temperature water heating, the last being well illustrated in his talk at this meeting.

The subject of Mr. Wiggs' speech was "The Central Heating Plant and Heat Distribution at Camp Gagetown, N.B."

Briefly, Mr. Wiggs informed his audience of the vastness of the Camp Gagetown project, illustrating the areas to be served and, as a result, the tremendous quantity of heat to be supplied. He indicated the problems arising on such a project and the methods used by his firm to combat these problems. A history and explanation of this method of supplying heat was given and further illustrated by an explanation of the plant which is being built at Camp Gagetown.

After, both Associations enjoyed the hospitality of the Officers' Mess which provided a chicken dinner for those present.

Town Planning Panel

On March 20, 1956, the Fredericton Branch held a supper meeting at the Students' Centre of the University of New Brunswick.

After the supper Prof. H. W. McFarlane was moderator for a panel discussion on "Town Planning". Members of the panel were: D. Johnson, provincial architect and chairman of the Fredericton Town Planning Commission; L. Mercereau of the Department of National Defence and closely associated with town planning for Oromocto, N.B.; H. Marshall of the N.B.E.P.C. and member of the Provincial Planning Board; and D. McN. Lowe of Defence Construction (1951) Ltd. who has been closely associated with town planning in England as well as Canada.

The discussion was opened by Mr. Johnson who explained the purpose of town planning and the problems which arise in striving to obtain a well-planned town.

Mr. Mercereau next spoke on traffic directions in planned towns, the strategic location of neighbourhoods and business sections and the planning of a network of roads to avoid congested traffic, the design of roads to eliminate speeding. He used the town of Oromocto, location of the permanent married quarters for the Army at Camp Gagetown, as an illustration of well planned traffic direction.

Mr. Marshall spoke from a property owner's point of view, of the rights of the property owner as well as of the responsibilities which he owes to his community in aid of town planning.

Finally, Mr. Lowe compared the type of planned town such as Oromocto with the gradually expanding town. He spoke of the ever increasing demand in the services for such a town under gradual expansion and the results of overloading these services. Also Mr. Lowe discussed the "garden cities" of England and Scotland, the ideal towns of 50,000 which are considered the most efficient types of town from both the planner's and the dweller's point of view.

An interesting discussion followed. Conclusions reached were that there should be more co-operation between town and province; that the public has not been exposed enough to town planning but that advertising of town planning is up to the town planning commission.

The underground power house at the Bersimis Power Development. This cavern is 565 feet long, 65 feet wide and 80 feet high. It houses eight Francis turbines—fifty-five feet apart—each rated at 150,000 h.p. under a 785-foot head at 277 r.p.m. The power house was constructed by Dufresne Engineering Company Limited.

HEARTIEST CONGRATULATIONS to Quebec Hydro-Electric Commission on the completion of the Bersimis Power Development.

This Company is proud of its part in this great engineering feat. We constructed the power house, excavated the tailrace open cut, supplied the mixed concrete for lining all tunnels and were responsible for the maintenance and operation of all machinery and equipment during the entire period of construction.

H. F. Peters Speaks on T.-C. Highway

The regular December meeting of the Halifax Branch was held in the main showroom of the Wm. Stairs, Son and Morrow new plant on Kempt Road, Halifax, N.S. Over 125 members attended.

H. F. Peters, federal supervising engineer for Nova Scotia on the Trans-Canada Highway, was the guest speaker.

Mr. Peters outlined the progress made on the Trans-Canada highway and some of the problems encountered. His address was of great interest to the large number attending and was illustrated by slides. A film entitled "Roadblock" was also shown and much enjoyed. Members were taken on a tour of the new plant and saw some of the largest and latest models of earth moving machinery.

Hon. R. H. Winters Addresses Branch

Guest speaker at the annual meeting of the Hamilton Branch in February was the Honourable R. H. Winters who spoke on "The Place of the Trans-Canada Highway in the Story of Canadian Communications."

Canada's Minister of Public Works was introduced by Mr. Cooch.

"The history of Canada," Mr. Winters said, "has been shaped by the development of communications perhaps more than by any other single factor; our growth has from the first been interwoven with the story of the development of water, rail. road and air transportation. Step by step, a web of communications has been built across this country and economic development has followed. By boat, train, motor and airplane, we Canadians have linked our communities, opened the way to our resources and stimulated our economy. Postal services, telephone, telegraphs, radio, news agencies and now television, have brought us closer together and have helped to interpret Canada to Canadians. This story is constantly being extended: at this very moment in fact, by great projects quite worthy to take their place with the episodes of the past.

"The St. Lawrence Seaway, the proposed Trans-Canada Pipeline, the Trans-Canada Highway — all these now are underway or planned; all of them fit into the broad perspective of Canada's eternal struggle with her environment; of the conquest of her space."

Mr. Winters, responsible federally for one of these three—the Trans-Canada Highway, said "the movement of population and trade first followed the waterways, then expanded westward along the line of the railway. A network of roads spread out between cities and towns and became important for long-distance travel with the coming of the automobile age. Finally the invention of the airplane enabled Canadians to develop the mineral wealth of our northern lands, and to bring our cities closer together through speed."

To all these, he said, we have meanwhile added the other forms of communications. We have linked our coasts and our communities by telephone. Through such agencies as the C.B.C. in the fields of radio and television, the Canadian Press in news-gathering, the Canadian National and Canadian Pacific Telegraphs in the field of telecommunications, we have brought our peo-

• Branch News

ple together and helped to make them one.

The fact that this is an aeronautical age does not mean that Canada's waterways have lost their significance or that the railways have become obsolete or that roads are no longer necessary. Under our constitution, he said, roads are normally considered to be a provincial responsibility. But since 1919 the federal government has shouldered part of the financial burden for road-building. For six years now provincial and federal authorities have been working together on the task of completing a 5,000 mile highway from St. John's to Victoria.

Trans-Canada Highway in 1960

"Nine provincial governments signed agreements with the federal government to complete their share of this project by December 9, 1956," he said. "But progress has been slower than we had hoped. At the end of 1955, just one year away from the anticipated completion date, about one-third of the total mileage remains unpaved and for some 250 miles of the route there is no highway of any kind. However, we have re-examined the problem and devised a new formula providing for increased federal assistance. It is designed particularly to close the gaps and we now expect to see the highway a completed reality by the end of 1960.

"The engineering tasks have been stupendous. Muskeg, the old C.P.R. enemy, has been an important difficulty in Northern Ontario as it has been in Newfoundland and elsewhere. A wide, marshy tract full of dead trees, leaves and debris must be excavated before a stable foundation can be laid, and in some places it goes as deep as 50 feet. Then there is the prairie "gumbo"—the treacherous, heavy clay soil covering 25 to 30 per cent of the route in this area. It requires the use of reinforced concrete and other special techniques. And in British Columbia the roadbuilding crews have literally had to move mountains.

The Annual Meeting

MONTREAL

The program is on Page 437 of this issue

Engineering Work Hazardous

"Work is hazardous in the extreme in the Fraser Canyon and the Kicking Horse Canyon, where hard-rock miners blast away the mountain wall 500 to 1,000 feet above a turbulent river, and land slides are frequent. Since in most places the railway runs below the new highway, great care must be taken to protect the tracks and tons of rubble must be carried away. In one nine-mile stretch between Field and Golden two million tons of rock and an equal amount of dirt have been moved, by means of 5,000 tons of explosives. The cost of construction in this area is estimated at $1 million a mile and one half-mile stretch has cost $1,500,000.

The various stages in our story of communications, Mr. Winters said, have each made their contributions to Canadian development. There could hardly have been a Canada without them. The Trans-Canada Highway is part of this story and part of the eternal job of nation-building. It is by no means un-

• Branch News

fair to compare it with the greatest of our transportation achievements of the past.

Mr. Winters was thanked for his informative talk by Hamilton Branch councillor, N. A. Eager.

During this meeting also, the minutes of the last annual meeting were read and adopted. These showed that Branch membership had increased from 465 to 474 over last year. Two Life memberships were announced: those of H. G. Bertram and J. Stodard. In addition, the 1955 Student and Junior Papers Night prizes were presented; and Bill Filer, director of the Professional Development Program, spoke of the success of the program and described the annual Employers' Night.

Chairman F. E. Milne introduced the new chairman, J. J. Kelly, and the members of the new executive after which D. Annan expressed the appreciation of the Branch of the work of the 1955 executive.

Employers' Night

The annual Employers' Night sponsored by the Professional Development group of the Hamilton Branch took place in February.

J. J. Kelly, chairman of the Hamilton Branch, introduced W. Filer, director of the Professional Development Program, who outlined the history of the program and its objectives. The treasurer then reported a small surplus. After the treasurer's report, the Nominating Committee announced the new executive which was elected unanimously. H. Hone, the newly elected program director, was then introduced. He referred to the need of assistance on the part of employers of engineers in Hamilton, after which G. Scheinder reported on the progress of the Constitution Committee.

G. E. Miller is Guest Speaker

The guest speaker, G. E. Miller, chief engineer, maintenance of way, for the Eastern region of Canadian Pacific Railways, was introduced by the chairman. Mr. Miller's subject was "Transportation is Important".

He said he was pleased to address a group of young engineers interested in broadening their perspective on topics outside their own particular fields, and to their employers who are interested in the professional development of engineers.

Among the various problems facing engineers in industry today is the major one of transportation. In his talk Mr. Miller emphasized the dependability of railway transportation throughout the year. Canada as a country, he said, has been developed first, by water routes, then by land, and finally, by rail. This particular sequence has now changed, however, with exploration by air, followed by the laying of railroads, and finally, and if economical, the building of highways.

Mr. Miller illustrated railroad building in Canada by means of a series of scenic slides.

Members from Smiths Falls, Perth, Lanark, Merrickville and Cardinal, attend a recent dinner meeting of the Institute held for the first time in Smiths Falls on February 29. Left to right, seated, W. G. Cooke, W. L. Dickson, R. H. Wallace, chairman, Brockville Branch; Robert Marshall, J. G. MacLaurin and L. F. Grant. Left to right, standing, F. Trewartha, K. R. Bullock, T. W. Reade, F. R. V. Billie, C. S. Dinsmore, W. N. Simmons, J. G. Kerfoot, vice-chairman, Brockville Branch, R. M. Powell, and F. Walsh.

Yukon River Watershed

The power development that is taking place in the Canadian Northwest was described to the members of the Ottawa Branch on February 23 by J. M. Wardle of Northwest Power Industries. Mr. Wardle outlined the preliminary work of the last three years which resulted in the decision to spend $800,000,000 over the next 15 years for the development of nearly 5,000,000 horsepower.

Canadian Development

Mr. Wardle recalled the application in 1947 of the Aluminum Company of America for permission to develop 1,500,000 horsepower on the Yukon River. This resulted in the decision in 1950 by the Canadian Government to establish a policy that all power developed on Canadian Waterways was to be developed by Canada herself. Northwest Power Industries, an organization formed jointly by Ventures Limited, Frobisher and Quebec Metallurgical Industries, investigated all rivers in the Northwest area to establish the best method of power development. Many factors had to be studied such as water storage, flooding of communities, sale of power, construction and operating difficulties and potential competition from atomic energy.

A satisfactory solution of each of these problems together with the known increasing demand for power resulted in the decision to proceed with the development. Water is to be obtained for the development of power by reversing flow in the Yukon River and by diversion of other river and lake systems to create a large storage to supply water to a tunnel emptying into a deep mountain valley which will result in a head greater than 1,000 feet.

News of Other Societies

The Canadian Standards Association (National Research Building, Ottawa). The 29th annual meeting will be held on Friday, June 8, 1956, at the Nova Scotian Hotel, Halifax, N.S.

•

American Society of Civil Engineers (33 West 39th St., New York 18, N.Y.) has arranged a symposium on arch dams to be held as part of the summer meeting of the Society at the University of Tennessee in Knoxville, Tenn., June 4-9, 1956.

Fifteen papers reviewing a wide scope of experience will be presented. *Civil Engineering* will announce the availability of papers, and discussions will be welcomed by the Symposium Committee chairman R. E. Glover, 1936 South Lincoln Street, Denver, Col.

•

Institution of Production Engineers (10 Chesterfield Street, London W-1). The production exhibition, Olympia, London, England, May 23-31, 1956, has for its purpose to provide technical information on ways in which British goods can be improved in quality and quantity and to demonstrate the research effort and production techniques.

The production conference of the Institution will be held simultaneously.

The organizers (Andry Montgomery Limited, 32 Millbank, London, S.W. 1, invite Canadian visitors to the exhibition.

• Branch News

Moderate Temperature

Mr. Wardle explained that due to the Japanese current the weather at the power development site is not extreme. He quoted figures to show that the mean monthly temperature was only a few degrees colder than Ottawa during winter and correspondingly only slightly cooler than Ottawa in summer. The lowest temperature ever recorded at the site is —27°F.

Industrial Site Planned

An industrial site for the use of power is to be created just inside Canada on an inlet through the Alaska Panhandle. Mr. Wardle illustrated the economics of establishing an industrial site in this area by pointing out that it was possible to bring ore a distance of nearly 6,000 miles to the site for about $3 a ton. When this figure is compared to the market value of certain metals which require great power consumption for their purification, it is apparent that it would be economical to process raw ores in this remote region of Canada.

Dean R. E. Jamieson is Speaker

At a luncheon meeting of the Ottawa Branch on December 8, Dean R. E. Jamieson of the faculty of engineering, McGill University, outlined some of the problems which are accompanying the increasing enrolment in engineering at Canadian universities. He reminded the audience that the present total university registration in Canada of 67,000 students is expected to increase by 31 per cent within five years and by 92 per cent in ten years. The engineering enrolment is expected to increase similarly. Dean Jamieson pointed out that enrolment had increased threefold since World War II with only minor increases in teaching facilities.

Defends Academic Standards

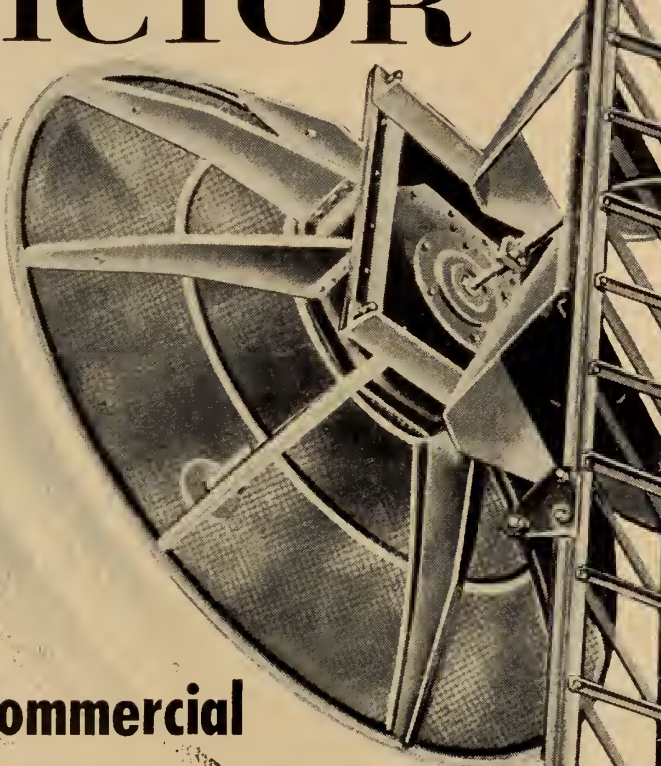
In defending the high academic standards which are maintained at Canadian universities, Dean Jamieson outlined a study of the individual performance of the students of two classes which had graduated from McGill: the first class of the World War I period and the second class of the World War II period. By comparative figures, he showed that the later group had faired academically as well or better than the earlier group. Therefore he recommended that further restrictions on entry to universities should not be imposed except as a last resort. Further he argued against any increase in student fees in an attempt to restrict entry.

Relief of Engineering Facilities

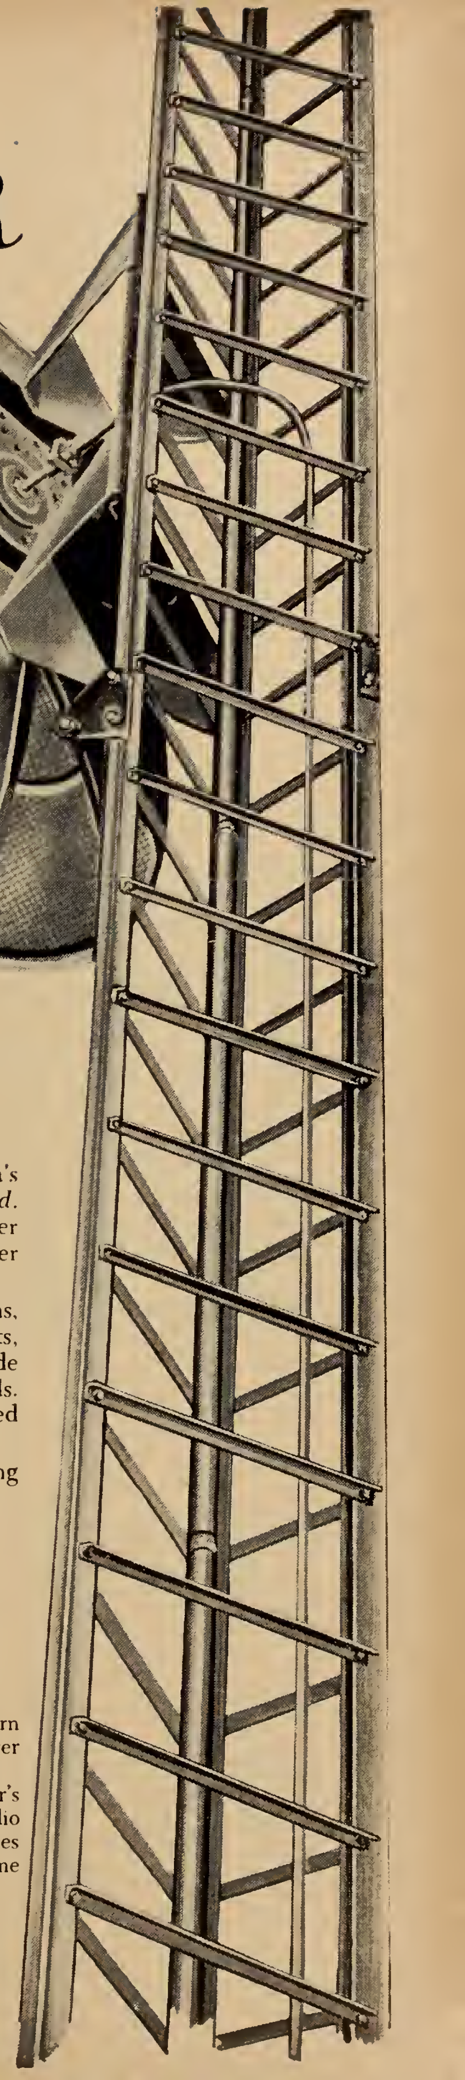
Dean Jamieson presented two ideas for the relief of the present engineering facilities at Canadian universities which must be doubled by the fall of 1964. First he recommended that the so-called "feeder" engineering schools be given increased support and secondly, that much greater financial support be given to the degree-granting universities. Dean Jamieson thought that the required financial support would be obtained with the backing of informed public opinion and he called upon the professional organizations to foster this development.

This luncheon was sponsored by the

RCA VICTOR



Builds Canada's Longest Private Commercial Microwave System!



