Born in Morrisburg, Ont., Mr. Anderson attended Queen's University, Kingston and joined the Federal Department of Public Works in 1914. During the First World War he served overseas with the Royal Naval Air Service and the Royal Flying Corps. Rejoining Public Works on his discharge from war service he was located at Sault Ste. Marie until 1941, acting as district engineer for a time. Moving to Ottawa he was senior assistant engineer for several years before being appointed district engineer for the Winnipeg district. In 1950 he was appointed district engineer at Fort William. Mr. Anderson has been a member of the Association of Professional Engineers, Province of Ontario, for over thirty years.

Frank C. Richardson has been appointed plant engineer of Avro Aircraft Ltd., Malton, Ont. Mr. Richardson graduated in engineering from the University of Toronto in 1935, joined Avro in 1954 as office and technical general supervisor in the plant engineering department. Prior to that he had engaged in engineering positions and on construction projects for General Electric Company, Dominion Tar and Chemical Company and the Aluminum Company of Canada.

Professional Recognition For Management

During the postwar years, the attempts of Canadian industry to keep pace with the country's rapid and persistent development have focussed much attention upon the engineering profession. Unfortunately, the spotlight has been on the profession in general rather than on individual engineers; and in many instances this has given rise to a latent feeling of dissatisfaction among professional engineer employees, particularly in the larger industrial and manufacturing companies. This dissatisfaction has often led to a feeling of frustration, which results in the engineer's turning to new and what appear to be greener fields.

Heavy turnovers in engineering personnel can jeopardize efficient operation. It has been established that job-switching by engineers is frequently the result of frustration which in turn is usually motivated by lack of professional recognition on the part of the employer. Management, in many cases where job-changing is evident, has not provided a climate in which engineers can work happily and effectively while still retaining their professional attitudes. The provision of an amosphere to encourage professional growth would go a long way towards dispelling frustration. An engineer with the "feel" of responsibility and pride in his profession is a greater asset to his employer than is a frustrated man.

A climate that will encourage and nurture professional growth among engineering employees will include:

—recognition of professional engineering as creative work.

—breakdown of a job to ensure that an individual is given the feeling of responsibility for a specific part.

—acknowledgement of achievement by the use of the professional seal, or by the signature of the individual on a specific part for which he is responsible.

Proper use of engineering personnel is a two-way street. It can be improved by good communications both ways, between management and engineers. Top management knows that professional engineer employees do better work when kept advised of long-term planning and company policy.

Communications should ensure that the ideas of top management reach the individual engineers and that the engineers' ideas reach a top level. Communications, like filing systems, require constant checking.

To The Professional Engineer

An engineer shows his professionalism by a ready acceptance of responsibility and a professional attitude. To begin with he is ambitious for himself; but the drive in him for his own welfare becomes channelled into a deep interest in the progress of his company and his profession. This broadened interest in its turn, resolves itself into a broader point of view than that of mere personal self-interest. The logical and ultimate result is a fusion of ambition with professional pride, in his association with the management team.

It is probable that much of the "engineer frustration" so widely commented on lately is caused by the engineer's hesitation to accept an adequate amount of responsibility while seeking the recogniion he believes he deserves. No one in any profession is entitled to recognition unless he is willing to assume responsibility proportionate to his job.

The fact that so many engineers advance into management positions can be attributed to their over-all type of thinking. They are the engineers who have successfully proved ability to accept many and diversified responsibilities.

An engineer, as an individual, is responsible for the success of his own career. The key to his success is the manner in which he sells himself to management. Paraphrasing the adage: "See yourself as others see you," an engineer might ask himself: "How does my employer rate me as an engineer?"

The rate of an engineer's professional development is directly linked with his professional recognition in the eyes of management. Without development in himself he cannot obtain recognition by others. And to attain both, the engineer must first ask himself: "Am I aware of my responsibility to myself and my employer?" And then he must implement his awareness in action.

Abstracted from a bulletin of the Association of Professional Engineers of Ontario, June 1956.

BRITISH COLUMBIA

Engineers in the News

W. B. Moffat has accepted a position as staff consultant to Western Plywood Co. Ltd. Mr. Moffat had been chief engineer of Sidney Roofing and Paper Company at Victoria, B.C.

H. P. Pfeifer will be an advisor on the United Nations Technical Assistance Mission to Ceylon, commencing Aug., 1956. Mr. Pfeifer was chief electrical field engineer for International Engineering at Kemano, B.C. a few years ago and until recently had a consulting practice in Oslo, Norway.

L. E. Johnson, until recently with the B.C. Engineering Co. is with the General Construction Company working on a project in the Dawson Creek area.

R. B. Fahrig of the Texas Petroleum Company is in Caracas, Venezuela.

Murray Munsell has left Alberni, B.C. to accept a position on the engineering staff of the Powell River Company, Powell River, B.C.

H. T. Miard is now assistant deputy minister, Department of Highways, Victoria, B.C.

D. D. Pringle, formerly mine superintendent at Copper Mountain, now becomes general superintendent in charge of operations at Copper Mountain, Allenby and Princeton, B.C.

L. E. Gower has left the Engineering Services Division of the B.C. Forest Service to accept the position of chief engineer of American Fabricators Limited. This will necessitate a move from Victoria to Burnaby, B.C.

D. A. MacLean has accepted a position in the power development branch of the B.C. Power Commission. Mr. MacLean had been senior hydraulic engineer, hydraulic investigations division, water rights branch of the organization.

H. L. Hinchcliffe, of the Shell Oil Company in Toronto has been promoted from manager distribution, head office, to manager of head office marketing operations.

C. R. de Lannoy has accepted a position as project engineer with the B.C. Power Commission on their upper Campbell Lake development. He had been with the Saguenay-Kitimat Company.

Eugen Ruus has left for Sweden. He intends to spend the next twelve months in that country before returning to the B.C. Engineering Company, Vancouver, where he has been employed for the past several years.

J. B. Twaddle has left the employment of Consolidated Mining & Smelting Co. at Trail and is now employed by Dutton-Williams Bros. of Calgary.

E. A. Peura has accepted a position with the Willock Manufacturing Company. He was previously employed by the Vancouver Rolling Mills.

William Ruck has left the employ of the Consolidated Mining and Smelting Company Limited as development engineer, acid & absorption plants, (chemical-fertilizer division) to join the new firm, North West Nitro-Chemicals Limited, as development engineer. He will move residence from Rossland to Medicine Hat.

W. J. Swanson, resident engineer with the Foundation Company of Canada, has been transferred from his job on the D.E.W. Line to construction of a pulp mill at Thurso, Que.

J. O. Hemmingsen has been appointed manager of logging, western district, for MacMillan & Bloedel, (Alberni) Limited.

Walter Johnson, western division engineer of Rilco Laminated Products, Incorporated has sent word that he has been transferred from the Tacoma office to the sales office in Los Angeles. He will be engaged in promotion, sales and service of engineered timber construction in the Southern California area.

J. C. Oliver, City Engineer, Vancouver, has accepted an appointment as Comissioner of Works on the new board of administration, City of Vancouver.

Randolph Martin, Deputy City Engineer, Vancouver, has taken over the duties of city engineer relinquished by Mr. Oliver. The change was effective July 1.

Professional Development in Canada

(Continued from Page 1195)

portunity for an interchange of ideas amongst the various branches of engineering. It presents an unparalleled opportunity for young engineers to become acquainted with other engineers. Such associations contribute to professional development.

How have these various avenues for professional development been utilized? As a result of the Monteith Report, a director was chosen to inaugurate a course at the University of Cincinnati in 1953. It follows closely work on a post-graduate level in engineering. To date it has been the only such course in the United States.

Professional development programs in Canada are based on continued education of a liberal, non-technical nature. The programs are planned to provide courses which cannot be duplicated at universities in the formal curricula. The organization and operation of Canadian groups varies with the locality, governed largely by the number of interested engineers in the area, and the availability of competent speakers and moderators. Some areas have sufficient engineers to run a course every second or third year. Others have the membership but find it desirable to ask a university to operate a lecture series for them. Of necessity these courses are more formal than those conducted by the membership. In each case however, the basic aim of continuing the young engineer's education is present.

Canadian professional development programs owe their existence to Col. L. F. Grant, field secretary of the E.I.C., whose untiring efforts have produced gratifying results and assisted many engineers through the post-college slump. His foresight in adapting the principles of the Monteith Report to Canadian requirements is apparent.

Organization of Hamilton Branch

The Hamilton Branch of the E.I.C. first sponsored a one-year program in 1951. From the outset it has been well organized. The directorate consists of the director, secretary, treasurer, past director and group chairmen. All matters of general program policy are conducted by the directorate, while individual group business is the responsibility of the group committee through its chairman. This provides the opportunity for the addition of new groups without affecting the whole organization. Since 1951 the Hamilton program has expanded to a four-year course. Membership has increased from thirty in the first year to one hundred and forty in 1956. The content of each group course is being continually assessed to determine how it may be improved. Suggestions from the membership for changes during the year are given careful consideration and may be adopted if beneficial to the group.

Diversity of subjects covered in the groups has made the program attractive and interesting. Group I covers a wide range of topics, such as culture, vocal expression and civil defence. Group II specialized on five major topics, human relations, government, horizons, public speaking, and business management. Each topic is subdivided into three or more subjects. Group III considers business management intensively under five principal headings, such as financial controls, production, and marketing. Group IV studies administrative practices under human relations and business policy. The case study method with a moderator is used to great advantage almost exclusively in this course.

During the year there are two joint meetings of all the groups. In the Fall the first meeting, known as Registration Night, introduces the program to the newcomers and enables members to register in the various groups. The second occasion is known as Employer's Night. The business superior of each member, and the leaders of local industry are invited to hear an outstanding Canadian engineer on a subject of general interest. The aims and operation of the program are explained. This meeting has been one of the highlights of the program.

The directorate is very much indebted to local industry for its genuine interest and support by encouraging its young engineers to participate, and by providing many of the fine speakers and moderators whom we have enjoyed.

Written Constitution a Guide

The Hamilton program reached a significant stage in its development this year with the adoption of a written constitution. Prepared entirely by the members, it is the first of its kind. As such it is anticipated that it will serve as a guide to other groups across the country.

It is not possible to over-emphasize the fact that technical competence is the necessary but not the sufficient condition for becoming a professional engineer. In Canada's expanding economy which is so dependent on industrial growth, the engineering profession will be expected and indeed required, to assume more power and influence. The young engineers of today will be the industrial leaders of tomorrow, making it imperative that they be prepared now for advancement.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Henry Waldron McLeod, M.E.I.C., who retired from the Canadian Pacific Railway in 1950 as principal assistant engineer for the prairie and pacific regions, died in Vancouver in 1955. He had been living there since the beginning of his retirement.

An eastern Canadian, from St. John, N.B., born on January 17, 1884, he received his education at St. John high schools and the University of New Brunswick. There he obtained a civil engineering degree. With the Intercolonial Railway, Moncton, and the Pennsylvania Railway, Columbus, Ohio for a total of three years' experience, he joined the Canadian Pacific Railway in 1906, beginning a career that was to last for forty-four years. During this time Mr. McLeod carried out his work in Calgary, Medicine Hat, Alta., Vancouver and Winnipeg. In 1929 he was principal railway assistant engineer at Winnipeg.

He was a life member of the American Railway Engineering Association and was one of the charter members of the Association of Professional Engineers of Manitoba. Active in the affairs of the Institute, he served as chairman of the Winnipeg Branch in 1948.

Mr. McLeod joined the Institute in 1913 as an Associate Member. He was transferred to Member in 1940, and granted Life Membership in 1949.

Angus McGugan, M.E.I.C., member of the three-man Canadian Maritime Commission died suddenly, in Ottawa, on July 7, 1956.

Mr. McGugan came to this country from his native Glasgow, where he was born on January 28, 1900. He attended secondary schools in that city and studied engineering at the Royal Technical College, Glasgow, from which he graduated in mechanical engineering in 1921.

Serving a five-year apprenticeship while also attending the Royal Technical College classes, he gained experience in mechanical engineering with two of his country's shipbuilding concerns, Fairfield Shipbuilding and Engineering Company Limited and the firm of Parsons and Brown-Curtis, and remained with the latter a year after earning his qualifications in 1921.

Transferring his services to Canada he was from 1923 to 1926 marine engineer officer with Canadian Pacific Steamships Limited. In 1926 he became associated with the firm of Williams and Wilson Limited, engineers and manufacturers, Montreal, where, from 1926 until the beginning of World War II he was engaged in design and sales engineering.

With the Department of Munitions and Supply at the beginning of the war, in 1940, he served as chief technical officer with the Inspection Board of the United Kingdom and Canada and in 1941 he became director of the naval shipbuilding branch of the Department. In April 1944, on the formation of the Canadian Shipbuilding and Ship Repairing Association, Ottawa, he became its first manager.

His appopintment as member of the three-man Canadian Maritime Commission was made in 1948.

Mr. McGugan joined the Institute as an Associate Member in 1938, and was transferred to Member in 1940.

W. R. Manock, M.E.I.C., who retired from the presidency of Horton Steel Works Limited in 1951, died in Chicago, Ill. on May 3, 1956.

From Farmer City, Illinois, he was born on August 25, 1886, educated at the University of Illinois and graduated with a B.Sc. in civil engineering in 1910. Two years later he became associated with Chicago Bridge and Iron Company in Chicago, transferring to the Canadian subsidiary, Horton Steel Works, in 1924 as manager of operations. In 1926 he was made secretary-treasurer of the company and in 1936 became vice-president and managing director. He was appointed president of Horton Steel Works Limited in June 1945.

A past vice-president of the Institute for the province of Ontario, in 1946, he also served as councillor for the Niagara Peninsula Branch from 1938 until 1942.

Mr. Manock joined the Institute as an Associate Member in 1927, and transferred to Member in 1940.

W. Arthur Wood, M.E.I.C., chief engineer and works manager with the Harrington Tool and Die Company Limited, Lachine, Que., died suddenly in Victoria, B.C., on July 22, 1956.

Born there on September 18, 1910, he had his schooling at the Victoria High School and studied for a B.A.Sc. degree at the University of British Columbia. Graduating in 1932 he found work shortly after with the Department of National Defence at Esquimalt, B.C., as a civilian draughtsman. In 1937 he joined the Vancouver firm of Pumps and Power Limited as draughtsman. Three years later he transferred his services to Defence Industries Limited as mechanical draughtsman in the layout of processing equipment for a short period, and in 1941 began his association with the Harrington Tool and Die Company Limited, Lachine, Que. Named engineer in charge of the design and draughting office, that year, he was in 1946 named works manager.

Mr. Wood joined the Institute in 1941.

Guy Joseph Desbiens, S.E.I.C., of Three Rivers, Que., died in an accident on May 27, 1955.

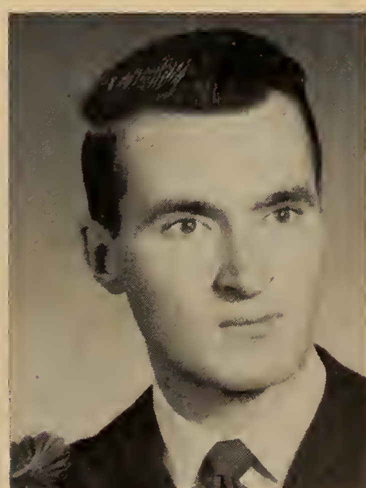
Born and educated in Three Rivers, he attended the Academy de La Salle and was among the graduates of the Ecole Polytechnique, class of 1955, in mining geology.

Mr. Desbiens had been employed with the Malartic Gold Field Mine, and was at Lac Matchi-Manitou at the time of the accident.

He joined the Institute as a student in 1950.

H. W. McLeod, M.E.I.C.

W. R. Manock, M.E.I.C.



G. J. Desbiens, S.E.I.C.

Personals

News of the Personal Activities of Members of the Institute.

Professor G. Ross Lord, M.E.I.C., has been appointed head of the department of mechanical engineering at the University of Toronto.

Professor Lord was born in Peterborough, Ont., and was educated at the University of Toronto, where he obtained his B.A.Sc. degree in 1929, and at the Massachusetts Institute of Technology. He studied in Berlin as Freeman Fellow of the American Society of Mechanical Engineers, and also at Munich and Karlsruhe. He obtained his Ph.D. from the University of Toronto in 1939.

A Member of the Association of Professional Engineers of Ontario since 1937, Dr. Lord was its president in 1946. He is also a member of the American Society of Mechanical Engineers, and was chairman of the Ontario Section last year. His other affiliations include the American Waterworks Association and he has been on the North York Planning Board since 1952.

Dr. Lord is a member of the Senate of the University of Toronto. He has served as consultant to the Ontario Department of Planning and Development on Flood Control since 1945, and to the Ontario Hydro Commission since 1937.

N. R. Crump, M.E.I.C., president of the Canadian Pacific Railway Company, Montreal, has been named "International Management Man of the Year", by the National Management Association.

Mr. Crump had his preliminary education in British Columbia and spent his very early years as a machinist apprentice with the C.P.R. in that province. Later, he worked at Winnipeg's Weston railway shops, began night university courses and from there went on to Purdue University, Indiana. In 1929 he returned to the C.P.R. in Winnipeg with B.Sc. and M.E. degrees.

During the next nine years he held various positions in Saskatchewan and Alberta, and in 1939 was moved to Winnipeg to become chief mechanical draughtsman for western lines. The following year brought him the appointment of assistant superintendent of motive power for western Canada.

Named assistant to the vice-president in Montreal in 1942, he was transferred to Toronto to carry out the responsibility of general manager for Ontario in 1943. Within a few months he took office as manager of the eastern lines.

Elected vice-president five years later, he held this position until 1955 when he became C.P.R. head.

Commodore (E) A.C.M. Davy, R.C.N., M.E.I.C. has retired from an active naval career after thirty-nine years' service. He will undertake an appointment with Columbia Engineering Company of Vancouver.

Originally from Montreal, Commodore Davy attended naval college at Halifax and then went on to England for training at the Royal Navy Engineering College at Devonport, England, in 1923.

Holding numerous appointments at naval stations across the dominion, at Halifax, Esquimalt, Vancouver and Kingston, through the years he has also served as director of naval engineering with the Department of National Defence, Ottawa, in the early thirties, and, during World War II, held the responsibilities of wartime director of shipbuilding for the R.C.N.

In 1946, then a captain, he was among those honoured with the award of the O.B.E.

Commodore Davy was appointed deputy chief of naval technical services and engineer in chief at naval headquarters, Ottawa, in 1949.

Lieutenant Colonel H. H. Minshall, M.E.I.C., for many years associated with Dominion Bridge Company and latterly erection manager in Vancouver, has formed the company of H. H. Minshall and Associates Limited, in that city. As president, he will offer services in the construction field, based on over thirty years of construction and engineering experience.

Lieut. Col. Minshall joined the staff of Dominion Bridge Company's Pacific Division in 1929 and with the exception of leave of absence for the duration of World War II, he has had twenty-seven years' service with the organization. Starting in the production and erection department, he has been instrumental in the erection of all major bridge projects carried out in British Columbia by his company since he joined it. On the Pattullo and Lion's Gate bridge, he was re-

Commodore (E) A.C.M. Davy, R.C.N., M.E.I.C.

Lieut. Col. H. H. Minshall, M.E.I.C.

sident engineer throughout the entire construction period. Vancouver's most recent Granville Street Bridge was built during his office as manager of the erection department.

Embarking on his construction career after his graduating from the University of Toronto, he was associated with the Northern Construction Company and J. W. Stewart Limited, Vancouver, in 1924, and with the Sydney Junkins Company of Vancouver and Winnipeg.

Dr. Thomas H. Hogg, M.E.I.C., internationally known consulting engineer and past president of the Institute, has been elected a director of the Brazilian Traction, Light and Power Company Limited.

Dr. Hogg was chairman of the Ontario Hydro-Electric Power Commission from 1937 to 1947 and is a director of a number of Canadian companies, including Sheritt Gordon Mines Limited, Canadian General Investments Limited, Chartered Trust Company, British Newfoundland Corporation Limited and Phillips Electric Company Limited.

Dr. Hogg was president of the Institute in 1940.

Lewis J. B. Forbes, M.E.I.C., president of Pilkington Bros. (Can.) Limited, of Toronto, has been elected to the Board of Directors of Canadian Vickers Limited.

Mr. Forbes is president of several Canadian firms and of the Association of British Manufacturers and Agencies. He was also elected a vice-president of Canadian Vickers Limited.

Professor Raymond Boucher, M.E.I.C. A major appointment at the Ecole Polytechnique, engineering school affiliated with the University of Montreal is that of Professor Raymond Boucher, head of the hydraulics section of the department of civil engineering who has been named chairman of the department of civil engineering.

Professor Boucher holds a master's degree in civil engineering from the Massachusetts Institute of Technology as well as an initial degree obtained at the Ecole Polytechnique and has been full professor of hydraulics and head of the section at Ecole Polytechnique since 1944. In 1949 Professor Boucher entered private practice in partnership under the name Boucher, Cartier, and Leclerc, consulting hydraulic engineers.

Professor R. Boucher, M.E.I.C.

E. R. Jacobsen, M.E.I.C., was recently appointed president of Cia. Meridional de Mineracao, the U.S. Steel Corporation mining subsidiary in Brazil. He will continue to act as president of Brazaço S/A., the commercial subsidiary of the U.S. Steel Export Company. This year Mr. Jacobson is also president of the American Chamber of Commerce in Sao Paulo.

I. R. Tait, M.E.I.C. consulting engineer, Canadian Industries Limited, was honoured this summer at the graduation ceremonies of Sir George Williams College, Montreal. He was presented with an honorary membership in the first graduating class of Sir George Williams, in honour of the active role he has played in the progress of the college. A governor, he is also chairman of the building committee and has been involved in the construction of the new college building in Montreal.

V. E. Vaughan, M.E.I.C. The award of the 1956 Franki Fellowship for graduate research in soil mechanics by the Franki Compressed Pile Company of Canada Limited has been made to V. E. Vaughan of the instructional staff of the Department of Civil Engineering, Nova Scotia Technical College, Halifax.

A native of Halifax and graduate of the above named college, Mr. Vaughan has been a member of the staff since 1946. He has completed graduate studies in soil mechanics at the University of Maryland and is working for a master's degree. The subject of his research under the Franki Fellowship, which is designed to stimulate and encourage the development of soil research by engineering graduates, will be the "Study of the Relationship Betwcen Energy per Blow and Compaction of Sands."

V. E. Vaughan, M.E.I.C.

T. C. Macnabb, M.E.I.C. Chairman of the Nipissing and Upper Ottawa Branch of the Institute this year is T. C. Macnabb of North Bay, Ont., assistant district engineer with the Canadian Pacific Railway.

A native of Manitoba, Mr. Macnabb had his schooling in Winnipeg schools, Earl Gray's School and United College, and then went on to engineering studies at the University of Manitoba. He graduated with a bachelor of Science degree in civil engineering, class of 1940. Many years with the railway following high school and in his undergraduate years, Mr. Macnabb saw service across the four western provinces. On graduation he was permanently employed in Toronto, but spent brief periods in Montreal and London, Ont. In 1944 he received the appointment of assistant special engineer in Montreal, and two years later was named special engineer in Toronto. He received his present appointment in 1952.

T. C. Macnabb, M.E.I.C.

Mr. Macnabb served on the executive of the Nipissing and Upper Ottawa Branch in 1954 and 1955.

He is a member of the Corporation of Professional Engineers of Quebec.

Arthur C. Abbott, M.E.I.C., was recently elected president of the Canadian Electrical Association for the 1956-57 session.

Vice-president in charge of distribution with the Shawinigan Water and Power Company in Montreal, Mr. Abbott has been for many years associated with the organization. He graduated from McGill University in mechanical and electrical engineering in 1925 and 1926 and was then placed on Shawinigan's staff as a student apprentice. In 1928 he was named assistant superintendent of the Beauharnois Electric Company, Ltd., Valleyfield, Que. The following year he was superintendent of the company.

Appointed distribution engineer for Shawinigan Water and Power Company's

*There's been a Revolution in Rubber

Can POLYSAR Add New Values to Your Products?

Yes, Polysar certainly can, because *there's been a revolution in rubber! Now...with Polysar chemical rubbers and the help of Polymer's research chemists . . . you can have the material that will give your products a strong competitive advantage.

Whether rubber now enters into your products or not, it will pay you to investigate the possibilities of Polysar. You'll find—as have manufacturers in 40 countries—that Polysar can provide new product qualities and production economies.

Polymer Corporation Limited—makers of Polysar rubbers—has the largest industrial research and development division in Canada. Why not make full use of these facilities and learn how Polysar can add new values to *your* products?

Write to our Sales and Technical Service Division, Sarnia, Canada.

Here's why POLYSAR Rubber Is Used In Floor Tiling

Polysar SS-250 and Krylene NS—special purpose polymers—have made possible the rubber tiling illustrated—richer in colour, longer wearing, and more resilient underfoot.

Manufacturers specify the combination of Polysar SS-250 and Krylene NS because it is reliably uniform . . . has a lighter white colour for easier, more accurate colour control . . . is non-staining and non-discolouring . . . and possesses good processing characteristics.

Polysar rubbers have improved floor tiling—they can improve your products, too.

newly formed commercial and distribution department in 1930, he has since that time held various appointments including those of electrical engineer, commercial and distribution department, and during the war acted as priorities officer for the company in its dealings with the department of munitions and supply. In 1945, returning to the commercial and distribution department he was responsible for general supervision over operation and engineering. He was named assistant manager of the department in 1947. He became manager three years later, and in 1952 received by his present appointment.

Mr. Abbott also holds membership in the Corporation of Professional Engineers of Quebec and the American Institute of Electrical Engineers.

Lillian Gilbreth, HON., M.E.I.C., was among seventeen women recently presented with a "Women of Achievement" award by the American Federation of Soroptimist Clubs.

Dr. Gilbreth was one of six eminent engineers on whom honorary membership in the Institute was conferred in December 1949. Two years ago she was presented with the George Washington Award for her "oustanding contribution to engineering and management, and for unselfish devotion to problems of the handicapped". A top engineering honour, presented for the first time to a woman, the award was made by the Western Society of Engineers and the American Societies of Electrical Mining, Civil and Mechanical Engineers.

Among her many accomplishments, as author, lecturer and engineer, Dr. Gilbreth has been president of the consulting engineering firm of Gilbreth Inc., Montclair, N.J. With her husband she pioneered the field of efficiency engineering and management and the principles and techniques of motion study.

Steve Dembicki, M.E.I.C.

Steve Dembicki, M.E.I.C., has been appointed director of engineering for the management consulting firm of Alliance Management Associates Limited with head offices in Montreal.

Mr. Dembicki is a graduate of the University of Alberta and holds a Master of Engineering degree from McGill University.

With the Verdun plant of Defence Industries Limited on various engineering projects during the war years, he was later associated with Dominion Electrohome Industries, Kitchener, Ont., as an industrial engineer. In 1951 he was associated with the head office industrial engineering group of Canadian Industries Limited and in the latter position he travelled between C.I.L's various plants on industrial engineering assignments. For the past two years Mr. Dembicki has been employed with the Drummondville plant of Canadian Celanese Limited where he organized, trained and managed an industrial engineering department.

Mr. Dembicki served on the executive committee of the Kitchener Branch of the E.I.C. in 1950 and has been

active on the membership committee of the Corporation of Professional Engineers of Quebec.

Colonel R. J. Carson, M.E.I.C., formerly command engineer at Western Command headquarters in Edmonton, with the rank of Lt. Col., has been promoted to the rank of Colonel, with the R.C.S.M.E., Camp Chilliwack, B.C.

Col. Carson has previously served as command engineer officer with Eastern Command in Halifax, and as G.S.O.1 to the chief engineer of the Canadian Army.

W. D. Pippy, M.E.I.C., 1955 secretary-treasurer of the Halifax Branch of the Institute has accepted a position with the Shawinigan Water and Power Company at Trois Rivières, Que. His duties commenced August 1.

With the Nova Scotia Light and Power Company Limited at Halifax recently, Mr. Pippy has also held the position of superintendent of the Edison Electric Light and Power Company Limited, at Springhill, N.S. in 1953. Much earlier in his career, in 1943, he was on the staff of the Nova Scotia Light and Power Company Limited. He graduated from the Nova Scotia Technical College with a B.Eng. in electrical engineering, class of 1937.

Dr. Bernard Ulrich, M.E.I.C., formerly general manager of the St. Lawrence Cement Company, both at Quebec and Villeneuve, Que., has been named executive vice-president of the company at Clarkson, Ont.

Dr. Ulrich followed his engineering studies at the Swiss Federal Institute of Technology, in Zurich, Switzerland. He is a 1942 graduate.

B. R. Lewis, M.E.I.C., formerly assistant superintendent of production engineering with Ford Motor Company of Canada Limited in Windsor, Ont., has accepted a position with Canadian Westinghouse Company Limited, Hamilton, Ont. His duties will be those of director of manufacturing and equipment engineering, with the headquarters manufacturing staff.

Mr. Lewis is a 1947 graduate of the University of Saskatchewan. He studied engineering physics.

J. H. McIntosh, M.E.I.C., known at one time in engineering circles in Canada as a student of the University of Toronto, and in British Columbia as an engineer with the British Columbia Cement Company Limited during the early thirties, now holds an executive status with two African cement companies. He is managing director of the Salisbury Portland Cement Company Limited, Salisbury, Southern Rhodesia, and director and consultant of Whites Southern African Portland Cement Company Limited, Johannesburg.

Serving with the 5th (B.C.) Coast Regiment R.C.A., during the war, as a major, he became associated with Portland Cement Manufacturers Limited in England on demobilization, in 1945.

Two years later he was works director in Johannesburg, S.A., with Whites (S.A.) Portland Cement Company Limited.

In 1951 he held the position of director with the organization.

John C. Hamilton, M.E.I.C., works manager for Canadian Resins and Chemicals Limited, at Shawinigan Falls and Ste. Therese, Que., since 1955, has been named vice-president-manufacturing.

Mr. Hamilton joined the company in 1943 shortly after graduating from Queen's University. He served as production supervisor and general superintendent of plants before undertaking his more recent appointments.

A. Sandilands, M.E.I.C., western regional manager of Phillips Electrical Company Limited in Winnipeg for the past three years has recently been named sales manager with the firm's head office in Brockville, Ont.

A graduate of the University of Manitoba, Mr. Sandilands was for a number of years associated with Automatic Electric (Can.) Limited as branch manager in Edmonton and Winnipeg. Earlier in his career he was on the staff of Canadian Telephones and Supplies Limited and the Power and Mines Supply Company, Regina and Edmonton. In 1940 he was assistant secretary of the Industrial Development Board of Manitoba.

R. W. Johnson, M.E.I.C., is in Jamaica, where he is with Sprostons (Canada) Limited as construction manager.

Earlier in his career associated with the Aluminum Company of Canada, he was known at Arvida, Que., and also at MacKenzie, British Guiana, S.A., as manager of the Demerara Bauxite Company Limited.

F. A. Davis, M.E.I.C., has accepted an apppointment as manager for the Toronto

CRAVEN BROS
LTD

office of Catalytic Construction of Canada Limited. The firm has its offices at Sarnia, Toronto, and Montreal.

F. A. Davis, M.E.I.C.

Experienced in the petroleum field, Mr. Davis was with the British American Oil Company for a number of years at Montreal and Toronto and in 1946 rose to the position of chief process engineer, Toronto. He worked in that capacity for some time.

A Queen's University graduate of 1940, Mr. Davis joined the firm that year.

John C. V. Bishop, M.E.I.C., formerly of the North Shore and Labrador Railway Company, Que., where he filled the position of assistant chief engineer, has joined the firm of Racey, MacCallum and Associates Limited, in Montreal.

Mr. Bishop is a graduate of the Royal Military College, Kingston class of 1939.

Dennis P. Herring, M.E.I.C., is the recent choice of the City of Belleville for the newly created post of city manager.

With the Polymer Corporation at Sarnia, Ont. for a number of years, he held the position of senior project engineer. Then, in 1954, he went into private con-

D. P. Herring, M.E.I.C.

sulting engineering practice, Hamilton, Ont.

Mr. Herring was formerly chairman of the Sarnia Hydro-Electric Commission and president of District 8, Ontario Municipal Electric Association.

He is a graduate of the University of Saskatchewan, class of 1942.

J. G. Dickinson, M.E.I.C. A recent appointment on the staff of the Northern

J. G. Dickinson, M.E.I.C.

Electric Company Limited is that of J. G. Dickinson who has been named assisant marketing manager with the general department of the company's sales division.

With the Northern Electric Company Limited all his graduate career, he joined the firm in Montreal in 1946 on graduation from the University of Manitoba. At first working as wire and cable sales specialist, later in 1950 he went to the mid-western district as wire and cable overhead and underground and power apparatus sales specialist. In 1951 he became power apparatus sales manager in that district and was in 1952 granted leave of absence to attend the Harvard Graduate School of Business Administration. He obtained an M.B.A. degree in 1954. In the same year he was named manager of marketing research.

D. F. Rhodes, Affiliate E.I.C., after five years in Montreal as chief research chemist with the lubricating oil and grease plant of Canadian Oil Companies, Limited, has moved to Sarnia, Ont., where he is assistant to the company's manager of manufacturing.

Mr. Rhodes has been associated with Canadian Oil Companies, Limited for twenty years, since leaving McMaster University, a graduate in mathematics and physics.

Lester W. Ziegler, M.E.I.C., has taken a position as staff specialist in the plant engineering department, Chrysler Corporation of Canada, at Windsor, Ont.

Mr. Ziegler was formerly with the Ebersol Farm Equipment Company, Mil-

verton, Ont., as general manager and in charge of engineering.

He obtained a B.Sc. degree in mechanical engineering from the Tri-State College, in 1941.

A. I. Wotherspoon, M.E.I.C., a Glasgow University graduate, class of 1949, is structural engineer with Durnford, Bolton, Chadwick and Ellwood, consultant architects, in Montreal.

Mr. Wotherspoon has been known in Canada in connection with his work with Dominion Bridge Company Limited in Montreal, and the Sault Structural Steel Company Limited, Sault Ste. Marie, Ont.

J. A. Hansford, M.E.I.C., who was formerly with the Hydro Electric Power Commission of Ontario has received an appointment with the Bell Telephone Company in the Mid-Canada Defence Line at Fort McMurray, Alberta. His work is that of supervisory engineer.

Leslie Keith, M.E.I.C., is with Blakeburn Constructon Limited, at Terrace, B.C.

Mr. Keith was at one time associated with the Civil Aviation branch of the Department of Transport in Vancouver. He also served the Department in Edmonton and Whitehorse.

R. C. Bezanson, M.E.I.C., has accepted a position with Montreal Engineering Company Limited.

A graduate of Dalhousie University and the Nova Scotia Technical College, class of 1951, Mr. Bezanson was at an earlier date associated with the Dominion Steel and Coal Corporation in Sydney, N.S., in connection with The Seabord Power Plant.

A. F. Gregory, M.E.I.C., a 1950 graduate from the University of Toronto in geological and chemical engineering has taken up work with the Sherritt Gordon Mines Limited, at Lynn Lake, Man.

Last year Mr. Gregory worked as a geologist in the exploration division of the Eldorado Mining and Refining Limited, at Eldorado, Sask.

G. R. Pritchard, M.E.I.C., has been appointed manager of the refrigeration and air conditioning division of John Inglis Company Lmited.

Mr. Pritchard joined the John Inglis Company Limited in 1947 and was until recently manager of the boiler and pressure vessel department. He had previously been associated with Canadian Allis-Chalmers and Canadian General Electric Company.

He graduated from the University of Manitoba in 1937 and is a member of the Associations of Professional Engineers of Ontario and Alberta.

L. E. Willis, M.E.I.C., has received an appointment as maintenance engineer for the City of Calgary.

With the Department of Public Works of British Columbia for a number of years, he was district engineer in Kelowna, B.C., in 1948 and in 1953 served as a divisional engineer with the provincial government.

Mr. Willis is a University of Alberta graduate in civil engineering.

John Macfarlane Bedington, M.E.I.C., a University of Edinburgh graduate has accepted employment with Perini Quebec Inc., at Labrieville, Que.

Mr. Bedington was last year associated with the construction division of the Hydro Electric Power Commission of Ontario, at Toronto, where he was an estimating engineer.

D. A. Fraser, M.E.I.C., who has held the position of roadmaster at Swift Current, Sask., with the Canadian Pacific Railway, has receved a transfer to Winnipeg. He has been assigned to duties of special engineer.

A graduate of the University of British Columbia in 1945, Mr. Fraser has spent a number of years with the company across Western Canada.

H. J. Barton, M.E.I.C., has moved from Dalhousie, N.B., where he was a member of the staff of the New Brunswick International Paper Company, to Gatineau, Que. He is now associated with the Canadian International Paper Company.

Mr. Barton is a Queen's University graduate, class of 1943.

René Dupuy, M.E.I.C., is now associated with the Montreal firm, Quemont Construction Inc.

Formerly with the Mitis Construction Company Limited, at Rimouski Que., in 1951 Mr. Dupuy became director and vice-president of that concern.

E. S. Babinszki, M.E.I.C., has accepted a position with Sandwell and Company, consulting engineers in Vancouver.

Mr. Babinszki has been employed by the Riverside Iron and Engineering Works Limited in Calgary since 1954. He received a diploma in mechanical engineering from the Stuttgart Institute of Technology in 1947.

Gordon F. Bayne, M.E.I.C., has joined the staff of Atlantic Sugar Refineries Limited in St. John, N.B. He was associated with Defence Construction (1951) Limited as project engineer in charge of the company's Chatham, N.B. office for some time previously.

Mr. Bayne received a degree in mechanical engineering at Queen's University in 1948.

H. G. E. Rhodes, M.E.I.C., has joined the staff of the George A. Fuller Company in New York City.

Briefly with the special contracts division of the Bell Telephone Company of Canada at the Pas, Man., this year, and the firm of Morrison, Hershfield, Millman and Huggins, in Toronto, he has also carried on private consulting work and has been associated with the City of Regina's engineering department.

L. W. Swain, M.E.I.C., formerly chief design engineer with W. C. Wood Company Limited in Guelph, Ont., has ac-

cepted an appointment in Galt with the firm of Babcock-Wilcox, and Goldie-McCulloch, steam power plant equipment and accessories manufacturers.

B. W. Anderson, M.E.I.C., employed with the St. Regis Paper Company, Montreal, is now associated with the firm at Cap de la Madeleine, Que.

Mr. Anderson is a McGill University graduate, class of 1944.

Leon Baskin, M.E.I.C., is with Universal Geotechnique Limited, in Toronto.

He was employed as an engineering geologist with H. G. Acres and Company Limited, construction engineers in Niagara Falls, Ont., in 1955.

Mr. Baskin is a Fellow of the Geological Society of London, Eng., and earned a diploma at the Imperial College of Science and Technology, in 1943.

W. F. Hull, M.E.I.C., a University of Toronto graduate in civil engineering, class of 1949, engaged in engineering in Bulawayo, Southern Rhodesia, holds the position of general manager, Laing and Roberts (Rhod.) Limited.

Mr. Hull has been associated with the firm for several years, in various parts of the country.

H. E. Dishaw, M.E.I.C., has joined the firm of J. D. Mollard and Associates

H. E. Dishaw, M.E.I.C.

Limited, Regina, Sask. In this capacity, Mr. Dishaw will assume charge of aerial photographic studies and ground investigations relating to the location of constructon materials and the selection and engineering analysis of construction routes.

Mr. Dishaw graduated from the University of Saskatchewan in 1951. As special projects engineer with the materials and research branch of the Saskatchewan Department of Highways, he carried out studies in soil exploration and soil testing, foundation design, and the mapping of sand and gravel sources from aerial photographs.

T. M. MacIntyre, M.E.I.C., is resident engineer for Kilborn Engineering (1954) Limited, at Bancroft, Ont., engaged in work concerning mill construction for Dyno Mines Limited.

Within the last few years Mr. MacIntyre has been associated with H. G. Acres and Company in Niagara Falls, Ont., and Victoria, B.C., where, in the latter instance he was field engineer on hydro electric projects for the British Columbia Power Commission.

He was with Gulf Construction Company at Clark City, Que., in 1953, and the following year worked with Cartier Construction Company at Labrieville, Que.

A. N. Campbell, M.E.I.C., construction supervising engineer in Montreal with the Dupont Company of Canada Limited since 1954 has been named assistant manager of the organization's Kingston nylon works.

With the company since 1946, Mr. Campbell is a mechanical engineering graduate of the University of Toronto.

M. F. Painter, M.E.I.C., a forestry engineering graduate of the University of British Columbia, class of 1950, formerly with the B.C. Forest Service at Kamloops, B.C., is at work in Vancouver as a consultant forester and engineer. He is associated with the firm of C. D. Schultz and Company Limited.

J. A. Ferrier, M.E.I.C., has been appointed plant engineer with the Terrace Bay, Ont., firm of Longlac Pulp and Paper

• PERSONALS

Company, Limited.

Although at work in Neenah, Wisc. in 1955, he formerly held the positions of plant engineer and maintenance engineer with the Spruce Falls Pulp and Paper Company Limited, Kapuskasing, Ont.

He is a graduate of Queen's University, class of 1937.

W. R. Sadler, M.E.I.C., formerly practicing engineering in Lethbridge, Alta., with Superior Masonry Products Limited, has moved to Edmonton where he holds the position of supervising engineer with the Department of Highways, main branch, for the Province of Alberta.

Earlier in his career in 1947, Mr. Sadler was resident highway engineer with the Department of Public Works in Edmonton.

Peter M. Baxter, M.E.I.C. Moved to Abbotsford, B.C., is P. M. Baxter, formerly with the Alberta Government Telephones, Calgary. He has accepted employment with the British Columbia Electric Company Limited as a distribution designer.

He came to this country from Edinburgh where he followed his engineering studies.

F. R. Thompson, M.E.I.C., for the past four years a mill engineer with Canadian Johns-Manville at Asbestos, Que., has accepted a position as design engineer with Consolidated Mining and Smelting Company at Trail, B.C.

Mr. Thompson studied engineering at the University of Saskatchewan. He was awarded a degree in mechanical engineering in 1946.

D. C. Rotherham, M.E.I.C., who has been associated with geological engineering since graduation from the University of Saskatchewan in 1951 is now at work with the Mogul Mining Corporation at Lake Cowichan, B.C.

Mr. Rotherham was geologist with Dee Explorations Limited at Saskatoon, Sask., in 1954, and last year at Trail, B.C., was employed by S.W. Explorations, Canadian Mining and Smelting Company.

E. H. Martin, M.E.I.C., has accepted a position with the British Columbia Power Commission at Victoria, B.C., as assistan construction engineer, following a number of years' service with the City of Winnipeg Hydro Electric System in the construction and design field.

He is a graduate of the University of Manitoba.

L. J. MacKay, M.E.I.C., a graduate of the Royal Technical College, Salford, England, class of 1948, and recently of the firm of Messrs. John Holt and Company, Accra, Gold Coast, Africa, is with Construction Management Corporation, New York, N.Y.

Mr. MacKay was known in Canadian engineering circles several years ago when he was associated with the firms of Dar-

• PERSONALS

ling Brothers, Montreal, and Fraser-Brace Terminal Construction, at St. John, N.B. in 1953.

F/O J. R. Rundle, JR.E.I.C., has joined the staff of the Royal Military College, Kingston, Ont. He will lecture in the Department of Civil Engineering.

F/O Rundle is a Queen's University graduate of 1954.

R. LeR. White, JR.E.I.C., has accepted employment as sales engineer with Mac-Craft Industries in Sarnia, Ont.

On graduating from Queen's University in mechanical engineering, in 1951 Mr. White joined the Allis Chalmers Manufacturing Company in Milwaukee, Wis., as a graduate trainee. Later in 1954 he transferred to the Montreal office of Canadian Allis Chalmers Limited.

G. H. Soberling, JR.E.I.C., is assistant production engineer with Canadian Pratt and Whitney Aircraft Company Limited at Longueil, Que.

Mr. Sobering has gained several years experience with Ford Motor Company of Canada, since receiving a mechanical engineering degree from McGill University in 1949.

Raymond E. Jonasson, JR.E.I.C., previously a sales engineer with the Canadian General Electric Company Limited in Winnipeg, has been named sales representative for the organization's mid-west district which includes Saskatchewan, Manitoba and the Lakehead area in Ontario. His headquarters are in Winnipeg.

Mr. Jonasson gained his engineering training at the University of Saskatchewan, graduating in the class of 1949.

R. K. Nicholson, JR.E.I.C., has been named sales manager, eastern district, Canadian General Electric Company Limited, with headquarters in Montreal. His territory will include the province of Quebec and the Ottawa district of the province of Ontario.

With the firm since shortly after graduating from McGill University in 1949, he was at first sales engineer wth the company in Toronto.

H. F. Pragnell, JR.E.I.C., is with the Eddy Match Company at Pembroke, Ont., after a period of employment with the Foundation Company of Canada Limited at Chalk River, Ont.

Mr. Pragnell joined the latter organization in 1949 on graduation from McGill University.

D. I. Ourom, JR.E.I.C., a Saskatchewan graduate in civil engineering, now employed as a metallurgist in the Ontario city of Kingston, holds the office of secretary-treasurer, Kingston Branch.

With the Aluminum Company of Canada for the last three years, Mr. Ourom has also spent some time as engineer with the Demerara Bauxite Company Limited, Mackenzie, British Guiana.

Prior to that he was a member of the legal surveys branch, Department of Mines and Technical Surveys, Ottawa,

and the Canadian Westinghouse Company Limited, Hamilton, Ont., plant engineering department.

Born and brought up in Saskatchewan, he was a 1949 graduate of the University, following a short career with the Canadian Army.

F. A. **Tayelor**, JR.E.I.C., has taken on the duties of resident engineer, with the Alaska Pine and Cellulose Limited's research division in Vancouver.

After a 1950 graduation in mechanical engineering from the University of British Columbia he became associated with Letson and Burpee Limited.

V. G. Barnden, JR.E.I.C., known in Montreal as a construction engineer with Atlas Construction Company Limited, has accepted the appointment in Australia of construction engineer and wood preservation division manager for Laxton Timber and Trading Limited, Victoria, Australia.

Mr. Barnden is a civil engineering graduate, class of 1949, from the University of Western Australia.

S. B. Carroll, JR.E.I.C., a 1953 graduate of the University of Manitoba, in civil engineering has recently moved from Regina, Sask., to Kitimat, B.C., where he is construction engineer with the Corporation of Kitimat.

Mr. Carroll joined the staff of the City of Regina shortly after receiving his degree.

R. M. Harry, JR.E.I.C., has accepted a position as sales engineer with the Husky Oil and Refining Limited in Regina, Sask.

Mr. Harry, who is a graduate of the University of Saskatchewan, class of 1949, has been associated with Canadian Allis-Chalmers Limited in Montreal and Milwaukee, Wis., where he attended a company training course.

S/L G. W. Flewelling, JR.E.I.C., one of McGill University's 1950 graduates in mechanical engineering who was last year officer commanding trade training for air frame and aero engine mechanics at the R.C.A.F. station at Camp Borden, Ont., has been posted to Aylmer, Ont.

He is known at Dorval, Que., and at Goose Bay, Labrador, where he was, in turn, officer in charge of servicing and aeronautical engineering officer.

Lawrence C. White, JR.E.I.C., formerly instrumentman and project engineer with the Department of Highways, in Toronto, has accepted employment with the firm of Angus Robertson Limited in that city.

S. C. Pike, JR.E.I.C., is with the Bell Telephone Company Limited in Beaconsfield, Que.

Formerly at work as a design engineer with the Matthew Conveyor Company Limited in Port Hope, Ont.

Mr. Pike earned his B.Eng. degree at McGill University in 1950.

C. E. Williamson, JR.E.I.C., who since graduation from the University of Toronto in 1950, has spent several years with the Plymouth Cordage Company at Welland, Ont., is now with the Canadian Kodak Company Limited in Etobicoke, Ont.

Howard R. Lumsden, JR.E.I.C., has left Imperial Oil Limited in Sarnia, Ont. He is with the Bell Telephone Company of Canada at Cranberry Portage where he is at work on the Mid Canada Defence Line.

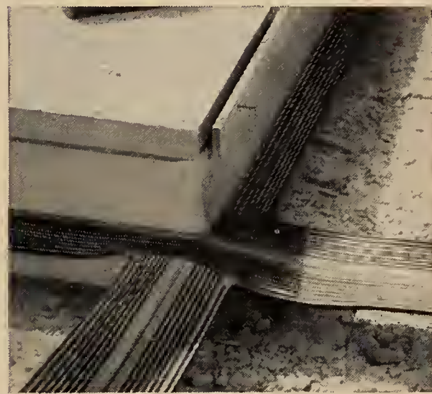
Mr. Lumsden graduated from McGill University in 1949 with a B.Eng. in civil engineering.

M. F. Luft, JR.E.I.C., a B.Sc. graduate in electrical engineering from the University of Alberta, class of 1951, has been named sales representative in the Alberta district of the motor and control department of Canadian General Electric Company Limited. His office is in Edmonton.

E. D. Mackie, JR.E.I.C., lately of the sales division of Electrical Contracting and Machinery Company Limited in Calgary has accepted a position in Vancouver. He is now employed with the B.C.

DURAJOINT® Polyvinylchloride=PVC WATERSTOPS

...specified—used in outstanding engineering projects around the world!



Architects and engineers the world over are convinced that "Durajoint" is a waterstop on which they can successfully stake their reputation. This thermoplastic waterstop, compounded of Polyvinylchloride=PVC, is extruded with specially designed longitudinal ridges on both sides that insure the distribution of critical pressures and enhance the holding power.

"Durajoint's" extreme elasticity and excellent tear resistance allow it to successfully handle vertical or lateral movements of masses of concrete without being sheared. Specify "Durajoint" with the comfort of knowing that this is a waterstop that will, undoubtedly, outlast the construction it's used in.

DURAJOINT® *Specified*

PATENT NO. 495,853

WHERE ONLY THE *BEST* WILL DO!

- ST. LAWRENCE POWER PROJECT, POWER HOUSE
  DESIGN ENGINEERS: Hydro Electric Power Commission of Ontario
  PURCHASED BY: Hydro Electric Power Commission of Ontario
  CONTRACTOR: Iroquois Constructors Ltd.
- WARSAK HYDRO-ELECTRIC PROJECT OF PAKISTAN
  DESIGN ENGINEERS: H. G. Acres and Co. Ltd. of Niagara Falls, Ontario
  PURCHASED BY: Canadian Commercial Corporation of Ottawa
  CONTRACTOR: Angus Robertson Ltd. of Montreal
- McCORMICK DAM, PROJECT No. 2
  DESIGN ENGINEERS: H. G. Acres and Co. Ltd. of Niagara Falls, Ontario
  PURCHASED BY: Manicouagan Power Co., Baie Comeau, Quebec
  CONTRACTOR: Atlas Construction Co. Ltd., Montreal, Quebec

The above are just a few of the thousands of outstanding engineering projects where "DURAJOINT" was specified and used.

Advantages

- √ Resistant to extreme waterhead pressures
- √ Tensile strength of not less than 1900 lbs. per square inch
- √ Superior holding strength . . . elongation ability of more than 350%
- √ Functions efficiently in temperature range of —54°F. to +176°F.
- √ Lifetime expectancy of approximately 300 years
- √ Chemically inert . . . resistant to acids, alkalis, weather, chlorinated water, oil, fungus, etc.
- √ Quickly, easily spliced "on the job" by merely applying heat and holding the ends together until bonded . . . requires no welding or vulcanizing equipment
- √ Available in lightweight, easy to handle 50 ft. coils . . . withstands abuse without damage

Engineering Company Limited's protection and control section in Vancouver.

Mr. Mackie received his engineering degree at the University of Saskatchewan in 1950.

J. H. Wright, JR.E.I.C., is with the Union Carbide International Corporation at Texas City, Texas.

Mr. Wright went to the United States as a scholarship winner shortly after his graduation from McGill University in 1949 and then gained employment with the Shell Chemical Corporation in New York, N.Y., and at Houston, Texas.

J. Urbain Moreau, JR.E.I.C., The choice of the St. Maurice Valley Branch of the Institute for chairman, 1956, is J. Urbain Moreau, consulting engineer of Trois Rivières, Que.

Commencing his education at the Academie de Quebec, Quebec City, with an Arts and Science degree obtained in 1941, Mr. Moreau studied various courses before embarking on his engineering training. With the Canadian National Telegraphs Company Limited in Montreal he studied a radio attendant course shortly afterwards. Joining the Canadian Army Active in 1943, he served until the end of the war. During this time he also studied at the University of Montreal. In 1946, again with the Canadian National Telegraphs he undertook a wire chief's course in Toronto. Two years later he was a graduate from McGill University with a B.Eng. degree in mechanical engineering.

His first graduate position was that of plant engineer with the St. Regis Paper Company Canada Limited, Cap de la Madeleine, Que. After two years with

J. U. Moreau, JR.E.I.C.

the firm he transferred his services to L. Massicotte Limited as construction engineer in the same locality.

It was in 1951 that Mr. Moreau went into private practice as a consulting engineer. He is engaged in mechanical and electrical design with related structural work.

He is a member of the Corporation of Professional Engineers of Quebec. Also active in Branch affairs of the Institute for some time he served as chairman of the Trois-Rivières Junior section, 1950-1951, was regional representative for the St. Maurice Valley from 1953 to 1955 and a Branch committee member from 1954 to 1956. In 1955 he served on the executive.

Donald I. Nelson, JR.E.I.C., has recently been named manager of the Sudbury branch office and warehouse, now under

D. I. Nelson, JR.E.I.C.

construction, for Canadian Ingersoll-Rand Company Limited, Toronto.

Following early warehouse and clerical experience with Ingersoll-Rand in Vancouver, Mr. Nelson joined the R.C.A.F., working for four years on radar equipment maintenance and operation. On demobilization he entered the University of British Columbia and in 1950 obtained a B.A.Sc. degree in mechanical engineering. Rejoining Canadian Ingersoll-Rand after graduation he was posted to Kirkland Lake, covering rock drills, detachable bits, compressors and general products. Prior to his new appointment he was on the staff of the Toronto branch handling sales engineering on general products.

He is a member of the Association of Professional Engineers of Ontario and the Canadian Institute of Mining and Metallurgy.

H. R. Stephens, JR.E.I.C., has moved from McMasterville, Que., to Nobel, Ont., where he is with Canadian Industries Limited.

He is a chemical engineering graduate of Queen's University, class of 1947. He was at that time employed as a chemist in the explosive division of C.I.L.'s plant at McMasterville.

A. A. Hills, JR.E.I.C., has left the staff of Ferranti Electric Limited, research division, and has joined the aeronautical division of Minneapolis Honeywell Limited, Leaside, Ont.

Mr. Hills graduated from Queen's University, with the class of 1949, then spent some time in the metrology department of National Research Council, Ottawa, as a junior research officer.

A. M. Garlicki, JR.E.I.C., a mechanical engineer with the firm of Timberland Machines Limited at Woodstock, Ont. until recently, is now associated with Eastern Steel Products Limited at Preston, Ont., in the design department.

He was employed with Babcock-Wilcox and Goldie-McCulloch Limited for several years since coming to this country.

• PERSONALS

Mr. Garlicki is a 1951 graduate in mechanical engineering from the Polish University College of London, Eng.

Ronald C. Getty, JR.E.I.C., has joined the Can-Met Exploration Ltd., at Spragge, Ont.

Formerly with Margison, Babcock and Associates in Toronto, he is a civil engineering graduate from the University of Toronto, class of 1950.

E. R. Bruce, JR.E.I.C., is with the Aluminum Company of Canada at Kitimat, B.C., after several years with the company in Montreal and Isle Maligne, Que.

Mr. Bruce joined the organization in 1951 after a Queen's University graduation.

Raymond Earle Chant, JR.E.I.C., has been named chairman and professor of mechanical engineering with the department of mechanical engineering, University of Manitoba, Fort Garry, Man.

In 1953 Mr. Chant received the appointment of associate professor of mechanical engineering with the University.

B. C. Cameron, JR.E.I.C., a University of Toronto graduate, class of 1952 in mechanical engineering is now in England with the firm of Babcock and Wilcox. He is located at the Castle Donington Power Station, Nr. Derby, England.

Formerly Mr. Cameron was with Canadian Industries Limited at Maitland, Ont., as a power house assistant.

Douglas R. Grimes, JR.E.I.C., is working as a structural engineer in the development branch, Department of Public Works, Ottawa.

A McGill University graduate, class of 1954 he gained an M.Sc. degree in civil engineering this spring at Queen's University. While attending the latter university he also lectured at the Royal Military College, Kingston.

J. R. McGovern, JR.E.I.C., is with Sola Electric (Canada) Limited in Toronto.

A McGill University graduate in electrical engineering, class of 1951, he was formerly associated with the Herbert Morris Crane and Hoist Company Limited in Toronto.

G. D. Langereis, JR.E.I.C., a Delft University graduate of 1954 is with the Montreal Engineering Company as design engineer.

A short time ago he was associated with Mannix Limited in Calgary, on estimating and field work.

J. H. A. Lavallee, JR.E.I.C., of the Bell Telephone Company of Canada at Trois Rivières, Que., has been nominated secretary of the St. Maurice Branch of the Institute.

J. H. A. Lavallee, JR.E.I.C.

A Montrealer, he was born there and received his secondary education at Chomedy de Maisonneuve high school. Before embarking on his engineering studies Mr. Lavallee spent a considerable length of time in the armed forces, as a pilot with the R.C.A.F. in England and the Middle East. In 1945 he enrolled at the Ecole Polytechnique in Montreal and began his professional studies in civil engineering. Concluded in 1951, he be-

• PERSONALS

gan his graduate career with Bell Telephone Company of Canada, outside plant section, engineering department, in Montreal. Following a company transfer in 1954 he has since been resident at Trois Rivières.

Mr. Lavallee is a member of the Corporation of Professional Engineers of Quebec.

T. C. Arnold, JR.E.I.C., has been transferred by the Aluminum Company of Canada Limited, from the Arvida works, Arvida, Que., to the head office, general purchasing department at Montreal.

At the Arvida works since 1953 he has held the positions of industrial engineer and mechanical maintenance engineer.

Mr. Arnold is a University of Toronto graduate in mechanical engineering, class of 1950. He also holds a master of Business Administration degree from the University of Western Ontario.

Prior to joining the staff of the Aluminum Company he was employed on the Canadian General Electric test course and was also associated with the Square D Company as a sales engineer.

Mr. Arnold has also been appointed a part-time lecturer with the Department of Commerce at McGill University.

R. C. Legge, JR.E.I.C., has been transferred from Lloydminster, Sask., to Calgary with the Husky Oil and Refining Limited. With the firm for a number of years he was a 1949 graduate of the University of Saskatchewan.

Frank S. Miller, JR.E.I.C., has joined the firm of Scarfe and Company Limited, Aurora, Ont., as a sales engineer specializing in industrial finishes.

Mr. Miller has been associated with several organizations since graduation in 1949. They include the Rubberset Company of Canada, Gravenhurst, Ont., and the Aluminum Company of Canada Limited.

Claude J. Blais, JR.E.I.C., has left the staff of the Canadian General Electric Company Limited at Montreal and has joined the Consolidated Paper Corporation Limited at Port-Alfred, Que.

Mr. Blais was an electrical engineering graduate of McGill University in 1952.

L. E. Parker, S.E.I.C., a 1955 graduate in mechanical engineering, from the University of Saskatchewan, is now living in Edmonton. An employee of the British American Oil Company, he was recently transferred to the west from the Clarkson Refinery, Toronto, Ont.

Adelbert J. Comeau, S.E.I.C., a 1956 graduate from the Nova Scotia Technical College has been placed on the staff of Avro Aircraft Limited, Scarborough, Ont. as junior engineer.

Mr. Comeau was awarded a B. Eng. degree in electrical engineering.

Severino Dozzi, S.E.I.C., a Queen's University graduate, class of 1956, in civil engineering, is on the staff of Dominion Bridge Company Limited, Lachine, Que.

Ian P. Campbell, S.E.I.C., is employed with Atomic Energy of Canada Limited, Deep River, Ont., following his recent graduation in mechanical engineering from the Nova Scotia Technical College which took place this spring.

P. Mantyla, S.E.I.C., a 1956 graduate of Queen's University in mechanical engineering has begun his professional career in Aruba, Netherlands Antiles, with the Lago Oil and Transport Company Limited.

T. P. Gilchrist, S.E.I.C., a University of Saskatchewan graduate, class of 1956, with a B.Sc. degree in agriculture has been taken on the staff of the Saskatchewan Department of Agriculture, conservation and development branch, where his work is that of project engineer.

D. G. Dueck, S.E.I.C., a 1956 graduate from the University of Manitoba in mechanical engineering has accepted a position with Brown Boveri (Canada) Limited in Montreal.

Secretary

Visit to Wire Rope Plant

One hundred and fifty Vancouver Branch members were recently welcomed by the British Ropes Canadian Factory Limited, Vancouver, when the wire rope manufacturing company held "open house" at its Grandview highway plant.

The engineers were taken on tour of the factory, and visited the plant of Grandview Industries Ltd., a subsidiary of British Ropes, engaged in the manufacture of plastic pipe.

Feature event of the afternoon was a demonstration of the new wire rope pre-stressing plant, which was recently completed on a site immediately north of the factory premises.

R. E. C. Cadman, British Ropes president, and other members of the company staff, were on hand to explain the operation of the pre-stressing machinery, and to discuss the applications of pre-stressed wire rope.

It was pointed out that pre-stressing removes the initial "give" from new rope, and allows engineers to determine the degree of elasticity.

Positions of cable bands and installations can be marked on the cables in the stretched condition they will assume under the design load.

Pre-stressed cables are used on suspension bridges, aerial tramways, and pipe line crossings. The British Ropes plant which was designed by Robert McLellan, has already pre-stressed the ropes for the Capilano Canyon suspension bridge, and the four giant 10,300 ft. cables for the B.C. Electric Jervis Inlet transmission crossing.

The two-inch diameter cable which was pre-stressed during Wednesday's demonstration will be used on the Shelley Crossing of West Coast Transmission's gas pipeline.

Prior to the building of the local plant, which is the only one west of the Mississippi, all pre-stressed wire cables used in British Columbia had to be obtained from eastern Canada, the U.S. or overseas.

1956 Engineers' Ball

An ambitious committee has noticed everyone getting healthy under the summer sun and concluded that all the accumulated excess energy must be given an outlet. The Engineers' Ball for 1956 will provide all that is to be desired.

Already plans are under way to eliminate any obstacle that could possibly stand in the way of its success. No effort is spared, no detail is overlooked.

Tell your wife now so she can enter the date on your social calendar and

At left: Harold Epps, plant engineer gives visiting members of the Institute facts concerning the powerful grips at the live-end terminal of the company's new wire rope pre-stressing plant. At right: R. E. C. Cadman, president, explains details of pre-stressing to Stuart Lefeaux, chairman of the Vancouver Branch. Others in the photo are, E. E. Lathrop, vice-president of the firm, H. P. Archibald, consulting engineer, Harold Epps, plant engineer. Kneeling: Alex Ross, sales manager and Professor W. O. Richmond, head of the University of British Columbia mechanical engineering department.

get your party together for Friday evening, October 5, 1956. Let's fill the combined Century and Burgundy rooms at the Fischer's Hotel in Hamilton.

Excellent music for dancing by Ted Hader and his orchestra from 9.00 to 1.30 a.m. Time out to draw prizes and a fine buffet lunch at midnight.

Tickets $6.00 per couple. Information as to how and where to get them will reach you through the mail soon. Act quickly and avoid disappointment.

TORONTO

Joint Committee, E.I.C., I.C.E., A.S.C.E.,
H. Fealdman, m.e.i.c.,
Chairman,
B. Hardcastle, m.e.i.c.,
Secretary

The Annual Report adopted at the Executive Committee Meeting at Toronto on June 4, 1956.

The Executive, Toronto Branch, Engineering Institute of Canada,
The Council, Institution of Civil Engineers,
The Council, American Sociey of Civil Engineers.
Gentlemen,

We, the chairman and officers of the Joint Area Committee, beg to submit a report on the operation of the first season, as follows—

Meetings

Four meetings were held during the 1955-56 season. These consisted of:

November 24, 1955 — "One Cycle Moment Distribution", by C. Hershfield. Mr. Hershfield discussed the simplified method which he has developed.

February 9, 1956 — "Waterworks and Fluid Mechanics", by D. G. Huber, who discussed what effect the introduction of fluid mechanics based on mathematical theory has had, or should have had, on the practical treamtent of waterworks design.

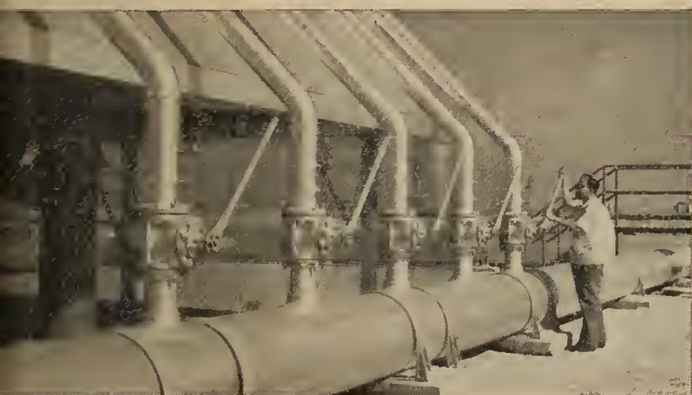
March 8, 1956 — "Foundation Problems and Small Structures", by D. J. Bazett. Mr. Bazett discussed foundation problems, investigation variations in the soil and the effects of trees and other vegetation were also discussed.

April 12, 1956 — "Loading Test on a Prestressed Concrete Beam at Cobourg, Ontario", by L. J. Marcon and W. R. Schriever. This paper described a field loading test on a hundred ft. continuous two span prestressed concrete beam designed as the main roof supporting member for some large Army warehouses at Cobourg, Ont.

Prior to each of the aforementioned meetings, the executive met for dinner in the faculty dining room at Hart House (University of Toronto), and entertained the guest speaker.

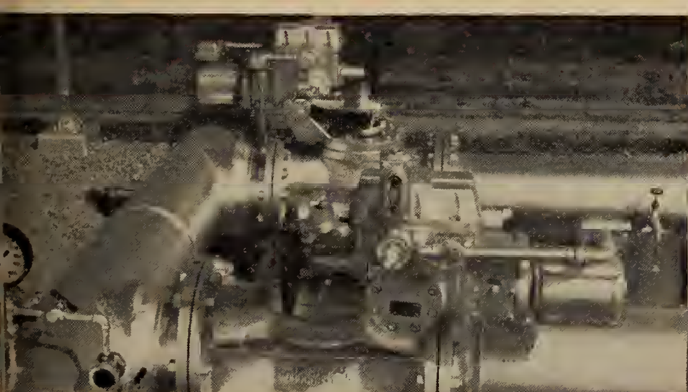
Bottlenecks

ROCKWELL-Nordstrom VALVES Keep Every Line On Stream



AT A GLANCE, you can tell whether a Rockwell-Nordstrom valve is open or closed. Costly, often dangerous guesswork and old-fashioned "feeling" a valve are eliminated.

BIG . . . BUT FAST. Every Rockwell-Nordstrom valve is fully opened or fully closed in one quarter-turn. On gear operated valves, this means operation is two to five times faster.



FOR POWER OPERATION, Rockwell-Nordstrom valves assure dependability and economy because simpler and less costly actuators are required for quarter-turn operation, and lubricant keeps them "ready to go."

For forty years, process engineers have insured better quality control and mechanical performance, greater safety, and lowest maintenance costs with Rockwell-Nordstrom chemical valves. They have been *proven* on every service from the earliest refineries to today's exacting demands of precise flow control in automatic chemical and processing plants. The facts speak for themselves . . . everywhere you use Rockwell-Nordstrom valves they will assure you greater "on stream" dependability at lower cost than any other valve you have ever used.

Look at these installation photographs for just a few of the reasons why Rockwell-Nordstrom valves can help you break production bottlenecks. *Canadian valve licensee:* Peacock Brothers Limited, Box 1040, Montreal, Que. Also, Sydney, Toronto, Sudbury, Winnipeg, Edmonton, Calgary and Vancouver.

ROCKWELL-NORDSTROM VALVES

• BRANCH NEWS

Attendance

While actual attendance figures for each of the meetings are not available, an average approximation would be one hundred members, which represents approximately 12½ per cent of the potential. This is considered extremely good for technical meetings in the Toronto area, and augers well for the future operation of the committee, and certainly justifies the co-operation and assistance so generously given by each of the parent bodies.

Membership

The current mailing list of the committee is composed of the following numbers, which include members, associate members, graduates and students:

Engineering Institute of Canada (Toronto Branch)	685
Institution of Civil Engineers	136
American Society of Civil Engineers	48
total listed	869
total served	812

Note: the totals differ slightly owing to dual memberships in the parent bodies.

Following the preparation of this comprehensive mailing list and the circularising of members prior to each meeting, many requests for inclusion on the list have been received by the members of the executive, and very gratifying comments have been made by individual members.

It is felt that this membership will grow in the future years, following the publication of pertinent details in the various journals of the parent bodies.

Third Annual
PROFESSIONAL ENGINEERS' BALL
of the

St. Catharines — Gavin Brown — Ontario Paper Company
R. N. Millman — Ontario Paper Company
Niagara Falls — H. J. Saaltink — H. G. Acres & Company Limited
Fort Erie — A. Zanatta — Horton Steel Works
Port Colborne — A. Zahavich — International Nickel
Welland — Eric Bergenstein — Reliance Electric

Make up your party now and reserve your tickets.

Finances

From the period of inception of the committee up to and including December 31, 1955, all of the expenses of the Committee were borne by the Toronto Branch of the Engineering Institute of Canada. This included the initial costs of setting up stencils for the bulk of the mailing list, and the cost of printing and mailing notices for the first meeting held on November 24, 1955. It will therefore be seen from the statement of expenses that the average cost per meeting for each of the three meetings held in 1956 was $64.88.

Two further meetings are planned for the current year and it will be seen therefore that an estimated deficit based on the above cost per meeting can be expected for the first year of operation. It also appears that, on the basis of five meetings per year, the annual approximate costs for a year of operation will be in the neighborhood of $360, allowing for miscellaneous minor contingencies.

It should be noted that the costs of members' dinners have been borne by the individuals concerned, and only the cost of entertaining the guest speaker has been included.

Organization

As presently constituted, the executive committee consists of the following—
Institution of Civil Engineers — two members.
American Society of Civil Engineers — two members.
Engineering Institute of Canada (Toronto Branch) — three members.

The committee has also added to its numbers by inviting a secretary and a

ATTENTION PLEASE!
E.I.C. BRANCH EXECUTIVES

Several months ago you were written to by headquarters' staff on the subject of new developments in your area of Canada, and the desirability—almost the necessity—of getting Journal papers to describe them. There is so much going on now, in so many places, that ordinary methods of keeping abreast of the engineering news may fail us. We hope not, but you can help us to be sure. Please organize your branch this year so as to cover these two things:—

1. When you hear about a new development in your vicinity, in engineering or technology, get a few facts together, plus the names of some of the principals, and send this information to the editor. We will take it up from there, if you wish.
2. When you have a paper delivered before your branch, if it is a reasonably worthwhile effort TRY to get a manuscript of it and send it to the editor. Some of our finest technical presentations are lost forever because of this lack, and no record exists beyond the memories of the comparative few who heard the speaker.

HELP THE EDITORS TO KEEP IMPROVING OUR JOURNAL treasurer from the E.I.C. (Toronto Branch). The chairman and the immediate past chairman of the E.I.C. (Toronto Branch) are also ex-officio members of the Committee, as also are Mr. E. A. Cross and Mr. R. F. Legget (Institution of Civil Engineers).

Mr. H. Fealdman was elected chairman by the members of the committee.

Executive Members

Engineering Institute of Canada (Toronto Branch) — D. G. Watt, C. Hershfield, M. Walkinshaw.

Institution of Civil Engineers — A. F. Staig, H. Fealdman.

American Society of Civil Engineers — M. S. Yolles, R. G. Watson; secretary, B. Hardcastle; treasurer, L. F. Bresoln; ex-officio, K. F. Tupper, M. W. Huggins, E. A. Cross, and R. F. Legget.

Future Plans

The committee is planning five meetings for the 1956-57 season, one of which will be an open night, for which endeavours are being made to promote a paper from a local member of the group. In this way, the committee hopes to stimulate interest in the presentation of local papers.

E.I.C. and Professional Development

Report of P.D. Courses in Canada

For over five years the Institute has been promoting courses in professional development within the branches. Believing that not many members had any concept of the scope of the Institute's interest and activity in this field, the following general report has been prepared for the attention of all members.

Although it is well known to those who have been associated with the acitivity, there are many who do not know that the field secretary Colonel L. F. Grant has been the "spark plug" throughout these many years. It is a pleasure to have this opportunity to acknowledge publicly the great efforts he has made on behalf of the young engineers, and the success that has attended them.

Summary Report on Professional Development

In 1950, the Engineers' Council for Professional Development published the report of a committee headed by Dr. Monteith (of Westinghouse) entitled, "The First Five Years of Professional Development". The theme of this was the "Continued

Education of Graduate Engineers".

In the United States, because they planned along very ambitious lines, they did not get a course started until 1954/55, in Cincinnati. They are now organizing a second course in Detroit.

However, Colonel L. F. Grant decided to get courses going in Canada right away, which would be self-supporting from a small fee, and more or less run by the young engineers themselves. The first courses began in the 1951/52 season, so that P.D. in Canada has completed its fifth year.

It is difficult to estimate the number of young engineers who have benefited but it is probably about 2,000. There were 15 courses operating in 11 branches in the past season with approximately 450 enrolled (and this does not include the Montreal Junior Section).

Colonel Grant felt that if a group of young engineers met weekly during the winter, and invited well known authorities to speak on non-engineering subjects, they would acquire not only valuable general knowledge but would get training in public speaking by acting as chairmen, introducers, thankers, and asking questions at the meetings. This has proved to be the case. Those who have taken the courses show a most decided improvement in manner and self confidence.

During the first years many of the branches set up courses which ran for two and three seasons; then in smaller centres because they used up the number of speakers available, and there was some repetition when the same members returned each year, they have either turned to something operated by a nearby university, or in some cases discontinued the courses. The Field Office has taken on the work of circulating literature and offering assistance, and in Toronto actually runs the two courses which have been in continuous operation.

Branch P.D. Programs

Last year eleven branches had courses, as follows:

Quebec: This is an engineering course directed through L'Universite Laval, and covers advanced design of structures and soil mechanics. The course lasts three years and includes three hours per week of lectures plus

• BRANCH NEWS

assigned work. Those who complete it and produce an acceptable thesis may be granted a master's degree by the university. This grew out of their original P.D. course and is considered as one of the Quebec Branch activities. One of the Provincial Government educational organizations gives the Quebec Branch $1,000 a year for this project.

Hamilton: The P.D. course in Hamilton is considered the model for all P.D. courses. They operate four groups with a total enrolment of 150.

Group one stresses general knowledge. Group two gives specialized study on five topics: business management, public speaking, government, human relations and philosophy. Group three takes up business administration. Group four studies administrative practices by the Harvard Case Method.

Hamilton seems to have achieved a continuity of enthusiastic committee officers which has assured the success of the course.

Kootenay: This branch has had P.D. for three years. Fifteen graduates of their P.D. I of 1954/55 formed a P.D. II in 1955/56, and arranged five talks on business administration and five general topics. They feel they will now have to discontinue for one year for lack of speakers.

Halifax: P.D. is in its fourth year in Halifax. The first year they had a general course; the second year they concentrated on public speaking only; the next year on investment; and during the past year had 12 lectures available through St. Mary's University extension.

Winnipeg: Here the second year of P.D. has been completed. They now have two courses, more along the lines of Hamilton and Toronto, which is the type of course Colonel Grant prefers, i.e., the first year general subjects (last year specializing in government and law), and the second year on the arts.

Ottawa: The general program at Ottawa last year included ten plant visits as well as general meetings. There was also an evening with refreshments, for university students.

Belleville: This branch has just completed a two-year course in business administration under the auspices of

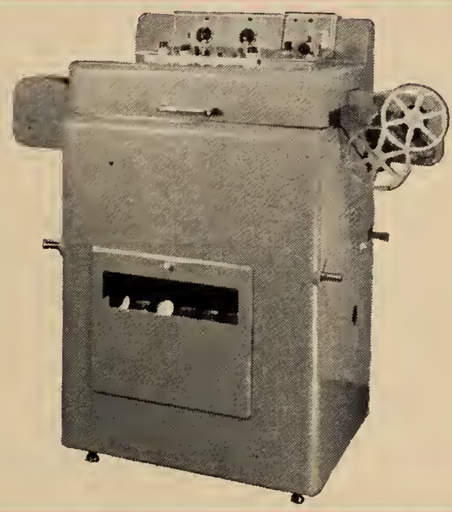
INSTRUMENTATION CAMERA
AND AUTOMATIC
TRI-FILM PROCESSOR

PRECISION'S PERFECT PAIR



SPECIFICATIONS

INSTRUMENTATION CAMERA TYPE T232 Mk7

Size:	7½" x 5⅞" x 6½"
Weight:	13 lbs.
Power:	28 volts DC; constant demand .4 omperes; intermittent up to 1.8 amperes. The Type T232 DC power supply, which operates from 110v 60 cps, is available to power the camera
Lens:	28mm Augenieux F3.5, or to customer specification
Magazine:	100 ft. 35mm standard sprocketed film, No. 10 daylight loading spool. 400 ft. magazine available on special order
Picture Formats:	18x25, 25x25 or 25x36 mm.
Exposure:	1/100 second, or longer with intervol-ometer control
Interval Time:	3 cycles per second maximum

AUTOMATIC TRI-FILM PROCESSOR TYPE T246 Mk3

Size:	54" long, 22" wide, 51" high
Weight:	400 lbs.
Power Consumption:	5 KVA maximum single-phase: 110 volts, 45 amps, or according to customer requirements
Process Capacity:	1 to 4 rolls 16 mm / 1 or 2 rolls 35 mm / 1 roll 70 mm } length to 400 ft.
Rate of Processing:	1½, 3 or 6 ft. per min.

Temperature-controlled solutions and dryer
Daylight operation except loading of film into magozine
Processes perforated or plain film

Here is the perfect answer to the problems of film recording and the obtaining of quick results without loss of quality. The Mark 7 Instrumentation Camera is completely flexible through the entire field of instrumentation and aerial survey positioning photography. The shutter is a focal plane type, the basic exposure speed of which is 1/100 second. The camera may be cycled from 3 frames per second to any desired longer interval. Interchangeable apertures permit photographs of 18x25, 25x25 or 25x36 mm. A high degree of accuracy is achieved in respect to lens alignment, focusing and format positioning. Main components designed on the "module" system make conversion from one camera type to another relatively simple should customer requirements change.

A fitting companion is the transportable Mark 3 Automatic Tri-Film Processor that develops and dries 16, 35 or 70 mm film at 1½, 3 or 6 feet a minute. Four 400-ft. 16 mm films can be handled simultaneously—or two 400-ft. 35 mm films—or one 400-ft. 70 mm length. The various film sizes are accommodated by simple adjustments of film separators. Separate temperature control of the processing solutions is possible on each tank from 60 to 110 degrees F, within ± 1 degree. The latest high temperature chemical resistant plastics and Type 316 stainless steel are used in all chemical areas.

Write for literature and quotations.

Important Meeting in Montreal

The Engineering Institute of Canada was happy to co-operate with The American Society of Mechanical Engineers through the ASME-E.I.C. International Council in arranging meetings at the Windsor Hotel, Montreal, on June 19 to 22 last, inclusive, of two important organizations from south of the border.

Once each year the ASME Boiler and Pressure Vessel Committee meets jointly with The National Board of Boiler and Pressure Vessel Inspectors in a location outside of New York City. This year an invitation to meet in Montreal was accepted and the occasion was rendered especially notable for two reasons. It was the 25th general meeting of the National Board and was also the first occasion on which the annual joint meeting of the two bodies has been held in Canada.

Work of the Committees

The ASME Boiler and Pressure Vessel Committee was set up originally by The American Society of Mechanical Engineers in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. The National Board of Boiler and Pressure Vessel Inspectors was organized in 1919 and is now composed of the chief inspectors of states and municipalities in the United States and of the provinces in the Dominion of Canada that make use of the Boiler and Pressure Vessel Code.

Registration for the meeting opened at 10 A.M. on Tuesday, June 19 and later in the morning an executive session of the National Board took place. After luncheon attended by the members and their guests, including the ladies, the meetings were formally opened with addresses of welcome by the following officials or their representatives: Hon. Antonio Barrette, Minister of Labour for the Province of Quebec, His Worship Jean Drapeau, Mayor of Montreal, Robert L. Dunsmore, M.E.I.C., vice-president, The Engineering Institute of Canada, Montreal, Gerald N. Martin, M.E.I.C., chairman, ASME-E.I.C. International Council, Montreal, Harry E. Boardman, Mem.ASME, chairman of the ASME Boiler and Pressure Vessel Committee, William A. Calvin, president, International Brotherhood of Boilermakers, Blacksmiths, Forgers and Helpers, Frank X. Gilg, Mem.ASME, representing William P. Heuser, president, American Boiler Manufacturers Association and Affiliated Industries.

At the conclusion of the welcoming ceremonies a most interesting technical paper was presented by I. N. MacKay,

National Board—ASME Boiler Code Committee meeting. Head table guests for the dinner which took place on June 21, were, left to right, H. G. Thompson of the E.I.C.; F. W. Smith of Salem, Oregon, president of the National Board; A. LaBissoniere, chief boiler inspector, Province of Quebec; C. O. Myers of Columbus, Ohio, secretary-treasurer of the National Board; G. N. Martin, chairman of the ASME-E.I.C. International Council; Wm. Ferguson, manager, Union Boiler Law Society, Hartford, Conn.; H. E. Aldrich, Vice-chairman, ASME Boiler Code Main Committee, New York; L. Austin Wright (behind the camera), general secretary, Engineering Institute of Canada.

Below. A session of the ASME Boiler and Pressure Vessel Committee and the National Board of Boiler and Pressure Vessel Inspectors meeting in Montreal.

• NEWS OF OTHER SOCIETIES

M.E.I.C., manager, engineering, Civilian Atomic Power Dept., Canadian General Electric Co. Ltd., Peterborough, Ont., dealing with "Atomic Power Developments in Canada".

Later the same afternoon the National Board entertained all members and guests together with their ladies at a reception and cocktail party in the York Room of the Windsor Hotel.

On Wednesday, June 20, the morning was devoted to a panel discussion on Sections I, II and IV of the ASME Boiler Code with Alfred LaBissonniere, Mem.ASME., examiner and chief inspector, Province of Quebec, as moderator. In the afternoon the same panel continued with discussions of Sections VIII and IX of the Code. The following morning, Thursday, June 21, simultaneous open meetings were held of the following ASME subcommittees: Unfired Pressure Vessels, Heating Boilers, Welding, Fire Tube Boilers, Power Boilers.

Thursday afternoon there was a panel discussion dealing with National Board "Recommended Rules for Repairs to Power Boilers and Unfired Pressure Vessels by Welding" with J. N. Briggs, director, Department of Labour, Province of Ontario, Toronto, as moderator.

Reception and Dinner

The main social event of the meetings consisted of a dinner and dance held in the Windsor Hall on Thursday evening. This was preceded by a reception and cocktail party in the Rose Room of the Windsor Hotel, arranged by the local committee. Through the very kind generosity of those Canadian companies whose interests bring them into contact with the work of the ASME Committee and the National Board.

The meetings concluded with open sessions of the ASME Boilers and Pressure Vessel Committee which carried on all day Friday and which were attended by all those present. The Canadian representation at all meetings was most gratifying and in addition to the provincial inspectors there were several members of the Canadian Standards Association B-51 Committee as well as many representatives of the steam power plant equipment, oil refining and paper industries present.

Ladies who accompanied their husbands to these meetings were made especially welcome and the local Ladies Committee, thanks again to the generosity of the contributing Canadian industrial and other organizations, were able to provide a bus tour of the Laurentians on Wednesday, including lunch at the Laurentide Inn, Ste. Agathe as well as a tour of Montreal with lunch at the Restaurant Hélène de Champlain on St. Helen's Island on the Thursday.

The participating organizations were most profuse in their expressions of appreciation for the excellent manner in which all of the local arrangements were carried out. Since these were due in very large measure to the local committees working under the auspices of the ASME-E.I.C. International Council, the members are named hereunder in sincere thanks for their efforts.

General Committee on Arrangements

National Board Executive, Alfred LaBissonniere, Mem. ASME.
Secretary, H. G. Thompson, M.E.I.C.

Ladies' Committee

Chairman, A. M. Bain, M.E.I.C., Mrs. A. LaBissonniere, Mrs. E. H. Brooke, Mrs. A. M. Bain.

Calendar

The Canadian Good Roads Association will hold the annual convention at the Chateau Frontenac Hotel, Quebec City, October 2 to 5.

Features of the program will be a review of developments at the site of the $12-million road durability test in Illinois, by Dr. Gordon Campbell, CGRA's engineer-observer on the Highway Research Board project; and the "Roads Round-up" in which senior government authorities will report developments.

CGRA offices are at 270 Maclaren Street, Ottawa.

The Association has also announced the award of two scholarships, valued at $2,000 each for post-graduate study in highway engineering in the United States.

The first, the Armco Drainage Good Roads Fellowship, has been awarded to Henri Perron of Quebec City. Mr. Perron has been employed by the Quebec Department of Roads since 1947.

The second, the Canadian Salt Good Roads Scholarship, goes to Robert B. Campbell, of Toronto, who has been employed by the Ontario Department of Highways since 1949.

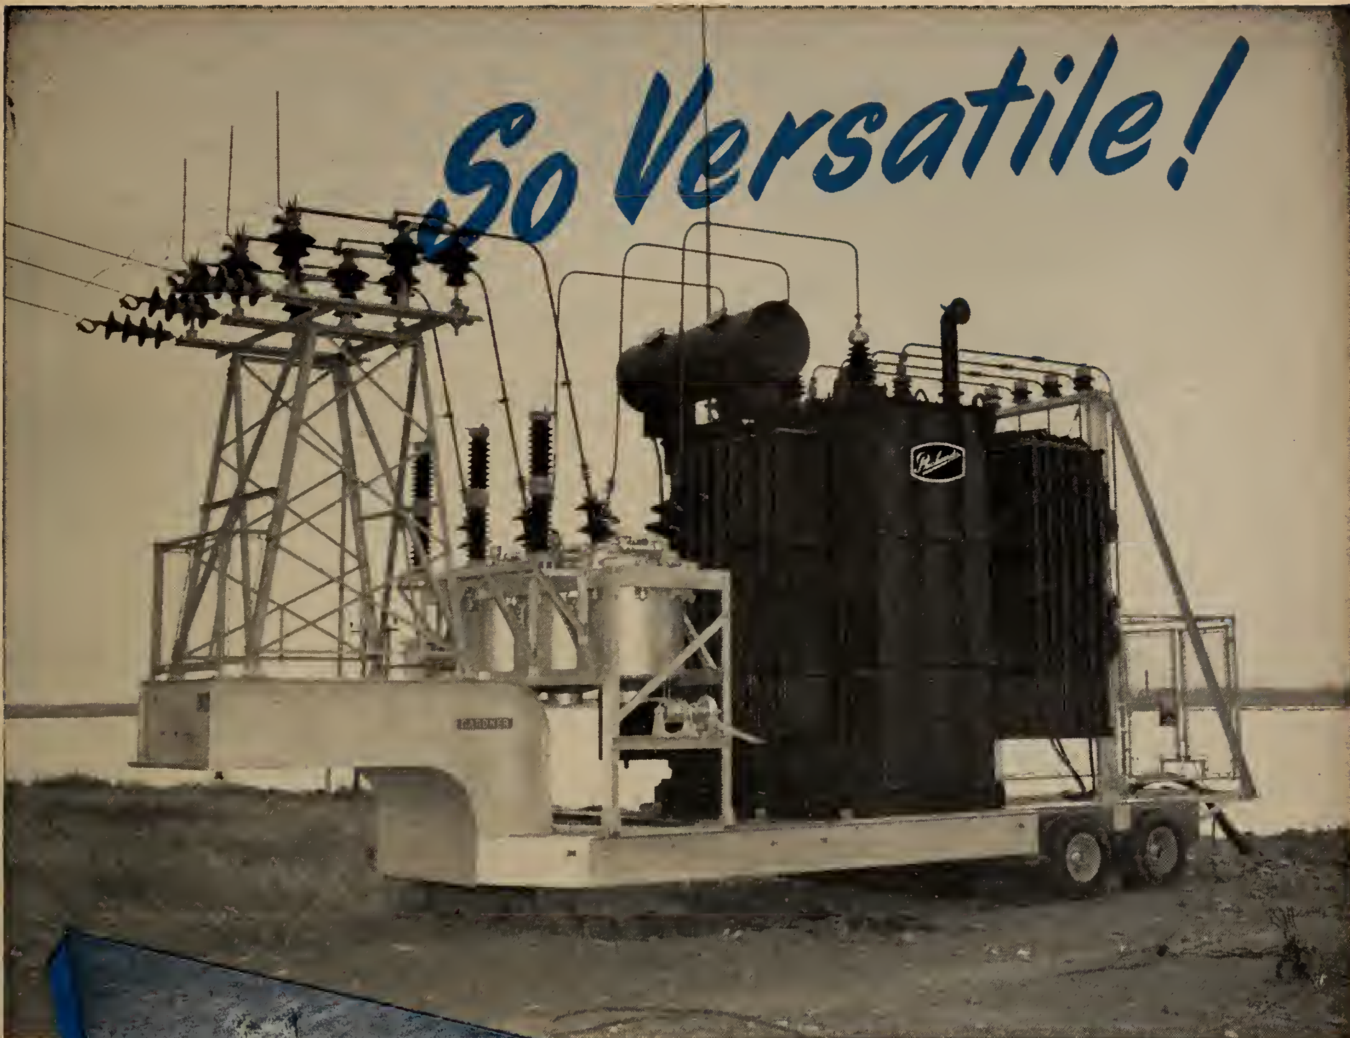
The Engineers' Council for Professional Development (29 West 39th Street, New York) will hold the twenty-fourth annual meeting on October 25 and 26, 1956 in Detroit, Mich.

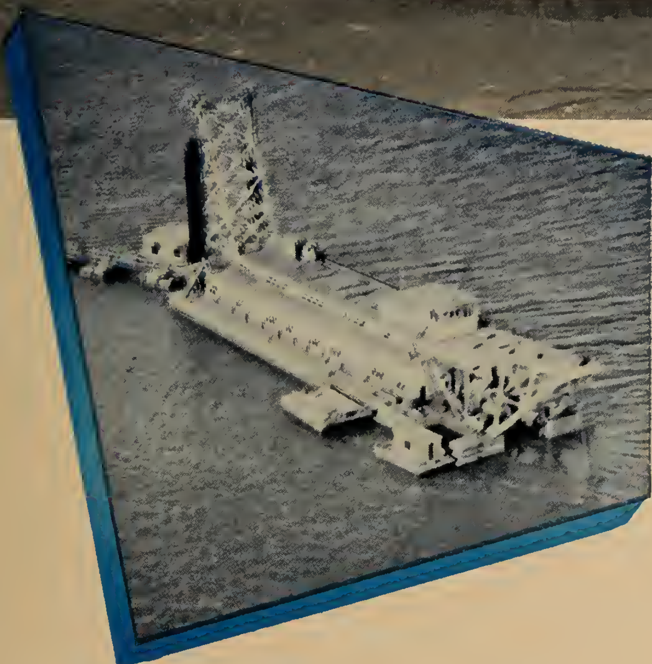
The meetings and luncheons, through the courtesy of the Engineering Society of Detroit, will be held at their Headquarters, at 100 Farnsworth Avenue.

Hotel headquarters will be the Statler Hotel, where the annual dinner and buffet supper will take place.

The printed invitations, reservation cards, and programs will be mailed a month or six weeks before the meeting. However, hotel reservations may be made now.

A splendid program is planned by the Training Committee, with emphasis on





Mounted on a 50 ton trailer, this mobile substation supplies current by submarine cable to the largest pipeline dredge in the world, the "Hydro-Quebec". The dredge is being used to deepen and widen the Beauharnois Canal to provide additional electric horsepower for the Quebec Hydro Electric Power Commission.

The 10000 KVA fan-cooled transformer, designed and built by PACKARD, is fed at 44000 volts and delivers power to the dredge at 13200 volts, 3 phase, 60 cycles.

The transformer windings are designed to give secondary voltages of 2300/2540/6900/7620 delta connected, and 4000/4400/12000/13200 wye connected, making the whole unit exceptionally versatile.

the project in Detroit these past two years. An interesting program is being arranged for the ladies.

The Ontario Section of the American Society of Mechanical Engineers, with the co-operation of the B-51 Committee of the Canadian Standards Association will hold a one-day seminar on the ASME Boiler Code and the ASA Code for Pressure Piping on September 21, 1956.

Readers are invited to submit questions which they would like to hear answered. It is expected that most questions will concern power boilers, unfired pressure vessels, code for pressure piping. In addition there will probably be questions arising from welding requirements and others arising from nuclear applications.

Information may be obtained from G. C. Smith, chairman, or D. Quan, secretary, Ontario Section, ASME, Box 511, Hamilton, Ont.

For the first time in its fifty-year history, the American Concrete Institute (182 West McNichols Road, Detroit 19, Michigan) will hold its regional meeting in Montreal this year.

Many of the 8,000 members of this association intend to be at the meeting which will be held at the Sheraton-Mount Royal Hotel in Montreal on October 24-25. In addition to the business sessions, the program calls for two full days of tours of plants and of the St. Lawrence Seaway Power and Canal developments.

The Montreal meeting will mark the second time that this annual conference is held outside the United States.

The American Concrete Institute has contributed in a large way to the development of concrete technology on this continent.

The Canadian Chamber of Commerce (Board of Trade Building, Montreal 1) will hold the 26th annual meeting at Quebec City, October 15 to 18, 1956. Meetings will be at the Chateau Frontenac.

D. E. Kertland, of Toronto, has been elected president of the Royal Architectural Institute of Canada for 1956-57, the Institute announced recently.

A. F. Duffus of Halifax is first vice-president; K. C. Stanley of Edmonton is second vice-president. The honorary treasurer is Maurice Payette of Montreal and the honorary secretary is Harland Steele of Toronto.

The British Nuclear Energy Conference will be held November 22-23, 1956 at the Institution of Civil Engineers (1-7 Great George Street, London SW1).

Sponsors are the Institutions of Civil, Mechanical, Electrical and Chemical Engineers and the Institute of Physics.

NEW

weather-resistant, corrosion-resistant

GRINNELL VARIABLE SPRING HANGERS...

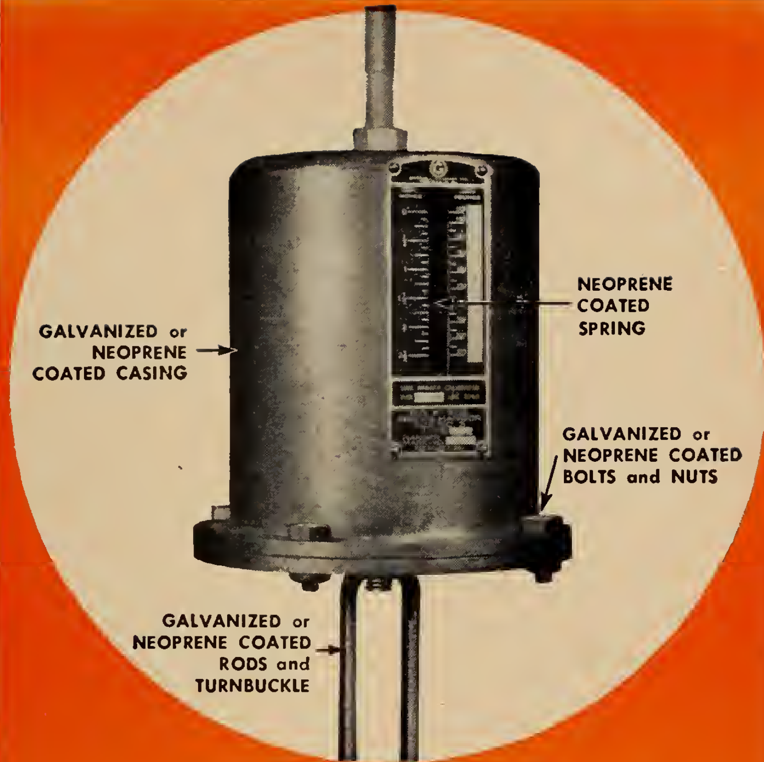
Another Grinnell First!

Grinnell pre-engineered spring hangers are now offered in two new lines to meet the need for spring hangers in installations subject to highly corrosive industrial conditions and to severe weather exposure.

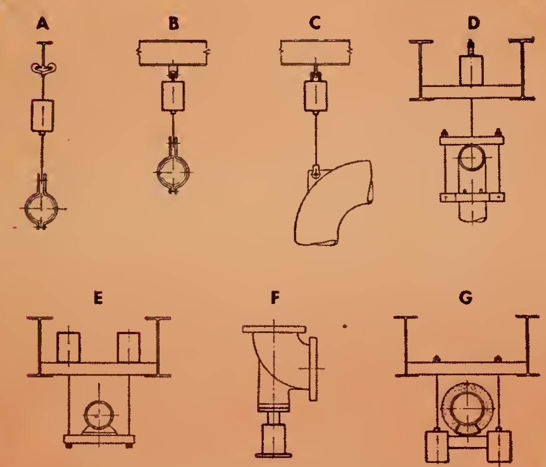
These hangers are the result of extensive experimentation with various coatings for Grinnell's standard pre-engineered spring hangers. In addition to providing flexibility in pipe suspension, they provide versatility of application through their corrosion-resistant characteristics. They are . . .

1. Neoprene coated — for highly corrosive conditions such as those found in chemical plants and refineries. *All* parts of the hanger are neoprene coated to protect the base metal from a wide range of corrosives. The flex life of the spring is unaffected by the neoprene . . . the coating resists cracking or flaking over a wide temperature range.

2. Galvanized — for outdoor installations where weather conditions are severe. All parts of the hanger are galvanized except the spring, which is neoprene coated to avoid alteration of temper, hydrogen embrittlement and decreased flex-life of the spring — usual hazards to springs from the galvanizing process.



AVAILABLE IN 7 TYPES FOR THESE TYPICAL APPLICATIONS



(A) Rod threaded to top cap (B) Furnished with single lug (C) Two lug style (D) Top adjusting (E) Adjustable top and bottom (F) For floor support (G) Trapeze assembly.

Along with the obvious advantages of such corrosion and weather-resistant characteristics, consider these features...

- Maximum variation in supporting force per ½" of deflection is 10½% of rated capacity — in all sizes.
- Precompression* assures operation of spring within its proper working range, as well as saving valuable erection time. Reduced over-all height saves space.
- 18 sizes available from stock for load ranges from 53 lbs. to 12,000 lbs.
- Available in 3 spring lengths for travel ranges of 1¼, 2½, and 5 inches.
- Installation is simplified by integral load scale and travel indicators.

*Precompression is a patented feature.

BOOK REVIEW

A guide for development;
Uranium City and district.

K. Izumi and G. R. Arnott. Regina, Department of municipal affairs, Community planning branch, 1956. 74p., mimeog.

This guide for the "fastest growing community" in Saskatchewan has a threefold purpose; to record existing conditions, to review initial premises and assumptions, and to outline requirements for future developments as a guide for local officials.

The committee preparing the report had very little information with which to work. For example, there was no detailed topographical information for other than the immediate townsite. At the time of he 1951 census Uranium City did not exist. Consequently, all estimates of future population, number, types ages, etc., have had to be based on techniques currently employed in planning new towns. This report supplements that issued in 1955 on the Beaverlodge Area in general.

Commencing with a brief history of the community from the arrival of the first inhabitants in 1952 up to September 1955 when there were some 1500 people living in the town, the report next considers location and climate.

The next few chapters consist of a population forecast, an estimate of the land required for both commercial and residential use, and a consideration of the sections of land in the area which will be usable for development. A forecast is made of the numbers of various types of accommodation which will be required, and suggestions are made as to minimum housing standards to be reached, methods of financing purchase, etc.

Suggested street plans are given for both residential and commercial districts, and recommendations are also made as to the numbers and types of commercial buildings which will be required eventually.

Other topics on which suggestions are made are education, recreation, transport, highways and traffic, utilities and services, and administration, including taxation, municipal officials and staff.

Although referring to one particular town, with its own set of problems, the report should be of interest to anyone concerned with establishing either a completely new town, or with planning new developments in an existing community. This is the second such publication we have received from the Saskatchewan Community planning branch within the past few weeks, and we think they are to be congratulated on the thorough way in which the plans are drawn up.

S. C.

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

BOOK NOTES

Prepared by the Library The Engineering Institute of Canada

* Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

Asbestos: its origin, production and utilization.

W. E. Sinclair. London, Mining publications, 1955. 365p., illus., 50/—.

Seeing that Canada supplies seventy-three percent of the world's asbestos, it is interesting to see this book which, although general in nature, tends to concentrate on conditions in South Africa and Souhern Rhodesia, also large producers of asbestos.

After a short history of the mineral, there is a detailed discussion of the various types of asbestos and the form and nature of their disposition, and world distribution. Production methods are discussed, mining, milling, classification, grading and marketing. The commercial applications of the fibre are considered and brief mention is made of synthetic asbestos.

There are many statistics on resources, production, consumption and cost, although unfortunately few of these are for later than 1952. A good bibliography and geograhical index complete this very interesting and useful book.

Atoms and energy.

H. S. W. Massey. New York, Philosophical library, 1956. 174p., illus., $4.75 (U.S.)

Written by the vice-president of the Atom scientists association who has already written three monographs on atomic physics, this book gives a non-technical account of the developments in atomic physics leading to the large scale release of atomic energy.

The first two chapters discuss the relations between electrons, protons, neutrons and atoms and the chemical energy in atoms. Also discussed are the large scale release of atomic energy, and the uses of atomic energy, both peaceful and otherwise. A final chapter details some of the present day research in atomic physics.

***Calculation of change gear ratios.**

E. H. Wang. Available from the author, 601 Monroe Drive, Xenia, Ohio, 1954. 116p., spiral binding, $3.50 (U.S.)

The problem of finding two, four, six, and more gear ratios that will approach desired ratio in the form of a decimal is an old one. The author here provides a systematic development of simple principles. Factor tables and sample work charts follow a step-by-step explanation of the methods. The most suitable practical ratio within a given permissible error may be found or, if wanted, the ratio with the smallest error.

***Design manual for roller and silent chain drives.**

Prepared by Jackson and Moreland. Indianapolis, Association of roller and silent chain manufacturers, 1955. 95p., illus., $3.50 (U.S.)

A practical manual covering the design of roller chains and sprockets, procedures for selecting roller chain drives for given requirements, and roller chain installation, lubrication, and maintenance. A chapter on the design of silent chain drives, a brief history of chain drive, and a discussion of the relative merits of chains, gears, and belts are also included.

The disposal of sewage, 3rd ed.

T.H.P. Veal. Toronto, British Book Service, 1956. 208 p., illus., $5.10.

A textbook on the subject, now in its third edition, the book covers the main principles and methods of sewage treatment and disposal. Descriptions of older

Me–I could write a buyer's guide!

WHEN IT COMES to equipment, you can't fool maintenance men. They know what stands the gaff—and what doesn't. They also know a lot of their work is due to faulty selection of equipment—mistakes in judgment of quality, mainly.

In buying valves, such mistakes usually happen when someone buys on price alone, or because "all valves look alike". In either case, today's penalty is excessive maintenance at the highest labor rates in history. And where valve trouble causes production loss, it, too, was never costlier.

Standardizing on Crane valves eliminates a lot of mistakes, and it's the thriftiest habit in piping equipment buying. Better Crane quality and bigger selection assure it.

For complete information on the Crane Valves to meet your particular requirements, ask your Crane representative, or Crane Branch—or write:

CRANE LIMITED

PLUMBING • HEATING

NATION-WIDE SERVICE THROUGH BRANCHES, WHOLESALERS and PLUMBING AND HEATING CONTRACTORS

methods of historical interest have been retained, but the rest of the material has been brought up to date, and a chapter has been added on the disposal of liquid industrial waste. Some of the topics covered are quantity of sewage, settlement processes, bacteria beds, bio-aeration tanks and disposal of sludge. There is also a suggested scheme for a city with a population of 50,000.

Electrical interference.
A. P. Hale. New York, Philosophical library, 1956. 122p., illus., $4.75 (U.S.)

The amount of knowledge available on electrical interference with radio and television reception is now quite large. It is, however, largely scattered throughout technical journals. In this book the author has attempted to cover the subject in a thorough and practical manner.

He discusses both the causes and effects of interference, the latter being illustrated by actual photographs of the different types of television picture distortion caused by different electric motors. Also covered are measurement, location and avoidance and interference, filters and Faraday cages. There is also a listing of British standards on radio interference and suppression.

Electronic computers and management control.
George Kozmetsky and Paul Kircher. Toronto, McGraw, 1956. 296p., $6.00.

Written by a business executive and a college professor, this book is intended for the business executive, and is written in non-technical language. Its purpose is to show how electronic computers can help to solve business problems, and how they can influence management planning and control.

Introductory chapters describe just what an electronic computer is, and surveys electronic methods of data processing. Actual applications of the use of computers are cited, and the extensive bibliography lists source material for those wishing to pursue the subject further. Included in the appendices are a description of the "language" used in a computer, programming for a computer, and details of the various types of electronic data-processing equipment.

Electrons, waves and messages.
J. R. Pierce. Toronto, Doubleday, 1956. 318p., $5.95.

An explanation, for specialists in other fields and for the general reader, of the principles of modern electronics and their applications, chiefly in long distance communication and radar. The author reviews some of the basic laws of physics concerning motion, electric and magnetic fields, and waves; shows these at work in such devices as transmission lines, resonators, antennas, and vacuum tubes; and explains how these components are combined in mocrowave systems. Other subjects discussed include television, communication theory, relatively, and quantum mechanics.

°Elementary nuclear theory, 2nd ed.
H. A. Bethe and Philip Morrison. New York, Wiley, 1956. 274p., $6.25.

This is an introduction to the subject for students and scientists who are not specialists in nuclear physics. As in the first edition, the central theme is the problem of nuclear forces treated from the empirical point of view. In this revision, more space has been devoted to the structure and reactions of heavier nuclei. In addition, the book has been expanded to twice the number of pages in order to take into account theoretical and experimental advances, particularly in the energy range of hundreds of Mev. The appended table of nuclear species and their masses has also been revised.

Engineering fluid mechanics.
Charles Jaeger. Glasgow, Blackie, 1956. 529p., illus., 60/-.

This English translation of a well-

• LIBRARY NOTES

known book is in effect a third edition, as it incorporates changes made in the French translation which appeared in 1954, and contains further additions and revisions.

Beginning with a section on fundamental hydraulic principles, this text has three subsequent major sections on steady flow, unsteady flow, and flow in underground strata. Particular attention is paid to basic hydrodynamic equations, open - channel flow, surge tanks, and water hammer. An appendix discusses experimental values for hydraulic calculations dealing with the effect of bends and other physical conditions. The value of the book is increased by the large number of bibliographical footnotes.

Handbook of radioisotope applications. (1)

Manual of nuclear instrumentation. (2)

New York, Nucleonics, 1956. (1) 144p., $1.00 (U.S.) (2) 96 p., 50 cents (U.S.)

Both books are compilations of articles which have appeared in the periodical Nucleonics.

The Handbook is concerned with the applications of radioisitopes, and after an introductory section on the sources of radiation, the other five sections cover applications in the industrial field; in food sterilization; chemical uses; and applications in the fields of biology, medicine, agriculture, geology and metallurgy.

The Manual of nuclear instrumentation is composed of twenty-four articles covering the latest instrumentation methods and devices. These include radiaion detectors, calibrators, beta gauges, counting methods, scintillation counters, monitoring of liquids for radioactivity, etc.

The hazards to man of nuclear and allied radiations.

Ottawa, United Kingdom information service, 1956. 128p., $1.04.

Prepared by the British medical research council, this report presents the medical aspects of the dangers of nuclear radiation.

After an introductory chapter on the nature of radiation and its action on living cells, the report considers the effect of radiation on health, and the genetic effects. Also discussed are the existing and foreseeable levels of exposure to radiation, and one chapter is devoted to the different ways in which people are exposed, ranging from workers in hospitals handling radioactive isotopes to the use of X-rays in fitting shoes.

This is a very clear presentation of a subject which is becoming of increasing importance.

Heat transfer and fluid mechanics institute, 1956.

Stanford, University Press, 1956. 278p., $5.75 (U.S.) (Preprints)

This Institute was the ninth in the series started to make available to engineers in the west a program of research in heat transfer and fluid mechanics. The papers are presented in this preprint form so that participants may have a chance of reading them before the meetings, and so stimulate discussion.

The seventeen papers presented covered a wide variety of topics, the emphasis being on those which cover more than one specific field. There were, in addition, two special sessions or irreversible thermodynamics.

Those already acquainted with this series do not need to be reminded of its value, which is further enhanced by the bibliographies given at the end of most of the papers.

Manganese steel.

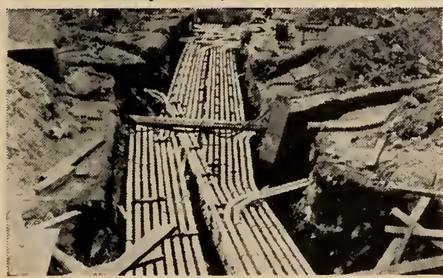
Hadfields Limited. Toronto, Clarke, Irwin, 1956. 128p., illus., $3.75.

Manganese steel was first produced by Sir Robert Hadfield in 1882. This book gives the history of that invention, and discusses the manufacture and properties of this extremely tough steel, under such headings as heat treatment; work-

Johnny Sparks says:

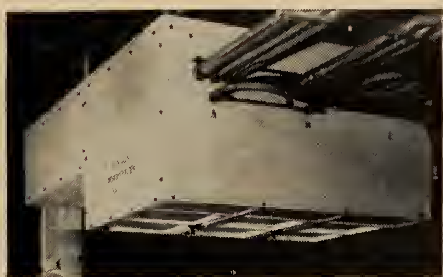
This Johns-Manville team helps keep power flowing safely

at lowest cost . . .



J-M TRANSITE DUCTS — Made of asbestos and cement. Transite Conduit and Korduct are inorganic and unaffected by electrolysis and corrosive soils. Long, lightweight lengths.

J-M DUXSEAL — A non-hardening adhesive plastic compound for sealing openings between cables and duct walls. Comes in handy package. Use it like putty. Won't harm hands.



J-M TRANSITE SHEETS — An asbestos-cement product. Excellent for housing electrical apparatus. Strong, durable, incombustible. It can be readily cut, machined or drilled.

J-M ASBESTOS EBONY — A permanent high-dielectric panel board material. Won't rust, rot, shrink or buckle. Available in sheet form or in pre-fabricated shapes to order.

The controlled quality in J-M Electrical Materials is consistently dependable. It has been achieved through nearly a century of operating experience and laboratory research. Specification of these materials will help to avoid waste, save installation time, cut maintenance costs and do much to promote safer handling of electrical energy. Immediate and long-term satisfaction is assured. Johns-Manville makes many other materials specifically for the electrical industry. For more information, write Canadian Johns-Manville, 565 Lakeshore Rd. E., Port Credit, Ont.

J-M QUINTERRA AND QUINORGO — New purified asbestos paper for class B and class H insulation. Widely used for interlayer and wrapper insulation in transformers, coils, etc.

hardening, abrasion and wear resistance; machining; welding; industrial applications.

Written by members of a firm most closely associated with its manufacture, this book may be regarded as a reference work on manganese steel.

Micro-indentation hardness testing.
B. W. Mott. Toronto, Butterworth, 1956. 272p., illus., $8.40.

Primarily for those in the metallurgical field, this book was written in order to provide as comprehensive a review as possible of the work which has been done on micro-indentation hardness testing. This is a relatively modern development, having taken place in the last twenty years, and the majority of the references in the five hundred item bibliography are taken from this period.

After an introductory chapter on the various concepts of hardness, and the relation of indentation hardness to other physical properties, various types of apparatus for low-load testing are considered. Following chapters cover the classificiation of factors involved in determining hardness, correct application of the load and accurate measurement of the impressions produced, variations on low-loads and the extensive range of low-load testing to a study of metals and non-metallic materials.

Future applications and problems for investigation are covered in the last chapter, while tables of hardness numbers for both metallic and non-metallic materials are given in the appendices.

Modern techniques of excavation.
H. L. Nichols, Jr. Greenwich, North castle books, 1956. Various pagings, illus., $9.00 (U.S.)

Land clearing, ditching, dewatering, landscaping, grading, tunneling, underground mining, and other operations are described in detail, with special attention given to planning, supervision, and techniques for solving problems that may arise. With the exception of a section on defects in equipment, the contents follow closely the chapters titled "The work" in the author's "Moving the earth", published in 1955.

Petroleum and its combustion in diesel engines.
John Lamb. London, Griffin, 1955. 264p., 26/–.

The author has based this work on his forty years' experience with diesel engines of all types.

He deals with the burning of diesel fuel, the special machines which purify residual fuels, and the production of petroleum. The book is full of advice on the trouble-free and economical running of engines, and contains much information on the easy diagnosis of irregularities in combustion. The book will be of particular value to ships' engineers and motorship owners.

Plastic design of steel structures.
J. W. Dolphin, A.M. Nelson and D. T. Wright. Kingston, R.M.C. and Queen's university, 1956. irreg. paging, mimeog., diagrs.

In recent years there have been rapid developments of the ultimate or plastic strength design methods for steel structures. A short course was given on the subject at Lehigh University in September of 1955, and in May of this year a short course for practising structural engineers was given jointly by the Royal military college and Queen's university under the sponsorship of the Canadian institute of steel construction.

This book presents notes of the ten lectures given at this course, and covers such topics as the simple plastic theory of flexure; collapse of indeterminate beams; collapse mechanisms; plastic moment distribution; and building design.

All those interested in this type of design will find this a most valuable and interesting book, supplementing as it does the scattered periodical literature on the subject. The value of the notes is increased by the bibliographies found at the end of each lecture.

Principles of color television.
Knox Mcllwain and C. E. Dean, eds. New York, Wiley, 1956. 595p., diagrs., $13.00.

Compiled from a series of reports prepared by the Hazeltine corporation, this book presents the features of transmitting, receiving and measuring equipment needed for colour television.

Some of the topics covered include colour perception, colorimetry, production of a composite colour signal, synchronization, equipment for producing the transmitted signal, and decoders. Also included are the television standards of the FCC, and a glossary of color television terms.

The value of the book is enhanced by the long bibliographies at the end of each chapter.

Principles of electric and magnetic fields, 2nd ed.
W. B. Boast. New York, Harper, 1956. 418p., diagrs., $6.00 (U.S.)

A textbook for undergraduate students taking a first course in electrical engineering, this book covers both electric and magnetic fields comprehensively.

Although not a complete revision, the text in this second edition has been brought up to date, and a new chapter has been added providing an introduction to Maxwell's field equations. No mathematics higher than elementary calculus are required, and the MKS system of units is used throughout.

Principles and techniques of applied mathematics.
Bernard Friedman. New York, Wiley, 1956. 315p., $8.00.

The author's aim in writing this book was to show that the abstract methods developed in pure mathematics can be used to systematize the techniques for solving problems in applied mathematics.

Throughout the book, stress is laid on ideas, and not the details of proof. These latter, together with many examples, have been placed in the appendices and problems occurring at the end of each chapter.

The first part of the book is concerned with a study of abstract linear spaces, and of operators defined on such

spaces. Chapters are also devoted to ordinary and partial differential equations.

Radiocarbon dating, 2nd ed.
W. F. Libby. Toronto, University press, 1955. 175p., $4.50.

The principles and techniques of estimating the ages of organic materials, especially artifacts of archeological interest, by measuring their radioactive carbon content is discussed in this book.

In this second edition, the latest advances in measurement and sampling techniques are included, and the list of dates determined by the author's laboratory research has been greatly enlarged. A chapter by Frederick Johnson discusses the importance of radiocarbon dating. The bibliographical references have also been brought up-to-date.

Techniques of plant maintenance and engineering, 1956.
New York, Clapp and Poliak, 1956. 248p., $10.00 (U.S.)

The importance of plant maintenance has been increasing for many years, and the advent of automation further enhances its importance. The series of books on the techniques of plant maintenance, of which this is the seventh, has proved itself of value to all plant maintenance engineers.

This book reports the proceedings of the conference held in conjunction with the seventh plant maintenance and engineering show and contains the texts of 16 papers, summaries of 15 round-table discussions and answers to approximately 1,100 specific questions.

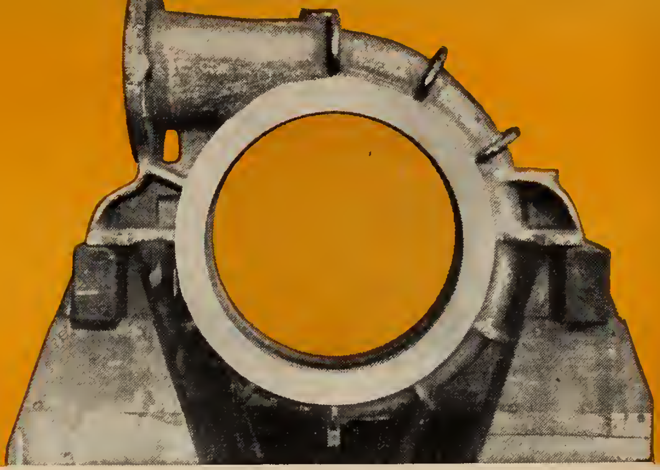
Subjects include preventive maintenance, getting maintenance people to work as a team, measuring the effectiveness of maintenance, sanitation, equipment replacement policies, independent contractors, 24-hour operation, painting, design and operation of maintenance shops, cost control, inspection procedures, building and yard structure maintenance, use of punched cards, electrical equipment, lubrication, machine tools, report writing, relationship between maintenance and purchasing departments, utilities, forms and reports, and tool room control.

Five industries were considered in particular at these sessions; air transport shops; chemical plants; petroleum refineries, paper mills and paper products plants; and textile mills.

The ultimate-load theory applied to the design of reinforced and prestressed concrete frames.
A. L. L. Baker. London, Concrete publications, 1956. 91p., $4.00.

The design of reinforced and prestressed concrete structures by the ultimate load method has been in use in some Continental countries for several years. A feature of this method of design is that it is based on the load causing failure of the whole structure instead of the elastic theory now generally used. This book discusses the probability of failure and its effects, and describes how a suitable factor of safety can be

NI-RESIST pump casing cast by Babcock-Wilcox and Goldie-McCullough Ltd., to handle "green liquor" in a Canadian pulp mill.



NI-RESIST*

ALLOYED CAST IRONS

no other cast metal provides such a unique combination of useful engineering properties

NI-RESIST casings on these Canadian Allis-Chalmers pumps give excellent service in salt water application at Nova Scotia Light and Power Company.

The Ni-Resist alloys form a group of high nickel alloy cast irons containing sufficient nickel to produce a complete change in the chemical and physical characteristics as well as in the metal structures.

Since its introduction in 1927, the Ni-Resist family of alloy irons has been widely adopted to reduce corrosion costs in the oil, paper and chemical industries; to maintain high quality of foods, plastics and soaps, and to prevent wear of vital machinery, power units, furnace parts and so forth.

Ni-Resist castings are readily available from authorized foundries in all of the important industrial areas across Canada.

THE INTERNATIONAL NICKEL COMPANY OF CANADA, LIMITED
25 King Street West, Toronto

INCO TRADE MARK

Corrosion Resistance
Solves countless problems involving the handling of acids, alkalies and salts.

Wear Resistance
Ni-Resist parts are particularly resistant to metal-to-metal rubbing, especially under corrosion conditions.

Erosion Resistance
Ni-Resist alloys belong to the few metals that show economical service under many erosion conditions.

Toughness and Low Temperature Stability
Considerably better than gray iron.

Controlled Expansion
Expansivities ranging from 2.2 to 10.6 millionths of an inch per °F are available with the different types of Ni-Resist.

Magnetic and Electrical Properties
Some types are non-magnetic and have high electrical resistance.

Heat Resistance
A high order of heat resistance is available. Certain types are recommended for service up to 1500°F.

Castability and Machinability
Foundry characteristics of these alloys permit complicated designs often difficult in some other metals. Machinability rates of same order as those of conventional pressure type gray iron.

STANDARDS REVIEWED

A.S.T.M. Standards, American Society for testing materials, 1916 Race St., Philadelphia 3.

Light metal and alloys.

This third edition includes specifications on light metal alloy die castings, aluminum wire and cable for electrical purposes, and aluminum and aluminum alloy arc-welding electrodes and for brazing filler metal.

The standards include ingots, castings, bars, rods, wire, forgings, pipe and tube, sheet and plate, wrought products for electrical purposes, filler metal, electroplating, and general methods of test. There is also included the ASTM codificcation system for light metals and alloys. 276p., $3.50 (U.S.

Some of the SMS-Francis Turbine units, rated at a total of 56,000 HP under a 124-foot net head at a speed of 112.5 RPM, are shown during shipment and installation for the Manicouagan Power Company, Ltd., Quebec.

GIVE YOU HIGHER EFFICIENCY

Where head and flow do not vary widely, SMS-Francis Turbines can be expected to give you higher maximum efficiencies than other types. For heads between 100 and 1,000 feet, their outstanding performance characteristics, rugged design and dependable operation mean top performance.

In Canada, and throughout the world, SMS-Francis Turbines representing more than 8,300,000 HP are installed or on order. They are the product of over 75 years' experience in the design and manufacture of hydraulic turbines and accessories. This broad engineering background is your assurance of equipment that will meet the highest standards. For full information, write to S. ond and third in a series for copper alloy valves for general purposes specify requirements for rating, design and manufacture, materials, dimensions and tests and markings. 6/— and 5/—.

B.S. 2718:1956 — Gas cylinder trolleys for use in hospitals

This British standard has been added to the series published during the past few years on tubular-framed equipment for hospitals.

It specifies the materials, dimensions and constructional requirements for gas cylinder trolleys primarily intended for use in hospitals. Two patterns are specified in sizes related to oxygen cylinders of 24, 48, 120 and 180 cu. ft. capacity, but the trolleys are suitable also for the carriage of cylinders of compressed air and other gases.

As a precaution against risks arising from the discharge of static electricity, all rubber on the trolleys is required to be of anti-static composition and the base plates supporting the cylinders are required to be finished with a conductive metallic coating, 3/6.

B.S. 2746:1956 — PVC insulation and sheath of electric cells

This standard has been prepared to bring together in a single publication the methods of test and test requirements for various types of polyvinyl chloride insulation and sheath taken from electric cables. A colour chart giving thirteen standard colours is included. 7/6.

B.S. 2G112:1956—Air-driven directional gyroscopes for aircraft. 3/—.

B.S. S523:1956 — 23/18 chromium-nickel steel sheets and strips (heat-resisting) 2/—.

Canadian standards, Canadian standards association, National research building, Ottawa.

B35-1956 — Binding head machine screws, 3rd ed.

This standard shows the series of sizes and pitches, with head dimensions, body diameters, and screw and thread lengths, for binding head screws. These screws are used in the electrical trade for the purpose of securely holding wires or clips, or as a substitute for round head screws where a larger head diameter with reduced head height is required. The range of sizes given is considered sufficient for all practical purposes, and should be adhered to whenever possible. 75 cents.

C22.2 No. 49-1956 — Construction and test of flexible cords and fixture wires, 3rd ed.

This specification applies to various types of flexible cords and fixture wires —except armoured cords — intended for use on power and lighting circuits in accordance with the Rules of Part I of this Code.

It is divided into seven sections, and covers cords with the following types of insulation: rubber, thermoplastic, asbestos, and cotton. It also covers heater cords and tinsel cords, and test methods and apparatus. $3.00.

C84.1-1956 — Enamelled round copper wire, 2nd ed.

This specification covers the dimensional and performance requirements for round copper magnet wire insulated with a coating of baked oleo-resinous enamel. It covers dimensions, electrical resistance and tests. $1.25.

C84.2-1956 — Vinyl acetal insulated magnet wire, 2nd ed.

The specification is based largely on that issued by the National electrical manufacturers association covering this type of wire. It covers the dimensional and performance requirements for round copper magnet wire insulated with a coating of baked vinyl acetal resin.

The Electrical Power Industry

THE AMENITIES OF modern life such as readily available light and heat, radio, television, and other domestic appliances are now too frequently taken for granted. So also, to some extent, is the great industrial expansion that is now under way in Canada as in other industrial countries.

A few moments thought will bring to mind that our domestic amenities, our transportation and the fuels to move it, agricultural equipment and chemicals, that permit the production of enough food — in short, almost any aspect of our existence— are largely dependent on electrical power for their manufacture or functioning.

Electric power is of particular import in Canada, which now has the second highest power consumption *per capita* in the world (the Province of Quebec actually has the highest figure) and stands second only to Norway in the *per capita* production of electricity from water power. Power production must keep pace with the need for expansion of the country's industry as a whole—without power, in the right place and at a reasonable cost, the industry will not be able to expand.

It has been estimated that firm energy requirements in 1955 were rather more than 72,000 million kilowatt-hours (kwh.); by 1959 these requirements will have increased by nearly 40 per cent to over 100,000 million kwh. These figures do not include the indicated reserve, which amounts to an additional 10 to 14 per cent. The capital investment required to keep up with the demand is estimated at $634 million in 1956, compared with $450 million in 1955 and $455 million in 1954. Experienced observers regard the next decade or so as the period of greatest potential expansion within the history of the electric power industry.

The engineer will play a very large part in this expansion.

The production of electric power in Canada has become associated in many minds almost exclusively with the country's great hydro-electric developments, and Canada is certainly among the leaders in this field. Furthermore, it is estimated that only about 27 per cent of the country's available water power has yet been developed, and that there is a potential of some fifty million undeveloped horsepower.

All this is true, and there is now great scope for engineers in the planning, design, and development of new hydro-electric plants and the extension of existing facilities. There is, however, a much wider aspect of the future of the power industry.

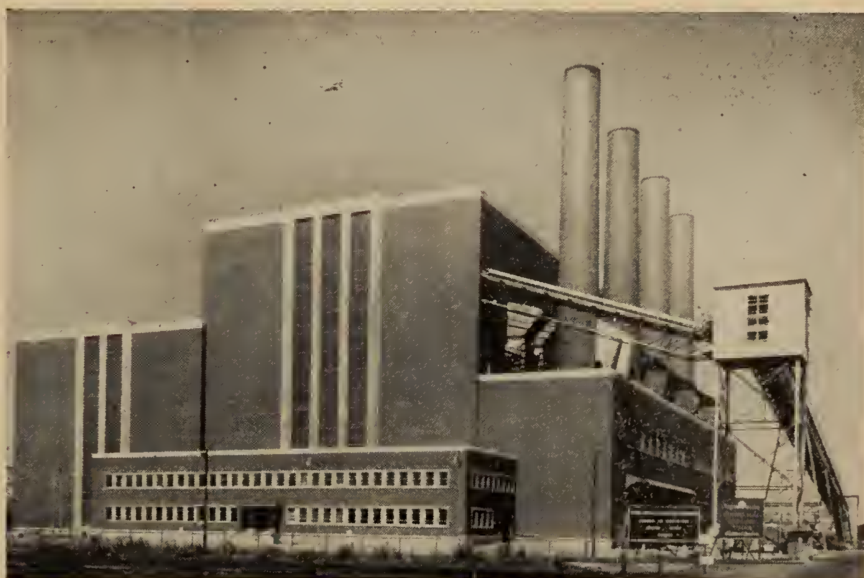
The huge potential of water power, at present rates of development, could well be exhausted within a generation. Moreover, not all this power could be developed economically enough to compete, in a given area, with other methods of power generation, perhaps because of a location too remote from the consumer and excessively high transmission costs. Consequently, future plans of the industry as a whole foresee a very great expansion in thermal generating stations, using coal, oil, and other conventional fuels, according to their availability, with nuclear energy as a long-term addition to the energy resources.

Thermal Power

The distribution of economically developable water power between provinces varies considerably. A notable example of the trend to thermal power generation is found in Ontario, where studies made by Ontario Hydro for their future expansion indicate that by about 1968 thermal generation will almost equal hydraulic generation, and after that time the system resources will become predominantly fuel-electric. (In 1955, the Commission's hydro/fuel generation ratio was approximately 5/1.)

Ontario Hydro further estimates total resources may be 23.6 million kilowatts (approximately 4.5 million kw. at present), of which 5.5 million kw. will be from hydro-electric generating stations, 10.6 million kw. from conventional fuel-electric

Thermal (fuel-electric) plants will play an increasing part in Canadian power production. Shown here is the largest thermal (pulverized coal) plant in Canada, which will have a capacity of 600,000 kw. when additions are completed in 1958.



stations, and almost 7.5 million kw. from nuclear-electric sources.

These figures, of course, refer to one province only, but they are indicative of the general future trend and of the great rate of expansion that is contemplated.

The demand for engineers is also considerably extended into the field of thermal generation. Improvements are constantly being sought and new techniques introduced as the result of engineering studies. In the 1920's coal-burning power plants required about three pounds of fuel per kwh.; today consumption has been reduced to one pound, or less, per kwh.

New problems arise with the introduction of the gas turbine into large-scale power production. A 100,000 h.p. gas-turbine generating station is to be built on Vancouver Island, the decision to use this form of power production having been made as the result of intensive engineering studies.

Probably the most intensive field of study, that is now in the process of developing on a large scale in Canada, is that of nuclear engineering. Nuclear power is not the quick answer to the question of how to meet future shortages; it is undoubtedly a long-term solution to many such problems, but only as the result of much fundamental work and the development of new engineering techniques.

Transmission

The scope of the industry under discussion does not end with the production of electric power. This power must be transmitted from its source to the consumer, quite frequently considerable distances over very difficult country, and the engineer is constantly faced with new problems of ensuring efficient transmission under all conditions and with the greatest efficiency and economy.

The Role of the Engineer

Many branches of engineering are involved in the electric power industry, and many engineers are needed.

This demand exists across the whole country, but as an example of the numbers of engineers involved one may take the Hydro-Electric Power Commission of Ontario, which (in 1955) employed some 1000 professional engineers, of whom about 100 occupied senior supervisory positions. Though not a necessary qualification, many of the senior executive positions of the power industry are filled by professional engineers.

The civil engineer finds work in the fields of reinforced concrete, structures, soil mechanics, hydraulics, plant layout and construction, and so on. The mechanical engineer may deal with such matters as design, construction and operation of coal- and oil-fired steam generators, large high - pressure high - temperature steam turbines, gas turbines, pumps, fans, ventilating and exhaust systems, and metallurgical studies.

The electrical engineer is responsible for the electric design of hydro and thermal generating plants, transmission lines, substations, distribution systems, high-speed switch-gear and relays, and electronic remote control and communication systems. The chemical engineer is also in demand for the study of feed waters and their treatment, insulating oils, and other materials.

Engineers of all categories find their place in such fields as rate and statistical study and analysis, and in general administration and management.

Opportunity for the engineer in the electric power industry is said to be exceptionally good during the present and foreseen period of expansion, which has already been outlined in this article.

Training

Most of the organizations within the electric power industry accept students for summer work, some of them on a considerable scale.

The graduate engineer, on entering the industry, is generally provided with on-the-job or special training for periods that may range up to about two years. In some cases the organization will help to pay for approved post-graduate courses.

Salary Scales and Benefits

Salaries throughout the industry are generally comparable and in accordance with the schedule recommended by the Associations of professional engineers across the country.

Other benefits, such as pension and health schemes, paid vacations, and so on, are customary.

Some Recent Developments

There are many papers and articles on the electrical power industry available for reference in the engineering libraries, but we would mention here some papers that have recently been published in *The Engineering Journal* and which give an insight into some of the problems tackled in recent developments.

Appointments and Transfers

Canadian Westinghouse Appointments—Recent appointments within Canadian Westinghouse Company Limited include: J. M. Bester, manager of product engineering, and M. K. Riddell, senior project engineer, engineering department of the defence apparatus division; W. G. Ratz, manager, standard induction motor engineering, and C. C. Sargeant, manager, large rotating machine engineering, in the engineering department of the power products division; G. S. Peabody, district service manager, Montreal district, and G. E. Matthews, district service manager, Moncton, N.B., in the service department of the district apparatus division. R. R. Guenett has joined the electronics division for special market development assignments.

Defence Production – The Right Honourable C. D. Howe has announced the appointments within the Department of Defence Production of David B. Mundy as director of the electronics branch, and of D. Lyn Thompson as acting director of the aircraft branch.

Minnesota Mining and Manufacturing – Kenneth J. Shea has been appointed vice-president and general manager of Minnesota Mining and Manufacturing of Canada Limited. Mr. Shea was previously vice-president and general sales manager with the company's international division.

K. J. Shea

English Electric Appointments – H. G. Nelson has been appointed managing director of the English Electric Company Limited, England, Sir George H. Nelson, Bart., having relinquished this position to devote all his time as executive chairman of the company.

Within the Canadian company, English Electric Company of Canada Limited, T. R. H. Jenkins has been appointed manager, circuit breaker engineering.

Canadian Car and Foundry—E. J. Cosford, president of Canadian Car and Foundry Co. Limited, announces the appointment of Allan C. MacDonald as executive vice-president. Mr. MacDonald has been managing director of Canadian Pacific Steamships Limited since 1952, and now also becomes president of the newly-formed Canadian Steel Foundries (1956) Limited (formerly Can Car's Steel Foundry Division). The new company is a separate corporate member of the A. V. Roe Canada Limited group: Mr. Cosford is chairman of the board and G. L. McMillin is vice-president and general manager.

Allan C. MacDonald

Robert M. Buchanan

Wallaces Barnes Appointment—Carlyle F. Barnes, president of the Associated Spring Corporation, and chairman of the board and acting president of its subsidiary, The Wallace Barnes Company Limited, has appointed Robert M. Buchanan general manager of the Canadian company.

Du Pont of Canada – J. H. Childs, division sales manager of the Du Pont Company of Canada Limited, announces the appointments of T. A. Day as sales technical manager and of W. B. McTavish as technical service supervisor in the films division of the company.

Trans-Canada Pipe Lines – T. H. Atkinson, former vice-president and general manager of The Royal Bank of Canada, has been elected a member of the board of directors of Trans-Canada Pipe Lines Limited, and appointed chairman of the company's finance committee.

Canadian Liquid Air–Paul J. Filiatreault has been appointed supervisor of the recently established retail marketing division of Canadian Liquid Air Company Limited. William C. Firth has been appointed manager of the company's recently established Niagara Falls branch.

Trane Appointments – Trane Company of Canada Limited announces the appointment of R. M. Fisher to their Hali-

It's a phantom bridge which nobody has ever seen, but all know it's there just the same. Traditions are its foundations, and ideals its lofty supports. Each span is a measure of hope in the future . . . each new span another link in the twin destinies of two friendly nations — the United States and Canada.

There have been many such links in the past. Here again, in the St. Lawrence Seaway Project, we've added another span — another instance of united action which will surely reap immense benefits to both peoples.

Yes, that bridge is there all right — invisible, yet never stronger . . . never wider . . . never more real than it is now — reaching over the International Seaway.

CANADA'S FIRST BANK
working with the U.S. and Canada . . .

Almost from the time of its foundation 139 years ago the Bank of Montreal has been contributing to the better understanding of the peoples of Canada and the United States by facilitating the flow of goods and information across the "border without bayonets".

It was in 1818, just one year after its establishment in Canada, that the B of M appointed Prime, Ward and Sands as its representatives in New York. Forty-one years later, the bank opened its own agency in New York, and followed later with offices in Chicago and San Francisco.

Today, with 675 branches across Canada, and with offices in New York and San Francisco and a special representative in Chicago, the Bank of Montreal is well qualified to help develop new and more fruitful relations between the two nations.

Canada's First Bank . . . WORKING WITH CANADIANS IN EVERY WALK OF LIFE SINCE 1817 fax sales engineering office and of Robert Chapman to the head office heating sales engineering department.

TV-Electronics Firm — Appointment of John M. McLean as vice-president and general manager of General Instrument —F. W. Sickles of Canada Limited is announced by General Instrument Corporation, parent company. An expansion plan now in hand will double the floor space of the company's Waterloo, Ont., plant.

Kenny Consolidated Engineering — W. F. Andrews is appointed sales manager of the separation and processing equipment department of Kenney Consolidated Engineering Industries Limited.

Dominion Rubber Company — Gordon A. Lamond becomes manager of sales of belting, v-belts, packing, cured stocks and tapes, mechanical goods division of the Dominion Rubber Company Limited.

Airco Appointment — P. F. Toner has been appointed assistant district sales manager, Air Reduction Canada Limited.

Josam Canada — J. S. Newman, vice-president and general sales manager of Josam Canada Limited announces the appointment of A. G. Stratton as Ottawa representative.

General Controls — George Crothers is appointed general manager of General Controls Co. (Canadian) Limited.

Ewart Greig

A. A. Cumming

F. Perry Wilson

Union Carbide Canada— At recent meetings of the board of directors of Union Carbide Canada Limited, the following senior appointments were made: Ewart Greig, chairman of the board; A. A. Cumming, president; F. Perry Wilson, vice-president (and continuing as president, Bakelite Company, Division of Union Carbide Canada). Also announced is the appointment of Philip O. Jeffrey as vice-president, Bakelite Company.

Naugatuck Chemicals — C. Ronald Howey is appointed development department manager of Naugatuck Chemicals, division of Dominion Rubber Company Limited.

Chiksan Field Engineer—Frank N. Land is named senior field engineer of Chiksan of Canada, Limited.

Glidden Company — Lionel Labreche becomes manager of the Glidden Company's new Quebec City branch.

Gardner-Denver Appointment — James P. Finnigan becomes general manager of Gardner-Denver Company (Canada) Limited, on the retirement of Charles E. Kaiser.

Canadian Ingersoll-Rand — T. M. Parr, manager, central region, Toronto, of the Canadian Ingersoll-Rand Company Limited, announces the appointments of John

J. K. Irwin

J. Knox

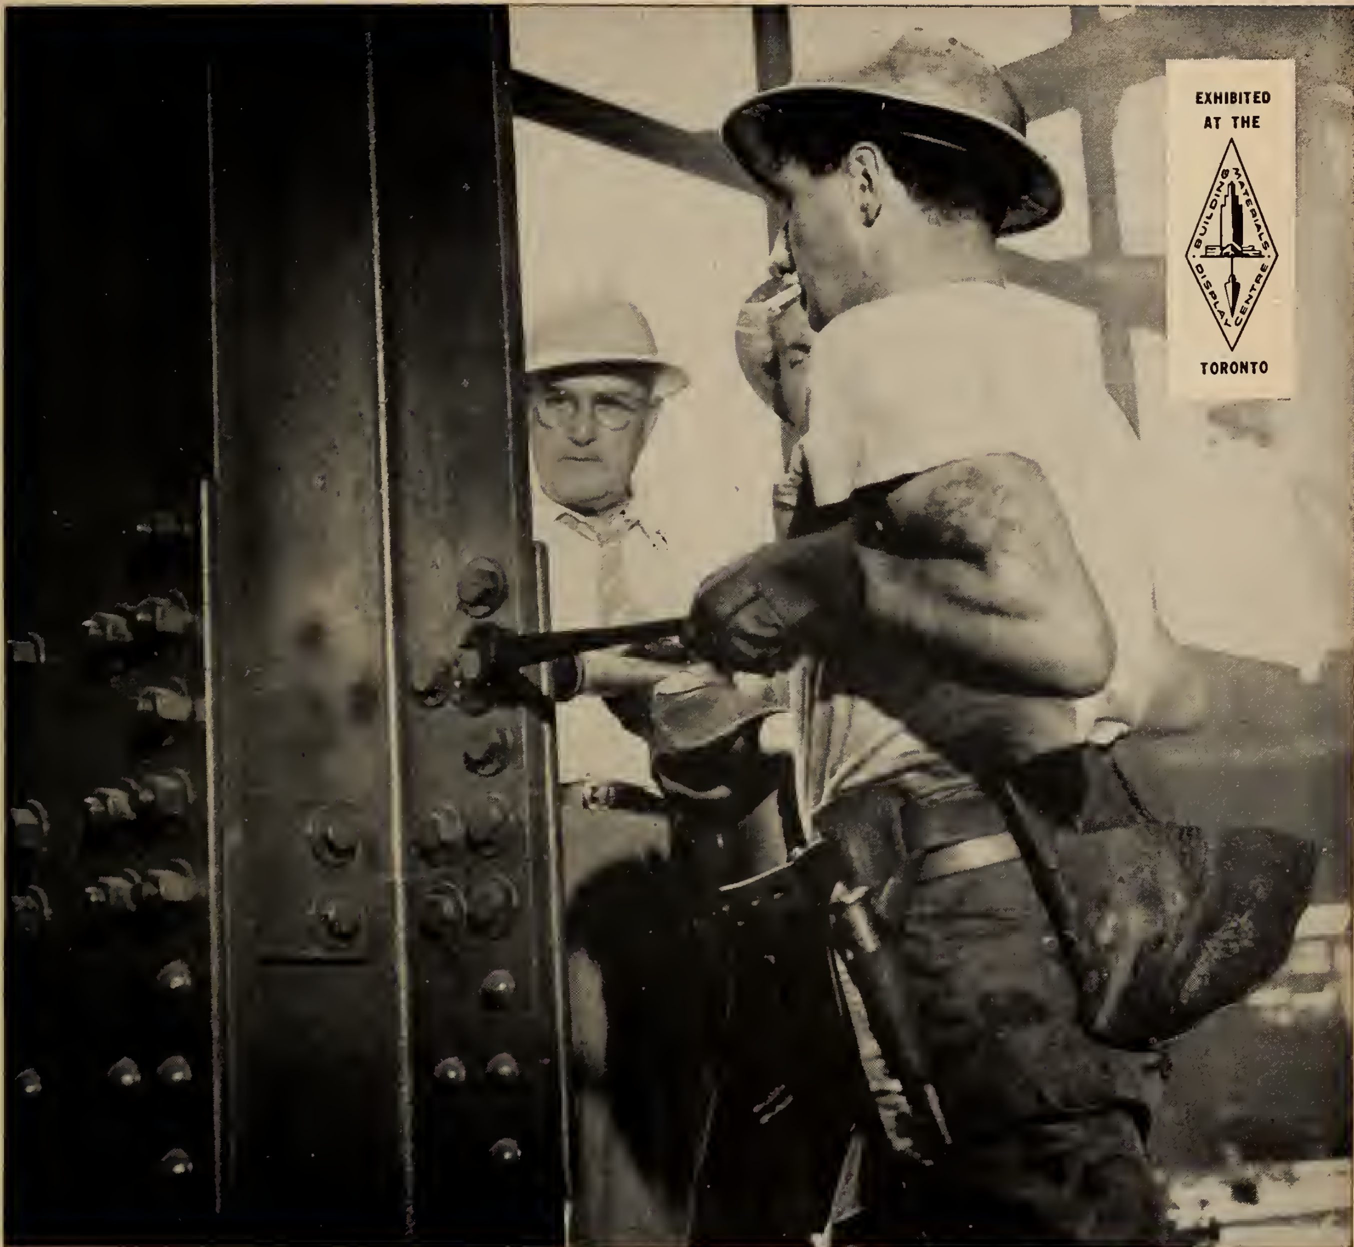
K. Irwin as manager of the company's Toronto branch, and of John Knox as manager of the Kirkland Lake branch.

Shell Oil—James S. Elliott has been appointed purchasing representative, Montreal, for the Shell Oil Company of Canada, Limited. Formerly assistant chief engineer, field, at Shell's Montreal East refinery, Mr. Elliott will now be responsible for the local purchasing for the refinery.

3M Appointment—Roy W. Keeley, former director of sales of Minnesota Mining and Manufacturing of Canada Limited has been appointed vice-president and general sales manager of 3M's International Division, St. Paul, Minnesota. He will be leaving the Canadian company to assume his new position early this fall.

J. H. Lock & Sons—W. J. Elliott has been appointed sales representative of the Steel Division of J. H. Lock & Sons, steel fabricators, Toronto. The announcement was made by W. Dalziel, manager of the Steel Division.

C-I-L Appointment—C. Scott Hannen has been appointed production manager of the explosives division of Canadian Industries Limited. He replaces Victor P. Row who has retired from the company.



Bolting beats riveting 3 to 1

The new Hiram Walker & Sons Ltd. Distillery Building in Windsor, Ontario, uses approximately 30,000 Stelco High-Strength Bolts.

Consulting Engineers:
Smith, Hinchman and Grylls, Detroit
Structural Steel:
The Canadian Bridge Co. Ltd., Walkerville, Ont.
Construction Engineer:
B. L. Bailie, Hiram Walker & Sons Ltd., Windsor, Ont.

High-Strength Bolts are quite commonly being installed at rates averaging 150 per man/day by crews with little or no previous experience . . . whereas 50 per man/day is a creditable rate of riveting, even for an experienced crew.

In addition, high-strength bolting requires less equipment, less training, less supervision, and causes less noise. It has also been proved both experimentally and in the field to produce stronger joints, with greater adaptability for future additions or alterations to the structure.

Finally, High-Strength Bolts in place on the job cost less than rivets. For a free technical booklet on this rapidly growing technique, contact any Stelco Sales Office.

Executive Offices: Hamilton — Montreal

Sales Offices: Halifax, Saint John, Montreal, Ottawa, Toronto, Hamilton, London, Windsor, Winnipeg, Edmonton, Vancouver. J. C. Pratt & Co. Limited, St. John's, Newfoundland.

New Equipment and Developments

New Desurger — A new desurger only one-sixth the size of older type devices has been announced by the Canadian Westinghouse Company. It can be used wherever a flow of liquid is maintainel. Available in sizes from one to eighteen inches.

Rechargeable Flashlight — Batteries that are recharged rather than replaced are a feature of Multi-Lite, a two-cell flashlight equipped with a 110 volt charger. The nickel cadmium cells deliver a steady bright light for a period equal to the average dry cell and are recharged by plugging the charger into the base of the light. The flashlight can be recharged 200 or more times according to Gould National Batteries of Canada Ltd., Toronto.

Turbo-Generators Ordered.—Orders for 200 Mw. turbo-generators for power stations in England and in Canada have been received by C. A. Parsons & Co. Ltd., Newcastle-upon-Tyne. The machine for Canada will be the first 200 mw. turbo-generator to be installed in that country, and the first 200 Mw. set to be exported from England. The machine has been ordered by The Hydro-Electric Power Commission of Ontario for the Richard L. Hearn Generating Station, Toronto. The new machine is of the cross compound design, the H.P. line running at 3600 r.p.m. and the L.P. line at 1800 r.p.m., each line being coupled to a 100 Mw. generator. The operating steam conditions are 1800 lb. sq. in pressure, 1000 deg. F. temperature, and with reheating of the steam to 1000 deg. F. after partial expansion.

Research and Development Laboratory. — A further addition to its research and development laboratory facilities will be made by Canadian Industries Limited. The new laboratory will be located on the site of C-I-L's "Fabrikoid" works at New Toronto, Ontario, and will service the company's plastics and "Fabrikoid" divisions.

The plastics section will replace the plastics laboratory at the C-I-L York works in Toronto, and will be equipped with modern commercial-sized extrusion, injection moulding, paper coating and wire covering machines. Its chief function will be to provide increased technical service to Canadian plastics converters, most of whom are located in the Toronto area. The new laboratory will work in conjunction with C-I-L's plastics development laboratory at Edmonton and research laboratory at McMasterville, Quebec.

New Plant.—Manning, Maxwell & Moore of Canada, Ltd., will build a new plant in Galt, Ontario, that will cost approximately $250,000, Chester H. Butterfield, vice-president, recently announced. To be built on a ten-acre site, the new plant will be a one-storey design and contain over 30,000 square feet of manufacturing and office space. Ball Brothers, Limited, Kitchener, Ontario, is the contractor and occupancy is to take place about January, 1957.

Arc-Welding Safety Slide Film.—The Air Reduction Canada Limited has available a new 20-minute sound slide film, entitled "Always On The Job", covering the basic principles of safety in electric arc-welding. A companion film to Air Reduction's prize winning oxyacetylene safety slide film, "The Guy Behind Your Back", the new film also features the light, cartoon approach to this serious topic. Record is 33-1/3 r.p.m. speed. This film is available from Air Reduction Canada Limited, 905 Hodge Street, Montreal 9, on a free-loan basis.

Most Powerful Kaplan Turbines.— S. Morgan Smith Company, of York, Pennsylvania, will build three 280-inch Smith Kaplan turbines for a U.S. Army, Corps of Engineers project. Installation will be at Ice Harbor Lock and Dam on the Snake river, 12 miles from Pasco, Washington. The turbines will operate over a head range of 78 feet to 102.5 feet. Their rating is 143,000 h.p. at 90 r.p.m. under an 89-ft. head. These will be the world's most powerful Kaplan turbines surpassing even McNary which has a rated capacity of 111,300 horsepower under 80-ft. head. Shipment of embedded parts starts December 1, 1958, with completion of the third unit, July 1, 1960.

Hydro-Electric Development.—The site of The Shawinigan Water and Power Company's newest hydro-electric development, Rapide Sans Nom or the rapid without a name, has been named Rapide Beaumont by the Quebec Geographical Commission. It is on the St. Maurice River about 10 miles above La Tuque, Que. Announcement of the naming of the rapids after Robert J. Beaumont. chairman of the Board of Directors of the Shawinigan Company, was made recently, and the new hydro-electric plant at the site, construction of which has started, will now be known as the Beaumont development.

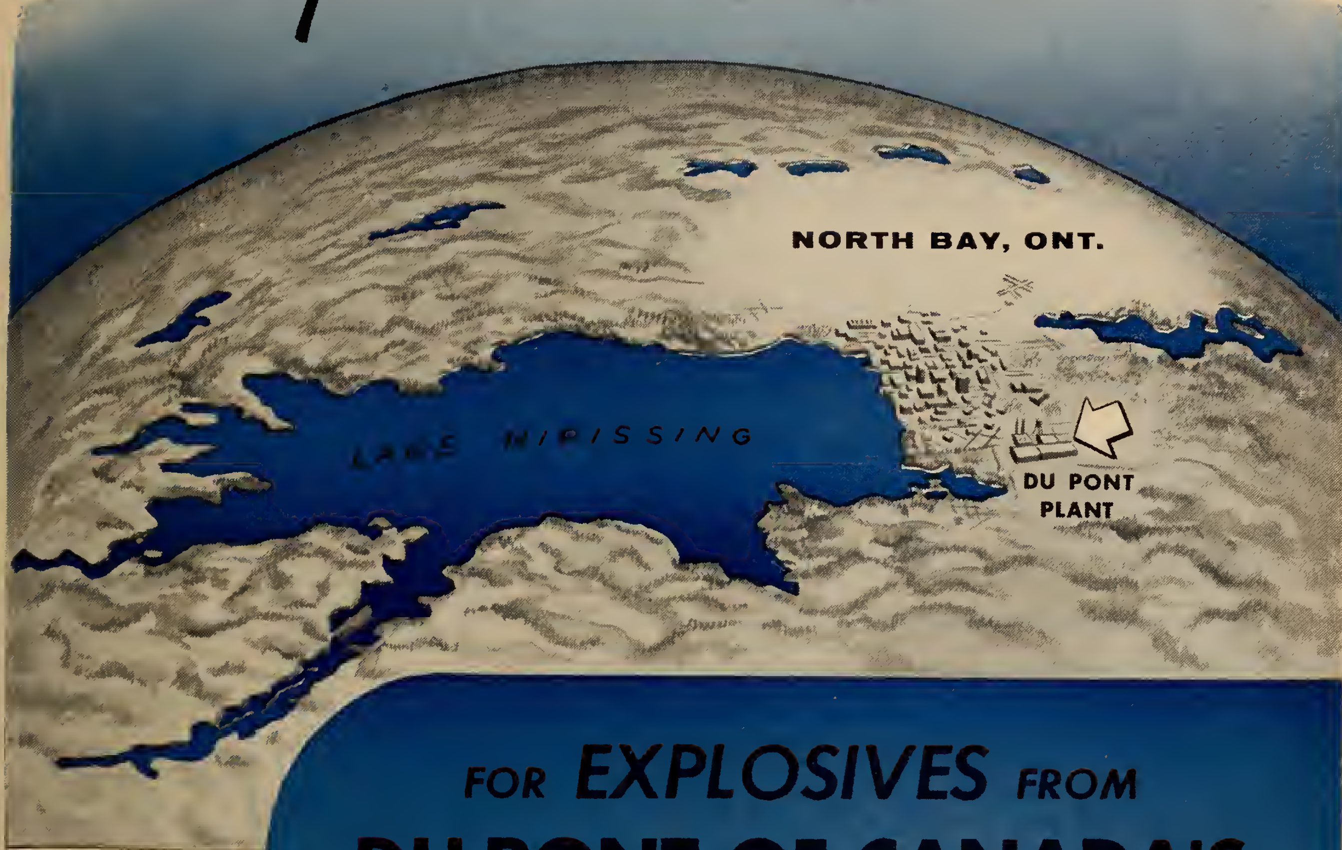
The plant will have an ultimate capacity of 246,200 kw. and first power is scheduled to be produced late in 1958. It is expected to cost about $56,000,000, including an additional transmission line to Trois-Rivieres.

New Sales Office.—Canadian Allis-Chalmers have announced the opening of a new district sales office in the Maritimes. Centre of operations will be in La Societe de L'Assomption Building. 232 St. George Street, Moncton.

Wire and Cable Plant.— Γ. A Lindsay, president of Phillips Electrical Co. Ltd., has announced that they will build a 1¼ million dollar factory in Vancouver. A plant site, approximately 14 acres of ground near Marine Drive, has been secured. A single storey structure is to be built by Dominion Construction Co. Ltd. Building and land will cost close to $650,000, and Phillips will spend over $600,000 on machinery and equipment for the new plant. The factory will occupy 57,600 sq. ft. of floor space with a further 6,950 sq. ft. for offices. Building designs call for a masonry and precast concrete structure, with a 20-ft. ceiling in the plant and a 10-ft. height for the office. The floor will be at railroad car level for easy loading into both trucks and box-cars.

A complete line of plastic covered telecommunications wires and cables as well as a full range of all types of

Next Year LOOK TO DU PONT



FOR EXPLOSIVES FROM DU PONT OF CANADA'S *Modern New Plant*

Strategically located at North Bay, Ontario, the new Du Pont of Canada Explosives Plant will be in a unique position to meet the needs of Canada's rapidly expanding mining, construction and allied industries with the latest and the best in explosive products.

Now under construction, the plant incorporates all the latest advances in design and will be one of the few on the continent employing the continuous nitration process.

Next year look to Du Pont for quality explosives and technical services, backed by the extensive experience of the Du Pont organization.

EXPLOSIVES
DU PONT

DU PONT COMPANY OF CANADA LIMITED — MONTREAL
Explosives Department

building wires and cables, also plastic insulated, will be produced in the new plant.

New Sling Splice.—"Wrap Loc" is the name of a new mechanical splice, now available on wire rope slings made by Canada Wire and Cable Company Limited and reported to develop the full catalogue strength of the wire rope itself. Slings with this splice will handle safe loads up to 30% higher, according to the company. The sleeve covering the loop splice is annealed seamless steel, not a casting, hence it adds to the strength of the splice and stands up to the abuse inherent in sling service. While "Wrap Loc" spliced slings can be made with fibre core steel rope, the company recommends wire rope with independent wire rope centres which provides 7½% greater strength and prevents deforming of wire strands, greatly reducing strength loss.

Coloured Protected-Metal.—Red, green, buff and grey are the four new colours of "Colour Galbestos" protected-metal roofing and siding now available from Robertson-Irwin Limited of Hamilton, Ontario. Company spokesmen report this new development now makes it possible to have coloured roofs and sidewalls on industrial and commercial structures at lower cost than before, because the surface is permanent and maintenance-free. Robertson can now supply "Colour Galbestos" with either one, or both sides coloured. Profiles available include: standard corrugated sheet (9/16 in. deep by 33 ins. wide), V-beam sheet (1¾ ins. deep by 29 ins. wide) and mansard sheet (1 in. deep by 33 ins. wide). Flat sheets are also available.

Sales - Engineering Representative. — Chemical & Industrial Sales, Ltd. (CISCAN), Edmonton, Alta., has recently been appointed sales-engineering representative for Conoflow Corporation. CISCAN will handle the provinces of Alberta and Saskatchewan, according to an announcement by John C. Koch, Conoflow's vice president in charge of marketing.

Canadian Distributor.—The Greist Manufacturing Company, New Haven 15, Conn., has appointed Upton Bradeen & James Limited, Toronto, as exclusive distributor in Canada for their Micro-Height gage, according to an announcement by Merritt D. Vanderbilt, president.

Plastics Representation.—Twinpak, Ltd., of Montreal and Toronto, has been appointed Canadian representative for Gomar Manufacturing Company, Newark, N.J., U.S.A., makers of continuous roll and sheet plastics and plastic laminates.

Federal Public Works Contracts.—Public Works Minister Robert Winters has announced that contracts involving expenditures totalling $4,099,095.56 were awarded by the Department during the month of June 1956. The amount for new works is $3,417,027.85; for the repair and maintenance of existing structures $311,587.27; and for dredging $370,480.44.

New Casting Technique—What is stated to be an entirely new system of producing castings, generally to within a few thousandths of an inch, has been perfected by a British firm. This will be of particular interest to industries that use accurate dies, plungers, and moulds for mass production.

The new system, designated "Tru-process", is an investment technique using a high-grade refractory material, resistant to attacks by steels and other special alloys of high melting point. In fact, it is a logical development of the lost-wax process, but is quicker and cheaper while having the same degree of accuracy.

The castings are produced from patterns made of wood, brass, aluminium, plaster of paris and plastics. The firm Darwins Limited, of Sheffield, England, claims that "Tru-process" castings have a satin surface finish which can, if necessary, be given a mirror finish by polishing. Its special alloy steels have been fully tested in the new process, including stainless steels, special corrosion and acid-resisting steels, heating-resisting and magnet alloys.

• BRIEFS

New Westinghouse Department—The formation of a new department, to deal specifically with power rectifiers, has been announced by the Canadian Westinghouse Company. The department is responsible for coordination of development and application engineering, design and manufacturing, negotiation service, order service, scheduling, testing and installation. S. M. Roberts has been named manager of the new organization.

Change of Address—After more than 30 years in the Drummond Building in Montreal, the entire staff and facilities of Stadler, Hurter and Company are being transferred to 1501 St. Catherine Street West, where, the various deparments of the firm will be on one floor. The new address becomes valid as of Sepember 15th.

New C-I-L Plant—The purchase of a tract of land in the Seven Islands area of the erection of a plant has been announced by Canadian Industries Limited. With the cooperation of the Quebec government a total of 3,400 acres of crown land has been acquired between the town of Seven Islands and Moisie River, on which a plant for the manufacture of blasting agents will be erected to supply consumers in the Quebec-Labrador area. M. J. Watson, general manager of the explosives division of C-I-L, said present plans are to have the first unit in production early in 1957.

Wire and Cable Expansion—Canadian Wire and Cable Company Limited is completing the doubling of its Vancouver plant this year as part of a long-range, $13 million expansion and decentralization program. In addition, two other major steps are intended: expansion of its B.C. operations by increasing present capacity and adding facilities for further lines including underground cable manufacture; and transfer of high voltage and submarine power cable facilities from Leaside, Ont., to a deep-water site in eastern Canada.

C.G.E. Plant Expansion—An expansion project which will more than double the floor area of the Canadian General Electric Company Limited small appliance plant in Barrie has been announced. The company said it plans to increase floor space at the plant by 120,000 square feet, bringing total floor space to 230,000 square feet, bringing total floor space to 230,000 square feet.

B. F. Goodrich Expansion—A $400,000 addition to the B. F. Goodrich plant at Kitchener, Ont., has been announced by M. G. Morgan, vice-president, manufacturing. The new structure will house the company's expanded roll covering and tank lining departments and will add 10,000 square feet of floor space to the present departments. The 40-foot high structure will be 180 feet long and 60 feet wide. Work on the new addition is expected to be completed early in 1957.

A $1,255,000 headquarters building for B. F. Goodrich Canada Limited will also be constructed in Kitchener, it was announced recently by Ira G. Needles, president. The combination head office and warehouse will be built on a 12-acre landscaped area and will be completed late in 1957.

New Pressure Pipe Plant—Pressure Pipe Company of Canada Limited, one of the Canada Iron group of companies, is proceeding with the construction of a $2,000,000 plant in the Meropolitan Toronto area to manufacture Hyprescon pressure pipe. The 100,000 square foot plant will produce Hyprescon steel cylinder reinforced concrete pressure pipe in sizes from 12 in. internal diameter up to 54 in. internal diameter in 16 ft. lengths. Production will average 1,000 feet of pipe per day. Plans call for production to start by the spring of 1957.

Pipeline Construction—Trans-Canada Pipe Lines Limited has opened a division office in Regina, from which construction of the Trans-Canada 34-inch natural gas pipe line from Burstall, Sask., to Winnipeg, will be directed. Division proj-

Here is the Goodyear H.D. Glass Cord Steam Hose coupled to the head of the high-speed steam hammer.

DRIVING TO BEDROCK

with Glass Harness!

Shown above is a general view of the bridge building activity. Work is progressing on schedule.

Goodyear H.D. Glass Cord Steam Hose carries the steam to sink heavy steel pilings.

At Toronto, Ontario, McNamara Construction Co., Ltd. are building a new Humber Bridge to link an expressway of the near future.

On the job is Goodyear H.D. Glass Cord Steam Hose carrying steam pressure of 125 pounds at 353°F. to the operating head of the pile driver to sink heavy steel piling thru' clay to solid bedrock at a relentless clip.

Goodyear H.D. Glass Cord Steam Hose is economical in ultimate cost - - - lasts longer, can't be cooked to bursting point by heat. It is safe - - - cuts accident rates and saves valuable working time. It is the lightest, most supple, easiest handled hose ever built to carry 200 pounds of saturated steam of 388°F.

There are more than 800 different types of hose especially designed by Goodyear. Every inch of Goodyear Hose is backed by 50 years of experience in producing industrial rubber products.

INDUSTRIAL RUBBER PRODUCTS ENGINEERED FOR THE JOB

For complete information write or call your nearest Goodyear office at—Moncton, St. John, Quebec City, Montreal, Toronto, London, Windsor, Winnipeg, Regina, Saskatoon, Calgary, Edmonton, Vancouver or Head Office, New Toronto.

ect engineer in charge is K. E. Britain and division right-of-way supervisor is D. C. Calder. District offices, which will co-ordinate the construction work in the field with the Regina division office, are being established at Swift Current, Sask., and Brandon, Man.

Publications

Industrial or trade publications received recently cover many fields of interest to engineers. For further information mail the reply card from this issue to The Engineering Journal.

Platinum Metals—The place of the platinum metals in industry is described in a booklet "The Platinum Metals". Major engineering uses are given. The International Nickel Company of Canada Limited, Toronto.

Carboloy Tools—An 8-page price list for the complete line of standard tools and blanks in Carboloy grade 300 series, with prices and stock grades for grade 330 series (bulletin SBT-7C). A 16-page bulletin showing specifications and prices for Carboloy toolholders, throw-away inserts, and on-end inserts (SBT-17A). Carboloy and Metals Section, Canadian General Electric Co. Ltd., Toronto.

Cable Suspension Idler—"Limberoller" belt idler booklet LD-105 contains design and application data for users of belt conveyors for bulk materials handling. Describes and suggests applications for the idlers and various brackets. Joy Manufacturing Company (Canada) Limited, Galt, Ont.

Fastening Tool—The "Canadian" fastening system features the only powder tool made in Canada. Four-page bulletin describes equipment and applications. Taylor, Phipps and Company Ltd., Toronto.

Testing Instruments — Reference book "Measurement Equipment Catalogue" covers 80 different devices in the field of testing instruments from simple thickness gauges to the mass spectrometer leak detector. Canadian General Electric Company Limited, Toronto (and branches).

Silicones—Silicone rubber compounds for rapid one-step thick section curing known as "Union Carbide" K-1025 and K-1028, have low compression set; uses include roll-covering. X-1034R silicone rubber compound fully meets requirements of Aeronautical Materials Specification 3301B; can be moulded, extruded or calendered with conventional or special catalysts. Data sheets available for these compounds.

Eight-page illustrated booklet describes silicones for the shell moulding process; parting agents available are LE-46 silicone parting emulsion, LS-46 parting solution, and L-46 modified silicone stock, a 100% silicone oil. Linde Air Products Company, Division of Union Carbide Canada Limited, Toronto.

Moulded Asbestos—Brochure describes Canadian production, in Sarnia, of "Caposite" moulded Amosite asbestos pipe-covering and block insulation. Products and their applications are illustrated and described. Cape Asbestos (Canada) Ltd., Toronto.

Fixture Hangar—New hook-on hangar for commercial and industrial fluorescent fixtures described in bulletin H-61-199. Canadian Westinghouse Company Limited, Lighting Division, Montreal.

Industrial Wastes—Illustrated Manual "W" outlines causes and effect of uncontrolled dumping of wastes, lists common waste materials, shows how to select the right type of device to intercept waste, illustrates the devices, and gives installation details. Josam Canada Limited, Toronto.

Flexible Steel Strap—Illustrated brochure describes Stelco "Constrap", a flexible steel strap for bridging joists, in place of wood braces. The Steel Company of Canada Limited, Hamilton, Ont.

Heaters and Fans—New 36-page catalogue describes range of industrial, commercial, and domestic fans and heaters (in French and English). Canadian Armature Works Inc., Montreal.

Refractory Concrete — Two new pamphlets from The Lafarge Aluminous Cement Company Limited are: "Monolithic Underground Flues in Refractory Concrete" and "Foundry Floors in Refractory Concrete". Canadian representative, Ciment Fondu Lafarge (Canada) Limited, Montreal.

Adhesives—Twenty-four ways of improving product design are described in "Only One Material on Earth", which illustrates the applications of adhesives, coatings, and sealers in industry. Minnesota Mining and Manufacturing of Canada Limited, London, Ont.

Water Pumps—Booklet MS-56 "'There's No Place Like Home' With Lots of Water" shows a complete line of water systems, pumps, and water softeners. The F. E. Myers and Bro., Co. (Canada) Ltd., Kitchener, Ont.

Resin Structural Panel—Folder 26-A-9 describes Stypolite resin structural daylighting panel reinforced with glass fibres. Panel matches profiles of all available corrugated industrial roofing and siding. Robertson-Irwin Limited, Hamilton, Ont.

Control Instruments—Bulletin 7202 describes Tel-O-Set quick-connect miniature controlling and recording instruments. Catalog 1531 "ElektroniK Controllers" and 1521 "ElektroniK Recorders and Indicators" describes range of industrial instruments. Minneapolis-Honeywell Regulator Co. Ltd., Toronto.

Teflon Tape—Cementable Teflon tape available in thicknesses as low as 0.005 in. described in catalogue AD 158. Garlock Packing Company of Canada Limited, Toronto.

Wood Preservation — Booklet marking 20th anniversary of the company also records activities and applications. Osmose Wood Preserving Co. of Canada Ltd., Montreal.

Drill Steels— Technical improvement, performance, and economy of drill steels and drilling noted in folder "Hard Facts About Sandvik Coromant Drill Steels". Atlas Copco Canada Ltd., Montreal Airport.

Air Conditioning—New 32-page catalogue gives data on unit dimensions and performance of air conditioning units. Alpha Manufacturing Co. Limited, Winnipeg.

Cranes — Illustrated 40-page handbook covers electric overhead travelling cranes and other handling equipment. Information given on latest developments in crane manufacture, classification of cranes, runways, electrical equipment and other data. Publication M-100. Dominion Bridge Co. Ltd., Montreal.

Expansion Shells—Dempsey expansion shells for rock bolts with details of types available described in leaflet. The Steel Company of Canada Limited, Hamilton, Ont.

the E.I.C., and given by Queen's University. This began when 19 Junior E.I.C. members wanted a P.D course. They were going to have a general course this winter, but decided to wait a year.

Cornwall: There has been one year of the Queen's course, above mentioned completed by Cornwall members; and they will continue in the second year.

Kingston: Seventy members have enrolled for this fall in the Queen's course.

Saguenay: P.D. has been available for four years. This branch uses correspondence courses to fill in when they cannot get a speaker. They have had public speaking, business administration, "How to Invest". This past year they had two courses, one in public speaking, and a chemical engineering refresher course. with a total enrolment of 20.

Saskatoon: Here there seems to be an annual enrolment of about 40. This is the first year of engineering at the university, and they use as their textbook the ECPD. publication "Speaking Can be Easy for Engineers, too . . ." and it is run by Professor Mantle. He now reports that he wishes to add a general knowledge P.D. course at Saskatoon and to start a P.D. in Regina.

Toronto: Like Hamilton, Toronto has completed its fifth year. Usually Toronto has two groups and one year had three. The enrolment varies from 80 to 100. Toronto follows the original P.D. plan. The Field Office gets the speakers for the first year and does the organizing of the course. P.D. II has some vocational speakers and several evenings of Harvard "cases".

Last year in Toronto there were 20 lectures in P.D. I, such as: The Political Situation in the Middle East, by Brigadier Quillian, O.B.E.; Communism Inside Canada, Assistant Commissioner McClellan, RCMP.; Criminal Law, Magistrate Tupper Bigelow; Ladies Night, with a lecture on "You and Your Husband's Job", by Dr. Lillian Gilbreth, Hon. M.E.I.C.; Reading for Pleasure and Profit, Dr. Sanderson, chief librarian, Metropolitan Toronto; Appraisal of Real Estate, Murray Bosley; Human Psychology, Dr. D. C. Williams. Other subjects were: investment, life insurance, good manners, public speaking, and a visit to the art gallery.

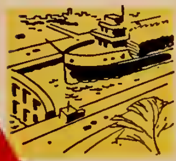
Regional Conference

Because Niagara Falls wishes to re-establish a P.D. course, it was decided to hold the 4th Regional Conference there on May 12, 1956. Twenty-one attended and it was an excellent meeting. This is an annual meeting of committee chairmen and officers at the end of the course year, to discuss problems and future programs.

Everyone connected with P.D. anywhere is invited but because of distance, it is usually a meeting of the Southern Ontario members. (Minutes are sent to all branch secretaries.) The meeting takes most of one day. This conference becomes more valuable and stimulating every year, and it is planned to hold the 1957 conference in London, Ont.

Looking Ahead

Any branches interested in operating a P.D. Course in 1956-57 may obtain further information and assistance from the Field Secretary's office, 236 Avenue Road, Toronto, Ontario.

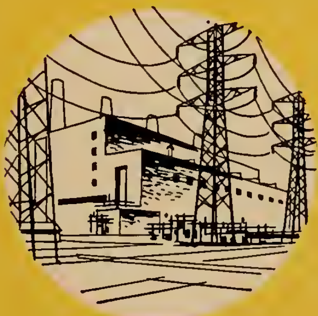


If you needed a starting point, you might say it all began at Craigellachie, B.C. on November 7th, 1885. In this tiny village the hammer blows that drove home the last spike of the Canadian Pacific Railway resounded around the world to announce the "coming of age" for Canadian engineers. Since that time, there have been many notable "Canadian" engineering achievements. The ingenuity that resulted in the telephone and the incandescent light has been a rich inheritance upon which to build. Shipsaw compares on all counts with any power project in the world. The Orenda jet engine and the CF 100 that it powers have blazed a trail across the pages of world aviation history. And now we talk of whole new towns to be planned on the new banks of a St. Lawrence that will be most unfamiliar to the ghost of Champlain —a St. Lawrence that will open the Canadian interior to the traders of the world and supply Canadian industry with the power to produce the needs of the world.