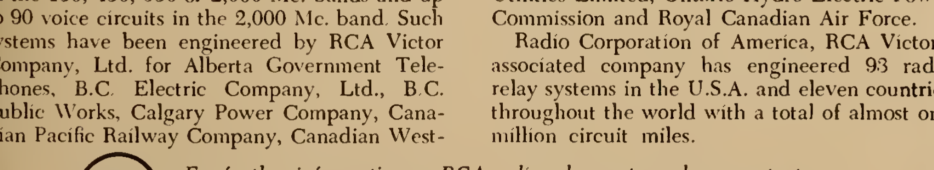
Hydro-Québec's BERSIMIS Project

Quebec Hydro-Electric Commission will control its Bersimis power houses by Canada's longest private commercial microwave system supplied by *RCA Victor Company, Ltd.* Beauharnois and Montreal will be linked by this microwave system with the new power development on the Bersimis River more than 440 miles away. Operation will start September 1st, 1956 to coincide with the commencement of operation of the first power house.

The microwave system operates in the 2,000 Mc. radio frequency band, has 15 stations, carrying 20 voice, 18 telemetering, 3 load frequency control circuits and 2 teletype circuits, ultimate capacity 36 voice circuits. The system is supplied on a turn-key basis to include buildings, towers, antennas, transmission lines, power supply units, fences and access roads. It will also feature complete UHF radio coverage for about 30 mobile radio equipped maintenance vehicles.

RCA Microwave Systems, like the Bersimis project, are engineered to carry the following circuits:

FACSIMILE SWITCHBOARD PRIVATE LINE PARTY LINE TELETYPE DATA RECEIVING



They are available for 12, 24 or 30 voice circuits in the 150, 450, 950 or 2,000 Mc. bands and up to 90 voice circuits in the 2,000 Mc. band. Such systems have been engineered by RCA Victor Company, Ltd. for Alberta Government Telephones, B.C. Electric Company, Ltd., B.C. Public Works, Calgary Power Company, Canadian Pacific Railway Company, Canadian Western Natural Gas Company, North Western Utilities Limited, Ontario Hydro-Electric Power Commission and Royal Canadian Air Force.

Radio Corporation of America, RCA Victor's associated company has engineered 93 radio relay systems in the U.S.A. and eleven countries throughout the world with a total of almost one million circuit miles.

Dr. Lillian M. Gilbreth, Hon. M.E.I.C., was the speaker for the Toronto Branch Professional Development Group at ladies' night on February 28. Her subject was "You and Your Husband's Job".

Application of Nuclear Energy

The regular monthly meeting of the Sudbury Branch was held at the Granite Club on Thursday March 8, 1956.

"The Application of Nuclear Energy" was the subject of an interesting lecture given to 35 members and guests by J. E. Matthew of the nuclear power division, Canadian General Electric Company.

NPD Plant Construction

Early in 1954, a study was begun on the feasibility of developing economical nuclear power in Canada. Following completion of the preliminary design study, Atomic Energy of Canada Limited, the Canadian General Electric Company and Ontario Hydro agreed to undertake the design and construction of a nuclear-electric power plant in Ontario. The plant known as NPD (nuclear power demonstration) will supply power to Ontario Hydro at a location adjacent to the System's existing Des Joachims generating station on the Ottawa River. Under the agreement, the Canadian General Electric Company undertook the design and manufacture of the reactor portion of the plant and the construction work for the project. Atomic Energy of Canada Limited was to provide special development services and data required for the reactor design.

In the group, from left to right: J. A. Gingrich, Jr.E.I.C., E. A. Cross, M.E.I.C., Dr. Gilbreth, E. M. Spencer, Jr.E.IC., and L. F. Grant, Hon. M.E.I.C.

NRX and NRU Experience Helpful

NPD is to be a heterogeneous reactor of the natural-uranium heavy-water moderated and heavy water cooled type. Experience gained from NRX and NRU at Chalk River indicated that this design would be as promising as any for the production of economic nuclear power in Canada. Natural uranium fuel type was considered because Canada has an abundant supply but has not built a plant for separating the uranium isotopes. This initial cost will be higher on account of high cost of heavy water (about $300. per gallon), but operating costs will be less because natural uranium may be used as a fuel.

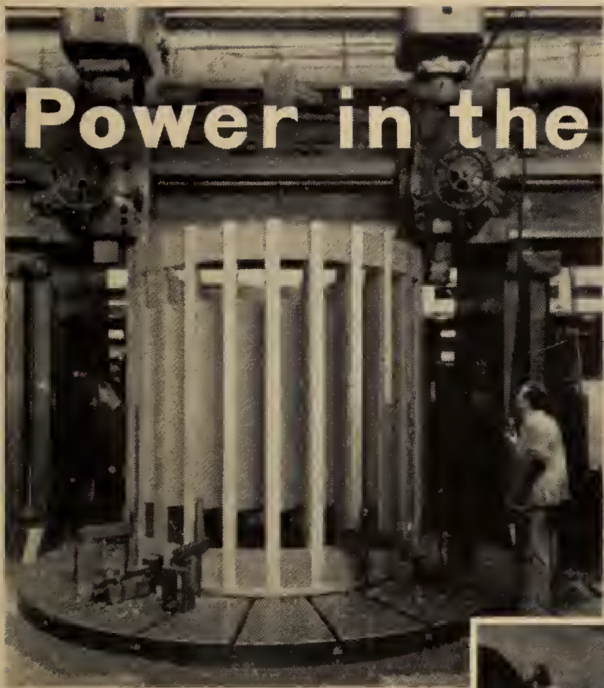
Mr. Matthew also mentioned the graphite moderated and the natural water cooled reactors and cited their advantages and many disadvantages.

Design Problems

Some of the design problems of NPD were considering the size of reactor, procuring proper type of pressure vessel and deciding upon type of head for it, containment of the process (securing pumps and valves to withstand the high pressures without wasting the expensive heavy water), heat generation, high heat transfer and releasing power.

The control and emergency shutdown of NPD will be accomplished by moder-

Power in the making...



Machining the rotor spider

BERSIMIS

Vertical water wheel generators of larger capacity than any hitherto constructed are being built by Metropolitan-Vickers for the Bersimis Lac Casse development of the Quebec Hydro-Electric Commission. Four generators will be supplied, each having an output of 138 MW at 277 r.p.m. These photographs illustrate some of the work in progress.

ator level. This results in no moving parts in the reactor vessel. This system provides fail-safe operation since moderator level falls if the circulating pumps or valves fail.

To Provide Information

"The high unit capital cost of this plant will prevent its unit energy cost from being competitive with that of water and steam plants at the present time but it will provide information for designing a future full-scale plant," Mr. Matthew said. Slides of diagrams of the power cycle were shown and a discussion period followed. Mr. Matthew was introduced by J. Smith and thanked by E. Savage.

Another highlight of the meeting was the showing of the Aluminum Company of Canada film, "The Kitimat Story". Mr. Monaghan of the Aluminum Company spoke briefly on the film. He was introduced by L. T. Lane and thanked by Roy Snitch.

Annual Meeting

The annual meeting of the Toronto Branch was held in the Fiesta Room of the Prince George Hotel on January 12, 1956. There were 140 members present.

The chairman, M. W. Huggins, introduced the guest speaker, Dr. C. R. Young, who is a past-president of the Institute, and dean emeritus of the Faculty of Applied Science and Engineering of the University of Toronto.

Dr. Young Discusses Engineering History

Dr. Young related some fragments of the history of engineering in Canada, in relation to five outstanding engineers of 100 years ago. His talk was about persons and personalities. He told how engineering grew with the advent of railways through the efforts of a few versatile men who turned their hand to whatever task called them. By mutual co-operation they enhanced the profession, and although they did not gain a great deal financially, they made great reputations. One of the engineers discussed came to America from Poland in middle life. He had no money, and no knowledge of the language, yet managed to study law in order to acquire facility in English.

Dr. Young emphasized the importance of history by quoting George Santayana: "Those who cannot remember the past are condemned to repeat it."

In thanking Dr. Young for his address, K. F. Tupper noted that the number of engineers in Canada had increased during the last 100 years from just a few to some 35,000 at the present time. It would now be extremely difficult to select as being outstanding among them any group of five individual engineers.

Business Meeting

During the business meeting which followed Dr. Young's address, Mr Huggins announced the student competition on construction topics sponsored by the Ontario General Contractors Association.

The minutes of the 1955 annual meeting, and the year's financial statement and auditor's report were accepted. The secretary-treasurer in the membership report indicated that total membership has decreased by 62 during the year to 1,791. Mr. Tupper reported informally on the work of the Papers Committee which met frequently. The members of this committee were applauded for the program they had prepared.

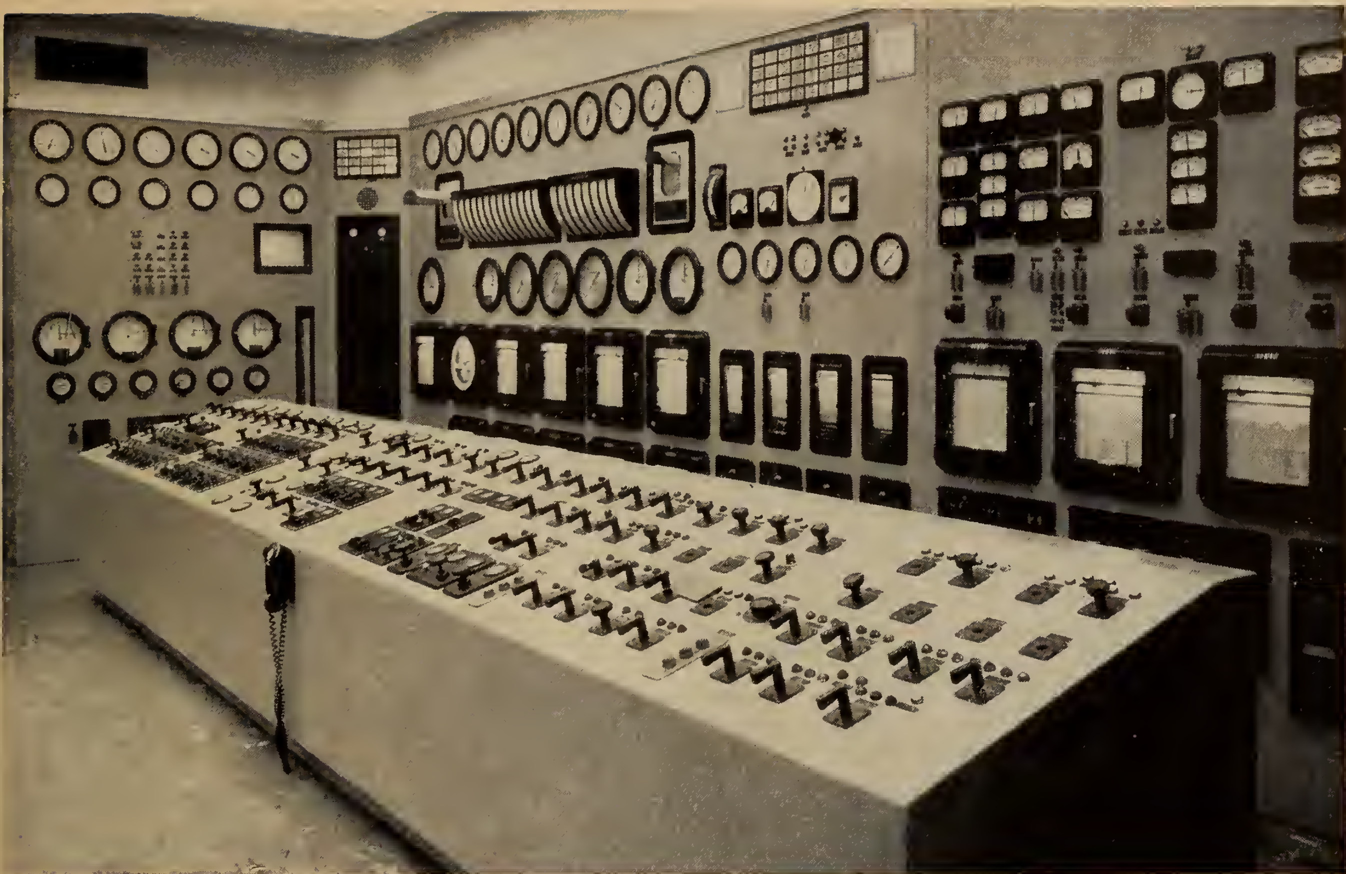
E. Spencer, chairman of Professional Development Course I, reported that there were two courses in operation. The basic course, P.D.I had been chosen to cover topics of other than business or engineering interest. Enrolment in this course had increased from 26 to 80. The advanced course, P.D.II had been chosen to cover business topics, and offered the Harvard Case Method of study. Enrolment in P.D.II is six. The continuing help of Col. Grant and Mrs. Robertson in these courses was gratefully acknowledged.

Tribute was paid by Mr. Huggins to those members who had become Life Members: J. R. Burgess, C. E. Bush, W. B. Dunbar, T. F. Francis, A. Hadley, O. Holden, H. C. Kendall, E. R. Logie, J. F. McLaren, and A. U. Sanderson.

Mr. Huggins, the outgoing chairman, reported on the year's activities. After the report of the scrutineers on the newly-elected executive had been accepted, Mr. Huggins presented the gavel to the incoming chairman, K. F. Tupper, after which M. McMurray expressed the appreciation of the membership to the retiring chairman, Mr. Huggins.

Panel Discussion at Joint Meeting

A joint evening meeting of the Toronto Branch of the Engineering In-



Centralized controls for station service switching, two 125,000 kw turbines, generators and boilers are in this room. Republic sub-panels on the bench board provide for either automatic or manual control of the boilers.

Operating Boilers Electronically at Alabama Power Company's NEW BARRY PLANT

At the new Barry Steam Plant near Mobile, Alabama, two 900,000 lbs. per hour pulverized coal fired boilers operating at 1875 psi and 1000°F. are controlled by a Republic Electronic Master Combustion Control System.

Electronic impulses control pneumatically operated fuel, draft, and feedwater regulators on the boilers. Master control signals are transmitted practically instantaneously, permitting fast control response and close boiler control.

To ensure that both final firing rate and air flow will rapidly and accurately follow changes in steam load, the control system normally follows a dual element master control. This master controls the boiler auxiliaries from a rapid and proportional steam flow function together with a stabilized steam pressure function. Such a system combines the features of derivative control with automatic correction for fuel variation in such a manner that the effects of load swings are minimized almost to the vanishing point. Other control problems such as feedwater control and steam temperature control are simplified by the coordination of boiler auxiliary functions due to this system of combustion control.

Boiler feedwater is controlled automatically by a Republic three-element feedwater control. To prevent heat damage to feedwater pumps during low flows, a Republic pump by-pass system has been installed. It automatically maintains a minimum flow of 125 gpm through each pump (two pumps per boiler) returning by-passed water to the deaerating heater storage tank.

Final efficiency tests recently completed at the Barry plant indicate the expected plant heat rate has been fully realized. There are Republic Automatic Combustion Control Systems — electronic or pneumatic — for all sizes and types of boilers, all methods of fuel firing and for any arrangement of draft equipment. For full details, write today.

REPUBLIC FLOW METERS CANADA Ltd.

352 Munster Avenue, Toronto 18, Ontario, Canada

• Branch News

stitute and the Toronto Section of the American Institute of Electrical Engineers was held on March 1 in the University of Toronto mechanical engineering building. Approximately 175 members of both Institutes and guests provided the panel with an attentive audience. After the panel members developed their topics, the listeners had numerous questions which pointed up the important ideas the panel had emphasized.

Dr. Otto Holden, chief engineer of the Ontario Hydro, was an able moderator. His pleasant commentary helped to knit the various discourses together to make the evening more enjoyable.

Dr. Percy Dobson

Dr. Percy Dobson led off the panel's remarks with an historical outline of power development in Canada. As Dr. Dobson said, all the information is available in greater detail, but he hoped to touch on the highlights only.

From the fundamental discoveries of Faraday and the mathematical statements of these discoveries by Maxwell came the generation of electrical power as we know it today. Canadian developments were emphasized, beginning with Barber's plant in Georgetown, Ont., in 1882, and J. J. Wright's plant in Toronto which ran first in 1881. Steam and hydro developed more or less side by side with hydro predominating where such sources were available. Hydro plants have grown larger and larger and have moved farther and farther from cities as sites near population centres have become fully developed. The transformer permitted this development, otherwise industry would have had to move to the power source.

An interesting sidelight on the troubles besetting the early generating plants was illustrated by the complaint made to the operator of an early generating plant in Calgary by the late Lord Bennett (then R. B. Bennett), ". . . Theodore, the light was very poor last night, I could hardly see to go to bed."

"Yes, Mr. Bennett, there wasn't enough water."

"It seemed to me there was too much water in the light," retorted Mr. Bennett.

George D. Floyd

George D. Floyd, assistant general manager of engineering for the Ontario Hydro, spoke on the topic of "Future Developments: Limitations of Hydro and Conventional Fuels". As far as future developments are concerned, the rate of increase is expected to continue indefinitely. The average increase for Canada is expected to be about six to eight per cent per year, that is, the generating capacity will have to be doubled every 12 to 16 years.

The Ontario Hydro has projected past trends into the future. It is expected that 1.1 x 10^6 kw. of hydro power presently undeveloped will be nearly all utilized by 1960. Steam plants will then be built to take care of the demand until 1965. From that point other sources must be utilized, particularly nuclear fuel plants. By 1975 about one-third of the total generating capacity will be powered by nuclear fuel. The

• Branch News

station at Des Joachims using nuclear fuel is for experimental purposes, and is not expected to operate much before 1958.

Hydro plants are limited by accessibility and cost. To keep costs down, transmission using d-c will have to be used. Steam plants are limited by the availability and cost of fuel. Size of unit also will be a factor. High pressure high temperature units of 300 mw. capacity will become fairly common.

Prof. A. E. Allcut

Professor A. E. Allcut discussed "Possibilities of New Sources and Improved Utilization of Existing Sources".

The demand for more power will increase with the population and the standard of living. Canada is not alone in this increasing demand. World supply and demand will affect the North American situation, and that in Canada as well. To show how the demand will increase, Professor Allcut quoted figures showing the change in world population. Numbers rose from 500 x 10^6 in 1650 to 2 1/3 x 10^9 in 1950 and are expected to reach 6 x 10^9 in 2050. Roughly three times as many people a hundred years hence will demand more power.

At the present time the primitive areas of Africa and Asia contain about a billion people, and as anyone can readily see, are stirring politically. Demands for improved living conditions by these people will bring demands for power. Obviously the Middle East oil reserves which form about half the world reserves will be cut off from the rest of the world by this demand. The western world will have to look elsewhere for fuel.

Energy consumption is rising at tremendous rates and by 2050 is expected to lie between seven and 30 times that of 1950, according to various estimates. Although there are great discrepancies in the estimates of energy resources, it is expected that the peaks of consumption for various fuels, regardless of how many new sources are found, and regardless of the depletion of known resources, will be 1955-60 for oil and gas, and 1975-90 for coal. Obviously new sources must be found. Remaining water power, fossil fuel sources, solar energy for heating, heat of the earth itself (volcanoes and hot springs), the heat pump, wind power and tidal power will all have to be used although the foreseeable contributions by each method are not large.

Improvement in methods of generating power will have to be made, and inefficient plants replaced. Larger plants will be employed, operated by highly skilled technicians. Gasifying coal at mines will probably be employed and gas will be used in gas turbines—a poor quality gas is advantageous here.

There are obviously numerous varied and crucial problems which must be solved. Our civilization depends on their solution.

W. L. Thompson

W. L. Thompson of the Bailey Meter Company discussed the engineering and manpower facilities required in the power industry. He spoke briefly but emphatically. Canada has neither the experience nor the equipment to design and build complete thermal units but could do so if necessity demanded. Mr. Thompson reiterated Mr. Floyd's remarks concerning the trend to large steam power plants.

Boiler efficiency is now 80-90 per cent and overall efficiency of steam power plants is between 30 and 35 per cent. About 1 kw. of power is being generated by 1 lb. of fuel.

There is manpower to build the plants but the plants themselves are critically understaffed. There is none for nuclear power plants and none for the large steam plant. Manpower requirements for a present day plant are about five professional engineers together with the necessary instrument mechanics and operating staff, who vary in number with the plant complexity. Some training is being undertaken for new staff, but the number being trained is nowhere near adequate.

Instrumentation and automatic control are adequate at present, and will obviously have to be used more and more in the future.

At no time in the discussion was the "standard of living" ever defined nor was there any thought given to the moral implication of the increasing demand for power. In the opinion of the branch news editor, this problem is worth exploring. Engineers as a body evidently do not feel that this aspect of the problem should be considered. Let the demand increase; somehow it will be met.

BOOK REVIEW

Design of piping systems, 2nd ed. M. W. Kellogg company. New York, Wiley, 1956. 365 pp., diagrs., $15.00.

Since the publication of the first edition of this volume in 1941, the Kellogg General Analytical Method for evaluating the stresses, reactions, and deflections in an irregular piping system in space, has been recognized as an important contribution to piping design. The demands of the war years were only a forerunner of the technological progress during the post-war decade which has resulted in a new concept of the importance of sound piping design. To meet this rapid expansion safety codes and rules have been set up and committees have been organized to keep abreast of developments.

The objective of this second edition is to supplement present information with specific mechanical design approaches for entire piping systems as well as their individual components. To achieve this, it contains material on the strength and failure of materials, followed by a study of the capacity of piping to carry various prescribed loadings. It also includes more detailed treatment of local flexibility and stress intensification. The Kellogg General Analytical Method is extended to include all forms of loading and more sample calculations are given.

There are new chapters on expansion joints and on pipe supports that offer what is believed to be the first broad treatment of these items with regard to critical piping. The subject of vibration is discussed in the final chapter from the standpoint of the piping designer.

This book will assist engineers in evaluating piping stresses as well as in understanding the significance of stresses on piping performance, and will help to solve other piping design problems.

M. R.

BOOK NOTES

Prepared by the Library
The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

Analysis of structures. M. Smolira. London, Concrete publications, 1955 173 pp., diagrs., $4.00.

The deformation method of analysing statically-indeterminate structures is described in this book. Continuous frames with curved members and Vierendeel trusses both continuous and simply supported are treated in detail. There are sixty examples covering nearly all types of frame and loading, including the effects of changes of temperature and settlement of supports. A useful feature is the treatment of beams on a rectangular or diagonal grid, a subject on which little has been published in the English language.

Arithmetic for engineers, 5th ed. C. B. Clapham. Toronto, British Book Service, 1955. 540 pp., $3.60.

Because this new edition was produced by the photo-offset process, few changes and little new material have been incorporated in the text. However, an addendum has been added at the end of the book which includes some new matter and more difficult exercises.

Both the theory of mathematics and its practical applications in engineering are contained in the eleven chapters which cover fractions, symbols, equations, logarithms, mensuration, graphs, the slide rule, and trigonometry.

Automatic process control for chemical engineers. N. H. Ceaglske. New York, Wiley, 1956. 228 pp., diagrs., $8.75.

Intended as a text for undergraduate chemical engineering students, this book presents the basic mathematical principles of process control and their application in an elementary form.

The various types of control system are described, and two chapters cover the derivation of all equations needed in the analysis of control systems, and the integration of first and second order equations. Also considered are the transient analysis and the frequency response of control systems. The final chapter shows the application of the procedures to the analysis and design of completely automatic process control systems.

Catalysts, special compounds and chemical-resistant materials. E. Molloy, ed. Toronto, British Book Service, 1955. 222 pp., illus., $3.60.

Written by specialists, this book provides an up-to-date survey of the main catalytic agents and of the special compounds which are now used in many chemical processes.

The first section includes a chapter on the platinum metals as catalysts, activated carbon and its applications, and catalytic gas purifiers.

The special compounds cover ion exchange resins, non-ionic compounds, the silicofluorides, the benzoates, ethylene glycol, dichlorodiethylether and dicyandiamide.

The concluding section discusses corrosion-resistant metals, ceramics, cements, plastics and glass.

Concrete and constructional engineering, 50th anniversary number: January 1956, v. 51, No. 1. London, Concrete publications, 1956. 258 pp., illus., 15/-.

Representatives of eighteen European nations and of the United States have combined to present a comprehensive account of new developments in reinforced and prestressed concrete in the most important concrete-using countries of the world. Included are descriptions of the use of high-strength steel, the economical use of materials, new methods of design, construction, and prefabrication. Historical notes are also given.

Control of nuclear reactors and power plants. M. A. Schultz. Toronto, McGraw-Hill, 1955. 313 pp., diagrs., $7.50 (U.S.).

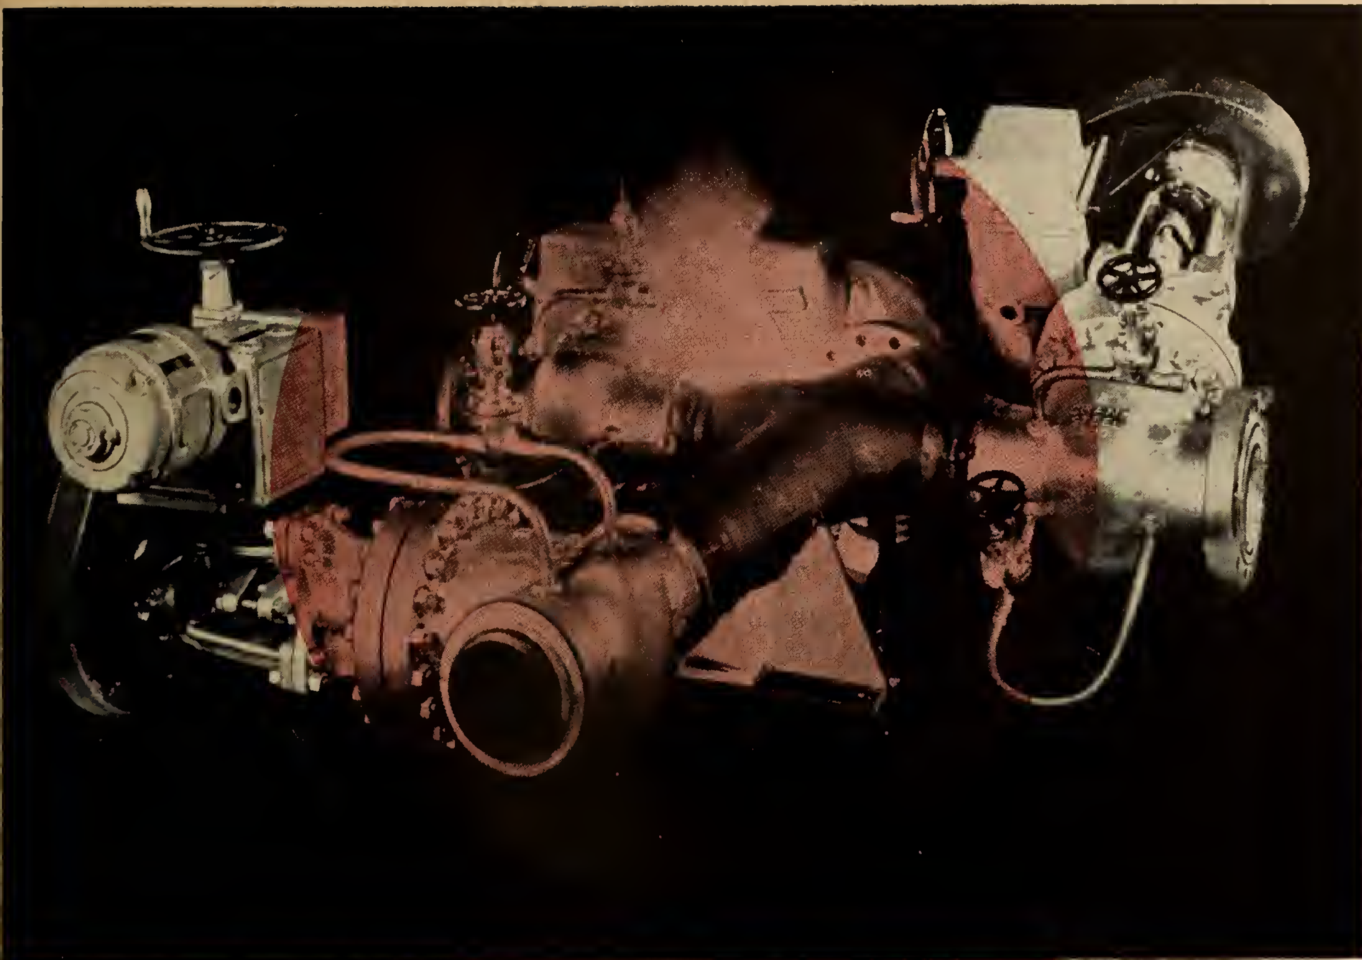
The currently available information on reactor and power plant control is here presented for the first time, treated from the viewpoint of servo engineering. The solid-fuel heterogeneous reactor is used for descriptive and illustrative purposes.

The book begins with a discussion of the interrelationship of the physics, servo engineering, and thermodynamic requirements of a nuclear control system, then develops elementary control concepts and definitions. The responses of nuclear reactors are described in engineering terminology.

Special attention is given to operating control problems during startup, power level operation, and shutdown. The author discusses many phenomena which have not been covered elsewhere.

***Design of a modern highway bridge.** Odd Albert. Brooklyn, Polytechnic Institute. Dept. of Civil Engineering, 1955. 103 pp., pa. $1.50 (U.S.).

The design method utilized in this pamphlet takes into account the fatigue strength properties of structural members as well as the static strength properties, and therefore opens with a paper on "the effect from frequency of heavy vehicles". Following sample stress and moment problems, the author presents the complete design of a typical continuous span highway bridge in its original form.



What's CRANE cooking up here?

Big Piping Savings for You . . .

The man behind the mask above is a *unit fabrication* specialist with a talent for saving you time, trouble—and dollars—in the long run.

He's part of a crew of experienced mechanics in the Crane Pipe Shop, where piping units like this 8-inch assembly are built *precisely* to specification.

And it's a complete as well as a quality service, for Crane takes over at the blueprint stage; supplies all valves and component parts—makes the pipe bends—does the welding. Right at hand are the best facilities for heat-treating or stress-relieving, radiography, etc., to assure uniform strength and dependability. The finished unit is pre-tested and proved in advance, ready for quick installation in your piping system.

You take no risk—you pay for no spoilages, and your erection crew is spared many a major headache. Why not let your Crane representative review your piping layout and help you decide where Crane Unit Fabrication will be to your advantage?

CRANE QUALITY COSTS NO MORE

For detailed information on any items from the complete Crane line of Valves, Fittings and Piping, ask your Crane representative, or Crane Branch—or write

• Library Notes

Diesel engine manual, 3rd ed. E. Molloy, ed. Toronto, British Book Service, 1955. 224 pp., illus., $3.00.

This is a practical manual on the installation, maintenance and operation of stationary, marine, and automobile diesel engines of the two- and four-stroke class. There are also detailed descriptions of fuel-injection equipment, governors and starting gear, testing methods for I.H.P. and B.H.P., and exhaust gas analysis tests.

Since the second edition, published in 1953, new material has been added on the Wilson & Kyle fuel injection system and the Simms GP pneumatic governor.

***Distillation in practice.** C. H. Nielsen, ed. New York, Reinhold, 1956. 133 pp., diagrs., $3.00 (U.S.).

This small book is made up of six papers delivered by a group of experienced engineers to an audience of young engineers. Basic, practical information is given on tower design, physical design of plate columns, techniques in petroleum fractionation, control systems, the operation of distillation equipment, and commercial aspects of vacuum distillation. This is the second volume in an "Experience in Industry" symposium series.

***Electronic transformers and circuits,** 2nd ed. Reuben Lee. New York, Wiley, 1955. 360 pp., $7.50.

The design of transformers and the effects of their characteristics on circuits are dealt with using a minimum of mathematics and stressing physical concepts. As in the previous edition, the arrangement of material is for the most part by general types of apparatus with design data for a particular transformer presented in connection with the purpose for which it is intended. Some sections have been deleted from this edition, some sections have been expanded, and new chapters on magnetic amplifiers and pulse circuits have been added.

Encyclopédie technologique de l'industrie du caoutchouc, v. 3. G. Génin et B. Morisson, eds. Montreal, Fomac, 1956. 614 pp., illus., $21.60.

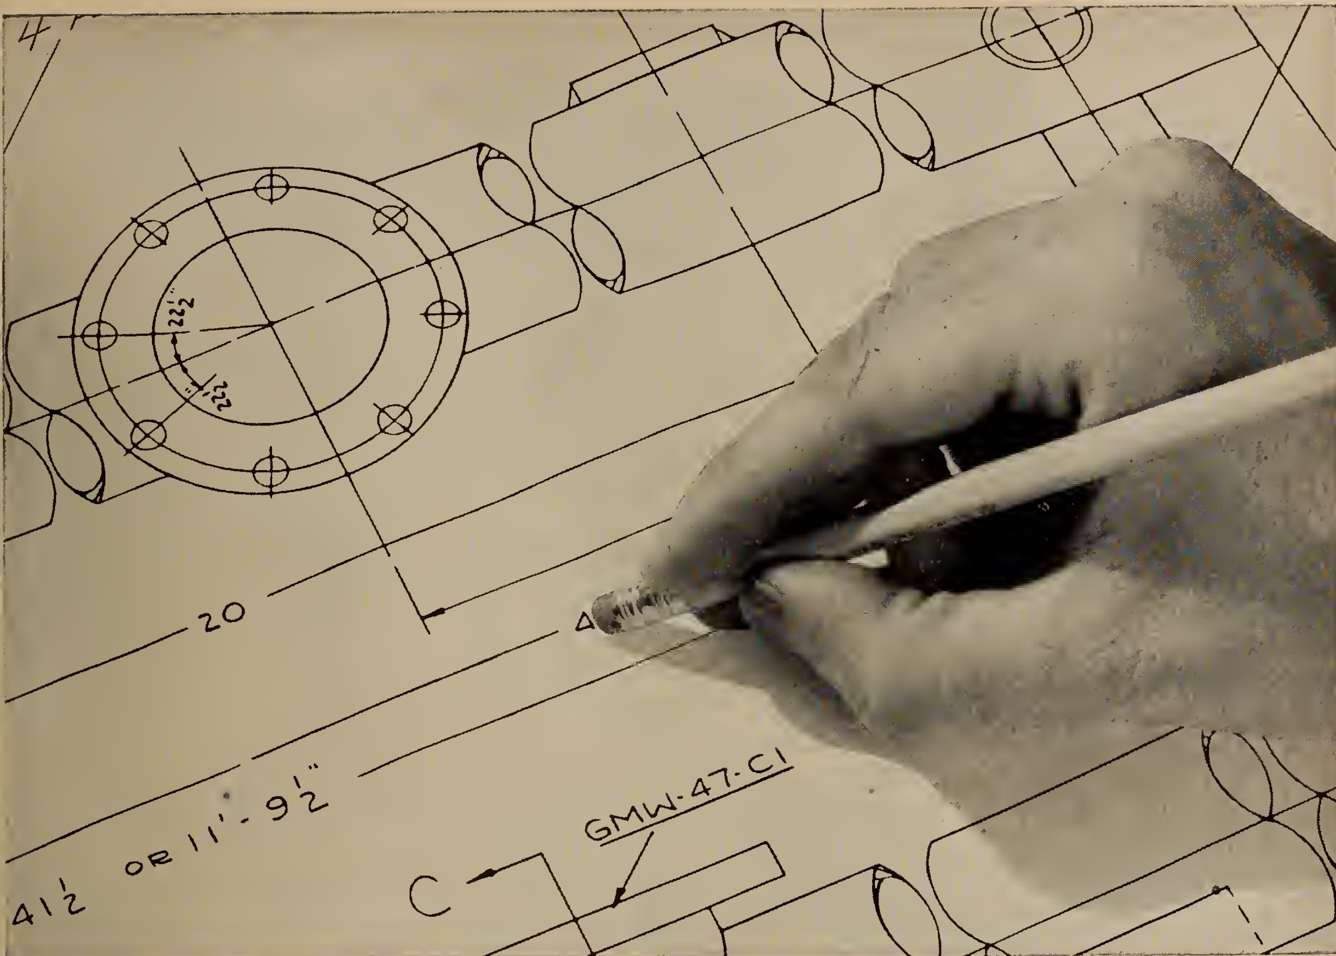
While this work will eventually consist of four volumes, dealing with all aspects of the rubber industry, the first two are still in the course of preparation. The third volume describes rubber technology and the various uses of the material.

Among the chapters in the first section are those covering the use of driving belts in the industry, rubber tube, molded and ready-made articles, the treatment of metals with rubber, rubber cylinders, cellular and sponge rubber, and hard rubber.

There are many uses of rubber described in the second part of the book, including the manufacture of boots and shoes, rubbers, carpets, cables, tennis and golf balls, and erasers. The concluding three chapters are devoted to the value of rubber in civil, military and industrial protective equipment.

Engineering drawing and geometry. R. P. Hoelscher and C. H. Springer. New York, Wiley, 1956. Various pagings, illus., $8.00.

Since this text was prepared for engineers rather than draftsmen, the em-



To simplify design changes

How many of your customers realize there is a photographic intermediate material from which detail can be erased with an ordinary moistened pencil eraser?

Every draftsman will welcome this short cut made possible by intermediates on Kodagraph Autopositive Paper Translucent. New design details can be added immediately with pencil or ink—an hour or more saved in revising a large drawing.

Be sure to remind your customers about this advantage of Autopositive Paper Translucent. And while you're at it, give them a run-down on all the other jobs you can do with Kodagraph Reproduction Materials.

Kodagraph Reproduction Materials

"The big NEW PLUS in engineering drawing reproduction"

- **Kodagraph Autopositive Paper Extra Thin** for high-quality photographic intermediates at lowest cost.
- **Kodagraph Autopositive Film** for very fast printing intermediates of highest quality.
- **Kodagraph Autopositive Paper Translucent** for faster printing, more durable easier-to-revise intermediates.
- **Kodagraph Contact Paper Translucent** for fast-printing durable, very high-quality intermediates.
- **Kodagraph Repro-Negative Paper** for black-line intermediates from negative-type originals.

• Library Notes

phasis is on the understanding of principles rather than on manual skills. Another objective is the development of visual perception in three dimensions and the stimulation of creative imagination.

The book is primarily for instructional use in university courses at the sophomore level. Each chapter contains problem sections while the necessary data for their solution is found in the Appendix. Uniform nomenclature and notation is a useful feature.