Canadian Engineers have been "Major League" for 69 years

CANADA WIRE ENGINEERS HAVE BEEN SETTING THE PACE

The complex projects of Canadian engineering development become simpler with the assistance of specialists at Canada Wire who have solved countless problems in high voltage power transmission and the development of every type of electrical conductor.



When a cable was needed to transmit the output of two 106,000 h.p. generators from the transformers in the heart of a mountain 2,000 feet through a cable tunnel to the high-voltage switch-yard at Alcan's Kemano River basin, Canada Wire engineers produced one. This cable is single conductor 301 kv. All-Aluminum oil-filled cable; hollow core conductor, low-viscosity, oil-impregnated paper, seamless Aluminum Sheath. This is the first 301 kv. cable system designed in the British Commonwealth.

When the new Richard L. Hearn Steam Generating Station, first of its type in Canada, was completed at Toronto, Canada Wire engineers produced two high voltage underground cable circuits 120 and 161 kv. to deliver 60-cycle power underground, to the Leaside-Thorncliffe Transformer Station. The hollow conductors used facilitated both the charging of the system and the maintaining of the insulation under nitrogen gas pressure.

When the St. Lawrence stood as a barrier to power transmission (a distance of 32 miles underwater) from Bersimis on the north shore of the river to the great new copper mining area in the Gaspé, Canada Wire engineers became pioneers both in design of the submarine cable, its manufacture, the unique "flaking down" and wharf handling procedures and the underwater installation. This is the largest high-voltage submarine cable system in the world.

The modern jet aircraft requires over 12 miles of wire. High tension cables for engine and ignition systems, low tension cables, conductors carrying current to fire rocket charges, and steel wire control cables all provide the muscles and the nerves for Canada's aircraft. Canada Wire is engineering and producing these essentials which are fulfilling the "rigid performance specifications" necessary to meet the demand for greater speed, greater safety and manoeuvrability.

Design of the Frobisher Yukon Project

(continued from page 1183)

highway would be built connecting the area with Juneau, Alaska, approximately 100 miles south on the Lynn Canal. The hearings were adjourned, to be continued in Victoria later.

Dr. Charles Camsell, M.E.I.C., representing the Frobisher - Ventures group in November 1955 at hearings before the Gordon Commission on Canada's Economic Future, stated negotiations were proceeding with a number of strong associates. He said the 5 million horsepower from Yukon - Taku was more than was needed to exploit the mineral resources of the Yukon and Northern British Columbia.

Meantime a dispute over the flow of international rivers crossing the boundary between British Columbia and the States of Washington and Idaho, and between Alaska and the Yukon, had arisen, which even the International Joint Commission was unable to resolve. A permit would be required from the United States before Frobisher Ltd. could divert part of the flow of the Yukon into Canadian territory. Fear was that the United States would claim downstream benefits on the Yukon. Thus the Nass project was studied as an alternative to the first stage of Yukon-Taku. It would involve less than 10 per cent of the total horsepower obtainable from the Yukon-Atlin-Taku development.

The south flowing Nass with its drainage area in British Columbia is entirely within that province, thus posing no international problems. It has the advantage of having a Canadian seaport within 25 miles distance at Alice Arm, B.C., for many years the site of a large mining operation. The townsite is east of Ketchikan, Alaska and almost due north of Prince Rupert, B.C.

The proposed power site on the Nass is a mile from Grease harbour. Two dams some 60 and 100 miles upstream will create storage reservoirs at Meziaden and Bowser Lakes. The average flow of the river as recorded over the past 18 years is 28,400 cubic feet per second. A head of 215 feet will be developed. Access to the power site will be over a new road from Terrace, B.C. which is projected to within 6 miles of the site.

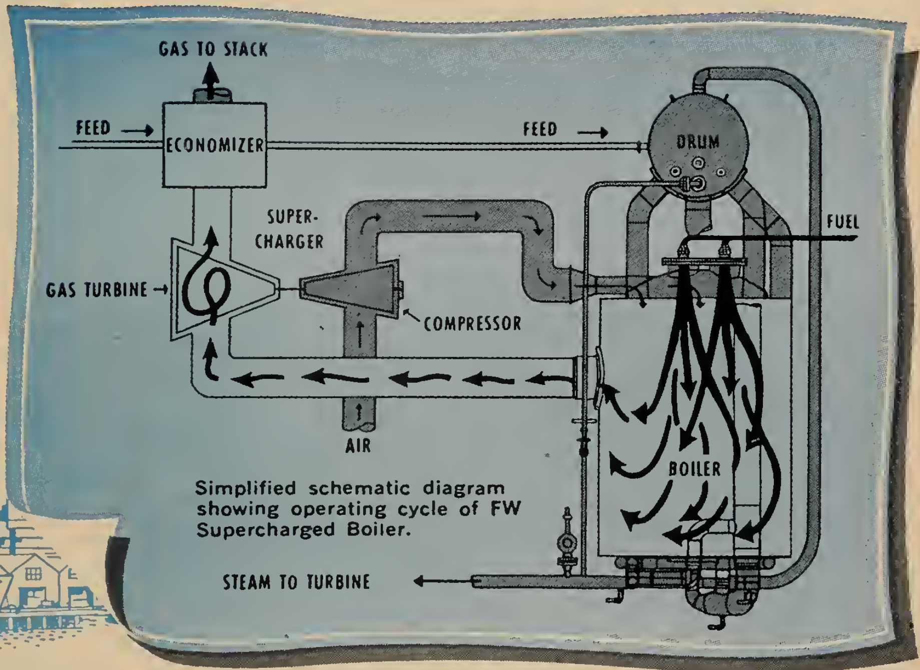
Nearly half a million dollars was to be spent during the summer of 1956 by Quebec Metallurgical Industries Ltd., an affiliated company, to bring the Nass power project as near as possible to the design stage, and for definitive surveys including diamond drilling on the Yukon-Taku project. Concentrating equipment installations will be expanded on three creeks of the B.C. Columbium Uranium project, where at least 65 million cubic yards of pay-gravel have been outlined.

Division of Power

During the early months of 1956 both Canadian and United States governments were looking for some face-saving formula for an exchange of Yukon River power for territory at tidewater in Alaska. In May, delegate E. L. Bartlett from Alaska proposed to U.S. Secretary of State

New SUPERCHARGED Boiler

- *Up to 75% less weight*
- *Improved cycle economy*
- *Up to 25% lower cost*
- *Shorter startup time*
- *Quicker load response*



Simplified schematic diagram showing operating cycle of FW Supercharged Boiler.

Foster Wheeler has developed a new supercharged boiler of far reaching significance to the marine industry.

In the supercharged cycle, diagrammed above, high pressure combustion gases leaving the boiler are used to drive a gas turbine which, in turn, compresses combustion air for the boiler. Spent gases from the turbine pass through an economizer and thence to the stack.

The following advantages are inherent in this supercharged boiler cycle.

1. Due to higher heat absorption rates and a reduction in refractory of up to 95%, a supercharged boiler may weigh from ½ to ¼ as much as a conventional boiler of equivalent capacity.

2. Since combustion air is supplied by the supercharger, cycle economy is increased by the saving in power that would otherwise be required for operating the fans of a conventional boiler.

3. Smaller size and weight permits savings of up to 25% or more in first cost.

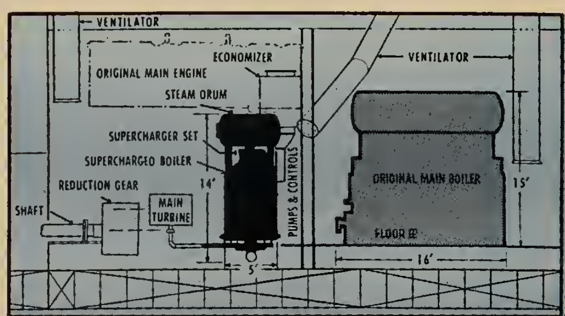
4. Small heat storage capacity results in extremely fast startup.

5. The supercharged boiler responds much more quickly to load changes.

The boiler unit is of exceptionally compact and symmetrical design, with boiler drum mounted above the furnace and connected to it by external risers and downcomers. The furnace is fully enclosed with waterwall surface and a metal baffle separates the furnace tubes from the convection section. Superheater pancake coils are located in the base of the firing chamber.

Foster Wheeler has built three supercharged marine boilers and a fourth is now under construction. All are for diesel fuel firing.

For complete information, write to *Foster Wheeler Limited, St. Catharines, Ontario.*



Supercharged boiler (black) for driving a 6,000 SHP turbine in a Liberty Ship. Conventional boiler (gray) has been left in to provide a comparison of size and space relationship. Boiler and supercharger weigh 35,000 lb and occupy 60 sq. ft. of floor space. This compares with two conventional boilers weighing 144,000 lb each and occupying 156 sq. ft. of floor space.

Dulles that Canada be given a corridor through south eastern Alaska. The question had been raised in Canada's House of Commons some weeks before by Minister of External Affairs Pearson, but Parliament had displayed little interest.

Mr. Bartlett suggested both countries should divide the power from the Yukon-Taku development, since an all-Canadian development does not appear economically or politically possible. In exchange for power, he believes, the United States should allow Canada a corridor along the old Dalton Trail leading in Alaska, from where the Alaska Highway crosses into Canada from Haines. This corridor would lead east and southeast to the ice-free port of Pyramid harbour a few miles south of Haines and now a ghost town. No transfer of land would be involved but merely the granting of a long term lease to Canada for the corridor.

More Production for Frobisher

A. J. Anderson, who succeeded Thayer Lindsley as president of Frobisher Ltd. last year, told the annual meeting of the company in Toronto early in June that Frobisher's latent assets are being converted into producing operations as quickly as possible with a view to providing future revenue. The inception of milling operations by three subsidiaries during the first half of 1956 constituted the first reflection of this policy, he said.

Industry and Education

(continued from page 1191)

standards to about the level described and then to try to accept any applicant who can meet these standards. They admit frankly that they do not now know how they are going to do this, but they have faith that a way will be found. If they could know that their incomes would be sufficient to carry the burden of additional students as their registrations increased, the problem would be well on the way to solution.

How and where to get additional teaching staff would pose a question which would have to be answered. Here we think that other faculties and departments might adopt more extensively the practice common in medical and dental schools. These, though they may have four or five hundred students, get along with absurdly small staffs of full-time teachers and a large group of part-time instructors, drawn from the ranks of practising physicians, surgeons and dentists, each giving only a few hours a week to his own particular specialty. So highly are these part-time appointments regarded by their holders that they carry the smallest of salaries and there is much competition for them.

Most of our universities and colleges are located in cities where all kinds of professional talent is available, if industry would only release that part of it which it controls. Why should not many subjects in engineering, pure science, commerce and journalism, for example, be taught be those who are daily using the principles they would expound?

Granted that a knowledge of one's subject does not necessarily make a good teacher, it is the first requisite. Our slight contact with part-time teachers makes us feel that a relatively short period of teaching experience, plus the help they can get from their full-time colleagues, will make quite acceptable instructors of them in most cases.

To summarize, we would like to see our industrial concerns get together and intensify their already great contributions to education. We would like to see this done in a systematic way, instead of in bits and pieces as at present. If any such action does come about, engineers will have a good deal to do with it, because, as executives and administrators, they occupy so many key positions. If they decide something should be one, it is fair to assume that it will be done.

R. DEL. FRENCH

Technical Papers in the October Issue

There will be five technical papers in the October issue of The Engineering Journal; the titles of these papers and their authors are given below.

Growth and Development of Large Electric Power Systems

W. R. Way, M.E.I.C., *vice-president and chief engineer, The Shawinigan Water and Power Company.*

Application of Welded Design to Hydraulic Turbine and Valve Manufacture

J. G. Warnock, *head, Hydraulic Department, English Electric Company Limited.*

Lateral Rigidity of Steel Building Frames

J. L. de Stein, M.E.I.C., **J. O. McCutcheon,** M.E.I.C., *Dept. of Civil Engineering, McGill University.*

Analysis of a Magnetic Control Circuit

C. H. R. Campling, M.E.I.C., *Dept. of Electrical Engineering, Queen's University.*

Current Developments in Air Pollution in the United States

L. C. McCabe, *president, Resources Research, Inc., Washington, D.C.*

There will also be further contributions to the discussion of technical papers.

President—V. A. McKillop
Treasurer—R. A. Emerson
General Secretary—L. Austin Wright

(A complete list of Officers appears in the issue of September, 1956)

Growth and Development of Large Electric Power Systems

W. R. Way, M.E.I.C., *Vice-President and Chief Engineer*
The Shawinigan Water and Power Company, Montreal

Read at the 70th Annual General and Professional Meeting, The Engineering Institute of Canada, Montreal, May, 1956

CHARLES F. BRUSH of Cleveland is given credit for establishing the first commercially successful enterprise supplying a series arc lighting system. In 1879 Edison produced the incandescent lamp which was intended for parallel operation. Such lamps could be operated in series but under such conditions dangerously high voltages would have been required in the home.

By 1882-5 commercial plants using direct current and the Edison incandescent lamp operating with the parallel connection became a reality. It was soon realized that, although the direct current system was ideal for distributing electric current within a limited area, alternating current had many advantages.

The transformer was invented in Europe in 1883 by Guillard and Gibbs, and a short time later George Westinghouse and Charles Stanley developed it into a practical device which could be used advantageously in industry. In 1886 the first commercial transmission of single-phase alternating current took place at Great Barrington, Mass. In 1888 Nicola Tesla invented the polyphase induction motor, and in 1893 the polyphase generator and transformer were successfully demonstrated at the Chicago World's Fair. This permitted a real start to be made towards the use of electricity for power customers instead of for lighting purposes only as had been the case previously.

The Original Development at Niagara in the United States

Possibly one of the greatest advances in hydro-electric generation and transmission occurred in the United States when investigation of the Niagara Falls development was initiated by a group of New York financiers. Reference to this enterprise is included here since it had a bearing on subsequent developments across the Niagara River in Ontario.

The paper reviews the progress that has been made during the past fifty years in the growth and development of large electric power systems in Canada. Reference is made to significant pioneer achievements prior to 1900, a number of technical advances and current practices are outlined, and some possible trends indicated. Although the paper deals with progress in Canada generally, the descriptive matter is limited to the larger power systems in the Provinces of Ontario and Quebec. The intention is to present a story that may interest engineers of all categories rather than electric utility engineers specifically.

The project was of such magnitude at the time that the question arose immediately as to how the power would be generated, transmitted and distributed. To study and advise on the many problems, the International Niagara Commission was appointed with Lord Kelvin as its chairman. Many prominent engineers and scientists were called before the Commission to present their views.

In 1893 the Commission recommended the electrical method of development using alternating current, two-phase 25-cycle power. A transmission voltage of 11,000 volts was selected on account of the large amount of power that had to be delivered to Buffalo, twenty miles away. A two-phase system was chosen using the rotated-field type of generator construction. A frequency of 25 cycles was selected as a compromise between 16 2/3 and 30 cycles, both of which were suggested. The speed of the waterwheel had already been set at 250 r.p.m. and this, to a great extent, also fixed the frequency at 25 cycles using a twelve-pole unit.

As early as 1890, however, Westinghouse engineers had advocated 30 cycles as standard for general electricity supply purposes and that organization strongly recommended the use of 30 cycles in this case. Nevertheless, a frequency of 25 cycles was adopted. This original Niagara Development of 1894-5 must be considered important in that the 5000 h.p. units were large at the time and that it was the first polyphase hydro-electric development in the world.

Situation in Canada in the 1890's

In the late 1890's, generation and distribution of electricity in Canada was confined to a few small isolated hydro plants, often provided with a standby steam station. During the course of the next ten years, many outstanding engineers and financiers began to visualize the tremendous future possibilities of Canada's hydro-electric resources.

However, manufacturing facilities were just being developed in the United States and Canada and it was difficult to obtain the required hydraulic and electrical equipment. A considerable proportion of the generators, hydraulic turbines, and other equipment had to be secured from England, Switzerland, and other European countries. There was little or no possibility of interconnection with neighbouring systems, rural distribution was non-existent, street lighting was rare and when provided was inadequate. In many cases apparatus had to be improved or developed by the engineers directly involved, often in collaboration with the manufacturers. This applied to such items as disconnecting switches, insulators, and bushings. Such was the general state of affairs in this era. (Fig. 1.)

The potential power resources of rivers such as the Niagara, Saguenay, St. Lawrence, Gatineau, and St. Maurice were recognized, and since the present large power systems of eastern Canada have been developed around these major power sources, the background of some of the earlier and larger hydro-electric stations will be briefly outlined.

Early Canadian Niagara Developments

The first large hydro-electric plant at Niagara Falls, Ontario, constructed by the Canadian Niagara Power Company, came into operation in 1904-5, consisting initially of three 10,000 h.p. vertical units of Swiss manufacture operating at 135 ft. head. Eventually, eight additional units were installed to bring the total capacity up to 121,000 h.p.

Simultaneously, the Ontario Power Company development was carried out and on completion consisted of fifteen units of the horizontal type operating at 180 ft. head and having an installed capacity of 195,700 h.p.

The third project, constructed by the Electrical Development Company, later the Toronto Power Company, commenced delivery of power in 1906. The eleventh and final unit of this project was installed in 1914, operating at 137 ft. head, bringing its total installed capacity up to 160,500 h.p.

The Ontario Power Company and the Toronto Power Company were acquired by the Hydro-Electric Power Commission of Ontario in 1917 and 1922, respectively, forming the initial basic generation owned and operated by the Commission.

Initial Developments on the St. Maurice River by the S.W. & P. Co.

No. 1 Development — This was a 30-cycle station located at Shawinigan Falls. The plant was placed in service in 1902 and consisted of horizontal units of various sizes operating under a head of 145 ft. with an ultimate installed capacity of 40,000 kw. The generators were two-phase 2,200 volts. The transformers were Scott connected to increase the voltage from 2,200 v. two-phase to 50,000 v. three-phase to transmit power to Montreal. This development is mentioned here since in 1900 it was considered a very ambitious undertaking. Eventually when all the 30-cycle power was replaced by 60-cycle power this station was dismantled to make way for a more efficient and larger 60-cycle plant.

No. 2 Development — In 1911 the Shawinigan Company began operation of its No. 2 Development at Shawinigan Falls. This was a 60-cycle station in which were installed eventually five 18,500 h.p. horizontal hydro turbines connected to 15,000 kva., 6600 volt, three-phase generators. Transmission voltage of 110,000 volts was made possible through the use of 15,000 kva., three-phase transformers which, at the time, were said to be the largest in the world. (Fig. 2).

This station was noteworthy at the time due to the care taken by the designers to obtain complete flexibility and freedom from some of the ordinary sources of failure previously encountered elsewhere. Double busses, many bus disconnecting switches, and duplicate circuit breakers on both high and low voltage busses were provided. This is understandable in view of the unreliability of electrical equipment at that time, the lack of adequate relay protection, and the desire to ensure maximum service continuity. Oil circuit breakers were used, but arc control devices had not yet been developed and serious oil fires occurred occasionally due to circuit breaker inadequacy and resultant failure.

These two plants were the original installations from which the present extensive system of the Shawinigan Water and Power Company has grown.

Early Development on the St. Lawrence

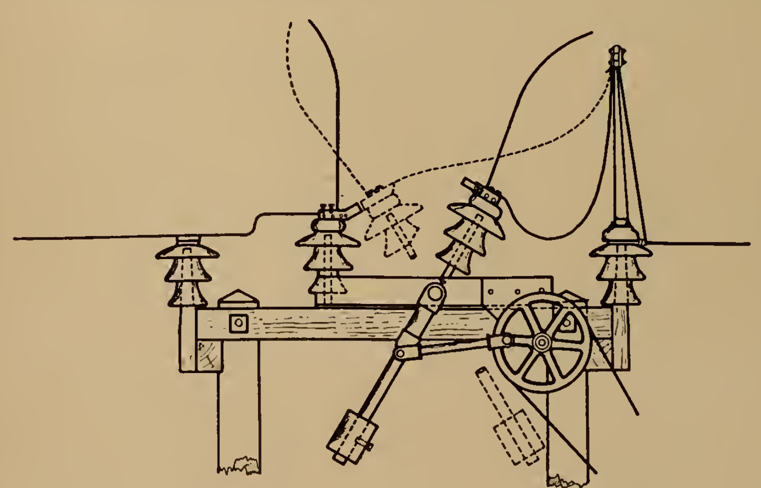
Another of the more important generating station undertakings was the development of the Cedar Rapids plant on the St. Lawrence River near Montreal by the Cedar Rapids Manufacturing & Power Co. The available head was 30 feet and the total output contemplated was 160,000 h.p. Work was started in 1912, and by 1915 the plant was ready to deliver power. The final installation comprised eighteen 10,800 h.p., 55.6 r.p.m. 63 cycles vertical units with a total capacity of about 200,000 h.p. (Fig. 3.)

This reference to the Cedars Station is included on account of the large physical size of the units with their 32 ft. diameter rotors and since it was the first large plant supplying the Montreal area then served by the Montreal Light, Heat and Power Company.

Initial Transmission

As the polyphase motor and transformer became readily available, load demands increased rapidly and this called for longer and higher voltage transmission facilities.

Fig. 1. Early horn gap disconnecting switch originated and utilized by The Shawinigan Water and Power Company.



50000 VOLT FULCRUM SWITCH
SHAWINIGAN FALLS
1908

For example, in 1897 the St. Narcisse-Three Rivers line in Quebec operated at 15,000 volts, and by 1898 the DeCew-Hamilton line was in service at 22,500 volts. In 1902, 60,000-volt lines were in operation between Niagara and Toronto and also between Shawinigan Falls and Montreal. A voltage of 110,000 was used for transmission by Ontario-Hydro and by the Shawinigan Water & Power Company in 1910 and 1911 respectively.

Concerning these earlier transmission lines, the properties of distributed capacitance, resistance, and inductance were recognized but, since electrical calculations were long and tedious, many short-cuts, as well as cut-and-try methods, had to be used to solve the problems that arose. Considering these factors, the early transmission systems operated with reasonable success but their performance fell quite short of present day standards.

Initially one of the great deterrents in extending the use of high voltage transmission was the type of insulators available. These were of pin-type design and limited the operating voltage to about 60,000 volts. The early insulators were made of dry process porcelain which was porous and in a short time became semi-conducting with eventual failure. Wet process porcelain was introduced about 1903-5 and this resulted in a greatly improved product but did not permit raising the maximum operating voltage materially.

It was not until 1907-8, when the cap and pin type suspension insulator was developed in the United States, that utilization of higher operating voltages was made possible. Subsequent improvements in design and manufacture together with rigid quality control has resulted in the modern high-strength suspension type of insulator which, since about 1920, has given excellent service.

Subsequent Developments in Generation, Transmission, Interconnection and Integration

System integration usually concerns the tying together of generating stations or major substations under control of the same organization by means of a grid or transmission network so as to make most efficient use of all facilities, to improve system service continuity, and to make more power available over a wider area than would otherwise exist.

System interconnection on the other hand usually refers to the tying together of electric power utilities, each of which is under the control of a separate organization, with the objective of obtaining better overall economy of operation as well as other important advantages. Full or partial co-ordination may be agreed upon, and the flow of power may be in one direction only or reversible.

Among the benefits to be obtained from interconnection and integration are the following:

(a) More efficient use of all available resources by taking advantage of the diversity in load, hydraulic conditions and generating capability.

(b) Better operating flexibility and improved equipment maintenance schedules.

(c) Increased system service security.

(d) Less combined spare generation needed and more complete utilization of surplus hydro energy.

(e) Possible deferment of individual system additions to generating facilities.

System Development—Province of Ontario

The Hydro-Electric Power Commission of Ontario was formed in 1906 with the intention initially of distributing power purchased from private power sources.

In 1914, visualizing the tremendous potentialities and the prominent role electric power would play in the future economy of the province, the Commission first considered a power development at Niagara Falls that would use the maximum economical head between Lake Erie and Lake Ontario. As a result of these studies construction of the Queenston-Chippewa development, now known as Sir Adam Beck-Niagara Generating Station No. 1, was started in 1917. The first 25-cycle vertical units operating at 292 ft. head were put into operation in 1922 and the tenth unit in 1930, bringing the total capacity of this plant up to 525,000 h.p. At the time this plant was built it was one of the largest hydro-electric developments in existence.

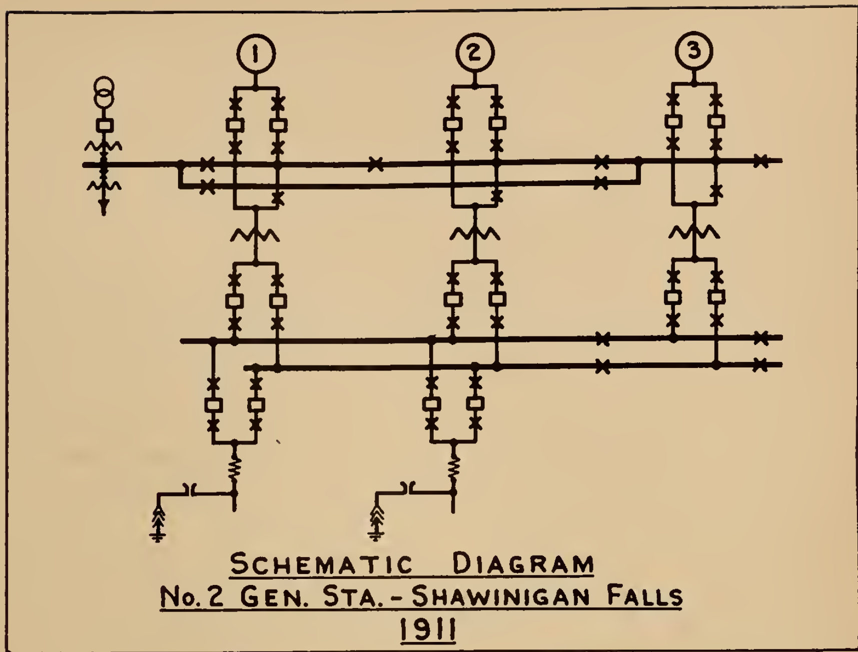


Fig. 2. Schematic diagram of an early generating station illustrating the use of duplicate switching apparatus.

With Queenston and other generating stations at Niagara as a base, the Commission embarked on a series of projects involving the purchase of large blocks of power from the Province of Quebec and the construction of additional generating stations of its own, all of which required an extensive high voltage transmission network.

For instance, the Gatineau Power Company carried out three hydro developments on the Gatineau River (Farmers, Chelsea, and Paugan) with an initial combined capacity of 528,000 h.p., of which the Commission purchased 340,000 h.p. To take delivery of this purchased power in 1928 the first 230,000 volt transmission line in Canada was constructed between the Paugan generating station and Leaside terminal station near Toronto. Subsequent installation of additional units has increased Gatineau Power Company's total generating capacity to about 735,000 h.p.

In addition, the first section of the Beauharnois development on the St. Lawrence River near Montreal came into operation in 1932 and commenced supplying part of its output at 25 cycles under contract to the Commission over another 230 kv. circuit to Leaside.

Since that time the system under control of the Ontario-Hydro has continued to expand and the Commission has added extensively to its generation and transmission facilities. The total load demand in 1955 was over 4 million kw. supplied through an integrated transmission network covering practically all settled parts of the province.

Among the larger generating stations constructed by the Commission in recent years were:

(a) The Chenaux, des Joachims, and Otto Holden hydro plants on the Ottawa River (699,000 kw.)

(b) The Richard L. Hearn steam station at Toronto (400,000 kw.)

(c) The J. Clark Keith steam station at Windsor (264,000 kw.).

(d) The Sir Adam Beck-Niagara Generating Station No. 2 on the Niagara River and its associated pumping generating station when completed in 1958 will have an installed capacity of 1,370,000 kw.

In addition, Ontario Hydro has interconnected agreements with the Ottawa Valley Power Company, MacLaren Quebec Power Company, Detroit Edison Company, and the Niagara Mohawk System, and is actively engaged in the construction of the Canadian portion of the international St. Lawrence power project near Cornwall. The Canadian plant will have a total installed capacity of 820,000 kw. in sixteen units, the first of which is expected to be in service in the fall of 1958. Thus the present power system controlled by Ontario Hydro ranks as one of the outstanding examples of modern and progressive interconnected and integrated systems in the world.

System Development— Province of Quebec

In the 1920's the Shawinigan Water & Power Company system developed rapidly with important additions to its hydro generating capacity, principally on the St. Maurice River. Although power had been supplied to Montreal for several years previously, a more adequate interconnection was established in 1923 with the former Montreal Light, Heat and Power Cons. system (now Hydro-Quebec) and with the Southern Canada Power Company's system in southern Quebec. (Fig. 4.)

The Saguenay Power Company's Isle Maligne plant on the Saguenay River was brought into operation in 1925 with eight 45,000 h.p. units, later increased to twelve and increasing the total installation to 540,000 h.p. In 1931 Shipshaw No. 1 was added with an installation of 300,000 h.p. The Saguenay Power Company contracted to supply 100,000 h.p. at Isle Maligne to the Shawinigan Company for transmission to Quebec City through a double circuit 187 kv. line 135 miles long. These circuits have since been reconstructed for 230 kv. operation and have been interconnected with the Saguenay Power Company's 154 kv. system through three 150 000 kva. three-phase auto transformers.

During the following years, many important additions to generating installations have been made, the majority of which feeds into an extensive 230 kv. and 115 kv. transmission network. Included in these additions on the Saguenay was the 1,200,000 h.p. Shipshaw No. 2 plant and on the Peribonka River were the Chute à la Savane and Chute du Diable plants with a combined installation of 550,000 h.p. On the St. Maurice River the Rapide Blanc, Trenche, La Tuque, and Shawinigan No. 3 plants were completed by the S.W. & P. Co. increasing that Company's present total generation, including Quebec Power Co., to 1,320,000 kw.

Thus at the present time this interconnected network in the Province of Quebec has a combined installed capacity of the order of 2,700,000 kw. It is noteworthy in that it is one of the few interconnected systems anywhere that relies on power and energy exclusively from hydroelectric sources.

Further Expansion in Quebec

There are several important developments projected or under construction in the Province which probably should be mentioned. These include the proposed addition of the 330,000 h.p. Rapide Sans Nom generating station on the Upper St. Maurice River (now Rapide Beaumont) by The Shawinigan Water & Power Company, as well as certain major projects now being carried out or under study by Hydro-Quebec.

The first section of Beauharnois was completed in 1948 with a total installation of 724,000 h.p. using 14 units. The second section was completed in 1953, so that the combined development now has a total installed capacity of 1,425,000 h.p. with twenty-six units. Six of these units operate at 25 cycles to supply power to Ontario-Hydro. Beauharnois is capable of further expansion by the addition of a third section with an installation of at least twelve more units or 640,000 h.p. so that the ultimate development at this plant will be of the order of 2,065,000 h.p.

Two important hydro developments are under construction by Hydro-Quebec on the Bersimis River which discharges into the St. Lawrence some 400 miles downstream from Montreal. These are known as the Bersimis No. 1 and Bersimis No. 2 projects.

Bersimis No. 1 plant will consist of eight 150,000-175,000 h.p. Francis type turbines operating at 785-870 foot head, driving a similar number of 120,000 kva. generators 277 r.p.m., 13,800 volts, 0.95 power factor, and providing an overall installation of 1,200,000 h.p. Delivery of power is expected by the fall of 1956 and all units are expected to be in operation by 1958 or early 1959. The generating units will be installed in an underground plant, the only one of its kind in the Province of Quebec, and similar in some respects to the Aluminum Company's plant at Kemano, B.C. Immediately outside the generating station will be located the 300 kv. switching station using air blast circuit breakers and the 24 single-phase 40,000 kva. transformers comprising 8 banks of 120,000 kva. each.

Transformers will supply the south shore, stepping down to 69 kv. to cross the St. Lawrence River using submarine cables some 31 miles long, and then stepping up again to 161 kv. to serve the Gaspe region about 140 miles away.

Two double circuit 300 kv. steel tower lines 235 miles long, using 21 suspension insulators per phase to support the conductors, are being constructed on the north shore of the St. Lawrence River to the Charlesbourg terminal station near the City of Quebec from which point a double circuit 300 kv. line 150 miles long will continue on to the new Bout de l'Isle terminal station on the island of Montreal.

The Charlesbourg terminal station will be equipped with four three-phase auto transformers of 150,000 kva. rating each, stepping the voltage down to 230 kv. to interconnect with the Shawinigan Company's extensive system at that point. These transformers will be equipped with load ratio control to regulate voltage and with phase angle control to adjust the load transferred through the transformers. Air blast breakers will be used throughout with ratings of 10,000,000 kva. at 300 kv. and of 5,000,000 kva. on the 230 kv. side.

At the Bout de l'Isle terminal station there will be installed six 100,000 kva. three-phase transformers with the required switching and auxiliary apparatus, thus adequately tying the Bersimis development to the present Beauharnois-Montreal-Shawinigan system at that point.

The Bersimis No. 2 development, on which construction has just started, will probably consist of five 165,000 h.p. generating units operating at 370 ft. head at a site some 25 miles below Bersimis No. 1 plant and is scheduled to be completed in 1960.

With the completion of these two Bersimis hydro developments, the total installed generating capacity of Hydro-Quebec will be over 2,800,000 kw.

To cope with the needs for still more power, and under study by Hydro-Quebec, are the possible development of Lachine Rapids on the St. Lawrence and Carillon on the Ottawa River near Montreal, completion of the third and final section of Beauharnois, and the harnessing of the Manicouagan River on the north shore of the lower St. Lawrence, with a combined potential installation of over 4,500,000 kw.

Summing up, therefore, by (say) 1965, when the plants now under construction and those contemplated will probably have been completed, the gross capability of the interconnected network in the Province of Quebec will be of the order of 8,000,000 kw. to 9,000,000 kw. with transmission extending to Gaspe in the east, to the Chibougamau area north-west of Lake St. John, southward to the U.S. border, and westward to the Ontario border. It is conceivable that, by that time, interconnection will have been established between the systems operating in the Province of Ontario and those in the Province of Quebec forming an interprovincial network or grid with a capability of possibly 16,000,000 kw. to 17,000,000 kw.

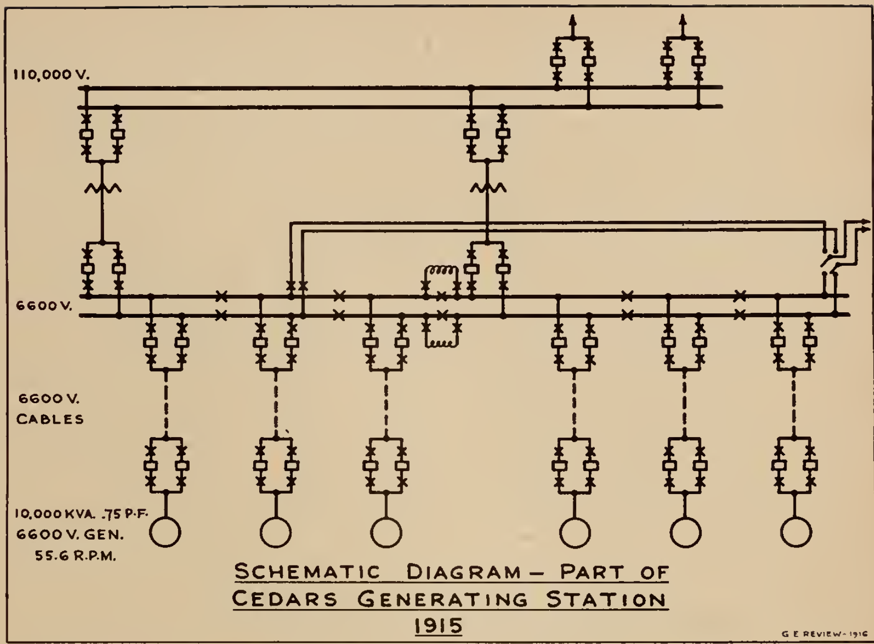

Fig. 3. Another example of the use of duplicate switching facilities.

Frequency

(a) Standards — In the early days there was no accepted standard frequency, and frequencies of 25, 30, 33, 60, and 66 cycles were used. During the 1920's, however, a trend developed towards the use of 60 cycles as a standard, and it was during this period that the Shawinigan Company changed over its 30-cycle system to 60-cycle operation. Near Montreal the Lachine plant, owned by the Montreal Light, Heat and Power Cons. had been constructed for 66-cycle operation, while the original power supply from Shawinigan was at 30 cycles. Parallel operation of these two systems was desirable, and in order to accomplish it, the 66-cycle system was operated at 63 cycles and the 30-cycle system was operated at 31½ cycles, permitting the two systems to be parallelled through 2/1 ratio frequency changers. These odd frequencies were maintained until 1927 when, by mutual agreement, the combined system frequency was gradually dropped over a period, and by March 1928 the 60-cycle standard was realized.

In 1949 a longer and a much more comprehensive and involved frequency-change project was started when the Hydro-Electric Power Commission of Ontario embarked on a program of converting the major portion of its 25-cycle system in southern Ontario to 60 cycles. The estimated time to completion orginally was fifteen years but great headway has been made and recent reports indicate that the entire job probably will be completed by mid-1959.

(b) Regulation — Frequency regulation, as such, was poor prior to 1922 compared with present standards. The 60-cycle frequency meters available usually had a scale of 10 cycles. Such variations did not normally exist, but extremely low frequencies and major variations did occur occasionally.

A contribution to frequency control was made in 1916 when Henry Warren of Ashland, Mass., was experimenting with a clock driven by a synchronous motor. He noted that when the clock was connected to the power company's system it lost some 10 to 15 minutes a day. It took some persuasion to convince the power company's operators that they were operating at a frequency lower than 60 cycles. The operating engineers of the power company, however, were quick to appreciate the value of this extra tool, which enabled them to keep much more constant frequency. Warren went on to develop various types of master clocks with which many are familiar.

The first Warren master frequency clock in Canada was brought into operation on the Hydro-Electric Power Commission of Ontario's system in 1922, and very shortly thereafter one was installed on the Shawinigan system. Following this development the whole matter of frequency regulation became more prominent.

About 1925 the first satisfactory

graphic frequency recorder was introduced, and from 1925 to 1929 power engineers became more conscious of the possibilities and necessity of closer frequency regulation. It became an accepted fact that power companies had to improve frequency regulation to reduce large load swings between plants and between systems to permit satisfactory system interconnection. Furthermore, the textile and newsprint industries were able to turn out more uniform products as frequency regulation improved. Under present conditions, in the Province of Quebec the 60-cycle frequency is maintained within a range of 0.2 cycles, and synchronous time is regulated within a maximum error of 10 sec.

Relay Protection

Effective relay protective schemes were practically unknown before, say, 1920 although the basic principles of overload protection and reverse power protection were known and utilized. On occasion, definite time and inverse time relays were employed but natural phenomena such as lightning and sleet caused many circuit interruptions and, with inadequate protection, played havoc with service continuity.

Considering the relatively complex nature of electric systems as they expanded or developed, and the necessity for substantial and essential improvement in the design of relays and relay protective schemes generally, great credit must be given to engineers such as Paul Ackerman for the pioneer work carried out in connection with the development of adequate relay protection and resultant improvement in service continuity, initially on the Toronto Power Company's system, then with the Hydro-Electric Power Commission of Ontario and finally with The Shawinigan Water & Power Company's system. Ackerman appreciated the necessity of isolating faults instantaneously and selectively, if power arc damage was to be avoided and system stability maintained, so that lines or equipment could be promptly returned to service and maximum customer service assured.

The important principle of the double-step directional impedance protection, now widely used by power companies, was discovered, developed, and applied by Ackerman in 1921-3 while he was associated with The Shawinigan Water & Power Company.

Although enormous strides have so far been made in perfecting relay protection schemes, the field is not static and new ideas are being constantly evolved, and new methods introduced. In general, the trend is towards greater speed and sensitivity. Whereas in the past electro-mechanical relays only were used, electronic protective schemes are now entering the picture. The use of automatic reclosing schemes will probably increase for both single-phase and three-phase applications wherever they can be advantageously applied. Carrier current as an adjunct of protection has been widely accepted and the use of micro-wave is becoming a competitor in this field.

Regardless of the improvements that have been made in protective relaying there is still much original development work to be carried out.

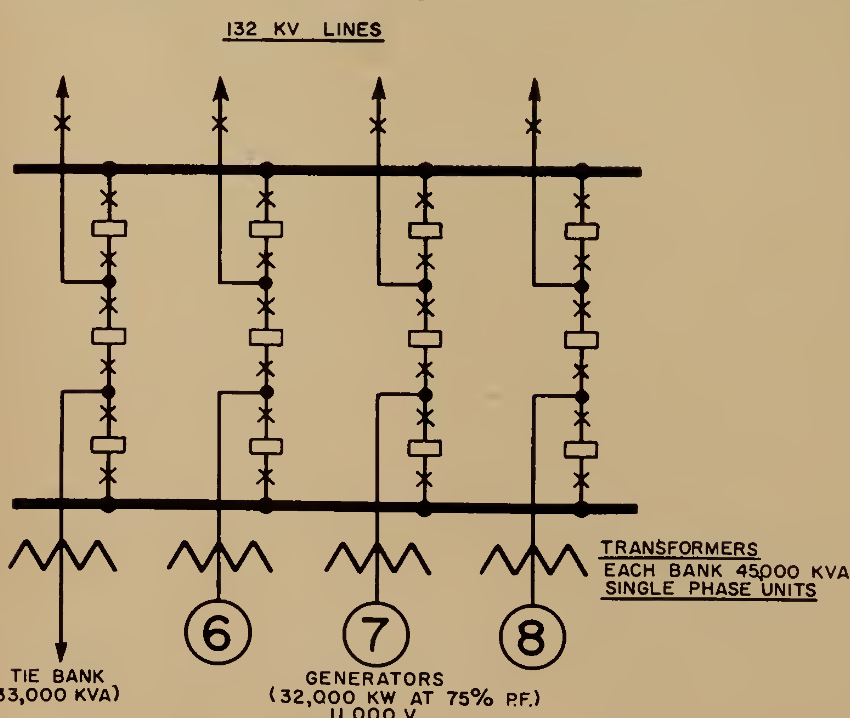
System Planning

To provide for system growth and the resultant rapid expansion of facilities, most large utilities have found it essential to set up system planning groups or divisions. The problems encountered are principally of a technical and economic nature. The system plan must be sound both from the immediate standpoint and from the long-term viewpoint and should be flexible to allow for changing conditions. Co-ordination of all factors is a major objective, including protective relay schemes as well as the proper selection of equipment such as circuit breakers and transformers to ensure suitable characteristics and adequate rating. Provision for service continuity and for satisfactory voltage, load, and frequency control is a major function of a system planning department. Substation and transmission line location, choice of voltages and installation levels could be added to a lengthy list.

The a.c. network analyzer is a valuable aid to system planning engineers and serves an important purpose in assisting in the design and operation of power systems. Essentially it is composed of small resistances, reactances, and a power supply, which may be set up and utilized to represent the power system in miniature under precise control. Use of the analyzer provides a suitable means for determining rapidly and accurately the behaviour of power systems including such features as, power and kilovar flow, voltage changes, losses, fault currents, and stability under various fault conditions.

Ontario-Hydro has had such a device installed since 1941, another is in service in British Columbia, a third is planned by the Calgary Power Company Ltd., and a fourth is under consideration in Quebec. A number of utilities in Canada, in the past, have been carrying out their studies

Fig. 4. Schematic diagram of a more modern generating station showing trend towards simplification with the low voltage circuit breakers eliminated.



using network analyzers on a rental basis in the United States.

System Control and Operation

Originally the chief operator at the principal generating station usually acted as co-ordinator as far as operation was concerned. When additional stations were connected to the system, however, or the system was interconnected with neighbouring utilities, it became necessary to set up a separate organization to handle overall operation and the load dispatching problems. Most large utilities have now adopted this form of operational control.

Today the system operating organization controls the load interchanged between systems and directs the operation of generating stations, transmission lines, and substations, using various types of communication facilities such as the open-wire telephone line, which was the original method of communication, as well as the more modern types of FM and AM space radio, multi-channel carrier telephony on power lines or telephone lines and micro-wave channels.

The system operator and his staff have switching diagrams available which indicate at all times the setup of the power system. Written procedures are prepared and distributed so that necessary operations mav be carried out according to a predetermined plan either with or without communication. The system operator's duties also include allocation of load to generating stations, supervision of the control of frequency, voltage and kilovars. Operation of storage reservoirs and pondage elevations on hydro systems, and scheduled outages of lines and equipment all come under his jurisdiction, while at the same time he maintains a variety of records. One of his principal duties is to supervise matters affecting customer service under both normal and emergency conditions.

System Security

With the rapid system growth in the 1920's utility engineers noted that the damage to equipment was becoming more extensive as short circuit values increased and users became much less tolerant of power interruptions or interference with service. Extensive research and development produced many technical advances all of which were to be reflected in marked improvement to system security and much better customer service.

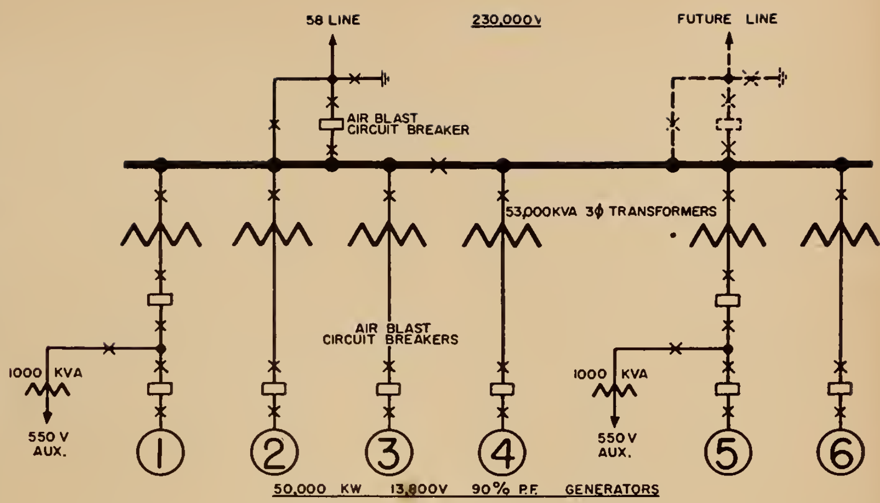


Fig. 5. Switching layout of the simplest design in a modern generating station.

Only brief comment can be made on a few of these improvements since the list is too extensive to be covered in any detail.

(A) Lightning

In the July 1930 issue of *The Engineering Journal* a paper entitled "Generation, Transmission, and Distribution of Electricity in Canada" reflected Canadian practice at the time in the use of overhead shielding wires on high voltage transmission lines and over substation structures, as well as practice in the use of lightning arresters, and the authors state: "Lightning presents a still unsolved problem for the transmission engineer".

At that time it was not fully realized that to attain maximum effectiveness, installation of overhead shielding wires should be associated with a lowering of the tower footing resistance using grillage bases, driven ground rods, or by connecting together the tower bases by continuous buried counterpoise wires. This concept, now accepted by utilities generally, was the result of extensive research by a number of manufacturers and utilities in the United States. Out of it came a much better understanding of the nature and behaviour of lightning, the magnitude of the currents and voltages involved, and improvement in the design and effectiveness of lightning arresters.

Application of these principles was carried out by one large utility in Canada whereby counterpoise wires were progressively added to its existing extensive transmission line system with great success and line outages were reduced to about one-tenth the original figures. (Fig. 6)

Today it is possible in most instances, using modern methods and suitable equipment, to design and construct high voltage transmission lines which are practically immune to damage or interruption from lightning, but study and research still continue.

(B) Circuit Breakers

The circuit breaker in combination with adequate relay protection, is the most important component of the power system to assure continuity of service, to protect equipment from damage, and to permit the removal or energizing of lines and equipment.

Until about 1930, in Canada, the high voltage circuit breaker in use consisted essentially of three tanks filled with oil in which separation of the contacts took place to interrupt the circuit. Time of arc interruption under fault conditions was of the order of 20 to 36 cycles on a 60-cycle base, but the rated interrupting capacity was not known with accuracy. During the 1930's and 1940's radically new methods were introduced by manufacturers to control the arc, using various forms of interrupters based on the principle of de-ionization of the arc path. By these means, operating times, internal gas pressure, and degree of carbonization of the oil were reduced quite markedly, and interrupting capability was increased considerably. Refinement in solenoid, motor-operated, and pneumatic mechanisms added to the reliability and reduced maintenance; staged field tests by utilities, in co-operation with manufacturers, helped the development.

Eventually there emerged the modern single-tank oil circuit breaker, a Canadian development, for voltages up to 138 kv. and rated up to 2½ million kva., 800 amperes, at 5 cycles. For 230 kv. operation, three-tank oil circuit breakers were introduced with ratings of 5 million kva., 1200 amp., 3 cycles, and in 1955 a number of 10,000,000 kva. oil circuit breakers were placed in service by Ontario-Hydro.

Air blast circuit breakers, first developed in Europe, were introduced into Canada about 1939-40 by the Shawinigan Company at its La Tuque generating station and this type of breaker has since obtained wide acceptance by utilities in Canada. Canadian designs of air blast breakers are available in certain ratings; the most recent development being the one described at the Engineering Institute's annual meeting in Toronto, in May 1955 (see ref. 9). Circuit breakers of the "minimum oil" design, also a European development, are being used by a number of utilities in Canada, particularly in the 69 kv. and 138 kv. ratings.

Research and new developments continue with the trend towards higher interrupting capacities, reduced operating times, and increased reliability.

(C) Automatic Reclosing of High Voltage Circuits

An additional method of improving service continuity is that of rapidly isolating the faulted phase or phases and reclosing automatically within 15 to 30 cycles. Since about 90 per cent of all high-voltage line faults are of a transient nature, some utilities consider it quite advantageous to employ automatic reclosing to restore the transmission system to normal as soon as possible after the fault has cleared.

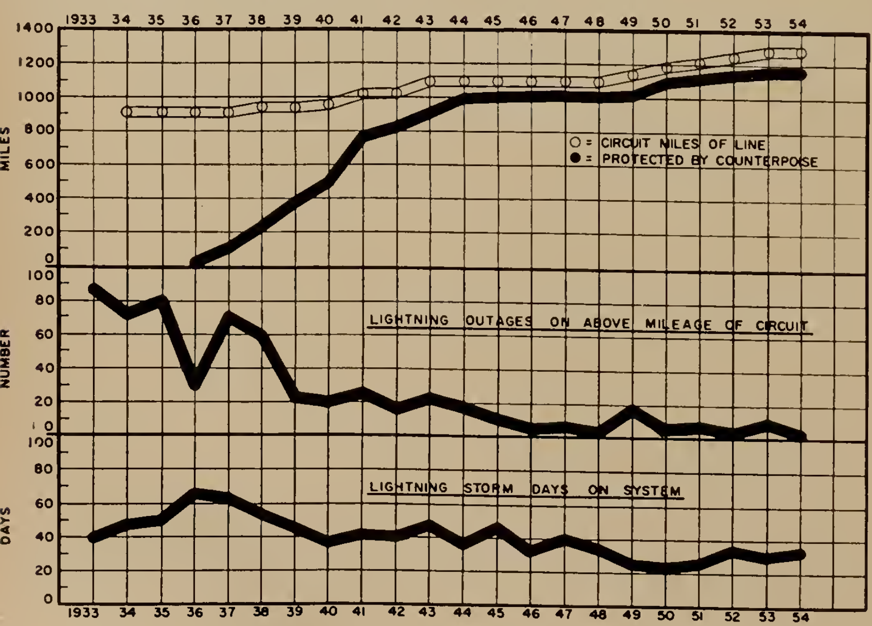
Although this scheme is not widely used in Canada, certain utilities are using the idea on 230 kv. circuits with resultant improved service reliability. On the lower voltages, particularly on radial lines, three-phase automatic reclosing is quite common.

(D) Transformers

Still another factor that has contributed markedly to service betterment has been the decided improvemen in reliability of the power transformer. This has been a gradual process. Improved cooling methods, such as forced-oil — forced-air or forced-oil with water-cooled heat interchanger, have eliminated the use of the iron, brass or copper cooling coils used originally in water-cooled transformers. Such coils occasionally developed leaks, causing failure and service interruption. Use of silicon alloy steel for the core, as well as better insulating materials and improved techniques, has resulted in a more compact and mechanically stronger unit with greatly reduced weight per kva. and greatly increased reliability.

Research in the high-voltage laboratory by manufacturers, including impulse testing of bushings and coils, has given the designer a better understanding of the electrical stresses.

Fig. 6. Curve illustrating the effectiveness of counterpoise installation in reducing lightning outages on transmission lines.



Summing up, therefore, the modern high voltage transformer is a most efficient device of such reliability that, when properly shielded from lightning and equipped with suitable lightning arresters, it ceases to be a factor of concern to utilities when appraising possible interference with service continuity.

(E) Miscellaneous Devices and Methods to Improve System Service

During the last fifteen or twenty years there have been a number of miscellaneous devices and methods utilized to improve the continuity or quality of service to the consumer. Here are a few briefly described.

(a) Fault locators of various designs to locate permanent or transient faults on transmission lines quickly and accurately.

(b) The permanently installed automatic oscillograph which, after system disturbances or interruptions, gives a graphic record of the magnitude of currents and voltages, phases involved, fault clearing times, etc.

(c) Automatic synchroscopes to eliminate the personal factor and to reduce time in synchronizing units or systems.

(d) Relay indicators to show which relays have operated and thus permit accurate analysis of the disturbance or interruption.

(e) Automatic switching schemes to reduce time of customer outage to a minimum by transfer to an alternate source.

(f) Transmission line tools to permit maintenance work to be done alive on high voltage transmission lines up to 230 kv.

To this list could be added: Improved centralized control of load, voltage, and frequency; system service analysis to study, record and appraise the cause and effect of all matters affecting service; supervisory control and telemetering; periodic testing and planned maintenance procedures to locate incipient faults, take remedial measures and thus assist in improving the quality of service to the ultimate consumer.

Possible Trends

Admittedly, one must be cautious in making predictions but here are a few observations and possibilities:

(a) Hydro Generation

Increased consideration will be given to constructing new hydro generating stations of the "outdoor" type, that is, with removable sections over the units as in the case

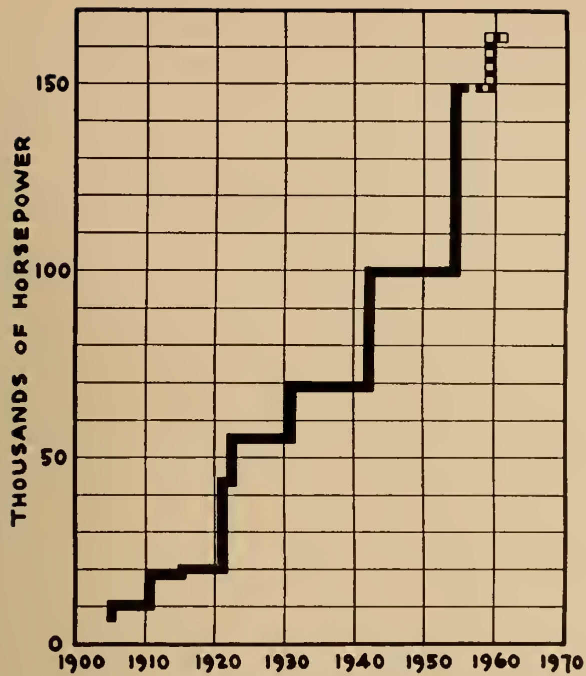


Fig. 7. Curve showing trend of growth in the size of hydro-electric generating units in Canada.

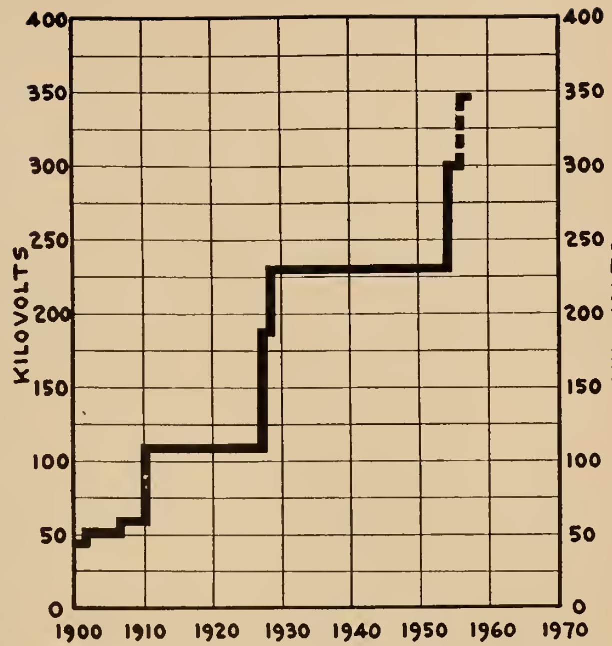

Fig. 8. Curve showing trend of maximum transmission voltage used in Canada.

of Chute du Diable and Chute à la Savane stations on the Peribonka River or at the projected St. Lawrence development near Cornwall. Where practical and economic, generators are being installed underground in the rock, examples of which are the Aluminum Company's Kemano station and the Bersimis No. 1 development.

The maximum capacity of hydro generating units, now just over 160,000 h.p., may increase considerably but such installations will be limited since there are few remaining undeveloped sites with sufficient potential outputs to justify any great increase in size. (Fig. 7.)

Generator voltage rating will probably continue at 13,800 volts for some time with the units totally enclosed, water-cooled and relayed so as to be isolated, shut down, and brakes applied automatically in case of failure. Great advances have already been made in newer types of insulation for generator coils and in the methods of coil construction, as well as in testing methods, both a.c. and d.c., to permit evaluation of the condition of the insulation from time to time. Research is continuing with the objective of improving still further the reliability and life of generating units in hydro plants.

(b) Generation other than Hydro

Improvements in the efficiency of thermal generating units together with the fact that most of the favourably situated hydro sites have already been developed, excepting those in British Columbia and Quebec, would indicate that more fuel-fired generating stations will have to be installed in Canada in future to supply the estimated needs. Dr. Hearn, of Ontario Hydro, announced recently that the Commission would proceed immediately with the addition of a 200,000 kw. unit to the Richard L. Hearn steam station in Toronto. Additional thermal generating capacity is planned for the Atlantic and the Prairie Provinces.

The gas turbine is attracting increased attention of engineers in Canada as a prime mover for the production of electric power. This is particularly apparent in the Western Provinces where abundant supplies of natural gas and oil are available under favourable conditions. The installation of a 6200-9375 kva. unit at Vermillion, Alberta, was completed in 1954 and projected installations at Calgary, Vancouver, and Edmonton have been announced. The two units for Edmonton are to be the largest in the world, each having an output of 25,000-37,500 kva. depending on outside air temperature.

Regarding the use of atomic energy as a source of heat for the production of electric power, active research, development, and plant construction are being carried out in Canada as well as in several other countries. Canada's first nuclear power station, with an estimated output of 20,000 kw., is to be installed near Chalk River, Ontario, as a joint effort of Atomic Energy of Canada Ltd., Canadian General Electric Company, and Ontario Hydro. It is expected to be in operation in 1958-59.

Dr. Hearn recently stated that in studying the development of future power resources, it is assumed that in 1965 nuclear fuel-electric stations will be more economical for base load operation than conventional fuel-electric stations.

In an article in the December 1955 issue of the *Electrical Digest*, entitled "Nuclear Power Outlook for Canada", James H. Goss summarizes the situation in a very concise manner. In this article are two significant statements, namely: (1) nuclear power will never be as cheap as efficient hydro-electric power, and (2) the impact of nuclear power will be a slow and steady one during the 1960's and 1970's and always on top of a growing base of power from conventional sources.

The trend appears to be that, beginning about 1965 in some areas of Canada, steam electric stations using nuclear fuels will begin to supplement and eventually replace steam electric stations using conventional fuels.

(c) Transmission

Transmission losses will get more attention due to rising power costs.

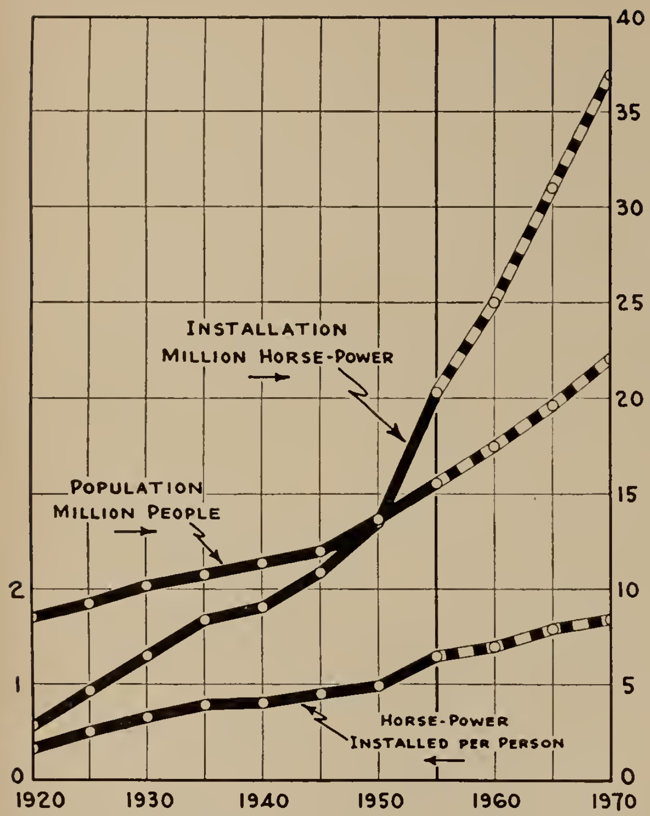

Fig. 9. Curve showing trend in the growth of electric power installations and population in Canada.

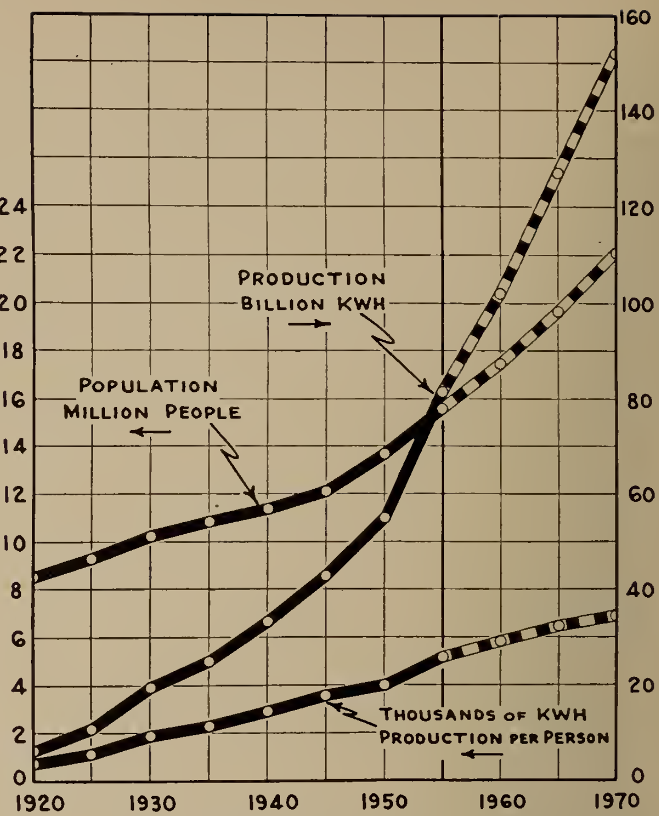

Fig. 10. Curve showing growth of total production of electric energy in Canada and energy production per person.

With increasing loads on power systems, the trend will continue in the use of higher voltages for transmission, distribution, and utilization to improve transmission efficiency. Transmission voltages of 300 kv. at Kemano and on Hydro-Quebec's Bersimis-Montreal system will be exceeded on the B.C. Electric Company's system by the new 345 kv. line which is to go into operation next year. In Europe, 400 kv. lines are in successful operation and some manufacturers are willing to quote on supplying equipment for 500 kv. operation. (Fig. 8)

As the number of high voltage transmission lines increases, especially through settled country, we will probably see more double circuit construction used on account of the greatly increased cost of right-of-way.

The fundamental basis on which high voltage transmission lines in Canada have been designed and constructed, has not changed materially for many years but the whole subject is now under review. The result will probably be a modification of existing standards and practices on a more realistic basis with the objective of reducing transmission line costs and still maintaining satisfactory electrical and mechanical performance. Special consideration will be given to evaluating the frequency and intensity of natural phenomena such as lightning, sleet, snow and wind storms in various areas.

(d) Kilovar Supply

Greater attention will be paid in future to the supply and control of reactive kilovars by utility engineers due to the increased distance involved in high voltage transmission, heavier circuit loadings, and desire to improve transmission efficiency.

There will probably be increased acceptance and use of high voltage shunt capacitors to counteract the effect of line reactance. One large utility has a number of such installations in satisfactory service at voltages from 11 kv. to 69 kv. in blocks up to 20 megavars, and plans to install even larger units in the near future for use at 115 kv. The use of shunt capacitors at receiving stations results in lower line losses, improved system capability and better voltage control. Synchronous condensers are equally effective, but shunt capacitors have the advantage of being lower in cost per kilovar, have negligible loss and require little attention. Furthermore they may be installed in increments and are silent in operation.

The selection of suitable switchgear for high voltage shunt capacitor installations is important in order to avoid or reduce restrikes or overvoltages that could result in service difficulties. Air blast breakers seem to be particularly suitable for capacitor switching.

(e) High Voltage Cables

There appears to be increasing acceptance and use of high-voltage cables in Canada, both of the underground and submarine types. Hydro-Quebec has several miles of 115 kv. cable in service in the Montreal area, as well as the recently completed 69 kv. submarine installation more than 30 miles long under the St. Lawrence River near Rimouski. The B.C. Electric Company is installing in the near future some 17 miles of 132 kv. submarine cable from the mainland to Vancouver Island and has announced recently its decision to install, by 1957, about ten miles of 230 kv. single core oil-filled cable in the city of Vancouver. The Aluminum Company has had its 300 kv. cable installation in service at Kemano since 1954.

(f) System Integration

Integration and interconnection of power systems will continue, particularly where the cost of providing the interconnection is small when compared to the potential benefits to be derived. These include increased firm capability as well as greater combined efficiency and economy of operation. Many of you here will, no doubt, see the large electric power systems in the Provinces of Ontario and Quebec adequately interconnected and normally operating in parallel with an estimated combined capability, say, in 1965, of 16,000,000 kw. to 17,000,000 kw. Conceivably, this network might be extended to include Manitoba and the Maritimes.

(g) Research and Standardization

Continued consideration probably will be given to standardization and interchangeability of equipment and various component parts to effect increased efficiency and reduction in costs. More automatic equipment and control devices will be developed and utilized to conserve manpower and to permit more effective control of operation. Continued research will ensure that new and better materials and methods are found and this will be reflected in lighter, stronger, and more efficient equipment being introduced. Silicon iron alloys, with vastly improved electrical characteristics, used in the construction of transformers and generators, the many new types of synthetic resins such as the polyvinyls and polyesters, and the silicones used for electrical insulation, are examples of what has been accomplished in recent years by manufacturers.

Utility engineers, as well as the many committees of the Canadian Electrical Association and the Canadian Electrical Manufacturers' Association have made important contributions, principally in the application field. The Research Bureau of Ontario-Hydro and the National Research Council have made many notable contributions in many phases of the electric utility field. In the broader aspects of standardization the Canadian Standards Association continues its excellent work as Canada's national standardization body.

(h) Future Growth

The steady growth of population in Canada from the present figure of 15.6 million to an estimated 22.1 million in 1970, and the continuing increase in the standard of living in Canada will certainly result in increased consumption of electricity. (Fig. 9) There is every indication of continuing and rapid growth in the utilization of electrical energy and saturation seems to be far off.

Annual domestic consumption, it is estimated, will increase from 3,500 kwh. per domestic customer in 1955 to about 5,000 kwh. by 1970. Maybe this estimate is too conservative.

Latest Dominion Bureau of Statistics figures show a generating capability for all Canada of 14 million kw. with a probable increase during the next five years of 6 million kw. making 20 million kw. in 1960.

Total production of electrical energy in Canada for 1955, based on Dominion Bureau of Statistics reports, amounted to about 80 billion kwh. and is estimated to increase to over 102 billion kwh. by 1960.

For the twenty years prior to 1950 the percentage of fuel-fired installations producing electric power to hydro-electric installations was between 6 and 7 per cent. With the expected increase in fuel-fired installations there are indications that by 1970 thermal power will account for about 23 per cent of the total installations.

Conclusions

This review of the growth and development of large electric power systems has described a few of the advances that have been made, particularly during the past twenty-five years. Technical research, use of new materials, improved manufacturing techniques and experience have played an important part in the development, requiring the combined efforts and co-operation of manufacturers, and utilities, as well as engineering and technical associations.

In general in the past, there has been a tendency for the load growth in Canada to double every eleven years, which is between 6.5 and 7 per cent compounded annually, and there are indications that this trend will continue. The important problem now facing the utility industry is to keep pace with the prospective future load growth. Another important problem is to attract and train engineers and other personnel capable of administering, planning, and operating the extensive power systems of the future.

References and Bibliography

The following list of technical publications, dealing mainly with Canadian developments and principally by Canadian authors, has been prepared in the hope that it may be useful to members wishing to follow up certain subjects in more detail.

Current Developments in Air Pollution in the United States

L. C. McCabe

President, Resources Research, Inc., Washington, D.C.

Read at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada, Montreal, May 1956

Automobile exhausts, incineration, sulphur dioxide, and fluorides are currently of major interest to investigators of air pollution in the United States. The Government is stimulating research in the evaluation of pollution levels and their effect on health.

ATMOSPHERIC pollution activities in the United States were stimulated during the past year by legislative action at Federal, state, and local levels and by an impressive quantity of information from research institutions throughout the country. Notable for scope and excellence of material during this time were: the First International Congress on Air Pollution, held under the auspices of the American Society of Mechanical Engineers; the American Chemical Society's symposium on air pollution, at the annual meeting at Minneapolis last September; and the special program sponsored by the American Association for the Advancement of Science at its annual meeting in San Francisco in December 1955. The Air Pollution Control Association held its largest annual meeting in Detroit in 1955 and extended its services to its membership through its new Journal and APCA abstracts.

The petroleum and automobile industries through the Coordinating Research Council continued to support important research in the chemistry of air contaminants and the control of automobile exhausts. The Air Pollution Foundation sponsored investigations in a number of laboratories throughout the country and during 1955 published ten technical reports on basic aspects of air pollution.

The enforcement and research budget of the Los Angeles Air Pollution Control District was in excess of 2½-million dollars for the fiscal year ending June 30, 1956. Throughout the United States there was an increase in money spent for research and enforcement at the municipal and state levels. Salaries for air pollution officials and their technical staffs continued to improve, and more individuals with formal scientific and engineering training entered the field.

Atmospheric pollution has received increasing attention in the Congress during the past four or five years. In addition to California, concern was expressed over growing atmospheric pollution in New York City, New Jersey, Philadelphia, Florida, the Gulf Coast embracing parts of Louisiana and Texas, Detroit, Denver, and the states of Oregon and Washington. Many smaller cities came in for debate. The problems reported varied from place to place—hydrocarbons from traffic and petroleum processing, industrial dust and odours, smoke, sulphur dioxide, fluoride damage to crops and cattle, and the burning of combustible wastes, all were subjects of complaint. This led the President to suggest to the Secretary of Health, Education, and Welfare that he invite other federal agencies, the Atomic Energy Commission, Agriculture, Commerce, Defense, Interior, and the National Science Foundation to participate at the policy level in an ad hoc Interdepartmental Committee on Community Air Pollution. In a report released by the Public Health Service on April 8, 1955, this committee made recommendations regarding the role of the Federal, state, and local governmental agencies in controlling and regulating community air pollution. It was agreed that the Department of Health, Education, and Welfare should sponsor legislation and direct the Federal program, that a continuing Interdepartmental Committee on Community Air Pollution should be established and that certain scientific research of the agencies should be supported from any funds appropriated by the Congress.

Public Law 159, passed by the 84th Congress in July of 1955, "authorized to be appropriated to the Department of Health, Education, and Welfare for each of the five fiscal years during the period beginning July 1, 1955, and ending June 30, 1960, not to exceed $5,000,000" to provide research and technical assistance relating to air pollution. The Surgeon General of the Public Health Service was authorized to direct the program.

Other sections of the act provide that the Surgeon General may conduct research and develop methods of preventing and abating air pollution through the facilities of the Public Health Service and aid state and

Published by arrangement with The American Society of Mechanical Engineers.

local government agencies and public and private organizations and institutions in similar activities. Contracts and grants-in-aid may be made to these organizations and to individuals for research, training and demonstration projects.

The last session of the Congress approved $595,000 for air pollution investigations in the regular budget of the Public Health Service and, following passage of Public Law 159, an additional sum of $1,190,000, making a total of $1,785,000 for the fiscal year ending June 30, 1956. These funds are allocated as shown in the accompanying table.

The kinds of projects which other Federal agencies have been asked to undertake are those needed by the Public Health Service to develop basic information or data necessary to solve specific air pollution problems and for which they are better qualified, by reason of staff competency or possession of special facilities, than is the Public Health Service. Generally, the projects are those in which the time required for the performance of the agreement can be stated and in which the limits of the work may be determined. The projects to be undertaken through memoranda of understanding with the other Federal agencies in fiscal year 1956 are as follows:

Bureau of Standards

(1) Development of methods of analysis and identification of gaseous contaminants. (Improved methods for sampling and analysis of gaseous pollutants are essential to both air pollution research and control efforts.)

(2) Reactions between pollutants at sources and among pollutants in the atmosphere. (Chemical combinations and separations are known to occur both within the plant site where air contaminants are generated — the "source" — and after emission due to the effects of solar radiation, moisture, pollutants from other sources, etc. An understanding of the nature and scope of these basic chemical changes is essential to developing knowledge of their effects and how these may be minimized.)

Bureau of Mines

(1) Incineration of combustible wastes. (The burning of community wastes — garbage and rubbish principally — contributes importantly to many local air pollution problems. Fundamental studies are needed on incinerator design and operating procedures to minimize the emission of pollutants from such sources.)

(2) Evaluation of sulphur dioxide removal processes. (Sulphur dioxide is a common air pollutant, emitted from combustion of most common fuels and from many industrial processes. Its removal in low concentrations from stack gases has been given considerable study, but no standardization of practice has resulted. Critical evaluation of available technical information will be of much value to control agencies and in determining the need for further investigative work.)

(3) Automobile exhausts evaluation. (Automobile exhaust gases are being implicated to an increasing extent as important factors in urban air pollution. Precise identification of exhaust gas components under varying conditions is being undertaken as a basis for further studies of effects and means of nullifying them.)

Weather Bureau

(1) Special participation in community investigations. (Non-routine meteorological observations as needed in assessing local air pollution problems.)

(2) Development of meteorological methods for forecasting critical air pollution conditions. (For practicable and economically acceptable air pollution control programs, it is essential that means be available for predicting the pollutant concentration in the atmosphere resulting from a known quantity of emission under critical weather conditions. Only with such knowledge can definitive determination be made in any control district of the maximum allowable emission of specific pollutants.)

Armed Forces Institute of Pathology

Survey of lung cancer types in relation to previous residence in areas characterized by high and low levels of air pollution.

Veterans Administration

Statistical studies of records of mortality and residence in areas characterized by high and low levels of air pollution.

The technical assistance program has been initiated by the Robert A. Taft Sanitary Engineering Center at Cincinnati, Ohio. Personnel have been assigned to assist the Los Angeles Air Pollution Control District through the Department of Health, State of California. Similar assistance has also been extended to Louisville, Kentucky. Requests for extensive investigations were received from 28 state governments and local communities in the first six months following passage of the act. The current resources are not sufficient to comply with all of the requests, though every effort is being made to participate in joint study of local problems to the extent of available trained manpower. Four short courses in the technical aspects of air pollution control were scheduled at the Sanitary Engineering Center during the first year of the act.

The direct research activities planned are being carried on directly by the Public Health Service in Cincinnati both at the Sanitary Engineering Center and the Occupational Health Field Headquarters. At the Sanitary Engineering Center, the nation-wide aerometric survey begun approximately two years ago is being continued and expanded. Preliminary estimates of classes and determinations of amounts of particulate loadings have been obtained from air samples collected on daily and weekly schedules in more than thirty representative communities. These include both urban and rural areas. Inorganic assays and quantitative analyses of certain organic constituents are made of the present particulate collections and it is

Allocation of Funds for Air Pollution Investigations

Engineering	
Direct research and technical assistance by Public Health Service	$ 435,000
Contract research with private institutions	50,000
Training of Public Health Service officials	40,000
Transfer to other Federal agencies for research work	400,000
Health	
Direct research by Public Health Service	160,000
Contract research with private institutions	200,000
Research Grants	
Health and engineering projects at universities, medical schools and research organizations	500,000
Total	$1,785,000

planned to supplement these by routine determinations of some of the non-particulate pollutants, i.e., gases and fumes.

At the Occupational Health Field Headquarters, work is already under way in determining the physiologic and toxicologic effects of certain chemicals, such as ozone, oxides of nitrogen, and sulphur-containing hydrocarbons known to be present in smog.

The $500,000 available for research grants in 1956 has been committed for support of air pollution studies. Most of these grants have been awarded for studies primarily related to the health effects of air pollutants. Investigations under way include broad epidemiological studies of the relation of human disease to air pollution, studies of the effects of specific contaminants such as fluorides and oxides of sulphur, and studies of physiological response to air pollutants. In the future, it is expected that research grants projects will include studies on the causes and prevention of air pollution as well as those concerned with its effects on health.

Dr. Justin M. Andrews, assistant surgeon general of the Public Health Service recently said: "The medical component of the community air pollution program is planning an extensive use of contract research to provide information concerning the health effects of subacute exposures to pollutants suspected to be harmful. This is probably the most important single fact to ascertain—yet it has been the most elusive thus far—as most air pollution control ordinances are written on the assumption that freedom from community air pollution will be healthful. It is hoped that organ function tests, especially pulmonary and cardiovascular, can be devised that are simple and accurate enough to be used on a mass basis. Such tests might be applied according to conventional epidemiologic patterns to population groups comparable in all important respects except for their exposure to high and low levels of specific air pollution. Similarly chest X-ray surveys may be made along epidemiologic lines to see whether lung cancer is more prevalent in populations exposed to continued, high levels of air pollution. Efforts are also planned to determine if tissue culture techniques offer a more sensitive indication of the toxicity of air pollutants than do intact test animals."

A current report of the National Cancer Institute states that: "One of several carcinogenic chemicals has been isolated from several agents representing variable chemical mixtures (soot, coal, tar and pitch, petroleum oils, gasoline and diesel engine exhaust). Wherever a definite identification of a specific causal agent has not been attained, the epidemiological evidence based on an evaluation of cancer incidence of relatively small occupationally circumscribed total populations at risk is sufficiently reliable to prove the presence of an occupational respiratory cancer hazard casually related to a specific industrial operation. Epidemiological, medical, and experimental data concerning these respiratory carcinogens attest to their high carcinogenic potency under occupational conditions, particularly when acting on humans. It is therefore reasonable to assume that inhalation of the same agents, in a mitigated form as air pollutants, by the general population is responsible for a considerable portion of the lung cancers attributable to such contacts."

Assignment of the direction of atmospheric pollution activities at the Federal level to the Public Health Service will have the effect of emphasizing the health aspects of problems, and, as the Service through long established procedures works through the health departments of the 48 states, there will be a tendency to strengthen air pollution work at the state level. The act provides for the assignment of Public Health Service personnel and for grants to support projects carried on by the states and local communities, and their personnel are being trained in Public Health Service laboratories. As the program expands, eligible individuals may be assigned to field service and demonstration projects throughout the United States for training.

Motor vehicles are considered to be the largest single source of air contamination in Los Angeles. The Air Pollution Control District estimates that 1050 tons of hydrocarbons are emitted to the air daily in the County from 2½ million automobiles, 200 tons from refineries, and 85 tons more in marketing. Contributions from other sources bring the total to about 1450 tons daily. The hydrocarbons react with ozone and the oxides of nitrogen in the presence of sunlight to produce a large part of the smog which reduces visibility, causes eye irritation and crop damage. Development of carburetor regulating devices or exhaust gas burners is well advanced. When such a device proves reasonably effective, no doubt it will be adopted for use on vehicles in that county.

Industrial installations for controlling air pollution at the source are increasing each year. It is estimated that, over the past eight years, industry in the Los Angeles area has spent $30,000,000 to control hydrocarbon losses, sulphur dioxide, dust, and fumes. Recovery of elemental sulphur from refinery operations now totals 450 tons per day in the county. Increasingly large sums are being spent in other industrial centres, possibly as much as $150,000,000 annually. The chemical industry alone estimates an expenditure of $40,000,000 per year in the control of atmospheric effluents.

Equipment development is keeping pace with the demand for more effective control devices. One manufacturer of control equipment states that more exacting requirements by the public bodies and more rigid enforcement of local regulations has stimulated the production of control equipment having efficiencies that were unheard of ten years ago. The small operation, the disposal of combustible rubbish, bus and automobile fumes, and the recovery of low concentrations of sulphur dioxide in large gas volumes are among the more refractory economic problems, but much research and development effort is being devoted toward their solution.

The technology of air pollution is now at the stage of water sanitation of perhaps a hundred years ago. It is probably a fair observation that progress is being made in the face of tremendous community and industrial expansion.

It is evident from recent studies that atmospheric pollution is fairly closely associated with density of population. At present, approximately 165,000,000 people live in the United States and 51 per cent of them live in 1.5 per cent of the total land area. The National Office of Vital Statistics forecasts a population of 221,000,000 by 1975. If present trends continue there will be an extension of the densely populated areas and a corresponding increase in the load of pollution the air must accommodate. This is one compelling reason for the continued activity in air pollution control.

Lateral Rigidity of Steel Building Frames

J. L. de Stein, M.E.I.C. and J. O. McCutcheon, M.E.I.C.

Department of Civil Engineering, McGill University

Read at the 70th Annual General and Professional Meeting of The Engineering Institute of Canada, Montreal, May 1956

The paper approaches the problem of required stiffness by means of rational analysis and on the basis of probable movements as related to building materials. The question of required rigidity for many buildings is at present rather empirical and tends to be left to judgment. The problem is topical, with the recent incorporation of new design methods in both British and Canadian design specifications and with the extensive use of continuous fenestration and panel-wall construction.

THE DESIGN of any building frame is concerned with the strength of the various members. For many frames the general rigidity or stiffness should also be a design consideration.

Members in a bent or a frame are designed for vertical loads, or for lateral forces such as wind, earthquake, or crane thrusts acting in combination with the vertical loads. The design of beams supporting vertical loads is often governed by a stiffness requirement. Depending on the materials being supported by the beam some building codes or design specifications limit the deflection to a specific amount, or place a restriction on the depth-span ratio of the member.

At present, North American design specifications place no limit on the deformation of a frame under lateral loads. For many frames the deformation could be relatively large without causing excessive stresses in the various components. However, some of the rather brittle cladding materials now in common use might be damaged by such deformations. Even with ductile or relatively flexible wall materials which are undamaged by frame movements, it may be that the limberness of the frame is not compatible with the functional use of the building. A rational design for certain building frames might accordingly include a consideration of lateral movement in view of the fact that it might establish the design or size of some of the members.

Mill buildings in the past were built both with masonry exterior walls and with clad walls, and it is likely that for many of these buildings the steel frame resists a considerable portion of the wind force. These buildings generally had travelling cranes with attendant stiff columns and relatively extensive lateral and longitudinal bracing, and where cranes were not used the bracing still tended to be extensive by modern standards. Because of the rigidity of these structures the lateral deformation is probably not excessive.

In the factory building of recent years the introduction of newer cladding materials, with translucent panels or continuous sash, has made the full exterior masonry wall an exception, and in general the frame must carry virtually all the wind force. Modern material handling methods require fewer travelling cranes, and the average frame is accordingly lighter. More exact design methods have also tended to lighten the modern mill building structure. A similar trend may be noted in the construction of commercial buildings where, with frequent use of panel walls and continuous fenestration supported from the steel, more wind load is brought to the frame. It follows that the modern building frame, tending to a lighter weight, and carrying a higher proportion of the wind force, may have excessive lateral deformations and correspondingly large plastic strains in the connections.

Experimental work has been done in recent years to establish rotation properties of common structural connections, such as web and top and bottom flange connections. With this information available, it is now possible to calculate the behaviour of frames with semi-rigid connections, including deformations and the stresses and strains in the various members. Such analyses may be extended to determine the adequacy of a particular connection and of a particular column size for a given frame.

In order to assess present design methods relative to building deformation, and to develop span and height limitations for various connections, some 64 single-storey building frames were designed using in each case the lightest member meeting the specification requirements. The lateral movement was then calculated for each frame.

Frame Analysis

The types of frames studied are indicated in Fig. 1 and in general consist of single bay bents, two bay bents, and three bay bents. Each unit was designed for 20 feet, 28 feet, and 36 feet spans, and with column heights of 15 feet, 20 feet, and 28 feet. This gave a total of 27 bay-span-height combinations. Each of these 27 combinations was

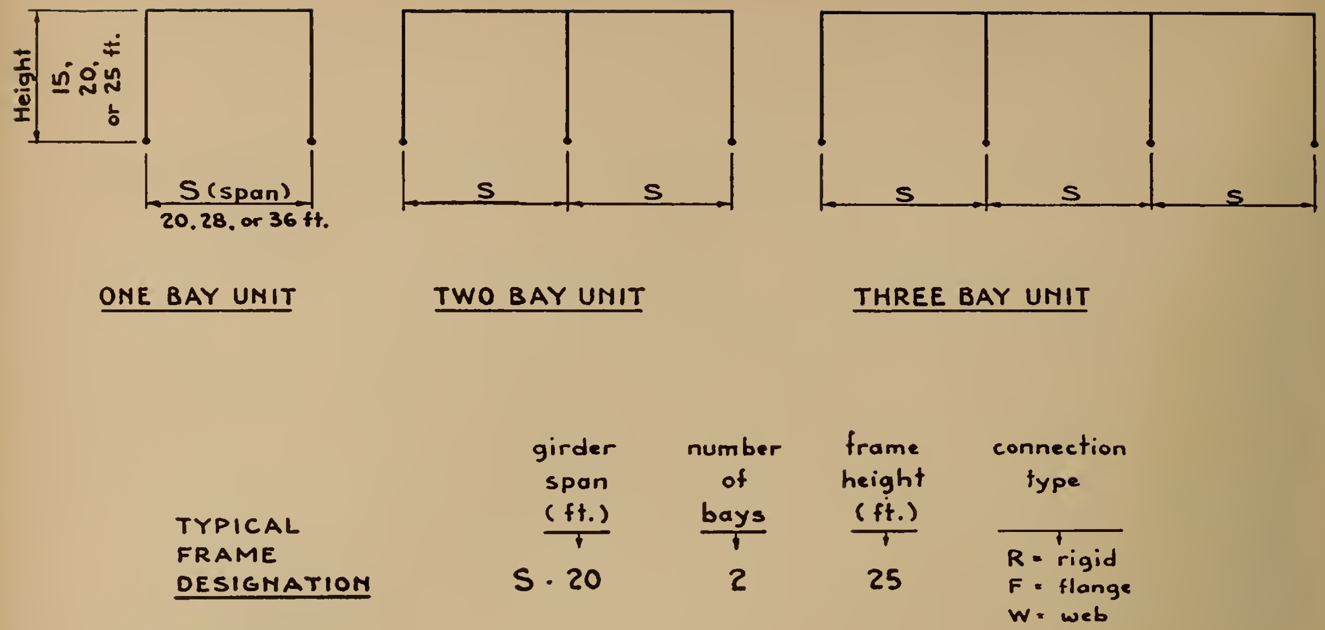

Fig. 1. Frame designations.

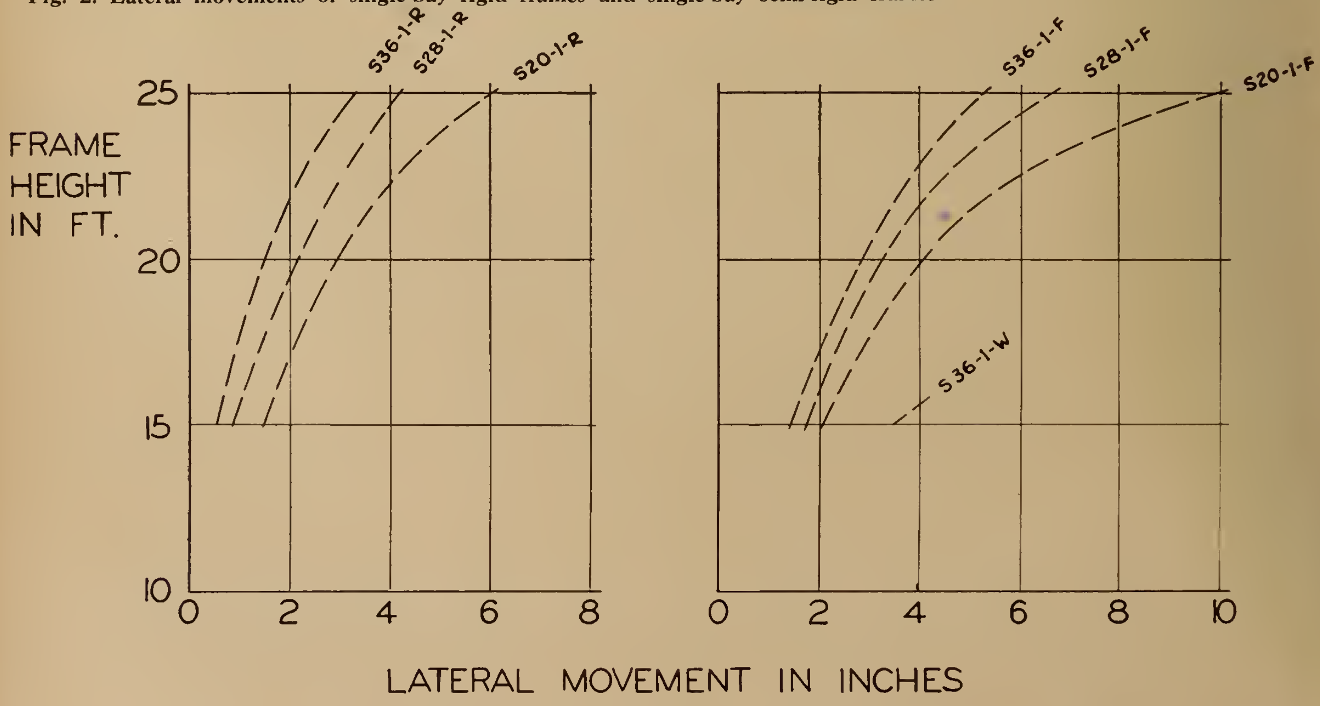
designed with rigid connections and re-designed with top and bottom flange connections and in some cases with web connections.

Each bent was considered to support a twenty-foot length of building roof and walls. Roof construction was assumed as tar and gravel roofing with insulation on pre-cast lightweight concrete slabs supported by steel purlins spaced from 6 ft. 8 in. to 7 ft. 3 in. on centres, giving a dead load, including steel, of 38 lb. per sq. ft. Snow loading was taken as 40 lb. per sq. ft. Wall construction was assumed to be cladding supported by girts framing into the columns so that the exterior columns had full lateral support about their weak axes. Wind loading was taken as 10 lb. per sq. ft. pressure on the windward wall and 10 lb. per sq. ft. suction on the leeward wall and was considered as acting on the steel frame from 3 feet above the base plates. The columns were considered to be pin-connected at their bases. For the rigid frames advantage was taken of the negative end moments in designing the girders while for the semi-rigid frames the girders were designed as simply-supported beams. The columns were designed taking into account connection moments induced from vertical and lateral forces but without restriction as to lateral movement. The Canadian Standards Association Specification S16-1954 was used for the design of the members.

The design and analysis of the frames with semi-rigid connections were based on moment-rotation (M-o) characteristics of web and of flange connections as obtained by test data. The connection details and the curves used for this work are shown and discussed in Appendix A.

Fig. 2. Lateral movements of single-bay rigid frames and single-bay semi-rigid frames.



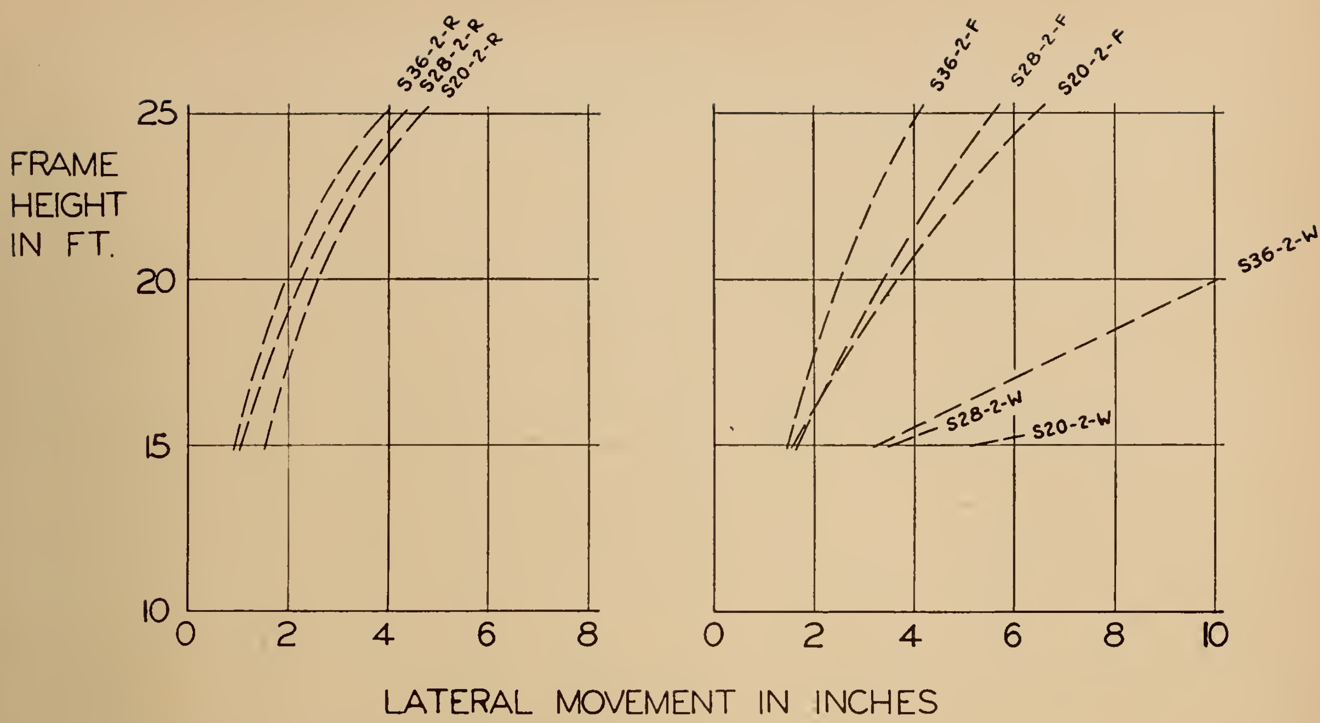


Fig. 3. Lateral movements of two-bay rigid frames and two-bay semi-rigid frames.

Using straight-line approximations for these curves, moment distribution was applied after stiffness and carry-over factors were obtained. Methods of analysis are outlined by Pippard and Baker[1], Johnston and Mount[2], and others.

It may be noted from the connecton curves in Appendix A that, within the working values, the ratios of relative rigidity of the top and bottom flange angle connection to that of the web connection are approximately as follows:

Beam Size	Relative Rigidity Flange Connection to Web Connection
14 WF	8 to 1
18 WF	6.5 to 1
21 WF	3.5 to 1

Results

Table I shows the results of the rigid frames study and Table II shows the results of the semi-rigid frames study. For each of the bents the economical beams and columns are listed, followed by the maximum moment on each connection and the calculated lateral movement of the building under the combination of dead load, half live load, and wind load. In Table II the total lateral movement of the semi-rigid frames has been broken down to show the amounts due to bending of the column, bending of the beam, and bending of the connection.

In Fig. 2, 3, and 4, lateral deformations of the building frames have been plotted against frame height. The single bay structures have been plotted in Fig. 2, with the rigid frame deformations shown separately from those of the semi-rigid frames. Figures 3 and 4 deal in a similar way with the deformations of the two and three bay structures.

Frame Deformations

The calculated lateral deformations of the rigid frames varied from 0.50 inch to 6.0 inches. These deformations result from bending of the girders and of the columns with the column contributing at least 75 per cent of the total. From Fig. 2, 3, and 4, it may be noted that for the 25-foot high frames the deformations are quite large and, even in the case of the three bay structures where the wind forces are resisted by four columns, these deformations vary from 3 in. to 5 in. Inspection of the curves indicates that deformations for the 20-foot and 25-foot frame heights do not vary appreciably for the one, two, and three bay structures considered.

The calculated lateral deformations of the frames with flange connections varied from 1.2 in. to approximately 10 in. It may be seen from Table II that in general, for the two and three bay structures, the deformation of the connection accounts for 15 to 20 per cent of the total movement of the frame, and for the higher single bay structures the connection deformation reaches 45 per cent of the total. The listed values indicate that even with semi-rigid flange connections, bending of the column still accounts for the greater part of the frame movements.

In the rigid frames where bending moment is a major factor in the design of the columns, the differences in lateral movement between the one, two, and three bay frames of a given height are not significant.

As might be expected, for any given height and girder span, the lateral movement in general decreases as the number of bays increases. However, where the depth of a column is changed, the general trend may reverse at that point. Because of the overlapping of depths in a weight listing of rolled sections, such discontinuities may be expected in design.

Some 15-foot and 20-foot high frames with web connections were designed and the results of their analysis are shown in Table II and in Fig. 2, 3, and 4. For some of the 20-foot and all of the 25-foot high frames it was impossible to obtain a design with web connections, as the moment on the connection either approached or exceeded the ultimate strength of the respective connection. The deformations of some of these designs are of unacceptable magnitude for a building frame. For the frames shown the connection deformation was responsible for 50 to 80 per cent of the total lateral movement.

For the three bay frames with web connections shown in Fig. 4, the deformations for the 15-foot high frames are similar, even though the connections for the various girders are quite different. At this height the moments on the web connections are quite small and the deformation is mainly from bending of the column.

Except for the single bay units, it is significant that the deformations of the semi-rigid frames with flange connection are not widely different from the deformations of the rigid frames. In the single bay rigid frames the deformations are approximately 60 per cent of those of the semi-rigid frames; the differences being mainly due to the larger columns required for the rigid frames because of the relatively high dead and live load moments on the columns.

It should be noted that wherever web connections have been used, the total deformation is 1½ to 3 times that of the corresponding frame with flange connections.

Table I—Rigid Frames

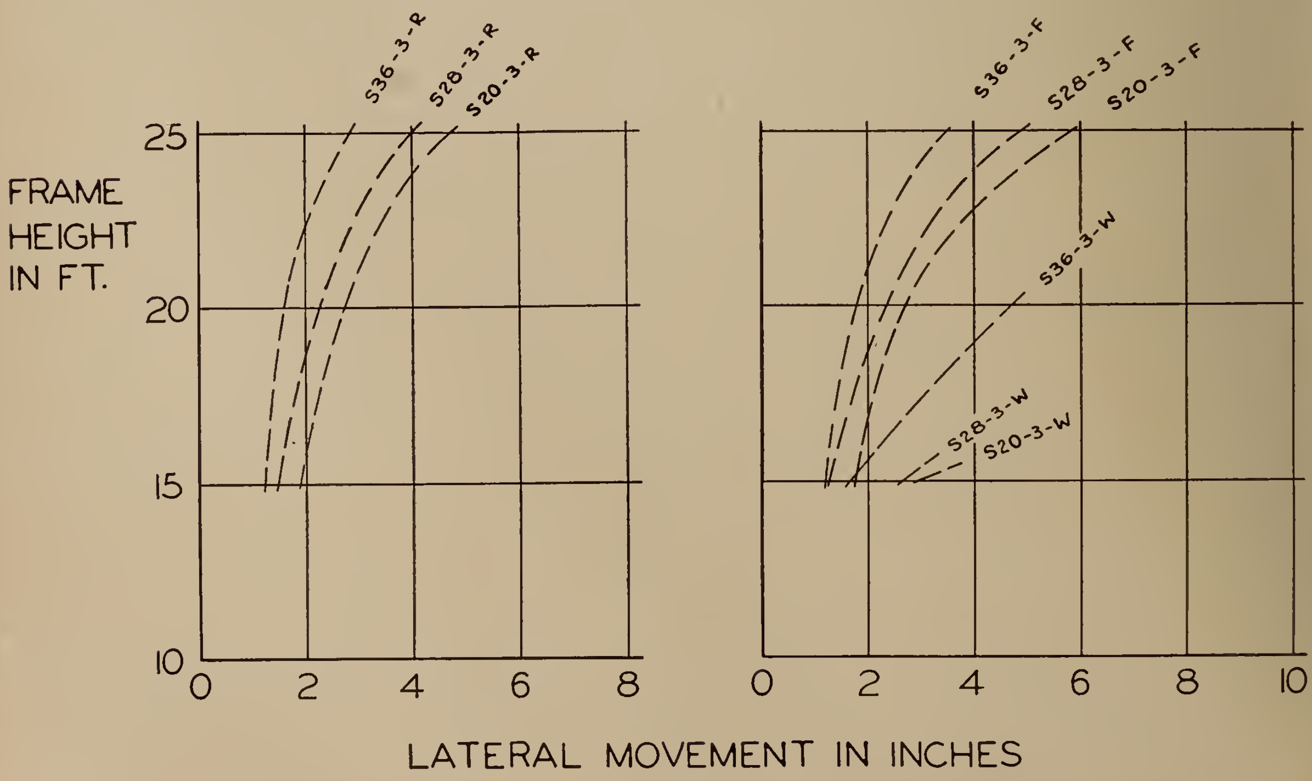
Connection Moments

Except for three cases, the maximum moment (dead plus full live plus wind) on the semi-rigid connections has not exceeded 65 per cent of the ultimate strength of the connection. It may be that in those cases where the moment on the connection is 50 to 65 per cent of the ultimate capacity of the connection, some designers would prefer a rigid connection or a stronger flange connection. However, it should be noted from the connection curves in Appendix A that a moment of 60 per cent

Fig. 4. Lateral movements of three-bay rigid frames and three-bay semi-rigid frames.



of ultimate corresponds to an angular deformation of about 25 per cent of the rotation at failure. A safe or reasonable design value to allow on the connection should take into account the ratio of design rotation to ultimate, the combination of loading, the lateral movement of the frame caused by the connection deformation, and residual deformation due to the plasticity of the connection.

If the deformation of the frame is acceptable, then it would appear that a design moment on the connection of 60 per cent of ultimate would be permissible.

Column Heights

As previously noted, the design and the calculations for lateral movement consider the columns to be pin-connected at the base. However a point of contraflexure may be some distance above the base, depending on the details. If, for a particular design, the location of the point of contraflexure can be approximated, the results of this study could be made comparable by deducting the distance to the point of contraflexure from the frame height.

Permissible Lateral Movements

The amount of lateral movement that might be tolerated in a given building should be related to the type of cladding material. In a building with masonry spandrel walls the amount of movement that might be tolerated would be quite small whereas in a building with some type of metal cladding a much larger movement might be acceptable. Where pre-cast cement or cement and asbestos units are used as cladding, the permissible amount of movement should be related to the bending properties of the material. Practical considerations might indicate that for some materials the permissible movement could range from 1/100th to 1/200th of the frame height. From Tables I and II it is apparent that many of the designed frames have lateral movements in excess of 1/100th of the height.

The calculated lateral movement might also be considered as a measure of the limberness of the frame. Where a lateral deformation of the order of 1/100th of the frame height may be satisfactory for the wall material the frame may still be too limber to be acceptable to the user of the building.

The whole question of permissible lateral movement is rather complex and, as mentioned earlier, there is no guidance available from the existing Canadian or United States specifications.

Conclusions

(1) This study has demonstrated that the analysis of a building frame with semi-rigid connections may be readily extended to include an exact calculation (within the limitations of the usual design assumptions) of lateral movements and of moments on connections where test data has established moment-rotation curves for these connections. However, there

* — approximate

is a need for the accumulation of additional test data for different sizes and types of connections.

(2) In Table II, it may be seen that for some of the frames where the lateral movements are large the connection deformation has been significant. In general, this indicates that the connection has reached its useful limit. The movement of the frame in these cases cannot be appreciably improved by stiffening the columns unless the connections are also stiffened. If the columns were stiffened without changing the connection, the dead and live load connection moments would be increased and the rotation of the connection under lateral forces would be greater.

(3) From Table II and Fig. 2, 3, and 4, where the building frame must resist a considerable proportion of the wind force, it would appear that web connections should not be used for the main column connections on single-storey buildings 20 feet or more in height and less than three bays wide.

(4) The results of this study may have some significance in the consideration of plastic design methods. The elastic design method applied to both rigid and semi-rigid frames has in general resulted in columns that are too flexible. If a plastic design or a limit design method results in a more flexible structure then it is apparent that a plastic analysis has little practical application for these single-storey frames.

(5) For buildings one, two or three bays wide, if the column design is based only on design specifications, the lateral movement of the buildings under wind load would in many cases be quite large. For the three bay structures (four columns resisting the wind) with heights of 25 feet, the lateral movements vary from 1/50th to 1/90th of the frame height. This ratio of movement to height is larger for the one and two bay structures. Within the combinations studied, if the lateral movement is limited to 1/100th of the height it may be stated that lateral movement would be a design criterion for the following rigid frames:

(a) all the 25-feet high structures

(b) the 20-feet high structures with 20-feet and 28-feet girder spans.

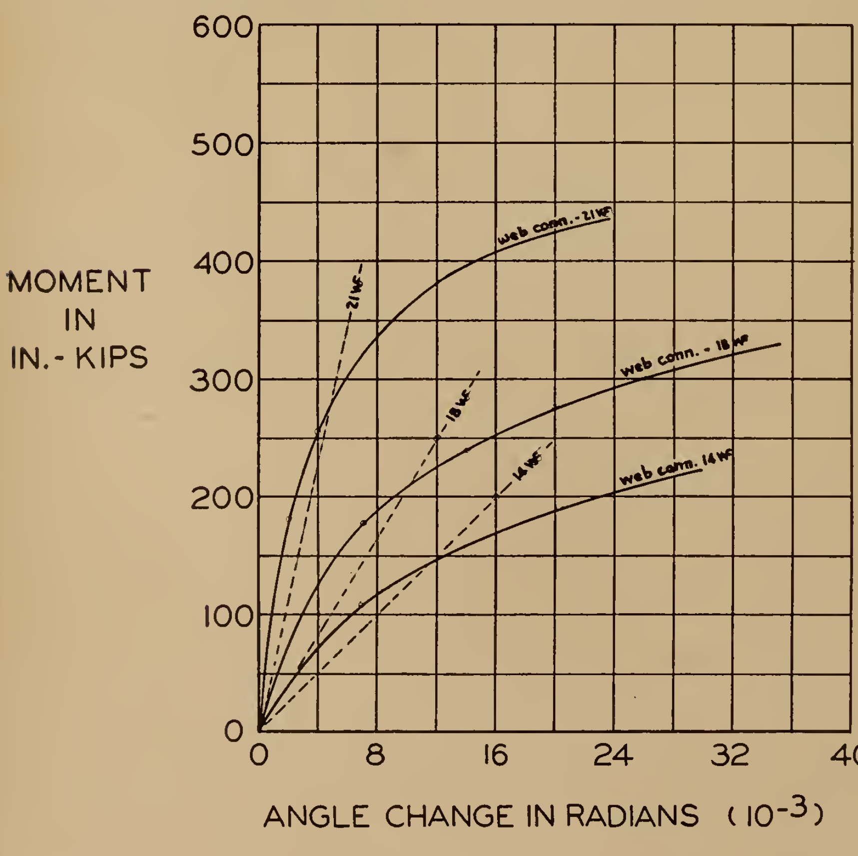
(c) the 15-feet high structures with 20-feet girder spans; and for the following semi-rigid frames:

(d) all the 25-feet high structures

(e) all the 15- and 20-feet high structures except the three bay 36-feet girder span.

If limited to 1/200th of the height, lateral movement would be a design criterion for every building designed in this study.

Fig. 5. Moment-rotation characteristics for web connections.



APPENDIX A

Figure 5 gives the moment-rotation characteristics (M-o curves) for web connections for the three beam sizes used in this analysis and Fig. 6 gives the corresponding top and bottom flange angle connections characteristics.

The curve for the 14 WF web connection was taken from Hechtman and Johnston[3] test No. 3 which used two 6″ x 4″ x ⅜″ x 8½″ angles on a 12 WF beam with ¾ rivets and with the 4″ leg on the column flange. Experimental data and a stress consideration shows that the width of the leg on the beam web is not an appreciable factor in the rotation properties. The bending of the leg attached to the column and the deformation of the rivets in that leg are the principal factors in the rotation and these would not be expected to vary significantly with the standard 4″ x 3½″ x ⅜″ angle. The corresponding curve from Rathbun[4] specimen No. 4, using two 4″ x 4½″ x ⅜″ x 9″ angles on a 12″ I with ⅞″ rivets showed good conformity.

The curve for the 18 WF web connection was taken from Hechtman and Johnston[3] test No. 8 which used two 4″ x 4″ x ⅜″ x 1½″ angle on an 18 WF with ¾ rivets.

The curve for the 21 WF web connection was taken from Rathbun[4] specimen No. 6 using two 4″ x 3½″ x ⅜″ x 15″ angles on an 18 I with ⅞ rivets. The number of rivets and the rivet spacing was identical to the A.I.S.C. standard for a 21 WF. Because of the use of ⅞ rivets and because the curve appeared somewhat out of line with the 14 WF and 18 WF curves, it was decided for the purposes of this study to modify Rathbun's values. Thus the ordinates of the curve for the 21 WF in Fig. 5 represent 80 per cent of the corresponding values reported by Rathbun.

The curve for the 14 WF top and bottom flange angle connections

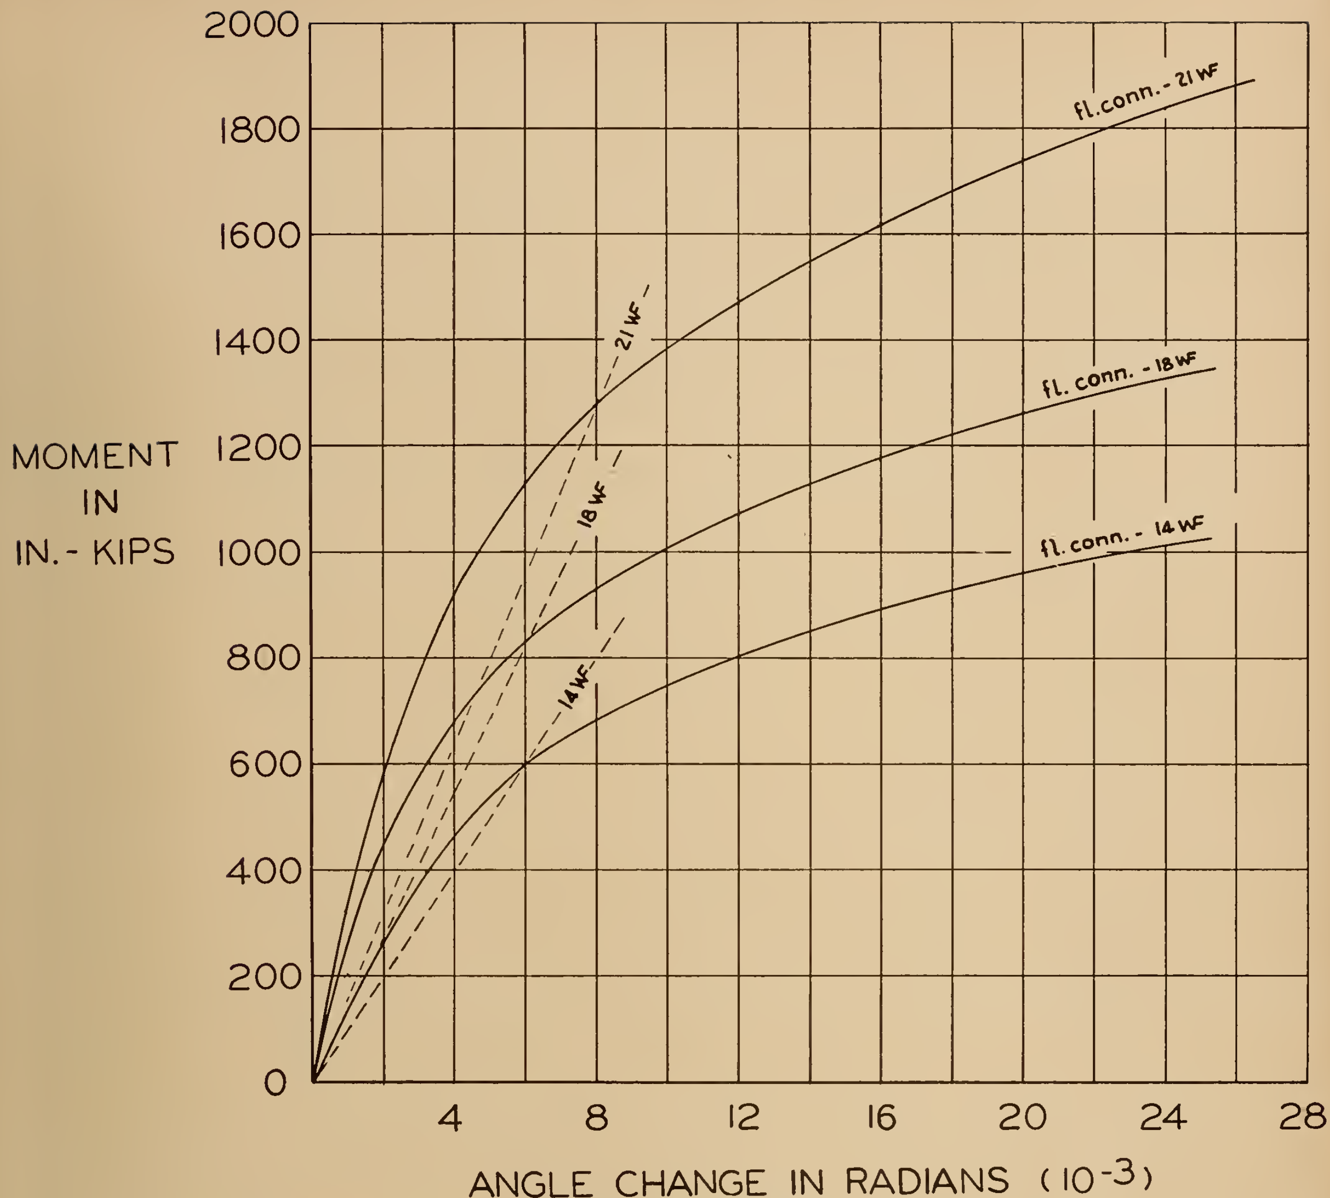


Fig. 6. Moment-rotation characteristics for flange connections.

was taken from Hechtman and Johnston[3] test No. 20 which used a 6" x 4" x ⅝" x 12" top angle with ¾ rivets on a 14 WF and with the 4" leg on the column.

The curve for the 18 WF top and bottom flange angle connections was taken from Hechtman and Johnston[3] test No. 9 which also used a 6" x 4" x ⅝" x 12" top angle with ¾ rivets on an 18 WF and with the 4" leg on the column.

The curve for the 21 WF top and bottom flange angle connections was taken from Hechtman and Johnston[3] test No. 25 which used a 6" x 4" x ¾" x 14" top angle with ⅞ rivets on a 21 WF and with the 4" leg on the column. Because of the use of ⅞ rivets and the ¾" angle thickness, it was decided to modify the curve in a similar way to that of the 21 WF web connection; the ordinates being 80 per cent of the reported values.

A straight line approximation for the working range of each curve has been shown in Fig. 5 and 6. The use of these lines simplified the moment distribution while the curves themselves were used for the deflection calculations. The modifications made to the 21 WF connection characteristics (M-o curves) do not appreciably affect the results.

Application of Welded Design to Hydraulic Turbine and Valve Manufacture

J. G. Warnock, *Head of Hydraulic Department,*
English Electric Company of Canada Limited

Read at the 70th Annual General and Professional Meeting of The Engineering Institute of Canada, Montreal, May 1956

The design and manufacture of hydraulic turbine and valve equipment, in common with practically every branch of mechanical engineering, has benefited considerably from the substantial advances made during the past thirty years in the techniques of electrically welding steel plate.

We have now reached the stage where some hydraulic turbine designs may incorporate up to 80 to 85 per cent of their total weight in the form of welded steel plate components, whereas in the early 1930's a comparable figure of 50 to 60 per cent would be considered relatively high. In the case of other associated hydraulic equipment, the percentage of steel plate components may be even higher, and all-welded large hydraulic valves are certainly a feasible proposition.

Application of Welded Design to Turbine Construction

There has been, however, in the water turbine field, fairly wide variation in the extent to which the various manufacturers have adopted this modern medium of construction. It is interesting therefore to review the factors influencing decisions whether to adopt fabricated construction in preference to iron and steel castings.

The principal reasons that must be taken into consideration by the designer may conveniently be summarized as follows.

(1) To overcome persistent difficulties in obtaining sound material and accurate form in castings.

(2) To improve structural design.

(3) To reduce the net weight of components.

(4) To reduce material and production costs.

(5) To provide a convenient means of manufacturing large, slender components, such as scroll cases, draught tubes, pit liners, etc.

(6) To provide corrosion and erosion resisting surfaces locally within large components.

(7) To improve surface finish within water passages.

(8) To extend manufacturing by foundry capacities.

Of these eight factors, only the first might be termed "negative". The positive advantages of the fabricated design greatly outweigh the negative, but disappointments in the quality of steel castings have provided in many instances the incentive to make the break with cast designs. From that point onwards, however, the advantages of the welded construction have established and consolidated it entirely in its own right.

It does appear that the standard of iron and steel castings conveniently available to a manufacturer may have a profound bearing on his design. There are, for instance, Canadian manufacturers who have been fortunate in obtaining castings from foundries where a high proportion of output was hydraulic machinery, which meant an incentive to the foundries to develop reliable techniques and to maintain a high standard of product. Unit costs were kept low and the serious disadvantages of casting rejections on manufacturing programs largely avoided.

An additional factor favouring the use of castings in Canadian water turbine production and in favour, too of the successful solution of foundry production problems, has been the opportunity for concentration on low and medium head developments involving a large number of units of repetitive design.

On the other hand, our own experience until 1952, in common with several other European and North American water turbine manufacturers, has been a scarcity of both steel and iron foundries specializing in water turbine and other hydraulic equipment castings; and also, of developments involving more than, say, three or four units over which pattern costs had to be divided. Gradually since the early 1930's, welded steel plate construction has supplanted more and more of the components which were originally cast. Now, even although thoroughly competent steel foundries may be available and multi-unit developments are being handled, the author's company finds little or no incentive to revert to cast designs.

The diagrammatic cross sections in Fig. 1 show the trend which has brought the reaction turbine, for instance, to its present state of over 80 per cent of welded design.

There has been a very wide and almost universal application of welded steel plate fabrication to three main components of water turbines which are produced from large conical and cylindrical forms, namely, scroll cases, draught tubes, and pit liners. The use of this method of construction for scroll cases and draught tubes was merely an extension of rivetted steel plate practice and began practically simultaneously with all manufacturers in the 1920's. The stage of final acceptance of all-welded joints over part-rivetted construction has, however, varied considerably. Now, with the better quality plate, electrodes, and weld-skills available, and with the application, where necessary, of radiographic control and even local low-temperature stress relief, field welded radial (and on occasions longitudinal) joints, are widely accepted on all but the heaviest steel plate casings.

The war years introduced for our company, and others, additional special problems in the supply of high quality steel castings; and this, no doubt, contributed to the impetus given to the development of fabricated designs which, by 1945, were commonly applied to speed rings, base rings, lower distributor rings, and guide vanes. At this stage, 55 to 68 per cent of the total net weight of medium head turbines comprised fabricated construction.

Large fabricated speed rings, such as that for a 35,000 b.h.p. Kaplan turbine, were demonstrating the advantages of smooth, rolled and formed steel plate sections for water passages throughout the turbine throat. Figure 2 shows the inner and outer head cover sections and regulating ring, all of fabricated construction, in position during the shop assembly of this Kaplan machine.

The past ten years have seen the ultimate extension of fabricated design to the complex construction of water turbine runners, and even to minor conventionally cast components, such as bearing housings, wicket gate levers, links and other sundry items.

Development of 18/8 austenitic stabilized stainless steels and of 12 to 14 per cent chromium ferritic and austenitic type of alloys has given us materials highly resistant to erosion and cavitation wear. Stainless clad steel plate in partciular is a recent development which has attained a high degree of reliability and adaptability to water turbine design. The bulk of clad plate has been produced from a process which entails coating a stainless steel slab with mild steel electrode deposit. Against this prepared surface is placed a mild steel plate, and a second coated

The paper reviews the progress of the past thirty years in the application of welded design to water turbine manufacture, with examples of the possible wide use of fabrication in almost every item of modern plant, and the advantages of this type of construction. Extensive use of electrically welded steel plate is being made in the manufacture of the main turbine and valve components for three of Canada's major hydro-electric developments — the Bersimis, Niagara - Sir Adam Beck, and St. Lawrence projects. The manufacture of the twenty-six major turbine units and eight straight-flow valves is being carried out by a Canadian company employing advanced techniques of welded design and production methods.

stainless slab is placed face to face with the first, "sandwiching" the stainless material between two mild steel layers, which are then welded along the edges to exclude air from the critical stainless surfaces. The assembled sandwich is rolled down to the required thickness and proportion of stainless cladding. The adhesive characteristics of this material even under hot forming have been found to be very satisfactory. Stainless steel and stainless clad steel plates have been extensively used in distributor facing plates. It is, however, in the construction of the higher specific speed runners in the medium and high head ranges that the most interesting applications of welded stainless alloy plates is to be found.

There has been a marked trend towards the application of higher and higher specific speeds for given head conditions. Cavitation tendencies with these higher specific speeds can be conveniently controlled by increased submergence or, within limits, by the application of stainless steel to the critical areas of the runner blading. There is a demand for the complete protection afforded by all stainless runners.

Solid stainless steel castings are, for the majority of developments, too costly. Fabricated runners, including all solid stainless steel materials, generally cost even more to produce. Some compromise has therefore been necessary, and this can best be reaized by the use of composite stainless and mild steel construction with a wide application of stainless steel clad plate.

The runner shown in Fig. 3 is for a 74,000 b.h.p. turbine operating under 392 feet, and is fabricated from cast and plate components. The runner crown, approximately 10 ft. 6 in. diameter, is cast in mild steel and partially machined prior to assembly. The runner blades are hot pressed from stainless clad mild steel plate and the skirt ring is formed from a lower band of stainless clad material with an upper rolled ring of mild steel forming the inlet to the skirt.

A fabricated runner assembly such as this requires the application of the highest welding skills and techniques. All the main junction welds of the runner vanes to the crown are carried out in a downhand position involving repeated repositioning. A strict welding sequence must be maintained to minimize distortion and the build-up of locked up stresses.

The high degree of accuracy associated with fabricated runners depends primarily on the initial forming of the runner vanes. Attaining the necessary standards of accuracy from the pressing operation shown in Figure 4 calls for the most careful control of preheating and pressing temperatures, transfer time to dies, and the pressing time. The blade being formed here has a maximum thickness of 2¼ in., and an area of 26 sq. ft. The initial shaping of the plate to approximate aerofoil section can be seen. The blades as formed require little additional grinding and a high degree of surface finish can easily be maintained.

An interesting variation of fabricated runner construction is the use of cast stainless steel blades and plates for high head reaction turbine runners in the head ranges above 800 feet. A typical runner in this category is shown in Figure 5 and is one of five 45,000 b.h.p. wheels

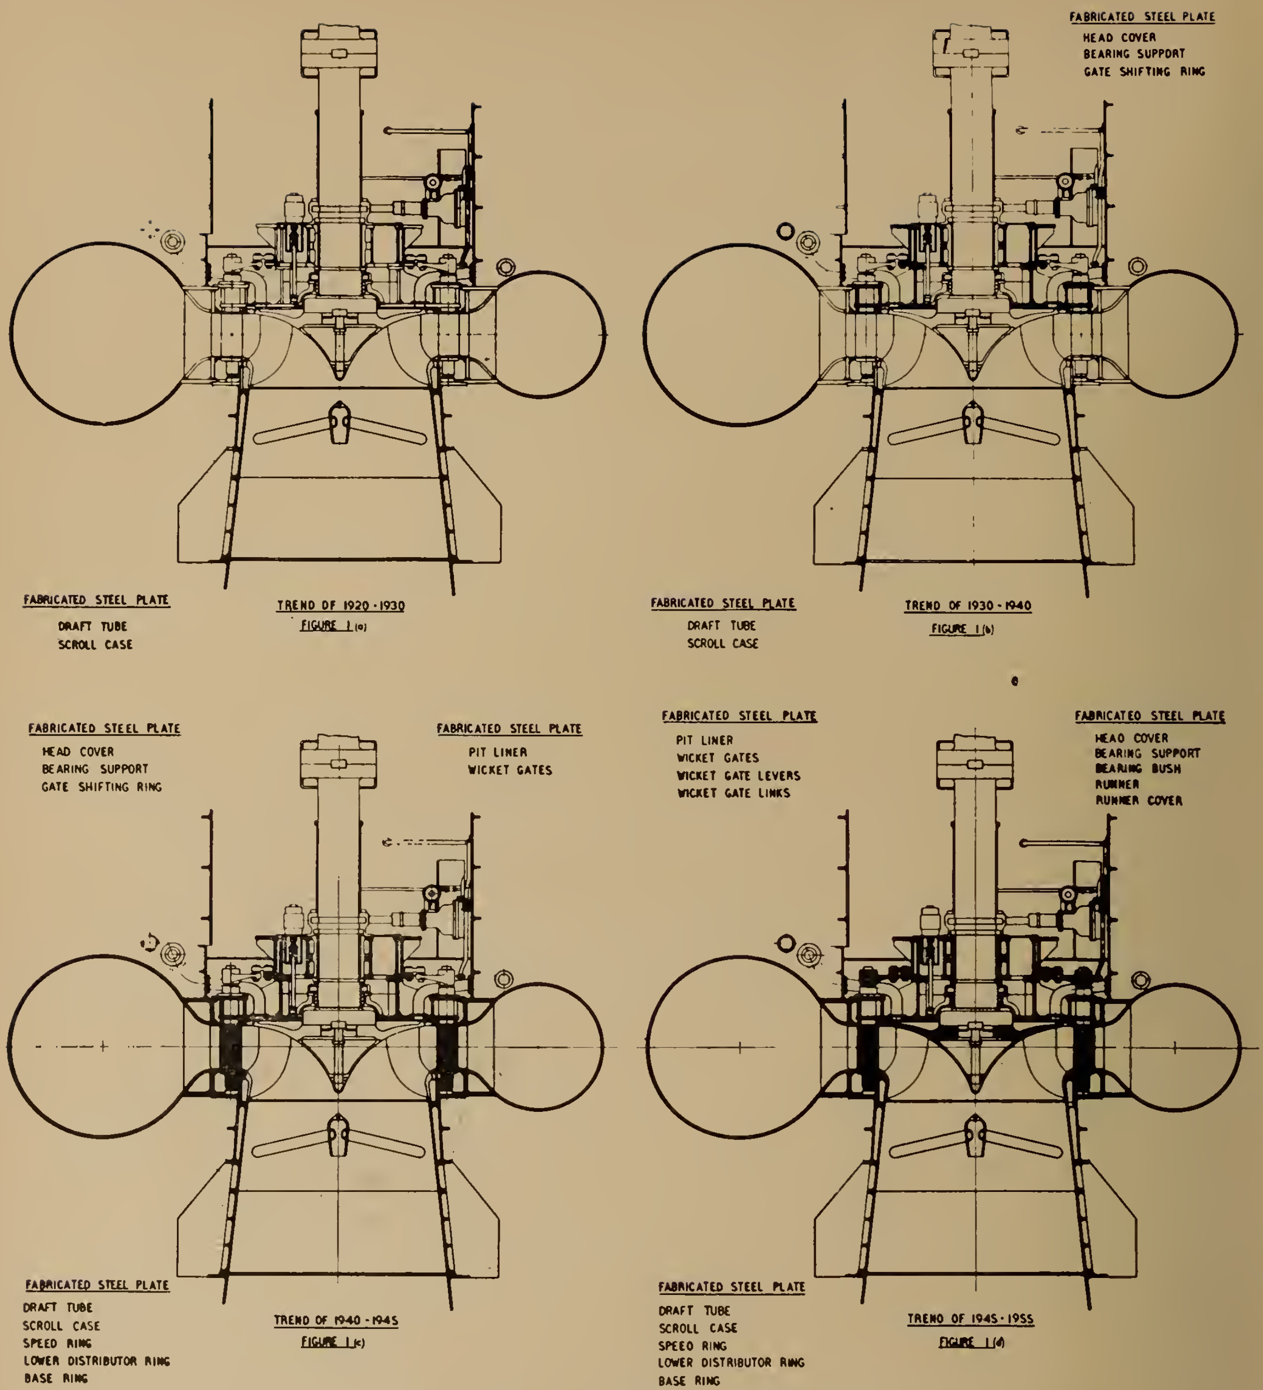

Fig. 1. Trend of application of welded design.

supplied to the North of Scotland Hydro-Electric Board.

With reaction runners of this low specific speed the problem arises of grinding blade forms within the very narrow exit passages. By casting the blades separately in stainless steel the surfaces can be easily prepared, and nose and tail forms conveniently shaped before assembly and fabrication.

The blades are then set to the correct pitch and water passage opening, and temporarily supported by the lower skirt band and seal ring. The vane edges are pre-machined for shaping prior to welding in the remainder of the water passage surfaces in the form of pressed and shaped stainless steel plates.

The heavy crown of the runner carrying the torque to the main turbine flange was cast in mild steel and securely key welded to the stainless steel water passage portion below. Alloy steel seal rings are then shrunk on to the crown and skirt rings.

With this form of construction a very high degree of accuracy throughout the water passages can be maintained.

We have, then, in the past thirty years seen the extension of plate steel fabrication from the simplest components of water turbine construction to the most complex parts such as reaction runners.

Design Considerations

The designs which have been involved, of course, do not necessarily follow conventional casting practices or shapes.

The principles of the use of rolled or knifed cylindrical or conical shapes are followed as widely as possible throughout fabricated design, but where necessary for hydraulic considerations, economic use may be made of relatively complicated forming shapes using pressing dies. The plate shapes produced by any of these methods — rolling, knifing or die forming — result in surfaces which require little or no further dressing or grinding to bring friction effects within acceptable limits.

The homogeneity and increased strength of steel plate has the greatest appeal to the designer. In comparison with cast iron, too, the additional rigidity must be taken into full consideration. By virtue of its higher elasticity modulus, a steel section has approximately 2½ times the rigidity of a cast iron member of identical cross section. It is from this factor that the substantially lower weight of fabrications for equal or improved rigidity arises.

In comparison with cast steel, improved consistency of good material and surface finish are the most important factors favouring mild steel plate fabrication. Allowable working stresses from 20 to 25 per cent higher than those adopted for steel castings may be safely used for plate of average tensile strengths. In many cases, too, there is no need with fabrications for casting considerations to take precedence over selection of sections for strength and rigidity considerations alone. Structural design may be thereby improved.

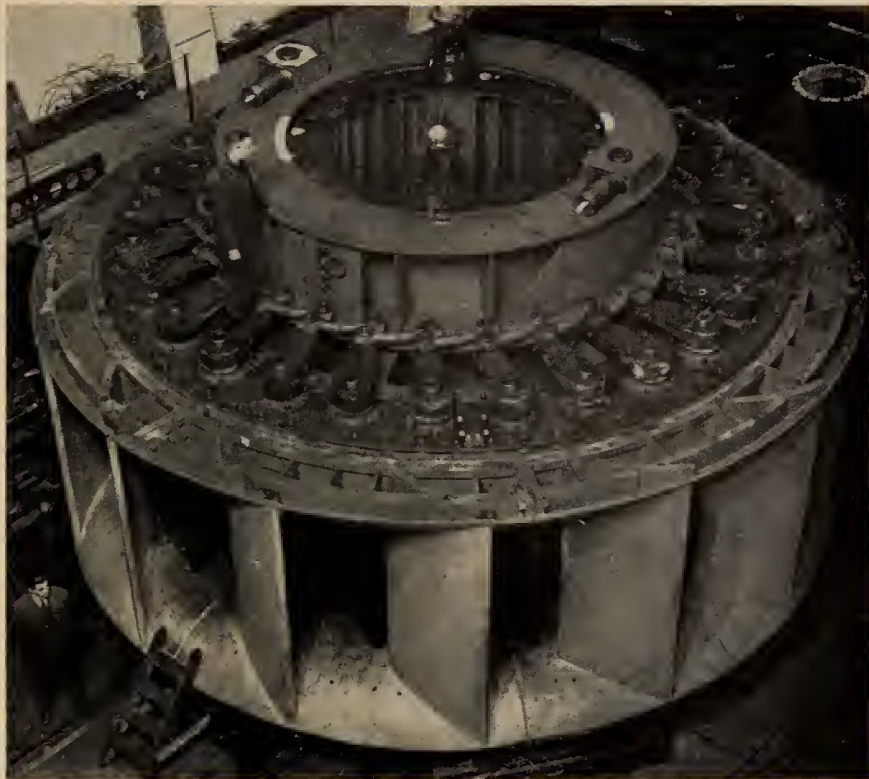

Fig. 2. Shop assembly of Kaplan turbine parts.

Accurate stress calculation in design of either cast or fabricated components of water turbines presents some difficulties, and this factor has contributed, no doubt, to the adoption of relatively low working stresses and high factors of safety.

Fig. 3. Fabricated runner for 74,000 b.h.p. medium head Francis unit.

Stress Analysis by Model Testing

The author's company has found during recent years that very useful information can be derived from the stress analysis, by strain gauge methods, of precisely scaled models of welded steel plate structures. Strain gauge testing of full size components, either in operation or on hydrostatic pressure test, has in the past provided useful stress data, but too often difficulties and doubts arise from the great care which must be applied to the placing of strain gauges on the stressed component. This work is better suited, we feel, to true laboratory conditions; and by doing this with scale models of approximately one-sixth full size, we believe that we have established a thoroughly reliable means of obtaining stress and deflection data. An additional advantage, of course, is that a far wider variation of designs can be tested before coming to a final conclusion and before manufacture begins.

The structural models used in our strain gauge analysis are true to scale in all general dimensions and have plate thicknesses correct to within 7 to 10 per cent. The selection of model plate thickness is made to the thinner, closest available standard size and thus will result in test results higher than actual values in the prototype.

The limit to the scale of the model is to a large extent determined by the smallest size of weld that can be produced to the correct form. It will be immediately obvious that it is not possible, for instance, to make welds smaller than 1/16 in., giving for general structural minimum sized welds of ¼ in. to ⅜ in., a minimum scale factor of 1 to 6. With extremely large and heavy plate components, scale factors may be increased to 1 to 10.

The stresses induced in the model due to the external loads applied on test are equal to those on the prototype structure. The deflections on the other hand are proportional to the scale factor, that is, the prototype deflections are approximately six times those measured during model testing.

Allowance is made for the fact that the model stresses due to the weight of the model components are smaller than the equivalent stresses on the prototype. These are, again, proportional to the scale factor. In applying loads to the models, forces proportional to the square of the scale ratio must be used. The moments are proportional to the cube of the scale factor.

In order to obtain a complete picture from the test results, both deflections of the model and principal stresses along all the main sections must be determined. It is found that interpretation of the experimental results is assisted if a fairly complete calculation of the stress distribution has been previously carried out. This enables account to be taken of any boundary effects which may influence results during the tests, and to make due allowance for these in predicting prototype performance.

Fig. 4. Die pressing of fabricated runner vane.

A very considerable amount of work has already been carried out in connection with deflections and stresses in standard components such as head covers, gate shifting rings and other turbine and valve parts of conventional fabricated design. Careful investigations are made on all major new designs. One example tested was a model of the inner and outer head cover sections for the St. Lawrence power project fixed blade propeller turbines. These turbine will develop 75,000 b.h.p. under 81 foot head and have a head cover diameter of 28 ft. 5 in. The load is applied to the model as full water pressure to the whole area of the head cover and gives in this respect more exacting conditions than would in fact occur in practice. Figure 6 shows this model on test, with the deflections directly measured by clock indicators. A large number of strain gauges determine radial and tangential stresses in cover plates and stiffeners. A series of comparative tests has also been run to determine deflections and stresses on a plain flat plate with various degrees of edge support and loading. This information gave a useful supplement to accepted formulas for this type of stress calculation.

Fig. 5. Fabricated runner for 45,000 h.p. high head reaction turbine under 880 ft. head.

In addition to model tests on structures of fairly conventional design, we have applied this same technique to assist in the development of new forms of structures.

An excellent example of this is the

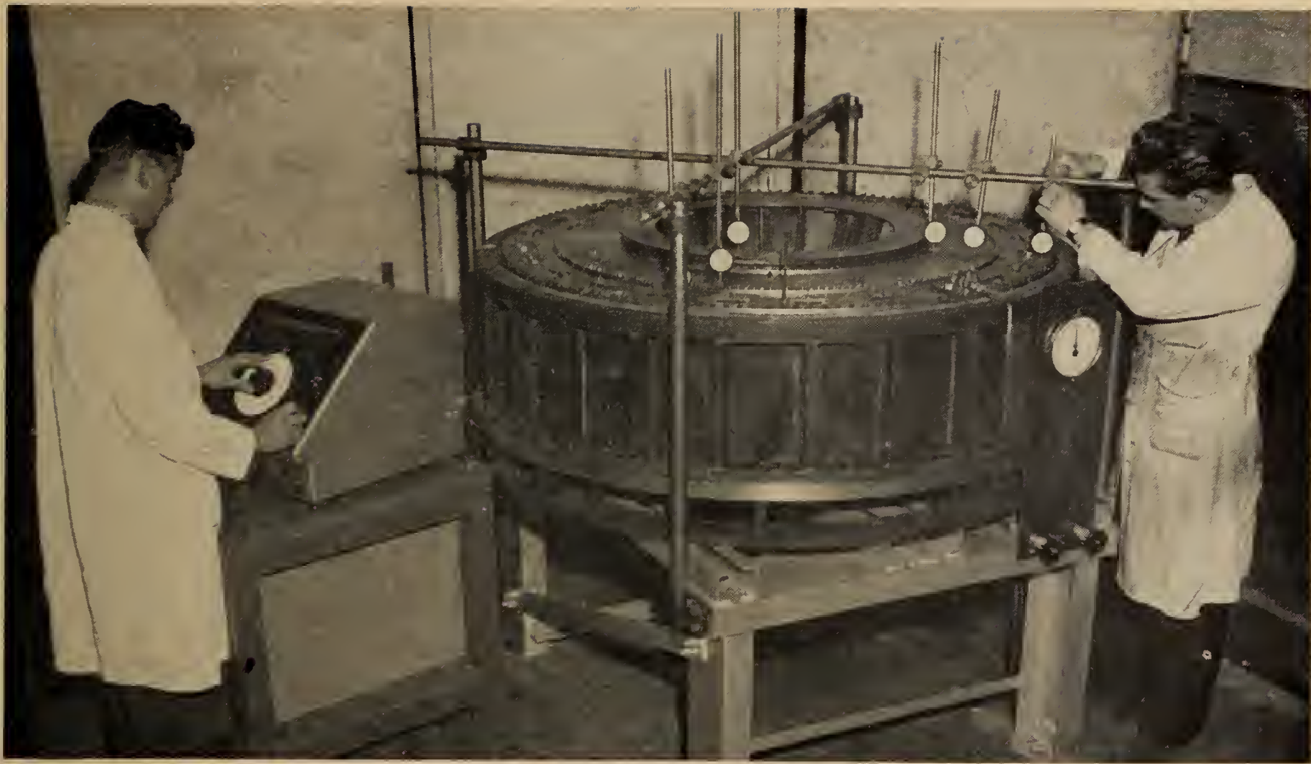

Fig. 6. Head cover model test in progress.

recent work carried out to assist the design of the speed ring diffuser of the reversible pump-turbines being supplied to the Hydro-Electric Power Commission of Ontario for the Sir Adam Beck-Niagara pumping-generating station. These units are of a special design developed specifically for this scheme, and will develop 45,000 b.h.p. under a head of 83 feet. When operating as pumps in reverse, a discharge of the order of 5,000 c.f.s. can be maintained over the full head range.

The pump-turbine units involve many unique features, both of design and construction, and extensive strain gauge testing was carried out on major components. In particular, elaborate tests were performed on the speed ring, both with and without scroll case plates in position, to determine plate stresses and to prove the method used for transmitting the heavy generator and concrete loads through to the foundations.

Fig. 7. Model testing of Niagara pump-turbine speed ring-diffuser.

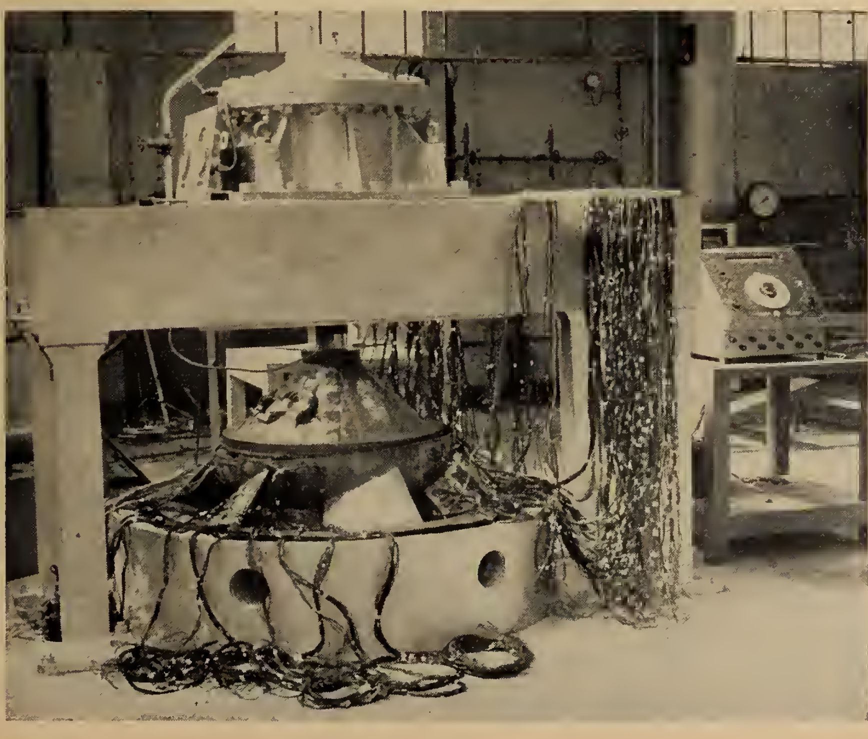

Figure 7 shows the test rig with the scale model supported on foundations of identical form to the prototype, and the loading applied by a hydraulic cylinder through a conical adapter. For this particular test, about 750 strain gauge rosettes were used, and a very thorough analysis of the stresses in stay vanes, upper and lower contour plates was obtained.

The strain gauge analysis proved the adequacy of the general design and the necessity for minor modifications and additional stiffeners in the closure section.

Manufacture of Large Welded Components

From the model we turn now to the prototype, and Fig. 8 shows the shop assembly of one of the large steel plate scroll cases for the Niagara pump-turbine development. This first casing was arranged for field rivetting, but subsequent units have been of modified design arranged for site welding. The casings are shipped in the largest possible sections to minimize the length of field-welded longitudinal joints.

In 1954, the author's company was favoured with the order for the six reversible pump-turbines for this contract, and the work on this unique plant, together with the manufacture of the four 175,000 b.h.p. turbines for the Bersimis development being constructed by the Quebec Hydro-Electric Commission and the sixteen 75,000 b.h.p. St. Lawrence power project turbines for the Hydro-Electric Power Commission of Ontario is being carried out in our Toronto plants. Each of these developments involves a relatively large number of units; four Bersimis turbines, eight straight-flow valves, six pump-turbines, and, giving the most excellent opportunities for manufacture, sixteen St. Lawrence units. The approximate proportions of fabricated construction in these designs are from 65 to 85 per cent of the total by weight.

Each development, too, involves special and interesting problems of its own. We have seen the basic development of the design of the speed ring for the Niagara pump-turbines. Fabrication of the thirty-six one-sixth sections represents the most exacting work of this type that we have yet undertaken in the water

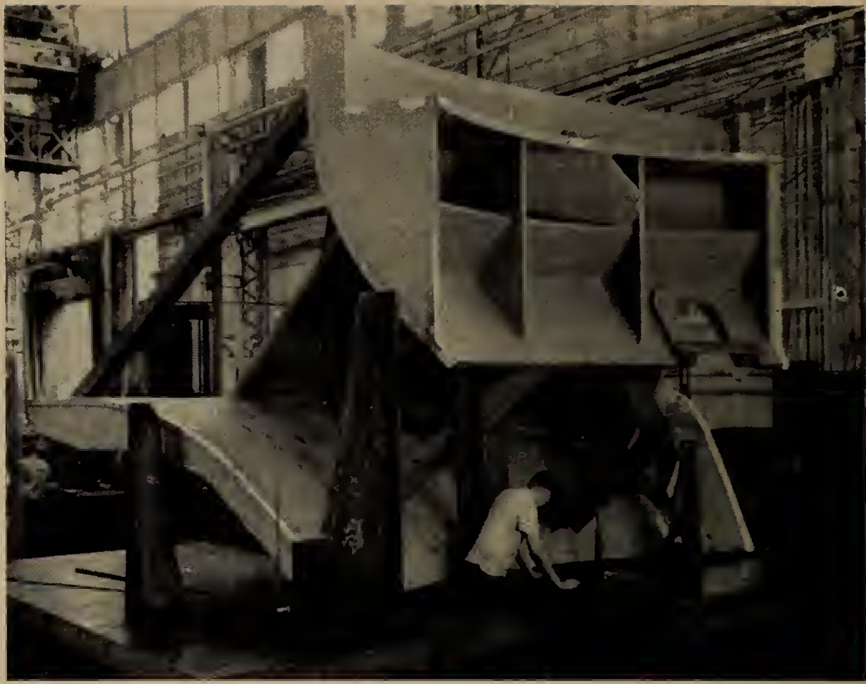

Fig. 9. Completed section of Niagara pump-turbine speed ring.

turbine field, and the ultimate accuracy of these components speaks highly for the methods used. The general form of this design involves conical water passages leading from an oblique scroll case. The physical dimensions of the major components, divided even into six segments, ruled out cast construction, and the design

Fig. 8. Shop assembly of Niagara scroll case.

was therefore developed from the outset on the basis of speed ring-diffuser, scroll case, head cover, runner envelope and discharge ring, all of welded steel plate design.

Geometrically, the design of the speed ring-diffuser section is difficult, involving intersections of spherical and annular curved surfaces with the irregular conical form of the stay vanes. The layout and assembly of each segment in turn would have involved repetition of elaborate development and measurement, as well as dangers of variations in the contours of mating sections. By preparing accurate fabrication jigs, however, the minimum amount of dimensional layout was required, and a high degree of consistency was maintained in the accuracy of sections. At the height of production of these components, four assembly jigs were in use, on which the formed plate was located and welded into upper and lower segments with their stiffeners and joint flanges. Stiffeners and joints are located in permanent slots and clamps, and the formed plate sections tacked into position.

By selection of closely approximate simple flat surfaces, the track for automatic gas-cutting torches was developed to fit the contour of the diffuser plates, which enables the slots through which the stay vanes were fed to be prepared with a high degree of accuracy and fit.

It is of interest to note that the major downward loadings are transmitted to the foundations of the unit directly through the formed plate stay vanes which project above and below the contour plates from the generator support ring to the foundation grillage. Figure 9 shows a completed segment being marked out on a layout table. The joint flange machining and drilling again employed jigging principles, which, after the first few segments had been individually proved, dispensed with this layout operation.

Figure 10 shows the completed speed ring being machined on the large 42 ft. diameter table vertical boring mill, installed by the author's company to handle work of this nature.

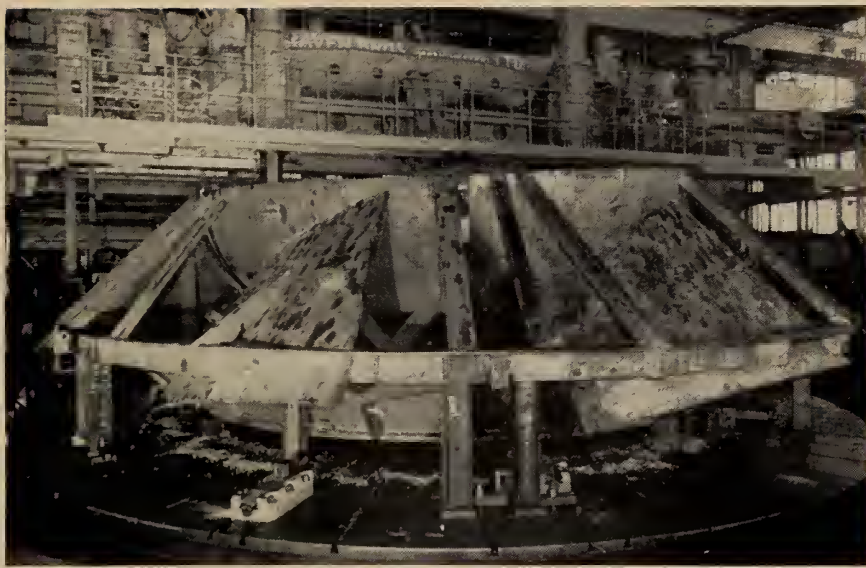

Fig. 10. Speed ring assembly during machining operations.

In the design of the runner envelope with its spherical surface in which the impeller blades rotate, another advantage of recent fabrication technique has been employed. The area of close running clearances is provided with added protection in the form of stainless clad steel plate into which the spherical form is machined. By utilizing plate sections dished in a type 405 non-air-hardening stainless cladding material forming over 40 per cent of the total thickness of the composite plate, we were able to secure outer ribbing and joint flanges to a mild steel surface, thus employing relatively simple weld procedures, and yet have a composite fabrication which could be safely thermally stress-relieved. Other grades of stainless steel with coefficients of expansion at wide variance with mild steel would have raised further difficulties.

Fig. 11. Fabricated head cover for Niagara pump-turbines.

Figure 11 shows the fabricated head cover for the Sir Adam Beck-Niagara pump-turbines. The construction of this component derives some advantage from the conical form of the water passages over the conventional "flat" head cover normally used in water turbine design. The rolled cones strutted apart with column members and radial beams give a very rigid construction. In view of its very large diameter, the head cover is fabricated in halves.

Other fabricated components include draught tube, discharge ring, pit liner and main generator thrust bearing support. The latter item incorporates heavy rolled beam sections carrying the thrust bearing loadings direct to the upper ring of the speed ring-diffuser. A more unusual application of welded plate in the design of these machines was to the main wall of the servomotor used to control the runner blades. Here we found it convenient to use a rolled steel plate of 5 in. thickness with a single heavy J-weld to replace the originally cast steel design. All six cylinders have been welded, radiographed, and stress-relieved successfully.

The extensive use and advantages of large formed steel plate sections in streamlined water passages is clearly evidenced by the Niagara pump-turbines, where the demands of the flow conditions have been adequately met.

Turning now to the design and manufacture of the eight large straight-flow valves for the Bersimis development, we find further interesting applications. These valves, weighing about 150 tons complete, have an internal bore of 93 in., and are designed for a working pressure of 540 p.s.i. The fabrication assembly of the main body is seen in Fig. 12. The outer shells are of spherical form pressed from heavy plate, section dished with a high degree of accuracy, involving the minimum of trimming and adjustment on assembly. Flanges and stiffeners are flame cut from steel plate of thicknesses up to 7 in. and fitted to the outer surfaces of the spherical shell before the heavy cast-steel shaped trunnion blocks are entered and welded into apertures flame-cut to accurate shape. The other main section of the valve body, the downstream half, was formed from conical pressings and was mounted on rotating equipment during final welding operations.

Fig. 13. Fabricated scroll case of 175,000 b.h.p. high head reaction turbine.

With the heavy plate sections involved, extensive preheating of welds was necessary. Submerged arc semi-automatic welding was used with success on more accessible circular joints, using both mechanical and hand traversing methods. By and large, however, hand welding was employed and attention concentrated on selection of optimum varieties of electrode for sound and economic welding. The main valve body welds are subjected to spot radiographic examination to maintain a high degree of quality control. As is the case with all major fabricated components, these pieces were thermally stress-relieved.

Fig. 12. Fabricated straight-flow valve body.

The closing member, or doors, for these high head valves are also fabricated from formed plate.

The application of welded construction to the manufacture of straightflow valves was concurrent with the basic development of the valve design, and hence many of the features have been entirely unaffected by transitions from cast to welded construction. In these valves, as in the pump-turbines, therefore, we have examples of basic welded design.

The manufacture of the 150,000/175,000 b.h.p. turbines for the Bersimis development during 1954 and 1955 represents the heaviest scroll case plate fabrication yet undertaken in Canada. The selection of maximum plate thickness of 2⅛ in. was made possible by use of high joint efficiencies with full radiographic examination of longitudinal welds and thermal stress-relief. Field welding of radial joints was not considered in this instance, and heavy bolted flanges were provided between the half scroll case and the two mating quarters incorporating the inlet and closing sections. Figure 13 shows the fabrication assembly proceeding.

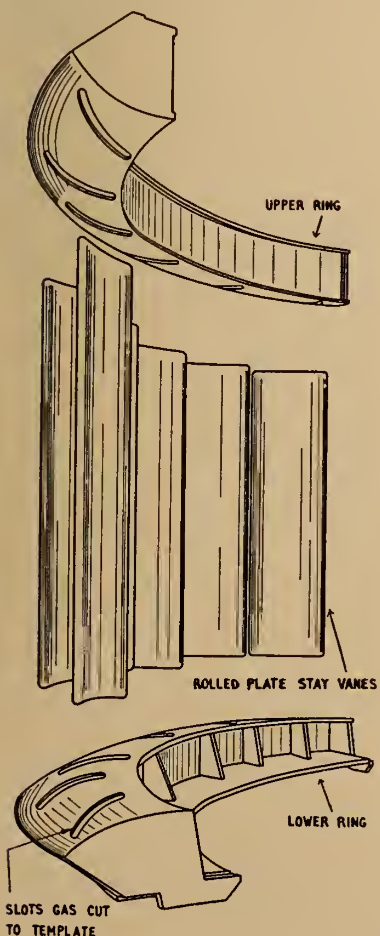
In the development of the high head reaction turbine, we have had experience of both heavy fabricated and cast steel scroll cases. From this experience, preference for the fabricated design is now well and firmly established.

Other major components which were fabricated from steel plate in accordance with our established practices were the head covers and gate operating rings for the Bersimis machines. In the case of the manufacture of these components, the advantages of batch production of weldments became apparent.

The manufacture of the sixteen St. Lawrence power project turbines has given subsequently a most excellent opportunity for concentration on the techniques of repetitive production. Sixty-four speed ring sections, thirty-two discharge ring halves, sixty-four outer head covers, three hundred and eighty-four guide vanes, all call for careful consideration of jig assembly fabrication procedures.

Taking, for instance, the speed ring section, the isometric diagrammatic view in Fig. 14 shows the three major sections which must be handled for sixty-four sub-assemblies. The upper and lower rings are fabricated from formed contour

Fig. 14. Isometric view of speed ring components.



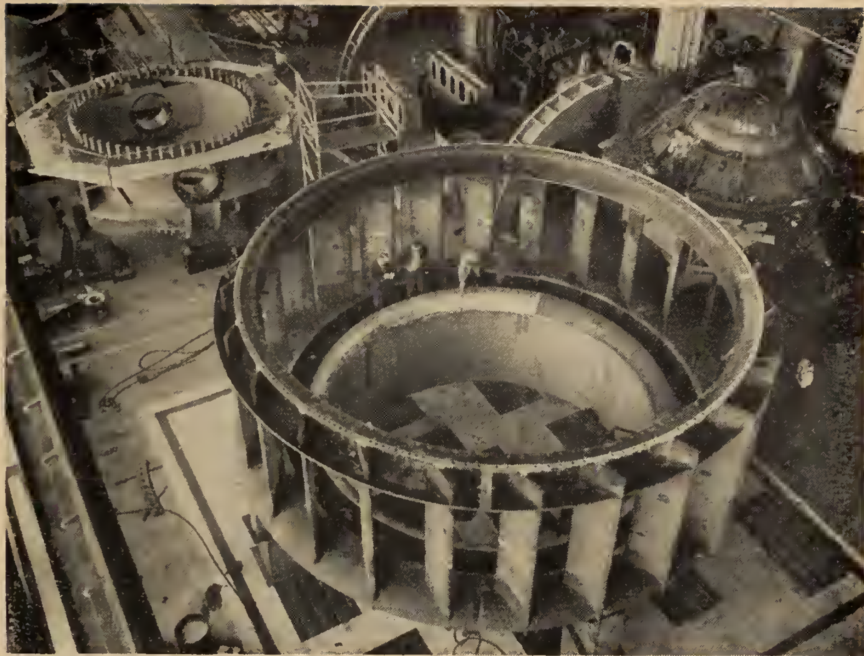


Fig. 15. Shop assembly of large fabricated components for St. Lawrence power project.

plates, ribs, and stiffeners in assembly jigs and completely welded before gas-cutting of the stay vane slots to metal templates. The rings are finally jig assembled with the stay vanes, and the speed ring quadrant fully welded.

Figure 15 shows the shop assembly of the two major embedded part components, the speed ring and discharge ring.

In the case of the St. Lawrence turbines, the size factor has weighed heavily in favour of the selection of fabricated construction. It is of interest to note that the predominance of welded components in these very large fixed-blade propeller machines is also apparent in recent manufacture in the U.S.A. of particularly large Kaplan turbines for multi-unit installations under similar head conditions and power station construction. There is little doubt that the adaptability of welded design has assisted in the extension of the manufacturing limits for hydraulic equipment.

Conclusion

For the future we can certainly predict an extension of the use of welded steel plate construction in the manufacture of water turbines and associated equipment. The author's company has already found from past experience that its merits are such that every endeavour should be made,

(1) to perfect applications to runner fabrication of all types, including perhaps impulse bucket wheels and components of Kaplan runners;

(2) to provide manufacturing facilities with heavy plate forming and welding capacity capable of handling sections of the largest reaction turbine components up to the limit of present day applications at about 1,500 foot head, and to the maximum diameters yet considered for low head ranges;

(3) to improve field welding techniques to take in heavier plate thicknesses.

In the Canadian water turbine field we have reviewed several important projects where fabricated design is applied to the fullest possible extent. It has been noted that this represents a break with Canadian tradition. There does not, however, appear to be any significant advance in the development, year by year, of the number, capacity or skills of steel foundries capable of handling major work of this type. It is likely, therefore, that in this country there will be an increase in the trend in the industry as a whole towards a much wider and more general application of fabricated design and construction.

In conclusion, I wish to record appreciation of the assistance, in preparing this paper, afforded by my colleagues in the English Electric Company Limited and our associated Canadian company, John Inglis Company Limited, where a major proportion of the fabrication work described was carried out.

Analysis of a Magnetic Control Circuit

C. H. R. Campling, M.E.I.C.

Department of Electrical Engineering, Queen's University

This paper presents an analysis of a control circuit which is related to the half-cyle-response magnetic amplifier introduced by Ramey in 1951. The analysis is presented in non-dimensional form, and the end results are curves of firing interval and normalized load current as functions of control circuit resistance. A distinguishing feature of the analysis is the combination of analytical and graphical methods.

THE basic half-wave magnetic amplifier introduced in 1951 by Ramey[1] is shown in Fig. 1(*A*). In this circuit the voltages e_{ac} and e_{ac}' are both derived from the same source and are related by the turns ratio of a transformer which is not shown in the figure. The same ratio exists between the turns of the reactor windings. In Fig. 1(*B*) there is shown a simplified version of this circuit in which e_{ac}' does not appear since it is the same as e_{ac}. The transformer has been eliminated, and the turns ratio of the reactor windings is unity. There is now of course no electrical isolation between the control circuit and the supply, but the principle of the circuit as a whole is unchanged.

The circuit of Fig. 1(*B*) can be rearranged and drawn as shown in Fig. 2(*A*). The control voltage e_c is assumed to be a half-wave rectified sinusoid. It is apparent that the effect of e_c can be obtained by inserting a variable resistor at these terminals. The resulting circuit is that shown in Fig. 2(*B*) with the additional modification that the core windings have been replaced by a single winding. No essential difference exists however since the turns ratio of the two windings in Fig. 2(*A*) is unity. The circuit of Fig. 2(*B*) has been discussed in qualitative terms by Attura[2].

The purpose of this paper is to present a complete analysis of the circuit of Fig. 2(*B*). The circuit has been referred to as an amplifier, but it may be more correct and more satisfying to call it simply a control circuit. The analysis presented here is quantitative (subject to the idealizing assumptions) and is carried to completion with a combination of algebraic and graphical methods. The results are presented in the form of normalized curves.

Analysis

Assumptions—It is common practice in the analysis and design of magnetic amplifiers and dynamic magnetic circuits in general to make certain idealizing assumptions regarding the core material. These assumptions may take various forms, but here it will be assumed that the core is of rectangular-loop material, that the saturation flux density and the remanent flux density are the same and that the winding on the core has zero inductance when the core is saturated. The rectifiers will be assumed to have infinite resistance in the reverse direction and zero resistance in the forward direction. The winding on the core will also be assumed to have negligible resistance. The assumptions regarding winding resistance and rectifier resistance are realistic to the extent that these effects can be included if necessary in the values assigned to the resistors R_C and R_L. It will also be assumed that the supply voltage e_{ac} is sinusoidal and of amplitude just sufficient to cause the core to cycle between positive and negative saturation when each of the resistors R_C and R_L is zero. This voltage will be designated as $-E_m \sin \omega t$. The sides of the dynamic hysteresis loop will be assumed to be vertical, and consequently the coil inductance is assumed to be infinite when a vertical side of the loop is traversed. The width of the loop can be taken as that corresponding to the frequency of the supply.

Equivalent Circuit

As a result of the assumptions stated the rectifiers may be treated as the equivalent of a single-pole double-throw switch which operates each half-cycle of the supply voltage at the instant when this voltage passes through zero. The equivalent circuit is shown in Fig. 3. The symbols shown in Fig. 3 are those which will be used in the analysis.

General

If the resistors R_C and R_L are not alike and if R_C is greater than R_L the core will traverse during each cycle of the supply voltage an asymmetrical hysteresis loop such as that shown in Fig. 4. During the so-called reset half-cycle the switch (Fig. 3) is thrown to position "*a*" and the current through the control resistor is determined for the most part by the hysteresis loop and is equal to I_c. At the conclusion of this half-cycle the flux in the core has been set to some value below the positive saturation level by an amount designated as ϕ_c. During the following or gating half-cycle the switch is thrown to position "*b*" and the current through the load resistor R_L is limited to the value I_c until the flux in the core reaches the positive saturation value. At this time the core is said to fire. The winding inductance becomes zero and the current drawn from the supply is limited only by the resistor R_L. It continues at a value determined by e_{ac} and R_L until e_{ac} is again zero and thereafter the same cycle is repeated. Any change in R_C causes a change in the flux excursion ϕ_c during the reset half-cycle which in turn will affect the time at which firing occurs in the gating half-cycle. If R_C is made very large, say infinite, no resetting occurs and the core remains saturated always so that maximum load power is obtained.

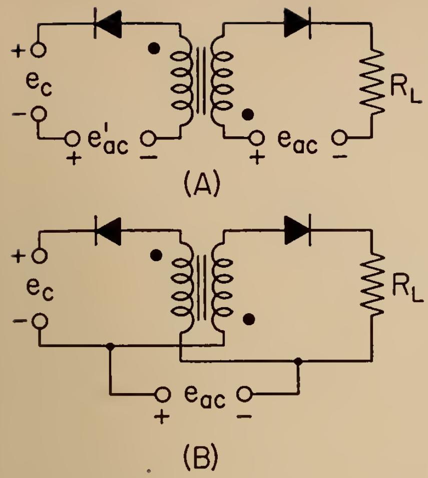

Fig. 1. (A) Half-wave Ramey amplifier. (B) Amplifier modified for unity turns ratio.

On the other hand there will be no firing in the gating half-cycle if $R_C = R_L$, and this is the condition for minimum output. The core in this case will traverse only a rectangular hysteresis loop just as it does if $R_C = R_L = 0$.

Reset Half-Cycle

A more detailed examination of the circuit will now be presented. If t_0 is taken as the time when the switch (Fig. 3) is thrown to position "*a*" then the waveforms of supply voltage, control voltage and coil voltage are as shown in Fig. 5 for the reset half-cycle. The points on the hysteresis loop corresponding to t_0, t_1, t_2 and t_3 are shown in Fig. 4. Between t_0 and t_1 the whole supply voltage appears across the control resistor since the coil inductance is zero. At $t = t_1$ however the coil inductance becomes infinite, and the current in it remains constant at the value I_c during the interval t_1t_2 while the voltage across the coil increases and then decreases in the form of a truncated sinusoid. In the same interval the core flux changes by an amount ϕ_c. At t_2 the coil inductance is again zero and the current is determined only by e_{ac} and R_C between t_2 and t_3.

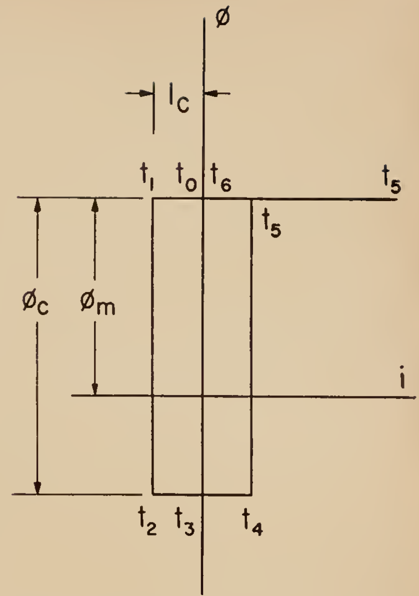

Fig. 4. Asymmetrical hysteresis loop for the magnetic core.

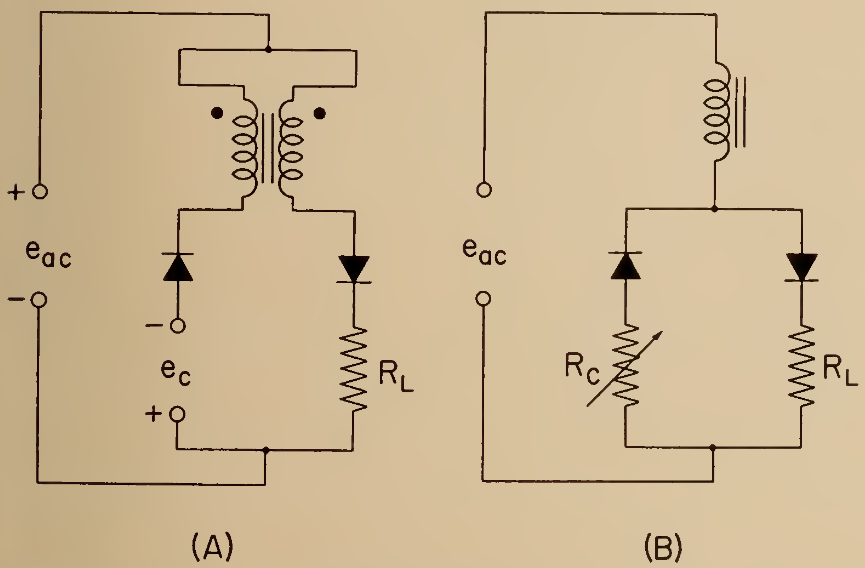

Fig. 2. (A) Alternative arrangement of Ramey circuit. (B) Modified circuit with resistance control.

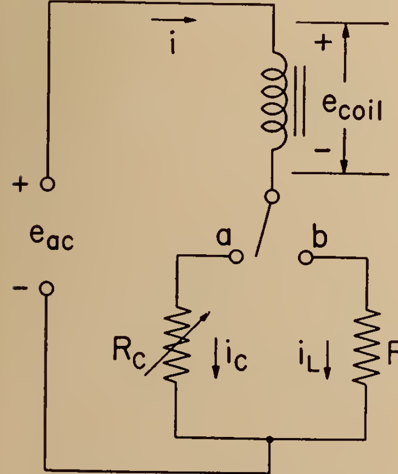

Fig. 3. Equivalent circuit for resistance control.

The following quantitative results apply. The time t_1 may be determined from:

$$t_1 = (1/\omega)\sin^{-1}(I_cR_C/E_m) \quad (1)$$

Between t_1 and t_2 the coil voltage is given by

$$e_{coil} = -E_m \sin \omega t + I_cR_C \quad (2)$$

and the flux change ϕ_c is given accordingly by

$$\phi_c = \frac{1}{N}\int_{t_1}^{t_2} e_{coil}dt$$

$$= (E_m/N\omega)(\cos \omega t_2 - \cos \omega t_1) + (I_cR_C/N)(t_2 - t_1) \quad (3)$$

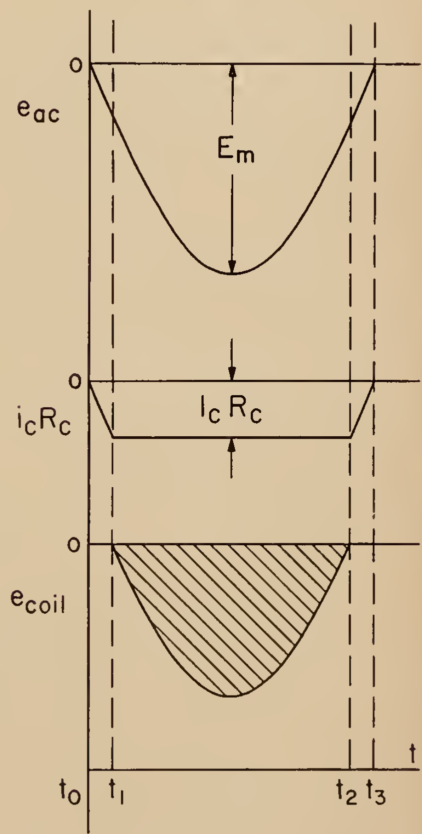

Fig. 5. Circuit waveforms for the reset half-cycle.

Between t_2 and t_3 the coil inductance is again zero and i_C is equal to e_{ac}/R_C.

Gating Half-Cycle

The waveforms for this half-cycle are shown in Fig. 6. At t_3 the switch (Fig. 3) is thrown to position "*b*". Between t_3 and t_4 the coil inductance is zero and no voltage appears across it. At t_4 however, just as at t_1, the coil inductance becomes infinite, the coil current is fixed at the value I_c, and the flux begins to change toward the positive saturation value. The time t_4 is given by:

$$t_4 = (1/\omega)\sin^{-1}(-I_cR_L/E_m) \quad (4)$$

The time interval t_3t_4 will be shorter than t_0t_1 so long as it is assumed that $R_L < R_C$. Likewise the drop I_cR_L will be smaller than I_cR_C.