The first section contains chapters on lettering, in which both upper- and lower-case letters are presented, on geometric projections, sketching, orthographic projection and sectional views. The authors then go on to such subjects as shop terms and processes, intersections and developments, axonometric and oblique projection, perspective, and charts and diagrams. The last chapters treat various types of drawing: map, architectural, structural, pipe, machine, tool, welding and patent office.

Flood estimation and control, 3rd ed. rev. B. D. Richards. Toronto, British Book Service, 1955. 187 pp., diagrs., $6.00.

The author considers flood estimation and control in this book from a theoretical point of view, beginning with factors affecting the intensity, duration and discharge of floods. He then goes into the subjects of flood formulas and rainfall, the progress of floods, and coefficients for their estimation, regulating reservoirs and storage basins as systems of flood control, and floods in relation to soil erosion.

In this new edition the "unit hydrograph" method of flood estimation is more fully treated, and the disastrous flood at Lynmouth is reviewed.

Fluidization. D. F. Othmer, ed. New York, Reinhold, 1956. 231 pp., diagrs., $7.00 (U.S.).

In this book, fluidization is taken to mean the maintenance of fine solid particles suspended by a vertically rising column of gas.

The work is based on a symposium sponsored by the Polytechnic Institute of Brooklyn and the American Institute of Chemical Engineers, and has for its purpose a description of fluidization as practised in many modern processes. The first chapters consider the interrelation of hydromechanics, heat transfer and mass transfer, and the background, history and possible applications of fluidization. The remaining chapters, written by engineers, consider the engineering aspects of the design and operation of plants.

***The frost penetration problem in highway engineering.** A. R. Jumikis. New Brunswick, N.J., Rutgers University Press, 1955. 162 p., $5.00 (U.S.).

The main part of this book deals with the application of the following methods and theories to the analytical treatment of frost penetration in soil materials for highways and airports: the steady-state flow of heat; the unsteady-state flow of heat, F. Neumann's theory; J. Stefan's theory; and the suction force theory. Brief introductory chapters discuss the structural parts of highways, factors

• Library Notes

causing damage, and the national importance of the frost problem. The concluding chapters cover remedial measures, factors to be studied in frost action research, and some of the better known frost criteria.

*__Hydraulic and pneumatic operation of machines.__ H. C. Town. New York, Philosophical Library, 1956. 192 p., illus., $7.50 (U.S.).

The first part of this book provides practical information on pumps, valves, circuits, and rotary drive; hydraulic machine tool operation; and hydraulic presses. Also dealt with in this part are general features of the design of cylinders, pipe lines, and protection devices; hydrokinetic automobile transmission; automotive controls; and hydraulic accumulators. The second part of the book covers air compressors; pneumatic tools; the design of pneumatic circuits; hydro-pneumatic operation; and applications of air control to jigs and fixtures, brakes, clutches, conveyors, and aircraft components.

International association for bridge and structural engineering. Publications. v. 15. Zurich, Leemann, 1955. 275 pp., diagrs.

The sixteen papers in this latest volume of the Publications, five in French and eleven in English, are written by specialists from all parts of the world.

While there is not space to list all of these important papers, they deal with such subjects as measuring damping and frequencies of high modes of vibration of beams, matrix-analysis of successive moment-distribution, analysis of suspension bridges by the minimum energy principle, stresses in non-uniformly supported cylindrical tanks, thin walled box beams under pure bending, and the design diagram of composite beams.

*__Knife-edge bearings.__ P. J. Geary. Chislehurst, Kent, British scientific instrument research association, 1955. 61 p., 10/6. (Bibliographic survey of instrument parts, No. 2.)

A bibliography of 166 references with a 29-page technical introduction dealing with the different aspects of the subject covered by the literature cited: materials, contact surfaces, friction, mounting, compound bearings, etc. In the bibliography, presented in three parts, principal texts are given relatively full abstracts, secondary references are briefly annotated, and supplementary references are listed without comment.

Law and the engineer. C. F. Mayson. Toronto, British Book Service, 1955. 470 pp., $10.75.

This new book on those aspects of English law which concern the engineering profession was written especially for mechanical and electrical engineers, and for the advanced engineering student. The author deals with civil law and presents basic principles combined with some practical application.

There are chapters covering the law of contract in most of its aspects, the law regarding negligence and nuicance, the law relating to employment, and safety rules. Patent and trade mark law are omitted.

Since the book is largely concerned with principles, Canadian engineers interesting in legal questions should find it useful.

The machinist dictionary. F. H. Colvin. New York, Simmons-Boardman, 1956. 496 pp., illus., $7.50 (U.S.).

Those engineers who design machine parts, operations men, purchasing agents, and many others, will welcome a dictionary which attempts to bring some order out of the confusion in machinery terminology. Arranged in a convenient form, this volume gives the reader information on present and past terms and on the many standards which have been adopted in the United States. Cross-references are included to assist in finding both the old and new terms. Some of the definitions are brief, while others contain detailed data.

Tables, charts, lists and illustrations are used to clarify and extend the information in the text.

Modern petrol engines, 2nd ed. rev. A. W. Judge. Toronto, British Book Service, 1955. 564 pp., illus., $9.65.

Since the appearance of the first edition in 1946 there have been many advances in engine design and performance and these have been noted in this new edition. New chapters are devoted to detonation research, combustion chamber design and alternative fuels for petrol engines, including those for high output and racing engines. Selected examples of engine types in the last chapter indicate the progress made in recent years.

Among the important chapters in the book are those describing the thermodynamics of the gasoline engine, maximum output and supercharging, cooling

• Library Notes

of engines, carburation and fuel injection, ignition, lubrication, and combustion chamber design.

The National Research Council Review, 1955. Ottawa, Committee of the Privy council on scientific and industrial research, 1955. 268 pp., illus.

The work of the National Research Council during 1954 is here reviewed, with some later work included. There are reports of the service units, the science laboratories, of the engineering laboratories, and of the committees associated with NRC.

Many of the important advances in Canadian science and engineering are contained in this review.

Paint and varnish manufacture. H. W. Chatfield, ed. Toronto, British Book Service, 1955. 440 pp., $6.00.

A large number of experts in the British paint industry joined forces to produce this practical guide to the background and modern developments of this branch of technology.

The first part of the book deals with the properties of raw materials used in manufacturing paints and varnishes. Among these are vegetable and fish oils, synthetic resins, natural resins, metallic soaps, cellulose derivatives, emulsifying agents, and pigments and extenders.

In the second section the use of these materials in producing finished products is described under the headings of Decorative products and Industrial finishes. The latter part includes information on car and furniture finishes, marine paints, insulating varnishes, special novelty finishes, and paper finishes.

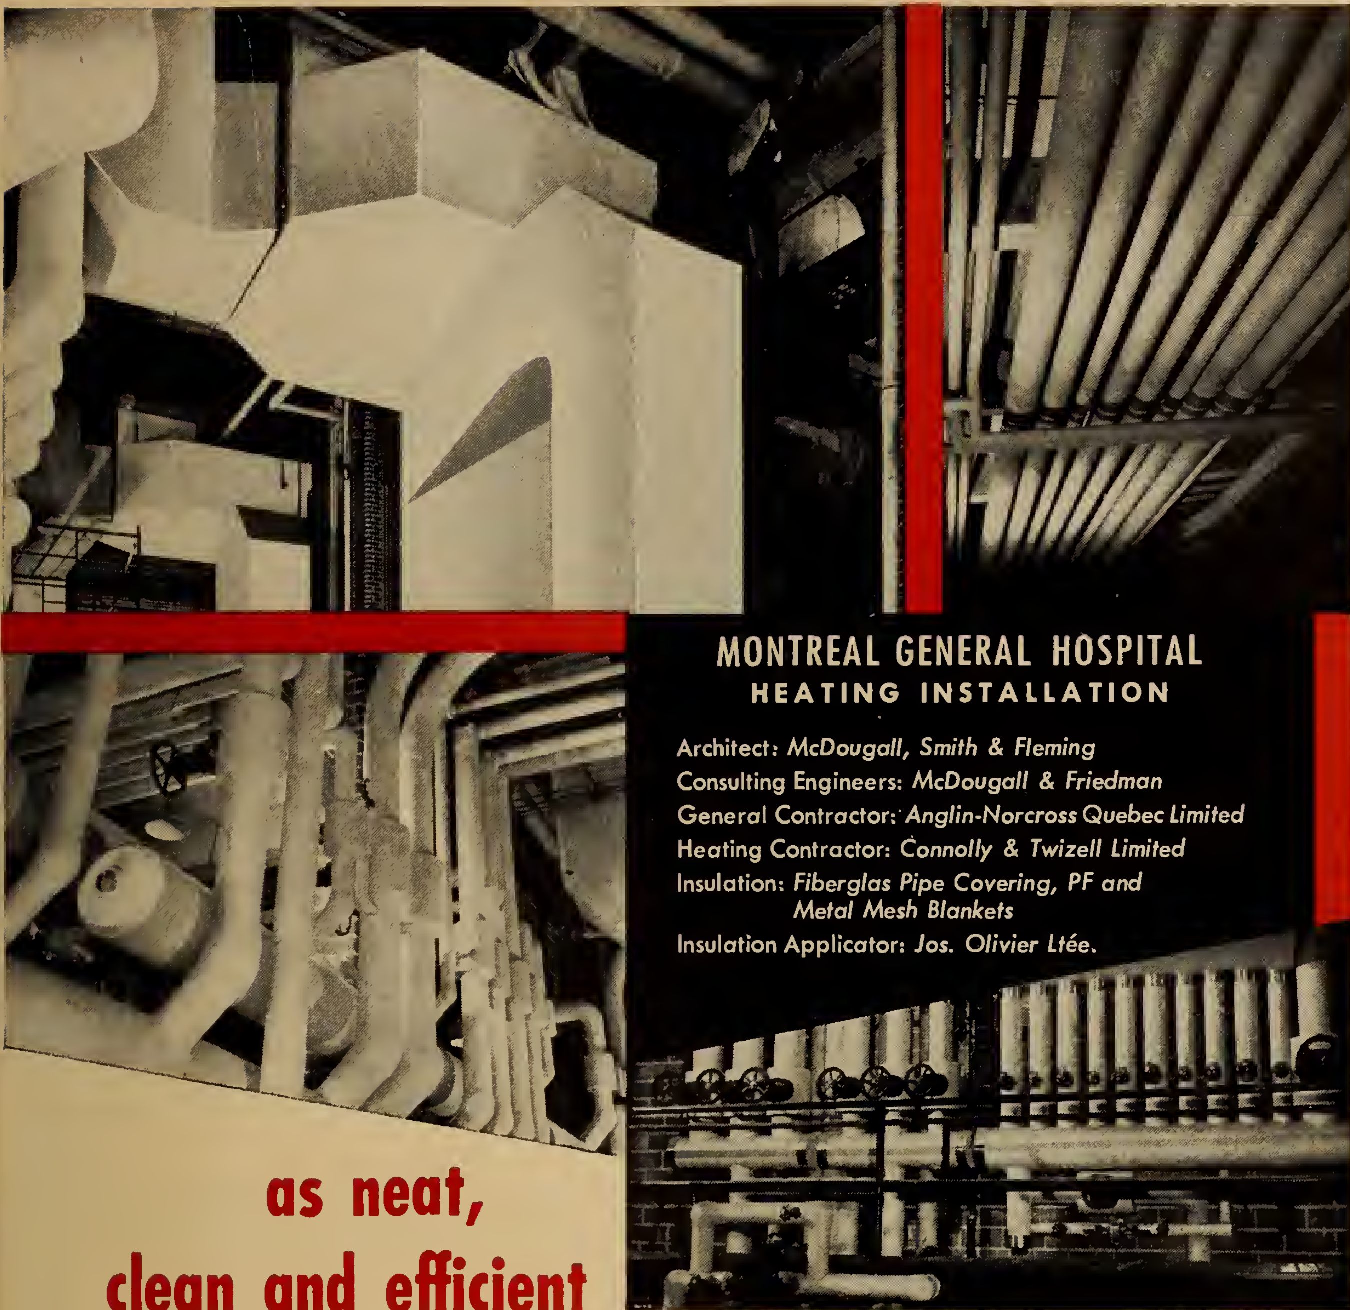
The physical properties of solid materials, 2nd ed. I. F. Morrison and G. Ford. Edmonton, University of Alberta, 1955. 192 pp., illus., $2.25.

The first edition of this book, which is used at the University of Alberta in courses on strength of materials and materials of construction, was published in 1937. While little new material is found in the new edition there has been a rearrangement of chapters which may help in a clearer understanding of the subject.

The purpose of the book is to link up the theories of Strength of materials with the practical aspects of the manufacture and properties of engineering materials. To do this, the authors have included chapters on tension, compression and shearing tests, toughness, hardness, and fatigue, stress-concentration and fracture, and the physics of materials.

Plastics progress, 1955. Phillip Morgan, ed. London, Iliffe, Toronto, British Book Service, 1956. 432 pp., illus., 50/-.

Based on papers given at the British Plastics Convention in 1955, this edition covers polymer structure and properties; expanded plastics; thermoplastics; extrusion; work study and productivity; injection moulding; patents; foundry resins and glass reinforced plastics. Some of the papers were based on original investigations and the whole book describes the more important developments in this rapidly expanding field.



• Library Notes

Power system plant. E. O. Taylor, ed. Toronto, British Book Service, 1955. 307 pp., illus., $5.10.

The material in this book was originally presented in lectures given at the Heriot-Watt College, Edinburgh, and its aim is to give the power system engineer a comprehensive knowledge of developments in all aspects of the subject.

Each chapter has been written by a specialist and many topics are discussed: synchronous machines of the non-salient and salient-pole type; transformers, reactors and voltage regulators; switchgear principles and practice; underground cables; and overhead lines.

Production control manual. J. A. Parton and C. P. Steres. New York, Chilton, 1955. 454 pp., diagrs., $6.00 (U.S.).

This manual presents the principles of production control, and their practical application. Much of the information given is based on experience, that of the authors' and of many companies.

The book is divided into three main sections, the first of which discusses the history, basic concepts and definitions of production control functions. The next six chapters consider functions which influence production control: engineering, tool manufacturing, methods, purchasing and quality control. The final seven chapters present the functions of production control: forecasting, scheduling, material control, stores control and dispatching.

There are many tables and diagrams, making this a valuable quick reference tool as well as a guide to the subject.

Spheroidal wave functions. J. A. Stratton and others. New York, Wiley, and Technology Press, M.I.T., 1956. 613 pp., $12.50.

This volume of tables is very important for several reasons. It provides a means for the electrical engineer and physicist to handle wave problems in spheroidal coordinates as easily as was previously posible for rectangular, circular, cylindrical and spherical coordinates. It also makes certain calculations in applied physics, acoustics, and radar more practicable. To make these complex tables more reliable than ever before, all the numbers were determined by the electronic digital computer Whirlwind I at the Massachutetts Institute of Technology, and the tables were computed, tabulated and printed automatically.

The book covers spheroidal wave functions appropriate for prolate or oblate spheroidal boundaries. Standard forms of their solutions are defined and a collection of formulas giving the important mathematical properties of these functions is included. There is also a set of tables from which values of the solutions can be obtained for the more interesting ranges of the variables.

Steels for the user, 3rd ed. R. T. Rolfe. New York, Philosophical Library, 1956. 399 pp., illus., $10.00 (U.S.).

Considerably revised since the publication of the second edition in 1941, this practical book considers carbon steels and their uses, mentioning alloy steels only in connections where carbon steels are unsuitable. Among the topics covered are bright and free-cutting steels, heat treatment of steels, casehardening, the use of steels at elevated temperatures and fatigue and weld testing.

Technique et utilisation des jauges de contrainte. U. Zelbstein. Montreal, Fomac, 1956. 255 pp., illus., $8.80.

This is a detailed treatment of strain gauges, beginning with their mechanical and electrical characteristics, and going on to their use in industry. A large section describes measuring methods with this type of gauge, including both static and dynamic measurements. The last section deals with the utilization of strain gauges in measuring the strain on turbo blades, measuring vibrations, etc., and with their use in determining physical and mechanical sizes and quantities.

Television: how it works, 2nd ed. J. R. Johnson. New York, Rider, 1956. 346 pp., diagrs., $4.60 (U.S.).

Intended for anyone concerned with television receivers, technician, student or hobbyist, this book explains in simple terms how they work. Among the

• Library Notes

topics covered are propagation, antennas, transmission lines, amplifiers, sound channels, synchronizing section, sweep circuits, the picture tube and power supplies. There is also a chapter on colour television. The book is illustrated with very clear diagrams.

***Temperature: its measurement and control in science and industry,** Volume II. Edited by H. C. Wolfe for the American Institute of Physics. New York, Reinhold, 1955. 467 pp., diagrs., $12.00 (U.S.).

The emphasis in the twenty-four papers contained in this volume is on the basic physics involved in temperature concepts and measurements. Included are discussions of temperature in very hot gases and in matter near absolute zero, standards and scales in use at present, the use of semiconductors and superconductors for measurement, and sound velocity as a measurement of gas temperature. Engineering aspects of the subject deal with standard and specialized methods of measurement, and with temperature measurement in steel making.

Les ventilateurs et leurs applications. D. Thin. Paris. Eyrolles, 1956. 152 pp., diagrs., fr. 1510.

In this book the author considers the actual use rather than the construction of ventilators. The approach is essentially practical, and there are sections describing the various types of ventilator for different uses, and maintenance and repair.

Last year the author published a similar book on pumps.

The world almanac and book of facts, 1956. Harry Hansen, ed. New York, New York World-Telegram and Sun, 1956. 806 pp., pa. $1.10 (U.S.).

Here again is a resume of world facts and events with their impact on the United States. New developments in relations with Russia highlight the 1956 edition but other major political events are covered as well. The almanac also reports on developments in the U.S., on scientific discoveries and on other fields too numerous to list.

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

STANDARD REVIEWED

British standards, British standards institution, 2 Park Street, London, W.1. British standards are available from the Canadian standards association, National research building, Ottawa, Canada.

B.S. 11: Part 1: 1955 — Flat bottom railway rails. 4/-.

Part 1 of this revised standard specifies quality of material, chemical composition and mechanical properties and includes requirements for lengths and for the condition of the finished rails, etc. It differs from the previous edition in a number of respects, the main changes being the deletion of grades other than the so-called 'medium manganese' grade and the inclusion of dimensional tolerances.

B.S. 24: Part 3B: 1955 — Helical and volute springs and spring steels — Railway rolling stock material. 4/.

The standard specifies the following:

1. Hot rolled spring steel bars for helical and volute springs.
2. Helical and volute springs made from the above material.
3. Steel helical springs cold coiled from a drawn material.
4. Ground spring bars for helical springs.
5. Helical springs made from round section ground steel bars.

Also covered are the chemical composition of the steels, the quality of the material, and the tolerances to which these springs are to be made. The Appendix contains the recommended method for calculating the total number of coils for helical compression springs.

B.S. 1490: 1955 — Aluminium and aluminium alloy ingots and castings for engineering purposes. 10 -.

This is a revision of the 1949 standard, and introduces four new alloys. Alloys L.M.17 and L.M.19, which were in the original edition, have been omitted.

Some of the alloys have been included in conditions not previously covered. A number of amendments have been made to the chemical compositions and mechanical properties of the other alloys.

ENGINEERING CAREERS

The Canadian Railways

THE RAILWAYS OF Canada are among the largest employers of industrial manpower, and the wide scale of their operations offers many opportunities for members of different branches of the engineering profession.

The undergraduate engineer is encouraged to learn the fundamentals of railway practice by taking advantage of the summer employment that is available, and which can show him the possibilities that exist in a railroading career.

To the graduate engineer there are many varied fields in which to apply his knowledge and to increase it through the training courses provided and through practical experience. As the country and the industry grow, so do the opportunities for advancement increase, and the engineer with the railways may progress through supervisory and administrative posts to the upper levels of management.

The fields open to the engineer may be covered in broad outline by considering the operations involved in running a railroad. Track has to be laid and maintained, bridges and buildings constructed, rolling stock must be operated and kept in operating condition, signalling systems installed and maintained, communications developed, power and other services provided, and research and development work carried out continuously to keep abreast of technical advances and operating progress.

Though the departments responsible for these operations may differ in detail (for example, in scope and nomenclature) between the different railway companies, the operations are the same in general and will be considered under the general headings that follow.

In general, the graduate engineer will be given practical training and field experience in one or more of these departments or divisions when he joins the organization, to familiarize him with different aspects of the work, before proceeding on the course of progress to which he is best suited.

RAILROAD ENGINEERING

Under this general heading are considered the design, construction, and maintenance of roadbed and the structures that accompany the system. The latter include station and warehouse buildings, bridges, wharves, culverts, and aqueducts. This field is largely that of the civil engineer, who can gain experience in design of structures, soil mechanics, basic instrument work, and construction in a variety of materials (steel, concrete, timber, etc.).

Signals

A particular, and highly important aspect of railroad engineering is signalling. This is mainly the province of the electrical engineer, who deals with design, installation, and maintenance of signalling systems to control train movements, and also such items as level crossing gates and warning signals at intersections of railway and highway.

Operation

As part of his basic training the engineer is also made familiar with the routine of train operation, a knowledge of which is necessary when planning work to be carried out without disrupting schedules.

The engineer may remain in one of the departments just discussed and proceed to senior positions in any of the fields, such as bridge or building construction, or signals.

MECHANICAL ENGINEERING

Mainly of concern to the mechanical and electrical engineer are the departments that deal with the maintenance, repair, and servicing of locomotives and rolling stock.

Though rolling stock is mostly purchased from outside manufacturers, the task of maintenance involves the operation of shops equivalent to a major manufacturing organization; also the railways have much to contribute to the design of the material to meet the exacting and very varied conditions of operation encountered across a continent the size of Canada, with its extremes of climate and topography.

Though the steam locomotive is eventually to be superseded, there is still much stock to be serviced, and new designs are constantly being developed for its diesel counterpart. The gas turbine is already making some progress in other parts of the world, and could well be another responsibility of the railway engineer.

Passenger and freight cars have also to be designed and maintained to meet modern service requirements. Air conditioning, heating, refrigeration, and lighting are among the services that have to be developed and installed.

Apart from the rolling stock itself, there is much static equipment to engage the mechanical and electrical engineer, including shop

The electrical engineer may deal with the design, installation, and maintenance of signalling systems.
(Photo: Canadian National Railways)

design, machinery and machine tools, and electrical and steam power plants. Standards and methods engineers may be engaged in promoting the efficiency of maintenance operations and the control of materials.

COMMUNICATIONS

The successful operation of an extended organization such as a railroad is particularly dependent on rapid communication and the transfer of essential information. The communications department of a railway may thus be likened to its nerve centre.

As is well known, the major Canadian railway companies operate public telegraph services and commercial communications services, but there is also a vast network of communications essential to the operation of the railways themselves.

The engineer has responsibilities in the planning and design of telephone, telegraph, and teletype circuits, and radio systems, together with maintenance of these facilities.

Particular examples include the maintenance of standards connected with open wire lines; cable loading, balancing and testing, and installation of gas pressure systems; planning and testing radio systems, including developing estimates, making initial layouts, and carrying out acceptance tests.

Standards are set for the field layout and installation of communications equipment. Standard inter-connection drawings and specifications are prepared for the guidance of plant forces installing equipment for multi-channel carrier telephone and telegraph, teletype switching, program broadcasting, train dispatching circuits, and micro-wave. Reports are also made on standard specifications proposed by the Canadian and American standards associations.

RESEARCH AND DEVELOPMENT

The civil, mechanical, electrical, and metallurgical engineer may find suitable opportunity in the fields of research and development. Research may be into purely technological problems or into the economic aspects of particular situations, usually with the aim of improving operating efficiency.

Examples of the type of problem tackled include the economic effects of converting from steam to diesel locomotives, improved methods of handling perishable freight, and development of new types of air-conditioning equipment for passenger cars.

Development concerns the expansion of existing facilities and the study of new areas of potential economic expansion and activity. Reports and surveys are made to investigate how best any such expansion or development can be served by railway facilities. The establishment of new industry is one aspect of this work; and another, the opening up of new and often hitherto inaccessible areas of great mineral wealth, has assumed great importance in recent years and will continue to be to the fore as Canada's natural resources are developed.

On the technical side, the engineer has to develop specifications and standards for materials used in the railway's wide operations. Inspection staff ensures that purchases comply with specification.

Materials testing and the development of new materials is also carried out in chemical, metallurgical, textile, spectrographic and physical testing laboratories.

One aspect that may concern the engineer is the construction of all types of switch yards and improvement of existing facilities. *(Photo: Canadian Pacific Railway)*

OTHER DEPARTMENTS

There are many other departments of a railway in which the engineer might find potential for applying his particular bent. These include finance, statistics, economics, and marketing.

Electronics

In common with many major industries, the railways are making ever wider use of electronics in fields other than communications. Electronic business machines are coming into general use for accounting, recording, computing, and so on, and the electronic engineer will be required to install and maintain such equipment.

SALARY AND BENEFITS

The salary scales for the graduate engineer in the railways compare favourably with those prevailing in other branches of industry, having regard to the different levels that apply in different geographical and economic zones. Salary increases are generally on a merit basis.

Benefits are also comparable with those in industry in general. They include pension schemes and health insurance.

TRAINING

As has been outlined before, training is available to the undergraduate in the form of summer employment, when he can learn different aspects of the work. The graduate joining a railway company is given a period of training with practical experience in all the departments necessary to his useful development and future progress. That progress, as stated earlier, can lead to supervisory, administrative, and management levels.

The St. Lawrence Seaway

mit shippers to compete with Lake Superior ore, which paid no tolls of any kind.

Regional Authority Needed For Montreal

Addressing the Montreal Branch, Engineering Institute of Canada, George S. Mooney, director, Montreal's Municipal Seaway Bureau, and C. E. Campeau, director of the Montreal City Planning Department, called for a regional planning and development authority.

Mr. Mooney stated the seaway and its related problems had brought the need for economic and physical planning in the city dramatically to a head. "There is need for close cooperation among and between the basic utilities which will be called upon to provide and extend their services to this area: railways, power utilities, water and sewerage services and the like," he said.

There is need, too, for soil surveys and conservation plans, both with respect to the forested areas in the Vercheres region and with respect to water supply throughout the area. Natural resources must be carefully appraised and plans made for their orderly control and use."

Mr. Campeau urged that the functional development of land and facilities be undertaken according to an integral master plan covering the whole region, from Sorel to Valleyfield, and from Pont Viau to St. Jean. A belt parkway would be indispensable to the south shore, with riverfront parks to serve the whole metropolitan region and protect well established communities. If the opportunity were lost it might never come again because natural beauties and amenities would have been destroyed.

Seaway Will Benefit Inland Cities and Towns

Seaway Authority President Chevrier, speaking at London, Ont., in March, forecast that the co-ordinated use of highway, railroad and water transport methods can have the effect of "putting inland cities and towns on the water's edge."

Stressing that the seaway will be of major importance for the carriage of bulk traffic, he pointed out it would also give freer play to the specialized advantages of water transport, and that on general mer-

(*Continued on page 600*)

The St. Lawrence Seaway

(Continued from page 599)

chandise traffic he felt a specialized traffic pattern would emerge.

He looked to a variety of new services springing up, including coordination of different types of carriers and improvements in existing services. "Benefit thus will be extended far beyond the immediate port areas," Mr. Chevrier believed. It was not to be supposed that the seaway would have the effect of drying up the flow of traffic on the existing land routes by rail or highway.

"With the coordination of the different means of transportation now moving out of the experimental state, we are undoubtedly on the verge of a new period of development in transport techniques, one with which completion of the seaway will coincide," Mr. Chevrier told his hearers, adding that "particular progress is being made in newer methods of handling, transferring, lifting, loading, where costs have been most burdensome."

"It is well to note that these costs can be particularly heavy to shippers located beyond the ports, such as in fact, the shippers of your own local industries, but the effect of the newer methods by eliminating extra handling between ship and shore, and between rail and truck will offer your industries a much wider range of transport services. It can have the effect, figuratively speaking, of putting inland cities and towns at the water's edge."

News of Other Societies

The Earthquake Engineering Research Institute is arranging a world conference on earthquake engineering at the University of California, Berkeley, June 12-16, 1956.

This conference marks the 50th anniversary of the San Francisco quake. Cooperating in the work are the American Society of Civil Engineers, the Structural Engineers Association of California, and the University of California.

Information can be obtained from the Department of Conferences and Special Activities, University of California, Berkeley 4.

•

The Society of Naval Architects and Marine Engineers (74 Trinity Place, New York 6, N.Y.) will hold the annual meeting this year in Canada for the first time. It will be at the Sheraton-Mount Royal Hotel, Montreal, May 3 and 4, 1956.

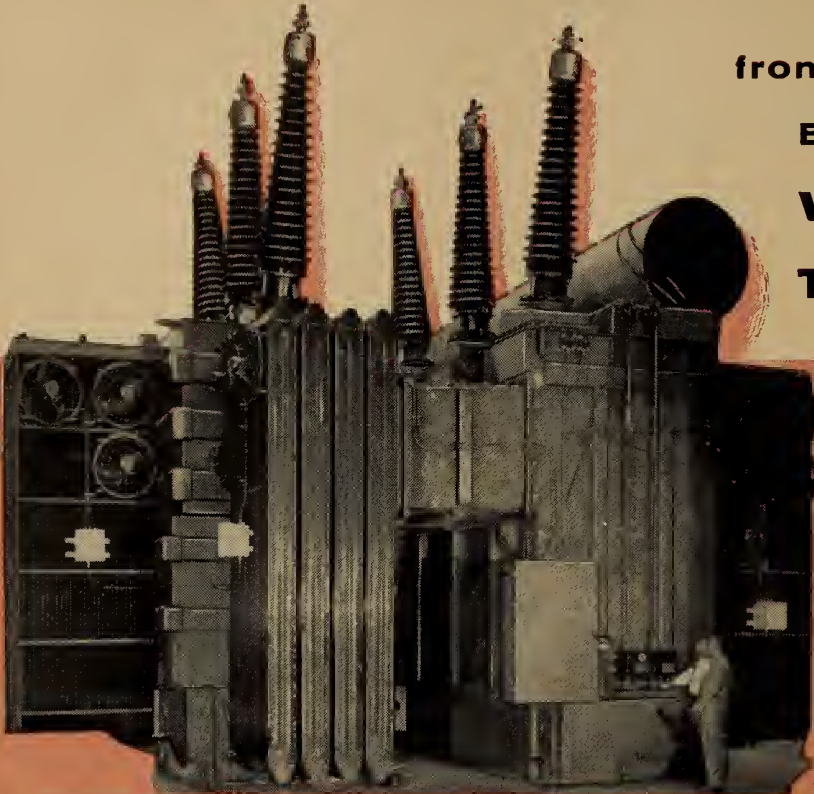
ALL THE POWER

from the giant
Bersimis system is
WESTINGHOUSE TRANSFORMED



Largest autotransformers with TCUL ever built in Canada, this is one of five supplied for the Bersimis system by Westinghouse.

Beneath the hills at right is the huge Bersimis generating station. Westinghouse transformers boost the voltage of the generated electric power for transmission over miles of countryside such as this.

The townsite of Labrieville.

One of the huge dams on the Bersimis system. These dams make possible a lake containing 350 billion cu. ft. of water.

From the underground generating station in Labrieville, townsite of Hydro-Québec's Bersimis River project and from the Lower Bersimis Generators will come 1,800,000 hp of electric energy. This power will travel over 400 miles of transmission lines to Quebec and Montreal.

Transformation of power on this system is accomplished by thirty-six Westinghouse power transformers, among them Canada's largest phase-shifting and autotransformers with TCUL* located at Charlesbourg and Bout de l'Ile to step down and shift voltage for the Shawinigan and Montreal systems.

Hydro-Québec has done a magnificent job. Westinghouse, a major supplier, congratulates the farsighted men who made Bersimis a reality.

Today, as in the past, it may be said of this, Canada's oldest land "Québec sont là!"

The Metal Bonding of Aircraft Assemblies

J. J. Waller,

Chief Materials and Process Engineer,
Canadair Limited.

In this paper is described the metal bonding process as we are using it in the manufacture of our CL-28 maritime reconnaissance airplane, starting with the basic decisions that had to be made, and following through to the time when we were in full production of bonded assemblies of specification quality. Although based on our experience with the application of metal bonding to a particular airplane, the principles and procedures involved would also apply to aircraft of other design, and could include the use of the process in other industries.

Metal bonding was found to be a necessity, rather than an alternative joining method, in the case considered here. Other advantages are also shown in this comprehensive description.

The CL-28 airplane, which is somewhat larger than the Douglas DC-7 and the Lockheed Super-G Constellation, will be used by the Royal Canadian Air Force for anti-submarine work over the coastal waters of Canada.

There are over 1500 metal bonded assemblies in the CL-28, many of which are of primary structural importance. They range in size from a few inches to those which are over thirty feet in length. Some of the problems we were faced with, because of this large range in sizes, will be described later in this paper.

Organizational Considerations

One of the first matters we had to consider when embarking upon this bonding program, was how to introduce into our production facilities, a process so radically different to anything we had used before. This was further complicated by the fact that we had a rather short-span engineering release and production schedule with which to contend. Co-ordinated decisions had to be made quickly and carried out effectively within our rather large organization. Until certain of these basic decisions had been made and we were well along in the experimental phase of production bonding, we considered that operating through our normal line organization would be too time-consuming, since there were so many other problems associated with the CL-28 program which had to be explored and settled.

Accordingly, it was decided to introduce bonding, as a production process, by means of a committee whose membership consisted of representatives of the various departments in our organization directly concerned with metal bonding. This committee, which was virtually autonomous, represented structures and design engineering, plant engineering, manufacturing engineering, the production department, quality control, and materials and process engineering. What this approach meant to us was that, within three weeks after the bonding department had been set up, we were able to produce bonded assemblies of specification quality. This elapsed time included that required for proving equipment and tools, as well as the training of production personnel who had had no previous experience in metal bonding.

Although we had done a certain amount of laboratory bonding of test specimens earlier, we soon learned that there is a large difference between laboratory and production procedures.

Selection of a Suitable Adhesive

We next had to decide upon the adhesive we should select for our use. There were several available in the United States and Canada, one of which was originally developed in the United Kingdom and which is being used there almost exclusively, with apparent success.

Amongst the adhesives available were those suitable for applications subject to the normal temperature range of −65°F. to +180°F., and those for the high temperature range of −65°F. to +500°F. Our requirements were for an adhesive suitable for use only in the normal temperature range. Also, at the time our decision had to be made, the high temperature adhesives available had not yet been adequately developed for practical use.

After visiting several airframe manufacturers in the United States and in the United Kingdom, all of whom were doing bonding under production condi-

Read at the 70th Annual General and Professional Meeting of The Engineering Institute of Canada, Montreal, May, 1956.

tions, we consolidated their reactions to the particular adhesives they were using, and selected as the best for our purpose FM-47 tape system adhesive[1]. This is a −65°F. to +180°F., adhesive covered by specification MIL-A-8331.

In addition to several others, our principal reason for selecting a tape-type adhesive, was our contention that a better and more consistent quality bond could be obtained than with a powder-type or a liquid-type adhesive.

FM-47 is a two-component material, consisting of a primer and a tape. The primer is composed of a partially polymerized or cured phenolic resin to which has been added a quantity of a vinyl resin. The tape, about 0.015 in. thick, consists of a loosely-woven Fiberglas cloth impregnated with a material similar in composition to the primer but with a very much higher solids content. The function of the glass cloth is that of a support for the adhesive. The cloth contributes very little, if anything, to the strength of the cured adhesive.

The presence of the vinyl resin in the formulation is to increase the ductility (and the peel strength) of the cured adhesive. Cured phenolic resins, by themselves, are extremely brittle. However, the presence of the vinyl resin lowers the shear modulus of the adhesive from approximately 1.5 million p.s.i., to about 0.75 million p.s.i.

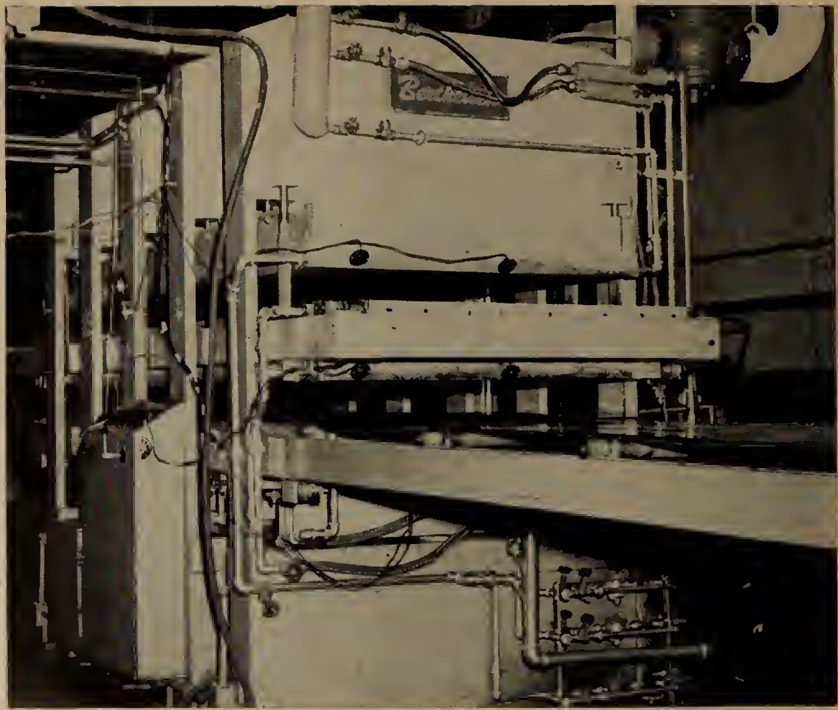

Fig. 1. General view of 5 ft. x 12 ft. platen press—two openings.