During the interval t_4t_5 the core flux changes until it reaches the saturation value ϕ_m. It reaches this value when the area under the e_{coil} — waveform in Fig. 6 is equal to the area under the e_{coil} — wave form in Fig. 5. These areas are cross hatched. Between t_4 and t_5 the coil voltage is given by:

$$e_{coil} = -E_m\sin\omega t - I_cR_L \quad (5)$$

The flux change ϕ_c, which is of course the same as that which occurs in the reset half-cycle except for sign, is given by:

$$-\phi_c = \frac{1}{N}\int_{t_4}^{t_5} e_{coil}dt$$

$$= -(E_m/N\omega)(\cos\omega t_4 - \cos\omega t_5) - (I_cR_L/N)(t_5 - t_4) \quad (6)$$

Normalized Solution

Normalized Equations

It is expedient to present some of the results in normalized form.

Let

$$k = R_C/(E_m/I_c) \quad (14)$$

Then:

$$\phi_c = (E_m/N\omega)\left[k(\pi - 2\sin^{-1}k) - 2\sqrt{1-k^2}\right] \quad (15)$$

It will be recognized also that:

$$E_m/N\omega = \phi_m \quad (16)$$

Hence we have:

$$\phi_c/\phi_m = k(\pi - 2\sin^{-1}k) - 2\sqrt{1-k^2} \quad (17)$$

Now for further normalization it is desirable to express the load resistance in a nondimensional form.

Let

$$k' = R_L/(E_m/I_c) \quad (18)$$

Then we have:

$$\omega t_4 = \sin^{-1}(-k') \quad (19)$$
$$= \pi + \sin^{-1}k'$$

Hence:

$$-\phi_c = (E_m/N\omega)\left[(\cos\omega t_5 + \sqrt{1-k'^2}) - k'(\omega t_5 - \pi - \sin^{-1}k')\right] \quad (20)$$

The problem here is to find t_5 when the value of ϕ_c is determined from the results of the calculation for the reset half-cycle. This problem reduces to that of solving the equation.

$$\cos\omega t_5 = k_1t_5 + k_2 \quad (7)$$

where k_1 and k_2 are constants. An accurate graphical solution is possible and will be discussed later.

At t_5 the core saturates and the whole supply voltage appears across the load resistance. Between t_5 and t_6 accordingly the coil and load current is given by

$$i_L = -(E_m/R_L)\sin\omega t \quad (8)$$

At t_6 the load current reaches zero and the cycle repeats.

Determination of ϕ_c.

It has been shown that the flux excursion during the reset half-cycle is given by

$$\phi_c = (E_m/N\omega)(\cos\omega t_2 - \cos\omega t_1) + (I_cR_C/N)(t_2 - t_1) \quad (3)$$

Also:

$$t_2 = (\pi/\omega) - t_1 \quad (9)$$

Hence:

$$\cos\omega t_2 - \cos\omega t_1 = -2\cos\omega t_1 \quad (10)$$

And therefore:

$$\phi_c = (I_cR_C/N)(\pi/\omega - 2t_1) - (2E_m/N\omega)\cos\omega t_1$$

Now:

$$t_1 = (1/\omega)\sin^{-1}(I_cR_C/E_m) \quad (1)$$

Hence:

$$\phi_c = (I_cR_C/N\omega)\left[\pi - 2\sin^{-1}(I_cR_C/E_m)\right] - (2/N\omega)\sqrt{E_m^2 - I_c^2R_C^2} \quad (12)$$

For maximum output $\phi_c = 0$ and the condition required for this output is that

$$R_C = E_m/I_c \quad (13)$$

For this value of R_C both terms in the expression for ϕ_c become zero.

And:

$$-\phi_c/\phi_m = \cos\omega t_5 - k'\omega t_5 + \sqrt{1-k'^2} + k'\sin^{-1}k' + k'\pi \quad (21$$

By combining equations (17) and (21) it is possible to obtain an equation in which the firing angle ωt_5 is given in terms of the dimensionless quantities k and k'. Thus we have:

$$\cos\omega t_5 - k'\omega t_5$$
$$= -k(\pi - 2\sin^{-1}k) + 2\sqrt{1-k^2}$$
$$- k'(\pi + \sin^{-1}k') - \sqrt{1-k'^2} \quad (22)$$

It is interesting here to note that if $k = k'$ the operation of the circuit should be symmetrical and we should have:

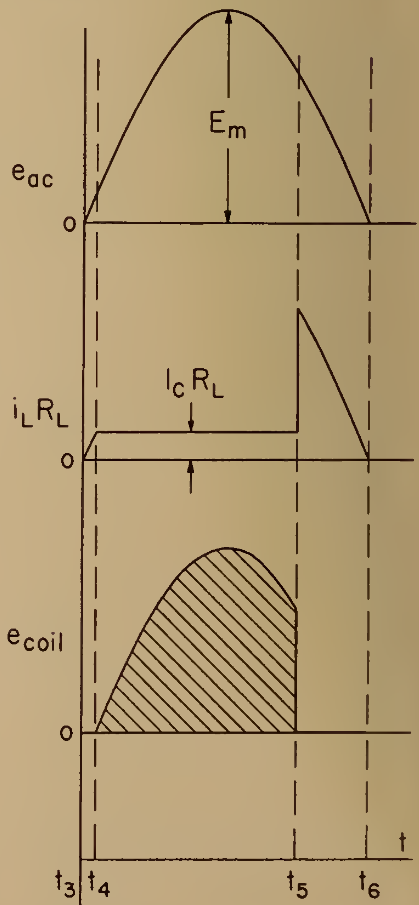
$$\omega t_5 = 2\pi - \omega t_1 = 2\pi - \sin^{-1}k \quad (23)$$

and

$$\cos\omega t_5 = \sqrt{1-k^2} \quad (24)$$

If these substitutions are made in equation

Fig. 6. Circuit waveforms for the gating half-cycle.



(22) the result is an identity as would be expected. In general however if $k = k'$ the ratio of ϕ_c to ϕ_m is given by:

$$\phi_c/\phi_m = k\pi - 2\sqrt{1 - k^2} - 2k \sin^{-1}k \quad (17)$$

This ratio is equal to two only if $k = k' = 0$, i.e. if both resistances are zero.

Determination of Firing Angle

The determination of the angle ωt_5 requires the solution of the equation

$$\cos \omega t_5 - k'\omega t_5 = f(k') + g(k) \quad (25)$$

where

$$f(k') = -k'(\pi + \sin^{-1}k') - \sqrt{1 - k'^2} \quad (26)$$

and

$$g(k) = -k(\pi - 2 \sin^{-1}k) + 2\sqrt{1 - k^2} \quad (27)$$

For any pair of values of k and k' the equation reduces to:

$$\cos \omega t_5 - k'\omega t_5 = K \quad (28)$$

where

$$K = f(k') + g(k) \quad (29)$$

and a solution may be found graphically from the intersection of the curve:

$$y = \cos \omega t_5, \quad (30)$$

and the line:

$$y = k'\omega t_5 + K \quad (31)$$

A generalization of this graphical solution may be obtained if it is recognized that for any particular R_L and k' the values of ωt_5 which correspond to various values of R_C and k may be found by drawing a set of parallel lines to intersect the cosine curve. Also for a certain k' we will have $f(k') = 0$. Let this value be designated as k'_o. Then:

$$y = k_o'\omega t_5 + g(k) \quad (32)$$

It is possible then to select a set of k's and find the y intercepts of the corresponding family of lines with slope k_o' by calculating only $g(k)$ rather than both $f(k')$ and $g(k)$.

Considcr another value of k' and call it k'_1. Also let

$$\omega t_5 = \omega t_5' - f(k_1')/k_1' \quad (33)$$

It follows that:

$$y = k_1'\omega t_5' + g(k) \quad (34)$$

Thus by shifting the y-axis by an amount equal to $f(k_1')/k_1'$ it becomes possible to plot a new set of lines having slope k_1' but for which the y-intercepts are the same on the *new* y-axis as those previously used for the lines having slope k_o'. By this process the rapid graphical determination of firing angles is made possible for all values of k and k'.

The form of the construction used is illustrated in Fig. 7. Note that the y-axis is shifted to the *right* by the amount $f(k')/k'$ because the value of $f(k')$ is itself negative. The results of this analysis are shown in the curves of Fig. 8 where the firing period, defined as $2\pi - \omega t_5$ is plotted against k, the normalized control resistance, for various values of the load resistance parameter k'.

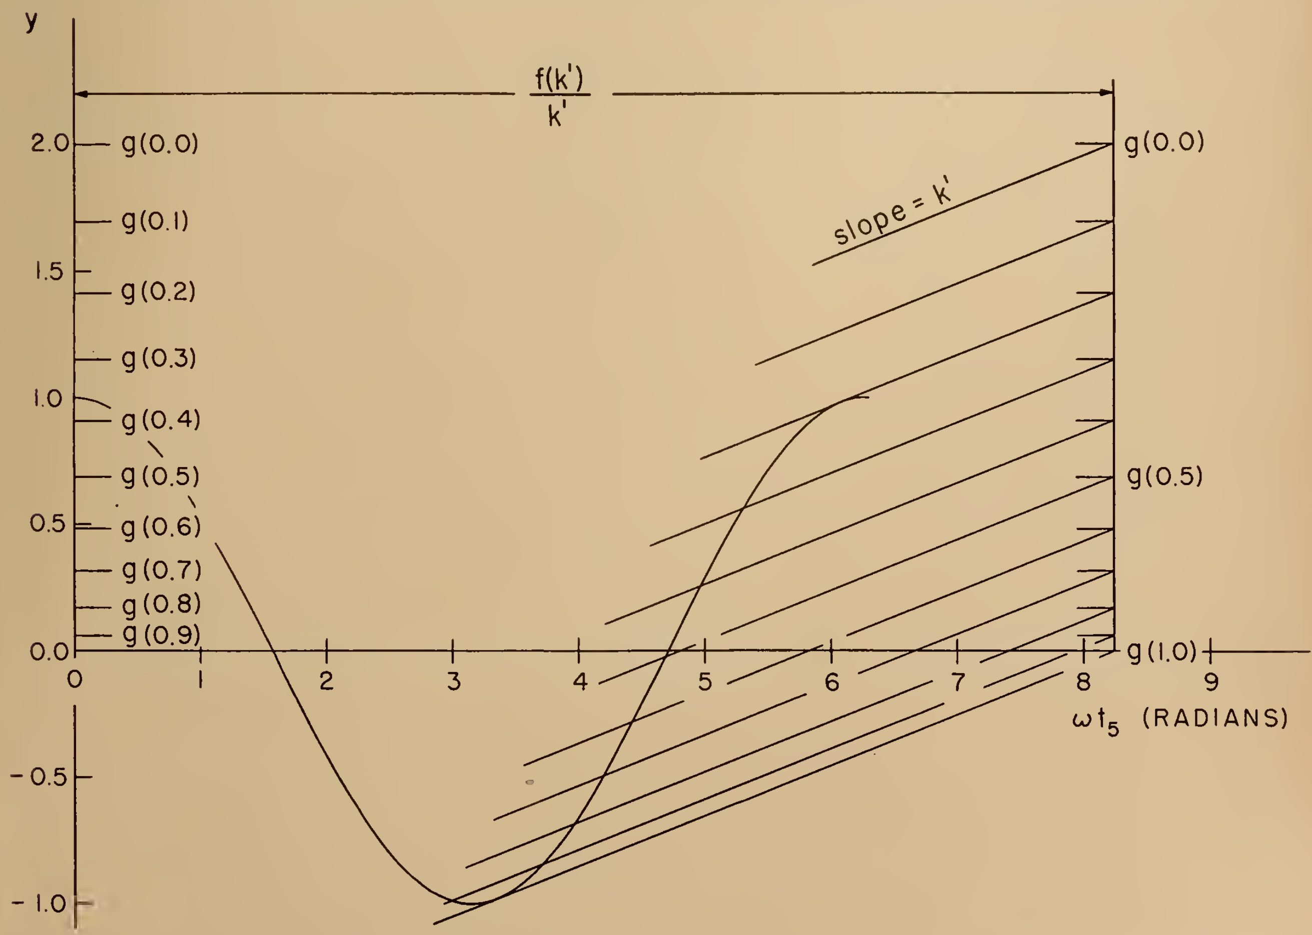
Normalized Power Output and RMS Current

The power developed in the resistor R_L is given by $I_{rms}^2 R_L$ and the rms current in the load is defined as usual by

$$I_{rms} = \sqrt{\frac{1}{2\pi}\int_{\pi}^{2\pi} i_L^2 d\omega t} \quad (35)$$

A complete expression for the square of the rms current may be found by piecewise integration. The result is shown in equation 36 (top of next page).

Fig. 7. Graphical construction for the determination of firing angle. Construction is shown for k′ = 0.2.



$$I_{rms}^2 = (1/2\pi)(E_m/R_L)^2 [(1/2 - k'^2)(\sin^{-1}k') + \pi(1 - k'^2) + \omega t_5(k'^2 - 1/2) - (k'/2)\sqrt{1 - k'^2} + (1/2)\sin\omega t_5 \cos\omega t_5] \quad (36)$$

The quotient $I_{rms}/(E_m/R_L)$ can be defined as a normalized or per-unit load current. If we call this normalized current k'' then k''^2 can be considered as a normalized load power since:

$$k''^2 = I_{rms}^2/(E_m/R_L)^2$$
$$= I_{rms}^2 R_L/(E_m^2/R_L) \quad (37)$$

The normalized current is given by (38):

$$k'' = \sqrt{(1/2\pi)[(1/2 - k'^2)(\sin^{-1}k') + \pi(1 - k'^2) + \omega t_5(k'^2 - 1/2) - (k'/2)\sqrt{1 - k'^2} + (1/2)\sin\omega t_5 \cos\omega t_5]} \quad (38)$$

Curves of the normalized current as calculated from the above expression are shown in Fig. 9. The value of ωt_5 is determined by the graphical method already described.

Interpretation of the Curves

It is helpful to relate the curves of Fig. 8 to the circuit waveforms in order to make their significance more clear and also to examine the performance of the circuit when $k > 1$ and when $k < k'$.

Let it be assumed that $k' < 1$. Then for all values of k between k' and unity the circuit behaviour follows the pattern already described. If $k > 1$ there is no reset action and the core is always saturated. Thus the curves of Figs. 8 and 9 are flat for $k > 1$. Note that the firing interval in Fig. 8 does not reach a maximum equal to π radians nor a minimum of zero and that in fact the maximum and minimum depend upon k'. This situation results from the definition of the firing interval. Its minimum and maximum values depend upon the breadth of the base of the truncated sinusoid formed by deducting $I_c R_L$ from $E_m \sin\omega t$. If the hysteresis loop is considered for this case ($k > 1$) it is found to have degenerated to a line at the level ϕ_m. The negative excursion of the coil current is now less than I_c and will reduce to zero if k becomes infinite. The positive excursion of i is equal to E_m/R_L.

When $k = k'$ the operation of the circuit is symmetrical and both the i_C and i_L waveforms are truncated sinusoids of amplitude I_c. If this state is approached by reducing k from some larger value the hysteresis loop when $k = k'$ will be a rectangle of width I_c. The positive flux excursion will be ϕ_m, but the negative flux excursion will be somewhat less. The total flux excursion will be less than $2\phi_m$ because k and k' are non-zero and because $2\phi_m$ corresponds to the volt-time area under one half-cycle of the supply voltage. If now k is made less than k' a transition process occurs. There will be first necessarily a greater flux change in the reset half-cycle, and the flux will decrease from $+\phi_m$ to some value closer to $-\phi_m$. Similarly in the succeeding gating half-cycle it will increase to a value somewhat less than $+\phi_m$. In other words the hysteresis rectangle shifts downward until its lower extremity is at the level $-\phi_m$. Because k is now less than k' the transition process is not complete until firing occurs in what has been called the reset half-cycle. Nevertheless if k' remains constant the power in R_L will remain constant and therefore the curves in Figs. 8 and 9 are flat at their lower extremities, i.e., for $0 < k < k'$.

The lower value of k'' at which the curves of Fig. 9 flatten can be determined analytically by setting $k' = k$ in equation (38). The value of ωt_5 which must be substituted in equation (38) in this case is:

$$\omega t_5 = 2\pi - \sin^{-1}k \quad (39)$$

The corresponding value for k'' is:

$$k''\Big|_{k = k'} = \sqrt{(1/2\pi)[\pi k^2 - k\sqrt{1 - k^2} + 2(1/2 - k^2)\sin^{-1}k]} \quad (40)$$

Alternative Load-Current Characteristics

Rather than plot the quantity k'' against k it is possible to plot the ratio I_{rms}/I_c. This dimensionless current ratio, which will be called α has the advantage that it does not itself depend upon k' in the same way that k'' does. In fact $k'' = k'\alpha$. The characteristics so determined give a better idea in dimensionless form of the orientation of the actual output characteristics for a specific circuit. These characteristics are shown in Fig. 10. For these curves the lower value of α at which the curves flatten is given by:

$$\alpha\Big|_{k = k'} = (1/k)\sqrt{(1/2\pi)[\pi k^2 - k\sqrt{1 - k^2} + 2(1/2 - k^2)\sin^{-1}k]} \quad (41)$$

Conclusions

An analysis has been presented of a half-cycle-response magnetic control circuit. The circuit, while simple, is a building block for many of the more complex magnetic amplifiers which have been widely discussed in the literature. The control resistor R_C may be replaced by various other circuit elements including transistors, in which case the amplifying properties become more readily apparent.

The features of the analysis include:

(1) A combination of analytical and graphical methods.

(2) A solution in dimensionless form which is extended readily to all values of the control and load parameters by the nature of the graphical method used.

(3) A recognition of the transition process which takes place when the core changes from operation in which it is saturated in one direction to operation in which it is saturated in the opposite direction. This effect is discussed for the case in which the supply voltage is just sufficient to cause operation of the core between positive and negative saturation when the resistance in series with the core winding is zero.

The Economic Position of Canadian Scientists and Engineers

John F. Haberer and F. L. W. McKim

Division of Administration, National Research Council, Ottawa

DURING the twentieth century Canadians have been steadily improving their standard of living. Originally this improvement depended almost entirely upon the export of basic raw materials and a triangular system of trade with Great Britain and the United States. However, since the Second World War, Canadian living standards have improved still further because of the very rapid development of secondary industries. As a result of this development, the present demand for scientists and engineers exceeds the supply, and interest in scientific research has never been greater. It is the purpose of this paper to discuss the professional and economic status of Canadian scientists and engineers over the last half century.

Growth of Research

It is difficult to determine accurately the amount of scientific research conducted in Canada since 1900. However, prior to World War I, it was limited and was connected mainly with primary industries and health. Government departments did some; university science faculties, overloaded with teaching responsibilities, did a little; and industry, which consisted mainly of subsidiaries of American and British firms depended chiefly upon foreign sources for new information.

World War I saw the establishment of the National Research Council, the first government agency whose objective was to promote scientific research. At first, its function consisted of granting monies for scholarships and research in the universities, in order to build up a corps of scientists and to stimulate the development of graduate schools. It wasn't until 1932 that the first of its present laboratories was opened. Growth was very slow during the depression years; by 1939 its scientific staff numbered only 79 persons. World War II saw a surge of government-sponsored research for defence purposes, and early in the war, the National Research Council was designated as the research laboratory of the Army, Navy, and Air Force. Since the war, government activity in all fields of scientific research has continued to increase, and at present, 564 scientists and engineers are employed in the laboratories of the National Research Council. The Defence Research Board and Atomic Energy of Canada Limited, two organizations that grew out of the Council's war efforts and that have since been established as separate units, employ 990 scientists and engineers. Thus in 17 years, one Canadian organization has become three separate establishments and the total staff has increased almost 20 times. Other research institutions (the universities, federal and provincial government departments and, more recently, industrial laboratories) have also shown phenomenal growth.

Organization of Research

In Canada the primary industries were the first to develop and, to meet their needs, research organizations were set up by the corresponding government departments, such as the Department of Agriculture. Secondary industries, which have come into operation more recently, are being served by federal and provincial research councils. Since many Canadian firms have parent companies in either the United States or Great Britain, with well established research institutions in the home country, Canadian industry has been slow to set up its own research organizations. As a result government support for industrial research is proportionately greater than in other industrialized countries. Federal government expenditures for research now total more than 100 million dollars annually, exclusive of the amount spent on defence development contracts.

Research work in the Canadian universities has also expanded greatly, and is supported largely by government grants from various departments. As an example, the National Research Council grants-in-aid and scholarships program has increased nearly twelve times since 1946 and now exceeds $3,500,000 per annum. An estimate of expenditures made by the Canadian Association of University Business Officers for 1954-55 shows that twenty-three universities and colleges spent a total of $7,280,000 on research projects. Over half of this amount was provided by government grants.

Until comparatively recently, industrial research activity has been the exception rather than the rule. The relatively very large pulp and paper industry, however, has organized a research association with its own laboratory. In other industries there is now a tendency for subsidary firms to establish research organizations in Canada, and an encouraging number of Canadian firms have recently built their own laboratories. Industrial research is growing rapidly, even though support by industry at the moment is still far behind that provided in other industrial countries.

The Scientific Profession

In 1911, the professional group as a whole made up approximately 4.4% of the persons actively engaged in all occupations in Canada. By 1951, this group had increased in size by more than 300% and its members constituted about 7.2% of those actively engaged in all occupations.

Figure I shows the distribution of various classes within the professional group. In 1911, approximately 6.6% of all professionals were included in the scientific and technological class. By 1941 this percentage had doubled and, by 1951, had tripled to 18.5%. In 1950, United States census data showed that more than 20% of the professional group was included in the scientific and technological class. In 1954, scientists and engineers made up about 35% of Russia's professional group.[1] The outstanding feature of the Russian scientific and engineering class is the large number of women that it includes.

A further indication of the growing importance of the scientific profession relative to other professions is shown by the number of people obtaining the doctor's degree. In 1925, the two largest Canadian universities awarded a total of 20 Ph.D.'s, 14 of which were in the scientific fields. In 1955, the number of doctor's degrees awarded to scientists by these same two universities was 126 out of 154 Ph.D.'s granted, 82% of the total and an increase of 12% in favour of the scientists in the intervening 30-year period.

Absolute numbers from census data show that there were twice as many persons included in the scientific and technological professions in 1951 as there were in 1941. The Technical Personnel Register of the Department of Labour shows that 32.344 engineers and scientists were registered in 1946, when registration was obligatory. In spite of the fact that registration is no longer compulsory, the number of scientists and engineers in the register has increased to 38,711 with 21,448 registered as professional engineers. Conservative estimates place the total number of professional engineers and scientists at between 55,000 and 60,000, with the professional engineering group numbering about 30,000. During the past few years university engineering graduates at the bachelor level have averaged about 1,300. In the fall of 1955 there were some 1,579 students registered for postgraduate work, 1,259 in pure science fields and 320 in the various fields of engineering.

Serious concern has been expressed over the years about the loss of Canadian scientists and engineers to the United States. The most recent figures available show that from 1953 to 1955 the total number of professional engineers emigrating from Canada to the United States averaged 280 per year — 8% of the total number of professional workers emigrating from Canada to the United States. Over the same period the immigration of engineers to Canada from the United States has averaged 140 and the total annual immigration of professional engineers into Canada has averaged 1,570. So over this recent period Canada has gained about six times as many engineers as she lost to the United States.

Salaries of Scientists in Relation to Wages

Figure II compares the relative change in the economic position of professional workers and wage earners in manufacturing over the period 1911-1955. The census data used in this figure is the only source of information on the earnings of professionals over this period. Although 1956 census data is not yet available, information obtained in recent surveys of scientific salaries indicates that, although the real earnings of the professional group have improved greatly in recent years, the percentage increase is still well below that of the wage earners. Over the forty-year period 1911-1951, real earnings of wage earners have increased nearly 250%. During the same time, the professional group improved its position by a mere 38%. The positive effect of unionization among the wage earners is clearly evident. The relative decline in the real earnings of professionals can be attributed also to the conditions of the thirties and

to the ensuing World War. Although not affected so severely by unemployment, the professional workers certainly suffered the effects of the depression through a decrease in real earnings. Later during the war period, professional salaries were frozen while wage earners continued to improve their position at an increasing rate; following the war and up to and including 1951, professional salary increases were largely offset by increases in the cost of living.

Since 1952 the consumer price index has held fairly steady while salaries and wages of both professional and non-professional groups have continued to rise. Between 1952 and 1955, wage earners in manufacturing increased their real earnings by 11%[2]. Average salaries reported in the National Research Council surveys of professional salaries indicate that scientists and engineers improved their position by 21% during the same period. Although there has been an upward trend to the advantage of scientific professionals in the past few years, over a longer period wage earners have done much better. This is further illustrated by Table I.

In 1955, Canadian Ph.D. scientists received an average of 1.93 times as much as wage earners in manufacturing as against 4 or 5 times as much in 1930. The 1955 ratio of American Ph.D.'s salaries to the earnings of non-salaried production workers in manufacturing was 1.8. United Kingdom Ph.D.'s are rewarded more liberally relative to wage earners in a selected group of manufacturing industries, their earnings being 2.65 times greater. The reports of recent visitors to the U.S.S R. indicate that a much higher ratio exists there.

Table I. National Research Council

Average Salaries for Various Categories of Staff as a Ratio of 1933 Salaries

Year at 1 July	Scientific	Prevailing Rate Workers
1933	1.00	1.00
1936	1.13	1.42
1939	1.08	1.70
1942	.89	1.77
1945	.94	2.19
1948	1.24	2.60
1951	1.50	3.12
1954	1.83	3.39
1956	2.07	3.68

Scientific Salary Spreads

It has been a common occurrence over the past few years for experienced professionals to find their salaries exceeded by offers made to new graduates. Competition for scientific personnel has caused the starting salaries for inexperienced people to increase at a faster rate than adjustments for experienced staff. This trend can be illustrated by a comparison of Ph.D. starting rates and the maximum salary for the senior research officer grade at the National Research Council. In 1939, new Ph.D.'s were offered $2,100 when the maximum senior grade salary was $5,200. The current starting salary for Ph.D.'s is $5.500, with the maximum for seniors at $9.000. Thus, from 1939 to 1956. the ratio of maximum scientific salaries to starting rates has decreased from 2.5 to 1.6. Another example of the compression of the maximum/minimum salary spread is found in the universities. In 1929, the maximum salaries of professors in the larger universities exceeded minimum salaries of lecturers by 4.3 times. By 1955, this ratio had been reduced to 3.1. While both starting and maximum salaries are higher, the monetary spread is still of the same order as in 1939. On the other hand money has only half the purchasing power it had and taxation is many times greater. (Table II).

The effect of compression is also felt at all intervening points. From 1952 to 1956, for example, in the

---

2 Dominion Bureau of Statistics, Labour and Prices Division, Ottawa.

government services,[4] the ratio of salaries of Ph.D.'s at 10 years to Ph.D. starting salaries has decreased from 1.38 to 1.31. This is also true for bachelors; government in 1951 paid bachelors with ten years' experience salaries which exceeded starting salaries by 1.63 times. This ratio has been reduced to 1.51 within the last five years. Similarly, the comparable ratio for bachelor scientists and engineers in industry has been reduced from 1.84 in 1951 to 1.70 in 1956.

The period of man-power shortage for engineers and scientists through which we are passing has so far greatly benefitted the new graduate, but it has left the experienced man in a less favourable position in relation to his junior colleagues.

Salary Treatment by Type of Employment

Some general observations on average salaries of professional engineers and scientists in Canada, United States and the United Kingdom can be made from a study of Figure III. Trend lines have been plotted for the average salaries of persons with comparable training and experience in industry, government and university.

In all three countries the average salaries in industry are highest, followed by those in government and university. In both Canada and the United Kingdom, industrial salaries lead government salaries by from 5 to 15%, while in the United States the difference is less than 5%. Looking at university salaries, the average salary line for bachelors and masters in Canadian universities is shown to fall about 35% below the industrial average as compared with a 20% differential in the United Kingdom.

The average salary lines provide an indication of the rate of advancement in the three countries under the three types of employer. In spite of the fact that at the junior levels

*** Column 4 = Column 3 + 1955 Federal income tax for a married person with no dependents.

United States' salaries are considerably ahead of Canadian salaries, the rates of advancement over the first ten years are approximately the same (5% per year) in all three types of employment in both Canada and the United States.[5] In the United Kingdom, the rate of increase is slightly greater (6.5%) and continues at almost the same rate for sixteen or

5 Average salary data for a broad sample of United States universities is not available. However, salary information from a few larger United States universities reported in "1955 Survey of Professional Salaries" National Research Council, Ottawa, indicates that the larger United States universities fall in line with United States industry and government.

Table III. Average Annual Salary, 1 July 1956[6]

(a) Bachelors & Masters

	Years from Bachelor Graduation 0	5	10	15	Median Year	Average Salary
Government	$4190	$5380	$6360	$7100	8	$6140
Industry	4270	5880	7200	7990	7	6530

(b) Ph. D.'s

	Years from Ph.D. Graduation 0	5	10	Median Year	Average Salary
Government	$5520	$6640	$7310	6	$6840
Industry	6520	7690	9130	5	8310

seventeen years, whereas in Canada and the United States there is a definite decrease in rate after the ten year level of experience.

Current Canadian Salaries

Engineers and scientists employed by government and industrial organizations in Canada have received substantial increases in salaries during the past year. Apart from starting salaries for new graduates, which increased by approximately 12%, the salaries showed increases from 7% to 10% over those for 1955.[6] Table III shows current average salaries from data supplied for the National Research Council 1956 Survey.

Average starting rates now paid by government for new bachelor graduates amount to $4190 while industry averages $4270. Both types of employers have increased their starting rates by more than $900 over the last four years, with half of that increase occurring within the last year.

United States industrial starting salaries for bachelors exceeded Canadian starting salaries by about $950 in 1955. However, during the last year, United States industrial starting salaries increased only to about $5,000 so that the gap between comparable United States and Canadian starting rates has been closed to about $750. Canadian-trained engineers and scientists have always been highly regarded in the United States. With the recent changes in Armed Service draft regulations in that country, the higher United States offers will be increasingly attractive to Canadian graduates.

Although government and industrial starting rates in Canada are competitive, the bachelor scientist or engineer in industry can look forward to a higher salary than can his counterpart in government employment. N.R.C.'s 1956 survey shows that ten years after graduation, industrial salaries exceed government salaries by about $800 or 13%. Moreover, the average salary for bachelors in industry is $400 greater than in government in spite of the fact that the average age of industrial employees is less than that of government employees.

In looking at the Ph.D. salary picture, Canadian government starting rates for Ph.D.'s are about $1,000 less than Canadian industrial starting salaries and United States industrial offers (in the neighbourhood of $7,500 per annum) exceed Canadian industrial offers by an additional $1,000. Increases of $500 in both government and industrial rates during the past year in Canada, show that Ph.D. salaries are receiving consideration but it is evident that there is need of still further adjustment.

The rate of advancement for industrial Ph.D.'s in Canada is slightly greater than for government Ph.D.'s, being about 40% vs. 33% respectively over the first ten years after Ph.D. graduation. The average salary in industry is $1,450 greater than the average salary for government and again we find that the average Ph.D. in industry has less experience.

In 1956, starting rates for Ph.D.'s in industry exceeded the salaries of bachelors five years after graduation by more than $600, whereas government Ph.D.'s starting rates were only $140 higher than those of bachelors with five years' experience in government service.

Conclusion

In Canada the growth of scientific research during the last half century has brought the scientific and engineering profession to a position of prestige and responsibility in the state. In spite of all this, the professional scientist and engineer has seen his economic status decline relative to the position enjoyed by the wage earner. Moreover, the scientist and engineer of today, after serving his employer for several years, often sees his salary being closely approached by that of the new college graduate. Many Ph.D. scientists receive little or no financial reward for their years of post-graduate training. It is also true that senior scientists have not yet received equitable salary treatment. However, many adjustments are currently being made and the remaining anomalies may soon disappear.

DISCUSSION

of Technical Papers

Growth and Development of Large Electric Power Systems

W. R. Way, M.E.I.C.

The Engineering Journal, 1956, Oct., p. 1329

Dr. René Dupuis, M.E.I.C. [1]

The paper just presented by Mr. Way, referring to large power systems, answers the ever pertinent questions:

From where and when did it start?

Where are we?

Where are we going?

The first question is history, the second is inventory, the last is almost speculation.

History started at many places and has been written around many successful experiments as well as failures, all occurring at about the same time. Except for slight differences attributable to later progress, the large systems throughout the industrial world are all in a high stage of effectiveness. Based on actual achievements as well as knowledge and combined with the possibilities of electronics, future developments may reach unforeseen and unexpected summits.

The talents of even such a writer as Mr. Way must have been taxed to present such an interesting tableau, selecting judiciously from such a wealth of material.

That history was made in many places at early dates can be substantiated easily by a few facts from the Quebec district.

1881 — Two newly formed companies — The Canadian Electric Light and the Quebec-Levis Electric — made electricity with steam on one of the main streets in Quebec City.

1885 (October 7) — The lure of the 220 - foot Montmorency Falls could not fail to attract hydro-electric-minded people who succeeded in generating power there and transmitting it eight miles to light the streets of Quebec.

1889 — Domestic lighting from the same source. The voltage was 52 volts and distribution was at night only.

1890 - 1900 — The Quebec district witnessed: 5,500-volt, 66-cycle, two-phase generators at Montmorency; the first electric cars in Quebec City and the first electric trains; 10,500-volt, 63-cycle, three - phase generators at Chaudière Falls, with a submarine rubber insulated cable of similar voltage crossing the St. Lawrence River; and power generated at Valcartier and transmitted at some 20,000 volts over a distance of more than 20 miles to Quebec.

Delving into history, a French writer once said; "If Queen Cleopatra's nose had been shorter, the fate of the world would have been different."

Recalling the time when alternating current was trying to disloge direct current, I wonder to myself what would have happened then in the choice of frequency if rotary converters had been as effective to convert 50 or 60-cycle power as they were to convert 8 1/3, 16 2/3 or 25-cycle power?

The trend in generation today is definitely towards the biggest possible powerhouses furnished with the largest possible equipment.

This system affords economic advantages not only in investments, but also in operation and maintenance costs. The Bersimis No. 1 and No. 2 power houses, with a total installed capacity of some 2,000,000 horsepower, and units of 150,000 to 165,000 h.p., are expected to be operated and maintained with a staff of less than 200 people. This means one person per 10,000 horsepower. Later on, when big power sites are taken up and we have to fall back on smaller power sites, I think we will have to develop automation or semi-automation to bring operating costs down to a decent level.

Although Mr. Way does not lay stress on it, our country has made many important contributions to the progress experienced in the evolution of large power systems. Manufacturers of generators, of transformers, of line equipment and protection have achievements to their credit next to none. Transmissions and operation problems of interest to the whole world have found their solution here through the co-operation of designers, manufacturers and operators.

One special achievement affecting large power systems very advantageously is worth noting because of the contribution made in this part of our country. I refer to storage reservoirs.

The Shawinigan Water and Power Company has pioneered in this special development. Already half a century old, its first experiments interested the Provincial Government and today form the basis on which actual developments stand. In all probability, it was considered nonsensical — even crazy—at that time to try this experiment on rivers believed completely frozen. Today, this experiment is an established practice that multiplies five or six times the minimum flow of our rivers, increasing thereby the firm capacity of our systems to the advantage of the electric utilities and of the industry at large.

It was announced recently that the third section of our Beauharnois plant would be completed even though the power canal is not sufficiently advanced to permit the low velocities necessary during freeze-up periods and in winter time. This will be possible by taking advantage of our Bersimis river reservoirs and plants. The run-of-the-river flow will

[1] Commissioner, Quebec Hydro-Electric Commission, Montreal.

be utilized during the summer, at night, and over week-ends to help re-fill the reservoirs at Bersimis. With proper installed capacities, these reservoirs will supply to the system necessary power that could not be obtained at certain periods at Beauharnois.

The interchange is taking place also between our publicly-owned power system and the Shawinigan Water and Power system as well as other private systems. You might be interested to learn that the best possible understanding exists here between public and privately-owned organizations.

I feel something should be said about nuclear energy and its possible influence on large systems. Nuclear power will surely play a major role in the large systems of the future. It is expensive at the present time because fission energy degrades itself to the lowest form of energy—heat—that has to build up to the higher form of "electrical energy". Transformation not only causes losses but is also very expensive. Could we hope that a short circuit or a by-pass will occur and that nuclear energy will be transformed directly to electrical energy? The latest I have heard from Dr. Lewis, the best informed scientist at Chalk River, is that nothing very promising has yet been noticed on the horizon which might indicate that possibility. He added, however, that hope should not be abandoned.

I assume it would be within the scope of this program for me to say a few words about the Lachine power development.

Long and serious study has been concentrated on this particular subject during the past 35 years, with Quebec Government and Hydro-Québec engineers participating in the deliberations.

Our experience has taught us that Lachine's problems are the most difficult along the entire St. Lawrence. We are not dealing here merely with a river flowing from upstream and disappearing quietly downstream. Instead, we have a river with a big downstream problem, because waters rise downstream during the winter, flooding 40 per cent of the head.

Further, we have to deal not only with one complicated river, but with three others: The Rivière-des-Prairies, the Mille-Iles, and the Ottawa rivers. The Ottawa has a flood flow of something like 300,000 c.f.s., which is 25 percent higher than the average flow of the St. Lawrence, and not far from the latter's maximum flow.

Add to this complication the ice problems that have already caused the failure of almost half a dozen electric plants in this district. Ice creates extremely delicate problems for us at the two existing power houses, Beauharnois and Back River.

There is another angle. The Lachine problem exists in the most densely populated area of the whole of Canada and, at the same time, involves the biggest inland port in the world. The interests of both must be safeguarded in any solution to the problem.

It is becoming increasingly evident daily that it was fortunate, as far as proper solution of the Lachine problems is concerned, that we proceeded with the new Bersimis power site. From it we will obtain the necessary power for Montreal requirements before Lachine could have been developed.

Incidentally, I may state now that the two million horsepower from Bersimis will have been installed and that from 60 to 75 per cent of its production will have been channelled to this district and absorbed by it *before* it would have been possible to realize anything from Lachine! This power is twice as much as will ever be firmed at Lachine.

Lachine's hydraulic problems are being studied most attentively since the decision was reached to proceed with regulation of the St. Lawrence in its International section. They are considered as part of the overall problem of the river. The solutions reached are engineering solutions worked out in the best spirit of co-operation by all parties interested. The flows of the river have been regulated to help solve the Lachine problems during ice-forming periods and plans for the Seaway channel have been modified towards the same end.

Actual studies for final plans are centered on a two-stage development —one at the foot of the Lachine rapids, with a 30-foot head, and the other below Victoria bridge, with a 20-foot head, if such proves economically possible. The major stumbling block will be the recession of the downstream waters, which might even flood the second dam under certain winter conditions. We are hopeful that this situation will be improved by means of deeper channels and proper ice-breaking operations.

Concentration of the full head at that point would have had to bear the ill effect of that downstream winter rise and, furthermore, would have imposed the building of dykes at elevation 80 on both sides of the river. These dykes would have extended from the foot of the Lachine rapids to a point below Victoria bridge — a distance of approximately eight miles.

With the two-stage development, the same dykes will be only at elevation 55 at the most. This will not only mean a big financial saving, but will also produce a bearable situation for the riparian population on both sides of the river.

There was another reason that induced us to put aside the concentrated falls. A considerable pool of water at elevation 70-72 would have been created in the Laprairie basin, raising the water by 50 feet at its lowest point. This would have exposed all the low lands, particularly on the south shore, to the grave dangers of infiltration; a real threat because of the geological formation in this district.

We are now pushing the Lachine studies diligently and carefully. We should be in a position to start actual construction as soon as the demand for power so requires.

F. L. Lawton, M.E.I.C. [2]

The author has presented a well-knit review of progress in the growth and development of large electric power systems since the early days of the power industry in Canada. In doing so, he has rendered a distinct service to the profession because an integrating type of paper, such as this, is valuable. Not only does it provide a comprehensive picture for younger engineers but it portrays, as well, the stature of the growth and development in the industry so as to foreshadow future developments of fascinating magnitude and nature.

It is all too frequently forgotten that many original and forward steps were first made in Canada, due to the visions of our engineering and financial forebears. Too frequently it is considered that the fountain head of engineerng advances in the power field lies in Europe and in our great neighbor to the south. We have benifited in no small measure but we have also contributed.

The paper foreshadows future developments in Canada in a manner

---

[2] Chief Engineer, Power Department, Aluminum Laboratories Ltd., Montreal.

justifying the prediction that the day is not far distant when interconnected power systems will stretch across Canada from sea to sea and add their sinews to the steel rails which forged the bonds contemplated by the Fathers of Confederation. It also indicates the bright future which lies before those younger engineers who associate themselves with the development and operation of Canadian power systems.

The Author

I wish to express my appreciation for the two discussions which have been submitted by Dr. René Dupuis and Mr. F. L. Lawton. No doubt, if more time had been available, there would have been some interesting discussions from the floor.

Dr. Dupuis has emphasized the role which The Shawinigan Water and Power Company has played in the development and use of large storage reservoirs in increasing the output of the St. Maurice River. He has outlined further some of the possibilities that will exist in this respect as a result of Hydro-Quebec's new power developments which will be of great importance in providing adequately for the power needs of the Province of Quebec. Dr. Dupuis hhas also supplemented the information concerning the problems involved in the future development of the Lachine rapids which, heretofore, has not been given much publicity. Certainly, as Dr. Dupuis points out, the integration and interconnection of electric systems to take full advantage of the diversity of load and hydraulic conditions has been one of the outstanding developments and, in general, his remarks considerably augment the picture of the future which I attempted to present.

In regard to Mr. Lawton's discussion, I can only concur with him regarding the fine future open to the young engineer who associates himself with the development of power systems in Canada. Mr. Lawton further draws attention to the pioneer work done in Canada and to the contributions Canadian engineers have made in the field of development of electric power systems, and I thank him very much for contributing to the discussion.

The Metal Bonding of Aircraft Assemblies

J. J. Waller, *Canadair Limited*

The Engineering Journal, 1956, May, p. 603

W. M. Diggle[1], **M.E.I.C.**

Mr. Waller is to be complimented on an interesting report of the bonding process in use by Canadair, also on a comprehensive appreciation of the problems with which he and his associates had to cope. It is on the latter aspect that I would like to comment.

Firstly the almost-autonomous committee seems like a most efficient approach to a problem which was complicated by the short time factor. Committees sometimes seem to have too much to say; and although in many instances I would hazard that fewer words could be used, yet I am convinced that there is no more expeditious way to approach a complicated problem which involves several departments or conflicting ininterests. Sometimes I think that it is perhaps the only way in which the optimum solution can be achieved.

The committee's selection of the most suitable adhesive was no academic exercise. Mr. Waller probably could have told you also of the assessment of the several adhesives in each of the proposed applications on the aircraft. That the selection was adequate for instance in the temperature range can be proven finally only after the new aircraft has been in service for some time. However, I am sure that the members of the committee are sufficiently certain of their factors that they are not apprehensive in the least.

Mr. Waller has said that quality control is probably more important in metal bonding than in any other process. An airplane often does not get a second chance — it cannot pull over to the side of the road because something goes wrong. Therefore, workmanship and materials must be of dependably uniform high quality. The quality control procedures by which this is assured are especially difficult where deficiencies may not be obvious — a defective rivet or a poor weld. Therefore, the production processes which must be controlled within narrow limits and such inspection checks that are practicable must give every possible assurance of acceptable standard.

Bonding permits light construction. Mr. Waller's estimate of 1000 lb. extra structure would have meant considerable penalty to the airplane. There is a rough rule-of-thumb that one pound increase costs ten pounds to make the airplane as effective as before the addition of the one pound. This, on the basis of Mr. Waller's estimate, would mean five more tons of airplane, engine and fuel to give the same capability on its mission.

Finally there is one word of caution that I would like to give on the use of bonding. It is aerodynamically cleaner than rivets which are raised above the skin; and of course it is simpler than flush rivetting. Nor is there any undue trouble when the surfaces to be bonded permit the assembly to be cooled without distortion. There might be some aerodynamical difficulty, however, when the bonding is intermittent between the surfaces permitting a contraction of one surface to form ridges in the other.

[1]Wing Commander, R.C.A.F., Department of National Defence, Ottawa.

J. R. Gray[2]

Mr. Waller's paper provides a lucid description of the method of metal bonding used in the CL-28 and very adequately describes the many details of such an operation. The discussion of the mechanism of bonding and its effect on the surface preparation of the metal is particularly interesting since this is of prime importance and is probably the least understood phase of the process.

The more consistent results obtained with tape-carried adhesives may be due to two reasons not specifically mentioned in the paper. The first is a closer control of glue line thickness in comparison with the spreading techniques used with paste type products. The other is that the supporting tape assists in distributing the stress throughout the bond. Both of these are of more importance with large or complex shapes.

The advantages of metal bonding as a method of joining large structures such as honeycomb panels is only now being recognized by industries outside the aircraft field. In this connection it might be well to mention that there are now avail-

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

POSSIBILITIES FOR DEVELOPING ECONOMIC SMALL REACTORS

Louis H. Roddis, Deputy Director, Atomic Energy Commission
Combustion, 1956, v. 57, n. 11, May.

The big question in the atomic power business today is — "what does it cost?" All predictions made now about cost of electricity produced from nuclear fuel are based on life expectancy estimates of widely varying degrees of validity. One method is to express all costs in dollars per kilowatt of installed capacity, a one-time total cost approach. Our people have worked up the following figures: For large steam plants averaging 224,000 kw. capacity, $700 per kw. of capacity; for small steam plants averaging 36,000 kw., $1,200 per kw.; and for diesel plants averaging 4,500 kw. in 4 units, $1,700 per kw.

With nuclear plants the variation is so wide that averages cannot be given. The range is from $220 to $960 per kilowatt. The first is for a proposed large N.Y. plant of Consolidated Edison. The second is for a military plant, the quite small Army Package Power Reactor being built at Port Belvoir, Va. Thirty years often is assumed as the life expectancy of nuclear plants.

Nuclear plant development is now bringing the first cost of these plants near the point at which they will be allowable in a competitive installation, and the biggest unknowns are in the region of operating costs. Hence the importance of getting on with the building and operation of some nuclear plants.

Following discussions of pressurized light water reactors, boiling light water reactors, aqueous homogeneous reactors, heavy water reactors, boiling heavy water, homogeneous heavy water, sodium-cooled heavy water types, organic moderated reactor type, liquid metal homogeneous fuel reactor, and gas turbine reactor plants, a table is given for estimated costs of some 17 nuclear power plants giving capacity, first cost per kwh., fuel used and total cost per kwh.

ATOMIC SPECULATION

***Engineering*, v. 181, n. 4708, June 1, 1956**

The game of speculation on inadequate information has a facination much like the pleasure of unravelling a detective story plot or reconstructing ancient civilizations on meagre archaeological evidence. The man outside the security fence is sometimes tempted, perhaps rashly, to play this game with atomic energy.

A good example is the Soviet announcement concerning their proposed atomic power station programme. In Mr. N. A. Bulganin's report to the 20th Congress of the Communist Party of the Soviet Union he stated, in a section covering work planned for completion by 1960, immediately after some figures for the electrical generating capacity of projected orthodox power stations: "A noteworthy feature of the Sixth Five-Year Plan will be the broad construction and utilization of atomic power stations."

The casual reader might expect that in Britain, atomic energy matters would be less clouded in security. But he would be mistaken. It is almost as difficult to see through the chicken wire round Harwell as through the now slightly perforated iron curtain, though perhaps the recent Open Days herald a more indulgent era. Again it is necessary to resort to speculation.

Advertisements are sometimes helpful, but could be very misleading since they are probably composed to give away as little as possible. Recently, for instance, Harwell was advertising for Scientific Officers "to work in a group engaged on research into novel methods of particle acceleration, in particular, methods capable of producing high beam intensities."

Since the Atomic Energy Research Establishment performs research generally with some practical object in view, and since accelerators are mainly used for fundamental research, it might be guessed that construction of a high-powered machine was envisaged for thermonuclear studies. As has previously been pointed out, hydrogen fusion reactions might be initiated in several ways; apart from methods employing pulsed electric currents through gases and shock waves caused by small explosions, particle accelerators could be used to give the high temperatures required (about a million deg. C.).

A further question relating to thermonuclear reactions concerns the purpose of the highlevel conference (which was called to discuss the fusion process, on June 4). Does this mean that the main problems of controlling the reaction have been solved?

Other problems which call for speculation are the future demand for electrical power in this country; the basis on which the published estimates have been made; and how economically nuclear power stations are likely to contribute towards the anticipated requirement.

Nobody doubts that power requirements will increase, but without knowing the method of analysis, industry cannot safely act on the conclusions.

New information on nuclear power costs is also due. In the White Paper (*Engineering*, vol. 179, page 240, 1955), it was suggested that the cost of electricity produced from the first commercial atomic station would be about 0.6d. per kilowatt-hour, so that nuclear stations would be competitive with coal-fired stations.

It is interesting to note that the Russians estimate the capital cost of nuclear stations to be 1½ times that of coal-fired stations, whereas in this country it is given as about double.

The future of the nuclear reactor as a means of propulsion is also worth considering. Its place in the air remains very doubtful owing to problems associated with the heavy shielding necessary and crash dangers. However, at sea the picture is quite different.

However, we cannot base industrial planning on our conclusions. A safe forecast can only be made on the basis of all available facts. That is the danger which follows from excessive security. No one can blame the Atomic Energy Authority; their orders come from a higher place, and scientists when free to be forthcoming are notoriously generous with their knowledge.

Nowadays firms can obtain information from the Atomic Energy Research Establishment, but presumably only if they know the questions they want to ask. This is sufficient for development but not for long-range planning; for this, a wide background knowledge is necessary, including data on current experiments.

GUIDES TO INVENTORY POLICY

Harvard Business Review, 1956, May-June.

This article, the third and final of a series, deals with a topic of key importance to many marketing as well as production executives: the amount of inventory needed to meet seasonal sales peaks.

Few companies are able to forecast seasonal fluctuations in demand with absolute accuracy, and so the problem inevitably arises of how best to balance the costs of overproduction with those of underproduction, and also to revise production schedules economically as sales actually materialize differently from the forecast. The author deals with these and other problems under the subtitle, "anticipating future needs".

Professionalism in business means a more analytical, objective approach to management problems. A manager may pour his blood and sweat into a company as much as ever before; he may become emotionally involved in his work. But if he is a professional, he will try to keep his judgments from being confused by his emotions and personal prejudices.

He will have an open mind about company policies, and one of his most important jobs will be to keep the management team asking questions: "What are we trying to do? What *should* we be doing? Is there a better way?" This is the spirit of enquiry which underlies the article.

Reprints of these articles are available at $1.00 each or $0.40 each, for 4 to 99, from *Harvard Business Review*, Soldiers Field, Boston 63, Mass.

HOW TO HELP PRODUCE THE ENGINEERS AND SCIENTISTS YOU NEED

L. R. Boulware, vice-president, General Electric Company
Edison Electrical Institute Bulletin, June 1956

Brain power may be the only limiting factor on how much energy we can produce. It may also be the determining factor in whether we can survive at all. The Soviet Union produced 682,000 specialists and technicians in the period 1928-1954, compared with 480,000 for the United States, is now training twice as many science and engineering graduates as the 45,000 the U.S. is producing yearly today.

General Electric has been looking at the problem more and more in terms of something for everybody to do everywhere, and this is primarily in terms of our individual communities. A plan to produce more scientists and engineers is by its very nature a long-range plan. It takes 30 years to make a professional engineer or scientist. Even after the 8th or 9th grade it still takes 9 to 12 years or more. The nation would be better served by augmenting the total pool of exceptional talent so all professions benefit rather than by giving exclusive attention to getting more talent into science and engineering.

General Electric's program is based on solving the problem at the local level in communities. It includes mailing G.E.s' series of "Adventure in Science" comic books to teachers for use in high schools and junior high schools, to glamorize the role of science and engineering. "Progress posters" are offered to classes by mail. G.E. today is telling a technical career story to 3½ million boys and an equal number of girls by these methods; their advertisements and motion pictures alert people to the problem and stimulate an interest in science. The company helps local high schools to obtain modern equipment for their laboratories. Local high school science fairs and engineering clubs are encouraged. Plant visits for teachers and students are organized.

G.E.'s apprentice program has 8700 graduates, and opens the way to a science career for the specially gifted or ambitious by providing college credit for some of the basic courses. Six-week summer fellowship programs for high school teachers were inaugurated in 1945, with G.E. underwriting the costs. Company officers, managers, and specialists address the teachers on various aspects of doing business and provide field trips to plants and laboratories. Graduates have already accumulated some 6000 teacher-years and have thus had some effect on the teaching of science and math to some 500,000 students.

RAPID READING

The Manager, May 1956

All managers complain that they have too much to read. In recent months a number of British firms have been experimenting with methods whereby individual managers can be trained to read faster, and hence to cope with their paper work more efficiently. In this article, a *Manager* staff writer describes how leading firms are tackling the problems and the results that they have achieved.

The present clamour for ways and means of speeding up the pace at which the executive may read and digest the mountain of printed matter which awaits him each morning undoubtedly has its roots in loose and verbose writing.

It would seem, therefore, that the basic solution of the problem lies in teaching people to write more concisely, rather than to read more quickly. Solve the writing problem and the reading problem disappears.

H. A. Robinson, clinical psychologist, division of student mental hygiene, department of university health, Yale University, wrote: "It is the usual experience in group reading instruction that marked and statistically significant gains in reading speed do occur, whatever methods or techniques are applied."

The first companies in this country to investigate the possibilities of efficient reading courses were Joseph Lucas Ltd. and Imperial Chemical Industries Ltd. Both used, as a basis for their work, the course developed at Harvard University by William G. Perry, Jr., and Charles P. Whitlock.

Commenting on the first course, Rex Strayton, assistant education officer, metals division, Imperial Chemical Industries, Ltd., wrote: "On the basis of initial and final tests only, the average reading of the group rose from just under 200 w.p.m. to about 355 w.p.m. — an increase of 80.6 per cent. For those who, like the instructor, feel diffident about basing net improvement figures on initial and final tests, a second set of figures revealed that, judged on an average of sessions 2 and 3 and sessions 12 to 15, the net improvement registered by the group was 40.7 per cent.

In order to read his minimum 250,000 words a week the businessman must read 50,000 words per working day — the equivalent of one novel or Sunday newspaper from cover to cover.

Most people would agree that this is perhaps a conservative estimate of what we have to read if we are to keep abreast of what is happening in the world in general and in our own line of business particularly.

More efficient reading is not likely to solve any of the major problems of management, but until more concise writing becomes universal it would appear that it can play a useful part in relieving the burden of the executive. As, in the light of experience and research, the courses are improved, they should prove more and more useful.

AUTOMATION: AN ADVANCE ON MECHANIZATION

Mass Production, 1956, v. 32, n. 6, June

Discussing the evolution of automation and the first techniques developed by Morris Motors in 1927 and by the Ford Motor Co. in Detroit twenty years later, the author (the Rt. Hon. The Earl of Halsbury, addressing the Royal Society of Arts) presents four techniques properly denotable as 'automation'; transfer machining, automatic assembly, control engineering, and information processing techniques. He warns that because they are technically independent of one another they do not, in their applications, interact.

Having thus described the four components of automation, their community of function, their technical independence, and their interaction in application, he concludes with the definition to which the foregoing will serve as a preamble, a preamble which will serve to make the definition both necessary and sufficient·

"Automation refers to a contemporary group of independent advances in the field of mechanisation. These advances characteristically employ discriminatory devices and automatic controls. Typical subjects classified as automative include transfer machining, automatic assembly, the whole field of control engineering and that part of communication engineering concerned with data processing, accountancy and calculation involving the use of electronic digital computers."

NEW YORK SCHOOL OF PRINTING

Green-tinted glass blocks will sheathe the facade of the 6-million dollar New York School of Printing in New York City. The building, designed by Kelly and Gruzen of New York City, will house the school which the New York Board of Education operates in conjunction with the printing industry. The glass blocks, a development of the Pittsburgh Corning Corporation, incorporate a blue-green diffusing screen to soften and diffuse the light, as well as cut down brightness and instantaneous heat gain.

KARIBA HYDRO-ELECTRIC POWER SCHEME

The World Bank has made a loan of $80 million in various currencies for the first stage of the Kariba hydro-electric power scheme in the Federation of Rhodesia and Nyasaland. The loan will help to finance the building of a dam and power plant with 500,000 kw. generating capacity at Kariba Gorge on the Zambesi River, and nearly 1000 miles of transmission lines to the copper belt in Northern Rhodesia and the principal cities of Southern Rhodesia.

The first stage of the Kariba development is expected to cost about $225 million. The Bank's loan will finance $80 million of this amount; the Federal Power Board will finance the remainder through long-term borrowings in the United Kingdom and from the Government of the Federation.

The full installation will generate and transmit 1.2 million kw. of power. In the first stage, now under way, a 400-foot high dam will be built

(*Continued on page 1384*)

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Progress by Ontario Hydro

New production records were established in August in dike building operations for Cornwall dike. A total of more than 425,000 cubic yards of fill material was moved and placed in the dike during the month, principally in sections 2 and 3. Dike building was accelerated by the addition of five more 18 cubic yard diesel scrapers, bringing the total number of these units to nineteen. An average of 20,000 cubic yards of material daily was being placed in the dike sections.

One part of section 3 approximately ¼ mile in length had reached maximum height. The only remaining work in that stretch was to top the dike with eighteen inches of gravel and to slope the face on the water side with one foot of gravel and three feet of riprap. Dike was 27 per cent completed.

Placing of concrete for the power-house structure in draught tubes 2, 3, 4 and 5 numbered from north end, continued at a steady pace during August. Approximately 215,000 cubic yards of concrete had been placed in this structure at month's end, which had then reached 28 per cent of completion.

Excavation of rock on the power-house site was well advanced. A total of 150,000 cubic yards of rock had been removed to date. Earth excavation had been completed on the power-house site, with 1,502,000 cubic yards having been removed.

Behind the "U" abutment at the north end of the power-house main dam, placing and compacting of fill continued during the month for the power-house end of the Cornwall dike. Approximately 190,000 cubic yards had been placed in that area for dike building and backfilling.

Concrete placing in the closure for Cornwall dike continued ahead of schedule. A total of 81,000 cubic yards of concrete had been placed in the wing walls and floor. Erection of the 48-inch diameter pipe, for the City of Cornwall water supply, in the closure structure was completed. At the same time, progress was being made on the earth excavation for the diversion canal, now 30 per cent complete, and work was started for the embankment construcion in the Robertson Creek area.

Dredging continued south of Spencer Island pier and west of Chimney Island, with three dredges operating. Some 630,000 cubic yards had been excavated in this area to August 31. Crib placing in the Spencer Island pier had been completed and placing of rock fill for the pier continued beyond the cribs. At the end of August the pier construction was about 60 per cent completed.

Favourable weather aided railway and highway work throughout the month. The four railway contractors made excellent progress in their various sections, and some 20 miles of double track had been laid, with rock ballast spread for approximately 16 miles. Railway relocation was 85 per cent complete. The highway contractor's work for relocation of No. 2 highway was accelerated during the month and an all out effort was being made to bring the highway into service by the end of 1956.

Moving of houses into new town No. 2 proceeded well during the month of August. Construction of basements was well ahead of the house moving program. Work had commenced on the extension of services to the additional 50 lots on Saunders Avenue. The original sewer and water main contract for the town had been completed. The sewage pumping station was in operation. Considerable activity was taking place in the townsite on the construction of new houses by private contractors.

Preparations were being made at new town No. 1 for moving houses now located in the Dickinson's Landing area. Construction of basements and preparation of access roads were underway. The contract was awarded for the construction of the public school and work commenced during the month.

At Morrisburg, excellent progress had been made on the sewer and water mains in the new subdivision. Construction of the sewage treatment plant and the water pumping station continued. In Iroquois, contracts were awarded and construction was underway for one high school, and two churches. Rehabilitation work was about 30 per cent completed.

The total work force employed by Ontario Hydro and the various contractors during August averaged approximately 4,450 persons.

Progress by NYSPA

August construction continued at a fast pace as working conditions remained favourable. Concrete placement to end of August in all project structures exceeded 690,000 cubic yards, excavation for all features exceeded 24 million cubic yards and employment averaged 5,650 for the month.

All gate guides and sills were in place for first stage of Long Sault dam, concrete was being placed in the spillway bridge beams and had been completed for the spillway apron. Concrete in the structure totalled 220,000 cubic yards, bringing the structure to 48 per cent of completion. Excavation continued for cut F, and piling from cofferdams A and B was being removed and driven in the cells of cofferdams DU and DD. Excavation and grading work has started for the access road on Barnhart Island to the north abutment of Long Sault dam. The cofferdam E cable was load-tested.

Concrete placement in Barnhart power-house continued, with a total of 238,000 cubic yards placed to the end of August in draught tube piers for 12 units and in draught tube floors of remaining 4 units, in ice sluices, as well as in training walls and intake structure. This brought the structure to 27 per cent of completion with mechanical equipment 30 per cent installed. Excavation for the switchyard and placement of embankment in the south forebay dike progressed.

At Iroquois dam, steel piling continued to be threaded for the stage 11 cofferdam concurrently with the extraction of piling from Stage I cofferdam cells. Excavation within the cofferdam area continued. Painting of gates and guides and the erection of the gantry crane progressed. Concrete placement to month end totalled 91,000 cubic yards, with the first stage of the dam some 60 per cent completed.

At Massena intake, now nearing 54 per cent of completion, concrete operations were continued with 111,000 cubic yards placed to end of August. Back-filling the downstream wing wall was in progress and dike construction continued. Construction of the Massena-Alcoa water facilities was on schedule and all pipe for both lines had been installed.

Excavation under the five channel improvement contracts was 37 per cent completed as work at the Galop Island south channel progressed to 91 per cent of completion. Excavation at Sparrowhawk Point, Toussaints Island, Chimney Island, Point Three Points and Leishman's Point was in progress. Clearing of Long Sault and Delaney Islands and adjacent mainland areas was essentially for 135 acres of reservoir clearing between Point Three Points and Red Mills Point. Land acquisition was about 13 per cent complete.

Approximately 80 per cent of the survey work for the Barnhart-Plattsburgh transmission line had been completed. Specifications were issued during the month for elevators in both power-house and Long Sault dam and moving stairs in the powerhouse visitor's area and relocation of highways 37 and 37b. Work on the engineering drawings continued on schedule. The contract for clearing Point Three Points and Red Mills Point was awarded.

Progress By SLSA

On the St. Lambert Lock, contract No. 24, at south end of Victoria bridge, the first concrete had been placed in May. This was ready-mix, but the concrete plant was put into operation on June 11, and thereafter all concrete was mixed there. A stacker with "elephant's trunk" is used *at the lock,* the concrete being carried from mixer to stacker by conveyor belt. For the approach wall, the concrete is brought in by dumpcrete trucks.

By the end of August the lower approach wall footings and various lifts had been poured in a dozen monoliths. The river side of the structure was beginning to take definite shape. At the lock itself, footings at various lifts had been poured in about half the monoliths on the land side. Ports for the filling and emptying culvert were already in place in these monoliths. Excavation was progressing well and was ahead of schedule.

Relationship between the Iroquois control dam and the Iroquois lock is shown here. The channel, still open over to Iroquois Point, soon will be cofferdammed and the water allowed to run through the sluices. The wall of the approach from upstream to the Iroquois lock, being built in Canada, is at upper left. Navigation uses the Galop Canal, which may be seen behind the lock.

On the Cote St. Catherine lock, contract No. 20, excavation of the upstream approach was proceeding well. Downstream, the turning basin cofferdam had been completed and the area pumped dry.

The concrete batching plant had been operating since July. Three high gantries on rails were operating, placing concrete with 3-cubic-yard buckets. Concrete is brought under the gantries from the batching plant in trucks and dumped into the buckets. Footings and various lifts on the river side of the lock had been poured. The filling and emptying ports had taken form here, also.

On the two Beauharnois locks, the contractor for the first stage had cut some 1800 feet length of one tunnel approach to the tunnel under the lower lock, through tough and abrasive sandstone, and had made a start on excavation for the lock proper. On the two contracts for construction of the upper and lower locks, both contractors were still setting up their plant, preparing and commencing excavation. Crib work for the approach from Lake St. Louis was making good progress.

On the Iroquois lock site, contract No. 6, over half the excavation had been completed. The upstream approach wall, which will extend some 3,300 feet, was over half completed. This wall is 47 feet high, 34 feet broad at the base.

Two high gantry cranes, one on rails, are used here to place the concrete in the forms directly from buckets of two and four cubic yard capacity, which are brought individually by trucks from the batching plant. Structural steel and plywood forms, 50 feet in height, are used here. The entire concrete structure here will be 6000 feet long and will require some 300,000 cubic yards of concrete.

On the nine contracts for channel excavation between Montreal harbour and Lake St. Louis, as well as on the various dredging contracts, work was generally well on schedule at end of August, with two contracts completed.

A contract for supply and erection of wire rope fenders at the Authority's five locks was awarded July 30 to Maritime Steel and Foundries Ltd., New Glasgow, N.S. at a value of $2,289,460. Fenders are required to protect lock gates and bridges if ships get out of control or are improperly handled. Each will stop a ship weighing 40,000 long tons moving at 3 miles per hour, in a distance of 68 feet. Installation must be complete by August 1, 1958.

A contract for collector sewer construction was awarded July 30 to S. D. Miller and Sons at a price of $1,836,424. Sometimes referred to as the Seaway Collector, it is a reinforced concrete storm water and sewage collector along the south shore between Anjou Street in Preville and a point 250 feet upstream from the Jacques Cartier bridge. Completion is called for by August 31, 1957.

A contract for supply and installation of operating machines for lock gates at the 5 SLSA locks was awarded August 17 to Canadian Vickers Ltd. at a price of $1,508,520. Supply and erection of sector gates at the Cote St. Catherine, Upper Beauharnois and Iroquois locks was awarded the same day to Dominion Bridge Co. Ltd. at a price of $2,589,477.

A contract for construction and maintenance for two years of a temporary approach to Honoré Mercier Bridge was awarded August 23 to Atlas Construction Co. at $864,908. This approach leads to the steel structure at the south end. Demolition of piers and deck of the existing south approach is also called for. Work must be completed within 90 days of the time traffic is definitely transferred to the proposed permanent approach, which will be built to provide 120 feet overhead clearance for vessels.

Award of these contracts brought to some $150 million the total value of contracts awarded by SLSA to date, divided as follows:
Lachine section, 25 contracts, $74 million; Soulanges section, four contracts, $32 million; Lake St. Francis section, three contracts, $6 million; International section, two contracts, $8 million; Welland Canal section, 4 contracts, $12.8 million; lock bridges, sector gates, lock operating machinery, pumps, electrical equipment, etc., $8.4 million; and various miscellaneous contracts in all sections, $7.6 million.

The approach walls of the St. Lambert lock. Great steel and wood forms are used to contain the concrete for each lift until it hardens, and then the forms are raised to the height of the next lift.

Other Seaway News

A United States steel company, believed to be the U.S. Steel Corporation, has optioned 400 acres of land, with 3,000 feet of water front, on the south shore of the St. Lawrence adjacent to the Iron Ore Co. of Canada transhipment pier at Contrecoeur.

Initial reports suggest the company will build a concentration plant for upgrading ore before shipping it on to its plants in the U.S. Great Lakes states. The ore might come from Venezuela or from Sept Isles. Cost of the plant would be $5 million or more. Primary production of steel in the area is believed to be only a matter of time.

With such a plant in operation the tonnage of Ungava ore concentrates passing through the seaway would probably be much smaller than the expected tonnage of untreated Ungava ore. Yet treatment of Venezuela ore as well at such a plant might sharply increase the total upbound seaway tonnage if this movement proved a cheaper alternative to the downbound movement of Mesabi ores or taconite from Michigan and Minnesota to Lake Erie ports.

Four new industries now building or recently completed in the area have a total value of some $35 million. Six other firms have purchased land and are planning to build. These include a French cement company, an oil company which plans a fuel oil terminal, an American oil company which plans a tank farm for storage of crude, a Swiss-American sponsored brick plant and a company to produce carbide.

Lake Michigan Level

President Eisenhower on August 15 vetoed a bill passed by Congress and Senate, to divert an additional 1000 cubic feet per second of water from Lake Michigan to better the flushing of sewage into the Illinois river. A similar bill had once before been vetoed by the President.

Approval would have cost Canada tens of millions of dollars, through lowering levels in the Great Lakes and the seaway. The power potentials at Niagara and at Cornwall would have been reduced. Canada's Ambassador Arnold Heeney had entered a protest with the State Department. NYSPA Chairman Robert Moses had predicted the U.S. alone would lose $78 million in the next 50 years due to reduced output of electric power, with Canada suffering similar losses.

Setting Seaway Tolls Difficult Problem

The pay-as-you-go principle, though a new one as far as Canada is concerned, was accepted before the St. Lawrence Seaway Authority was established by Act of Parliament. The Wiley Act, passed by the U.S. Congress, also recognized the toll principle.

After a careful survey of major industries that would use the seaway, Canada's Department of Trade and Commerce assessed the traffic potential at 31 million tons a year for the first few years of operation. The U.S. Toll Committee made a similar survey, and predicted traffic of 36½ million tons yearly.

The purpose of tolls is to recover capital and operating costs of the seaway. Legislation calls for construction cost to be recovered within 50 years, though not necessarily spread evenly over each year.

The task facing the Canadian and United States toll committees is to agree on the type and amount of traffic through the seaway over the next half century and then agree on a system of tolls high enough to recover the cost of building and operating the canals and low enough to attract the traffic. The committees have been meeting regularly. By 1958 they will have to reach a joint conclusion.

Questions they must settle include: will there be different rates for different commodities? Will tolls be based on tonnage or commodity, or on a combination of the two? What will be the division of toll receipts between the two countries, will it be based on each country's contribution to the cost of construction or will it be divided according to use? If according to cost, which projects, completed years ago, should be included in costs? If, however, agreement cannot be reached, each country will still be free to follow the path of its own self interest and set its own toll schedule.

Canada's Great Lakes-St. Lawrence Ports

Lakehead Ports

The twin Lakehead ports of Fort William and Port Arthur, with a combined population of 80,000, have a waterfront area of 34 miles, with authorized depth of 25 feet, 40 per cent of it available for additional harbour use. About $50 million has been spent over the years in dredging and breakwater construction.

There are 25 terminal grain elevators with capacity of 93 million bushels. Twelve railway freight and transfer sheds accommodate 70,000 tons. Currently these ports handle over 11 million tons yearly. Over 1,600 cargoes are cleared in a navigation season. A dozen or more 2,000 ton ocean vessels load grain yearly. The present ore dock is 1,200 feet long. Last year it handled 2,265,000 tons of Steeprock ore.

$250 millions will be spent over the next few years for expanding industry in the surrounding area. Plans are already afoot for increasing iron ore shipping facilities fourfold. There will be greatly increased shipments of pulp and paper. Port Arthur has one of the best equipped shipbuilding plants on the Great Lakes, with a drydock 750 ft. long and 78 ft. wide.

Harold M. Mayer of Chicago, in an economic report for the government of Manitoba on the effects of the seaway, observed that while elevators were reasonably adequate and could serve ocean vessels with little change in facilities except for deepening channels, the general cargo terminals were already obsolete. Sheds are designed for side-port loading and discharging from lake package freighters. Modern ocean vessels discharge through vertical hatches, while most port traffic will be handled shoreward by highway carriers.

Sault St. Marie.

Sault St. Marie sees a promising future ahead for itself as a transhipment point on the seaway. With Chicago destined to become a major port of call for foreign ships, goods for Western Canada would be carried on Chicago-bound vessels. Such cargoes would be too small to make the run across Lake Superior economically sound, thus transhipment at the "Soo" would be the logical result.

To take advantage of this situation however, the city needs greatly expanded facilities. Dockage and wharfage facilities are inadequate. At least two 800-ft. wharves with sheds to accommodate 8 000 ton cargoes would be needed, with necessary trackage, scales and bonding facilities, as well as refrigerated sheds for cold storage.

The major resources of the region are lumber and minerals. The city feels it needs a sugar refinery, an oil tank farm, and a big grain terminal. Planning for the seaway era is in a preliminary stage, much depending on financial help from senior governments.

Sarnia

Mainly due to its petro-chemical industries, Sarnia is already Ontario's second ranking port in seaway export trade. It may become an important transhipment port as well. With two railways serving it Sarnia has a five day advantage over Chicago, Duluth and other Upper Lake ports.

Overall existing dock area is more than 11,000 feet, and dockage can accommodate 31 ships of the 350 foot class at one time. There is little or no waterfront property available for additional dockage facilities. There are, however, several thousand feet of Indian Reserve river frontage within the city, the choicest potential industrial land available.

In 1953 the Government authorized a 300-ft. extension to its dock, and a 100-ft. extension to the warehouse, dredging of an elevator slip and improvements in loading facilities. Up to 1954, $400,000 had been appropriated for improvements. Dredging and two steel pile cellular dolphins were completed in 1955.

Windsor

Windsor, with a population of 189,000 and many large industries, is fifth in Canada in volume of capital investment for new industrial construction and equipment according to official estimates for 1956. Its growth has been steady. No longer has it an economy of 'boom and bust', according to the demand for automobiles.

A civic harbour committee is working on behalf of the Chamber of Commerce for establishment of a harbour commission. Once legislation has passed parliament, Windsor's present 6,400 feet of dockage will be expanded, with cranes and warehouses to handle ocean going vessels. Dredging at the docks will be simple, as most docks have a depth of over 19 feet, on a mud-clay bottom. The city is better off than Detroit for space and availability of land for dock expansion. Three miles downstream, at Ojibway, locations are available for slips and modern docks. In Detroit nearest available land for dock construction is 20 miles south on the Huron river.

The full benefits of the Seaway will not reach Windsor until the 21-ft-deep bottleneck in the Detroit river at Amherstburg is dredged. This work will be started by the United States this year, with completion called for by 1963. But ocean commerce on the Detroit river, according to U.S. Army engineers, will increase tenfold in the next 10 years. Windsor's share should be 120 ocean ships or more yearly.

One problem in the past has been quantities too small to warrant ships stopping at Windsor, thus most goods have been handled through the Detroit terminal. An idea which is gaining support is provision of bonded warehouses in Windsor to break down and tranship cargoes to various locations in the mid-west.

Hamilton

Hamilton handles more tonnage than any other Canadian port except Montreal and Vancouver. The harbour commission controls 14,600 ft. of docks, most of it suitable for cargo ship use. Private docks owned by industries total 21,000 feet. The Federal Government is spending $2 million for extending the Wellington Street dock area. Other proposals are for a new terminal and docks at Ship Street and a new slip and dock at Strathearne Avenue at the east end of the harbour. Longer range plans call for filling in the bay side of Burlington beach.

Fifty one shipping lines now use the port, of which 19 are foreign. 1566 vessels entered or left the port in 1955, while an all time record for tonnage of 7½ million tons was recorded. Outward commodity shipments of package freight totalled 312,000 tons. The port aspires to become the leading trading and industrial centre on the Great Lakes, with the aid of the seaway.

Toronto

The port of Toronto, with a metroplitan market of some 1½ million people and a prosperous hinterland, has ample accommodation for all classes of shipping. Piers have been built for possible dredging to 30-ft, depth without endangering foundations. The new terminal on Pier II was opened in the spring of 1955, adding berths for four ships and close to two million cubic feet of covered cargo stocking space.

The harbour commission is keeping its planning three years ahead, its financing two years ahead and its building one year ahead of needs. The central portion of the harbour has been set aside for package freight terminals. The Federal Government has just added 26 acres to the harbour between Pier 12 and Parliament St. Some five city blocks in length, the 3,300-foot retaining wall was built at a cost of $1½ million. The dock was created by dumped fill from city projects including the subway. Dredging has also been completed.

Waterborne trade has expanded year after year to 4½ million tons in 1955, a nineteen-fold increase in 35 years. 792 entrances and clearances of foreign ships were recorded last year. Commissioners have recently established a Trade Development Department to encourage the movement of merchandise both inward and outward through the port. They also look for increasing development of transhipment to lake carriers, rails or trucks, to save uneconomical runs of large vessels further up lake with small tonnages.

Port Credit

Fifteen miles west of Toronto the government is building a million dollar 850-ft.-long dock to handle overflow business of Toronto's port. Completion is expected early in 1957.

Kingston

Kingston is spending $4 million on dredging and other construction. The port does not come under the jurisdiction of the National Harbours Board.

Brockville

Brockville has in hand two possible docking sites. The first would cover an area of ½ square mile with three piers jutting out 600 ft. east of Brockville Island Park. Each pier would accommodate two freighters. Construction would be off rail facilities and coal terminals lining the shore off Water Street. A more logical alternative plan calls for three piers of similar dimensions to the first plan situated west of the blockhouse. No estimates are available of the amount of dredging needed for larger vessels. The town has arranged to have itself declared a port and a port authority has already been established.

Existing facilities for shipping consist of privately owned docks. The C.P.R. wharf is the largest, but is not extensively used. Warehousing is very limited.

Cornwall

Cornwall, at the lower end of the huge lake to be created above the seaway power development, is strategically located to derive maximum benefit from the seaway. With an eye to greater industrial activity the city plans to purchase or expropriate 200 to 300 waterfront acres for lease at reasonable prices. Its planning commission has made provision for a considerable length of waterfront east of the city with docks and warehouses on the shoreline. Served by both Canada's rail systems, the city provides excellent freight service through the Cornwall street railway and trucking services.

Government docking facilities are provided by docks 1,450 feet in length along the 14-foot canal, while one industry, two oil companies and a coal company have their own docks.

Cornwall has never developed as a large port owing to its proximity to Montreal and because vessels exceeding 14-ft. draught cannot proceed upstream beyond Montreal. Opening of the 27-ft. seaway channel will open up new opportunities.

Montreal

Montreal's earlier fears that the seaway would adversely affect its port activities and retard the growth and development of the surrounding region have long since subsided. Today there is optimism and confidence that the seaway will benefit and enhance economic activity and maintain its traditional role and status as Canada's chief Atlantic port and transportation centre.

Present facilities include ten miles of wharves, piers and jetties which provide berths for 142 vessels of deep ocean draught. 32 of the berths are equipped with transit sheds, providing more than 2.3 million square feet of floor space. Cargoes are handled by trucking and a 62-mile terminal railway connected with two great rail systems.

While all types of cargo and commodity shipments move through the port, grain is by far the largest. Montreal's position as world leader in grain shipments was established in the "twenties" and is likely to be enhanced by the seaway. In the three year period 1953-55 grain accounted for 65% of total outbound cargo tonnage, flour 8%, and grain products 2%. Other bulk commodities and general cargo accounted for the balance.

Over the same period petroleum and its products accounted for 40% of incoming shipments, with coal 9%, sugar 8%, cement 6%, and iron and steel 4%. General cargo accounted for the balance.

In recent years some 1,700 ocean going vessels pick up and discharge cargo yearly. Foreign cargoes average 9 million tons annually — 4.1 million tons inbound and 4.8 million tons outbound.

Two new wharves each 1,500 ft. long are under construction, with provision for unloading berths for large 'lakers'. New transit sheds and improvements to grain conveyor galleries are also underway. Of a $7 million program planned in 1955 to improve Montreal's port facilities, $2 million was spent in 1955. Dredging to connect the seaway channel with the St. Lawrence ship channel, together with a turning basin, is presently being carried out. One of the factors underlying the sharp increase in land values along the south shore of the river is that the 16 miles between Contrecoeur and Laprairie offer great possibilities for future extension of the port. Here many large industries have purchased sites and are already planning plant expansion facilities in the area.

Trois Rivières

With approach channels dredged to 35 feet, Trois Rivières is an important port for shipment of pulp. It has 5 miles of railway, three wharves with berthing space of 8700 feet in length, 193,000 square feet of transit shed space, 500 cubic feet of cold storage and 2 million bushel elevator capacity. It is operated under the National Harbours Board and addition of more wharfage space, sidings and sheds is contemplated. Tonnage handled yearly averages 2½ million tons inbound and one million tons outbound, mostly pulp, coal, and grain.

Quebec

The Port of Quebec, like Montreal and Trois Rivières, is under National Harbours Board jurisdiction. With 35 feet depth for its approach channels, it has 23 miles of harbour railway, 36 wharves, piers and jetties containing total berthing space of 743,600 square feet. There are 528,000 cubic feet of cold storage space and elevator space for 4 million bushels. Coal storage capacity is 215,000 tons, oil tank storage capacity 54 million gallons. In preparation for the anticipated increase in shipping due to the seaway, improvement is being made to the elevators and cold storage sheds. The St. Charles Estuary, on which is situated the Davie Shipbuilding plant, is due for further dredging. Inbound freight yearly averages close to two million tons, outbound one million tons, mostly pulpwood, coal and petroleum products.

Canadian Pipeline Projects

During August construction on the two natural gas pipelines to carry Peace River gas to the Pacific Northwest and Alberta gas eastward as far as Winnipeg, was well under way. Westcoast was approaching 25 per cent of completion, with no foreseeable hold-ups threatening. Trans Canada, delayed by retarded pipe deliveries due to the steel strike, was forging ahead on two 110-mile spreads, covering the western third of the line from Alberta to Winnipeg.

Each "spread", fully manned, employs 200 men more or less. After the clearing comes the ditching crew, equipped with a large ditcher; the bending crew follows with a giant pipe bender to fit the pipe to the overbends, sags and lateral curves in the line. Next comes the welding crew, making four welds per joint. Each welder is tested for proficiency. Welders are scarce and high priced, earning up to $50 per day each with overtime.

A ditch is cut through the Saskatchewan prairies by a huge ditching machine operating on the Trans-Canada Pipe Lines project.

The doping crew follows the welding crew, cleaning the pipe and removing rust and scale. The pipe gets a priming coat of enamel and then a coat of bitumastic. It is then wrapped by machine with spiral sheets of wrapping. The lowering-in crew then hoists the pipe with a tractor-mounted derrick and special slings, and lowers it into the trench, after which the trench is backfilled with bulldozers. Four or five inspections of the pipe are made at various stages.

Westcoast Transmission

Westcoast construction crews had caught up with their progress schedules by mid-August, and spreads 1, 2, and 3 were each laying pipe at the rate of one mile a day on the south central portion of the line. 400 miles of line had been cleared. Pipe for a total of 404 miles had been delivered, 184 miles had been ditched, 143 miles were welded, 134 miles doped and wrapped, and 120 miles laid. Officials were confident no delays would be caused by the U.S. steel strike.

On the six suspended crossings, work had been about 20 per cent completed over the Peace River; foundations were completed for a crossing over the Fraser River at Shelley; excavation had been started at Quesnel, at one crossing over the Thomson River and two other Fraser crossings. Compressor sites had been started at Fort McLeod and at a point 20 miles south of Quesnel. Crews were laying steel for two gas processing plants in the Peace River area.

It is estimated the pipeline will be in service about September, 1957. In preparation, Pacific Petroleums had already drilled some 70 wells in the Fort St. John area where 10 drilling rigs were in action. Only 10 of these were dry wells. Thus with 10 indicated producers the company was more than half way to the objective of 120 producers by the fall of 1957. It was reported two major chemical plants were planning to establish plants at Taylor Flats.

Meantime from south of the border comes word that the first gas was turned in to the Pacific Northwest Pipeline system, with which Westcoast connects, on August 11. The gas came from the "Big Piney" field in Wyoming which has a 750 million cubic feet reserve. First sale of the gas was made to customers in Monticello, Utah, at 41 cents per 1000 cubic feet The wellhead price is 15 cents per thousand over the first five years, one cent being added each five year period.

At the end of August, some 83 miles of pipe had been placed in the ground by the two contractors working on the western section between Burstall, Sask., and Winnipeg. Working on the project are Majestic Contractors Limited, from Burstall, to Leinan, north of Swift Current, and Canadian Bechtel Limited, from Leinan to Pense, east of Moose Jaw. Each contractor has a spread of about 110 miles.

Right of way had been cleared and graded for 186 miles, pipe had been strung 109 miles, 110 miles of ditching had been completed, 91 miles of bending, 88 miles of pipe had been welded, 86 miles of pipe had been cleaned, primed, coated and wrapped, 83 miles had been lowered in the ditch, 73 miles of ditch had been backfilled, and 74.5 miles of right-of-way had been cleaned up, terraced, tilled and had fences restored.

Majestic had almost completed its construction through the Great Sand Hills, south of Leader, Sask. Operations in this area were not as difficult as had been anticipated. There were few cave-ins of the ditch and the coating and wrapping operations, preceded by a clamshell ditcher, were not delayed.

Majestic had moved its base of operations from Leader to Cabri, and Canadian Bechtel had moved from Swift Current to Moose Jaw. Trans-Canada's western division construction office is at Regina and the district office remains at Swift Current.

Canadian Bechtel Ltd., had set up a double-jointing yard at Morse, 40 miles east of Swift Current, and planned to move the yard to Archydal, northeast of Moose Jaw, as the construction progressed. The yard was set up so that less field welding and pipe handling would be necessary on the right-of-way, special equipment could handle the pipe more efficiently, automatic welding could be more closely controlled and shelter would enable work to continue despite weather conditions and working schedules of the line crews.

Double jointing of line pipe in central yards is paying off handsomely on Ohio pipelines. By doubling 30-ft. joints into 60-foot lengths, spreads have increased their daily pipeline laying there by 20 per cent. Even in hilly country the normal spread output using double joints has been raised to 8,500 feet per day. Cost per mile is also cut but not so sharply as output.

Trans Canada Pipelines

The western leg of the pipeline from the Alberta-Saskatchewan border to Winnipeg will have six compressor stations, one of 17,500 horse power at Burstall, Sask; one of 10,500 horse power at Swift Current, Sask.; while the remaining four at Moose Jaw and Deveron, Sask., and McCauley and Bagot in Manitoba will have initial capacities of 10,500 horse power each. These stations are not needed to operate the line in 1957 since first year's gas from the Bindloss field has enough field pressure to push it to Winnipeg.

Late in August it was reported by a representative of the U.S. Steel Corporation, which is supplying 34-inch pipe for the entire 574 miles of the western portion to Winnipeg, that mills should be able to resume shipments about September first. Together, the two suppliers could produce about 10 miles of pipe daily, and might be able to complete the order by mid-October.

The cleaning and priming machine rides the pipe under its own power. At the front revolving knives scrape dirt and rust from the pipe, after which revolving brushes coat the pipe with a priming base for the coal tar coating.

Bannister Construction Ltd. had moved equipment into Brandon early in August. They started on the distribution system for Great Northern Utilities, including 15 miles of 8-inch pipe from the main pipeline.

Dutton-Williams Ltd., was awarded a contract in mid-August for seven miles of pipeline by B.A. Oil, in connection with their gas recycling plant at the Pincher Creek gas field. Completion is called for by late fall, 1956.

While Trans Canada officials stated late in August that reports of financing for September were premature, it appeared possible the marketing might take place by November. It is already clear that FPC approval for export to United States is not now needed to satisfy potential investors of sufficient income under firm contract to service debt and provide reasonable profit. The company had signed up Canadian sales contracts in excess of 250 million cubic feet daily under 20 year contracts in the early summer and the total is fast approaching 400 million.

Bridge at Trois Rivières

Royal assent was given on June 7 to legislation authorizing construction of a $12 million toll bridge across the St. Lawrence River near Trois Rivières, Quebec. The federal legislation, necessary because the bridge crosses a navigable international waterway, will permit construction of the span by a six-man corporation which has already been set up by an act of the Quebec Legislature. The bridge was first proposed some ten years ago.

Tunnel under Fraser River

Construction of a tunnel under the Fraser River at a cost of some $16 to $17 million was given final approval by the B.C. Cabinet on June 26. The tunnel, which will carry highway traffic under the river near its mouth at Deas Island, will be completed within two years. It will eliminate a bottleneck caused by cars from the Pacific highway now using Pattullo bridge on the main highway to and from the United States.

(Canadian Developments section continued on page 1424)

KARIBA HYDRO-ELECTRIC POWER SCHEME

(Continued from page 1376)

across the Zambesi River at Kariba Gorge, about 170 miles from Salisbury. The dam will be about 1800 feet long at the crest; hydraulic head will be 300 feet. The reservoir will be 190 miles long and a maximum 40 miles wide.

Two underground stations will ultimately be built, one on either side of the dam, each equipped with six 100,000 kw. units. First stage will comprise one station with five units and also construction of a grid to interconnect the major load centres in the Federation. A high-voltage transmission line will run northward from Kariba to Kitwe, the main power switchyard in the copper belt; southward to switchyards at Norton and Umniati, and thence to Bulawayo and Salisbury, the two largest cities in the Federation. Combined length of lines to the south will be 650 miles.

The Federal Power Board has retained an international group of engineers to plan and supervise construction of the project. Preliminary works are under construction and power production is expected by 1960. The first stage is expected to reach its full potential of nearly 4000 million kwh/year by 1963. The second stage of the Kariba scheme will be carried out as the growth in power demand justifies it.

The Metal Bonding of Aircraft Assemblies (Discussion)

(Continued from page 1373)

able solvent-free adhesives based on epoxy resins which require neither the high-temperature cure nor the solvent-drying and pre-cure procedures necessary with the vinyl-phenolic types.

The Author

In regard to Mr. Diggle's comments, I have nothing further to state. However, in regard to Mr. Gray's discussion, I would like to submit the following.

The epoxy adhesives by themselves would be unsuitable for structural applications where there must be a close relationship in shear modulus between that of the adhesive and that of the adherents. The problem associated with the use of a brittle adhesive (such as an epoxy) with a ductile metal (such as aluminum) is obvious from the point of view of the transfer of load from one element to another.

The epoxy adhesive could be plasticized with a rubber or another resin such as polyvinyl butyral but this would introduce the solvent problem which Mr. Gray mentions that epoxy adhesives avoid.

The strength of a bonded joint is line thickness. Unfortunately, the epoxy adhesives which, at least, are known to the writer at the present time, are not only very viscous and difficult to apply uniformly but also cannot be appplied to any desired thickness as is the case with the fiberglas cloth-supported phenolic adhesives mentioned in my paper.

Application of Welded Design to Hydraulic Turbine and Valve Manufacture (Discussion)

J. G. Warnock, *English Electric Company of Canada Limited*

The Engineering Journal, 1956, *Oct.*, *p.* 1350

H. M. Viberg [1]

Our organization would like to take this opportunity to present some pertinent data on steel castings to alleviate any doubts as to their industrial value.

The industry as a whole spends large sums of money for technical research in plants, universities and associations; it is ever searching for ways to improve design and pattern equipment, production processes, and inspection in the foundry. Great advances have been made in metallurgical control and heat treatment. Melting and pouring temperatures are constantly checked by pyrometers and improvements of pouring practice, heading and gating are going on all the time; even the selection of scrap is under laboratory control. Improvements have been made in furnace controls and operation. The modern foundry today is equipped with modern sand preparation equipment, new moulding machines and improved cleaning machines. Foundry engineers are co-operating with the customer to improve designs. Many intricate designs may be cast in order to distribute loads properly with specifications laid down to make use of cast steel's high impact values obtained through the addition of alloys and subsequent heat treatment.

Product development has done much to reduce weight, improve appearance and reduce costs. Today's requirements for new equipment operating under higher pressures and at higher temperatures are calling for new designs.

These castings must be homogeneous and the design must be such as to facilitate foundry practice to produce a good dependable sound casting. These castings are further subjected to "Magnaflux" and radiograph inspection which ensures the internal integrity of the casting to both the producer and consumer.

Report on Investigation into the Failure of Two 100-Mw. Turbo-Generators

Sir Claude D. Gibb, C.B.E., D.SC., M.E., F.R.S.

The Engineering Journal, 1955, March, p. 213.

V. S. Thompson, M.E.I.C., Ottawa.

I was once again impressed by the honesty of the C. A. Parsons and Company Limited in making public the findings into the failure of two generators at Toronto.

A similar illustration of such an attitude was the investigation into the Comet disasters. Both of these reports must increase the respect of all engineers for the manufacturers who have not tried to conceal any weakness in their products when general benefit may accrue from publicity.

In comparison, it would seem a great pity that the investigations into a recent failure of an important Canadian bridge have not been made public for the benefit of all structural engineers.

I suggest that the Engineering Institute should endeavour to obtain this information "to facilitate the acquirement and interchange of professional knowledge among its members".

Atlantic Provinces Professional Engineers

1956 Biennial Meeting

As most readers are aware, every second year the Atlantic Provinces Branches of the E.I.C., together with the Associations of Professional Engineers in those provinces, hold a regional meeting. It has become the custom for these gatherings to alternate in locale between Digby, Nova Scotia and St. Andrews, New Brunswick. This year, during the three days of September 5, 6, 7, the meeting centred around and in the Algonquin Hotel at St. Andrews.

If it is reasonable to judge by numbers of those attending, and by genuine enthusiasm, the 1956 meeting was the one to eclipse all previous occasions. Probably the best way to describe the event, and this is from the point of view of one of the ordinary participants, would be to say that it was an example of well organized informality. The committee in charge obviously had as their objective a program designed to develop friendship, in keeping with their ideas of professional dignity and technical advancement, and they succeeded — most admirably.

Two council meetings occupied the afternoon the opening day, providing an opportunity for regular deliberations by the councils of the E.I.C. and of the New Brunswick Professional Engineers Association. These were followed by an informal dinner, and later the evening was spent in get-together manner at the E.I.C. president's reception. Old friends renewed acquaintance, and newcomers were welcomed.

The morning periods on Thursday and Friday were devoted to the

A council meeting was held at St. Andrews during the Atlantic Provinces meeting. President V. A. McKillop presided. Above, R. E. Heartz, vice-presidents R. L. Dunsmore and H. W. Doane, Mr. McKillop and the general secretary, L. Austin Wright; below, the councillors.

Cover Picture

The cover picture shows a new terminal station which went into operation recently at Chaudiere, just south of the Quebec Bridge. It is one of a series of new Shawinigan installations nearing completion.

"The Growth and Development of Large Electric Power Systems" is treated by W. R. Way of Shawinigan Water and Power Company in a paper on page 1329 of this issue.

presentation of the technical papers. It was to be expected that the authors would deliver talks of particular interest to Maritime audiences, and these were as follows:—

An Appraisal of the Potentiality of High Voltage Direct Current Transmission, by E. V. Leipoldt, vice-president, Shawinigan Engineering Limited.

Sub-Surface Foundation Exploration by the Seismic Method, by Emery Holzl, chief engineer, S.E.M. Prospecting Limited.

Smelting of New Brunswick Manganese Ores, by Dr. Marvin Udy, Consulting Engineer.

Canada's Approach to the Economic Fuelling of Nuclear Power Reactors, by Dr. A. V. Mooradian, superintendent of engineering development, Atomic Energy of Canada Limited.

In addition to the technical sessions, the program included guest speakers at two luncheons, and at the banquets which were held on the evenings of the second and third days. In the order of their appearance, we heard from V. A. McKillop, E.I.C. president, who spoke of the very important relationship of the engineer and his community, then at dinner the same day Brian H. Colquhoun, M.E.I.C., engineering advisor to the International Bank for Reconstruction and Development gave some interesting and important details of the workings of that organization.

At noon on Friday the 7th, a popular speaker was Mrs. T. P. Lusby of Halifax, the president of the Professional Engineers Wives Association of that city. She covered some amusing, yet fundamental, aspects of the wife's place in an engineer's life. The guest of honour at the final banquet was the Right Honourable C. D. Howe, Hon.M.E.I.C., who gave the meeting his views, both personal and as a cabinet minister, on the question of shortage of Canadian engineers and technical personnel.

On Thursday afternoon, the second day, we enjoyed one of the highlights of the convention. In fine clear crisp weather the MV. "Grand Manan" took a large party of engineers and ladies for a three-hour cruise through the bays and channels which may some day form the workings of the long discussed Passamoquoddy Power Project. The size and importance of this vast proposal were made evident to the passengers, and the cruise itself was a pleasant diversion.

The social side of the meeting was carefully organized and well carried out — probably deserving of more prominent mention than at the end of this account. We had an evening cabaret show, well attended and very amusing, a golf tournament on the fine St. Andrews Course, and the wind-up event was the grand ball on Friday night, one of the nicest dancing parties it has been our pleasure to attend in recent years.

It is possible to see, in these regional meetings, the pattern of our Canadian engineering conventions of the future. As the nation and the profession grow, the time will undoubtedly come when the great all-provinces annual meeting must give way, from sheer difficulty of size, to other gatherings of more local interest and colour, such as this one recently concluded at St. Andrews. We hope that they will be planned and carried through by such able and dynamic committees as the one headed by general chairman Joe Donahue, M.E.I.C. of St. John, N.B.

Mrs. T. P. Lusby

AT THE ATLANTIC PROVINCES MEETING

There were two banquets during the Atlantic Provinces meeting, at which the speakers were the Rt. Hon. C. D. Howe, HON. M.E.I.C., and Brian H. Colquhoun, M.E.I.C., of London, England. Mr. Howe is shown in the picture below left, with Mrs. Webb and D. R. Webb, president of the Association of Professional Engineers of New Brunswick. V. A. Ainsworth presided at the Thursday banquet. He is at right in the photograph below, with Mr. Colquhoun, and Mrs. Ainsworth. Others are Mr. and Mrs. Norman F. Stewart, and H. W. L. Doane.

Cruise on M. V. "Grand Manan" through the proposed Passamaquoddy power project area.

I.A.E.S.T.E.* Travelling Bursaries

As was explained in the September *Journal,* one of the chief obstacles in the way of full scale Canadian participation in the IAESTE student exchange has been the deficit incurred by our students in trying to meet their travelling expenses out of European summer earnings. The dollar equivalent of what they can clear above living expenses is just not sufficient.

In July we had with us for several weeks James Newby, IAESTE secretary for Great Britain, and formerly general secretary for the whole organization. He was equally disturbed about the very small numbers of Canadian undergraduates who are taking advantage of employment offers in the U.K., and he decided, with our consent and encouragement, to do something about it. Mr. Newby felt that if this situation was explained in a straightforward manner to some of our larger industries, they might be willing to contribute funds toward closing this gap in the exchange plan. He sounded out a few key personnel, and the response was almost immediate — they liked the idea.

It has been decided therefore to go ahead with this travelling bursary proposal, and the necessary machinery will be organized and set up through Institute headquarters in the next several months. Close touch will be maintained at all stages with the industries concerned and with the university authorities. The objective will be to see that simple but effective procedures are worked out to ensure that assistance, in proper amounts, reaches the hands of recommended Canadian engineering students on their way to IAESTE positions abroad.

It is not difficult to foresee the advantages, both direct and intangible, that will result to our industry, and to Canada, from participation in this bursary plan. Our first consideration should be the reward to the individual student, technical and cultural, from having spent a few very informative months working in a European community. As more and more take advantage, this will of course become cumulative, and the nation will benefit. At the same time, a Canadian industry looking for young engineers (and who isn't?) will quickly recognize how it may affect their chances of gaining a student's allegiance — or at least his friendship — when it is their money which is helping to make his trip overseas possible. It is intended that each of these bursaries will be named after the company contributing it.

Three generous donations from Canadian companies have already been received, and more are expected to come in during the next few weeks. The *Journal* suggests that others might well give this travelling bursary plan some serious study.

* International Association for the Exchange of Students for Technical Experience.

Service To Consultants

For several years the Institute has maintained a register of consulting engineers in Canada.

There are over 300 firms so registered.

The steadily increasing use of the register by industry and government and the rapid expansion of the fields or interest of most engineers, have emphasized the need of bringing the register up to date.

The latest additions to the experience records of the registrants were made for most firms in 1953. In the three intervening years many of them have entered new fields, and in many instances it is to these fields that the current inquiries apply.

In order to bring everything up to date the Institute recently has sent to every registrant the complete file that is with the Institute. The request is made that the record be reviewed, brought up to date, and returned to Headquarters with the least possible delay. Prompt action is requested so that the records will not be absent from the file when inquiries are received.

It is not possible to inform consultants of instances where the names and records have been submitted to inquirers, but it can be said that many millions of dollars' worth of work has been placed with firms whose names were supplied by the Institute register.

Naturally the Institute cannot recommend one firm in preference to another. On receipt of an inquiry the procedure is to examine the classification file to determine which firms have had experience of the kind requested. These names are submitted along with copies of the experience record of the firms, so that the prospective client may select for himself the firm or firms to which he may direct his further inquiries.

The service is free to the engineer and to the client and is not restricted to members of the Institute. One of the prime purposes for creating it was to meet at least partially the frequently offered defence for employing foreign consultants, "We did not know of any Canadian consultants who could do the work." With the Institute's register so well established there is no longer any excuse for lack of information.

Consultants! Be sure to return your records promptly. It is essential that we have them promptly to continue our service.

Elections and Transfers

At a meeting of Council held on September 5, at St. Andrews by the Sea, N.B., a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

For Admission as Member

H. M. Brownrigg, Joliette
I. T. Burke, Ottawa
G. B. Carter, Shawinigan Falls
G. H. Currie, Winnipeg
A. E. Fee, Ottawa
F. A. Fell, Balmertown, Ont.
T. C. Hirst, Montreal
J. F. Leaver-Power, Wythenshaw, U.K.
F. S. Maconachie, Ottawa
J. D. Mayo, Toronto
S. H. McClure, Montreal
W. F. McDougall, Montreal
E. S. Szekely, Arvida
B. S. Thornton, Montreal
H. F. Wooster, Vancouver
G. B. Wray, Cornwall

For Transfer from Junior to Member

D. B. G. Dutton, Waterloo, Ont.
R. L. Nordlund, Vancouver
J. D. Smith, Toronto

For Admission as Junior

J. A. Fordham, Toronto
W. E. Stone, Vancouver

For Transfer from Student to Junior

G. G. Hurlburt, Toronto

For Admission as Student

H. J. Coulombe, Laval University
D. C. Bouras, McGill University
B. de Cardaillac, McGill University
R. L. Hicks, Nova Scotia Technical College
A. T. Isaacs, Nova Scotia Technical College.
R. A. Morrow, Queen's University
D. M. Robertson, B.Eng. (Civil), 1956 N.S.T.C.
R. M. Watson, B.Sc (Elec), 1956 Univ. of Alta.
L. J. C. Almassy, Passed test at Sir Geo. Williams for entrance in Science in Mar./56

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Association of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members

H. L. Hogge
K. Kamra
L. Keet
J. W. Poole
E. M. Searcy

Junior to Member

B. Smolensky

SASKATCHEWAN

Members

A. R. Byers
J. K. Diebel
R. E. Harris
C. G. Holthouse
W. O. Kupsch
G. J. Sladek

Junior to Member

W. A. Byskal
R. B. Godwin
A. W. Holroyd
T. A. Kajewski

Student

G. T. Dewhurst

MANITOBA

Junior to Member

H. A. MacDiarmid

NOVA SCOTIA

Members

I. MacInnis
H. C. McGee

Junior to Member

H. C. Maitland
D. H. Waller

There Is Something New

At the last meeting of the Council of the Institute approval was given to the creation and distribution of a new insignia of the Institute. This is to be in the form of a miniature slide rule, made up as a tie clip. The initials "E.I.C." appear on the slide.

An experimental number were made in time for some distribution during the annual meeting but these disappeared very quickly and further orders have now been placed.

Council has ruled that a tie clip will be given to each new Student member as his application is approved by Council. Clips will be available to other student members at the price of $1.00 each and to Members and Juniors at the price of $2.00 each.

The clip is a first class piece of jewellery and will be an ornament to any engineer, either young or old. It is expected they will be popular with members in all parts of Canada.

The following experience is an illustration of how popular it is expected they will become.

At the Council meeting six clips were distributed so the councillors could see what was being discussed. When Council agreed that the clips would be sold at $2.00 each six separate payments of $2.00 reached the head of the table but not a single tie clip was returned.

The wearing of a tie clip would identify a person as an engineer just about as clearly as does the iron ring and it is hoped that eventually there may be as many tie clips in use as there are iron rings.

It is regretted that it isn't possible to present every student member with one of these useful articles. However, there are today over 3500 students on the membership list and when it is considered that the clips cost almost as much as the selling price it will be realized that the initial cost would be more than the Institute could bear. Council hoped that by offering them to the present student members at $1.00, they would meet the situation satisfactorily.

Members desiring clips may obtain them from headquarters, although at the moment the stock is very low. It is planned to have a supply at each university centre this fall.

Aid to Education in Canada

That industry should take its part in solving our educational problems is commendable, and the growing conviction is that it is a necessary trend.

There are many instances of co-operation between industry and the universities. One remarkably generous program of financial aid to education is supported by the International Nickel Company of Canada.

Recently it was announced that this company's contribution to higher education in Canada will be $2,500.000, to be paid over a five-year period in grants to 140 institutions in the ten provinces.

Approximately 80 per cent of the amount will be for use by the universities and colleges in their programs to provide for anticipated increase in requirements throughout the country in the next few years.

Two-Phase Program

The program has two major phases. One authorizes approximately $2,000,000 in grants to the 140 universities, liberal arts colleges and technical colleges for use in strengthening and expanding their educational programs.

The second phase covers the allocation of approximately $500,000 for scholarships, fellowships and special projects, including assistance to teachers of science and mathematics and guidance counsellors in preparatory and high schools. It will increase the company's present fellowship program and establish one fellowship in each of Canada's 13 major universities; it will establish 40 scholarships, half of which will be restricted to study in the fields of geology, geophysics, mining, metallurgy and engineering; it will include a fund of about $150,000 for special projects.

Of special interest in this program, is the fact that each fellowship and scholarship awarded to an individual is accompanied by a grant of $500 to the institution in which the student is placed. Thus, in these instances, the gap between tuition fees and the actual cost of education is bridged.

The policy of the company has been expressed as follows: "Financial aid by Canadian corporations to education in this country is sound business policy. It is an investment by these corporations in their own future."

The proposal to give such a substantial amount direct to the universities must greatly encourage the university officials. It helps them meet the burden of increased enrolment, and it shows the appreciation of the employer, who after all is the one who absorbs about 90 per cent of their end product.

Contribution to Education

Recently on the death of one of the members of the Institute, his family requested that persons who wished to pay respect to his memory send contributions to the Education Fund of The Engineering Institute of Canada rather than to send flowers.

This is the first time that this thoughtful action has been taken, and both the Council of the Institute and the trustees of the fund are extremely grateful for the kindness and the thoughtfulness of the family.

At the present time the amount of money contributd to the Education Fund is approximately $250.00, and information has reached the Institute that further amounts are forthcoming. This is a substantial assistance in the accomplishment of the objectives of the Fund.

Would it be improper to suggest that similar action might be taken by the next of kin of other members of the Institute? Certainly there are few ways which money can be used to better advantage than in education, and indeed within the field of engineering there are few funds that are more worthy than this one of the Engineering Institute.

Incidentally, contributions made to this fund are deductible from income for tax purposes.

The Covered Bridge

Everyone who does much commercial flying will have expeprienced the unpleasantness of having to embark or disembark in a pouring rain. Usually it is a long way from the plane to the terminal building and particularly so in a rainstorm. The Lockheed Company have come up with something that may be the answer. At least it works now for freight transportation and it should not be difficult to adapt it to passenger needs.

The device is simply a long covered platform that can be wheeled up to the door of a plane at one end and to the passenger or freight terminal at the other.

This telescopic portable covered bridge has a maximum length of 84 feet. It is 10 feet wide inside with a height of 8 feet 6 inches. It is fitted with roller conveyors but tests are underway with powered rollers and powered belt. It is claimed that 18,000 pounds of cargo have been removed from a DC4 in less than 18 minutes, and the same amount loaded in 35 minutes. It is planned that the aerobridge will save at least one hour in turnaround time.

The bridge is being tested now at Travis Air Force Base in California, and a second unit is being installed at Tinker Air Force Base, Oklahoma where it will be tested and evaluated by the Air Materiel Command.

A view of the bridge may be seen in the photograph reproduced below.

The "covered bridge" developed by Lockheed Company for use at air terminal in bad weather.

THE CONTINUED EDUCATION OF THE GRADUATE ENGINEER

ASME-EIC Engineering Education Conference

UNIVERSITY OF WESTERN ONTARIO
LONDON, ONTARIO

OCTOBER 18-19, 1956

Session No. 1.	THE ENGINEERING TECHNICIAN
Moderator	DR. L. S. BEATTIE, Superintendent of Secondary Education, Province of Ontario.
Panel Members	KIMBALL C. CUMMINGS, Associate Director Aero Research, Minneapolis-Honeywell Co., Minneapolis. DR. H. H. KERR, Principal, Ryerson Institute of Technology, Toronto. KARL O. WERWATH, President, Milwaukee School of Engineering, Milwaukee. R. S. EADIE, Vice-President and General Manager, Eastern Division, Dominion Bridge Company Limited, Montreal.
Session No. 2.	THE PRODUCT OF THE ENGINEERING BACCALAUREATE CURRICULUM
Moderator	G. ROSS LORD, Head, Department of Mechanical Engineering, University of Toronto.
Panel Members	JOHN T. RETTALIATA, President, Illinois Institute of Technology Chicago. PROF. STUART LAUCHLAND, Head, Department of Engineering Science, University of Western Ontario. A. M. ANDERSON, Manager of Technical Education, General Electric Company, Schenectady. E. T. W. BAILEY, Combustion Engineer, Steel Company of Canada, Hamilton.
Dinner address	FUNDAMENTAL CONCEPT OF EDUCATION
Chairman	C. J. FREUND, Dean of Engineering, University of Detroit.
Address by	DR. G. E. HALL, President, University of Western Ontario.
Session No. 3.	TRAINING AND ORIENTATION OF THE GRADUATE ENGINEER ON THE JOB
Moderator	A. C. MONTEITH, Vice-President, Westinghouse Electric Corporation, Pittsburgh.,
Panel Members	C. A. PEACHEY, General Manager, Communications Equipment Division, Northern Electric Company, Montreal. JOHN GAMMELL, Director, Graduate Training, Allis Chalmers Mfg. Company Milwaukee, (General Machinery Divn.). M. J. J. MCAULIFFE, Superintendent of Graduate Training, Canadian Westinghouse Company, Hamilton. LEO. L. CASE, Chicago Blower Corporation, Detroit.
Session No. 4	AMPLIFYING THE BACCALAUREATE EDUCATION
Moderator	H. G. CONN, Dean of Engineering, Queen's University.
Panel Members	CORNELIUS WANDMACHER, Head, Department of Civil Engineering, University of Cincinnati. DR. B. B. HILLARY, Research Co-ordinator, Dow Chemical Company, Sarnia. R. E. JAMIESON, Dean of Engineering, McGill University. F. E. VERDIN, Management Consultant, Cleveland.
Session No. 5.	FORMAL GRADUATE STUDY
Moderator	NEWMAN A. HALL, Professor of Mechanical Engineering, Yale University, New Haven.
Panel Members	DR. MORRIS KATZ, Occupational Health Division, Department of Health and Welfare, Ottawa. WARREN C. STOKER, Director, Graduate Centre, Rensselaer Polytechnic Institute, Hartford. D. S. SIMMONS, General Manager, Manufacturing, (Refining and Engineering), Imperial Oil, Toronto. SYDNEY B. INGRAM, Director, Education and Training, Bell Laboratories, New York.
Dinner address	MEETING THE SHORTAGE OF ENGINEERS AND SCIENTISTS
Chairman	VERNON A. MCKILLOP, President, The Engineering Institute of Canada, General Manager, London Public Utilities Commission.
Speaker	DR. JOSEPH W. BARKER, President, American Society of Mechanical Engineers, President, Research Corporation, New York.

New Trustee for the Education Fund

Dr. Otto Holden, M.E.I.C. assistant general manager of the Hydro-Electric Power Commission of Ontario recently has been appointed by Council as a trustee administering the Harry F. Bennett Education Fund of the Engineering Institute of Canada.

Dr. Holden is replacing V. A. McKillop, M.E.I.C., the president of the Institute, who for many years has acted on the board. It is the policy of Council to change the trustees from time to time on the basis of a three-year term of service for each.

The Education Fund was established in 1946 by the Institute in memory of the late Harry F. Bennett, former chairman of the Committee on the Training and Welfare of the Young Engineer, and past-chairman of three different branches of the Institute. It is administered by three trustees who have full control as to the disposition of the monies.

The other trustees who will act with Dr. Holden are Dr. I. R. Tait, M.E.I.C., of the Canadian Industries Limited, Montreal, and Mr. Hugh C. Nourse, M.E.I.C., of the Bell Telephone Company, Montreal.

At the end of 1955 the fund totalled $33,000.00. Within the last year the activities have increased greatly, in the form of loans to worthy engineering students. In 1955 loans amounted to $6,400.00 and at the end of that year there were seventy-nine loans outstanding.

The fund was quite active early in 1956 but in view of the fact that the greatest number of requests for assistance come in the fall of the year, there are no significant figures to present for this year so far.

The increasing use of the fund is proving the wisdom of having established it many years ago. Seventy-nine students are today benefiting from the fact that money can be secured from the Institute in this way. It is expected that the number will increase substantially within another year's time.

Donations to the fund are deductible from income for tax purposes and members are asked to keep this worthy cause in mind when they wish to do something helpful for the young engineer and for education.

ASME-EIC Engineering Education Conference

The Engineering Institute is taking part, with the American Society of Mechanical Engineers in a second Engineering Education Conference, this time at the University of Western Ontario, London, Ontario, October 18-19, 1956.

The first such meeting was two years ago at Clarkson College of Technology, Potsdam, N.Y., and our members will recall that then the matter under discussion was "Trends in Mechanical Engineering Education".

This year the theme is "The Continuing Education of the Graduate Engineer". The general purpose of the conference is to dramatize the vital importance of the continuing education of the graduate engineer in its various phases, to clarify the responsibility of the engineer, the employer, and the engineering school and to report successful methods.

Because of the importance of the engineering technician in amplifying the usefulness of the graduate engineer and the need for developing this usefulness, the opening panel session is devoted to this subject.

Because of limited accommodation, attendance at these meetings must be by invitation, only. However it is planned that there will be a full report in *The Engineering Journal* for the benefit of our members who are unable to participate.

The program of the meeting appearing on the opposite page will demonstrate the importance of this meeting.

Nominees for Office

The report of the Nominating Committee, as accepted by Council at the meeting held on September 5th, 1956, is published for the information of all corporate members as required by Sections 19 and 40 of the by-laws:

President	C. M. Anson	Sydney, N.S.
Vice-Presidents		
*Zone A (Western Provinces)	S. C. Montgomery	Trail, B.C.
*Zone B (Province of Ontario)	W. J. Ripley	Copper Cliff, Ont.
*Zone C (Province of Quebec)	Albert Deschamps	Montreal, Que.
Councillors		
†Yukon Branch	John L. Phelps	Whitehorse, Y.T.
†Vancouver Island Branch	P. F. Fairfull	Victoria
†Vancouver	W. O. Richmond	Vancouver
†Central British Columbia	M. L. Wade	Kamloops
†Kootenay	W. K. Gwyer	Trail
†Edmonton	R. N. McManus	Edmonton
†Saskatchewan	W. L. Sharpe	Weyburn
†Winnipeg	W. D. Hurst	Winnipeg
†Lakehead	E. T. Charnock	Fort William
†Sudbury	F. A. Orange	Sudbury
†Nipissing & Upper Ottawa	R. R. Prescott	Temiskaming
†Border Cities	P. S. Dewar	Windsor
	R. J. Trinder	Windsor
†London	G. E. Humphries	London
†Port Hope	R. C. Wilson	Port Hope
†Belleville	S. Sillitoe	Belleville
†Kingston	C. H. R. Campling	Kingston
†Brockville	J. S. Waddington	Brockville
†Ottawa	W. B. Pennock	Ottawa
‡Toronto	K. F. Tupper	Toronto
§Montreal	E. D. Gray-Donald	Montreal
	J. H. Budden	Montreal
	R. B. Winsor	Montreal
†Saguenay	A. B. Sinclair	Kenogami
†Lower St. Lawrence	L. P. Dancose	Mont Joli
†St. Maurice Valley	W. G. Seline	Three Rivers
†Eastern Townships	G. J. Cote	Sherbrooke
†Corner Brook	Ernest Leja	Corner Brook
†Newfoundland	William Watson	St. John's
†Prince Edward Island	W. S. Veale	Charlottetown
†Amherst	A. G. Baxter	Amherst
†Halifax	W. A. Devereaux	Halifax
†Fredericton	S. B. Cassidy	Fredericton
†Saint John	A. G. Watt	Saint John

* One vice-president to be elected for two years
† One councillor to be elected for two years.
‡ One councillor to be elected for three years
§ Three councillors to be elected for three years each.

THIRTY-FIVE YEARS AGO

Comment on the Journal of October 1921

A policeman's lot may not be a happy one, but neither is that of the editor of a society journal. Ideally, he should follow the policy of his directors to the line; publish only what his readers want and nothing else, turn down authors whose offerings are unacceptable so gracefully they will feel honoured by his rejection and keep the content of his magazine such that his advertising manager can fill the pages allotted to him without stirring from his chair. Moreover, such an editor must depend almost entirely for his material upon that submitted by the members of his society.

It goes without saying that this ideal editor never has existed and does not and never will exist. Judging by any standard, the best would not have a batting average of more than about five hundred, which may be high in the big leagues, but is not too good here.

One of the greatest difficulties in publishing a society journal is to get enough suitable material to give each issue that plump and satisfying look which betokens the prosperity of its sponsors. Of course, the larger the society, the easier this task becomes.

The Institute of 1921 had about 4,000 members, today it has some 17,000. The difference shows up in the *Journal*. That for October, 1921, contained three technical papers totalling sixteen pages; the July, 1955, issue, which happens to be lying before me, has six papers occupying forty-three pages. The 1921 *Journal* could say all it wanted to editorially in three and a half pages, but it took the editor of 1955 about twelve pages to unburden himself. Only twenty-one members received personal mention in 1921 as against about a hundred in 1955. The employment service had four *items* then; today it occupies half as many again *pages*.

The Engineering Index disappeared from the *Journal* long ago, but in its place it now carries regular features unknown in 1921—abstracts of current literature; Month to Month; news of the professional associations and of the Corporation; library notes; business and industrial briefs; and, of course, these recollections of thirty-five years ago! Some of these features would probably have been added to the *Journal* in any event, but it should not be overlooked that a large part of whatever improvement it has been possible to make in the *Journal* in recent years has been made possible by an increase in its income from advertising. Not only has the volume of advertising increased, but so have rates, and yet they are not excessive for a magazine of the *Journal's* character and coverage.

But I seem to have got somewhat off the track. I set out to see what the *Journal* of October, 1921, was saying and I find I have in effect been telling you that the good old times were not so good as the good new times.

Study of Corrosion

The intense interest in 1921 in the effect of alkali soils on concrete led to a parallel interest in their effect on metals. In Winnipeg the corrosion of cast iron pipe had led to the suspicion that electrolysis was at work. But much of the damage had occurred in areas where there was no possibility of electrolysis.

W. Nelson Smith, M.E.I.C., and Dr. J. W. Shipley had conducted a long series of experiements to determine the effect of various metallic salts on cast iron and reported their results in this *Journal*. They arrived at certain conclusions:

"The corrosion of cast iron by salt solutions . . . in natural soils is readily accomplished . . . without access of stray current . . . Magnesium salts are the most corrosive . . . and magnesium sulphate . . . is the most . . . (active)."

They had a low opinion of the protective coatings then in use . . . "The treatments with tar, dips and paints have generally . . . proved futile . . . The life of cast iron pipe in a wet, salty soil could (probably) be lengthened . . . by backfilling the trench with quartz sand or washed gravel . . ."

While there is no absolutely certain method even yet for protecting buried cast iron or steel pipe from corrosion, coatings have been developed by the designers and builders of our long gas and oil pipe lines which are pretty efficient, so corrosion is no longer the great bugbear it once was.

Western Irrigation Schemes

In 1921, the west's eyes were on irrigation, so that a paper describing the various schemes then completed, under construction or contemplated, by G. M. Houston, M.E.I.C., was timely. Sixteen of the principal schemes in Alberta and Saskatchewan were shown on a map accompanying the paper. They ranged from the Lethbridge Southeastern Project of half a million acres, down to the Little Bow Project of a mere 3,000, and totalled 1,760,000 acres, not including one which had not yet been surveyed. Mr. Houston had no doubts of the results of irrigation: "Irrigation has only just started in the prairie provinces and if the schemes now projected proceed to completion and are operated successfully, southern Alberta and Saskatchewan will be the garden spot of the Dominion."

Roads Committee

The October, 1921, *Journal* announced the appointment by Council of a "Roads and Pavements Committee" of nineteen members, most of them connected with the provincial highway departments or with the larger cities. There was no hint as to what the committee was supposed to do, but it "has its work well in hand so that definite results may be expected in the near future."

Employment

Unemployment among engineers was becoming a problem, which moved the editor to say: "To those who are fortunate enough to be . . . secured in their positions an opportunity is presented to demonstrate that there is a faternal spirit . . . among members of the profession . . . Letting a man out (now) is almost equivalent to condemning him to unemployment . . . for . . . months; . . . it is practically impossible for an engineer . . . to secure a position. Would it not be well for those who influence engineering positions to make a special effort to hold their men . . . even though it (means) a temporary reduction in pay?"

I suppose the fact that there was nothing to excite one in this issue of the *Journal* is evidence that the Institute's affairs were running smoothly, but such placidity does not make for the interest one finds in other *Journals* where there were sometimes rather hot arguments to report.

R. DeL. F.

Professional Standards and Employment

A report recently issued by the Engineers Joint Council entitled "Professional Standards and Employment Conditions", was finally adopted only after review by the E.J.C. executive committee and a special task committee, and after approval by the board of directors.

It was, therefore, not the work or view of one individual and perhaps everyone will find some part of it with which he does not fully agree. It does, however, represent a significant appraisal of employment factors which deserve attention.

Emphasizing that "there is no simple solution" toward raising professional standards or improving employment conditions of engineers, the report makes seven recommendations (that):

1. Management utilize the services of engineers more effectively and thereby afford them the opportunity for advancement and economic improvement.
2. Management recognize its responsibility to make engineers feel that they are a part of management.
3. Management survey areas of communication, recognition, and salaries and, where found wanting, correct to conform with standards of professional practice.
4. The engineer takes inventory of his services and his actions to make sure that he has a professional attitude toward his work.
5. Engineering societies establish and employ appropriate means to maintain high standards of ethical conduct for professional achievement.
6. Engineering societies encourage the professional development of their members and promote proper recognition of the profession.
7. Engineering educators emphasize the characteristics of the profession.

The E.J.C. board of directors endorsed these recommendations and strongly urged the constituent societies to examine the entire study carefully. Copies of the report may be obtained without charge from: The Engineers Joint Council, 29 West 39th St., New York 18, N.Y.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Major W. E. Blue, M.E.I.C., retired Gatineau Power official, of Ottawa, died in that city during August, 1956.

Born in Toronto on February 27, 1889, he followed his engineering studies at the Royal Military College, Kingston, Ont., and graduated with a diploma in 1910. Before the beginning of World War I, he had three years' experience as an engineer in charge of various surveys and river metering for the Department of Public Works, mainly on the Ottawa and St. Lawrence rivers.

A concrete inspector on the Chaudiere dam, Ottawa, while a student in 1908, he was resident engineer for the Department of Public Works on the Chaudiere dam at Lake Nipissing, late in 1913 and until the early part of 1914.

At this point in his career he joined the Canadian Expeditionary Force, Canadian Field Artillery, commanding a field battery overseas, and was for a time adjutant of the brigade. For his service he was awarded a D.S.O.

By June 1919 he had once again taken up duties with the Department of Public Works, Ottawa, as an assistant engineer. In 1922 he was associated with the Riordin Pulp Corporation Limited. Within the next few years, in 1926, he joined the Gatineau Power Company in Ottawa, where he became manager of the development department, a position he retained for many years. He retired in 1954.

Long associated with the Institute, Major Blue was granted Life Membership in 1955. He was a Student Member in 1910, a Junior in 1913, transferred to Associate Member in 1919 and to Member in 1940.

H. G. Bertram, M.E.I.C., for many years president and general manager of John Bertram and Sons Company Limited, Dundas, Ont, died suddenly on June 16, 1956, in Dundas.

Born there on May 9, 1886, he was educated in Dundas public and high schools and in 1910 graduated with a bachelor of science degree from Queen's University.

Mr. Bertram's professional career began in Costa Rica and Mexico, where he did construction work and was assistant engineer with the Mexican N.W. Railway, shortly after graduation. In 1913, once again in Canada, he joined the firm of John Bertram and Sons Company Limited as a shop engineer. Five years later he was plant engineer and superintendent of the shell shop, concerned with the design of machine tools. He progressed to executive posts, becoming general manager in 1926.

He was named secretary and treasurer of Pratt and Whitney Company of Canada Limited in 1928 and 1931 was vice-president and general manager of his firm, John Bertram and Sons and of Pratt and Whitney. He received his appointment of president of the latter organization in 1943, and retired from business in 1951.

Enjoying a far-reaching career in matters relating to engineering, Mr. Bertram had been a member of the executive of the Canadian Manufacturers' Association. In 1939 he assured the British premier, along with J. G. Morrow of Hamilton, in a conference, of Canada's industrial co-operation in the event of hostilities. During his stay in England, at the time, he interviewed the authorities in the war office and had the foresight to bring considerable technical information regarding the manufacture of guns which previously had never been made in Canada. He secured designs for gun boring and rifling machines which speeded production at the local plant in Dundas.

He was also on the advisory board of the Royal Trust Company and retired last December as a director of the Equitable Life Insurance Company. For many years he served on the University Council and Trustee Board of Queen's University, and it was there that he was awarded an honorary LL.D. degree in 1947. At the time of his death he was a member of the Board of Governors of Hamilton College.

Members of the Institute may recall the late Sir Alex Bertram, treasurer of the Institute from 1919 to 1926, whose nephew Mr. H. G. Bertram was.

Mr. Bertram joined the Institute in 1920 as a Member, and was granted Life Membership on Jan. 1, 1956.

William John Dyne, M.E.I.C., of Deep River, Ont., died on May 2, 1955.

Born at Maesteg, Glamorganshire, South Wales, on April 6, 1926, he studied engineering at Loughborough College., Leicestershire, Eng., and was graduated in 1946 with a diploma in mechanical engineering.

He served a two year period with the Royal Engineers, work services branch, from 1947 to 1948, as a second lieutenant. Employed with a power station in Surrey, Eng., from 1948 to 1950, he later gained experience with the British Coal Utilization Research Association as an assistant research engineer, and with the British Oxygen Company.

Resident in Canada in 1952, he became an assistant engineer with the Canadian Western Natural Gas Company at Calgary. Most recently Mr. Dyne was an assistant research officer with Atomic Energy of Canada Limited, at Chalk River, Ont.

He joined the Institute in 1953 as a Member.

ONTARIO

Instructor Teacher Shortage
An editorial reprinted from the Bulletin of the Association of Professional Engineers of Ontario.

We read and hear much about shortages of various kinds — shortages of basic commodities, shortages of engineers, and anticipated shortages of facilities for educating engineers and technicians during the next decade or longer.

All are of concern to our profession, but one which merits particular consideration is the existing and continuing shortage of teachers and instructors in the field of engineering. For many months we have been facing what President Sidney Smith of the University of Toronto calls the "crisis of numbers". He and many other educators qualified to know point to the rapid and unprecedented increase in Canadian youth reaching the age of eighteen in the years just ahead of us. This situation needs no detailed blueprint to make us appreciate the problem of the engineering faculties and technical institutes. Even with today's enrolment the scarcity of instructors is all around us. Tomorrow's problems will be many times greater and more urgent.

The role of the teacher is an old and honourable one and if service is one of the distinguishing badges of a profession, teaching is indeed a profession of a high order. It is more than gratifying to see the grass roots growth of educational programs within industry. It is a pleasing indication of awareness of the problem we are facing and practical evidence of a willingness to come to grips with the problem.

A number of our profession have directed their life work to teaching in our secondary schools, in our technical institutes and in our universities. Others are contributing of their spare time to the same work in their plant or in more formal places of learning. It is hoped that others of our members will sense the need and be guided by the direction of their conscience. We all are not blessed with those special gifts that make an outstanding instructor but in the emergency many of us may acquire some of the teaching technique which will help. Age, too, need be no barrier in making a needed and worthwhile contribution.

BRITISH COLUMBIA

Engineers in the News

J. P. Hague, has been appointed senior location engineer with the Department of Highways in Victoria. He had previously held the position of maintenance engineer in the Department.

S. K. Thorneycroft, of Crown Zellerbach (Canada) Limited, was recently transferred from Ocean Falls to the Company's central engineering office in Vancouver as paper mill engineer.

G. D. Trethewey, research chemical engineer with Alaska Pine and Cellulose Limited, has been transferred from woodfibre to the research division in Vancouver.

E. E. Olson, a 1952 civil graduate of U.B.C., has returned from California to accept an engineering position with the City of Nelson.

P. S. Herring, city engineer of Kamloops, recently accepted a position with the engineering department, city of Vancouver. He will be assistant to the engineer in charge of operations.

W. G. Edward, a 1949 mechanical graduate of U.B.C. is now assistant chief engineer, Lumber Division, Potlatch Forest Inc., Lewiston, Idaho.

R. A. De Bou, formerly with the Shell Oil Company has joined the staff of H. H. Minshall and Associates.

I. R. Corey, of the Consolidated Mining and Smelting Company at Tulsequah, B.C. has sent word that he is leaving for Ireland where he will be with the St. Patrick's Copper Mines Limited, Avoca, County Wicklow.

H. M. Matson, is now in Lima, Peru, as chief construction engineer for the Utah Construction Company and Morrison-Knudsen Joint Venture and engaged on the Toquepala Development for the Southern Peru Copper Company.

Municipal Engineers' Convention

The annual convention of the Municipal Engineers' Division of the Association of Professional Engineers of B.C. took place in Penticton from September 20 to 22.

The program included a pre-convention annual meeting of the Municipal Supplier's Association.

The main topics of technical discussion were:

Frost Damage, treated by a panel of speakers consisting of C. P. Harford, city engineer, Prince George; R. C. Thurber, materials engineer, Department of Highways, Victoria; and D. McMullen, Meteorological Services, Department of Transport, Vancouver.

Services of the Provincial Water Rights Branch, discussed by W. A. Ker, Deputy Comptroller of Chief Operations Division, Water Rights Branch, Victoria.

Foundations and Soil Mechanics, a paper by R. M. Hardy, Dean of Engineering, University of Alberta, Edmonton.

Traffic Problems, a paper presented by F. R. Hole, of the City of Vancouver.

R. P. Walrod, of B.C. Tree Fruits Ltd., was the guest speaker at the annual banquet

and the Associations of Professional Engineers
of New Brunswick, Nova Scotia, Prince Edward Island
and Newfoundland

Personals

News of the Personal Activities of Members of the Institute.

Prof. E. A. Allcut, M.E.I.C., head of the department of mechanical engineering at the University of Toronto retired recently with the title of professor emeritus.

Prof. E. A. Allcut, M.E.I.C.

Named to the staff of the university in 1921 as an associate professor of mechanical engineering, he has served in the capacity of professor since 1931.

Originally from England, Prof. Allcut graduated from the University of Birmingham with an M.Sc. degree in engineering in 1909 and gained eleven years industrial experience in Great Britain.

Prof. Allcut has been associated with a number of professional groups in whose interests he has served widely. He became a member of the Royal Aeronautical Society in 1939, and was named president of the Affiliated Engineering Societies of Ontario in 1946.

He is a Fellow of the American Society of Mechanical Engineers, a member of the A.S.M.E. Power Test Codes Committee, and a member and past chairman of the Ontario Section of the Society. He is a chairman of the Canadian Advisory Committee of the Institute of Mechanical Engineers.

He has also served the National Research Council on various committees.

In 1955 Professor Allcut became chairman of the newly formed Canadian Standards Association committee, on Air Pollution Control. He is chairman of the Air Pollution Board of Toronto, has served as chairman of the E.I.C. Committee on Air Pollution Control and as a member of the committee on Air Pollution Control of the American Society of Mechanical Engineers. Last year he was appointed a member of the Industrial Design Council for a two-year period.

Winner of a number of awards during thirty-five years work in the profession in Canada, Dr. Allcut received the Duggan Medal and Prize of the E.I.C. in 1952; the Plumber and Gzowski Medals of the Engineering Institute in 1943 and 1947 respectively; and the Herbert Akroyd Stuart prize of the Institution of Mechanical Engineers in 1930.

Professor Allcut is the author of the following books; Materials and Their Application to Engineering Design; Engineering Inspection; An Introduction to Heat Engines, Principles of Industrial Management, and many technical articles and papers.

John C. Hamilton, M.E.I.C., has been named vice-president, manufacturing, of Canadian Resins and Chemicals Limited, Montreal.

Works manager of the company's plants at Shawinigan Falls and Ste. Therese, Que., since last October, he was previously general superintendent of plants. Mr. Hamilton joined Canadian Resins in 1943 and, prior to becoming general superintendent in 1953, was successively plant production supervisor and production superintendent.

Douglas G. Darling, M.E.I.C., has been appointed president and general manager of the Wayne Forge and Machine Company Limited, Toronto

A graduate in mechanical engineering with an M.A.Sc. degree from the University of Toronto, Mr. Darling was, until his new appointment, chief engineer of the Toronto Brick Company Limited.

He is a past chairman of the Ontario Section of the American Society of Mechanical Engineers, and a member of the Association of Professional Engineers of Ontario.

D. G. Darling, M.E.I.C.

Dr. George Sinclair, M.E.I.C., associate professor of electrical engineering at the University of Toronto has been promoted to the rank of professor.

Dr. Sinclair received his Ph.D. degree from Ohio State University in 1946, following the degree of M.Sc., in electrical engineering, obtained at the University of Alberta, during the thirties.

In 1954 he was named a Fellow of the Institute of Radio Engineers, following extensive work in that field. During World War II Dr. Sinclair had been director of the antenna laboratory of Ohio State University and was consequently awarded a certificate of appreciation by the United States War Department. Later he became president of Sinclair Radio Laboratories Limited while carrying on the duties of associate professor.

J. A. Stewart, M.E.I.C., has been appointed general manager and a director of Creswell Pomeroy Limited. Mr. Stewart served seven years with Cresswell Pomeroy Limited, from 1946 to 1953, as contracts manager and subsequently as plant manager. During the last three years he was manager, sales and engineering, with Walter Kidde Company Limited.

A graduate of Queen's University, Mr.

J. A. Stewart, M.E.I.C.

Stewart's early affiliations were with Ford Motor Company of Canada and the International Nickel Company of Canada Limited. He also served with the R.C.E.M.E. overseas during World War II.

W. A. MacDonald, M.E.I.C., of Sydney, N.S., has been appointed manager of the Seaboard Power Corporation Limited.

Mr. MacDonald began his career in 1929 with the Northern Electric Company in Montreal, and went later to the Provincial Highways Department of Nova Scotia. In 1934 he joined Dominion Steel and Coal Corporation, Sydney, as an assistant to the chief electrical engineer, carrying out field and construction work. He was appointed field engineer in 1942 and was associated with engineering and construction of the more recent units added Seaboard's expanding facilities. The company supplies electrical energy for industrial and domestic purposes in Cape Breton.

Leon R. Marsh, M.E.I.C., formerly sales manager with Lion Equipment and Supplies Company Limited in Montreal holds the position of regional export manager (Canada), for Stork Werkspoor, the Dutch V.M.F. group of companies, engaged in the manufacture of heavy industrial and marine equipment.

Mr. Marsh received an M.A. degree from Cambridge University in 1952.

Jacques Gariepy, M.E.I.C., has recently been appointed chief engineer, Marine Industries Limited, heating division, at Montreal.

Mr. Gariepy graduated as a civil engineer at the Ecole Polytechnique, in 1946. The same year he was awarded the degree of bachelor of applied science from the University of Montreal.

Formerly a field engineer and assistant superintendent of construction, with Canadian Celanese, he has also served as supervisor of the construction of French trawlers and cargo ships for Marine Industries Limited. In 1948 he joined the heating division of the organization and since that time has taken on the responsibilities of selling, supervision and installation. His present promotion will put Mr. Gariepy in charge of all engineering requirements for the heating division.

Fernand Dugal, M.E.I.C., has been appointed chief engineer of the shops and transportation department of the Quebec Hydro-Electric Commission.

Educated at McGill University he received a degree in mechanical engineering in 1939. Prior to joining Hydro-Quebec in 1949 as assistant chief engineer of the department he now heads, he was associated with Canadian Car and Foundry. He has served as technical adviser and field engineer with Canadian Associated Aircraft, as technical officer of the Royal Air Force Transport Command at Dorval, Que., and as consulting engineer and works manager of Cartier Industries Limited. He has also worked with Montreal Locomotive Works and American Locomotive at Schenectady, N.Y.

M. M. Davis, M.E.I.C., a member of the staff of the Department of Highways, Province of Ontario, until recently, has received the appointment of assistant professor of civil engineering at the University of Toronto.

A Queen's University graduate, class of 1945, Mr. Davis has been with the Department of Highways since 1947, apart from a year devoted to further study. He obtained an M.Sc. degree in civil engineering from Purdue University in 1949.

P. A. Soicher, M.E.I.C., associated with Dominion Engineering Company Limited, Montreal, since 1946, and at the time of his present appointment serving as project engineer for propellor turbines and pumps, has been named sales manager for the hydraulic division of the firm.

Mr. Soicher received a B.Eng. degree

F. Dugal, M.E.I.C.

from McGill University in 1940 and the following year was awarded an M.Sc. degree from the University of Michigan.

H. Lillie, M.E.I.C., of Vancouver, has joined the J. Muirhead Association in that city, and will eventually take over the firm when the founder, J. Muirhead, consulting engineer, goes into his announced retirement.

Previously managing director of the Alliance Engineering Company Limited in Vancouver, Mr. Lillie has also been associated with the Ford Motor Company Limited in Windsor, Ont., as an electrical engineer and with Bepco Canada Limited, in Montreal. Mr. Lillie came to this country from Great Britain as representative to the latter concern for Bruce Peebles and Company Limited of Edinburgh.

Mr. Lillie had his education in Scotland, graduating from the Royal Technical College, Glasgow.

James W. Kerr, M.E.I.C., has been elected a vice-president of the Canadian Westinghouse Company Limited.

With the firm since the outset of his career, Mr. Kerr, a graduate of the Uni-

J. Gariepy, M.E.I.C.

P. A. Soicher, M.E.I.C.

J. W. Kerr, M.E.I.C.

versity of Toronto, class of 1937, enrolled in the Canadian Westinghouse graduate engineering course before starting on a career as a sales engineer in the Toronto district. Later he served overseas with the R.C.A.F. and at the close of World War II was discharged with the rank of squadron leader.

Again active in the company he was within a short time manager of transformer sales, assistant manager, central station sales, and then manager. In 1949 Mr. Kerr became manager of apparatus sales and, three years later, manager of power products division.

He is now in charge of the apparatus products group which includes the power products division, the defence apparatus division and the district apparatus division.

S. B. Moro, M.E.I.C., of the Shell Oil Company of Canada has been transferred from the Montreal refinery to Vancouver's Shellburn refinery. Now chief engineer, he moves up from the position of assistant chief engineer which he held at his eastern post.

Mr. Moro has been with the Shell Oil Company since his graduation from Queen's University in 1945, progressing from general engineering duties to the posts of preventive maintenance engineer, project engineer, plant engineer and chief inspector, all at Montreal.

A. Sandilands, M.E.I.C., western regional manager of Phillips Electrical Company Limited in Winnipeg, was recently named sales manager with the firm's head office at Brockville, Ont.

A 'Personal' on his appointment appeared in the September issue.

D. E. Haig, M.E.I.C., of Phillips Electrical Company Limited, formerly sales engineer for the West, has been named manager of the western region. He is responsible for sales in Saskatchewan, Manitoba and North western Ontario, with headquarters located in Winnipeg.

Earlier a power sales engineer with the City of Winnipeg hydro-electric system in Winnipeg, Mr. Haig is an electrical engineering graduate of the University of Manitoba, class of 1944.

P. E. Peele, M.E.I.C., of the Canadian General Electric Company, apparatus department in Toronto, has been transferred to Peterborough, Ont. where he will be concerned with the motor and generator department of the company.

His entire career spent with the General Electric Company, Mr. Peele gained his early experience at the Peterborough plant. Since then he has held a number of company positions which include those of sales engineer in Vancouver and Calgary which latter position he held for many years. He was manager of the apparatus division of the firm in Calgary in 1947 and by 1953 was locomotive and car equipment sales manager in Toronto.

Mr. Peele was chairman of the Calgary Branch of the Institute in 1945, secretary-treasurer in 1940 and 1941.

Brig. **Murray Dillon**, M.E.I.C., president of M. M. Dillon and Company Limited, consulting engineers of London, Ont., and Toronto, has announced the formation of an organization known as Allied Consultants of Canada Limited.

The company, with head office in Toronto, is comprised of three firms of consulting engineers, Canadian, British and American. Names of the companies involved are, M. M. Dillon and Company Limited of London, Ont., and Toronto; Sir William Halcrow and Partners of London, Eng.; and Edwards, Kelsey and Beck, of New York, N.Y.

The president of Allied Consultants, Brig. Dillon has been a well-known consulting structural engineer in Canada for many years. Known before World War II for his work in the design of important buildings in London, Ont., he has since 1946 maintained the present company.

Brig. Dillon saw extensive service in both wars, won the Military Cross during the first conflict and was active in Canadian military circles in peacetime.

Vice-presidents of the firm are **H. D. Morgan**, London, Eng., and **L. T. Beck**, M.E.I.C., of Edwards, Kelsey and Beck, consulting engineers of New York.

Directors are **V. A. M. Robertson**, M.E.I.C., of the British firm; **G. E. Humphries**, M.E.I.C., senior partner in the firm of M. M. Dillon and Company Limited who has been in partnership with Brig. Dillion since the end of World War II; **D. E. Edwards**, M.E.I.C., of the New York firm; and **L. W. Brockington**, Q. C., of Toronto, Ont.

Appointed secretary-treasurer is **R. A. Crysler**, M.E.I.C., director and manager of the Toronto office of M. M. Dillon and Company Limited. Mr Crysler became professionally associated with Brig. Dillon in 1953, after twenty-one years with the Canada Cement Company.

R. E. Williams, M.E.I.C., is chief engineer for the E. G. M Cape Company, builders and contractors, at Fort William, Ont, on the mill expansion being undertaken by Great Lakes Paper Company at that centre.

Within the last few years Mr. Williams has been affiliated with several firms which include the Thompson Construction Company Limited, at Galt, Ont., the Canadian Comstock Company Limited, at Montreal, and the Canadian Paper Company.

R. M. Coons, M.E.I.C., has left the Lloydminster Development Company, where he was vice-president in charge of operations, and is a consultant and permanent member of the Saskatchewan Conservation Board.

Mr. Coons has worked as a consultant for five years under the name Edmunds, Coons and Akehurst, at Lloydminster, Sask., and has also been associated with Excelsior Refineries.

He is a geological engineering graduate of the University of Saskatchewan.

David H. Johnston, M.E.I.C., has been appointed manager of the engineering

A. Sandilands, M.E.I.C.

D. E. Haig, M.E.I.C.

D. H. Johnston, M.E.I.C.

department of the Electrohome Products division of the Dominion Electrohome Industries, Kitchener, Ont.

Formerly associated with the Canadian General Electric Company Limited electronics division in Toronto, he became manager, manufacturing section, of the firm's electronic equipment department, in 1954.

Mr. Johnson is an electrical engineering graduate of Queen's University, class of 1941.

J. P. Leroux, M.E.I.C., of Montreal is an engineer with the National Harbours Board.

Mr. Leroux who has spent seventeen years in government service, started in the civil aviation branch of the Department of Transport in Montreal in 1940. Later he saw three years service with the R.C.E. overseas but returned to the Department to resume his work in the field of civil aviation.

In 1948 he transferred to the marine services branch of The Department of Transport serving as an assistant in the Montreal district office and as district engineer at Sorel, Que. and remained in that work until his present appointment.

Mr. Leroux graduated from the Ecole Polytechnique in the class of 1939.

W. L. Lindberg, M.E.I.C., of Edmonton was appointed in June, manager for H. F. Clarke Limited, a heating and control equipment firm, in that city.

Prior to his recent appointment Mr. Lindberg was associated with M. C. Minton Company Limited and Lockerbie and Hole Western Limited, also in Edmonton.

He is a 1949 graduate of the University of Alberta in mining engineering.

P. G. Campbell, M.E.I.C., an Ontario Hydro-Electric Power Commission employee for a number of years, formerly project manager of the Manitou Falls development of the organization, now serves the firm as a construction engineer-generation, in Toronto

B. L. Phomin, M.E.I.C., of Toronto is a resident engineer with the St. Lawrence Seaway Authority at Montreal.

Mr Phomin was formerly associated with the Department of Public Works in Toronto which he joined in 1946 on discharge from the R.C.E.

He graduated from the University of Manitoba in 1938 and gained his initial engineering experience with Dominion Bridge Company, Winnipeg.

Reside McCallum, M.E.I.C., is with the communications equipment division of the Northern Electric Company, Montreal. He is assistant superintendent, of test facilities.

He has recently returned to the manufacturing engineering department. For the past three years he was concerned with production, as assistant superintendent, manual and toll equipment.

J. Douglas Campbell, M.E.I.C., has accepted the appointment of general manager with Guelph Sand and Gravel Limited, at Guelph, Ont.

Employed with the Steel Company of Canada Limited in Hamilton from 1942 to 1945 he became manager of Chemical Lime Limited at Beachville, Ont., in 1945.

H. W. Willcock, M.E.I.C., is with the Halifax office of Defence Construction (1951) Limited

Mr. Willcock was previously associated with the Central Mortgage and Housing Corporation in that city as office engineer.

F. W. Iveson, M.E.I.C., has joined the staff of the Foundation of Canada Engineering Corporation Limited, in Montreal.

He was formerly with Giffels and Vallet, Windsor, Ont.

Elmore G. Gagnon, M.E.I.C., of the Northern Electric Company Limited, in Montreal, has been named contract services manager for the telephone contract division.

In 1952 Mr. Gagnon received the appointment of manager, following that of chief engineer of the communications

FOR BETTER RESULTS WITH LESS TROUBLE ...PICK ONE INSTEAD OF TWO

1½" or 2" Style 3 Meter matches performance of complicated compound ... with less cost and fuss

For 1½" and 2" water service lines, the Trident Style 3 meter is simpler, costs less to buy and maintain, is every bit as accurate, and produces just as much revenue over a wide range of flows as any compound, including our own. Trident was *first* to give you an easy-to-set pressure adjustment. And since modern Style 3 parts fit older meters, there's never any obsolescence.

So why put up with the fuss and expense of *two* measuring units when *one* Style 3 will do the job? You'll find conclusive evidence in your own records . . . or ask your Neptune man.

NEPTUNE METERS LIMITED

equipment division which he held for five years.

P. L. Brisson, M.E.I.C., of Montreal, is working with the firm of Brett and Ouelette, consulting engineers in that city.

Practicing engineering in Canada since 1951 Mr. Brisson came to this country from France where he had worked since graduation in civil engineering from the Ecole Centrale de Paris in 1935. Gaining experience in various fields of engineering, his last position in France was that of repair depot chief.

In Canada Mr. Brisson has been associated with the Standard Construction Company Limited as a design engineer and with Canadian Arsenals Limited, explosives Division, at Valleyfield, Que.

K. H. Wheatley, M.E.I.C., who was at work with Defence Construction Limited, Halifax, N.S., earlier this year, has moved to Oceanside, Calif, where he is employed with D. F. Dresselhaus, a consulting engineer, in that city.

Mr. Wheatley is a graduate of the University of Sydney, Australia, class of 1952.

Bruce Wm. Hamer, M.E.I.C., is with the Department of Fisheries, Ottawa, following a transfer from the Prince Rupert office where he held the position of district engineer.

Mr. Hamer has at an earlier period of his career been engaged in engineering in Ottawa. In 1954 he was with the City of Ottawa as resident engineer.

A mining engineering graduate from the Nova Scotia Technical School he obtained the degree B.Eng. in 1939.

James S. C. Dunn, M.E.I.C., has taken up employment with the Standard Oil Company of British Columbia Limited as technical service engineer in Vancouver.

He was formerly associated with Canadian Industries Limited, polythene division, in Edmonton, as a technical assistant in 1954, and prior to that was assistant research engineer with the Research Council of Alberta, in Edmonton.

Mr. Dunn received a B.Sc. degree in chemical engineering in 1948, followed by an M.Sc. degree in the same field in 1952.

R. J. B. McNally M.E.I.C., has joined the staff of Northwest Nitro-Chemicals Limited, Medicine Hat, Alta, as a plant engineer.

A 1944 graduate in mechanical engineering from the University of Saskatchewan, Mr. McNally was formerly associated with Polymer Corporation in Sarnia, Ont., as maintenance methods engineer, and more recently was assistant works engineer with Sherritt Gordon Mines Limited, Fort Saskatchewan, Alta.

William M. Wood, M.E.I.C., has transferred his services from the Fraser Construction Company Limited, Winnipeg, to the Rolmac Construction Company Limited, in Hamilton.

Mr. Wood is a University of Manitoba graduate, class of 1939, in civil engineering. Some of his professional experience has been with Burns and Company Limited, Kitchener, Ont., as resident engineer in 1950; with Winnipeg Supply and Fuel Company Limited, Winnipeg, as a construction superintendent; and with the Universal Contractors Limited in that city, as general superintendent.

S. J. Medwadowski, M.E.I.C., has accepted a position with the firm of John Sardis and Associates, consulting engineers, in San Francisco, Calif.

Mr. Medwadowski was previously an associate in civil engineering on the staff of the civil engineering department of the University of California.

He received an engineering diploma from the Polish University College, London, Eng., in 1950 and was shortly after employed with the Canadian National Railways as a structural designer in Toronto. In 1952 he was on the staff of Foundation of Canada Engineering Cor-

JENKINS
ITALY FOR MARBLE...
FOR VALVES!
It pays to deal with specialists
The whole world admires it — richly polished Italian marble, the proud product of generations of marble-working specialists In producing valves, too, superiority depends on specialized craftsmanship — and in this field Jenkins long has been recognized as supreme.
For Jenkins Bros. Limited have been making valves — and only valves — for decades. This complete dedication to a single superb product has earned Jenkins world-wide fame for the finest in valve manufacture.
That's why it pays to specify Jenkins valves. You can rest assured of their unrivalled dependability . . . enjoy the greater confidence which comes from dealing with specialists!
Making Quality Valves Is Our Business — Our Only Business.
Sold through leading industrial distributors.

poration of Montreal as a project engineer.

Bernard G. King, JR.E.I.C., has joined the staff of Ford Motor Company of Canada Limited, Windsor, Ont., in their plant engineering office.

For some time employed with B. Perini and Sons, Canada Limited, in Ottawa, and the C. D. Howe Company, Mr. King was among the civil engineering graduates of McGill University, class of 1952.

A. M. Clark, M.E.I.C., formerly branch manager with the Canadian Blower and Forge Company Limited in Toronto, has been moved to the firm's Hamilton office. He again serves as branch manager.

Mr. Clark is a University of Saskatchewan graduate in mechanical engineering.

E. H. Allen, M.E.I.C., has left the employ of Costain John Brown Limited and is with the London, Eng, firm of Leverstart Limited, precision engineers. He holds the position of factory manager with the company.

Mr. Allen joined the former company in 1952 and served at that time as deputy resident manager of a refinery at Essex, Eng.

R. C. Mordan, M.E.I.C., formerly with the Inter-provincial Pipe Line Company central division at Regina, Sask., is superintendent of the firm's disric No. 1, Edmonon, Alta.

Mr. Mordan is a University of Toronto graduate of 1949.

R. Westwood, JR.E.I.C., graduate of Imperial College, London University, is with the atomic energy division of the Canadian Westinghouse Company Limited in Hamilton, Ont.

He was at one time associated with the C. D. Howe Company Limited in Montreal and the Austin Motor Company in Grimsby, Ont.

D. J. P. Coleman, M.E.I.C., formerly of the Aluminum Company of Canada at Isle Maligne, Que, has accepted a position with Noranda Mines Limited, Noranda, Que.

He is a Queen's University graduate in mechanical engineering, class of 1947.

G. E. Matthews, JR.E.I.C., is district service manager, Moncton district, for the Canadian Westinghouse Company Limited, district apparatus division.

In 1953 he was an apparatus service engineer with the company.

He is a McGill University graduate, class of 1951 in electrical engineering.

Donald H. Pyne, JR.E.I.C., is with Canadian Wire and Cable Company Limited, at Smith Falls, Ont.

Last year Mr. Pyne was with Pigott Construction Company at Toronto.

Mr. Pyne graduated from the University of New Brunswick in 1954, with a degree in civil engineering, and then joined the Ontario Hydro-Electric Power Commission as a junior engineer.

G. D. Stephen, JR.E.I.C., is forest engineer with the timber division of Canadian Colleries Limited.

A B.A.Sc. graduate in forest engineering, class of 1951, from the University of British Columbia, he has had previous experience with the Pioneer Timber Company and with the Alaska Pine and Cellulose Company Limited, also in British Columbia.

John D. Dorey, JR.E.I.C., has moved from Toronto to Montreal in order to accept a position with the Sperry Gyroscope Company of Canada Limited.

Mr. Dorey has previously been affiliated with the Rogers Majestic Electronics

A. E. Toole, JR.E.I.C., has accepted a position with the National Research Council in Ottawa.

A mechanical engineering graduate of Queen's University, class of 1951, he has formerly been engaged in work with Canadian Industries Limited at their nylon intermediate plant at Maitland, Ont.

T. J. Rusk, JR.E.I.C., has accepted a position with the Public Health Engineering Division of the Department of National Health and Welfare in St. Catharines, Ont.

W. J. Roy, JR.E.I.C., has become waterworks production engineer with the City of Calgary.

Mr. Roy has been associated with the engineering department of the City of Lethbridge and was Town engineer at Fort MacLeod, Alta.

K. E. Kummant, JR.E.I.C., holds the position of superintendent of electrical maintenance with the Mannesman Tube Company Limited, Sault Ste. Marie, Ont.

K. E. Kummant, JR.E.I.C.

Until early this year employed with the Canadian General Electric Company in Peterborough, systems application engineering section, he is originally from Vienna, where he received a diploma in electrical engineering in 1950.

G. W. Morgan, JR.E.I.C., has been appointed chief engineer of Coast Steel Fabricators Limited, Vancouver.

G. W. Morgan, JR.E.I.C.

A graduate in civil engineering, Mr. Morgan received his degree from the University of British Columbia and for the past six years has been associated with the structural steel industry, most recently as chief design engineer of Standard Iron and Steel Works Limited, Toronto.

W. A. Grobicki, JR.E.I.C., has joined the staff of Messrs. Ewbank and Partners (Canada) Ltd., engineering consultants in Toronto.

Mr. Grobicki has for the past four years been associated with the Northern

TURBINE INSTALLATION AT B.C. POWER COMMISSION'S GEORGIA STATION . . .

When the new Georgia Generating Station of the British Columbia Power Commission goes into operation in 1957, it will be the largest Gas Turbine station in the world.

Designed as a standby source to carry peak loads and to augment the output of hydro stations during low river flow, the four General Electric Gas Turbines can be brought into operation a year sooner than a coal-fired steam plant and much quicker than a new hydro development.

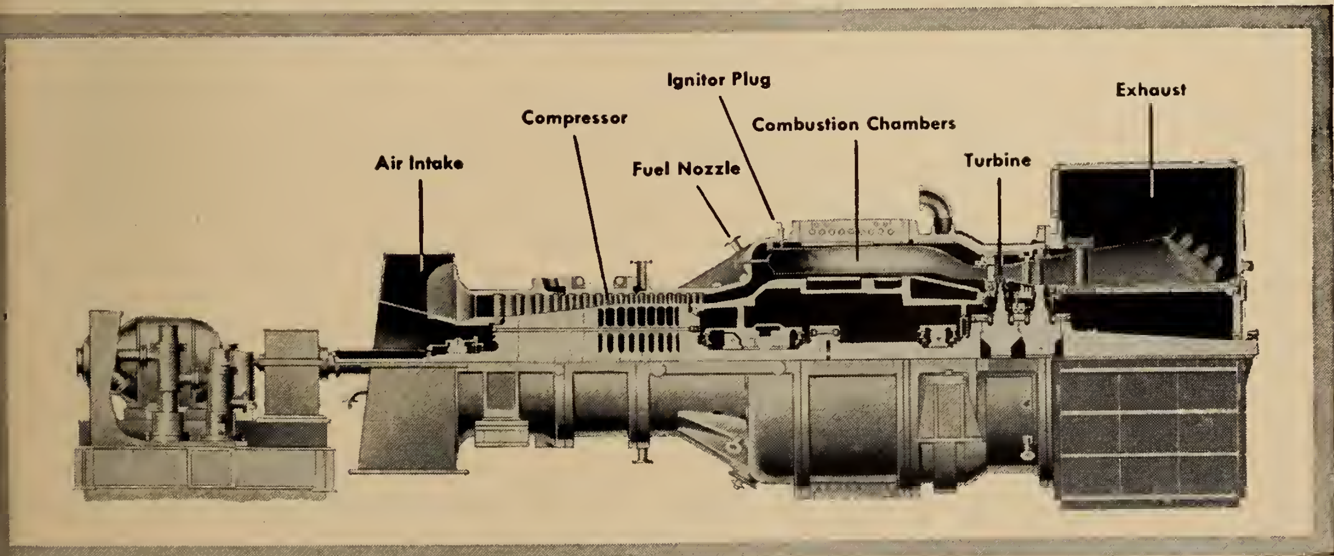
G-E Gas Turbines are economical to install . . . require only simple foundations and structures and incorporate the minimum of accessory equipment. Added to which they are easy and quick to start . . . can pick up the load rapidly in an emergency.

These Gas Turbines burn low-grade Bunker "C" oil, but can be readily adapted to use natural gas. They represent the most economical and one of the most modern methods of peak load power generation.

To take advantage of the capacity of these gas turbines at low ambient temperatures, each of these units will have hydrogen-cooled generators rated 25,600 KVA, giving a total station capacity of 102,400 KVA.

Sandwell & Co. were the consulting engineers.

When planning future expansion of your power generating facilities, it will pay you to investigate General Elecric Gas Turbines. For more information simply contact your nearest C-G-E Sales Office or write to: Apparatus Department, Canadian General Electric Company Limited, 107 Park St. North, Peterborough, Ont.



The compactness of the simple-cycle, single-shaft gas turbine is illustrated in this cutaway view.

ELECTRIC COMPANY LIMITED

Electric Company Limited, in the communication equipment division in Montreal.

Mr. Grobicki studied at the Polish University College in London and obtained a diploma in engineering in 1951.

Ronald J. Rushka, JR.E.I.C., is working with the industrial products division of the Canadian Westinghouse Company Limited at Hamilton, Ont.

Formerly with the Canadian Comstock Company at St. Catharines, Ont., he is a 1949 graduate of the University of Saskatchewan.

A. T. Nikiforuk, JR.E.I.C., is with Defence Construction (1951) Limited, at Vancouver. He has previously served the company at Edmonton.

Earlier in his career he was an electrical inspector with the Department of Industries and Labour, Province of Alberta, at Edmonton.

Mr. Nikiforuk graduated from the University of Alberta with a B.Sc. degree in electrical engineering, in the class of 1951.

O. J. Gratton, JR.E.I.C., recently of the City of Montreal engineering department has accepted the position of building and grounds superintendent at the University of Montreal.

Mr. Gratton joined the Franki Compressed Pile Company of Canada at Montreal shortly after receiving a B.A.Sc. degree from the Ecole Polytechnique in 1949 and in 1952 was with Cimentaciones Franki de Mexico. More recently he has been associated with J. D. Campbell and Company, in Montreal.

Robert McWhinnie, JR.E.I.C., lately of Canadian Bridge Company Limited, Walkerville, Ont., has joined Smith, Hinchman and Grylls, Inc., at Windsor, Ont.

He is a graduate of the University of Toronto in civil engineering, class of 1953.

A. H. Ruddell, JR.E.I.C., is with the Dupont Company of Canada engineering department at Montreal following a period of employment in the United States. Mr. Ruddell was a design engineer with the Industrial Rayon Corporation at Cleveland, Ohio, and prior to that was in 1953 associated with the American Ship Buildng Company, also at Cleveland.

He is a Queen's University graduate in mechanical engineering, class of 1952.

James G. Boone, JR.E.I.C., is at Grand Falls, Newfoundland, as design engineer with the Anglo-Newfoundland Development Company Limited.

After graduation from the Nova Scotia Technical College in 1953, with a B.Eng. degree, Mr. Boone accepted a position with Lever Brothers Limited, Toronto.

Maurice Paquet, JR.E.I.C., formerly of the firm of Leblanc, Montpetit and Dorval at Quebec, Que., has gone into private practice as a consulting engineer in that city.

Mr. Paquet has had professional experience with Canadian Fairbanks-Morse Company Limited and the firm of Tasse, Sarault and Associates at Quebec, since graduation from Laval University in 1950. He studied electrical engineering.

E. L. Littlejohn, JR.E.I.C., has been appointed sales manager for thermoplastic products, of the Bakelite Company division of the Union Carbide Canada Limited, at Montreal.

Mr. Littlejohn joined the Bakelite Company after graduating from the University of Toronto in chemical engineering in 1949. He spent some years in the production department before transferring to the sales department in 1954.

He is the treasurer of the Quebec section of the Society of Plastics Engineers.

• PERSONALS

L. G. Boucher, JR.E.I.C., a Laval University graduate of 1949 in electrical engineering holds the position of branch manager for Reliance Electric and Engineering (Canada) Limited at Trois Rivières, Que. With the firm for some time, he was a sales engineer with the company in Montreal in 1951.

Ralph G. Smylie, JR.E.I.C., was recently named production manager of Dominion Bridge Company Limited's Pacific division at Vancouver.

Mr. Smylie was born in Vancouver, where he received his early education. After service with the R.C.A.F. in World War II, he graduated from the University of British Columbia in mechanical engineering.

He joined the company in 1950, since then he has held positions in the drawing office and as chief inspector. For a brief period in 1954 he was superintendent of the firm's pipe-coating plant in Regina during the completion of the major portion of the Buffalo Pound pipeline project.

Keith Ebbern, JR.E.I.C., has been appointed contract engineer with Dominion Bridge Company Limited for the Winnipeg area, Manitoba and Saskatchewan.

Mr. Ebbern was born in Manitoba, graduated from the University of Manitoba in civil engineering in 1948 and later obtained his master's degree at the University of Toronto.

He has been associated with Dominion Bridge Company since 1948, chiefly in the drawing and design offices before entering sales work some years ago.

W. R. MacLean, JR.E.I.C., is with the Department of Highways, Province of British Columbia, at Merritt, B.C.

A 1952 graduate of the Nova Scotia Technical College, Mr. MacLean has spent some time in western Canada being previously associated with the Trans-Canada Highway and the Department of Public Works in that province.

L. M. Bluteau, JR.E.I.C., associated with the Canadian Pacific Railway Company since 1941 has accepted a position with the Du Pont Company of Canada Limited as a steam plant design engineer in Montreal.

Working with the railway on a permanent basis for the last six years, he resigned as assistant engineer of tests.

Mr. Bluteau is a McGill University graduate, class of 1950.

Douglas W. Hawes, JR.E.I.C., has joined Ewbank and Partners (Canada) Limited, engineering consultants, in Toronto. He was formerly associated with the Canadian General Electric Company and the National Steel Car Corporation Limited.

Mr. Hawes is a 1950 graduate of McGill University in electrical engineering.

Paul Henri Fillion, JR.E.I.C., has been appointed executive in charge of Janin and Company Limited, general contractors, for the Quebec district.

A graduate of Laval University in civil engineering, Mr. Fillion recently obtained his master of science degree at Laval University. Prior to this he attended a post-graduate course in Paris at the Ecole Nationale des Ponts et Chausees. He was also engaged in civil engineering projects in France for a period of six months.

C. Bachovzeff, JR.E.I.C., is design engineer with the Ford Motor Company of Canada mechanical section, plant engineering staff, at Windsor, Ont.

An Athlone Fellowship winner, Mr. Bachovzeff studied at the Manchester College of Technology, following his graduation from McGill University in 1951 in mechanical engineering.

Shortly after this he began a period of employment with the Aluminum Company of Canada at Arvida, Que.

Jean Ghanime, JR.E.I.C., has been transferred from Quebec City to Montreal with Canadian General Electric Com-

pany. Formerly at work in the capacity of meter engineer his new appointment will be that of sales engineer.

Mr. Ghanime joined the organization shortly after graduating from the Ecole Polytechnique in 1952.

Charles P. Bennett, JR.E.I.C., has moved from Winnipeg to Edmonton where he is associated with Texaco Exploration.

Formerly with the Winnipeg and Central Gas Company in Winnipeg he was a 1950 graduate of the University of Manitoba.

N. Moysa, JR.E.I.C., has resigned from the Shell Oil Company of Canada Limited preventive maintenance department and is now employed with the Sidney Roofing and Paper Company Limited in Victoria, B.C.

A University of British Columbia graduate, class of 1953, he has worked in eastern Canada with the Hydro Electric Power Commission of Ontario on the Sir Adam Beck No. 2 generating station at Niagara Falls, Ont. in 1954.

John J. Killin, JR.E.I.C., is now associated with the firm of Porritts and Spencer (Canada) Limited, in Hamilton, Ont.

A University of New Brunswick graduate in civil engineering, class of 1950, he was formerly employed by the Great Lakes Paper Company Limited, at Fort William, Ont.

Mr. Killin was secretary-treasurer for the Lakehead Branch of the Institute in 1955.

A. H. Austin, JR.E.I.C., a 1953 graduate of the University of Toronto has left the staff of the Ontario Hydro Electric Commission as design engineer in Toronto and taken up work in Guelph, Ont., with the Armco Drainage and Metal Products.

At the beginning of his graduate career, Mr. Austin was known in British Columbia as a field engineer with Stone and Webster Canada Limited at Trail, B.C.

S. A. Luciani, JR.E.I.C., holds the position of assistant superintendent with the Quebec Iron and Titanium Corporation at Havre St. Pierre, Que.

Mr. Luciani was formerly maintenance supervisor with Shawinigan Chemicals Limited, carbide division.

He graduated from the University of Detroit, class of 1951.

R. E. Chamberlain, JR.E.I.C., is with the Bailey Meter Company Limited in Montreal as production engineer.

A B.Eng. graduate in civil engineering Mr. Chamberlain received his degree at McGill University in 1951 and later was awarded a Ph.D. degree from the University of Birmingham. Since then he has been associated with the structural design department of the Dominion Bridge Company Limited, Lachine, Que.

J. Looyestein, JR.E.I.C., civil engineering graduate of Delft University, class of 1952 is a designer for reinforced concrete structures with H. G. Acres, Niagara Falls, Ont.

He joined the firm of consulting engineers in May, after an association as resident engineer with Underwood, McLellan and Associates Limited of Saskatoon, Sask., in 1955.

Emiro Noussan, JR.E.I.C., of the Polytechnical Institute of Torino, Italy, who was at the beginning of this year associated with Willie St. Laurent, consulting engineer in Montreal, has accepted a position with E. G. M. Cape and Company, Spanish American Mine, Spragge, Ont.

Selwyn Fox, JR.E.I.C., who this year gained a master of science degree in timber engineering at the University of Toronto is with the Canadian Institue of Timber Construction, Ottawa.

Mr. Fox was awarded a Fellowship to carry out his recent studies in Toronto by the Canadian Lumberman's Association. In 1952 he was among the graduates of the University of British Columbia in forest engineering.

Lloyd E. Davies, JR.E.I.C., a University of Saskatchewan graduate, class of 1954,

• PERSONALS

formerly with the Department of Highways government of Saskatchewan, has accepted a position with Haddin, Davis, and Brown Limited, in Calgary.

D. Keith Marshall, JR.E.I.C., formerly of the Foundation Company of Canada Limited, Chalk River, Ont., has transferred his services to the firm of H. G. Acres and Company Limited, consulting engineers of Niagara Falls.

Mr. Marshall is a 1952 graduate of the University of New Brunswick.

F. Panchuk, JR.E.I.C., has joined the B. F. Goodrich Canada Limited in Kitchener, Ont., as development engineer.

He was awarded the degree Master of Business Administration from the University of Western Ontario in May of this year.

I. C. Smith, JR.E.I.C., is on the staff of the Nova Scotia Light and Power Company Limited.

He is a 1954 graduate of the Nova Scotia Technical College, with a B.Eng. degree in electrical engineering.

J. Paul Chamberland, JR.E.I.C., has been an operation engineer with the Beauharnois division of the Shawinigan Water and Power Company in Valleyfield, Que., since February this year.

An Ecole Polytechnique graduate of 1952 in mechanical engineering, Mr. Chamberland was an industrial representative with the company at Montreal in 1953.

L. B. Gendreau, JR.E.I.C., has accepted a position with Canadian Allis-Chalmers Limited at Montreal.

Mr. Gendreau was formerly located at Ottawa with the Department of National Defence, naval technical services, as a mechanical engineer. Prior to that he was with Sorel Industries Limited, Sorel, Que.

R. P. Proctor, JR.E.I.C., is employed with the Nova Scotia Light and Power Company at Halifax, N.S.

Mr. Proctor's previous engineering affiliations include Canadian Celanese Limited at Drummondville, Que., and the Dow Chemical Company of Canada.

He is a 1947 graduate of the Nova Scotia Technical College.

J. Ross Raymond, JR.E.I.C., has accepted a position with Municipal Planning Consultants in Toronto.

A 1953 civil engineering graduate of the University of Toronto, Mr. Raymond was previously a planning engineer in the department of development of the Municipality of the Township of Toronto and prior to that worked with the Department of Development in Cooksville, Ont.

John S. Pringle, JR.E.I.C., formerly of the Canadian International Paper Company, Three Rivers and Temiskaming, Que., has transferred his services to firm of Hygrade Containers Limited, Montreal.

He is a B.Eng. graduate in mechanical engineering from McGill University, class of 1953.

R. Youngberg, S.E.I.C., a 1955 graduate of the University of Manitoba who this year obtained an M.Sc. degree in civil engineering from that University has joined the staff of the Aluminum Company of Canada at Vancouver. His work is that of engineering-town planner.

A. D. Nordstrum, S.E.I.C., a University of Saskatchewan graduate, class of 1955, holds the position of field engineer with Ford, Bacon and Davis Construction Corporation at Medicine Hat, Alta.

Last year he was employed with Canadian Industries Limited at Edmonton.

E. A. Daoust, S.E.I.C., a 1956 graduate from McGill University who was awarded a B.Eng. degree in civil engineering has found employment with the firm of Delisle and Laquerre, at Chicoutimi, Que.

News of Other Societies

Canadian Industrial Management Association

The fourth annual conference of the Canadian Industrial Management Association will be held at the Royal Connaught Hotel in Hamilton, Ontario, October 30 and 31, 1956.

The conference is presented, in line with the association's primary aims and policies, "to develop in industry, a wider adoption of scientific organization and managerial methods, as an aid to finding ways to compete against rising production costs, intensive domestie and low-cost foreign competition."

The program promises a comprehensive discussion by eminently qualified speakers from the United States and Canada, on such pertinent and timely subjects as: production scheduling, operations research, problems of decentralization, linear programming, profit sharing, plant layout, inventory control, new developments in time study, job evaluation and merit rating, promotion of executives, employee motivation, evaluation of automation, employee selection and testing, preparation and use of statistical presentations.

At a luncheon on October 30, G. L. Wilcox, president of Canadian Westinghouse Co. Ltd., will speak on "New Approaches to Modern Management". The Hon. Dana Porter, Q.C., M.A., Provincial Treasurer for Ontario, will present a talk at a dinner the same day on "Management's Responsibility to the Province and the Nation". The subject "Management and Its Responsibility to Society" will be taken up by Rt. Rev. W. A. Bagnall, Bishop of Niagara, at a luncheon on October 31.