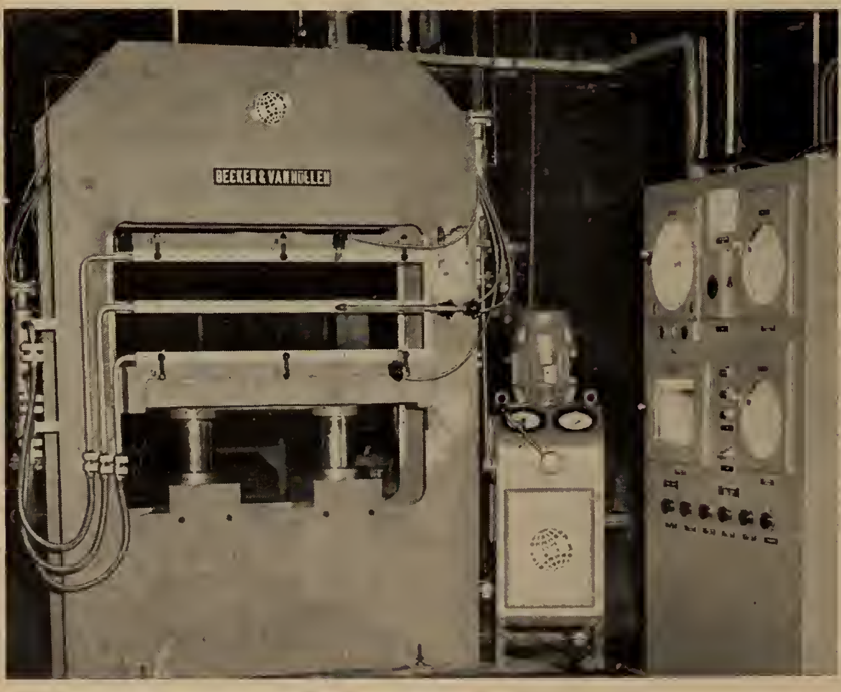
This adhesive, when properly used, will produce minimum shear strengths of 2500 pounds per square inch in aluminum alloy assemblies.

Selection of Equipment

The next phase of our program which had to be investigated was the selection of the equipment necessary for production bonding.

We had to plan for a rather limited rate of production and, since the assemblies to be bonded varied in size from those which are very small to those which are very large, we had to select equipment which would be versatile and at the same time require bonding tools which would be relatively inexpensive to make. We considered the "pants presser" type of tooling, the inflatable-diaphragm type and the integral pressure, and heating type, as well as many other similar types, to be uneconomical for our requirements.

Fig. 2. General view of 2 ft. x 4 ft. platen press—two openings.



Accordingly, one of the basic decisions we arrived at was that, in general, all flat parts would be bonded in platen presses, and all contoured parts in autoclaves. On this basis, most flat parts would not require any tooling whatsoever, while the tools required for autoclave bonding would be of the lightweight, inexpensive type made principally of sheet metal.

Two platen presses were purchased, each with two openings and platen sizes of 2 feet x 4 feet and 5 feet x 12 feet. The platens are heated by steam and cooled by water. Steam was selected in place of electrical resistance as the heating medium, because of the widespread reports we had received that the latter did not provide a fast heat-up time on an economical basis, nor did electricity provide as uniform a temperature distribution as did steam.

The pressure for platen press curing was selected at 200 pounds per square inch.

It was decided to purchase one autoclave only, having the working dimensions of 8 feet in diameter and 35 feet in length, so as to accommodate the largest part which had to be bonded. The maximum pressure for autoclave bonding was chosen to be 100 p.s.i., as higher pressures would involve a great deal of expense and time, and the safety hazards would be greatly increased.

Heat in the autoclave is obtained by means of a steam heat exchanger and a fan-type circulating system located inside the autoclave. Although some firms are believed to be still using wet-type autoclaves—that is, the live steam contacting the parts to be bonded—the trend for several years now has been toward dry units so as to obtain the desired flexibility of temperature and pressure. An arrangement is also provided to circulate cold water through the heat exchanger coils, for cooling the inside of the autoclave at the end of the curing cycle.

The curing temperature selected for both press and autoclave methods of bonding is 310±10°F. This selection was made so as to obtain the fastest curing time without tending to anneal or soften the aluminum alloy parts being bonded.

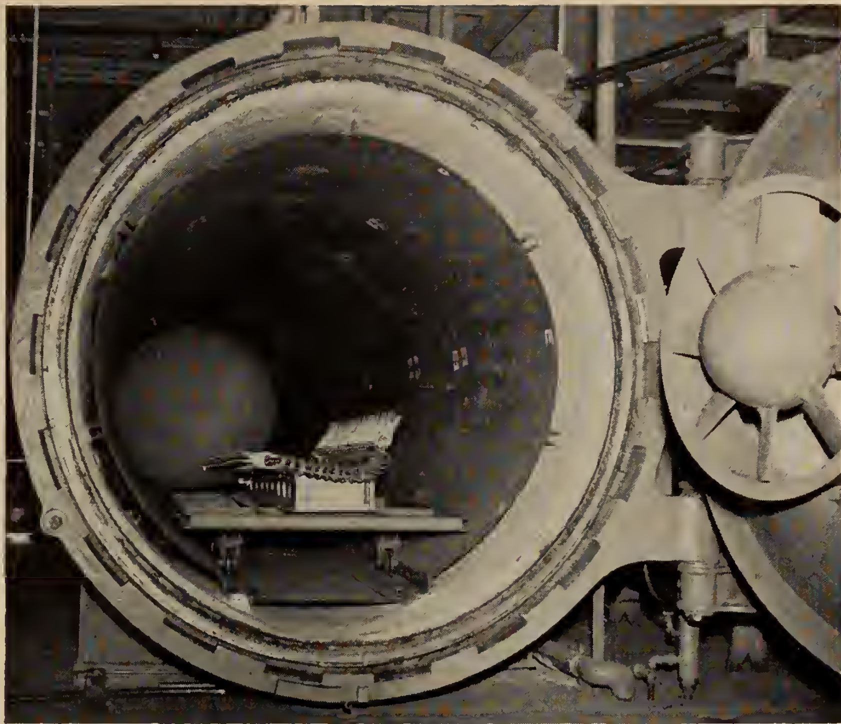


Fig. 3a. Autoclave door with air circulating fan and motor. Assembly in position ready for curing of the adhesive.

Bonding Tools

I would now like to describe briefly the general design of bonding tools selected.

As mentioned previously, our press bonding tools were held to a very small number, since when bonding a flat part to a flat part no tools are really necessary. For example, when bonding a flat spar web reinforcement to the web itself, the detail parts are placed between the platens of the press, separated on each side by a thin sheet of heat resistant rubber and a thin sheet of soft aluminum. We found the soft aluminum sheet to be necessary since, at a pressure of 200 pounds per square inch, the rubber flows, and the high friction developed between it and the parts being bonded creates a tendency for one of the parts being bonded to shift relative to the other—even when they are tack-rivetted together—the rivets being sheared.

The instances where tools are required for press bonding are for such items as corrugated assemblies, for example, where only certain areas of a detail part have to be bonded.

The tools which are used for autoclave bonding are made principally of aluminum sheet with the supporting structure made of thin aluminum plate. The sheet is contoured to the same shape as the assembly being bonded. This shape is supported by "ribs" fastened on to a base which, in turn, supports the whole bonding tool. Connections are provided for vacuum lines. I believe the simplicity of this type of tooling is self-evident.

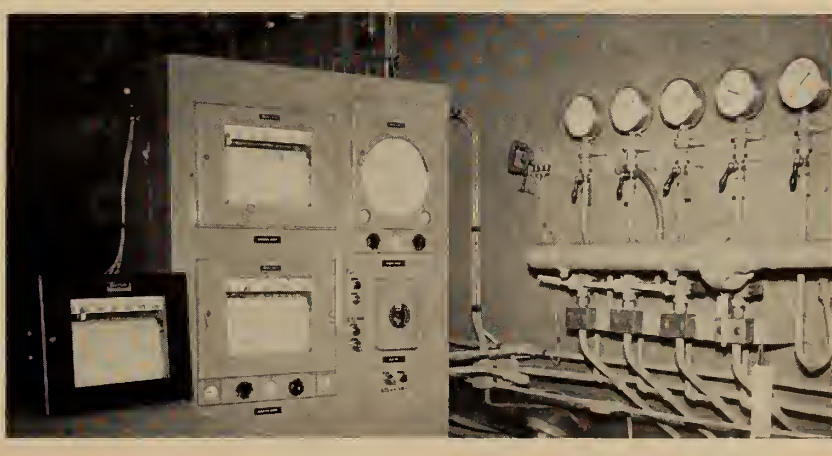
Bonding Pre-Treatment

I would now like to deal with the subject of the pre-treatment of aluminum alloy parts to be bonded, since this constitutes a very important phase of the process.

The first stage consists of removing the oil, grease and other soil from the surfaces to be bonded. This can be done in several ways using either or both vapour phase degreasing or alkaline solution degreasing methods. For reasons of economy and because it lends itself to "production line" methods, we selected the use of an alkaline solution. I will not go into the details of this phase of the pretreatment since it is a process in general use throughout the metal working industry.

The next stage of the process is the rinsing operation. We have found that the only way of ensur-

Fig. 3b. Autoclave instrumentation.



ing complete rinsing is by the use of spray rinse tanks instead of the ordinary immersion type. This consists of a conventional tank, adequately drained, with rows of spray nozzles running down the length and on each side of the tank.

Perhaps it should be emphasized at this point that cleanliness of the material to be bonded is of extreme importance throughout the whole process—more so, perhaps, than in any other process we are using.

The next stage in the pre-treatment is the etching of the aluminum, in a solution of sodium dichromate and sulphuric acid maintained at a temperature of 145°F. The time of immersion is 10 minutes.

Then follows a cold water spray rinse, in turn followed by blowing the parts dry with a jet of clean, dry compressed air. Strangely enough, the sodium dichromate-sulphuric acid solution is the only one found, so far, which will produce metal bonds with consistently high strength. It is strange, because this solution oxidizes and does not deoxidize the surface of the aluminum.

I would like, here, to discuss the theoretical aspects of the mechanism of metal bonding, since it is closely associated with the sodium dichromate-sulphuric acid etching of the material to be bonded.

Clad aluminum alloy sheet, when it is received from the mill and degreased, has a surface contact resistance in the range of 500 to 2500 microhms or perhaps even higher. A bond made on such a surface has low and inconsistent strength. Now, if this aluminum sheet is deoxidized in a reagent such as hydrofluosilicic acid, it will have a contact resistance in the range of zero to 10 microhms. A bond made with material so treated is also low and inconsistent in strength.

Then, again, when we treat this aluminum in a sodium dichromate and sulphuric acid solution and measure the contact resistance, we find the value to be in the range of approximately 500-700 microhms. Bonds made with material so treated have consistently high strengths. The question is "why"?

Firstly, of course, the sodium dichromate-sulphuric acid solution etches the surface of the aluminum and the microscopic "hills and valleys" so developed, not only increase appreciably the surface area of the material, but also develops a "keying" surface for the adhesive. However, this is generally considered to play only a minor role in the development of high strength bonds.

The oxide on the aluminum material as it is shipped to us by the mill is formed by natural or ordinary atmospheric exposure. It is a comparatively slow process. This oxide coating may be considered to be poorly adherent to the parent metal and non-uniform in properties and thickness. The oxide formed by the sodium dichromate-

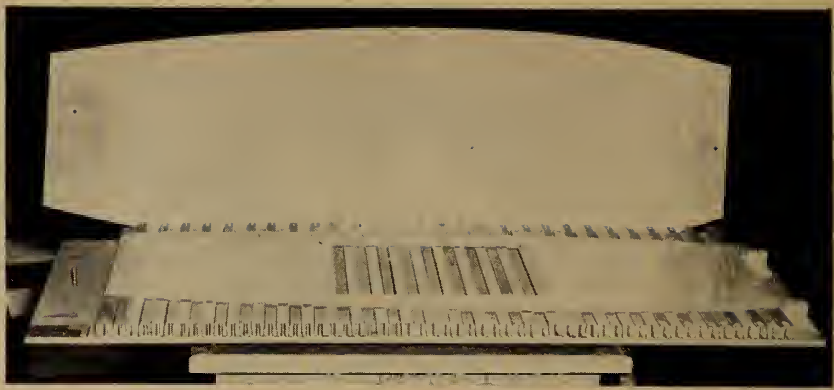


Fig. 4 and 5. Tooling for corrugation bonding.

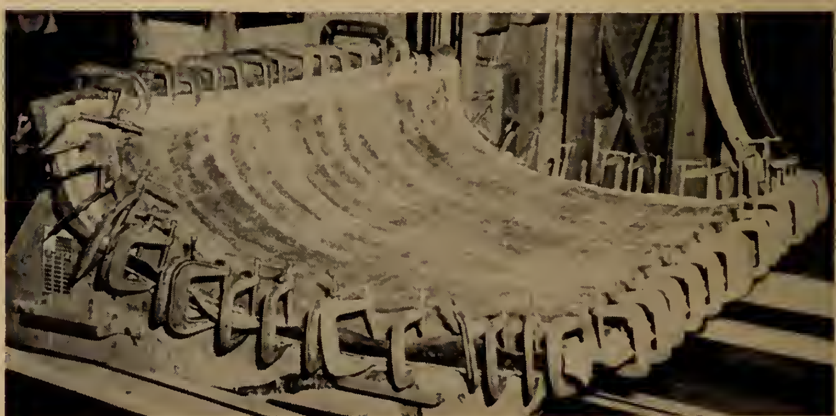
Fig. 6. Autoclave bonding tool.

Fig. 7. Autoclave bonding tool.



sulphuric acid solution, on the other hand, is not only firmly adherent but is also uniform.

The major role in a good bond is played by polar molecules. The aluminum oxide molecule and its variations, which is firmly attached to the surface of the etched aluminum, is asymmetric and polar. That is, the electrical charge at one end is farther from the centre of the molecule than the electrical charge at the other end. Consequently, the neutralizing effect of one charge by the other is not as pronounced as in the case of a symmetrical molecule. That charge farthest from the centre of a polar molecule will have a high electrical affinity for another molecule, particularly of the polar type. In this case of metal bonding, the other molecule with polar characteristics is the adhesive.

One of the essential characteristics of a good adhesive is that it not only wets thoroughly or comes into intimate contact with the metal or the oxide of the metal being bonded before it is cured, but, after curing, it must be a molecule with polar characteristics. Adhesives like FM-47 have such characteristics and this wetting action and polar attraction between the molecules of the adhesive and that of the metal surface are chiefly responsible for the high strength bonds obtained.

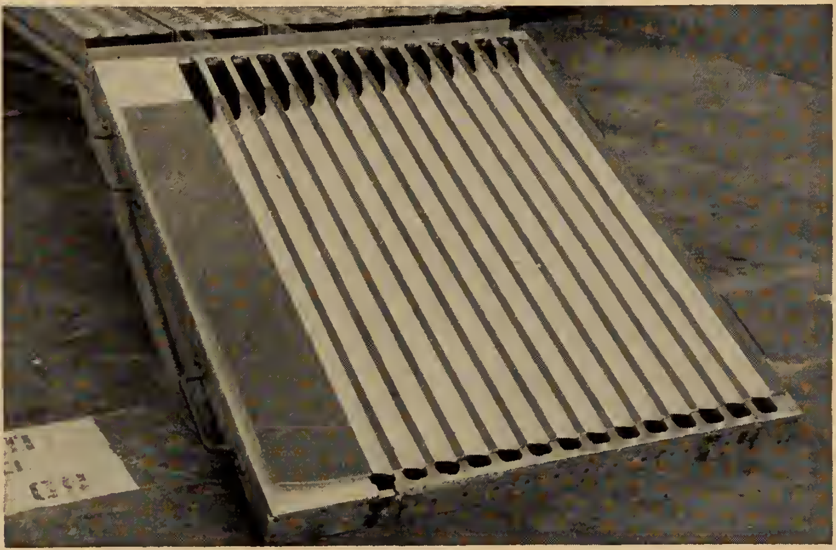


Fig. 8. General view of pre-treatment tanks.
Fig. 9. Adhesive in place.

Fit-Up of Parts To Be Bonded

One of the first and important operations to be carried out in bonding work, is to determine whether the parts to be bonded fit together properly, so that they achieve the necessary close contact during the curing operation. We have made it a general rule that ordinary hand pressure should bring the detail parts into good contact with one another—in all areas where bonding is to take place.

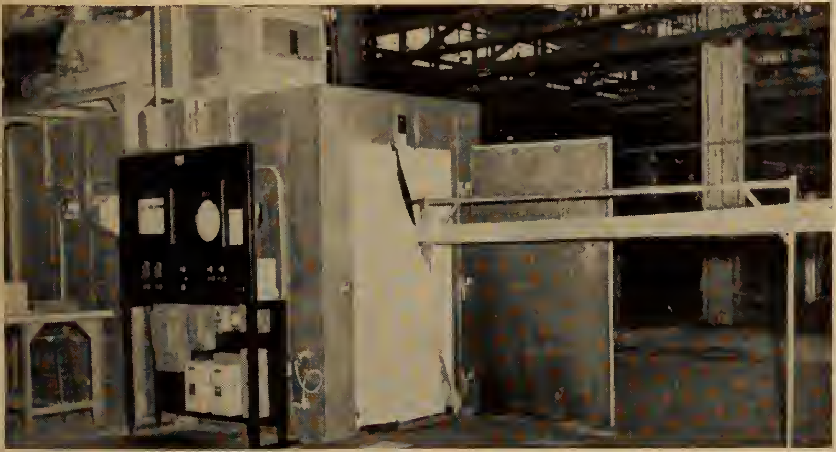
This requirement for good contact is sometimes difficult to achieve, particularly when one has to deal with complicated shapes such as contoured corrugations.

When the inspector concerned is in doubt as to whether a fit-up is adequate, he uses the dye transfer method for checking. This consists of applying, by brush, to one faying surface, a coating of die-maker's dye, fitting the parts together in the bonding tool and applying vacuum only. If the dye transfer to the other faying surface is complete, then, under normal curing pressure, the requirement for close contact will definitely be achieved.

After the fit-up has been checked, the detail parts are pre-treated in the manner described previously.

To add another note about cleanliness; after the parts are pre-treated, they are handled only by personnel wearing clean cotton gloves.

Fig. 10. General view of drying oven.



Application of Adhesive

The faying surfaces of the parts to be bonded are sprayed with adhesive primer to give a dry film thickness of 0.001-0.002 in. The adhesive tape is then applied to one faying surface only and rolled firmly into place using a hard rubber roller. The adhesive is then air-dried for two hours followed by force-drying for one hour at 225°F. This careful drying is essential so as to remove all traces of solvent from the adhesive, and avoid poor

Fig. 11. Press-cured bonded assembly.

bonds from being developed as a result of the solvent evaporating in the glue line during the curing operation.

Curing of the Adhesive

After the force-drying is completed, thermocouples, made from wire 0.005 in. in diameter, are attached to the adhesive tape in the significant areas so as to determine when the glue line reaches the required curing temperature. The parts are then nested together and placed in the bonding tools or directly on the press platen.

In the case of press curing, the heated platens, with the work in place, are brought together under very low pressure, about 5 p.s.i. The glue line is allowed to come up to 310°F., and to dwell at this temperature for 8 minutes. The press is then opened for 2 minutes.