More information about this national conference can be obtained from W. E. Jolliffe, executive secretary of C.I.M.A., Suite 303, 33 Front St. W., Toronto 1, Ont.

Fellowship Offered

The Canadian Construction Association (Construction House, Ottawa) is offering a fellowship of $2,000 for post-graduate study in construction. The fellowship will supplement C.C.A. awards to senior undergraduate engineering students at Canadian universities.

The association wishes also to encourage the establishment of such courses in Canada. President A. Turner Bone has said, "The commencement of a post-graduate course in highway engineering in 1957 at the University of Alberta will be additionally welcome as a step in this direction. At the present time, however, specialized courses in building construction or construction engineering are not available at any of our universities."

Applications may be made by engineering graduates of a recognized university who are Canadian citizens and who have had at least three years' employment in some phase of construction operations since graduation. Fellowship winners may attend the university of their choice, provided that it meets with the approval of the C.C.A. selection board.

Application forms are available from the Association, Construction House, 151 O'Connor Street, Ottawa 4, Ont. Applications may be made no later than December 31, 1956.

Calendar

The International Union of Crystallography has accepted the invitation of the National Research Council of Canada to hold its fourth assembly and congress in Canada from July 10 to 17, 1957, followed by two symposia on the subjects "Physical Techniques of Crystallographic Interest" and "Electron Diffraction" on the 18th and 19th

Through the cooperation of McGill University and the University of Montreal, the meetings are being held in the city of Montreal.

The Canadian National Committee on Crystallography is preparing to provide details of the technical program, and accommodation. Secretary of the Canadian Committee is Dr. W. H. Barnes, Division of Physics, National Research Council, Ottawa 2, Ontario. (Communications should be marked "Personal").

Canadians attending the Road Show in Chicago next January will enjoy special privileges provided by the International Road Federation, it has been announced by C. W. Gilchrist, managing director of the Canadian Good Roads Association (270 Maclaren Street, Ottawa).

The IRF, with which CGRA is affiliated, will maintain an International Centre for guests from outside the United States, from January 28 to February 2, 1957. IRF has arranged an excellent program of discussions on highway design and construction methods, equipment, soils problems and research developments.

To take advantage of the services provided by the International Centre, reservations must be made through the Canadian Good Roads Association (270 Maclaren Street, Ottawa, Ont.).

The Canadian Construction Association have announced the sixth annual award for theses on construction subjects.

Brian Akins, S.E.I.C., a 1956 graduate of the University of Manitoba has received the top prize in this competition for which there were entries from senior engineering students at eight Canadian universities. The subject of his thesis was "Techniques of Winter Construction".

Delegates of 34 member countries are expected to attend the third congress of the International Commission on Irrigation and Drainage, at San Francisco, Cal, April 29 to May 4, 1957. This is the first such congress to be held in the United States, former ones having taken in India in 1951 and in Algeria in 1954.

Information can be obtained from the United States National Committee, P.O. Box 7826, Denver 15, Col.

The 64th annual meeting of the Society of Naval Architects and Marine Engineers will be held in New York City at the Waldorf Astoria Hotel on November 14 to 17, 1956.

Further information can be supplied by Harold M Wick, chairman of the Public Relations Committee of SNAME, c/o American Bureau of Shipping, 45 Broad Street, New York 4, N.Y.

The Canadian Chamber of Commerce

• NEWS OF OTHER SOCIETIES

annual meeting is scheduled for October 15-18, 1956, at Quebec City, Que.

The American Society of Mechanical Engineers (29 West 39th St, New York) lists the following meetings: October 24 25, 1956, ASME-AIME Joint Fuels Conference, Sheraton Park Hotel, Washington, D.C., November 25-30, 1956, the ASME annual meeting, at the Hotel Statler, and the National Power Show at the Coliseum, New York City; March 10-16, 1957, E. J. C. Nuclear Engineering and Science Congress, Convention Hall, Philadelphia. For the Nuclear Congress, final date for submitting papers is November 1, 1956.

The Association of Canadian Testing Laboratories held its fourth annual meeting in Toronto in August. Members represented testing laboratories in every province, discussed ethics and standards guaranteed by membership in the organization.

New officers elected at the meeting are: president, J. H. White, Haileybury; vice-president, J. C. O'Neill, Toronto; secretary-treasurer, Wm. Gerrie, Swastika; publicity, J. E. Burgener, Toronto; membership, Dr. Kerr Lawson, Sudbury.

A new association for the growing field of cost engineering as organized in June for the United States and Canada under the name of American Association of Cost Engineers.

The Community Planning Association of Canada (77 Maclaren St., Ottawa 4) plans for the annual National Planning Conference in Ottawa, sessions on Urban Development, The Objectives of Redevelopment in Canadian Cities, City Renewal in Action, and Methods of Strengthening Town and Regional Planning. There will also be a review of redevelopment in our cities.

The National Planning Conference will be at the Chateau Laurier Hotel, Ottawa, from October 28 to 31, 1956.

The fourteenth annual conference on electric furnace steel at the Morrison Hotel, Chicago, December 5-7, 1956, will commemorate the fiftieth anniversary of the electric arc process in steelmaking.

This meeting will be arranged by the American Institute of Mining and Metallurgical Engineers (29 West 39th Street, New York 18, N.Y.).

The first European Congress on Corrosion will be held in Paris, France, 22 Nov. to 3 Dec.

The British Nuclear Energy Conference will hold a symposium on the Calder Works nuclear power plant at the Institution of Civil Engineers in London, England, 22 and 23 Nov.

The 36th annual meeting of the American Petroleum Institute will be held in Chicago, Ill., 12-15 Nov.

C.I.M.M. Western Meeting

The Canadian Institute of Mining and Metallurgy (906 Drummond Building, Montreal, Que) announce their annual western meeting at Vancouver, for November 5-7, 1956.

The theme of the meeting will be a salute to Western Canada's expanding mineral industry. All six of C.I.M.M.'s technical divisions are contributing to the technical program, for which eight sessions have been arranged. Subjects of these sessions are: industrial minerals, physical metallurgy, petroleum and natural gas, metal mining, extractive metallurgy, coal mining.

What is a "Good" Casting?

"Good" is the measure of performance. A good casting measures up—in performance—to all the requirements of its buyer and its end user.

If, during its life, it must withstand repeated thermal shocks, then it must be heat resistant; if it is going to be subjected to constant friction, then it must be wear resistant; if it comes into contact with salts or acids, then it must be corrosion resistant.

"Very true," you say, "and also very obvious. It is one thing to make fine castings to fit the job but can you make the price fit the castings? That's a requirement, too."

We can. That's where our Special Products Plant comes in. It is run by experienced men, controlled by a first class laboratory and equipped with modern foundry equipment—it's an operation that's geared to meet quality *and* price requirements.

Our electric furnace, for example, allows flexibility, versatility and far greater uniformity of composition in the production of all types of iron.

The result: the best possible assurance against being let down half way through the machining operation. Your shop investment is thus protected.

So when *you* need "good" alloy castings, delivered clean and on time, order them from:

Canada Iron
foundries, limited

FOUNDRY & MACHINE DIVISION

HEAD OFFICE: 921 Sun Life Bldg., Montreal

TORONTO OFFICE: 171 Eastern Ave., Toronto

Literature is available on the following engineering irons and alloy irons produced by our Special Products Plant:

If you would like valuable information on any or all of these irons, tick them off and mail this coupon.

• CANADIAN DEVELOPMENTS *(Continued from Page 1383)*

Two More Aluminium Projects for Quebec

Canadian British Aluminium Co. Ltd. awarded a $15 million contract in mid July to Anglin Norcross Ltd. and Atlas Construction Co. Ltd., for construction of its new aluminum smelter at Baie Comeau, Que. The contract calls for construction to proceed in two stages. The first, to be completed in the fall of 1957, will be for production of 80,000 tons annually for 1958. The second stage is to extend the project for ultimate production of 160,000 tons, but as yet no firm commitment has been made to go ahead with the latter program. Power will be supplied from the Outarde and Manicouagan Rivers.

British Aluminium Ltd. entered the aluminum picture in Canada last fall in partnership with Quebec North Shore Paper Co., a subsidiary of Ontario Paper Company. Canadian British Aluminium is a subsidiary of British Aluminium Co. Ltd. of London, England. Total cost of the project is estimated to reach $130 million.

Announcement of this project follows the award a short time earlier of a $135 million contract by Aluminum Co. of Canada to a joint venture group including Perini, MacNamara and Quemont Construction Companies, for construction of a hydroelectric power development on the upper Peribonka River at Chute des Passes. First power will be available in about three years.

A few miles below the existing storage dam at Passe Dangereuse, an intake tunnel 6 miles long will be built to a point downstream where a gross head of 636 feet can be developed. Here an underground generating station will be installed. The project will add 700,000 firm horsepower to the Saguenay system as a whole and will reduce chances of recurring power shortages.

This power project is part of a $250 million expansion program in Northern Quebec announced earlier this year by Aluminium Ltd. Included therewith will be 120 tons of new aluminum smelting capacity at Isle Maligne in the Saguenay Valley.

This Quebec expansion, together with the British Aluminium Ltd. project at Baie Comeau, added to Arvida production and ultimate output from Alcan's Kitimat project in British Columbia, will bring Canada's total aluminum production to well over a million tons by 1955 and close to 1¼ million tons with British Aluminium's second stage.

Announcement of these two projects for Baie Comeau and Isle Maligne, which together will add 230,000 tons of ingot production raises conjecture whether they are merely designed to meet the growing demand for ingot, or as a hedge against possible breakdown of negotiations for developing the huge Volta project in Africa's Gold Coast, which would have an equivalent capacity when completed.

Polythene offers industry ALL these properties combined in ONE versatile material
TOUGHNESS
LIGHTNESS
FLEXIBILITY
H 2SO4
CORROSION RESISTANCE
EXCELLENT ELECTRICAL INSULATION
EASILY MOULDED, EXTRUDED, HEAT SEALED
WATERPROOF
REMAINS FLEXIBLE AND STRONG EVEN AT SUB-ZERO TEMPERATURES
NON-TOXIC
– used for these products and many others!

BOOK REVIEW

Who's who, 1956

London, Black, Toronto, Macmillan, 1956. 3301p., $16.50.

Are you in the latest edition of Who's Who? No? Don't let it worry you, there are millions who aren't, but for authoritative up-to-date information on everyone who is anyone in the world today, this is *the* reference book.

Now in its one hundred and eighth year of issue, this indispensable source of accurate facts contains over forty thousand biographies, including nearly one thousand new ones. The main factors contributing to the value of this work are three. First, coverage is worldwide, for although it is published in England, included are many biographies of members of the Commonwealth and of outstanding figures from all over the world, from Professor Waino Aaltonen of Finland to Arnold Zweig. Secondly, inclusion is determined by an anonymous board of editors; nobody can pay to be included. Finally, the information given is as accurate as possible, for each biographee is sent a proof of his entry for correction or revision.

In general the details given include full name, nationality, age, address, telephone number, parents, education, publications, career, decorations, hobbies, etc.

Who's Who 1956 is fascinating reading, as well as an essential reference book for any library.

S.C.

BOOK NOTES

Prepared by the Library The Engineering Institute of Canada

* Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

Abac or nomograms

A. Giet. London, Iliffe, Toronto, British Book Service, 1956. 225p., 35/-.

In this translation from the 1953 French edition, some adaptions have been made to make the text clearer to British readers.

Written primarily for engineers rather than mathematicians, this is essentially a practical book, and shows both the applications of nomograms, and the methods of constructing charts for them. Both Cartesian abacs and alignment charts are considered, and the practical examples given are drawn from the fields of mechanics, physics and electrical engineering.

This English edition will prove very useful to anyone needing a time saving method of performing repetitive and complicated calculations.

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

LIBRARY HOURS

Monday to Friday
9 a.m. — 5 p.m.
Saturday 9 a.m. - 12 noon.

A. C. switchgear, v.1.

J. R. Mortlock. Toronto, British Book Service, 1956. 387p., diagrs., $8.50.

This volume has been written to give some guidance to systems engineers in the problems associated with the determination of the ratings of switchgear. It considers the principles of operation of different types of protection and relay, the measurement of fault currents and voltage. The voltage aspects of the problem are discussed under such topics as the initiation of arcs, restriking voltages, and insulation.

The second volume, to be published later, will cover the details of switchgear and the basic design principles.

American universities and colleges, 1956.

Mary Irwin, ed. Washington, American council on education, 1956. 1210 p., $12.00 (U.S.)

This seventh edition brings up-to-date a classic reference for student counselors, college administrators and others. It provides full descriptive data on 969 accredited universities and colleges in the United States and its territories, and brief data on 2016 approved professional schools in 23 fields. Seven chapters on the administration and organization of higher education in the United States constitute another important feature.

*Applied structural design of buildings, 2nd ed.

T. H. McKaig. New York, Dodge, 1956. 442p., diagrs., $12.50 (U.S.).

This practical handbook for structural and plant engineers, architects, draftsmen, and license applicants contains a wide range of formulas, tables, and typical computations for the design of steel, concrete, and wood structures. The eleven sections of the book contain data and calculations covering properties of materials, properties of sections, beam and column design, connections, wind stresses, shallow bins and bunkers, etc. Design procedures are based on the various standard codes.

Body engineering; design and construction of motor vehicle bodywork, 2nd ed.

S. F. Page. Toronto, British Book Service, 1956. 190p., illus., $4.25.

In this second edition, alterations have been made to bring the text up to date, and information has been included on such developments as the introduction of rubber fenders and the use of plastics.

After an historical introduction, the remaining sections cover materials used, design, draughting, sheetmetal projection, trailers, bodywork interior and bodywork construction.

The book is well illustrated, and carrying as it does the recommendation of the Institution of engineering draughtsmen and designers, will prove most useful to all those connected with the automobile trade.

CAMBA register, 1956-57, of British products and Canadian distributors.

London, Iliffe and Kelly's Directories, 1956. 729p.

Now in its fourth edition, this Register is published to stimulate trade between Canada and the United Kingdom. In the buyers' guide are listed over 4,000 British products available for export, together with their manufacturers. The names and addresses of 4,500 British firms interested in the export trade are listed together with their Canadian agents or distributors. Lists of proprietary names, trade marks and a French glossary complete this very useful book.

Cams: designs, dynamics, and accuracy.

H. A. Rothbart. New York, Wiley, 1956. 350p., diagrs., $9.50.

Intended primarily for the designer concerned with high-speed machinery, mechanical computers, etc, this work is an up-to-date treatment of kinematics, dynamics and machine design, using

cams as a basis. Some of the subjects covered are basic curves; cam size determination; cam profile determination; advanced curves; and polydyne cams.

Although this is essentially a theoretical work, the author makes concrete recommendations on such topics as mass, acceleration, materials, and the type of cam and follower to use. He does not go into the details of cam manufacture. There are bibliographical references at the end of each chapter.

Canadian trade index, 1956.

Toronto, Canadian manufacturers' association, 1956. 1107p., $10.00.

Once again the Trade index is packed full of valuable information. In addition to the classified section, listing alphabetically all the products manufactured in Canada, together with the names of the firms manufacturing them, there is also an alphabetical list of manufacturers, giving for each address, products manufactured, and foreign representatives, if any. There is a French key to the classified section.

Short articles discuss the export trade and how to enter it, and there are lists of Canadian commercial representatives abroad.

Chambres d'équilibre.

André Gardel. Lausanne, Rouge, 1956. 158p., diagrs., Sw. fr. 24.85.

Based partly on experiments conducted in the laboratories of the University of Lausanne, the object of this book is to present simplified methods for the calculation of surge tank size.

In the first part of the work, the various factors influencing size are considered, including the dimensions of the upstream basin.

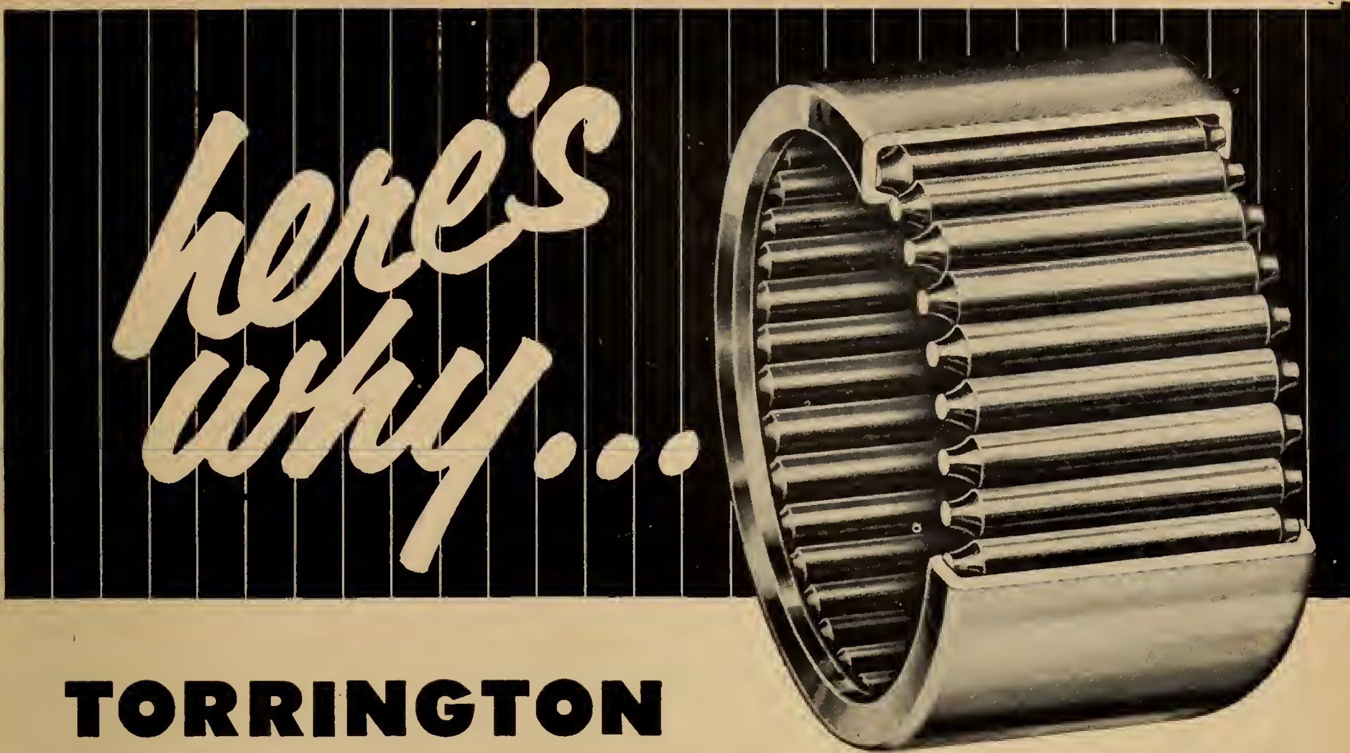
The second part of the book presents the method of calculating tank sizes by the use of abacs. It is also possible to construct graphs which will give the size of the tank.

Written by an engineer who has a wide knowledge of the subject, this will prove a very valuable addition to the information available on surge tank design.

°The chemical process industries, 2nd ed.

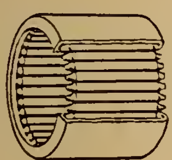
R. N. Shreve. Toronto, McGraw-Hill, 1956. 1004p., illus., $11.50.

This text and reference book presents a cross section of the manufacturing procedures employed by modern chemical industries. For the most part, a separate chapter is assigned to a given industry such as glass, paper, rubber, or sulfuric acid, and within each chapter the discussion is developed around flow sheets which are used to show the sequence of operations and processes. Selected references are listed after each chapter, and a section of problems is given at the end of the text.

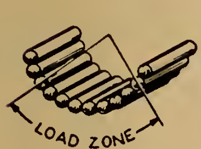


TORRINGTON

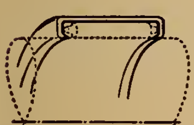
DC needle bearings give high-capacity performance in minimum space



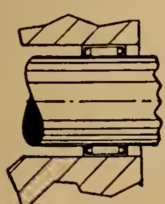
Unique construction—accurately drawn, surface-hardened shell retains rollers and serves as outer raceway.



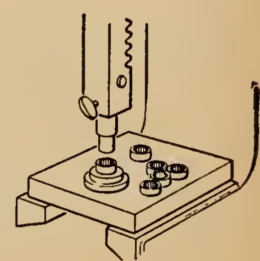
Full complement of small diameter rollers—precision-ground and through-hardened—assures top capacity by distributing load over large number of contacts.



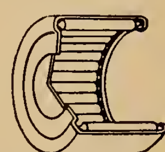
Turned-in lips of the case-hardened outer shell keep dirt and grit out, lubricants in—while retaining trunnion ends of rollers. All wear surfaces of outer race are case-hardened.



No inner race required on surface-hardened shafts—reduces space requirements, lowers unit costs.



Simple assembly—arbor press seats bearing in round housing bore. No collars, shoulders or retaining rings needed.



Closed end type DC Needle Bearings are available for stub shaft applications. The closed end provides a perfect seal at no extra cost.

Needle Bearings are made in a Precision Series for most applications and an Extra Precision Series where low radial play and minimum eccentricity are required. Easy lubrication through optional hole in shell or through hole in shaft assures long service life. Bearings can be pre-packed with suitable grease for those applications requiring grease lubrication.

See our new Needle Bearing Catalog in the 1955 Sweet's Product Design File—or write direct for Catalog No. 55.

• LIBRARY NOTES

The climate of central Canada.
W. G. Kendrew and B. W. Currie. Ottawa, Queen's Printer, 1955. 194p., illus., $1.00.

For the purposes of this report, "Central Canada" includes the Prairie Provinces and the Districts of Mackenzie and Keewatin, some forty per cent of the whole of Canada.

There is a description of the general climatic features of the region, and the physical factors determining these features. The remainder of the book is divided into five chapters, each covering one region of the area, and discussing in each case topography, winds, temperature, humidity, clouds, sunshine, precipitation and visibility. Climatological tables for each region are also given, based on data which, in some cases, is available for a very few years only.

The report, condensed from that written by Dr. Currie, is one of a series describing the climate of a large part of Canada. The series should prove invaluable to those whose work is any way influenced by the climate.

Commercial waxes, 2nd ed.
H. Bennett, ed. New York, Chemical publishing, 1956. 668p., $15.00 (U.S.).

The revised edition of this reference work on commercial waxes has been expanded to include data on the new waxes, and new applications of natural and synthetic waxes which has accumulated since the first edition was published.

For the purpose of this volume, "wax" is "a plastic, slippery solid which is easy to melt", and includes mineral, vegetable, animal, synthetic and compound waxes. Data given for each wax includes melting point, specific gravity, hardness, surface tension. and other chemical and physical properties. There are chapters on wax technology and the uses of wax in industry, and there is an extensive wax formulary.

Concrete roads; design and construction.
Gt. Brit. Road research laboratory. London, H.M.S.O. 1955. 404p., illus., 25/-.

Rather than attempting to present a complete textbook on concrete road construction, the authors have confined their remarks to topics which have been investigated at the Road research laboratory. The greater part of the book was written in 1954, and at that date there had been little large scale post-war construction of concrete roads in Britain.

The book is divided into three sections, the first of which deals with the properties of cement, aggregates and water, and the mixes used in road construction. Section two considers pavement design, and the estimation of stress in concrete road slabs, together with some discussion of prestressing, joints, and defects occurring in concrete roads. Finally in the third part, there are several chapters on the use of machinery in mixing and placing concrete.

Although the book is based on English conditions and practices, much of it is applicable to Canada, and the references at the end of each chapter will prove specially useful.

Co-operative electrical research, no. 1.

Leatherhead, Surrey, Electrical research association, 1956. 2/6 an issue.

It is planned to issue this new publication semi-annually. It will contain articles by the staff of the ERA, reviewing the Associations' activities in more detail than is possible in the annual report.

Electronic measurements and measuring instruments.

F. G. Spreadbury. London, Constable, Toronto, Longmans, Green, 1956. 459p., illus., $10.00.

The use of electronics in measuring techniques is relatively new, but there are already many different instruments in use. Two of the earliest instruments, the valve voltmeter and the cathode-ray oscillograph now form essential parts of other instruments of much greater complexity.

Although there are so many instruments, there are certain types and techniques which are basic, and these the author describes. Covered are instrument stability, and that of their components; valve characteristics relative to measurement; stabilization by negative feedback; a number of basic-type instruments; and the potentials of various instruments.

Facing the atomic future.

E. W. Titterton. Toronto, Macmillan, 1956. 379p., illus., $4.00.

Written for the layman by a distinguished atomic scientist, this book presents clearly declassified information on atomic energy and atomic weapons. The author also discusses the international, sociological, political, ethical and military problems which have been created by the advent of atomic energy, and concludes by stating his belief that this new power has come before man is prepared for it. He believes, however, that man can meet the challenge which is now facing him.

***Handbook of welded steel tubing, rev. ed.**

Cleveland, Formed steel tube institute, 1956. Various paging, $10.00 (U.S.) each part.

This handbook is in two parts, the first part dealing with welded carbon steel tubing, the second part with welded stainless steel tubing. Both parts provide designers, engineers, and fabricators with a wealth of information on manufacturing processes, available sizes and shapes, specifications and tolerances, properties, ordering from mills, and structural, mechanical, and pressure applications in a wide range of industries. In addition to the engineering data given in the text, an extensive section of design information is appended. There is also a glossary.

***History of American technology**

J. W. Oliver. New York, Ronald Press, 1956. 676p., $6.50 (U.S.)

This is a comprehensive account of the status and development of the various areas of technology — mining, manufacture, transportation, communication, etc. — during each of the four historical periods into which the book is divided: pre-Revolutionary, Revolution to Civil War, Civil War to 1900, and 1900 to the present. Stressed throughout is the influence of technological progress on the economic and political growth of the United States and on American civilization as a whole.

Industrial wage and salary control.

R. W. Gilmour. New York, Wiley, 1956. 261p., illus., $7.50.

A detailed presentation from a practical viewpoint of the development, installation, and administration of point evaluation plans for wage and salary programmes. The methods described are intended for use in a large decentralized company, but can be adapted for use in a smaller organization.

In addition to the theoretical development of the subject, many actual work sheets and examples have been included, and there are explanations of the statistical techniques involved for those who do not have a detailed knowledge of the subject. The author is careful to point out the dangers resulting from adopting plans not specifically adapted to the needs of the company.

A useful bibliography of books and periodical articles on the subject is included.

An introduction to the theory of structures.

W. Merchant and A. Bolton. Glasgow, Blackie, 1956. 210p., diagrs., 30/-.

Intended as a text for undergraduate students, the book is based on a series of lectures. It can also be used as a basis for more advanced developments.

The book covers the theory of statics, then considers beams, trussed frames, deflection of beams, and fixed end and continuous beams. Further chapters discuss stress, stress distribution, the use of theory in design, earth pressures and retaining walls, moving loads, pillars and slope deflection and movement distribution.

As the authors state in their preface, the book is essentially a re-interpretation of the classical principles of the subject.

Kraftfahrtmechanik, Teil 1.

Alfred Jante. Leipzig, Teubner, 1955. 237p., diagrs., 16.50 DM.

After a brief historical introduction, this undergraduate text on automobile mechanics considers traffic density and allied problems; road location; automobile and road operating expenses; and traffic safety. The two main chapters of the book discuss the kinematics and kinetics of automobiles. There are many diagrams and graphs, and a bibliography of periodical articles in German. The second volume, which is in preparation, will deal principally with gears and gearing.

• LIBRARY NOTES

Linear transient analysis, v. 2.

Ernst Weber. New York, Wiley, 1956. 452p., $10.50.

The first volume of this work, published in 1954, covered lump-parameter two-terminal networks. This second volume covers two-terminal-pair networks in filters and in transmission lines.

There is a brief introductory review of the Fourier and Laplace transforms and of their importance in the analysis of fourpoles and lines.

The first section of the book is devoted to two-terminal-pair networks (fourpoles) including both passive and active fourpoles, network characteristics, etc. The second part of the book considers transmission lines, noninductive cables and approximations and solutions for the general transmission lines.

Although essentially a mathematical presentation, practical applications are shown, and the various methods of solution are presented by means of problems worked out in the text.

***Marine cargo operations.**

C. L. Sauerbier. New York, Wiley, 1956. 548p., $10.50.

The main part of this detailed treatment of the theory and techniques of efficient and economical cargo handling deals with the following subjects: weight distribution, stability, longitudinal stress, and other principles; planning for stowage; stowage of different types of cargo; loading and discharging equipment; materials handling principles and equipment; and ventilation of cargo holds. Two short chapters are devoted to administrative organization for handling cargo and to responsibility for cargo. The last chapter reviews recent research in the field.

***Neutral grounding in high-voltage transmission.**

R. Willheim and M. Waters. Toronto, Van Nostrand, 1956. 669p., illus., $16.50.

A comprehensive discussion of the the various European and American methods of neutral grounding and other measures for reducing the fault rate in transmission systems. The first third of the book, devoted to ground faults and grounding practice, deals with the theory of neutral grounding, transient phenomena in three-phase systems, and methods of fault suppression. The rest of the book is a detailed treatment of resonant grounding, covering the theory, design, applications, and testing of the ground fault neutralizer (arc suppression coil). A great many numerical examples and actual tests and measurements are included, and each chapter is followed by a list of references and a bibliography.

***Petroleum refining with chemicals.**

V. A. Kalichevsky and K. A. Kobe. Toronto, Van Nostrand, 1956. 780p., $16.00.

This volume is a systematic treatise on the use of chemicals and solvents in the preparation of liquid petroleum products and waxes. Crude oil emulsions, petroleum composition, and testing methods are dealt with in introductory chapters, and the next five chapters cover refining with acids, alkalies, adsorbents, desulfurizing agents, and solvents. One chapter is devoted to deasphalting and dewaxing, and the last two chapters describe the use of additives in non-viscous petroleum fractions and in lubricating oils. Over 8000 literature and patent references are included in the bibliographies following each chapter.

***Practical design of simple steel structures, vol. 1, 4th ed.**

D. S. Stewart, London, Constable, Toronto, Longmans, Green, 1955. 221p., illus., $3.75.

A new edition of a standard British text written as a detailed guide to actual design procedures. This first volume covers the choice of sections; the making of drawings and templates; simple riveted joints of plates; flange-plate and other splices; eccentric riveted connections; wind pressure calculations; and beams. The last two chapters present complete designs of a joist and channel crane gantry girder and of a gallery, suitable for light work, to be attached to existing columns of a workshop. Tables giving properties of rolled sections, rivet values, bolt values, and other data are included in the appendix.

***Reactor shielding design manual.**

Theodore Rockwell, ed. Toronto, Van Nostrand, 1956. 472p., diagrs. $6.50.

A detailed presentation of procedures and data used in the design, construction, and testing of shielding for the reactor plants of the Naval Reactors Program and for the Shippingport Pressurized Water Reactor. Intended as a practical guide for designers of stationary as well as mobile reactors, the manual covers basic theory, setting allowable radiation levels, core and cooling system shields, plant layout as a factor in design, materials, provision for access for repair and maintenance, the effect of irregularities in shields, and the effect of the geometry of radiation. Basic data and calculation aids are provided in the last chapter.

***Resistance welding, theory and use.**

Resistance welding committee, American welding society. New York, Reinhold, 1956. 163p., illus., $4.50 (U.S.).

A review of fundamental principles and techniques, intended as a manual for experienced engineers and designers as well as an introduction to the subject for those unfamiliar with the method. The book treats spot, seam, projection, flash, upset, and percussion welding; describes the different types of welding machines, electrodes, and controls used; and discusses weldability, quality control, and testing.

Rural water supply and sanitation, 2nd ed.

F. B. Wright. New York, Wiley, 1956. 347p., illus., $4.96.

Almost completely rewritten, this edition includes many new developments in the field of water supply and sewage disposal.

• LIBRARY NOTES

The first part of the book considers the sources of water available, methods of calculating the amount needed and of securing an adequate supply, water treatment, and the design and installation of plumbing systems, both for water supply and sewage disposal.

Part two describes a variety of problems which may be encountered in installing and maintaining water and sewage disposal systems.

Science and civilization in China, v. 2. History of scientific thought.

Joseph Needham. London, Cambridge, Toronto, Macmillan, 1956. 696p., illus., $13.50.

This second volume of the author's scholarly work on science and civilisation in China is devoted to the history of scientific thought, which is equally as complex as that of Europe.

The Confucians are considered first, for although their contribution to science was almost completely negative, they had great influence over all later Chinese thought. The great Taoist school of organic naturalism was founded during the Confucian period, and its beliefs lie at the basis of all Chinese science. Other influences were the Mohists, Logicians and Legalists.

In the Chinese middle ages, the dominant force was provided by the theories of the naturalists: the theories of the Five Elements, and the Two Fundamental Forces. Dr. Needham then writes of the sceptical tradition, the effects of Buddhist thought, and the Neo-Confucian climax of Chinese naturalism. In the final chapter there is a discussion of the concept of the laws of nature and human law in China and in the West.

This extremely interesting and valuable work concludes with three lengthy bibliographies of Chinese and western books and periodical articles.

Soviet air power.

R. E. Stockwell. New York, Pageant press, 1956. 23Bp., illus., $7.50 (U.S.).

The author, a former editor of Aviation Age, reports on the great advances made in the Soviet Union in the last ten years which have transformed its air force from a backward force to one of the stongest in the world. The information in the book has been obtained from personal interviews, foreign contacts and written material, and the author quotes his sources. A separately bound supplement contains technical data on seventy Soviet aircraft.

***The steel skeleton, v. 2, Plastic behaviour and design.**

J. F. Baker, M. R. Horne and J. Heyman. Cambridge, University Press, Toronto, Macmillan, 1956. 40Bp., diagrs., $10.25.

A report of investigations made by the Steel structures research committee of the department of Scientific and industrial research in Great Britain. Detailed accounts are given of tests and theoretical studies on rigid frames, beams, and columns, made in order to develop a simplified method for the design of steel structures, based on their plastic behaviour. A proposed design method for multi-story frames is presented, and some actual applications of the method are briefly described.

***The structure of turbulent shear flow.**

A. A. Townsend. Toronto, Macmillan, 1956. 315p., diagrs., $6.75.

This is an attempt to develop a consistent view of the nature of turbulent flow by considering the properties of simple forms of turbulent flow, and to apply this view to the analysis of the more common types of turbulent shear flow. The analysis covers jet, wake, and boundary-layer flow as well as flow in pipes and channels and shear flow between rotating cylinders. A bibliography is included.

Supersonic inlet diffusers and introduction to internal aerodynamics.

Rudolf Herman, Toronto, Minneapolis-Honeywell, 1956. 378p., illus., $16.00.

This systematic and comprehensive treatment of supersonic inlet diffuser flow characteristics is by an engineer who has had many years experience in the field, both in Germany where he was a director of the rocket programme, and in the United States where he has worked with the Air Force, and with Minneapolis-Honeywell.

Much of the material used in the book has not previously been published, and stems from research done under the author's supervision on two-dimensional and spike inlet diffusers. The fundamentals of one-dimensional, two-dimensional wedge-type and axisymmetric conical inlet diffusers are covered. The author has evolved a new condensed notation system to simplify the theoretical analysis.

***Technical education.**

P. F. R. Venables. London, Bell, Toronto, Clarke, Irwin, 1955. 645p., $8.00.

This study of the present state and likely developments of British technical education includes two chapters devoted to engineering education. One of these is a general survey, the other a discussion of the relationship of university engineering education to technical education. Most of the book, however, is a critical survey covering curricula, selection of students, teaching staffs, and other aspects of education in technical institutes. Special studies of education for the building trades and of art, commercial, and science education are also included.

Television engineering; principles and practice, v. 2.

S. W. Amos and D. C. Birkinshaw. New York, Philosophical library, 1956. 270p., illus., $15.00.

Another in the series of training manuals issued by the B.B.C., this volume describes the fundamental principles of video-frequency amplifiers and examines the factors which limit their performance at the extremes of the passband.

A wide variety of circuits is described, and the use of feedbacks is also considered.

The first volume in the series dealt with basic television principles, and subsequent volumes will cover waveform generation and circuit techniques.

The theory of prestressed concrete design: statically determinate structures.

H. J. Cowan. Toronto, Macmillan, 1956. 264p., illus., $6.15.

In two brief introductory chapters the author outlines the fundamental principles and manufacture of prestressed concrete, and the properties of the steel and concrete used.

The main part of the book is devoted to a theoretical, mathematical treatment of the design of statically determinate prestressed concrete strucutres in accordance with British, American and Australian practices. It deals with direct design and covers the assessment of losses, the bending resistance of pretensioned sections for any condition of loading, resistance to shear and torsion, deflection and ultimate strength. A final chapter is devoted to prestressed concrete tanks and pipes, while numerical tables giving the properties of various sections are included in the appendix.

***Transistors handbook.**

W. D. Pevitt. New York, Prentice-Hall, 1956. 410p., diagrs., $9.00 (U.S.).

The first half of this practical manual for engineers, technicians, and students covers fundamental concepts, measurements, noise and temperature effects, methods of analysis, and characteristics of the different types of transistors-point-contact, junction, power, tetrode, pentode, photodiodes, and phototransistors. The last half of the book deals with specific circuits and practical applications, including audio and radio frequency amplifiers and oscillators, power amplifiers, amplitude and frequency modulation, radio and television receivers, relaxation oscillators, and computer circuits.

STANDARDS REVIEWED

**A.S.T.M. Standards, American society for testing materials,
1916 Race St.,
Philadelphia, 3.**

Copper and copper alloys

A compilation of 127 standards covering copper, copper-alloy, and copper covered steel electrical conductors; copper and copper-alloy plate, sheet, strip, and rolled bar; rod, bar, shapes, and die forgings; castings; filler metal; and methods of test for copper and copper alloys. Fifty of these specifications are revised and a new specification for threadless copper pipe is included. 654p., $5.75 (U.S.)

Electrical insulating materials

This 1956 edition includes 12 revisions and 2 new items covering methods of testing silicone insulating varnishes and a recommended practice for cleaning plastic specimens for insulation resistance testing. Specifications and test methods widely used in the electronics industries for the following materials are given: insulating shellac and varnish; plates, sheets, tubes, rods and molded materials; mineral oils for electrical insulation; ceramic products; solid filling and treating compounds; insulating fabrics and papers; mica products. Also included are proposed recommendations for writing statements on the usefulness of tests of electrical insulating materials, proposed methods of test for dielectric contant and dissipation factor of aviation fuels, and a number of electrical tests and conditioning requirements for electrical testing, which are generally applicable to insulating materials. 656p. $6.00 (U.S.)

Metallic electrical conductors

These standards cover: copper, copper alloy and copper covered steel: wire, stranded conductors, rods and bars; aluminum: wire, stranded conductors, rods and bars; galvanized steel core wire; and galvanized iron and steel guy, messenger, span, overhead ground, and line wire. 300p. $3.50 (U.S.)

**American society of heating and air-conditioning engineers,
62 Worth St.,
New York.**

A.S.H.A.E. code for testing and rating heavy duty furnaces and direct-fired unit heaters.

This code is applicable to forced warm air furnaces and direct-fired unit heaters having output ratings in excess of 250,000 Btu an hour. Eight sections cover purpose, scope, definitions, rating limits, testing equipment, testing procedures and rating procedures. 10p. .50 (U.S.)

**American society of mechanical engineers,
29 West 39th St.,
New York 18.**

**Boiler and pressure vessel code.
Section 8. Unfired pressure vessels.**

This edition "contains rules covering the use of all classes of materials and methods of fabrication that have been approved for code construction. These rules are to be used without supplement from earlier editions or from code cases applicable only to earlier editions. Code cases which apply to the 1949 edition have been annulled. It is the intent of the Boiler and pressure vessel committee that vessels built after January 1, 1957, in accordance with the 1949 and earlier editions should be marked with the Code symbol."—preamble. 194p. $5.00 (U.S.)

OMISSION

In the review of "Foundations: design and practice" in our August issue the author's name was inadvertently omitted. He is Elwin E. Seelye.

ENGINEERING CAREERS

The Petroleum Industry

THE OIL INDUSTRY in Canada has developed enormously in the past ten years, since the discovery of great oil reserves in the western provinces. Proved reserves of crude oil now exceed 2,500 million barrels, Alberta natural gas reserves exceed 15,000 billion cu. ft., and new discoveries and developments continue to increase these figures. Refining facilities are being developed to keep pace with increasing demand for petroleum products, and crude oil is finding markets outside Canada, particularly in the United States. The demand for Canadian oil is likely to continue to increase and will be promoted by such factors as higher tanker freight rates and uncertainties about supplies from the Middle East.

The industry may be roughly divided into three main groups — production, manufacturing, and marketing — and there is scope for engineers in each of these.

Exploration and Production

The search for crude oil may be taken as the starting point for a review of the industry and the place of the engineer in it.

Initial exploration is carried out by geological teams, but when the basic data on a possible oil-bearing area are established the co-operation of engineers with field experience is required to work out the best means of developing the field and what equipment will be needed. Under the broad term petroleum engineer, men with varied technical backgrounds work on problems of drilling, well completion, operation of electrical and mechanical equipment, and so on. Electrical engineers and engineering physicists may find scope in the field of geophysical exploration.

Storage and distribution facilities for crude oil — and for the increasingly important petroleum product, natural gas — have to be provided.

By far the largest producer of crude oil and natural gas at present is the province of Alberta, but Saskatchewan and Manitoba are playing an increasing part in the western oil industry.

Manufacturing

Although the main source of Canadian petroleum is in the west, the largest refining (manufacturing) centres are at present in the provinces of Quebec (Montreal) and Ontario, near the major Canadian markets. However, there is also considerable refining capacity in Saskatchewan, Alberta, British Columbia, and Manitoba, which together amounts to some two-thirds of that of the two eastern provinces and will undoubtedly continue to grow.

Mechanical, electrical, civil, and chemical engineers play an important part in manufacturing operations. The design of a modern refinery calls for specialized engineers and incorporates a great amount of electrical and mechanical equipment. Refinery operation demands engineers for technical and supervisory posi-

A corner of a typical control room in a modern petroleum refinery. The control room is the heart of the refinery process and here the plant operators can observe operating variables and overall conditions at any time. Many processes are almost fully automatic, and mechanical, electrical, and electronic recording and controlling instruments play a large part in the successful operation of the plant.

tions for the safe and efficient running of the plant. Processes are more and more approaching the fully automatic, and consequently involve much mechanical, electrical, and electronic control apparatus which may be part of the responsibilities of the engineering staff.

Civil engineers are required for the construction of refineries and their associated facilities for storage and distribution.

Technical positions in manufacturing operations may lead to administrative posts such as chief engineer, refinery manager, or other appointments.

Marketing and Distribution

The third major division of the petroleum industry is the field of marketing, and this is a major undertaking not only for its competitive nature, but because of the increasing complexity of petroleum products and their applications.

Apart from the distribution of various types of fuel (gasolines, fuel oils, petroleum gas, and so on), such fields as lubrication are becoming more and more specialized. Lubrication engineers have to be experienced in many branches of industry and the particular problems of lubricating such diverse equipment as that found in a steel rolling mill or in a pharmaceutical processing plant.

Another increasingly important field is that of the petroleum-chemical industry, for which the oil industry supplies the raw materials. A subsequent article will deal with the role of the engineer in the chemical industry, including petro-chemical manufacturing.

The distribution of petroleum products (and of crude oil and natural gas) requires the construction and operation of various facilities and permanent installations. The two major ways of distributing petroleum products are by tanker and by pipeline. Considerable engineering experience is needed during the planning and construction of a pipeline and its attendant storage and pumping facilities.

Engineers are also required for the construction and maintenance of other distribution outlets such as local bulk distributing plants and service stations.

Many oil companies have marine departments, in which there are usually only limited opportunities for the engineer, apart, of course, from the field of marine engineering. Marine and lake terminals may have to be constructed and maintained as part of the overall distribution system.

Opportunity

In all, then, there are many positions within the petroleum industry to be filled by the civil, electrical, chemical, and mechanical engineer, and the engineering physicist.. Opportunities for advancement are good, most companies generally filling senior posts by promotion from within their own organizations.

There is a wide range of responsibility in the fields in which the engineer can apply his professional training and experience, and there are also opportunities for him to progress to senior administrative and management positions.

Crude oil and petroleum products must be transported over great distances, and the pipeline is the chief means of overland distribution. The picture shows a centrifugal pump and speed increaser at a pump station of one of the major pipeline companies. Engineers play a large part in pipeline construction.

Training

Most oil companies take students for summer work, particularly in the refineries.

Graduate engineers, on joining a company, are trained to fit them for their future career in the industry.

In general, training schemes in the industry are carried out over a considerable period and may be based on on-the-job experience to give the new engineer a broad background in the operations involved. In addition, the sales engineer usually receives intensive training in all aspects of the products marketed and their applications. As mentioned above, the lubrication engineer is one example of those who must have considerable specialized knowledge in a particular field.

Salary and Benefits

Starting salaries for newly-graduated engineers are generally competitive with the rates current in other industries. Advancement is then based on ability and experience, and salaries are usually reviewed at regular intervals. The highest executive positions may be reached by the right man.

Paid vacations, pension and health plans, and other benefit schemes are general in the industry.

Further Information

There is much material available in the libraries on various aspects of the petroleum industry, but two recent articles in *The Engineering Journal* give an insight into the overall industry in Canada and into the particular problems involved in the construction of a modern refinery. These are:

(1) Canada's Petroleum Industry; G. M. Furnival, M.E.I.C. *The Engineering Journal,* 1955, Aug., p. 1035.

(2) Engineering for a New Petroleum Refinery in Montreal; J. Alexander, M.E.I.C., and E. Alzner, M.E.I.C., ibid, 1956, April, p. 421.

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Union Carbide Canada — John S. Dewar is appointed vice-president of Union Carbide Canada Limited, continuing as president of that company's division, National Carbon Company. It is also announced that Gordon W. Patterson has been appointed vice-president of National Carbon Company.

B. F. Goodrich — P. B. Mason, production superintendent, B. F. Goodrich Canada Limited, has announced the following appointments: E. R. Current, staff manager; R. Knowlton, production manager, tire division; and Marshall W. Roth, manager, tire construction, will report to the production superintendent.

William B. Flora becomes vice-president, sales.

Air Reduction Canada — J. R. Morrison has been appointed to the technical sales staff of Air Reduction Canada Limited.

Stewarts and Lloyds — The appointment is announced of George F. Clark as the Toronto manager of Stewarts and Lloyds of Canada Limited.

George F. Clark

International Nickel — Kenneth B. Young has been appointed to the staff of the Canadian development and research division of The International Nickel Company of Canada, Limited.

Canadian Ingersoll-Rand — James W. Kennedy has been appointed manager, pump division, of the Canadian Ingersoll-Rand Company Limited with headquarters in Montreal.

Thompson Products Limited — J. K. Abel is appointed manager, replacement division, Thompson Products Limited, comprising the sales organizations Thompson Service, Toledo Steel Products, and Ramco Rings.

Le Roi Division — Milton R. Conroy has been appointed manager of Canadian sales for the Le Roi Division, Westinghouse Air Brake Co., Milwaukee, Wis. Mr. Conroy's offices are in Toronto.

B. J. Coghlin Co. — F. O. Peterson, chairman of B. J. Coghlin Co. Limited, announces the appointment of S. H. Dobell, D.S.O., as president of the company and of its subsidiaries, Watson Jack-Hopkins Limited and Boulevard Equipment Limited.

E. G. M. Cape Appointment — E. G. M. Cape and Company announce the appointment of Robert Devlin as general superintendent in charge of a number of the company's projects in Ontario. Mr. Devlin's headquarters are at 688 The Queensway, Toronto 14.

Progressive Welder, Canada—The board of directors of Progressive Welder, Canada Limited announce the appointment of E. J. Formhals as general manager of Canadian operations, with headquarters in Chatham, Ont.

Josam Canada Appointments — J. S. Newman, vice-president and general sales manager of Josam Canada Limited has announced the appointments of Harvie Ashman as Northern Ontario representative, and of Roy Gibbon Agencies as sales representative in the Lakehead territory.

J. W. Hutchinson

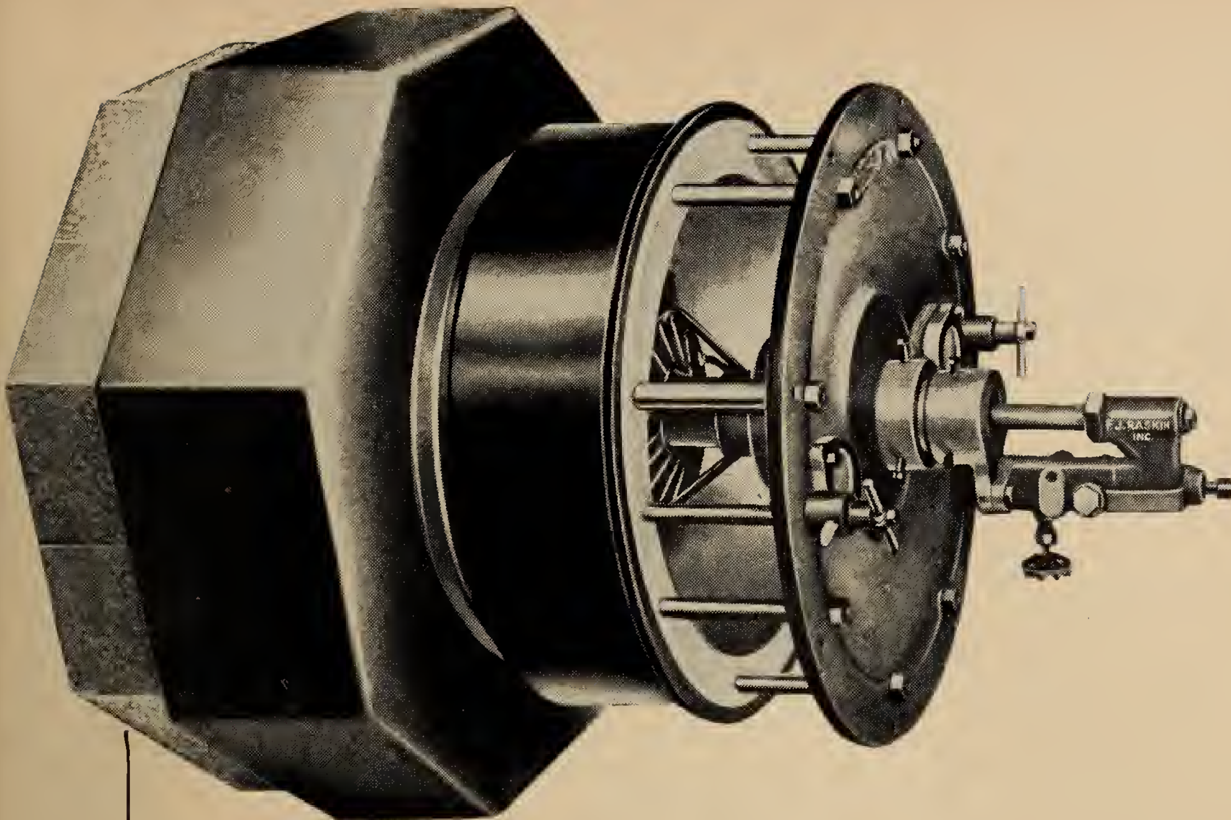
Powerlite Devices — J. W. Hutchinson has been appointed manager, switchgear and accessories engineering, Powerlite Devices Limited.

Canadian Zurn Engineering — Kenneth H. Tremain has been elected vice-president of Canadian Zurn Engineering Ltd.

Dominion Bridge Subsidiaries — Several changes are announced in the senior staffs of Manitoba Bridge & Engineering Works Limited, and Manitoba Rolling Mill Co. Ltd., subsidiaries of Dominion Bridge Company Limited. A. Campbell, M.E.I.C., becomes president of both Manitoba companies on the retirement of H. A. Mackay; J. Stewart Campbell, M.E.I.C., becomes manager of Manitoba Bridge & Engineering Works, Ltd.; Hugh Lindsay Smith, formerly works manager, becomes manager of Manitoba Rolling Mill Co. Ltd. Operating staff changes include: J. Munro E. Dale, works manager, Manitoba Bridge, on the retirement of P. G. Meurer; R. G. Honeyborne, superintendent; and H. A. Mackay Jr., superintendent, Manitoba Rolling Mill.

Collins Radio Company — Appointments announced by Collins Radio Company of Canada Limited are: Anthony Davies,

(Continued on page 1476)



CSA *Approved*

RASKIN
OIL AND GAS BURNERS

The above illustrated oil burner unit, approved by CSA Approvals Laboratories, is equipped with "Raskin" steam atomizing oil gun. It is adaptable to either natural, induced or forced draft operation and in many installations proved a capacity range of 25 to 1 without having to change the burner tip or move the gun in and out. Through its simplicity and efficient operation it has made many friends for itself among consulting engineers and plant operators. Now that gas is coming into wider use, many customers will realize the advantages of this unit which is so easily adaptable to gas firing.

If you wish to obtain any free literature, tear off this page and mail to us. We will forward to you our catalogue No. DN-54 showing industrial oil burners. We shall also include a reply card which indicates many other "Raskin" products.

"Raskin" representatives are located from coast to coast. They are capable to solve most problems and to service all types of "Raskin" burners. Please ask for name and address of "Raskin" Representative nearest you.

F. J. RASKIN INC. 4220 IBERVILLE ST. MONTREAL CANADA director of sales; Albert C. Petrasek, sales manager of ground communications equipment; and E. H. Edge, general communications sales department.

Spannall of Canada — Murray Griffin has been appointed Canadian sales representative for Spanall metal horizontal shoring for concrete floor forms.

Mines and Technical Surveys—W. Keith Buck is appointed chief of the mineral resources division, Department of Mines and Technical Surveys, as announced by Mines Minister George Prudham.

Canada Iron Foundries—R. Lyle, vice-president sales, Canada Iron Foundries Limited, announces the appointment of K. E. Walker as district sales manager, pipe division, Toronto, succeeding George M. Gass, who has retired after 45 years service.

New Equipment and Developments

Canadian Agent— The English Electric Company of Canada Limited has been appointed Canadian agent for the products of the P. and B. Engineering Company Limited, of England, who manufacture thermal relays for motor protection, thermal indicators to register maximum demand and maximum load, earthing clamps and operating poles, cable tracers and instruments for cable fault detection.

Rolling Stock Manufacture—E. J. Cosford, president and managing director of Canadian Car & Foundry Company, Limited, of Montreal, has announced that his company had been licensed by the Budd Company of Philadelphia to build and sell all-stainless steel railway passenger cars, railway disc brakes and Budd Rolokron, an anti-wheel slide device. The agreement will permit the Canadian manufacture of all types of stainless steel passenger equipment, including the Budd self-propelled rail diesel car and scenic dome type passenger equipment.

Laticrete Distributors—The appointment of three distributors for Laticrete has been announced by W. M. MacLean, general sales manager of the Latex and Reclaim Division of Dominion Rubber Company Limited. The distributors appointed are Bostwick and Company, Moncton, New Brunswick; Roy Gibbon Agencies, Port Arthur, Ontario; and Industrial Coatings Limited, Vancouver, British Columbia. Laticrete, developed in Canada by Dominion Rubber, is now also being produced under licence in the United States. It bonds readily to concrete, steel, or other materials, and is widely used to repair damaged concrete, or over sound concrete or steel where properties of corrosion resistance, skid-proofness, non-sparking qualities, and flexibility, are desired.

Chain Link Fence— An announcement has been made recently of arrangements having been completed between The Steel Company of Canada, Limited, Hamilton, the Dominion Bridge Company Limited, Vancouver, the Riverside Iron and Engineering Works Limited, Calgary, the Standard Iron and Engineering Works Limited, Edmonton, and the Manitoba Bridge and Engineering Works Limited, Winnipeg, to provide a complete chain link fence service throughout Western Canada. Through the arrangement, complete stocks of Stelco fence materials have been established at Vancouver, Calgary, Edmonton, and Winnipeg where the companies representing Stelco are prepared to offer a service which includes surveys, without obligation, of properties to determine the fence requirements and estimates of cost with or without erection.

New Airco Distributor— It is announced by Air Reduction Canada Limited that

(Continued on page 1480)

NEW..."M" Frame Molded Case Circuit Breakers are fully designed for 800 ampere applications

C.S.A. APPROVED

For applications which formerly required larger and more expensive equipment, you can now use the new I-T-E "M" frame molded case circuit breaker without sacrifice of quality. It offers optional pressure connectors for double or triple cable connections per phase contained within the circuit breaker case. Exclusive 3″ pole center design dimensions permit easy accessibility for front cable or rear bus and stud connections. And the "M" frame breaker is ideally suited for use in panelboards, power panels, switchboards, motor controls, bus duct plugs, and individual enclosures.

Available with interchangeable trip units providing continuous 600, 700 or 800 amp ratings in 2- or 3-pole construction for 250 volt d-c and 600 volt a-c service. Interrupting ratings (NEMA test procedure): 600 v a-c, 25,000 amp; 480 v a-c, 35,000 amp; 240 v a-c, 50,000 amp; 250 v d-c, 20,000 amp.

EASTERN POWER DEVICES LTD.

29 WABASH AVE. TORONTO.

Triple cable connectors accommodate three 300-400 mcm cables per phase.

Optional double cable connectors accommodate two 400-500 mcm or 600-700 mcm cables per phase.

• BRIEFS

Standard Welding Supplies Limited, of Montreal, is an authorized distributor of Airco Products.

Josam Representatives—Josam Canada Limited announce the appointment of Marshall, Turnau, Boucher & Company as Josam sales representatives for the Province of Quebec.

Magnetic Drives—Tormag Transmissions Ltd., Vancouver, has granted The Whitney Chain Company of Hartford, Conn., manufacturing and didstribution rights for the United States and Canada of products to be known as Whitney-Tormag Magnetic Drives. The units will be manufactured by The Whitney Chain Company in their factory at Hartford, Conn., and distributed throughout the United States and Canada. The Tormag unit transmits power through the use of permanent magnets and therefore requires no mechanical connection between the driving and the driven elements, nor does it need any electrical connection or hydraulic fluid.

Sales Agreement — A reciprocal sales agreement has been signed between Canadian Marconi Company, Montreal, and National Aeronautical Corporation, Pennsylvania, U.S.A. whereby Canadian Marconi will distribute NARCO standard line equipment for business aircraft, and the new Sapphire line of navigation and communications equipment, which is type certified by C.A.A. for airline use. At the same time Canadian Marconi announced that NARCO will market Marconi's new automatic direction finder (CMA 301) through its regular channels throughout the United States.

Air Conditioning Units—The complete range of Westinghouse Air Conditioning units is now being marketed in Canada by the B. F. Sturtevant Company of Canada Limited (a subsidiary of Canadian Westinghouse Co. Ltd.). Sizes are available from the smallest half-ton window unit to the 100 ton hermetic compressor for large central plant systems. The complete Westinghouse line has recently undergone many changes in basic design and structure. Also announced is the introduction of a new air-cooled condenser for use with central type home units and certain of the packaged commercial models.

Separator Distribution—Pacific Industrial Engineering, Inc. announces the appointment of H. J. G. McLean Ltd. of Brantford, Ont., for the sale and service of Pacific separators in the Provinces of Saskatchewan, Manitoba, Ontario and Quebec. The Pacific separator operates on the fully pressurized flow flotation principle and is supplied in models ranging from 25 to 2000 U.S. gal. per minute.

B.C. Oil Refinery—A major interest in X-L Refineries Limited, Dawson Creek, first British Columbia refinery to process Peace River crude oil, has been acquired

• **BRIEFS**

by Pacific Petroleums Ltd., pioneer of the B.C. gas and oil fields, it was announced by George L. McMahon, president of Pacific. The 3000-b/d Dawson Creek refinery will be operated in conjunction with the new $20 million Peace River gas processing plant which Pacific and Westcoast Transmission Company Limited are building at Taylor Flats, B.C. This latter plant will clean the natural gas from Peace River fields before it enters the Westcoast pipeline. Production from the plant will include sulphur, propane, butane, natural gasoline and other liquid hydrocarbons. This is the first processing of B.C. crude.

Plant Expansion– A $500,000 expansion of the offices, laboratories and plant of Alchem Limited at Burlington, Ont., is announced by the company's vice president and general manager, W. C. Heim. The expansion will include a new two-storey wing to the offices and laboratories and a one-storey addition to the plant. Contract for the project has been awarded to the W. H. Cooper Construction Co. Ltd. of Hamilton. Prack and Prack, also of Hamilton, are the architects.

A.E.C.L. Fuel Element Contract– A long-term contract to fabricate fuel elements has been awarded to AMF Atomics (Canada) Limited by Atomic Energy of Canada Limited. A new 30,000 sq. ft. plant and nuclear laboratory will be built on a 30-acre site at Port Hope, Ont. This will be the first unit of a large nuclear facility and will be staffed by Canadians. AMF Atomics (Canada) is one of the first private companies in Canada to be organized solely for nuclear research and development engineering. Denton Massey is general manager.

New Company Formed– Formation of a new company, Prenco Products Company, Lakeshore Road, Clarkson, Ontario is announced by John M. Atwood, general manager. Specializing in treatment of porosity in metal castings of all kinds, the new company will manufacture foundry supplies and equipment of various types. Initial products to be made are Porlox seal, a metal oxide type seal for casting impregnation, and See-O-Two core binder which is used in the production of foundry cores and moulds by the carbon dioxide hardening process.

Dynapump Representatives — Jenkinson and Company Ltd., Toronto, have been appointed by The Fostoria Pressed Steel Corporation as exclusive Canadian representatives of the new improved Dynapump. The outstanding characteristics of this new pump are the high head, up to 25 feet, capacities to 1330 square feet of radiation, elimination of noise, improved flange design, simpler installation and one size for all small building applications.

Engineering Office– Arthur G. McKee & Company of Canada, Ltd., has opened a Canadian engineering office on Toronto's lakefront, H. E. Widdell, president, has announced. Carl L. Nilson has been named general manager of the new engineering office.

To Manufacture in Canada–The Ric-wiL Company of Canada Limited announces establishment of manufacturing facilities in St. Thomas, Ont. It is affiliated with Ric-wiL Incorporated of Barberton, Ohio, U.S.A. H. S Boring is president of Ric-wiL Incorporated and the Canadian company; Earle R. Hall has been elected vice-president; and Charles Hammersley, former chairman of the St. Thomas Industrial Board, has been appointed works manager. Production of Ric-wiL insulated piping systems has begun.

Organization Changes– A change in organization structure has been announced by CHAIN Belt Company, Milwaukee. The present divisional structure will remain unchanged with each division responsible for its own operations, but it is now planned to group these divisions in accordance with the major end use of their various products. An industrial

Corrosion-Resistant, Heat-Resistant EXTRUDED Steel Pipe

Curtiss-Wright's Metals Processing Division now offers the petroleum, petrochemical and power industries a line of high-quality, extruded steel tubular products to meet the most severe demands of modern processing. Inherent corrosion and heat-resistant properties of the steel alloys used are amplified by extrusion because the finished tube is produced with only one heat, in one pass of the giant 12,000 ton press . . . formed under compression in a matter of seconds without seams, in lengths up to 50 feet. Extra margins of resistance to corrosion and heat are built in easily by extruding heavier pipe wall thicknesses at no sacrifice in production speed. The most up-to-date quality control facilities, including ULTRASONIC TESTING, are employed in production.

Curtiss-Wright's extrusion facility is a specialty mill, ideally equipped for the production of special purpose, premium quality tubing. Conformance to A.S.T.M. specifications and other exacting standards is assured by an experienced engineering staff and the most modern metallurgical testing equipment.

When higher pressures and temperatures, or more corrosive service conditions demand more than the ordinary in large diameter pipe, let Curtiss-Wright serve you through the nearest Metals Processing Division Branch Office, or write to the address shown below.

equipment section and a construction machinery section are therefore being established. The industrial equipment section will be made up of the company's Roller Chain Division, the Chain and Transmission Division, the Conveyor and Process Equipment Division, and the Shafer Bearing Division. The construction machinery section will consist of the Construction Machinery Division, Milwaukee, the California Division, Los Angeles, and CHAIN Belt (Canada), Toronto.

Steam Generating Station— As part of the Commission's long-term planning for the northwestern part of the province, Ontario Hydro property officers are arranging options on possible future sites for a steam generating station at the Lakehead. It is expected that, in the near future, crews will go into the area for test-boring of the sites under consideration. The activities now under way are stated to be a safeguard for the future power supply of this rapidly expanding district.

Canadian Oil Expansion— Contract for the $3,000,000 petrochemical plant at Canadian Oil's Sarnia refinery has been awarded to The Fluor Corporation of Canada, Ltd., refinery and chemical-engineer contractors of Toronto. The contract calls for the engineering and erection of a Udex plant having a design capacity of 3,650 barrels a day, and a 4,400 barrels per day Platforming unit. Completion of the new plant is scheduled for next summer. A modern glass and aluminum building in Toronto will house the new head office of Canadian Oil Companies, Ltd. A feature of the new structure, which will be named the Canadian Oil Building, is multi-storey parking. This comprises five storeys—two and a half storeys above ground and two and a half below ground—accommodating 110 cars. Modelled on the Lever Building in New York City, the Canadian Oil Building is of steel construction with aluminum curtain walls, plate glass windows, and structural glass spandrel panels.

Power for Ore Bridge— All electrical drive equipment for the Algoma Steel Corporation ore bridge will be supplied by the Canadian Westinghouse Company. The bridge, to be the fastest in North America, will be located at Algoma's Sault Ste. Marie, Ontario, plant and will be built by Heyl & Patterson Inc. of Pittsburgh. It will have a free digging capacity of 1,540 gross tons per hour.

The main drives, bucket hold and close, trolley and bridging are adjustable voltage d.c. The adjustable voltage drives are controlled by Rototrol speed regulators, with Magamp current limit override. Power is brought on to the bridge at 2300 volts, 3 phase, 60 cycle. A six unit M.G. set comprising a 1000 hp. synchronous motor, two 300 kw. d.c. generators for the bucket drives, two 300 kw. d.c. generators for the trolley drive and a 50 kw. constant voltage d.c. generator, powers the main drives and d.c. auxiliaries

The 20 gross ton bucket is driven by hold and close motors, each rated 250 h.p., 1 hour. The trolley is driven by two 250 h.p. continuous rated motors. Bridging is done with the hold generator powering four 45 h.p., 30 minute, pier leg motors, and the close generator powering two 65 h.p., 30 minute, shear leg motors. A power centre, 150 kva., 2300-575 volts, provides power for bridge lighting, the apron hoist and rail clamp drives, and auxiliaries. The bucket turntable is driven from 250 volts d.c. constant voltage.

Core for Nuclear Reactor— The John Inglis Co. of Toronto, who have just completed the construction of the heart of the new Chalk River NRU reactor, are

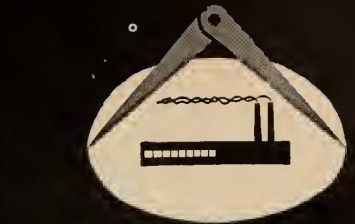
NEOPRENE • HYPALON®



in Industry

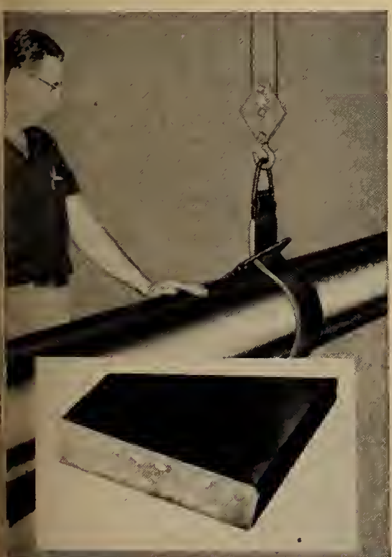
NEOPRENE sling handles highly finished metal stock

Long service life is expected from the neoprene-cushioned sling shown below handling a piece of finished bar-stock. The conventional woven wire sling has been completely encased in neoprene, providing a soft, smooth cradle that won't mar the highly polished surface.

The manufacturer used neoprene for the sling because of its superior resistance to oils, greases and aging. Even under the most severe service conditions, neoprene offers long, dependable performance.

In your plant, neoprene offers cost savings wherever you need a durable, resilient material. Hose, belts, gaskets, tank linings and many other applications profit by neoprene's unusual resistance to heat, oil, chemicals, aging and flex cracking.

Use the coupon for more complete information on neoprene. If you have a specific problem, let us know on the coupon.



Neoprene wire slings can be supplied in any length or width, used in a basket or choke hitch for handling a variety of metal shapes. Sling pictured is 4" wide and 5' long.

New rubber-based paints resist ozone, chemicals, heat and weather

There's a new kind of industrial maintenance paint on the market. These paints are based on HYPALON, Du Pont's new synthetic rubber. They resist ozone, strongly oxidizing chemicals, heat and weather. And, what's more important for color-conscious plant engineers and purchasing agents, HYPALON paints come in a range of colors, all of which are stable to sunlight exposure.

HYPALON coatings can be brushed or sprayed. A sprayed coating, applied with standard lacquer or enamel spray equipment, gives a glossy finish and can be built up in the same way as other coatings.

Whichever method you use, you can get colors that start bright and stay bright —applied inside or outside of your plant. They can be used to color-code piping systems or to color-condition your equipment. In all cases, your equipment is protected by a resilient, long-lasting coating. The end result is reduced plant maintenance costs.

We'll be glad to send you a list of suppliers. Write "Suppliers list" on the coupon. Clip the coupon, also, for information on the many other uses for HYPALON.

EASY TO APPLY, HYPALON coatings are brushed or sprayed on like enamel. They add bright, light-resistant color and long-lasting protection to your plant equipment.

to build another for India. They are to supply, under the Colombo Plan, the pile core components and the control and shut-off rods for a special research reactor that will be installed near Bombay. This new reactor is similar to the NRX, constructed for Chalk River some years ago, but incorporates latest modifications. It is scheduled for delivery about the middle of 1957.

Plant Completed— Leo E. Ryan, president of Monsanto Canada Limited, announced the completion in September, of the new synthetic resin plant at Clover Bar, Alberta, near Edmonton. Production of phenolic and urea resins is under way. The plant was built on schedule, with operations in progress four months after ground was broken.

Mill Lubrication System— A contract has been awarded Dravo Corporation, Pittsburgh, for a custom-designed mill lubrication system to be installed on the Minton vacuum dryer section of a new pulp mill for British Columbia Forest Products Ltd. at Crofton on Vancouver Island, B.C. Dravo was given the order by Dominion Engineering Co. Ltd., of Montreal designers and builders of the 178-inch pulp machine which will be equipped with a Minton dryer. The lubrication system will have a metered flow of 115 U.S. gallons per minute of 900 SSU oil at 100 deg. F.

Surface Grinders— Atlas Copco Canada Ltd. has announced two new air-powered surface grinders—the 6 lb. LSS 61 model developing 1.3 h.p. at 600 r.p.m. and the 12 lb. LSS 81 developing 2.6 h.p. Both machines are effective for sanding and polishing, for grinding with the new reinforced-hub wheels at surface speeds up to 15,000 feet per min. as well as for heavy work with cup wheels or wire brushes to which LSS 81 is particularly adapted. Reliability and low maintenance cost stem from extreme simplicity of design. Main housing is a single light alloy casting, while governors do not require adjusting.

New Scholarships— The setting up of six $500 scholarships and one $2,000 fellowship annually in four Canadian universities was announced recently by Walter C. Koerner, president of Alaska Pine & Cellulose Limited. Four scholarships each worth $500 will go to the University of British Columbia, one each in forestry, chemical engineering and civil engineering. One $500 scholarship will be open only to sons and daughters of Alaska Pine & Cellulose employees. One $500 scholarship in chemical engineering will go to both McGill and the University of Saskatchewan. In addition a $2,000 fellowship in graduate chemical engineering will be established at the University of Toronto with preference in this case being given to a student coming from British Columbia. All scholarships go into effect this fall.

E.I.C.
TECHNICAL PAPERS

The Institute maintains a fund for the separate publication of high-calibre original technical papers. Interest in such papers is limited to a relatively small audience of specialists in the subjects to which the papers relate, and it is not economically sound to publish them in the *Journal* which aims at the interest of some 16,000 engineers in all branches of the profession.

It is an obligation of the Institute to publish original works which contribute to the reference literature of the profession. The Technical Papers are distributed to the world's major engineering societies and technical libraries. Similarly it is an obligation of those engineers qualified to write these papers to submit them for possible inclusion in the literature. The publications committee invites authors to present such manuscripts for submission to qualified reviewers and publication if warranted. Written discussion will be accepted and published as supplements.

Technical papers issued to date are:—

No. 1—Flow in Conduits and Canals:— *French and Wood.* Comprises tables and diagrams for the solution of problems of flow in open and closed channels. Price $1.50

No. 2—A Revised Manning Flow Formula:— *Blench.* A discussion of the various hydraulic flow formulae in use or proposed. The author, formerly Director of Irrigation Research, Punjab, Pakistan, and now on the staff of the University of Alberta, concludes that the Manning formula, with modifications, is the best now available. Price $1.00

No. 3—Air Entrainment by Water in Steep Open Channels:—*Priest.* A theoretical solution of a problem of interest to hydraulic engineers $1.00

No. 4—Graphical Solution of Partial Differential Equations with Engineering Applications:—*Wood.* Solution by simple, almost automatic, methods of equations arising from the study of water hammer phenomena, impact, and other common engineering problems. This paper will be of particular value to hydraulic engineers and structural and machine designers. Price $3.00

No. 5—Economy in Rigid Frames:— *Monti.* Charts and diagrams to facilitate rapid preliminary design of the common types of rigid frames, eliminating the cut-and-try methods previously necessary before a final analysis could be attempted. This paper belongs in the library of every structural designer. Price $1.00

N.B.—Remittance with order please, payable at par in Montreal.

Problems of

Development of International Rivers

on the Pacific Watershed of Canada and the United States

General A. G. L. McNaughton, M.E.I.C.

Chairman, Canadian Section, International Joint Commission

Paper presented before the Fifth World Power Conference, Vienna, Austria, 17-23 June 1956

The northern portion of the Pacific watershed of North America divides between the jurisdictions of Canada and the United States. In this region many of the more important rivers, including the Columbia and the Yukon, rise in Canada and in their course to the Pacific Ocean flow across the international boundary into United States territory. By the Boundary Waters Treaty of 1909 the riparian state is vested with exclusive jurisdiction and control over the use and diversion of all waters on its own side of the line subject only, should injury result on the other side, to the same legal remedies as if such injury took place in the country where the diversion or other interference occurs.

Not only are the flows of the rivers in question very large, but the heads which may be created by diversion amount, in several cases already investigated, to 2,000 or more feet, with consequent potentials for power development measured in terms of millions of kilowatts.

The jurisdictional, topographical and hydrological conditions and problems at issue in the watershed are indicated and the solution proposed in the Canadian portion of the basin of the Columbia is described as an example.

THE problems presented to Canada in the development of her water resources in the Pacific region are partly international under the several treaties which govern relations between Canada and the United States and partly national as between the federal, provincial and territorial authorities concerned with particular areas. Then, these external and internal jurisdictional aspects being resolved, there are great questions of engineering to be answered by the acquisition of comprehensive data in regions as yet only partially surveyed; also in the selection of projects which will not only make optimum use of resources within river basins but will also take advantage of the topography of the Pacific coast where inlets from the ocean penetrate the coastal mountain ranges into close proximity with southern, eastern and northern drainage. The great lakes and rivers, which exist in the high valleys, open up imaginative possibilities of immense storages at high altitudes and of diversions of substantial flows to be used in the large and concentrated heads available on the Pacific slope. Here, the power plants may be placed in easier access for the supply of raw material to be processed and for the despatch of finished goods to markets. The milder climate and more pleasant living conditions of the coastal region, warmed by the Japanese current, is also a very significant advantage for the residents of the many new communities which will come into existence in consequence of the power developments.

Within the restricted limits of this paper an outline of the international and national jurisdictional aspects will be given sufficient to show the wide choice of action which is open to Canada in the particular Treaty and legal situation which exists and which, with recent legislation, has now been firmly gripped by the Parliament and Government of Canada for the Canadian people.

Space does not permit detailed description of the multiplicity of projects which are under investigation and study in various stages. However, data for the several river systems sufficient to indicate the order of magnitude of the possibilities will be included.

The possible projects in the Columbia system including diversion into the Fraser will be described in general outline. The studies of these particular projects are at present well advanced but the descriptions given are subject to verification in details when reports are received on the field investigations currently in progress.

International Boundaries

Figure 1 is an outline map of the Pacific watershed of Canada and the United States showing the international, provincial and territorial boundaries in the south, in the west, and in the north. The principal drainage basins and their rivers and important tributaries are also depicted. In this region sovereignty is

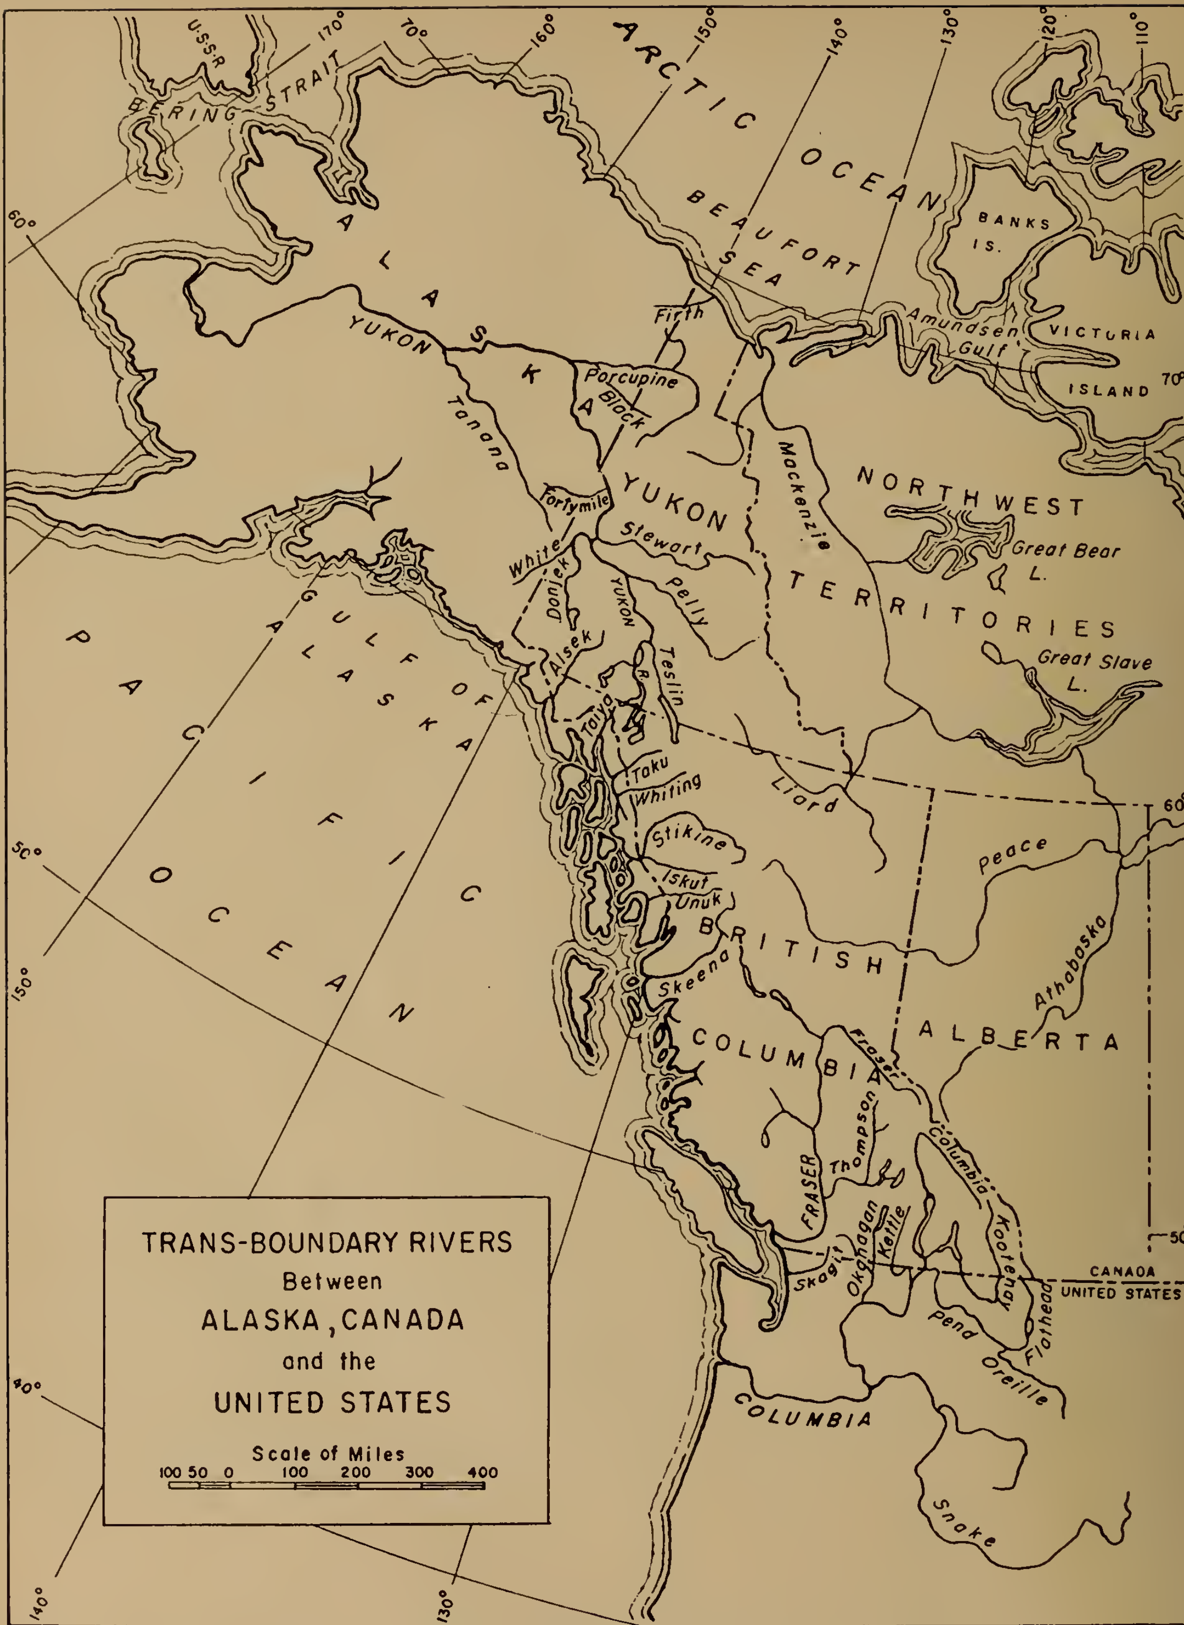

Fig. 1. Outline map of the Pacific watershed of Canada and the United States, showing the trans-boundary rivers between Alaska, Canada, and the United States.

divided between Canada and the United States as follows:

In the south by the 49th parallel of north latitude; on the west, along the Alaska panhandle, by a line following the summits of mountains some ten marine leagues back from the ocean, including the principal fiords extending inland therefrom, until the 141st degree of west longitude is reached; thence the boundary follows this line north to "la mer glaciale".

In every case along these boundaries the rivers which are of international concern flow from one country to the other *across* the boundary.

Treaty Provisions in Respect to Jurisdiction over Waters Flowing Across the Boundary

The international provisions for jurisdiction and control of such waters are contained in the following articles of the "Treaty between His Majesty and the United States of America relating to Boundary Waters, and questions arising along the boundary between the United States and Canada", signed at Washington, 11 January, 1909.

Article II — "Each . . . reserves . . . exclusive jurisdiction and control over the use and diversion . . . of all waters on its own side . . . but . . . any interference with or diversion from their natural channel . . . resulting in any injury . . . shall give rise to the same rights and entitle . . . to the same legal remedies as if such injury took place in the country where such diversions or interference occurs . . .; neither . . . surrender any right, which it may have, to object to any interference with or diversions of . . . productive of material injury to the navigation interests on its own side . . ."

The Parliament of Canada in approving the Treaty of 1909 vested the Exchequer Court of Canada with "jurisdiction . . . in all cases in which it is sought to enforce or determine as against any person any right or obligation arising or claimed under or by virtue of this Act".

Article IV — "The High Contracting Parties agree . . . not permit the construction or maintenance . . . dams or other obstruction . . . or in waters at a lower level than the boundary *in rivers flowing across the boundary, the effect of which is to raise the natural level of waters on the other side* . . . unless . . . approved by . . . the International Joint Commission."

Article VIII — ". . . In cases involving the elevation of the natural level of waters on either side of the line as a result of . . . obstructions . . . or in waters below the boundary *in rivers flowing across the boundary*, the Commission shall require . . . protection and indemnity of all interests *on the other side* of the line which may be injured thereby."

The Treaty of 1909 contemplates that matters other than those in which jurisdiction has been vested in the International Joint Commission may be arranged by "special agreement between the parties". (Article III and Article IV.)

Article IX — ". . . any other questions or matters of difference . . . along the common frontier . . . shall be referred . . . to the International Joint Commission . . . to examine into and report upon the facts . . . together with such conclusions and recommendations . . . subject, however, to any restrictions or exceptions which may be imposed . . . by the terms of reference."

On occasion the Commission's recommendations in references under Article IX have included a request for the approval by the Governments of particular provisions for further action beyond the authority specifically vested in the Commission by the Treaty in order that the Commission might undertake to solve particular difficulties or matters of difference. And, when these recommendations have been approved, the powers of the Commission have been enlarged accordingly.

By such procedures a measure of flexibility is given to meet conditions which could not have been fully foreseen or provided for specifically in the Treaty itself.

Jurisdiction over waters flowing from within to without Canada

In the session of 1955 the Parliament of Canada enacted "the International Rivers Improvements Act", which states that an "international river" is "water flowing from any place in Canada to any place outside Canada" and that "an international river improvement" is:

"a dam, obstruction, canal, reservoir or other work, the purpose or effect of which is:

(i) to increase, decrease or alter the natural flow of an International River, and,

(ii) to interefere with, alter or affect the actual or potential use of the International River outside Canada".

By this Act, Parliament has given precision to powers over water which flows from within Canada to without Canada which are implicit to the Federal Government in the terms of the British North America Act which accomplished Confederation in 1867.

For the future, any "International River Improvement" will require a permit from the Federal Government. Similarly the export of electricity generated in Canada has for many years been controlled by the requirement for a permit from the Federal Government which is only issuable or renewable for a single year at a time.

The Sovereign Right to Divert

It will be noted that the basic concept of international water law in "rivers flowing across the boundary" which is defined in Article II of the Treaty of 1909, quoted above, is in sharp difference to the riparian law under which a person on the banks of a stream has the right to have its water come to him "undiminished and undefiled" and he has an obligation to permit it to pass downstream in like volume of flow and freedom from pollution.

The only restrictions on the absolute sovereign power of a state given by Article II of the Treaty of 1909 to divert water, within its territory which in its natural channels would flow across the boundary, is the somewhat unique provision which has been added to this clause requiring the national authority itself to provide the means whereby, if anyone in the other country is injured, he may seek redress in the law courts of the upstream country where the diversion or interference occurs.

In the Pacific watershed, Canada, in almost all cases where major possibilities of diversion exist, is the upstream state; and in consequence, in this region of immense potentialities, Canada for the first time in the history of her relations with the United States over the use of water becomes the beneficiary of the sovereign powers of diversion prescribed in Article II of the Treaty of 1909.

It is important to recall that this Article was included in the Treaty on the insistence of the United States Secretary of State, Elihu Root, as a matter of fundamental United States policy, and as an inescapable requirement for any agreement. Since that time representatives of the Unit-

ed States have quoted this Article, in cases where that country has been the upstream state, to the disadvantage of Canada and in the result an extensive body of precedent has become established through argument presented to the International Joint Commission principally by learned counsel for the United States and for various States of the Union. Analysis of these presentations shows, with reasonable clearness, the position which has been maintained consistently by the United States both as regards their claim to absolute right to make diversions in their territory and perhaps even more importantly what would and what would not, in their view, constitute an injury to parties in the country below the boundary which would entitle those parties to legal remedy.

It is perhaps needless to say that the position indicated in the following paragraphs is entirely consistent with the practice which has been urged by the United States in like circumstance.

International Rivers in the Pacific Watershed of Canada and the United States

In Table I, the "International Rivers", shown on Fig. 1, are listed and the place of crossing the boundary is given together with the elevation above mean sea level and the flow at that point so far as available data permits.

These waters originate mostly in the higher altitudes from the melting of snow and ice and the precipitation of moisture laden clouds sweeping in from the Pacific. Since remote ages, the rivers have kept their passage open to the sea by continued erosion of the mountain barriers as these have been pushed up by geological action. And in the result, the upper river courses run in rapids and falls through deep narrow valleys cut in the rock where conditions favour the construction of dams. In contrast, in the lower and often in the middle reaches, the valleys are sedimentary and are usually wide with long traverses of gradual slope. Here the concentration of head for at-site power development presents difficulties. On the other hand, immense potentialities for useful development are presented by the close proximity of the upper basins of some of the rivers in Canada to the fiords extending at near sea level well into the hinterland. Waters from the upper basins, it has been found, can often be diverted by comparatively short and moderately priced tunnels through the "divide", enabling the flows to be brought to places where very large heads can be concentrated. These favourable topographical conditions open the way to an advantageous use of water in the development of power which in many cases would not otherwise be possible — at least with like efficiency.

In this paper, all that can be undertaken is to give, as an example of the possibilities, a general description of the plans which are contemplated for the rearrangement, to the greater advantage of Canada, of the flows of the Upper Kootenay River into the Columbia River at the source of the latter, and the further diversion of the combined flows of the upper waters of these rivers into the Fraser which, from its source to its outlet into the Straits of Georgia near Vancouver, British Columbia, is a wholly Canadian river.

Another example of a similar rearrangement of flows now under consideration is the reversal of the direction of flow of the upper Yukon River and its diversion together with that of certain of its tributaries into the Atlin Lakes from which the waters will be taken by a series of tunnels into the valley of the Taku. Space does not permit a discussion of this project in this paper.

Canadian Studies in the Rearrangement of Flows

Figure 2 is an outline map of the Columbia Basin showing the location of the principal dams, power plants and reservoirs, built or planned, both in the upper basin in Canada and downstream in the United States; the adjacent basin of the Fraser and the routes of diversion thereto, which are under study; and other additional information which could not be shown on Fig. 1. Table II gives the elevation, head, mean annual flow, and installed capacity, existing or planned, at various sites in Canada and the United States, on the Kootenay, the Pend Oreille and the Columbia as far downstream as Grand Coulee Dam and tributaries thereto.

Reservoir capacity, existing or planned, is given in m.a.f. (million acre-feet, or 1.233×10^9 cubic metres) of storage usable for annual or cyclic release as the case may be.

The Columbia River rises in Columbia Lake, flows north-northwest to its junction with Canoe River at the Big Bend; thence south past Mica Creek, Revelstoke and through the Arrow Lakes; thence past Castlegar and Trail to cross the international boundary and enter Franklin D. Roosevelt Lake, the reservoir created by Grand Coulee Dam.

Figure 2 shows also the Kootenay River which rises on the high slopes of the Rocky Mountains, near the Continental Divide, which constitutes the Alberta-British Columbia boundary; flows southward to the near proximity of Columbia Lake which it passes at about the same altitude, and thence continues to cross into the State of Montana at Newgate, British Columbia.

In the United States the Kootenai* flows in a great loop through the northern parts of the States of Montana and Idaho and re-enters Canada just north of Porthill, Idaho. In this traverse, the Kootenay falls from approximately elevation 2309 feet (703.8 metres) to elevation 1743 feet (531.3 m.) — a total of about 566 feet (172.5 m.), of which it seems 194 feet (59.1 m.) at Libby and 263 feet (80.2 m.) at Katka, a total of 457 feet (139.3 m.), might be capable of development.

After entering British Columbia, the Kootenay flows into Kootenay Lake and along its west arm past Nelson and thence through the six power plants there situated, falling a total of some 360 feet (109.7 m.) to its junction with the Columbia near Castlegar, British Columbia. The hydraulic capacity of the power plants on the lower Kootenay is 13,500 c.f.s. (382 cubic metres per second) which is only about half the mean annual flow as will be seen from Table II. To use more water than this would require an expensive redevelopment not considered economically justifiable in the Canadian interest.

Another important tributary to the Columbia, the Pend Oreille, enters Canada from the south, near Nelway, British Columbia, flows for some 16½ miles (26.5 km.) westward just north of the boundary, falling a total of approximately 426 feet (129.8 m.) to its mouth. At Waneta, the lower of two power sites of similar potentialities, about 216 feet (65.8 m.) of head has been developed and the power plant partly equipped with turbines and generators.

Below Waneta the Pend Oreille joins the Columbia about one-half mile north of the international boundary.

To complement this information, the profile given in Fig. 3 shows the height of the water surface above mean sea level along the Columbia and Kootenay and also by way of the contemplated Columbia-Fraser diversion near Revelstoke and along the South Thompson and the Thompson to its junction with the Fraser at Lytton, and thence along the Fraser to the vicinity of Hope, British Columbia, at an elevation of approximately 100 feet (30.5 m.).

The bar graph in Fig. 4 gives the mean annual flows naturally occurring at representative points, both in c.f.s. and m.a.f. and as these would be rearranged by the possible diversions to be discussed later.

The Canadian Plan

Briefly, the Canadian plan for the most effective possible use, within Canada, of the flows of the Kootenay and Columbia, envisages the construction of a dam on the Kootenay River above the Bull River to elevation 2710 feet (826 m.) which will cause the Upper Kootenay to flow across the low divide at Canal Flats, into Columbia Lake. On the Columbia at Luxor, below Lake Windemere, another dam with similar top elevation will be built and will complete the Bull River-Luxor Reservoir, which will have a usable annual capacity of some 3.4 m.a.f. (4.2×10^9 cu.m). The contemplated diversion from the Kootenay above the

NOTE: Existing plants and reservoirs in bold face.
Mean annual flows for period of record—No diversions assumed.
Terminal date 1948 unless otherwise noted.
‡ Installed capacity based on mean flow of Columbia supplemented by 5000 c.f.s. mean flow diverted from Kootenay.

Bull River expressed as mean annual flow is planned as approximately 5,000 c.f.s. (142 cu.m./sec.).

The dam at Bull River may be equipped with motors and pumps by means of which it would be possible to raise an additional 3,000 c.f.s. (85 cu.m./sec.) of water, derived from the Bull and the Elk Rivers, to the Luxor-Bull River reservoir from a pool to be created by a dam at Dorr. The factor of energy gain to Canada in bringing this water into the Bull River-Luxor reservoir at elevation 2710 feet (826 m.) for use in the Columbia and Fraser in conditions of full development would compensate several times over for the use of this water otherwise possible at the Dorr Dam, 43 feet (13.1 m.), and on the Lower Kootenay, 360 feet (109.7 m.).

The waters of the Bull River-Luxor reservoir, including a mean annual flow of 5,000 c.f.s. (142 cu.m./sec.) from the Kootenay, after use through power plants at Luxor (47,000 kw.) and Donald Canyon (135,000 kw.), will flow into the Mica reservoir at elevation 2435 feet (742.2 m.). In this reservoir the usable annual capacity contemplated is 11.8 m.a.f. (14.5 x 10^9 cu. m.) at 35 per cent drawdown. The average effective head at Mica will be 563 feet (171.6 m.) and the installed capacity 1,320,000 kw.

From the tailrace of the Mica power plant, the water will flow through a run-of-river plant at Priest Rapids with 780,000 kw. installed; thence into a pool to be created by a dam at the Little Dalles. From the Little Dalles pool at elevation 1610 feet (490.7 m.), a gravity tunnel will connect to Griffin Lake in the western slope of Eagle Pass, presently at an elevation of approximately 1490 feet (454.2 m.), raising it to approximately 1507 feet (459.3 m.) and utilizing it as a stilling basin and forebay for the envisioned power plant. The tunnel required for this project may possibly be some 16 or 17 miles (25.7 to 27.4 km.) in length.

On the South Thompson, the Thompson, and the Fraser, the head which might be utilized is at present the subject of investigation. For the purpose of preliminary studies, 1,000 feet (304.8 m.) of the 1610 feet (490.7 metres) elevation at the Little Dalles pool has been taken as an estimate of early possibilities.

Figure 5 gives hydrographs showing the mean monthly flows at a few representative points along the Kootenay, the Columbia, the Thompson, and Fraser Rivers respectively. Plots for high and low, as well as mean flows are given and also, on a separate graph on the right, the mean annual flow for each year of record to illustrate the very wide variation which occurs from year to year as well as from month to month.

This information emphasizes the great importance of storage, both annual and cyclic, as an essential facility in any comprehensive scheme for the economical development of rivers which depend primarily, as do the Columbia and Fraser systems, on ice melt.

Included on Fig. 5 (see D and E), superimposed on the hydrographs of the Thompson at Spences Bridge and of the Fraser at Hope, are lines showing the regulated flow which can be obtained in the low water period at these places from the addition of 15 m.a.f. (18.5 x 10^9 cub. m.) and 10 m.a.f. (12.3 x 10^9 cu. m.) respectively, of Columbia water.

It will be noted that with an added flow of 15 m.a.f. (18.5 x 10^9 cu. m.) the minimum dependable flows for the low water months have been increased, at Spences Bridge from about 4,500 c.f.s. (127 cu. m./sec.) to 42,000 c.f.s. (1,190 cu. m./sec.), and at Hope from about 17,000 c.f.s. (481 cu.m./sec.) to 60,000

Fig. 2. The northern portion of the Columbia River basin, showing developed, possible, and potential dam sites.

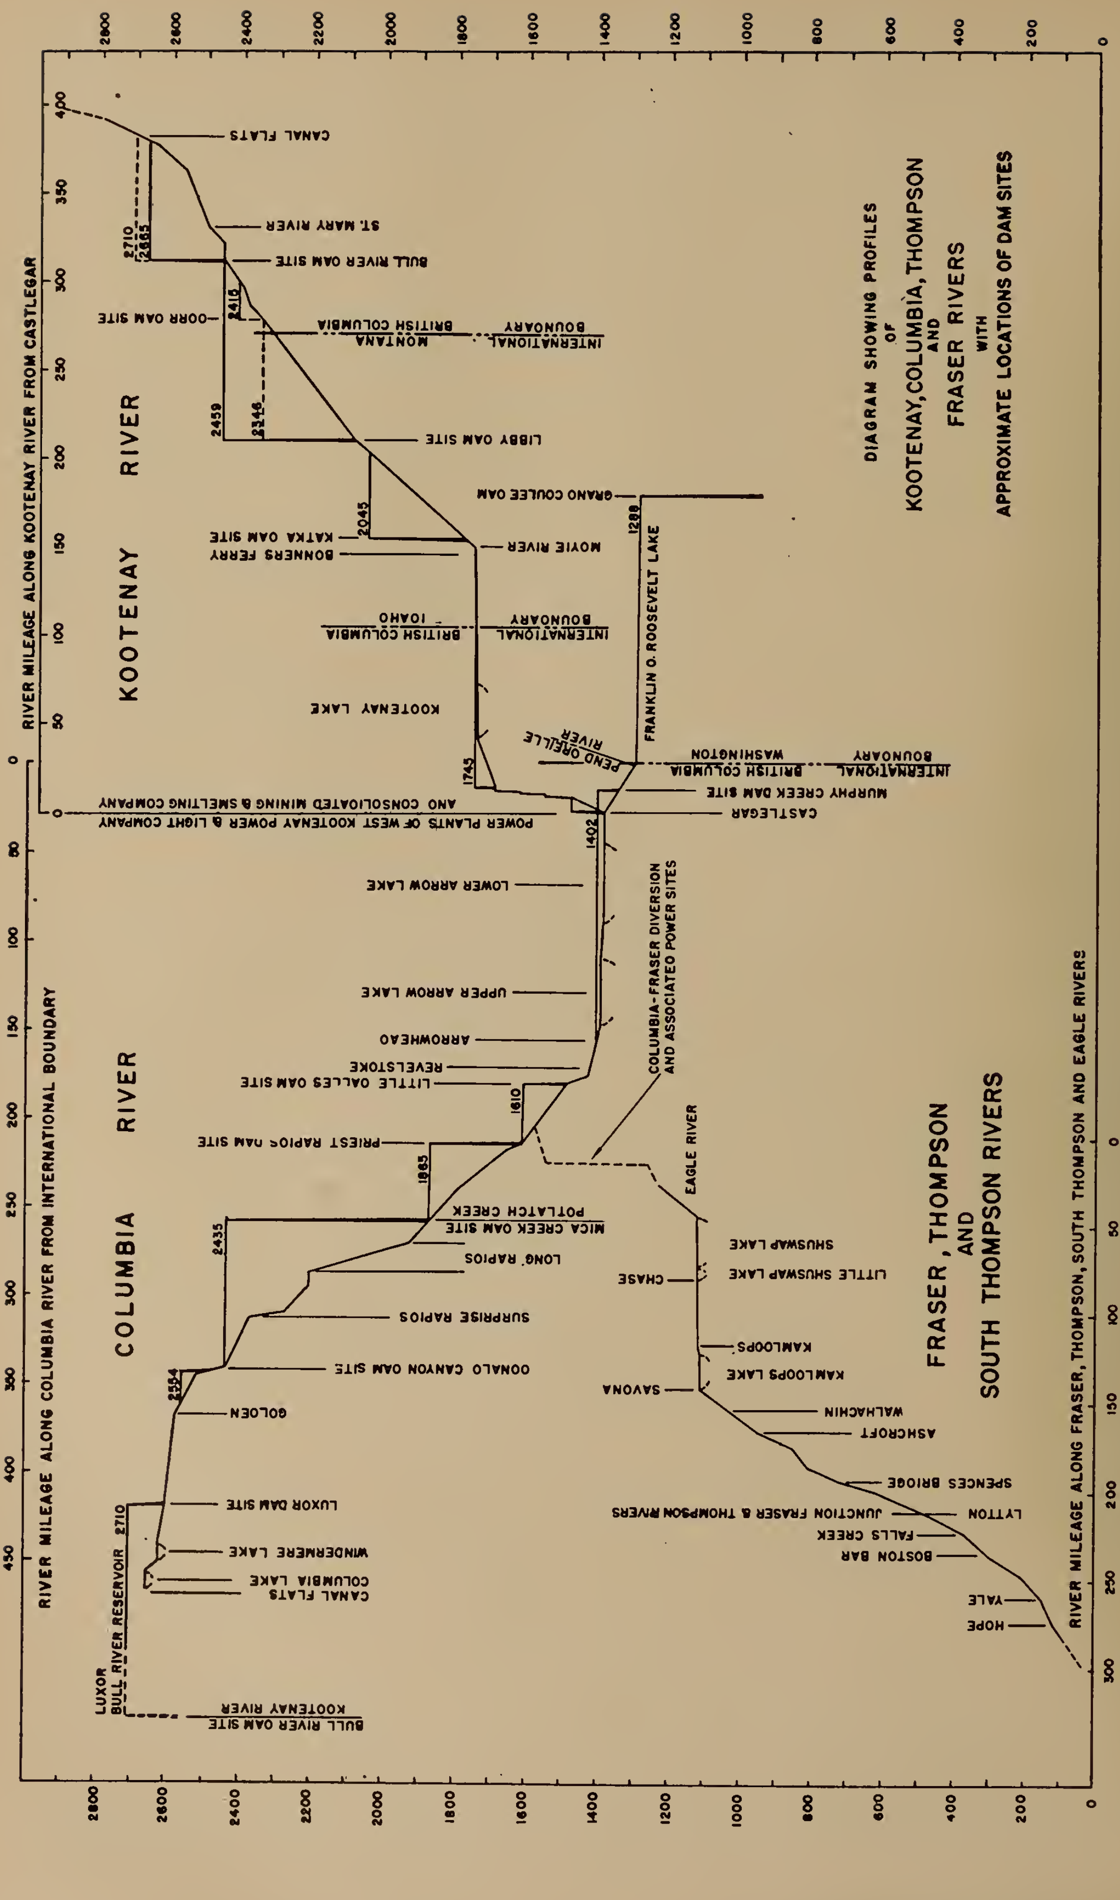

Fig. 3. Profile showing height of water surface above mean sea level along the Columbia and Kootenay, and also by way of the contemplated Columbia-Fraser diversion.

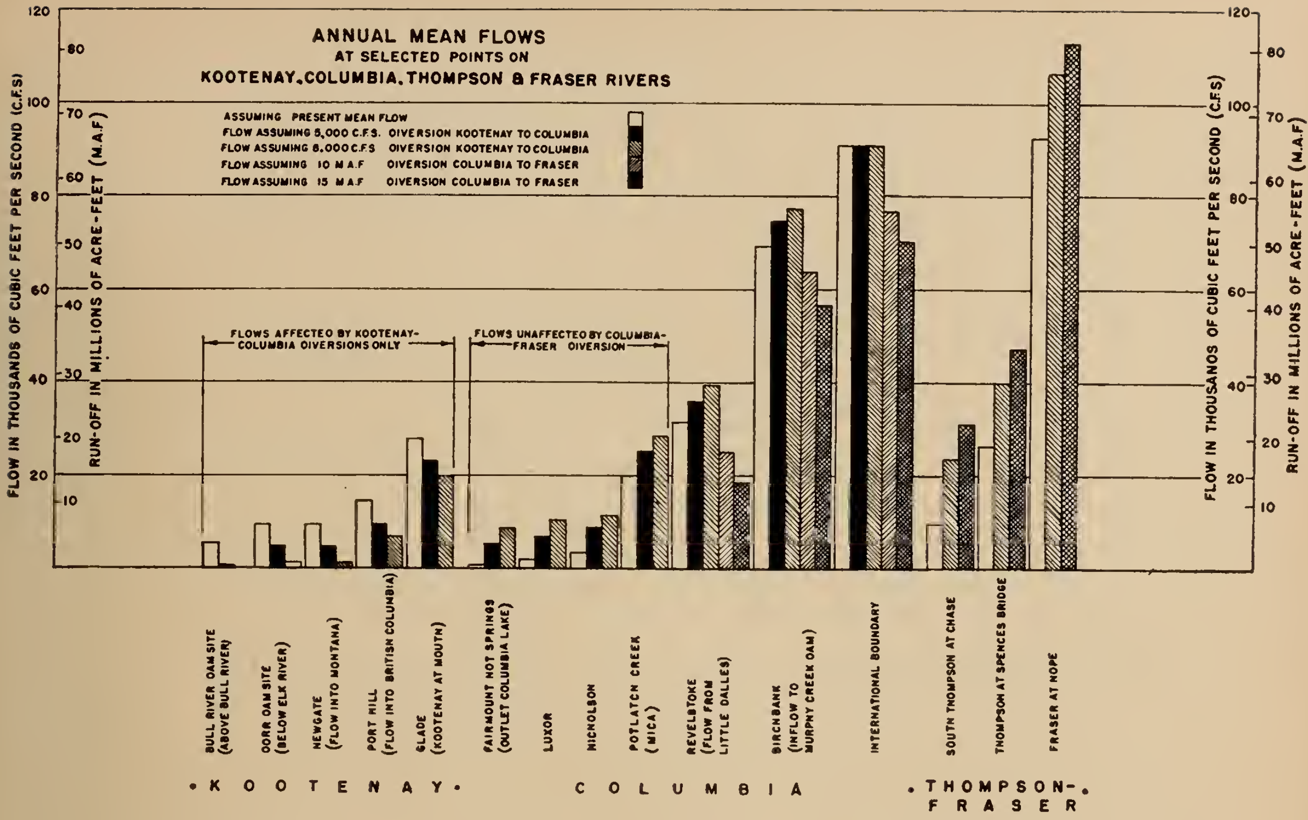

Fig. 4. Annual mean flows at selected points on the Kootenay, Columbia, Thompson, and Fraser Rivers.

c.f.s. (1,700 cu.m./sec.), that is, by a factor of more than 9.0 in the Thompson and of about 3.5 far down the Fraser.

This very desirable result opens the way to a development of the Thompson and the Fraser below Lytton at a reasonable cost; otherwise it is unlikely that hydro-electric development of these rivers could be undertaken at all for the reason that up to this time Canada has given primary consideration to the Fraser basin for the propagation of salmon. As matters stand on the Fraser River system it is not possible to store any considerable volume of water by raising the level of the lakes or creating new reservoirs by the construction of high dams which might interfere with the upstream migrations of salmon and their spawning and the growth and downstream passage of the young fish.

It is to be noted from these same hydrographs on Fig. 5 that the water diverted from the Columbia to the Fraser system will be added to coincide with the season of low flow, October through the following April only; in consequence the present serious flood problem on the lower Fraser will not be aggravated. Salmon migrations upstream to spawn and downstream to the sea occur in the natural high water seasons only, and so will not be affected by the diversions.

Until the field investigations in progress have been completed and the results studied, it will not, of course, be possible to give a precise estimate of the power capabilities of the South Thompson, the Thompson and the Fraser below Lytton, which may be made practicable for development by the diversion from the Columbia.

On the conservative assumption of a developed head of 1,000 feet (304.8 m.) below the Little Dalles pool, the energy generated from the 15 m.a.f. (18.5 x 10^9 cu.m.) to be transferred from the Columbia will be some 13 billion kwh. annually, for winter use in the regulation of peak loads. It seems that this will make economically possible the use of Fraser basin flows in the generation of at least three times this amount of energy in addition. That is, the power plants on the Thompson and the Fraser below Lytton will probably have an installed capacity in excess of 4.5 million kw. From this gain in power potential on the Fraser, there should be deducted 225,000 kw. approximately from the Little Dalles and 80,000 kw. approximately at Murphy Creek on the Columbia, because of the reduction in flows at these sites by reason of the diversion.

The figures given for the Fraser system development do not take into account the possibilities which may open in the future, either for the storage of water in the system itself, or of the large powers which may be developed on the Fraser itself above Lytton as and when the problems connected with the migration of the salmon are solved and the construction of high dams and reservoirs comes to be permitted.

If the regulated flows from Mica Creek reservoir, in the amount of 15 m.a.f. (18.5 x 10^9 cu.m.), were permitted to flow down the Columbia from the Little Dalles pool, the power plant there would probably have an installed capacity of 420,000 kw. and below the Arrow Lakes, at Murphy Creek, the installed capacity would be about 250,000 kw. After passing these projects the water would flow across the international boundary into Franklin D. Roosevelt Lake for use at Grand Coulee and the plants existing, being or to be built downstream.

on the main stem of the Columbia in the U.S.A. have been completed the total U.S. head will approximate 1200 feet (365.8 m.). With this head and the regulated flow permitted by the use of the 11.8 m.a.f. (14.5×10^9 cu.m.) of stored water from the Mica reservoir together with the additional 3.4 m.a.f. (4.2×10^9 cu.m.) from the Bull River-Luxor reservoir an additional 15 billion kwh. of electric energy could be generated to supply winter peak loads through the use of turbines and generators in the then existing plants. Much of this equipment would otherwise be idle because of low flows. In the absence of the regulated flow from Mica and Bull River-Luxor reservoirs to help carry on-peak loads, the alternative open to the downstream interests, until they can develop a like amount of storage, is the construction of thermal generation at costs now running to 7 mills* and more per kwh. when used intermittently. These costs are unlikely to fall below 5 mills even for the most modern thermal plants operating semi-continuously on base load.

For comparison, the present contract price in the Bonneville Administration, an almost solely hydro-electric system in the northwestern United States, is $17.50 per kw. year, which is equivalent to 2.0 mills per kwh.

An offer has been made by Canada to discuss the question of allowing the flows of regulated water from Mica and Bull River-Luxor reservoirs to continue for a relatively short period, at the end of which time it is expected that the additional water, largely conserved from the flood flows, would be fully needed for power development in the Fraser system. This would result in substantial assistance to the United States power entities in bridging the forthcoming period of serious shortages which are developing due to the very rapid load growth taking place in the States of the Pacific Northwest.

Canada has offered to discuss also the raising of the water level of the Columbia River at the international boundary some 42 feet (12.8 m.), flooding back into Canada to the foot of the proposed Murphy Creek dam. This 42 feet (12.8 m.) might be added to the height of Grand Coulee Dam, increasing the output of existing turbines and generators by some 230,000 kw. and adding 3.3 million acre-feet (4.1×10^9 cu.m.) to the storage capacity of the reservoir behind the dam.

A similar suggestion has been made in respect to 37 feet (11.3 m.) on the Kootenay River beween the Dorr site and the international boundary which might be added to the height otherwise fixed for the proposed power dam at Libby, Montana.

A further measure of assistance which has been offered for discussion is the cyclic use of the possible 4 million acre-feet (4.9×10^9 cu.m.) of storage at Murphy Creek, which would be of particular value to United States plants in years of extreme low flows.

In all these cases Canada will no doubt require from the United States due recompense for natural resources used in the various projects and for services rendered.

The investigation of the upper basins in Canada of rivers which traverse the Alaska Panhandle and the Yukon-Alaska boundary is being proceeded with as available resources and staff permit. In addition to the diversion of the Yukon to the Taku already mentioned there are indications of immense further possibilities on the Stikine, for example, and probably elsewhere as well. However, with the limited information at present available these potentialities cannot yet be assessed either as to the amount of power to be produced or as to the preferred locations for development.

* 1 mill is equivalent to 0.1 cent.

Fig. 5. Hydrographs showing mean monthly flows at representative points along the Kootenay, Columbia, Thompson, and Fraser Rivers.

Editorial Comment

A recent issue of *The Financial Post* has placed the spotlight on the crux of the Columbia River waterpower situation in these clear paragraphs:

"British Columbia can become the future industrial empire of the North American West. It can become the only now-settled area of North America with plentiful reserves of really cheap power. It can enjoy for decades to come all the advantages of owning great blocks of cheap power at a time when the rest of the continent is paying steeply rising power costs.

This is the foreseeable outlook for British Columbia. Only two things could upset it:

• If atomic power becomes available—by some unforeseen new discovery—at no more than about three mills per kwh. within about 25 years. No atomic expert has yet prophesied anything like this.

• If Canadian politicians barter away B.C.'s power heritage for the sort of quick return that always appeals to politicians—or to avoid unpleasantness with the United States —or for any other of the reasons that politicians like."

As *The Engineering Journal* has endeavoured to point out on previous occasions, and as informed members of the Institute believe, the second "upset" described above need not happen—and indeed must not ever occur. Our case in the forthcoming negotiations will be in capable and experienced hands. The Canadian Section of the International Joint Commission, under General McNaughton's leadership, needs only our full and outspoken support. They can handle the rest of the job.

It can no longer be any secret that heavy pressures are being brought to bear on the American officials who are charged with these responsibilities. This is obvious to any one following the press accounts these days, and we can sympathize with these men. We would not like to be in their shoes. Ottawa reports indicate that these pressures are even spilling over into Canada.

If calm judgment can prevail through the end of these talks, and it usually does in our important relations with the United States, two basic points will have been established. The *Journal* hopes that it will be useful to state them now:

1. There is not the slightest doubt that Canadian development will ultimately need all of this flood water.
2. If the U.S. authorities will take time to examine the Canadian proposals in detail, they will learn that our plans will actually work out to their own advantage.

Water, Steam, and Refrigeration for a Modern Brewery

R. E. J. Layton, M.E.I.C.

Chief Mechanical Engineer, T. Pringle & Son Limited

Read at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada, Montreal, May 1956

REPORTS of growth and development in Canadian industry are not uncommon today. It is natural that, as we expand our known boundaries, extend our use of raw materials, increase our numbers and develop our personal and national resources, new ideas and operations will be found.

Perhaps typical is the expansion programme of the brewing industry with new plants and building extensions being constructed in all parts of the country. One most recent example is the self-contained brewery built by John Labatt Ltd. in Ville LaSalle, P.Q., close to the city limits of Montreal.

Differing from the average industrial plant, a brewery requires services which must meet the simultaneous demands of process and building. Quality, quantity, cost, and reliability of operation and control are all factors to be considered in the selection and application of the water, steam, refrigeration and drainage services.

In this paper, it is proposed to review design factors and to describe resulting applications as found in the company's new brewery.

General Description

This plant, now in production, includes under one roof five operating divisions. Approximately 850 feet long and 200 feet wide, the building is largely of concrete construction—steel frame being provided for the warehouse. Division No. 1 houses a grains handling system and a brewhouse (with initial capacity of over 1500 barrels a day); division No. 2 includes the ale and lager fermenting areas and their yeast storage rooms; division No. 3 covers the finishing storage cellars; division 4 the filtering and carbonating equipment and bottling plant; and division 5 the shipping-receiving warehouse. All these units are incorporated into a radical one-storey arrangement, using a straight-line process flow principle.

The paper describes the general layout of the brewery buildings and their function. The equipment for water and steam supply and for refrigeration, all of great importance in the brewing process, are discussed at greater length, with details of design, application, and economic considerations. Other essential services are also discussed.

The Grains Handling Area—Here malt and adjuncts delivered by rail are unloaded and transported pneumatically to storage silos, prior to use in production and also where wet spent grains are furnace dried before shipping. Baled hops are handled and stored separately in a refrigerated storeroom designed and sized to take an annual shipment of hops in season.

The Brewhouse—Here the grains and barley malt follow the brewing process, namely "cooking", "mashing", "boiling" of the extracted wort in the brew kettle, where hops are added for flavour, "separating" out of hops and "cooling" of the wort in preparation for fermentation.

Hot water, steam and refrigerated water at temperatures and in quantities as required to bring some 90,000 pounds of liquid and grain to 212 deg. F. and back to 50 deg. F. in just a few hours are some of the service requirements of the brewhouse.

The Fermenting Rooms—Fermenting is a process in which the sugars of the mashing process are converted to alcohols and small quantities of secondary products through the addition of yeast.

"Bottom fermenting" yeast in closed tanks produces the "lager" beer which has become so popular in recent years. The CO_2 gas, tapped off these fermenters, is liquefied for later use in carbonating.

Ale, on the other hand, is fermented with "top fermenting" yeast in open stainless steel tanks, the CO_2 from this process being collected and exhausted to protect the building occupants.

Both ale and lager fermenting processes, being organic reactions, require controlled temperatures and clean atmospheres to protect against contamination. Part of the yeast, drawn off during fermentation, is stored for use in future production. The new brewery provides separate refrigerated storerooms for ale and lager yeast storage where proper cultivation can be maintained.

The Finishing or Storage Cellars—After completion of the fermenting cycle, the beer is pumped into glass lined tanks in one of two sealed storage rooms. Held here for fourteen to twenty-one days at 32 deg. F., the beer develops some of its taste characteristics while yeast and other materials are settling out.

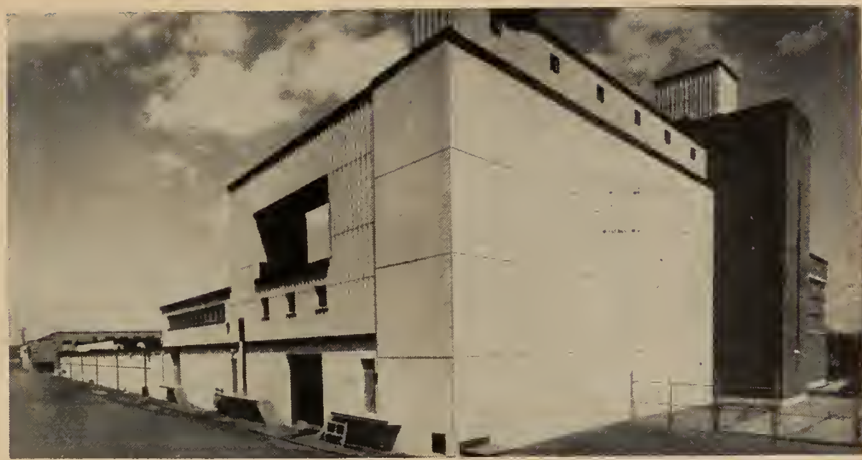
Conditions in these beer processing and handling rooms are affected by the wet floors which result from an almost continuous washing and flushing programme.

From storage, the beer is transferred to a cooling, carbonating and filtering cycle and then back again to storage. This cycle is repeated for accurate control of clarity and carbonation just prior to bottling.

The Bottling Plant — A modern high-speed operation, such as a bottling plant, will always attract the interest of an engineer. At the new Labatt brewery, this operation includes: soaking, where bottles are sterilized in caustic solutions and rinsed; filling, where the ale or lager is bottled at rates up to 400 bottles per minute (constant pressure is maintained at the filler by means of controlled counter pressure on the "bottling" storage tanks) crowning, where agitation of the bottle produces foam and eliminates air, at which moment the bottle is capped; pasteurizing, where the bottles and their contents are brought to a temperature of 140 deg. F. and held before being cooled, all by means of sprays; and finally labelling and packaging into the various containers in which beer can be found today.

The Shipping Warehouse—Conveyors carry completed cartons into the warehouse for transhipment by truck. Empties are also received here both bv truck and rail. Approximately 1,000,000 cubic feet of storage space has been provided, together with mezzanine offices and a truckers' lounge.

Not involved in the product flow, but, nevertheless, an integral part of this new brewery, are the offices and visitors' reception room, both of which are air-conditioned.



A general view of the new plant (from the right hand end of Fig. 1).

Services Building—The many operating divisions of the plant are linked by a service piping tunnel. This "right-of-way" for mechanical services originates in a separate building which houses the steam generating system, the refrigerating equipment and the water filtration plant.

Here, then, is the mechanical heart of a modern brewery. (Fig. 1)

General Service Requirements

The quantity requirements of the three major mechanical services are summarized in Table I.

Table I. Summary of Water, Steam and Refrigeration Requirements

Service	Initial Design
1. Water	525,000 g.p.d.
2. Steam	24,000 lb./hr.*
3. Refrigeration	400 tons

* Includes winter heating requirements

Each of the three major mechanical services will now be reviewed to indicate both design procedure and final design selection.

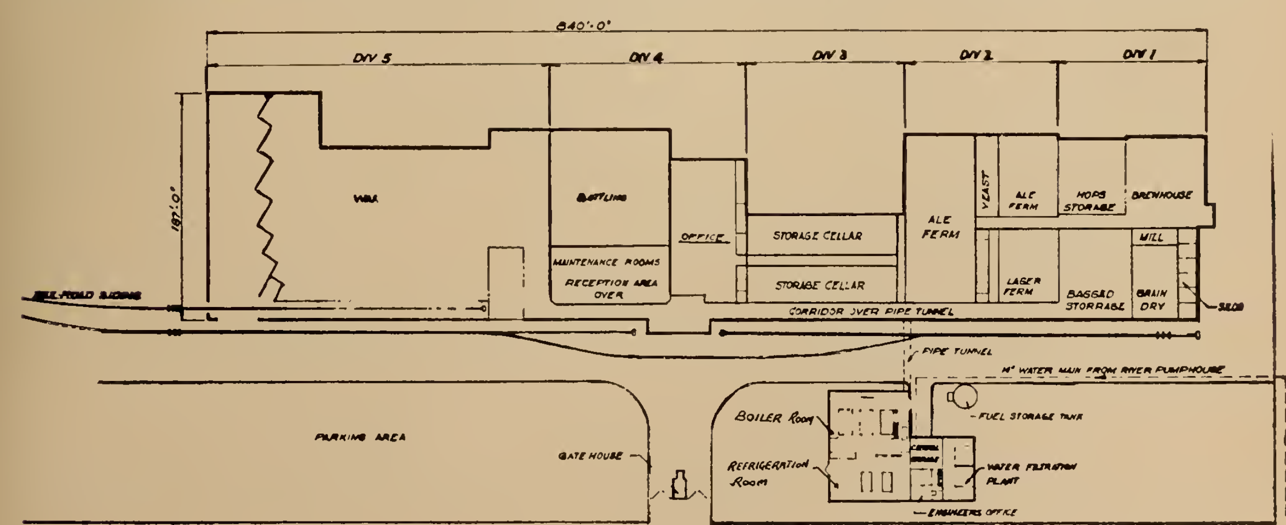
Although the initial kettle installation will limit the daily output of the brewhouse to 1,750 barrels, provision has been made in the process and building plans for an ultimate production of over six times this amount. In the mechanical design, an analysis of the effects and costs of future loads was necessary to compromise the initial requirements. In the interests of economy, this compromise was limited wherever possible to pipe sizing and space allocation.

Water Supply

The quality specifications for water to be used in the brewery are as follows. The water must be

(1) free from turbidity;
(2) free from organic matter;

Fig. 1. General area plan of the Labatt brewery at Ville LaSalle, Que. Design features single-storey straight-line flow.



(3) "zero" colour, i.e. less than 5 p.p.m. or equal to the best found in municipal service;
(4) controlled pH at 6.7 to 6.9;
(5) free from chlorine;

and, perhaps the most important factor of all, the water standard must be accurately and continuously maintained.

The site in Ville LaSalle was chosen for the new brewery for a number of reasons, one of which was availability of sufficient quantities of water. Being a little more than one quarter of a mile from the St. Lawrence River, the site permitted consideration of the river as an alternate source to the municipal supply and a study was made to compare the economics of a private water treatment plant compared with a contract for municipal service.

In favour of a city water connection is the rather negligible first cost for piping and connections. However, with the high plant demand — initially over 500,000 gallons per day, plus refrigeration condensing requirements — the annual water cost would total approximately $35,000.

Developing costs for a private water treatment installation includes consideration for river intake design, pumphouse and pump equipment, water piping from river to plant, chemical treatment, filtration equipment and building, and service pump requirements.

A summary of the estimated peak water loads for the process and plant are listed in Table II. The total of these loads indicates a peak demand of 700 Imperial gallons per minute. Operating experience in other plants indicates, however, that a continuous rating of 350-400 g.p.m. would be more realistic for the initial stage of this brewery. It is interesting to note from Table II that the largest water demand load comes from the hoses, many of which are in near constant use in the process areas.

Table II. Summary of Estimated Peak Water Demands

Equipment or Use	Water Req't. I.g.p.m.
1. Wort cooler	125
2. Soaker - Rinser	75
3. Pasteurizer	100
4. Hoses	350
5. Domestic	25
6. Boiler (peak make-up)	15

The condensing water requirement of the refrigeration compressors, though not treated, is included in the capacity of the river pumps and, therefore, the total anticipated first stage load on these units is 1,200 and 1,400 I.g.p.m.

The ultimate, rather than the initial requirements of the brewery dictate the size of intake pipe and force main to the plant as these two items would be very costly to expand in the future. On the basis of 3,600 gallons per minute, the intake in the river was set at 36 in. diameter and the 3,000 foot main from river pumphouse to filtration plant was selected as 14 in. diameter.

A large factor to be added into the first cost of the private system is the cost of the water treatment plant itself, including chlorinators, clarification equipment and gravity filters, controls, clear-water storage reservoir and plant service pumps.

The total cost of the private supply system was estimated at $160,000. Owning and operating costs were estimated as follows:

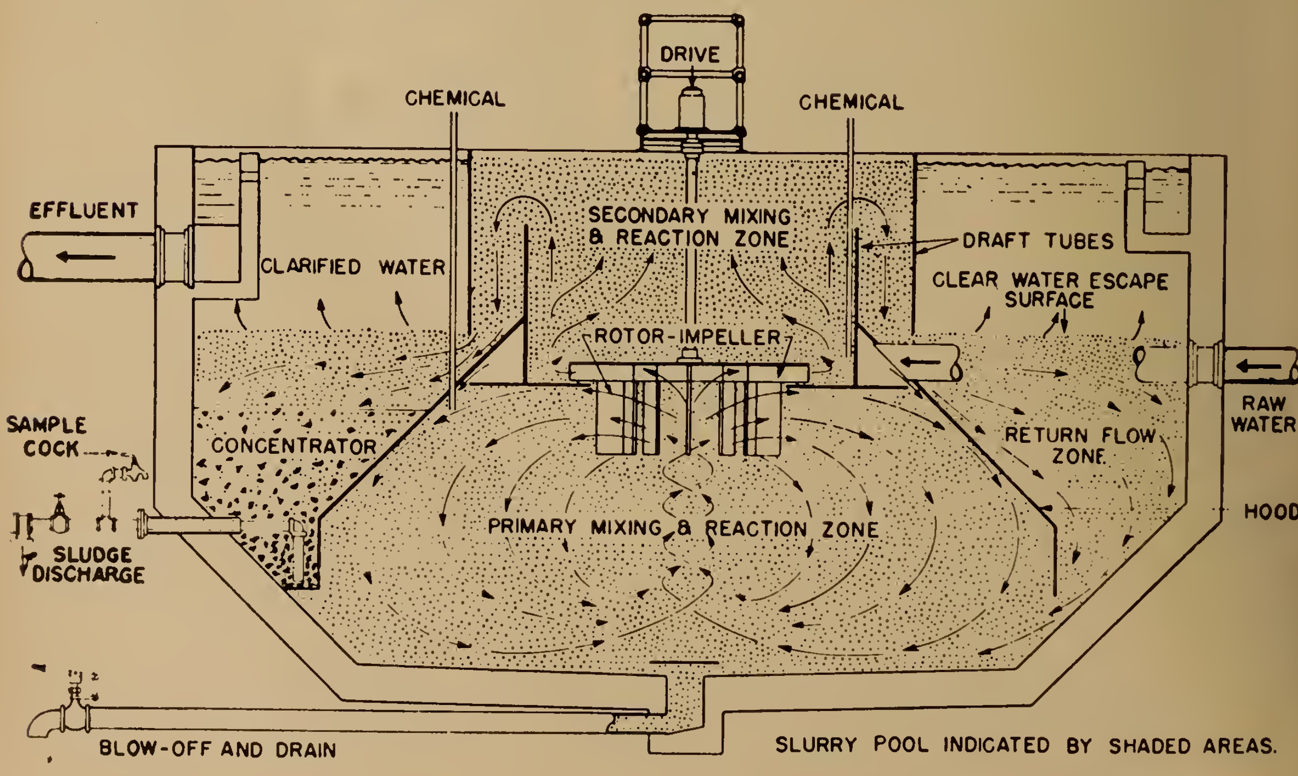
Operators	$5,500
Chemicals	2,500
Pumping	2,100
Depreciation and Interest	13,000

These figures total $23,100 and an annual saving of nearly $12,000 is indicated. Hence a decision that the design be developed on the basis of a private water supply system.

The growing interest in fluoridation of municipal water further justifies this decision, as the equipment necessary to remove the fluorine would be very costly.

Further refinements are now possible within the design scope of a private water treatment system.

Fig. 2. The Accelator high-rate water treatment unit incorporated in the design of the water treatment system.



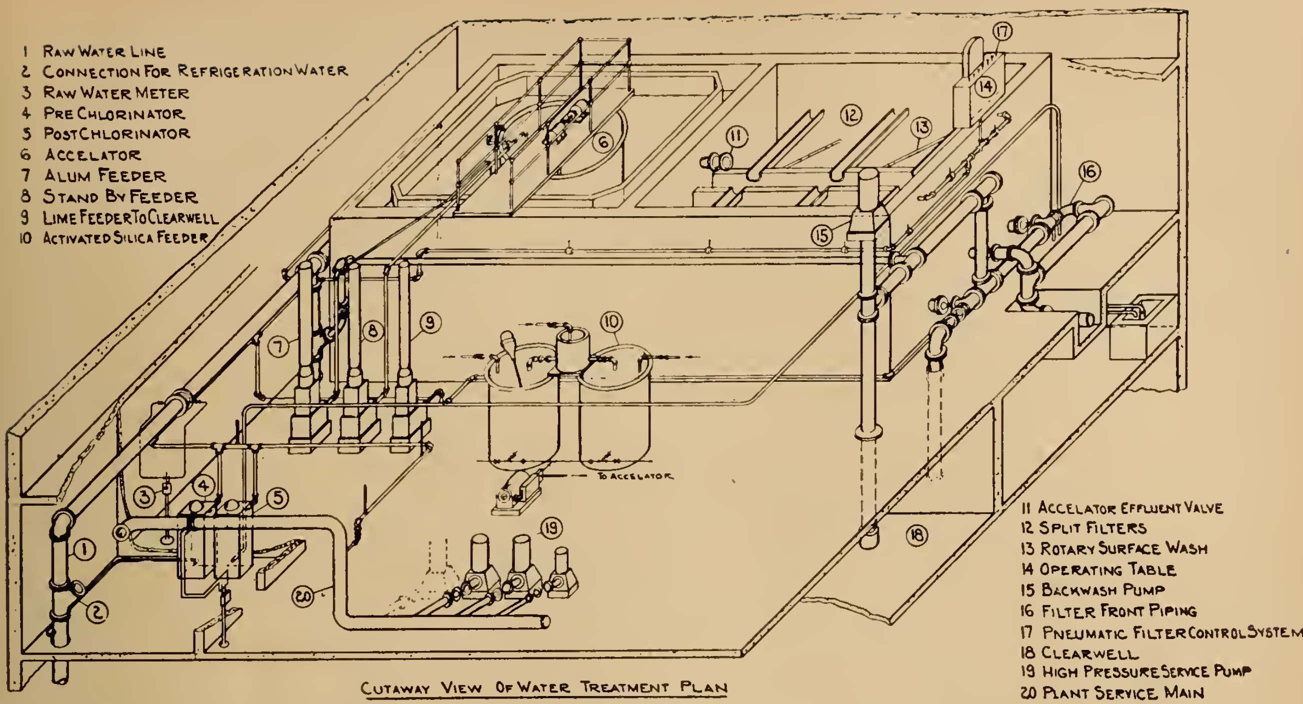


Fig. 3. A sectional view of the water treatment plant at the brewery, showing layout of piping and equipment.

Developments in the water treatment industry provide the designer with alternative selections for any particular application. There is the "conventional" system which calls for separate mixing, coagulating and sedimentation, and the high rate treatment plant which combines these operations into one unit.

An analysis of costs for these two methods of treatment shows that, for this brewery application, there is an installation and operating saving in favour of the "high rate" treatment system. Following approval by the Provincial Department of Health, an industrial high rate unit ("Accelator") was selected and the design of the treatment plant was completed to suit this equipment.

The Water Treatment Cycle

The Labatt Accelator consists of a formed concrete basin, an inverted conical steel baffle which encloses the primary and secondary mixing zones, and a radial blade impeller which is driven by a motorized reducer. (See Fig. 2.)

Raw water, having been prechlorinated, enters the primary mixing and reaction zone beneath the impeller. Alum and activated silica are introduced and the reactions take place. Coagulation tests on river water samples established that the combination of alum and activated silica would produce the most effective treatment. Cost studies indicated that this combination would also be most economical. A fixed quantity of "slurry" water which contains particles or floc resulting from the chemical reactions, is circulated upwards by the low head impeller through the secondary mixing zone and over a peripheral weir into the "slurry" pool. The greater part of this water volume is then re-circulated back under the conical baffle into the primary mixing zone. The remainder, equal in amount to the raw water, is separated off from the "slurry" pool as treated and clear water. Continuous concentration and automatic withdrawal of excess solids as sludge give positive control of conditions in the Accelator at all times. The clarified effluent flows on to "split-type" gravity filters where all traces of suspended matter are removed. This divided filter provides a saving in operating controls. The water flow from these gravel and sand filters passes into the clearwater reservoir where, for further protection, the water is post-chlorinated. The residual chlorine protects the water in storage and in transit to the brewhouse. Just prior to use in the brew cycle, this residual chlorine is removed by activated carbon purifiers.

During treatment, the pH of the water, originally 7.3, is reduced to 6.6, or slightly under the requirement for brewery water. This is corrected by feeding lime directly to the clear-water reservoir. Automatic control of the filters and Accelator is achieved pneumatically from the level in the clearwater reservoir. Alarms are provided to warn the operators of control or equipment failures.

Steam System

The steam services of the brewery are designed to meet three conditions.

(1) Process requirements of the brewhouse and bottling room. The steam pressure provided for these process purposes is 40 p.s.i.g. at the load and there is an estimated peak demand of 12,000 pounds per hour.

(2) Building heating and domestic requirements. This load, including all miscellaneous steam requirements, will also have an estimated peak of 12,000 pounds per hour.

(3) Steam for the power turbine on the refrigeration compressor.

The present boilerhouse is designed for three boilers, but only one of the final units has been installed in this first stage. (See Fig 1.) The steam generating unit is a cross-drum watertube boiler, equipped with cast iron economizer. The boiler has automatic combustion control on steam assisted mechanically atomizing burners designed for firing with bunker "C" oil. The boiler has been designed for 300 p.s.i.g. pressure, and a superheater has been added to give steam temperatures of 510 deg. F. at full load, and 480 deg. F. at half load conditions. The guaranteed boiler efficiency (including the economizer) is 84.8 per cent at full load, and 83.2 per cent at half load.

A finned type air heating steam coil is located between the forced draught fan and boiler. The purpose of this coil is to act as an extra condenser for the power turbine, increasing the available steam flow through the turbine, and thereby to contribute to the heat balance.

A pressure reducing valve with desuperheater provides steam to the low pressure system during cycles of low refrigeration and high heating requirements, such as will develop during the winter holidays. Both the high pressure and the low pressure steam headers are mounted at a convenient height in the refrigeration room with all valves arranged for easy access and identity.

The boiler feed water is conditioned by means of both external and internal treatment, the make-up water from the water filtration plant is softened by the Zeolite filters, all the feed water deoxygenized in a spray type de-aerating heater and finally conditioned by the chemicals supplied directly to the boiler drum.

The boiler is also equipped with a continuous blow-down and heat recovery system.

All pumps and fans which are vital to continuous boiler plant operation, such as the feedwater pumps, the oil pump and the forced and induced draught fans, are provided with both motor and turbine drives. This arrangement permits the completion of a brew cycle even in the event of an electrical power failure. Each turbine outlet is provided with a three-way valve, leading either to the low pressure header or to atmosphere. This arrangement allows for isolation of a turbine from the header without the risk of turbine damage due to a closed and forgotten valve. It is safer and also less expensive than the use of full capacity safety valves on each turbine. Furthermore, the turbine can be operated with direct exhaust to atmosphere, if and when such operation becomes desirable.

A stand-by boiler with capacity and pressure to meet summer shutdown or emergency loads is also provided in the steam plant.

This latter unit is a fire-tube "package type" boiler, selected for its economy, its adaptability to the system and its relative ease of relocation at the time of steam plan revisions. The steam pipe from this unit is connected directly to the low pressure header which is provided with a multiport-type relief valve for protection of either the stand-by boiler or the power turbine when high pressure steam is being produced.

Refrigeration System

Perhaps one of the most interesting of service designs for a brewery is refrigeration. With controlled temperature the requirement both in the process and the space which surrounds it, a refrigeration system is essential to the proper operation of the plant. The size and cost of the equipment and distribution systems requires an economic study similar to that for water, with initial and operating costs evaluated for each of the many alternatives.

To begin with, the design loads, which are summarized in Table III, consist of two main types — process and air conditioning. Included under the former heading are wort cooling, "fermentation heat", beer transfer cooling, and CO_2 liquefaction. Requiring air conditioning are hop storage and yeast rooms, fermenting storage cellars, carbonating and bottling tank rooms and lastly, for comfort, the offices and reception area.

With the design load established, answers must then be found to the questions of reciprocating versus centrifugal type refrigeration compressors and brine versus direct expansion as an "in-house" distribution system. From cost data, it is apparent that the first costs of a direct expansion system with electric motor would be lowest. However, these are offset by operating costs when the economics of heat balance and maintenance are applied to the centrifugal compression and brine system.

Table III. Maximum Refrigeration Loads

Process	*tons*
Wort cooling	80
Attemperators	50
Beer coolers	90
Co_2 liquefying system	25
Air Conditioning	
Ale fermenting room	47
Lager fermenting room	20
Storage rooms	30
Carbonating rooms	24
Hop storage	8
Bottling tank room	15
Yeast storage "ale"	8
Yeast storage "lager"	8
Office air conditioning	25
Brewery ventilation unit	40

The total of these calculated peak loads is 470 tons. However, when a diversity factor is applied, this total can be reduced by 15 per cent giving a net total of 400 tons for equipment selection purposes.

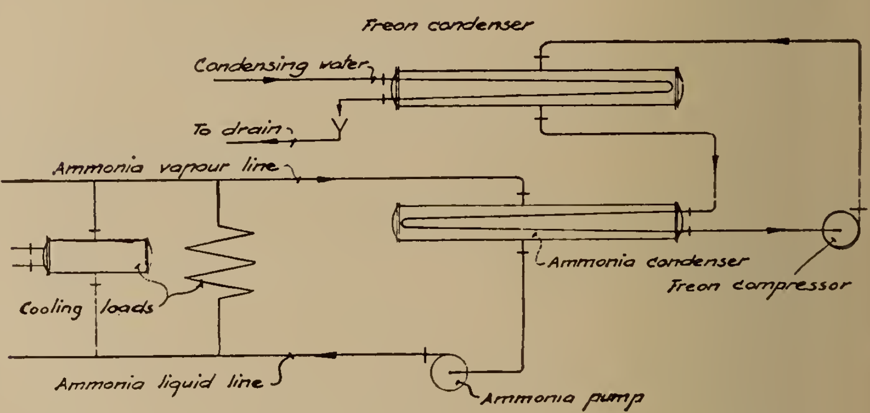

Fig. 4. Diagram showing the principles of the ammonia condensing cycle.

The refrigeration compressors with their drives, rated at this total, are designed to accommodate an overload of 50 tons.

The new Labatt brewery is equipped with two centrifugal compressors and an "ammonia condensing" in-house refrigeration system. This latter refinement — the use of ammonia in place of a standard brine — allows for a considerable reduction in piping and pumping costs due to the use of the latent heat of the ammonia brine rather than just the sensible heat of a standard brine. It also has many of the advantages of the direct-expansion system, without the ammonia having to come into direct contact with the compressors.

This is the first application of this system in a brewery in Canada, although installations in the United States date back to 1935.

The distinctive feature of the ammonia condensing system lies in the fact that low pressure ammonia gas returning from the brewery evaporators, or cooling surfaces, instead of being compressed to high pressures and consequently higher temperatures in order to liquefy it, is condensed at low pressure and temperature in the cooler of the centrifugal machine. The "collapse" of the ammonia, in changing from gas into a liquid, induces the flow of more gas to the cooler of the centrifugal machine, which in this case assumes the function of an "ammonia condenser". The accumulated low-pressure low-temperature ammonia liquid is then circulated to the various evaporators by an ammonia liquid pump. The ammonia portion of the system is free from oil contamination and variations in load (causing "liquid" slugs) would not be in the least harmful to the system, so often the case when a reciprocating compressor is used to compress and circulate the ammonia. The absence of oil in circulation with the ammonia refrigerant also greatly improves heat transfer and makes possible the more efficient use of the transfer surfaces available.

The principle is perhaps best illustrated by the diagram in Fig. 4.

The ammonia condensing cycle eliminates flash gas in the liquid due to the fact that the ammonia pressure is raised by the ammonia pumps after condensation rather than being condensed after pressurization as in conventional refrigeration systems.

A number of other factors contributed to the decision in favour of the selected refrigeration system including the flexibility of centrifugal compressors for capacity control permitting quick balance at each load condition, the higher efficiency of the centrifugal compressor at partial loads (variable speed control versus step unloading), lesser maintenance and the fewer shut-downs expected of centrifugal type machines.

It is apparent from the earlier reference to heat balance that the use of steam for power is also a factor in the compressor selection. Centrifugal compressors are very suited to turbine drive and, at relatively high operating speeds, they permit the application of a steam power-heating cycle without risk of oil being transferred to the steam lines and boiler.

However, before reviewing the economics of this application, a description will be given of the refrigeration equipment and its control.

The calculated maximum refrigeration load in the present plant is 400 tons, occurring in summer on days with extreme outside air temperature and humidity, when the river water temperatures come up to 75 deg. F. and when the brewery is in full production.

The refrigeration machinery consists of two centrifugal compressors, each with 200 tons nominal capacity.

The main line unit is driven by a back-pressure type steam turbine, while the second unit for stand-by and peak load duty has a variable-speed wound rotor electric motor drive.

The output of the compressors is adjusted automatically by means of an ammonia temperature recorder-controller with its sensing element in the ammonia receiver. This instrument controls both the steam turbine speed regulator and the suction damper of the motor driven compressor.

A second controller, sensing pressure and located in the medium pressure header, operates to limit the load on the turbine driven unit during cycles of low steam demand when both compressors are operating. As the steam demand in the brewery increases, the pressure starts to drop. The pressure instrument then overrides the ammonia temperature controller and calls for a higher turbine speed. The dropping ammonia temperature will, in turn, reset the suction damper on the electric motor driven compressor, thus decreasing the capacity of this to balance the increase in the alternate machine. In this manner, the loading of the steam turbine driven compressor is made to follow the cycling steam demand of the brewhouse, acting as a pressure reducing valve with an adiabatic power-producing pressure drop. (Fig. 5.)

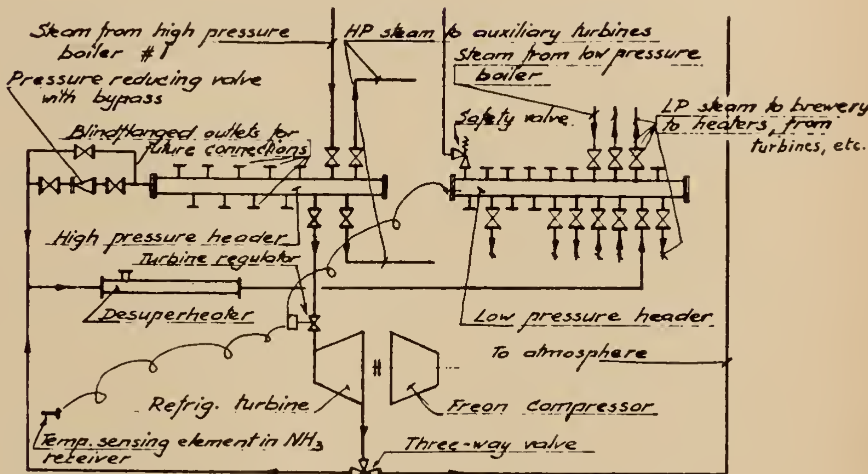

Fig. 5. Diagram showing the steam header and turbine hook-up.

If, during peak refrigeration demand, the steam requirement in the brewery should drop to such a low level that the refrigeration need cannot be met with the combined capacities of the electrical compressor and the steam driven unit, as limited by the steam requirement, a high limit thermostat sensing ammonia temperature will ring an alarm bell and switch the control of the turbine governor over to the ammonia temperature regulator.

On the opposite hand, there will be times, during winter, that heating and process steam demands far exceed the steam required to produce refrigeration.

The turbine in this case would be regulated only by the ammonia temperature. A pressure reducing valve is provided to supply the additional amount of steam from the high pressure header via spray type desuperheater.

Refrigeration capacity is therefore automatically controlled and balanced by refrigeration load. The only manual operation to be done by the operating engineer is decreasing the speed of the wound rotor motor or reducing the number of operating steam nozzles on turbine at decreasing capacities to improve the efficiencies of the units at partial load conditions.

Application of a combined power generating and heating system to get highest plant thermal efficiency requires a thorough study of time load characteristics and also of equipment for steam generation and utilization. It is seldom the case in smaller industrial developments that the process-heating steam demand has the characteristics to justify power generation. The ideal heat-balance situation where high pressure steam is used for power generation and exhaust low pressure steam for process purposes and heating becomes uneconomical in cases where the steam demand for power generation and process heating are poorly balanced and where electrical energy is cheap. In the case of this brewery, however, the steam requirement for power and process can be balanced rather ideally by proper choice of steam pressure and engine but, on the other hand, the hydro-electrical energy in this area is relatively inexpensive. With this background, a study was necessary.

Using a steam turbine as an energy generating reducing valve can be accomplished in several ways, of which the three principal solutions are listed below:

(1) Using bleeder type condensing turbine with steam extraction for process and heating, and separate condensation. With this system, the entire electricity requirement of the brewery could be generated by its own turbine generators. All process and heating requirements would be taken as back pressure steam from being condensed in a vacuum condenser.

(2) Using a back pressure turbine-generator. Only that much steam would be fed to the turbine as could be used for process and heating demands — the balance of the electric energy would be bought from the utility company.

(3) The major power consumer—the refrigeration compressor—would be direct-coupled with an individual steam turbine.

A quick analysis shows that alternatives (1) and (2) could give little, if any, economical advantage over alternative (3), but would require a much higher initial investment. Only by placing emphasis on the possibility and effect of shut down as a result of a national emergency could private power generation be justified.

Due to the size and characteristics of the steam, electricity and refrigeration requirements, and the circumstance that the biggest power consumer in this plant — the refrigeration compressor — would be located centrally in the mechanical services building, alternative (3) is clearly established as having the highest value and was therefore set aside for comparison with the all-electrical drive alternative.

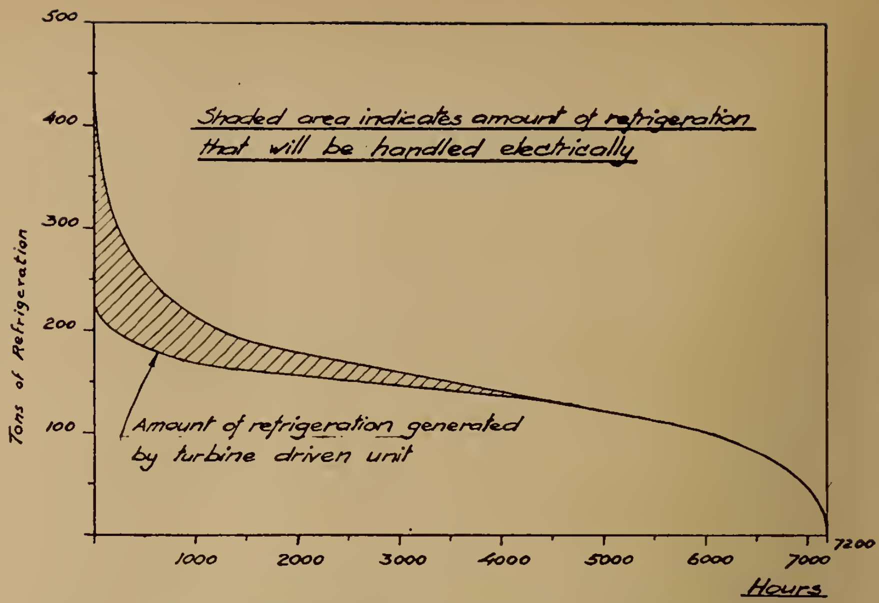

Fig. 6. Probability curve for refrigeration requirement.

Further study is needed to establish steam conditions before this final comparison can be made. Boiler design standards indicate that pressures of 600 p.s.i.g. and 300 p.s.i.g. would each provide the highest boiler value of the respective design ranges. The study of these two pressures as design inlet conditions for the power turbine indicates that:

(A) The refrigeration requirement could be completely covered with a back pressure turbine driven unit without steam loss to the atmosphere, if steam with at least 600 p.s.i.g. pressure and proper superheating is used in a high efficiency multi-stage turbine.

(B) A combination of 300 p.s.i.g. steam with moderate superheat and an inexpensive single-stage turbine could not cover the peak refrigeration requirement without producing too much low pressure steam.

However, when operated in conjunction with an electrically driven refrigeration compressor, the turbine in this latter alternative could give an overall economy very close to that of the higher pressure system and would have a number of distinct advantages, namely:

(i) Lower first cost.

(ii) Greater ease in the locating and securing of operators due to the relative scarcity of high pressure steam plants in Quebec.

(iii) Better economy on weekends in summer when the electric compressor could be used for the cellar refrigeration requirements at a time when steam would have to be discharged to atmosphere.

The difference in efficiency and operating economy between these two alternatives can perhaps be best illustrated by a review of the expected refrigeration load-hour curve. (Fig. 6.) This curve, when computed on an annual basis, is similar to many others which reflect seasonal load variations. From the graph, it can be seen that the 200-ton steam turbine driven unit will meet all but a small percentage of the loads. Consequently, the electric power that would be saved if steam were used to produce all the refrigeration is relatively small when compared to the amount saved by the back pressure turbine and would hardly be enough to justify the extra initial equipment cost.

Once the selection of the back pressure turbine-electric motor drive combination has been justified in this way, the final analysis between the steam-electric and all electric drive arrangements can be made. To simplify the recording of this initial owning and operating cost review, the former will be known as scheme S.E. and the latter as scheme El.

First cost comparison

It is estimated that the premium for boiler, piping and accessories for the steam electric arrangement would total $17,000. This would be reduced by $5,000, the estimated premium for wound rotor motor with its gear, controller, and primary power service costs over the steam turbine with its controls. Therefore, the net additional cost of scheme S.E. would be approximately $12,000 more than scheme El.

Operating cost comparison

The reduction of the annual electricity costs could be found by comparison of the monthly power consumption curves for the two alternatives, but can be more easily estimated by the following calculation.

For the calculation, we assume that, during every month when both compressors will have to be operated to meet the demand, the peak capacity of both units will be needed at least once and that, during the months when only one of the units is needed, again at least once, the unit will have to run at full load. This assumption comes very close to real conditions — in winter months the process cooling requirements come occasionally close to the nominal capacity of one unit, while in summer months the climatical conditions here in Montreal show a high probability for odd hot days even early and late in the summer season.

The contract for power calls for the following charges:

$1.30	Service charge per kw. of billing demand (monthly).
0.015	First 50 hours use of demand.
0.007	Next 100 hours use of demand.
0.003	Excess.

Now, when the operating assumption described above is applied, the annual saving in the electricity service charge for scheme S.E. would be:

350 x 1.3 x 12 = $5,460 where 350 is the motor size for one compressor unit.

The annual load probability curve (see Fig. 6) shows that nearly 1,000,000 tons of refrigeration would be produced with the steam turbine unit in scheme S.E. To produce this amount of refrigeration with an electrical unit would require at least 1,400,000 kwh., and more if an effective compressor speed regulation is not applied.

The calculation of the electricity saving in scheme S.E. can now be completed:

50 x 350 x 0.015 x 12	=	$ 3,150
100 x 350 x 0.007 x 12	=	2,940
(1,400,000 — 150 x 350 x 12) x 0.003	=	2,310
Service charge as calculated before	=	5,460
Total annual electrical saving		$ 13,860

In reality, it is likely that, during the off-season months when two units have to be operated, the loading of the compressors would not need to reach the maximum capacity. This is especially so when process peaks could be avoided by production planning. A decrease would therefore result in the estimated service charge for those months and also more power would be used at the least expensive 0.3 cent per kilowatt hour rate.

Reduced by as much as 20 per cent, the calculated annual saving of electricity in scheme S.E. would still be over $11,000. Conversely to this applied reduction, it should be mentioned here that the electricity costs estimated above are based on careful compressor speed adjustment to match the actual loads. In practice, this could only be achieved by utilizing an expensive automatic hydraulic drive. In cases such as the one under discussion where this expense cannot be justified, the human factor must be accounted for in the estimates and the electricity consumption will certainly be higher.

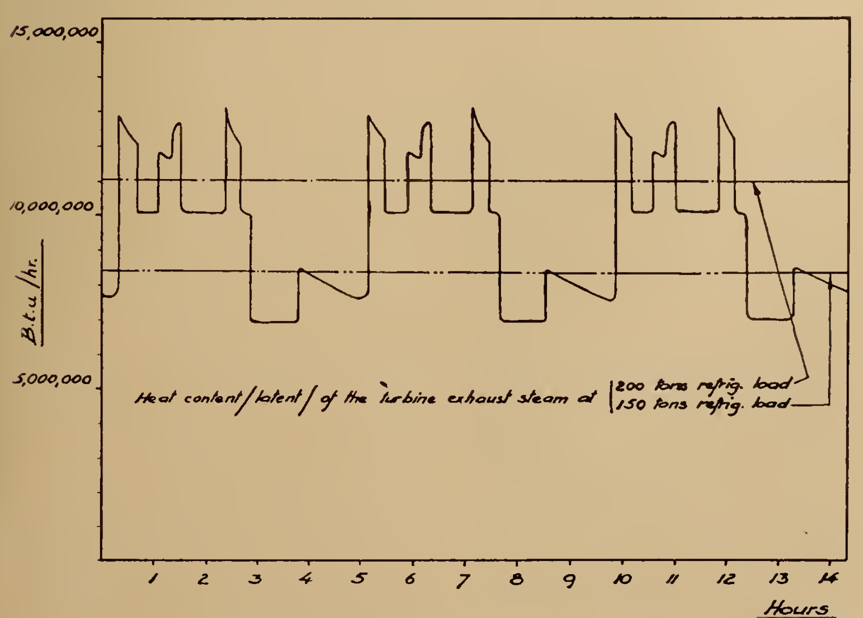
The electricity saving for scheme S.E. has to be reduced by the increased fuel cost for power generation.

To produce the power for the operation of the turbine-driven compressor, 4,000,000,000 B.t.u. per year will be required. Assuming a boiler efficiency of 80 per cent and the use of bunker "C" fuel oil with a heating value of 186,000 B.t.u. per gallon at a price of 9.3 cents per gallon, the annual fuel cost increase for scheme S.E. will be:

$$\frac{4,000,000,000 \times 0.093}{0.8 \times 186,000} = \$2,500$$

The net anticipated annual operating saving for scheme S.E. is therefore $11,000 minus $2,500 or $8,500. To estimate the cost of "owning" the additional $12,000 which would be invested in this scheme, an overall depreciation rate of 10 per cent is used, giving a cost of $1,200. The total "owning and operating" saving of the steam turbine-motor combination would therefore be $7,300.

Fig. 7. Calculated process heat requirement curve at summer operation.



Summary

We have found that first cost would be $12,000 higher and owning and operating costs $7,300 per year lower for scheme S.E.

Expressing this in another way, it is clear that the higher installation cost for scheme S.E. will be offset by the operating savings within two years.

It should be mentioned here that when, in the future, the brewery is extended, the process steam requirement will increase in proportion to the production increase but that the refrigeration load will increase to a much lower degree. This will result in a further improvement in the economy of the selected system.

Refrigeration Equipment in Brewery

The "in-house" side of the refrigeration system includes many interesting features. The loads which make up the design total for the system have been listed in Table III and a few of these will be discussed in some detail.

One of the largest process cooling requirements in the brewery is the cooling of hot wort after extraction from the kettle. Leaving the hot wort storage tank at a temperature of over 200 deg. F., the wort is cooled to 50 deg. F. in stainless steel plate type heat exchangers. These heat exchangers are designed for two-stage operation. The first stage makes use of river water from the water treatment plant to drop the wort to approximately 90 deg. F. in summer. Lower river water temperatures in other seasons will increase the cooling range of this stage. The second stage provides the final degree of cooling by means of chilled water. The cooling water from the first stage having been heated to temperatures of 155 deg. F. and higher, is discharged into hot water reservoirs for later use in brewing. This heat exchanger, therefore, works as a wort cooler, process water heater, and waste heat recovery unit simultaneously.

The chilled water is circulated through the second stage of the wort cooler from a sprayed pipe cooler, called a Baudelot cooler in the brewing industry. In this unit, the water is distributed through adjustable troughs over vertically mounted ammonia pipe coils and collected in an accumulating tank. The refrigeration storage capacity of the tank is considerably increased by allowing some of its contents to freeze to ice. This accumulating ability of the tank spreads the short cycle (1½ hours) wort cooling load over a period of five hours, thereby decreasing the required compressor capacity and improving the synchronization between the process steam and refrigeration requirements.

A second large process cooling load is caused by the exothermic process in the fermenting tanks. Each pound of sugar in the wort gives off approximately 250 B.t.u. during fermentation. Some of this fermentation heat is transferred from the tanks to the rooms by convection and radiation and, in the case of open tanks by evaporation from the surface. Each tank is equipped with brine cooled attemperator coils to keep the fermentation temperature at constant predetermined levels and later to cool the beer quickly to the desired discharge temperature. The brine for the attemperators is chilled in shell and tube type exchangers to 17 deg. F. for lager fermenting and 25 deg. F. for ale. These exchangers operate directly on the suction pressure of the ammonia condensers or at approximately 11 deg. F. The Baudelot cooler also operates without a back-pressure regulator. Other cooling appliances are equipped with regulators, which control the ammonia evaporation temperature in the respective coils to desired limits. Gate, plug, solenoid, and pressure relief valves complete the control equipment at each unit.

Turning to the air conditioning loads, it is recorded earlier that a number of the storage and processing rooms have controlled temperatures. These temperatures range from 32 deg. F. (storage cellars) to 50 deg. F. (ale fermenting room). The rooms are conditioned by individual fan driven units with prime surface type ammonia cooling coils. The refrigeration loads include transmission heat from the environment, heat from lighting, motors, occupants, ventilation heat, the part of the fermentation heat transferred into the rooms by transmission and evaporation, and latent load from the washing of the floors. This last item can be very high, particularly in summertime due to the high vapour pressure difference between 75 degree river water from the filtration plant and 32 degree room temperature, and the frequent or practically continuous washing with hoses in most of those rooms. In order to reduce this evaporation load from wet floors, a large number of floor drains are installed and the bulk of the washing water is carried away quickly, thereby reducing considerably the latent load which otherwise would be introduced to the room.

This effects a saving in both equipment and operating costs, and decreases the defrost requirements of the cooling coils.

The CO_2 generated by fermentation is collected from the closed lager tanks for re-use in beer carbonation. The ale fermenting tanks, being open. generate CO_2 gas which escapes to the room and creates a high ventilation requirement, adding considerably to the total refrigeration load. The standards of the Department of Health (Division of Industrial Hygiene) recommended a maximum concentration of 0.5 per cent CO_2. To keep this condition uniformly throughout the space, a total of 264,000 cubic feet of fresh air would have to be induced to the room every hour. To reduce this ventilation requirement and consequently the high refrigeration load it imposes, the tanks are provided with a direct CO_2 exhaust system, consisting of adjustable inlets above the beer surface connected into a separate piping system through which the gas is pumped to atmosphere. Due to the fact that the CO_2

A general view of the modern high-speed bottling plant.

Canadian Design and Construction of High Voltage Overhead Transmission Lines

V. F. Crowley,
Manager, Transmission Division,
The Shawinigan Engineering Company Limited

Read at the Conférence Internationale des Grands Résaux Electriques à Haute Tension, Paris, France, May/June 1956

The design and construction of high voltage overhead transmission lines in Canada are being extensively modified and revised in order to produce economies consistent with acceptable operating efficiency. These changes are based on past operating experiences, combined with investigations, studies and experimental installations. While some of these changes are being adopted to a varying extent, both individually and in combination, others are still under consideration.

The rapidly expanding systems of the Canadian electrical power utilities are materially changing the conceptions of high voltage overhead transmission line design. Reduction in material and erection costs are being effected while maintaining an effective level of operating safety and efficiency.

FOR some time now various Canadian electric power utilities have been examining the possibilities of revising, or modifying, the presently accepted standards employed in the design and construction of high voltage overhead transmission lines. The primary incentive in making these studies is the rising cost of materials and labour.

Many Canadian lines show a very high degree of operating efficiency. Mechanical and electrical failures have been nil, or extremely rare. The question arises whether this condition indicates that the lines have been designed to an exact level of efficiency, or with safety or overload factors which are greater than necessary.

In the light of increased knowledge and experience obtained over many years of investigation and operation of high voltage overhead transmission lines under Canadian climatic and topographical conditions, it is felt that the commonly accepted standards and practices could be modified to produce more economical transmission lines and still maintain an acceptable level of operation and reliability, both mechanical and electrical.

These modifications are being incorporated in present designs to a varying degree and operating results to date appear to justify the trend in this direction.

Very little consideration is being given to the possible revision of the co-efficients involved in the various formulae used in the calculations, but rather in the results arising from the application of these formulae.

The major amount of investigation and revision is, of course, on the structures themselves, but other factors involved in the design and construction of high voltage lines are being considered. Field construction procedures are receiving attention, both as they affect the design and the labour costs of erection. The trends in the revisions of high voltage overhead transmission lines involve both wood and steel structures. However, the greatest emphasis is on steel towers, as the majority of high voltage lines are being constructed in steel. The trend towards extra high voltage overhead lines, with their much greater mechanical loadings, practically necessitates steel supporting structures.

This paper does not attempt to cover all the factors and design assumptions which may produce savings in high voltage transmission line costs, but presents in outline form only those receiving the primary attention of transmission engineers in Canada. It is recognized that the overall problem is extremely complex, as each factor requires an extensive study in itself as well as an intricate correlation. All this in turn must be applicable to the specific problems existing on each electric system.

Planning and Scheduling

Since the end of World War II an urgent demand for electrical power has required that many high voltage transmission lines be constructed according to extremely tight schedules. This acceleration, over the normal period of time required for designing and constructing a line, has drastically reduced the opportunities for incorporating economies.

There is a definite trend now under way to attempt to schedule all operations so as to obtain time for adequate study of the design and the planning of the construction program.

Substantial savings are being realized and following are some of the various items under study:

(*a*) Investigation into design and construction as outlined in this paper.

(*b*) Standardization of structures in a given classification of lines in order to reduce both labour and material costs.

(*c*) Purchasing of materials in large quantities.

(*d*) Reduction in construction delays by obtaining the complete right-of-way prior to commencing construction.

(e) Avoidance of costly construction delays due to lack of material, by assuring that all materials for small projects should be on hand before beginning construction. For longer lines, materials to be scheduled for delivery so as to allow distribution during the most advantageous season and ahead of the time required for actual erection purposes. Distribution of material on many of the transmission lines in Canada may be more economical during the winter than in other seasons of the year. In cultivated areas there is less damage to the farmer's crops and fields. In rough mountainous terrain and swamp sections, transportation is often more readily facilitated by the use of temporary winter roads. The transportation of men and materials to tower sites is faster and more economical over these roads as they permit the use of specialized vehicular equipment.

(f) Actual construction being scheduled so as to take advantage of seasonal conditions.

It is recognized that some operations in certain areas may be more economically carried out in winter than in summer and *vice versa*. Excavation work in swamp areas during the winter season has been facilitated as the frost inhibits the flow of fluid soils and water, and either eliminates or reduces to a minimum the use of crib-work or sheeting.

Thus with more efficient construction methods and specialized equipment, it has been found that transmission line work may be carried out during winter conditions as economically as during other periods of the year. This enables the construction organizations to carry a more balanced and experienced labour force, which is more efficient than engaging less experienced personnel for seasonal work only.

Classification of Transmission Lines

A useful method of evaluating the possibilities of reducing the costs of high voltage transmission lines is by classifying lines according to the various design assumption factors. This may assist in relating the electrical and structural performance of the line to the cost of construction and maintenance. This information will enable management and the operating staff to select a suitable type of construction, correlating the lowest overall cost with the required operating efficiency, thus assuming a "calculated risk" with a fair degree of assurance based on experience. The degree of such classification would depend upon the individual system and the localized problems.

However, general divisions for a system employing transmission line voltages up to 230 kv. have been suggested as follows:

(a) *Prime* electrical and structural classifications for radial lines which are the sole means of transmission to an important load terminal. This classification would incorporate all existing maximum design and construction factors.

(b) *Prime* structural classification but reduced electrical security: for lines where electrical interruptions are controlled by high speed reclosing.

(c) *Prime* electrical classification but reduced structural strength: for lines where expected loadings are not so severe and outages of a day or two could be handled by switching loads.

(d) Reduced electrical security and structural strength for lines where higher class parallel circuits exist.

(e) A further reduction in electrical and structural design factors: for tie lines of minor importance.

Some organizations are examining the past operating performance of their lines together with the existing and proposed future system connections in an endeavour to produce a reasonably practical and useful classification. While there is a general trend in this direction, some difficulties are encountered in evaluating the importance of the various transmission lines due to rapidly expanding systems.

Structure Loading Specifications

There appears to be a very definite feeling by most Canadian transmission engineers that substantial economies may be gained by an intelligent reappraisal of existing transmission structure loading specifications.

Tower loading specifications are generally set forth in a relatively arbitrary manner, e.g., a wind pressure of eight pounds per square foot, one-half inch radial thickness of ice with one broken conductor. Towers are designed on this basic consideration and steel detailers then produce a tower in which failure will theoretically occur at precisely the point set by these loading specifications. Designers, while recognizing the inconsistencies of this step, are the first to defend the loadings, maintaining that the extra strength incorporated into the towers by these loadings is essential to cover the multitude of possible stresses that may exist in erected towers. Such items as incorrect fabrication, improperly set footings, the unequal settlement of footings, all combine to add extra stresses in the towers after the line has been completed. Unbalanced forces might also be set up in the towers by the action of galloping conductors, unequal ice loads on conductors, stringing operations during construction, etc. While these stresses are indefinite and largely indeterminate, the towers must be able to withstand them.

These considerations may offer a sound argument for maintaining the conventional loadings, but, in the final analysis, the optimum in transmission line design is one in which the annual cost is the minimum. Hence, the annual costs of maintenance, emergency repair work, and value of power lost during outages. must be considered together with the capital cost charges.

It is possible to produce an almost impregnable line if enough money is spent on it. There is, however, a point of diminishing returns beyond which the extra steel built into a line does not supply a proportionate extra margin of safety. In view of the extremely small number of line outages due to the structural failure of towers, that have been reported over the last ten to fifteen years, it appears that this point of diminishing returns has been passed. The problem is essentially economic, that is, the charges on capital cost of extra steel versus money saved by fewer outages.

When consideration is given to the relative importance of each line, its load and location within the grid, it should be possible to accept a limited number of outages per year on certain circuits without detriment to the calculated performance of the overall system.

In an attempt to predict the performance of a line employing lighter towers, and recognizing that there are "intangible strengths" and "indefinite and indeterminate" stresses, it is difficult to arrive at a sound conclusion from a purely theoretical approach. Engineers are accordingly examining the performance records of existing lines in order to obtain data and information which will be of assistance in carrying out their studies.

(a) Design stresses and safety or overload factors.—It is possible to decrease the weight of transmission line towers by using higher design stresses or lower safety factors. The average basic steel stress has been for some time accepted at 24,000 pounds/sq. in. (1,687 kg./sq. cm.) on ordinary carbon steel members. (Canadian Standards Association Specification G 40.4-1950). There is a trend to increase this to approximately 28,000 pounds/sq. in. (1968 kg./sq.cm.). Several companies have already designed and constructed lines to this revision. The use of a higher stress is equivalent to reducing the loadings, i.e., raising the design stress from 24,000 pounds/sq. in. to 28,000 pounds/sq. in., is the same as reducing the tower loadings by 16 per cent. Although the consideration of this method is an indication that towers, in general, are felt to be stronger than necessary, the method does not permit emphasis to be placed upon any specific loading.

A general reduction in the overload or safety factor, which is normally 1.5 based on the yield point of the steel at 36,000 pounds/sq. in. (2,531 kg./sq.cm.), is effectively the same as increasing the design stress. In some areas the practice has developed of varying the safety factor for each of the different loading conditions. This is effectively the same as reducing the loadings, and has the advantage that it can be applied in a varying measure to each of the loading conditions in turn.