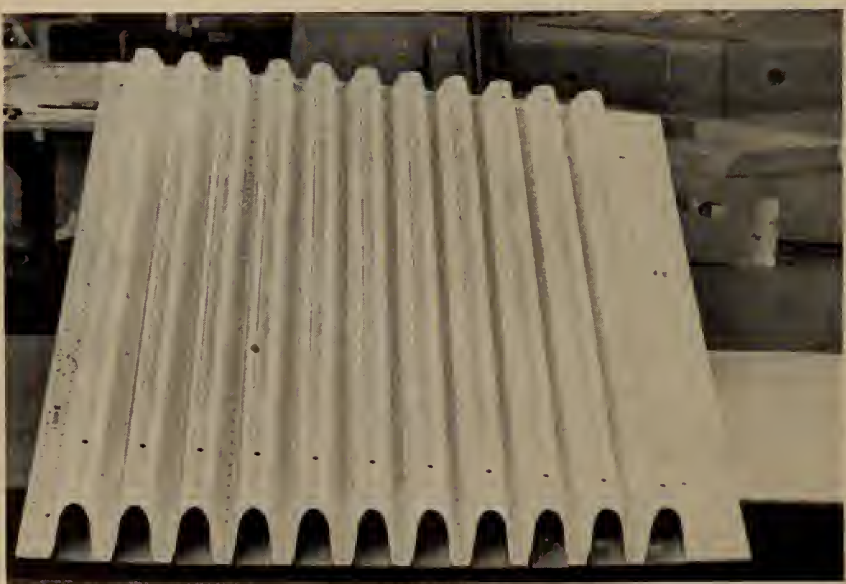
The purpose of this pre-cure is to start the polymerization of the phenolic resin. During this initial joining together of the molecules the by-product is water—which, under the existing temperature, is in the form of a vapour. Opening the press for the two-minute period allows this water vapour to escape and thereby diminishes the tendency for voids to develop in the glue line.

After this pre-cure stage, the press is closed to a bonding area contact pressure of 200 p.s.i., and the adhesive is finally cured at 310°F. for approximately 30 min.

After the 30-minute cure, with the 200 p.s.i., pressure maintained, the cooling system of the press is turned on. This is accomplished by flowing cold water through the hollow platens of the press, where the steam had previously circulated. When the glue line has reached approximately 180°F. the press is opened and the bonded parts are removed.

The purpose of cooling down to 180°F. while the assemblies are under pressure is that, at 310°F., the cured adhesive has comparatively low strength. Consequently, handling the parts at this temperature may allow one detail part to shift relative to the other. Also, if there is any tendency for springback of the parts to take place, a void could develop.

Fig. 12. Press-cured bonded assembly.



In autoclave bonding, much the same procedure is followed in curing as in the case of press bonding. The pre-cure as an individual stage is not carried out, since the continuously applied vacuum between the rubber blanket and the part draws off the water vapour evolved. The curing pressure used in the autoclave, as mentioned previously, is only 90-100 p.s.i.

Finish Treatment of Bonded Assemblies

FM-47 adhesive, after it is cured, is extremely stable chemically. In fact, we have been unable to find any reagent to dissolve it.

Because of this property, we are able to treat bonded assemblies for protection against corrosion, in the same manner as for assemblies joined together by any other method.

The treatment used consists of immersion in an alkaline cleaner followed by rinsing in water. Clad assemblies are then immersed for 5 minutes in a 5 per cent solution of chromic acid maintained at 130°F. Non-clad assemblies are treated by immersion to obtain one of the proprietary chemical conversion coatings such as Iridite 14-2 or Alodine 1200. The assemblies are then coated with zinc chromate primer in the usual manner.

Quality Control and Metal Bonding

One aspect of metal bonding which has not yet been covered and which is extremely important, is that of quality control.

Since, by present methods, a metal bonded assembly cannot be examined for good bonding by other than destructive methods, it is extremely important that each phase of the process is constantly and carefully controlled for quality.

This includes taking such precautions as testing each incoming shipment of adhesive, frequent chemical analysis of the pre-treatment solutions, checking carefully the fit-up of detail parts to be bonded, controlling accurately the curing temperature, pressure and time, enforcement of practices which ensure cleanliness of the parts being bonded, keeping flow times between various stages of the process to an absolute minimum, and finally the liberal use of shear test specimens which are processed along with each batch of production parts.

Quality control is probably more important in metal bonding than in any other process.

Inspection of Bonded Assemblies

The procedure used at present for the inspection of bonded assemblies is to tap them with a lightweight hammer having an aluminum alloy head. Voids will make themselves evident when a change in the noise caused by the tapping is heard. It must be admitted that this is a very unsatisfactory method, particularly since voids in heavy gauge materials are difficult to locate in this way.

Stanford Research Institute along with the Convair Division of General Dynamics, in Texas, have developed a more exact method of distinguishing between good and poor bonds. The equipment is basically the same as the ultrasonic equipment used for the detection of defects in metal, except that the bond testing equipment functions on the principle of measuring changes in mechanical impedance. Although we do not yet have such equipment in use in our facilties, I have had the opportunity of examining bonds by this method and it certainly gives a positive indication. The equipment is known as a Stub or a Stubz meter but is not yet commercially available.

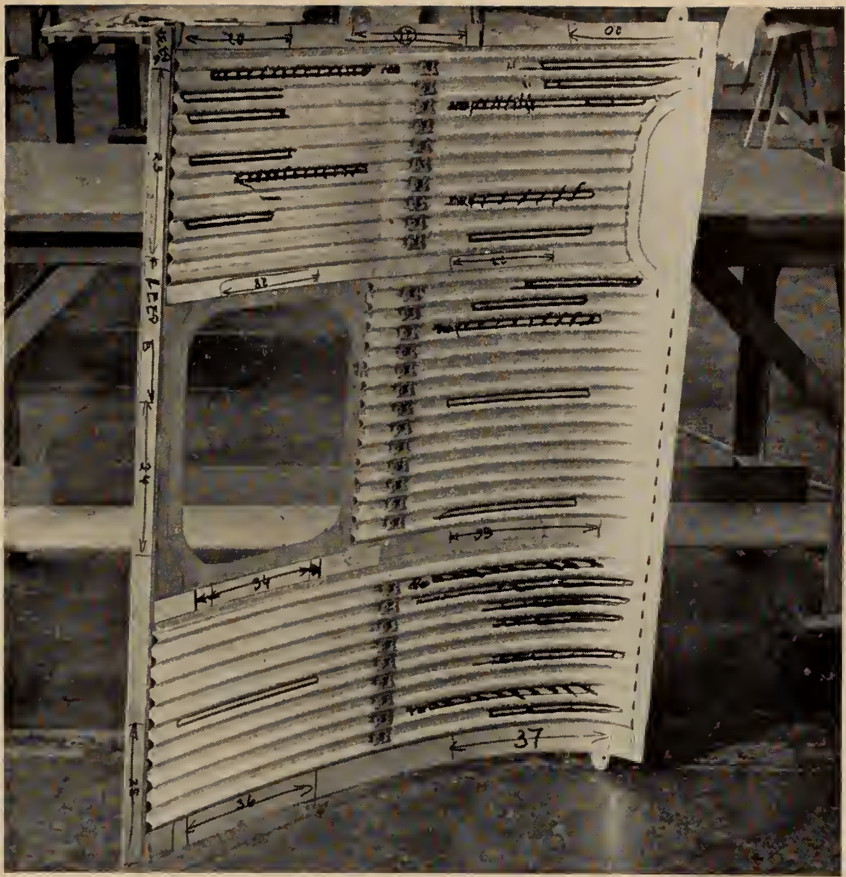


Fig. 13. Autoclave-cured bonded assembly.

Bonding of Metals Other Than Aluminum

Throughout this paper, the metal bonding of aluminum only has been discussed. Other metals such as magnesium alloy and stainless steel have been bonded successfully, although the shear strengths developed are generally not as high as those obtained with aluminum. Again, the whole problem is to treat the surfaces of these metals chemically so as to obtain a coating whose molecules are firmly adherent to the parent metal and also have polar characteristics.

CONCLUSION

In conclusion, some may wonder whether all this apparent trouble one has to go through to make properly bonded assemblies, is worth it or not—particularly in this day of automatic rivetting and resistance welding, which processes fit in closely with the current trend towards automation.

We have wondered about this too, until we discovered that going to joining methods, other than bonding, would have cost us approximately 1000 pounds in structural weight. On this basis, metal bonding becomes a necessity and not a process to be considered as a choice between it and some other joining method. Apart from the saving of weight, for certain critical assemblies, bonding will afford a much longer fatigue life than other methods of joining. Also, for high speed aircraft, bonding gives a smoother surface from aerodynamic considerations.

Also, apart from obtaining low weight, high strength and smoothness which the aircraft designer is constantly concerned with, there are certain applications where metal bonding proves itself to be more economical than other joining methods.

The Mackinac Bridge

How it was designed for aerodynamic stability

D. B. Steinman, M.E.I.C.
Consulting Engineer,
New York, N.Y.

The Mackinac Bridge, a suspension bridge 8,614 feet long with a main span of 3,800 feet, was designed to have exceptional aerodynamic stability. Wind-tunnel tests have proved that the designed high degree of stability against all forms of oscillation has been obtained. A perspective drawing of the bridge is shown at the head of this page.

•

The design of the $100 million Mackinac Bridge in Michigan, now under construction, with a main span of 3,800 feet and for which the writer is consultant, was predetermined in final form, without groping, cut-and-try experimentation or successive modifications of design to overcome aerodynamic instability. Now, extensive wind-tunnel tests have been completed on a large-scale dynamic model of the bridge; no modification of the original design has been found necessary or desirable. The wind-tunnel tests show conclusively that the Mackinac Bridge, as designed, has complete and absolute aerodynamic stability against all forms of oscillation — vertical, torsional, and coupled—in all modes at all wind velocities and all angles of attack. This goal has not before been attained nor approximated in any bridge section investigated.

With the destruction of the Tacoma Narrows Bridge in 1940 by cumulative oscillations in a mild gale, the engineering profession was awakened to the importance of considering the aerodynamic problem in bridge design. To resist these potential destructive forces, the more obvious, elementary methods ordinarily pursued tend to produce structures that are extravagant in cost and clumsy in proportions. In the case of the Mackinac Bridge, a different course was adopted. A bridge of ideal, assured aerodynamic safety has been secured without sacrificing either economy or graceful proportions. By scientific design, utilizing the new knowledge of suspension bridge aerodynamics, the Mackinac Bridge has been made the most stable suspension bridge, aerodynamically, that has ever been designed.

This result has been achieved, not by spending millions of dollars to build up the structure in weight and stiffness to resist the effects, but by scientific design to eliminate the cause of aerodynamic instability. The vertical and torsional aerodynamic forces tending to produce oscillations are not merely resisted; they are scientifically eliminated.

Read at the 70th Annual General and Professional Meeting of The Engineering Institute of Canada, Montreal, May, 1956.

FUNDAMENTAL PRINCIPLES

The fundamental principles of successful design are as follows:

1. The phenomena of aerodynamic instability are not mysterious, but can be solved by scientific analysis and then prevented. A science of bridge aerodynamics is a reality.

2. It is more scientific and more economical to eliminate the cause of aerodynamic instability by scientific design than to build up the structure, in weight and stiffness, to resist the effects of aerodynamic instability.

3. All bridge cross-sections do not behave alike aerodynamically. They may be differentiated and classified as aerodynamically stable and unstable sections, of different degrees of stability or instability, in the three different kinds of potential oscillation—vertical, torsional, and coupled.

4. The aerodynamic characteristics of any proposed bridge section are either already known or may be determined by simple model tests on a small-scale model. Expensive and time-consuming wind-tunnel tests on a full bridge model or on a large-scale oscillating section-model are not required in predetermining the design.

5. The aerodynamic behaviour of a bridge may be qualitatively and mathematically predicted from the lift and torque graphs recorded for different sections, or obtained for a new section from a small-scale static section-model in a small wind tunnel. The slopes of the graphs determine stability or instability. The curvature of the graphs determines limiting amplitudes.

6. The ideal bridge section, aerodynamically, is one that has zero slope of both the lift graph and the torque graph. Zero slope in both graphs denotes complete elimination of the lift forces and moments that produce aerodynamic oscillations, vertical, torsional, and coupled.

7. Bridges of assured aerodynamic stability may be economically secured by simple modifications of the usual bridge sections.

SIMPLE MODEL TESTS

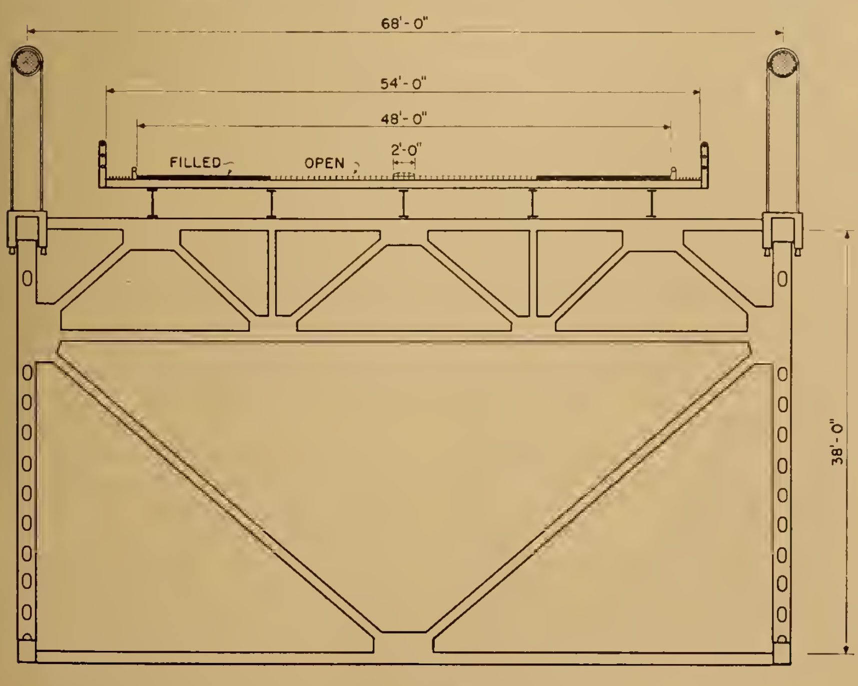
Based on fundamental conceptions of the aerodynamic forces and moments acting on a bridge section, simple modifications of the conventional bridge cross-section have been devised to eliminate the concentrations of differential pressure and the surfaces on which those pressure differences acted. These modified sections were easily and inexpensively tested and developed by means of simple, home-made office models, suspended from light springs and exposed to the breeze from an electric fan.

The results of these elementary tests, confirmed and refined by tests made on a small-scale non-oscillating section-model in a small wind tunnel, provided the basis for the design adopted for the Mackinac Bridge.

The confirmatory tests on a small-scale section-model of the Mackinac Bridge were made by Professor F. J. Maher at the Virginia Polytechnic Institute. The model, only 8½ inches wide and 15 inches long, was constructed to represent a 120-foot length of bridge to a scale of ⅛-inch to the foot, in accordance with the cross-section shown in Fig. 2. Open-grid sections of the deck and open railings were simulated in the model by use of wire screening. Graphs giving the variation of aerodynamic lift, drag, and moment with the angle of attack of the wind for this stationary section-model were plotted. These three graphs supplied the information to assure the aerodynamic stability of the bridge. The total cost of the model and the tests was only $500.

Those who do not understand the consistent simplicity of fundamental scientific principles have challenged this procedure by declaring that nothing can be learned from experiments on small scale models. These critics forget the history of scientific thought. Newton did not require an elaborate model of the universe in order to discover the universal law of gravitation; his mind grasped the fact that the forces acting on a falling object obeyed the same simple law as the forces acting on the largest planet. The most costly, elaborate research equipment may not be a substitute for the creative mind.

Fig. 2. Cross-section of the aerodynamically stable Mackinac Bridge.



DESIGN FEATURES

The essential features characterizing the design of the Mackinac Bridge for perfect aerodynamic stability are shown in the cross-section, Fig. 2.

The outstanding original feature contributing to high aerodynamic stability is the provision of wide open spaces between the stiffening trusses and the outer edges of the roadway. The trusses are spaced 68 feet apart and the roadway is only 48 feet wide, thus leaving open spaces 10 feet wide on each side, for the full length of the suspension bridge. These wide lateral openings are located where the maximum aerodynamic pressure differences would otherwise be concentrated; such pressure differences ordinarily produce the critical alternating vertical forces inducing and amplifying vertical oscillations, together with the maximum lever-arms for these vertical forces in inducing and amplifying torsional oscillations. These lateral openings serve a dual purpose:

1. They equalize the aerodynamic pressures above and below the deck in the critical areas adjacent to the stiffening trusses or girders, thereby cancelling the resultant alternating vertical forces.

2. They remove the area of solid deck on which these pressure differences would otherwise act. A pressure cannot exist and cannot produce a force without an area on which to act.

The alternating pressure differences ordinarily concentrated in these corners of a bridge cross-section not only create the biggest alternating forces causing cumulative amplification of vertical oscillations, but they also operate with maximum leverage to produce the alternating torques causing cumulative amplification of torsional oscillations.

For still further aerodynamic stability of the Mackinac design, the equivalent of a wide longitudinal opening is provided in the middle of the roadway (see Fig. 2). The two outer traffic lanes, each 12 feet wide, are made solid, and the two inner lanes and the centre mall (24 feet wide) are made of open-grid construction.

Model tests have shown that a design with open grid over the full width of the roadway does not produce aerodynamic stability. The solid deck, or a substantial part of it, is needed for damping by atmospheric resistance. The Mackinac Bridge cross-section provides the solution. The two solid roadway lanes, each 12 feet wide, supply the necessary atmospheric damping. Even in the two open lanes, a large measure of atmospheric damping is afforded by the friction of the airflow through the grid, with the velocity of this airflow augmented by the effect of the adjacent solid deck.

Wind-tunnel tests have confirmed the high aerodynamic stability of this design of cross-section.

An additional design feature introduced for the still further increase of the aerodynamic stability of the Mackinac Bridge is the use of open-web, trussed floorbeams (see Fig. 2), instead of the usual solid-web floorbeams. Aerodynamic oscillations of a bridge have usually started under the action of winds blowing at angles of approximately 45 degrees to the axis of the bridge. The component parallel to the bridge axis and acting on the transverse floorbeams and on the arched camber of the span, tends to start the oscillations; the component acting across the span then amplifies the initial oscillation if the cross-section has aerodynamic instability. The use of open floorbeams eliminates an important source for the initiation of oscillations by gusts and quartering winds. The aerodynamically stable cross-section eliminates the amplification of oscillations, whether originated by gusts or by the imperceptible vibrations due to traffic. Any initial vibration is quickly damped instead of being sustained and amplified.

STATIC LIFT GRAPH

The static lift graph is obtained by plotting the measured vertical lift force on a small section-model held stationary at various angles of attack in a wind tunnel.

For comparison and contrast, the static lift graphs for three significant bridge sections are shown in Fig. 3, superimposed and plotted to the same scale. The corresponding static torque graphs for the same three bridges are shown in Fig. 4. Taken from official records and published reports, the graphs for the Golden Gate Bridge were obtained in the wind tunnel at Stanford University, the graphs for the original (1940) Tacoma Narrows Bridge were obtained in the Guggenheim Aeronautic Laboratory of the California Institute of Technology, and the graphs for the Mackinac Bridge were obtained in the wind tunnel at the Virginia Polytechnic Institute.

The slope of the static lift graph represents the rate of increase of vertical lift with angle of attack. A small correction, the "drag correction", is made in the plotted graphs in order to take into account the fact that the model is inclined, instead of the wind direction, to provide the various small angles of attack.

The slope of the static lift graph is significant. A negative slope (lift decreasing with increasing angle of attack) would represent dangerous instability in vertical oscillations. A bridge section possessing this characteristic would be subject to cumulative amplification of vertical oscillations to catastrophic amplitudes.

A positive slope of the static lift graph identifies "stable sections," so designated to distinguish them from "catastrophically unstable" sections. This distinction is clear-cut in the case of narrow geometric sections, such as lenticular sections, with the depth exceeding the width. In bridge cross-sections, however, a "stable" section, that is, one with positive slope of the lift graph, is subject to limited aerodynamic oscillations in certain critical ranges of wind velocity. These aerodynamic oscillations usually occur at low velocities. Although they are not "catastrophic", these low-velocity oscillations are alarming, and tend to shorten the life of the bridge by fatigue. This is the type of oscillation, commonly known as "galloping", which characterized the Tacoma Narrows Bridge (1940) during the four months of its life.