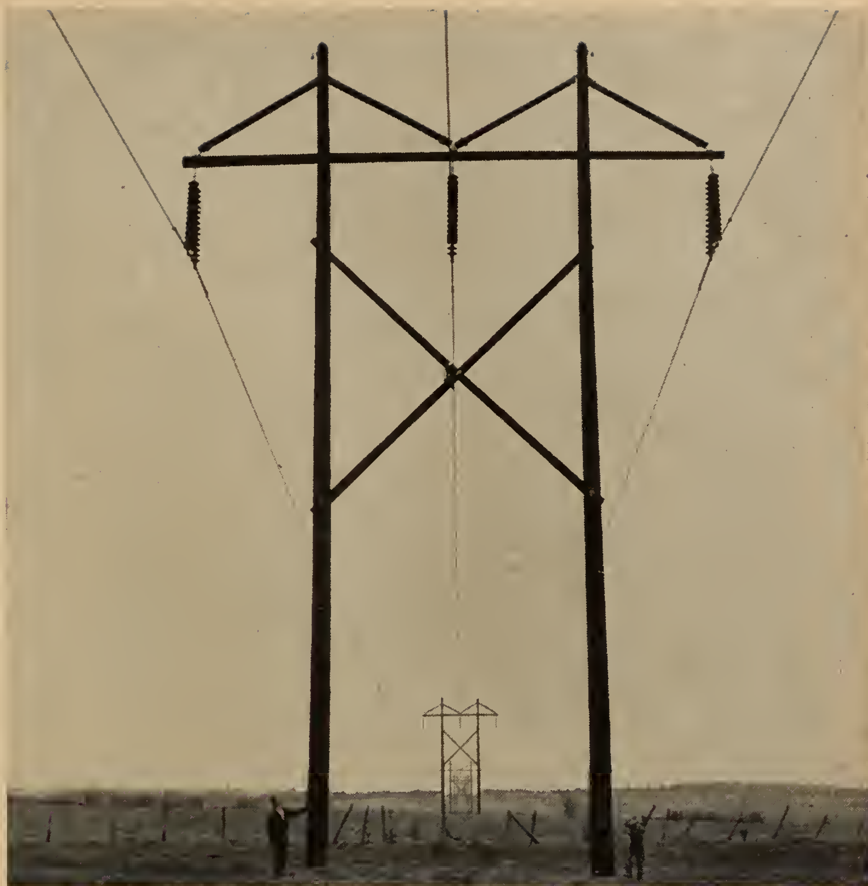

Fig. 2. 230 kv. single circuit, wood pole, H-frame construction with all spar members. Two overhead ground wires. ***(The Shawinigan Water and Power Company)***

There appears to be a trend towards the use of a higher yield strength steel, particularly in the larger tower members such as the leg angles and main compression members. This can result in a tower weight reduction of approximately 10 per cent, over an all carbon steel design, but this is largely offset by the premium price demanded for the Canadian high tensile steel. The net result is usually a very small saving in cost in favour of the combination of a carbon and high tensile steel tower over the all carbon steel tower.

(b) Conductor ice and wind loads.—The general Canadian practice is to use a conductor tension of approximately 40 to 50 per cent of the ultimate strength with an applied specified ice and wind load at 0 deg. F.

Many years of operating experience, together with extensive recordings on ice and wind conditions accumulated by the various government and private organizations, offer reasonable arguments for a modification of the present loading specifications for various areas. Although there appears to be justification for the specified individual ice and wind loads, there is substantial evidence that the maximum wind loads do not occur with maximum ice loads. Various combinations of ice and wind loads as indicated by the meteorological data are being carefully examined as to their effect on structure designs.

(c) Angle of suspension insulator swing. — To design a transmission line for a specific angle of suspension insulator swing is a fairly complex problem as there are several variables entering into its computation. While this may be calculated fairly accurately for a given set of conditions, at a specific tower, it will not necessarily apply to the entire line. The assumptions governing the variables have been fairly widely investigated and are now being modified in many instances so as to produce in the design a smaller angle of suspension insulator swing.

If the angle of swing is reduced, savings in structural weight are effected. For many years the angle of swing incorporated as a design factor in Canadian practice has been taken as 45 deg. from the vertical. This is now considered excessive and an angle somewhere in the order of 30 to 35 deg. may be more realistic. It is understood that in some European countries the swing has been reduced to under 30 deg. on certain lines.

The angle is dependent upon the wind velocity in the transverse direction, the diameter of the conductor, its weight, and the angle in the line for which the tower is designed. It is now generally recognized that the maximum velocity of the wind squall has a relatively narrow front and, while this may be applied to any individual tower, the mean velocity over the relatively long spans used on high voltage transmission lines is considerably less, thus resulting in a smaller angle of insulator swing. With the trend to the larger conductors, required with higher voltages, and the necessity to reduce corona loss as well as radio, television and radar intereference, an extremely high wind velocity is necessary to produce the standard 45 deg. insulator swing angle.

It has been estimated that tower weights may be reduced by approximately 5 per cent on a 230 kv. single circuit tower line if the angle of insulator swing is reduced from 45 deg. to 35 deg. Several Canadian high voltage transmission lines are now designed for an angle of insulator swing of 35 deg. and this reduction is gaining increased acceptance.

(*d*) *Electrical clearances.* — Electrical tests and studies show that the generally accepted clearances between the line conductors, or its hardware parts, and the supporting structures are larger than required. This is especially true regarding voltages greater than 110 kv. Presently accepted clearances assume that switching surge voltages or impulse voltages occur during gale or hurricane winds. This is felt to be rather drastic and that a more reasonable view may be assumed.

A reduction in this clearance factor results in closer phase and circuit spacing thus shortening the cross arm length and producing such advantages as a reduction in reactance, narrower right-of-way and a saving in structural weight. Some steps are being taken in this direction, although with caution, as the resultant savings are rather negligible.

(*e*) *Insulation.* — The transient voltages which influence the design and operation of a high voltage transmission line are being re-evaluated in regard to their effect on the line insulation. The usual practice has been to add extra units over the minimum number required to provide adequate insulation for the 60 cycle impressed voltage. This addition provides a margin for the lowering of the insulation value of the units due to contamination and also for abnormal electrical stresses. The lowering of switching surge voltages due to improvements in circuit breaker design, the increased knowledge of the isoceraunic levels, together with the extensive use of buried counterpoising and the protection against lightning strokes by means of overhead ground wires, all tend to a general acceptance of a smaller number of insulator units per string. The problem of contamination is usually studied on a local basis and the insulation increased to the estimated degree only on the structures affected. The economies ensuing from insulator reductions are mainly in the steel of the structures rather than a saving in actual insulator costs. It is generally agreed that shielding rings are not required on voltages of 230 kv., but are being used on voltages of 300 kv. and over.

(*f*) *Broken wire loading assumptions.* — In the search for further economies in line construction, serious consideration is being given to the effect of the longitudinal loads imposed on the towers by the so-called "broken wire loading" conditions. The general practice has been to assume the value of the "broken wire loading" to be the conductor tension produced under specified maximum ice and wind conditions. This loading is then combined with maximum vertical and transverse loadings in the designing of the structure. It is evident that a relaxation, or omission of this "broken wire load-

Fig. 3. 230 kv. single circuit V-strung suspension structure with 16 ft. 6 in. phase spacing. Two overhead ground wires. (*The Shawinigan Water and Power Company*)

ing assumption" would result in a appreciable reduction in the weight of structures. There appears to be little justification for retaining this full requirement in view of present experience on lines of modern construction. The improved technique of conductor jointing and careful stringing of the conductors have both combined to make the occurrence of a mechanical break an extremely rare event. Experience in Canada has been that modern high voltage line conductors do not break under heavy ice loads, as the safety factor incorporated in the stringing tensions is sufficient to resist the ice loads that are likely to occur. Where breaks have occurred in the past, these have generally been under ice-free conditions.

Consideration has been given in many ways to the loading imposed bv broken conductors, and some of the assumptions and proposed solutions are discussed as they relate to Canadian views.

The elimination of all longitudinal loading requirements results in a completely flexible line, with the suspension towers supported longitudinally under broken wire conditions by overhead ground wires attached at intervals to rigid dead end towers. Reports on unfortunate experiences with this type of line, in which a single tower failure has resulted in towers between the dead end structures collapsing progressively, make this solution appear somewhat less than ideal. It is therefore not being seriously considered for Canadian high-voltage steel-tower transmission lines.

Some attempts have been made in the past to use a quick release clamp that allows the conductor to pass through a tower when the insulator swings out beyond a certain angle. Tests on a clamp of this type indicate that the clamps may work effectively, protecting the tower from damage, but that there is a tendency for the clamps to act at several towers thereby dropping the conductor to the ground. The cost and duration of the resultant interruption can be as serious as if the structural damage were greater but confined to one tower.

The standard suspension clamp has an approximate slip strength value slightly greater than the normal conductor tensions, and tests have been made to determine the load applied to a tower crossarm when a conductor is suddenly broken. From an analysis of these tests, it was concluded that the full tension existing in the conductor prior to failure was transmitted as an impact load to the tower crossarm. It should be noted that this impact load could cause failure of the tower crossarm and, because of the energy absorbed in this failure, the damage may not progress further. The torque load applied to the tower would be reduced because the moment arm will be reduced by the swing of the crossarm and by the decreased tension in the span. It is also recognized that the impact strength of a structure, such as a transmission tower, is usually higher than the long time loading capacity.

Fig. 4. Three 230 kv. single circuit transmission lines. Two overhead ground wires. Seen from right to left, respectively, are lines constructed in 1934, 1950, and 1955. (*The Shawinigan Water and Power Company*)

These considerations assume that a broken crossarm would be an acceptable amount of damage. Where this condition is tolerated, the effect has been achieved by the use of a crossarm designed to fail at a specific loading. Similarly, some designs are based on a shear pin or link which would fail and permit the crossarm to swing and thus relieve the tension.

Regarding the relationship of the slip strength of a suspension clamp to the broken wire loading, it is necessary to consider the following variable factors. The suspension clamps must be able to hold a conductor against slipping on lines strung in hilly country when ice occurs on some spans and not on others; under dynamic loadings, such as those produced by "galloping" conductors. Judging by past experience, the standard clamp produces sufficient strength to meet this requirement.

There appears, then, to be some justification that the slip strength of the clamp can be considered as the maximum limit of the broken wire loading, and some Canadian high voltage transmission line structures are being designed to this factor, resulting in a considerable reduction in the weight of structures.

Some operating groups specify loadings equal to the maximum design tension of the conductor with no other major loads on the towers; others accept a lower factor of safety when designing for broken wire loading. These are all steps in the same direction and have apparently resulted in lines with satisfactory performance records.

V-Stringing of Insulators

A suspension insulator arrangement using two strings of insulators at each conductor support point, installed transversely to the line at 90 deg. to each other, is generally designated as V-stringing. Several high voltage lines, using this method of stringing, have been constructed in Canada primarily to reduce the phase spacing.

This method may offer some further possibilities of reducing the cost of transmission systems. The restriction of transverse swinging of conductors allows the lines to be installed on a narrower right-of-way. There is some saving in tower weight as the torsional load on the structure is reduced. The mechanical load imposed upon each individual insulator string is also reduced. A decrease in the line reactance, by permissible closer phase spacing, may result in equipment saving and operational economies. V-stringing has also been used, with advantage, to increase the horizontal offset distance of conductors erected in the vertical plane on double circuit towers.

The main disadvantage to V-stringing is that the cost of suspension insulators is doubled in addition to an increase in the hardware cost. There is also a greater possibility of an electrical flash-over due to defective, broken or contaminated insulators.

There are reports of severe galloping on lines with V-string single suspension clamp supported conductors during winds of gale force. A theory has been advanced that the galloping of conductors may be inhibited if each individual string of insulators supports the conductor by means of its own suspension clamp placed a short distance apart. Experimental installations of this type have been erected, results of which appear favourable, but are not considered conclusive.

Wood Structures

Experience has shown that there are very definite economies to be obtained in transmission line construction in Canada by the use of wood. Improved preservative solutions and treating methods have materially increased its life expectancy. The preservative solution preferred by most operators is pentachlorophenol in a vehicle of light oil, applied by the hot and cold immersion or pressure treating methods, depending upon the nature of the wood involved. Further economies are being achieved by the use of spar members for cross arms and braces. The previous objection to the use of spar members was the difficulty of developing adequate connections, but framing hardware is now available which will transmit the applied stresses, thus insuring the necessary overload safety factors. By the application of the various methods of reducing phase spacing, the length of cross arms and cross braces has been reduced, thus making wood pole H-frame cross-braced structures more economical and mechanically attractive. In addition, the rapid rise in the cost of steel has aided a swing towards a more extensive use of wood for transmission line construction. Many Canadian high voltage transmission lines (for all voltages up to and including 230 kv.) have been installed using wooden supporting structures. The application of wood becomes less economical as the higher voltages are reached but still offers substantial savings up to 230 kv. An increase in conductor size with a consequent greater conductor tension, increases the loadings on the structures. The size and lengths of poles are limited and eventually a balance point is reached in the number of structures per mile where overall costs dictate the use of steel structures.

All-Aluminum Conductors

It appears that considerably greater use might be made of all-aluminum conductors (AC) on medium and high voltage lines, than is at present the case. Some Canadian companies have used them to varying extents for heavy, medium and light loading conditions with excellent results.

Fig. 5. Three examples of double circuit lines. Left to right: 230 kv., two overhead ground wires; 230 kv., single overhead ground wire; 115 kv., single overhead ground wire. (*right background*) (*Hydro-Electric Power Commission of Ontario*)

On many early lines using all-aluminum conductors, conductor breakage was experienced resulting from what is now known as fatigue failure due to aeolian vibration. The cause of the trouble was not found at that time and the apparent weakness of aluminum was overcome by introducing a steel core to provide a conductor of greater strength. When vibration failure persisted, a satisfactory remedy was found in the use of vibration dampers, armour rods and improved hardware designs.

Possibly the most important problem in the use of all-aluminum conductors is that of determining the sagging tension which affects tower heights and spans and which governs the vibration life of the conductor. If an all-aluminum conductor and an equivalent cross-section area of aluminum conductor steel reinforced (ACSR) were sagged so that under a specific maximum loading they both reach tensions which are the same percentage of their ultimates, then the sag in the all-aluminum conductor will be greater than the sag in the ACSR. Thus, the structures must be higher, or the spans shorter, and this has been one of the major factors in the change-over to ACSR conductors.

Serious consideration is now being given in Canada to a possible re-orientation of thinking in regard to the almost universal use of steel reinforced aluminum conductors for high voltage transmission lines. Application of the advances in technique and improved fittings developed for ACSR to the design and construction of an all-aluminum conductor line is a good starting point. The following advantages and design features are being studied:

1. The cost of an all-aluminum conductor per unit length is much less than that of ACSR of equivalent area.
2. The weight of an all-aluminum conductor is less and the diameter smaller than that of ACSR; consequently, both the vertical and wind loads at a tower are less.
3. Where the ratio of maximum working tension to ultimate tensile strength for each type of conductor is the same, the tensions at dead end towers, and the transverse loads

at angle towers, are less for an all-aluminum conductor than for ACSR.

4. For spans of a predetermined length and for conductors of a specific cross-sectional area of aluminum, the sags, resulting from the use of an all-aluminum conductor may be less than for an ACSR conductor, if a limit is placed on the loaded tensions.

5. Compression splices and dead ends are much more readily made on an all-aluminum conductor, as it is possible to dispense with the steel sleeve required for ACSR.

Other factors involved in a change from ACSR to an all-aluminum conductor are receiving further study and may or may not prove to be a deterrent to the change.

1. The relatively light all-aluminum conductor may be more susceptible to galloping than the ACSR.

2. Wind, acting on the light all-aluminum conductor (with or without ice) will produce a greater angle of swing of the insulator string at a suspension tower. Longer arms may be required to maintain clearances, but, with the reduced tensions, the torque loads on the tower may still be less than the ACSR. It is possible that V-string suspension insulator assemblies or weights might be used to advantage in such a case.

3. On lines in rolling country, some form of hold-downs may be required on lightly loaded suspension towers.

Investigations into the stress distribution of ACSR have shown that the aluminum strands under normal conditions may be stressed to a higher percentage of their ultimate tensile strength than the percentage for the complete cable. In a homogeneous conductor, such as all-aluminum, this condition does not exist; therefore, it appears that all-aluminum conductors have a relatively higher resistance to fatigue than ACSR.

There may be, in addition, the problem of long term creep depending upon the normal loads applied to the all-aluminum conductor. Only a few of many aspects of the problem have been mentioned here and preliminary discussions on this subject have already led to investigations into some of the more obscure problems.

Fig. 6. 345 kv. single circuit suspension structure; bundled conductors. Wahleach to Vancouver transmission line. (*B.C. Electric Co. Ltd.*)

Bundled Conductors

The proposed development in Canada of hydro-electric sites more distant from the load centres is bringing to the fore the use of bundled conductors. From studies so far made, the opinion is that for lines requiring the transmission of 100 Mw. or greater, over a distance in excess of 250 miles at 60 cycles and voltages of 230 kv., or more, the use of bundled conductors should be considered. Another application arises on older transmission lines which were originally constructed on heavy loading assumptions, where it may be both economical and practicable to rebuild the conductor assembly with twin conductors of heavier total cross section. However, up to the present time very little practical experience has been developed in Canada with bundled conductors.

Double Circuit *vs.* Single Circuit Lines

There is a greater trend towards the use of double circuit transmission lines in Canada today. This trend is being accentuated by the rapid development of urban areas and the general rise in cost of land values in these areas as well as farming districts. Furthermore, the cost of clearing heavily wooded properties and the maintenance of these rights-of-way is becoming an increasing factor in the overall cost of transmission.

The basic reliability of a single circuit transmission tower line is an important factor on radial lines or on other services where security is a predominant requirement. Here, again, the growth of the high voltage network frequently affords duplicate facilities or possibilities of rerouting the supply of power.

Difficulties experienced in double circuit tower lines arise mainly from the local climatic conditions. Where the middle phase of a double circuit line is not well offset, the sudden release of ice or wet snow from a conductor may react sufficiently to make contact with the conductor above. Unequal sags are also caused by a conductor being loaded with ice or wet snow and raising the unloaded conductor in an adjacent span to the extent that clearance between phases is reduced to a dangerous degree.

Standard Conductor Loadings

The loading on conductors is assumed to be the resultant loading per foot equivalent to the vertical load per foot of the conductor, ice covered, combined with the transverse loading per foot due to a transverse horizontal wind pressure upon the projected area of the conductor, ice covered, to which resultant shall be added a constant. In the accompanying tabulation are the values for ice, wind, temperature and constants used to determine loading.

Values Used to Determine Conductor Loading

	Loading area	
	Heavy	Medium
Radial thickness of ice (inches)	0.50	0.25
Horizontal wind pressure in pounds per square foot	4	4
Temperature (deg. F)	0	+15
Constant to be added to the resultant in pounds per foot:		
For bare conductors of copper, steel, copper alloy, copper covered steel and combinations thereof	0.29	0.19
For bare conductors of aluminum (with or without reinforcement)	0.31	0.22
For weatherproof and covered wire	0.31	0.22

It has been noted that heavy ice does not usually form on conductors in a heavy wind, hence the transverse loading assumed is deemed to be sufficient for the purpose, but it is not sufficient to represent the vertical load which is imposed on the conductors by heavy deposits of ice which sometimes form in still air or with a light wind. In order to apply a total loading to conductors representing more clearly the conditions encountered in practice, constants have been added to the conductor loading. In applying loadings to bare stranded conductors, the coating of ice is considered as a hollow cylinder touching the outer strands.

It is also noted that in areas where extreme low temperatures are encountered the tension in the conductors resulting from such low temperatures may be greater than those for ice and wind loading.

Fig. 7. 345 kv. single circuit suspension structure; bundled conductors. Bridge River No. 2 transmission line. (*B.C. Electric Co. Ltd.*)

These loadings are specified by the Canadian Standards Association Electrical Code only for crossings over railways and communication circuits. They are generally applied however, to the lines located in the designated districts.

Appendix

Since compiling the information for the foregoing paper, certain interesting high voltage transmission line designs have been installed or are being seriously considered for early construction.

Probably the most unique project was the installation of a permanent arrangement of stranded steel cables across the Kildala Pass to support conductors on a section of the Kemano-Kitimat transmission line. These cables replace several towers which were carried away by snow slide. (*The Engineering Journal* — July 1956). The economy and effectiveness of this principle has led to further investigation into its application for high voltage transmission lines which are to be located through narrow valleys with high sides.

Further extra high voltage lines (300 kv. and over) are being contemplated employing two conductors per phase. This design results in economies for some utilities while others find that their system is best served by 230 kv. transmission.

Aluminum alloy conductors have been studied but are as yet not favourably received as it is generally felt that existing types of conductors are quite adequate. There is instead a trend to the use of A.C.S.R. conductors with special strandings. The size and number of aluminum and steel strands may be varied to produce an economical balance between the required electrical characteristics and the mechanical characteristics in order to meet certain conditions.

All this, in addition to further structural studies now being carried on, show that the electrical utilities are keeping abreast of the problems involved in transmitting the electrical power for Canada's expansion.

Hamilton River Survey - Labrador

G. V. Eckenfelder, W. P. Harland, and E. N. Webb, M.M.E.I.C.*

Read at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada, Montreal, May 1956

Until recently Labrador has been largely unknown to man. In 1954 a survey was made to define the leading features for a hydro-electric development. The work covered three main divisions: the catchment, regulation, and storage area; the power development proper; and transportation, communication, and other administration. This paper describes the survey work that was done.

FROM EARLIEST times, Labrador has been regarded as a bleak, barren, uninhabitable area which, in consequence, has remained practically unknown and untouched by man. The curious and adventurous had, for many years, been drawn to the great chute known as Grand Falls below Jacopie Lake, but the flat and desolate plateau lands above were left unknown and untravelled save by a few Indians, missionaries, trappers and prospectors. In a high degree, it is still a virgin land, little changed since the last glacial age.

Investigation of power potential on the Hamilton River was provoked by the unceasing demand in Canada for ever more electricity which has approximately doubled each decade over the past 20 years. The major part of this paper describes the ensuing surveys and related enquiries.

A purely preliminary survey of the river up to Grand Falls and in the immediate vicinity had been carried out for Newfoundland Government in 1947-48 by Comdr. G. H. Desbarats[1] who estimated a potential around 3¼ million continuous horsepower. However, this conclusion was based on little more than an ascertained difference of river level and an estimate of run-off by analogy. The field work was restricted to that which could be done by ground parties dependent on canoe and pedestrian transport. In a total working season of less than four months with the effective working time sadly curtailed, the record left by this investigator with the means at his disposal and in the face of so many natural obstacles is a highly creditable one.

The objectives of the 1954 investigation† were essentially to define the leading features of the best discernable scheme for a hydro-electric development, and to establish the feasibility and economics by preparing preliminary designs and estimates. The survey proper resolved itself into: preliminary reconnaissance on which to identify the mode of eventual development and the operations ancillary to it, adequate topographical coverage of the essential areas, measurement and check of rainfall, river flows, and run-off, and collection of all possible information regarding engineering, materials, geological formations, climate, and so on.

Remoteness of the area and extreme shortness of the working season called for large survey forces and intensive organization to achieve conclusive results within one year—which subsequently was extended to two years, in order to check, elaborate and improve the engineering information up to the pre-design and pre-construction stage. Thus, the work was allocated to the three parties concerned in three main divisions: (1) the catchment, regulation and storage area; (2) the power development proper; and (3) transportation, catering, radio and general administration, access and transmission also being included here.

Historical

The Hamilton River was named in 1821 after Sir Charles Hamilton, Governor of Newfoundland. John McLean of the Hudson's Bay Company saw the falls in 1839, and is thought to have been the first white man to view the awe-inspiring cataract. Various other explorers visited the falls during the latter part of the 19th century; notable amongst them was A. P. Low, [2] a geologist of great energy and fortitude, who travelled far and wide over the Labrador tableland and whose report described the falls in detail.

The first reported enquiry into the power potential of Grand Falls area was in 1915 by W. Thibaudeau who made a reconnaissance of the power possibilities of Grand Falls, and he and his group may have been the first to visualize development of the site by the so-called "Channel Scheme" (Fig. 3). Their surveys provided a profile of the river from Jacopie Bay to the foot of Portage Creek showing that approximately 1,000 ft. of head existed in that reach. They also obtained a profile along the chain of lakes between these points.

---

*The authors are associated, respectively, with Montreal Engineering Company Limited, Shawinigan Engineering Company Limited, and British Newfoundland Corporation Limited.

† by the British Newfoundland Corporation Limited.

Desbarats' survey[1] comprised levels from the foot of Muskrat Falls near sea level, to Jacopie Lake, and traversed the reach of the river adjacent to Grand Falls; incidentally, Thibaudeau's scheme for power development was shown to be practicable. Desbarats also made a preliminary reconnaissance of possible sites for utilizing the head between Grand Falls region and the sea. Moreover, he gave some attention to storage and drainage areas, as ascertainable from the Topographic Survey of Canada's small scale maps.

All of this information became available to the authors, and the elevation of Desbarats' bench mark at the crest of Grand Falls was used as the datum for the Corporation's 1954 and 1955 surveys.

Winter Reconnaissance

While results of previous investigations were helpful in a preliminary evaluation of the power site, they shed little light on the catchment area above Grand Falls. The photographs from which the uncontrolled maps of the Topographic Survey had been plotted were available, but gave little idea of ground elevations or of relative heights of lakes.

It was obvious that a ground reconnaissance must be made before any serious survey could commence. The general topography of the entire area had to be examined to determine: (a) elevations of lakes; (b) possibility of diverting the Naskaupi and of a diversion route; (c) feasibility of creating one large storage reservoir out of Sandgirt, Lobstick, and Michikamau Lakes; (d) locations of damsites for diversion and storage; (e) possibility of diverting the Unknown branch of the Atikonak; and, (f) locations of camp sites and aircraft landing areas.

On 3rd March, 1954, an expedition of ten men, under the leadership of engineers from the consulting firms, was based on the Menihek power station[3] about one hundred miles northwest of Grand Falls. Using two Beaver aircraft, the party made daily trips into the Grand Falls area over a period of three days during which the elevations of 12 stations were determined and a diversion route was reconnoitered. Still based on Menihek and using Beaver aircraft in sub-zero weather, two weeks were spent in the storage area, examining the country in order to become familiar with the topography and to find possible damsites. The required information hinged mainly on elevations which were obtained almost entirely by means of surveying altimeters. The Wallace and Tiernan instruments capable of detecting 1 ft. difference in elevation, were preferred.

Where it was important and feasible to obtain accurate levels, a spirit level was used.

The barometric levelling was done in two ways, the "single base" and the "leap frog" method. In the former, one barometer at a base station is read at prescribed intervals, while the other is carried by plane from lake to lake. Readings from the base barometer provide corrections to the elevations obtained by the other, the plane returning to base to compare instruments at the end of the day.

In the "leap frog" method, after readings have been taken simultaneously at the base and at the lake of which the elevation is required, the base instrument is brought forward in one plane and landed at this lake where the instruments are read side-by-side. Repeating the procedure, one plane (with barometer) remains in position until the other plane (with barometer) has landed at a new point when simultaneous readings are again taken. Radio communication is essential for this method.

All elevations were checked in the field by repetition, a minimum of six determinations being made for each lake. The "leap frog" method proved the more accurate of the two. In the "single base" method, the distance from base often became so great that local variations in air pressure produced inconsistent readings. In the "leap frog" method one is measuring differences and, virtually, the base moves along near the roving plane, which gave a closing accuracy of about plus or minus four feet on courses up to 120 miles long. During two weeks, the elevations of 76 lakes were obtained.

An overall picture of the ground to be surveyed emerged as a result of the winter reconnaissance. It was found that a flood channel existed through which the Naskaupi could be diverted into the Hamilton watershed, and that it was possible to divert the Unknown River branch of the Atikonak. Combining Sandgirt, Lobstick, and Michikamau Lakes presented no major obstacles, the reservoir thus created being contained by high ground, except at natural outlets where alternative sites for necessary dams were noted to exist. The elevations obtained, along with visual impressions of the topography, indicated no major obstacles to the Channel Scheme and two possible routes, one possessing natural advantages. A great many lakes were shallow and boulder filled, but lakes suitable for aircraft landings with related camp sites were found and noted. Lake ice was ascertained to be 40 in. thick, permitting the landing in winter of large aircraft with heavy loads.

All this information was of great importance, as it was now possible to determine within narrow limits the extent of the surveys required and to plan the summer's work accordingly.

The winter operation was not without hazards — low temperatures, blustery weather, unreliable visibility and radio — wherefore, safety precautions were essential. Aircraft carried emergency rations and camping equipment; flight plans were always filed, so that each pilot knew where the other was operating; and whenever men were left on the ground, even for a few hours, they were equipped to be self-sustaining.

Under severe winter conditions in a remote and totally wild region, a great deal of essential knowledge, far beyond expectations, was gained in less than three weeks and at a surprisingly low cost.

Control Surveys for Topography

The greater part, by far, of the ensuing field work consisted of establishing ground control for photogrammetric mapping. The type of information sought and the conditions prevailing in the storage area differed so widely from those in the power phase of the investigation that the methods used in each were necessarily different. However, the same principles applied in both areas.

Two types of control were required for photogrammetric mapping —horizontal and vertical. The firms engaged to carry out the photogrammetry indicated on prints of the aerial photographs the control which they would require, choosing small prominent objects that stood out well on the photographs as "H" or horizontal control points. The abundance of lakes and ponds provided the "V" or vertical control. Large lakes extending over the area of one or more photographs afforded natural vertical control and reduced appreciably the amount of levelling to be done.

(a) Storage Area — In the stor-

Fig. 1. Map showing general location of Grand Falls relative to important centres and physical features in Eastern Canada.

age area, great reaches of ground had to be contoured, and closed traverses were neither feasible nor essential. The country having little relief, maps with a close contour interval but on a relatively small scale were required. In the absence of closed traverses, azimuth checks were obtained by frequent sun observations — these in preference to star shots to avoid overnight vigils at stations far removed from the camps.

Since it was necessary to cover very elongated areas, the "H" points were tied to an open traverse which was run near the axis of the strip photographed. As a ground profile for making preliminary estimates was aimed at, so far as possible the line of traverse was selected along the high ground where visual reconnaissance indicated the containing dams might be located.

Vertical control along the main traverse was established by a double line of levels, elevations of the lakes chosen as "V" points being fixed by level loops from the main traverse. Permanent bench marks were set in rock at least every five miles along the main traverse.

(b) Power Area — In the power area, the ground surveys were divided into two broad categories; viz. control for photogrammetric mapping, and tentative location surveys for the proposed structures and installations. Effort was made to combine the two wherever possible.

After careful consideration, it was decided that closed traverses would be preferable to triangulation for horizontal control, if only for the additional information about the terrain that would be gained. Loop closure accuracy of 1 in 1,000 or better was maintained. As in *(a)*, a double line of levels provided the profiles along the traverses. Many miles of traverse round lakes were obviated by the chaining on ice accomplished by the 1954 advance party in May of that year. For orientation purposes, transit observations on Polaris were used for the basic azimuths.

A co-ordinate system was laid out, such that all of the power area would fall within one quadrant. All co-ordinate computations were referred to a selected base, to which line also convergency corrections were related. The Geodetic Survey of Canada station on Lookout Mountain was tied into this grid, so that the whole system can be readily converted to geographical co-ordinates when required.

"H" points were tied into the closed traverses, and the elevations of "V" points were fixed by level loops. Unlike the storage area, it was necessary to provide a small scale 20 ft. interval contour map of the whole area, as well as large scale 5 ft. contour maps of limited areas. To provide the vertical control for the 20 ft. contours, some elevations were determined barometrically, the "single base" method being used with not less than two sets of readings taken on different days.

No mention of control surveys would be complete without reference to an unusual role played by the helicopter. When beginning a traverse between two points in the bush, it is often difficult to determine in which direction to head. The helicopter assisted greatly by hovering over the point of destination at just sufficient altitude to be seen by the instrumentman at the start of the traverse. When the helicopter was on position, a red flag weighted by a stone was lowered some 15 ft. to 20 ft. as a signal for the instrumentman to take a sight, which device saved considerable time and unnecessary length of traversing.

Topographic Detail Survey

Compared with the area which was mapped from aerial photographs, the topographic coverage on the ground was quite small. In the vicinity of Grand Falls, some 9 square miles were mapped in 1954, principally in the eastern portion of the area where lighter bush and an old burn facilitated stadia work. The plane table was little used, owing to general inclemency of the weather in 1954.

No field topography was done in 1954 in the diversion area, the bush in the vicinity of the river being too dense. Time and effort were considered spent more profitably in taking underwater soundings, especially as maps from aerial photos could be produced from control already provided. In 1955, the sections mapped in the field were restricted to anticipated sites for some of the principal structures.

During the first winter's study of the Channel Scheme in the office, some of the contemplated works were defined to an extent that justified proceeding with detailed surface investigation and seismic profiles. Others were so indefinite that a larger area needed to be analyzed, for which purpose large scale maps already prepared from aerial photographs appeared adequate, thus requiring no additional field work in 1955.

In the case of the Naskaupi diversion and the Ossokmanuan damsites in the storage area, the height of land along which containing dams were needed was so well defined that an extensive band of topography had not been thought necessary. Much of the ground could be covered adequately by a single profile, with topography only at the main river crossings. The 1954-55 winter studies, using 5 ft. contours plotted from stadia and level data obtained in 1954, suggested an alternative scheme for the Ossokmanuan diversion, which made it advisable to obtain contours over a wider area. In 1955, this area was photographed and a new control survey made.

Traditional methods of ground topographic surveying played but a minor part in this investigation and only modern techniques could have provided the information in the short time allowed. It must be admitted, however, that detailed field surveys, where applied, afforded excellent opportunity to become familiar with the characteristics of the ground.

Photogrammetry

Aside from the obvious advantage of economy, the photogrammetric method of mapping was ideal for the prescribed purpose, in that actual field work could be reduced to a minimum.

The aerial photography and photogrammetric mapping were done by several firms. In the Grand Falls area, some 300 square miles were photographed at three different altitudes consistent with plotting at three different scales. In the event, only two scales were utilized: 800 ft. to 1 in. with a contour interval of 20 ft., and 200 ft. to 1 in. with 5 ft. contours. The entire Grand Falls site area, amounting to 228 square miles, was mapped at 800 ft. to 1 in.; while 30.5 square miles, including all localities for proposed structures, were covered at 200 ft. to 1 in. The smaller scale was considered adequate for general location of access roads and material deposits and for preliminary layouts, while the larger scale would suffice for setting out structures in detail.

Fig. 2. Map of the catchment and storage area, showing location of surveys.

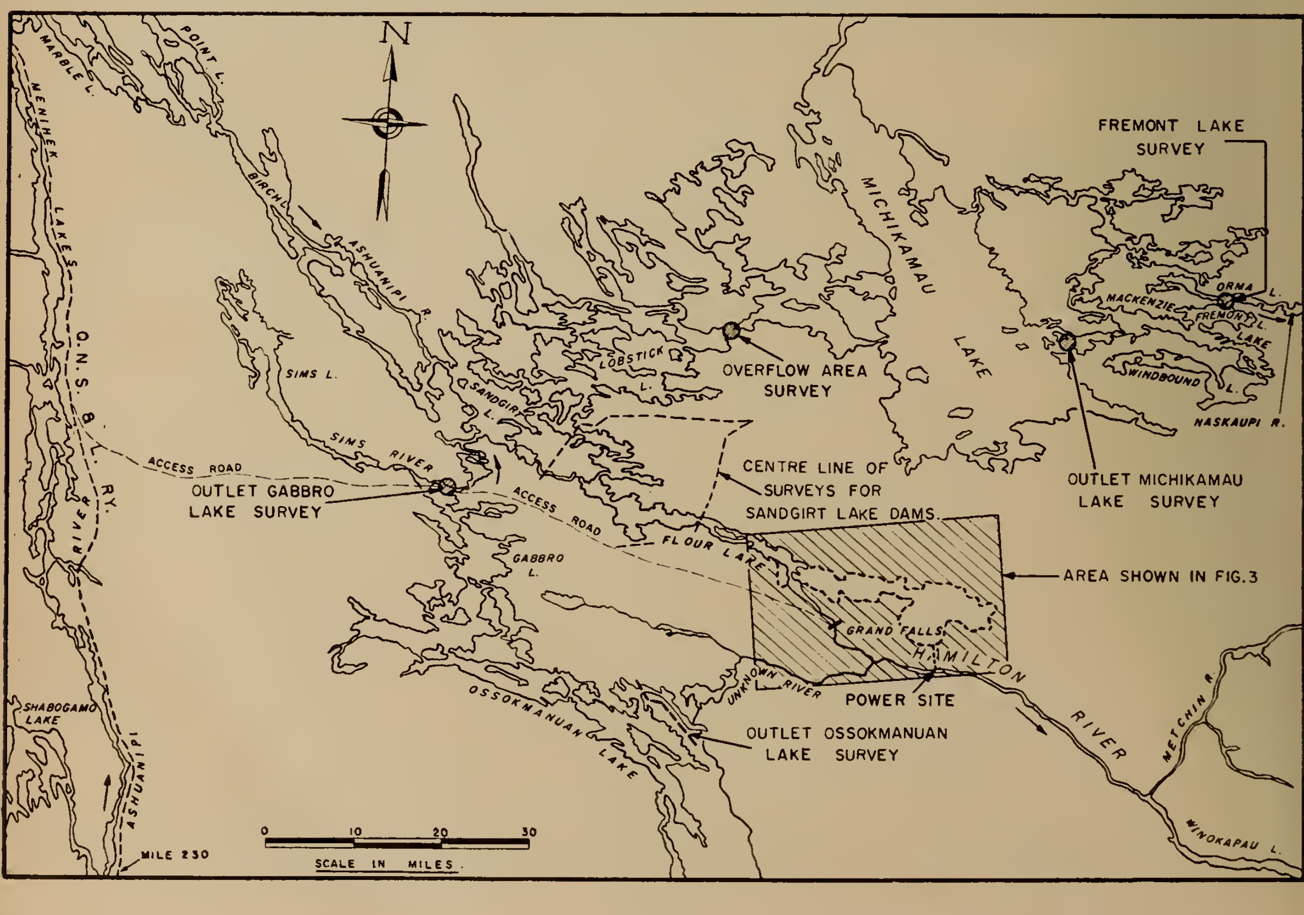

Fig. 3. Map of power development area, showing location of proposed engineering structures.

All storage areas were mapped to a scale of 400 ft. to 1 in. with a contour interval of 5 ft., which was adequate for the detail required and yet did not result in an excessive number of sheets; 145 square miles of ground were covered in this manner during 1954 and another 40 square miles in 1955.

Organization of the ground control generally followed the same pattern throughout, being varied according to individual circumstances. With minor exceptions, the firms undertaking the mapping sent their own photogrammetric experts into the field to define the control required and to supervise the survey work in progress. Where the parties concerned had mutual confidence based on prior experience, such specialist participation became a minimum. In all cases, the results were well up to the requisite standard.

In addition to being fast and comparatively inexpensive, photogrammetry produces very accurate maps. The recognized specification for contours is that they be correct within half a contour interval and, providing the vertical control is adequate, this stipulation is usually met without difficulty.

Where horizontal control is adequate, well-defined physical features can be plotted within 0.02 in. (hardly more than the thickness of a line) of their absolute positions. However, contours cannot be plotted with quite such accuracy, but their relative positions usually are very good.

Aerial photographs are invaluable in the field. Even the best of maps cannot provide the detail and information that is readily available from a pair of photographs and a pocket stereoscope.

Marine Soundings

In the diversion area, very extensive underwater soundings were required in order to provide basic information for the planning of various structures. In the storage area, the extent of cut necessary to divert the Naskaupi could be determined only by means of underwater topography. During the 1954 season and the early portion of the 1955 season, soundings were taken in the traditional manner by lead and line; but in the latter portion of last summer an echo sounder was introduced for this work. However, the Michikamau diversion soundings, being well advanced by this time, were completed by lead line and sounding pole.

Unfortunately, a great deal of the required underwater topography was in fast flowing water on the Hamilton River itself, which fact necessitated a rather elaborate organization for locating each sounding, whether taken by lead line or by echo sounder. In the usual procedure, two parties, each comprising a transitman and a notekeeper, were installed ashore on two stations of the river triangulation network, whence they could intersect the position of the boat as each sounding was made. These stations were so selected that the intersected angles lay between 30 deg. and 150 deg., and were close as possible to 90 deg.

After some experimenting, co-ordination between the instrument parties and the sounding party was systematized as follows. All parties synchronized watches before beginning a run, and soundings were then taken at pre-arranged intervals, every tenth sounding being indicated by a signal. With this system, up to 100 soundings could be made per hour using lead and line, and 360 per hour using the echo sounder.

The leads varied in weight between 4 lb. and 20 lb., depending upon the velocity of the water. After trial of various types of line, the most satisfactory was found to be "cod line" actually carrying the lead and having a metallic cloth tape loosely attached to show the depths.

At the Michikamau diversion, shallow water rendered it possible to sound with a pole. Soundings were fixed by two transits at shore stations but, as the distances were small, the angular fixes could be checked by stadia. Some 2,300 soundings were obtained in this way.

The echo equipment used, although inexpensive and intended primarily as a navigational aid for pleasure craft, exhibited an accuracy of 1 ft. for soundings between 0 and 60 ft. Electrical impulses at the rate of 30 per second are converted by a submerged "transducer" into mechanical waves which travel to the bottom and are reflected back to the transducer, there to be reconverted to electrical impulses. The time elapsed between the emission and return of the signal is indicated on a dial graduated in feet. Excellent results were obtained at any reasonable boat speed, even in the rapids. While river bottom conditions gave satisfactory operation of the echo sounder, at some places on the lakes a bottom of soft organic matter was found to absorb the mechanical waves and no reading resulted. This, however, did not affect the usefulness of the equipment to this survey as it was used entirely in the river.

Altogether, 6,900 soundings (2,300 at Michikamau) were taken during the two seasons over an area of approximately 600 acres.

Levelling and Water Transfers

It was important that the surveys of the widely separated areas comprising the Grand Falls power and storage scheme be related to a common datum. No geodetic bench marks or other datum existed above the head of Grand Falls, and the elevations obtained by barometer during the winter were of quite inadequate calibre for the contemplated surveys. In the event, Desbarats' bench mark at Grand Falls was adopted to relate the surveys to sea level, pending re-survey of the lower Hamilton. A line of levels was carried from this bench mark via Sandgirt to Ossokmanuan; also, up to and across Michikamau, over the height of land and on to the headwaters of the George River.

The map shows how much of the country is covered by water and full advantage was taken of this fact. Whenever possible, elevations were carried by water transfer across lakes, in order to reduce the amount of levelling work. This was only possible on lakes, or on streams with negligible gradient and during dead calm weather. Several readings of water level were taken simultaneously at each extremity of the lake or reach of river, and no elevations were accepted unless the successive

Fig. 4. Grand Falls and approach rapids.

readings agreed within 0.01 ft.

Where no suitable body of water existed, levels were run by instrument along the shortest route between lakes. All levelling was done using two rodmen, two sets of readings and two sets of notes, thereby providing a continous check.

One party was engaged during the 1954 summer solely in running these levels; and again, in 1955, a profile of the Hamilton River from Portage Creek to Muskrat Falls was obtained generally by the same method. To cover these great distances in so short a time, the party had to be highly mobile. The 1954 party comprised an instrumentman familiar with the method of water transfer, a rodman, and two axe-rod-canoe men, transported by two seventeen foot canoes each equipped with a ten horsepower outboard motor. Camping equipment was limited to essentials, and was selected for light weight and compactness, each man carrying an eiderdown sleeping robe. Four small Scotch silk tents and gasoline cooking stoves were used. Fuel caches were established along the line of travel by aircraft, and at least once each week weather permitting, an aircraft visited the party and left about a week's food, fuel, and other supplies. A portable radio kept the party in touch with Sandgirt base camp and provided fairly dependable contact at surprisingly long ranges.

In the 80 days campaign of 1954, this levelling party covered about 550 miles of land and water.

The men engaged in other phases of the investigation were housed in static camps where it was possible to provide a reasonable standard of comfort; but, for the level party, life was bared of all frills. Camp was pitched where nightfall found them, on rocky shore or edge of swamp; the course of the canoes often took them through wild rapids and across windswept lakes; they were more often wet than dry. Yet it was a happy camp, and the quality of the work was consistently high.

Seismic Sounding

As may be seen in Fig. 3, any development of the Channel Scheme would require structures covering a considerable expanse of territory. To divert and control the water from Jacopie Bay to an intake near Portage Creek, would involve some 3½ miles of excavated canal and 15 miles of earth-fill retaining dams. Evidently, investigation of depth and type of overburden along the lines of these canals and dams would be impracticable within the short season available, if attempted by test-pitting and borings alone. Geophysical exploration by seismic sounding appeared to be the answer.

The seismic refraction method used[4] is based on the principle that longitudinal seismic waves behave very similarly to sound waves, in that the velocity of the wave front varies with the density of the medium through which the wave passes. In operation, twelve special seismometers, known as geophones, are set out at regular intervals on a tangent which has already been profiled. The spacing between geophones may vary but usually is 15 ft., giving a set up length of 165 ft. which normally suffices to determine bedrock at depths up to 30 ft. or possibly more. If greater depth to bedrock is anticipated, the geophone spacing is increased accordingly.

The seismic impulse is produced by a dynamite charge, the size and location of which depends on the nature and anticipated depth of the overburden. These seismic waves travel through the earth to the geophones where the mechanical impulses are converted into electrical ones and recorded on a strip of moving film. The increments of time between the arrival of seismic waves after having passed through media of different densities provide the data for computations to determine the depth to bedrock.

There are, of course, various combinations of conditions which can complicate the interpretation of the seismic data. Therefore, it is necessary to conduct a geological surface examination of the area prior to the seismic work, and to sink a certain number of test pits or borings after. Correlation of the data thus obtained assures interpretation within the required limits of accuracy.

During the 1954 season, seismic investigations were confined to ascertaining depths of overburden along the lines of principal structures. However, during the following winter the additional possibilities inherent in the method prompted its wider application to procure fuller information regarding the nature of the overburden at the sites of structures, and the extent of available deposits of construction materials. In combination with adequate test-pitting, this application proved generally successful and effective. Determination of bedrock profiles along the centre lines of structures was continued in 1955 and, by locating the test pits strategically, the nature of the overlying material also was ascertained.

In addition, the depths of major deposits of pervious and impervious fill were defined by seismic sounding. A preliminary examination of a deposit selected by map and aerial photo was made by the geological party, who then dug shallow test pits to get a general "feeling" of the area and thereby to deduce the most suitable line for a seismic profile. After plotting the seismic results, the position for a deep test pit was chosen to afford the maximum of information from a minimum of excavation.* Such test pits elucidated the causes of "discontinuities" or changes in velocity and provided identification of the various materials represented by different velocities. The seismic profiles then enabled extrapolation laterally of the information obtained from the test pit.

Through the use of seismic methods, a continuous rock profile was obtained for the full length of all proposed dams and canals. Moreover, by combining other available data, the nature of the overburden at these sites was deduced with confidence. Depths of overburden investigated varied from 0 to over 200 ft. and averaged about 20 ft. The work done on natural deposits of pervious and impervious fill has made possible close estimates of the quantities actually available. No more than a small fraction of this diversified information could have been gained from surface examinations and test-pitting only.

A total of 79,635 ft. (15 miles) of seismic profile was produced by the

equivalent of one party working for seven months.

Rainfall and Run-Off

Scant knowledge of the Hamilton watershed run-off existed at the start of this investigation. Until a continuous stream flow record of several years duration existed, the energy potential of the river could not be assessed with any precision. Therefore, it was of the utmost importance that stream gaugings be started at the earliest possible moment. For the immediate appraisal of the size of development upon which to base preliminary design of structures, extended flow records being non-existent it was necessary to make a reasonable guess, using such fragments of knowledge as obtainable of the climate and of the characteristics of the watershed.

Discharge measurements had been started at Muskrat Falls in October 1953 and at Menihek Rapids in June 1952, but the latter were not continuous. The Department of Transport had established a weather station at Sandgirt Lake in 1943, where precipitation and temperature observations were made until April 1948; but, mining operations having begun at Knob Lake in 1949, the weather station was transferred there. In addition, continuous meteorological records have been kept at Goose Bay since May 1942. Goose Bay, however, is too distant for its records alone to be of much value in estimating run-off from the upper reaches of the watershed.

No evaporation observations had been made in the area, wherefore the proportion of the precipitation appearing as river discharges was not known. Nevertheless, by giving due consideration to climatic characteristics, terrain, meteorological conditions and the like, one could deduce the probable evaporation in Labrador. This, deducted from the minimum annual precipitation disclosed by the Sandgirt and Knob Lake records, gave a figure for run-off during the driest year in the period covered. The run-off thus derived was adjusted to allow for the probability of greater precipitation along the southern fringe of the watershed, and was then reduced to compensate for the effect of a drought cycle. Thus, an appraisal was made of the water available for a power development.

Having thus estimated the dependable annual run-off, there yet remained to define how this run-off was distributed throughout the year, in order to determine the extent of storage necessary for regulation. The twelve months of continuous records at Muskrat Falls gave the shape of the hydrograph at that point and, for the time being, the characteristics of the hydrograph above Grand Falls were assumed the same.

Stream-Flow Gauging Stations

The extreme paucity and sketchiness of the data available for computing a run-off figure will underline the urgent need for much more information. As soon as the survey parties reached the field in the summer of 1954, a temporary recording gauge was installed on the Hamilton below Portage Creek, and two discharge measurements were made at this point during the summer. Four permanent gauging stations were planned, one on the Hamilton above Jacopie Lake, one at each of the two outlets of the Atikonak, and one on the Naskaupi at Fremont Lake; considerable preparatory work was done at these sites before freeze-up.

During the fall and early winter, cable car installations at each of these sites were designed and material was ordered. In January 1955 a crew of men proceeded to the field and the material was air-lifted to the sites. The heaviest single package weighing nearly two tons was the cable for the Flour Lake crossing (1126 ft. span), which required a DC-3 on skis to carry it and more than 20 men on snowshoes to drag it the remaining 2½ miles to site. In all, about 20 tons of material were brought in, while large quantities of local wood, stone, etc. also were used in the various structures.

By spring, all four cables had been installed in time for the engineers of the Dominion Water Resources Bureau to measure the discharge at the spring flood. During the summer, safety guys and backstays were added, and settings were built for the recording gauges. Calibration meterings are now being made at regular intervals.

Fig. 6. Typical survey camp, showing usual transport facilities.

Geology and Soils

Investigation of the surface geology and into the occurrence of "soils" proceeded during the whole field seasons of 1954 and 1955. The earlier work by two geologists and two assistants which aimed at providing the general geologic background at the proposed engineering sites, was expanded in 1955 to obtaining detailed surface and subsurface information at locally important sites and, with the addition of an engineering 'soils specialist' graduate, to comprehensive investigation of "soils" deposits.

The 1954 reconnaissance followed on pre-season study and interpretation of aerial photographs, during which an impression had been gained of topography, outcrop distribution, soil cover, types and location of construction materials and other surface features of possible engineering significance. These features were assessed more fully during the field season, using a helicopter for spot-checking, and final detail was obtained by ground traverses and shallow test pits.

Outcrops in the vicinity of proposed sites were mapped geologically by ground traverses, special note being taken of possible major bedrock features which might affect future engineering structures. This work prepared the way for diamond drilling and further seismic investigations in 1955. On these traverses, shallow pits were dug and the soil sampled to determine the nature of the overburden.

In the course of investigating sources of construction materials, some 120 test pits were dug with pick and shovel to depths between 5 ft. and 15 ft. About 170 mechanical analyses were made of material in the range from ¾ in. to 200 mesh; material below 200 mesh was not sub-divided, while that above ¾ in. was only estimated by eye. Construction material was thus classified as to grain size and also according to geologic origin which information, compiled in report form incorporating test pit logs, grading curves and 7 geologic soils maps, covered the 150 square miles reconnoitered.

During the 1955 season, the work developed into two separate related phases, surface and sub-surface investigations. The soils enquiry required more detailed assessment of suitability and quantities of deposits at locally important sites. Briefly, this involved test pit digging, sampling and testing, interpretation, and determination of quantities. Also, the search was extended into other areas, where numerous shallow exploratory test pits were dug. Six test pits were dug to depths between 20 ft. and 41 ft., using a winch with bucket and shoring the pit sides with local black spruce — this under engineering supervision.

Field tests of soil samples included: (a) mechanical analysis of material between 200 mesh and ¾ in. size; (b) colour tests for organic contamination; (c) visual estimates of material above ¾ in.; (d) in-place density tests; (e) moisture content determinations. For more detailed tests, 50 lb. samples were sent to Montreal.

Surface and sub-surface investigations of the bedrock consisted of detailed surface geologic mapping and diamond drilling. For the latter, two

Fig. 7. The deepest test pit, 41 feet, dug in two weeks.

drills operated in two ten-hour shifts through most of a three months period. Six thousand feet of core provided a satisfactory picture of subsurface conditions, and further drilling at this stage was not considered necessary. Results of surface mapping and of drilling were combined to produce a plan and profile of local rock structure.

Access Route

A programme of reconnaissance during the summer of 1954 aimed at defining the most feasible and economical mode of access to Grand Falls. Air transport was not contemplated seriously and access by water was deemed unpractical as the open season is only 4½ months a year; therefore, investigation was confined to land routes.

The Quebec North Shore & Labrador Railway passing within 100 miles of Grand Falls is the obvious artery for heavy traffic into the Hamilton basin and thus, also, is the logical starting point for the access route. A road was envisaged in preference to a railroad, because of its lower cost and greater flexibility.

Possible routes were first selected by study of the three available sources of information: (a) the 8 miles to 1 in. map, showing the general geographic features of the area; (b) the R.C.A.F. aerial photographs covering the area at ½ mile to 1 in.; (c) existing Q.N.S. & L. Rly. facilities, such as railroad sidings, airstrips and tracks.

Five alternative routes were picked out, and then examined from the air in order to discern the more promising one; which, in turn, were investigated by on-the-ground reconnaissance to ascertain how best such obstacles as river crossings, swamp areas and solid rock outcrops might be overcome. Results proved conclusively that a road along the most northerly route would best serve the overall development plans. Although the short field season permitted only a cursory examination of this route, it yielded ground data which, with supplemental studies of the aerial photos, enabled the compilation of a ½ mile to 1 in. map showing tentative location line, type of terrain, swamp areas, river crossings, etc. This information proved invaluable for planning the engineering survey undertaken in 1955.

Starting from a siding at Mile 286 on the Q.N.S. & L. Rly., the route goes almost due east for 100 miles to the major crossing of the Hamilton River above the falls; thence, generally north and east to the power site. The preliminary survey in the summer of 1955 had as objectives: (a) to mark out and survey the actual road alignment; (b) to procure adequate information regarding quantities for reliable estimates; (c) to obtain full engineering details of all major obstacles;

and, (d) to establish the economic merits of the chosen route.

A field engineer party of eight men, assisted part time by specialists, carried out the survey in some 4 months. The main survey camps were established and serviced by Beaver aircraft, while the placing of subsidiary camps and daily transport of men were effected by helicopter.

Altogether, 100 miles of road were traced, surveyed by compass and chain, pegged at 500 ft. intervals, and flagged every 2,000 ft. for 80 miles. Gradients and lateral slopes were determined, along with sufficient information regarding clearing, nature of ground, etc., to provide reliable cost data; particular attention was paid to lengths and depths of swamps. Complete pre-design data were obtained for four major water crossings.

In addition to this general location survey, the first 12 miles from the railroad siding were set out in detail, full information for precise estimating being recorded.

Suitable soil materials were identified in some convenient areas, but a wider occurrence of gravel and sand deposits would be advantageous; however, the investigation was not conclusive. Construction of a road presents no major difficulty; while costs would be high, they can be anticipated to compare not unfavourably with projects of a similar kind.

Electrical Transmission

Disposal of power from so remote a place inevitably is a major problem to which long distance transmission affords one solution. The amount of power and the distances involved call for the highest practicable voltage, and modern developments require that direct current be not overlooked.

Various considerations suggest the north shore of the St. Lawrence as a potential scene for industrial development and application of such a block of power, while technical and commercial attractions point to Seven Islands. Accepting this as a typical case, a transmission route to Seven Islands was selected — mainly from 'paper reconnaissance' — in 1954, as a basis for estimating. This was elaborated in 1955 to reconnaissance by air and on the ground, combined with intensive study of aerial photos and collation of much pertinent information from other sources.

In this way, a highly practicable transmission route has been defined, adequate information for reliable preliminary estimates has been secured, an. detailed plans with costs for final survey of the line have been formulated.

Logistics

Decision in February 1954 to investigate the Grand Falls power potential during the ensuing four-month summer season posed exceptional targets of field work and of finality within one year, all despite very little knowledge of the conditions likely to be experienced. The winter reconnaissance confirmed the broad outlines of the field programme and emphasized the factors involved in maintaining camps, scattered over 2500 square miles and 250 miles from the nearest supply centre. These factors were crucial in the organization of such a field survey contemplated for completion in one season only.

Of necessity, the survey was directed from Montreal, with principal line of communication and transport to the field via Seven Islands, whence the Corporation's base camp between Mile 224 and Ross Bay on the Ashuanipi River was reached by a twice-weekly freight and passenger service on the newly completed Q.N.S. & L. Rly. This left 65 miles to the nearest survey camp, or 105 miles to the proposed power house site, to be covered by air.

To save both time and money, bulk stores for the field force of 180 men were flown into the area from Mile 224 base and landed on the ice during April. This eased the pressure on transport in early June, when the ice went out and prompt movement of men and fresh foods was essential to commencement of field work.

Although adequate landing facilities for heavy aircraft were not numerous during the ice-free period, all bulk transport was by heavy plane as far as possible before transferring to lighter and more versatile aircraft. Once camps had been established, two Beaver aircraft and two Bell helicopters provided nearly all transport services. Scheduled flights were found impracticable due to weather, the number and diversity of the camp sites, and the flexible nature of the survey; constant supervision and adjustment were necessary to prevent wasteful use of aircraft, or hindering the work.

Total flying time for all aircraft in the 1954 summer season was 2,578 hours of which one-half was attributable to camp service. The other half comprised: 23 per cent for survey work, 16 per cent for moving personnel, and 11 per cent ferry flights. During 1955, with 150 men in the field, the same number of aircraft was used but total flying time was 2,202 hours; ratios remained almost unchanged.

In order to expedite the survey work, to control and co-ordinate aircraft movements, and to supply all camps, a good radio net was essential. Voice radios of 80 and 85 watts output operating in the 3 to 5 megacycle band were installed in the major camps and provided contact with aircraft also. Effectiveness of communication depended on conditions and was generally good between all parts of Labrador, Northern Newfoundland and Seven Islands, but erratic with Montreal. Smaller camps and vehicles operated on the same frequency with portable sets of 3 to 15 watts output. Radio maintenance required a full-time technician during the summer.

Once communications had been established, camp supply, administration and catering followed routine patterns. Camps (with one exception where an abandoned meteorological station was used) were under canvas, both summer and winter; lighting was by gas lamps, cooking and heating by wood stoves. During the first summer, the blankets and camp beds issued to all personnel proved inadequate for cool Labrador nights. Sleeping bags were found to be essential and had the added advantage of making all personnel mobile and independent — a necessity under the uncertain travelling and living conditions.

Catering was done by contract, and the highest level practicable was maintained. Although most food kept well in the cool Labrador summer, a refrigerator was installed at Mile 224 base. One difficulty experienced was the deterioration of food during shipment from Montreal which was overcome in 1955 when bulk supplies of fresh foods became available in Seven Islands. Approximately 7 lb. of food per man-day were supplied.

Whenever possible, mechanical aids were used — canoes fitted with outboards, and power saws for line and fire-wood cutting. Most machines,

Project Vanguard—
The IGY Earth Satellite

F. R. Furth

Vice-President, Farnsworth Electronics Company, Fort Wayne, Indiana.

Read at the 70th Annual General and Professional Meeting of The Engineering Institute of Canada, Montreal, May 1956

PROJECT VANGUARD represents a practical progression in the techniques of very-high altitude research. It is the first step beyond balloons, which cannot go above the earth's atmosphere, and rockets, which cannot stay aloft for an extended time. While essentially an extension of these proven research techniques, the Vanguard satellite program is the beginning step of a new phase, which presumably will be susceptible of continued improvement to permit longer and higher flights and more advanced instrumentation.

Vanguard is also significant because of the magnitude of the project. It could not be accomplished without the cooperation of many different organizations with experience in various scientific and technical fields, and extensive logistic support, to establish and maintain a suitable launching facility and tracking stations. Successful construction and launching of the satellite will demand going to the present limits — or beyond — of our engineering knowledge in many fields.

Project Vanguard is a three-year project. Many of the broad and most of the detailed engineering decisions concerning the first satellite and its launching have yet to be made. Because of the Navy's prior experience in upper-atmosphere research, it has been possible to move ahead rapidly in sketching in the broad outlines they intend to follow.

The National Academy of Sciences is sponsoring the satellite program as part of the United States' International Geophysical Year effort. The Department of Defense has been charged with responsibility for designing, constructing, testing, and launching a scientific vehicle. Their purpose is to implement the Presidental announcement of July 29, 1955, regarding an earth satellite, and to accomplish all the work in time to lauch the satellite during the International Geophysical Year.

Before his retirement in January 1956, Rear Admiral Furth was Chief of Naval Research, U.S. Navy, and therefore is well qualified to write of the earth satellite that is to be launched as part of the International Geophysical Year program. The paper was presented at the annual meeting of the Institute under the auspices of the American Rocket Society, Inc.

Within the Department of Defense, the Navy has been selected to manage the technical program. The Army and the Air Force will participate primarily in the field of logistics. The Chief of Naval Research will manage the program for the Navy, and coordinate the efforts of the other military departments and Government agencies. The Naval Research Laboratory will be the primary organization within the Navy to implement the program.

It is important to remember that both the Office of Naval Research and its Naval Research Laboratory are scientific agencies, although their ultimate purpose is to support military preparedness. They have been supporting, and conducting basic research for many years. As a result, they have the organizational structure, the personnel and the close day-to-day contacts with the scientific world that are necessary to carry on the Vanguard program.

Both ONR and NRL are very much at home in the field of upper atmosphere research, in which they have carried on much of the pioneering work. The Office of Naval Research and its predecessor, the Office of Research and Inventions, have supported high altitude research since 1945. They realized the necessity for a stable platform from which scientific observations could be made, to gather information of value in upper-atmosphere physics, cosmic radiation and future high-altitude flight. Then, as now, the basic problem was to devise a vehicle capable of carrying a payload to sufficient altitude and remaining there long enough to make the desired observations.

Inherent limits of aircraft and rubber balloons used in high altitude studies precluded their use for carrying scientific instruments above 100,000 feet. The development of plastic balloons permitted some advances. (Rockets could go higher but could stay aloft only a very short time. The total flight time for a Viking, for example, never exceeded ten minutes.) Instruments can be taken to 100,000 feet for periods ranging from a few hours to a day or more with balloons. More than 1000 such flights have been made under ONR sponsorship, and newer techniques that employ balloon-rocket combinations have also been devised. Rockets fired from plastic Skyhook-type ballons at 70,-

000 feet have telemetered scientific information from altitudes of more than 250,000 feet.

The purpose of these ballon and balloon-rocket flights has been to obtain cosmic ray, meteorological and other geophysical data. The cosmic ray studies have been jointly supported by the Atomic Energy Commission and ONR. The Air Force has also adopted these techniques for high-altitude studies.

The Naval Research Laboratory has been using large, high altitude research rockets since 1946. It has fired twelve Viking rockets and many of the smaller Aerobee rockets. They are instrumented research vehicles that have yielded much scientific information. It is also a matter of interest that the highest photographs ever taken of the earth's surface were taken with a camera mounted in a Viking rocket, from 158 miles up.

The Naval Research Laboratory as a whole has been doing original work in the physical sciences since its founding in 1923. It is well known for its work in radio and radar, among other things, and for the research carried on in connection with the Viking-rocket project. Several of its thirteen research divisions are particularly well fitted by experience to contribute to the project. They include atmosphere and astrophysics, optics and nucleonics. These divisions are well-staffed with scientists who are recognized in their fields and who have been prolific contributors to the scientific literature of upper atmosphere research.

Normal Procedure

Project Vanguard is being approached as the Navy would approach any other large-scale scientific venture. Since both ONR and NRL have employed, as contractors or consultants, nearly all of the nation's leading scientific authorities in geophysics, astrophysics and rocket research, and have actively participated in these fields, there is no problem of establishing contacts with key people outside the Navy. For the NRL scientists, Vanguard essentially means accelerated work of the same type which they have been performing in the past.

Since the earth-satellite problem does differ in several respects from the bulk of NRL's work, however, it will be prosecuted outside the division structure of the Laboratory. A separate project office reporting directly to the Laboratory director of research has been established. It will be neither necessary nor desirable to set up a large, complex organization to coordinate the project. Much of the necessary coordination of the technical program is carried out on a day-to-day basis by scientists and engineers at the working level in the Navy, other services, and industry.

Working-Level Communication

The Army and the Air Force have designated Project-Vanguard liaison officers who have official responsibility for keeping their services abreast of the status of the project, and who keep ONR and NRL workers informed of their services' potential for participation in any given phase of the work. In addition, the day-to-day coordination at the working level goes on among the services. Army, Navy and Air Force military and civilian personnel involved in rocketry and other aspects of upper-atmosphere research have used formal machinery and informal contacts for threshing out mutual problems for many years. This same working-level communication network is being used to attack problems that must be solved before the satellite can be launched.

The primary difference between Vanguard and the previous upper-atmosphere research projects is introduced by the time element. The Vanguard satellite will be launched during International Geophysical Year, which ends in December 1958. It is not possible to proceed with separate component development, building up the rocket and satellite design on the basis of continuing developments in each field, and making modifications as component advances permit. The project director and the technical director have had to decide at the outset what the total design is going to be, then go ahead and build it. They will try to develop a complete definition of the specifications before major work begins. Feeding into this are the results of about two dozen design studies now in progress. They represent an attempt to define the launching system.

This does not mean that actual work is being held up pending a complete set of specifications. In certain technical areas they do not have a choice. These are areas where components already developed must be used to the greatest extent possible, and in these areas certain hardware is now being built. The first-stage rocket motor is one example.

The Navy's approach to the management of Project Vanguard has been shaped by the project's mission. Their technical responsibilities can be discharged only with assistance from the Army, Air Force and American science and industry. They have already turned to industry for construction of the three-stage rocket vehicle that will carry the satellite to its orbit.

The Glenn L. Martin Company of Baltimore, Maryland, has been awarded the prime contract for construction of the rocket. This company built the Viking research-rockets for the Navy. The first-stage rocket will be of cylindrical monocoque construction, consisting of skin, frames and longitudinal members, using integral propellent tanks.

Martin has awarded a sub-contract for construction of the first-stage rocket motor to the General Electric Company of Schenectady, New York. This engine will be more efficient than the present Viking engine, and therefore more powerful. It will have a thrust of 27,000 pounds at sea level, and an operating time of about 140 seconds. The engine consists of a regeneratively-cooled thrust chamber, gimballed mounting, propellant valves, turbopump, and high-pressure lines. The propellants will be liquid oxygen and a mixture of ethyl alcohol, gasoline, and silicone oil, which will be forced into the thrust chamber by turbine-driven pumps. The turbine will be powered by the decomposition products of hydrogen peroxide. In this type of turbine liquid peroxide is converted in a steam generator into hot steam, which is directed against the turbine blades.

Finless Rocket

This first-stage rocket will be essentially similar to a Viking rocket, but improved in two principal ways. The first is the more efficient engine. The second basic improvement over the Viking phase of research rockets is the removal of fins, to produce a rocket that is completely stabilized by the thrust of the motor. This is possible through mounting the motor in a gimbal, which permits controlling the direction of the thrust in any direction by actual movement of the rocket motor. The Vanguard gimbal mounting will be designed to permit angular deflection of the motor-thrust vector by $\pm 5^0$ from the centre line of the vehicle. A gyroscope controls the direction of the motor. For years many rocket experts have felt that this was the direction in which the development of large rockets

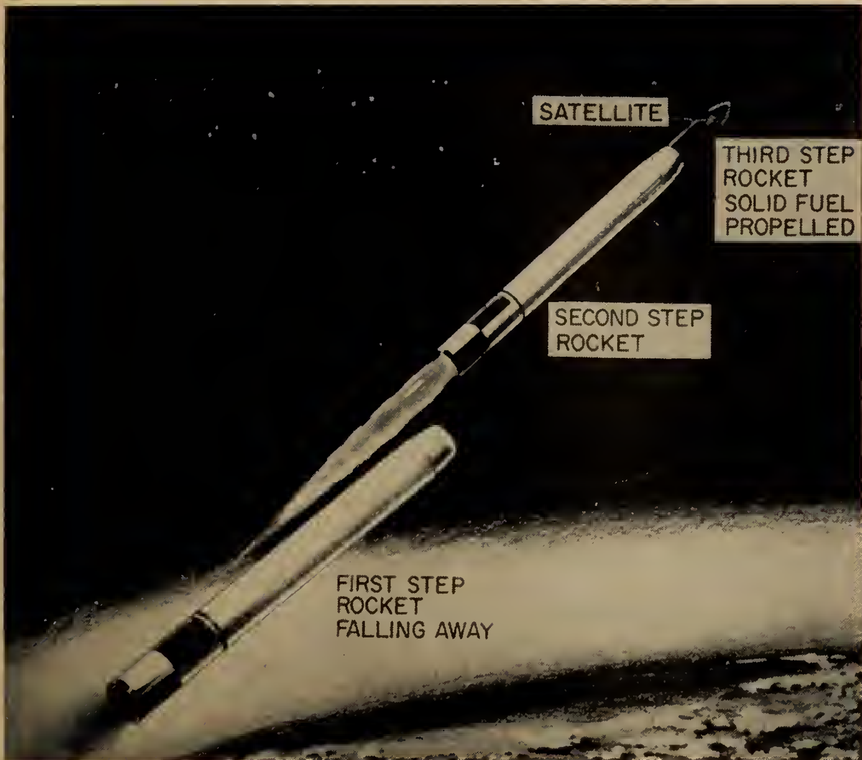

Fig. 1. An artist's conception of the Vanguard rocket at the end of the first stage.

should go. The gimbal structure was built into the first Viking, and into all the subsequent ones, although they also had fins to assist in stabilization.

The move to a finless rocket illustrates one way in which ten years of research with the Vikings is valuable background for the present project. It was known in 1946 that the use of fins for longitudinal rocket stabilization produced unwanted moments in roll and added weight to the rocket's structure. Furthermore, they give no assistance to the rocket's course at the moment of launching, when its forward speed is low and near the end of its powered flight when it is above the earth's atmosphere.

The finless rocket has been under study for about five years and a few small rockets have been fired experimentally. The Martin Company has performed much analysis that has proven the finless type theoretically workable and has sufficient confidence to go ahead with a large finless rocket for Vanguard.

The second-stage rocket will also be a finless cylindrical airframe of monocoque construction. A sub-contract for construction of the second stage has been awarded to Aerojet-General of Azusa, California. This power plant will also consist of a regeneratively cooled, thrust-chamber, and will be mounted in a gimbal. Nitric acid will be the oxidizer and unsymmetrical dimethyl-hydrazine the fuel. Flow of these propellants to the thrust chamber will be effected by helium pressure in the propellant tanks, rather than by a steam turbine, as in the first-stage motor.

The third stage of the Vanguard rocket will be powered by a solid-propellant motor, and will consist of the motor, a structure for attaching it to and for imparting spin to the air frame, and the satellite package and mounting structure. Several contractors are now bidding on the third-stage rocket motor.

One of the first programs begun when Vanguard was initiated was a set of studies to determine the optimum weight for each stage of the rocket. Preliminary estimates had to be made for weight, propulsion, and aerodynamic parameters. The optimum stage-weights are functions of these parameters and will vary as the parameters are changed. A change in the thrust of one of the engines, change in weight of the payload, or shape of the missile would change the way in which total weight should be distributed among the three stages. The stage weight itself must be considered as a variable, since it consists of fixed weights, such as the power plant, and variable weights, such as the propellant. The final determination of many design details for the rocket and the satellite will depend on the results of these optimization studies.

At the time this paper was written, the gross weight had not been decided upon, but it will probably be between 20,000 and 25,000 pounds.

In general appearance, the Vanguard rocket can be expected to have the outline of a thirty or fifty calibre bullet, but much more slender. (Figure 1 shows an artist's conception of Vanguard.)

When the Navy scientists come to the satellite vehicle itself, they enter an area necessarily characterized by compromise. Many conflicting requirements must somehow be reconciled. The satellite should be as large as possible, in order that it can be easily tracked by optical means. The bigger the object, the greater will be its visibility. On the other hand, weight considerations demand that the satellite be as small as possible. The scientists and engineers who design and build the Vanguard satellite will not be worrying in terms of pounds; they will be trying to shave ounces off the weight of the object which ultimately goes into the rocket. So a compromise must be reached in order to build a vehicle small enough to be successfully placed in the orbit yet large enough to be useful scientifically. It must be small enough to fit into the nose of the third-stage rocket. The most desirable configuration for the satellite itself now appears to be a sphere in the neighborhood of 20 inches in diameter, weighing about 21½ pounds. One obvious advantage to a spherical shape is that it would make it easier to convert the data on air drag into figures for the density of the upper atmosphere.

Other considerations in designing the satellite and determining its payload stem from the physical stresses to which it will be subjected. It must be transported to altitude in a rocket that has high acceleration and intense vibration. It must be strong enough to withstand the G-stress imposed upon it by each of three stages of rocket firing, but strength must be gained without use of excessive weight.

The problem of aerodynamic heating during ascent has been investigated. If the satellite package were to be the nose of the vehicle, it could become too hot, probably in excess of 1000 deg. F. The satellite will be protected in the early parts of the flight by a disposable nose cone. Since the heating would occur during the last part of the first-stage flight and the first part of the second-stage flight — i.e., after high speed has been reached and before the denser portion of the atmosphere is left behind — the conical nose could be jettisoned near or at the end of the second stage. The use of such a cone would provide a weight penalty for the second stage flight, and this is one of the many factors that is being considered in the weight studies being made in connection with arriving at design specifications for the Vanguard rockets.

The satellite must survive for a certain length of time after it has been placed in its orbit. While circling the earth it will face danger from two main sources, temperature extremes and meteoric dust. Solar radiation will tend to heat the satellite and its payload to very high temperatures, perhaps of the order of 300 to 400 deg. F. While in the earth's shadow its temperature may drop to well below 0 deg. F. The instruments required for a successful scientific experiment cannot stand wide temperature variations. The temperature range through which certain electronic components, such as transistors, will survive is roughly 40 deg. F. to 120 deg. F. — this presents a problem of satellite design to stabilize its inside temperature satisfactorily.

It is known that meteoric dust at the altitudes to be traversed by the satellite will eventually cause some deterioration. The rate and extent of the harm is not known; in fact, one of the objects of these experiments is to find out the density of meteoric dust in space. One possible method for measuring density of meteoric dust would be to have the satellite shell coated with a conductive material to form an electrical circuit. As dust wore the shell thinner, electrical resistance would change proportionately. This dust might score the surface of the satellite, and thus affect its ability to reflect light, with a consequent effect of the inside temperature and upon optical tracking. The assumptions that have been made here on the surface of the earth, in order to arrive at design specifications, might be changed when the satellite gets beyond the atmosphere and is acted upon by meteoric dust. It will not be known until the first one is fired.

It has not been decided what material is to be used for the satellite shell. Every material that held promise of being practicable has been studied and the choice has been narrowed down to a few. Some of the necessary considerations in choosing the material are rigidity, fabrication difficulties, weight, and reflectivity. Different fabrication techniques are also being explored.

The problems of the amount and kind of instrumentation in the first satellite must be solved and compromises agreed upon. Subject to weight and space restrictions, it must send aloft enough instruments to do some scientific work. The Navy's job is to put into an orbit an object capable of doing work of importance to the scientists and the fields they represent. The first satellite cannot completely satisfy the men in each field — it cannot do all the things they would like to see done. If they tried to build a satellite capable of yielding large amounts of diverse scientific data, they could not get it up into its orbit, and would wind up with nothing. The Vanguard technical program must result in a satellite that will be workable, yet scientifically useful. On the technical side, this means sacrifices in terms of accepting larger size and greater weight, with resultant engineering problems. On the scientific side, it means sacrifice in terms of the useful payload which the first satellite will carry. A reasonable fraction of its weight — perhaps one-fourth or one-third — will consist of scientific research instrumentation and its power supply. The remainder will be devoted to structure, a tracking transmitter, turn-on equipment and power supply.

More Than One Rocket

Several Vanguard rockets will be built in connection with the program because, to be reasonably certain of successfully putting a satellite into an orbit, there must be more than one rocket available.

Technically, the chances of failure of a single shot would affect the attitude of everyone connected with building the rocket and its cargo. They are working in a field that places great demands upon everyone's knowledge and calculations of probable performance. Much money is involved. If all of this money and all of this effort were risked on one shot, the project officers and technical workers would be always confronted with the desire to make one more calculation, one more adjustment or one more test flight before firing, in order to be more certain of success. Yet, to complete the job on time, every step of the program must be marked by bold, confident engineering in which the Navy must be prepared to take the consequences of falling short of perfection.

Attendant Programs

The determination of specifications for the launching rocket and the satellite, and their construction, represent the major phase of the technical program for Project Vanguard. The project director must be equally concerned, however, with all of the attendant programs required to make it succeed. A launching site has been tentatively selected. The Vanguard satellite will probably be fired into its orbit from Patrick Air Force Base, Cocoa, Florida. This base meets the operational requirements for large rocket launching and appears suitable to the scientific needs of the program. As soon as the project was established, Navy scientists and scientific and facilities officers began a series of continuing consultations with their Army and Air Force counterparts to determine the best launching site, the requirements for logistic support and how they will be met by the three services, and how problems of establishing and manning tracking stations will be handled.

Several tracking stations will be set up. Each station must have communications circuits linking one another and linking each to a central collecting and computing agency. Each station must have a complement of technicians, observers and operators, although a minimum of construction will be required. Perhaps one quonset type structure for an operations building, trailers tracking antennas, and communications antennas would constitute a typical tracking site.

Scientists are now working to determine the primary orbit of the satellite and the specific tracking methods. Both optical and radio tracking will be used. Time, speed and position information from many separate sightings at different tracking stations must be fed rapidly into a central electronic computor which will determine the orbit on the basis of this information. Data on the orbit must then be broadcast quickly throughout the world to enable scientists of the IGY to pick up the satellite with little difficulty.

A tracking system known as "Minitrack", which uses radio devices, is under development at the Naval Re-

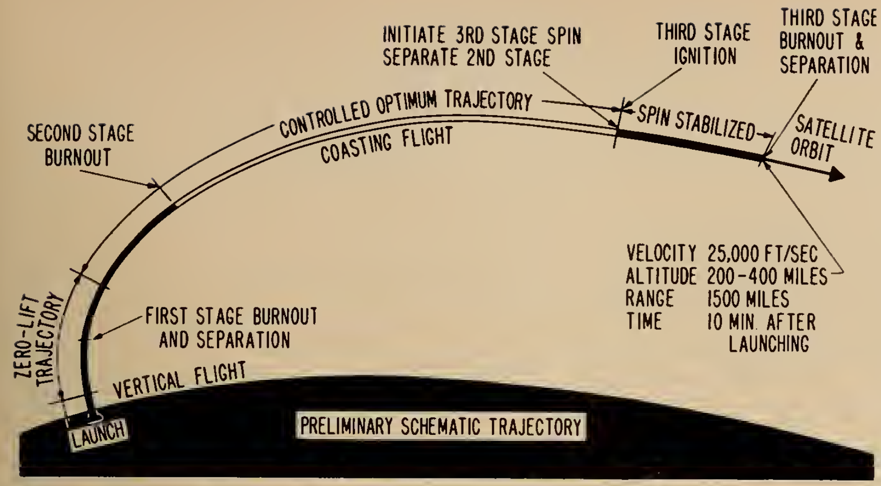

Fig. 2. Schematic diagram of the stages in the trajectory of the Vanguard satellite.

search Laboratory. This method uses a miniature radio transmitter in the satellite. It radiates a continuous signal to receiving equipment on the ground. Employment of this method would also aid optical tracking by furnishing estimated satellite position predictions but would require placing a line of observing stations — probably in the Western Hemisphere — to intercept the satellite on its orbit.

A major consideration in the telemetering system is to select the best —for the purpose — of the components now available, perhaps modify them for this specific task, and make as many improvements as possible before installation and testing. For example, the designers want to require as little power as possible from the transmitter in the satellite; therefore, they would want to improve the ground antenna system as much as they can. Improvements to the antenna would, of course, also permit better coverage of portions of the trajectory.

(Previous theoretical research is now proving of considerable assistance in working out optical tracking problems. For the past several years, scientists in the optics division of the Naval Research Laboratory have been conducting studies on the visibility of stars at night and during the day. In connection with this work, calculations were made on the conditions under which small earth satellites might be seen. For purposes of this study, the scientists assumed a satellite that was a 21-inch sphere travelling in an equatorial orbit at an altitude of from 200 to 1000 miles. As a result of these studies, " . . . it has been concluded that if one knows exactly where and when to look, a satellite when nearly directly overhead and at 200 miles altitude would first be visible through 7 x 50 binoculars when the sun is 2° below the horizon, and would be visible to the naked eye for solar depression angles greater than 9. To see such a satellite earily, however, and to be sure of observing it when its position is not known exactly, some telescopic magnification, such as 7 x 50 binoculars would almost be a necessity and observations of the satellite should not be attempted until the sun is 5 below the horizon.")

When the rocket and its satellite payload are ready to launch, and all of the launching facilities and tracking equipment and stations are in readiness, the Project Vanguard satellite will be fired up into its orbit. Only a general summary of the procedure is possible at this time, using figures that stem from preliminary design thinking. More precise data must await extensive detailed planning and engineering. (Figure 2.)

The first-stage rocket will start the entire assembly vertically on the first part of its flight, and when it is a few miles off the ground, its guidance system will begin to steer it gradually toward a near horizontal trajectory. When its fuel is exhausted, the first stage will drop off and fall into the sea. This will take place at 30 to 40 miles up, and the rocket will have reached a velocity between 3000 and 4000 miles per hour. The second rocket, deflected from the vertical, will continue the satellite upward. It will burn out at about 130 miles up, and the rocket then will be travelling at about 11,000 miles per hour. It will then coast into the satellite trajectory, with only very slight deceleration. At an altitude of about 300 miles, the second stage will separate, fall free and the third rocket motor will ignite and accelerate the satellite vehicle to a velocity of about 18,000 miles per hour. It may then separate from the satellite proper. (How to separate the satellite from the rest of the third stage presents something of a problem. In the Viking rocket firings, for example, it was decided to slow down the rocket's fall to lessen impact damage to the instruments. This was done by destroying the rocket's aerodynamic shape through use of an explosive charge that blew the nose free of the rest of the rocket.) The satellite will then be headed almost horizontally into its orbit, at orbital speed. A portion of the total velocity will be gained by launching the rocket toward the east, to take advantage of the earth's rotation. Thus, before the rocket is even launched, it will have a substantial horizontal velocity due to the rotation of the earth.

The satellite will start into its orbit with a spin imparted prior to ignition of the third stage rocket. However, eddy currents generated in the metallic skin of the satellite by the earth's magnetic field will soon reduce the spin to the vanishing point.

The satellite's orbit will be elliptical, rather than circular. Perigee, the point of nearest approach, will be about 200 miles from the earth, and apogee, the most distant point in the orbit, will be about 800 miles out.

The problem of guidance, to ensure that the satellite is projected almost horizontally into its orbit, is especially difficult. If the angle of entry is either too high or too low, perigee will be too close to the earth, and the satellite will dip into the denser portons of the atmosphere and disintegrate before it has made enough revolutions to complete its mission. It has been determined that on the basis of theoretical calculations, the angle of projection should not deviate by more than a few degrees from the horizontal for a launching altitude of 300 miles. If it misses by more than this, the perigee altitude, will be roughly half of the launching height, which would cause the satellite to dip well into the denser parts of the atmosphere and cut short its life. The guidance system must therefore be designed to ensure an error of no more than a few degrees in the angle of projection into the orbit.

The consequences of missing the planned orbit are not so serious in terms of the satellite's lifetime, but would pose problems of tracking. The satellite will transit different areas of the earth on each revolution. If a revolution is completed in 90 minutes, as is now contemplated, the earth will have completed roughly one-sixteenth of its daily rotation during this time, so that the satellite will appear at a different longitude for the same latitude on its next trip.

Although the portion of the atmosphere through which the orbit will pass is extremely thin (just how thin is one of the facts that the satellite may establish) the cumulative effect of the drag of this thin air will be sufficient to bring the satellite gradualy closer to the earth. As the satellite enters the denser atmosphere, it is expected to disintegrate harmlessly in the same manner as a meteorite, because of intense heat and probable mechanical collapse. The lifetime of the satellite is being estimated on the basis of a number of assumptions concerning the composition and density of the upper atmosphere. It may be several days or several weeks or even months, depending upon what is up there.

Water, Steam, and Refrigeration for a Modern Brewery

R. E. J. Layton, M.E.I.C. *(Continued from page 1512)*

gas is much heavier than air, it rests on the beer surface and can easily be removed without the complicated hood systems normal for exhaust applications. A secondary exhaust system includes grilles placed at low levels for additional protection against gas concentration. The temperatures in the cellars and process areas are controlled by room thermostats, operating the fans and liquid line solenoid valves. The suction temperatures of the different coils are set between + 30 and + 14 deg. F. and are selected with consideration to latent and sensible heat ratios and desired room humidity conditions. Changing the setting of the modulating back-pressure valves in the suction lines will give an adjustment of humidity conditions if necessary.

The units are defrosted automatically by individual timers with water at 60 deg. F. A separate circulation system is also provided for heating and reheat purposes. The ventilation air for the process cellars is filtered and cooled or heated in a separate fresh air unit with sprayed cooling coil, working at a suction temperature just above the point where frost formation begins.

The temperatures in the conditioned rooms, together with the brine and chilled water temperatures, can readily be checked by the operating engineer from the 16 point temperature recorder-indicator provided in the mechanical services building.

Other Brewery Services

To complete this review of the design of mechanical services in the brewery, a brief description will be given of those systems not yet considered.

Waste products from the brewhouse, the yeast rooms and fermenting cellars and from the beer filters and bottling shop all impose special conditions on the brewery drains. Two separate underground systems are provided; one for process and a second for storm and sanitary requirements. These are combined just before being run into the municipal sewer — an arrangement which will permit processing of wastes if such an operation becomes justifiable. To improve operation, the water, which has been used for condensing in the refrigeration machines, is collected and pumped to points in the brewhouse and the "carbonating" room. Here it is used for flushing out the drains when waste grains and process materials are being disposed of.

To produce the air used as counter pressure when the beer tanks are being unloaded and also to meet the other compressed air requirements of the brewery, two oil-free type reciprocating air compressors are provided in the mechanical services building. To reduce the "sun effect" and thereby the temperatures or the cooling loads of the space covered, roof flooding systems are provided on both divisions 4 and 5. These divisions of the brewery contain the warehouse, bottling shop and office areas. Not discussed, but also part of the design, are the ventilation systems which are applied as required throughout the building.

In this paper, an attempt has been made, not only to describe an installation, but also a basis for design. It is evident that modern breweries such as the one considered here provide many interesting fields for mechanical design.

The valuable assistance of Mr. Harald Tamm, a member of our staff who contributed largely both to the design and to the preparation of this paper, is gratefully acknowledged.

Hamilton River Survey — Labrador *(Cont. from p. 1530)*

and in particular the gas-driven generators for the radios, operated satisfactorily until the second summer, when it became clear that complete replacement would be more economical than on-the-spot maintenance.

Two first-aid men were in the field continuously through both summers. Accidents were relatively minor, most of these being axe cuts.

Conclusion

That conclusive results of the order indicated were achieved in the time and under the conditions prevailing in Labrador is a glowing tribute to the enthusiasm, skill and team spirit of all personnel on the one hand, and on the other to the use of the most modern appliances and techniques. Photogrammetry and seismic sounding played a major part, made possible only by aircraft in the versatile fixed and rotating wing forms flown by Canada's well-known "bush pilots". Aircraft alone could have provided the necessary transportation for all purposes over the final hundred miles into the work area. However, the ultimate objective, real knowledge of the ground surface and composition, could have been attained only by men on foot who, individually, covered hundreds of miles of Labrador wastes in this manner.

While the actual field survey and general services were performed by many different concerns, the general direction and co-ordination were provided throughout by the Corporation to which the authors wish to express warm thanks for permission to present this paper.

DISCUSSION

of Technical Papers

WATER, STEAM, AND REFRIGERATION FOR A MODERN BREWERY

R. E. J. Layton, M.E.I.C.

The Engineering Journal, 1956, November, p. 1504

R. E. Crossey, M.E.I.C.[1]

Mr. Layton has presented an excellent treatise on the factors involved in the design of the new Labatt's Brewery. The subject is extremely broad and therefore he had to omit some of the more interesting design problems which were encountered.

In the design of the refrigerant piping for the ammonia condensing system, the designer is given the opportunity of effecting large savings in pipe and installation cost. He is no longer bound to conservative pipe sizing charts by the necessity of minimizing the production of flash gas. The liquid lines for this system may be designed by selecting for each branch a pipe size which will give a pressure drop equal to the differential in the pump discharge pressure and the evaporating pressure. The lines with the lowest evaporating temperature and pressure can therefore be sized for a greater pressure drop than the lines with the higher evaporating pressures. In all cases, these pipe sizes are considerably smaller than those obtained in the design of the conventional direct compression system. In an installation the size of Labatt's, this represents a considerable saving.

In a brewery, the relative humidity is an important factor along with the dry bulb temperature. In the hop storage area, the vapour pressures in the air and the hops must be close to equilibrium to prevent a moisture exchange which would harm the quality of the hops. This condition is obtained at 34 deg. F. at approximately 65 per cent relative humidity. In other areas a low relative humidity is desirable to reduce the maintenance on steel tanks and the production of stray yeast and moulds.

The relative humidity is controlled most readily by a brine chilling system which permits the use of a modulating valve on the brine line. When the ammonia condensing system is used, it is not as convenient to alter the dewpoint to give the desired relative humidity. To accomplish this, it is necessary to use a relatively expensive temperature-compensated back-pressure regulator. However, in a brewery the change in latent loads is very gradual and the required relative humidity can be achieved by a careful selection of coil surface area and surface temperature, combined with manual adjustment to compensate for seasonal change in latent loads. As the brine chilling system is more expensive than the ammonia condensing system, the advantages obtained in ease of control do not warrant its use in the design of this brewery.

[1]Jas. P. Keith & Associates, Consulting Engineers, Montreal.

G. N. Martin, M.E.I.C.[2]

The author treated his subject in a thorough manner, acquainting his readers with his clients' design requirements. This writer had the opportunity to visit the plant in operation and see the application of the principles set in this article. He was also engaged in the supply of the steam power plant equipment.

Before the selection of an economizer was made as heat recovery equipment, the use of an air preheater was investigated. For the conditions obtaining at this plant the choice of the former proved more economical and satisfactory.

The boiler is fired with bunker "C" oil and provision is made for the possible conversion to solid fuel firing at a later date, if required. Continuity of service is ensured by the use of a "package" boiler installed on a temporary basis and to be used until the plant expansion calls for the addition of a twin water tube steam generator.

Advantage was taken of using medium and low pressure steam circuits thereby establishing an interesting heat balance without having to complicate the system of auxiliaries.

HAMILTON RIVER SURVEY, LABRADOR

G. V. Eckenfelder, W. P. Harland, and E. N. Webb, MM.E.I.C.

The Engineering Journal, 1956, November, p. 1521

Howard J. McLean, M.E.I.C.[3]

The paper on the Hamilton River Survey gives an excellent outline of the planning and the field methods used in appraising one of the world's great power sites (the Grand Falls of the Hamilton River) which includes the creation of storage and regulation of the river flow.

Obviously, a great deal more time, effort and money would have been spent in acquiring the necessary essential field information for a project of this magnitude if aerial photographic surveying and seismic methods had not been available.

The field work by ground forces was confined to establishing the elevations of lakes, doing the control surveys, check traverses and levelling, and the minimum test pitting and drilling which was necessary to supplement and aid the accuracy of the aerial photography for photogrammetric mapping and seis-

[3]Construction superintendent, Montreal Engineering Co. Ltd., Montreal.

mic work. Large mapped areas were required, but topography was needed only at selected portions including the sites for dams and diversion structures.

The preliminary general appraisal of the surface topography was done in mid winter to determine the lake elevations and the locations of the ordinary and the flood channels. This work reduced the chaos of wilderness, dotted with lakes, to definite drainage patterns and permitted the general planning of the work to be done and the selection of the areas to be mapped by aerial photographic surveys. The necessary ground control for photogrammetric mapping was aided by the abundance of lakes for vertical control, and traverses were run, where possible, along ridges and connecting prominent points for the horizontal control.

The results obtained from the aerial photographic mapping confirmed that this was the best method for obtaining the necessary information for such a large area.

As described by Mr. Harland, helicopters were used to advantage in the work and one of the interesting points mentioned was signalling from the helicopter to indicate the direction of a traverse. A helicopter is a most economical time saver to trained reconnaissance engineers in difficult areas when working on a carefully planned programme.

Those of us who have taken soundings in rivers, a laborious painstaking job, will appreciate the description of the echo equipment used, which does accurate work in a fraction of the time required by the lead and line method.

As stated in the paper, seismic soundings, when preceded by a geological surface examination of the area and supported by sufficient test pits and borings, can be used to yield a large amount of most useful information regarding the depth and type of overburden overlying the bed rock, the rock profile at each dam site, and the extent of deposits of construction materials. This information combined with the sub-surface investigations by geologists and soil specialists (based upon test pit and boring) have proved the locations and quantities of construction materials.

This latter, the locating and testing of materials available for construction of earth-fill dams and dykes, and finding good supplies of concrete aggregates, is most important. Use of suitable materials convenient to the selected locations of structures to be built, will save millions of dollars.

In remote areas, the use of suitable local construction materials, when available, usually favours earth fill construction for dams and dykes for their lower capital cost, low maintenance, and lack of troubles from frost action in northern latitudes. The earth fill structures are practically indestructible if well designed, and properly built and maintained. The more costly concrete (with long haul of cement) must of course be used for diversions, sluice dams and control works, powerhouse foundations and substructures, etc., but in the interest of economy, can be kept to the minimum amount necessary.

The access road from Mile 286 on the Quebec North Shore & Labrador Railway to the crossing of the Hamilton River near Grand Falls (mentioned in the paper) will become the first step towards construction of the great power development. I understand that construction of this road will be started in early June of this year.

The authors of the paper on the Hamilton River survey are to be commended for their good description of the methods used in obtaining the field information. These methods would apply equally well for investigations of other large projects in remote areas where the essential information is required quickly and economically.

The Authors

The comments by Mr. McLean are appreciated and do not appear to call for any reply.

AIR POLLUTION CONTROL PROBLEMS

E. A. Allcut, M.E.I.C.

The Engineering Journal, 1956, April, p. 387

Walter C. Wagner[1]

Mr. Allcut has left but little to be added, and such additions would be quite secondary in importance.

I would recommend that his name be added to that of John B. R. Neilson, director of smoke abatement, of Toronto, as a member of Air Pollution Control Association, the Canadian-U.S. organization that has served both nations so effectively over the years. I agree with Mr. Allcut in his thought that definitions for example, adopted in different areas are not comparable. As he states, "This is a very undesirable situation, which can only be rectified by agreement on an international basis." While this activity must necessarily be on a less tangible basis than that relating to the international steam tables, nevertheless something in the way of active collaboration must be faced, to the mutual advantage of all nations substantially concerned.

Convinced that an international interchange of research and developments should be initiated the board of directors of the Air Pollution Control Association recently approved the proposal to form a committee of the Association to sponsor the creation of an "International Commission on Air Pollution".

[1]Consulting Engineer, Chamber of Commerce of Greater Philadelphia, Philadelphia, Pa.

Letters were then sent to representatives of the foreign nations understood to be substantially concerned. A part of the letter reads:

"We are now convinced that all nations which are increasingly concerned with this subject can individually and collectively make greater technical progress if their air pollution control organization are members of an international organization. In this way, each of the important technical subjects constantly arising which are of common interest to many countries could be given more direct and collective attention by special commission committees of representatives of those countries. Greater progress, through a wider distribution of related information, such as the results of pure and applied research and of applications, would in this way be made continuingly available to all members of the International Commission."

The replies received to date uniformly indicate great interest and a willingness to participate actively in the program.

As a result, a "task force", consisting of past presidents of the A.P.-C.A., including past president Louis James Cudbird of Toronto, is now developing an outline of the Commission organization and its scope of activities. The "task force" includes members who are on other technical international commissions and who have some knowledge of related activities of many of the European and other nations.

The outline, when completed, will be submitted for review and comment to all such organizations, including of course those organizations concerned in our two countries.

Referring again to Mr. Allcut's extremely valuable and timely technical and administrative contribution, I join with many others in the hope that a way will be found to make it generally available not only to regulatory authorities, but also to industrial and commercial interests substantially concerned.

The Author

I am glad to know that Mr. Wagner and his associates are taking some steps toward the co-ordination of work in the field of air pollution control. This matter is being studied by the committee recently appointed by the Canadian Standards Association and I hope that some liaison will be possible with our colleagues in the U.S.A. During my recent visit to England I also discussed the matter with some of the British authorities in this field and they expressed interest in the project. As a result of these activities I hope that some international body will be set up. The principal question at the moment is "who is to bell the cat" — and how, and when?

INDUSTRIAL POWER DISTRIBUTION

J. R. Auld, M.E.I.C.

The Engineering Journal, 1956, April, p. 405

R. C. Short,[1] JR. E.I.C.

It is with a great deal of pleasure that I compliment Mr.. Auld on a splendid paper. As he pointed out, the design of industrial power distribution systems has evolved into a most important engineering project. Flexibility to facilitate future load growth is one of the most salient factors to be considered in this design. Capacity to meet future needs must, of course, be balanced against initial capital investment, and transformers with provision for forced air cooling can be applied very nicely to these circumstances.

Provision for forced air cooling to be added later involves the following transformer design features:—

(1) The transformer is designed from the beginning on the basis of the forced air cooled rating which is usually 33⅓ per cent greater than the self-cooled rating.

(2) All conductors, including coils, cable connections and bushings, are specified with adequate capacity for the forced air cooled rating.

(3) A well is provided in the cover of the transformer to receive the controller element for the fans.

(4) All conduit for control wiring is provided, and provision is made for mounting the control cabinet.

This provision only, for future addition of forced air cooling, costs approximately 2½ per cent of the price of the straight self-cooled transformers.

When the load climbs to the point where the forced air cooled capacity is required, the control element, wiring and fans are purchased and installed. The fans can be operated from either top oil temperature or winding temperature, and will turn on and off automatically, depending on the loading of the transformer.

I note with interest that in this case, provision has been made for four times the present load by purchasing transformers larger than necessary and also making provision for addition of fans. The fans we will supply will be propeller type, blowing the air horizontally over the radiators and individual thermal overload protection will be provided. In the event of a failure of one fan the others will carry practically all of the load and the loss of one fan is not serious.

In this case, the fans will be controlled from winding temperature and will only run when needed.

The winding temperature equipment is responsive to a current in the high voltage winding, but the calibration is set on the hottest temperature in any of the three windings at full load fan cooled conditions. This means that proper division of load between the two windings must be watched, but actually this is not too critical, unless the transformer is running at maximum load.

When the transformer is underloaded, division of load between the two windings is not critical because the oil temperature is less than normal and, consequently, the overload capabilities of either of the secondary windings is increased.

[1]Packard Electric Co. Ltd., Tramways Building, Montreal.

N. E. Hudak[2]

As Mr. Auld points out electric power is the life blood of industry. Without electrical power, industry could never have progressed in such gigantic strides. It is therefore essential in our present age of electrification, that considerable thought and effort should be made by every industrial concern to weigh the merits of its power distribution system. Too often, much too often, the power system in a plant is taken for granted. It is not until failure occurs and plant shut-down takes place that the importance of a power distribution system is realized.

Now is a good time to study more closely the basic industrial power distribution systems. Mr. Auld has reviewed six of the approximately eleven basic industrial power systems. He has used simplified, single line diagrams to illustrate each of the basic systems and has reviewed each system particularly well from the maintenance and economic standpoint.

For those who are interested in pursuing further any of the basic systems discussed, or other basic systems, particularly from the standpoint of flexibility, continuity of service, future expansion, interrupting capacity, protection and control, much can be found in the AIEE Committee Report entitled "Electrical Power Distribution for Industrial Plants", AIEE papers, reference books and many other recent papers and reports.

After discussing each of the six basic systems, Mr. Auld proceeded to show with illustrations, the electrical distribution system of the Maitland nylon works of the DuPont Company of Canada Limited. He has discussed factors such as cost, choice of voltage, type of system, future load, location and size of substations; factors which arise each time a plant distribution system is being planned. He has appropriately concluded by outlining a formula for the selection of a satisfactory power distribution system.

The Author

I appreciate the interest shown by Messrs. Short and Hudak in the subject, and I am in agreement with the ideas they have expressed.

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

A BRIEF ON THE NATIONAL BUILDING CODE OF CANADA

Presented to the Royal Commission on Canada's Economic Prospects

The National Building Code of Canada is essentially a set of minimum regulations respecting the safety of buildings with reference to public health, fire protection, and structural sufficiency. The code is not intended for use with specialized civil engineering structures. Its essential purpose is the promotion of public safety, through the use of desirable building standards throughout Canada.

It is an advisory document only, having no local standing until and unless it is adopted for specific use by a provincial government or municipal administration. It may seem strange, at first sight, to find an agency of the Federal Government issuing a document which is essentially a local municipal ordinance.

The fact that the National Building Code is actually printed in the form of a by-law is evidence of its unusual character. Under the terms of the British North America Act regulation of such essentially local matters as building operations was made the responsibility of the provincial governments. They have, in turn, delegated this responsibility for urban areas to local municipal governments, through their Municipal Acts. Building regulations throughout Canda are therefore essentially local municipal ordinances, commonly called "building by-laws".

Municipal building regulations are, however, directly responsible for the control of the design and erection of all buildings in their respective municipal areas. Local building by-laws are therefore municipal ordinances of some importance. In almost all cases they have been developed locally through the years and follow no general pattern. The result has been a collection of local ordinances which vary greatly throughout the land, not only in arrangement, but also in technical content.

It was in the mid-thirties that the seriousness of this problem, and its full complexity, appears first to have been recognized. The introduction of the first National Housing Act led the Administrator of the Act, to consult with municipalities as to the local regulations then available for the control of house building under the terms of this Act. It was then that the difficulties of the municipalities in this connection first became generally evident. No municipality had the necessary financial resources for work on the revision of its building by-law, or for the preparation of a building by-law where none existed.

No Solution at Municipal Level

It was clear that no solution could be expected at the municipal level. Appeal was made to the then president of the National Research Council, General A. G. L. McNaughton. Jointly with the Department of Finance (then administering the National Housing Act), the National Research Council thereupon apppointed a representative committee to investigate the problem; a secretariat was formed; building codes of other countries were examined; and it was finally decided to prepare a National Building Code for Canada.

This was envisaged as an advisory document which would be prepared by representative national committees. If and when it was legally adopted by any municipality for this purpose it could be used as its own building regulation. Work was commenced in 1937. In 1941 the first National Building Code of Canada was published by the National Research Council — a volume of over 400 pages — and sold for one dollar a copy to all who wished to have it.

The years of war naturally interfered greatly with the use and general recognition of this pioneer document. It is now in use, either directly as the local building regulation, or indirectly as a reference document for use in association with the local by-law, in over two hundred municipalities. Its acceptance by provincial and municipal authorities throughout Canada showed that the idea of such a national service was locally acceptable.

Soon after 1945, it became obvious to Council authorities that the National Building Code should be reviewed, if it was to fulfil its intended national purpose. At about the same time, Central Mortgage and Housing Corporation was established by the Federal Government, being charged with the administration of the revised National Housing Act. The original intention to associate work on the code with research in the building field was revived. For this, and other associated reasons, the Council established in 1947 its Division of Building Research. By agreement, the Council undertook this responsibility, setting up an Associate Committee on the National Building Code.

Terms of Reference

The terms of reference of the Committee are to promote uniformity of building regulations throughout Canada and to maintain the National Building Code of Canada as an up-to-date and progressive document. After full deliberation, the Committee decided to achieve its first objective by concentrating on the second. A year's work resulted in a completely new scheme of arrangement which appeared to meet all objections, ever though it was regarded by many experts in the field as unpractical. It was adopted; it has proved completely successful in use. Under the guidance of the Associate Committee, the 1941 Code was then completely revised in accordance with the new arrangement.

The Code is now published in the form of a by-law, ready for adoption by any municipality merely by the insertion of the appropriate name, provided the contents are found to be locally acceptable. Its unique feature, derived from the new arrangement, is that the entire document is arranged in a number of completely independent parts. In consequence, it is really only necessary to change this part to permit of the adoption of the Code anywhere in Canada, all technical provisions being independent of purely local requirements. Local climate will come immediately to mind as an inevitable variable. This is covered in a special climate part of the Code so that peculiar local climatic features may be obtained for any municipality for appropriate use with the design parts of the Code.

Canada has therefore today a national advisory building code, so flexible in arrangement that it can be kept in close accord with all major advances in building practice, its servicing based upon more than a decade of experience with municipal use of the 1941 Code. With every local adoption of the Code one more step is taken in the elimination of senseless, and usually minor, variations in building practice between municipalities. This can have an immediate, even though minor, effect upon building costs and especially upon the costs of housing.

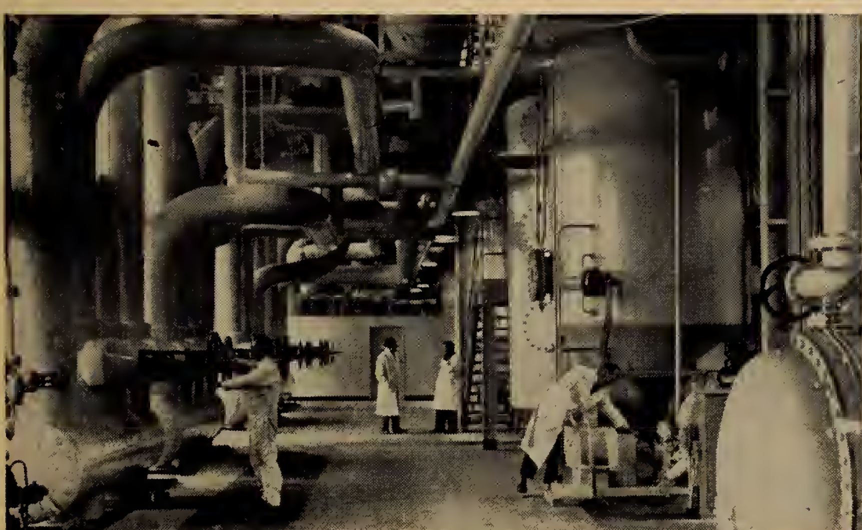
During the last quarter of a century house building has changed from being the erection of a relatively simple type of shelter with a minimum of special features to the construction of buildings which are technically complex. This technological advance is now in full swing. The next quarter of a century may be expected to see a continuation of this change but eventually some levelling off as house design approaches a state of technological saturation. It is therefore apparent that the best and most flexible controls possible should be available for use in connection with all such modern building in Canada. It is the firm belief of the Associate Committee on the National Building Code that the widespread use throughout this country of the National Building Code can achieve these ends.

FIRST LARGE-SCALE NUCLEAR POWER PLANT OPENED

On October 17 Her Majesty Queen Elizabeth II officially opened the U.K. Electricity Authority's nuclear power plant at Calder Hall, Cumberland, England. This is the first nuclear plant in the world to supply significant amounts of economically-produced electrical power into a country's commercial power distribution system, though nuclear-electrical energy has previously been generated and used on a small scale in Britain, the United States, and the U.S.S.R. A second station, Calder Hall "B" is well on the way to completion and is due to go into service in 1958.

For each generating station there are two reactor buildings, based on concrete rafts, 11 feet deep, each containing some 5600 cu. yd. of concrete. Reinforced concrete walls, 7 feet thick, rise 90 feet above the rafts to form an octagonal biological shield. The walls of the shield were built to plus or minus 1/10 in. on vertical and plan true dimensions; and a concrete density of 162 lb./sq. ft. was obtained.

Each reactor is contained in a pressure vessel, and 500 slabs of 6-in. steel plate, each weighing three tons, are placed between the vessel and the concrete shield. Cylindrical steel heat exchangers, 17 ft. diameter and 80 ft. high, are sited at



General view of the Calder Hall nuclear power plant shows two 300 ft. high cooling towers, one of the two reactor buildings, centre, and administrative and turbine buildings (behind the transmission tower). The view of the basement of the turbine room (left) shows part of the steam feed system between the reactors and heat exchangers.

corners of the reactor buildings.

A more conventional group of buildings houses the four 23,000 kw. turbo-alternators, the control block, administration, and workshops.

Three of the main contractors involved, the Taylor Woodrow Group, English Electric, and Babcock and Wilcox, have formed a group prepared to build similar nuclear power stations anywhere in the world.

CAN MAN'S POWER DEMANDS BE MET?

Times Review of Industry, Aug. 1956

In this article two important conferences are discussed. The Tidal Power Conference, held in Paris and St. Malo, was largely devoted to schemes projected for the Brittany coast and the pioneer work of French engineers on the design of water turbines and the use of temperature differences in tropical seas.

Members of the conference on tidal power visited a model established at St. Malo, where tidal cycles are reproduced, which is fully described in the article. The great economic deficiency of a tidal power scheme is that it does not provide "firm" power. It only saves fuel and cannot help peak problems. This apparently insuperable difficulty has been largely overcome by the "bulb turbine generator", the action of which is discussed. Possibilities of extracting power from wave action and from temperature differences between top and bottom of tropical oceans, were also considered.

The fifth World Power Conference, held in Vienna, surveyed progress throughout the world, a valuable feature being that, for the first time, Russian engineers gave extensive data on the existing and potential hydro resources of the U.S.S.R.

The aim of this conference was to explore and open up powers which 'must not be misused for destruction but harnessed only for universal joint progress'. Atomic power, though discussed for a full day, did not dominate the conference. Papers presented clearly indicated that world demand for power continued unabated. There was a tendency, particularly in Europe, to try to coordinate the energy needs of neighbouring countries. Long distance transmission of extra-high voltage a.c. power was discussed. An urgent need was revealed for more uniform statistical data concerning energy reserves of all kinds.

Energy used in the form of electricity, it was stated, only accounted for about 9 per cent of the world's total usage of energy in any form. Demand for electricity was growing so rapidly that by 1957 perhaps as much as half of the intake of energy would be distributed electrically.

Russian engineers reported that the U.S.S.R.'s total theoretical gross water-power potential was 3680 billion kwh. annually. There are 50 rivers with a potential power production of more than 10 billion kwh. About half the potential was theoretically exploitable. In 1950, 1850 stations with total generation of 586 billion kwh. utilized sections of rivers with total theoretical potential of about 1000 billion kwh. More than 2,250,000 kw. of water power had been installed during the last five years.

Other sources of energy, such as the fuel cell, wind power, geothermal power, power from sea temperature differences and solar energy were also dealt with, as well as the heat pump. Though nuclear power was not regarded as the sole answer to energy problems of the future, the session on the subject was one of the most important of the whole conference.

It was clear that no country other than the U.S.S.R., the U.S.A., and Britain could hope to find in atomic power a solution to its power problems within the next two or three decades; nevertheless, uranium deposits already known leave no doubt that mankind will be able to satisfy its needs for energy for a practically unlimited time.

HOUSE WILL STORE HEAT FROM SUN

United Kingdom Information Service, *Trade Topics*, July 1956

A solar-heated house has been invented by a Bristol, England, man. The designer claims that cooking and heating will be at about one-tenth of the normal electricity cost.

The equipment will be capable of storing heat for at least 18 months.

Ventilation is provided by moving the windows, which are fixed on rollers in specially built frames. Interior walls are twice as thick as normal inside walls and ceilings are made of concrete. Heavy steel girders are placed around the base of each interior wall.

Production models of the new house will cost approximately the same as conventional dwellings.

REVIEW OF I.C.A.O. POLICY AND PROGRAM

Presented at the I.C.A.O. Assembly, Venezuela, July 1956

I.C.A.O. policy with regard to the planning of air navigation facilities and services includes objectives of airways, airports, and navigation facilities for international civil aviation and the promotion of safety of flight.

In this review (Agenda item 20) policy is found to be adequate in scope. The I.C.A.O. program is briefly described and its adequacy discussed in relation to fulfilling existing requirements, concluding that lack of funds is the greatest remaining barrier to satisfactory implementation. Possible methods of providing for new finance and technical assistance are suggested.

Conclusions drawn in part IV of the paper include the following.

(1) Provision of air navigation facilities and services in many areas falls short of requirements. Consequences of shortcomings in implementation will grow more serious as new flying equipment comes in service and density of traffic increases. It is imperative that new financial resources be made available from the States themselves or from users of air transport through the airlines.

(2) Importance of having earliest possible information on new equipment and projected operations to permit long-range advance planning is evident.

(3) States should study the problem in broadest terms and consider alternative means for solving the financial problem.

(4) Provision of finance will not of itself solve the manning problem but will simplify it. With expectation that money for real estate and equipment will be forthcoming, intensified attention to training personnel and development of technical assistance under I.C.A.O. control would be indicated.

Appendix B reviews statistical indications of future expansion of world air transport.

Appendix C reviews the trend of civil transport aircraft development over the next ten or twenty years.

Copies of Agenda item 20: A10-WP/13, EX/11 are obtainable from Public Information, International Civil Aviation Organization, International Aviation Building, Montreal, Que.

PENSIONS FOR PROFESSIONAL ENGINEERS

Engineering, 1956, v. 182, n. 4714, July 13.

The Engineers' Guild is to launch a pension scheme for professional engineers in the autumn. The object is to provide cover for the professional man throughout his career. The scheme is to be open to all members of the Guild and to other members of the Institutions of Civil, of Mechanical, and of Electrical Engineers who are eligible to become members of the Guild. The Guild points out that it had been preparing a scheme of this sort for some time before the concessions on pensions for the self-employed were announced in the last Budget.

How far this scheme when published will offer attractions beyond those available under other group schemes remains to be seen. Two basic issues are apparent at this stage. If the terms offered are attractive and the scheme is well supported in consequence, as it will deserve to be, the Guild will have built a bridge in its own right between the professional institutions — an object it has had in mind for some time and which has not been easy so far to accomplish. Another point is this. If this move is successful it will draw the attention of engineers, especially those engaged in professional work, to the possibilities of using insurance arrangements and annuity devices as a means of perpetuating partnerships on terms attractive to the younger men who need security, and who often do not have capital to buy their way into an organization.

BRISTOL BRITANNIA AIRCRAFT IN CANADA

The Britannia turboprop airliner recently made an extensive tour of the North American continent, including stops at Montreal on its arrival and final departure. The aircraft has been ordered, in various versions, by several operators, including Canadian Pacific Airlines.

The Britannia types include the prototype series 100 and the series 300, with longer bodies and more powerful engines, both of which are flying. The series 310 is a long-range version, destined for the North Atlantic run; this can make a non-stop crossing in either direction at all times of the year. Other series include the 320, a 133-passenger medium range development of the 310; and a cargo/passenger version.

The 300 and 310 series will be powered by the Proteus 755 free-turbine engine, a development of the earlier 705; the 755 engine produces 4,120 e.h.p. and each of the four engines drives a de Havilland four-blade 16-ft. airscrew of hollow steel blade construction. Maximum take-off weight of the 310 Britannia is 175,000 lb.; the range in still air, with a 28,000 lb. payload, under standard conditions, is 4758 st. miles; and mean cruising speed is 391 m.p.h. The Royal Canadian Air Force has chosen a version of the Britannia, known as the CL28, for maritime reconnaissance work, and these aircraft are being built for the R.C.A.F. by Canadair Limited, in Montreal. As service involves extreme range patrol at very low altitude, the CL28 will be powered by compound piston engines, which are economical in fuel consumption at low altitude.

The Bristol Britannia turboprop airliner is scheduled for London—New York service in 1957. It will carry 132 passengers at 400 m.p.h. Range is some 6,000 miles.

CONTRACTS FOR KARIBA DAM

Italian Business, Sep. 5, 1956

Italian firms have been granted a $98,000,000 contract to dam the waters of the Zambesi river in the Kariba gorge. (The project was reported in the October issue of *The Engineering Journal*, p. 1376.)

The "Impresit" group of companies bid for the dam construction at $70,-778,400, beating the next lowest offer by over $4 million.

The second contract was granted to Societa Anonima Elettrificazione, of Milan, for electrical work including construction of lines and cables extending over 900 miles. The bid was $26,203,362.

The success of the Italian firms caused some controversy, including suggestions that government favours were involved — which was publicly denied. It is stated that technicians and other Italian workers will be paid at the same rates as the British bidders would pay their European labour; the total American bid was lower than the British, although American pay rates were much higher.

THE DOMESTIC HEAT PUMP

Engineering, 1956, Aug. 24.

The heat pump is not a new idea. Its principle was proposed by Lord Kelvin about 100 years ago. Recently considerable attention has been given to it in the U.S.A., Switzerland and Germany. Main advantage is low operating cost, since two to five heat units are given out for each heat unit of electricity.

A possibly more efficient use of electrical energy is by employing the heat pump cycle. The overall efficiency for electrical heating can be raised from 28 per cent to over 100 per cent and all advantages of electric heating maintained. The principles of a heat pump are similar to those of the refrigerator.

Before assessing the economy of using a heat pump, a theoretical analysis must first be made. Then consideration must be given to the possibilities of adopting the heat pump in the home for space and water heating. The latter presents the more difficult case.

Economic circumstances alone make the heat pump a "must" and no doubt the traditional way of heating (in Britain) is on its way out. Heat pumps will initially become the conventional means of water heating; later they will provide central heating and air conditioning. The Beaver Report on Air Pollution has indicated the need for ending smog. Furthermore at least one third of Britain's coal, 63 million tons a year, is used for domestic heating. This is clearly a justification for the industry to develop heat pumps.

This article is accompanied by numerous graphs, tables, diagrams and formulae, and explains how to determine the economy of using the pump, how to design the installation and how to adapt it for the home.

COSMIC RADIATION RESEARCH ON THE JUNGFRAUJOCH

H. Wäffler, Professor of Experimental Physics, University of Zurich

In a deep notch between the Jungfrau and the Monch, in the Bernese Oberland, there is a narrow ridge of rock some 330 ft. high and 200 yards wide at the edge of a glacier depression. The Sphinx, as it is called, rises to a height of 11,700 ft. and contains the highest railway station in Europe, a very comfortable hotel, and a research centre with the most modern equipment, in the heart of the mountain. For 25 years research workers differing widely in nationality and outlook, have worked here on problems of medicine, physiology, astronomy, physics, etc., forming a big international family which has come together for the sole purpose of adding to the common stock of human knowledge.

Of the various branches of physics studied at this centre, the most important is cosmic radiation—one of the most fascinating natural phenomena known to modern science. The earth's surface is continuously bombarded by a hail of electrically charged particles which far exceed in energy anything we can produce in our laboratories. The problem of the origin of this radiation and the nature of the particles composing it has been of greatest interest for science for years. Although its origin remains a mystery, scientists now know a great deal about the particles of which this radiation is composed. Experimental research conducted on the Jungfraujoch and at other elevated centres has enabled us to form a picture which may be described in broad outline as follows.

Each square centimetre of the topmost layer of the atmosphere receives particles from outer space at a rate of about 30 per minute. Some ninety per cent of them are protons. The proton and the electrically uncharged neutron form the material of which all atomic nuclei are composed. Of the other 10 per cent some nine tenths are the nuclei of helium atoms, the second lightest element, while heavy nuclei of lithium, boron and carbon account for the remaining tenth. The speed of these primary cosmic particles is enormous, being only a fraction of 0.1 per cent less than the velocity of light (300,000 km./sec.). The kinetic energy of the particles is correspondingly high. If we take as a measure of this energy, as is common practice in atomic physics, the difference of potential through which these charged particles would have to pass in order to be accelerated to such speed, we find that we must reckon with potentials of 10^{12} volts. While penetrating the atmosphere, these primary particles collide with the atomic nuclei of the air (nitrogen, oxygen). As a result of these high-energy collisions, the kinetic energy of the particles involved is materialized and new particles are formed known as mesons. All mesons—about ten different kinds are known today—are characterized by great instability. They decay spontaneously in less than two microseconds into other kinds of mesons, which in turn decay until finally we have left high-energy electrons and photons as the last experimentally demonstrable products of decay.

On their journey through the atmosphere the various kinds of particles successively radiated achieve equilibrium. In the uppermost layers of the atmosphere the primary particles and the mesons produced as the result of nuclear collisions predominate, together with secondary protons and neutrons which are also released by the nuclear collisions. At sea-level, on the other hand, nearly all these particles have completely "died out". It is the process involved in the nuclear collision that is of particular importance to modern research. It throws light on the nature of the interactions between the "bricks" forming the atomic nucleus, i.e. the protons and neutrons. The still unknown laws of this interaction determine the structure of the nuclei, and thus the structure of the whole material world. Nature's laboratory provides us, so to speak, with experimental material all ready for use. All we have to do is to avail ourselves of it in the proper place, namely, at the highest possible attitude.

The Wilson Cloud Chamber

The apparatus giving us the most useful information in this research is the Wilson cloud chamber. By rapidly expanding a super-saturated vapour mixture in the cloud chamber it is possible to render visible the tracks of the particles causing the collisions, making them appear like the condensation trails sometimes left by the exhaust gases of high-flying aircraft. By placing the cloud chamber in a strong magnetic field, the nature of the charge and the momentum of the particles passing through it can be determined. By placing plates of suitable material in the chamber, the principles governing the nuclear collisions in that material can be studied together with the properties of the mesons thereby produced.

An efficient cloud chamber with a strong magnetic field weighs several tons. It occupies a lot of space and consumes several kilowatts of electric power. For this reason such an apparatus can only function satisfactorily in well-equipped laboratories with an abundant supply of current. The research centre on the Jungfraujoch is particularly well placed in this respect. It is accessible by rail throughout the year, it can take current from the supply line of the Jungfrau railway, and it possesses large laboratories equipped with every technical refinement. Switzerland can count itself fortunate to possess such an effective research centre.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Weather conditions during September hindered construction operations generally. A total of 4,300 persons were employed on the Ontario Hydro section of the project during the month.

Progress by Ontario Hydro

At the end of September all subgrade work had been completed for the 40-mile relocation of the main line of the C.N.R. between Iroquois and Cornwall. More than half the double track was laid and ballasted. Preparatory work had begun for the grade separations. The sites had been prepared for the four new stations to be constructed.

Sub-grading was practically completed on five of the six sections to replace No. 2 highway between Iroquois and Cornwall. Surfacing work should commence next month.

At the power-house site, earth excavation was completed and 90 per cent of rock removed. Concrete placement had proceeded to unit 8. The draught tube form used for unit No. 1 had been erected in unit No. 3 and was ready to receive concrete. A total of 260,000 cubic yards of concrete had been placed in the Ontario Hydro section of the powerhouse structure, with intakes poured for six units. Outstanding progress had been made on the construction of the Cornwall dike closure structure for diversion of Cornwall canal. About 85 per cent of the concrete had been placed in the structure and half the backfill required was placed.

Wet weather had hampered Cornwall dike construction work. However, the contractor moved more than 20,000 cubic yards of material per day during favourable conditions.

All equipment for the 1956 stage of the St. Lawrence transformer station was in service. Work is proceeding ahead of schedule on the 1957 stage.

Channel improvement work progressed favourably during September. At Galop Island, the large cofferdam at the north end had been dewatered. A total of 6,000,000 cubic yards of earth had been excavated and approximately 275,000 cubic yards of rock had been excavated. Dredging was progressing favourablv in the Chimnev Island contract with a total of 720,000 cubic yards of material removed. Work had begun on the Iroquois Point contract. Clearing operations were well underway.

A total of 66 houses was moved by the end of September into new town No. 2. Construction of basements continues to be well ahead of house moving. In new town No. 1 work was concentrated on the completion of water and sewer services, as well as roads in the eastern half of the town. A temporary water pumping station was placed in operation to provide fire protection. Meanwhile, the permanent water pumping station, sewage pumping station, and sewage treatment plant were nearing completion.

At Morrisburg, good progress was made in the construction of sewers and water mains for the new subdivision. Construction of footings for the new shopping centre had begun. Similarly at Iroquois, activity was centered around construction of the new shopping centre. Considerable street paving and landscaping work was in progress at Iroquois. Construction of the new public school and the superstructure for the new high school was underway.

Long Sault dam. Stage 1 piers have been completed and construction of the roadway is in progress.

Progress By NYSPA

During September construction moved steadily ahead as work continued on an around the clock basis. Concrete placement in all project structures exceeded 780,000 cubic yards, excavation for all features exceeded 26 million cubic yards and employment averaged 5,200 for the month.

Concrete placement for the stage 1 construction of Long Sault dam was complete except for the parapet walls. With excavation of cut "F" approximately 88 per cent complete, its downstream plug was breached and water was admitted into the cut area, as removal of the plug continued. Grading for the westerly section of Barnhart Island road had been completed and work on the north dike was progressing. Cofferdams "A" and "B" were being removed and construction of stage 2 cofferdams was progressing. The contractor's access bridge to stage 2 cofferdam was completed. Placement of rock material in stage 3 cofferdam "E" was started on September 13.

Concrete placement in Barnhart power-house continued with a total of 313,000 cubic yards to September 30. Concrete placement for the switchyard tunnel was started. Excavation for the switchyard continued and placement of embankment in the south forebay dike exceeded 430,000 cubic yards.

At Iroquois dam, stage 1 concrete placement was completed, and all 15 control gates placed in position. Excavation within the stage 1 cofferdam area was completed and thirteen cells of the stage 2 cofferdam were in place.

At Massena intake, placing of concrete was continued with 123,000 cubic yards placed to date. Back-filling around the wing walls and dike embankment placement continued. Construction of the Massena-Alcoa water facilities was essentially completed.

Excavation under the five channel improvement contracts was 43 per cent completed as work at the Galop Island south channel progressed to 94 per cent of completion.

Contracts were awarded for the relocation of New York State highways 37 and 37B. Bids were opened for seeding and topsoiling of channel improvement spoil areas in the vicinity of Galop Island, south channel and reservoir clearing between Waddington and Barnhart Island power plant.

Approximately 95 per cent of survey work for the Barnhart-Plattsburgh transmission line had been completed. Production of construction drawings and specifications continued at rapid pace. Expediting of major items of equipment was pressed to insure delivery of manufactured components at the project in time to meet the tight schedule.

A start was made in September on stilling the turbulent Long Sault rapids. Rock and earth fill is being dropped into the water some eight miles west of Cornwall from an aerial cableway strung between steel towers, linking Long Sault Island with the Canadian mainland.

Some time in December, when the spillway in the first stage of construction on Long Sault dam is completed, first stage cofferdam removed and second stage cofferdam in place, the upstream earth 'plug' presently blocking the river flow through "cut F" will be removed by blasting, which will divert the flow of the river to the south channel and through openings in the Long Sault dam spillway.

Progress by SLSA

The mile and a quarter long Iroquois lock, due for completion by November 1957 at a cost of $6½ million, requires excavation of 4½ million yards of glacial till. More than half of this quantity had been removed by the end of September, leaving a gaping hole 100 feet wide, 90 feet deep and several thousand feet in length. Most of it came from around the 1300 foot lock structure and upper guide walls. Little earth had been dug for the lower guide-walls of lower approach channel.

A few base blocks had been poured for the walls of the lock structure, but most of the 80,000 cubic yards of concrete placed to date had gone into the upstream guide wall, which was 75 per cent completed. For half of the 1300 foot length it had been built to a height of 47 feet. It is 34 feet wide at the base and will be six feet wide on top. One of its functions is to serve for mooring ships waiting to pass downstream through the lock.

Contracts were awarded in mid-June for the upper and lower Beauharnois lock structures at prices of $14.44 million and $11.2 million respectively. Designed wide enough to ultimately permit ships to pass one another, the lock structures will at present be built wide enough for one ship except at the entrances and for a short two-lane section at the downstream end of the lower lock.

The contractor for the upper lock had set up his camp and plant, and was crushing and stock-piling aggregates. His contract includes excavation. About 15 per cent of the earth excavation and 10 per cent of the rock had been moved up to the end of September.

For the lower lock a separate contract had been awarded last March at a price of $3,480,000 for rock excavation for the lock structure and guide walls, for full width and length to a depth of some 40 feet. This contract also included more than half a mile of four lane highway approach road at each end of a 200 ft. long lined highway tunnel 26 feet in height under the lock structure. This excavation, all of it in tough sandstone, was practically completed at end of September.

The contractor for the lower lock structure had also built his camp and was setting up the mixing plant and stock piling concrete aggregates.

In the Lachine section, a contract for the Côte St. Catherine lock was awarded in August 1955 at a price of some $7.1 million, for completion in July 1958. The work here extends a distance of two miles and includes a turning basin below the lock, regulating works for controlling the canal water level above it and a reservoir pool upstream. The lift will be 30 feet, overcoming the major fall of water in Lachine rapids.

In addition to much excavation, the contractor had placed concrete for a number of monoliths upon which the walls of the lock structure will be based.

Also in the Lachine section opposite Montreal at the south shore end of Victoria bridge is the 2 mile long St. Lambert lock, overcoming the 15 foot drop between the Laprairie channel and the Seaway entrance channel in the harbour of Montreal. A contract was awarded in 1955 for this lock at a price of some $7.4 million, and work commenced last January. Completion is called for in August 1958.

Here most of the 2½ million yards of excavation had been completed. On the south or land side of the lock structure above the Victoria bridge, alternate blocks of the concrete wall were poured almost to bridge-floor level with the remaining sections following close behind. The downstream guide wall on the land side was taking definite shape below Victoria bridge.

Many miles of channel in the shallow riverside and overland in the Lachine section have still to be excavated. Dredging of the seaway entrance at Montreal harbour and of channel reaches in Lakes St. Louis and St. Francis and elsewhere will continue for two more years.

Miles of these channels have been dug or dredged already. Several minor contracts and one major one are completed in the Lachine section. One of the three dredging contracts in Lake St. Francis is completed. Of the three contracts for enlarging the Welland ship canal to a depth of 27 feet, one is completed.

Three more contracts were signed at Montreal on September 14th by the St. Lawrence Seaway Authority, totalling some seven million dollars, as follows:

(1) Dominion Bridge Co. Ltd., for construction of superstructures for two vertical lift bridges on the Canadian Pacific Railway's double track bridge near Caughnawaga, $3,031,097.

(2) Atlas Winston, Ltd., Montreal, for excavation of channel and construction of dike, embankments and CPR substructure, $3,259,525, at Caughnawaga.

(3) Timberland Machines Ltd., Woodstock, Ont., for supply and erection of 10 stiffleg derricks with winches at five SLSA locks, $649,000.

Award of these contracts brought the value of SLSA contracts awarded to date to over $156 million.

The cornerstone for the Seaway Authority's Cornwall headquarters building was laid on September 11 by president Lionel Chevrier of SLSA. Speakers at the ceremony included the Hon. George C. Marler, Minister of Transport, Mayor Aaron Horovitz of Cornwall, and Albert Lavigne, M.P. for Stormont. To be the tallest building in the city, it is already built to its full height of seven storeys, and is due for completion next summer.

Progress by SLSDC

At end of September excavation at the Eisenhower lock was completed for the upstream approach channel and for the lock structure and upstream guide walls, but not for the lower guide walls and downstream approach channel. Rock was excavated for the lock itself.

Some 120,000 yards of concrete had been placed in the lock proper, out of an estimated total of half a million yards for the whole job, bringing the lock walls up to about one third of their final height. Excavation was under way for the approaches to the highway tunnel under the lock.

At the Grasse River lock, cost of which will be $26.8 million, excavation for the lock structure was complete but little excavation had been done for the guide walls and channel approaches. Concrete had been poured for the walls of the lock throughout its length to approximately half the final height. No work had been started on the highway approaches.

Placing of concrete on these two American locks will be discontinued during the winter months, in contrast to the five Canadian locks where concrete work will be continuous.

Earth for the Long Sault main dike and for the Richard's Landing dike on the American side is obtained by dredging from the navigation channel, but is paid for by NYSPA. The main dike was about 40 per cent completed while the Richard's Landing dike was some 33 per cent completed, at the end of September.

The 14 cubic yard dragline named 'The Gentleman' had been moved to an island in the forebay for recasting fill. About 25 per cent of the 12 million yards of excavation for the Long Sault navigation channel had been completed.

Most of this channel can be done 'in the dry' and will be continued well into the cold weather. On a three mile stretch between the two American locks across swampy land a pool was formed by pumping, and a dredge is pumping material from the pond to the spoil area, at a considerable saving below the cost of shovel excavation.

Clearing was completed on Long Sault Island and partly completed on Delaney Island, and was proceeding on other wooded areas within the St. Lawrence Park limits.

The St. Lawrence Seaway Development Corporation will ask Congress next session for authority to borrow further money. Rising costs for labour and materials are blamed by the agency for an additional $5 million on the original estimate of $105 million. Actually $17 million of additonal borrowing power will be asked, but $12 million is for contingencies and will not likely be needed. Redesign of the bridge at Cornwall, making it a suspension structure, will save $2 million and mean no delay in final completion of the project. As of September 1, 1956 the project was claimed to be on schedule.

Dredging at Cornwall Island

SLSA president Lionel Chevrier, addressing members of the Cornwall Board of Trade on September 20, explained that a channel 450 feet

Iroquois dam. Stage 1 construction is nearing completion as one gantry crane is in position and runway beams are being completed.

in width and 27 feet in depth must be dredged on the south side of Cornwall Island to provide navigation from the upper end of Lake St. Francis to the entrance to the Grasse River lock.

The Cornwall Island south channel must also be deepened, widened and straightened so that the velocity in the navigation channel will not exceed 4 feet per second. This will reduce the flow in the north channel, he pointed out, and therefore it becomes necessary to do compensatory dredging in the north channel to maintain the flow distribution under natural conditions.

The Cornwall Island dredging, amounting to approximately $35 million, will be shared by all four entities now working on the development of the river. However, the actual dredging will be carried out by the St. Lawrence Seaway Authority and the Saint Lawrence Seaway Development Corporation.

"The matter of the north channel dredging," remarked Mr. Chevrier, "is under discussion between the two governments of the United States and Canada, and no final statement can be made until the matter has been determined on that level."

Plans Revised for Ogdensburg Cornwall Bridge

A major change in Seaway plans for the International area near Cornwall was announced on September 20. One high level suspension bridge will be built instead of four smaller structures called for in earlier plans. In addition, the New York Central will abandon its line into Canada when the south channel bridge is replaced by the high level span.

Cost of the new bridge will be $6 million, or some $2 million less than the earlier plan to build connecting bridges across the Polley's Gut area. It will be located about 1000 feet west of the existing Roosevelt rail-highway bridge between the U.S. mainland and Cornwall Island. For the present no announcement is made on plans for alteration or removal of the second bridge from Cornwall Island across the north channel to the Canadian mainland.

The new span will be an international project. Canada will build the substructure and the U.S. will build the superstructure. The bridge will be completed by July 1958 and the old structure over the Seaway channel will be torn up. The question of tolls will be taken up at a later date. Tolls are charged on the existing bridge. NYCRR shareholders have approved sale of the 70 mile line from Helena, N.Y. to Ottawa to the St. Lawrence Seaway Authority.

Harbour Improvements Authorized

Over the next three years the National Harbours Board will spend about $50 million on eight big federal harbours, to catch up on postponed harbour remodelling and the need to provide for fast efficient handling of ships' cargoes; $20.5 million will be spent this year, about $15 million in each of the years 1957 and 1958.

Of this, ports along the Seaway will have some $16 million in improvements this year. Quebec will get $1.7 million for a new oil wharf and for rebuilding berth 8 at Pointe-a-Carcy. Another $5 million will be spent for a two-million bushel elevator and berthing for large lakers.

Montreal will get $6 million for new wharves to provide 3100 linear feet of berthing, for raising of Sutherland and Laurier piers, for extension of oil wharves, and for a new grain jetty, as well as $1 million for further dredging and $2.4 million for grain conveyor galleries. A possible further $7 million will be spent for grain storage elevators.

Short Cut to Upper Lakes

A short-cut system to link Georgian Bay with major southern Ontario markets and lower sections of the seaway is being reviewed. This was a major political issue half a century ago but was abandoned when the Welland canal was improved. A connecting waterway through Lake Simcoe to some point between Toronto and Oshawa is under study. The channel would start from Collingwood or Midland and follow the Nottawasaga valley or some reaches of the Trent canal, which at present carries 250 tons of freight yearly.

Cost of the original 440 mile schemes from Georgian Bay to Montreal was estimated at $100 million early in the century and would take 10 years to build. The 100 mile route now under review would take a more direct line to Lake Ontario. Costs, of course, could not be compared.

Rocket Launching Site

The Arctic launching site for rockets at Fort Churchill was ready in October for its part in the International Geophysical Year (IGY) to begin officially next July. This was announced recently by Dr. Joseph Kaplan and Mr. F. T. Davies, chairmen respectively of the United States and the Canadian national committees of the IGY.

The program of rocket launchings in the Arctic is part of the intensive international study of the earth, the atmosphere and the sun, to be conducted over the entire world from July 1957 to December 1958. From this program scientists of all nations hope to gain a better understanding of the earth's structure and various effects in the atmosphere such as aurora and airglow, cosmic rays and solar activity.

Mr. Davies, assistant chief scientist of the Defense Board of Canada, is also a member of a co-ordinating committee for the IGY appointed by the president of the National Research Council. Other members are Dr. C. S. Beals, Dominion Astronomer; Dr. D. W. R. McKinley, Radio and Electrical Engineering Division, N.R.C.; Dr. D. C. Rose, Pure Physics Division, N.R.C. Mr. Rose is chairman of this committee.

Rocket experts chose Fort Churchill for its accessibilty and because it lies within the "Arctic auroral belt" where Northern Lights are most easily observed. The rocket launchings are part of the scientific effort of the United States to explore the atmosphere in the Arctic to a height of 180 miles. Aerobee rockets will be used for high altitudes and smaller two-stage rockets for lower altitudes.

Preliminary rocket flights were to begin in late October or November under the direction of the U.S. scientists. Canadian scientists co-operating in the tests at Fort Churchill will make observations on the ground which will tie in closely with measurements taken by the rockets.

The Fort Churchill rocket site is a multimillion dollar establishment financed by the U.S. Many branches of the U.S. Defence Services are lending their support to this scientific venture.

Scientific instruments carried by the rockets will measure density temperature, pressure and wind velocities in the Arctic atmosphere at heights never before studied. They will also take measurements of the ionosphere — the upper region of rarified, ionized gas between 50 and 250 miles above the earth's surface — which reflects radio waves in long - distance communication. The rockets will record effects of the sun's light at high altitudes, and such phenomena as Northern Lights, cosmic rays, and the earth's magnetism.

Canadian Pipeline Projects

In a progress report at mid-September, Westcoast Transmission disclosed that some 2000 men were at work, 1964 on pipeline construction and the balance on the absorption plant and compressor stations. More than a third of the pipe had been laid for the main 30-inch pipeline from the Peace River area to the International Boundary.

Westcoast Transmission

220 miles of pipe had been covered, 254 miles had been welded and pipe had been delivered for 448 miles. One of the contractors, Canadian Bechtel Ltd., claimed a record in pipelaying of 1,200 feet in one day, while four spreads laid 30 miles in one week or an average of over one mile each per day. A contract had been awarded for two 18,000-h.p. compressor stations to Dutton Williams Ltd., at Australian and Fort McLeod, with initial capacity each of three 4,500-h.p. units.

Pacific Petroleums has purchased a major interest in XL Refineries of Dawson Creek, and is building an $18-million gasoline processing plant at Tavlor Flats, to be integrated with XL Refinery operation to serve a substantial market along the Alaska highway and in the Peace River valley.

Gas reserves in the Peace River area are estimated at close to 4 trillion cubic feet. Some 2¾ trillion of this is controlled by Pacific Petroleums. Well-head prices are set tentatively at 6 cents till January 1958 and 10 cents for the next five years, increasing to 12½ cents the eighteenth, nineteenth, and twentieth years. Westcoast plans to move 3 million c.f.d. during 1957 and 400 million c.f.d. in 1958, out of an ultimate 650 million c.f.d.

Dr. George S. Hume, one of North America's outstanding geologists who has been director general of scientific services, department of Mines Ottawa, is joining Westcoast Transmission Company Limited, as vice-president and chief geologist.

Dr. Hume, who has been with the federal government since 1920, has been acting deputy minister of mines for the past year and a half. He has also taken a leading role in the development of Canada's natural gas reserves and in the establishment of natural gas pipelines for services to all parts of Canada.

Inland Natural Gas

Dutton-Williams Bros. Ltd., has been awarded a $9 million contract for general construction on the new distribution system of Inland Natural Gas Co. The project involves some 360 miles of trunk lines from Savona east through Kamloops to Oliver, and east to Nelson. Fifty miles east of Kamloops a spur will serve Salmon Arm. The line will supply gas to some 25 communities. Pipe is ordered from Canadian Western Pipe Mills at Port Moody and Alberta Phoenix Mills, at Edmonton, in 12, 10, 8, 6, and 4-inch sizes at a cost of $6½ million. The company will spend $22 million during the next 12 months and a total of $28 million by 1960.

Inland has been confirmed as supplier of gas to the City of Nelson B.C. Ratepayers approved the sale of its municipally owned propane-air gas system to Inland and the granting of a franchise to Inland to provide natural gas. Inland plans to maintain the plant to provide service until gas becomes available and to act as a standby plant thereafter.

Two additional northern communities have also been added to the list of those to be served by Inland; Little Prairie, east of Dawson Creek, and Hundred Mile House, will be served by stub lines from the Westcoast Transmission pipeline. Apart from subsidiaries, Little Prairie becomes Inland's most northerly B.C. customer, though Dawson Creek and Grand Prairie in Alberta are also customers.

Inland has incurred commitments worth almost $7 million during the current year to date. Pipe has been ordered at a cost of $6½ million. In the near future the company will commence laying some 360 miles of pipeline and the entire system involves 875 miles of pipe including local mains and services. During 1956, Inland has become a certified gas utility, and within a few months the company will finance the major operation of building its pipelines. Cost of the entire project is estimated at $25 million.

J. R. White, president of Imperial Oil, warned recently of too much optimism regarding possible petrochemical developments around Edmonton and the Peace River area. Any major industry using Peace River gas was more likely to be established near Vancouver, he predicted. Such plants must be convenient to large population centres with easily reached markets. High freight rates out of Peace River and even Edmonton were a handicap to building there.

Trans Canada Pipelines

Arrival of the first trainload of 34-inch pipe at Cabri, Sask., on September 20, with almost continuous shipments promised to follow, has resulted in a return to all-out pipelaying operations on Trans Canada's western leg to Winnipeg. Two more spreads have started work. Up to mid-September less than a fifth of the 575-mile line had been laid, due to interruption of pipe deliveries since the steel strike and to a critical shortage of welders.

Final pipe shipments may not be made until February, however, according to suppliers; thus prospects are that the entire line may not be completed before midsummer of 1957. Possibly only half of the western leg will be laid before winter weather calls a halt to pipelaying.

Trans Canada has been harder hit by the steel strike than any other pipeline. Long term future for pipe deliveries is difficult to forecast because of the increase in pipe orders over recent months, it is difficult now to arrange for pipe delivery for a major project before 1959.

Majestic Contractors Ltd., had been temporarily shut down on the first spread from Burstall to Leinen, due to lack of pipe, with 52 miles of pipe in the ground. Canadian Bechtel Ltd., on spread 2 will soon have enough pipe to complete its 110-mile section. This contract includes the only river crossing in Saskatchewan, over Swift Current creek.

Intercity Gas Ltd., a wholly owned Manitoba enterprise incorporated in 1954 to distribute gas to towns and villages in the province, has obtained exclusive franchises for Portage la Prairie, Neepawa, Rivers, and Hamiota. Further franchises are being sought. Initial expenditures for the network of mains to connect with Trans Canada pipelines are set at $1.1 million, plus a further $500.000 if new franchises are allowed. Mains are nearing completion for the four towns under franchise. Financing is now being carried out.

A build-up of gas sales in the Montreal area had been planned to commence as soon as a further supply of Texas gas was available. Import of this gas depends upon F.P.C. action on an application which is consolidated with the application for export of Canadian gas at Emerson.

The Quebec Natural Gas Corporation was incorporated in 1954 by interests allied with Trans Canada to distribute gas in the Montreal area and to negotiate with Hydro-Quebec for purchase of the Montreal Coke Company. Pipe for the line from Toronto to Montreal is on order, but according to pipe delivery schedules the earliest date gas could be made available to Montreal would be 1958-59, even if no hitch occurred in financing. The import of Texas gas may be authorized even later than that by F.P.C.

Gas Treaty Proposal Gets Cool Reception

Proposals for a natural gas treaty between Canada and the U.S. made on October 1 before the Federal Federal Power Commission met cool reception in diplomatic circles of both nations. In formulation of a national energy policy, a firm and definite line is already set on electricity;—that since it can never be recovered it should never be exported. A parallel was suggested which would put natural gas in the same category. That would, however, cut across the Trans Canada pipeline program under which gas would be exchanged.

It is Canada's policy to be most particular about export of natural resources, considering each case as it arises. This policy runs counter to blanket agreements on exchange of natural gas.

FPC Hearings

Early in October during FPC hearings, Examiner Francis Hall recommended a disregard, for the time being at least, of objections by competitors and the coal industry to the Tennessee Gas Transmission Company's pipeline from Emerson, Manitoba to Portland, Tennessee, to be built by Midwestern Gas Company. To reject the plan now would not be in keeping with the public interest or past practices, he observed. But, he warned, his recommendation for further study must not be taken as an indication of future approval. This was considered by observers as a victory for the proposed pipeline, even though a final ruling is up to the full F.P.C.

Financing

A third advance, in the amount of $4,183,000 was made on September 27 by the Crown Corporation to Trans Canada Pipelines. This brought the amount advanced to finance the western section of the pipeline to $15.083,000.

Financing plans for the entire project, exclusive of the Northern Ontario section to be built by the Crown Company, are now almost completed. Financing is now imminent and should be carried out within a few weeks. The first mortgage bonds for at least half the total issue will be placed privately with investing institutions. Debentures and common shares will be offered exclusively in Canada. No decision is yet made as to interest rates on debt securities, nor on the issue price for the common shares.

Export to U.S. Still Needed

Trans Canada officials and gas producers generally regret the Hon. C. D. Howe's statement in a speech at Toronto on September 18, that "gas committed to Trans Canada has been sold in Canada, and export to the United States is no longer necessary." This, they feel, may influence the Federal Power Commission against giving a permit to export Canadian gas to the U.S. via Emerson, Man. They give two reasons why Trans Canada must seek all possible export markets; first, the slow build-up of markets versus the faster growth of reserves, and secondly, pipelines do not want any limitations set on their growth.

Millionth House

A million houses have been built in Canada since the end of World War II. Completion of the "millionth house", in Scarborough, in September called for some comment on the past and the future of housing in Canada, by Robert Winters, M.E.I.C., Minister of Public Works.

Approximately 1½ billion man-hours of work have been done on construction sites alone—one facet, only, of the economic effect. The construction labour force now numbers nearly 400,000 workers. Land and building have involved the expenditure of $9 billion.

Canadians are now building more than enough dwellings to take care of the annual increase in the number of families, of population movement. and to replace dwellings destroyed. They are cutting into the backlog of need. It is possible, therefore, to move in the direction of replacing substandard housing.

More Iron Ore from Ungava

Four iron ore companies are spending an estimated $1 million this year in development and engineering studies of the low-grade iron ore deposits around Ungava Bay. They plan to market several billion tons of beneficiated ores in European countries.

Consolidated Fenimore Iron Mines Ltd. has already spent some $2 millions in development and studies over the past three years. Two Cyrus Eaton companies, Atlantic Iron Ore Co. and International Iron Ore Co. have also been investigating the area for three years.

A harbour would likely be established on Ungava Bay, which is open to navigation for only two or three months of the year. Present plans call for transhipment of ore by shuttle service in two months of open navigation to a port in Greenland on Rype Island one mile from Gothaab. From this port, where storage of 3 million tons of ore would be set up, ships of up to 45,000 tons could transport the ore all the year round to European mills.

Hydro-Quebec is looking over the area for a possible hydro-power site. Ottawa's hydrographic surveys branch is studying Ungava Bay for a harbour site. Transportation routes to tidewater, metallurgical and mill methods for concentrating the ores are also under study. Estimated capital cost of developing the Fenimore property for production of a million tons of concentrates yearly, using magnetic separation, is about $16 million.

COMMENT AND CORRESPONDENCE ELECTIONS AND TRANSFERS

Technical Manpower Conference

It was bound to happen sometime. All the talk about shortages and education, could be resolved only by some sort of get-together of people who were interested.

Under the auspices of A. V. Roe Canada Limited, the interested people met at St. Andrews, N. B. on September 9-10-11. Much credit must go to the company for its courage in tackling the problem about which so many were talking and so few doing anything. The company handled the complete job including the organizing and the financing, and did it all well. It must have been particularly gratifying to have everything go so well, including the acceptance of two previously prepared resolutions which point the way for the future.

The resolutions proposed the establishment of an Industrial Foundation on Education, and the appointment of a committee to explore the feasibility of establishing a National Advisory Committee on the Advancement of Education.

To the conference were invited many leaders in industry, education, government, professional societies and labour. The roll call showed about a hundred there. It was a notable assemblage for a notable purpose.

The two reports which were approved without a dissenting voice read as follows:

First Recommendation

A proposal to establish an Industrial Foundation on Education as a permanent factfinding and executive organization, to be financed entirely by industry and to perform broad functions on behalf of industry in the field of education, as related specifically to needs and acknowledged responsibilities of industry.

Basis For the Recommendation

This Conference would fail in its larger purpose if its deliberations did not culminate in some positive action.

Since the Conference is predominantly industrial in representation it therefore devolves upon industry to seek a course of constructive action toward solution of the truly appalling problems we face in the supply of professional and skilled manpower and the educational problems related thereto.

But industry can only do so much without encroaching upon responsibility and authority in other areas of this many-sided problem in which it can only plead, advise and offer opinion and support.

What, therefore, can industry do?

We of the Advisory Committee to this conference, believe that the immediate contribution of industry in the step-by-step solution should take the form of an Industrial Foundation on Education.

This Foundation would be a fact-finding and executive organization, permanent in nature. It would be the voice of industry in the field of education, the

Among those attending the Technical Manpower Conference were, left to right: Dr. L. Austin Wright, E.I.C. general secretary, Dr. C. B. Purves, president, Chemical Institute of Canada, V. A. McKillop, president of the Engineering Institute.

Cover Picture

Pipe in the Alberta-Winnipeg section of Trans-Canada Pipe Lines' 2,250-mile natural gas transmission line is 34 inches in diameter, weighs more than 355 tons per mile.

Sideboom tractor, shown raising a string of pipe for cleaning and coating, is probably the busiest piece of equipment on the job. Next step is to lower the heavy pipe into the six-foot deep trench.

vehicle by which individual components of industry would state and expound upon their aims, and support all necessary steps to greater efficiency in the educational system as related to the needs and future of the national economy.

Such an organization could have many functions.

A rapid enumeration suggests these examples:

1. Sponsorship and organization of in-plant training programs.

2. Adminstration of industrial contributions to educational advancement whether for individuals by way of scholarships, institutions by way of grants and fund-raising campaigns, or the cause of education generally by contribution of influence and promotional talent and/or funds.

3. Continuing study on educational problems specific to industry and commerce with periodic recommendations toward solution of these problems.

4. Public information programs designed toward motivation of career decisions, attracting more people to teaching careers, providing more technical training facilities, more and better university facilities and buildings.

5. Assistance in career counselling.

6. Guidance in effective utilization of professional and technical skills.

7. Influencing the training of many more women as scientists, engineers and science and engineering teachers.

8. A continuing program to influence scientists, engineers and technicians to remain in the fields for which they were trained.

9. Cooperation with the professional societies on matters of status and recognition whether for practicing engineers and scientists or those teaching.

Many more likely and necessary functions could be added to the list — the foregoing are but examples of necessary objectives which we believe can only be attained through an industry-wide organization.

Such an organization can be established and put to work for relatively little money.

Members of the Advisory Committee can serve as a Board of Directors, while initial staff requirements are as follows: Executive Director, Research Analyst, Secretary, Clerk Typist, and possibly one Illustrator.

Annual operating expenses are estimated at $50,000. Initial capital costs for furniture and equipment would be in the region of $3,000. These funds, for the first year of operation, have already been pledged.

Second Recommendation

A proposal to appoint a Committee to Explore the Feasibility of establishing a National Advisory Committee on the Advancement of Education as a permanent and national fact-finding and policy making organization having a broad responsibility in the entire field of education and to have representation from government, industry, education, the professional societies and organized labour.

Basis For the Recommendation

The Advisory Committee is convinced that the problems we face in education generally, and especially as related to the urgent needs of today and for the future in technological skills, can only be solved in total by attack on a broad, national front. While the proposed Industrial Foundation can accomplish much, its function and likely achievements can only constitute one piece of a much larger fabric.

The Committee believes that it has been clearly established by research and through discussion at this Conference that these problems constitute a national emergency which so far has not been comprehended on any national scale.

We are therefore recommending that an investigation be undertaken on a national scale whereby the main segments of our organized society may be brought together in an attempt of broad dimensions to find a vehicle by which the educational problem may be kept under close scrutiny continually and in centralized and closely coordinated manner.

The initial step, we propose, should be the appointment by this Conference of a Committee of Five, representing education, industry, professional societies and organized labour, under a Chairman, and with necessary staff, to explore the feasibility of establishing a permanent national advisory body on education, representing government at appropriate levels together with the other entities mentioned above. This national advisory body would be charged with the responsibility of studying trends and improving levels of efficiency across the broad field of education in the interests of national well-being in all aspects.

We propose that this Committee should be empowered by this Conference to start its work immediately and to report its findings within the next three months. Funds will be required and the need is estimated at some $50,000 for a thorough-going study.

As a basis for consideration — and in no sense a set goal — the kind of national body we visualize might be called the National Advisory Committee on the Advancement of Education.

This organization, by present concepts, could emerge as shown in the illustration.

Here we would have a fully representative body which, through its various committees, would be in constant and timely communication with people at the many grass roots of the problem.

What would be some of the principal functions of such an organization?

1. Development of plans for expansion of educational facilities.

2. Assessing costs and formulating financing plans for such expansions.

3. Constant review of curriculum content.

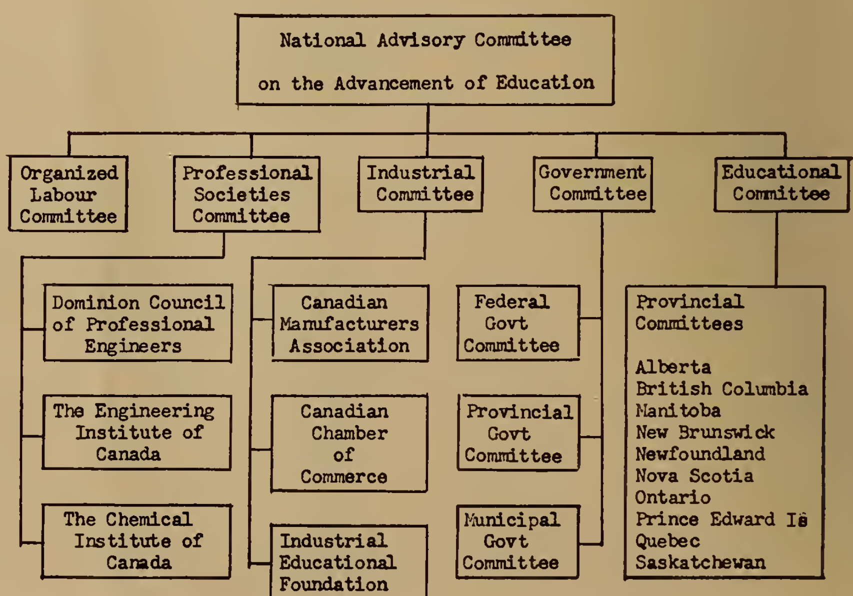
4. Investigation of teacher problems and formulation of plans to overcome them.

5. Motivation of students toward acceptance of responsibilities and essential roles in our complex industrial society.

6. Investigation and development of teaching methods and training aids.

7. Public information programs on education problems, financial needs and public responsibilities in education.

8. Investigation into scholarships, grants, loan plans for students and other



financial aids to worthy but needy students.

9. Investigation into programs and proposals for further education leading to professional or technician status outside established institutions and methods (for example, cooperative educational institutions for engineers, in-plant training programs).

These are but some of the functions a fully-representative national organization on education could undertake and constitute but a glimpse of the highlights of the many aspects of the entire problem where action is required.

We believe they indicate quite clearly the need now to investigate and work toward early establishment of such a national organization.

The Foundation will be financed entirely by industry. Its chairman will be Crawford Gordon, Jr., president of A. V. Roe Canada Ltd., Toronto. Executive director will be S. H. Deeks, Toronto, who prepared the brief which served as the general theme of the Conference. Cost of maintaining the Foundation and the exploratory committee for its first year will be $100,000 pledged by the industrialists.

The proposed National Advisory Committee on the Advancement of Education would be a permanent and national fact-finding and policy-making organization with a broad responsibility in the entire field of education. It would have representation from government, industry, education, the professional societies and organized labour.

Its chairman is James S. Duncan, Toronto. Other executive members will include Dr. G. Edward Hall, president of the University of Western Ontario, London; D. W. Ambridge, Toronto, president of Abitibi Power & Paper Co. Ltd.

Speaking on behalf of the educators gathered at the Conference, Dr. Hall endorsed the two "cornerstones" laid, as being "satisfactory to the universities in principle."

The general conference chairman was James S. Duncan. Leader and special speakers were Dr. O. M. Solandt, Hon. M.E.I.C., A. H. Frampton, J. D. Barrington, P. R. Woodfield, D. W. Ambridge and A. F. B. Stannard.

The speaker for the closing dinner was the Rt. Hon. C. D. Howe, Hon. M.E.I.C. Mr. Howe agreed there was a shortage of engineers and that every effort should be made to overcome it, but he did not think there was any reason for hysteria. A shortage of engineers was a clear indication that the country's economy was sound. He said he would really begin to worry when there was no such shortage.

The Engineering Institute of Canada was represented by its president, V. A. McKillop. The Chemical Institute of Canada had its president Dr. C. B. Purves there, and the Dominion Council was represented by its president E. J. Durnin of Regina who is also chairman of the Saskatchewan Branch of the Institute.

The Conference was a success. If the support offered in the future in carrying out the proposals equals that of the Conference, they too will be successful. They are far reaching, sound and well thought out. They merit wide support from all parts of Canada and all groups of people.

Hamilton Branch Expands

Recently the chairman of the Hamilton Branch has announced that a technical division has been formed within the branch membership.

An elaborate canvass was made of the membership several months ago which showed clearly that there was a demand for more technical papers. The strongest demands were in the fields of electrical and mechanical engineering and accordingly the branch has undertaken to start out with a joint mechanical, electrical division.

It is proposed for the first season there will be six sessions of the division each held on a Monday evening. The subject will be the same throughout the series, namely nuclear energy. Arrangements have already been made for speakers for the entire series and it appears as if the attendance would be very encouraging.

Other branches also are studying the advisability of creating technical divisions. It is expected there will be further developments along this line in many branches within the coming season.

Transatlantic Telephone Cable

Service on the transatlantic submarine telephone cable was inaugurated with due ceremony on September 25. To observe the historic occasion, groups gathered in London, New York and Ottawa to witness the first use of the new telephone system connecting London with North America.

Representing the Engineering Institute at the International ceremonies was B. G. Ballard, past vice-president of the Institute. His report is herewith.

On January 24, 1957, the cable will be put to use in a very apt way to connect London and New York with Montreal for a joint meeting arranged to discuss the technical features of the system. Participating societies will be the Institution of Electrical Engineers, the American Institute of Electrical Engineers and the Engineering Institute of Canada.

Report of Ottawa Ceremonies

As agreed, I represented the E.I.C. at the official opening of the first transatlantic telephone cable between Canada, the United Kingdom, and the United States, on Tuesday, September 25, 1956.

It was an impressive event at Ottawa. Similar groups were assembled in both London and New York, and with the time differential between England and this continent, the ceremony became a pre-dinner event in England and a pre-luncheon event in North America.

Each guest was provided with a telephone which, not surprisingly, handled one-way traffic only.

Promptly at 10.30 a.m. the ceremony began, with a short talk by Mr. Bowie, the president of the Canadian Overseas Telecommunications Company, describing the general plan of the system and expressing appreciation for the complex and cooperative effort which the completed installation had entailed. Mr. Bowie was followed by Mr. Thomas Eadie, M.E.I.C., president of the Bell Telephone Company of Canada, Mr. Merchant, the United States ambassador to Canada, Mr. Pritchard, the acting high commissioner for the United Kingdom, and Mr. Marler, minister of the Department of Transport.

At this point, guests were requested to put the telephones to their ears, and at exactly 11.00 a.m. C. R. Craig, chairman of the board of the

American Telephone and Telegraph Company came on the line, speaking from New York. He sent his greetings to Dr. Charles Hill, postmaster general of England, who reciprocated cordially. It is difficult to describe adequately one's impressions of such an outstanding event. To have the opportunity of listening to the first exchange of conversation over a transatlantic cable is a privilege which cannot be held lightly. Even in an age of scientific miracles, I found the clarity of speech and the absence of background noise almost startling. Despite the rather abnormally low sensitivity of my ears, I did not, at any time, experience difficulty in hearing distinctly every word and every syllable.

Perhaps I should have devoted more attention to the actual messages which were exchanged, but I fear that I was more preoccupied with the marvel of this achievement, and I could not dismiss from my mind contemplation of the delicate electronic equipment and the relatively innocent-looking cable buried miles deep in the Atlantic, exposed to thousands of pounds of pressure per square inch and capricious sea currents, performing so perfectly in obedience to the brilliant minds who had conceived them. I envied those who had contributed to the success, and I acquired a renewed pride in the engineering profession.

There followed further conversations between Mr. Marler, Mr. Craig, and Dr. Hill, and at 11.06 a.m., eastern daylight time, the system was declared open for service.

At the conclusion of the ceremony, free transatlantic service was made available to guests, and I endeavoured to send the greetings of E.I.C. to Sir George Nelson and W. K. Brasher, both of whom I expected to be present at the London function, and who were the only senior officials of our sister institutions in Great Britain whom I know personally.

Subsequently, a reception was held, and then a most delectable luncheon at which Mr. Eadie of the Bell Telephone Company of Canada spoke briefly and Mr. Marler was presented with the telephone through which he had made the first telephone call by transatlantic cable from Canada to the United Kingdom. It was a rather magnificent instrument, trimmed with gold.

It was a memorable event, and I am very glad that it should have been my privilege to represent the E.I.C.

B. G. BALLARD

Civil Defence Forum

Late in September, for the first time in Canada, civil defence authorities met with engineers to discuss mutual problems and make some plans for future action. Through the week of September 17, thirty-seven key engineers from points in nine provinces, assembled at the Canadian Civil Defence College in Arnprior to constitute a forum on basic C.D. issues with which engineers are concerned. They came at the invitation of the Federal Civil Defence coordinator Worthington, and represented government, public utilities, professional societies and associations, city engineers, consulting engineers, and regional civil defence staffs. At the time of the forum the E.I.C. president and general secretary were engaged on their tour of the branches in the Atlantic Provinces, but were officially represented by two other senior Institute delegates, R. E. Hayes, councillor, Ottawa, and E. C. Luke, assistant general secretary.

The program for the five days was excellently organized, very interesting, and the visitors must certainly have had their eyes opened to the complexities of civil defence and to its vital importance to the nation and to the safety of the Canadian people. For the writer, at least, the forum cleared away the haze which had shrouded "C.D." in his mind, and demonstrated the real, practical nature of the plans and recommendations which these people are trying earnestly to put into effect.

The first days were devoted to giving the engineers the essential background information on such topics as nuclear warfare, disaster effects, radioactive fall-out, rescue organization, communications, welfare, and all the associated subjects. This was accomplished by means of lectures and films in the school's efficient and well appointed training wing building. At the appropriate times, the engineering problems were introduced. In general these are questions concerned with the provision and maintenance of emergency services in the reception or support areas and, later, the restoration of normal life in the target zones. A wide range of engineering responsibilities was outlined, including such items as transportation, power and water supply, heavy equipment and construction materials, sewerage, debris removal, fire-fighting, stockpiling, and the organization of engineer services.

Best results were obtained from the presence of such a broadly rep-

This group of engineers followed a Civil Defence course at Arnprior, Ont., recently.

resentative group by active participation. The vistors were divided into half a dozen syndicates, in staff college fashion, and were given the outlines of various practical problems — based on imaginary but typical situations involving some phase of disaster action resulting from atomic attack. These were investigated by each syndicate group separately, followed by general discussion in the large theatre and comparison of notes. Unresolved problems were noted for future study. The results were encouraging, and showed keen interest by those attending. Both college staff and engineers profited from the frank development of ideas.

A suggestion was made which was strongly endorsed by the forum in general session. The Canadian Civil Defence College should conduct more meetings of the same kind and endeavour to obtain the attendance of engineers who are in executive positions in management — presidents, general managers, and other top level men whose interest and influence are essential to give the C.D. plan the impetus it needs.

A lot more sustained effort will be required, and considerable expense, to get the Canadian civil defence organization into proper working shape. The results will be well worth this money and effort. To do our collective part the Institute has offered its facilities in the investigation of special engineering problems, or its help in any other practical way that Council may decide. Many members will recall the leading part that the Institute took in these matters in the last war. The support of the present membership is requested in future civil defence efforts which we may be called upon to undertake.

The Honourable Paul Martin, Minister of National Health and Welfare, when discussing civil defence in the recent parliamentary debates, made the following statement:

"I am now able to inform the Committee that the Government has reached the following decision:

"That our civil defence policy should now be based on the development and testing of plans for the orderly evacuation on short notice of the main urban areas in Canada should the possibility of attack on such areas by nuclear weapons appear to be imminent.

"Canada's military authorities have now advised the Government that it must be anticipated that in any major war the North American Continent will be attacked with high-yield nuclear weapons from the outset with little, if any warning. Accordingly, our civil defence policy must be so designed as to ensure the survival and safety of as many of our population as possible in the event of a nuclear attack on this country."

Knewstubb Lake

Nearly thirty years ago the chief hydraulic engineer with the British Columbia Department of Lands and Forests, Water Rights Branch, advanced the theory that one of the greatest potential hydro electric power sites of North America was on the Nechako River.

This engineer was Frederick William Knewstubb, M.E.I.C.

This year, the lake created as a reservoir for Kitimat power by the Kenny Dam of the Nechako-Kemano-Kitimat development, was officially designated by the Canadian Board of Geographical names as Knewstubb Lake.

There is reason to attribute the existence of this great power development to the early survey and research work carried out by Mr. Knewstubb and his associates. The later investigations for the Kitimat project confirmed his early findings made at a time when a project of such magnitude was startling, transmission of power for great distances was uneconomical, and no immediate need for such power existed. Engineers verifying his calculations, were impressed by the accuracy of the data gathered long before under much more difficult conditions, and the conclusions which indicated a vision of today's great developments.

In 1928, when Mr. Knewstubb was 54 years old and had worked with the Water Rights Branch since 1911, the government started to catalogue its water resources on a systematic basis. This policy was administered by the late J. C. MacDonald and was carried out by Mr. Knewstubb as chief hydraulic engineer.

In a paper given to the British Columbia Natural Resources Conference in February 1954, W. H. Sparks of the Aluminum Company of Canada, Ltd., Kitimat, said, "There is on file a memorandum from Knewstubb to the comptroller dated 1928 in which he outlined the possible combinations of diverting the lakes and rivers of the upper Nechako watershed through the coast range to develop large blocks of power. One of the schemes he mentioned is in substance the one carried out by the Aluminum Company so there is little room to doubt that he had thought out and planned his projects well in advance, for it was not until several years later that the surveys had made sufficient progress to provide the data for more than an educated guess."

In 1929 a start was made on the investigation which resulted in the Aluminum Company of Canada's Nechako-Kitimat development. "This investigation", said Mr. Sparks, "was another case where his vision and imagination supplemented by the careful collection of basic data proved to be correct, for when this report was reviewed just prior to the receipt of the application of the Aluminum Company his almost uncanny estimates needed no changing."

There has been comment on the wisdom of obtaining and providing information of this kind. The B.C. government's research in the prewar years has had demonstrable effects other than the Kitimat project. For example, the Campbell River survey laid the groundwork for what later became the John Hart development; the Skeena River was surveyed with a view to developing the Kitsilas Canyon. Studies of the storage possibilities of the Babine and Stuart Lakes recognized their importance to any development of the Fraser River. Early investigations of the Quesnel and Murtle Rivers have been under active discussion again in recent years.

Frederick Knewstubb was originally from England, but was a graduate of McGill University in civil engineering. He served in World War I and for the rest of his life suffered a loss of hearing and a partial paralysis. He originally had joined the Water Rights Branch in 1911 as a draughtsman. He became a member of the Engineering Institute of Canada in 1915.

In the years until his death in 1937 he travelled the province extensively for the Branch. Knewstubb Lake, as it will appear on maps in the future will honour a great engineer and express the indebtedness of the Province and all of Canada.

President McKillop Visits Maritime Branches

The Moncton Branch greeted Mr. and Mrs. McKillip. Above, left to right: L. McIsaac, R. M. Wickwire, Mr. McKillop, G. E. Franklin, V. C. Blackett and Mrs. McKillop.

The ladies, God bless them. Mrs. A. W. Purdy, Mrs. M. F. K. Leighton, Mrs. Blackett, Mrs. T. H. Dickson, Mrs. Franklin, Mrs. Wickwire, and Mrs. McIsaac.

Mr. and Mrs. McKillop visited Memorial College, St. John's, Nfld. At right they are shown with S. J. Carew, dean of engineering, and Dr. Raymond Gushue, president of Memorial (right).

Corner Brook dinner meeting (above). Gordon Tibbo, Mrs. Bugden, A. Martin, Mrs. McKillop, L. Austin Wright, Branch Chairman F. H. Clark, the president, Mrs. Clark, Mayor A. Bugden, Mrs. Martin.

Amherst. Secretary W. G. Miller, Mrs. Alexander, Pro-Mayor E. J. Moore, Mrs. Wilson, President McKillop, Chairman R. L. Alexander, Mrs. McKillop, Vice-Chairman John Wilson and Mrs. Moore.

At the Amherst meeting: (below) Mr. and Mrs. J. F. C. Wightman, Mr. and Mrs. L. E. Burrill, Mr. and Mrs. C. L. Archibald, and Dr. F. Binns.

The president and the Mayor of Charlottetown, Jack Stewart.

At Government House, Charlottetown: (above left) W. R. Brennan, C. W. Currie, Lt. Gov. T. W. L. Prowse, the president, and N. F. Stewart.

Branch meeting, left to right, above, E. K. Macnutt, N. F. Stewart, Mrs. McKillop, Chairman G. J. Hayes, Mrs. Stewart, President McKillop and Mrs. Hayes.

Halifax. Here the president called on H. W. L. Doane, Senior (above). He and Mrs. McKillop dined with Chairman G. A. Cunningham and Mrs. Cunningham, and Vice-President H. W. L. Doane at branch meeting (above right).

Harvey Doane was host for a yacht tour of Halifax harbour. With Mr. McKillop in this group are Past President Ira P. Macnab, Mrs. R. D. T. Wickwire, and G. A. Cunningham.

Nova Scotia Technical College President Alan Cameron received the president at the university. Left to right, Harvey Doane, Mr. McKillop, R. D. T. Wickwire, President Cameron, and G. A. Cunningham.

THIRTY-FIVE YEARS AGO

Comment in the Journal of November, 1921.

What must have been a very early, if not the first, attempt to make silica brick, in Canada, is reported in the *Journal* for November, 1921, in a paper by A. W. McMaster, A.M.-E.I.C.

Wartime restrictions had made it difficult for the steel company to import silica brick from the United States, the usual source of supply, so it experimented with quartzite from three Nova Scotia areas as a raw material. All made good brick, one a superior quality which was better than the imported article.

R. J. Blair, the Forest Products Laboratories' pathologist, wrote on decay in wood in this *Journal.* He emphasized that wood decay was due to one cause only, fungus infestation, thus exploding many popular beliefs and ended his paper with an exhortation: "It is time that the wood-using public realized that . . . trouble (from decay) may be avoided. Long and saisfactory service may be obtained by using wood if it is handled with a knowledge of its inherent properties and of the agencies which bring about its deterioration."

A plea for the immediate the compulsory adoption of the metric system of weights and measures was made before the Border Cities Branch by David A. Molitor, M.E.I.C., and is reported in this *Journal.* Although Mr. Molitor was one of the best-known and influential engineers of the United States, and although his arguments in favour of the metric system are as valid today as they were then, we are still about where we were.

I.J.C. Decision Reported

This Journal included the International Joint Commission's decision as to the division of the waters of the Milk and St. Mary rivers between Canada and the United States, handed down in October, 1921. Western Canada had been waiting impatiently for this, for it had several irrigation schemes with which it wanted to proceed, which were to take water from these rivers.

Sir John Kennedy, K. B., Hon. M.E.I.C., the grand old man among Canada's engineers, died on October 25, 1921, at the age of eighty-three. The author of his obituary in this November *Journal* is unknown to the writer, but whoever he was, he succeeded well in expressing the feelings of Sir John's engineering contemporaries:

"The passing of Sir John Kennedy . . . marks the removal from the engineering profession of one who occupied a warm place in the affections of his fellow engineers and who stood at the pinnacle of his profession in this country. Ripe in years, rich in experience and endowed with those . . . sterling qualities which made him a credit to the profession, his judgment respected and his presence welcomed, his death removes one of those . . . who organized the Canadian Society of Civil Engineers, and is a monument to the service which engineers may render humanity."

The evergreen question of the engineer and his status was never out of print for long. Here we read of a speaker at the Victoria Branch who "gave it as his opinion that to a very large extent . . . (engineers) were themselves responsible for the low standing of the profession in the sight of the public." A variety of views was expressed by speakers at the Toronto Branch — that the engineer was rather too much of a monk; that he needed to be more publicity conscious; that he was the victim of "excessive modesty"; that he paid too little attention to economic problems; and that he was probably the world's worst speaker in public. At any rate, we were willing to criticize ourselves.

A Branch in Lethbridge

A group of members in Lethbridge decided to work for the establishment of a branch there and appointed a committee under the chairmanship of S. G. Porter, M.E.I.C., to take the necessary steps. They expected to start off with a membership of about sixty; in fact, that many had already attended a preliminary meeting to listen to a talk on "Recent Development in Concrete", expounding the next water - cement ratio theory.

R.DEL.F.

Watch For E.I.C. Film Catalogue

In order to fill a need long felt by branch program committees, for a reliable source of information on films of engineering interest, the Engineering Institute has compiled a film catalogue which will be ready for distribution by the time this is read. The catalogue lists not only the films available in the Engineering Institute film library but also films from more than 80 other sources. It contains 40 pages of titles, classified according to the various branches of engineering. Including cross - references, it provides over 1,000 references.

Choosing a film by its title can be very disappointing, like choosing a breakfast food by the colour of its wrapper. For this reason great care was exercised in providing brief and accurate descriptions. The catalogue contains 122 pages of film descriptions, each of which indicates the theme of the film, the method of treatment and, wherever possible, the type of audience for which the film is best suited. The program committee will then be able to make an intelligent selection and not be embarrassed to find, after the showing, that they have been trying to teach the rudiments of arithmetic to experienced engineers.

Other sections of interest indicated by the table of contents are: how to use the film catalogue, procedures on the loan of films and, good projectionist practice. First examination of the catalogue will show that its usefulness will last for many years.

A copy of the catalogue will be mailed to the secretary of every branch immediately.

E.I.C. tieclip, described in last month's Journal. Picture is twice the size of tieclip.

ONTARIO

Seeks Solution Postgraduate Training Problems

The 15,000-member Association of Professional Engineers of Ontario today called upon governments at all levels to give immediate support to Canadian industry in financing the expansion of university facilities to provide adequate post-graduate training.

The Association's stand resulted from a statement made yesterday by Dr. G. N. Patterson, director of the University of Toronto's Institute of Aerophysics, to the effect that the institute was unable to accept even half of this year's applicants for advanced studies due to lack of facilities.

The reputation of the Institute has become such that applications from young scientists in many parts of the world have been received for postgraduate work.

In the Association statement issued today, Merritt W. Hotchkin, Kirkland Lake, Association president, said: "How is Canada to maintain and expand her leadership in the aeronautical field if we are not prepared to provide financial means for adequate postgraduate training?"

"The federal government is spending millions of dollars annually in aircraft development, yet because educational facilities are starved, we find aerophysics director, Dr. Patterson having to make the shameful admission that because of the lack of $500,000, less than half the applicants in this important branch can be accepted."

Need for Immediate Action

"The present grave situation as indicated by Dr. Patterson emphasizes the need for immediate action by the federal government in helping Canadian industry to implement the recommendations made at the recent National Manpower Engineering Conference at St. Andrews, N.B.," Mr. Hotchkin added.

The Association official also referred to a statement made Sept. 24 by Dean R. R. McLaughlin of the University of Toronto's faculty of applied science in which the dean described present facilities for engineering applicants as "completely inadequate". He added the situation was threatening to create a problem with respect to proper training of postgraduate students.

Engineers in the News

George O. Grant has been appointed to the position of deputy roads commissioner for metropolitan Toronto. In this post he will succeed B. W. Bemrose, who will become chief project engineer. The Metro Roads Commissioner is Leslie B. Allan.

Mr. Grant graduated from Queen's University in 1942 in civil engineering and from that date until 1946 served with R.C.E.M.E. Following his discharge he joined the Ontario Department of Highways and was for five years division engineer in Ottawa. In 1954 he was appointed assistant to the deputy minister of Highways in Toronto. In 1955 Mr. Grant was awarded a scholarship by the Canadian Good Roads Association and obtained his master's degree from the University of California.

Fred H. Chandler, of the Hydro-Electric Power Commission of Ontario, has been appointed director of engineering. Mr. Chandler succeeds J. R. Montague, who has retired to the position of consultant.

Mr. Chandler graduated in engineering from the University of Toronto in 1915 and joined the Power Commission in 1918 as an assistant engineer. Until 1943 he took an active part in engineering related to Commission power stations. For the past ten years stations engineer, he was in 1953 named assistant director of engineering.

Arthur Kendall, of the Utah Construction Company of San Francisco, has returned to Korea and is located in Seoul, Korea, where he is associated with the construction of a chemical treatment plant for the purification of tungsten concentrates. The contract is with the Korea Tungsten Mining Company which has one of the largest known deposits of scheelite ore in the Free World. Mr. Kendall's postal address is c/o Utah Construction Company, APO 102, San Francisco, Cal.

Dr. J. W. Rutter, has moved to Schenectady, N.Y., where he is a research associate with the General Electric Research Laboratory.

Dr. Rutter obtained his B.A.Sc. in metallurgical engineering at the University of Toronto in 1948, where he also obtained master's and doctor's degree. Prior to his move to the United States he was engaged in post-doctorate research in physical metallurgy in the department of metallurgical engineering at the University of Toronto.

James W. Britnell, has been appointed County engineer for the county of Huron, with headquarters at Goderich, Ontario. Mr. Britnell graduated in civil engineering from the University of Toronto in 1952 and was formerly with Imperial Oil Ltd., in London, Ontario as asphalt sales engineer.

Dr. W. L. Fairbairn, of Gypsum, Lime & Alabastine, Canada, Ltd., has moved to the Toronto office of the company, where he is chief engineer. Previous to the move Mr. Fairbairn was plant manager at the company's plant on Lakefield Ave., Montreal.

Stanley C. Roberts has moved from St. Catharines, Ont., to Toronto. A member of the engineering staff of H. G. Acres and Company Limited, in his latter position, he now serves Eastern Power Devices Limited, of 29 Wabash Avenue, Toronto.

Michael A. Harrison, has left Toronto for London, Eng., with his wife, to take up studies at the London School of Economics under the Athlone Fellowship. During his stay in England Mr. and Mrs. Harrison will reside at 13 Norfolk Place, Welling, Kent.

Mr. Harrison, who graduated in electrical engineering from the University of Toronto in 1952, has held the post, with the Canadian Broadcasting Corporation, of administrative assistant to the Ontario director of CBC.

Dr. A. E. Berry, of the Ontario Department of Health, is chairman of the newly formed Advisory Health Group of the National Building Code of Canada. He was recently appointed general manager of the Ontario Water Resources Commission.

The Advisory Group will include sanitary engineers from all provinces in Canada, together with medical officers of health, engineers, architects, building inspectors, as well as a representative of the Central Mortgage & Housing Corporation. These specialists have been called together to guide the future development of the National Building Code of Canada as it pertains to matters of public health. It is expected that this group, the only one of its kind in Canada, will become a recognized national authority.

Tullis N. Carter, of Toronto, who is vice-president and general manager of the Carter Construction Co. Ltd., and a member of the council of the Ontario Association of Professional Engineers, is a national vice-president of the Canadian Construction Association for 1956. **Norman A. Eager**, president and general manager of Burlington Steel Co. Ltd., Hamilton, and a past member of council, is honorary secretary of C.C.A. for this year.

C. G. E. Downing, head of the department of agricultural engineering, at the Ontario Agricultural College, Guelph, Ontario, has been appointed chairman of the Education and Research Division of the American Society of Agricultural Engineers. He also serves the council of the American Society for Engineering Education, representing A.S.A.E.

Dr. P. J. Sandiford, of Toronto, was elected vice-president of the Canadian Association of Physicists for 1956-57 at its annual meeting in Montreal.

E. N. Baker, is employed as a sales engineer with the Linde Air Products Company, division of Union Carbide Canada Ltd. Mr. Baker graduated in engineering and business from the University of Toronto in 1954 and has since attained the degree, Master of Business Administration from the University of Western Ontario.

L. J. Lacey, of Toronto, has been appointed associate director of electronics with the management advisory services division of Price - Waterhouse & Company, Toronto. He was formerly mathematician-in-charge of Ontario's Hydro's computing centre and more recently chairman of Hydro's data processing team.

L. A. Coles, of Ontario Hydro has ceased to act as technical and trade training officer, personnel branch, Toronto, and has become operating superintendent of Hydro's east central region, Belleville, Ont.

Faculty Changes at the University of Toronto

A number of staff changes in the engineering faculty of the University of Toronto, announced by president Sidney Smith include promotions to the rank of professor, conferred on **J. E. Reid**, of the department of electrical engineering, to associate professor **Dr. I. I. Glass**, aerophysics, and **Dr. A. I. Johnson**, chemical engineering. Promotion to the rank of assistant professor goes to **Dr. G. K. Korbacher**, also of the aerophysics department.

Dr. G. B. Craig, who has been with the Physical Metallurgical Research Laboratories in Ottawa joins the department of Metallurgical Engineering as assistant professor.

MANITOBA

Publish News-Letter

The Manitoba Association of Professional Engineers began publication of a bi-monthly news - letter, appropriately called, the Manitoba Professional Engineer. Named editor was Gordon T. Christie, managing editor, W. H. Dickens, and E. M. Scott and D. E. Haig, associate editors. Appointments as reporters go to A. R. Towler, of Pine Falls, M. N. Collison, Flin Flon, and R. Diamond, of the faculty of engineering, University of Manitoba.

Membership Mounts

Opening its own office in February 1956, the Manitoba Association has recorded greater activity and interest in Association matters. Since the beginning of 1956, membership has increased forty percent. More applications for membership have been received this year than in the last three years.It is anticipated that membership may reach the 1,000 mark by the end of the year.

September Meeting

In order to profit by a prolonged and uninterrupted meeting, the Council of the Manitoba Association spent forty-eight hours at a camp at Waugh, in the Lake of the Woods area, on Indian Bay, Man., for their September meeting. It is the first time in the history of the Association that Council has met outside the City of Winnipeg.

Golf Tournament

The Manitoba Association held its annual golf tournament for the Sullivan cup at Elmhurst Golf and Country Club on September 11, 1956. Winner of the cup was George Flavell, other winners included Joe Sill, Joe Brako, and Gerry Foley.

Win Four Major Team Matches

Well represented at the annual Dominion of Canada Rifle Association service rifle matches held at Connaught Ranges, Ottawa, in August, were Manitoba's engineers. Four major team matches were won by the Manitoba team — the Provincial match, London Merchant's match, Barlow match and Coates Match, and in addition placed three men on the Canadian Bisley team, which will travel to England next year to shoot in the annual matches at Bisley. Manitoba engineers who participated in the matches were **W. L. Bunting, J. W. Battershill,** and **A. R. Towler.**

Reunion—Class of '46

Graduates of the 1946 engineering class at the University of Manitoba held a very successful reunion in Winnipeg this summer. Dinners, dances and stags were enjoyed by engineers from Fonthill, Ont., Port Arthur, Toronto, Peterborough, Kenora, Yorkton, Sask., Los Angeles, Minneapolis, Erie, Pa., and Oklahoma City. Thoroughly enjoyed by all who attended, the class plans to reunite again in 1966.

Engineers in the News

Larry A. Kay is spending a period of twelve months in New Delhi, India, with Indian and American personnel, on public health projects sponsored by the Colombo Plan. He will return to Winnipeg at the end of his stay.

G. McDermid has been appointed assistant general manager of the Greater Winnipeg Transit Commission. A graduate of the University of Manitoba in electrical engineering, he entered the service of the Winnipeg Electric Company in 1928, employed in maintenance and construction work.

Cornelius Rempel, who has been with the Manitoba Paper Company at Pine Falls for several years, was recently transferred to the head office of the Abitibi Power and Paper Company in Toronto. For the past year and a half Mr. Rempel has been design engineer for the speed-up and modernization program at Pine Falls, which in its present phase, is nearing completion. He will find a similar position in Toronto for the enlarging of the Abitibi "Mission" mill at Fort William, Ont., which will include a new paper machine, additional grinder capacity and much auxilliary equipment.

T. J. Halme has been appointed manager, system sales and application engineering for Canadian General Electric Company Limited, with headquarters in Peterborough, Ont.

Hugh A. MacKay, former plant engineer, Manitoba Rolling Mill Company Limited, has been promoted to the post of superintendent.

BRITISH COLUMBIA

Municipal Engineers' Convention

The fourteenth annual convention of the Municipal Engineers' Division of the Association of Professional Engineers of B.C. concluded its three-day session on Oct. 22, at Penticton, with a record-breaking attendance of 300 delegates and wives from 42 cities and municipalities throughout the province.

Saanich was chosen for next year's

meeting, with municipal engineer H. P. Dawson as chairman of the convention committee. Other members of the 1956-57 executive are R. M. Martin, Vancouver; J. C. Garnett, Victoria; J. Graeme, Esquimalt, and D. P. I. Hawkins, West Vancouver. Continuing members are E. R. Gayfer, past chairman, of Penticton, A. S. G. Musgrave of Oak Bay, honorary secretary, and J. A. Merchant, of Vancouver, secretary-treasurer.

A lively discussion took place during the open forum on Friday afternoon concerning responsibility of the provincial and municipal governments for flood damage. The convention endorsed a resolution recommending the immediate formation of a committee of provincial and municipal representatives to study the problem and recommend immediate steps for its solution.

Panel Discussion Opens Business Sessions

Opening business sessions Thursday morning was a panel discussion on "Frost Damage", led by G. P. Harford of Prince George; E. B. Wilkins of the Department of Highways, Victoria; and D. McMullen of the Meteorological Services branch, Department of Transport, Vancouver. Successful experiments made in Prince George to combat the sustained freeezing condition last year for the city water system, by connecting electric currents to the house mains were discussed as well as various matters pertaining to the frost-warning service to fruit growers.

The second half of Thursday morning's session was devoted to a joint paper on "Services of the Water Rights Branch", delivered by W. A. Ker, deputy controller, and co-authored by T. A. J. Leach, chief engineer of the branch.

Dean R. M. Hardy on "Foundations and Soil Mechanics"

Dean R. M. Hardy, Dean of engineering, University of Alberta, stimulated an animated question period with his paper on "Foundations and Soil Mechanics". He dwelt in considerable detail on a variety of specific problems common throughout the country, such as backfilling in trenches and around buildings, and the question of building on fills. He stated that if a higher standard of backfilling is to be achieved it must be accomplished by compaction. Contrary to widely held opinions about the hazards of construction on fill soil, Dean Hardy maintained that under controlled conditions of compaction, it is possible to maintain a stable material superior in bearing capacity and uniformity to the natural soil at the sight. With reference to road construction, he stated that millions of dollars have been wasted in Canada within the past ten years by building flexible pavements of insufficient strength for the traffic they have had to carry. He expressed conviction that under-building could be as extravagent as over-building, and strongly urged the construction of asphalt surfaces with a safety factor adequate for all foreseeable contingencies.

In later discussion on frost damage to highways he expressed the opinion that the Vancouver area was probably the most difficult in all Canada because of the frequent variations above and below freezing temperatures, and the fact that freezing, when it takes place, is comparatively shallow. A seeming paradox was confirmed by several engineers present, in that underground pipes can be frozen during a thaw because of a thermo-dynamic phenomenon resulting in the sinking of the freezing zone during rising surface temperatures.

Traffic Problems Discussed

Final discussion on the first day centred around a paper on "Traffic Control of Intersections", delivered by F. R. Hole, assistant director of traffic for Vancouver. A great deal of practical detail on methods for determining the precise nature of controls required under different

(Continued on page 1642)

Above, this candid convention shot shows, left to right, R. H. Hardy, dean of engineering, University of Alberta; E. R. Gayfer, superintendent of works, Penticton; R. P. Walrod, B.C. Tree Fruits, Kelowna; Mayor Oscar Matson and Alderman E. A. Titchmarsh, of Penticton.

Some of the members of the newly elected 1956-57 executive of the Municipal Engineers' Division shown below are, left to right, E. R. Gayfer, Penticton; A. S. G. Musgrave, Oak Bay; H. D. Dawson, Saanich; R. M. Martin, Vancouver, and J. A. Merchant, Vancouver.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Dr. A. L. Clark, Hon. M.E.I.C., former dean of science at Queen's University died at Kingston, Ont., on September 19, 1956.

Doctor Clark was born at Worcester, Mass., on February 19, 1873. He received a B.Sc. degree from the Worcester Polytechnic Institute in 1894, and in 1905 was awarded the degree, Ph.D., at Clark University.

His initial experience gained as foreman in charge of the plant and mains for the New Rochelle Gas and Fuel Company at New Rochelle, New York, he later served as professor of physics at Bates College, Maine. Named to the staff of Queen's University as professor of physics in 1906, he was appointed dean of the faculty of applied science at that university in 1920.

Besides carrying on his administrative functions, he made intensive studies in physics and particularly in thermo-dynamics. In 1919 he spent some time in Holland working on thermondynamics problems, at the University of Leyden.

Chairman of the Service Control Board for Queen's Engineering Society, he was in 1947 awarded the Montreal Medal for outstanding contributions to Queen's University. Clark Hall, housing technical supplies and the science students' club rooms, was named after him.

A Fellow of the Royal Society of Canada he was also a member of the National Research Council, a chairman of the University Research Committee, and a member of the Board of Governors of the Ontario Research Foundation.

Retiring in 1943, Dr. Clark continued to serve the university as a consultant on the administrative problems of the faculty.

Dr. Clark joined the Institute in 1920 as an Affiliate Member, and became an Honorary Member in 1922.

Louis D. W. Magie, M.E.I.C., retired works engineer with the Peterborough plant of Canadian General Electric Company Limited, died in Peterborough, Ont. on June 7, 1956.

Born at East Orange, New Jersey, on April 8, 1872, he was educated in the United States, but moved to Canada in 1894, after initial engineering experience gained with two American firms. One of these was the Stanley Electric Manufacturing Company, at Pittsfield, Mass., from which concern he was transferred to the Canadian General Electric Company in Montreal. Works engineer in that city for six years, he first went to Peterborough in 1900 as chief engineer of the plant and held this position during the next thirty-eight years of development of electrical engineering in Peterborough and in Canada generally.

Very largely responsible for the development of the Canadian company, Mr. Magie had, at the time of his retirement in 1938, built up Canadian General Electric engineering to the point where it was stoutly able to stand on its own feet. He was also vitally concerned with organizing the student committee of which he was chairman for years. That committee selected and supervised the training of the university graduates who were looking for the opportunity of postgraduate experience.

He joined the Institute as a Member in 1920 and attained Life Membership in 1950.

Langdon Pearse, M.E.I.C., sanitary engineer for the Sanitary District of Chicago for forty-seven years, died at his home in Winnetka, Illinois, on July 20, 1956.

A native of Boston, Mass., Mr. Pearse graduated from Roxbury Latin School in 1895 and obtained a B.A. degree from Harvard College in 1899. Later, enrolling at the Massachussetts Institute of Technology he studied for a B Sc. degree, attained in 1901, followed by an MSc. degree the following year.

Various civil engineering connections leading to employment on the water and sewage systems of Columbus, Ohio and Oakland, Cal., occupied the first five years of his professional career.

His long association with the Sanitary District of Chicago began in 1909 when he became assistant engineer assigned to the development of a system for dispoal of sewage by artificial treatment. Mr. Peare organized and carried through the program of research which led to development of principles of sanitary engineering. This became the basis on which the present Chicago and suburban system is served.

A member of the Institution of Civil Engineers, the American Institute of Consulting Engineers, he was also a Life Member of the American Society of Civil Engineers; an honorary Fellow of the Institute of Sanitary Engineers, London; an honorary member of the Central States Sewage Works Association; a fellow of the American Public Health Association and the American Academy of Arts and Sciences.

Mr. Pearce was the author of many technical reports and publications.

He was recognized as an expert witness in court cases and served as consultant in matters pertaining to public health and sanitary engineering.

He joined the Institute in 1926 as a Member and attained Life Membership in January, 1956.

John Elmer Mikkelson, M.E.I.C., senior engineer with the Bechtel Corporation, San Francisco, died February 8, 1956.

Born at Salmon Arm, B.C., on October 15, 1918, he attended the University of British Columbia, graduating with the degree, B.A.Sc. in chemical engineering in 1942.

Mr. Mikkelson worked for the Canadian government, on the Inspection Board of the United Kingdom and Canada, before joining the Pearl River Paper and Pulp Mills of Canada. Later he went to the Bahrien Islands in the Near East on an assignment for the Caltex Company. He remained there for four years.

Returning to the United States, he went to work for Arthur G. McKee, Inc., at Union, New Jersey, in 1948. In 1950 Mr. Mikkelson joined Stone and Webster in Boston and later transferred to their Froomfield, Canada, project. He also worked for Hall Inc., of Toronto, as resident engineer for their Sarnia Refinery. In 1952 he joined the firm with which he was associated when taken ill, late in 1955.

Mrs. Mikkelson, also an engineer, has returned to her profession and practices in San Francisco.

Mr. Mikkelson joined the Institute in 1955.

Frank Taylor, M.E.I.C., retired member of the engineering department of the Canadian Pacific Railway, Montreal, died at Westmount, Que., August 27, 1956.

Eighty-three years old, Mr. Taylor was born in Birmingham, Eng., on October 20, 1872. Elucated there, he came to Canada in 1889, joined the C.P.R. and began his career as a rodman with the railway's eastern division.

By 1905 he was an assistant engineer in the chief engineer's office, Montreal. Three years later he went to North Bay as a division engineer. In 1916 the railway company named him right of way and tax agent, a post he continued to fill until, 1938, the date of his retirement. He had served the company forty-nine years.

A Life Member of the Institute since 1938, Mr. Taylor was first known to the Institute in 1898, became an Associate Member in 1904, and a Member in 1910.

Frank Taylor, M.E.I.C.

Personals

News of the Personal Activities of Members of the Institute.

Dr. F. L. West, M.E.I.C. New vice-president of Mount Allison University is Dr. Frank Leslie West, for a number of years dean of the university's faculty of science.

A graduate of Mount Allison and McGill Universities, in civil engineering, Dr. West returned from service with the R.C.E. at the close of World War I and joined the staff of Mount Allison University. Since that time, during thirty-six years of service he has held the posts of professor of civil engineering, professor of engineering, and director of the McClelan School of Engineering, before being appointed dean of the faculty of science in 1949.

Officer commanding the New Brunswick Rangers for ten years prior to World

Dr. F. L. West, M.E.I.C.

War II, Dr. West commanded them in the Active Force from 1939 to 1942. He was later attached to National Defence Headquarters, on the army education staff. In 1945 he became head of the physics department of the Khaki University and commanded the unit until it was disbanded. He retired from the army in 1946 with the rank of lieutenant-colonel.

Long an active member of the Institute and a Life Member since 1955, Dr. West served the executive of the Moncton Branch in 1937, became vice-chairman in 1938, and the following year held office as chairman.

He is a member of the Association of Professional Engineers of New Brunswick and is an associate member of the American Society of Civil Engineers.

In 1952 the honorary degree of Doctor of Engineering was conferred on him by the Nova Scotia Technical College.

As a practising engineer, Dean West has at various times been associated with the Canadian Northern Railways, the Imperial Munitions Board, and the Canadian National Railways. He was engineer for the town of Sackville for a ten-year period, 1929 to 1939. He has been consultant on numerous surveying and engineering projects.

Dr. H. W. McKiel, M.E.I.C., vice-president of Mount Allison University since 1949 has retired from the faculty after forty-three years of service.

In 1908 a Queen's University graduate with a B.A. degree in chemistry, he went on with studies leading to the B.Sc. degree, awarded him at that University in 1912. Following this he did post-graduate work and also lectured at Queen's before beginning his career with Mount Allison University in 1913, as professor of mechanical engineering. Chosen as Brookfield Professor of Engineering in 1920, his other appointments were those of secretary of the faculty of applied science, dean of that faculty, and dean of the faculty of science, to which post he was named in 1934. He also served in a consulting capacity to a number of prominent maritime industries and gave his time to professional development and engineering education while carrying out his regular duties.

Awarded the honorary degree of Doctor of Laws in 1943, he was called upon to receive the degree of honorary Doctor of Engineering at the Nova Scotia Technical College during this year's convocation exercises.

An active Rotarian throughout his life, he has successively held the positions of maritime district governor, Canadian director and third vice-president of Rotary International.

He has behind him the record of councillor of the Institute in 1927, vice-president, 1936-37, and in 1939 was honored in holding office as president of the Institute.

Portrait of Dr. H. W. McKiel unveiled at 1956 convocation in May, by Dr. R. E. Heartz.

Dr. R. L. Hearn, M.E.I.C., chairman of the Hydro-Electric Power Commission of Ontario, took part in the annual dinner of the Institution of Mechanical Engineers in London, Eng., on October 18, 1956. He responded to the toast to the guests. The toast was proposed by Professor Saunders, vice-president of the Institution, along with a toast to the Institution which was proposed by Sir Brian Robertson and replied to by the president of the Institution.

N. F. Moodie, M.E.I.C., has left the National Defence Headquarters, R.C.N., at Ottawa, to take up a position with Dutton-Williams Brothers Limited at Calgary.

Mr. Moodie graduated from the University of British Columbia in 1936 with a B.A.Sc. degree in mining engineering and then worked for Canadian Mining and Smelting, Sudbury, Ont., and the International Nickel Company. In 1940 he joined the United Kingdom Technical Mission and the British Admiralty Technical Mission in the United States, and remained in that work for three years. In 1944 he became an R.C.N.V.R. armament supply officer and officer in charge of armament depots. Since 1946 he has held a number of posts with the R.C.N., which include those of ordnance officer with H.M.C.S. Magnificent and H.M.C.S. Sioux, resident naval ordnance overseer at

Vancouver, and staff officer, ordnance personnel, at Ottawa.

J. A. Vance, M.E.I.C., president of the Institute in 1950, has been awarded the Julian Crandall Trophy at a ceremony held recently at London, Ont. The award is made annually to the Canadian who has contributed most to the conservation of Canada's natural resources, soil, forest and water.

Mr. Vance, who has an engineering business in Woodstock, Ont., has been chairman of the Board of the Canadian Forestry Association for the last three years. A member of the Association for more than seventeen years, he was intrumental in the formation of the Ontario branch of the Canadian Forestry Association during 1947 and 1948, and was its president for three years. His work in this branch resulted in an effective educational campaign now extending to some one million persons each year in conservation and forest fire prevention.

He is also a keen supporter of the Canadian Tree Farm Movement which encourages farmers and woodlot owners to grow trees for profit and for conservation measures by employing recognized forest management principles.

In summing up his attitude on forest conservation at the National Forestry Conference at Winnipeg recently, Mr. Vance declared, "Since the forests represent the largest single item of our national resources, I believe that every Canadian should be interested in doing everything possible to promote and assist in the proper management of this country's forest resources."

Mr. Vance is a native of Tavistock, Oxford County, Ont., and a graduate of the Univerity of Toronto in civil engineering.

In 1953 Mr. Vance was awarded the Sir John Kennedy Medal of the Institute in recognition of outstanding merit in the profession and noteworthy contribution to the science of engineering and to the Institute.

W. A. Mather, Hon. M.E.I.C., chairman of the board of the Canadian Pacific Railway, was recipient of an honorary Doctor of Laws degree at McGill's Founder's Day convocation on October 5, 1956.

Mr. Mather, whose career with the C.P.R. began at the age of eighteen, was in 1942 elected vice-president of the company, and six years later, in 1948, became the seventh president of the C.P.R. and the first civil engineer to hold this office. In May 1955 he was appointed chairman.

G. G. M. Eastwood, M.E.I.C., of the Spruce Falls Power and Paper Company in Kapuskasing, Ont., has been transferred to the firm's head office at Neenah, Wisconsin, where he is working in the automation-instrumentation section of the research and development division of Kimberley-Clark.

Mr. Eastwood has, therefore, been obliged to resign from the post of councillor for the North Eastern Ontario Branch of the Institute, to which he was this spring elected to serve a two-year term.

John W. Tomlinson, M.E.I.C., has been appointed vice-president-engineering of Northern Ontario Natural Gas Company Limited, Toronto.

Last year Mr. Tomlinson was named assistant sales manager of Trans-Canada Pipe Lines Limited in Calgary, with offices located at Trans-Canada's sales headquarters in Toronto. Previous to that, Mr. Tomlinson had five years' experience with the Saskatchewan Power Corporation and was one of the leaders in the development of the Saskatchewan natural gas industry. His record in introducing natural gas to cities, towns and villages in Saskatchewan, as general manager of the Saskatchewan Power Corporation led to his appointment to his present position. Mr. Tomlinson's responsibilities will include design and construction of transmission and distribution facilities, as well as industrial gas sales, contracts, gas rates and measurement and despatching and operation of the system.

J. W. Tomlinson, M.E.I.C

Mr. Tomlinson is a graduate of the University of Manitoba.

J. R. Mills, M.E.I.C., formerly secretary of the Foundation Company of Canada Limited, has been appointed a vice-president of the organization.

Mr. Mills joined Foundation Maritime Limited in 1941 as an engineer. He was appointed secretary of the Foundation Company of Canada Limited in 1951. He is president and a director of Geocon Limited, a director of the Construction Equipment Company Limited, assistant secretary of Foundation of Canada Engineering Corporation Limited and secretary of Chemiebau Canada Limited.

R. J. Askin, M.E.I.C., of the Abitibi Power and Paper Company, Limited, Toronto, has become vice-president of development and engineering with the firm.

A past-councillor of the Institute, Mr. Askin has been associated with the pulp and paper industry for many years, join-

Labatt's Brewery Installs . . .

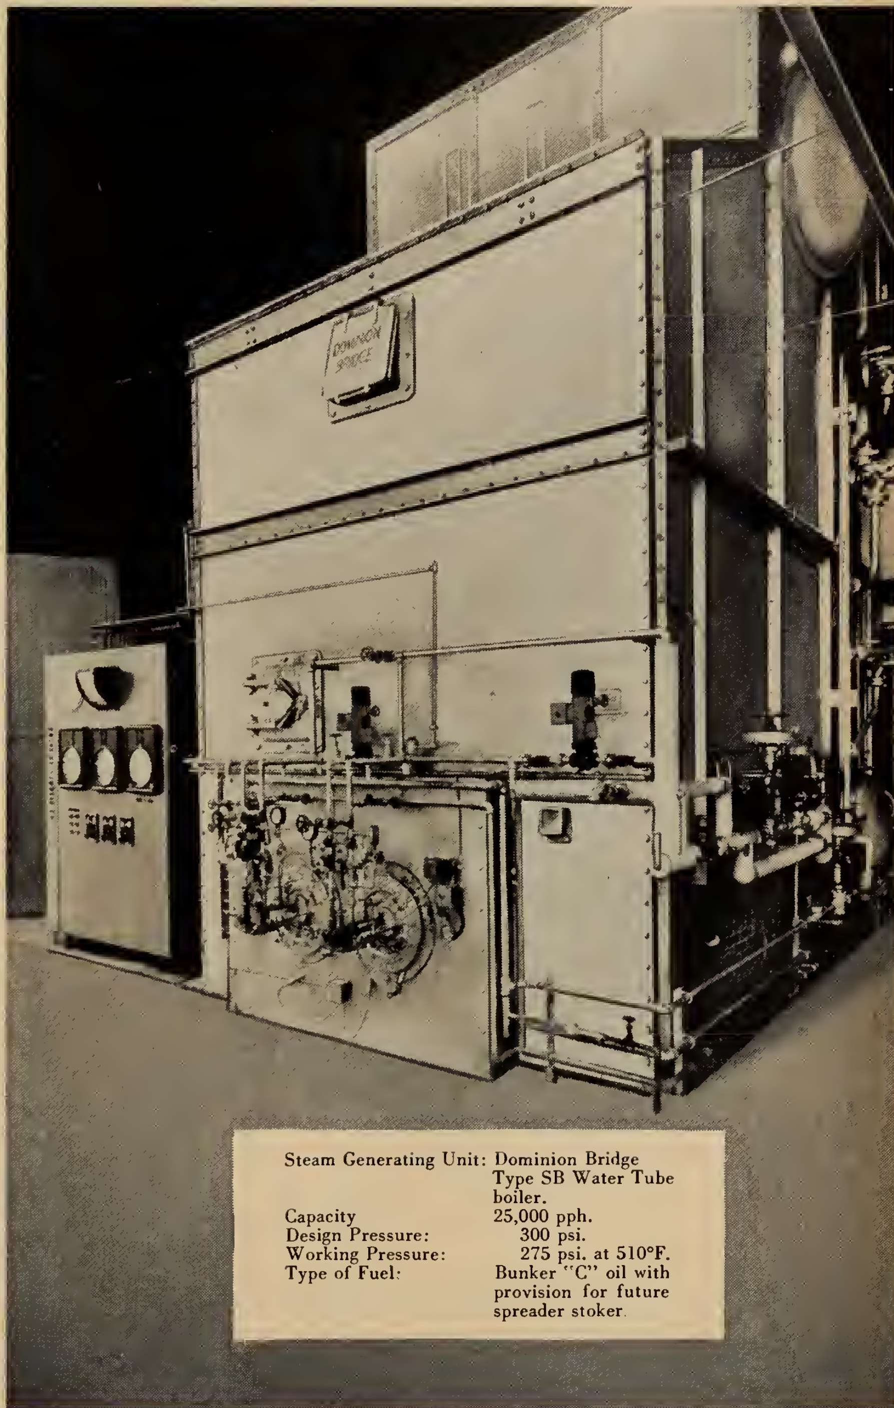
Economy of operation and flexibility in meeting varying load conditions are two important reasons why Labatt's Brewery Ltd. installed Dominion Bridge boilers for its new brewery in Ville LaSalle, P.Q.

The Dominion Bridge Type SB Water Tube boiler shown here supplies super-heated steam to drive a back pressure steam turbine used as a prime mover in the refrigeration operations, and for process and heating requirements. Labatt's also purchased a Dominion Bridge Scotch Dry Back boiler of 9000 pph. capacity for standby service. It is a portable unit which can be used in other plants when steam loads require the use of an additional generator.

Provision has been made in the design of the building for the installation of additional Water Tube boilers.

Auxiliary equipment, consisting of oil pumping and heating set, oil burners, forced draft and induced draft fans with drives, metering and automatic combustion control equipment, deaerating feed water heater, feed pumps, water softeners and continuous blow-off equipment was also supplied and installed by Dominion Bridge.

Information on Dominion Bridge Type SB Water Tube boilers is contained in Catalogue No. B [illegible]-113. Copy will be sent to you gladly, on request.



Steam Generating Unit:	Dominion Bridge Type SB Water Tube boiler.
Capacity	25,000 pph.
Design Pressure:	300 psi.
Working Pressure:	275 psi. at 510°F.
Type of Fuel:	Bunker "C" oil with provision for future spreader stoker.

ing the Fort William Paper Company, Fort William, Ont., in 1923, shortly after a Queen's University graduation in mechanical engineering. With Abitibi Power and Paper Company, Limited since its merger with the Fort William company, he was in 1930 appointed manager of the Thunder Bay division. In 1942 he moved to Toronto as assistant manager of mills. Until his recent appointment, Mr. Askin held the office of vice-president manufacturing.

L. H. Laffoley, M.E.I.C., of the Canadian Pacific Railway has been appointed engineer of hotels, with headquarters at Montreal.

Mr. Laffoley, whose railway service dates to 1919, graduated from McGill University in 1916 with a B.Sc. degree in civil engineering. He served overseas with the Royal Flying Corps during the closing years of World War I. Employed as draughtsman during his early years with the C.P.R., he became an assistant engineer in 1923, and assistant engineer of buildings in 1937. Named engineer of buildings in 1946, he held that position until his present appointment.

L. H. Laffoley, M.E.I.C.

J. G. Sutherland, M.E.I.C.

J. G. Sutherland, M.E.I.C., has been named engineer of buildings for the Canadian Pacific Railway, with headquarters at Montreal.

Mr. Sutherland joined the C.P.R. in 1930, on graduation from the University of Toronto, with a B.ASc degree. Through the thirties he served the company as transitman, assistant engineer, and division engineer, at various points in Eastern Canada. In 1943 he became assistant engineer in the chief engineer's office at Montreal, and the following year was assistant engineer of track.

Since 1946 Mr. Sutherland has been assistant engineer of buildings.

G. A. Morison, M.E.I.C., has received the appointment of assistant engineer of buildings with the Canadian Pacific Railway at Montreal.

Mr. Morison is a 1943 graduate of the University of Manitoba, with a B.Sc. degree in civil engineering.

In 1946, after two years' service with the Canadian Army he joined the C.P.R. at Montreal, working as a building inspector. Later that year he was transferred to the chief engineer's office. In 1948 he received the appointment he has held until the present, which was that of assistant engineer at Montreal.

G. A. Morison, M.E.I.C.

E. G. Gagnon, M.E.I.C., was recently appointed contract services manager of Northern Electric Company Limited, following service as sales manager of the communications equipment division.

With the company since 1928 he has had experience as equipment service superintendent, in the communications equipment division. During the war, he was superintendent of government sales and was chief engineer of the communications equipment division for more than five years.

Mr. Gagnon is a graduate of McGill University in electrical engineering.

G. D. Lewis, M.E.I.C.

G. D. Lewis, M.E.I.C., secretary of Dominion Engineering Works Limited, has been transferred to the paper machinery division of the company. He becomes research engineer in product and market planning. In his new capacity Mr. Lewis will be in contact with all phases of manufacturing in the pulp and paper industry with the objective of co-ordinating Dominion Engineering's expanding research and production facilities to the needs of that industry.

Mr. Lewis is a graduate of the Nova Scotia Technical College and Dalhousie University and has been with his present firm since 1946.

R. T. Mactavish, M.E.I.C., of Brown Boveri (Canada) Limited has joined the organization of Gordon Russell Limited at Vancouver under an arrangement which augments the engineering and sales services of Brown Boveri Products to British Columbia clients.

Mr. Mactavish has been with the Brown Boveri organization for three years during which time he has received training in the company's factories in Switzerland and Canada, and latterly served as a sales engineer at head office, Montreal.

A native of Cumberland, Eng., he is a graduate of Faraday House Electrical Engineering College and Oxford University.

R. H. Stokes-Rees, AFFIL. E.I.C., president of Hydrotechnic Limited, Montreal, has been elected a director of the Abitca Lumber and Timber Corporation Limited, Montreal. He has also been appointed a vice-president of the firm.

Named a vice-president of the Kaiser Engineers Division of Henry J. Kaiser Company (Can.), Ltd., Montreal in 1953 he also became a director with Rubenstein Brothers in 1955.

Brig. Noel D. Lambert, C.B.E., M.E.I.C., of Vancouver has been appointed a director of Central Mortgage and Housing Corporation.

A director of the Corporation from its inception in 1946 until 1951, he is also president of Northern Construction Com-

* There's been a
Revolution in Rubber

Can POLYSAR Bring to Life Your Product Ideas?

Yes, Polysar *can* give reality to many product ideas, previously impractical with other materials. Why? Because *there's been a revolution in rubber.* Now . . . with Polysar chemical rubbers and the help of Polymer research chemists . . . you can have a rubber tailor-made to fit the exact requirements of *your* product idea.

Whether rubber now enters into your products or not, you owe it to yourself to investigate what Polysar can do for them. You'll find—as have manufacturers in 40 countries—that Polysar can make a world of difference.

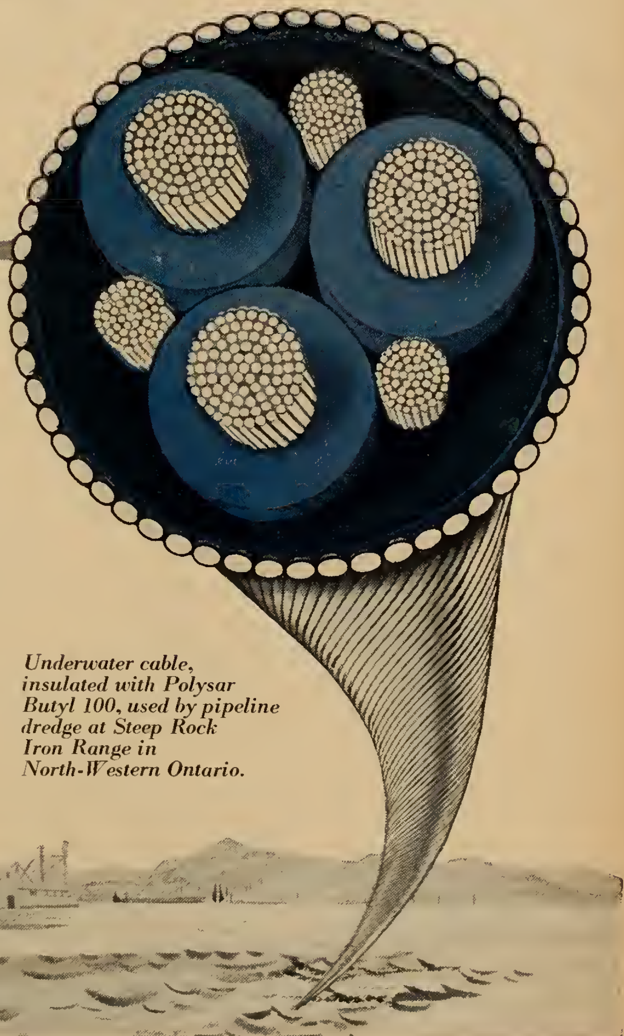
Polymer Corporation Limited, makers of Polysar rubbers, has the largest industrial research and development division in Canada. Why not make full use of these facilities and learn how Polysar can improve present products and create new ones?

Write to our Sales and Technical Service Division, Sarnia, Canada.

Here's How POLYSAR Beat a Critical Insulation Problem

When Northern Electric Company Limited was looking for an insulation rubber—to be used in underwater electric dredge cables subject to extremely rugged treatment—they chose Polysar Butyl 100. This special type of Polysar gives high resistance to ozone, water, heat and cold; provides excellent dielectric properties; has good flexibility; and is readily processed.

If you, too, have a critical rubber problem, Polymer will be glad to help find the solution.



Underwater cable, insulated with Polysar Butyl 100, used by pipeline dredge at Steep Rock Iron Range in North-Western Ontario.

pany and J. W. Stewart Limited, Vancouver.

Brig. Lambert graduated from the University of British Columbia in civil engineering, served with the R.A.F. during World War I and in the second conflict was in 1941 appointed director of engineering services at National Defence Headquarters. A year later he was named Deputy Quartermaster General and promoted to the rank of brigadier.

D. C. Jones, M.E.I.C., has been chosen for the office of chairman of the Calgary Branch of the Institute for the term 1956-57.

A native of Calgary, and educated at the University of Alberta and McGill University, he holds a B.Eng. degree in mechanical engineering from the latter college, gained in 1937.

Following service in the R.C.A.F. Joint Air Training Plan, he spent a short time with Dominion Bridge Company in Calgary and then joined the Canadian Western Natural Gas Company where he remained for a period of six years, associated with the special projects department. In 1951 he moved to the consulting firm of Denton-Spencer Company and spent three years as gas project engineer.

Mr. Jones' present professional capacity is that of superintendent of gas operations with Hudson's Bay Oil and Gas Company Limited at Calgary. He is also a director of the Alberta Gas Trunk Line Company.

Joseph A. Chalmers, M.E.I.C., who has served on the City of Ottawa engineering staff since 1953, resigned from this position in April and has established a practice in that city as a consulting engineer specializing in municipal works.

Mr. Chalmers came to this country in 1952 after extensive experience in municipal engineering in Great Britain. A Corporate Member if the Institution of Structural Engineers and the Institution of Municipal Engineers since 1944, he had his education at the College of Technology, Leeds, Eng., and at Leeds and Glasgow University.

J. M. den Hartog, M.E.I.C., has accepted a position with the Aluminum Company of Canada, at Arvida, Que.

Mr. den Hartog was previously a junior engineer with the Canadian Natural Gas Company at Calgary.

Commodore Frank Freeborn, R.C.N., M.E.I.C., previously principal naval overseer of the Montreal area, has been recently promoted to his present rank and elevated to the position of naval-constructor-in-chief for the Royal Canadian Navy, at Ottawa.

In his former capacity Commodore Freeborn was in charge of the construction of H.M.C.S. St. Laurent.

Prior to that he was manager of the construction department of the Department of National Defence, Naval Service at H.M.C. Dockyard, Esquimalt, B.C.

H. S. McCleave, M.E.I.C., who has been associated with the New Brunswick Telephone Company Limited, at St. John, N.B., for a number of years, has been transferred to Moncton, N.B., as an engineering supervisor, outside plant engineering department. He is concerned with the planning, detailing and estimating of outside plant work for the eastern section of New Brunswick, from the Nova Scotia boundary to Campbellton.

Mr. McCleave is a 1947 graduate of the University of New Brunswick, in electrical engineering.

A. P. Balodis, M.E.I.C., formerly of the Department of National Defence, Ottawa, has joined the staff of the Polymer Corporation Limited, at Sarnia, Ont., and works as a senior engineer in the design section of the engineering and construction department.

Mr. Balodis worked as a construction engineer with F. C. McRostie, consulting engineer and surveyor, in Ottawa, in 1953.

He came to this country from Latvia, where in 1940 he was awarded an engineering diploma from the University of Latvia.

R. M. Wickwire, M.E.I.C., building engineer with the Canadian National Railways, Atlantic region, has been elected chairman of the Moncton Branch of the Engineering Institute.

• PERSONALS

A native of Yarmouth, N.S., he was educated there, at Acadia College, and at the Nova Scotia Technical College. He received a B.Eng. degree in civil engineering at N.S.T.C. in 1947.

Following graduation Mr. Wickwire joined the Canadian National Railways an an instrumentman at Campbellton, N.B. He remained there a year before being transferred to Moncton, where he was at first engaged to work on the staff of the building engineer. He was appointed to his present position in 1953.

Maintaining an interest in affairs of the Institute since joining as a Junior Member in 1949, Mr. Wickwire has also served a term on the Branch executive.

Percy C. Toft, M.E.I.C., is now employed with the Canadian General Electric Company Limited, civilian atomic power department, Peterborough, Ont.

A University of New Brunswick graduate, class of 1949, Mr. Toft has previously been associated with Imperial Oil Limited, Sarnia, Ont.

E. H. Fisher, M.E.I.C., of the Canadian National Railway has been named manager of work equipment with the company's engineering department in Montreal He was previously system superintendent of mechanical maintenance for the road transport department of the railway, which appointment he received in 1953.

He is a 1944 graduate in mechanical engineering from the University of Saskatchewan.

J. R. Harvey, M.E.I.C., formerly western branch manager of Babcock-Wilcox and Goldie-McCulloch Limited at Calgary, has been transferred to head office at Galt, Ont.

Graduating from the University of Toronto with a degree in mechanical engineering in 1945, Mr. Harvey joined Babcock-Wilcox and Goldie-McCulloch Limited at Galt, as a junior engineer engaged in design and service work. Transferred to Montreal as an engineer in 1953 he later that year became manager at Calgary.

R. L. Sanders, M.E.I.C., of the firm of Babcock-Wilcox and Goldie-McCulloch Limited, Galt, Ont., has received the appointment of manager of the firm's western branch at Calgary.

With the firm in Galt, in 1952, Mr. Sanders worked as an erection superintendent. Prior to that time he was associated with the Power Corporation of Canada Limited, at Montreal.

He is a 1941 graduate in mechanical engineering from Queen's University.

A. B. Danard, M.E.I.C., has been appointed sales engineer with the firm of Babcock-Wilcox and Goldie-McCulloch Limited in their eastern branch offices at Montreal.

A 1945 graduate of the University of Toronto in mechanical engineering, he spent a short period of time with the Royal Canadian Artillery and then joined Foster Wheeler Limited at Montreal as a sales engineer, where he has been employed until recently.

A. L. Berry, M.E.I.C., is principal pipeline engineer with the Westcoast Transmission Company Limited, Calgary, Alta.

A University of Alberta graduate in civil engineering, Mr. Berry has also held affiliations with Northwestern Utilities Limited, and Denton Spencer Company Limited, both at Edmonton.

Frank Hollingworth, M.E.I.C., of the University of Manchester, class of 1951 in civil engineering, has gone to Afghanistan as an assistant field engineer with Morrion Knudsen Afghanistan Inc., on an irrigation project.

Last year he spent some time as a design engineer with P.F.R.A., at Regina, Sask., and with the B.C. Engineering Company Limited, Vancouver.

J. G. McLellan, M.E.I.C., of the Northern Electric Company Limited, formerly manager of and also a director of the Fort William branch of the firm, has been transferred to Montreal where he acts as communication and export sales manager of the wire and cable plant.

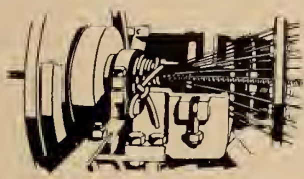
Employed by Northern Electric since 1936 and his graduation from the University of British Columbia, he has served the firm in Vancouver, Calgary and Montreal and went to Fort William in 1954.

In February 1954, BICC were awarded a contract by the British Columbia Electric Company to supply and lay a submarine power link between Vancouver Island and the mainland.

MADE BY BICC

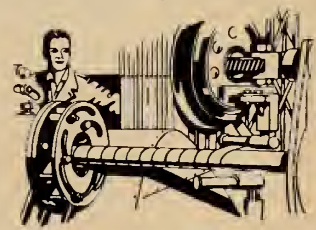
The contract required some 91 miles of 138,000-volt, gas-filled cable—*including five continuous lengths of over 15 miles.*

A special single-core gas-filled cable was designed with a hollow duct conductor, for operation at a pressure of 300 lbs. per square inch. This was necessary in order that the cable's gas pressure should always exceed the water pressure at the bottom of the Georgia Strait, some 600 feet deep in places.



The cable was sheathed in lead alloy and reinforced against internal gas pressure by bronze tapes. A layer of vulcanized rubber protected the tapes against corrosion. Finally, the cable was armoured with galvanized steel wires for mechanical protection and to take the strain during coiling and laying operations.

With the design settled, special plant was installed at a BICC Group factory in Manchester close to the docks, and production commenced.



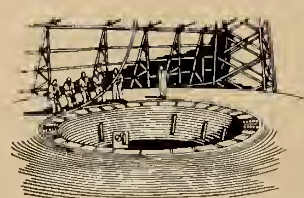
15 mile CONTINUOUS LENGTHS of SUBMARINE POWER CABLES

MADE & LAID by BICC

LAID BY BICC

From Manchester to Vancouver (via Panama) it is some 8,700 miles. But the first few hundred yards of this journey presented one of the greatest problems . namely, moving the very long and heavy lengths of cable (some weighing 800 tons) from the factory to the ship.

A 45 feet high gantry with power winches was built to carry the cables, first to the coiling down shed for testing and storage, and later, when all the cables had been made, over the docks area to be loaded aboard the "Ocean Layer." This up-to-date, 4,600 ton vessel is the second largest cable-layer in the World. Equipped with a Pleuger active rudder, housing an auxiliary propeller, she has the extreme manœuvrability essential for cable laying. The long journey to Vancouver was uneventful. Laying operations were successfully carried out under the control of BICC engineers, who also terminated and tested the installation. Thus, from start to finish, design, development, manufacture, transportation, and installation were undertaken or controlled by BICC—*the only organization with the facilities to manufacture long, continuous lengths of power cable and to install them anywhere in the World!*



Now, after only two and a half years, this joint Anglo-Canadian venture has been completed, on schedule. Thanks to the courage and enterprise of the British Columbia Electric Company and the engineering skill of the BICC Group, the swiftly growing and highly important timber, pulp and paper industries of Vancouver Island can now obtain adequate power from the hydro-electric generating stations on the mainland.

BICC CABLES THE name for cables-everywhere

BRITISH INSULATED CALLENDER'S CABLES LIMITED, 21 Bloomsbury Street, London, W.C.1, England

• PERSONALS

Col. C. W. Jones, M.E.I.C., commandant of the Royal Canadian Electrical and Mechanical Engineers School, Kingston, is the 1956-57 chairman of the Kingston Branch of the Institute.

Col. Jones, who was born in Ottawa, and attended schools in that city, received his engineering training at Queen's University and graduated with a B.Sc. degree in mechanical engineering in 1939. Then, prior to joining the army, he was, for a short time associated with Babcock-Wilcox and Goldie-McCulloch. During the war he served in the Royal Canadian Ordnance Corps, as an ordnance mechanical engineer, and later transferred to the Royal Canadian Electrical and Mechanical Engineers. He served in No. 2 Army Field Workshop and in Light Aid Detachments, Second Field Regiment of the R.C.A., and the Second Canadian Infantry Brigade in England, then with the Directorate of Mechanization, Ministry of Supply, and finally with the Inspection Tanks and Mechanical Transport Inspection Board of Canada as the assistant director.

Since the war he has held the appointments of assistant director and deputy director of electrical and mechanical engineering, at Army headquarters, prior to his appointment as commandant of the R.C.E.M.E. School at Kingston.

J. N. Ford, M.E.I.C., for the past five years chief electrical engineer with Canadian Utilities, Edmonton, has been appointed manager of operations of the electric utility.

A native Albertan, from Calgary, he is a University of Alberta graduate, class of 1934, in electrical engineering, and was at an earlier date associated with the Calgary Power Company Limited, at Calgary.

W. M. Brenan, M.E.I.C., formerly on the staff of Wiggs, Walford, Frost and Lindsay, consulting engineers in Montreal, has joined Giffels and Vallet of Canada, Limited. Attached to Polymer Corporation, Limited, at Sarnia, Ont.; his position is that of project engineer.

Mr. Brenan is a University of New Brunswick graduate of the class of 1941 in civil engineering.

J. L. Hope, M.E.I.C., is with the Department of National Defence, inspection services branch, in Ottawa.

Last year Mr. Hope was project development engineer with the English Electric Company at St Catharines, Ont.

D. R. Beckett, M.E.I.C., has accepted a position with North West Power Inc., Ottawa.

Resident in Port Arthur, Ont., for a number of years, Mr. Beckett has been associated with the C. D. Howe Company Limited, and the Marathon Paper Mills of Canada Limited.

He graduated from Queen's University in 1945 with a B.Sc. degree in civil engineering.

Col. C. W. Jones, M.E.I.C.

Eric F. Walker, M.E.I.C., has joined the staff of Atomic Energy of Canada Ltd., commercial products division, at Ottawa.

Mr. Walker has within the last few years been employed with Picker X-ray Engineering Limited as maritime manager at Halifax, and with the medical X-ray division of Philips Industries Limited, Toronto, as a divisional manager.

J. E. Reardon, M.E.I.C., of the Public Service Commission, Halifax, has been elected secretary-treasurer of the Halifax Branch of the Institute

A native of Halifax, Mr. Reardon graduated from the Nova Scotia Technical College in 1946 with a B.Eng. degree.

Herve Gauvin, M.E.I.C., has been named to the post of general manager of A. Belanger Ltd., at Montmagny, Que.

With Clare Brothers and Company Limited, as general manager at Preston, Ont., for some time, he has been associated with his present company previously as general superintendent from 1937 until the onset of World War II, at which time he entered military service.

A. Campbell, M.E.I.C.

J. S. Campbell, M.E.I.C.

A. Campbell, M.E.I.C., since 1952 vice-president of Dominion Bridge Company Limited and manager of its western division, has been elected president of the Manitoba Bridge and Engineering Works Limited and the Manitoba Rolling Mill Limited.

Beginning an engineering career with Western Steel and Iron Works, Winnipeg, Mr. Campbell underwent millitary service in World War I and then attended McGill University. He graduated in civil engineering in 1924, received an M.Sc. degree from that University two years later, and in 1927 joined Dominion Bridge Company Limited's contract department. Later assigned the duties of contract engineer, western division, he held this position until his appointment as vice-president and manager of Dominion Bridge Company Limited's western division.

J. Stewart Campbell, M.E.I.C., has been appointed manager of the Manitoba Bridge and Engineering Works Limited.

Mr. Campbell, who has spent his entire engineering career with Manitoba Bridge and Rolling Mill Companies, has held a number of positions since graduating from McGill University in 1937.

Until his recent appointment Mr. Campbell's duties were those of secretary and assistant general manager of both companies. He will however continue to hold the office of secretary.

M. B. Allan, M.E.I.C., has accepted a position with the Toronto firm of Cassels, Desfries and DesBriss.

Mr. Allan was previously associated with the C. D. Howe Company Limited at Montreal a a mechanical engineer.

• PERSONALS

He is a University of Toronto graduate, class of 1946.

Alex J. Branch, M.E.I.C., has been elected chairman of the Lethbridge Branch of the Institute for the 1956-57 season.

Originally from London, Eng., Mr. Branch began his professional career as assistant to an architect and a surveyor

Alex J. Branch, M.E.I.C.

in that city. After a few years experience he came to Canada in 1910 as an assistant to the town engineer at MacLeod, Alta, on waterworks and sewers construction. Then came World War I and a five year tour of duty overseas with the Canadian Engineers. In 1919, returning to Alberta, he took a position as leveller and topographer with the Dominion Irrigation Department. The following year he became instrumentman and inspector on the construction of the Lethbridge Northern Irrigation District. Named water master of the District, in 1923, he was promoted to assistant engineer in 1939, and has remained in this capacity until the present.

Mr. Branch previously served as chairman for the Lethbridge Branch of the Institute in 1939.

Ralph E. Crysler, M.E.I.C., a 1949 graduate of the University of Toronto, and formerly of the firm of M. M. Dillon and Company Limited, London, Ont., has accepted a position with W. S. Atkins and Associates Limited, of Toronto.

A. F. Bauer, M.E.I.C., has accepted a position as project engineer with Mannix-Stolte, at the Cheakamus Powerhouse, Squamish, B.C.

Mr. Bauer obtained his engineering training in Vienna where he was awarded a diploma in mechanical engineering in 1948. Since coming to this country he has held professional affiliations with the B.C. Power Commission, Victoria, and H. A. Simons Limited, Vancouver, both in 1955.

Max Schuller, M.E.I.C., has joined the staff of the Catalytic Construction Company of Canada as a project engineer at Sarnia, Ont.

A McGill University graduate in chemical engineering, his professional affiliations have included Defence Industries Limited and Canadian Arsenals Limited.

R. O. Jonasson, JR.E.I.C., a 1949 civil engineering graduate of the University of Manitoba, has joined Dominion Bridge Company, sales department, Winnipeg.

Mr. Jonasson was with the firm previously for three years after receiving his degree, and was engaged in the detailing and designing of structural steel. In 1952 he went to Trail, B.C., working until recently on a smelter revision project with Canadian Mining and Smelting Company Limited.

A. F. Tiesdell, M.E.I.C., is employed with the Sarnia Board of Education as

Mr. Giovannetti obtained his engineering training at the Nova Scotia Technical

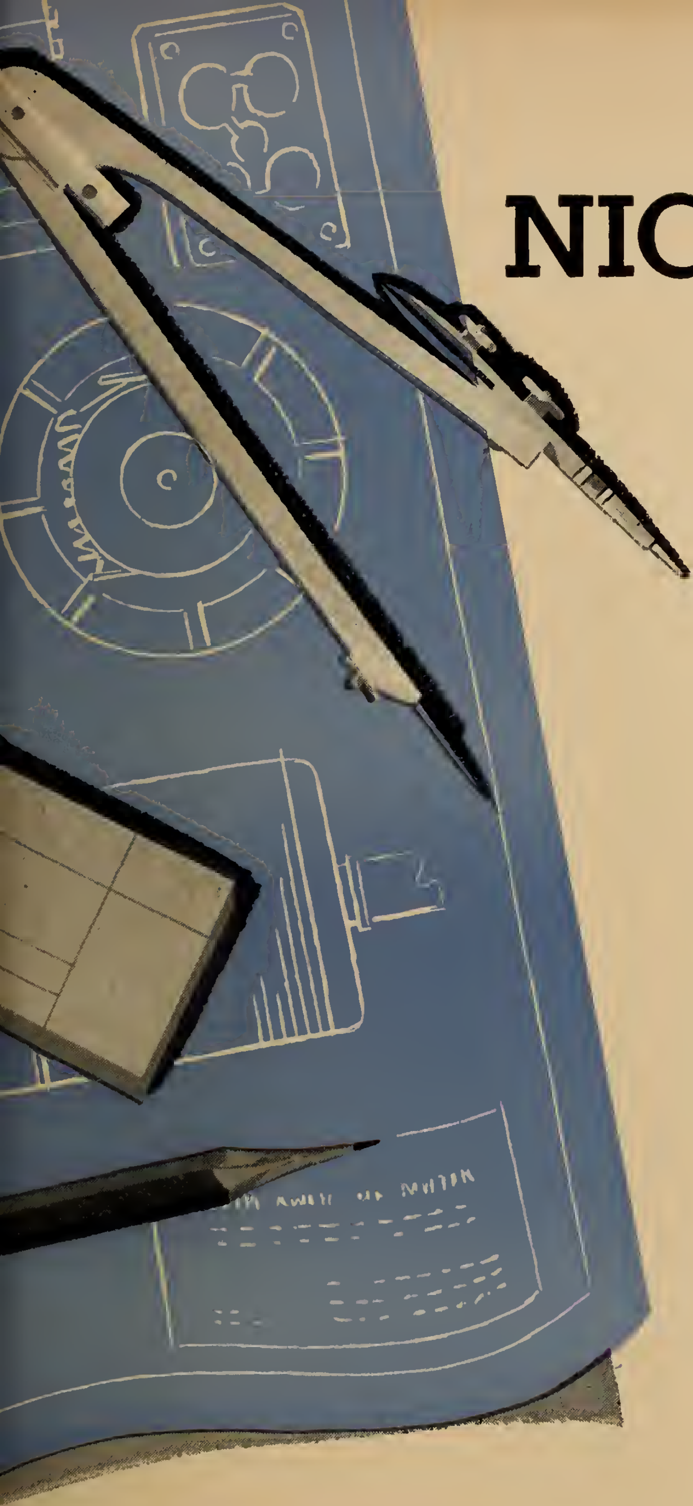
Corrections

It was reported in the Personals column, October issue, that A. M. Clark, M.E.I.C., of the Canadian Blower and Forge Company Limited, Toronto, had moved to the Hamilton office. This statement was incorrect. There is no change in Mr. Clark's position as branch manager for the company at Toronto. The error arose from a misinterpretation of mailing instruction.

In the October issue of the Journal it was reported that R. E. Chamberlain is employed with Bailey Meter Company in Montreal. This is correct.

However there are two Junior members of the Institute by the name of R. E. Chamberlain, both of whom now work in Montreal. Unfortunately, biographical material used for the Personal was confused, and does not pertain to Robert Ernest Chamberlain as it should but rather to Ross Edwin Chamberlain of Dominion Bridge Company Limited.

The Journal regrets this error and extends apologies to both gentlemen. A corrected Personal will appear in the December issue.



• PERSONALS

College, graduating with a B.Eng. degree in mechanical engineering in 1952.

D. H. Smith, JR.E.I.C., has joined the staff of Consolidated Mining and Smelting Company of Canada Limited, at Trail, B.C.

Mr. Smith, who graduated from the University of British Columbia in 1952, with a B.A.Sc. degree in mechanical engineering, has since been affiliated with the Electric Reduction Company of Canada Limited in Toronto.

R. B. Kerr, JR.E.I.C., has been appointed manager of Cooper-Bessemer of Canada Limited in Edmonton.

For a number of years associated with the Canadian Westinghouse Company Limited at Hamilton and Edmonton, he is a University of Saskatchewan graduate in electrical engineering, class of 1948.

Lt. Cmdr. G. L. Hopkins, R.C.N., JR.E.I.C., previously deputy electrical officer on the cruiser H.M.C.S. Quebec, is now serving at the R.C.N. Air Station, H.M.C.S. Shearwater, at Dartmouth, N.S., also as deputy electrical officer.

Lt. Cmdr. Hopkins graduated in electrical engineering from McGill University in 1952.

Gabriel Gagnon, JR.E.I.C., employed for several years with the Lower St. Lawrence Power Company, Rimouski, Que., has joined the operating department staff of the Quebec Power Company in Quebec City, Que.

Mr. Gagnon graduated from Laval University in 1948 with a B.A.Sc. degree in electrical engineering.

F. George Pack, JR.E.I.C., is a design engineer with Giffels and Vallet of Canada Limited, Windsor, Ont.

Last year he was employed by Dominion Structural Steel Limited in Montreal as a reinforcing manager.

He is a 1950 graduate in civil engineering from Queen's University.

Allan E. Toole, JR.E.I.C., is on the staff of the National Research Council, Ottawa. He is a design engineer working in the power section of plant engineering services.

Mr. Toole is a Queen's University graduate, class of 1950, and was previously employed with Canadian Industries Limited.

C. G. Thompson, JR.E.I.C., formerly plant engineer on the staff of Simmons Limited, Montreal, has transferred his services to the Escambia Bay Chemical Corporation, Pensacola, Florida.

He is a 1949 graduate in mechanical engineering from McGill University.

Lieut. (E) R. A. Williams, R.C.N., JR.E.I.C., carrying out administrative and engineering work with the R.C.N. is posted at H.M.C.S. Ontario at Esquimalt, B.C.

Lieut. Williams graduated from the University of New Brunswick in 1953 with a B.Sc. degree in mechanical engineering and then underwent a period of naval and engineering training with the R.C.N. In 1954 he joined the cruiser H.M.C.S. Quebec, and obtained further qualifications as a marine engineer. Last year Lieut. Williams was sent to the Royal Naval Engineering College, Plymouth, Eng., for a twelve month course in marine engineering theory.

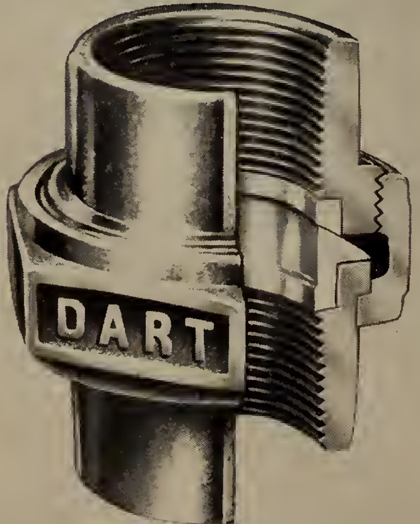
R. P. Baronet, JR.E.I.C., is with Ford Motor Company of Canada Limited, production engineering department at Windsor, Ont.

Mr. Baronet graduated from McGill University with the degree B.Eng. in mechanical engineering in 1950 and then gained experience with the Singer Manufacturing Company.

C. Markopoulos, JR.E.I.C., is an electrical engineer with Aluminium Laboratories in Montreal.

Formerly associated with A. D. Ross and the Canadian Comstock Company in Montreal, he is an electrical and mechanical engineering graduate from the National Technical University of Athens, class of 1950.

H. L. Bachman, JR.E.I.C., is employed with Pacific Car and Electric, power



transmission engineering design section, at San Francisco, Calif.

Since graduating from the University of Manitoba in 1949 Mr. Bachman has gained experience in electrical engineering with the Manitoba Telephone System in Winnipeg, the Canadian Westinghouse Company Limited, Hamilton, and most recently has been associated with the B.C. Electric Commission transission department at Vancouver.

Flt. Lt. J. P. Pagnutti, R.C.A.F., JR.E.I.C., is assistant professor of mechanical engineering at the Royal Military College, Kingston, Ont.

Flt. Lt. Pagnutti graduated from Queen's University with a degree in mechanical engineering in 1953 and then spent some time with the technical training unit of the R.C.A.F. in Vancouver.

Jean Choquet, JR.E.I.C., of the British American Oil Company has been transferred from Montreal to Calgary where he is employed as a refinery engineer.

Mr. Choquet joined the B.A. Oil Montreal east refinery shortly after he received a degree in civil engineering from the Ecole Polytechnique in 1948.

K. A. Mellish, JR.E.I.C., of the Department of Health and Welfare, Public Health Engineering Division, formerly of Truro, N.S., has been transferred to Regina, Sask., where he will hold the position of district engineer.

Mr. Mellish was graduated from the University of New Brunswick in 1950 with a degree in civil engineering.

R. A. Carter, JR.E.I.C., is employed with Canadian Industries Limited as an assistant project engineer.

Mr. Carter has been associated with Canadian Refractories Limited at Kilmar, Que., and shortly after his graduation from the University of Manitoba in 1949 gained experience with Duplate Canada Limited at Oshawa, Ont.

J. C. Gilmore, JR.E.I.C., has been named assistant manager of the Port Arthur Public Utilities Commission, Port Arthur.

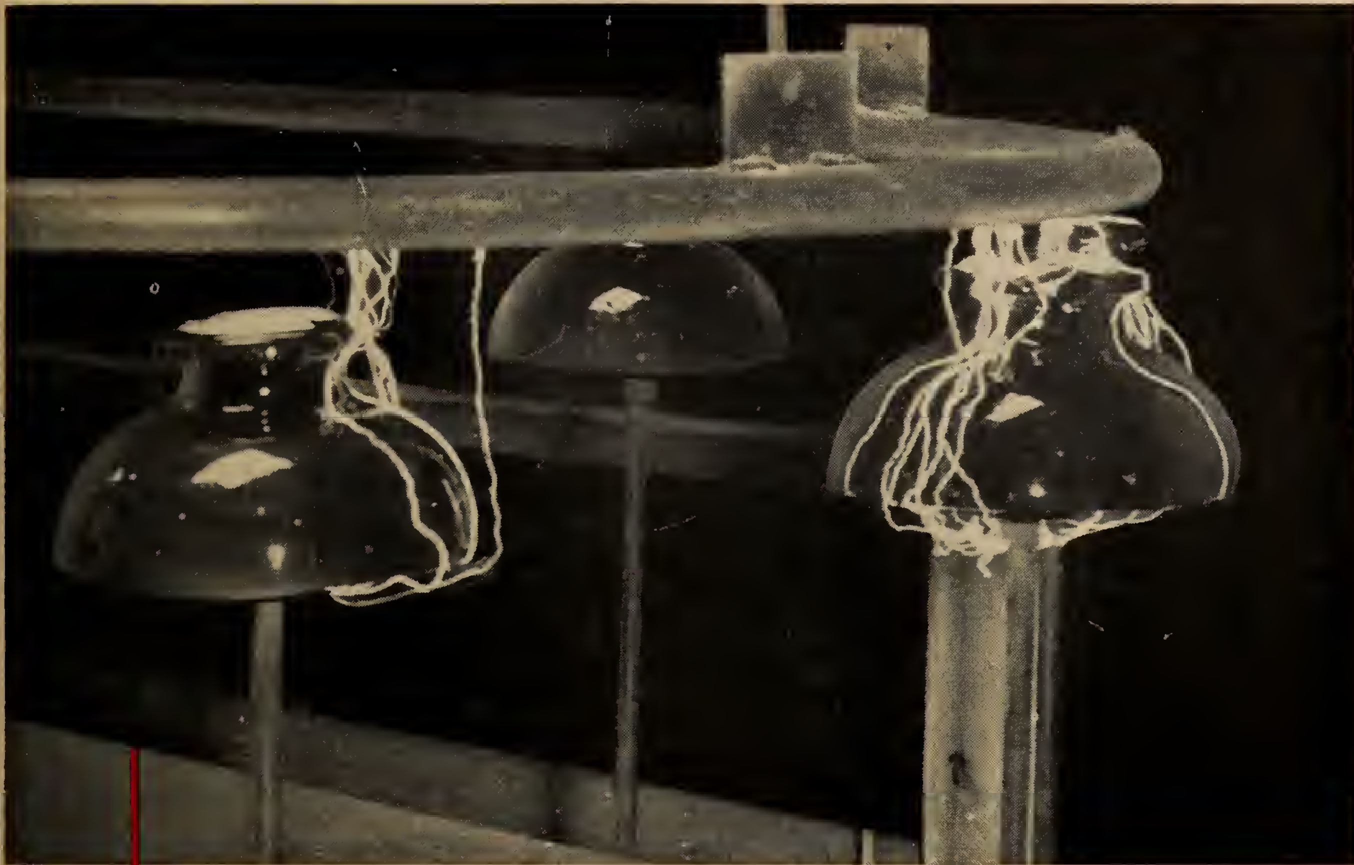
Mr. Gilmore has served the Commission for two years, since transferring his services from the Gatineau Power Company in Ottawa. He is a graduate of the University of Manitoba, class of 1949.

D. W. Durst, JR.E.I.C., a 1949 graduate of Cambridge University is employed as a development engineer with Hayward, Tyler and Company Limited, at Luton, Bedfordshire, England.

In 1951 he was associated with the Canadian General Electric Company Limited at Peterborough, Ont.

W. R. Hammond, JR.E.I.C., has accepted a position with Super Oil Seal Manufacturing Company Limited in Hamilton, Ont.

Most recently a design engineer with Martlin and Lawrie Limited, Hamilton, he has also been employed with Canadair Limited in the same capacity.



He is a University of Toronto graduate, class of 1953.

Robert J. Cream, JR.E.I.C., is employed as an economic analyst with Polymer Corporation's economics department at Sarnia, Ont.

A chemical engineering graduate with a B.Eng. degree awarded him in 1952 at McGill University, he has since been employed with Donnaconna Paper Company at Donnaconna, Que., and has been engaged in post-graduate studies in business administration at the University of Western Ontario.

R. L. Nordlund, JR.E.I.C., originally a graduate of the University of British Columbia, class of 1951, has returned to Canada from the University of Illinois where he was recently awarded a Ph.D. Degree in civil engineering. He has accepted a position with Raymond Concrete Pile Company in Vancouver.

Dr. Nordlund has also studied at the University of Texas. He received an M.Sc. degree in civil engineering from that university in 1954.

Eric E. Lang, JR.E.I.C., of Canadian Industries Limited, has received a transfer from the Brownsberg, Que., plant, where he has been methods engineer in the industrial engineering section, to the Millhaven works, at Kingston, Ont. where he will continue to hold the position of methods engineer.

Mr. Lang graduated from the University of Toronto in 1950 and then gained experience with Ford Motor Company and Bickle-Seagrave, Limited before joining the company he now serves.

Lieut. C. A. Leech, JR.E.I.C., a 1953 graduate of the University of Manitoba in civil engineering is serving a two-year term of duty with the First Field Squadron, R.C.E., Second Canadian Infantry Brigade Group in Germany.

Lieut. Leech was formerly with the Royal Canadian Engineers in Chilliwack, B.C.

J. M. S. Cherry, JR.E.I.C., is working as a civil engineer at Downsview, Ont., with the structural department of the firm of J. B. Parker and Associates, Toronto.

Mr. Cherry was employed with Canadian British Engineering Consultants of Toronto in 1955. He received a B.S.Eng. degree from Leeds University in 1954.

M. Erdstein, JR.E.I.C., a Purdue University graduate of 1955 with an M.Sc. in civil engineering has accepted an appointment as structural design engineer with Aluminium Laboratories Limited, in Montreal.

Earlier this year he was engaged in the same type of work with the Shawinigan Engineering Company Limited, Montreal.

W. J. Swanson, JR.E.I.C., has been transferred from the position of resident engineer on the DEW Line to work in the same capacity on the construction of a pulp mill at Thurso, Que., for the Foundation Company of Canada.

Mr. Swanson first became associated with the firm in 1951, on graduation from the University of British Columbia in civil engineering.

J. A. M. Bell, JR.E.I.C., until recently concerned with seismic work in Alberta has taken a position with Canadian Industries Limited, Vancouver, in the technical services section of the company's explosives division.

Mr. Bell obtained a B.Sc. degree in civil engineering at the University of New Brunswick in 1950.

George P. Miller, Jr.E.I.C., has been appointed to the engineering staff of L. E. Shaw Limited, Halifax, N.S.

Mr. Miller received a B.Eng. degree in civil engineering from the Nova Scotia Technical College in 1951 and then joined the Montreal Engineering Company Limited as a structural designer, remaining with the firm until the present time.

Raoul Verret, JR.E.I.C., has recently joined Werner Textile Consultants of New York. His first assignment with the firm of management consultants for the textile industry has taken him to Rio Grande do Sul, Brazil.

Previously employed with Dominion Textile Company in Valleyfield, Que.,

• PERSONALS

he is a graduate of the Ecole Polytechnique, class of 1952.

J. D. McIlveen, JR.E.I.C., formerly divisional supervisor (Eastern Canada) for Defence Construction (1951) Limited, in Ottawa, now holds the position of branch manager for the firm in Toronto.

He is a Queen's University graduate, formerly associated with the Central Mortgage and Housing Corporation, Toronto, and the Department of Highways.

John E. Sackville, JR.E.I.C., has joined Canadian Westinghouse Company Limited, industrial products division, at Hamilton, Ont. His position is that of associate engineer.

A University of Saskatchewan graduate in electrical engineering, class of 1950, Mr. Sackville has for some time served the firm of Wheaton Electric Company Limited in Saskatoon, Sask.

W. M. Carr, S.E.I.C., a graduate in mechanical engineering from the University of Toronto, class of 1955, holds the position of sales engineer with C. A. Dunham Company Limited in Hamilton, Ont. He also supervises the installation of heating equipment and services and advises on their maintenance.

A. O. Dyregrov, S.E.I.C., a 1955 graduate from the University of Manitiba. is employed with the St. Lawrence Seaway Authority in Montreal.

Kaare Hoeck, S.E.I.C., formerly at work with Haddin, Davis and Brown at Regina, Sask., has accepted employment with the Foundation of Canada Engineering Corporation Limited in Vancouver.

Mr. Hoeck followed civil and structural engineering studies in Denmark and raduated with an M.Sc. degree in 1955.

J. Claude Allard, S.E.I.C., a mechanical and electrical engineering graduate of the Ecole Polytechnique, class of 1955, has gone to Kingston, Jamaica where he is employed with Sprostons (Jamaica) Limited.

Until recently Mr. Allard was employed with the firm of J. A. Beauchemin and Associates, consulting engineers, in Montreal.

Georges Blouin, S.E.I.C., a 1950 graduate of Laval University in civil engineering is in La Oroya, Peru where he is employed with an American mining concern, the Cerro de Pasco Corporation. He holds the post of staff engineer in the construction department.

Jack B. Lutz, S.E.I.C., a Queen's University graduate of 1956 in mechanical engineering has found employment with Imperial Oil Limited, Sarnia, Ont.

G. A. D. Reed, S.E.I.C., a B.Eng. graduate in chemical engineering from McGill University, class of 1956, has joined the staff of Johnson and Johnson Limited, Montreal, in their new Canadian Research Centre.

Secretary-treasurer

W. A. H. FILER, JR.E.I.C.,
Branch News Editor

Tour of Aircraft Plant

The Hamilton Branch commenced its fall activities on September 14, 1956, with a tour of the De Havilland Aircraft plant at Downsview, Toronto. Some fifty members enjoyed an extremely well organized tour in groups of four or five with aeronautical engineers as guides. Aircraft production in general is similar to automobile production in so far as assembly line procedure is concerned. However the basic material is sheet aluminum instead of tin plate and there is much more custom work since there are many varied uses to which these planes are put.

Two planes currently in production, the Beaver and the Otter, have a similar basic structure for all orders but the future use of the aircraft determines whether it will be equipped with wheels, floats or skis and to some extent how the interior will be finished. The Beaver, a single-engined, high wing monoplane is now in operation in thirty countries throughout the world. Its uses vary from taxi service in South America to military service with the United States and Canadian armed forces. The Otter, a similar but larger plane capable of carrying ten people, is used on commercial air routes in Norway and also by the armed forces. Several are to be used in the Antarctic next year for survey work forming part of the Geophysical Year activities. These planes have been used extensively by bush pilots in northern Canada.

Major components of both these aircraft are fabricated by subcontractors and the assembly is completed at this plant. The Pratt and Whitney piston engines forming the power plant for these craft are not new. It is interesting to know that no new engines as such are in production but those used are completely rebuilt.

De Havilland is making a major contribution to both civilian and military air power. Bush pilots and air force pilots alike are assisted in their various roles by these sturdy craft.

Professional Development Program Re-Opens

The Professional Development Program sponsored by the Hamilton Branch began its courses on Wednesday, Sept. 19, with Registration Night. Applicants for the four groups totaled two hundred and ten. This course offers engineers continued education in non-technical subjects varying from public speaking to business administration. Hamilton can be proud that it has the largest of eleven such programs operating across Canada. An outline of the aims and operation of the program was given by the director, W. H. Hohn. Mr. J. J. Kelly, Hamilton Branch chairman, spoke on the advantages of membership in the Institute. Colonel J. M. Muir represented the Association of Professional Engineers of Ontario. Colonel L. F. Grant, field secretary of the E.I.C., and the originator of these programs in Canada, provided a history of the establishment and advance of them since 1950.

TECHNICAL SECTION

E. R. BUSHFIELD, JR.E.I.C.,
Chairman

Technical Section Formed

A technical section has been formed within the Hamilton Branch of the E.I.C. This has come about as a direct result of enthusiastic response to the technical questionnaire. Due to numerous requests a committee was formed consisting of D. B. Williamson, R. G. Vicarv, M. M. Kennedy, D. W. Hawes, G. Elliot and E. R. Bushfield

Because of the heavy response of the mechanical and electrical engineers to the survey, the committee sought a technical subject which would appeal to this group — and also appeal to the remaining members who were good enough to send us their opinions.

Lecture Program on Atomic Energy

The committee decided on "Atomic Energy" and proceeded to organize a lecture programme on this interesting science which will become such an important factor in daily and industrial living.

Having arrived this far the committee were then very fortunate in obtaining two well-known and personable nuclear physicists to conduct the program. These gentlemen are: Dr. M. W. Johns, of McMaster University, and Dr. D. M. Roberts of the Canadian Westinghouse Company.

The lectures and subsequent discussions are planned so that any member of the E.I.C. may come, learn and enjoy the science of nuclear energy. The course consists of six lectures beginning with the basic theory of nuclear composition — graduating to elementary reactor design. These lectures interlock so that any engineer can pick up the subject through regular attendance from the first lecture on. Two texts which will assist you in enjoying the nuclear subject will be used as reference.

Provides Grounding for Future Study

The approach is such that the groundwork this season will provide a position from which to move into more specialized nuclear fields in following years, provided sufficient interest is shown.

For the first year it has been decided to make no charge for the course to E.I.C. members, despite the considerable expense. Non-members will be charged $10.00 for the program.

Lectures were arranged for the first Monday of each of the winter months, from 8.00 to 10.30 p.m.: at Canadian Westinghouse Electronics Auditorium, Longwood Road.

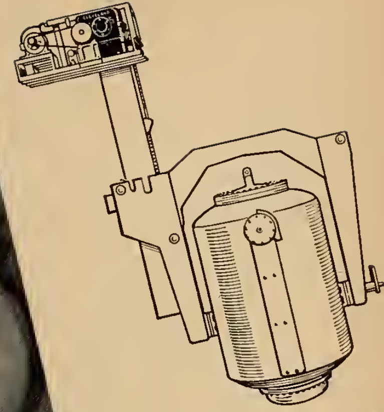
Outline of Lectures

Lecture 1—(October 1)	The nucleus and nuclear Radiations.
Lecture 2—(November 5)	Neutrons: The biological effects of radiation.
Lecture 3—(December 3)	The fission process and nuclear reactor principles.
Lecture 4—(January 7)	The reactor as a tool for industry.
Lecture 5—(February 4)	Nuclear reactor design.
Lecture 6—(March 4)	Problems of the reactor engineer.

KOOTENAY

G. T. J. HUGHES, M.E.I.C.,
Branch News Editor

The Kootenay Branch of the Institute, meeting over a turkey dinner in Trail,



Close-up of CLEVELAND Series 63F Double Reduction Worm Gear Speed Reducer used to raise and lower this G.E. 2-million volt X-Ray Tube Head.

CLEVELAND positions 2,000,000 volt X-ray machine

QUITE an X-ray machine, this—built by General Electric to serve the New England Deaconess Hospital in Boston, Mass. Quite a job, too, to raise and lower its head—it's heavy, it's delicate, and it has to be positioned accurately. That's why Cleveland was specified to transfer the speed of the motor into slow, smooth and dependable power.

For, with Cleveland worm gear speed reducers, smooth torque flow is assured by virtue of the sliding action of worm on gear. Constant angular velocity assures positive control. Precision matching of case-hardened steel worms to nickel-bronze gears insures 100% dependability.

Experience has demonstrated that a Cleveland actually improves with use. Even when operating under continued severe overloads, danger of sudden failure is remote. Thousands of Clevelands, in fact, operate for the life of driven machines.

Why not get the complete Cleveland story by writing for Catalog 400 today! Peacock Brothers Limited, P. O. Box 1040, Montreal 3, Que. Branches in Sydney, Toronto, Sudbury, Winnipeg, Edmonton, Calgary, and Vancouver.

PEACOCK BROTHERS LIMITED

B.C., on September 19, heard R. Fraser Mitchell, superintendent of maintenance and construction at the Warfield plant of Consolidated Mining and Smelting, describe his impressions of a recent trip to Hong Kong.

Visiting the East on a business trip sponsored by the International Co-operative Administration of New York, Mr. Mitchell went there to advise the Taiwanese on the starting of a new coke ammonia plant. Slides of rural, domestic and industrial life illustrated his talk and drew attention to the contrast between present day conditions in the Orient and in the West.

LETHBRIDGE

R. D. HALL, JR.E.I.C.,
Secretary-treasurer

Dr. L. B. Thomson Addresses Meeting at Vauxhall

The Lethbridge Branch was very sorry to hear of the recent death of Dr. L. B. Thomson of Regina, director of P.F.R.A. Dr. Thomson had addressed the dinner meeting following a trip to The Bow River Project of the P.F.R.A., on Saturday, September 15, 1956. A personal friend of a number of Lethbridge Branch members, Dr. Thomson was well known and held in high esteem by his associates and his staff, a number of whom belong to the Lethbridge Branch.

Trip To Bow River Project

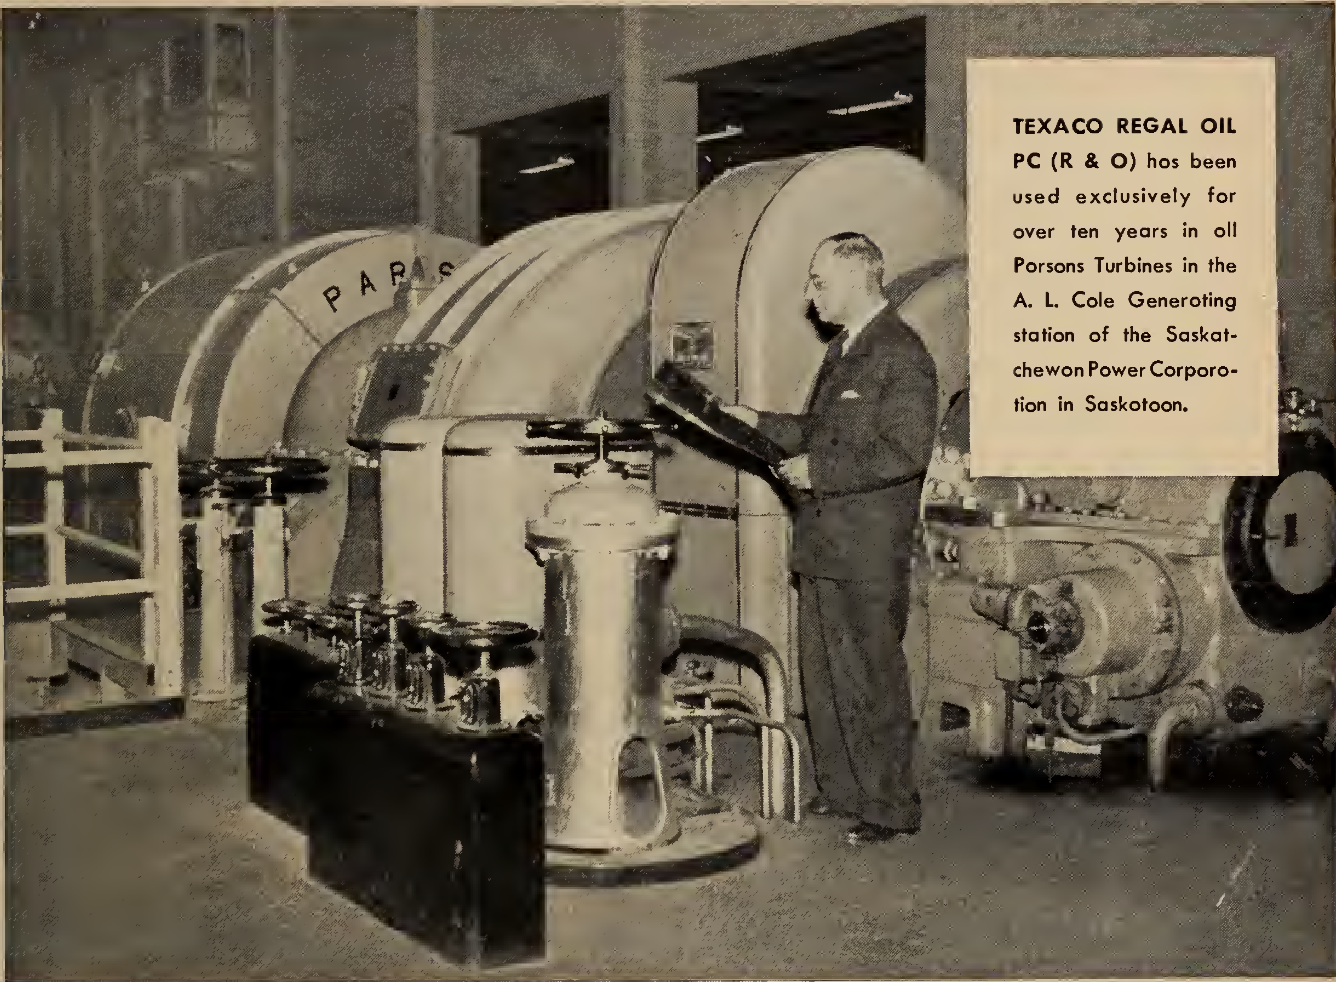
Some 50 members of the Branch and their wives toured a portion of the Bow River project of the P.F.R.A. commencing at the Travers dam, about 40 miles north of Lethbridge.

Travers dam is 3,000 ft. long, 1,000 ft. wide at the base, of earth fill construction and containing some 4½ million cu. yds. of earth and gravel fill. It was built at a cost of 2½ million dollars and serves the double purpose of eliminating 6 miles of steep and sliding sidehill canal and provides 100,000 acre feet of live water storage in the reservoir.

From Travers Dam the party followed the main canal, past the Little Bow Dam and reservoir and visited a number of concrete drops and check structures. The tour terminated at the Expanse Coulee siphon, an inverted siphon of wood stave construction, 4,810 feet long, 10½ ft. in diameter.

The portion of the project toured was the central portion of this undertaking. The whole project extends from the Bow River diversion works at Carsland, 30 miles south east of Calgary, for some 140 miles to Medicine Hat. Ultimately 227,200 acres of land will be irrigated. and about 99,000 have water available at present.

W. F. Hall, M.E.I.C., and W. D. Gray.



TEXACO REGAL OIL PC (R & O) hos been used exclusively for over ten years in oll Porsons Turbines in the A. L. Cole Generoting station of the Saskatchewon Power Corporotion in Saskotoon.

"TURBINE SYSTEMS completely Free of deposits, oxidation and foam"

Mr. W. R. Riddell, Superintendent of this plant, states: "Texaco Regal Oil PC (R & O) has always given dependable performance as a turbine lubricant. All systems remained free of deposits, oxidation and foaming conditions. We are also very impressed by the length of service your oil continues to give."

Texaco Regal Oil R & O has been proved by test to have *ten times the oxidation resistance* of ordinary turbine-quality oils—far greater ability to keep systems free from sludge, rust and foam. And there is a complete line of *Texaco Regal Oil R & O* approved by all leading turbine builders for all types and sizes of turbines—as well as types and sizes of hydraulic equipment.

Let a McColl-Frontenac Lubrication Engineer help you select the proper one to keep *your* turbine and hydraulic equipment trouble-free. Just call the nearest of the many McColl-Frontenac Bulk Stations across Canada, or write: McColl-Frontenac Oil Co. Ltd., 1425 Mountain Street, Montreal 25, Quebec.

• BRANCH NEWS

M.E.I.C., were in charge of the tour. Mr. Hall and other Vauxhall members looked after arrangements for the field trip and dinner meeting.

Vauxhall Laboratories

Following the tour, a visit was made to the Vauxhall laboratories, operated jointly by the P.F.R.A. drainage division and the Dominion Experimental Station, Department of Agriculture. It was noted that the work of soils testing for suitability to irrigation; drainage without which land under irrigation soon becomes ruined by alkalinity; and development and testing of suitable crops is some of the work carried on at this station. E. A. Olafson, M.E.I.C., outlined the work performed by the P.F.R.A. and W. L. Jacobson briefly described the projects carried out by the Dominion Experimental Station.

Dinner Meeting

Members and their wives enjoyed a cocktail hour and dinner at the P.F.R.A. station following the tours. A. J. Branch, chairman of the Lethbridge Branch was in charge of the dinner meeting.

Mr. Olafson introduced the speaker, paying tribute to the part he has played in the development of irrigation in Western Canada.

Some Aspects of Irrigation Development

In his address, the late Dr. Thomson stressed the need for teamwork between agriculturists and engineers in irrigation development.

P.F.R.A., which had its beginning in depression years sought to reduce the drought problem then being experienced. Investigations were made into problems of soil drifting, water storage and land suitability. P.F.R.A. has spent about 20 million dollars in an effort to bring a better balance to agriculture. Wheat is still Canada's number one industry, with pulp number two. The movement of people from unsuitable to suitable land is one of the major projects in Canada's irrigation development. Dr. Fairfield, former head of the Dominion Experimental Station at Lethbridge was credited with the successful promotion of the Lethbridge Northern Irrigation Project. This project together with the St. Mary's and Milk River Irrigation Development under the joint efforts of federal and provincial governments has resulted in expenditures of between 40 and 50 millions of dollars.

Projects under development or planning now include the Red Deer projects which will irrigate 400,000 acres, and the South Saskatchewan River project which will assist in water conservation and irrigate 600,000 acres of land.

Drainage is important if land is to remain productive, and the biggest job is to make the most efficient use of land, which in turn is responsible for the largest portion of Canadian economy.

In conclusion the speaker stressed again the need for continuing co-operation between members of the agricultural and engineering professions, and cautioned all persons in irrigation work to constantly consider the men who are to farm and are farming irrigated lands.

OTTAWA

STEWART G. FROST, JR.E.I.C.,
Branch News Editor

Talk by R. G. Johnson Opens Program For 1956-57

Over $925 million worth of contracts have been processed by Defence Construction (1951) Limited during its six years of operations. This was disclosed by R. G. Johnson, president and general manager of D.C.L., speaking to the Ottawa Branch at a luncheon meeting on September 10, 1956.

Mr. Johnson outlined the wide range of activities of his crown corporation; from dams to gate houses, from Pakistan to France. New construction work is being awarded at the rate of $12 million per month, mainly buildings, and is being performed at a rate of half a million a day.

Need for Construction Management

Speaking of the construction industry, Mr. Johnson stressed the need for construction management. Small family size construction firms are finding it necessary to merge into large companies in order to meet the need for proper planning and management of large complicated projects. Men with sound engineering knowledge and experience and capable of assuming administrative and management positions are urgently needed.

He added that winter construction must be increased, explaining that D.C.L. had been forced into winter construction due to the urgency of its work, and was now carrying out almost half its work each year between November and April. Some extra costs are involved but these must be accepted if progress is to come.

Mr. Johnson's talk opened the 56-57 program of the Ottawa Branch. Other luncheons will be addressed by Premier J. S. Smallwood of Newfoundland and Mr. D. C. MacCallum of Racey-MacCallum Associates. A field trip to the St. Lawrence Seaway and an Architects'—Engineers' Dance are also planned.

SARNIA

T. H. DOBBIN, M.E.I.C.,
Secretary

K. J. RADCLIFFE, JR.E.I.C.,
Branch News Editor

The first meeting of the Sarnia Branch of the Institute this season was held on

Sept. 27, 1956, at the Vendome Hotel with Charles Phelps, M.E.I.C., chairman of the Sarnia Branch of the Institute presiding at the meeting. Guest speaker was J. R. Nickolson, who was at one time associated with the Polymer Corporation in Sarnia, as general manager and later as executive vice-president. Recently returned from Brazil, where he was vice-president of the Brazilian Traction and Power Corporation and senior resident executive officer in that country until his resignation last spring, Mr. Nickolson was introduced by G. R. Henderson, M.E.I.C., and addressed the group on "Modern Developments in Brazil".

Too Rapid Development a Problem

Mainly a result of too rapid development of the country, are the problems arising in Brazil today, Mr. Nicholson felt after five years residence in the country, noting that it is trying to go from an oxcart to a jet plane economy overnight. As an example he described the major power development with which he was associated in the South American Republic--the Lagos underground power plant, and the Paraiba-Parai River diversion. In less than five years the entire project, which included diversion of two major rivers, construction of tunnels through solid rock, construction of dams, penstocks and powerhouses was completed, as well as the new power station, adding 350,000 kilowatts of power to the system, which feeds Rio de Janiero and Sao Paulo.

He said that the pumps which raise water from one intermediate reservoir to a second, 115 feet above it, have a capacity of 10,000 gallons per second each, and four pumps are in constant use.

Twelfth Annual Dance

MONTREAL BRANCH — JUNIOR SECTION

on

NOVEMBER 23, 1956

at

Sheraton-Mount Royal Hotel
Champlain Room

A feature of this dance will be a fashion show, presented by France-Del Modes, with furs by Reid, hats by Yvette Brillon, jewels by Jane Harvey.

Fashion Show — 8:30 p.m. Price — $5.00 per couple
Dancing — 10:00 p.m. — $2.00 per couple (for students)

Music by Stan Bankley's Orchestra and Trio

Tickets available from:—
E.I.C. Headquarters—PL 5078
D. H. Walkington—PL 2211, loc. 504
J. A. Laporte—RI 8-7361 — office
DE 4191 — home

Door Prizes and Novelties Dress Optional

D. H. Walkington — entertainment

Total output of Brazilian Traction and its subsidiaries now is 1,700,000 kilowatts, or about twice the output when Mr. Nickolson went to Brazil five years ago.

Mr. Nickolson added that while political upsets in the country have contributed to making life difficult for senior executive or administrative officials in Brazil, and economic unrest, due to a period of drought has also accentuated the nation's difficulties. However, the sense of humor, seldom lacking in Brazil, keeps it from being as difficult a country as it might be, in which to live and do a good job.

Ted Dill, M.E.I.C., thanked Mr. Nickolson for the seventy-five members and guests present.

Sao Paulo—City of Skyscrapers

Sao Paulo, a city of Skyscrapers, studded and surrounded by modern factories producing textiles, high quality footwear, automotive, glass, electrical, chemical, rubber, steel and countless other products, has grown from less than 400,000 people to nearly 2,700,000 in thirty-five years. This growth is due largely to the ready availability of power.

Natural resources, which include deposits of manganese, bauxite, tungsten and nuclear metals, gold, precious and

Described on the following pages is a field trip undertaken by the Vancouver Branch to Crown Zellerbach Box and Paper Converting plant, Lulu Island. Shown above are, left to right, S. S. VANCOUVER

A. D. CRONK, JR.E.I.C.,
Secretary

T. F. HADWIN, M.E.I.C,.
Branch News Editor

The 1956-57 program committee of the Vancouver Branch of the Institute arranged a fall program which had sufficient variety to appeal to all members, with their wives not forgotten. Also the newly formed structural section of the Branch prepared an attractive schedule of papers up to November.

On September 26, 1956, H. T. Libby, M.E.I.C., spoke on "How Natural Gas Will be Introduced to Vancouver". The meeting of October 13 featured "Ladies Night", with games and dancing, and on October 24, J. T. Madill, M.E.I.C., addressed members on "Installation and Operating Experiences with 2500 foot Head Kemano Impulse Turbines". Field trips were organized to Crown Zellerbach Box and Paper Converting plant and to Sicks' Capilano Brewery, where a succession of small parties also visited.

The Structural Section met on September 18 to hear O. Safir, M.E.I.C., discuss "Precast Concrete Construction," and on October 16, L. Narod, M.E.I.C., spoke on "The Design of the La Connor Bridge". On November 13, P. Christofferson addressed the group on "Structural Design Using Model Analysis".

Field Trip

The Branch chairman, S. S. Lefeaux, was successful in negotiating a pre-official opening inspection of the new Crown Zellerbach box and paper converting plant on Lulu Island on September 18. The thirty visiting members of the Institute were met by executives of the plant, including W. C. Gigler, plant manager, R. Dyrsmid, resident engineer, A. Morrow, engineer, O. Carlson, public relations manager, and F. Webb, production manager.

Building

The main building has an area of about 8½ acres and is the second largest area under one roof in Canada. The foundation for the building on river silt presented many problems and the walls are of precast construction. A visitor is struck by the lack of obstructions and excellence of lighting.

Ramp

Paper is brought to the plant by barge from Ocean Falls and ultra-modern facilities are provided for the efficient unloading of this paper to railway cars for transhipment or to the factory for con-

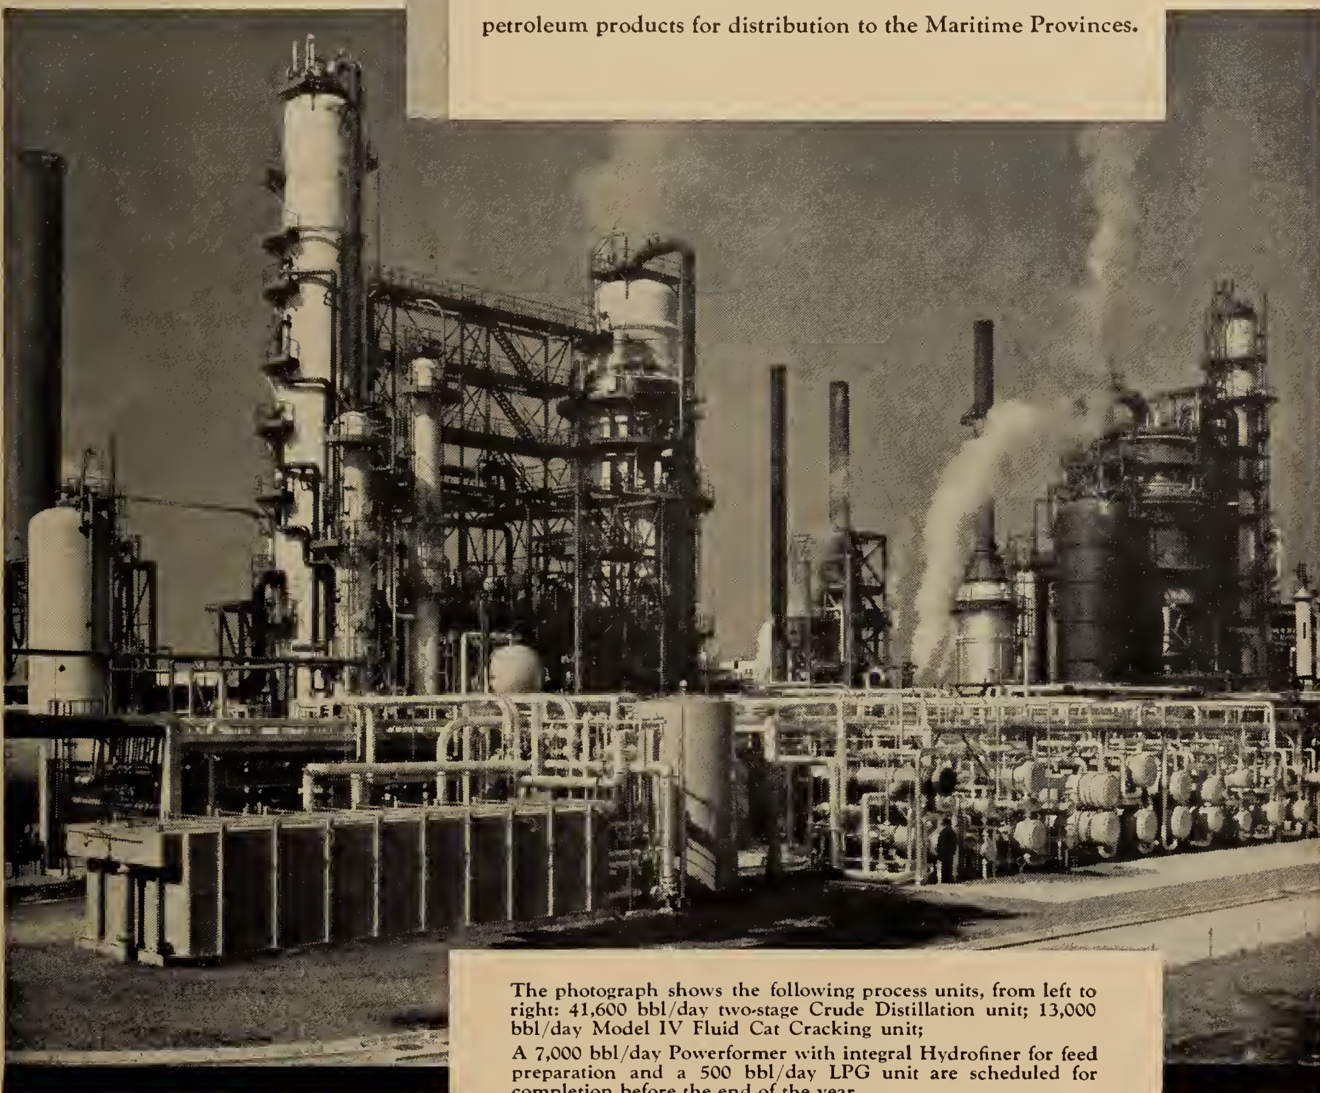
IMPERIAL OIL LIMITED

At the Halifax plant of Imperial Oil Limited, a completely new and up-to-date refinery is now "On Stream". All the processing units and the utility plant were designed and constructed by Foster Wheeler.

On the occasion of the formal opening, Foster Wheeler welcomes the opportunity to congratulate Imperial Oil on the completion of their modern refining facilities producing superior quality petroleum products for distribution to the Maritime Provinces.



The photograph shows the following process units, from left to right: 41,600 bbl/day two-stage Crude Distillation unit; 13,000 bbl/day Model IV Fluid Cat Cracking unit;

A 7,000 bbl/day Powerformer with integral Hydrofiner for feed preparation and a 500 bbl/day LPG unit are scheduled for completion before the end of the year.

CGRA Meets at Quebec

The annual convention of the Canadian Good Roads Association was held at the Chateau Frontenac, Quebec City, October 2 to 5, with an attendance exceeding 1000.

The Hon. P. A. Gagliardi, minister of Highways for British Columbia, was elected president of the Association for the coming year.

Roads Roundup

The Tuesday afternoon session was devoted to 'Roads Roundup', the annual feature in which reports are presented by highway officials, as follows:

Trans Canada Highway

At the time of the federal-provincial highway conference held in Ottawa November 14-15, 1955, there was not more than 10 per cent of the mileage of the trans-Canada highway within any province on which no highway existed. To accelerate construction, Ottawa proposed increasing federal participation by 40 per cent on 10 per cent of the highway, contingent on completion of a good standard of paved road by the end of 1960, and on maintenance by provinces of outlays excluding the 10 per cent share on selected sections equal to their average for 1954-55. The maximum limit to be contributed by Canada was increased from $150 to $250 million.

Up to September 15, commitments for the year by nine provinces over the past seven years totalled $285 million. Total mileage in participating provinces and national parks is some 4,470 miles, of which 2,356 miles have been approved for grading with 1,990 miles completed. Some 1,625 miles are approved for paving with 1,348 miles completed. Added thereto is 1,320 miles of paved road along the designated route built prior to 1949.

British Columbia

With a 1956 highway budget of $80 million, British Columbia is exceeding even last year's record. A total of 149 miles of highway has been built, 62 of which were on the trans Canada highway and the balance on other arterial highways.

291 miles of Trans Canada is now built to standard; 95 miles are paved to low standard; 90 miles are under construction; 19 miles are gravel-surfaced, and 90 miles are under survey; a total of 585 miles through the province. Due to a change of location from the Big Bend to the Rogers Pass route because of the Mica Creek dam, the distance has been reduced by 100 miles. The province now has a total of 2,498 miles of good highway, paved to a high standard.

The province is pioneering with a four lane highway tunnel under the south arm of the Fraser River at Vancouver. From today's date it will take 2½ years to complete.

During the year, 21 bridges were built by contract at a cost of $3.8 million, exclusive of bridges built under the Toll Bridges and Highway Authority. Of the major toll bridges the Agassiz-Rosedale will be the first to be completed, in October. To follow are the Oak Street bridge at Vancouver over the Fraser River, in May 1957; the $15 million Second Narrows bridge in three years; and the bridge over the Kootenay River at Nelson, to be opened by October, 1957.

Alberta

Alberta appropriated $61.9 million for highways in 1956. Of this $32 million will be spent on provincial highways, and $7.5 million on the trans Canada highway. Municipal maintenance and grants will total $8.5 million; $6.5 million was voted for bridges, $6.25 million for bridge maintenance and $3.7 million on highway maintenance.

Greater emphasis was placed on paving, with 267 miles base course and 308 miles of asphaltic plant mix. 324 miles of subgrade and grade will be built and more than 257 miles will be gravel-surfaced, as well as 22 major bridges and two grade separation structures.

The trans Canada highway is practically complete from the Saskatchewan border to Calgary. 67 miles from there to Banff is under construction. The province's four lane divided highway program has been given prominence, with 39 miles completed and 43 more miles graded.

Saskatchewan

1956 will establish a record in highway improvement. The province appropriated $19.7 million and total expenditure including the TCH will exceed $26 million. This excludes expenditure on local roads by grants and other services. There was a large carry-over from 1955. Wet weather in June and July retarded surfacing. Construction equipment has been short of demand. Supply of materials has been adequate and no serious labour shortage occurred, though engineers are scarce.

All trans Canada highway work excepting 5 miles of surfacing and some seal coating is completed. New pavement is complete from the Manitoba border to Regina and between a point 70 miles west of Swift Current and the Alberta border. There is a completely paved route across the province.

Manitoba

Manitoba's overall program may be summarized as follows: (a) Early completion of the trans Canada highway and international connections; (b) Reconstruction to modern standards of the existing provincial trunk highway system; (c) Extension of the system into established production areas; (d) Construction of development roads into areas of potential natural resources.

Extension of the TCH agreement has permitted a reversion to stage construction on certain sections. Highway budgets at all levels were increased for the past season. The cabinet approved a resurfacing program equal to nearly half the total annual vote. The early part of the season saw most road building equipment and personnel engaged on a system of permanent diking in the Greater Winnipeg area.

Ontario

Total highway expenditure for Ontario in 1956 will probably amount to $226 million, calling for 800 miles of new paving, 350 miles of resurfacing, 780 miles of grading and 156 structures. Tenders are being called for $25 million of new work to begin in 1956.

Up to the end of August 312 miles of dual highway, most of it controlled access, had been completed, with another 140 miles under construction. Every effort is being made to complete key sections of the trans-provincial controlled-access highway 401, 504 miles long. There is now a complete by-pass across metropolitan Toronto east and west. Another 26 miles from Tilbury to Windsor and 20 miles at Kingston, 140 miles of '401' is open for traffic, with an additional 38 miles expected to be opened by bypassing cities in western Ontario.

The Queen Elizabeth Way is resur-

MATCHED BELTS ARE IMPORTANT

to assure extra belt life ...equal pull...less slippage

Matching of Multi-V belts is in fact precise length measuring done under working tension —very close limits are maintained. Matching is important because it is your assurance of V-belt sets in which each belt has proven its ability to work with its team-mates longer, without unequal stretch, uneven wear or wasteful slippage. Each belt carries its full share of the load. In addition, matched Multi-V sets will transmit more power per dollar . . . will hold power waste to a minimum.

BELT MATCHING IS MIGHTY IMPORTANT AT GOODYEAR! Each set of Goodyear Multi-V belts is subjected to length inspection on a precision matching machine. Each V-belt must match . . . must measure up to its companions in the set . . . and the set can be identified by the red tag.

THIS RED TAG IS IMPORTANT TO YOU! It signifies the best in Multi-V belts. It is backed by Goodyear's 50 year experience in producing industrial rubber products. Only matched sets of Goodyear Multi-V belts carry this tag.

GOODYEAR MATCHING PAYS OFF! No matter what your multiple V-belt drive problem . . . whether light or belt killing, Goodyear has a Multi-V belt set matched and tagged to deliver all the power you pay for.

GOODYEAR

INDUSTRIAL RUBBER PRODUCTS ENGINEERED FOR THE JOB

For complete information write or call your nearest Goodyear office at—Moncton, St. John, Quebec City, Montreal, Toronto, London, Windsor, Winnipeg, Regina, Saskatoon, Calgary, Edmonton, Vancouver, or Head Office, New Toronto.

faced from Burlington to Niagara. Work on the Burlington Skyway bridge is progressing well and is scheduled to open early in 1958. The Allumette bridge near Pembroke will be completed in October.

This year a five-year program for completion of Ontario's 1,465 mile share of the trans Canada highway was begun at a cost of $75 million. This calls for annual expenditure of $15 million.

Quebec

Quebec's highway budget was increased from $50 million in 1950 to over $100 million for 1956. During the last year 670 miles of asphalt and concrete roads were completed; grading and gravelling were done on 521 miles of main highway, and 1,000 miles of rural roads were rebuilt or improved. Highways leading to adjoining provinces were improved and in some cases rebuilt to Trans Canada standards. Last winter 25,000 miles were maintained and kept open at a cost of $7 million.

The main highway on the Gaspe peninsula is near completion and Lake St. John and Saguenay highways have been completed this year. The Quebec-Murray Bay section of the Quebec-Seven Islands highway was also completed this season but the balance will take two or more years to complete. By year-end Quebec's road network of 45,000 miles will have 31,000 miles of improved road —9,000 paved with concrete or asphalt; thus 72 per cent of the network is in good condition.

New Brunswick

For 1956 the province allocated approximately $7 million from capital account for roads and bridges. An additional $14½ million was earmarked for roads and bridges including maintenance for same, plus ferries, etc.

This year the province is laying some 52 miles of new pavement and another 44 miles of recap on existing pavements, on pavements where recap could carry them along for a reasonable time. By year's end some 324 miles of surface treatment will be finished, plus some 114 miles of seal coating. About 263 miles of grading and gravelling projects were also scheduled for the year.

An extensive bridge building program includes new large bridges at Fredericton, Hartland, Rexton, Andover, Coles Island, Eel River, and Edmundston. Design is completed for two bridges at Oromocto for access to the army camp at Gagetown.

Nova Scotia

Nova Scotia will spend over $13 million on maintenance and $12 million for capital construction including the trans Canada highway. Thirty miles of grading and 18 miles of paving on the Trans Canada will be done in 1956, as well as preparing 80 miles for paving, and paving 140 miles on other highways, all by contract. Fifty miles of highway will be paved by the Roads Department. The province this year will thus have at least 208 miles of new pavement.

Prince Edward Island

During the current year, the province built 10½ miles of subgrade, 7 miles of concrete pavement and 17½ miles of asphalt pavement for the trans Canada highway, completing 90 per cent of the province's TCH mileage.

Elsewhere the hot plant mix asphalt road total is being increased by 5 per cent and light pavement is also being increased. Construction of gravelled roads will be less than in previous years.

Newfoundland

The province's reconstruction program for 1956 is about the same as for 1955, with work limited to improvement of drainage and addition of ballast, so that a greater mileage can be conditioned for traffic during spring breakup. No paving is being built this year.

Construction of the trans Canada highway now permits traffic from Port au Basques to a point 35 miles east of Gander airport. Between there and Clarenville a 50-mile gap occurs, over which the C.N.R. operates a daily rail-car ferry. Contracts are being let for 16 miles of this section for completion in 1957. It is then proposed to operate a car ferry on the two-mile stretch of water at Clode Sound on Bonavista Bay, making road travel possible for the full 600 miles from Port au Basques to St. John's.

Since 1949 the province's highway program has made road travel available to 150 communities having a population of 50,000. Almost a fourth of the province's population has been connected with a central highway system.

The Hon. Antonio Talbot, retiring president of CGRA, addressing the meeting, said, "Bearing in mind all the obvious limitations and possibilities for substantial error inherent in long-range estimates, we can predict that up to $30 billion may have to be spent on the construction and maintenance of Canada's roads and streets in the next 25 years. This would imply an average annual road expenditure of $1,200 millions for the next quarter century, or not quite double the amount devoted to road purposes this year."

National Forestry Conference

The first National Forestry Conference in fifty years was held on September 17, 18 and 19 in the Fort Garry Hotel in Winnipeg. Sponsored by the Canadian Forestry Association, The Canadian Chamber of Commerce, the Canadian Institute of Forestry and the Engineering Institute of Canada, the Conference was the first step in the establishment of a strong partnership between the public owning the forests, and private individuals and industry harvesting, fabricating and marketing their produce. The Conference was a public forum—not a pressure group—which allowed the various non-forest elements of Canadian life and its people along with officers of the governments to whom the care of our forests had been entrusted, to sit down with those in the forest industries and other private forestry organizations to study forestry problems and opportunities and to determine what can be done to meet and grasp them.

Lowell Besley, Chairman, Woodlands Research Department, Pulp and Paper Research Institute of Canada, delivering the theme address on September 17 pointed out that it would be difficult to over-estimate the value of the forest industries to Canada's economy. "Their net value of production", he said, "every year is more than a tenth of Canada's entire net national income. They are furnishing more than a third of Canada's domestic exports and contribute well over a billion dollars a year towards a favourable balance of trade . . . the forest industries are maintaining and even increasing their importance in Canada's economy."

Mr. Besley expressed his belief that the people of Canada — vigorous, energetic and creative — will seize their wonderful opportunities and face up to their responsibilities of managing the forests, which they themselves own, as the living and renewable resources which these forests are. Mr. Besley went on to say that Canada's forests will properly respond to good treatment and will produce in the years to come greater and greater wealth and better living for all Canadians. "But to bring about this happy state of affairs, we must first learn to appreciate what we have now, we must secondly learn what is required to establish our forests as a truly going concern, and lastly, but most important of all, we must put our forests to work producing wood and fibre to be fashioned into the thousands of products so useful to man."

G. S. Thorvaldson, Q.C., past president of the Canadian Chamber, addressing a luncheon meeting of the Conference on September 19 told his audience "that it is good business to see to it that everything possible is done to ensure perpetual crops of timber in this great country of ours. This calls for a public awareness of the value of forestry in our economy, which must be done largely through education."

During the three day Conference a great deal of valuable information was made available to the 130 delegates and to Canadians generally through the medium of the press. It is sincerely to be hoped that this "first step" will be but the beginning of an educational process which cannot help but result in benefit to all Canadians.

Reprinted from Newsletter of the Canadian Chamber of Commerce, No. 166.

PICTURE OF A MOUNTAIN ON THE MOVE

THROUGH THIS PIPELINE, solids are travelling. Every hour of every day, at one of the largest mines in Northern Ontario, thousands of tons of ore concentrates are pumped along pipes like this. Over the year, if you gathered all that material together, it would make a sizeable mountain.

Rock is crushed and ground, mixed with water to form a heavy sludge, then pushed into and along the pipes by CA-C rubber-lined pumps. This one mining company alone has over 300 of these pumps in continuous operation. The saving in labour and transportation costs over conventional methods is estimated to be $1,000,000 a year.

With this and many other kinds of mining equipment, Allis-Chalmers is helping to build a more prosperous Canada. In fact, there is hardly an industry contributing to our better living that is not served by Allis-Chalmers. For further information, please write Canadian Allis-Chalmers, P.O. Box 37, Montreal, Que.

• NEWS OF OTHER SOCIETIES

Calendar

Aeronautics

The Canadian Aeronautical Institute (Commonwealth Bldg., Metcalfe St., Ottawa) and the Institute of the Aeronautical Sciences will hold the 1956 international meeting on November 26 and 27 at the Royal York Hotel, Toronto.

Chemical Engineering

The annual meeting of the American Institute of Chemical Engineers (25 West 45th St., New York 36) will be held at the Hotel Statler, Boston, December 9-12, 1956.

The ninth national chemical exposition, is scheduled for November 27 to 30, 1956, at the Cleveland Public Auditorium. It is sponsored by sections of the American Chemical Society.

Welding

An invitation is extended to Canadian engineers to attend the annual assembly of the International Institute of Welding, at Essen, Germany, June 29 to July 6, 1957.

Canadian engineers were also invited to present at this meeting unpublished papers on the metallurgy of welding, under the following topical headings: Gas Absorption and Its Influence on Weld Metal; The Behaviour of Welds as Regards Aging and Caustic Embrittlement; The Metallurgy of Brazing; The Metallurgy of the Welding of Stainless and Heat Resisting Steels of Ferritic, Semiferritic and Austenitic Types; The Metallurgy of the Welding of Non-ferrous Metals: titanium and its alloys, magnesium and its alloys, aluminum and its alloys; nickel and its alloys.

Titles of papers and information about the authors were requested by the Canadian Council of I.I.W., so that this information could be transmitted to the German Committee by November 15. The full paper must be submitted by December 31, 1956.

In the matter of receiving papers the responsible Canadian Committee members are R. A. Dunn, general sales manager, Canadian Liquid Air Company Limited, 1111 Beaver Hall Hill, Montreal; and R. W. Stickney, Canadian Welding Bureau, 1393 Yonge St., Toronto.

Mr. Dunn and Mr. Stickney are the provisional chairman and executive secretary, respectively, of the provisional Canadian Council for the International Institute of Welding, recently formed. Further information about the formation of the Canadian Council will appear in an early issue of the Journal.

Steel

Fifty years of electric furnace steelmaking will be celebrated at the annual electric furnace steel conference, sponsored by the American Institute of Mining, Metallurgical and Petroleum Engineers, 29 West thirty-ninth Street, New York 18.

The conference will be held in December 5-7, 1956, in the Morrison Hotel, Chicago.

Soil Mechanics

The Associate Committee on Soil and Snow Mechanics of the National Research Council of Canada, will hold the tenth Canadian Soil Mechanics Conference in Ottawa, December 17 and 18, 1956. Landslides will be the main theme of the conference.

Anyone interested in the field of soil mechanics is invited to attend. Further information can be obtained from Edward Penner, c/o Division of Building Research, N.R.C., Ottawa 2.

IATA Meets in Edinburgh

The twelfth annual general meeting of the International Air Transport Association was held in Edinburgh September 17 to 21, 1956. Lord Douglas of Kirtleside, chairman of British European Airways, took office as the new president of IATA, succeeding Juan T. Trippe, president of Pan American World Airways.

Sir William P. Hildred, the director general, told presidents of the association's 74 member carriers that while prospects are good for greatly increased traffic by 1960 to fill the jetliners they have ordered, airlines are being pressed to continue fare reductions at a time when their margin of profit on all operations is only 1.1 per cent and their international operations as such show an actual loss. "With profits consistently cut to less than a bare minimum we could not withstand for long any decline in traffic," he warned.

Hildred reported that 1955 traffic results "gave the lie direct to those who said the expansion in air transport could only go on at a decreasing rate". Passenger traffic went up 16 per cent during last year, as compared with a 13 per cent increase in 1954; while in 1955 rate of increase in cargo was 18 per cent after hovering at 10 per cent during three previous years. He said, however, that a 14 per cent increase in mail loads was "somewhat disappointing."

North Atlantic traffic rose 19 per cent to a total of 700,000 passengers in 1955. "It will not be long before the airlines carry a million people a year across the Atlantic — and when we do, we shall be carrying as many as the ships do now," he predicted. Total revenues of all airlines from both domestic and international operations were just over $3 billion last year, but operating profit was only $33 million before taxes, interest and similar charges. "On international operations alone," he said, "we appear to be making a $3 million loss."

Reporting that the airlines will in the next few years add to their fleets anything between 200 and 300 jet aircraft, he pointed out that "each new jet aircraft on order will be able to carry more passengers in a year than a large transatlantic liner like the Queen Mary; and their overall capacity will exceed by a substantial margin that of the existing IATA fleet of 2,500 aircraft."

Hildred said his own forecast of the future, "lies halfway between the extremes" of those who hold that the airlines have gone on "an irresponsible equipment spree" and those who believe there will be more traffic than even the jets can carry. But he cautioned that to fill their capacity in the 1960s, "airlines must find out how to go all out for the mass market and recommend to governments a fare pared down to the lowest level consistent with sound operation."

The advent of the jet "had emphasized the obsolescence of current facilities and services, magnified the problems of inadequate and crowded airways and had raised weighty technical and economic questions," Hildred declared. "The airlines have invested hundreds of millions in new equipment to make air travel available to a far greater number of people."

"Operation of jets will require substantial improvements in air traffic control," Hildred said. He attacked the unnatural and outmoded practice "of setting up air traffic control areas on the basis of national boundaries," asserting that with the jet these areas will be "totally impracticable." Better training and status for "that much abused and seldom praised individual, the air traffic control officer," was also recommended, he said. The ATC officer should have as personal a part in the operation as the flight crew themselves. Jets would also require more up to date and better co-ordinated airport buildings and apron facilities to speed ground handling.

The high speeds of jet aircraft and the need to get maximum use out of them will make aviation "a round the clock operation" by 1960, Hildred declared. Passengers will have to accustom themselves to departures at any time of the day or night and airports, airline offices and customs and immigration checkpoints will have to provide full facilities at any time of the day or night.

BOOK REVIEW

Noranda.

Leslie Roberts. Toronto, Clarke, Irwin, 1956. 223 p., illus., $5.00.

The history of the growth of the city of Noranda and the company from which it takes its name is a part of the history of the growth of Canada, and finds many parallels in the vast expansion which is taking place in the Canadian North today.

When Ed Horne was prospecting in the wilderness Rouyn area of northwestern Quebec forty years ago, the Province's vast mineral potential was practically untapped, and its extent was unknown. In those days the search was for gold; today there are many minerals of interest to the prospector and mine owner.

Leslie Roberts begins the story of Noranda in the days when Ed Horne, with a grub-stake of $225, went by canoe to the present site of the mine. He tells of the difficulties of the prospectors, the efforts to form a company, the early explorations, the building of the railroad and mine buildings, the planning and construction of a new town, and he brings to life the people, many of whom he knew.

He concludes his story with the expansion of Noranda Mines into the Gaspe and the development of the copper mines which has brought a new era to the peninsula. We should be grateful to Mr. Roberts for writing this history, and hope that he, or another, will do the same for other areas. S. C.

ASTM manual for rating motor fuels by motor and research methods.

Philadelphia, American society for testing materials, 1956. 192p., $6.75.

Careful study and use of this Manual for rating motor fuels by motor and research methods should enable qualified personnel to install and operate knock testing equipment for both the motor and research methods. Methods are: standard method of test for knock characteristics of motor fuels, by the motor method (D357), and standard method of test for knock characteristics of motor fuels by the research method (D908), commonly referred to as the motor and research methods. Also included are six appendices (I-Apparatus; II-Reference materials and blending accessories; III-Operation; IV-Maintenance; V-Installation and assembly; VI-Building requirements and utility requirements) containing valuable and necessary information for conducting standardized octane ratings on motor fuels. Short statements on the essential features of each method are included. The Manual is illustrated throughout. In addition to drawings and photographs there are numerous tables and charts.

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

Applied electrical measurements.

I. F. Kinnard. New York, Wiley, 1956, 600p., diagrs., $15.00.

The basic principles of commonly used electrical measurement devices are covered in this work, and their application to the measurement of electrical and non-electrical qualities is shown.

The author maintains an analytical approach. For each subject and method of measurement, the fundamental laws of the operation are given. These serve as a review of the basic physical and mathematical principles. There are many references for further reading given.

The first section of the book deals with the measurement of electrical quantities, while the second covers the measurement of nonelectrical quantities such as light, heat, sound, liquids, gases, static and kinetics and time.

The book serves to show how indispensable electricity has become to all types of measurement.

Arc-welded machinery construction in mild steel.

A. G. Thompson. London, British welding research association, 1956. 36p., illus., 6/—.

This booklet deals with the design of arc-welded machinery construction, and includes details on the welds used and the static and fatigue stresses imposed on them. Two chapter cover factors for the reduction of costs and information required for manufacture. The bibliography contains more than fifty references.

Argon-arc welding of aluminium alloys, parts 1 and 2.

London, British welding research assoc., 1955-56.

These are the first two booklets in projected series which will cover all aspects of argon—arc welding of alu minum and its alloys.

The first booklet covers general principles, and provides a general introduction to the subject. The second, Electrical characteristics and equipment, discusses the electrical requirements of the A.C. argon—arc process and the function of each item of the equipment.

Other publications in the series will deal with metallurgical considerations, design, applications and costs, techniques and procedures and inspection and testing.

The art and science of protective relaying.

C. R. Mason. New York, Wiley, 1956. 410p., diagrs., $12.00.

This is an elementary textbook on protective relaying, and to understand it the reader requires a knowledge of only the fundamental principles of electrical engineering. The approach is essentially practical, and proofs are not generally given, although reference is made to the sources where these may be obtained. Selected bibliographies list further readings on the subject.

Relay protection of all elements of a power system against all abnormal operating conditions is dealt with, and the relation of relaying to the other power system elements is discussed. The material in the book is applicable to any make of relay.

Up front with the fire fighters — CRANE VALVES

No idle bystanders are Crane valves at a fire. You find them up front where the action is hottest—helping pumper engines and fire-boats direct water flow to make hose streams effective. On sprinkler systems and standpipes, these valves respond instantly to operation even when unused for years.

The rigid quality standards so essential here have for 100 years guided the production of Crane valves—one of Crane's main products. Keeping quality first and foremost has made Crane traditionally the first choice of thrifty, value-minded buyers.

In every industry, piping systems have a longer life of peak efficiency—with lower maintenance cost—when they're Crane equipped. That's why more Crane valves are used than any other make.

Crane makes valves and fittings for every piping need—in brass, iron, steel, and corrosion-resistant alloys. Leadership, in completeness of line as well as quality, makes Crane . . .

Industry's first choice for better piping materials

Basics of phototubes and photocells.

D. Mark. New York, Rider, 1956. 128p., illus., $2.90.

Phototubes and photocells have many uses in the fields of industry, communications and warfare. Principles, practices, circuits, and practical applications of photoelectricity are here presented for the non-specialist. Subjects covered include: the photoelectric effect, photoconductive cells, photovoltaic cells, phototubes, photocurrent amplifiers, instrument applications, commercial applications.

A bibliography is appended, giving references to more detailed coverage of these subjects and their applications.

°Bibliographic survey of corrosion 1952-1953.

Houston, National association of corrosion engineers, 1956. 382p., $12.50 (U.S.)

Summaries of over 3000 references on corrosion and corrosion prevention are arranged in the following main goups: general, testing, characteristic phenomena, corrosive environments, preventive measures, materials of construction, equipment and industries. The references are indexed by subject and by author. An appendix has been included to aid the user in locating and obtaining copies of foreign or domestic journals or articles.

°Careers in engineering, 3rd ed.

L. O. Stewart. Ames, Iowa State College Press, 1956. 105p., $1.25 (U.S.)

This booklet gives information on the nature of the engineering profession; the aptitudes, interests, and personality necessary for the study of engineering; factors that determine success in college and after; and the engineer's fields of work. The engineeering fields are considered from three points of view: by degree-granting departments of universities, by industries employing engineers, and by function such as design, construction, research, etc. Aids to counselors and teachers and other books on the profession are listed in an appendix.

°Chemical engineering kinetics.

J. M. Smith. Toronto, McGraw-Hill, 1956. 402p., $9.60.

This is a presentation, for practicing engineers and advanced students, of design methods for reaction equipment and their application to practical problems. Emphasizing process rather than plant design, the book reviews the fundamentals of thermodynamics and kinetics, presents the construction features and design principles for several types of reactor, and discusses in detail the design of homogeneous batch, homogeneous flow, semibatch, and catalytic reactors. The next to last chapter discusses heat and mass transfer in catalytic reactors as preparation for the final chapter which deals with the complex problem in which heat transfer, mass transfer, and chemical reaction processes all affect the design.

Climatic summaries. v. 3, Frost data.

C. C. Boughner and others. Toronto, Department of transport, Meteorological division, 1955. 94p., 30 cents.

The incidence of frost is of great importance to an agricultural program. This publication contains charts of summaries of frost data by meteorological station throughout Canada, probabilities of last spring and first fall temperature of 32 deg. or lower, probability of duration of frost free period, as well as maps showing mean dates.

The condensed chemical dictionary, 5th ed.

Arthur and Elizabeth Rose, eds. New York, Reinhold, 1956. 1200p., thumb indexed, $12.50 (U.S.)

This enlarged edition of an indispensable chemical reference book provides concise data on chemicals, chemical terminology, trade-name products and related substances.

There is also information on containers, shipping regulations, safety instructions, and new use of chemicals in nuclear energy, chemotherapy and other fields.

For greater convenience the book is thumb-indexed, and there are many cross-references. The revision has been six years in preparation.

Earth satellites as research vehicles.

Philadelphia, Franklin institute, 1956. 115p., diagrs., $2.50 (U.S.)

During the International Geophysical Year (IGY) 1957-58, it is hoped to launch man-made satellites into the outer atmosphere, to be used for scientific experiments.

The purpose of the Symposium held in April by the Franklin Institute was to emphasize the peaceful uses which can be made of rockets and other guided missiles.

The papers presented discussed the IGY earth satellite programme, the moon rocket, astronautical and space-medical research with automatic satellites, astrophysical research with an artifical satellite, an artificial celestial navigation system, and the recovery of data in physical form from satellites.

Electric utility economics.

R. E. Caywood. Toronto, McGraw-Hill, 1956. 236p., $12.00.

This is a practical guide to the economic and technical factors involved in utility rate making, pointing out their interrelationships. Rate work involves a knowledge of engineering, accounting, sales, statistics, engineering economics, etc.

This book considers the fundamentals

of the electric utility business, the theoretical basis of the price structure and the tariff, metering, statistical methods and cost analysis, earnings, depreciation, etc. There is a long bibliography keyed to the different chapters.

The first book on the subject to be written for some years, this should prove a useful addition to the library of many engineers, and may well form a basis for training in rate-making.

Fraser's Canadian trade directory, 1956.

Montreal, Fraser, 1956. 1784p., $6.00.

With this forty-third edition, Fraser's directory appears in a new format. It is now in one, cloth-bound volume, although the arrangement of the contents is the same.

The classified section lists over 6,500 products, and their Canadian manufacturers, all with their street addresses. There are some 11,500 Canadian manufacturers in the alphabetical listing, and more than 15,000 names appear in the list of trade names. Ten thousand foreign companies are listed, together with their Canadian agents.

There is a useful Market Section giving information on foreign trade, cities and towns in Canada with over 1,500 population, Canadian transportation companies, utilities, banks, etc.

This is one directory which should be in every library.

Frequency modulation engineering, 2nd ed.

C. E. Tibbs and G. G. Johnstone. Toronto, British Book Service, 1956. 435p., illus., $7.75.

Written by two British engineers, this book attempts to give a survey of the whole field of frequency modulation engineering. The field had, prior to 1954, not been as widely exploited in England as in the United States, owing to wartime difficulties.

Some of the topics covered in this revised edition are interference and noise structure, the suppression of interference, propagation, aerials, transmitters, receivers, limiters and discriminators and practical uses of F. M. signals. There are lists of references, many being of American publications, at the end of each chapter.

General education in engineering.

Urbana, American society for engineering education, 1956. 122p., 25 cents.

The question of incorporating humanistic-social studies into an engineering course is one which is raised periodically. This report by the humanistic-social research project of the Society considers the whole question, and its findings are based on the results of visits to some sixty engineering schools.

Excerpts from the reports are given, as are representative courses in the humanities already in operation at the various schools.

***The generation of electricity by wind power.**

E. W. Golding. New York, Philosophical library, 1956. 318p., illus., $12.00 (U.S.)

This account of recent research and development work on the use of wind power on a significant scale is divided, roughly, into three parts. Part one is devoted to wind behavior and its determination: wind distribution, measurement of velocity, energy estimation, and the selection of sites for wind power units. The remaining two parts deal, respectively, with types of wind driven machines and generators and with economic considerations. In addition to chapter bibliographies, a bibliography on surface wind data is included. A glossary of French, German, and English terms is appended.

Géophysique et mécanique des sols dans leurs applications practiques.

G. Aliberti. Montreal, Fomac, 1956. 159p., diagrs., $10.80.

In an introductory section the author presents a brief outline of geologic definitions, and the characteristics of various earth formations.

The three chapters in the second section are concerned with the different soil types, and their values as foundation material. Chapter six considers the statics of foundations.

The final section, occupying nearly half the book, is devoted to worked examples calculating earth pressure, stability and many other problems likely to be encountered in this type of work.

Government contracting in atomic energy.

R. A. Tybout. Ann Arbor, University of Michigan Press, 1956. 226p., $4.50 (U.S.)

In addition to opening up a whole new field for the source of power, atomic energy has introduced a new phenomenon into the American economy — public ownership and private operation.

This work studies the various types of contract which may be entered into by government and industry, and although the study is specifically concerned with the atomic energy industry in the United States, its findings are equally applicable in other fields.

Types of contract considered are: fixed-price, variable-price, and cost-plus-fixed-fee. In an evaluation of cost-plus-fixed-fee contracts, the author has considered incentives and uncertainties, controls, and government and business practices in this field.

The study was made possible by a grant from the University of Michigan, and much of the information on which it is based was obtained from interviews with the Atomic Energy Commission and the contractors concerned. The questions asked at these interviews are reproduced in an appendix.

***The growing shortage of scientists and engineers. Proceedings of the sixth Thomas Alva Edison Foundation Institute, November 1955.**

New York, University Press, 1956. 132p., paper, $4.00 (U.S.)

The speeches and panel discussions recorded in these proceedings deal with the present and future supply and demand for scientists and engineers, the efficient utilization of scientific manpower, means for increasing the supply of engineers, the encouragement of scientific talent, the failures of scientific education, and methods for improving science teaching.

Jig and fixture design.

P. S. Houghton. Toronto, British Book Service, 1956. 256p., diagrs., $6.50.

Growing from a course of lectures on production engineering given by the author, the book owes much to his many years of experience as a mechanic, draughtsman and works manager.

As the author points out in his preface, careful, skillful planning of the machinery used can produce results far in excess of what might be expected. The various topics covered in this book give the bases from which this planning should evolve. Included are planning production and material, design notes, standard clamping methods, indexing mechanisms, drilling, tapping, boring, grinding, air-operated equipment, motion study, etc.

• LIBRARY NOTES

Mineral resources policy.

London, Institute of mining and metallurgy, 1956. 145p., 10/6.

This book contains the record of a symposium held in London in September 1955. The six papers forming the basis of the symposium covered: mineral resources strategy; aspects of the mineral industry in East Africa; economic considerations in a British mineral resource policy; the Canadian mineral industry; a proposal for a central ore treatment laboratory.

The papers were circulated in advance, and were not read at the meeting, when only discussions on them were heard. Both the papers and the discussions are reproduced in this book.

***Polyesters and their applications.**

Bjorksten research laboratories. New York, Reinhold, 1956. 618p., $10.00 (U.S.)

A comprehensive summary of information on raw materials, resin manufacture, fillers, reinforcements, shaping, finishing, and uses of polyesters, including both unsaturated and saturated (linear fiber-forming and di-isocyanate-modified). A brief exposition of the theory of high polymers and of polyesters is included, and separate sections are devoted to physical properties of commercial resins, testing methods, and health hazards. The accompanying bibliography of over 3000 annotated references covers patents, books, articles, and manufacturers' publications.

Power system stability, v. 3, Synchronous machines.

E. W. Kimbark. New York, Wiley, 1956. 322p., diagrs., $10.00.

The first two volumes of this work covered the elements of the stability problem, the factors affecting stability, methods of making stability calculations, power circuit breakers and protective relays. This third volume deals with the theory of synchronous machines and their excitation systems.

Discussed in detail are such effects as saliency, damping, saturation and high speed excitation, giving the reader a greater understanding of power system stability than can be obtained by reading the first volume only. Steady-state stability is given a more detailed treatment than was possible in volume 1, whilst also considered are the characteristics of synchronous machines, reactances, time constants, short-circuit currents and amortisseur winding.

Radioisotopes, the wonder tool; a non-technical source book on practical uses of radioisotopes in industry.

W. A. Shead, ed. Washington, Atomic energy guideletter, 1956. 90p., $7.50 (U.S.)

This publication, concerned with the industrial uses of radioisotopes, lists such information as: commercial sources and

services, various isotope labeled compounds, gauges and other instruments, and publications for radiosotope users. One section gives examples of the uses made of radioisotopes by particular industries.

The pulp and paper manual of Canada, 24th ed.

Gardenvale, Que. National business publications, 1956. 465p.

A useful manual, this edition includes, besides a variety of miscellaneous information, flow sheets for 26 mills, indexes of machinery, supply and service companies, trade names, foreign firms and their Canadian representatives, and a classified index of machinery and supplies.

Rocket propulsion elements, 2nd ed.

G. P. Sutton. New York, Wiley, 1956. 483p., illus., $10.25.

This revised edition of a basic work on rocket propulsion contains a broader treatment of the basic elements and technical problems of rocket propulsion systems. There are also more complete descriptions of the physical mechanisms, application and design of the systems.

The first chapters provide a historical background, and give the general principles of thermodynamics, chemistry and heat transfer as applied to rockets. There are three chapters on liquid propellant rockets, their working fluids and design, and three new chapters on solid propellant rockets, their fundamentals, design and working substances. Two final chapters discuss flight performance and rocket testing.

There is a forty-page bibliography of references for further reading.

Satellite!

Erik Bergaust and William Beller. Toronto, Doubleday, 1956. 287p., illus., $4.75.

With the projected launching by the United States of the earth satellites developed under Project Vanguard not many months away, the appearance of this book is most timely.

The authors, both engineers connected with aviation publications, answer many questions relating to the manufacture, launching and scientific value of earth satellites, in non-technical language.

For those who wish to pursue this fascinating, and, as it is being proved, practical, field further, there are several pages of references for further reading.

The stateman's year book 1956.

S. H. Steinberg, ed. Toronto, Macmillan, 1956. 1622p., $6.75.

The information contained in this ninety-third edition has been brought up to date as much as possible, although in some cases figures given are of necessity estimates.

The book is divided into four sections, the first dealing with international organizations, including the United Nations and its specialized agencies, the World council of churches, the Council of Europe, the Colombo Plan, etc.

In the remaining three sections, the British Commonwealth, the United States and the rest of the world, information given for each country includes details on government, area, population, religion, education, justice, finance, defence, production and industry, banking, etc.

Lists of selected reference books and sources of statistical information are given for each country, and there is a detailed index.

This is an indispensable reference book.

Studies in ancient technology.

R. J. Forbes. Leiden, Brill, New York, Heinman, 1955. 268p., illus., $5.50 (U.S.)

There are to be eleven volumes in this series of essays on pre-classical and classical technology. The first volume dealt with bitumen, petroleum, alchemy and water supply. The second volume covered drainage, land transport and road building, power, and the first domestication of the canal.

The essays in this third volume reveal the secrets of the cosmetics and perfumes used in antiquity. For those interested in ancient recipes, the references in the essays on food and alcoholic beverages might result in some palate-pleasing products.

Other essays deal with grinding, salts and preservation processes and paints, pigment, inks and varnishes.

These glimpses into the achievements of early technology show very clearly how grateful the modern world should be to the engineers who have made possible the great advances of more recent times.

La thermodynamique et le théorème de l'énergie utilisable.

R. Marchal. Montreal, Fomac, 1956. 208p., diagrs., $7.45.

The course given at the Ecole nationale du Génie rural, which forms the substance of this book, was intended to explain the workings of various heat machines, either moving or refrigerating, and the book is essentially practical in outlook. Mathematics are kept to a minimum. Some of the topics covered include temperature, heat, the first and second laws of thermodynamics, the properties of ideal gas, etc.

Written by an engineer for engineers, this should prove a most useful book.

La turbine à vapeur en exploitation.

E. A. Kraft. Montreal, Fomac, 1956. 476p., illus., $21.65.

This treatise on steam turbines is addressed to the user rather than the designer, and consequently details of their construction and function are given only in as much as they are essential to clarify problems with which the user may be confronted.

The first section of the book deals with installation, and covers such topics as transportation to the site, foundation, condenser, assembly and alignment of axial turbines, regulation, etc. Part two,

service, includes detailed instructions for first putting the machine into service, and for measures to take in the different circumstances which are likely to arise while the machine is in use.

Part three deals with the various faults which may develop in service, giving cause and remedy.

The author has drawn on his many years of experience in writing this book which is well illustrated, and contains a thirty page bibliography, most of the items listed being in German.

UFO and the Bible.

M. K. Jessup. New York, Citadel, Toronto, McLeod, 1956. 126p., $3.00.

The author, an instructor in astronomy and mathematics at the University of Michigan and Duke University, has done a great deal of research on unidentified flying objects, and has written two other books dealing with them.

In this work Mr. Jessup presents the thesis that many of the miracles in the Bible can be explained by the presence of flying saucers and other UFO. He shows that many of the phenomena reported in the Bible are very similar to those being reported today. Coming as it does with the announcement of a film documentary showing UFO sightings, this book will doubtless provoke much discussion and speculation.

Vacuum-tube circuits and transistors.

L. B. Arguimbau. New York, Wiley, 1956. 646p., diagrs., $10.25.

An extension of the author's Vacuum-tube circuits, this work includes information on transistors, frequency modulation, inverse feedback and noise. As the author points out in his preface, the field is constantly changing, and much that was new in 1920 is now completely passé. For this reason, the author has concentrated on fundamental principles, and mathematics as much as possible.

The book is concerned primarily with circuitry, although in the case of transistors, the physics involved have been considered in great detail. Each chapter begins with relatively simple material, and considers more advanced points later in the discussion.

The weldability of high-tensile structural steels.

C. L. M. Cottrell and others. London, British welding research association, 1956. 79p., illus., £1.

This report describes the research carried out between 1948 and 1954 on the metal-arc welding of high tensile structural steels.

The investigation was concerned with the problem of cold cracking in the heat-affected zone of welds made in low-alloy structural steels. The first two parts of the report deal with the development and testing of special steels, and the second two with the mechanism of hard-zone cracking, the assessment of weldability and the influence of hard-zone cracking on fatigue life of fillet-welds.

A useful bibliography is included.

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Automation.

Automation and electronics, a bibliography. H. C. Thole. (Management research service)

Construction industry.

Apartment building standards. (Central mortgage and housing corp.)
Canadian construction association. Proceedings of the 38th annual general meeting.
Choosing a house design. (Central mortgage and housing corp.)
Selected bibliography on building construction and maintenance 2d ed. (U.S. National bureau of standards, Building materials and structures report no. 140)

Copper and copper alloys.

Elevated temperature properties of coppers and copper base alloys. (A.S.T.M. s.t.p. no. 181)

Electrical engineering.

The insulation level of power transformers. (B.E.A.M.A. publication no. 156-1956).

Inverse feedback (New York, Rider, 90 cents)

TV manufacturers' receiver trouble cures. v.8 (New York, Rider, $1.80)

Roads and streets.

Joint spacing in concrete pavements (U.S. Highway research board. Report 17-B)

Report on the AASHO road test project. G. D. Campbell. (Canadian good roads association)

Water resources.

India. Irrigation research institute. Annual research report. 1954.

Waves, water.

Approximate response of water level on a sloping shelf to a wind fetch which moves towards shore.

A laboratory study of short-crested wind waves (U.S. Beach erosion board. Technical memoranda nos. 83, 81.)

Miscellaneous.

The appraisal of executive performance. Bibliography. (Princeton. University. Industrial relations section, selected references, no. 71)
The renascence of city hall. New York City.

STANDARDS REVIEWED

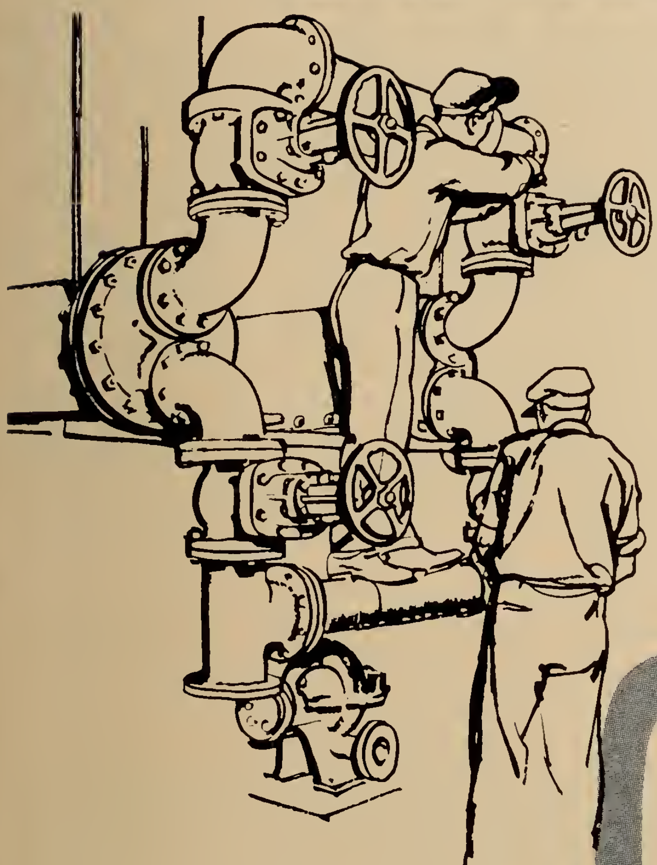
A.S.T.M. Standards, American society for testing materials, 1916 Race St., Philadelphia 3.

Engine antifreezes

A compilation of all ASTM methods of tests pertaining to engine anti-freezes, containing 11 standards. In addition to the test methods and specifications it contains an appendix including notes on significance and interpretation of the glassware corrosion test.

The contents include: methods for sampling, determining freezing points, THE NEW *Labatt's* BREWERY:

where PIPING *really counts*



The new Labatt plant in Montreal marks yet another milestone in the industrial development of Canada . . . as in the growth of CONNOLLY & TWIZELL LIMITED who were entrusted with the Plumbing, Heating and Process Piping installations.

Our own new building, just completed, houses the staff and facilities of Connolly & Twizell, and of its associated companies, **CONNOLLY & TWIZELL SPRINKLERS LTD.** and **COMBUSTION & POWER EQUIPMENT LTD.** in a manner designed to facilitate the execution of such contracts as Labatt's, and other important industrial and institutional buildings.

2655 BATES ROAD • MONTREAL • RE. 1-6441

physical testing, chemical testing, and specifications for a hydrometer-thermometer field tester and thermometers. 52p., $1.50 (U.S.)

Mineral aggregates and concrete.

This is the latest edition of standard and tentative specifications, test methods, and definitions of terms pertaining to mineral aggregates, concrete, and selected nonbituminous highway materials, or those involving aggregate gradings or tests. It also contains pertinent specifications for cement, and reference to specifications on concrete reinforcement bars (steel).

Subjects covered include specifications and methods of test for aggregates (crushed stone, crushed slag, gravel, light weight); ready mixed concrete; air entraining admixtures; methods of test for air content of concrete, compressive strength, flexural strength, freezing and thawing, slump test; brick and block pavement materials; concrete curing material; expansion joint fillers; cement. 360 p., $3.75 (U.S.)

British standards, British standards institution, 2 Park St., London, W.1. Also available from the Canadian standards association.

B.S. 23: 1956—Trolley and contact wire for electric traction.

A revision of B.S 23:1949 containing an additional standard size of contact wire (0.166 sq. in. section) primarily for use in high voltage alternating current railway electrification. The requirements are substantially the same, for both copper and cadmium-copper wires, but a bending test is now specified in addition to the tensile, elongation and torsion tests. The electrical resistance is now related to the standard reference temperature of 20 deg. C. adopted generally in the British standards for electrical conductors. 4/-.

B.S. 2755:1956—Copper and cadmium-copper stranded conductors for overhead electric traction systems.

This standard provides a range of standard stranded conductors suitable for overhead electric traction systems. Contact wire has been standardized for many years, but with the extensive electrification of railways a need has arisen for standard stranded conductors for such purposes as catenaries and feeders. 5/-.

B.S. 2757: 1956—Classification of insulating materials for electrical machinery and apparatus on the basis of thermal stability in service.

This classification is identical with the International electrotechnical commission document of 1954. Three new classes are introduced and the former class 0 has been re-designated class Y. The basis of the new classification is not the chemical composition of materials but rather their ability to withstand the temperatures assigned to their class. These temperatures are stated and a general description of each class is given. An appendix gives guidance on the classification of a number of particular insulating materials. It should be noted that the temperature rise specified in any particular standard need not in every case be such as to bring the maximum total temperature to that assigned to a particular class of insulation in this classification. 4/-.

B.S. 2762:1956—Notch ductile steel for bridges and general building construction

This publication is based on the fact that there is no general agreement about

• LIBRARY NOTES

tests, however the Charpy 'V' notch impact test, carried out at sub-atmospheric temperatures, provides guidance. The low temperatures used for the impact tests do not necessarily imply that the steels described are guaranteed as being completely satisfactory for use at these temperatures, though in general they can be regarded as progressure improvements over ordinary mild steel. The specification covers four grades of notch ductility and each grade is covered in two tensile ranges. 3/-.

B.S. 2765:1956—Dimensioning system and terminology for industrial temperature-detecting elements and pockets.

This standard defines the terms relating to thermometer elements and pockets, and their protective devices, and describes a dimensioning system, together with appropriate letter symbols, which may be employed in the preparation of purchasing specifications for industrial applications. The temperature-detecting elements to which this standard applies are component parts of liquid-filled, mercury-filled, gas-filled and vapour-presure thermometers, glass-stem thermometers, and resistance, thermocouple and bimetallic thermometers. It is limited in scope to detecting elements. An endeavour has been made throughout to achieve Anglo-American accord in terminology and lettering symbols. Included, as an appendix are some preferred dimensions for attachment threads and attachment flanges, the use of which will be a step toward securing interchangeability of the elements as complete units. 2/6.

B.S. 2771:1956—Electrical equipment of machine tools.

The subject-matter of this standard deals with control apparatus, motors, wiring and related accessories which are furnished as part of the machine tool and originate at its isolating switch. It specifies the conditions under which the equipment is applied on machine tools. The varied existing requirements directly affecting machine tools have been brought together as far as possible. A close check was kept on overseas regulations so as to minimize the difference between it and other such documents. 5/-.

Canadian Standards, Canadian standards association, National research building, Ottawa.

C50-1956—Transformer and switch oils.

Methods and tests used are all in accordance with those issued by the American society for testing materials. 75 cents.

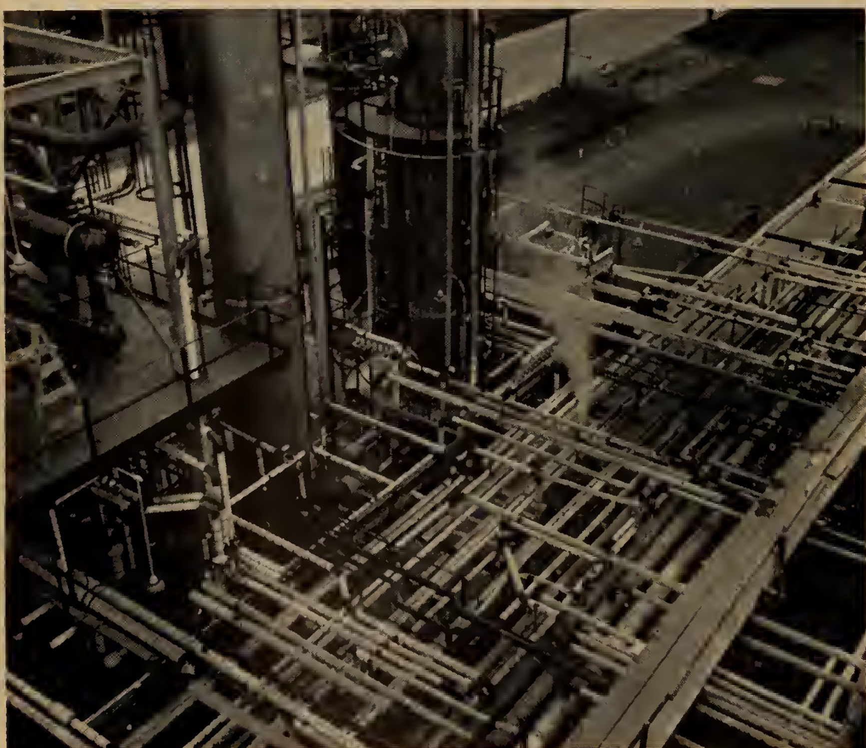
The Chemical Industry

There are still many people, and by no means all of them laymen, who regard the chemical industry as a major employer of chemists and of little else in the way of technically trained men. This view is very far from the truth, particularly where engineers are concerned, for they are essential to the industry and their services are ever more in demand as production, new products, and new techniques are developed.

The Canadian chemical industry has expanded continuously, especially in the last ten years or so, until the 1955 value of chemicals and allied products exceeded $1000 million. This expansion is likely to continue, and an estimated $165 million is to be spent during 1956 on capital expansion in the form of new construction, machinery, and equipment for the industry.

What is the chemical industry? The industry is now a complex combination of producers and processors and in many cases cannot be sharply defined; for example, the pulp and paper industry and the petroleum industry now include major chemical operations. Are petro-chemicals a part of the petroleum refining business or of the chemical industry?

A corner of a modern petroleum-chemical plant shows the complexity of a process industry. The need for engineers for plant design and operation is considerable.



A simple way in which to indicate the scope of the chemical industry is to quote the main divisions into which it is divided for the purposes of the government statisticians. These include: coal tar distillation; heavy chemicals; compressed gases; fertilizers; medicinals and pharmaceuticals; paints and varnishes; soaps and washing compounds; toilet preparations; inks; vegetable oils; adhesives; polishes and dressings; primary plastics; and a miscellaneous group that includes such items as explosives, hardwood distillation, insecticides, matches, and dry colours.

The manufacturing facilities of the chemical industry are well spread out across the country, with certain concentrations such as at Sarnia, Ont., where a large petroleum-chemical industry has grown alongside the established petroleum refining centre. The statistics for 1955, covering the chemical and allied products divisions of the chemical industry listed above, show that over 1100 establishments were involved, employing more than 50,000 people, who earned over $180 million. The cost of fuel and electricity used in the operation of these plants exceeded $33 million, and the cost at plant of materials used was over $480 million. Conservative estimates of the future of the industry foresee an expansion to three times the present volume in the next twenty years.

Agriculture, forest products, and mineral extraction are of major importance in Canada's industrial growth, and all three are major users of chemicals — fertilizers, pest controls, plant foods, bulk acids and alkalis, and so on.

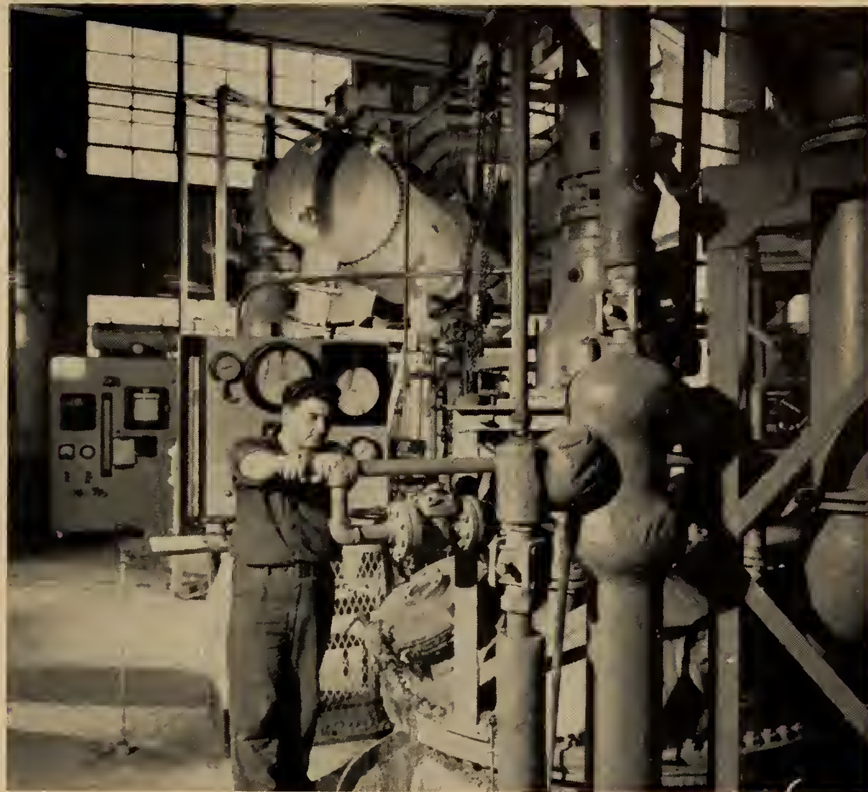
Design and Operation

Many of the chemical products of today are made by continuous processes; that is, in plants designed for continuous operation. Batch processes also play a large part in the industry, but whatever the process the design of plant is all-important.

As new products and techniques are evolved the operating conditions within plants tend to become more and more severe. Extremely high temperatures and pressures are often required and such problems as chemical attack on plant and equipment, already serious enough under normal conditions, become almost insuperable. Almost, but not quite (or there would be no progress) thanks to the continuing development of new materials and the efforts and ingenuity of the design engineer and his associates in various fields of research.

Engineers are required for the design of new projects, for additions to existing facilities, and for changes to layout and equipment. They are also needed for the construction of plants and facilities, and for the continued operation of the plant. The services of mechanical, electrical, civil, and of course chemical engineers are widely used by the industry for the phases of design construction, and operation.

A modern chemical process plant is frequently almost fully automatic in operation and incorporates large installations of automatic control equipment — hydraulic, mechanical, electrical, and electronic — with a consequent need for a knowledge of control and instrumentation. Large quantities of materials are often involved, and products are usually made to strict specifications; men are therefore needed with experience in the fields of materials handling and quality control. Plant maintenance is often a very important field, because of the high rate of attack on vital equipment that may occur.



A typical view of a plant for the production of primary plastics. Recording and control equipment and instruments are a familiar part of the scene in process plants.

Development

Apart from the design and operation of plant, the engineer is becoming more concerned with the development of new products and their application.

A good example of this trend is seen in the plastics industry. The chemist and chemical engineer are largely involved in the development of new materials and the processes for producing them, but the application of these new products is spreading into many other industries and supplementing or even superseding traditional materials.

The electrical industry is using more and more plastic and other synthetics; laminated materials are among those finding use in the mechanical field, for such applications as gears, and in the construction industry; and the rapid growth of new textile materials is well known. For these and all the many other existing and potential applications of products of the chemical industry, there is a constant effort to expand —and many engineers are involved in this work.

Other Opportunities

As was mentioned earlier, there is some doubt about where the chemical industry begins and ends. The borders are always expanding, and with them the scope for the talents of the engineer.

In addition to the fields of opportunity for the engineer mentioned so far—design, construction, and operation of plants, research and development, and application of products —there is quite extensive scope within the industry for the engineer in sales work and in administration up to the most senior positions.

The industry includes large organizations covering a wide range of operations and products and also smaller specialist organizations in certain specific fields.

Salary and Benefits

The chemical industry follows the usual pattern of starting salaries for the graduate engineer, based on ability and experience and largely in line with other major Canadian industries.

Paid vacations, health and pension schemes, and other benefits are usually of the high standard that is widely found in industry today.

Training

Most companies take undergraduates for summer work.

Training schemes are generally provided for the graduate engineer who joins an organization, and are designed to develop his knowledge to the best advantage.

NEW "Unionmelt" Welding Assemblies

for greater job versatility- performance dependability

Versatility and dependability are yours at an all time high in an improved new line of UNIONMELT welding assemblies . . . These units embody the greatest variety of machine combinations, job applications, and design features ever offered for submerged arc welding.

Wire feed units are simply constructed and are highly efficient . . . Identical mounting dimensions for heads, brackets, and slides allow for any number of desired assembly combinations.

Welding heads have exceptional flexibility because of sturdy new mounting fixtures which provide for vertical, horizontal, and rotary adjustment. Stationary and self-propelled combinations are also available.

The wide variety of standard and custom UNIONMELT welding assemblies can easily be made to fit your particular applications—at costs lower than many current standard models.

See your local LINDE *representative today for information on the many other new features—or write for free illustrated literature.*

coupled with sound engineering training, are the principal qualifications required. File No. 5864-V.

ENGINEERING SALES' REPRESENTATIVE required by leading Material Handling Equipment Company with head office and plant located in Montreal. We require a man 25 to 35 years of age with an electrical engineering or technical background to train for a sales and engineering position. The job offers a good future with an expanding company and the employees can participate in group hospitalization, pension and insurance plans. Reply stating age, qualifications, and salary anticipated. File No. 5868-V.

TWO MECHANICAL OR ELECTRICAL ENGINEERS to handle production problems. One of these Engineers would be placed in charge of producing new instrument designs to specifications already established by our United States factory. This would call for occasional trips to the American plant, building initial models and working out production problems with the shop foremen. The other Engineer would be concerned primarily with panel layouts and production. This work calls for the arrangement of Instruments on graphic panels so that the operator can visualize the process and use the Instrument to best advantage. It would also call for liaison work with our United States plant and with our selling agents. While some previous experience with Instruments would be desirable it is not essential. The men would be given training for limited time and should preferably be under thirty years of age. File No. 5869-V.

GRADUATE ENGINEER required by major oil company for Sales Engineering position in Montreal and surrounding territory. Involves broad training in all petroleum products and their application in industry. Experienced and bilingual engineer preferred, between 25-30 years of age. File No. 5874-V.

PROFESSIONAL ENGINEER with broad experience in engineering work including chemical, and mechanical branches, capable of original design and able to exercise good public relations. Required to sell industrial process equipment in stainless steel and nickel alloys to the chemical, pharmaceutical and beverage industries. File No. 5877-V.

SALES ENGINEERS. Well-known Canadian sales and manufacturing organization with Head Office in Montreal has several attractive vacancies for recent engineering graduates with aptitude and interests in technical sales. Company is of medium size with steady record of expansion and sells engineering and industrial equipment to most of Canada's major industries. Successful candidates will undergo a training program with advancement depending only on performance. Please write in full confidence to File No. 5879-V.

TWO GRADUATE ENGINEERS, wanted for permanent positions, involving design and field work on construction and maintenance, one Electrical and one Civil, with a minimum of 1 to 2 years' experience, for engineering staff of expanding paper company, location Ontario. Applicant to furnish complete details of experience, age, marital status, etc. to File No. 5884-V.

ENGINEERS REQUIRED for expanding clay products industry in British Columbia and Alberta. Opportunities available in plant engineering, process engineering, and production engineering. Please reply stating personal information, experience and qualifications, etc. to File No. 5885-V.

MECHANICAL or ELECTRICAL ENGINEERS. Excellent opportunities leading to supervisory positions with large open pit iron ore mining project now in production in Northern Quebec. Please reply stating: age, education, full particulars regarding engineering experience. File No. 5895-V.

ASSISTANT or ASSOCIATE PROFESSOR in Mineral Engineering for appointment January 1, 1957, to give undergraduate and post graduate instruction in mining engineering, mining geology and allied subjects. First appointment will depend upon qualifications and experience. Salary ranges — Assistant Professor $4380 to $5100. Associate Professor $5100 to $6360 with superannuation and hospital insurance. Research and professional employment encouraged. Location Halifax, Nova Scotia Technical College. File No. 5898-V.

HEATING & VENTILATING ENGINEER. To assist in the design of heating & ventilating systems for industrial plants, offices & laboratories. The work will also involve preparation of estimates & selection of equipment. Preference will be given to graduate engineers with 2 to 10 years' experience in similar work. Starting location will be Montreal. File No. 5906-V.

MINING, MECHANICAL OR CIVIL graduate engineer to act as plant engineer, manufacturer in Ontario. The engineer selected should have a limited amount of experience & the duties involved would be general engineering draughting, surveying, estimating & Administration. Production processes involve the quarrying & production of lime products & separate production facilities cover the manufacture of mortar-mix. Applicants must be interested in production. Salary will be commensurate with experience and ability of applicant. File No. 5912-V.

LARGE NEWSPRINT AND SULPHITE MILL located in central Newfoundland requires Mechanical and Chemical Engineers for design, layout and maintenance control work in general and plant engineering departments. Engineers also required to carry out process control development work aimed at increased operating efficiencies and improved product quality in Technical Control Department. Experience in the Pulp and Paper Industry is preferred, but not essential. Salary commensurate with qualifications and experience. Excellent opportunities for advancement. Appplications should be made in writing, giving age, education and a summary of experience. File No. 5913-V.

PLANT ENGINEERING. Openings for senior and junior engineers in the design and construction of buildings and building services, in Montreal. Please apply in writing only including full particulars as to education and experience. Your confidence will be respected. File No. 5918-V.

INDUSTRIAL ENGINEERS required by a leading asbestos producer with an extensive industrial engineering program. Prefer engineering or science graduates. Non-graduates or time study engineers will be considered who have a thorough knowledge of wage incentives, job methods, etc., or high school graduates with mining experience. These positions are interesting and challenging and offer scope for advancement. Attractive starting salary, excellent working conditions, five day week, wide range of employee benefits. File No. 5919-V.

AIRCRAFT INSTRUMENT MANUFACTURER has immediate openings for intermediate & senior engineers & designers for an advanced navigational project involving experience in analogue computer, precision mechanical design, servo controls and associated radar, fire control & positioning systems. Candidates must be Canadian Citizens or British Subjects & positions are available at various levels of responsibility. File No. 5923-V.

ENGINEERING DEVELOPMENT OPPORTUNITY in South-Eastern B.C. Excellent opportunity for a young metallurgist or engineering graduate with the engineering development section of a leading metals & chemical fertilizers producer. Interesting work in the investigation of mechanical & material failures, application testing of metals & alloys, & non-destructive testing of all types can be expected. Previous experience in development work is desirable. Training will be provided if necessary. If this interests you, write giving full particulars of education, experience and approximate starting salary expected to: File No. 5926-V.