In both cases, catastrophic instability (negative slope of lift graph) and limited instability (positive slope of life graph), the degree of instability is proportional to the slope of the lift graph. The steeper the slope, the greater is the rate of amplification of the oscillations. The rate of increase is logarithmic; the smallest tremor is automatically amplified a thousand fold to an amplitude of one or more feet in a few minutes.

Since the foregoing relationship applies to all lift graphs, of either positive or negative slope, the conclusion is clear:

The ideal bridge section is one that has zero slope of static lift graph.

In this respect, the goal sought in an ideal bridge section is quite different from that sought in wing sections for airplanes. "Flight stability" is something quite different from "aerodynamic stability". In the case of airfoil design, the objective sought is maximum lift, and the ideal airfoil is one that yields maximum ratio of vertical lift to horizontal drag. The idealized airfoil has a steep lift graph, with a slope of +6.28. The ideal bridge section should have a flat lift graph with a slope of zero.

The foregoing distinction is

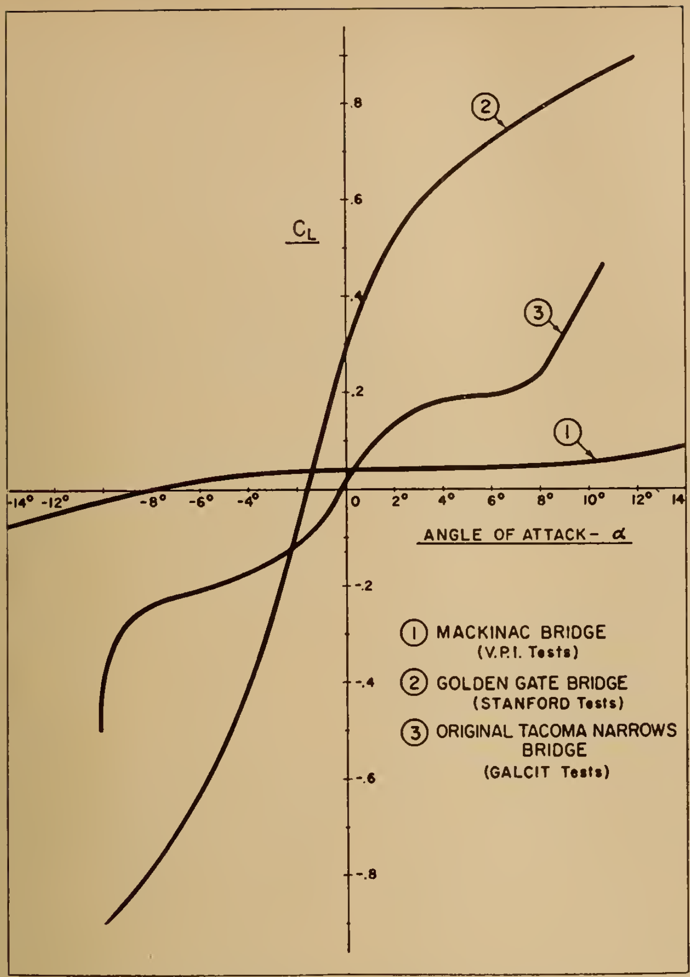


Fig. 3. Comparison of static lift graphs for three suspension bridges.

overlooked by those who seek to apply the formulas of conventionalized airfoil theory to bridge sections, since airfoil theory assumes that the section is an idealized airfoil of fixed characteristics, including steep slope of lift graph. Such misapplication of inappropriate theory and formulas fails to give due credit to the more stable bridge sections, scientifically designed, in which the slope of lift graph is greatly reduced or eliminated.

In Table I are listed the comparative slopes of the static lift graphs (corrected for drag) for some notable bridge sections; the idealized airfoil and the ideal bridge section are included for comparison.

Table I. Slope of Static Lift Graph

Golden Gate	+10.5
Idealized airfoil	+ 6.28
George Washington	+ 6.2
Tacoma (original)	+ 5.5
Bronx-Whitestone	+ 5.0
Mackinac (grid covered)	+ 1.9
Mackinac (grid open)	+ 0.03
Ideal bridge section	0

For the Mackinac Bridge as designed (see Fig. 3 and Table I) the slope of lift graph is +0.03, virtually zero. This degree of perfection has not before been approximated or attained. This remarkably flat slope of the Mackinac lift graph should be compared with the comparatively steep slopes of the lift graphs (+5.0 to +10.5) recorded for prior large suspension bridges, and with the steep slope (+6.28) for the idealized airfoil.

Using the slope of lift graph as a measure of vertical instability, Table I shows that the Mackinac Bridge, as designed, is 350 times safer than the Golden Gate Bridge against vertical oscillations or "galloping".

For completeness of presentation, Table I also includes the hypothetical case of the Mackinac Bridge with the grid in the middle of the roadway (24 feet of width) assumed completely covered, as by ice and snow. Even for this extreme assumed condition, the slope of lift graph has the unprecedentedly low value of +1.9, or five and a half times as safe as the corresponding figure (+10.5) for the Golden Gate Bridge. Moreover, for this assumed extreme condition, the ice and snow packed in the meshes of the grid and any ice and snow on the solid portions of the deck would greatly increase the structural damping, thereby offsetting the effect of the small increase in the slope of the lift graph.

The recently completed large-scale wind-tunnel tests on a model of the Mackinac Bridge in the specially built laboratory at the University of Washington confirm the fact that the Mackinac Bridge has complete and absolute aerodynamic stability against vertical oscillations at all wind velocities to infinity and at all angles of attack.

STATIC TORQUE GRAPH

For the static torque graph, as in the consideration of static lift graphs, the ideal slope is zero. Zero slope of torque graph means the complete absence of all forces and moments tending to induce and to amplify torsional (twisting) oscillations.

In the writer's formulas, the logarithmic increment (or rate of amplification) is found to be proportional to the slope of the static torque graphs. The complete mathematical analysis utilizes, in addition, a supplementary static torque graph obtained with a curved model of the cross section.

In addition to the steepness of the slope, its direction is of critical significance. A negative (downward) slope of torque graph identifies catastrophic torsional instability. This is the dangerous type of instability that was revealed in the torsional oscillations that destroyed the Tacoma Narrows Bridge.

A positive (upward) slope of torque graph identifies a so-called "stable section" in torsion, but such a stable section is also subject to potential aerodynamic oscillations in torsion. In this case the aerodynamic oscillations are non-catastrophic; they are of limited amplitude, from a few inches to several feet, and they occur at low wind velocities. Even such limited oscillations are troublesome and alarming and they weaken the structure by fatigue.

From the foregoing considerations, the conclusion is clear:

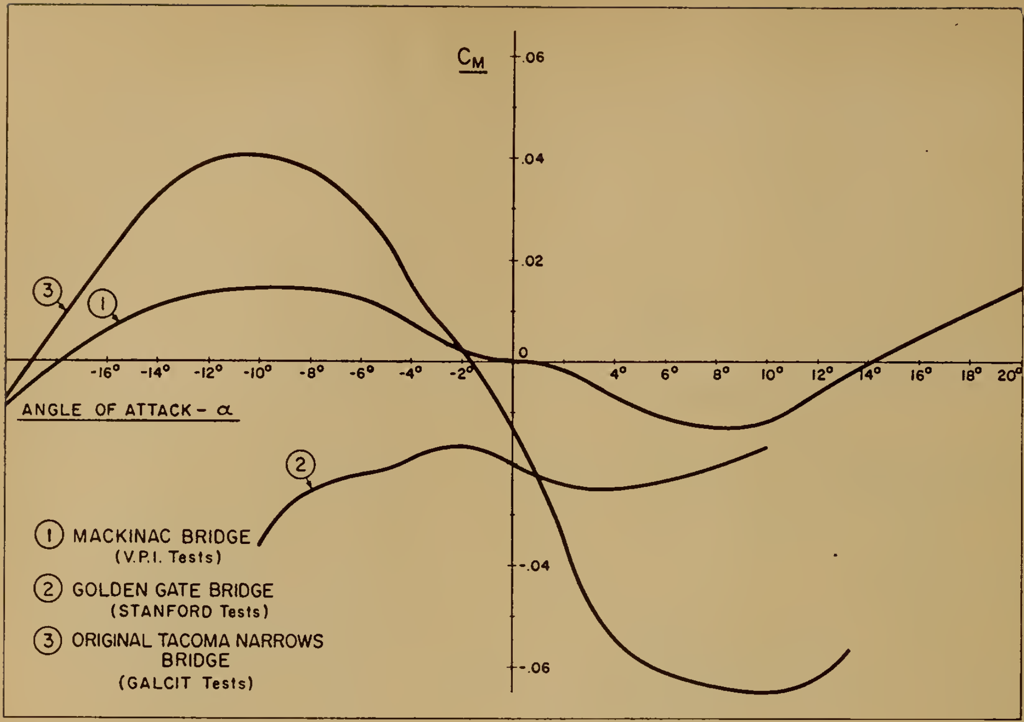

Fig. 4. Comparison of static torque graphs for three suspension bridges.

The ideal bridge section is one that has zero slope of static torque graph. This criterion is parallel to the corresponding conclusion with respect to slope of lift graph.

For comparison and contrast, the static torque graphs for three significant bridge sections are shown in Fig. 4, superimposed and plotted to the same scale. The three bridges represented are the original Tacoma Narrows Bridge, the Golden Gate Bridge and the Mackinac Bridge. This diagram shows clearly the steep negative slope of the torque graph for the Tacoma Narrows Bridge, representing the catastrophic torsional instability which destroyed that structure. In contrast, the diagram shows the flat torque graph for the Mackinac Bridge, indicating ideal torsional stability. Slopes are measured at the middle of the graph, corresponding to horizontal wind and the limited small inclinations of the wind.

In Table II are listed the comparative slopes of the static torque graphs for some notable bridge sections; the idealized airfoil and the ideal bridge section are included for comparison.

Of the sections listed in Table II, the idealized airfoil is the only one having a positive slope of torque graph. For bridge sections, a zero slope or a slight negative slope is preferable. If the lift graph and the torque graph both have a positive slope, the section is vulnerable to coupled oscillations, representing a dynamic combination of automatically synchronized vertical and torsional oscillations. In the case of airfoils (airplane wings and tail surfaces), such coupled oscillations, known as "flutter", are a source of danger and have repeatedly proved disastrous. That is why zero slope of lift and torque graphs, or a slight positive slope of lift graph combined with a slight negative slope of torque graph, represents the ideal for bridge sections, eliminating all possibility of vertical, torsional and coupled instability.

Table II. Slope of Static Torque Graphs

Tacoma (original)	—0.52
Bronx-Whitestone	—0.50
George Washington	—0.19
Golden Gate	—0.13
Mackinac (grid open)	—0.02
Mackinac (grid covered)	0
Ideal bridge section	0
Idealized airfoil	+1.57

Using the respective slopes listed in Table II as a measure of torsional instability, the tabulation shows that the Mackinac Bridge, as designed, is 26 times safer against torsional oscillations than the original Tacoma Narrows Bridge, 25 times safer than the Bronx-Whitestone Bridge, 9.5 times safer than the George Washington Bridge, and 6.5 times safer than the Golden Gate Bridge. For the hypothetical case of the grid completely covered, the foregoing ratios are actually improved, yielding an infinite ratio of superior torsional stability for the Mackinac section.

Combining the data of Tables I and II as a measure of safety against coupled oscillations, the Mackinac Bridge section, as designed, is 6.5 to 350 times safer than the Golden Gate Bridge, and 26 to 183 times safer than the Tacoma Narrows Bridge.

The graphs (Figs. 3 and 4) show how a section of assured aerodynamic stability was selected for the Mackinac Bridge. This simple procedure is the key to the safe, speedy, scientific design of future suspension bridges for assured aerodynamic stability.

The recently completed large-scale wind-tunnel tests on a model of the Mackinac Bridge in the special laboratory at the University of Washington confirm the fact that the Mackinac Bridge has complete and absolute stability against both torsional and coupled oscillations at all wind velocities to infinity and at all angles of attack.

DEPTH OF STIFFENING TRUSS

A suspension bridge ignorantly designed, or one otherwise unsafe aerodynamically, may be made safe by the crude and simple device of providing excessive depth of the stiffening girder or truss.

In 1945, the author of an engineer's handbook, though not a bridge engineer, included in his advertisement the claim that his handbook told how to design a suspension bridge so as to assure its safety against becoming a "Galloping Gertie". His prescription was very simple—to make the truss depth one-fortieth to one-sixtieth of the span. This prescription is technically correct, but it would represent a sacrifice of good engineering in order to cover ignorant design. For all but the shortest spans, it would represent extravagance and would yield needlessly heavy, awkward and ill-proportioned structures.

A more scientific formula has been derived by the writer. It gives the safe recommended depth of stiffening truss for various lengths of span, but adds the saving clause: "unless aerodynamic stability is otherwise assured".

By this formula, the required truss-depth for the 3,800-foot-span Mackinac Bridge, if it were unscientifically designed, would be 46 feet, or 1/82 of the span. But even this depth would be extravagant in cost and wasteful of steel.

For the Mackinac Bridge an ultra-conservative truss-depth of 38 feet was adopted, yielding a convenient ratio of 1/100 of the span. In view of the assured high aerodynamic stability of the design, a shallower truss-depth would have been entirely safe. In a suspension bridge, when correctly designed, the cost increases rapidly with increasing depth of stiffening truss. By reducing the depth from 46 feet to 38 feet, several million dollars were saved.

Because there are many who do not know or understand the fundamental principles of the aerodynamic problem and its solution, the design had to be ultra-conservative and to forego the additional cost-saving through any further reduction of truss depth. A barrage of uninformed criticism and attack had to be overcome. It was necessary to make certain sacrifices in order to retain the confidence of the public, the investors and the insurance companies. The ultra-conservative design was the price that had to be paid in order to sell the project.

DOUBLE LATERAL SYSTEM

As a further contribution to the assured ultra-aerodynamic safety of the Mackinac Bridge, a double system of lateral bracing was adopted. By providing two planes of horizontal bracing, at or near the planes of the top and bottom chords of the stiffening trusses, respectively, and extending over the full length of the suspension bridge, we secure the effect of a hollow rectangular section in torsion. The torsional stiffness of the structure is thereby greatly augmented, together with a corresponding high increase in the structural damping in torsion.

For the Mackinac Bridge, in the light of the scientific design of the cross-section to eliminate any trace of aerodynamic instability, the extra high measure of torsional resistance secured by providing a double lateral system was really not necessary. It was provided in order to be ultra-conservative, as an additional concession to public confidence.

By the addition of the extra plane of lateral bracing, the torsional rigidity of the Mackinac Bridge was increased seven-fold from 115,000 lb. to 832,000 lb. against one-segment oscillation (the main span assumed to deflect in a single segment); and nearly fourteen-fold from 160,000 lb. to 2,200,000 lb. against two-segment oscillation (the main span assumed to deflect in two segments, the mode that wrecked the Tacoma Narrows Bridge).

As a direct result of the manifold increase of torsional stiffness contributed by a double system of lateral bracing, the calculated frequency ratios (ratios of theoretical harmonic frequency in torsional oscillation to theoretical harmonic frequency in vertical oscillation) exceeded 3.5. These high (favourable) frequency ratios were unprecedented and exceeded the available range of the test equipment in the aerodynamic laboratory at the University of Washington. New modifications of the equipment had to be devised and installed before the Mackinac Bridge model could be tested.

The abnormally high calculated frequency ratios for the Mackinac Bridge, resulting from the provision of a double lateral system, constitute a further safeguard against any possibility of coupled oscillations. On account of the high frequency ratios, the wind velocity necessary for such coupled oscillations, even if they were possible, would be fantastically high.

TESTS CONFIRM STABILITY

Soon after the Mackinac Bridge bonds were sold and contractors were notified to proceed with the construction of the bridge, arrangements were concluded in March, 1954, for a thorough aerodynamic investigation by Professor F. B. Farquharson in the Suspension Bridge Laboratory at the University of Washington. The purpose of these additional tests was to secure impartial, authoritative confirmation of the high degree of aerodynamic stability achieved in the design of the bridge. These investigations, costing $15,000, were completed and the results recorded in Professor Farquharson's final report, dated May 20, 1955.

The model used for these wind-tunnel tests was a 1/50-scale section-model, 60¾ in. long, with details of shape reliably duplicated. (See Fig. 5.) The tests were made

Fig. 5. Dynamic model used in the wind-tunnel tests at the University of Washington. Accurately built to 1/50 scale, the model represents a 253-foot section of the Mackinac Bridge.

in a specially built open-jet wind tunnel with a wind-jet 12 feet long and 4 feet high.

The high aerodynamic stability of the Mackinac Bridge exceeded all prior experience in aerodynamic investigations. Professor Farquharson had to revise his test equipment when he found that this bridge had features of stability higher than had ever been previously investigated. In fact, some of the features of stability of the Mackinac Bridge, such as the very high frequency ratio of 3.5 and the high estimated damping of 0.10 for the iced condition were too high to be fully duplicated in the model.

When the model was tested for the normal operating condition of the structure, namely, with the grids in the central portion of the roadway and the sidewalks open, absolutely no motion developed at any angle of attack up to the extreme value of plus or minus 20° (the limits of the wind tunnel) and over the full range of velocities available. These tests were conducted under very low damping conditions (0.005) which would reveal the slightest trace of instability; the actual structural damping in the bridge will be ten to twenty times as high (0.05 to 0.10), emphasizing still more this tested confirmation of complete aerodynamic stability.

The wind-tunnel tests showed conclusively that the Mackinac Bridge, as designed, has complete and absolute stability against vertical, torsional and coupled oscillations at all wind velocities and all angles of attack.

Professor Farquharson also tested the Mackinac Bridge model with all roadway and sidewalk grids closed solid, to represent the hypothetical, abnormal condition of all openings completely closed by ice. For this condition the aerodynamic stability is found to be so nearly perfect that the difference is practically meaningless.

The Mackinac Bridge will have an exceptionally high value of structural damping, resisting any tendency to start oscillations. The high vertical rigidity and the still higher torsional stiffness contribute this high value of the structural damping. The magnitude of the structural damping factor, or logarithmic decrement, will certainly be at least 0.05. Professor Farquharson has estimated for the Mackinac Bridge a structural damping factor of approximately 0.08. For the abnormal condition of all deck openings completely closed by ice and snow, the action of the interlocked ice and the packed snow will contribute further to the structural damping, and for this condition the structural damping may be estimated as 0.10.

Table III

Bridge	Critical Wind Velocity
Bronx-Whitestone (after addition of stiffening trusses)	30 mph.
Golden Gate	40 "
George Washington	55 "
New Tacoma Narrows	76 "
Mackinac (with deck closed)	632 "
Mackinac (with deck open, as designed)	Infinite

For a minimum assumed value of 0.05 for the structural damping, the wind-tunnel tests for the bridge with the deck completely closed show complete and absolute stability against vertical and torsional oscillations at all wind velocities and complete and absolute stability against coupled oscillations at all wind velocities up to 524 miles per hour for the lowest mode of oscillations, 779 miles per hour for the next mode, and 800 miles per hour for the next higher mode.