GRADUATE ENGINEER required for Industrial Engineering Department of Spruce Falls Power & Paper Co., Ltd., located in Northern Ontario. Young, vigorous department of four requires an additional Engineer. Recent graduate preferred. No previous Industrial Engineering experience required. Opportunities excellent. Starting salary $4,800, on or up, depending on qualifications. File No. 5930-V.

CONTRACT ESTIMATOR. We are looking for an ambitious man of about 35 years of age to be trained for Senior responsibilities in our Contract Estimating Department. The position will lead to the administration of one or more of the functions of analysis of labour and cost performance, and the development of original estimates and projection of future costs for all phases of manufacturing. A graduate in mechanical engineering or commerce with five to ten years' manufacturing experience of some responsibility would be preferred, but persons with equivalent experience will be considered. The position will provide sufficient interest, authority and salary to attract an exceptional man. Response to the advertisement will be treated in the strictest confidence. Location Montreal. Please reply in writing, giving full particulars of academic background and work experience to File No. 5933-V.

CIVIL AND MECHANICAL ENGINEERS. Two openings with challenging opportunities for work related to construction research and housing research are available in Eastern Canada. Requirements: Good academic records with 3 or 4 years' experience in building work. Full particulars will be sent to applicants to File No. 5934-V.

RETIRED ENGINEER required by consulting firm in Montreal to assist in the reproduction department which comprises: filing of blueprints, photographic machine, etc. Construction experience useful. File No. 5937-V.

ASSOCIATION NEWS —British Columbia

(*Continued from page 1561*)

traffic conditions stimulated a lively discussion period.

Equipment Maintenance Costs

F. A. MacLean, mechanical superintendent of the Department of Highways in Victoria, led off on Friday with a paper on "Maintenance of Equipment". He cited records, operation, supervision and mechanical, as the four elements contributing to the cost of maintenance, and outlined specific methods for dealing with each of them.

Keen Interest in Swimming Pools

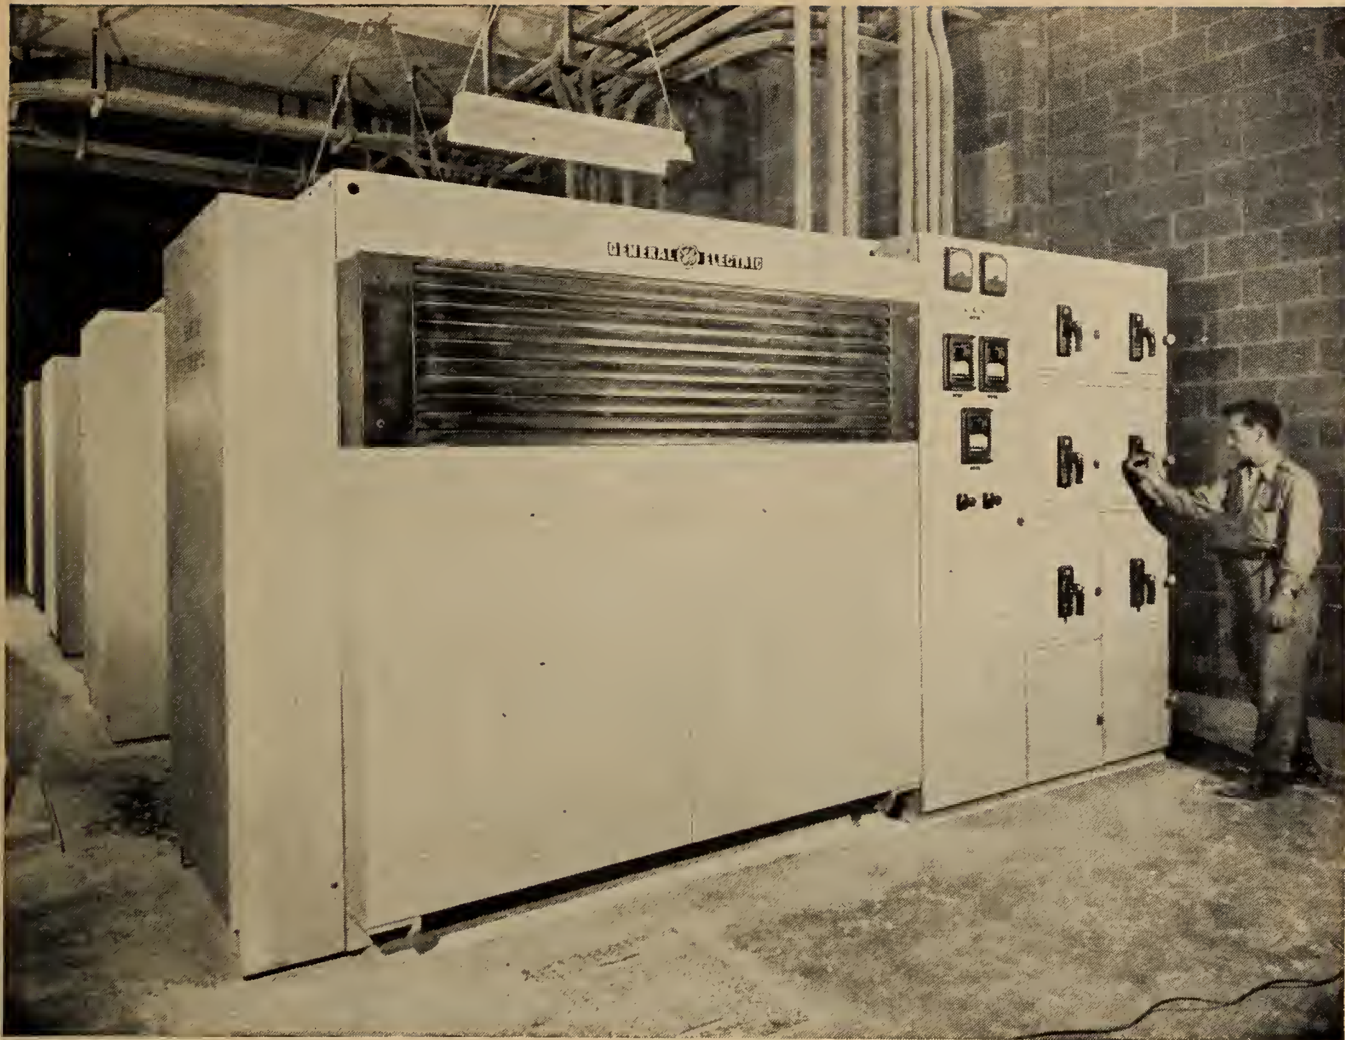
Considerable interest was aroused at the afternoon session by the paper on "Layout and Operation of Swimming Pools", by S. S. Lefeaux, assistant superintendent of the Vancouver Parks Board. He stressed that indoor public pools are expensive to maintain and operate and that recreational swimming for the public can be more adequately and economically provided with outdoor swimming facilities during the summer when the demand is greatest. He recommended a filtered re-circulated type of pool as most satisfactory for water clarity and purity.

Aspects of the New Municipal Act Outlined

J. E. Brown, Deputy Minister of Municipal Affairs, concluded the scheduled sessions with a talk on "Aspects of the New Municipal Act" which is to be submitted to the B.C. Legislature. It will combine into one act applying to all classes of municipalities, the matters now covered by six or seven different acts. Provision is to be made for additional types or classes of local governments, according to size and population, so as to permit an orderly progression of powers and duties from one class to another. The basis of municipal franchise is to be changed and municipalities will be required to prepare and abide by an annual budget.

Guest speaker at the annual banquet was R. P. Walrod, president and managing director of B.C. Tree Fruits, and the social programme included a dinner dance aboard Penticton's famous landlocked steamship "Sicamous".

The convention concluded with a field trip to a fruit packing plant, and a showing of technical films on Saturday morning.



These General Electric Load Centre Unit Substations are installed in an important Quebec mine. They are rated 1000 KVA, 2400 to 600 volts, with dry type 3 phase transformers and drawout, low voltage, air circuit breaker switchgear.

Save on installation costs with . . .
GENERAL ELECTRIC Factory-assembled Unit Substations

You save on installation costs with G-E Indoor Unit Substations because they are factory-assembled and shipped in easy to handle sections.

By specifying General Electric Unit Substations, you save valuable engineering time and obtain equipment which is completely coordinated by one manufacturer . . . enjoy the advantages of undivided responsibility and eliminate multiple component part expediting.

The standardization of manufacture of the component parts permits wide-scale interchangeability . . . makes relocation of a substation relatively simple. This "building block" method means that these dry-type unit substations can be quickly and easily installed anywhere in your mill, mine or plant . . . enables you to carry high voltage power right to the point of utilization with the resulting reduction in conductor sizes. At the same time it makes excellent provision for future load growth.

The compact design of G-E Unit Substations allows for easy access . . . greatly reduces inspection and maintenance costs. It will pay you to standardize on General Electric Load Centre Unit Substations. For further information, contact your nearest C-G-E Sales Office or write to: Apparatus Department, Canadian General Electric Co. Limited, 107 Park Street North, Peterborough, Ontario.

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Canadian Westinghouse appointments — Canadian Westinghouse Company Limited announce the following appointments: R. H. Cairns has been named to head up sales and contract administration for the atomic energy division; F. N. Holdsworth has been appointed head of manufacturing.

Canadian Steel Foundries (1956) Limited — The appointment of G. A. Gowdy as comptroller has been announced by G. L. McMillin, vice-president and general manager of the company.

Monsanto Canada Ltd. — Russell B. Bridges has been appointed to the newly created position of product sales manager, adhesives and resins.

Minnesota Mining and Manufacturing of Canada Ltd. — K. J. Shea, vice-president and general manager, has announced the appointment of John V. Powell as director of sales. It is also announced that E. H. Lill has been appointed sales manager tape and ribbon products for the company.

Electro Metallurgical Company — The appointment of Donald J. MacIntyre and Gordon E. Willey as vice-presidents is announced by G. O. Loach, president of the company (Division of Union Carbide Canada Limited).

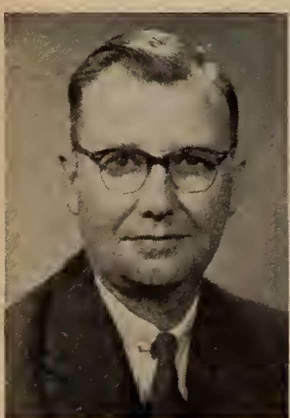
Thomas A. Edison of Canada, Limited —Charles H. Goddard has been elected vice president and a director of the company. Simultaneously was announced the establishment of four district offices with newly-appointed district managers, viz: Toronto — William H. Chalmers; Montreal — R. A. Thomas; Ontario — H. F. E. Smith; Vancouver — Stuart L. Slade.

Shawinigan Chemicals Limited — It has been announced by Dr. R. S. Jane, president, that George A. Donald, assistant secretary-treasurer, has been named treasurer of the company; Percy W. Wright, formerly secretary-treasurer, will continue as secretary and has been made a director of the company.

Surpass Petrochemicals Limited — The appointment of Fred W. Evans as assistant to the president of Surpass Petrochemicals Limited, Scarboro, Ontario, and Alox Corporation, Niagara Falls, New York, has been announced by James E. Shields, president of the two companies.

Linde Air Products Company — David S. Lloyd, president of the company (Division of Union Carbide Canada Limited), has announced the appointment of Whitford S. Wyman as vice-president and general manager.

G. E. Willey



D. J. MacIntyre

W. S. Wyman

R. W. Stevens

Dominion Engineering Company Limited — R. W. Stevens has been transferred from the position of assistant chief engineer, mining machinery and hydraulic presses, to sales manager of the industrial division.

The Canadian Kellogg Company Limited —Henry W. Wurdemann, general manager, has announced the appointment of E. W. B. Kleinsteiber as manager of procurement, and T. L. Lech as manager of accounting.

Collins Radio Company of Canada Ltd. —It is announced that Walter C. Ward has been appointed as resident manager, Ottawa office.

RCA Victor Company Ltd. — The board of directors have appointed Frank R. Deakins chairman, and P. J. Casella president and chief executive officer.

Joy Manufacturing Company (Canada) Ltd. — The following appointments are announced: D. W. M. Ross takes over the active direction in Canada as vice-president and general manager, with his headquarters in Galt; Edgar R. Edwards, previously manager of sales operations in the province of Quebec, succeeds Mr.

hidden cables deliver the power

Big Behind-the-Scenes Job

By providing for a constant delivery of power, those who instal power cables perform a major service to industry, mining, and the public utilities. Like the steel beams of a building, these power cables are an essential part of the distribution system but are often hidden from view. No matter what the power requirement, there is a Phillips cable designed to serve at every step of the way.

This is particularly important in the transmission or distribution of large blocks of power, where Phillips cables are the most efficient answer to your requirements. In reliability of long term operation, these cables offer a substantial advantage o the user.

For full details and advice contact your nearest Phillips office. Branches are located in Montreal, Ottawa, Toronto, Hamilton, Winnipeg, Regina, Edmonton, and Vancouver. The Phillips Electrical Co. Ltd. is the Canadian affiliate of the British Insulated Callender's Cables group, largest cable organization in the world.

Ross as general sales manger; M. S Cranston moves from Kirkland Lake to Galt as assistant general sales manager.

James Morrison Brass Manufacturing Company Limited — Gordon B. Harrison has been appointed general sales manager of the company.

Monsanto Canada Limited — The promotion of J. W. Lindsay to the position of group leader has been announced by Dr. A. F. McKay, director of research and development for the company in Montreal.

Federal Wire and Cable Company Limited — Eber Pollard, assistant chief engineer, has been appointed chief engineer in place of Bob Oldham who has gone to England.

E. Pollard

New Equipment and Developments

Crown Property Purchased—The Right Honourable C. D. Howe, Minister of Defence Production, recently announced that Avro Aircraft Limited and Orenda Engines Limited had purchased approximately $18,000,000 worth of Crown-owned machinery and equipment in their Malton plants. Avro's share of this total purchase was $3,768,000 and the Orenda portion $13,954,159. Avro Aircraft now owns its entire plant and facility, including all machine tools and equipment. The main plant was bought from the Government in 1945. Additional facilities were purchased in 1952 and 1953. Orenda Engines Limited bought its main production and engineering plants at Malton from the Government in 1953. The latest purchase of equipment gave Orenda ownership of virtually all facilities within these plants. The terms of purchase included agreement by both companies to maintain, for ten years, facilities for aircraft and jet engines development, manufacturing, repair and overhaul, and to give the Government priority on these whenever needed during that period.

Northern Research Station—President E. W. R. Steacie of the National Research Council recently officially dedicated the new Northern Research Station of the Council at Norman Wells, N.W.T. This station, consisting of a soils laboratory and a residence building for research, staff, has been developed by the Division of Building Research of the Council as a centre for its permafrost research work in Northern Canada. A small station was established in 1951 at Norman Wells, with the co-operation of Imperial Oil Limited.

The Eagle Pencil Company of Canada marked the passing of twenty-five years in Canada this summer by a reception and dinner party. Paul D. Normandeau, manager of the factory, presided at the meeting and the keynote address was given by Alfred C. Berol, president of Eagle Pencil Company, New York, which is now celebrating 100 years in business.

Portable Rotary Compressor—Canadian Ingersoll-Rand Company Limited announces the addition of a new 85 c.f.m. size to its line of GYRO-FLO compressors, now increased to six sizes — 85 c.f.m. through 900 c.f.m. The GYRO-FLO 85 weighs only 1840 pounds ready-to-go, fully equipped with tool boxes, fenders and two-wheel spring-mounted running gear. The light-weight and compactness of this new compressor also make it ideal for truck mounting. As a truck-mounted unit, the GYRO-FLO 85 weighs only 1375 pounds and stands only 42 inches high.

Fluid Cooler Equipment—Trane Company of Canada, Limited, have announced that their fluid cooler equipment (special heat transfer products) for radio, radar and TV Klystron vacuum tube cooling is now available for applications requiring the dissipation of from 1 kilowatt to 100 kilowatts of heat. The fluid cooler equipment is in compliance with commercial and military requirements, and is designed for operation anywhere in the world. (The Klystron tube is an electronic tube that converts direct current into ultra-high frequency current through electromagnetic sorting of electronic velocities.)

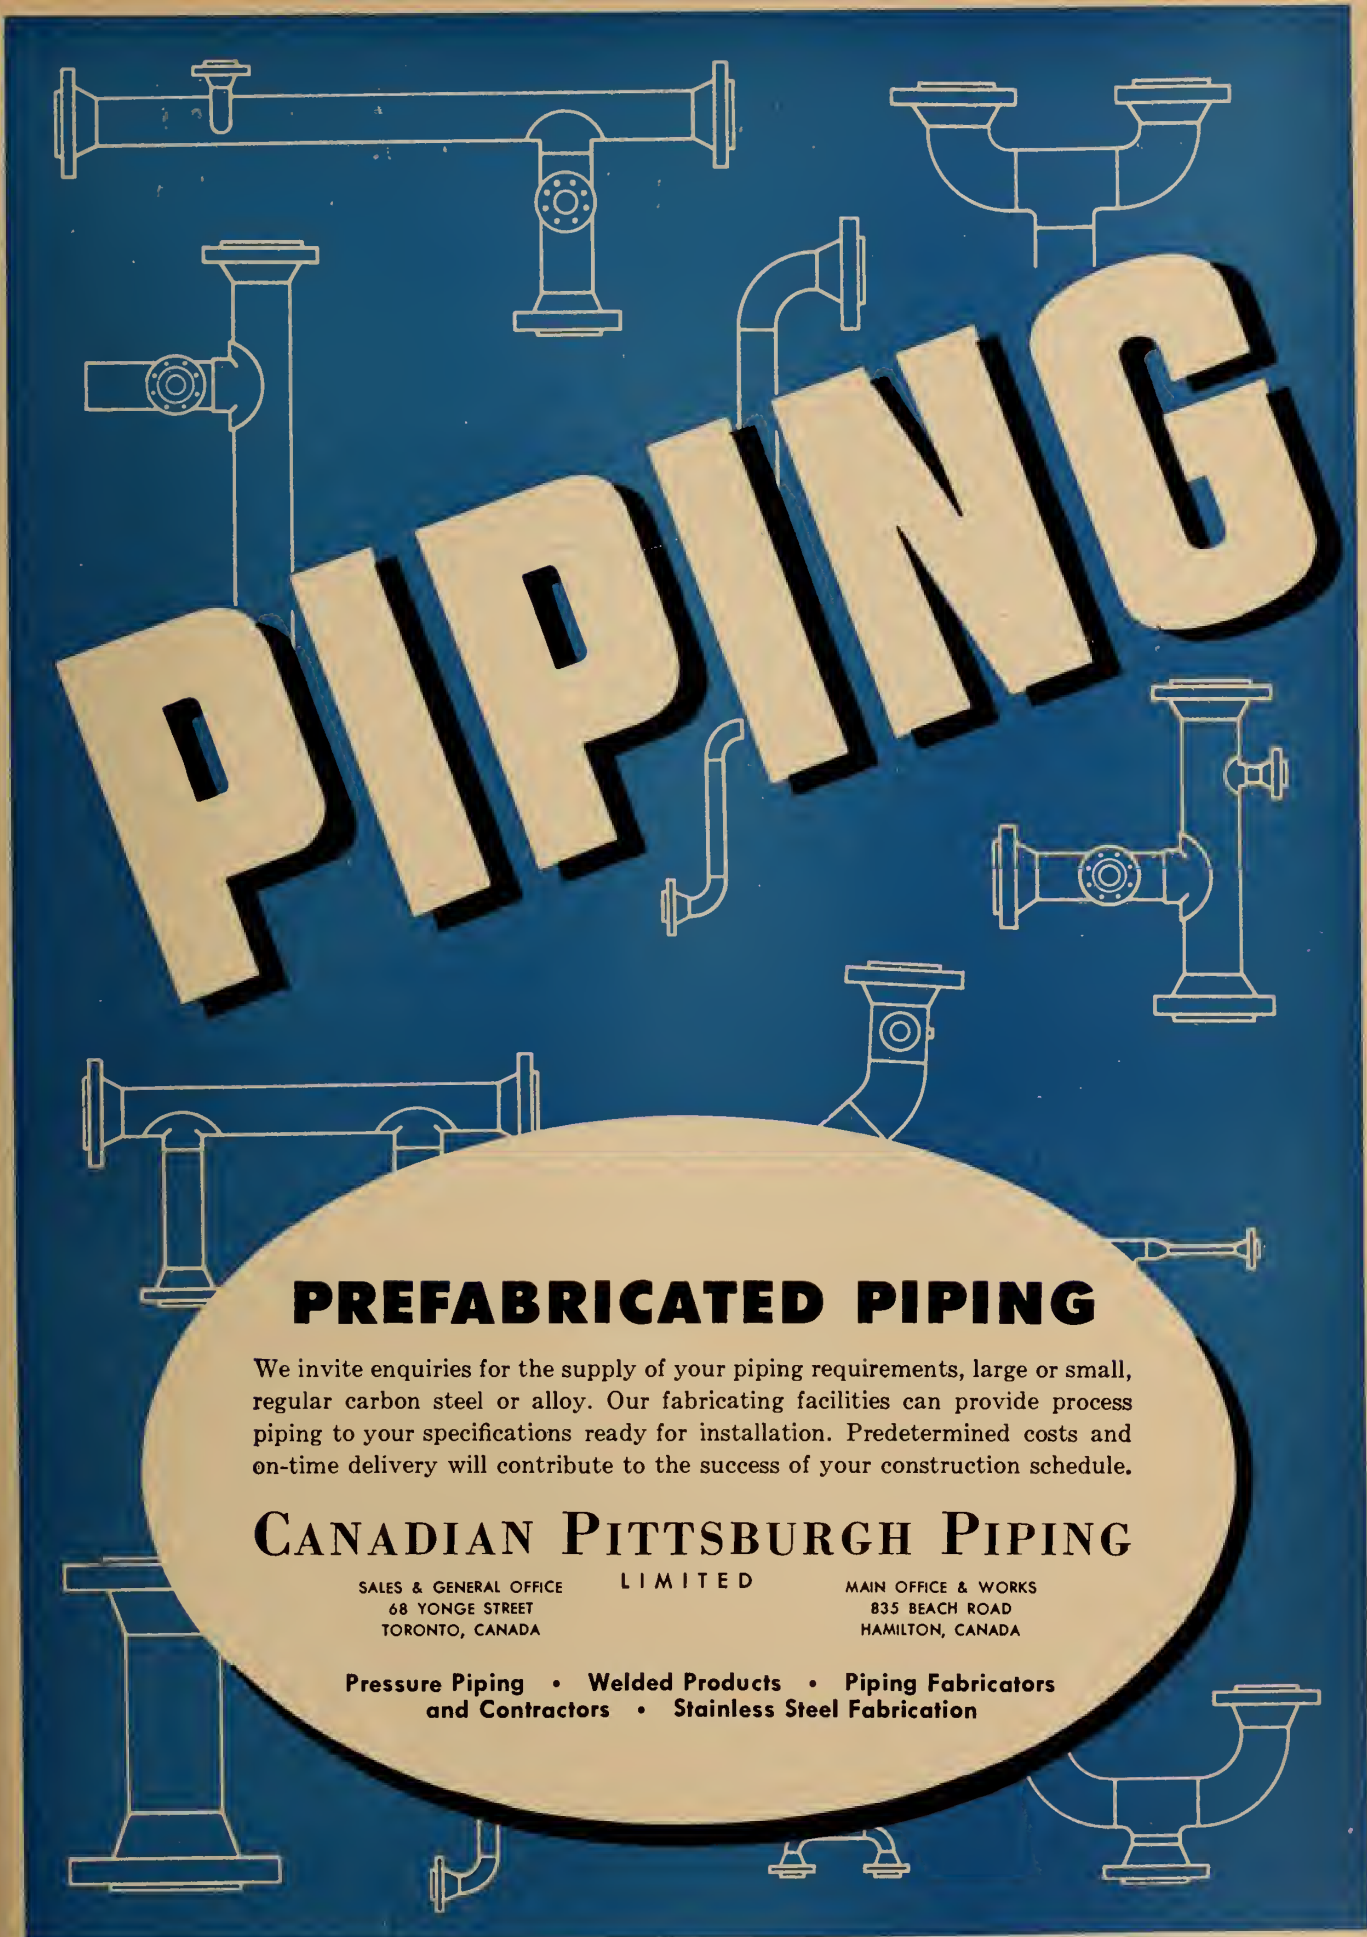
Asbestos Cement Sheet—A newly designed asbestos cement sheet for roofing and siding, made by Canadian Johns-Manville Co. Limited, is for application over skeleton-steel and wood-frame buildings. Introduced under the name "Transitile", this new product was engineered in the Johns-Manville laboratories. Corrugations in this improved design of roofing and siding material, are spaced approximately 13-1/3-in. apart, creating structural lines of a modern decorative appearance. Application economies result from lighter weight with no loss of strength. Among other advantages, the manufacturer stresses Transitile's non-combustible quality, its ability to retard the path of fire, its resistance to gases, fumes and climatic conditions.

B.C. Electric Order—The B.C. Electric Company Limited has placed an order with the Canadian Westinghouse Company for 39 outdoor oil circuit breakers and 4 duplex switchboards. The circuit breaker order is composed of seven type 230 GW 7500, 1200 ampere, 7500 Mva. interrupting capacity, 230/196 kv. oil circuit breakers; eight type BNOB, 15 kv., 1300 Mva. interrupting capacity, 4000 ampere oil circuit breakers and, twenty-four type 150 BJ500, 15 kv., 500 Mva. interrupting capacity 600 ampere oil circuit breakers. The switchboards are for the control, metering and relaying of the Newell and Mainwaring substations and the Clohom and La Joie generating stations.

Seawater Treatment—The second contract this year for more than a million pounds has been placed with G. & J. Weir, Ltd., Glasgow engineers, for seawater evaporating and distilling plant. This will supply 4,000 ton (896,000 gallon) of fresh drinking water daily to the Netherlands Antilles island of Curacao off the coast of Venezuela, with provision for future extensions. Weir's contract also includes power station buildings boilers, turbo-generating sets, pumps and piping. Two sextuple-effect evaporators will be supplied at first, the heating medium being exhaust steam from the turbo-generators at 30 lb./sq. in. The Weir scale prevention system will allow continuous maximum heat transfer in the evaporators, and no operating time will be lost in shut-downs for de-scaling. The power station plant will include two high pressure boilers each evaporating 81,000 lb./hr., supplying steam to the turbo-generators at 775 deg. F. and 650 lb./sq. in.g. Weir pumps are made in Canada by Peacock Brothers Limited.

Control Thyratron—A new control thyratron with three different base connections, is available from Canadian General Electric Company's Tube Section. The tube will give improved performance, yet be less expensive than the GL-5545 which now is superseded. The three new types of this 6.4-ampere negative control characteristic thyratron—GL-6807, GL-6808 and GL-6809 — all incorporate element and envelope construction de-GL-6807 has a pin-type base and can be used interchangeably with the GL-5545. The GL-6808 has flexible "flying" leads and the GL-6809 is made with spade lug terminals extending from the base.

Because they carry high commutation factory ratings they are particularly suited to motor control and other inductive



PIPING
PREFABRICATED PIPING
We invite enquiries for the supply of your piping requirements, large or small, regular carbon steel or alloy. Our fabricating facilities can provide process piping to your specifications ready for installation. Predetermined costs and on-time delivery will contribute to the success of your construction schedule.

load circuits without cushioning. Their ability to operate over a wide ambient temperature range (- 55 to + 70 deg. C) and a quick-heating cathode (1 minute) are features of particular usefulness in industrial applications. Maximum average cathode current of these motor control thyratrons is 6.4 amperes and fault current 1120 amperes. Maximum negative control grid voltage before conduction is minus 250 volts and during conduction minus 10 volts. Maximum positive control grid current is 0.20 amperes with the anode positive and 0.10 amperes with the anode negative.

Wagon Drilling — Joy Manufacturing Company (Canada) Ltd. announce new self-propelled Jr. Challenger model (CTM-1). Track mounted, it drills up to 3½ ins. diameter holes to depths of 40 ft. in any formation—vertical bench holes, toe holes, horizontal holes to 7½ ft. height, and angle holes both up and down from the horizontal. Tracks 6" wide are protected by heavy-gauge metal covers. Tramming power is provided by two Joy AM-3 piston air motors (one for each tread), which are direct-connected, thus eliminating drive chains. Drill and feed are mounted on a U-bar, which is raised and lowered by two double-acting hydraulic cylinders.

Silicone Rubber Cloth—A silicone rubber cloth coating compound for ducting which can carry air at temperatures as high as 700 deg. F. and remain flexible at 120 deg. below is available from Chemical Materials Sales, Canadian General Electric Company. Designated SE-701, this compound is of particular interest for such applications as hot air ducts, jet engine starter hose, flexible connectors for metal ducting, and aircraft fire wall seals. In addition to its wide temperature operating range, SE-701 also boasts resistance to flow under clamps, outstanding flame retardancy, and low swell in such fluids as Skydrol 500 and 700, JP4, gasoline, MIL-o-7808, and MIL-5606.

Low Hydrogen Iron Powder Electrode—Air Reduction Canada Limited announces a new all-position, low hydrogen electrode with an iron powder added coating for high welding speeds. The new Easyarc 328 is recommended for welding hardenable steels where no preheat is used. In addition high sulphur-free machining steels, cold rolled steels normally exhibiting excessive porosity when welded with conventional electrodes; low alloy or mild steel when stress relieving normally would be required but cannot be done and weldments to be vitreous enamelled after welding are well suited to Easyarc 328.

The physical properties of the weld deposit (as welded-unaged) are tensile strength 86,200 p.s.i., yield strength 70,-950 p.s.i., elongation in 2" 30.0% and reduction in area 61.8%. Easyarc 328 is an ac. or d.c. reverse polarity electrode.

High-Speed Recording Potentiometers—High-speed self-balancing recording potentiometers for use with analog-to-digital conversion devices have recently been announced by The Bristol Company of Canada Limited. Designed to give full-scale traverse in 0.4 second, the electronic Dynamaster can be equipped with most of the standard digital read-out devices presently available. Ample torque is available for operating retransmitting slidewires, alarm contacts, and other auxiliary devices, without affecting the dynamic characteristics.

Round chart models are also available for such service, for use where prominent indication of the variables is needed while feeding digitized information to data handling equipment.

PERMANENCE
FLEXIBILITY
ECONOMY

G-E FIBERDUCT
was the choice for

Sun Life Building	Montreal
Bank of Montreal Building	Toronto
British American Oil Building	Toronto
Bank of Commerce Building	Winnipeg
Saskatchewan Government Administration Building	Regina
Drumheller School	Alberta
Oil Exchange Building	Calgary

PERMANENT — FIBERDUCT is an extra strong underfloor raceway system that will not rust or corrode, and offers complete protection to wires and cables. FIBERDUCT'S design provides a concrete arch over the duct when the concrete is poured—strengthening the concrete above duct—eliminating the possibility of the concrete cracking along the line of the duct.

COMPLETELY FLEXIBLE — FIBERDUCT can be installed in any type of concrete floor construction — monolithic, slab and fill, and in all of their variations. It is adaptable to any type of floor finish — linoleum, tile, terrazzo, concrete, wood. No need to know the number and location of outlets beforehand — "*FIBERDUCT is the system that permits the installation of outlets anywhere along the line of duct — anytime during the life of the building*".

ECONOMICAL — FIBERDUCT is low in initial cost. Light weight and easy handling cuts installation costs. FIBERDUCT is the preferred underfloor wiring system for economy and service.

Please send me FREE Catalogue on G-E FIBERDUCT Underfloor Wiring Systems.

version. The ramp from barge to wharf is of special interest to engineers with its provision for a smooth surface for trucks under all conditions of tide and stream flow.

Paper Converting Plant

All phases of paper conversion to adhesive tapes, toilet paper and bags, were observed. The use of titanuim dioxide to obtain wax paper opacity was of interest. The largest corrugated paper machine west of Chicago can turn out eight foot wide stock at the rate of 600 feet per minute. This stock is printed, cut and folded into shipping containers for apples, cans, or other uses and a special testing laboratory has been set up for sampling production and testing the strength of new designs.

General

The visitors were impressed with the smoothness of the flow to finished product, all done with a minimum of manual effort, due to the use of automatic machines and miles of conveyors. The company is to be congratulated on its contribution to B.C. industry and its courtesy to visitors.

H. T. Libby Speaks on Natural Gas

Councillor H. T. Libby, M.E.I.C., manager of gas distribution of the B.C. Electric Company, spoke on "How Natural Gas will be Introduced to Vancouver" at the first speaker meeting of the 1956-57 season.

Mr. Libby has an extremely detailed knowledge of his subject but limited time restricted him to a few highlights.

Natural Gas Arrival

Natural gas should reach Vancouver in November, 1956 and will be initially imported from the San Juan fields of New Mexico until the West Coast Transmission line is completed to Peace River. At that time, Peace River gas will flow into Vancouver and also across the border.

Conversion of Appliances

The metropolitan area has been divided into a number of sections and these sections will be converted one at a time from manufactured gas to natural gas. About 300 trained men will work in each section as it is converted to redrill burner and make adjustments. 20,000 drills are on hand for this work on 100,000 appliances.

Gas Pressures

The transmission line pressure will be about 780 lbs. per square inch and this will be reduced in steps until it reaches the appliances at about four ounces of pressure.

Cathodic Protection

Pipe lines in rural areas will have cathodic protection but this is impractical in urban areas where pipes of all services may be in contact.

Reliability of Supply

Reliability of supply to consumers will be assured by the alternative sources of Peace River or San Juan and the provision of a propane plant and an oil gas plant.

Control

A new building will be the center for gas distribution control. Here meters will record pressures telemetered from check points scattered over the metropolitan area. Other telemeters will indicate the ate of consumption of the whole area and remote controls will enable pressure adjustments to be made at key points. With this centralized control using equipment proved elsewhere, the maximum of customer satisfaction should be obtained.

Structural Section

C. P. JONES, M.E.I.C.

The first regular monthly dinner meeting of the structural section, held on September 18, 1956, was attended by twenty-five members.

During coffee Gordon Ellis, M.E.I.C., gave a talk on the deformation of concrete columns under long-time loading.

Keith Douglas spoke briefly on the proposed criteria for prestressed concrete being prepared by the section committee under his chairmanship, for submission to the City building inspector. If these criteria are accepted by the building inspector, it will be possible to do prestressed work within the City of Vancouver.

Following dinner, Otto Safir, M.E.I.C., discussed "precast concrete construction", illustrating his talk with a number of excellent coloured slides. The talk was followed by a half hour discussion period.

Tour Welland Ship Canal

Thirty-eight members and friends of the Niagara Branch were guests of the engineering and management staff of the Welland Ship Canal for an inspection tour of some of the major works on the canal on September 20. Feature of the day was a trip through the triple flight locks at Thorold aboard the steamer "R. Bruce Angus". Invited to ride the lower foredeck for the trip through the first lock the group later inspected the engine room, which proved to be a model of cleanliness in white paint and gleaming metalwork.

Lock Control Room Visited

Returning ashore when the lower flight of the locks was reached, the guests visited the lock control room. The present Welland Canal which is the fourth in the succession of waterways connecting lakes Erie and Ontario, has been in operation nearly twenty-five years, but it remains as one of the major achievements of Canadian engineering. It is one of the largest and most important artificial waterways in the world. The triple flight twin locks at Thorold, although smaller than the Gatun locks in the Panama Canal, have a total lift of 139½ feet, as compared with 85 feet for the Gatun locks. The latter measure 1,000 x 100 feet while those at Thorold are 820 x 80 feet.

In the lock control room, the gate, valve and guard cable controls were explained and the operations were witnessed as the "R. Bruce Angus" passed on through the lower gate to the reach of the canal below.

Conducted Through Powerhouse

Moving on, the group were conducted through the canal power house at the foot of the locks where three 5,000—kva vertical waterwheel generators are installed to provide power for the operation of the locks and other waterway equipment.

Next point in the tour was a vertical lift road bridge. Conducted to the control room and engine room a routine raising and lowering operation of the bridge was witnessed.

At a dinner meeting following the tour W. A. O'Neil of the St. Lawrence Seaway Authority, D. J. Moon, J. H. Travers and P. E. Ellis of the Welland Canals department were spokesmen for the evening. Mr. O'Neil addressed the group on the subject of the deepening of the canal, being done as part of the St. Lawrence Seaway development. Electrical, mechanical and operational features of the canal were explained by Messrs. Moon, Travers and Ellis.

Chairman of the Branch, P. L. Climo, conducted the meeting. E. C. Little, vice-chairman, was responsible for the arrangements for the day.

Engineering of Post-War Expansions

at Courtaulds (Canada) Limited

A paper by Courtaulds (Canada) Limited engineering staff under the direction of P. H. Nasmyth, M.E.I.C., *Chief Plant Engineer.*

The Courtaulds Group, which grew up from a family silk weaving business located in a small village in East Anglia, is today one of the world's leading producers of man-made textile fibres, with numerous plants in the British Isles and with manufacturing interests in the U.S.A. and Canada, and many other countries.

Courtaulds Limited pioneered the production of Rayon by the Viscose process in the U.S.A. and the organization which was created developed into the American Corporation. During the late war, Courtaulds Limited sold the American Viscose Corporation in order to provide dollars to the British Government for the purchase of war materials, but since the war, they have re-entered the American rayon industry through their investment in Courtaulds (Alabama) Inc., the youngest of the American viscose staple fibre producers.

A further note about Mr. Nasmyth appears in the Personals section.

THE viscose rayon industry came to Canada in 1925, when Courtaulds built a five-storey mill building in Cornwall, Ontario, and began to produce continuous filament rayon yarns. Twenty-four rayon spinning machines went into operation at this time, and production of yarn was at the approximate rate of one million pounds per year.

Almost immediately, the plant started to expand, in order to keep pace with a constantly growing demand for viscose yarns. In 1926 and 1927, building extensions were added to the original No. 1 mill, and 19 more spinning machines were installed.

In 1932, No. 2 mill was erected, with installation of another 32 spinning machines of an improved type. Only two years later, in 1934, No. 3 mill was built and a further 42 spinning machines of the latest type went into production. Another major plant expansion took place in 1938, when No. 4 mill was constructed to house an additional 88 spinning machines, 50 of which were installed prior to World War II, the remaining 38 being installed progressively between 1942 and 1948.

So it was that Courtaulds (Canada) Limited, from its modest beginning in a single building in 1925, had grown in the short space of 14 years into a large industry occupying four major mill buildings and producing in 1939 at the rate of some 12 million pounds per year. This annual output was almost entirely in the form of continuous filament textile yarn for the clothing industry; for such materials as printed dress goods,

Title picture: Aerial view of whole plant. No. 5 mill, centre; No. 1, 2, 3, and 4 mills in middle background (No. 1 is the large building nearest the St. Lawrence river, background). knitted goods, linings, crepes, and hosiery.

Up to this time, all yarn was produced on box spinning machines (Fig.1). This type of machine spins liquid viscose into a sulphuric acid spinning bath where it coagulates and forms viscose yarn, which is picked up by two godet wheels and deposited, by a sort of batch process, in acid cakes that are formed inside rotating bakelite spinning boxes. These acid cakes subsequently have to be desulphurized, washed, dried, and coned or beamed before the yarn is ready for shipping.

However, expansion of textile yarn production up to 1939 was only the beginning of bigger things to come. In the late 1930's, development by the Courtaulds organization of high-tenacity heavy-denier rayon yarns, opened the way for use of viscose rayon in the industrial field; in automobile and truck tires and in conveyor belting. During the war years, the place of viscose rayon as a superior tire yarn was firmly established, and it became apparent that large scale tire yarn production would be a necessity at the Cornwall plant.

As early as 1943 and 1944, as a part of Canada's war effort, the 32 box spinning machines in No. 2 mill were converted for box production of tire yarn. This conversion consisted largely of the addition of hot water stretch baths to the machines, and installation of tanks, pumps, and piping required to circulate hot water (about 200 deg. F.) through

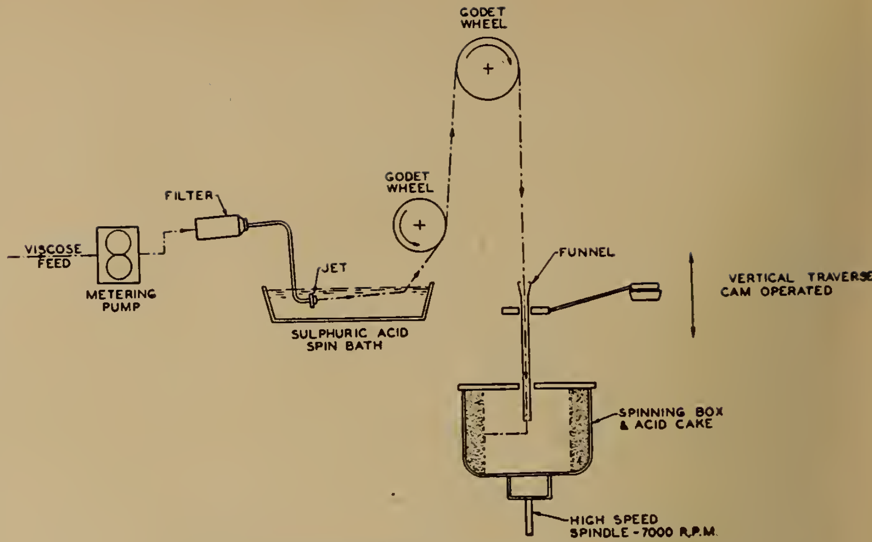

Fig. 1. Schematic diagram of box spinning machine.

the new bath sections on all machines.

Simultaneously, the Courtaulds organization and the textile industry were developing and perfecting new uses for viscose staple fibre, many of them depending on blends of viscose staple with the natural fibres of wool and cotton. These blends with other textile fibres proved so acceptable to the Canadian market that, by 1945, a large demand existed for a variety of deniers and lengths of rayon staple fibre.

So it was that the years immediately following World War II found Courtaulds (Canada) Limited, now producing textile and tire yarns at a combined rate of 14 million pounds a year, engaged in planning a large-scale expansion program that would answer the new and growing demands for tire yarn and staple fibre.

Main requirements were as follows:

(a) Production of high tenacity tire yarn by a process new to the Cornwall plant, called continuous spinning, and involving installation of a number of rayon spinning machines of an entirely new type.

(b) Production of staple fibre, on another new type of spinning machine similar to those recently developed in both the United Kingdom and the United States, and involving the installation of cutting, washing, drying, opening, condensing, and bal-

Central viscose plant adjoins, right centre, with churn house (five storeys) at far end. CS_2 storage building behind top of stack; sulphuric acid tanks at right centre.

ing machinery; all of them new to the Cornwall Plant.

(c) A new viscose plant, that would completely replace the old viscose producing unit, already outmoded and of inadequate size, and that would supply viscose for all three major products; textile yarn, tire yarn, and staple fibre.

(d) Supply of services for these three proposed plant expansions, involving extensive additions to all the important services installations; steam, water, electric power, refrigeration, and compressed air.

Expansion projects that evolved from full study of these requirements were:

(a) Construction of a large new building, to be known as No. 5 mill, which would house the new central viscose plant, the new staple fibre plant, and also the new compressor room, and which would also provide for greatly expanded facilities for handling and storage of raw materials.

(b) Installation of new tire yarn machines in the east end of No. 2 mill, where they would replace the old acid reeling and bleach departments, already obsolete.

(c) Expansion of the acid recovery department to provide for recovery of the greatly increased volumes of spin bath that would be in use.

(d) Installation of additional yarn processing machinery.

(e) Services expansions to provide for the requirements of these new projects.

Each of these projects was to be carried out in a way that would provide for further expansion in the future.

Construction of the New Plant

Construction of No. 5 mill was started in the spring of 1946. The central viscose plant and the staple fibre plant went into production progressively between the summer of 1948 and the autumn of 1949.

Originally it was intended to locate No. 5 mill directly west of the other four main mill buildings. However, the load-bearing capacity of the subsoil in this area, which lies over an old stream bed, was found to be so small that the entire building would have had to be supported on piles. It was found that the cost of piles, in comparison with the value of the buildings themselves, would have been prohibitive. Accordingly, the new plant was established in its present location, farther north than originally planned (Fig. 2). In this new location, only about one third of the structure, at the east end, still lies over part of the old stream bed, and is supported on piles. Steel piles were considered, but the subsoil was so soft in places, being a slippery blue clay, that the number of steel piles would have been excessive, and because of this it was decided to use compressed concrete piles. These are reinforced concrete piles poured in place by a special process, and have more load bearing capacity than steel piles.

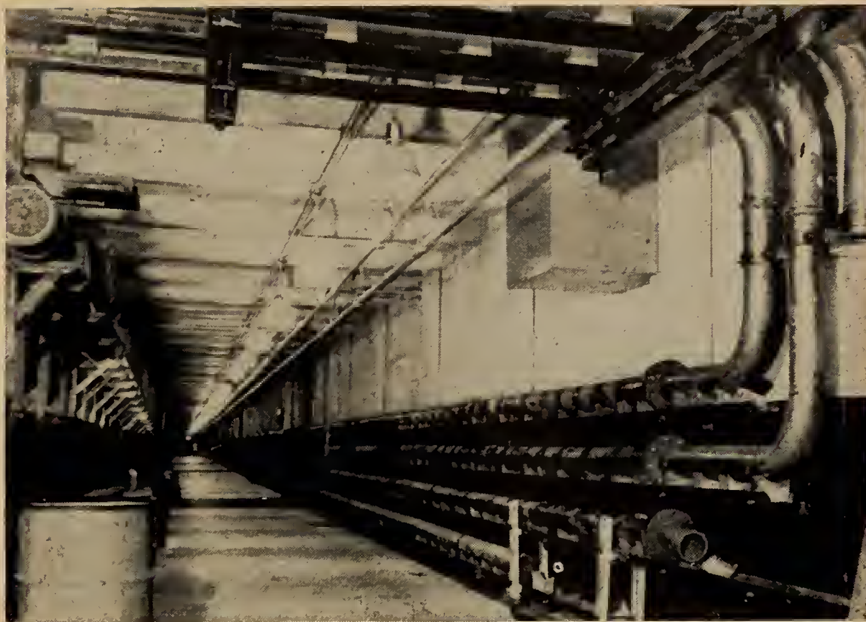

Fig. 3. One of the underground tunnels interconnecting major buildings. Four lead pipes carrying spin acid (right wall and across ceiling) are carried on wood blocks evenly spaced in steel channels supported on brackets from the wall.

The eastern third of No. 5 mill is supported on approximately 1400 concrete piles varying in depth from 10 to 40 feet. Piles are placed so as to give direct support to every steel column and all load-bearing foundation walls, and in some places are spaced at intervals of six feet in both directions under the basement floors. In the case of the new churn house, at the extreme east end of the new mill, where soil conditions were very poor, the basement floor is a reinforced concrete slab carried on a network of reinforced concrete beams spanning the distances between pile caps. In other words, the basement floor in this case rests entirely on the piles and does not depend on additional support from the soil.

All the major buildings of the Cornwall plant are interconnected by underground tunnels which serve as pipe corridors as well as for personnel traffic (Fig. 3). Three such tunnels were constructed to link No. 5 mill with the boiler house, the acid recovery building, and with No. 4 mill.

Design and installation of parapet walls around the roofs of the new plant presented an interesting problem. Less than a year after the buildings were completed, broken flashing blocks were noticed where the roof membrane was flashed into the parapet walls. It turned out to be impossible to repair these blocks properly without dismantling most of the parapet walls. In addition, soft spots appeared in the roof areas adjacent to the parapets, indicating presence of moisture in the insulation.

Tests were made over a considerable period of time, and it was found that water easily penetrated the artificial stone coping and found its way into the wall. (Fig. 4.). Also it became apparent that the through-wall flashing, consisting of two-ply tarred cotton fabric, was not effective in stopping this entry of moisture into the wall behind the flashing blocks. Freezing of this moisture in cold weather caused spalling and disintegration of the flashing blocks.

The original parapet walls would have been satisfactory if the through-wall flashing had been made of an impermeable material such as lead. Addition of counter flashings over the through-wall flashing and roof flashings would have assured good construction.

After many repair methods had been considered and investigated, it was finally decided that the condition would be best corrected by completely removing the parapet walls. This was done, and a new cant strip was poured around the perimeter of the building. A 2 in. x 10 in. fascia board was then bolted to the outer face of the cant strip and flashed with sheet aluminum, and the top of the cant strip and inner edge of the aluminum flashing were covered with 4-ply tar and gravel roofing. This method of construction has proved satisfactory in every way. All subsequent building additions have been constructed without parapet walls, their roofs being finished around the building perimeters as described above, with cant strip and fascia board flashed with sheet aluminum.

Drainage System

The biggest problem in economical design of a drainage system for the new plant was the long distance to be travelled by the effluent lines from the plant to the river. Also, it was necessary to carry different chemical effluents in separate pipes. The drainage system consists of four sewer pipes, all laid on gravel-fill in the bottom of the same trench, and backfilled first with gravel, then with earth. To obtain proper flows in the pipes, it was necessary to excavate in some places to a depth of almost 30 feet. Manholes are spaced approximately every 200 feet on each line, the manholes on all four sewers being grouped together at each location into single reinforced concrete structures. Manholes are lined with trowelled-on asphalt to protect the concrete from chemical attack.

The four sewers consist of:

(a) One 48 in. reinforced concrete storm sewer, carrying storm water, floor drains, roof drains, and non-corrosive chemical effluents.

(b) One 24 in. viscose sewer, constructed of vitrified tile pipe poured solid in concrete, carrying diluted viscose waste, caustic soda, soap, bleach, and other alkaline chemical effluents.

(c) One 18 in. acid sewer, constructed of acid-proof vitrified tile pipe poured solid in concrete, carrying all acid effluents.

(d) One 8 in. cast iron sulphide sewer, carrying sulphide wash effluent from staple fibre washing area.

Raw Materials Handling and Storage

Following are the principal raw materials used in manufacture of viscose rayon. Approximate annual consumptions are shown at the 1955 level:

	million lb.
Wood pulp	85
Caustic soda	70
Carbon bisulphide	30
Sulphuric acid	120

Approximately ten days' to two weeks' supply of each of these materials is kept in storage in the plant.

Raw materials arrive at the Cornwall plant by road transport and by rail; the majority by road transport. Rail service is by electric locomotive over a rail spur entering the plant on the north side from the main Cornwall switching yards of the C.N.R. and C.P.R. Road transports have direct access to the plant through the main gate on No. 2 Highway about two miles east of downtown Cornwall. Materials entering the plant by road are weighed over a large road scale at the plant entrance.

Wood pulp is received in 500-pound bales loaded in rail box cars. Pulp bales are removed from the box cars by battery-operated high-lift fork trucks which carry them, 4 bales at a time, to the pulp storage room where they are stacked 8 bales high. Several different types of pulp are used, and these are stacked in different areas of the storage room (Fig. 6). When needed for use, pulp bales are removed from storage by fork truck, 4 bales to a load, and deposited on a mechanical pulp tilter which feeds them on to a long live roll conveyor which carries them into the pulp blending room. Here the bales are manually transferred to a series of gravity roll conveyors that permit the correct blending of different types of pulp in preparation for loading into steeping presses.

Caustic soda is received at 50 per cent concentration by road tank transports and by rail tank cars. These are unloaded through flexible pipes by gravity into a soda receiving tank from which the soda is pumped to a battery of 20,000-gallon storage tanks. When needed for use, the soda is pumped from storage tanks to special make-up tanks where it is diluted with water or with recovered soda. In this diluted form it is pumped through steel pipes to the steeping presses.

Carbon bisulphide is stored in a separate CS_2 storage building located some 300 feet north of the central viscose plant. No other buildings are permitted in its vicinity. This precaution is necessary because of the highly inflammable nature of the liquid and the highly explosive nature of vapour-air mixtures. CS_2 is received in rail tank cars, from which it is removed by displacing its volume with water. By water pressure, it is piped into a batterv of speciallv-constructed 11,000-gallon storage tanks which are kept submerged in water within the storage building. CS_2 is a liquid which is heavier than water (specific gravitv is 1.3) and which does not mix with water. This makes it possible to do all moving of the liquid with water pressure.

When kept in tanks, it is sealed from contact with air bv a laver of water. At every step in the handing if this liquid, great care is taken to prevent static sparks by electrically grounding tank cars and all handling equipment. The CS_2 storage building is specially ventilated with a continuous supply of fresh air in order to ensure that no pockets of vapour can collect. CS_2 is circulated by water pressure through nickel pipes from storage tanks to churn house. These pipes are carried overhead on a line of steel posts joining the two buildings. In the churn house the CS_2 passes through a specially constructed heat exchanger which provides automatic temperature control, to a head tank where it remains until drawn off in automatically measured batches for use in charging the churns.

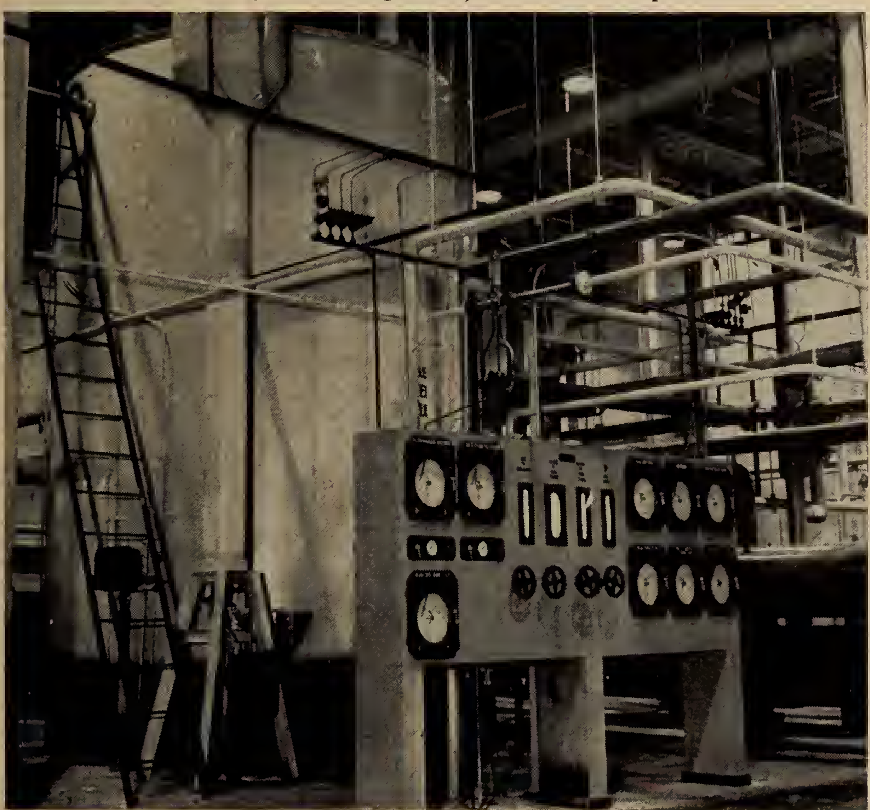
Fig. 7. One of the automatic control panels in the soda preparation department. At left is one of the large soda storage tanks, insulated for temperature control.



Sulphuric acid is received at 94 per cent concentration in both rail tank cars and road tank transports. These are unloaded by air pressure and the acid is piped to a battery of 14,000-gallon storage tanks located just south of No. 5 mill. A single 6 in. extra heavy steel pipe, running horizontally close to the ground, connects the bottom of each storage tank to a small acid well located outside the wall of the strong acid pump room in the main building. Inside the pump room, four vertical, self-priming, centrifugal pumps are located about ten feet above ground level. Each pump has its own suction pipe dropping into the acid well outside the wall. These pumps deliver strong acid to the acid preparation areas for each of the three main spinning departments; textile, staple fibre, and tire yarn. The pumps are started and stopped electricallv by float switches on the strong acid supply tanks, one in each acid preparation area.

Viscose Manufacture

First step in production of viscose (Fig. 8) takes place in steeping presses. Here the pulp sheets are steeped in caustic soda. After steeping, excess soda is removed bv hvdraulic ram which moves forward and exerts a total pressure on the sheets of over 100 tons. The steeped pulp sheets are discharged through the press ends into shredders where they are broken into small white particles called crumbs, similar to breadcrumbs in appearance. The complete steeping cycle, after manual loading of pulp into the press, is controlled automatically by cycle timers, relays, and limit switches. Shredders are jacketed for temperature control of the crumbs during the shredding operation. Temperature is controlled by automatic regulation of the flow of chilled water through the jackets.

Crumbs from the shredders are dumped into large cylindrical crumb cans, where they are lightly consolidated by pressing on a crumb can press. Battery-operated low-lift platform trucks move the crumb cans to mercerizing rooms. Here the crumbs are stored, or mercerized, for a number of hours at constant temperature automatically regulated to within ± 0.5 deg. F. This close control of room temperature is obtained by using a large number of conditioning units throughout each room. A conditioning unit consists of a fan and two sets of coils, one for cooling with chilled water, the other for heating with low pressure steam. Automatic control of flows of chilled water and steam gives very accurate regulation of room temperature.

From mercerizing, the crumb cans are moved by battery-operated, low-lift platform trucks to crumb can elevators which lift them to the fourth floor of the churn house. They are removed from the elevators by special battery trucks with spark-proof electrical construction, and placed over the churn chutes, through which the crumbs fall by gravity into churns on the floor below.

In the churning operation, carbon bisulphide is mixed with crumbs to form cellulose xanthate. This operation is hazardous, and elaborate precautions are taken to minimize both the possibility of explosion and the damage that would result if an explosion occurred. Churns are evacuated by a separate vacuum system in order to vaporize the CS_2 as soon as it enters. This improves the reaction between crumbs and CS_2, and also provides for removal of CS_2 fumes and reduces explosion hazard. After crumbs and CS_2 have reacted for a time, charges of water and caustic soda are dropped into the churn to form a coarse slurry with the xanthate. Large, slowly rotating paddles in the churns give a thorough churning action to the crumbs, xanthate, and slurry throughout the churning operation. The entire churn cycle is automatically controlled by cycle timers, relays, and limit switches. Churns are jacketed for automatic control of temperature during the churning operation. Temperature control is obtained by automatic regulation of the flow of chilled water through the jackets.

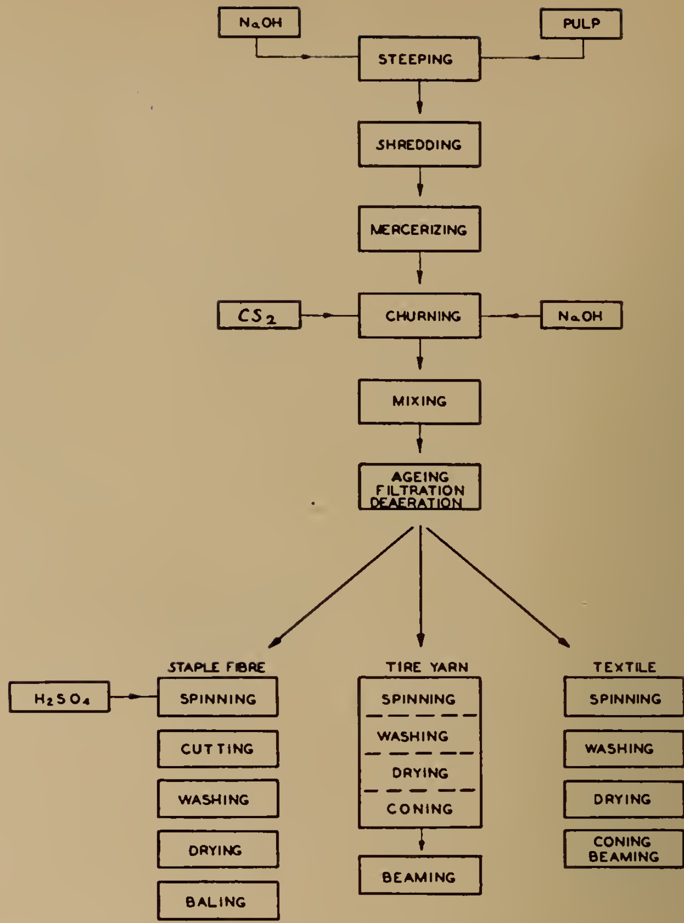


Fig. 8. Flow sheet of the viscose rayon process.

Xanthate slurry drops from the churns into mixers. These are vessels fitted with large slow-moving paddles. In the mixers, all remaining solid particles in the slurry become dissolved, and the resulting amber-coloured, syrupy liquid is known as viscose. Mixers are also jacketed for automatic temperature control of viscose during the mixing operation. Temperature control is obtained by automatic regulation of the flow of brine at 15 deg. F. through the jackets.

The churn house building is fitted throughout with double explosion sash. The entire electrical installation, except within the switch rooms, consists of explosion-proof fittings and materials. All lighting circuits, and the electrical intercommunications system, are explosion proof. To avoid additional high cost of explosion-proof switchgear, the switchrooms were isolated and pressurized so as to make entrance of combustible fumes impossible. All conduits leaving or entering the pressurized switchrooms are sealed to prevent passage of gas.

Viscose from the mixers is collected in tanks and pumped to the three viscose caves, located near the staple fibre, textile, and tire yarn spinning departments. All pipe lines carrying viscose are covered with three inches of cork insulation to maintain constant viscose temperature. Viscose caves are equipped with automatic temperature control to ± 0.5 deg. F. in the same way as mercerizing rooms. In the caves, the viscose is aged, and then passes through plate-type filters dressed with cotton batting and other fabrics. It then passes to de-aerating tanks where all entrained air is removed in preparation for spinning. De-aerated viscose is pumped through another bank of plate-type filters dressed with fabric, and thence to the spinning machines where the cellulose is regenerated by action of sulphuric acid, and filaments of viscose yarn are formed.

Staple Fibre Plant

On staple fibre spinning machines (Fig. 9), viscose is extruded through multi-hole jets into a sulphuric acid spinning bath, where acid reacts with soda in the viscose, permitting regeneration of cellulose into a continuous filament from each hole in the jet. Staple fibre jets contain from 2500 to 10,000 holes each. The holes are approximately 0.003 in. diameter. Jets are made of an alloy of platinum and rhodium. Filaments from each jet are drawn out of the spin bath by glass godet wheels. Yarn from many godet wheels converges along the machine to form a large tow containing up to one million filaments. All parts of the spinning machines coming in contact with acid or acid fumes are constructed of or covered with lead, neoprene, hard rubber, porcelain, or other acid-resisting material.

The yarn tow is drawn away from the spinning machine by large lead-covered tow drums located over the staple fibre cutters. From the tow drums it drops into the cutters which cut it off into staple lengths which can be varied from ½ inch to 6 inches. A cutter consists of a rotating horizontal disc around the periphery of which several knife blades are evenly spaced. The tow enters the disc through an axial opening at the top centre, and passes outward through the disc by centrifugal force through a radial hole connecting with the centre opening and emerging at the disc periphery. As tow emerges from the disc it is cut off into staple lengths by the cutter knives. All materials used in disc and knife construction are acid resistant. The area surrounding tow drums and cutters is lead covered. Heavy concentrations of carbon bisulphide and hydrogen sulphide fumes are liberated in spinning and cutting operations, and an elaborate system of foul air extraction is always in operation in these areas. Both spinning machines and cutters are enclosed by windows in order to make fume extraction more effective.

Cut tow from the cutters falls into stainless steel bowls from which it passes on to the staple fibre washing machines. Washing machines move the product forward in blanket form by the walking beam principle. Through the length of the machine, the staple receives many types of washes, rinses, and chemical treatments, each requiring use of materials that will satisfactorily withstand corrosive attack by the chemicals being used. Materials of construction include lead, wood, reinforced plastics, stainless steels 304, 316, and 317, Carpenter 20 stainless alloy, rubber, polyvinyl chloride, and Teflon. A pair of squeeze rolls extracts excess moisture from the blanket before its entry into the staple fibre driers.

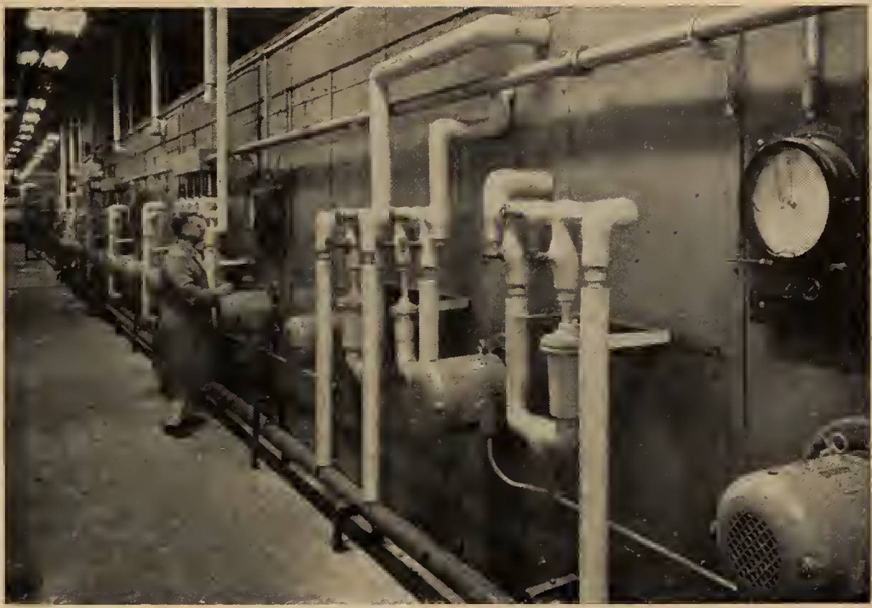

Fig. 8A. A staple fibre drying machine. Electric motors (seen projecting from side of the machine) circulate hot air; temperature recording and controlling instruments are also shown. The insulated pipes carry steam and condensate.

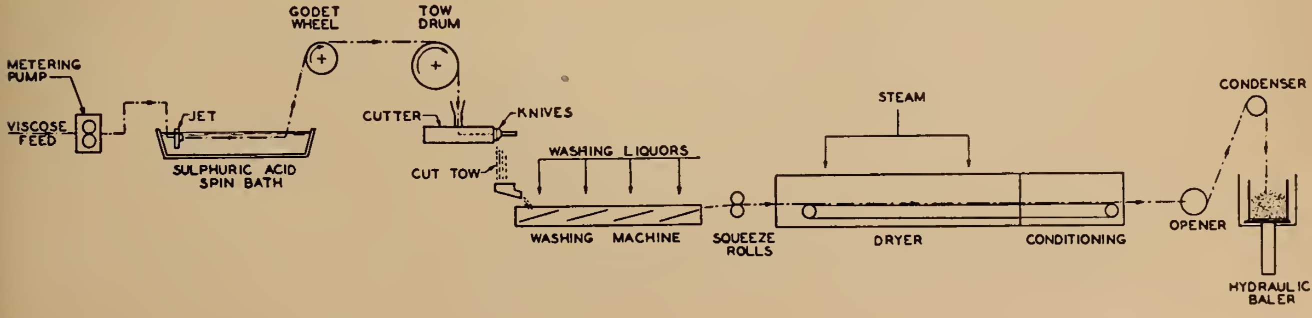
The blanket from the washing machine squeeze rolls is broken up by a beater as it enters the drier. The broken pieces are then re-distributed into another blanket on the drying machine conveyor. This conveyor carries the blanket slowly forward through successive drying stations, each of which is automatically temperature controlled. The dryers use steam heated coils and forced air circulation in each drying section. (Fig. 9.)

When it leaves the drying machines, the staple is opened by conventional textile openers, and then is carried pneumatically into textile condensers, from which it falls as staple fibre into large vertical baling presses. Staple fibre balers are hydraulically-operated presses. They compress the staple into 500 pound bales ready for shipping. Bales are carried away to storage and shipping, four bales to a pallet, by battery-operated, high-lift fork trucks. Staple fibre is shipped by road transport and by rail.

Tire Yarn Expansion

Up to this point, all the expansions and installations that have been discussed have been located in or near the new No. 5 mill, and have involved erection of new equipment in new buildings. As previously mentioned, the tire yarn expansion involved in-

Fig. 9. Schematic diagram of the staple fibre production process.



stallation of new equipment and machinery within older, existing buildings. This fact resulted in very different types of engineering problems. Space available for new installations was very often insufficient for straight-forward planning. Sometimes there was not enough headroom to allow proper sloping of pipe runs; sometimes there was not enough area, or the area available was not the right shape. Installations and layouts had to be trimmed and altered to fit, and to function properly, in spaces that could be made available. In several cases, reinforced concrete basement floors had to be broken up, excavated, and re-poured some four feet lower than their original level. This was usually necessary in order to provide correct slopes on acid return lines that must flow by gravity. In some cases, even lowering the floors was not sufficient to obtain correct gravity flows, and entire acid circulating systems had to be modified so that liquids could be pumped under pressure instead of flowing by gravity.

Another type of problem resulted from overloading of existing column footings caused by excessive weight of the new installations. In some of these cases it was possible to add new structural steel members within the building so as to distribute the new load over more columns. In other cases, the column footings had to be excavated and strengthened. In still other cases, additional steel columns resting on new footings were added.

As already mentioned, the tire yarn machines were of an entirely new type, representing a new concept in the spinning of viscose rayon yarns. They are known as continuous spinning machines. They are distinct from box spinning machines used to produce textile yarn in that the continuous machines, as their name implies, spin the viscose into yarn in a continuous operation, there being no interruption of the spinning process in the manner of box machines, where spinning is stopped every few hours to allow removing of acid cakes of yarn from spinning boxes. On continous machines, viscose is coagulated or spun through spinning jets into an acid spin bath, and the resulting yarn is picked up on glass godet wheels which carry it into hot stretch baths. The yarn is stretched through these hot baths and then passes over bakelite drums where it is washed acid free with warm soft water. From the wash drums, the yarn passes through a finish bath, down through drop tubes to the floor below, where it passes over steam-heated dryer drums, and is finally wound on to cones. All this happens in one continuous operation. Full cones are doffed and new cones are started without interrupting the flow of yarn through the machine.

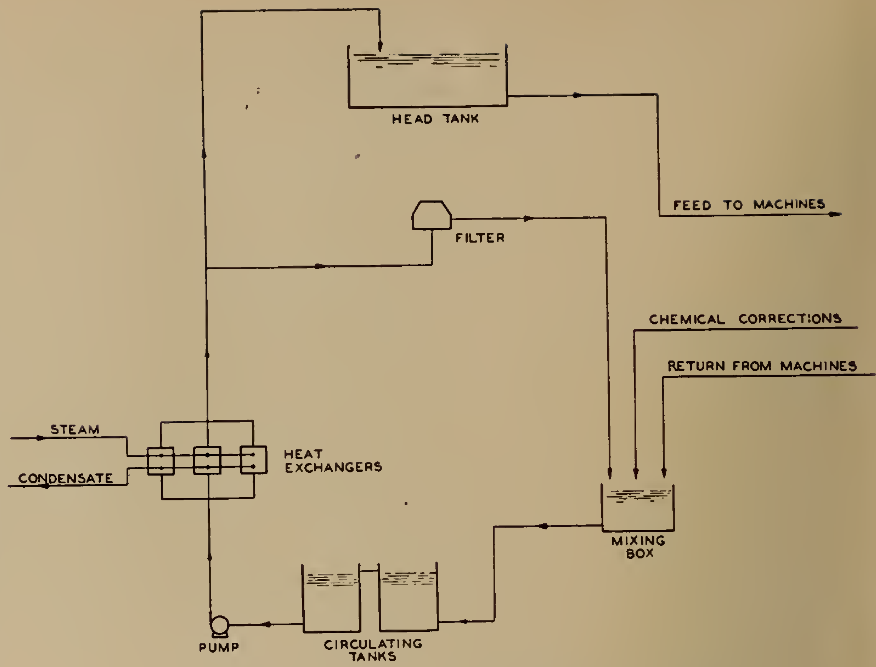


Fig. 10. Schematic layout of a typical spin acid system.

First installation of continuous spinning tire yarn machines involved erection of eight of these machines, together with acid and fluid systems and various services facilities in the east end of No. 2 mill. This project was started in 1946 and completed in 1949. Almost continuous further expansion of this installation has taken place during the succeeding years.

The tire yarn machines themselves have some interesting features. Viscose pumps, bottom godets, top godets, wash drums, dryer drums, and coning machines—all these rotating groups — must be driven at different speeds, and all speeds must be independently variable so that different qualities of yarn may be produced. All the rotating elements on each machine, except the coning machines, are driven by a single 10 h.p. main drive motor housed at one end of the machine. This motor transmits power through a specially designed series of variable speed drives to give a separately controllable speed to each of five shafts that run the length of the machine. From these shafts, the individual pumps, godets, wash drums, and drier drums are driven through gear trains at speeds that may be adjusted to give various linear volocities to the yarn.

Coning machines are driven independently of the main machine. Each coning head is driven by its own individual motor.

Godet and wash drum drive shafts are carried in fabricated steel housings extending from end to end of the machine, and these housings constitute the framework or backbone of the machine. This entire framework, together with the acid bath, is completely covered with sheet lead to protect the mechanism from corrosion by acid attack. All parts coming into contact with the acid, or even with acid vapour or fumes, are made of such acid resistant materials as glass, bakelite, polyvinyl chloride, porcelain, lead, and hard rubber. The spinning jets themselves are made of an alloy of platinum and rhodium, and they are carried by rounder ends made of stainless steel and covered with hard rubber or p.v.c.

The ever-present problem in designing, building, operating, and maintaining viscose rayon spinning machines, is to find materials and methods that will better withstand acid corrosion and that will give better means of sealing the driving mechanisms from entry of acid in liquid form or as vapour.

Acid Preparation Systems

A typical acid system (Fig. 10) is located in an area, usually two or three floors in elevation, in the vicinity of a group of spinning machines. The purpose of acid systems is to supply spin acid, hot stretch fluid, and soft finish solutions to the machines at correct concentrations, flows, temperatures, and clarity. Equipment installed in these areas includes pumps, tanks, filters, clarifiers, mixers, heat exchangers, air blowers, and associated control equipment. (Fig. 11.)

All pieces of equipment handling spin acid and hot stretch solutions are made of acid-proof or acid-resistant materials. New materials are constantly being developed, tried, and installed that will better withstand the corrosive attack of acid solutions. Hot stretch liquors are the most corrosive, because of their high temperature and low acid content. Tanks are lined with sheet lead or with hard rubber. Rubber lining gives good service on spin acid tanks, but is not suitable for the high temperature of hot stretch solutions. Pipes carrying these liquids have traditionally been made of lead. However, of recent years, hard-rubber-lined and Saran-lined steel pipes have been replacing lead pipes in spin acid systems, and double-tough glass and reinforced plastic pipes have been replacing lead pipes in hot stretch systems. Soft finish solutions are carried in stainless steel pipes. Lead valves are used extensively for all acid solutions. Rubber lined diaphragms are also suitable for most of the highly corrosive liquors.

Choice of suitable pumps for spin acid and hot stretch services is very important. High speed centrifugal pumps fail from corrosive attack faster than low speed pumps. Almost all pumps used are designed for operation at less than 1800 r.p.m., many of them operating at speeds of 1200 r.p.m. and 900 r.p.m. Lead bodied pumps with lead or high nickel alloy impellers are used successfully for spin acid. Pumps made of stainless alloys are used for moving hot stretch solutions. Other pumps that are used in smaller numbers in acid systems are: carbon pumps, reinforced plastic pumps, porcelain pumps, and glass lined pumps.

Traditionally, standard practice in heating spin acid called for installation of large, lead lined steel acid heating tanks on the top floors of acid preparation areas. From these heating tanks, acid flowed by gravity, sometimes through quartz filters, to the spinning machines. Heating the acid was done by hot water circulating through lead coils immersed in the tanks. The water in turn was heated by steam in conventional shell-and-tube heat exchangers. This was the acid heating system installed for the first eight tire yarn machines in No. 2 mill. It so happened that there was ample room to install this equipment on the upper floor, directly above the machines; and this acid heating system was expanded in subsequent years to serve a total of 22 machines.

However, when it became necessary to build another complete acid system for more tire yarn machines, enough space for acid heating was not available on the top floor, and a very different type of acid heating system was necessary. In this case, the entire acid heating system had to be constructed in the basement area. A solution was found in the use of cubic carbon heaters. This type of heater consists of a cube of impervious graphite, held in compression by two end plates bolted together. (Fig. 12.) The graphite block is perforated by two series of holes running through the block in successive layers, each layer of holes at right angles to those on either side. Thus the cube is like a honey comb, with the liquid to be heated flowing through one series of holes in one direction, and the heating medium flowing through the other series of holes in the other direction, the heat transfer taking place through very thin walls of highly conductive impervious graphite.

Steam is used directly to heat the acid in these heat exchangers,

Fig. 11. Two settling tanks in one of the spin acid preparation departments. Sediment is drawn off from the conical bottoms; clear acid through the side connections. Steel plate tanks are lined with sheet lead burned in place after installation. Lead pipes at ceiling are supported on wooden blocks in steel channels.

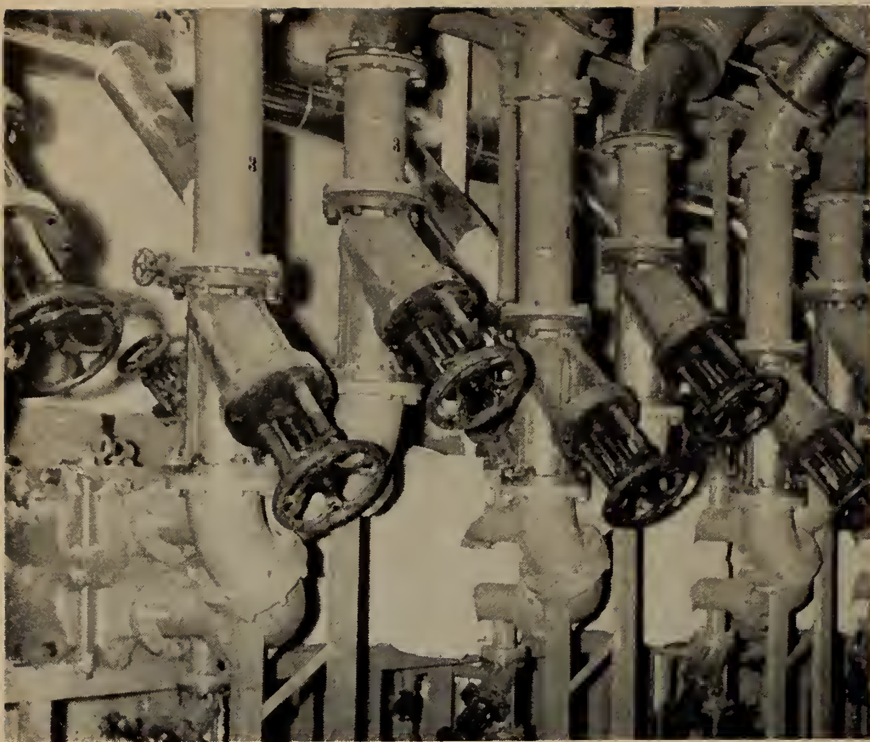

Fig. 12. A battery of cubic carbon heat exchangers in one of the spinning acid heating installations. Spinning acid enters through bottom front and leaves through top front connections. Steam enters through ports on sides of units. Exchanger at left is not lagged; others are insulated by removable asbestos bags filled with rock wool. Rubber-lined steel pipe and lead valves carry acid.

thereby eliminating the use of water as a middle agent, and greatly increasing the efficiency of the heating operation.

In this installation, 14 cubic heaters do the same job as was accomplished in the more conventional system by: nine 1500-gallon tanks, 54 lead coils, two shell-and-tube heat exchangers, and two centrifugal water pumps, together with all associated piping. Initial cost of the cubic heater installation was much lower than that of the heating tank system, and the efficiency was higher. This was a case of necessity being the mother of invention. The modified heating system necessitated by acute lack of space turned out to be a much better system, lower in cost, lower in maintenance, and higher in efficiency.

Ventilation

Adequate supply of fresh air to spinning and acid preparation areas and to other process departments, and effective removal of fumes from spinning machines and acid tanks and other areas, are very important considerations in every viscose rayon plant. Fresh air is required for personnel comfort and safety. Also, fresh air at controlled temperature and controlled humidity, is required by many parts of the process. Foul air extraction is necessary for removing chemical fumes and excess heat that are liberated from many processes, particularly from the spinning machines themselves and from tanks and heaters in the acid systems.

Hydrogen sulphide and carbon bisulphide, both highly toxic and dangerous gases, are liberated when viscose is coagulated in the spin bath. For this reason, design of every spinning machine incorporates a large foul air duct, running the length of the machine, which removes these gases as they are given off. It is important that these ducts be located and branched in such a way that fumes are collected as close as possible to the points where they are released, and also that movement of air from room into machine be such that a stream of fresh air is always passing inward past the operators' heads as they do their work. Foul air systems are designed to give a static suction of 2½ to 3 inches of water in the exhaust ducts in the spinning areas. Fresh and foul air systems are designed to ensure that H_2S and CS_2 gases are never present in the atmosphere of any part of the plant in quantities more than ten parts per million. Normally, maximum gas concentrations in spinning and acid preparation areas are held below five parts per million.

Part of the H_2S and CS_2 gases liberated in the spinning operation becomes dissolved in the spin acid and circulates around in the acid system to be released into the atmosphere at places where the acid is agitated and exposed to air. For this reason it is highly important to extract fumes from all acid tanks and launders, and to ventilate properly and remove foul air from all acid preparation areas. Foul air removal from these areas also serves the purpose of removing excess heat that escapes from the system in spite of considerable thicknesses of lagging applied to all hot equipment.

Corrosion conditions are very severe in foul air ducts, especially in ducts drawing from spinning machines and acid systems. Here high temperature, high acid content of the extracted fumes, and heavy condensation of moisture within the ducts. combine to give the most corrosive conditions found in ventilation systems. Lead ducts stand up very well under these conditions, but are very expensive because of large size of the ducts and the large amount of reinforcing required. Steel ducts lined with plasticized p.v.c. or hard rubber are now being used to replace lead ducts in areas where condensation is heavy.

Aluminum ducts are used in locations where the extracted fumes are drier, or where they already lost much of their moisture. Main ducts leading to large foul air fans are usually constructed of reinforced concrete lined with acid proof brick or with trowelled-on asphalt. Corrosion is not so severe in these main ducts because the extracted fumes have already lost much temperature and much humidity while passing through the branch ducts. In most cases these main exhaust ducts, because of their large size, form an important part of the building structure. In buildings used for spinning and acid preparation, footings, foundations, and building framework are conformed to suit the layout of main foul air ducts.

Main foul air ducts in each major production unit converge into a large plenum chamber adjacent to one of the foul air fan rooms. Here the main foul air fans are mounted. Before 1950, large centrifugal fans were installed on foul air service. They had capacities up to 150,000 c.f.m. and produced in the ducts static suctions up to 2½ and 3 inches of water. They were driven through V-belt drives by

75 h.p. and 100 h.p. electric motors. Most of them had steel casings that were lined with trowelled-on asphalt after installation. Fan wheels were of steel construction, painted with asphalt once or twice a year. These asphalt-painted wheels had a life of 12 to 18 months on the more severe services. Specially constructed steel wheels, lined with 1/16 in. and ⅛ in. sheet neoprene, are now used in these fans and give good service for a number of years.

Foul air fan rooms constructed since 1950 have been fitted with large axial-flow fans. These are lower in initial cost and require less maintenance than centrifugal fans of the same performance. Axial-flow fans are mounted directly in the airstream. They do not require large plenum chambers. This means that they can be mounted in simply constructed fan rooms. Sometimes they can be mounted in the foul air duct itself, thus requiring no fan room at all. They can be mounted either horizontally or vertically, in this respect being much more adaptable to different conditions than are fans of the centrifugal type. Axial flow fan casings are constructed of aluminum for small sizes and of fabricated steel for larger sizes. Steel casings are asphalt-painted for service under mild corrosive conditions, and are lined with sheet neoprene or hard rubber when required to withstand severe corrosion. Fan impellers are made of cast aluminum. This material gives good service even under fairly severe conditions. Neoprene or rubber covered steel impellers are used where corrosive conditions are very severe.

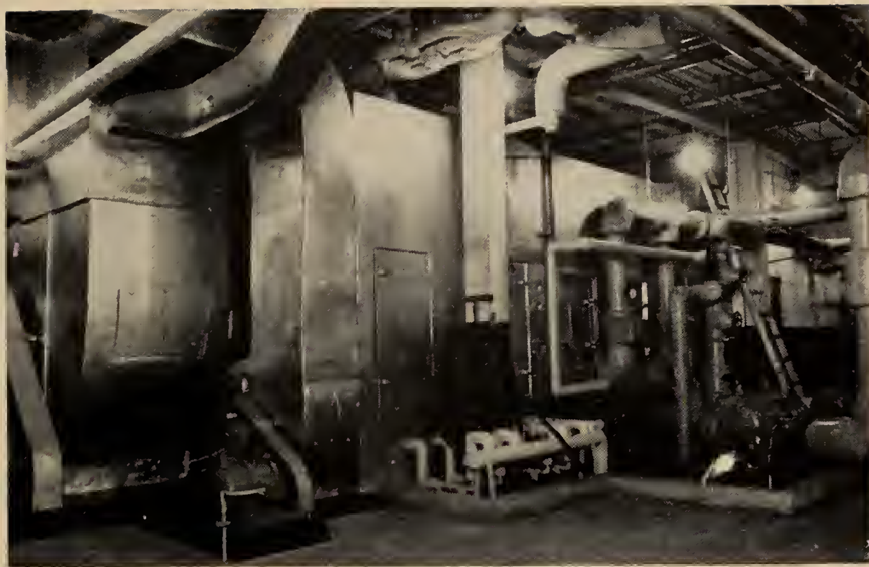

Fig. 13. A large air conditioning unit which supplies spinning and other process departments. Fresh air fan at left; air heating and washing compartments, centre and right; water circulating pumps at extreme right. Unit and ducts are insulated.

Small foul air fans, located close to the source of acid fumes, must stand up under the worst corrosive conditions. Large main foul air fans, located at considerable distances from spinning machines and acid tanks, and handling cooler, drier fumes, are not so subject to corrosive attack.

All main foul air fans discharge through underground or overhead ducts into one of the fume stacks. These are brick chimneys, acid-proof brick lined, having inside diameters of about 15 feet, and rising 225 feet or more above the ground. One foul air stack serves the entire continuous spinning tire yarn installation. Into it a total of five main foul air fans discharge acid fumes at a total rate of approximately 500,000 c.f.m. Three other such stacks carry away foul air from the other spinning and acid preparation areas throughout the plant. Total volume of foul air being exhausted continuously through the stacks is in excess of one million cubic feet per minute. A total of 12 main foul air fans discharge into the foul air stacks.

Fig. 14. High speed tire yarn beamer, with creel. Partially-filled beam, foreground, is fed from cones of yarn on the creel, right background.

Fresh air, with controlled temperature and humidity, is supplied to spinning and acid preparation areas and to all process departments, in amounts approximately equal to the volumes of foul air being extracted. Fresh air fans are similar in size and numbers to the foul air fans already described. Both centrifugal and axial-flow fans are used on fresh air services. All main fresh air fans draw in outside air through heating coils, air washers, and humidifiers. Fresh air distribution ducts are made of sheet aluminum or galvanized sheet steel. (Fig. 13.)

Acid Recovery

The process of spinning viscose rayon involves a chemical reaction that takes place between sulphuric acid in the spin bath and sodium hydroxide in the viscose. This reaction results in formation of sodium sulphate and water. Water thus formed dilutes the remaining acid in the spin bath solution. In order to maintain the necessary acid concentration in the spin bath, every acid preparation area includes a continuous correction of strong sulphuric acid. This results in gradual formation of an excess volume of spin acid and an excess of sodium sulphate. These excesses are removed in the acid recovery process.

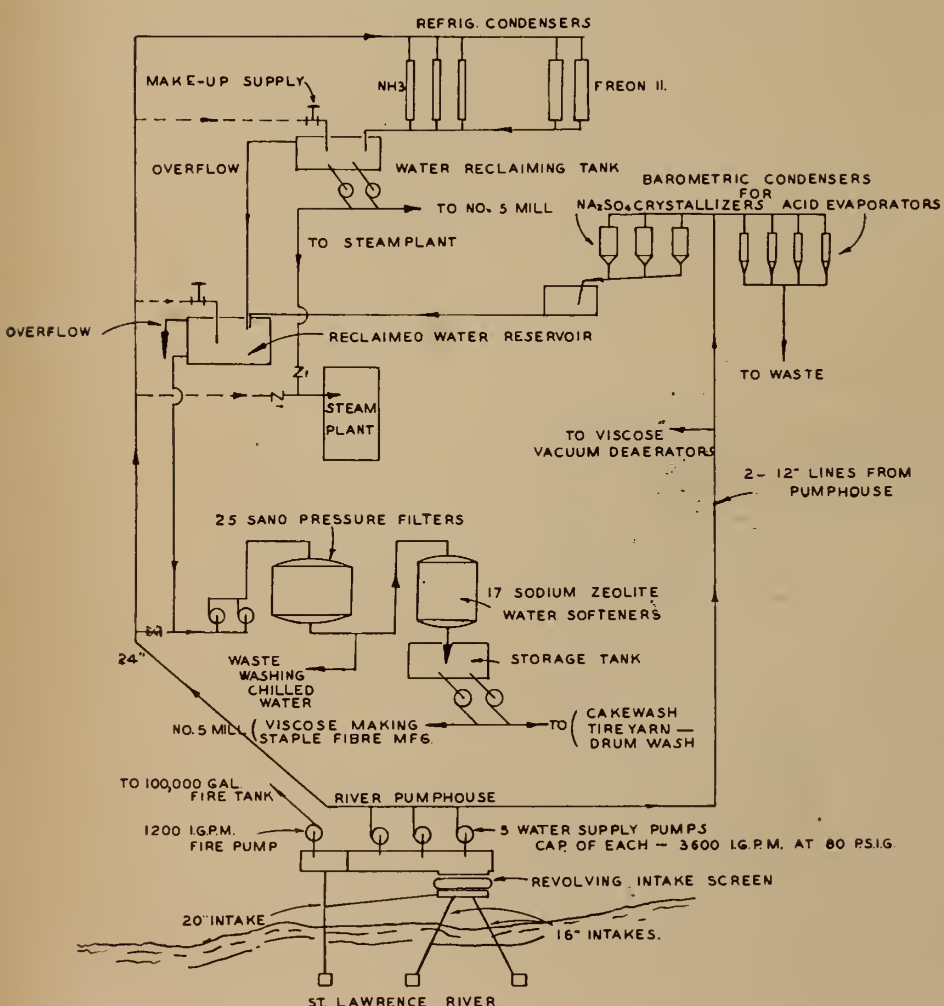
From each acid preparation area, there is a continuous flow of excess acid back to the acid recovery building, where it gathers in large acid collecting tanks. From these tanks it is pumped to head tanks on the top floor, from which the acid flows by gravity into crystallizers and evaporators. In the evaporators, excess water is boiled off and the acid increases in strength until it can be returned to the spin acid circulating system from which it came. In the crystallizers, acid is cooled by evaporation so that excess sodium sulphate crystallizes and forms a magma with the cool acid. This magma drops by batches into large magma tanks from which it is pumped to rotary vacuum filters where Glauber's salt crystals are removed, making the acid suitable for returning to the spin acid system from which it came.

Staple fibre and tire yarn expansions have greatly increased the total volume of spin acid in circulation throughout the plant. Consequently, large expansions to acid recovery installations have been required. Each major phase of expansion in spinning has necessitated a corresponding increase in acid recovery service. The job of keeping the acid recovery process in step with expanding spinning operations has been complicated by the fact that there are now three separate products, acid from each one of which must be treated separately in the recovery processes. In order to obtain reasonable flexibility of operation under these conditions, it has been necessary to arrange recovery piping so as to cross-connect between many pieces of equipment, so that such units as evaporators and crystallizers can readily be changed by valving from one product to another.

Since 1945, three separate extensions have been added to the acid recovery building. In them have been or are being installed five additional crystallizers, ten more evaporators, and three more rotary filters. The staple fibre plant alone, because of its long distance from the acid recovery building, required installation of approximately 8000 feet of five-inch lead pipe in the tunnels joining the two departments. Large quantities of lead pipe, hard rubber-lined steel pipe, and saran-lined steel pipe are installed in the acid recovery building itself. Crystallizers are hard rubber lined, and have acid-resisting bronze or homogeneously lead lined evactor heads, and acid-resisting bronze or pure nickel venturi throats. Evaporators are hard rubber-lined and have heating elements fitted with carbon tubes mounted in lead or pure nickel tube sheets.

Before 1954, Glauber's salt, or hydrous sodium sulphate, removed from the acid by the rotary filters, was sluiced into the plant drainage system and wasted. A small portion of it was retained in bins for use in acid correction stations and for sale as Glauber's salt. In 1954, another extension was added to the acid recovery building to contain a new anhydrous sodium sulphate recovery process. Belt and oscillating conveyors were installed in the existing buildings to carry wet Glauber's salt from the rotary filters to the new building. Here, in the new process, the hydrous salt is circulated in the form of a thick slurry through two new evaporators which remove water of crystallization, thereby further concentrating the slurry, until it is ready for final filtering. Filtration is done by a large rotary vacuum filter, which is fed by hot air at 750 deg. F. from an oilfired furnace, and which removes the salt from the slurry, thoroughly dries it, and deposits it, in the form of a hot dry white powder, in a screw conveyor as anhydrous sodium sulphate. The hot salt passes through an attritor into the boot of a bucket elevator which carries it to the top of large reinforced concrete storage bins, into which it is distributed by another screw conveyor. From the bottoms of the storage bins, the salt is removed by twin-screw conveyors, lifted by bucket elevator, and falls by gravity either into box cars and hopper cars for shipping as bulk salt, or into bagging

Fig. 15. Schematic arrangement of the water system.



machines where it is prepared for shipping in paper bags.

Yarn Processing

The final step in manufacture of yarn is to package the products in forms suitable to the requirements of the industries that will use them. Tire yarn is shipped almost exclusively on beams. Textile yarn is shipped on cakes, cones, or beams. Yarn processing machinery is installed in No. 1 mill, from which the original spinning machines have long since been removed. Since 1948, to keep pace with constantly increasing output from the spinning departments, a number of new tire yarn beamers, new textile yarn beamers, and new slashers have been installed (Fig. 14). Beams of yarn weigh approximately 1200 pounds each. They are lowered from the beaming and slashing departments and stored on specially constructed beam racks located at the east end of the ground floor of No. 1 mill. A beam transfer elevator is used to move beams between racks for storage. Battery-operated forklift trucks remove them from the other end of the storage racks and place them for shipment on steel racks built into road transport trailers. All beams are shipped by road transport.

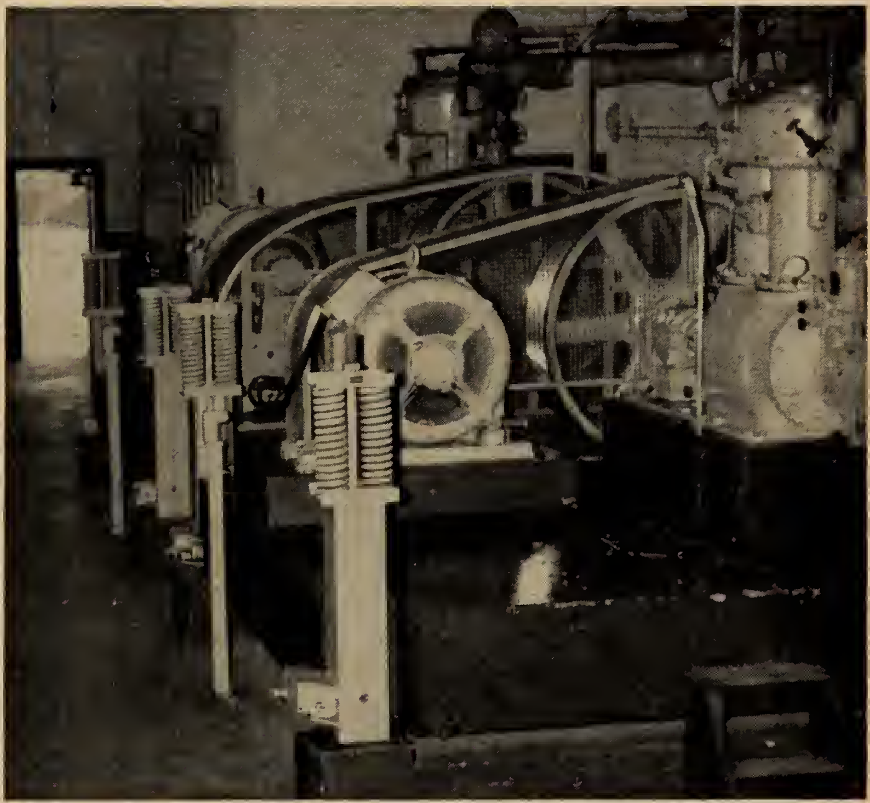


Fig. 16. Two V-belt driven ammonia compressors mounted on reinforced concrete inertia blocks. The entire block, carrying motor and compressor, is suspended from four vibration isolators (each a pair of coil springs in compression). Cylindrical neoprene blocks under compression, at bottom of the spring pedestals, limit motion of the inertia blocks. Piping connections are flexible.

Services

Power, heat supply, and heat removal together account for a considerable portion of the cost of manufacturing viscose rayon. This portion is largely made up of the following services. (Figures are approximate consumptions for 1955.)

Water	5000 x 10^6	Imp. gal.
Coal	115,000	tons
Refrigeration	150,000	tons
Electric Power	88 x 10^6	kwh.

The size of these figures, together with the necessity of controlling temperature within ± 0.5 deg. F. in many parts of the plant and process, requires continuous effort to improve and control services, if viscose rayon is to be manufactured efficiently and at top quality.

Expansion of services installations has been almost continuous through the years since 1945. One building extension has been added to the

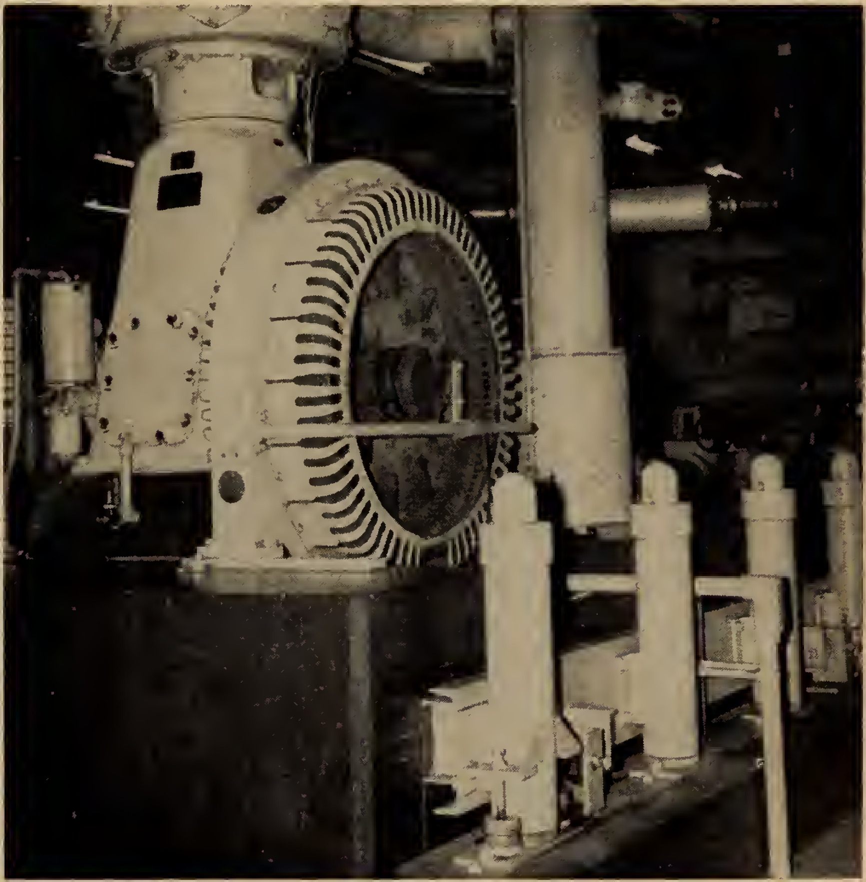

Fig. 17. Double-cylinder L-type air compressor with 100 h.p. synchronous motor; intercooler stands at right of motor. Entire unit is mounted on a concrete inertia block suspended by eight springs in compression. Cylindrical neoprene blocks at bases of two end isolators, on each side, limit motion of the inertia block. Flexible connections are used.

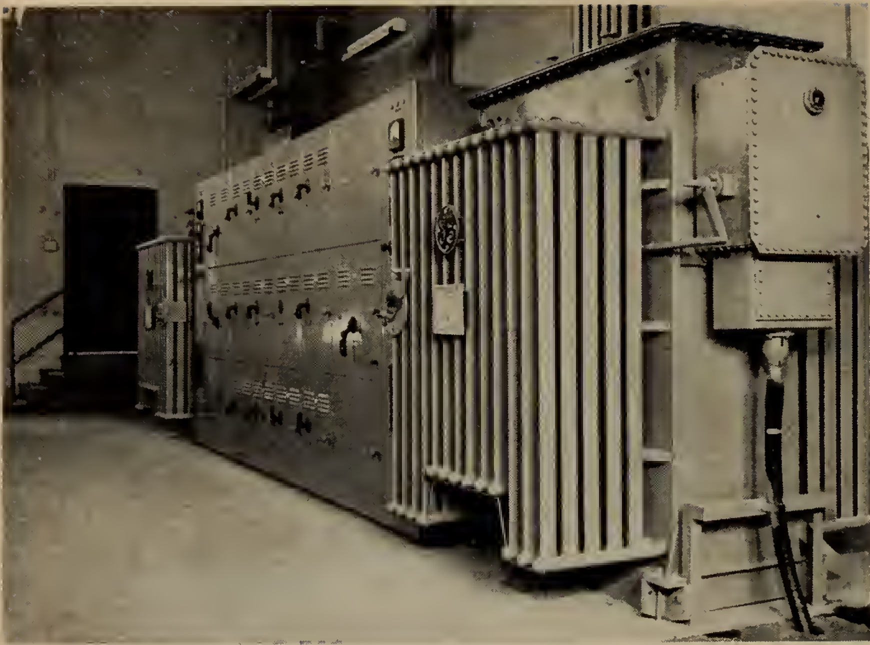

Fig. 18. No. 4 substation supplies electric power to the staple fibre plant. Transformers are mechanically interlocked.

river pump house, and all new pumps and completely new pump discharge piping have been installed.

A completely new compressor room has been built and put into use; a new electrical distribution system has replaced the old outmoded and inadequate system; and many other changes and improvements to services equipment, too numerous to mention here, have been completed.

A constant problem in all this work has been to design and carry out the projects without interrupting supply of services to the plant. Since viscose manufacturing and all spinning processes are continuous, and since shutdowns are very expensive, it has been necessary to plan all plant changes so that they could be completed with the absolute minimum of interruption and disturbance of operating departments. Many of the services expansions have been carried out without interruption of the service involved. In cases where this has not been possible, final end connections for new installations have often been delayed until they could be made at a plant or departmental shutdown scheduled for other reasons, or at the annual plant holiday shutdown in July.

Water Supply System

Water is used throughout the factory in three general forms:

(*a*) Direct river water for general cooling.

(*b*) Filtered water for cooling where algae growth may be troublesome.

(*c*) Softened water for viscose manufacture and product washing.

Approximately 300 million gallons per month are pumped from the river. This water flows into the pump house suction well by three intakes, passing through an automatic, revolving, debris-removal screen in the process (Fig. 15). The water enters the river intakes from the top. Each intake is protected by a six foot by six foot grid having 1¼ inch openings. These grids have to be cleaned twice a year.

Five 3600 g.p.m. pumps supply water to the factory, taking their suction from the intake well directly below them. This water is used for direct cooling in refrigeration shell-and-tube condensers and in barometric condensers of the acid recovery evaporators and crystallizers.

Cooling water from the refrigeration system and the crystallizers is reclaimed. This amounts to approximately 200 million gallons per month, and this reclaimed water is used to supply all other factory requirements.

Water from the reclaiming reservoir is pumped through 25 sand pressure filters, and from the filters through 17 sodium zeolite pressure softeners. From the softeners it drops into collecting tanks and is then distributed throughout the factory. The amount of softened water used is about 60 million gallons per month. Water enters the softeners at approximately 130 parts per million of calcium carbonate hardness, and the effluent has a hardness between 5 and 8 parts per million.

About 100 million gallons of filtered water is used each month. This includes the softened water. The turbity of Saint Lawrence River water varies between 5 and 10. After filtration it becomes about 3 to 5. These values are based on Hellige turbidity meter readings. Because of the reclaiming system the water taken direct from the river is reduced by two fifths. Heat pick-up amounts to approximately 10 deg. F. Both these points assist plant economy.

So far seaway and power developments, although much activity has taken place within a few miles of the plant, have not seriously affected the factory water supply system. Dredging and resulting current changes have re-distributed the areas of ice jamming. This caused some difficulty in 1955 but may well be a passing phase. To-date, no noticeable increase in turbidity or colour of the water has been noted. There should be none when construction is finished. Just what the effect will be when coffer dams are removed and when dredging starts in the vicinity of the factory remains to be seen.

Steam Generation and Distribution

In winter months, total steam load is about 400,000 pounds per hour. Steam is generated at 200 p.s.i.g. One-half of it is used at this pressure and the remainder at about 20 p.s.i.g. This reduction in steam pressure provides a potential for economical by-product power generation. Although this is not done at present at Courtaulds (Canada) Limited, because of an economical power rate, it is done in other Courtaulds plants.

Steam is generated by six water-tube, chain-grate, stoker-fired boilers. Five of the units are equipped with economizers. Overall steam generating efficiency is 80 per cent. The following points in the steam distribution system are of interest: —

(*a*) All auxiliary steam is measured. This includes soot blower steam and steam used for the creation of turbulence in the furnace. By measuring auxiliary steam, it has been found that the boiler house uses 6 per cent of total steam generated.

(*b*) Arrangement of the steam distribution system is such that pipe line difficulties in the boiler house never necessitate a complete shut down of the factory.

Constant effort is required to bring back condensate to the boiler house. Thirty per cent of the steam is used directly, so that condensate returns cannot exceed 70 per cent of total steam produced. Condensate returned from the factory generally runs between 62 and 68 per cent of steam supplied to the factory. Condensate is a problem because from some processes it can be highly acid, from others highly alkaline. Acid and alkali contaminated condensate is handled in a special three-tank batch system. This system provides for automatic dumping of the condensate to drain before it reaches the batch tanks if pH becomes too low. Each tank is again checked for pH before it is emptied into the main condensate collecting tank. Automatic caustic injection, controlled by a pH meter, guards against low pH values.

Refrigeration System

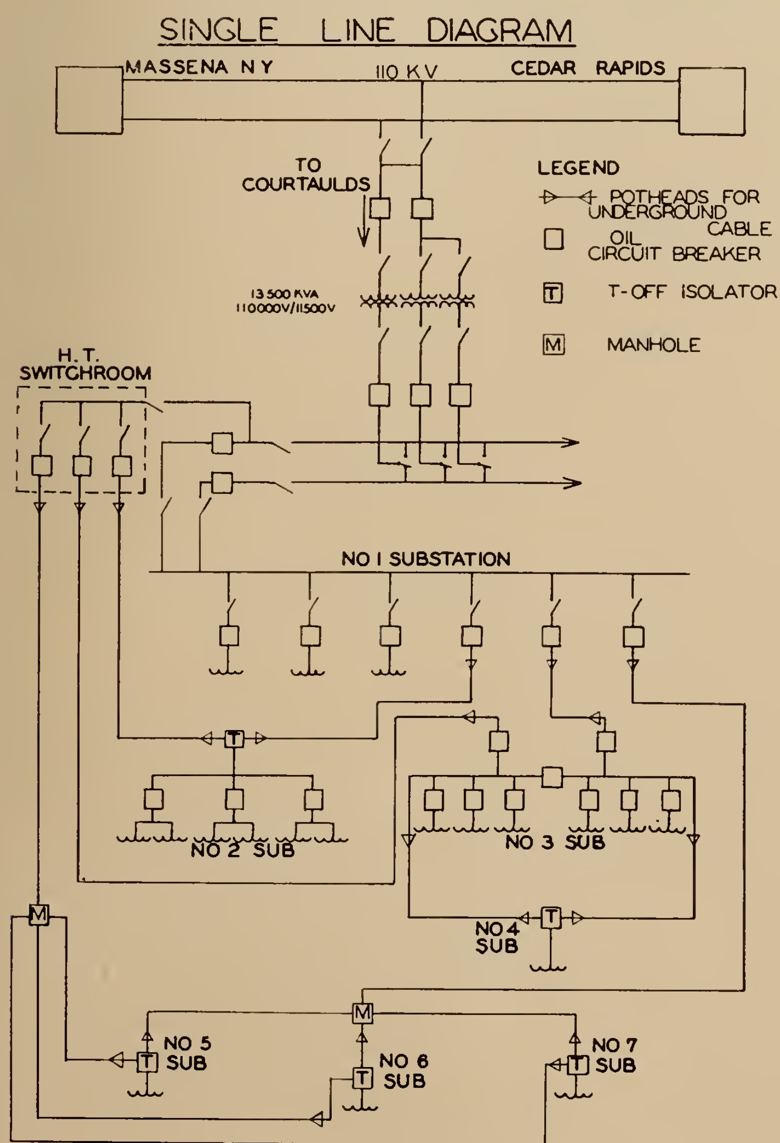
In the manufacture of viscose rayon, speeds of chemical reactions, and consequently properties of the product, are materially affected by temperature. To control process temperatures, two independent refrigeration systems are used at Courtaulds (Canada) Limited. These consist of:

(a) A 375-ton ammonia system, using calcium chloride brine as the refrigerating medium.

(b) A 1200-ton Freon system, using chilled water as the refrigerating medium.

Originally the factory had ammonia-brine refrigeration only. However, when No. 5 mill was built in 1946-48, it was decided to obtain the additional capacity required by the expanding plant by installing centrifugal refrigerating machines, using Freon as refrigerant. These were mounted in the new compressor room that was built as part of No. 5 mill. Also installed in the new compressor room were most of the ammonia units, air compressors, and vacuum pumps from the old compressor room.

Fig. 19. Single line schematic layout of electrical distribution system.



The ammonia-brine system, having a standard capacity of 375 tons, consists of five single-acting vertical compressors, discharging into ten shell-and-tube condensers. (Fig. 16) Ammonia collects in a receiver, from which it is piped to five brine coolers. Rate of cooling is controlled by float operated expansion valves. Calcium chloride brine is pumped through the coolers by the main brine circulating pumps. It enters the coolers at about 18 deg. F. and leaves at about 10 deg. F. Brine from the coolers is piped to all parts of the plant. Temperature control throughout the factory is maintained by threeway loop control valves in departments, and by flow regulating valves at individual pieces of equipment. The three-way control valves are automatically positioned by differential pressure so that they permit some brine to flow through the departmental loops to the equipment requiring it, and allow the remainder to by-pass back to the brine circulating tank. This arrangement ensures a constant pressure differential across the individual flow regulating valves, and also ensures that cold brine is always available whenever the temperature controllers call for it.

The Freon-chilled water system consists of three centrifugal refrigerating machines, each having a capacity of 400 standard tons. Each unit is complete in itself, having its own two-stage centrifugal compressor, condenser, and cooler. These machines were installed in 1948. They are driven by 2300 volt, 1200 r.p.m. synchronous motors. Through speed increasers, the compressors rotate at 4700 r.p.m.

Chilled water is pumped through the Freon coolers by the factory chilled water circulating pumps. Water enters the coolers at 50 deg. F. and leaves at 45 deg. F. In the chilled water system throughout the plant, temperatures are maintained by three-way loop control valves and individual flow regulating valves, in the same way as in the brine system. However, whereas in the brine system output of the ammonia compressors is varied to meet demand by manually stopping and starting com-

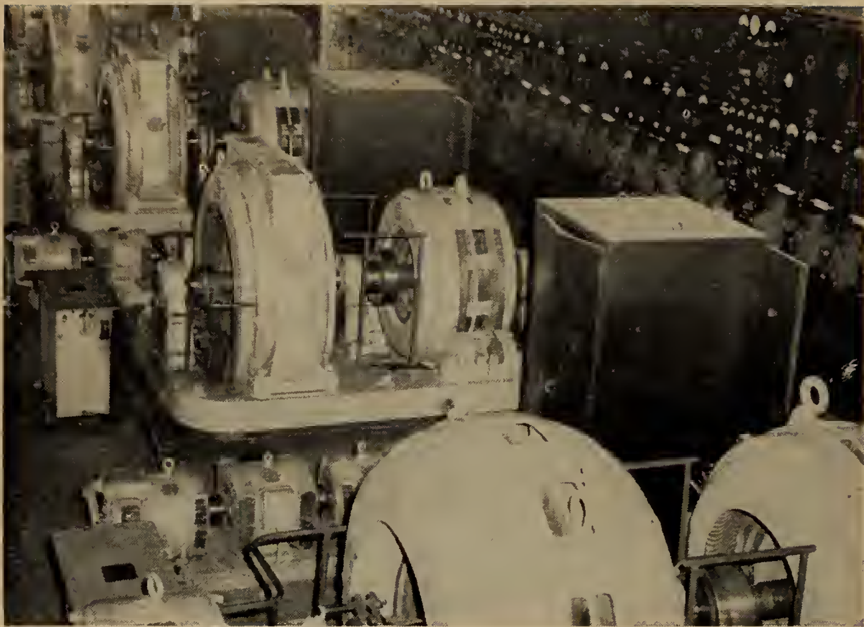


Fig. 20. Frequency changing equipment in the alternator building. Automatic controls for alternator output are on main switchboard, right. Full voltage magnetic starting controllers are beside frequency changers (centre) directly in front of motor generator excitation sets. Reactors, left, act as current limiting devices.

pressors, in the chilled water system output of the centrifugal machines is varied automatically. This is accomplished by dampers in the compressor suction lines, which regulate gas flow in accordance with temperature differential between chilled water entering and leaving the coolers.

Anti-corrosion protection is necessary in the refrigeration systems. Both brine and chilled water are closed systems. In making up the brine, calcium chloride inhibited with sodium bichromate is used. This has been found satisfactory, and no further steps against corrosion are taken. In the chilled water system, corrosion and algae growth are guarded against by maintaining the following conditions:

(*a*) Sodium bichromate concentration of 475 to 500 p.p.m.

(*b*) pH of water of 8.3 to 8.4.

Compressed air is supplied to the factory from five reciprocating compressors discharging at a pressure of 70 p.s.i.g. One of these units is an old one with twin horizontal cylinders, moved from the old compressor room when the new compressor room was built. The other four are modern, double cylinder, L-type compressors.

Compressor room installation is unusual in that all the compressors are mounted on an upper floor and not in the basement, thus necessitating protection of the building from vibration of the heavy reciprocating machines. The compressor room floor is a structural concrete slab designed for a live load of 750 pounds per square foot, carried on structural steel beams and columns, with column footings being integral with pile caps. Reciprocating compressors are mounted on large reinforced concrete inertia blocks, each block weighing between eight and twenty tons depending on relative size and frequency of unbalanced forces (Fig. 17). Vibration of the inertia block and machine assemblies is isolated from the building by means of mechanical spring type vibration isolators that permit movement of the inertia block and machine up to ¼ inch in any direction. Excess motion of the inertia blocks is dampened by snubbers made with Neoprene, cork, or mechanical springs. The 'floating' machines are connected to suction and discharge piping by flexible pipe connections.

Electrical Power and Distribution

Electric power is received from Hydro Quebec's Cedar Rapids power plant on two 110,000 volt transmission lines. These lines terminate at Courtaulds' No. 1 substation, where three 13.500 kva. transformers reduce the voltage to a plant distribution level of 11.500 volts. Switching is arranged to allow parallel operation of two or more of the transformers on either incoming line. The two secondary circuits supply the main 11.5 kv. distribution switchboard by underground cables, with switching available at this point. This provides for changeover from one incoming circuit to the other without interruption of power supply to the plant.

The secondary system, operating at 11.5 kv., incorporates an underground ring main that takes a circuitous route around the plant, covering a total area of some 75 acres. and feeding seven substations ranging in capacity from 1,000 to 8,000 kva. (Fig. 18.) Substations are located near strategic load centres throughout the plant. (Fig. 19.) T-off isolators at underground cable terminals in each substation provide flexibility for maintenance and testing. Since the ring main is energized at both ends, this system ensures a stand-by alternative source of power for each substation, and hence for each important section of the factory.

Since any unplanned shutdown of one or more of the spinning departments is a very costly event, every precaution is taken to ensure that there will be no electrical power failures caused by faults in the plant distribution systems.

Box spinning machines contain large numbers of spindle motors, one to rotate each spinning box. These spindle motors operate at 7200 r.p.m. They require current at 120 cycles, 45 volts. Approximately 14,000 spindle motors are in use. Electric power to drive these spindle motors is supplied from five frequency changer units located in the alternator building (Fig. 20). Each frequency changer is rated at 840 kva., 120 cycles, 528 volts. They operate in parallel. Operation of these units is made fully automatic by an impulse regulator system which holds electrical output from the machines constant at a set value.

Power factor correction is obtained in three different ways:

(*a*) Several old and unused frequency changer sets have had their alternators removed, and their large synchronous motors have been converted to operate as synchronous condensers. These are connected into low-power-factor feeders.

(b) Induction motors of sizes over 100 h.p. have capacitors connected at the motor terminals.

(*c*) Air and refrigeration compressors in the compressor room are driven by synchronous motors varying in size from 100 h.p. to 300 h.p.

As a result, overall plant power factor is maintained constant at 94 per cent.

Highway Turbine Interchanges

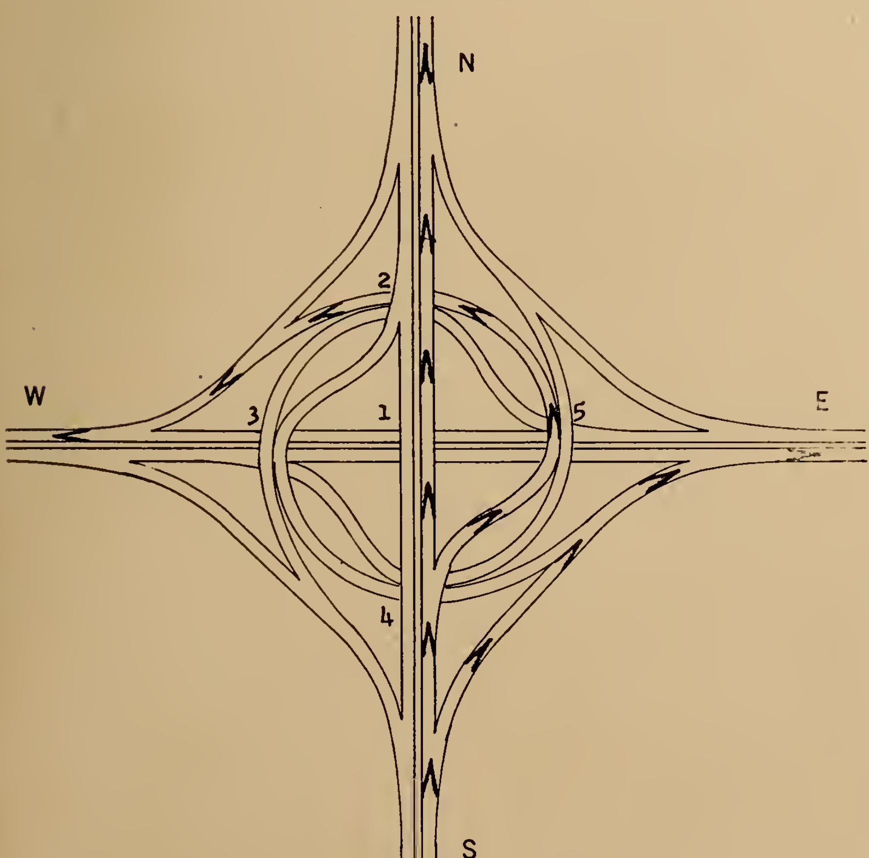
S. M. Breuning, M.E.I.C.*

INTERCHANGES are defined in the "Highway Capacity Manual" as: "A system of interconnecting roadways in conjunction with a grade separation or grade separations providing for the interchange of traffic between two or more roadways or highways on different levels".

This definition is rather general; it does not refer in any way to possible interferences between different traffic streams. It obviously assumes that the grade separations eliminate at least the most serious interferences in an intersection at grade. The degree to which interferences of traffic streams are eliminated determines the efficiency of the interchange.

Interchanges of highways with limited access must be designed according to some fundamental rules. Exits and entrances from the through roadways must be provided at the outer, right-hand side of the roadway so as to keep the inner, left-hand lanes undisturbed by turning vehicles. Exits and entrances also must be designed in such a way that the turning vehicles, either leaving or entering the main roadway, may manoeuvre without unduly affecting the through traffic, and especially without accident hazard. In addition all streams of turning traffic, considered as the minor traffic streams, should interfere as little as possible with each other.

Fig. 1. Turbine interchange.



Comparison With Cloverleaf and Rotary

The turbine interchange (Fig. 1) can best be explained in comparison with the cloverleaf and the rotary interchanges.

The cloverleaf is the most commonly found interchange on highways. It is simple except for the left-turning movements, yet even these are by now well accepted by the motorists. Left-turns are accomplished by making a three-quarter right turn. This is sometimes a little confusing to the driver, who easily loses the sense of direction. It also requires rather sharp curves which can be negotiated only at speeds much lower than used on the open highway. This required reduction of speed definitely is one of the drawbacks of any interchange, especially the cloverleaf. Its correction would be possible only with prohibitively large layouts which are not economically justifiable. Another drawback of the arrangement of the left-turning movements in a cloverleaf is the weaving of each left-turning path with two other left-turning paths. This problem, demonstrated in Fig. 2A is of no importance, as long as the volumes of traffic of the turning movements are low. When the turning volume gets heavy, as it often

*Post-graduate student in transportation engineering at Massachusetts Institute of Technology.

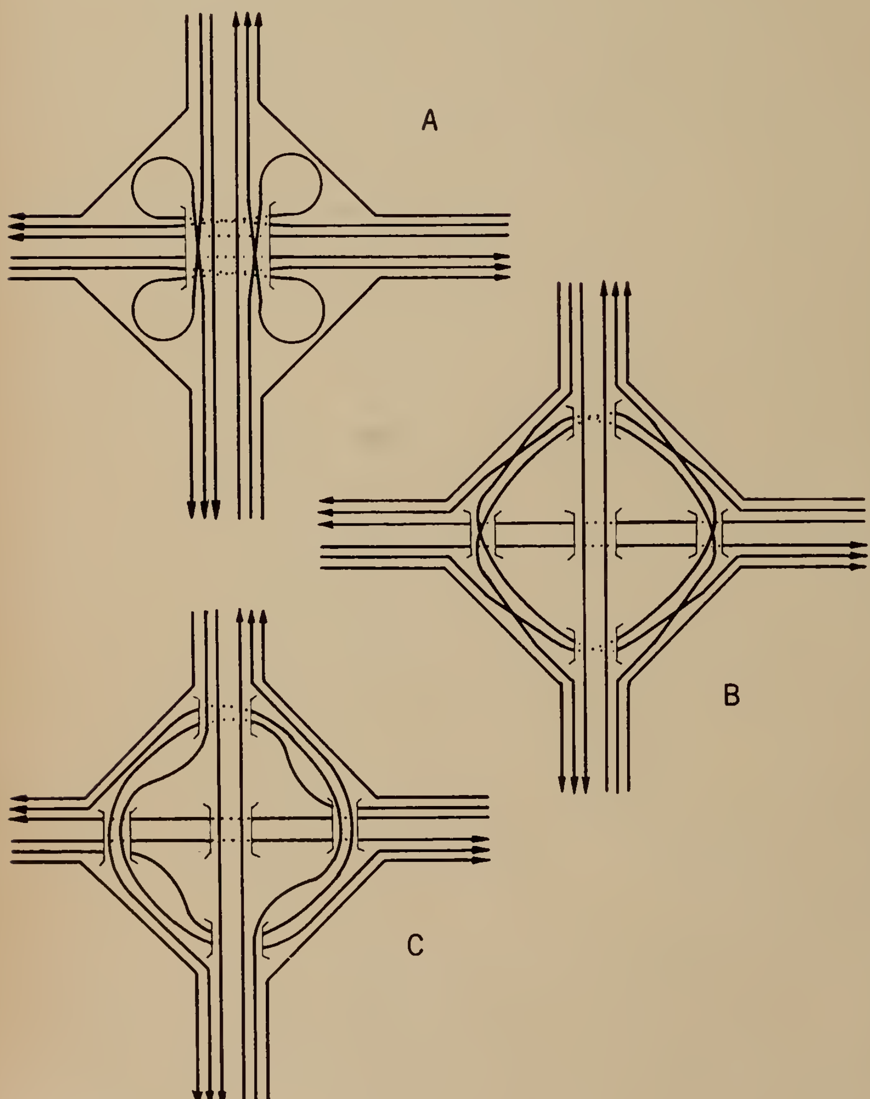
does in suburban intersections, vehicles negotiating conflicting left-turning movements will no longer be able to weave, and a bottleneck will result.

The rotary interchange is less often found on modern superhighways. It is developed from a surface rotary intersection by addition of one (or two) through highways with grade separations. The rotary roadway is a circular one-way roadway, driven in a counterclockwise direction. Traffic enters it and leaves it from the outer, right-hand side. All movements except right-turns therefore must weave with some other traffic streams. Thus the capacity of the rotary also is limited by the volume of the two largest weaving traffic streams. In Fig 2B a rotary is shown with two through highways. Only the turning vehicles enter the rotary, and the right-turning traffic streams do not have to weave. The left-turning movements, however, have to weave four other left-turning traffic streams. Thus the rotary is limited by the volume of the two largest conflicting left-turning volumes.

The curves necessary for a rotary are not quite as sharp as for a cloverleaf covering the same area, but five bridges are required instead of one for the cloverleaf.

The turbine interchange is similar to the rotary described above, except for the entrance of the left-turning movements into the rotary. Instead of coming from the outside of the circle, the left-turning traffic first crosses the rotary along with the main highways and then enters from the inner, left-hand side of the rotary roadway. By this simple change, left-turning movements no longer cross each other, although they may run parallel for some distance on the rotary.

Fig. 2. Flow diagrams.



The structural requirements for the turbine are essentially the same as for the rotary discussed above. The entrance lanes for left-turning movements are the only fundamental difference. These must be built with somewhat sharper radii in order to provide a smooth S-curve from the through roadway to the rotary. Therefore the speeds permissible for left-turning traffic are lower than in the rotary, but still as high or higher than in the cloverleaf, occupying the same area.

Principle

The layout of the turbine, as shown in Fig. 1, consists of

the intersecting main roadways (SN,NS,WE,EW),

the right-turning roadways (SE, EN,NW,WS),

the left-turning roadways (SW, ES,NE,WN).

The main roadways and the right-turning roadways are essentially the same as in any conventional interchange.

The left-turning roadways have given this type of interchange its name, because as in a turbine, the left-turning traffic enters the rotary from the inside, gradually proceeding to the outer edge in the course of accomplishing the left-turn, and finally leaving in its new direction. Traffic making left-turn SW for instance enters upon a sharp S-curve right after it has crossed the rotary at point 4, Fig. 1. The roadway then proceeds to join the rotary which, in this case, is a circular roadway made up of pieces of left-turning roadway. SW follows the rotary from point 5, where it crosses over the main highway (EW) until point 2, where it crosses under the main highway (SN). After point 2 the roadway leaves the rotary and enters into the main highway (EW).

Naturally, the left-turning roadways can also be led through the rotary entering from the outside and leaving from the inside (Fig. 3), a complete reversal of the previous design. This would be advantageous for fast traffic because the sharpest curves occur towards the end of the turning roadway rather than towards the beginning.

In the foregoing designs the right-turning roadways determine the outer limit of the whole interchange. In cases of extreme scarcity of land it might be preferable to put the right-turning roadways within the circle (Fig. 4).

The obvious disadvantage of this design is a crowding of exits and entrances of turning lanes from the open highways to the structures. Such arrangement requires generous layouts of the bridges in order to provide ample visibility and room for the necessary manoeuvres of the vehicles.

Vertical Arrangement

There are three possibilities for the vertical layout of the roadways in a turbine interchange.

(1) Rotary *over* intersecting highways

(2) Rotary *under* intersecting highways

(3) Rotary *over* one and *under* the other intersecting highway.

Only the left-turning vehicles must change grade in the first two arrangements. The left-turning roadway has an ascending (or descending) slope in the first quadrant, then it stays at the elevated grade and descends (or ascends) in the last quadrant.

The disadvantages of this arrangement are the rather steep slopes or long ramps required, which tend to govern the size of the interchange as a whole. The advantage of appearance can be disputed. The use of the grades as aids for deceleration and acceleration is doubtful, because of the curvature and the restrictions at the entrance into the other roadways.

Leading the rotary roadways in turn over and under the main highways provides a more versatile solution (Fig. 1). It may be assumed that the two intersecting highways are at different grade, thereby facilitating a grade separation. All turning vehicles stay at their initial elevation throughout the first quadrant, and change grade in the second, remaining at the new grade in the third.

This arrangement has grades in less critical locations, where vertical curves can be fitted easily and no driver distraction occurs. It also should provide greater versatility for adaption to existing topography.

Driver Acceptance

Highway interchanges are no longer instinctively understood by the driving public. Elaborate route and directional signs and familiarity on the part of most drivers are necessary to enable large volumes of vehicles to flow through an interchange without delay for orientation. Nevertheless, it is always desirable to maintain a logical layout of the roadways so that drivers do not get the feeling that they are on the wrong road. Making a three-quarter right-turn instead of a one-quarter left-turn still is rather confusing to many drivers.

The turbine intersection provides in its rotary roadway a common focus which should enable drivers to orient themselves more easily within the layout. The entrance on to the rotary from the inside may be a disadvantage because it is somewhat hidden immediately after the crossing of the rotary roadways.

The rotary roadway of the turbine offers the additional advantages of crossovers at the locations of the crossings with the through roadways. These crossovers provide for drivers who take the wrong turn and would like to continue straight through and, more important still, for traffic turning around.

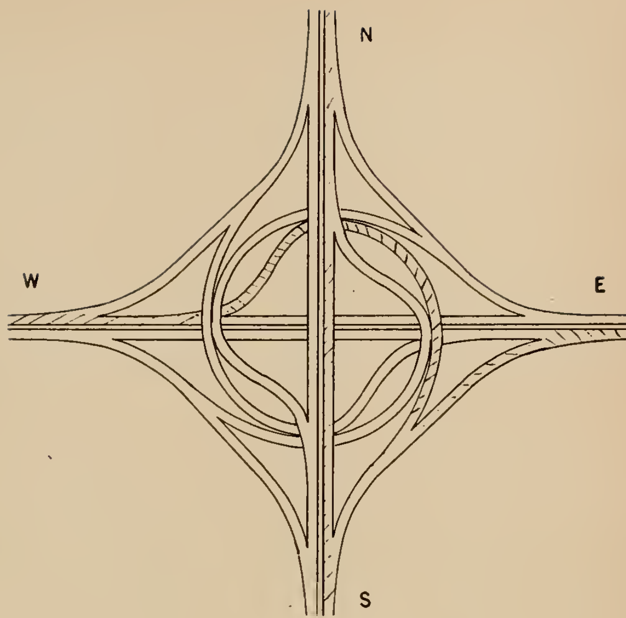


Fig. 3. Turbine interchange (reversed).

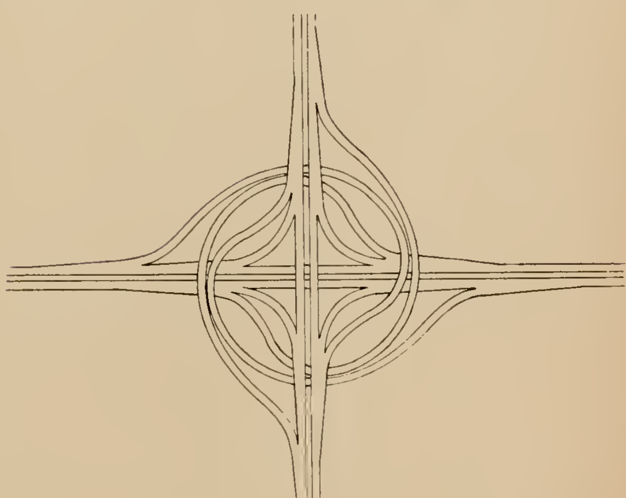

Fig. 4. Turbine interchange with right turning roadways within the rotary.

Structures

For the turbine interchange as outlined here five structures are required: one crossing structure for the crossing of the main highways (Pt. 1 in Fig. 1), the same basic structure that would be provided for a cloverleaf; and besides this, four smaller bridges to lead the rotary roadways over or under the main intersecting roadways.

Geographic Adaptability

The larger number of structures required for this interchange and the necessity to make these structures as simple as possible make it desirable to have fairly flat land at least within the area of the rotary roadway. The possibility of varying the relative elevation of the crossing roadways with the requirements of the topography make the design more flexible than it may seem at first.

Feeder Roads

A special application of the turbine principle to intersections of a superhighway with a feeder or other secondary road is shown in Fig. 5. The feeder road is not handled as a separate through roadway. Its through traffic (SN) enters the rotary roadway together with the left-turning traffic (NW) at the crossover (4) to the left-turning roadway (WN) from the main highway. This provision for crossing over has been pointed out before as an advantage for drivers who lose their way. In the case of the feeder road, however, the crossover eliminates one structure and reduces two more structures to cross one instead of two roadways.

Considering through traffic as the main traffic stream this layout no longer provides entrances and exits from the outer, right-hand side of the roadway on the feeder road.

There are however still no weavings or hidden intersections within the interchange.

Curved Main Road

It is not absolutely necessary that the main road be straight through. It could be curved (for instance SE). Such layout still requires two large and two small bridges, yet it eliminates one left-turning roadway which is led through the centre as the through road.

This design mainly serves to illustrate how versatile interchanges of the turbine principle can be if special requirements are considered.

Simplified Feeder Road

In order to eliminate two of the four bridges that were necessary in the previous designs, some interfering traffic may be required to weave.

In Fig. 6 there are four weaving sections. (These could be reduced to two with little change in the design, yet the number of weaves would remain the same.) As demonstrated on the flow sketch, the left-turns from the feeder road each have to weave with three other traffic streams, the through traffic on the feeder road and the left-turns from the main road each have to weave once.

This layout therefore has little advantage over the cloverleaf in terms of weaving. The separation of the structure into two one-way bridges and the necessary curvature for the through traffic of the feeder road are definite disadvantages of this design. Provision of a continuous rotary provides somewhat more flexibility to the layout.

Turbine Rotary

As a last design in this series the turbine rotary without through roadway should at least be mentioned. In contrast to the standard turbine this design leads all entering roadways into the centre, thereby eliminating all weaving. This rotary has an unlimited capacity as long as the roadways are sufficiently wide.

Its main advantage is the possibility of converting existing rotaries which are very inadequate into turbines by adding the separate entrance roadways.

Conclusions

The turbine interchange is an improved rotary interchange. The left-turning traffic enters the rotary from the inside and leaves it from the outside, thereby eliminating all weaving or crossing of traffic streams.

This design, although expensive in construction, is especially adaptable for intersections with large volumes of turning traffic, such as suburban intersections, connections of feeder roads with superhighways, and one-way street intersections in cities.

The turbine is more versatile than it seems at first. It can be built in stages or existing rotaries can be converted into turbine rotaries by adding the entrance ramps and grade separations.

X-Ray Techniques

Ursula Martius

Research Fellow, Ontario Research Foundation

IT IS THE PURPOSE of this paper to give a brief survey of X-ray techniques, stressing general principles rather than practical details.

Nature of X-Rays

X-rays are electromagnetic radiation, just as light, but their wave length is 100 to 1000 times shorter than that of visible light. Consequently, the human eye cannot see X-rays, but a photographic plate is sensitive to them as it is to light.

X-rays are produced when electrons of high energy impinge on a solid surface. The electrons are absorbed and most of their energy is transformed into heat, but about 5 per cent is converted into X-rays. The wavelength of this radiation depends on the energy of the electrons (which can be varied by varying the tube voltage) and on the material of the solid surface, the "target". Since most of the energy of the electrons produces heat, the major limiting factor in the design of high intensity X-ray tubes is the dissipation of this heat. Tubes are water, air or oil cooled; common target materials are copper, tungsten and molybdenum.

Interaction of X-rays with Matter

The comparison between X-rays and light will help to illustrate what happens when X-rays interact with matter. In the case of light we are used to distinguishing between materials that are transparent and substances that absorb light or reflect it. We know that this classification is very approximate and that in reality all three things happen simultaneously; for instance, even in a transparent substance a certain fraction of the light is absorbed and a certain fraction is reflected.

X-rays are similarly transmitted, absorbed and "diffracted". Depending on experimental conditions one of these types of interaction will be predominant. We will discuss the different X-ray techniques according to the type of interaction on which they are based.

Just as in the case of light, different materials are more or less transparent to X-rays. It depends on the atomic weight of the material how strongly X-rays of a given wavelength are absorbed, (not, as in the case of light, on state of aggregation, state of binding, crystallographic properties). The absorption of X-rays is roughly proportional to the fourth power of the atomic weight (actually the atomic number) of the absorber. Thus, substances of different atomic weight can show striking differences in their capacity to transmit or absorb X-rays.

This article presents a brief review of X-ray techniques and gives an insight into the possible use of X-rays. These techniques are finding increasing application both in research and industry.

Radiography

These laws of transmission of X-rays are the basis of all medical X-ray work and of industrial radiography. The reason why an X-ray film of a hand can show the structure of the bones and joints is that the X-rays are absorbed much more strongly in the calcium of the bones than in the light elements of the tissue. It is really the "shadow" of the bones in the X-ray beam that appears on the film.

Industrial radiography is mostly concerned with the detection of defects, cracks, etc. in commercial products. These techniques are used widely in inspection and control, although today radioactive isotopes begin to take over some of the functions of X-rays in this line of applications. But, be it X- or gamma-rays, all radiographhic techniques are based on the selective transmission of these radiations.

Micro-radiography is a refinement of radiographic techniques, based on the above mentioned relation of absorption and atomic weight. By means of micro-radiography it is possible to detect regions of different composition in, for instance, an alloy on account of their different X-ray absorption coefficients. Fig. 1 shows the microradiograph of a 70-30 Cu-Pb alloy. The black dendrites are the copper - rich phase, the white background is lead.

This technique works best when the components to be distinguished have very different atomic weights. The severe drawback of this method, since it is based on the transmission of X-rays, is the fact that only sections of a few thousandths of an inch thickness can be used.

To overcome this difficulty we have recently tried to develop a technique which works in "back reflection" rather than in transmission, using strictly monochromatic X-rays. We can use standard metallographic specimens and will be able to compare directly microscopic and micro-radiographic observations.

X-Ray Diffraction

Though the straight transmission and absorption of X-rays and light are in many ways similar, the "diffraction" of X-rays and the reflection of light cannot be compared directly.

X-rays can be "diffracted" from a crystalline substance to form a diffraction pattern, which can be recorded on film or by means of a

Geiger counter. The type and the dimensions of these diffraction patterns are determined by the distance between the atoms of the crystal and wavelength of the X-ray beam. This means that the wavelength of X-rays can be determined from the diffraction pattern of crystals of known interatomic distances. Conversely, the structure of a crystal can be established by investigation of the diffraction of X-rays of known wavelength on this crystal. Many techniques have been developed for the latter type of work, using single crystals or crystalline powder, employing monochromatic or polychromatic beams. Figure 2 shows the diffraction pattern of ZnO powder.

In the course of the last thirty years a very large number of crystal structures have been established and tabulated. These data are readily available in form of a reference file to which supplements are issued every year or two. This information makes it possible to identify an unknown substance by its diffraction pattern because an X-ray diffraction pattern is something like a fingerprint of a compound. This type of identification work can be carried out with a very small amount of material; these X-ray techniques are non-destructive and can also be applied to mixtures of a number of compounds. The limitations of these methods are: (a) the lack of data on the crystal structures of less common substances like silicates, organic compounds, special alloys, etc.; and (b) the complexity of the pattern of a mixture, which limits the number of components that can be identified unambiguously.

It should be stressed that identification by means of X-ray diffraction always yields the compounds, not the ions. For instance, a mixture of rock salt and magnesium sulphate would be identified as $NaCl$ and $MgSO_4$, whereas chemical analysis would only find Na, Mg, Cl and SO_4.

Another field of X-ray application, which makes use of known diffraction patterns and known interatomic distances, is the study of deviation from normal crystal structures and dimensions.

Let us assume, for instance, that an X-ray photograph is taken of a

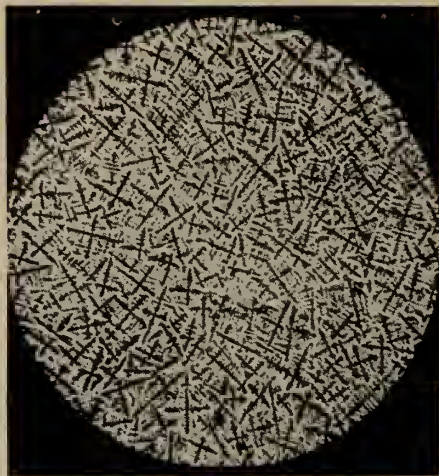

Fig. 1. Microradiograph (100x) of 70-30 copper-lead bearing lining: copper-rich dendrites, black; lead, white.

highly stressed metal. If the interatomic distances of the unstressed material are known, then the difference between this and the corresponding value of the stressed material is directly related to the magnitude of the stresses in the material. A number of techniques have been developed for stress determinations by means of X-rays; all of them precision determinations of the lattice constants.

Precise determinations of lattice dimensions are also frequently used in the study of phase diagrams where the solid solution of one constituent in the other may change the lattice dimensions, rather than produce a second phase (which would appear as a second pattern and could also be detected by means of X-rays).

The lattice dimensions of a crystal do not only change under stress or in case of solid solution, but they also change with temperature. There are today techniques available which record X-ray diffraction patterns as a function of changing specimen temperature, both at high and at low temperatures. Data on thermal expansion are also obtained in the course of these investigations.

An X-ray diffraction pattern of a polycrystalline substance records not only the lattice dimensions, but also the relative orientation of the grains with respect to each other. In other words, from a diffraction pattern we can see whether the grains are randomly oriented or whether certain orientations occur with higher than average preference.

The study of preferred orientation is of great importance if one is concerned with the working of metals or with the properties of fibres. Without X-ray techniques it would have been impossible to establish today's knowledge of the deformation and annealing textures of metals or of the mechanical behaviour of fibres and polymers.

When we speak about "deviations from normal crystal structures and dimensions" we have to realize that the "normal" or "perfect" crystal is only a theoretical concept and that all real crystals are more or less "imperfect". The study of crystal imperfections and their relation to mechanical and electrical properties has been of greatest interest to physicists and engineers during recent years. Very precise measurements of the small changes in diffraction pattern (both in dimensions and intensities) which are produced by different degrees of imperfection have added much to our knowledge of the processes of plastic deformation, grain growth, and solidification. It is in this field that we may expect a number of new developments in the near future, both along the lines of more specialized experimental techniques and in the field of new applications.

Since X-ray diffraction patterns with the characteristics outlined above are produced by crystalline substances only, X-ray diffraction techniques are useful to determine the degree of crystallinity, for instance in glasses, ceramics, and fibres. X-rays are also diffracted from liquids and from amorphous substances, but the character of these diffraction patterns is different and will not be discussed here. However, it may also happen that crystalline

Fig. 2. X-ray diffraction pattern of ZnO.

particles are too small to give rise to a well defined diffraction pattern. Particles of less than 50 microns will produce diffuse diffraction patterns, and methods for the determination of particle size are based on this fact.

X-Ray Spectroscopy

This third group of X-ray techniques is based on a different physical phenomenon than X-ray diffraction or radiography.

We have seen above that all X-rays are more or less strongly absorbed by matter. In radiographic techniques we are interested in the fraction of the X-ray beam that is not absorbed but transmitted, because this is the fraction of the beam we record. Now, however, we should ask, "What happens to the absorbed X-rays?" Most of their energy is transformed into heat, but a portion is used to excite new X-rays in the material of the absorber analogous to the processes in the target-surface of an X-ray tube. These new X-rays are of distinct wavelength which are characteristic of the material of the absorber. They are, therefore, called fluorescent or characteristic X-rays. Every element has its characteristic X-ray spectrum which consists of only a few lines of distinct wavelength, just as an element has a characteristic optical spectrum. But, in contrast to optical spectra, X-ray spectra are characteristic of the atom only; they are independent of the state of binding and aggregation; in other words, the X-ray spectrum of iron is the same regardless of whether the sample is a sheet of steel, iron oxide powder or a solution of iron sulphate. There is no X-ray analogy to "molecular spectra".

It is thus possible to identify an element by exciting and recording its X-ray spectrum. In practice this is done by absorbing an intense X-ray beam of high energy in the specimen and measuring the wavelength of the characteristic radiation which is emitted by the sample. The wavelength measurement is accomplished by diffracting the characteristic radiation from a single crystal of known lattice dimensions — the "analysing crystal". Rock-salt, lithium fluoride, mica or quartz are frequently used as analysing crystals. In an X-ray spectrograph the analysing crystal fulfills the function of the prism in an optical spectrograph. Figure 3 shows schematically the principal components of a spectrograph.

The fundamental properties of X-ray spectra have been known since 1912, but only recently improvements in high energy X-ray sources and in high sensitivity recording equipment have made X-ray spectroscopy a feasible routine technique. The first X-ray spectrograph of the type now commercially available was built during and after the second world war and only during the last five years has X-ray spectroscopy found large-scale industrial applications. Whereas there is a very large amount of reference literature available for X-ray diffraction problems, few data and no books exist as yet dealing with X-ray spectroscopy.

Today X-ray spectroscopy is mostly applied to analytical problems. X-ray spectra are simple and their identification is comparatively easy; the technique is non-destructive and solid or liquid samples can be used. These, together wth the high speed of operation are the main advantages of X-ray spectroscopic analysis.

X-Rays + Matter

transmitted	absorbed	diffracted
Radiography	**X-Ray Spectroscopy**	**X-Ray Diffraction**
macro-	Analysis	Crystal structure
micro-	Absorption coeff.	Identification
	Segregation	Stress determination
	Surface composition	Preferred orientation
		Textures
		Crystal imperfections
		Particle size

Every element has its characteristic X-ray spectrum. However, the spectra of the light elements are "soft", i.e. their wavelength is long and these spectra are usually absorbed in the air path between the specimen and the counter, or in the window of the counter. That is why today only elements that are heavier than phosphorus or sulphur can be detected by their X-ray spectra, even if the air in the path between specimen and counter is replaced by helium. New experimental developments to overcome this limitation can be expected soon.

Though analytical work is the main field of application of X-ray techniques it is by no means the only one. Studies of composition changes due to segregation, measurements of absorption coefficients and investigation of surfaces can well be carried out with an X-ray spectrograph.

The applications mentioned in the preceding paragraphs are summarized in the accompanying table. They are grouped according to the type of interaction principally involved.

Fig. 3. Diagram of basic geometry of fluorescence-analysis method.

Progress in the development of

The Energy Resources of Canada

Compiled by the Water Resources Branch, Department of Northern Affairs and National Resources and the Dominion Coal Board

Paper presented before the Fifth World Power Conference, Vienna, Austria, 17-23 June 1956

THE ENERGY RESOURCES of Canada and their development were reported in a paper presented at the Fourth World Power Conference in London in 1950. There have been significant changes since that time in the discovery and development of new oil and gas fields and the harnessing of large supplies of hydro-electric energy while the combination of recent discoveries of uranium with the technical developments in the production of atomic power shows promise of major growth in resources of atomic energy.

Report of Progress

Energy Sources — There has been a gradual change in the sources of energy as petroleum has taken over more and more of the market formerly supplied by coal. In Fig. 1 there is a graphical record of the supply of all but one of the various forms of energy from 1927 up to and including 1955. The exception is wood which supplies a proportion of the energy requirements. Accurate data on which any estimate could be based are not available in the earlier part of the years covered by this graph.

Water Power

Water power constitutes one of Canada's great natural resources and has provided the principal source of energy for the rapid industrial development of the country. The extent of water-power resources and their development were reviewed in detail in papers presented at the First and Second World Power Conferences and also a brief review was given at the Fourth Conference. However, during the period 1949 to 1954 inclusive, development has been very rapid; also, there has been a certain amount of revaluation of resources, particularly for the Province of Quebec. Total potential and developed resources, as of the end of 1954, are shown in Table I.

The figures in this table were computed on the standard bases of stream discharge and power rating as adopted for the Statistical Year Book of the World Power Conference. The totals of available power may be said to represent only minimum power possibilities as explorations are incomplete. However a considerable proportion of the remaining available power lies in rather inaccessible regions, although frontiers are being extended and feasible transmission line distances increase.

This paper was prepared late in 1955 for discussion at the World Power Conference Plenary meeting in Vienna in June 1956. Since its preparation, energy requirements in Canada have expanded at increasing rates, and it may be expected that the energy requirement forecasts herein should now be revised upwards.

During the six-year period 1949-1954 inclusive, developed capacity increased by 4,146,500 kilowatts, being 50 per cent greater in 1954 than in 1948. This increase was widely distributed across Canada but the larger developments were made in the Province of British Columbia, Ontario and Quebec. A brief review of major projects is given below.

One of the high lights of hydro-electric construction during the period was the successful completion in British Columbia in 1954 of the first stage of the great Kemano-Kitimat project of the Aluminum Company of Canada. Water is diverted through the Coast Range and the three Pelton wheels each of 112,000 kv. operate at 2485-foot (757-metre) head in the first Canadian underground power house. The fourth unit is under installation and ultimate capacity is about 1,500,000 kw. Power is transmitted at 300 kv. to Kitimat for operation of the new aluminum smelters.

Other major additions to capacity in British Columbia in the period were: (1) the British Columbia Electric Company increased its Bridge River Plant installation by 139,000 kw. to its present capacity of 185,000 kw., added a total of 127,400 kw. at three other sites, and had under construction in 1954 two new plants totalling 111,000 kw.; (2) the British Columbia Power Commission with plants on Vancouver Island and the mainland increased its capacity by 135,800 kw.; (3) Consolidated Mining and Smelting Company of Canada Limited added 27,600 kw. to its Brilliant plant and completed the first half of a 358,000 kw. ultimate installation at its Waneta plant on the Pend d'Oreille river.

In the Province of Alberta, Calgary Power Limited, which serves a large part of the southern part of the province from hydro - electric plants in the Bow River basin, increased its hydro capacity by a total of 112,900 kw. through construction of four new plants and additions to two existing ones.

The Province of Saskatchewan is

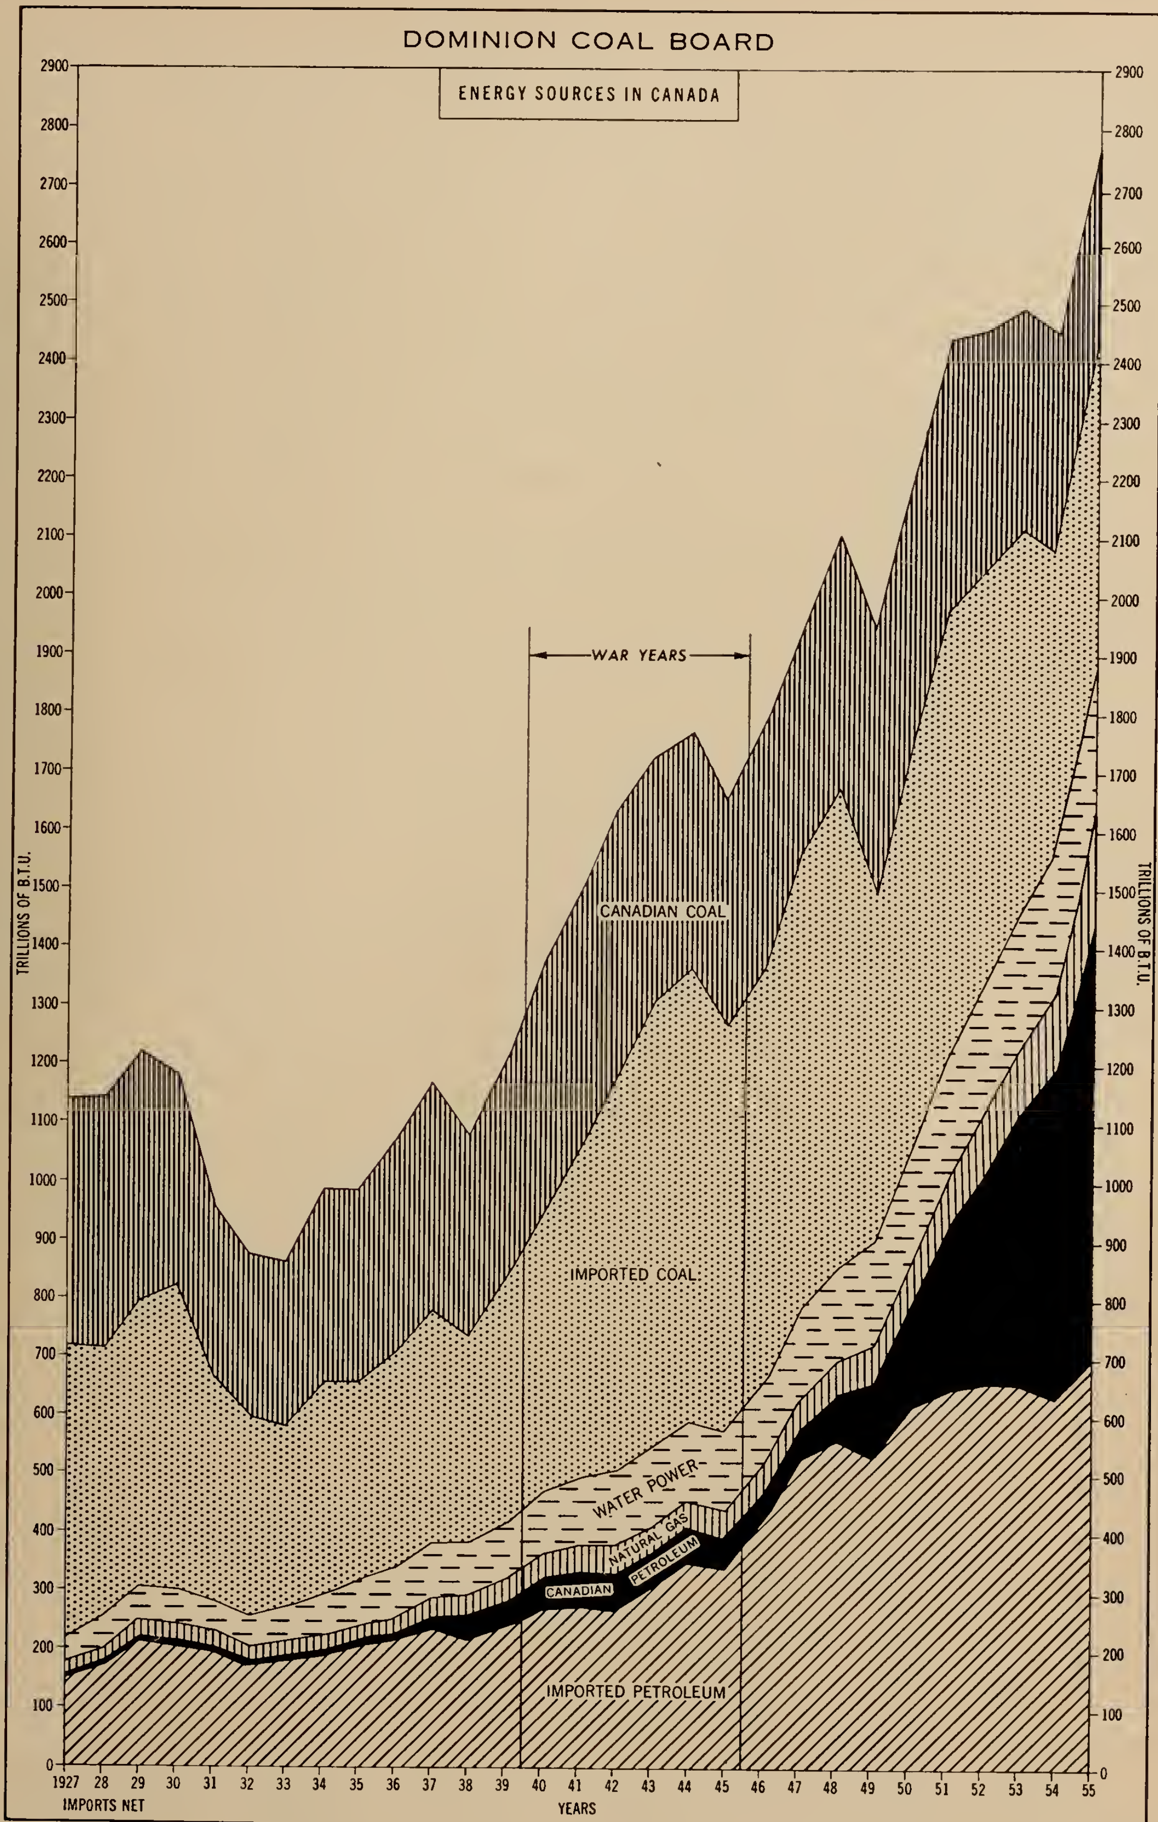

Fig. 1. Chart of energy sources in Canada over the period 1927-1955.

served principally by fuel plants and no new water-power developments were made.

In Manitoba the Manitoba Hydro-Electric Board increased its capacity by 211,200 kw. in two new projects and redevelopment of its Seven Sisters plant, all on the Winnipeg river. In the more northerly area of the province a 5200 kw. development was made by Sherritt-Gordon Mines Limited.

In Ontario, with its very diversified industries and heavy domestic and rural power demands, electricity is supplied principally by the Hydro-Electric Power Commission of Ontario, which increased its hydraulic capacity by nearly 1,500,000 kw. in the period. Three large plants were completed on the Ottawa river totalling 698,300 kw. At Niagara Falls a new major development involving a pumped storage scheme and a total capacity of 1,370,000 kw., which was initiated in 1951, had reached an installation of 548,000 kw. at the end of 1954 in a continuing construction program. In Northern Ontario the Commission added 171,600 kw. in new plants on the Nipigon and Mississagi rivers and initiated construction on a plant on the English river. The Great Lakes Power Company which serves the Sault Ste. Marie area increased its capacity by 36,000 kw. in two new plants and an addition to an existing plant on the Michipicoten river.

It may be added here that by 1955 the Hydro-Electric Power Commission of Ontario had started construction of the works for its power project on the international reach of the St. Lawrence River which is designed to add 900,600 kw. to Ontario's installed capacity. This represents the last of that Province's large remaining hydro power potentials.

The orderly development of the great water-power resources of the

Table I. Available and Developed Water Power in Canada at end of 1954

Province	Available Gross Capacity 100% efficiency at Q 95 (thousands of kilowatts)	Available Gross Capacity 100% efficiency at Q 50 (thousands of kilowatts)	Developed Capacity (Turbine) (thousands of kilowatts)
British Columbia	6,549	12,101	1676.2
Alberta	474	1,384	193.0
Saskatchewan	513	1,232	81.9
Manitoba	3,108	6,120	564.6
Ontario	5,042	7,990	3614.7
Quebec	10,160	22,497	5799.8
New Brunswick	115	368	122.4
Nova Scotia	24	172	127.5

Newfoundland	894	3,030	241.1
Yukon and Northwest Territories	357	895	24.2
	27,236	55,792	12,446.3

Province of Quebec was continued during the period and capacity was increased by more than 1,500,000 kw. principally to serve the metallurgical and forest-product industries.

The Quebec Hydro-Electric Commission completed the Beauharnois No. 2 Plant of 497,000 kw. on the St. Lawrence river and constructed two small plants totalling 36,000 kw. on the Upper Ottawa river. Moreover, in 1953 the Commission started construction of a project of 895,000 kw. capacity on the Bersimis river. This plant which is rapidly nearing production stage involves a 17½ mile (28.2 km.) lined tunnel of 31½ feet (9.6 m.) diameter which will convey the water to turbines operating under a head of 875 feet (266.7 m.) in an underground power house. In the latter part of 1955 it was announced that the Commission would proceed immediately with construction of a second plant of nearly 400,000 kw. on the Bersimis river.

Other major additions to capacity in Quebec were: (1) The Shawinigan Water and Power Company added two new plants, totalling 387,500 kw. on the St. Maurice river and in 1954 had work under way on a total addition of 118,000 kw. at these plants; (2) The Aluminum Company of Canada in 1952-53 built two new plants totalling 418,000 kw. on the Peribonka river; (3) The Manicouagan Power Company brought into operation the initial 83,600 kw. of a 251,000 kw. ultimate development on the Manicouagan river. Other important additions by Price Brothers and Company, Northern Quebec Power Company, Gatineau Power Company, and Gulf Power Company totalled 122,600 kw.

In New Brunswick the New Brunswick Electric Power Commission constructed a new plant of 20,000 kw. on the Tobique river and started construction of a plant on the St. John river for an initial installation of 68,000 kw.

The Nova Scotia Power Commission added 15,700 kw. in two plants and the Nova Scotia Light and Power Company increased its capacity by 16,800 kw. at four sites.

In Newfoundland the Newfoundland Light and Power Company added a total of 25,300 kw. to its capacity at four plants on the island while Iron Ore Company of Canada installed 9,000 kw. in a plant on the Ashuanipi river in Labrador.

Although there has been a considerable increase in primary production of electricity from fuel-powered

1954	9,381,007	2,228,286	1,920,307	13,529,600	2,499,229	14,356,537	16,855,766	30,385,366

Note: 1 metric ton = 2204.62 lb. = 0.9842 long ton plants, and there is a trend in Ontario towards auxiliary steam plants for peak loads, water power remains the principal source of electricity for central stations which produce power for sale in Canada or for export to the United States. In 1954, 95 per cent of central-station power was generated from water power and the total hydraulic production amounted to 65,846,000,000 kilowatt hours, an increase of 52 per cent since 1948. Of hydraulic installations in Canada, 86.9 per cent are central stations, 5.6 per cent are exclusively for pulp and paper production, and 7.5 per cent are for other purposes, principally metallurgical production in British Columbia. It may be noted that the plants serving the aluminum industry in Quebec are classed as central stations for the reason that they are owned and operated by separate (although subsidiary) companies; however, this is not the case in British Columbia where the larger plants producing power for metallurgical purposes are directly owned by the power consuming companies. As of 1954, Canada was exceeded only by the United States in total water-power installation and only by Norway in average installation per capita, the Canadian rate being 0.82 kw. per head of population.

Coal

There have been no significant increases in the reserves of coal since the last report to the World Power Conference and the decline in requirements for coal does not offer much inducement for further exploration at the present time. The increasing competition from oil and gas in the house heating and industrial markets and the conversion of railway locomotives from coal steamers to diesels have all combined to cut seriously into the market. This change to other fuels has been particularly marked in Western Canada where the greatest proportion of Canadian coal reserves are located.

Canada, by reason of geography, has for many years depended upon imports of coal from the United States to supply a substantial portion of the overall requirements. No picture of coal supply is complete unless imported coal is included and there is reported in Table II the supply of coal for Canadian requirements over the last ten years.

Coal in Canada has never been of the same order of importance as a prime mover fuel in industry, as it has in many other countries. Industrial production has been largely concentrated in the central provinces of Ontario and Quebec and it is in these areas that hydro-electricity has been most fully developed. Almost all the major prime movers have therefore, been driven direct by hydro-electricity. Coal has been used mostly as a fuel for space heating and for process heating in industry. In fact, secondary electricity has occasionally been used in large quantities in electric boilers as a cheaper source of process steam than coal and is being so used at present although in limited amount.

There has been a growing shift in the production and consumption of coal. The decline in railway and household requirements has affected the supply of anthracite and bituminous coal. The development of strip-mining in Western Canada has, however, led to an increasing production of sub-bituminous and lignite coals at a price low enough to find increasing markets in the industrial field. This trend will probably continue and plans are being carried into effect that will call for increasing supplies of these coals for the production of thermal power. This change in the types of coal produced and imported appears clearly in Table II which shows the total available by varieties.

The last five years, therefore, have been years of decline and change in the position of coal. These changes are still in progress and will probably continue for some years to come. On the other hand, the available resources of undeveloped hydro power within practical range of the large consuming centres have been declining. The Prairie region is largely dependent upon thermal plants for electric power while the Maritime provinces are also facing the exhaustion of their cheaper hydro resources. There is, therefore, a growing development of thermal power stations in which coal, gas or oil are the prime mover fuels. This trend will probably increase substantially over the years.

Table III. Estimate of Wood Used as Fuel

	Cords Wood	10^9 k. Cal. @ 5,040,000 k.Cal./cord
1945	11,220,000	56,548
1946	11,000,000	55,440
1947	10,780,000	54,331
1948	10,560,000	53,222
1949	10,340,000	52,114
1950	10,120,000	51,005
1951	9,876,000	49,773
1952	9,520,000	47,981
1953	9,170,000	46,217
1954	8,820,000	44,453

(1 cord = 128 cu. ft. = 3.62 cu. metres)

Note: 1 k. Cal. = approx. 3.97 B.t.u.

Oil

It is in this field that substantial changes have taken place, changes that have had effect upon other fuels as well as on the overall national economy.

In 1950, the consumption of petroleum and petroleum fuel products was approximately 21,268,000 kilolitres. This quantity was supplied by a native production of 4,629,000 kl. of crude oil and the import of 12,749,000 kl. of crude and 3,890,000 kl. of oil products. In other words, only 22 per cent of the total oil requirements was of Canadian origin. (1 kl. is approximately 220 Imp. gal., or 6.275 bbl.)

In 1954, the consumption had increased to 33,458,000 kl. or by 63 percent. The supply has also shifted so that 15,392,000 kl. of crude were produced from Canadian wells, 12,534,000 kl. of crude oil were imported and 5,532,000 kl. of products were supplied from sources outside the country. In the four years, therefore, the proportion of our total oil requirements originating in Canadian wells rose from 22 to 46 percent.

Even this record does not tell the whole story as the production of crude has had to be held down by government regulation to fit in with available refinery and distribution capacity. The production possible in 1954 from existing wells would have been approximately 24,000,000 kl.

This advance has been the result of the discoveries of major oil fields in the Prairie regions of Western Canada. These discoveries have been the basis of a wide and expanding programme of exploration for other fields which is at present in full progress. It was estimated as at December 31st, 1950, that there were reserves of oil available in proven fields of some 191,000,000 kl. in the form of either petroleum or the lighter natural gas liquids. It is reported as at December 31st, 1954, that the reserves established as proven amount to 385,000,000 kl. or twice the amount reported only four years previously. These reserves are growing at the the rate of almost 64,000,000 kl. per year and it is confidently expected that the increasing fund of knowledge of the types of occurrence wedded to the expanding programme of exploration will maintain this rate of growth for many years.

The largest consumption of oil and oil products is in the heavily industrialized areas of Ontario and Quebec. The major concentration of refineries has therefore been in the central Ontario area using oil from the United States and Ontario fields and in the Montreal area of the St. Lawrence valley processing oil from South America and the Middle East. There have also been refineries in the Vancouver area taking oil from California and South America by sea and supplying the coastal market. Smaller refineries situated in the Prairies consumed both local oil and crude from the United States, while the Maritime market was supplied with oil from South America to refineries at Halifax and Saint John.

This distribution was not adapted to the use of oil from the Alberta discoveries and it has been necessary to restrict the production of crude oil to the limits imposed by the available transportation and the delays in building new refineries.

Over the past four years a pipe line has been built from the major oil fields in Alberta to Vancouver that will not only supply the whole Canadian market in that area but will also carry oil to refineries in the Seattle Puget Sound area of the United States. At present, the Vancouver refineries are operating entirely on Canadian crude. A second pipe line has been built from the Alberta fields to Sarnia and Toronto which carried some 10,800,000 kl. in 1954 or practically the whole requirement of the refineries in the area. The capacity of this line is being increased by adding new loops and pumping stations to meet the growing demands in the market area.

Projected increases in distributing and refining capacity will reduce and possibly eliminate the present demand for imported products. There will, however, remain for some years need for imported crude oil for the refineries on the Atlantic and St. Lawrence.

Natural Gas

There has been a major development in natural gas concurrent with that reported for petroleum. In this case, however, neither the market nor the distributing facilities have been developed on the scale evident in the oil field.

Although natural gas has been used extensively in Alberta and in Central Ontario for many years, the market has been limited to the local areas. The distribution facilities have been correspondingly limited and the supply or production has been held down to the capacity of these facilities.

The expanding programme of exploration for oil in Western Canada has resulted in the discovery of a series of major gas fields both independent from, and associated with, oil. These fields supply the local fuel market in Western Canada, and in 1954 the total production (exclusive of field waste and gas for repressurizing oil wells) amounted to 3,424,593 thousand cu. metres, of which 3,036,286 was produced in Alberta, 97,721 in Saskatchewan, 284,611 in Ontario and 5,975 in other sections. The production over the five years to 1954 was as follows:

1950	1,920,495	thousand cu. m.
1951	2,250,073	thousand cu. m.
1952	2,511,295	thousand cu. m.
1953	2,859,590	thousand cu. m.
1954	3,424,593	thousand cu. m.

(Note: 1 cu. m. = approx. 35.3 cu. ft.)

The sales of gas in 1954 have been reported as:

Domestic	1,050,550	thou. cu. m.
Industrial	857,996	thou. cu. m.
Commercial	560,671	thou. cu. m.
Misc.	8,495	thou. cu. m.
Total	2,477,712	thou. cu. m.

The remainder amounting to 946,881 thousand cu. metres is unaccounted for in the present statistics and is probably largely distribution loss.

The increasing production has been accompanied by a much greater increase in the reserves. It was reported that there were reserves in 1946 of 153 x 10^{14} cu. m. which increased by 1952 to some 306 x 10^{14} cu. m. It is now reported that proven reserves in 1954 totalled some 612 x 10^{14} cu. m. and that these reserves are being increased every year by some 4.2 x 10^{14} to 5.5 x 10^{14} cu. m.

Table IV. Energy Requirements by Types of Use (k.Cal. x 10^9)

	Domestic	Industrial	Railway & Bunkers	Air & Road	Transformation Losses	Total
1945	169,022	125,179	113,487	41,575	11,610	460,873
1946	175,751	121,360	106,459	47,530	12,568	463,668
1947	182,920	140,844	112,992	53,560	11,001	501,317
1948	186,438	151,022	111,887	58,919	15,157	523,423
1949	183,595	150,078	107,690	65,579	17,502	524,443
1950	197,541	151,701	102,924	71,366	15,933	539,465
1951	196,249	166,933	106,879	78,572	14,946	563,579
1952	192,890	171,052	102,436	90,809	17,422	574,609
1953	189,452	176,188	90,234	95,711	18,245	569,830
1954	193,335	174,860	78,847	100,699	15,018	562,759

Note: 1 unit is equivalent to approx. 3.97 x 10^9 B.t.u.

The major problem has been to develop a remunerative outlet for this vast store of energy. The energy consumers in Western Canada where this gas is so abundant have at their disposal cheap local oils, coals and to some extent relatively inexpensive hydro-power. There is, therefore, no immediate large scale market in sight although increasing population plus growing development of the petrochemical market will gradually provide wider outlets.

The large energy consuming areas of the Pacific Coast and of Central Canada and the United States are being considered as future outlets and much work has been done on planning pipe lines to serve these markets. At present it seems assured that a pipe line will soon be built from the gas fields to serve the Pacific Coast area both in Canada and the United States. The larger proposition of a major pipe line to bring Alberta gas to Ontario and possibly the central region of the United States is still under consideration. The economics of the proposal are not yet firmly established and, though the project is physically possible, there apparently remains some doubt that the proposal for a Canadian supply only would be financially remunerative.

It is probable that a decision will

be reached in the near future and that this line will be built to supply some 10,336,000 cu. m. of gas per day to Eastern markets although whether these will be entirely Canadian or not remains to be decided.

Wood

No report on energy in Canada can be fully complete without including wood. It is true that wood is of little importance in the industrial field but it does supply a substantial proportion of the househeating requirements. In this northern area, househeating is one of the major outlets for energy. Statistics on wood consumption are incomplete, particularly since a large proportion is cut and used by individuals. There is, however, a reasonable base for estimates in the census reports of household equipment and it can be estimated that the amount of wood used as fuel in the last ten years has been as reported in Table III.

Atomic Energy

Discussion of progress in the development of the energy resources of Canada would be incomplete without noting the important advances that are being made in the atomic energy field. New finds of fissionable ores, notably uranium, have been commonplace in recent years over widespread sections of the country. The reported finds indicate that Canada possesses very large but unmeasured resources of this new-found energy.

In order to stimulate production of the uranium finds the Canadian Government has announced a policy whereby it has undertaken to purchase the output of all acceptable uranium concentrates which are offered under a published price schedul up to March 31, 1962. August 1955 saw two uranium mining companies come into production with total milling capacity of 2,250 tons daily, while Eldorado, Canada's original producer, was increasing its mill from 700 to 2,000 tons daily, and other companies were approaching production stage. Much of Canadian production is exported through arrangements with the United States Atomic Energy Commission under which Canada may divert production for use in Canada when needed.

Opportunity for economic utilization of atomic energy for power purposes in Canada varies sharply between different parts of the country. Atomic power will not compete with existing economic sources of hydro and thermal power but may be expected to supplement Canada's requirements in those areas where economic sources do not now exist or are not likely to exist in the future. British Columbia, Manitoba, Quebec and Newfoundland have large resources of undeveloped hydro power. Alberta and Saskatchewan have very great reserves of oil, gas and low-cost coal. On the other hand, highly industrialized Ontario is now developing the last of its large hydro power sites, and thermal power in this province is dependent on imported fuels. Nova Scotia also has utilized practically all of its hydro sites and thermal power costs there and in New Brunswick are high.

While Ontario's large and growing market appears to offer the most fertile opportunity for the introduction of large scale atomic energy units the expanding needs of the Maritime Provinces may be expected to present power markets favourable to atomic energy developments. Much smaller and isolated markets for atomic energy are possible in the high cost power areas of the far north. The proportion of the expanding Canadian market for power that can be supplied from atomic sources will grow rapidly if and when atomic energy can be produced at a price to compete with existing sources of supply.

The peaceful use of atomic energy has been the subject of much quiet research by Canadian scientists, principally through the use of reactors built at Chalk River, Ontario. A promising development from this research is embodied in the project of Atomic Energy of Canada Limited, Canadian General Electric Company, and the Hydro-Electric Power Commission of Ontario to build an atomic power plant of 20,000 kw. capacity in Ontario. By means of this experimental plant, which is known as Nuclear Power Demonstration, it is hoped to prove the economic feasibility of nuclear plants, to obtain practical data on the economics of power production with nuclear plants, to gain experience and to train personnel in the design and operation of such plants, all with a view to the development of larger economic units.

Forecast of Future

Forms of energy have become more and more interchangeable in Canada as the years have passed. Process steam is produced from wood, coal, coke, oil, gas and electricity. Electricity is produced from coal, gas, oil and falling water. The energy of oil, through the internal combustion engine, or of electricity, through the electric motor, is directly productive energy of motion without an intermediate medium such as steam. All these variations make any attempt to sum up the total energy used or produced a matter of difficulty in selecting a proper unit that is common to all.

For the purpose of such studies the British Thermal Unit has been adopted in some papers but for this

Table V. Energy Consumption by Source of Energy (k.Cal. x 10^9)

	Coal and Coke		Wood		Petroleum		Natural and Artificial Gas		Electricity		Total
	Units	%	Units	%	Units	%	Units	%	Units	%	Units
1945	280,042	60.8	56,549	12.2	76,896	16.7	15,264	3.3	32,122	7.0	460,873
1946	272,117	58.7	55,440	11.9	88,539	19.1	14,189	3.1	33,385	7.2	463,668
1947	286,191	57.2	54,331	10.8	108,774	21.7	16,624	3.2	35,397	7.1	501,317
1948	298,925	57.2	53,222	10.1	118,441	22.6	18,837	3.6	33,998	6.5	523,423
1949	286,924	54.8	52,114	9.9	130,492	24.9	19,278	3.6	35,635	6.8	524,443
1950	278,289	51.5	51,005	9.5	148,915	27.5	22,418	4.3	38,839	7.2	539,465
1951	273,312	48.5	49,773	8.8	173,295	30.8	23,650	4.2	43,549	7.7	563,579
1952	260,055	45.3	47,981	8.3	194,288	33.9	24,876	4.3	47,409	8.2	574,609
1953	239,072	42.1	46,217	8.1	207,691	36.3	26,402	4.6	50,448	8.9	569,830
1954	213,243	38.0	44,453	7.8	222,135	39.4	29,689	5.3	53,239	9.5	562,759

Note: 1 unit of 10^9 k. Cal. = approx. 3.97 x 10^9 B.t.u.

paper the equivalent metric unit, the large calorie (k. Cal.) will be used. The energy contents of the fuels are readily available from published reports while in the case of electricity 1 kwh. of electricity will be taken as equivalent to 3,412 B.t.u. or 861 k. Cal.

Energy requirements in Canada for ten years to 1954 by types of use have been as reported in Table IV.

The heading "Transformation Losses" defines the energy consumed in the transformation of a primary energy to other forms such as from coal to coke and gas or from fuel to electric power. It does not include energy consumed or lost in the production or the refining of the primary energies such as that used in coal, oil or gas production, consumed or lost in oil refining, and so on.

The decline in the last three or four years in the energy consumed by railways and bunkering may be noted. This decline is due in large measure to the changeover from steam to diesel power. Since the diesel is from three to four times as efficient as the ordinary steam locomotive the change in the amount of energy used does not reflect a corresponding change in traffic.

These requirements have been met in the past by coal, oil, gas, wood, and hydro electricity. As noted earlier, the supply and consumption of wood fuel is, by necessity, largely an estimate. In calculations of this order, however, it is believed that the scale of error is not significant. The sources of the energy consumed over the ten years have been as set out in Table V.

The supply and consumption of energy has followed the increases in population both by birth and by immigration and it is assumed that this present rate of increase will continue for the forecast period. It is recognized that, concurrent with an increasing population, there will probably be some increase in the energy requirements *per capita* due to new developments in power uses and higher standards of living. This factor is difficult to define and appears mostly in the increasing demand for electricity. In the estimates presented later, this use increase is taken into account in the estimate of electricity but is omitted in the case of the fuels.

The fact that Canada is a northern country imposes a heavy demand for fuel energy for space heating purposes. Civilized life would be impossible in most of the country without heat in the winter months. Several of the larger industries such as pulp and paper also require large volumes of process heat. Both these demands are supplied by the direct combustion of fuels in various types of furnace and burner equipment. Energy for motion, however, whether driving machinery or for transportation is nearly all supplied by either electricity or by the use of fuel in the internal combustion engine. There are many locomotives still in operation using direct combustion and steam but these are decreasing in number and will probably be all gone in the next fifteen or twenty years. There are, therefore, two distinct types of use of energy.

It is possible on the record of the past to make an estimate of future energy needs. It is, however, necessary to lay down certain basic assumptions. It will be assumed for this purpose that

(a) the population of Canada will increase to 19,367,000 in 1965 and 23,287,000 in 1975.

(b) there will be no world war or other large scale disturbance in the period.

(c) the demands of the estimated population for goods, services and fuels will continue at approximately the present rate of growth.

On these bases an estimate has been made of the prospective consumption of energy in 1965 and in 1975. This is reported in Table VI.

Table VI. Forecast of Canadian Energy Requirements

(Units used are k. Cal. x 10^9 or approx. 3.97 x 10^9 B.t.u.)

	1965	1975
Fuel Energy		
(a) Domestic use	261,012	313,622
(b) Industrial use	183,676	230,657
(c) Railway & bunker use	65,833	65,873
(d) Air & Road use	146,318	212,704
(e) Transformation losses	31,852	65,735
(f) Sub-total	688,691	888,591
Electric Energy		
(a) All Uses	109,721	179,837
TOTAL ENERGY	798,412	1,068,428

For comparison, the total energy required for these purposes was in 1945, 460,873 units at 10^9 k. Cal. and in 1954, 562,759 units of 10^9 k. Cal.

Under present shifting conditions, it is not possible to state the sources from which this energy may be supplied. There are, however, certain definable fields or areas. The atomic power field is uncertain, but it is assumed that in the period noted there will be no *net* addition of energy from atomic sources. Though there will be developments in the production of energy from atomic sources in the form of useful heat or electricity, the amount of energy from other sources that will be needed to mine, process, and refine the atomic fuel and to build and maintain the reactors and produce the accessory materials, such as heavy water and special metals, will be approximately equal to that derived from the atomic fuel in the reactors.

The liquid fuels by 1965 are expected to carry all road and air transportation and all but some 6 per cent of the railway and bunker requirements. By 1975, it is expected that all transportation will be supplied with energy in liquid form.

Domestic heating currently uses 32.5 per cent coal, 24.4 per cent wood, 34.1 per cent liquid fuel, and 9.0 per cent gas. Over the forecast period, there will probably be a continuing trend away from the solid fuels. In this field, cost and convenience are the determining factors and there could be developments in combustion equipment or in competive costs that might reverse the trend.

Industrial requirements are now partly supplied by heavy residual oil. There is some disagreement as to whether this trend will continue or whether the prospective increase in the demand for gasolines and light fuel oils will be so profitable that the heavy residuals would be reprocessed to produce more of the lighter fractions. In the gas producing areas,

Fundamental Concept of Education

G. E. Hall

President, University of Western Ontario

Presented at the joint ASME-E.I.C. Engineering Education Conference, London, Ont., 18-19 October, 1956

"PROGRESSIVE universities are an index to a progressive society, stabilized universities to a stabilized society, stagnant universities to a stagnant society. Flourishing universities cannot exist in a community folding its hands to sleep."

These words spoken many years ago with respect to European universities should be reminders to us in this generation. We, in Canada, are not in a stagnant society; we are not in a stabilized society. We are in a progressive society!

We are in a period of exciting development. We are seeing our forbidding frontiers being pushed back by science, by engineering, by the determination of enterprising, pioneering people. We are seeing the impossible being made possible. We are experiencing the twentieth century rediscovery of Canada. Our population is increasing, our standard of living is increasing and our responsibilities are increasing. The complexity of our society heightens — the challenges to education are made greater. These are stimulating, impelling, changing times, demanding forthright thought and courageous action.

Last year I had the opportunity of addressing a section of the Engineering Institute of Canada and selected as my subject "The Tide and Crisis." It was a subject of concern to us all. It dealt with the specific, new concrete problems facing the universities during the next ten years—the simple problems of economics coincident with a growing nation, the problems associated with a doubling of the numbers of university students during that period. I stated at that time, "more and permanent facilities will have to be provided; more university teachers will have to be prepared and appointed. Higher salaries will have to be provided for the members of the staffs—so that they too may share in the material benefits of an increasing standard of living experienced already by most groups in Canada but largely denied to university teachers."

This was a dinner address by Dr. Hall at the ASME-E.I.C. Engineering Education Conference, held this fall at the University of Western Ontario, with the theme "The Continued Education of the Graduate Engineer". Further comment on the conference will be found in the Month to Month section.

A crisis, by the way, simply means "a turning point in the progress of anything"; "also a state of affairs in which a decisive change for better or worse is imminent." The crisis to which many have referred is not "for worse"; it is, I believe, "for better." Better because thousands more young men and women will be given the opportunities of higher education, of sharing in the greater responsibilities coincident with our expanding economy, of making Canada a finer place for their having lived in it, and of bringing to further realization our hopes of equal opportunities for all.

The economic expansion of Canada has been rapid. It has outrun the available manpower. The manpower shortage, so often considered as temporary and referable chiefly to scientists and engineers and technicians, is anything but temporary. It would appear to be continuing and long-ranged in its implications. And it is not limited in its pattern—it is a total manpower deficiency. The so-called "Tide and Crisis," being faced by the universities and other educational institutions, should therefore be considered as our great hope, as the real rainbow in Canada's economic horizon, as the sunshine after the storm. The "crisis" is a great opportunity for Canada.

There are problems to be sure, the greatest of which, I think, is the scarcity of teachers—particularly science and mathematics teachers at the secondary school level. But from the vast reservoir of young men and women can come the brains and the skills which can not only overcome our manpower shortage but provide a constant and even an ever increasing supply of talented young people upon whom the future of this country is, in such large measure, dependent. These young men and women, able as the majority are, gifted as many of them are, must be brought along to the extent of their capacities, stimulated towards higher levels of education in whatever line of endeavour they choose—Canada can utilize all of them. Those who graduate in the humanities and social sciences — those who, one day, will solve the great social problems of our industrial and scientific civilization—are just as vital to this country as are the presently and urgently needed graduates in engineering and the natural sciences. The same attention has not been focused on this aspect as much as it should be. In directing our attention to the whole problem we should not lose sight of any single portion.

But at the moment let us focus our thoughts on engineering education — the theme of this conference.

The professional engineer to-day is fulfilling a role in to-day's economy, somewhat different than that of 25 or 50 years ago. Important as he was then he is an even more important figure to-day in directing the course of our industrial and economic development. He is, to a large extent, management. Speaking generally, of course, the "leather britches" have been replaced by the striped trousers; the transit and chain have been exchanged for the golf club and caddy cart; the high leather boots have given way to polished shoes; the drafting board has given way to the mahogany desk, tracing paper to financial statements and blue-prints to annual reports. Ten years after graduation the largest single group of engineers are in managerial positions. They are not civil engineers or electrical engineers or mechanical engineers. They are businessmen and business leaders with an engineering background. They are management in a scientific world. In other words, the engineer has become the manager of men, money and materials in his efforts to utilize science. These efforts, it is hoped, are for both the immediate and future benefit of mankind.

Change is Slow

The changing of a concept is slow. The changing of an educational pattern is slow. In many instances this is a good thing; it minimizes changes simply for the sake of changes; it sponsors a deal of thinking, of planning and of careful action. But it would be a denial of education itself if changes did not occur — minor changes with some degree of frequency, major changes perhaps less frequently.

And in the field of engineering education we see changes being implemented — changes which are based upon changing concepts, changing objectives and changing philosophies. Such changing objectives and philosophies are accepted by many charged with responsibilities of curricula planning and indeed by many interested in the broad aims of higher education. On the other hand there are, naturally, some who oppose any major alteration of the basic organization of engineering education and maintain the validity of the status quo. Let us have a look at the situation as a whole.

The universities on this continent have become, in general, a collection of relatively independent faculties, schools and training centres, rather than as originally conceived, and more than ever necessary, a unity of purpose in education. University education, in my opinion, can no longer be thought of as a collection of detached parts, of courses, of subjects, each growing and functioning in isolated splendour. Consequently, I feel that the exposition of one part of knowledge cannot logically be delegated to and subsequently designated as the exclusive prerogative of one department or group of departments. Education is bigger than that. A greater degree of integration of courses, a more purposeful and sympathetic appraisal of curricula is no longer just an intellectual abstraction; it is in the interest of education; it is relevant to the progressive society in which we live; it is common sense.

Specialization

The programme of engineering education is perhaps consistent in its present degree of specialization with historical trends in many fields. But, I feel, the intellectual and physical separation of the different phases of engineering instruction gives the student the deceptive impression of departmental completeness and tends to breed further specialization. Civil, mechanical, electrical, chemical — this departmentalization, at undergraduate level, suggests self-sufficiency. This, I think, is not entirely warranted. I say this, knowing full well that many will not agree with me and many will challenge my right even to express an opinion. But may I remind all of you, and I consistently try to keep this in mind myself — progress is unusual in any situation where everyone agrees! The forces which influence social changes do not leave untouched the fundamentals of education.

Engineering education, as it becomes more and more scientific in its content, must, I think, become more and more an integral part of total university education. The professional, yes, even the social and economic barriers between engineering and the arts and sciences — the academic and administrative adjustments to be made and the spirit of cooperation and mutual respect to be fostered constitute a wall, artificial to be sure, but a wall sometimes difficult to penetrate. But penetration is not the only way to get to the other side of the wall. The wall can be climbed. The wall can be stormed. But one can also reach the other side by having the double locked door unlocked on each side and entrance made through the mutually opened portal.

The members of our departments of mathematics, geology, physics, chemistry, history, philosophy, geophysics and indeed the whole of University College opened the door to the engineers, and the engineers welcomed their new colleagues with enthusiasm, with trust and with understanding of their joint responsibilities to education.

The Correct Approach

An effective programme of engineering cannot be accomplished simply by cursory decisions; neither can changes. The traditional approaches must be respected as proven. New approaches should be made only after a dispassionate, critical study of aims, objectives, course content and method of presentation. The locale of the institution may be a factor in the decision. The present and future place of the university should never be forgotten.

It is my firm conviction that as a professional faculty or school, engineering, or applied science, belongs in a university; on the other hand technical training does not belong there and should not, under any circumstances be a part of university activity. This matter is fundamental. "Training is aimed at a fixed objective while education is directed toward a moving one." (Dr. Allen Gregg, I believe.) Engineering teaching consequently must be directed toward education rather than training, toward principles rather than practices, towards the acquisition of knowledge rather than skills. The days of proprietary schools of medicine and schools of engineering in Canada have long since been relegated to history.

And on the basis of this philosophy and recognizing the fundamentals of any form of higher education, a course was introduced at this University in 1954, after two years of planning, and with the help of many engineers and engineering societies. The course in Engineering at Western is not the traditional type with major specialization in one field of engineering. It is primarily a four-year common programme with some electives in the two final years. (And here it should be pointed out that it is a four year course from grade XIII.)

Some 20 per cent of the time each of the four years is devoted to the humanities and social sciences—regular courses as offered in University College and not in any way directed towards engineering. Four years of mathematics, four years of physics, three years of chemistry etc. set a pattern for the basic science content of some 25 per cent of the total programme. Emphasis is placed on theory — fluid mechanics, thermodynamics, electronics, atomic energy, etc. — engineering science rather than engineering skills. And naturally engineering design, analysis etc. have not been neglected.

Many factors led us to adopt this type of engineering science course. We believe that it is a realistic approach to the education of engineers in today's and tomorrow's economy in Canada and the United States. We believe that it is both educationally and philosophically sound. Economically it is, additionally, extremely attractive. The cooperation of industry in permitting us to use, in a really educational and serious manner, many of their facilities and staff, for major laboratory work, will be most helpful.

Dr. G. E. Hall, president, University of Western Ontario, speaking at the recent meeting of the National Conference of Canadian Universities, of which he is also president.

Adopting a New Approach

Not having had previously an Engineering School, there were no obstacles to the adoption of this new approach to engineering education. Having no traditions in this field, no major compromises in curricula were necessary. And it is interesting to note that the main recommendations contained in the report of the ASEE, published in 1955, were in effect in our programme planned in 1952-53. Please don't misunderstand me. This simply indicates that a great deal of thinking, by many people and in many places, relative to engineering education had been shifting to a more basic and less specialized approach. We were in a position, as it were, to inaugurate an idea of our own which was later found to be the idea of many, many others.

Our first graduates will receive their Bachelor of Science (Eng.) degree in June 1958. Subsequent classes will add to the increasing flow of engineers into our Canadian society. Time alone will be the judge of the success of this experiment in engineering education.

It is as impossible as it is unwise to discuss engineering education without giving consideration to technical training. This of course is a subject for discussion at this conference. I do not wish to anticipate the outcome of those deliberations nor to detract from any recommendations which may arise. But I do wish to clarify my own position once again.

On many occasions over the past six years, and more frequently during the past two years, I have pointed out publicly and at conferences, the urgent necessity of developing many more technical institutes at post-high-school level. Thhe work of the Ryerson Institute of Technology is recognized; its contributions to industry and business, through its graduates, commend it; its overcrowding indicates its acceptance by students, by parents and by employers. But there are not enough of them. Ontario alone needs not one, not two, not three, but conceivably eight or ten or more of them, strategically located in areas of major urban populations.

The future of this country is to be guaranteed, not alone by more university graduates, but as well by more and more skilled technicians, by more and more craftsmen.

The graduates from such institutes of technology — the technicians and the craftsmen, gaining experience within industry and business, will be found, as they are now, working as a team with the engineers and with the pure scientists.

These technical institutes have an important place in industry, in business, and indeed in our whole society; so too have the universities. The universities are not, never have been and never should be, in competition with the technical institutes. Their purposes are distinct and different. The craftsman and the technician should be respected by the engineer and the scientist, the engineer and the scientist respected by the technician and craftsman. There should be no conflict relative to the values and virtues of each. There should be no conflict relative to the educational approach for the engineer, the craftsman or the pure scientist. They are all of great importance. But there is a difference between training for a job, vital as that job may be, and education. A university is, and should remain, an institution of higher education.

Engineering education must prepare students for about forty years of self-development and self-education.

Someone has said that education is a journey and not a destination.

Long Range Planning in an Atomic Age

A Management Panel Discussion

Held at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada, Montreal, May 1956

ONE OF THE features of the 1956 Annual Meeting of the Institute that aroused very wide interest was the management panel discussion, which had as its theme "long range planning in an atomic age".

A distingushed panel was assembled under the able charmanship of Lt.-Col. L. F. Urwick, joint chairman, Urwick Currie Limited. The panel members were: S. M. Finlayson, M.E.I.C., president, Canadian Marconi Company; L. A. Forsyth, president, Dominion Steel and Coal Corporation Limited; J. G. Notman, M.E.I.C., president, Canadair Limited; and R. B. Smith, vice-president, The M. W. Kellogg Company, New York.

After introducing the panel, the chairman presented some of the problems that were facing industrial management today. He then called on individual members to express their views on the subject, after which there was a short session for members of the audience to submit questions, which were answered by the panel. The account that follows is a summary of the recorded proceedings.

The Chairman

Thirty years ago the late Edward A. Filene wrote "Successful Living in this Machine Age". His theme was that the great unsolved problem of business was distribution. This afternoon, thirty years later, we are considering what is really a fresh phase of that same problem. As far as North America is concerned, the thought which preoccupied Filene is now realized. Mass distribution is redeemed as a reality, but the process of technological development has accelerated and expanded and it will continue to do so at a continually more progressive rate.

Among the possibilities seriously advanced as probable within the next twenty years are, electronic light, producing startling substitutes for present types of illumination; atomic batteries, providing power for years from small units, without re-charging; purification of sea water on a scale that will make deserts blossom; better ways of releasing nuclear energy than by fission; automation may be used for industrial process control, legalized industrial economic planning, and for many other purposes; probable human intervention in atmospheric and climatic matters within a few decades.

Lt. Col. Lyndall F. Urwick

The more useful technological advances are, the more unstabilizing their effects can be. It is in the time lag in our individual and social power to assimilate what technology has to offer, that the real danger lies. Much of our thinking is still encumbered by the uncleared ruins of ideas only appropriate to a handicraft age.

Half a century ago the American engineer, Frederick Winslow Taylor, urged that a business management suited to a scientific age must be scientific. He recognized clearly that to achieve this condition would involve a mental revolution. What are we, as business management, doing about that mental revolution?

Peter Fraser's latest book, "The Practice of Management" emphasizes the longer time which is beginning to elapse between basic research and actual sale. The manager is dealing with constantly protracting futures.

The entrepreneur used to be somebody who perceived the demand and then followed the market, but today the ordinary principles of using mechanized equipment quite rules out following the market. You have to create and lead the market. That leads to the problem how are we to do this longer-range planning which modern management methods require and the economic and technological situation make mandatory? The problem is whether the same minds can do the long-range planning and lead tomorrow's battle.

Ought we to re-vamp our business organization so that by segregation of planning for the future, an active command for tomorrow is achieved? At least we can try to develop a next generation, competent to handle these innermost problems.

How are we to turn technical engineers into first class general managers, and, if we continue, to persuade highly skilled technical engineers to submit cheerfully to the leadership of boys with Arts degrees who don't know one end of a spanner from another, and so on? These are some of the problems that face industrial management in the heat of the development of our time.

L. A. Forsyth

If I had the time I would take issue with some of the things our chairman said. In the first place, we are not yet living in an atomic age, but I believe that most people look forward to the advent of the atomic age with equanimity. People adapted themselves eventually, from the stone age to the iron age, and thence to the machine age. In these successive developments the tempo was stepped up, but there is no revolution in thought or in the method of approaching new problems.

One of the things I try not to do is to plan too far ahead, because I think it dangerous to tie the hands of somebody who is going to succeed me by committing them to a long-range plan that may have to be altered or abandoned.

I am not prepared to say that nuclear fission will not create many interesting situations, but I have above all other things the responsibility for the employment of thirty thousand people, and in planning I think that I must maintain a vigilant outlook; I must impress upon those working with me the necessity for observing what is going on around them and to take every new idea coming forward and apply it, so that we will keep abreast of the times.

That brings me to the long distance planning that I find us wholly unable to cope with — the education of the rank and file of those employed in the industry, and those who are going to be employed in the years to come.

Obviously we are going to require more skilled people. And there I think is perhaps the weakness of all planning with respect to the forthcoming atomic age. If I could know that the next generation are provided with adequate facilities for education and guidance during the course of their education, I would feel a very great deal better about the whole thing.

So far as the use of nuclear energy is concerned, I don't believe that its practical use is quite as close as some of us would like it to be. I think we are still living in the machine age, and it is a different machine age from what is was when it started. It has brought us airplanes, television, radios, the automobile and a host of things that have improved and speeded up our production.

Personally, I believe that the time is not yet for us to forget what we have learned, and proceed to learn something else. I don't believe that we have to forsake the old philosophies or the old methods. I still believe a clear head and hard work, backed by education, will solve most of these new problems.

J. G. Notman, M.E.I.C.

L. A. Forsyth

In my long distance planning I must see that there is some advantage in what is exploited today to the utmost; that I continually improve the calibre of my organization. I feel that if we hold to that policy we will meet the challenge of the atomic age when it comes.

Ronald B. Smith

I think we all recognize that there is too much of the element of Buck Rogers in our approach to the problem of the atomic age. At the same time we must recognize that we are in a gigantic stage of transition. I submit we cannot look only at the problem of atomic power when we think of this atomic age. We have many other problems which can be very revolutionary to our business and our outlooks as a result of the application of nuclear effects to the concept we now have.

Our whole concept of petroleum refining and of the chemical industry may be altered in a major way by the submission of these materials to control radiation. This can change the whole pattern of our life, and the whole pattern of industry. For instance, it may change the whole pattern of our clothing industry, and of our food industry and its related refrigeration.

If we are ever going to approach this problem capably and effectively we have to adopt a very flexible long range plans policy, one that is concerned with the development of adequate managerial talent to cope with the problems of the future. This needs a long range plan; it involves more than the strike-by-lighting that probably characterized too much of the long past.

I think two of the things that have created difficulty in the management problem in the past are going to be

S. A. Finlayson, M.E.I.C.

R. B. Smith

extended to the future. Certainly one of these is going to be the increased complexity of the problem and probably its increased tempo, but I think also that a period of transition is likely to take place, where most of us in a management position are not equipped to understand the problem's complete technicalities.

Now, there is liable to be, for a period, a rather sudden change from the way we have operated in the past. We may find the need to bring more and more highly skilled technical people into the realm of management, and we must gear ourselves to take and develop them into strong sound management material.

In our long range plan approach, it seems to me that the one region we can be sure of, is to keep ourselves in a flexible position until perhaps our course is a little clearer.

S. M. Finlayson

It seems to me that in addition to the problems being created by the harnessing and control of nuclear fission there are many others of a technical character pressing upon our community, which may perhaps be of even greater importance in the near future.

Therefore, it would seem wise to cast our thinking on very broad terms if we are to hammer out a pattern of procedure that will be useful, not only in the next few years, but for a couple of generations.

Frequently we fail to recognize that the real challenge ahead of us all, whether we be engineers or managers or professional people, is to find some means of making our problem clear and apparent to the rest of the community.

We all know that nearly everything is reducible, with a little bit of thought, to a fairly commonplace, simple, plain explanation, either directly or by way of analogy. We know one of the main purposes of engineers is to fraternize, to interchange their ideas and discuss their problems. It seems to me we have got to carry that procedure the whole way so that as we advance into this new, complicated and much faster moving era, we will be able to help others to look upon the forthcoming age, not as a prologue to some form of disaster but much more, as a challenge and an opportunity.

Our problem is to find some way in which we can take the whole of the public into our confidence, explain to them the values, and thus gain their support in an orderly, peaceful, and useful development, instead of letting the thing run haywire, as it is almost certain to, unless those of us who have knowledge are willing to share that knowledge with others and give them a chance to become associated with us in the solution.

J. G. Notman

In the first place, nuclear physicists have given us a tool to work with, which has a potential source of heat with unlimited bounds. But the harnessing of this heat for the use of mankind presents manifold problems, not heretofore coped with on the scope that is now envisaged.

Safe practice with radio-activity is based on over fifty years of experience on the effects of radiation and radio-activity on human beings; safe practice that may be engineered into every phase of a nuclear project, in varying degrees.

I think too few people realize the fact that when you start your fission you necessarily produce radio-activity, and that means having to design every piece of equipment used in a nuclear plant to safeguard human beings.

It would seem, in developing nuclear energy, that the most logical way to use it first of all will be to produce electricity in a nuclear power plant. This has been done, and in some cases where it is now difficult to procure the ordinary type of full supervising engineers, the situation is becoming critical.

I believe that we must, as far as possible, be active in the nucleus of a group of people who are knowledgeable on this subject and that, with the cooperation of the Government we should be doing what we can in producing those who will be able to help us make the best possible use of this equipment.

Question

"Do you think we might persuade the universities to undertake to train technological interpreters who might be capable of explaining one technology to another, and all of them to the general public?"

Mr. Finlayson

I don't know whether it will be practicable to train a special race of interpreters. My own view would be we should do what we can to encourage the universities, and we have a great duty and responsibility toward the universities; we are going to develop some of their problems, but I think our university education could be made less specialized than it seems to have become, so that they would develop people who have more broad basic education than seems to be the case at the moment.

I do feel it would be better even to eliminate some of the more highly specialized technological studies, and add to the broad and sociological and economic general knowlege of the graduate, than it would be to try to develop a race of interpreters. My fear is they would go only half way towards solving the problem.

Question

"Should not part of industry's long range planning be to get the Government out of the atomic energy business?"

Mr. Forsyth

I have no conception of any private industry in Canada that could tackle the job and provide the capital for it, knowing the original investment, so far as any particular industry is concerned, to be entirely unprofitable.

Mr. Rose

"At what level can we interest the young engineer to obtain greater education in applied sciences? Can we not emphasize and encourage more development and education in the field of mineralogy for instance, that has been last from the money standpoint?"

Mr. Notman

I think it is an admirable idea. I do think that is one of the things we are faced with — the problem of developing technical thinking among boys to be more technically minded in school than the stage where they can go to college.

I am rather surprised to read in the McGill Annual Report that, of the boys entering engineering the last two or three years, only 54 per cent have actually graduated. I think it is a good idea that people should give a lot of thought to development in the primary schools, particularly that of more technical knowledge.

Mr. Forsyth

At a luncheon the other day I met people, all connected with the study of mathematics in our universities, who had the same experience in the last two years. They put to me the rather astounding proposition that the boy or girl who graduates from some of our high schools could go

(Continued on page 1696)

DISCUSSION

of Technical Papers and Other Articles

LONG RANGE PLANNING IN AN ATOMIC AGE

A Management Panel Discussion

The Engineering Journal, 1956, December, 1688.

J. Thoburn Rose[1]

In this discussion the problem arises, how our people could best be educated for an atomic age. It is evident that the need for revision of our educational methods is important. The writer ventures to ask: "How soon can our young people be expected to prepare for a definite career? How much can they be guided to develop hobbies which will provide a background for future preparatory school and university work?"

Some years ago a prominent wild life authority said he despaired of finding sufficient candidates for mammalogical sections of the wild life division in the Civil Service of Canada. His own collection of wild life specimens had been started early. He declared that unless such studies were started early as hobbies, few young people could have the best of academic training without the background of long years of collecting and study from which there might be developed a keen interest that no monetary incentive, in later years, could replace. It is generally said that scientists are born to their calling, or at least have an enthusiasm early developed by earnest teachers of high calibre, well informed and dedicated to their profession.

It is widely recognized that university training of four years, with five months or more taken off each year to earn enough to get through successive years, is not enough to qualify a youth for the offices of the atomic age in many of the demanding positions so rapidly developing. Will it not become increasingly evident that more planning for employment of undergraduates of universities, and even of our high schools, be general? High school teachers advise that too many are lured into industry, neglect to go on to finish or even matriculate. It seems that industry, and possibly the civil service, to be assured of the highly trained young people necessary to carry on in an atomic age, must screen and offer them chosen employment with the possibility of continuous training even to half their time. Similarly, taken as far as the graduate stage, training must come to be recognized as a duty to our developed requirements and both employers and employees must realize their joint obligation to society to train intensively to the high degree necessary.

The idea of including the liberal arts must be kept in mind in order not to become a regimented state. Recent enlistment from the British has brought out the fact that their young scientifically trained men have a much better grounding in basic subjects which here are often minimized or not thoroughly developed. Too often the high school teachers do not engender enthusiasm, or pupils are distracted by extra-curricular activities, so that, combined with too little strictness in large classes, good material dissipates its time and a career is shattered in early high school.

Though the tendency is to plan and attract graduates for the many new professional positions it seems this must be started with counselling and career training at a much earlier age than has been our practice. Possibly a much more extensive scholarship structure must be started to ensure that none of the available supply are lost to our urgent requirements. This may require an early reorientation of our educational system and employment.

A PILE LOAD TEST

D. F. Coates, M.E.I.C., *Department of Civil Engineering, McGill University.*

The Engineering Journal, 1956, March, 228

Floyd K. Beach, M.E.I.C.[2]

Professor Coates has an interesting study of a pile load test. As an encouragement to engineers who may have a problem on their hands where piles cannot be driven to refusal, may we recall a pile trestle that successfully carried rail traffic for years over Kootenay Lake with no sign of settlement, yet the only apparent support for the piles was skin friction.

The bridge was built before I arrived on the scene in 1908, so I have only hearsay evidence to submit. The story was that on driving the first pile it went so far with each stroke of the hammer that it looked as if a bridge would be out of the question. The pile was left overnight and on resuming work the next day several blows were needed to start it down. A decision was made on the spot to drive pile bents with a suitable length of pile in the mud, frame them and lay the bridge on top.

As I recall, each pile went some 20 or 30 feet into the mud and, some years later, I could see no sign of irregularity in the rail line on top of the bridge.

The shore rocks are, I think, pre-Cambrian and are most competent, but the bed of Kootenay Lake is a loose, unconsolidated mud, some of which may date back into Tertiary time or earlier, but is mostly the accumulation of Pleistocene to Recent sedimentation. It is quite safe to

[2]Consultant, Calgary, Alberta.

believe from all evidence to be seen that there is a much deeper mud deposit than there is any hope of penetrating with piles.

I regret that I cannot give the weight of hammer nor its length of fall and I cannot say how far each pile was driven.

I can suggest that no two situations are likely to be exactly the same and that it would be most difficult to find values for the variables suggested in the formulas that Prof. Coates quotes, particularly when a pile driver is on the job with a crew of men waiting for direction. However, this bridge appeared to stand very largely because of adhesion to the pile shaft (skin friction), and that adhesion did not develop until the pile had been static for some hours. The best indication that could be had was the fact that several hammer blows were needed to start it after standing over night. Doubtless the framing of several piles into a bent gave a combined bearing in excess of what would be obtained as the product of the bearing of a single pile by the number of piles in the bent.

The Author

Mr. Beach has mentioned an interesting case where piles were driven into a sensitive clay, allowed to sit until the clay had regained its strength (i.e., similar to the thixotropic regain mentioned in the paper), and then used assuming the adhesion of the soil to the pile to be sufficient for the design loads.

This may be a reasonable procedure when the nearest bearing stratum is at excessive depth. It is done today — in some cases without analysis, in other cases where analysis should indicate two things: (1) that the safety factor against failure of the adhesion is commensurate with those incorporated in the superstructure; and (2) that the immediate and consolidation settlement of the structure is not likely to be excessive.

Regarding Mr. Beach's last sentence, I would point out that the *maximum* allowable bearing capacity of a group of piles would be equal to that of a single pile multiplied by the number of piles — in most cases for piles not on bedrock the allowable bearing capacity of the group should be less than this product.

I agree with Mr. Beach's observation that it is difficult on many jobs to determine the appropriate values for the variables required in the different analyses of pile capacity. This is rather a counsel of despair for it means that, even with a reasonable amount of soil testing and, as a check, with conservative and measured constants in a dynamic formula, in many soils (particularly those of a semi-granular and semi-cohesive nature) you still cannot be confident of the static reaction and settlement of each pile. This seems to indicate that in such conditions for jobs involving the use of several hundreds of piles an extensive program of load testing together with a probability analysis of the results would be the rational and economic procedure.

In case I give the wrong impression, it should be realized that in many cases of piles supported by soils a reasonable amount of soil testing and/or the use of a dynamic formula allows one to predict pile capacities quite accurately.

DEVELOPMENT OF INTERNATIONAL RIVERS

General A. G. L. McNaughton, M.E.I.C., *Chairman, Canadian Section, I.J.C.*

The Engineering Journal, 1956, November, 1493.

General McNaughton has added the following information as a further commentary on his paper.

The Author

I would mention specifically, in relation to power, the help we have offered as an interim measure to reduce the prospective heavy energy deficiencies in the Pacific Northwest by the use of Mica storage downstream in the Columbia in the U.S.A. in the period of from fifteen to twenty-five years before load growth in the Vancouver area requires flows diverted from the Columbia for the further progressive regulation of the Fraser; the added heads at Grand Coulee and Libby made possible by permissions to flood 42 feet and 37 feet into Canada, respectively, at the boundary; and the use of Murphy Creek storage for release in years of exceptionally low flow — all this of course on the basis of a fair bargain in respect to the recompense to Canada for the benefits conferred.

In addition, I would mention the very great benefit to flood protection downstream which would result from the withdrawal, primarily from the crest of the flood flows, of a total of some 26.3 million acre-feet in major projects only which might be possible through Canadian co-operation. (The details are in the table.)

As matters stand, the United States has about 9½ million acre-feet of storage on the main stem of the Columbia, of which, even with the extensive changes now being made at Grand Coulee, perhaps no more than 5 million could be effectively operated for flood prevention. The requirement has been put at 27 million acre-feet to reduce possible peak flows to tolerable proportions.

To illustrate the acuteness of the flood menace on the Columbia in the U.S.A., in the 1894 flood the river had a maximum flow of 1,240,000 cubic feet per second at the Dalles; this is more than three times the maximum measured flow of the St. Lawrence at Lachine.

The Columbia flood of 1894 did 5 million dollars' damage. If this same flood occurred today the damage is estimated to exceed 350 million dollars, that is, a factor of increase of 70.

The 1894 flood on the Columbia is by no means to be regarded as an isolated incident, because there is historical record of some nine other floods where the flow exceeded 800,000 c.f.s.

	Reservoir	Storage (million acre-feet)
Canada		
Columbia River	Bull River-Luxor	3.4
	Mica	11.8
	Murphy Creek	4.0[1]
Kootenay River	Duncan	1.0
	Kootenay Lake	1.1[2]
		21.3
U.S.A.		
Columbia River	Grand Coulee	3.3[3]
Kootenai River	Libby	1.7[4]
		5.0
	Grand Total:	26.3

[1]Might be operated so as to be available for flood control, though this is not at present planned.
[2]Of which 0.4 m.a.f. might be added to existing storage.
[3]Extra storage due to 42 feet flooding being permitted at the boundary.
[4]With 37 feet flooding at the boundary; without this privilege conferred by Canada the project would be uneconomic.

Canadian Section, I.J.C.

In our editorial comment on the above paper, mention was made of the tasks facing the Canadian Section of the International Joint Commission. Supporting the chairman, General McNaughton, the other members of the Canadian Section are Hon. George Spence, AFFIL.E.I.C., and J. L. Dansereau, M.E.I.C.

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

EXTENSIVE LOANS BY THE WORLD BANK

The International Bank for Reconstruction and Development, widely known as the World Bank, has recently made extensive loans to various countries, including Austria, Italy, Thailand, and Uruguay.

Two loans, totalling $31 million, were for expansion of electric power in Austria. One project is the Ybbs-Persenbeug hydro-electric plant on the Danube, some 80 miles up-river from Vienna, which will have a capacity of 192,000 kw. from six units installed in two powerhouses; half the units should be operating early in 1958. The second loan was for two thermal power plants, using domestic brown coal for fuel, in south-western Austria. Additions will be 65,000 kw. at Voitsberg (now 60,000 kw.) and 100,000 kw. at St. Andrae (now 67,500 kw.). Total capacity of the newly-financed projects will be 357,000 kw.

A loan equivalent to $74,628,000 has been made to the Cassa per il Mezzogiorno for the agricultural and industrial development of southern Italy. This raises the total of loans for similar Italian programs to nearly $165 million. The Cassa per il Mezzogiorno is the governmental agency established in 1950 to administer a 12-year program for the development of southern Italy (and Sicily and Sardinia). The $2 billion program has reached the halfway mark.

Agriculture will be aided by the Flumendosa irrigation scheme to divert waters now flowing into the sea to some 123,500 acres of arid plain in south-western Sardinia. Bank funds will also be re-lent to the principals of ten industrial projects: two cement factories, two glass factories, a vegetable cannery, an automobile assembly plant, a plant for the construction of bus and truck bodies, a fertilizer factory, and plants for the production of hardboard and polyethylene.

The Cassa will also re-lend funds to power companies for expansion of facilities, including three hydro-electric plants on the mainland and a thermal plant at Augusta, Sicily. The projects will increase installed capacity of the Cassa area by 217,000 kw., or 14 per cent, and the annual generation of power by 17 per cent. All plants will be operating in 1959.

The loan to Thailand is for $3.4 million to the country's Port Authority for the purchase of three dredges and auxiliary equipment to be operated in the channel leading to the port of Bangkok and in the harbour. A previous loan was used to deepen and widen a channel, which can now accommodate vessels of up to 10,000 dw. tons; the dredging equipment is needed to maintain sufficient depth in the channel and harbour.

Uruguay has received a loan of $25.5 million for electric power development, to help construction of a hydro-electric plant at Rincon de Baygorria, on the Rio Negro, and additional transmission and distribution facilities. The project will increase generating capacity in Uruguay by about one-quarter, and will consist of three generating units with a combined capacity of 103,000 kw. Also included in the project is a plan for the improvement of the primary distribution system in Montevideo.

DIESEL-HYDRAULIC LOCOMOTIVE ROAD-TESTED IN CANADA

A Diesel - hydraulic locomotive, built and owned by Maschinenbau Kiel Atkiengesellschaft of the Western zone of Germany, is being road-tested this year by both Canadian railways, to determine its usefulness for switching and branch line service.

Known as the "MaK Diesel", it is powered by an 8-cylinder, in-line, supercharged Diesel engine of 9 1/16 in. bore and 11 13/16 in. stroke, rated at 800 h.p. at 750 r.p.m.

Power is transmitted to the wheels by a Voith hydraulic tranmission gear operating in conjunction with a MaK reduction and reversing gear, a lay-shaft, and side-rods coupling the four pairs of driving wheels. The hydraulic transmission gear is similar in some respects to the automatic transmissions in late model automobiles. There are two speed ranges, from 0-30 m.p.h. in low gear and from 0-50 m.p.h. in high. The locomotive must be stationary to change from one speed range to the other or to change from forward to reverse movement. Maximum tractive effort in low gear is approximately 40,000 pounds.

The smooth application of torque and the fact that all driving wheels are coupled with side rods, improve the co-efficient of adhesion. This co-efficient is related to starting friction and is defined as the ratio of the tractive effort at the point of slipping of the wheels to the weight on the driving wheels. According to information received from the office of the chief of motive power and rolling stock of the Canadian Pacific Railway, these features allow a co-efficient of adhesion of 33 per cent when starting a train on a good rail. Under similar track conditions, steam locomotives average 16 per cent and diesel-electric units have a co-efficient of 25 per cent.

Because of the wheel arrangement, described as 0-8-0, the track curvature which can be negotiated by the MaK locomotive is somewhat less than that which can be negotiated by locomotives having two trucks. Maximum track curvature is 24 degrees.

Of interest to railway men is the possibility of easier maintenance due to the absence of complicated electrical circuits. In the Diesel-electric locomotives currently in service, certain parts of the electrical system have been found vulnerable to vibration and dust.

RUGBY — ONE OF WORLD'S MOST MODERN RADIO STATIONS

United Kingdom Information Service (from an article by John Godwin).

The Rugby radio station first went into operation in January 1926 as a radio-telegraph transmission station, and was the first high-power unit to use thermionic valves. Since then it has expanded steadily, the most recent extension having been completed in 1955 ,at a cost of £ 1,000,000.

A year after its opening, Rugby operated the first radio-telephonic service between Britain and the United States. The recent expansion was largely due to the rapid growth of this service; radio-telephone calls via Britain to the U.S.A. rose from 31,322 in 1937 to 81,669 in 1954, and the rate is increasing.

The station site, originally 900 acres, has grown to 1620 acres and now houses an additional twenty-eight high-power transmitters, each capable of handling several messages simultaneously and automatically controlled from a central control position. Though the station has nearly doubled in size and power, staff has increased only from 128 to 167, thanks to extensive use of automatic control, which frees most of the staff for necessary maintenance work.

Power is supplied via three underground cables, each capable of carrying full load; three standby diesel generators are installed at the station. There are some 240 miles of wiring at the station, and 750 miles of cable conductor link the equipment of the new extension. Supply tanks holding 10,000 gallons of distilled water are provided where water-cooled valves are still in operation.

Twelve 820-feet high steel masts dominate the scene, but the number of aerials is kept low by the use of multi-wire rhombics, which are non-resonant and operate over a wide range of frequencies.

A technician at Rugby radio station, England, making a radio-telephone call to New Zealand. The recently-extended station has 53 transmitters.

Apart from the uses already mentioned, Rugby broadcasts Greenwich mean time, accurate to 1/100th second, news reports, and meteorological reports for shipping; radio-telephone service is maintained with several ocean liners. For the Department of Scientific and Industrial Research (comparable with Canada's N.R.C.), the station transmits standard frequencies, accurate to one minute in 100 years.

All is not strictly utilitarian, however. The water supply for fire-fighting is held in an ornamental lake, complete with aquatic plants and goldfish; furthermore, Rugby once sent a message of goodwill to the planet Mars on behalf of a member of the British public — unfortunately no reply has been received.

GET EDUCATED BEFORE YOU SPECIALIZE TOO MUCH

S.A.E. Journal, 1956, August, 63.

There were 180 specialized engineering degree courses in mechanical engineering alone in the United States just a few years ago. The majority of these still exist. The desire for specialization in many colleges in Canada and United States is actually handicapping the student and costing employers money. Statistics show that less than 20 per cent of engineers are practising in the field of engineering for which they prepared themselves in college.

What do we in industry want to find in a newly graduated engineer? What should we do, and what should he do to further his training after he graduates?

An "educated man" regardless of his profession or business, should have some knowledge of history and human development; he should have capacity to enjoy our cultural heritage in arts, letters, music, literature, and so on. He should have an understanding of contemporary society and of himself as a human being; an understanding of one's emotional nature and the capacity to subject oneself to self-discipline. And he should have acquired certain skills and information which he can turn to practical use to make a living.

Industry as a whole requires young engineers:

(a) Capable of applying basic principles to the creative solution of new problems

(b) Capable of contributing to the solution of man's social problems.

(c) With an educational program sufficiently flexible to meet the changing desires which come with maturity.

Industry in its turn must provide the training in specific applications not available in college. There is no substitute for industrial experience, no way to develop mature judgment or an up to date knowledge of current practice, other than by growing up in the proper industrial atmosphere.

For complete paper write SAE Special Publications (price 35c to members) address, Business Press, Inc., 10 McGovern Ave., Lancaster Pennsylvania.

AUTOMATIC OPERATION OF WATERWORKS PLANT

The Journal of the Institution of Waterworks Engineers, 1956, August.

This is a series of three papers prepared independently, then coordinated. A tabulation sets out some of the factors most commonly used to effect control in waterworks, some processes of control and some means of actuation and transmission, in the case of suction pressure, rate of flow, speed or power, suction and delivery levels, pressure time, availability of grid power and tariff for grid power.

Various safety measures, giving the process of safeguarding and means of actuation or transmission, for each of a number of risks involved, are presented in a further table. Examples covering much of the range of these tables are found in the following three papers.

The first paper deals solely with the subject of pumps driven by electric motors and discusses the following divisions: (1) Necessity of boosting. (2) Conditions governing the selection of plant. (3) Types of booster pumping plant. (4) Detailed descriptions of typical plants.

The second paper points out the advantages to be gained by automatic control for water pumping and treatment plants. It deals in turn with main pumping stations, standby arrangements, booster plant, maintenance control gears, pumps, motors, valves, and the pump house. In conclusion a brief summary is given.

The third paper describes automatic control at Castle Hill booster station of Cambridge University and Town Waterworks Company. Outlining the conditions to be met, a brief description of the new plant is given and the basic and actual control systems in use.

A fourth paper gives further examples of automatic control, as used by the Metropolitan Water Board's Sunnyside, Chingford, and Ashford Common pumping stations and by the Bristol Waterworks Co. at its Chew Stoke pumping station. Several pages of verbal discussion and written communications end the series.

HOW FAR DO WE GO WITH INSTRUMENTATION?

Industrial and Engineering Chemistry, 1956, August.

The true solution of how far we go with instrumentation is a balance of cost of controls versus advantages gained by them. How far we go depends on optimum product quality desired, final product cost, and hazards involved in the process. Once the advantage under consideration is established, the final question is: "Can we afford to spend that amount of money to achieve the expected advantage?"

Remote operation and automatic control are achieved by instrumentation. The two together provide many advantages to the modern chemical plant: greater safety of operation; better quality of product; greater operating economy. Instrumentation will accomplish things which it may be impossible to do manually. Processes can operate faster and more continuously when mechanized.

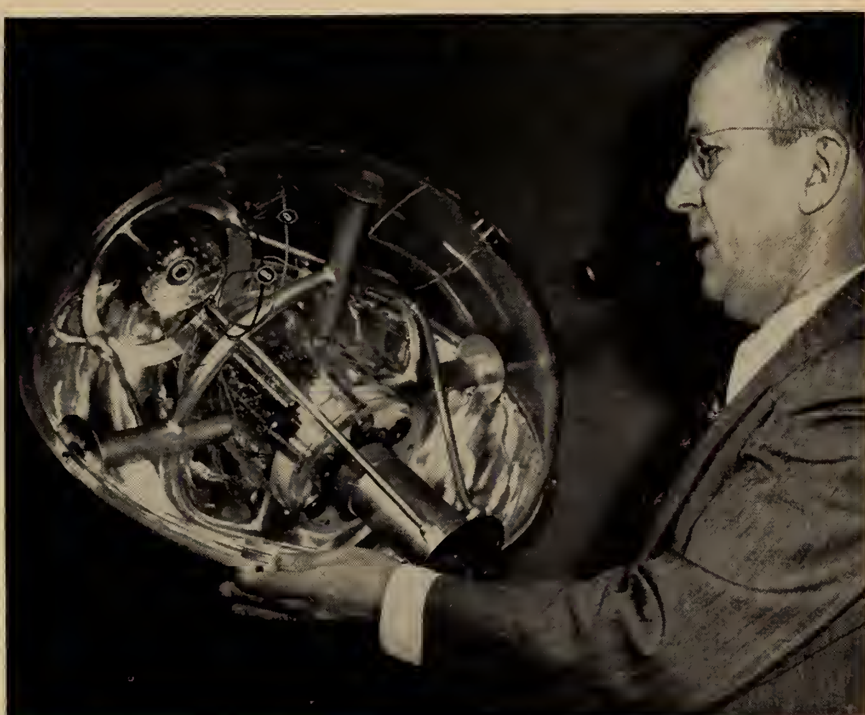
But Professor Thomas Walsh of Case Institute of Technology warns that "further automation of currently used large scale chemical processes is unlikely because it would only add 1 or 2 per cent to the efficiency of such processess." The author, who is not entirely in agreement with this conclusion, believes how far we can go depends on several important factors such as: optimum product quality required; final product cost; and hazards involved in the process of manufacture.

If control systems can be devised to produce a better product quality than can be produced by others, we may be able to compete in new markets, he believes. How well we achieve and maintain an attractive position in the chemical field may depend on how far we go with instrumentation.

THE PROJECT VANGUARD EARTH SATELLITE

The November issue of *The Engineering Journal* (p. 1531) contained a fully descriptive technical paper, by Adml. F. R. Furth, on the earth satellite, known as Project Vanguard, to be launched during the International Geophysical Year. The photograph below shows Dr. John P. Hagen, director of Project Vanguard at the Naval Research Laboratory, holding a model of the 20-inch diameter, 21.5-pound spherical satellite. Through the transparent plastic half of the model can be seen the internal arrangement of the delicate recording and transmitting instruments that will be incorporated in the satellite.

(Official U.S. Navy photograph released by the Department of Defense)



CANADIAN AIRCRAFT ON INTER-CITY TAXI SERVICE

Two Canadian-designed aircraft have been operating, from April to November, on a rapid transportation service between downtown Detroit and downtown Cleveland, carrying passengers and freight.

The aircraft, an 11-passenger DHC3 Otter and a 6-passenger Beaver, both float-equipped, were operated between the port facilities of the two cities by Taxi Air Group, Inc. (known as TAG Airline). Some 3600 passengers were carried during the season.

Despite unfavourable weather, 98 per cent of planned schedule was attained, at an average load factor of 49 per cent.

The service has stopped for the winter, since float operation is not practical, but will be resumed in May 1957. In the meantime the company has bought a second Otter and is converting the original one to land use for an air-taxi service out of Miami to the Florida Keys and other resorts.

A Canadian-designed Otter aircraft taking on passengers at the Detroit seaplane base for a flight to downtown Cleveland, which can be reached in less than an hour.

Progress in the Development of the Energy Resources of Canada *(Continued from page 1684)*

it is probable that new industries based upon cheap gas will develop, but in the more distant areas gas will probably be too highly priced for industrial use except possibly on an intermittent dumping basis.

Finally, as evidenced by the projected increase in the energy required for transformation processes, ective in the type of energy required. The demand for electricity cannot be supplied by any other type of energy, and the internal combustion motor must, at present, be supplied with liquid fuel.

In these two special fields,, it may be estimated that the requirements will be as shown in Table A.

Table A	1965	1975
Electricity for all uses	127,684 x 10^6 kwh.	209,513 x 10^6 kwh.
Petroleum products for internal combustion	24,189,500 kl.	33,066,240 kl.

there will be substantial developments in electric thermal power requirements for fuel. Here again the fuel chosen will be selected on the basis of cost and economy of use.

There are two particular fields of consumption that are inherently sel-

There remains the large field of direct heating, and this may be supplied by any of the fuels. The total energy requirement for this purpose will be approximately 483,005 x 10^9 k. Cal. in 1965. This would be equivalent to approximately — 64,-400,000 m. tons of coal, or
54,274,000 thou. cu. m. natural gas.

The probable course of development will be for oil and gas to secure as large a proportion of the market as the cost will permit, when considering the advantage of ease of use, with coal to supply the reminder.

By 1975, however, the requirements of fuel for direct heating will have increased substantially to 610,-014 x 10^9 k. cal. This, in turn, would be equivalent to approximately
81,400,000 m. tons of coal, or
66,407,000 kl. of petroleum, or
68,545,000 thou. cu. m. natural gas.

A study of quantities of this magnitude, particularly the estimated additional requirement of 33,066,240 kl. of petroleum for use in internal combustion engines, leads to the opinion that coal will be required to carry an increasing proportion of the energy supply.

This development will, in turn, revive interest in the resources of energy available for use in the coal reserves.

Long Range Planning in an Atomic Age

(Continued from page 1690)

through the whole high school course and never study mathematics.

It seems to me that there ought to be some influence at work in our schools that would try to unveil to young people the wonderful field that the study of mathematics offers. The instruction in applied science, I suppose would be almost valueless to a youngster who was not acquiring some knowledge of mathematics.

R. B. Smith

Within our high schools . . . there are not now a group of people who are professionally interested in physics and applied science; and I submit one of the main reasons for that situation is that the number of students graduated from our colleges, and eligible to teach physics and mathematics in our high schools, are tempted by so many offers to enter industry in the atomic age, and receive offers with a much more attractive figure than our school systems can offer, that we are now short at the places where we have to start.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

October was marked by a major progress milestone, the diversion of the St. Lawrence flow through the completed first stage Iroquois dam. Overall construction, with the passing of this milestone, approached the halfway mark on schedule and prepared to swing down the home stretch. Concrete placement to end of October exceeded 860,000 cubic yards, excavation for all features exceeded 29½ million cubic yards and employment averaged 4,670 for the month.

Progress by NYSPA

At Long Sault Dam, both gantry cranes were moved from the erection site to the completed stage 1 dam and load testing of both cranes was in progress. Spillway gates were in place and being welded. Removal of the downstream plug of cut F was completed and the upstream plug was narrowed in preparation for diversion of the river through completed stage 1 construction.

Concrete placed in St. Lawrence power dam (Barnhart Island powerhouse) increased the total in place to 388,000 cubic yards. Excavation in the switchyard continued and concrete placement in structures has been started. Embankment placed in the south forebay dike exceeded 660,000 cubic yards at month end.

At Iroquois dam, seventeen stage 2 cofferdam cells had been placed. Stone riprap had been placed along the excavated slope and removal of the downstream cofferdam was started in preparation for total diversion of the St. Lawrence River through the dam.

Stage 1 concrete placement at Massena intake was nearing completion as backfill was being compacted at the west abutment and riprap was being placed. Excavation for the diversion channel was started and stage 2 cofferdam cells were being driven.

Excavation under the five channel improvement contracts was 49 per cent completed at the end of October as work at the Galop south channel neared completion. Topsoiling and seeding of channel improvement spoil areas in the vicinity of Galop Island south channel had been started and was progressing satisfactorily.

Three contracts were awarded for reservoir clearing between Waddington and St. Lawrence power dam, involving clearing of approximately 9,200 acres. (All required reservoir clearing work is now under contract.) A contract was awarded for clearing and chemical treatment of the Barnhart-Plattsburgh transmission line right-of-way.

Relocation of highway route 37 including construction of bridges and relocation of railroad was progressing at a rapid rate and relocation of route 37B was under way. Approximately 97 per cent of the survey work for the Barnhart-Plattsburgh transmission line had been completed.

Progress by Ontario Hydro

Throughout October weather conditions were most favourable for construction progress. Good advances were made in all sections of the development. The work force remained steady with some 4,360 persons employed by Ontario Hydro and the Commission's contractors.

At the end of October, all excavation work on Ontario Hydro's section of the power-house had been completed. A total of 170,000 cubic yards of rock had been removed and some 1,502,000 cubic yards of earth had been taken out of the north channel for the foundation of the main structure.

Concrete placing had been speeded up, and foundation concrete had continued out to unit 16. To the end of the month, a total of 315,000 cubic yards of concrete had been put into the main dam and power-house. Significant progress had been made in the construction of the units for the power-house. The first speedring was put in place for generating unit No. 1. Concrete work is steadily advancing for the next three units. This will enable the acceleration of the work of installing equipment for the generating station.

Favourable weather greatly aided construction of Cornwall dike. More than half the fill material had been placed and compacted on the 3½ mile long dike. Some 1,500,000 cubic yards of compacted till had been put into the dike by month end. During October, construction of the concrete closure structure for Cornwall dike and the diversion canal was essentially completed. A total of 134,000 cubic yards of concrete had been put into this structure, and backfill had been completed at both walls. Good progress was being made on excavation of the mile-long diversion canal both east and west of the closure.

On the relocation of the C.N.R. mainline, the double track had been laid for the entire 40 miles from Cornwall to Iroquois, and two-thirds of the ballasting was finished by month end. Work was being pushed in installing the telegraphic equipment and block signal system. Under the direction of the Ontario Department of Highways, grading was being carried out for the remaining 35 miles of the new road to relocate No. 2 highway between Iroquois and Cornwall.

Good weather aided channel improvement work. The contractor on Galops Island was able to make favourable progress. A total of more than 400,000 cubic yards of rock had been excavated and over 6,700,000 cubic yards of earth removed in this contract to date. A large area of the west end, enclosed by cofferdams, was unwatered at the beginning of the month. On the Chimney Island contract, the Spencer Island pier had reached its full length.

Ontario Hydro's work forces are concentrating on the 1957 phase of the St. Lawrence transformer station installation. This will receive the power from the new Robert H. Saunders generating station during the latter part of 1958.

A total of 90 houses had been moved by month end into new town No. 2. Sidewalk construction at the new townsite was underway and landscaping was in progress. Extension of services and construction of roads for an additional 50 lots had been completed. Some 35 homes were under construction by private contractors.

At new town No. 1, which is being named "Ingleside", installation of water and sewer services was virtually completed. Construction of roads also was nearly finished. Work is advancing on the water pumping station, sewage pumping station, and the sewage treatment plant.

Construction of footings for the new shopping centre at Morrisburg was well advanced. A new sub-division in Morrisburg was taking shape. Construction of sewers and water mains had been virtually completed for this new sub-division. At Iroquois, work had been concentrated on the new shopping centre. Development of the industrial area and the semi-commercial area was underway.

Hydro Model Shows More Power Available

General A. G. L. McNaughton of Ottawa and Leonard Jordan of Washington, joint chairmen of the International Joint Commission, during an inspection trip over the seaway work on October 18, stated they were completely satisfied with the progress to date on construction.

General McNaughton revealed that studies made by Ontario Hydro with the help of a model set up at Islington, Ont., has added about 1¼ per cent to the power potential of the project. These studies, he said, had saved about one foot of 'head' at the power site, which meant the addition of some 27,000 horsepower to the initially planned 2,200,000 horsepower to be divided equally between the two countries.

Progress By SLSA

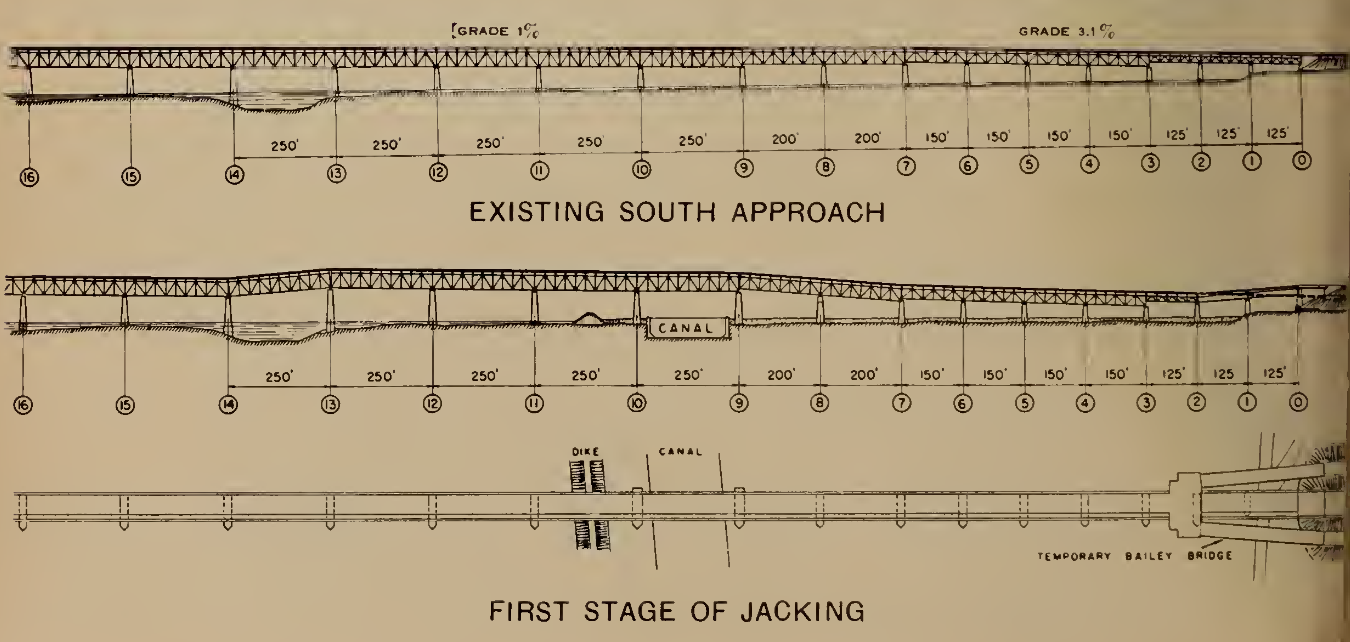
Excellent progress was made on excavation and dredging for navigation channels during the mild and dry weather throughout October, as construction forces strove to make a good showing before winter curtailed earthwork and closed down dredging contracts. Meantime, walls on three of the five Canadian locks were rapidly taking shape. Placing of concrete for some of the lock structures may continue throughout the winter, while at others the mixing plants will be closed down.

At the Iroquois lock, with some 80 per cent of earth excavation already completed by the end of October, 110,000 cubic yards of concrete, or 35 per cent of the total, had been placed to date, most of it in the north side upstream entrance wall, now practically completed. A start had also been made on the placing of concrete for the lock structure itself.

At Beauharnois, rock excavation continued at the upper lock and the New York Central railway had been diverted on to a temporary trestle, though no concrete had been placed. The contractor for the first stage was nearing completion of the rock excavation for the lower lock, while Canit Construction Co. had commenced pouring concrete on the highway approaches to the tunnel underpass under the lower lock.

At the Côte St. Catherine lock the contractors, who were delayed last spring due to flooding, had caught up and were again on schedule. Some 90,000 cubic yards of concrete or 26 per cent of the total for the contract had been placed over the entire length of the north wall of the lock on the river side, and a

Proposed Lifting Stages of the



start had been made on pouring the south wall and a few sections of the lock floor.

At the St. Lambert lock, with excavation substantially completed except for the upper approach channel, some 60,000 yards of concrete or 15 per cent of the total for the contract, had been placed in the shore-side wall of the lock structure west of Victoria bridge, and in the entrance wall on the river side east of the bridge, which was completed to full height for some 2000 feet of its length.

Elsewhere, at the Jacques Cartier bridge, widening and raising of piers 1 to 11 at the south end was proceeding, with some 10,000 cubic yards of concrete placed in the pier bases. The contractor for the raised bridge span over the navigation channel was preparing for diverting traffic to a temporary approach.

At the Honoré Mercier bridge the contractor was at work on the temporary south end highway approach, and had widened and rebuilt the underpass on the Malone highway under the New York Central railway.

Cornwall Dredging

Canada's Seaway Authority has called for tenders on dredging the 27-ft. channel north of Cornwall Island which has been in dispute with the U.S. government. This does not imply agreement has been reached for completion of the channel up to Cornwall, though agreement is still hoped for.

Tenders are also called for dredging from the entrance of Lake St. Francis upstream to a point some 1000 feet from lock 15 on the 14-ft. canal. This is the western end of the channel needed for the 27-ft. access to Cornwall. Both the work and the cost will be divided evenly between the two countries. Each will pay out some $17 million and be repaid about $6 million from the power authorities. Officials emphasize Canada has no present plans for duplicating the U.S. canal and locks in the International Section.

Progress by SLSDC

Bids were opened on October 10 for the superstructure of the international high-level highway bridge across the south Cornwall Island channel of the St. Lawrence, together with the viaduct spans at each end, and for earthfill and pavement on the mainland approach.

The bridge, cost of which will be about $6 million, is a suspension type with a 900-foot main span and 450-foot side spans. There will also be 2145 feet of viaduct spans. The substructure will be built by Canada's Seaway Authority, and must be completed in October of next year. The bridge must be opened for traffic by July, 1958.

The month of December will be an important one for the seaway. It will be the month for diverting the flow from the Long Sault rapids and turning the flow of the St. Lawrence river through a man-made course around the south side of Long Sault Island and over the first half of the Long Sault dam.

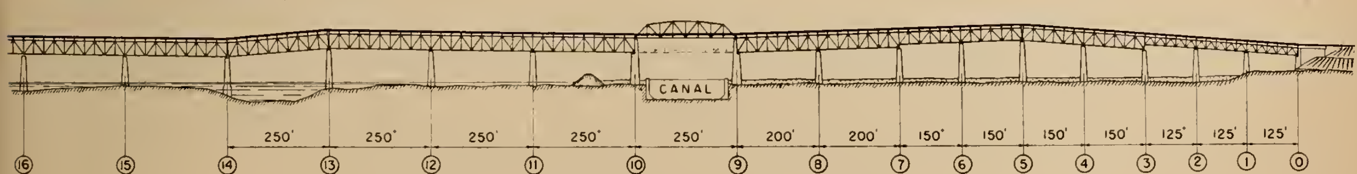
For some weeks past a rock fill had been under construction by aerial cableway across the head of the Long Sault rapids. Last year an earth fill plug had been placed across the channel through Cut "F" south of Long Sault Island. This plug is now being narrowed in preparation for blasting it open to allow water to pass down the south channel and through openings in the partly completed first stage of the Long Sault dam.

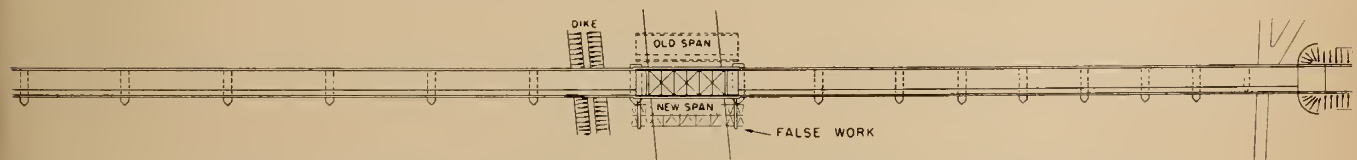
It will take about a month for the plug to be completely washed away. While this erosion of the fill goes on, the rock fill above the rapids will be raised, gradually forcing more and more of the flow through the south channel.

When the rock fill is completed, a downstream cofferdam will be completed for the second stage of the Long Sault dam between Barnhart and Long Sault Islands. This will permit dewatering the rapids, and work can begin on building the remaining half of Long Sault dam.

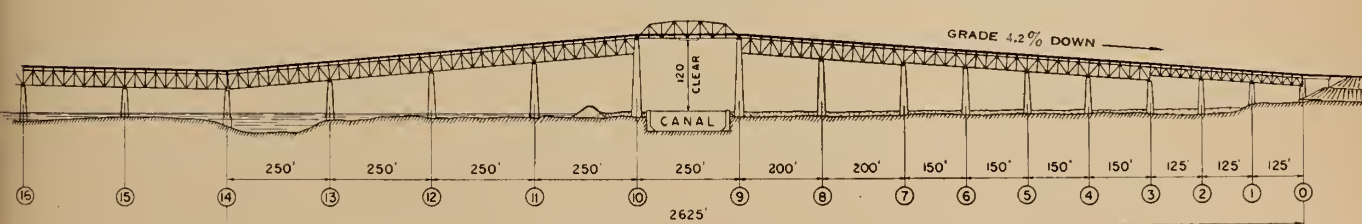
Upon completion of Long Sault dam the rock fill and the downstream cofferdam will both be removed and the water allowed to flow in its old channel. But instead of rapids this stretch will be merely a deep pool backed up by Long

Jacques Cartier Bridge, Montreal.





SECOND STAGE OF JACKING AND REPLACEMENT OF CANAL SPAN



FINAL STAGE

Sault dam and the Barnhart Island power-house downstream.

Planning the Seaway's Future

Dr. R. N. Danielian, president of the Great Lakes St. Lawrence Association, testifying on August 30 before the Great Lakes sub-committee of the Senate Foreign Relations Committee, stated that a medium sized ship must pay between $5000 and $6000 per transit through Suez, and nationalization by Egypt may substantially increase this amount. The seaway must contend with scales of toll charges comparable with these figures.

Thus every user of the seaway had a vital interest in the total investment costs and the tolls they must pay. "Unless we stir up business," he observed, "the revenues will not be there to sustain the investment" . . . If the dream of making the Great Lakes area a new economic frontier is to be realized, he warned, the various interests, federal, state, municipal and industrial will have to learn to work together.

Questions are planned at the next session of Parliament seeking to establish what Canada has done in the way of overall study of means of exploiting the potential commerce that will be opened up with completion of the seaway. Attention to the need of such survey has been called by announcement that the U.S. Corps of Engineers has been assigned to do a survey of the entire U.S. Great Lakes region, in addition to the various local and district surveys.

McGill Study Group

Since its formation about a year ago, as reported in our June, 1955 issue, the McGill Executive Study Group's efforts have been concentrated mainly on the probable effects of the seaway on the Port of Montreal. Movements of bulk commodities in and out (coal, grain and ore) were studied in order to discover trends.

The next step was to determine the nature, significance and timing of expected economies in transport due to the opening of the Seaway. Research also included technical aspects — sizes and capacities of existing channels and locks; numbers, dimensions and capacities of vessels plying the Great Lakes; coal and ore dock facilities, grain elevators, etc.

With these studies substantially completed last March, an interim report was issued to members of the group. This report also contained a summary of informed opinions currently being discussed and tested, though not derived from research activity of the group.

The third step will be an attempt to foresee what effect the conditions found from studies to date would have on the trade pattern and the final influence they would have on Montreal's future as a shipping centre. No date is yet announced for publishing its first report.

Canadian Pipeline Project

Westcoast Transmission

By mid-October good weather and working conditions had speeded construction, and work continued on schedule. More than 350 miles of 30-inch pipe were welded, with 325 miles laid and ready for testing. 1911 employees were at work on pipelaying, river crossings, compressor stations and the absorption plant at Taylor Flats.

Work was also under way on the gathering system in the north eastern British Columbia gas fields. Clearing and grading on the 18-inch Fort St. John gathering trunk had been completed and ditching started. 39 carloads of pipe were in transit for the area. Clearing and grading was also continuing on the main British Columbia trunk from the West Buick Creek field. More than 585 miles of main line right of way had been cleared, 450 miles graded and 475 miles of 30-inch pipe had been delivered.

Until such time as Westcoast gets a pipeline laid across the strait of Juan de Fuca from the U.S. mainland to serve towns and cities on Vancouver Island late in 1957, Vancouver Island Gas Co. plans to supply the city of Nanaimo with butane and propane gas. The requirements will be shipped in from Alberta by tank car.

A second gas pipeline from northeastern British Columbia to the southern part of the province is proposed by Peter A. Schwerdt, a B.C. oil promoter. Within ten years, he claims, at least three pipelines will be needed to transport available natural gas to markets from northern British Columbia gas fields.

Trans Canada Pipelines

By the middle of October the first two spreads working on Trans-Canada's western section to Winnipeg had laid some 160 miles of pipe and expected to complete a further 50 to 60 miles before the end of the month and a further 60 to 75 miles before cold weather called a halt. Pipe had been trickling in at rate of only a few carloads daily throughout the month and the good weather had been largely wasted. The ditch was being cut several miles ahead of pipelaying however, due to lack of danger from caving in the compacted sandy clay terrain on section I, though the ground in section 2 was not so well compacted. Majestic had completed 83½ miles of pipe stringing, and Canadian Bechtel 87 miles.

Little work will be done other than clearing and grading until next spring on sections 3 and 4. Universal Pipeline Corporation, which has 92 miles in section 3, had set up its office in Regina and had started on the 14 road crossings. Dutton Williams Ltd., which had the contract for the 80 miles of section 4, had its office in Grenfell, Sask., and had started clearing by the end of September. Both these spreads hope for an early freeze-up to facilitate haulage of pipe in winter over the large mileage of bog. They will leave pipelaying until next summer, though welding may be continued throughout November.

Two major river crossings over the Assiniboine had been started by Marine Pipeline and Dredging Co. of Vancouver, one at Miniota and the other 10 miles north of Portage La Prairie, with Parkhill Pipe Stringing Ltd., doing the stringing. No action had been taken on contracts for the remaining three sections between Willen, Manitoba, the eastern end of section 4, and the Winnipeg field gate at St. Norbert.

Trans Canada has set up an engineering and planning office at Winnipeg for the survey of the 800 miles of line between Moose Jaw, Sask., and Port Arthur, Ontario. This is a resumption of the work done two years ago by Bechtel, Mannix, Hester, Ltd. The right of way east of Winnipeg is being relocated to miss all lakes. Negotiations are proceeding for contracts on the last 188 miles of 34-inch pipe from Willen to

The natural gas line from Alberta to Eastern Canada moves ahead despite winter working conditions.

Winnipeg, which are all short sections.

A new 20-year gas contract recently concluded between Trans-Canada and Consumers Gas Co. of Toronto is the largest Canadian gas contract signed to date. It involves sales up to 165 million cubic feet of gas daily the fifth year of contract operation. Consumers' decision to greatly expand its requirements above what it requested in earlier stages of negotiation enabled the company to obtain Alberta gas at terms fully competitive with gas now being imported from Texas and Louisiana.

Financing

Trans Canada has thus gained new impetus for financing the $375 million pipeline now under construction. Federal and Ontario governments will finance the $125 million stretch of pipe across Northern Ontario, leaving the $250 million remainder to be financed by Trans Canada. It now appears that with this financing imminent, the company will draw less than $40 million of the $80 million Ottawa agreed to loan the company for the 575 miles of line to Winnipeg.

Trans Canada's financing, completion date for which has been extended to December 1, 1956, will be placed before the Board of Transport Commissioners on October 30. Placing of $144 million of first mortgage bonds is now going on. Marketing of the remainder of $90 million in debentures and stock is dependent on the placement of bonds. Next year Trans Canada will complete the pipeline to Winnipeg and build on as far as the Ontario border, while Trans Canada or the Crown Corporation will handle the second section from the Ontario border to Lakehead.

Deficit Seen in Early Years

Trans-Canada will operate at a deficit for from three to five years, predicts President N. E. Tanner. It was necessary for the company to go back to the producers to alter the contracts and take much less gas at a lower rate in the initial building stages. The company was now engaged in renegotiating contracts with the producers and good progress was being made, he said.

While Canadian sales had been greater than expected, and enough gas had been sold under contract to take all the Alberta gas under permit, there would be an inevitable market buildup lag, he warned. The company still needed the 200 million c.f.d. export to the United States through Emerson for immediate profitable operation, though without it deficits could be taken care of within the three to five years.

L.P.G. Pipeline Gets Permit

Canadian Hydro Carbons Ltd. has received the permit for its subsidiary Hydro Carbons Pipeline Ltd. to build Canada's first 800-mile L.P.G. pipeline from Alberta to Winnipeg and possibly later to Lakehead, at a cost of some $60 million. It will be integrated with Trans Canada and will transport butane, propane and other hydro carbons not handled by the gas pipeline. Dutton Williams Ltd., consulting engineers are now conducting engineering studies, which must be completed before the plans are laid before the Alberta Petroleum and Natural Gas Conservation Board.

Though the exact route is not yet established, it is expected a gathering system will form a grid in central and southern Alberta and will feed the line to Winnipeg, to be located between the Interprovincial and Trans Canada pipelines. Preliminary design calls for 8-inch pipe from Edmonton to Regina and 6 inches from there eastward. Terminal points for delivery of products in bulk stations and refineries will probably be set up at Edmonton, Calgary, Moose Jaw and Winnipeg. Initial capacity will be between 10,000 and 12,000 barrels per day. Some of the gathering facilities and the main line into southern Saskatchewan will be built in 1957 with completion scheduled for late 1958.

University of Alberta Mining and Metallurgy

The Department of Mining and Metallurgy has recently undergone extensive structural alterations and expansion.

To the established degree courses in mining engineering, a new degree course, metallurgical engineering has been introduced. This involves specialization in physical metallurgy in the students' third and fourth years.

Courses leading to the degree of master of science in mining engineering and in metallurgical engineering are also offered.

Two major research projects are being carried out:

1. The sink-float treatment of uranium and other ores by the Driessen Cone, sponsored by the Atomic Energy Control Board and Eldorado Mining and Refining and directed by Professor E. O. Lilge, head of the department.
2. Physical metallurgy of titanium base alloys, sponsored by the Defence Research Board of Canada and directed by Dr. J. Gordon Parr.

The department's building now comprises a mineral dressing pilot plant including a specially designed crushing and grinding room, mineral dressing laboratories, fire assaying and chemical control laboratories, physical metallurgy laboratories classrooms and offices.

Wintertime Construction

The National Joint Committee on Wintertime Construction, having met for the third time in September this year, reported that the campaign to reduce seasonal unemployment in construction activity had been an important factor in the reduction by 20,000 in the number of construction men laid off last winter compared with the year before. It was agreed, however, that the problem was far from being solved.

The Committee recommended that the Government watch closely the effect of credit curbs on the construction program as affecting winter work, and ensure that adequate supplies of mortgage funds be made available for wintertime construction, especially in the housing field.

Members pointed out that peak employment on sizeable projects occurred six months or so after their start. Curbs against new projects during the summertime when materials and labour were in shortest supply would have their main effect during the wintertime when it was desired to increase the volume of construction employment.

In the case of housing, it was reported that many lenders had used up their appropriation for mortgages for the year and could advance no new loans until 1957. This situation would reduce the number of "fall starts" and the volume of winter building.

Members pledged themselves to continue and increase their organizations' efforts to publicize the facts that modern techniques made the traditional wintertime shut-down out of date. The production of films by the National Film Board was advocated as an extra medium of publicity to this end.

Member organizations of the National Joint Committee on Wintertime Construction include the Canadian Construction Association (sponsor), The Canadian and Catholic Confederation of Labour, The Canadian Chamber of Commerce, The Canadian Labour Congress, The Canadian Legion, The Canadian Manufacturers' Association, The Engineering Institute of Canada, The National House Builders' Association, The Royal Architectural Institute of Canada. Associated with the project are the National Research Council and the Federal Department of Labour.

An intensive study of Scandinavian methods brought forth information of mixed value for Canadian operations. The 10 per cent differential between the volume of summertime and wintertime construction was held to be the goal in at least one Scandinavian country. In Canada this ratio had already been obtained with regard to the defence construction program where urgency of completions was of vital concern. During the past four years Defence Construction Ltd. estimated that roughly 45 per cent of its work was carried out each year in the six winter months between November and April. 1600 construction men were employed last winter at the Camp Gagetown project alone.

The N.R.C. Building Research Division has prepared "A Bibliography on Cold Weather Construction", as well as a booklet on "Winter Construction", the sixth in its "Better Building" series. The Division also sells a "Climatological Atlas of Canada" containing data on snow fall, design temperatures, etc. The Canadian Construction Association has recently published the paper "Techniques of Winter Construction", the prize-winning thesis in the 1956 competition.

There is, therefore, being compiled more and more information on the technical aspects of wintertime construction. The Library of the Engineering Institute of Canada is a source of further information on the subject.

Passamaquoddy Board

The International Joint Commission has established the International Passamaquoddy Engineering Board to "carry out all the engineering investigations and studies necessary to enable the Commission to prepare and submit to the governments of the United States and Canada a comprehensive report on the proposed Passamaquoddy Tidal Power Project".

Board members are as follows: Canadian Section, Brigadier J. P. Carrière, M.E.I.C., chairman, and C. K. Hurst, M.E.I.C.; American Section, Lt.-Gen. S. D. Sturgis, Jr., chairman, and Francis L. Adam.

Vancouver-Squamish Railway Line

The Pacific Great Eastern Railway completed in June this year the railway line from North Vancouver to Squamish, which will help to integrate the coast economy with that of the northern interior of British Columbia and the Canadian north country.

The new rail line overcomes the need to ship by ferry to Squamish, to connect with the Squamish to Prince George line which has been in operation for many years. The difficult route of the new line, going along the rugged Howe Sound coast discouraged the project until recent years. Backed by the provincial government, the work was undertaken in 1954. In two years it was completed, providing a system equipped with radio communication between Vancouver and Squamish and all trains.

North of Prince George, some 330 miles are now under construction. The present objective is a railway system with 800 miles of main line.

Research Centre

Dupont of Canada Limited opened the doors of its research centre to representatives of the technical press on September 20.

The research laboratory built in Kingston, Ont., at a cost of $1½ million applies the most modern design to the problems of the research environment.

It was explained by Dr. O. C. W. Allenby, laboratory manager, that in the view of the Company "industrial research is complicated and the equipment used is expensive. Invention today is largely a team effort".

The scientist uses equipment unknown, or unavailable, ten to twenty years ago. It is usually highly complex and specialized.

The experience is that it costs up to $30,000 per year to support the work of one scientist and to supply him with the help of technicians, library facilities, etc.

The long term view in this instance of a company with American affiliations is to base objectives on Canada's future needs, after establishing whether there are reasonable technical prospects for a solution.

COMMENT AND CORRESPONDENCE ELECTIONS AND TRANSFERS

1956 University Registration in Engineering

This issue of the *Journal* continues our practice of listing, once a year, the full university registration in engineering in Canada. The tabulation is on pages 1708 and 1709.

The total enrolment in engineering courses in Canada at recognized institutions, shows a somewhat comforting increase of 12.2% for the new year now started. The actual number of students is 12,723 against 11,341 a year ago. This is the best annual increase for several years, and compares with 10% last year.

The highlight of the survey comes from the figures for the new freshmen classes. Except for a few, these are consistently well up, and in several instances at some of the smaller colleges this year's freshman enrolment has actually doubled last year's intake. Other increases of 62%, 50%, 48% and 42% are reported. Perhaps the most startling development is shown at University of Saskatchewan, where the largest single increase of 146 engineering students jumps their old figure of 305 last year to 451 for 1956-57. This makes it the second largest freshman class in Canada, led only by Toronto with 725. New enrolment throughout the three western provinces is above the norm this year, with B.C. in third place in the Dominion with 404 potential new engineers signed up. Alberta has 386.

Readers will note that Sherbrooke (Quebec) appears on the list for the first time. As reported in the March 1956 *Journal*, a partial engineering course of recognized standing is now available at the University of Sherbrooke, and we are glad to welcome this college to our roster of Canadian engineering educational institutions.

Another item which will be discovered by the careful observer is the slight fall off in total engineering registration at the Services Colleges. The figure shows a decrease of about 7% since last year.

Considering the various branches of engineering, civil remains the most popular with 1,828 students now engaged in this division of study. This is followed by the other two of the "big three", electrical showing 1,359, and mechanical 1,329. Chemical engineering leads the remainder with 960 students enrolled.

One interesting fact uncovered by this year's survey is the high rate of freshman registration in engineering physics. The figure has jumped 40% from 404 to 566. This shows the intensity of interest that must be building up these days in nuclear fission and similar sciences concerned with the use of the atom. This bears watching, as it will have a direct and important effect on Canada's scientific future and our place in the atomic age.

Based on the present size of the senior classes, 1,826 engineering students could obtain their degrees and graduate into the profession in 1957. This represents an increase of 9% over last year, but at the same time it is a large drop from the forecast for 1957 of some 10% which was made in this commentary a year ago. Whether or not this can be accounted for through normal attrition, or perhaps shows that advanced students are falling in the temptation of ready jobs, is hard to say. The persistent demand for help must be having some effect.

UPADI—Fourth Conference

The Union of Pan American Engineers Associations (UPADI) held its fourth regular convention in Mexico City from October 7th to the 12th inclusive. Previous conventions were held at Havana, Cuba, New Orleans, Louisiana, Sao Paulo, Brazil.

This was probably the most successful of all conferences. The attendance, although no official count is given as yet, must have come close to 300, with almost 100 being official delegates. Out of 22 member countries, 13 were represented. It is interesting to discover that of all the South American countries, only Nicaragua is not a member.

The program consisted of a miscellany of formal functions, committee meetings, technical tours, sight seeing tours and distinguished social events.

By far the most important work of UPADI is done by its committees.

Cover Picture

The cover picture was derived from the photographic exhibit which was part of the Institute's annual meeting of 1956. It is one of the six award-winning pictures.

It is a view of the Southern Trans-Provincial Highway on Anarchist Mountain in British Columbia.

B.C. Government Photograph

Formal opening session of UPADI conference. Some of the Canadian delegates and their wives can be seen in the left foreground. In the front row, the president and Mrs. McKillop, I. R. Tait and Mrs. Tait; behind them, the general secretary, Mrs. Anson and Mr. Anson.

The following is a list of the committees and the Institute's representatives on each.

Administration,
V. A. McKillop
Legislation,
C. M. Anson
Technical matters,
Dean Henri Gaudefroy
Relations,
I. R. Tait
UPADI Fund,
J. A. Vance

The Canadian delegation consisted of 13 people, including 7 official delegates. They were as follows:

President of the Institute — V. A. McKillop and Mrs. McKillop
The president elect — C. M. Anson and Mrs. Anson and their daughter
Past President — James A. Vance, Woodstock, and Mrs. Vance and their grandson
Past vice-president — I. R. Tait and Mrs. Tait
Past councillor — Dean Henri Gaudefroy and Mrs. Gaudefroy
General secretary — L. Austin Wright

From the Institute's point of view one of the outstanding events was the reception given by the Institute to all delegates. This took place in the del Prado Hotel, which is the leading hotel in Mexico. There were in the neighbourhood of 200 guests present, all of whom were received at the door by the reception line made up of the entire Canadian delegation.

As part of this reception Mr. Vegh Garzon was presented with a certificate as an honorary vice-president of the Institute, in virtue of the fact that he is the Institute's alternate representative on the Board of Governors, representing Mr. Vance. He has done a splendid job for the Canadians and they were happy to have this opportunity to recognize his services.

All committee meetings and formal meetings were held at a building identified to the delegates as "SCOP". This is a combination of the letters representing in the Spanish language the building which houses the headquarters of the Government's offices controlling all communications. It is a new building and from a North American's point of view is fantastic.

Some of the outside walls are mosaics from the ground line to the roof line, probably a height of a hundred feet. They are done in brilliant colours and with a bold conception. To the North American eye they were at least startling, but it is easy to believe that if one stayed there long enough these things would fit themselves into the background and become very pleasing and perhaps inspirational as well, as they are now to the Mexicans.

The building is ultra modern in

The Canadian party. Seated: Mrs. Gaudefroy, Mrs. Tait, Mrs. Anson, Mrs. Vance, and Mrs. McKillop; standing: Henri Gaudefroy, I. R. Tait, C. M. Anson, J. A. Vance, President V. A. McKillop, Miss Anson, L. Austin Wright, James Stevens, and C. R. Vegh Garzon, Canadian alternate on Board.

Greetings from Canada. President McKillop presents the message from Canada. At table, sixth from right, is president of the Republic, Adolfo Ruiz Cortiniz. Many of the others are members of his cabinet. Third from right is Luis Giannattasio of Uruguay, president of UPADI.

every detail and the auditorium in which most of the sessions were heard was fully equipped for multiple translations, with three completely separate lines of communication from the microphones to the translators and back to the ears of those in the audience. This is all built-in equipment and indeed was a great convenience to the conference.

The conference opened with a real "tour de force". The president of the Republic, Adolfo Ruiz Cortiniz, was there for the entire meeting and representatives from each delegation presented their greetings, at the conclusion of which the president himself made an address in Spanish which, judging from the reactions of the audience, must have contained all the right things.

Foundations

A portion of one day was devoted to visiting the site of a new hospital, where thirteen buildings were being erected. The thing that makes this so unusually interesting is that Mexico City has the most unusual soil conditions. The land is largely made land as the country originally was a series of islands, consequently there is no firm foundation at any reasonable depth. In fact, the engineer in charge of the hospital work told the delegation that his bench mark was 250 feet below the surface. He had to go that far before he could find a bed of sand that would remain reasonably stable.

The buildings are designed as if they were floating in a body of water. No attempt is made to drive the foundations down to a firm level. Instead, piles are pushed down below the foundation framework of the building and are placed in such a way that a beam from one pile to another passing through a column can be used to raise or lower the side of a building in order to keep it level in spite of any settling that takes place. Throughout the entire foundation of the building these beams and jacks are installed, apparently with the intention that the level of the building shall be tested every day so that the necessary adjustments can be made immediately.

Certain of the older buildings around Mexico City show how bad the condition is. It is nothing to find some of the more monumental buildings to have sunk at least six feet. It was reported that the Fine Arts Building had actually gone down eleven feet. The Institute is endeavouring to get a paper for the *Journal* that will tell the members something of the most unusual and disturbing conditions.

A closing function was a "Baile", which as the reader will suspect is a ball. The ball was due to start at 10:00 p.m., but actually in accordance with South American standards it began about 11:30 p.m. Dinner was to have been served at midnight, but it too turned up somewhere around 1:00 o'clock, but nobody seemed to care.

This event was one of the most outstanding that could have been staged any place in the world. It took place in the court yard of a very old building, where the top had been covered over with canvas in order to protect the three or four hundred guests from the elements.

From the gallery around the courtyard it was one of the most beautiful and impressive sights this writer has ever seen. The decorations were all in flowers and the decorative lighting and the spotlighting were extremely well done. It was like a picture out of an old book to look down on the floor and see all the couples dancing, with the ladies mostly in what might well have been old-fashioned hoop skirts.

An unadvertised feature of the meeting was a downpour of rain which ripped right through the canvas coverings of the courtyard and came through onto the dance floor, but again, nobody seemed to care. A few tables were drowned out but the water missed the orchestra and certainly did nothing to reduce the enthusiasm and the fire of everyone who was present, including the Canadians. This will be a long remembered event.

The Canadian delegation was very happy to have with them as guest the Honourable Douglas Cole, the Canadian Ambassador to Mexico. Mr. Cole is an engineering graduate of McGill University and also speaks Spanish. It is not difficult to imagine what a sensation he was before all these South American people.

In the final session a decision was made as to where the 1958 convention would be held. Upon the motion of the delegates from Argentina, seconded by those of the United States, it was agreed that in 1958 UPADI would meet in Montreal, Canada. This date was selected because of the fact that the 1958 meeting of the World Power Conference takes place in Montreal, and it was felt that those attending one conference would like to attend the other.

Meetings for UPADI have now been determined for September 3, 4, 5 and 6; for the World Power Conference the 7, 8, 9, 10 and 11.

A Valuable N.C.C.U. Conference

The announcement by Prime Minister St. Laurent that he would recommend to Parliament that annual federal grants to universities should be doubled greatly pleased the delegates to the recent meeting of the National Conference of Canadian Universities. No less dramatic was the pronouncement of opinion by leaders of the Quebec universities that federal grants (at least for capital expenditure) should be accepted by them, despite the opposition of Premier Duplessis.

The Prime Minister proposed that the federal grants voted by Parliament each year should be handed to the N.C.C.U. for distribution. After consideration by the N.C.C.U. finance committee, the executive committee issued a statement that "The N.C.C.U. . . . accepts the responsibility of receiving federal funds for subsequent distribution to the institutions of higher learning in Canada. Steps have been taken to incorporate the N.C.C.U. and to provide the necessary organization for assuming these new responsibilities should Parliament make the proposed appropriations". Also welcomed was the Prime Minister's further proposal to create the Canada Council (for the arts, humanities, and social sciences) and to recommend the appropriation of $50 million to be distributed by the Council over a period of ten years as capital grants to universities equal to 50 per cent of the cost of specific building or capital equipment projects. If federal grants cannot be immediately accepted by any university, their share will be held in trust until they are able to accept such aid.

The conference was held, 12-15 November, in Ottawa under the general chairmanship of Dr. G. E. Hall, president of the N.C.C.U. and of the University of Western Ontario. Attending delegates represented the Canadian universities, federal and provincial governments, various national organizations, including organized labour, and distinguished educational bodies in the United States. The conference was supported financially by the Carnegie Corporation of New York.

Sessions were held on various aspects of education and papers were presented on technological and scientific education, the use of human resources, problems in securing staff, and finances. Particularly valuable was the animated discussion of these and other subjects.

A list of the papers and their authors is appended; papers and proceedings are to be published later by the University of Toronto Press.

Prime Minister Louis St. Laurent is greeted by Dr. C. T. Bissell at the N.C.C.U. Conference. Looking on are R. D. Mitchener, of the Higher Education Division, Dominion Bureau of Statistics, and Dr. G. E. Hall, N.C.C.U. president (next to the Prime Minister). Dr. Bissell was officially inaugurated as president of Carleton College, Ottawa, at a colourful ceremony on 13 November.

Thirteen Resolutions

At the end of the conference a series of thirteen resolutions, drafted by the resolutions committee, were unanimously adopted. These, in effect, cover the problems discussed at the conference and some of the practicable solutions. The main features are summarized below. Copies of the first nine resolutions are to be sent to the federal and provincial governments.

(1) A statement of the concern of the universities at their current and unforeseen difficulties in maintaining standards, leading to a resolution that the people of Canada be warned of this concern, and that the emergency can be solve only " . . . by the energetic and immediate assistance and cooperation of all governments in Canada, of business and industry, and of private benefactors."

(2) Particular importance is attached to the part of the Prime Minister's statement that federal aid alone was not enough and that provincial government contributions should continue. The resolution states that "without such additional and increasing aid the universities cannot hope to solve the crucial problems now confronting them".

(3) It is hoped that all present and future members of N.C.C.U. will be able to benefit from the implementation of the Prime Minister's proposals.

(4) Income and succession duty taxes, both provincial and federal, should be revised to encourage citizens, business, and industry to make grants to universities.

(5) Central Mortgage and Housing Corporation rules should be amended so that universities could borrow money for residences and housing on most favourable terms, on a self-liquidating basis.

(6) The N.C.C.U. executive should accept immediately the invitation to cooperate with the Industrial Foundation on Education.

(7) The ratio of staff to students should not be allowed to fall still lower in the face of increasing competition; the educational profession should be made more attractive through better salaries, and enrolment encouraged.

(8 Every effort should be made, especially by scholarships and other

financial aid, at high school, college, and post-graduate levels, to identify, encourage, and support young people who have the will and the ability to profit by further education.

(9) The conference commends to the provincial governments the desirability of establishing more institutes of technology comparable to the Ryerson Institute of Technology, in Ontario, and other institutions for vocational and technical training at a non-university level.

The remaining four resolutions expressed the thanks of the conference members to the Prime Minister, the Carnegie Corporation of New York for their grant, the organizers, and the authors of papers.

Co-Ordination of Effort

Perhaps the most valuable result of this conference, which had followed many other recent meetings on the subject of education, will be the ultimate coordination of effort on the part of all those whose hearts are set on a satisfactory solution to "Canada's crisis in higher education", to quote the conference theme.

The federal government has adequately expressed its concern and willingness to help the educators, who themselves had a unique opportunity of discussing all sides of their problems. The voice of industry was heard in discussion of the ways and means of industrial aid to education; between the extremes of an independent body collecting from industry as a whole and distributing the proceeds over the educational field, to specific contributions from one firm to its chosen university, there arose some agreement that industrial support should be encouraged and that industry, generally, was willing to contribute and would often welcome advice on the best way it could help, even though it might reserve the right to direct its support towards certain chosen fields. The conference learnt more of the Industrial Foundation on Education and resolved to cooperate with that body.

Though the advantages of higher education are still far from evident to many Canadians, particularly in some of the large industrial centres, there is a growing awareness of these advantages among the ranks of organized labour. Eugene Forsey, director of research of the Canadian Labour Congress, pointed out that the CLC had recently considered, in detail, many of the very problems that had been discussed at the present meeting. In general, the CLC was in entire agreement with the opinions expressed at the N.C.C.U. conference and, although Canadian trade unions were far from enjoying the affluence of their counterparts in the United States, it was hoped that they might find the means to support higher education in some practical way, particularly by helping talented young people. The Rev. H. J. Somers, president of St. Francis Xavier University, told of the enormous increase in university enrollment from Cape Breton county, where the great majority of the working population is engaged in coal mining or steel-making; from a handful some thirty years ago there are now over 500 students, an increase apparently encouraged by parents who have realized the advantages of higher education.

Engineering Education

Although this conference was called to cover all fields of higher education, the engineer was widely discussed.

Opinion was strongly expressed that the university years should be devoted to giving the engineer, just as the pure scientist, as thorough a grounding as possible in the fundamental principles of his profession. This did not mean cramming a student with facts and figures, but properly training his mind to use the knowledge he can acquire.

The universities could not, and should not, be expected to turn out men trained to fit into a particular industry. Although there is some evidence of industry bringing pressure to bear on universities to produce engineers "to specification", it is generally considered that enlightened industry realizes its own responsibility for training the newly-graduated engineer to give him an adequate knowledge of the industry's operations and his place therein. (This is amply borne out by the replies received from the many Canadian industrial organizations and individuals who have been asked for information on which is based the "Engineering Careers" series published in *The Engineering Journal.)*

Above all, there must be no reduction of the standards of engineering (and other) education in the Universities in order to try to meet the demand for technicians.

The results of this conference (and government action) are that, with approval of Parliament, annual Federal grants to universities will be doubled (to some $16 million) and the money will be distributed by the N.C.C.U.; other funds will be provided through the Canada Council for scholarships and capital grants; it is hoped that provincial governments will extend their financial support; and a long step has been taken towards closer co-operation between the N.C.C.U., industry, and organized labour on the many problems associated with higher education.

The universities clearly do not demand assistance from all these sources as their right; but they do need this revenue for the essential service they provide to the country and all its communities. How unfortunate, therefore, that in accepting the support of the Government of Canada "everyone is out of step" but the premier of the province of Quebec. One can only hope that, in accord with the general tone of this conference, reason will ultimately prevail.

N.C.C.U. Conference Papers

A list of all the papers given at the Conference is published below. The Prime Minister, The Rt. Hon. Louis St. Laurent, also addressed the conference at a dinner on November 12, when he re-affirmed the proposals for increased federal government grants to universities.

General Statistics—C. T. Bissell, president, Carleton College

Educational Structure

English-Canadian Universities: Sidney E. Smith, president, University of Toronto.

French-Canadian Universities: Maximilien Caron, vice-dean, faculty of law, University of Montreal.

Technological and Scientific Education

The Responsibilities of the Universities in the Training of Scientists and Technologists: E. W. R. Steacie, president, National Research Council.

The Role of the Humanities and Social Sciences in the Training of Scientists and Technologists: J. E. Burchard, dean of humanities and social sciences, Massachusetts Institute of Technology.

The Use of Human Resources

Who goes to University? (1) English-Canada: R. W. B. Jackson, assistant director, educational research, Ontario College of Education, Toronto.

(2) French-Canada: Arthur Tremblay, professor of education, Laval University.

(3) Failures and Misfits; Wastage in Human Resources in the Universities: T. H. Matthews, registrar, McGill University.

Problems in Securing Staff

The Humanities: A. S. P. Woodhouse, professor of English, University of Toronto.

The Physical and Natural Sciences: P. Gendron, dean, faculty of pure and applied science, University of Ottawa.

The Social Sciences: B. S. Keirstead, professor of economics, University of Toronto.

University Salaries: V. C. Fowke, professor of economics, University of Saskatchewan.

Finances

Government Support of Canadian Universities: N. A. M. MacKenzie, president, University of British Columbia.

Private and Corporate Support of Canadian Universities: Rev. H. J. Somers, president, St. Francis Xavier University.

A Comparative Study of Methods of Financing Universities in the United Kingdom, Canada, and the United States: F. Cyril James, principal, McGill University.

*Students in Agricultural Engineering who will proceed to their final year in Mechanical or Civil Engineering at the University of Toronto on completion of their studies at Guelph.

The Continuing Education of the Graduate Engineer

This was the topic of the joint ASME-E.I.C. conference which was held at the University of Western Ontario on October 18 and 19, 1956. Nearly one hundred delegates took part, representing educational and industrial institutions from the United States and Canada.

It was a lively conference. The topic was subdivided into five subtopics, each handled by a panel composed of a moderator and four panel members. The conference program was published on page 1390 of the October *Journal.* Conference material will be published in *The Engineering Journal* in this and succeeding issues. The address by Dr. G. E. Hall, president of the University of Western Ontario will be found elsewhere in this issue, under the title, "The Fundamental Concept of Education". This will be followed in January by the address delivered by Dr. J. W. Barker, president of the ASME, under the title, "Meeting the Shortage of Engineers and Scientists". The panel presentations will be published in succeeding months, one presentation in each issue.

It is unfortunate that the discussion which took place at the panel sessions cannot be published. Experience has shown that the vitality of spontaneous exchange of ideas is lost when discussion periods are reported, either verbatim or in digest. Yet the discussion periods were almost as interesting as the panels. Discussion was vigorous, reflecting at times wide differences of opinion. Several of the delegates began their remarks by saying: "I know I may be sticking out my neck but . . ."

The session on "The Product of the Engineering Baccalaureate Curriculum" was possibly the one concerning which opinion differed most widely, particularly during the first part of the discussion period. The question of the specialized course versus the general course received another going over and actually overflowed into all the other discussion periods. When the smoke of battle cleared, it appeared that the courses now taught by the universities were not too bad after all, and that the baccalaureate curriculum, based on two years of common fundamental principles followed by two years of limited specialization, was turning out graduates which were acceptable to the majority of prospective employers. However, large industrial organizations which developed and manufactured the complex machines of today would still have to provide their own programs of supplementary on-the-job instruction. The graduate engineer has become a long-term investment with an increasing rate of return. This rate and its increments are determined, not only by the capital investment of engineering education but also by the development of guided experience.

Dr. Joseph Barker, president of ASME, was the speaker at a dinner during the conference. Shown at the head table, left to right, Mrs. McKillop, Dr. Barker, President McKillop of the E.I.C., chairman of the dinner meeting, Dr. G. E. Hall, Mrs. Gordon Henderson. Others at the head table were Newman A. Hall of Yale University, Gordon Henderson past vice-president of E.I.C., Mrs. Austin Wright, and C. E. Davies, secretary of ASME.

The audience for one of the panel sessions.

The proposed course of Engineering Science now being developed at the University of Western Ontario received considerable attention, particularly by the university representatives from the United States. This course will be even more general than those taught at other Canadian universities and is expected to produce the general practitioner of engineering.

Considerable concern was expressed regarding the growing tendency of engineers to leave engineering, a few years after graduation, to become supervisors, managers or sales engineers. More significant, however, was the realization that many engineers were doing work which could be done by trained technicians or engineering aides. The first panel session on "The Engineering Technician" explored this aspect of the problem. The need for more and better technical institutes, proper recognition of the trained technician and his role in amplifying the work of the graduate engineer, were discussed.

Notwithstanding that this was definitely a working conference, with day and evening sessions, there was unanimous approval of a resolution, read at the closing dinner, that there should be another conference, possibly in two years' time. This would ensure continued study and interest in the education of the engineer. It would also keep this important subject of engineering education in true and dynamic perspective, at a time when the shortage of graduates might lead to the cutting of corners.

E. V. Buchanan,
Julian C. Smith Medal

Edward V. Buchanan, M.E.I.C., of London, Ont., consulting engineer, and former general manager, Public Utilities Commission and London Railway Commission, will receive the Julian C. Smith Medal of the Institute for "Achievement in the development of Canada". The Council reached this decision at the meeting of November 10, the award to be presented at the annual meeting in Banff, June, 1957.

Mr. Buchanan was born and educated in Scotland, graduating from Royal Technical College, Glasgow.

He has contributed greatly to professional affairs, serving the Institute as branch chairman and councillor and as a representative on the Engineers Council for Professional Development. In 1948 he was awarded the Fuller Memorial Award of the Canadian Section of the American Waterworks Association.

E. V. Buchanan, M.E.I.C.

ECPD Meets in Detroit

The twenty-fourth annual meeting of the Engineers Council for Professional Development was held in the beautiful building of the Engineering Society of Detroit on October 25 and 26. From every point of view it appears to have been the most successful meeting ever held.

The Engineering Institute is the Canadian member of this Council. Most of the Institute's working members of the Council and of its many committees were present and the president was there as well.

Speakers

There were three speakers in addition to the chairmen of committees, and the president. At luncheon on the 25th the speaker was Dr. Kenneth McFarland, educational consultant for General Motors Corporation. It is doubtful if any other man could wrap up so serious a message in so much side-splitting wit and humour. To hear him was an experience long to be remembered.

The annual dinner Thursday night was presided over by the president, Thorndike Saville, dean of engineering, New York University. He gave an interesting and inspirational "boil down" of his annual report. It was clear that ECPD had a big year, but it was even clearer that a bigger one was ahead. The speaker was J. H. Foote, president of Commonwealth Associates of Jackson, Michigan.

Friday's luncheon had as its speaker N. W. Dougherty, dean emeritus, College of Engineering, University of Tennessee. His message was that in spite of all the counselling, guidance and other forms of assistance that were offered the young man, he would become a professional person and recognized as such only when his own behaviour showed he merited it.

Committees

The Council works through a group of well established committees. These committees demand much of their members because there is much to be done and none of it comes easily. It can be said that this Council has no existence outside of its committees. Every action taken throughout the year is taken by or on behalf of a committee. The reports of the several committees were presented at Detroit and this *Journal* account makes available to Canadian engineers an abridgement of each one.

ECPD is the first successful cooperative organization in North America to survive over a reasonable period of time. It has done a great work for the profession and every year sees it growing in size, accomplishment and recognition. As each field is opened and developed, new fields are attacked, so that the ECPD program takes on the character of a healthy tree whose branches grow longer and stronger, whose stature increases steadily and whose roots go deeper and deeper.

The Institute is proud to be associated with the great United States societies, in the outstanding work that is the purpose of ECPD.

Guidance Committee

Chairman,
K. F. Treschow, Secretary,
Engineers Society of Western Pennsylvania, Pittsburgh.
E.I.C. Representative,
R. F. Shaw, Vice-President,
Foundation Company of Canada, Montreal, Que.

The Guidance Committee, with a well developed organization in the United States, Canada, and Hawaii, built up by former chairmen of this committee, has with the fine cooperation of regional, state, and local chairmen and their committees continued to bring student guidance to an increasing number of secondary schools, especially in the outlying districts.

Following recommendations made in last year's report, the revised fourth edition of the folder, "After High School—What?" will be mailed the latter part of this year to superintendents and principals of all secondary public, private, and parochial schools. With the mailing of this folder, the usual offer is being made for counselling by committee members at the schools if application is made to the state chairman. The state chairman refers such requests to his local committee in or near the locality from which the request is received.

Local Activities

Forty-three state chairmen have submitted annual reports giving number of schools visited, number of students contacted, and brief outlines of the various types of programs. Sixteen - hundred - and - fifty schools were visited and 118,260 students were contacted. However, the number of schools given is no indication of the students reached as practically all of the large cities sponsored Career Days to which students in all of the local schools are invited. The number of these schools is not included.

In general, local programs consist of Career Days, speakers at the schools, inspection trips to industry, speakers at PTA meetings, and meetings with school counsellors. A number of committees have arranged radio and TV programs. We regret that space does not permit our giving a more detailed report on the many programs sponsored by local committees.

Education and Accreditation Committee

Chairman,
Harold L. Hazen,
Dean of Graduate School,
Massachusetts Institute of Technology,
Cambridge, Mass.

E.I.C. Representative,
Professor C. H. R. Campling,
Queen's University,
Kingston, Ontario.

This year's work of the Education and Accreditation Committee has taken on substantial elements of new thinking arising from new problems in what appears superficially to be a semi-routine and standard program of visitation, appraisal, and recommendations to Council on engineering curricula.

The impact of accelerating technical sophistication in industry and defense is being felt in our engineering schools, through several channels. One of the most important channels is the Evaluation Committee report of the American Society for Engineering Education, accepted in June, 1955. Related to and in some sense growing out of this report are the "Additional Criteria for Engineering Curricula," appearing as part of last year's report of this committee. These have had the general effect of raising the sights both of engineering education and of ECPD standards for engineering curricula. There is a widespread recognition that the art of technology and engineering practice must take a role secondary to sound grounding in science, and the development of these methods of thought by which science can be applied with understanding and judgment to the solution of new problems. The degree of acceptance of these ideas and of the essential place of general education in an undergraduate engineering curriculum has been indeed notable across the country.

Simultaneously with these raised levels of performance that engineering educators have set for themselves, inflationary effects have appeared that work against achievement of these levels. Employers of engineering graduates strive mightily to increase the attractiveness of industrial employment at the same time that general economic inflation is decreasing the attractiveness of an academic career in comparison with an industrial career. The effects of these trends on faculties pose problems in appraisal and judgment to ECPD visiting committees that are at once challenging and difficult. Engineering faculties, especially in smaller departments, tend now to be much less stable than in less dynamic times, and the committee finds necessary a correspondingly large number of short-term recommendations.

Technical Institutes

Considerable attention was focused on technical institute education during the past year through three unprecedented actions. Early in the year, Engineers Joint Council held a general assembly in New York City at which the topic of the engineering technician received considerable attention for the first time. In addition, during the summer the President's National Committee for the Development of Scientists and Engineers created a working group to design an action program for the development of more and better qualified engineering technicians. Also, during the year, it was announced that in an effort to establish and compile a body of factual information on the subject of the engineering technician, the Technical Institute Division of The American Society for Engineering Education requested and received from the Carnegie Corporation a grant for the purpose of studying technical institute education in the United States. With this growing interest shown by government, industry, and education in the extended use of technicians in the "engineering team", the function and responsibility of the technical institute becomes a matter of concern to a growing group of persons.

Financing Accrediting Activities

The accrediting activity is no more immune to rising costs than any other activity. An increase in the charges appears inevitable for the coming year. This charge will be designed in accord with the following principle approved by the Executive Committee. The profession, through ECPD, will supply the overhead of the central office administrative expense, while the institutions inviting visitation with a view to accrediting will bear the expenses associated with arranging, carrying through, and evaluating the results of the examination of their curricula.

Chairman's Conclusion

At the conclusion of his last report as chairman of this committee, the chairman bears testimony to the satisfactions of working in this activity. Even when curricula and operations of an institution have been criticized vigorously, the character of its considered response has reflected deep dedication to cause rather than the personal reactions which would be only human under the circumstances.

Even more intimate have been the satisfactions of working with the members of this committee and its headquarters staff. In their sense of personal dedication and generous contributions of professional and personal service to a common cause for the profession, the spirit of this group is outstanding. Individually and in groups they not infrequently face problems quite as delicate, difficult, and demanding of the highest skills and judgment as those for which the professional executive or counsel is paid an impressive salary or fee. Yet the members of this committee contribute their services (and members of inspection teams as well) out of extremely busy schedules and frequently from time otherwise available for consulting or other personally or professionally profitable activity. It is a privilege and pleasure of the highest order to share the activities of such a group.

Student Development Committee

Chairman,
N. W. Dougherty,
Dean of Engineering,
University of Tennessee

E.I.C. Representative,
H. Brian White,
Montreal, Que.

A brief review of some materials on professionalism may be helpful to those who are doing instruction

(Continued on Page 1715)

Elections and Transfers

At the meeting of council held at Victoria B.C., November 10, 1956, a number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected.

MEMBERS

H. R. Baines, Hamilton
J. S. Bright, Toronto
E. S. Buhayar, Montreal
L. B. Crossing, London, Eng.
R. J. A. Fricker, Montreal
R. A. H. Galbraith, Ottawa
R. D. Gilbert, Windsor
G. C. Gregory, Toronto
W. R. Haynes, St. John's
T. L. Hennessy, Sudbury
C. N. Hopkins, Shawinigan Falls
J. V. Laurient, Calgary
D. H. Lee, London, Eng.
J. R. Lindsay, Montreal
C. L. Moon, Brampton
W. E. Morden, Brockville
R. W. McCurdy, Shawinigan S.
R. D. Perry, Trail
E. N. Reed, Ottawa
L. S. Roullier, London, Eng.
V. F. H. Samson, Montreal
D. Segal, St. John's
J. R. Simpson, Toronto
J. R. Traves, Montreal
P. Tuck, Peterborough
W. H. Wisely, New York, N.Y.
J. E. A. Yeats, Montreal

JUNIORS

Y. J. Fokkinga, Montreal
G. J. Jakobson, Montreal
P. L. Mullen, Montreal
A. P. Ruffo, Montreal
W. L. Sutherland, Brockville
M. A. Wilson, Hamilton

Confederation

Word has just been received from Charlottetown, P.E.I., that the first joint meeting between the branch of the Institute and the Association of Professional Engineers was held there on Thursday, October 25.

The business of the Association was to appoint officers for the ensuing year. This was done very simply, by electing to the various posts the persons who occupied similar posts on the executive of the Institute branch. Herewith are the officers so elected.

Chairman, Norman F. Stewart
Vice-Chairman, C. W. Currie
Secretary-Treasurer, C. F. Buckingham
Members of the Executive Committee, R. D. Donnelly, John MacDonald, Laurie Coles, Gordon Milligan
Councillor, Stuart Veale

This same procedure is followed precisely in the province of Saskatchewan and almost precisely the same in the province of Manitoba. Those provinces seem to like this procedure and it is interesting to see that P.E.I. has followed their good example.

This is indeed Confederation. It is a policy quite similar to that adopted by these provinces that many members of the Institute have in mind when they speak of Confederation. It is simple, it is economical and it is effective.

Ball and Rod Mills. An award-winner in the E.I.C. Photographic Exhibit, 1956, this picture was exhibited by Dominion Engineering Works, Limited.

ECPD Meets in Detroit

(Continued from Page 1712)

in this area. The chairman was a member of the EJC Committee on Employment Relations which studied employment practices for some two years and came up with recommendations which were published as an EJC report on "raising professional standards and improving employment conditions for engineers." The report gives a brief discussion of employment conditions, including the impact of collective bargaining on the employment of engineers. It further defines professionalism and makes suggestions regarding solutions of the employment problem. One short paragraph will give a glimpse of its contents: "Prestige, however, is something which must be won. It cannot be bought or automatically accorded through affiliation with an organization. It is something that one can *command* but never *demand*. In the final analysis an engineer achieves professional standing only to the extent that he accepts his responsibility to himself, to his client or employer and to society."

Guidance for Student Engineers

A major activity begun by the committee during the present year is guidance of students while they are in college. Average losses are more than 50 percent of the entering students. Studies which have been made indicate a number of causes as, for example, discouragement due to low grades, developing a new interest, financial problems, entering the armed services, etc. A University of Missouri follow-up of engineering drop-outs summarizes the problems as follows:

1. Lack of guidance in high school.
2. Lack of good preparation for engineering.
3. Need for better orientation, advisement, and student-staff understanding.
4. Knowledge of the requirements in engineering causes the student to change to some other activity.
5. Many of the dropouts thought the engineering program was not practical enough, though very few of them thought there should be a reduction in mathematics.

There is a lack of understanding on the part of some students, and parents as well, that certain scholastic standards must be maintained to remain in college. Many feel that once they are in college the college is obligated to give them an education regardless of the time it may take to do it.

Failures are due to:

1. Lack of motivation.
2. Lack of aptitude.
3. Counsellors advising an engineering college when a technical institute is in order.

1. There seems to be no way of psychologically measuring or otherwise determining motivation. Boys showing high aptitude for engineering sometimes just do not have the motivation to exert the effort, and it is doubtful that it can be cultivated to last for more than just a short-time spurt. It is something innate to the boy's makeup. This deficiency may occur in boys from wealthy families who never had to struggle for their existence. There is not much that can be done after they arrive in college, although parents think that colleges should imbue them with the enthusiasm that they themselves failed to develop in the growing-up period.

2. There are boys who lack aptitude but have intense interest. Many of these boys succeed eventually simply by persistent effort usually over an extended period of time. Often interest is mistaken for aptitude, particularly on the part of parents and the boy is forced into a program too heavy for his abilities. It is particularly difficult for counsellors to get the parents to understand this.

3. This is related to 2 above. Parents often force a boy into engineering college because of a demonstrated aptitude to build a radio receiver or to service the family car, even though he shows up poorly in mathematics in high school. Such a boy should be guided to a technical institute or to some other field of activity, but once he is in college and his deficiencies begin to show up he feels that he is being degraded to be advised to transfer elsewhere. He therefore persists in college, until the tragedy of failure catches up with him.

Actually, counsellors in the engineering colleges need some good information on technical institutes and their programs so as appropriately to advise boys and parents of the dignity and useful aspects of such types of training. This could save some misfits in college and at the same time help relieve the engineer shortage by providing more technically trained assistants.

Professionalism

Many engineers have the strong feeling that the professional attitude is something that "can't be taught but must be caught". It is a mien, a mannerism, a personal characteristic that the student gets by association with professional people; he gets it from his teachers, his preacher, his banker. That puts a real responsibility on his teachers in particular, and it is here that engineering teachers are somewhat lax. Careless dressing, sloppy handling of pipe or cigarettes, public drinking, swearing, and poor English are all contributors to the public's lack of respect for the engineer. One often sees much more dignity in the medical, law, and divinity schools than he does in the engineering schools.

The Cult of Mediocrity

We oldsters "view with alarm" some of the trends of present-day engineering education. Our schooling was in a period of small numbers and individual contacts with faculty members. Just ahead, the schools will increase their enrollments and at the same time they will have more difficulty in finding qualified faculty members. There will be a temptation to mold students into a pattern, to make them as uniform as group education can devise and, as a result, we may border on the cult of mediocrity.

Training Committee

Chairman,
Edwin L. Yates,
Director, University & College Relations,
General Motors Corporation—Detroit
E.I.C. Representative,
George L. Schneider,
Hamilton, Ontario

Major attention of the committee during the past year has been focused on activities designed to implement "The First Five Years of Professional Development" program in specific communities.

The project was introduced to the Detroit industrial community last fall in a meeting sponsored by the local committee at the Engineering Society of Detroit. Representatives of some 200 companies attending the meeting heard Mr. George Porter, chairman of the local sponsoring group; Mr. J. C. McKeon, director of training, Westinghouse Electric Corporation; Professor Cornelius Wandmacher, University of Cincinnati; and members of the local committee tell of objectives of the Five Year Program and plans for its application in Detroit.

In Cincinnati the local committee has continued active in promoting the objectives of the program first started in this community in 1952.

Part-time graduate study for practising engineers, directly supported during the past three years by the local industry committee, is now well established as a regular part of University services to the community. The first advanced degrees awarded primarily on the basis of part-time work may be expected to be granted in June, 1957. A new program in nuclear engineering has attracted wide attention from practising engineers both within and beyond the First Five Years Program.

Professional Development Programs, as operated in Canada, are built on the six points promoted by the Training Committee. Many of these programs are now in their seventh year in Canada. Currently, projects are in full swing in such centers as Quebec, Hamilton, Halifax, Winnipeg, Ottawa, Belleville, Cornwall, Kingston, Saguenay, Saskatoon, and Toronto.

With respect to "Continued Education of Graduate Engineers," The Engineering Institute of Canada branches presently are sponsoring some fifteen courses. These not only deal with technical subjects, but are primarily lectures and courses in the nontechnical field designed to promote a broadened outlook to enable young engineers better to express themselves, and in general to foster their over-all development. During the past year approximately 450 young engineers enrolled in such courses, and it is estimated that since their inception, over 2000 engineers have benefited from these programs.

Recognition Committee

Chairman,
George H. O'Sullivan,
Electrical Engineer,
T. G. White Engineering Company,
New York, N.Y.
E.I.C. Representative,
Guy Savard,
Montreal, Quebec

A number of studies have been started or continued during the past year, each of which is treated in some detail herein:

Definition of Engineering

The subcommittee has continued its study. Since the publication of a suggested definition in the 1955 report, well over fifty letters have been received from individuals and groups, all of whom obviously have given a great deal of consideration to the subject, and many of whom have contributed helpful suggestions and criticisms. Most of the reactions have been favorable, with suggestions for improvements, although some have found considerable fault with the definition.

As a result of a study of all criticisms and suggestions received, the following definition is suggested. Several points on which a number of comments have been received are discussed.

Engineering is the Profession in which a knowledge of the mathematical and physical sciences gained by study, experience and practice is applied with judgment to develop ways to utilize, economically, the materials and forces of nature for the progressive well-being of mankind."

It has been suggested that the profession provide itself with a new designation to replace "Professional Engineer". A subcommittee under Mr. Goodkind is now studying this problem.

A committee of EUSEC is now studying foreign experience and practice on this matter, and the findings of that committee will be included in our study.

Meanwhile several suggestions have been received from individuals, and these, too, will be considered.

Prestige for Young Engineers

An important phase of the problem of developing and maintaining the interest of young men in our profession is that of increasing the use of their creative abilities and minimizing the amount of routine work. To many, this takes precedance over salary but we must provide recognition of their attainments.

Since professional service is basically a service of individuals who have individual responsibilities, it behooves those of us having engineers under our direction to guide each one in his professional development. Our Training Committee has established guideposts to assist in orientation of the young engineer, encouraging his self - development through self-analysis and continuing study. We can encourage him to participate actively in his engineering society. A professional man will willingly accept the privilege of serving his profession. He should attend meetings and present papers. He should participate in leadership through committee work and Section activities. He should advance to Associate Member and full Member grade as he becomes eligible. When he is qualified, he should establish his legal standing by registration as a Professional Engineer.

In his day-to-day work as he acquires judgment and is responsible for engineering work, it should be recognized. Why should not drawings and specifications be certified by the young engineers who actually do the engineering work, as well as by the head of the department in charge? This would aid in the prestige of the growing engineer. It would serve to recognize him as an individual professional man rather than as a doer of routine work.

Model Law

It has been suggested that the Model Law be revised to include a clause covering practice by others than individuals. Since the entire subject of such practice is now under study by a committee on which ECPD is represented, the Recognition Committee has not considered this suggestion.

Ethics Committee

Chairman,
C. J. Freund,
Dean of Engineering,
University of Detroit
E.I.C. Representative,
J. E. L. Roy,
Hydro Quebec,
Montreal, Que.

During the past year the Ethics Committee has undertaken a new phase of activity and responsibility.

The original task of the committee was to formulate the Canons of Ethics, to obtain approval of the Canons by ECPD, and to publish them. The formulation of the Canons was a difficult assignment because of much difference of opinion in the engineering profession. These differences of opinion had to do with the structure and phraseology of Canons of Ethics, with their scope, and the detail to which they should be worked out. There has been at no time any lack of agreement concerning essentials of ethics in the profession. Furthermore, a number of constituent societies of ECPD had already published codes of ethics or professional practice of their own, and the Canons of ECPD necessarily had to conform to these various codes and standards.

In spite of difficulty the committee succeeded in time in constructing Canons which were accepted not only by Council, but by the governing bodies of the constituent societies.

Thereupon the committee undertook to prevail upon American and Canadian engineering societies to endorse or accept the Canons. Over a period of years, in excess of 80 engineering societies have endorsed the Canons, and several of them have adopted the Canons as their own codes of practice and ethics.

A New Outlook

During the year it has appeared to the committee that this phase of its work has been largely accomplished, and that the committee should begin new projects. This does not mean that the committee will discontinue its efforts to interest societies in the Canons; it means rather that to interest them should no longer be the committee's principal assignment.

Accordingly, the committee has determined hereafter to concentrate upon the creation of much greater interest in ethics among engineers, particularly as a means for increasing professional understanding and consciousness among them. The committee believes that too many professional engineers look upon ethics as an academic or abstract problem which does not directly concern them. It is apparent that there are engineers who do not appreciate the relation of ethics to professional status, and that there are even some who do not know just what is meant by ethics as applied to the profession.

Both Technical Competence and Integrity

For instance, there seems to be a tendency among engineers to assume that technical competence is the sum total of professional responsibility. Of equal importance to the professional man is his integrity. He commands the confidence of his employer or client not merely by knowing his business but likewise by his reputation for honesty. The ordinary lay employer or client is not competent to appraise the engineer's work. Hence, the employer or client is completely dependent upon him. Since he is completely dependent upon him he must be assured both that the engineer is technically competent and that he is morally responsible.

To be morally responsible means that he subscribes to and complies with an established set of ethical principles which is recognized by the profession. Such an established set of ethical principles are the Canons of ECPD.

Information Committee

Chairman,
Walter E. Jessup,
Editor,
Civil Engineering,
New York, N.Y.
E.I.C. Representative,
L. Austin Wright, Editor,
The Engineering Journal,
Montreal, Quebec

The Publication Fund of ECPD is used, on approval of the Executive Committee of Council, for printing ECPD publications. All but 20 percent of the sales of publications is credited to the Publication Fund, the 20 percent is credited to the general operations account to offset overhead costs of handling, postage, and envelopes. As the stock of publications is depleted the Publication Fund grows.

The Information Committee approved revision or the reprinting of the following several publications, the cost of which will be close to $17,000.

The Second Mile. Since the edition of 1950, 10,000 copies of *The Second Mile*, an address by the late Dr. William E. Wickenden, have been sold.

Canons of Ethics for Engineers. In July 3000 copies of the *Canons of Ethics for Engineers* were reprinted, enough for about one year's sales.

Professional Guide for Junior Engineers. In July, 5200 more copies of the popular *Professional Guide for Junior Engineers*, originally written by the late Dr. William E. Wickenden, were reprinted. Each year the ASME, AIME, and EIC send a copy of this booket to their recent graduates.

Engineering—A Creative Profession. Two years ago 75,000 copies of *Engineering—A Creative Profession* were printed. By November 15 the third edition should be ready for distribution and sale. An edition of 100,000 has been authorized.

Manual for Engineering Career Advisors. The Guidance Committee revised the text of the *Manual for Engineering Career Advisors* and on recommendation of the Information Committee, the Executive Committee authorized a printing of 5000 copies.

Reading List for Engineers. The Training Committee revised the text for the pamphlet, *Reading List for Engineers*, and the Information Committee had 5000 copies printed to replenish depleted stock.

Personal Appraisal for Junior Engineers. Close to 1000 copies of the Personal Appraisal Form for Junior Engineers are requested each year. The stock was replenished in August.

ECPD-EJC Joint Committee on Practice of Engineering

Chairman,
Charles Molyneaux,
New York, N.Y.
E.I.C. Representative,
G. Ross Lord,
Professor of Mechanical Engineering,
University of Toronto,
Toronto, Ontario

This committee was appointed in August, 1954; since that time it has met several times and carried on extensive correspondence. The membership of the committee gives a wide sampling of professional affiliations, geographical location, and points of view. Our studies ranged widely over the "Practice of Engineering" and our interim reports to the appointing boards reflected the general nature of our assignment.

At our January, 1956, meeting the committee decided that it was ready to direct its attention to specific aspects of professional practice and so reported to the board of EJC. The report and appearances of the chairman at the February and March meetings of EJC resulted in the following specific assignment:

1. To consider corporate practice.
2. To consider the responsibilities of partnerships.
3. Reciprocation in licensing.

Recognizing the national scope of EJC and ECPD, as well as their representation of all branches of the profession, the committee has concerned itself with principles rather than specific instances.

Corporate Practice

With reference to corporate practice, the committee recommends that it be the policy of EJC and ECPD that:

> Under certain conditions, corporations should be allowed to provide engineering services.

In an engineering corporation a majority of the officers, as well as those responsible for the engineering work, must be registered professional engineers in the State of incorporation, and that the engineers supervising work must be licensed in the State in which the engineering duties are performed.

Partnerships

The committee is of the opinion that the usual obligations of partnerships are very clear in the law. It also recognizes that questions of ethics, by their nature, go beyond law, and it is the unanimous recommendation of the committee that our boards go no further in questions of partnerships than to recommend that the Codes of Ethics of the constituent societies be made absolutely clear on the point.

ECPD-EJC Joint Task Committee On Survey of the Engineering Profession

Chairman,
Morris D. Hooven
E.I.C. Representative,
K. F. Tupper,
Toronto, Ontario.

At the 1955 ECPD Annual Meeting in Toronto on October 14, Council passed a resolution that it sponsor a survey of the engineering profession, seeking the concurrence of its constituent societies in undertaking such a survey. The Council referred this resolution to its Executive Committee for implementation.

At the December 5, 1955, meeting of ECPD's Executive Committee in New York, it was voted that EJC be requested to act with ECPD in appointing a joint steering committee for implementation of the resolution passed in Toronto.

At the January 25, 1956, meeting of the Board of Directors of EJC, it was voted to authorize the president of EJC to appoint the EJC members of an ECPD-EJC Joint Task Committee on Engineering Profession Survey.

The formation of this committee was completed in April. It met on May 18 in New York and worked throughout the summer in preparing a proposal for presentation by ECPD and EJC to their respective constituent societies for endorsement. Their proposal will appear in the next issue of the *Engineering Journal*.

Dr. Louis S. Pariseau Honoured

Dr. Louis S. Pariseau, M.E.I.C. of Montreal, retired superintendent of Quebec canals for the Federal Government, celebrated his one hundredth birthday on October 22, 1956. This great event received the attention of the engineering profession, and was marked by L'Ecole Polytechnique, Montreal, at an informal reception held on October 30 under the auspices of the Graduates Society. Dr. Pariseau graduated with the first engineering class of Polytechnique, in 1877.

Dr. Pariseau was earlier awarded an honorary doctorate of engineering by L'Ecole Polytechnique on the occasion of its seventy-fifth anniversary celebration in 1948.

Doing honour to the revered centenarian who served the engineering profession for fifty-three years were the officials of L'Ecole, its professors, students and Graduates Association, as well as the Corporation of Professional Engineers of Quebec, and The Engineering Institute of Canada.

An engraved certificate was presented to Dr. Pariseau by Dean Gaudefroy, on behalf of L'Ecole. R. L. Dunsmore, vice-president of the Engineering Institute, offered the gold Engineering Institute membership pin and commented on Dr. Pariseau's long and honourable service to the engineering profession since the time that he became a charter member of the Institute in 1887. He attained Life Membership in 1917. E. D. Gray-Donald, M.E.I.C., chairman of the Montreal Branch of the Institute was also present.

P. A. Dupuis, M.E.I.C., president of the Polytechnique Graduates Association, read a moving address which was responded to by Dr. Pariseau. Mgr. Irenee Lussier, P.D., rector of the University of Montreal, extended his best wishes to Mr. Pariseau.

The Corporation of Professional Engineers was represented by Leo Roy, president.

Some notes on Dr. Pariseau's career make an interesting story: In 1877, he was named a professor at Ecole Polytechnique, at a salary of $50 per month. In 1879 he started his work with the Federal Department of Railroads and Canals as a chainman. He was later associated with work on the Grenville canal, surveys of the Richelieu River, and surveys for the Lachine canal. He was appointed superintendent of canals for Quebec in 1923. He retired in 1930, well known as a pioneer in construction methods for public works.

At reception honouring centenarian engineer L. S. Pariseau are, E. D. Gray Donald, Henri Gaudefroy, Dr. Pariseau, and R. L. Dunsmore.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

Title of "Engineer" for Use by Individuals—Not Corporations

The Act governing the practice of engineering in Quebec stipulates that the title "Engineer" is reserved exclusively to members of the Corporation of Professional Engineers of Quebec. Consequently, a firm not being eligible for membership in the Corporation may not legally use this title.

In the past the Corporation has tolerated the use of the title "Engineer" by firms owned or managed by professional engineers or employing professional engineers. However, this practice has led to serious abuse and the Corporation has reached the conclusion that it would not be properly fulfilling its main duties to the public if this practice was allowed to continue. In addition there is evidence that the prestige of our profession is adversely affected by these abuses.

Consequently, it was decided a few years ago to request all firms using the title "Engineer" in their advertisements to discontinue this practice in the best interest of the profession and of the public which it serves.

Many firms have undertaken to comply with this request on a voluntary basis and in a spirit of cooperation. The Council has recently decided to enforce this request now that every interested party has been given ample opportunity to abide by the law on a voluntary basis.

Wish Annual Meeting

The question of the use of the title "Engineer" in advertisements, letterheads and elsewhere differs from the question of the practice of engineering by the same firms. It will be recalled that a debate was held on this topic at the last annual general meeting of the Corporation and that the Council has agreed to postpone any definite action on this second question until it has been thoroughly debated at committee Council and general meeting levels. Particularly Mr. MacCallum's opinion as expressed at the annual meeting was to be discussed by the committee on directing principles of the engineering profession.

Committee on Advancement of Employee Engineer

A very important committee is at work this year at the Corporation, namely the committee on the advancement of the employee engineer. In order to insure participation of all the membership in the work of the committee, five subcommittees have been set up in various areas of the province. These sub-committees will respond to a co-ordinating committee composed of the chairmen of the subcommittees. It is felt that the creation of this committee will provide the membership with an excellent opportunity to express their views and comments on the status of the employee engineer as well as on the problems which confront him.

Salary Schedule

Our membership was recently advised that during September two copies of the June 1956 issue of the schedule of salaries have been forwarded to the director of personnel of each of the organizations with whom our members are associated. Our mailing list did not include the consulting engineers and those firms whose management was known to us as belonging to the Corporation.

1957 *Annual Meeting*

The next annual meeting of the Corporation will be held on March 23, 1957, at the Mount-Royal Hotel in Montreal. As part of this meeting, there will be an exhibition of films and slides. This is in keeping with a tradition established some years back, which makes it possible for those of our members who engage in art work during their leisure time to receive public recognition of their effort.

(*from the Bulletin of the Professional Engineers of Quebec, October* 1956)

Quebec City may have been a historic site once more on Saturday, September 22, when ten members of the Corporation sat at the conference table in the Cercle Universitaire to consider a proposal for confederation of our profession. This was the first meeting of the newly formed committee on Plan for Unity, appointed by your Council to examine a proposition jointly endorsed by a national committee of the Engineering Institute of Canada and a committee of the Dominion Council of Professional Engineers and presented at the annual meetings of these bodies last spring. Each professional Association and the Corporation have been invited to study carefully the proposal and to submit their reaction to the Dominion Council Committee whose chairman is still J. H. Smith, originator of the Plan some years ago.

The Council has entrusted the following thirteen members with the responsibility of examining the Plan from the standpoint of the Corporation.

Guillaume Piette, chairman, Messrs. Hector Cimon, E. E. Copping, Geo. M. Dick, J. B. Edwards (substituting for W. G. Seline), Henri Gaudefroy, E. D. Gray-Donald, C. C. Louttit, L. Nadeau, R. Painchaud, W. J. Riley, W. G. Seline, and J. St. Jacques.

PRINCE EDWARD ISLAND

ELECTION OF OFFICERS

October 25 was the date set for the election of officers to the Association of Professional Engineers of Prince Edward Island, for the term 1956-57. Choice of the members for the duties of chairman was N. F. Stewart, JR.E.I.C.; vice-chairman, C. W. Currie; and secretary-treasurer, C. F. Buckingham, M.E.I.C.

Executive posts were accorded R. D. Donnelly, M.E.I.C., J. D. M. MacDonald, JR.E.I.C., L. A. Coles, JR.E.I.C., and G. H. Milligan, Affil. E.I.C.

Elected councillor for the Association was W. S. Veale, M.E.I.C.

ONTARIO

Open-Door Policy Stressed

Urging that no undue limitations be placed on engineering student registration, the Association of Professional Engineers of Ontario, in a recommendation passed at the quarterly executive council meeting of the fifteen thousand member Association, called upon the presidents of Ontario universities with engineering faculties, "to see that all possible practical steps are taken to ensure an open-door policy with respect to admittance of engineering students deemed suitable."

The resolution was tabled during a discussion on the possibility that universities might consider limiting registration in the engineering faculties due to current overcrowding, particularly in the freshman year. The Association promised its assistance "in any way possible."

It was pointed out that there were more than seven hundred first-year engineering students enrolled at the University of Toronto, with a total registration in the faculty of applied science of two thousand.

Discuss Enlargement Facilities

During the meeting delegates discussed the possibility of establishing a second university in Toronto or expanding the University of Toronto's present facilities by adding a second campus for engineering students. This would be similar in principle to the former engineering establishment at Ajax, twenty miles east of Toronto, set up by the university after World War II to cope with the increased veteran student enrolment.

Figure Increasing

It was pointed out that 70 per cent of the University of Toronto's present student enrolment is drawn from Metropolitan Toronto and that this figure will increase. Until recently it was only 50 per cent, with the remaining half coming from other parts of Ontario and Canada.

Main problem facing most Canadian universities at present is lack of adequate buildings and teaching staff.

At the meeting, it was announced that during the first nine months of 1956, one thousand three hundred and thirty-six applications for registration in the Association had been received. This compared to a 1955 figure for the same period, of one thousand three hundred and sixty-nine.

Scholarship Program Revision

The Council also announced a revision in the Association's scholarship program which would see both the University of Toronto and Queens' University each being granted $250.00 scholarships for the first, second and third year students. A loan fund has also been opened to engineering students in the first three years at both universities with amounts up to $200.00 per student. Previously the loans were made to high school graduates who were entering university.

Field Representative Appointed

An increase in membership and the expansion of engineering activities has resulted in the appointment of **Blakeley H. Goodings**, as field representative of the Association of Professional Engineers of Ontario. He will work out of the Association's headquarters in Toronto. The A.P.E.O. now has a membership of fifteen thousand registered professional engineers in the province and is the largest professional group in Canada.

In his new position, Mr. Goodings will represent the Association in its liaison with industry and members of the A.P.E.O. throughout the province.

A native of Port Colborne, Ont., Mr. Goodings is a graduate of the University of Toronto in mechanical engineering. Until recently, he served on the staff of the adjutant-general at Canadian Army H.Q., Ottawa, as a captain. He is a graduate from Army Staff College, Kingston, 1955.

Throughout his army career, he served in Ottawa, Kingston, Montreal, and Korea. He spent one year in Korea, and while there, received a citation from the South Korean Government in recognition of his administrative services with Korean troops attached to the Commonwealth forces.

B. H. Goodings

During his Army service he gained considerable experience in the organizing of engineering and administrative work.

Engineers in the News

George Glinski, of Ottawa, has begun the sixth year of lectures on electronic computations and data processing at Carleton College, Ottawa. He has also commenced a new course at McGill College, Montreal, on the application of electronic data processing for business use.

Mr. Glinski, who has long been associated with the electronic computer industry is in charge of the Canadian operations of Electro-Data Division of Burroughs, with headquarters in Ottawa.

D. G. Billings, has resigned from the engineering staff of the Canadian General Electric Co. Ltd., to join the fuel-electric generation department of the Hydro-Electric Power Commission of Ontario in Toronto.

Mr. Billings joined the General Electric organization in 1937 and latterly held the position of manager of an engineering section of the Lansdowne plant in Toronto. He has been active in Association committee work for a number of years and from 1946 to 1949 inclusive, was a member of council of the Association, representing the mechanical branch.

H. L. Hewitt, formerly with Foundation Company of Canada, York Township, and the bridge office of the Ontario Department of Highways, has joined the Department of Public Works, Ottawa, as a supervisor of the bridge section of the development engineering branch. Mr. Hewitt graduated in civil engineering from the University of Toronto in 1927.

James L. Clark, has left the employ of Ontario Hydro in Toronto, where he was with the transmission department, and has moved to San Francisco, Cal., where he has accepted a position with the power division of the Bechtel Corporation of that city.

E. W. Owen, is presently an instructor and part-time graduate student at the Rensselaer Polytechnic Intitute, Troy, N.Y.

Mr. Owen, who graduated in electrical engineering from the University of Manitoba in 1951, was previously assistant distribution engineer with the Ottawa Hydro Electric Commission.

H. W. Whitham, has joined the staff of the Provincial Institute of Mining in Haileybury, Ont.

Ivor Glazer, formerly with Babcock-Wilcox and Goldie-McCulloch Ltd., Galt, Ont., has accepted a position as project engineer in the power engineering department of The Fluor Corporation Ltd., Los Angeles, Cal.

Gordon A. Zinn, Toronto, has recently joined Franklin McArthur Associates Ltd., Downsview, Ont. Mr. Zinn, who graduated in engineering from the University of Toronto, was formerly with C. A. Meadows & Associates Ltd., of Toronto.

The first recipient of the Canadian Industrial Development Award is Col. L. F. Lyle, Toronto. The award, was made at the recent annual conference of the Council at Charlottetown, P.E.I. by the Provincial Governments' Trade and Industry Council.

Col. Lyle served with distinction in R.C.E.M.E. during World War II and in 1945 joined the Ontario Department of Planning and Development as director of the trade and industry branch. Latterly he has acted as consultant to the Hon. W. M. Nickle, Minister of the Ontario Department of Planning and Development.

During his service with the Department he has been instrumental in establishing the Provincial Governments' Trade and Industry Council, the aims and object of which are to provide inter-provincial consultation and co-operation on matters of trade and industrial development; to supply traders and manufacturers from Canada and abroad with a nation-wide provincial service in these fields; to promote greater understanding throughout Canada of the economic conditions affecting the developments of each of the provinces and all of Canada.

In the citation of the award Col. Lyle is described as a person who "has made the most significant contribution to the industrial development of Canada in the public interest".

Harris Popplewell, of Toronto, has been named as sales manager of the new industrial products division in Canada of American Biltrite Rubber Co. (Canada) Ltd. of Sherbrooke, Que. The American Biltrite Rubber Co. recently acquired controlling interest in the Boston Woven Hose and Rubber Co., of Cambridge, Mass., and its line of production is now available in Canada.

Mr. Popplewell, who has had an extensive experience in the industrial rubber goods field, will make his headquarters at 2149 Yonge St., Toronto.

Itienne L. Kenez, has moved from Toronto to Montreal and is a design engineer in the concrete section of the general engineering department of the Aluminum Company of Canada, Ltd.

Colin G. Campbell, has left the Powell River Company, of Powell River, B.C., and has joined the Transport Division of Boeing Aircraft at Renton, Wash.

D. P. Murray, of Hamilton, Ont., has accepted a position as sales engineer with American Air Filter of Canada Ltd., and is at present working in the Niagara peninsula. Mr. Murray was formerly associated with Otis Elevator Co. Ltd., in Hamilton.

W. E. Gladney, has become associated with Pigott Contruction Co. Ltd., 1250 Bay Street, Toronto, in the capacity of project engineer.

G S. Arthur, is now living in Niagara Falls, Ont., and is employed at the Welland Plant of North American Cyanamid Co. Ltd., as an industrial engineer.

Mr. Arthur obtained his engineering degree at the University of Toronto in 1951 and prior to his move was a work standards and methods analyst with Ford Motor Co. of Canada Ltd., in Windsor.

R. B. Sweet, of Canada Paper Co., Windsor Mill, Que., has been appointed mechanical superintendent. His previous position was that of assistant mill superintendent.

Michael O. Jones, has recently been transferred from the Singapore assembly plant of Ford Motor Company of Malaya to the Ford Motor Company of New Zealand and Lower Hutt, New Zealand, where he is assistant to the general manufacturing manager. Mr. Jones graduated in engineering from the University of British Columbia in 1951 and very shortly thereafter joined the Ford Motor organization in Windsor, Ont.

Dr. P. J. Sandiford, has been appointed director of operations research in the management advisory services division of Price Waterhouse and Co., Royal Bank Building, Toronto. Dr. Sandiford was formerly chairman of the operations research group in the Hydro-Electric Power Commission of Ontario in Toronto.

W. S. Allen, of Racey, MacCallum and Associates Ltd., has been transferred from the Toronto office of the company to Vancouver, B.C. where the address of Racey, MacCallum and Associates Ltd., is 742 Denman St.

Arthur C. Simpkins, has been made president of Reg. H. Steen Ltd., heating and ventilating contractors, 1119 Davenport Rd., Toronto. Mr. Simpkins, an engineering graduate of McGill University, formerly held the post of secretary-treasurer of the company.

Michael Lasko, of the Canadian Standards Association Testing Laboratories, is moving from Toronto to Winnipeg, Man., to become Winnipeg district engineer of the Laboratories.

Mr. Lasko is a native of Winnipeg and graduated in electrical engineering from the University of Manitoba in 1933. In 1941 he moved to Toronto to serve as a design engineer with the Inspection Board of the United Kingdom and Canada and later as specification engineer with Research Enterprises Ltd. He will be in charge of the new C.S.A. Testing Station at the University of Manitoba which is being established for use by the manufacturers of electrical equipment in the three prairie provinces. He will also be reponsible for all inspections in these provinces and in certain parts of the United States.

R. L. Cavanagh, who was formerly assistant director of the department of engineering and metallurgy of the Ontario Research Foundation, has accepted the position of president with the Non-Destructive Testing Corporation (Canada) Ltd., 16 Advance Road, Toronto, 18. In addition to his administrative duties, Mr. Cavanagh will act in a consulting capacity to industry on metallurgical problems.

Vincent Lautier, has recently returned to Canada and is employed as a patent examiner in the Canadian Patent Office, Ottawa, Ont.

James S. McBride, of Williams and Williams Ltd., Chester, Eng., who recently was with the company's New York office, is now residing in Neston, Cheshire, England.

He has recently attended a course of the Administrative Staff College, at Henley-on-Thames which he reports as excellent not only as a refresher but for the opportunity it afforded for the exchange of views of sixty young executives who came from all part of the world. Mr. McBride expresses the belief that Canadian companies interested in Anglo-Canadian business, will find it profitable to investigate the possibilities of the course.

H. C. Brown, is now employed by Computing Devices of Canada Ltd., Ottawa.

Alan Wilson, who was employed by The National Industrial Fuel Efficiency Service, London, Eng., has accepted a position on the engineering staff of Unilever Limited, St. Bridget's House, London, E.C. 4. Eng.

David J. Olver, has left the employ of the Canadian Comstock Co. Ltd., St. Catharines, Ont., to take a position as electrical designer with the Bechtel Corporation in the head office of its power division in San Francisco, Cal.

G. E. Bourne, of the Canadian General Electric Company Limited, has moved from the Toronto office to the Peterborough plant of the company, where he is specialist, marketing personnel development in the apparatus department.

M. E. Oattes, of the Bell Telephone Company of Canada Ltd., has been moved from North Bay, Ont., to Brantford, where he is supervising engineer.

E. N. Chorney, has recently accepted a position with American Standard Products Limited, of Windsor, Ont. He was formerly employed by the Ford Motor Company of Canada Ltd., also in Windsor.

J. K. Denver, has been appointed assistant mill superintendent, Kerr-Addison Gold Mines, at the Chesterville Property, Virginiatown, Ont. Mr. Denver, who graduated from Queen's University in 1947, was formerly mill superintendent at Macassa Mines Ltd., Kirkland Lake, Ont.

Barry K. Laramy, has recently joined Johnson & Higgins, (Canada) Ltd., of 44 Victoria Street, Toronto.

M. Z. Cerps, is employed by A. D. Margison and Associates Ltd., 30 Eglinton Avenue East, Toronto, Ont.

Andrew J. Elder, has been appointed to the position of load tap changer engineer with Packard Electric Company of St. Catharines, Ont. He was formerly in the power transformer section of Canadian General Electric Company Limited, at Guelph, Ont.

Bernard L. Kellam, of John Labatt Limited, has been transferred from London, Ont., to Shea's Winnipeg Brewery Ltd., 137 Colony Street, Winnipeg, Man.

Dr. Gordon E. Willey, of Welland, Ont., has been appointed a vice-president of the Electro-Metallurgical Company, a division of Union Carbide Canada Ltd.

Dr. Willey graduated from McMaster University in mathematics and physics in 1936, subsequently obtaining his master's degree in 1938 and a doctorate in physical chemistry and metallurgy in 1940 from the University of Toronto.

Prior to joining the Electromet organization in 1954, Dr. Willey spent five years with the Ontario Research Foundation and ten years in industry, eight of which were spent in positions of increasing responsibility with a Canadian major steel producer. Since joining Electromet he has been responsible for ferro-alloy sales and technical service to Canadian steel producers and has carried out investigations on new and special products in which the company is interested.

Donald J. MacIntyre, of Streetsville, Ont., has been appointed a vice-president of Electro-Metallurgical Company, a division of Union Carbide Ltd. A 1935 graduate, in electrical engineering of the University of Toronto, he joined the Electromet organization at that time.

After being in charge of works engineering, he was appointed general superintendent in 1954, having direct responsibility for all operations at the Welland and Beauharnois plants and the quarries at Killarney, Ont., and Melockeville, Que. His experience includes maintenance, construction, industrial relations and production. He has been actively concerned with the installation and construction program which has taken place almost continuously at the Electromet plants during the past fifteen years.

John H. Bradbury, formerly assistant chief metallurgist with John Inglis Co. Ltd., in Toronto is now metallurgist of the Elliott Company, Jeannette, Pa.

Donald E. G. Schmitt, has been transferred to Noranda Mines Limited, Noranda, Que., where he is assistant manager. Mr. Schmitt was previouly at the Pamour Porcupine Mine.

BRITISH COLUMBIA

Engineers in the News

John Guthrie, of the Alaska Pine and Cellulose Co. has been appointed resident manager of the chemical cellulose mill at Port Alice, B.C. Mr. Guthrie had held a similar position at the Woodfibre Chemical Cellulose Mill.

R. H. Richmond, formerly resident manager of the Chemical Cellulose Mill at Port Alice, will go to the large Rayonier Mill at Port Angeles, Washington, as assistant resident manager.

W. A. Williamson, is now general manager of Riley's Vancouver Ltd. Mr. Williamson had been general manager of Electric Panel Ltd. in Vancouver until recently.

D. W. Thomson, has been elected president of the American Society of Heating and Air Conditioning Engineers, B.C. Chapter, for the 1956-57 season.

R. A. Fisk, has been appointed district engineer for Canadian National Railways at Edmonton. He has been serving as assistant engineer, maintenance of way department, at Winnipeg since 1954. Mr. Fisk, who first joined the C.N.R. in 1941 before enlisting with the R.C.A.F., is a 1950 civil graduate of U.B.C.

W. C. Reuger, formerly with John Laing and Son (Canada) Ltd., is now on the staff of Laminated Structures Ltd.

W. Suboch, a 1955 chemical graduate of U.B.C., recently resigned from the Consolidated Mining and Smelting Company at Trail, B.C. and is now taking part-time graduate courses at the University of Toronto.

W. E. Kenny, of the B.C. Power Commission has been promoted from maintenance engineer to operations control engineer and will move his residence from Nanaimo to Victoria.

D. A. MacIntosh, a 1955 civil graduate of U.B.C. and a lieutenant in the R.C.S.M.E. has been posted from Chilliwack to Germany for a two year period.

H. R. Cameron, of the engineering department, Richmond municipality, was appointed municipal engineer of Richmond on October 1.

G. F. Smith, a 1954 electrical graduate of U.B.C., has left a position with the Canadian Broadcasting Corporation in Montreal and is now a distribution designer for the B.C. Electric in Vancouver.

W. O. Codrington, of the Aluminum Company of Canada, has been transferred from Kemano to Montreal.

D. C. MacVicar, has established the rental equipment utilization service at Merritt, B.C. Until recently Mr. MacVicar has been district engineer with the Department of Highways at Merritt.

D. S. Nielsen, formerly with Phillips, Barratt & Partners, is now employed by Alaska Pine & Cellulose Limited in Vancouver.

B. Davis, is now in Montreal as a designer with the Paper Machinery Division of Dominion Engineering Works Ltd. He has been with the Powell River Co.

O. T. Foss, has left Swanson Wright & Co. and joined Westminster Iron Works as a design engineer.

W. V. Rudd, has accepted a position with B.C. Engineering Company Limited. Mr. Rudd had been with H. A. Simon Limited.

Walter Maslanka, has accepted a position with the Powell River Company at Powell River, B.C. Mr. Maslanka recently resigned from the Finning Tractor Equipment Company in Vancouver.

T. G. Lynch is now with Wescoast Transmission Co. as communications engineer. Mr. Lynch had been with Canadian General Electric and recently, Crossman Machinery Limited in Vancouver.

S. D. Cavers, formerly research engineer with the B.C. Research Council, is now associate professor of chemical engineering at the University of British Columbia.

E. Marzocco, who is superintendent of production, coastal region, with the B.C. Power Commission has been transferred from Victoria to Nanaimo.

J. E. Holdsworth, has accepted a position as project engineer with Canadian Schenley Ltd., at their Valleyfield plant, Quebec. It is expected that this position will lead to that of plant engineer at the company's North Vancouver operations. Mr. Holdsworth had been with Canadian Forest Products at Port Mellon. for the past several years.

D. S. Rae, is with the engineering department of MacMillan and Bloedel (Alberni) Ltd., Pulp and Paper Division, Port Alberni, B.C. He had been with Canadian Forest Products at Port Mellon.

J. C. Cant, previously with Dawson, Wade and Macco at Campbell River, is now with the North-West Telephone Co. in the Manning Park area.

W. A. G. Bell, has been transferred from plant engineer, B.C. Forest Products, Youbou, B.C. to assistant project engineer, B.C. Forest Products, Vancouver.

S. C. Maplethorp, previously with Canadian Western Pipe Mills at Port Moody, B.C., is now with Timber Preservers Ltd., in New Westminster.

J. H. Irvine has retired. Mr. Irvine, a life member of the Association, has been in engineering for over 42 years and is well known throughout British Columbia. His last position was that of project engineer with Defence Construction (1951) Ltd. at Vedder Crossing. Mr. Irvine plans to move to Vancouver shortly.

George Wallbank, is now in Oakland, California with Kaiser Engineering. He had been employed by Letson & Burpee Ltd. in Vancouver.

B. E. Valde, has been appointed chief engineer of the Pacific Great Eastern Railways and is located in Vancouver. He had been at Squamish as engineer of maintenance.

J. H. Parliament, of the Granby Consolidated Mining, Smelting & Power Co. Ltd., has been named manager of Phoenix Copper Company Limited, Grand Forks, B.C.

J. M. Stitt, previously design engineer with Granduc Mines Ltd., is also on the staff of the Phoenix Copper Company.

THIRTY-FIVE YEARS AGO

Comment on the Journal of December 1921

So far, in these mirrorings of the *Journal's* past, only one paper of a truly historical character has been found, but the issue for December, 1921, had two. One was an account of the development of the Montreal water works, by the late A. E. Doucet, M.E.I.C., who was then the chairman of the Montreal Water Board, and the other was "Engineering Theory and Practice at the End of the Seventeenth Century", by the late D. S. Ellis, M.E.I.C., of Queen's University.

Prior to 1800, Montreal got its water supply from private wells, from the numerous small streams which drained into the St. Lawrence river and from the river itself. Peddlers also sold water by the "bucket" from puncheons on carts hauled through the streets. Montrealers were paving from about four dollars to as much as sixteen dollars per thousand gallons for their water, prices which seem appallingly high today.

At about this time, the city, with a population of approximately 9,000, provided a limited number of public wells and pumps. The "Companv of Proprietors of the Montreal Water Works" was incorporated in 1800 and received a fifty-year exclusive franchise. It got its supply from a spring on the western flank of Mount Royal and brought it to a reservoir in the town, along the river front, through an unreliable line of wood pipe. The company, in financial difficulties, sold out to another in 1819.

This second company got its supply from the St. Lawrence through new cast iron pipe, some of which was still in service the last this writer knew. By 1843 it had fourteen miles of pipe and was pumping 90,000 gallons a day. The service was poor and the quantity inadequate, which led to the purchase of the system by the city in 1846.

Following the great fire of 1852, the city engaged T. C. Keefer, to design a new system. Mr. Keefer recommended a four and a half mile "aqueduct" from the St. Lawrence above the Lachine Rapids to the Little St. Pierre river to develop about three hundred horse power for pumping. This canal also served as an intake.

This project was carried out and its subsequent history is a record of successive enlargements and modifications. Finally, hydraulic power was abandoned in favour of electricity and since then the growth of Montreal's water works has followed the usual pattern — a new intake, additional pumps, enlargements of the filtration plant and reservoirs, more feeder lines and the like.

Engineering in 1739

Dean Ellis had picked up an old book *"La Science des Ingénieurs dans la Conduite des Travaux de Fortifications et d'Architecture Civil* written by Belidor, a professor at the Royal Artillery School in Paris and published there in 1739. It appears to have been the civil engineer's handbook of the time, for the contents included sections on the mechanics of materials, engineering design, the materials of engineering, earth pressure and retaining walls, foundations, cost keeping, contracts and other subjects.

On reading Dean Ellis' abstracts from and comments on this book one will readily agree with him: ". . . One can conclude that except for mechanical improvements in the way of tools and transportation, there has not been much change in engineering since the time of this old book. And if we were to compare the modern engineer with the engineer of 1700, we would find them very similar in their ideas and methods."

Belidor's theory of beams was much like ours, but he had no conception of the neutral plane and therefore thought that all the fibres of the cross section were in tension, but he realized that the stress in these fibres varied, those at the bottom being the most highly stressed. His experiments on beams taught him that a beam with fixed ends would carry more than one with ends free; by a process partly guesswork and partly induction he concluded that the ratio of the strength of such beams was as two to one. Columns he didn't investigate; they were always of masonry then.

His theory of earth pressure was really our sliding prism theorv. It gave the point of application of the resultant earth pressure as 38.5 per cent of the height of a wall just within the middle third of the base.

Regarding foundations, Dean Ellis had this to say: " . . . Our more advanced methods of calculation and the results of our (analyses) of materials give us an . . . advantage in regard to superstructures, yet when we . . . consider foundations we are not much better off than (the old engineers) were." This was true in 1921, but the case is not so hopeless today.

Those who have the idea that cost keeping is a modern frill should read Belidor's precise instructions on how to keep records of costs which would not only apply to work in progress, but would be good enough to use in estimating.

Most large work was done by contract. Belidor quotes de Vauban, the great French engineer on the subject of contractors: "When we can find contractors solvent and who have the capacity to handle a general contract, it is best to deal with them. But it is rare indeed to find heads steady enough to carry a burden so heavv as a general contract . . . It should be noted that . . . it is well to go through all the forms, but not always to award (the contract) to the lowest bidder. For it is necessary to see if the (bidder has) the intelligence to carry out the contract."

Professional Matters

The formation of two new branches was announced in this *Journal*, one in London and the other in Lethbridge, bringing the total number of branches to twenty-two, not a bad record for only four years. The rest of the branches were holding meetings and listening to papers, but seem to have been in thoroughly peaceful frames of mind. The Calgary Branch, however, was scolded by a member of the press because of the "absolute inabilitv" of most engineers to write anything except "in technical jargon quite incomprehensible to the public." Everv engineer should be able to write clear and concise English, but to condemn all engineers was too drastic.

Nothing had been heard of unemployment among engineers since September, so perhaps it is fair to assume that the depression which had affected them was disappearing. At any rate, the *Journal* closed its fourth volume with this number in a state of apparent content, though, of course, still convinced that engineers' salaries should be raised and that somehow their professional status ought to be improved, two matters which still engage a lot of attention.

R. DeL. F.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Dr. Lionel Clare Charlesworth, M.E.I.C., former deputy minister of public works, railways and telephones and early member of the Alberta civil service, died in Edmonton on September 11, 1956.

Born in Windsor, Ont., on November 17, 1873, he attended Wellesley Public School, the Jarvis Street Collegiate Institute, Toronto, and graduated in 1893 from the School of Practical Science, the engineering branch of the University of Toronto.

Engaged for a time in engineering work at Welland, Collingwood and Rat Portage, Dr. Charlesworth later became an Ontario Land Surveyor in 1898, and a Dominion Land Surveyor in 1903. From 1899 to 1903 he served as Mining Lands Agent of the Ontario government at Kenora.

In 1903 he was appointed district surveyor at Medicine Hat for the government of the North West Territories, and, on the formation of the provinces of Saskatchewan and Alberta, became director of surveys for the government of Alberta.

Appointed deputy minister of public works in 1915, Dr. Charlesworth held this position and also that of deputy minister of railways and telephones, until 1921. From that time until his retirement from active work in 1945, his life was devoted to the highly important work of irrigation. A very live issue in southern Alberta during the series of dry years that commenced in 1917, Dr. Charlesworth played an active part in the preparation of the Irrigation District Act, passed by the legislature, to provide for development of that kind.

Later, when the provincial government became pressed for financial assistance for the construction of irrigation projects and proceeded to guarantee the bonds of certain districts, an irrigation council was appointed. This was a government body exercising certain jurisdiction over all irrigation districts. Dr. Charlesworth became chairman of the Irrigation Council. He also assumed the duties of official trustee of the Lethbridge Northern Irrigation District, which organization had been advanced large amounts of money by the government. During the following years a number of other projects got underway.

countered by settlers on irrigated lands, in meeting the whole cost of construction of the irrigation works, a commission was

In 1929, as a result of difficulties en-

set up to study the situation. Certain recommendations of that commission, in which Dr. Charlesworth was a member, were later put into effect.

In 1930 he accepted an appointment as director of Water Resources, retaining at the same time the post of chairman of the Irrigation Council and official

trustee of the Lethbridge Northern Irrigation District.

Following the proposal of settlers in the eastern block of the C.P.R. Irrigation District to take over the project from the railway company, in 1933, Dr. Charlesworth was requested to report on the matter to the government and was involved in the ensuing negotiations. The result of this was the passing of an act in 1935 establishing the Eastern Irrigation District.

He continued to serve as chairman of the Irrigation Council and director of Water Resources until his superannuation in 1939. From that time until his retirement in 1945 he devoted himself to the duties of general manager of the Eastern Irrigation District, with headquarters in Brooks.

Awarded an honorary degree of doctor of laws by the University of Alberta in 1950 he also received a senior citizen's certificate from the Province of Alberta, on the occasion of the province's golden jubilee in 1955.

In earlier years Dr. Charlesworth was one of those who took a strong interest in the formation and development of the Iron Ring ritual in Canada.

A past president and Life member of the Alberta Land Surveyors Association, he was also a past president of the Professional Engineers Association of Alberta.

Dr. Charlesworth joined the Institute in 1918 as a Member and gained Life Membership in 1946.

Colonel H. M. Bailey, M.E.I.C., city engineer at Yorkton, Sask., for more than twenty years, and veteran of two world wars, died September 8, 1956 at Yorkton.

A native of Eastern Canada, he was born at St. Mary's, Ont., on January 20, 1889, and educated there. His early engineering experience was gained with the Kirkton Telephone Company, St. Mary's, Ont., Stromberg-Carlson Telephone Company, Huron County, and the Tuckersmith Telephone Company, at Seaforth, Ont.

Col. Bailey moved to Saskatchewan in 1911, six years after its formation as a province. His first project was the building of the Davis Telephone System. With Sask. Government Telephone the following year he was responsible for the construction of long distance lines in the north of the province. In 1913 and until the outbreak of World War I, he was superintendent of the electrical department for the town of Melfort, Sask.

Overseas from 1914 to 1919, on command to the Canadian Corps Signals, he did a great deal of work in construcing underground cable systems, in connection with the 172 Tunnelling Company which was in charge of the construction of Vimy fortifications and with the Fourth Army Troop Company engaged in constructing a hydraulic water supply in North Flanders.

Once back in Canada he returned to Melfort to resume his duties as superintendent of the electrical department for the town of Melfort. He became superintendent of public works and utilities in 1921 and in 1922 he relinquished these duties to accept the appointment of town engineer at Melville, Sask. Seven years later, in 1936 he began his long career as city engineer at Yorkton, which was in 1939 interrupted by the onslaught of World War II. Colonel Bailey again offered his services to the Allied cause and left for overseas duty early in 1940. He served with the Seventh Corps which included the First Canadian Division. In 1946 he returned to carry on the work of city engineer at Yorkton.

Colonel Bailey held memberships in the American Public Works Association, the American Waterworks Association and the Canadian Institute of Sewage and Sanitation, as well as the Association of Professional Engineers of Saskatchewan.

Colonel Bailey joined the Institute as an Associate Member in 1922 and was transferred to Member in 1940.

Henry Cormack Grant Ligertwood, M.E.I.C., for many years associated with the Winnipeg Electric Company, died on September 19, 1956, at Winnipeg.

A native of Aberdeen, Scotland, where he was born on September 23, 1896, he had his high school education at Kelvin Technical High School, Winnipeg, and studied engineering at the University of Manitoba from which he graduated in 1924 with the degree B.Sc. in civil engineering. After considerable student engineering experience with the Canadian National Railway and the Manitoba Power Company during the summer months, he accepted a position with the C.N.R. on graduation, as instrumentman and inspector in the bridge engineer's office. Two years later in 1926 he transferred his services to the Manitoba Power Company and Northwestern Power Company also in Winnipeg and worked as an office engineer for a period of five years. In the early thirties he found employment at Regina, Sask., as a sales engineer for Canada Ingot Iron Company. His affiliations with the Winnipeg Electric Company at Winnipeg began in 1937. At that time he was engineer in charge of the construction of transmission lines. In 1939 he assumed the duties of resident engineer in charge of concrete repair work and became construction engineer with the company in 1946. He was named assistant to the manager of the surveys and construction division of the firm in 1953.

Mr. Ligertwood was a member of the Association of Professional Engineers of Manitoba. He joined the Institute as a Member in 1947.

Personals

News of the Personal Activities of Members of the Institute.

Air Commodore Sir Frank Whittle, Hon. M.E.I.C., has been awarded the coveted Franklin Medal, highest honor of the Franklin Institute of the State of Pennsylvania, presented annually to a worker in physical science or technology without regard to country, at the Institute's annual Medal Day ceremonies, held October 17, 1956 at Philadelphia.

Sir Frank Whittle has been mechanical engineering specialist for the Royal Dutch Shell Group since 1953. He is being recognized for his vision in realizing the limitations of the conventional propellor type of power plant for high speed aircraft, his conception of the combination of the principles of the gas turbine and rocket, and his pioneering development of the turbo-jet aircraft engine which has revolutionized high speed flight.

Born in Coventry, Eng., in 1907, Frank Whittle entered the R.A.F. as an aircraft apprentice in 1923. Later, while qualifying as flying instructor he conceived the idea of the turbo-jet engine and in 1930 filed application for a patent. In 1936 Power Jets Limited was formed for the manufacture of an experimental jet propulsion gas turbine to be built according to his design. Later he was appointed to the Special Duty List to proceed with jet engine design, during which period of his career British Thomson-Houston Company used his design to build an experimental engine. Whittle subsequently was put in charge of the design of Power Jets' engines.

In 1944, holding the rank of Temporary Air Commodore, he was awarded the C.B.E. (Commander of the Order of the British Empire). Also at that time the government company, called Power Jets (Research and Development) Limited, was formed to purchase the assets of Power Jets Limited. Whittle remained with the company meanwhile but in 1946 resigned and became technical advisor on engine design and production, to the Controller of Supplies (Air) of the Ministry of Supply. In 1947 he was awarded the C.B. (Companion of the Order of the Bath). Forced to retire from the R.A.F. in 1948, due to ill health, he was also knighted that year. He held the appointment of Honorary Technical Adviser to the British Overseas Airways Corporation, 1948 to 1952.

He has received many honorary degrees as well as a number of awards internationally recognized.

Frederick Krug, M.E.I.C., president of the International Power Company, Limited, Montreal was among those who received a citation at the recent convocation of the Cooper Union for the Advancement of Science and Art.

The convocation, held in New York, October 6, 8, 9, 1956, inaugurates its Centennial Program. Panels of outstanding educationalists, engineers, scientists, and businessmen discussed the topic, "Tapping Hidden Resources for America's Future Engineers and Leaders."

The program included the presentation of citations to twenty-five distinguished alumni who were selected by their peers as the recipients of the first alumni citations the Cooper Union has awarded.

D. B. Armstrong, M.E.I.C., was appointed during this year an Engineering Institute representative on the executive committee of the Column Research Council. Mr. Armstrong is chief engineer of the eastern division of Dominion Bridge Company Limited, Montreal.

The Column Research Council is a project of the American Society of Civil Engineers, founded to sponsor and carry on research in civil engineering and particularly in the theories of columns and other compression members. It is a technical board with about fifty members representing technical societies, universities, trade groups and industry.

Engineering Institute representatives are P. L. Pratley, M.E.I.C., consulting engineer, of Montreal, and John N. Finlayson, M.E.I.C., of Vancouver, former dean of the faculty of Applied Science of the University of British Columbia.

W. A. Dawson, M.E.I.C., was re-elected national president and chairman of the board of directors of the alumni association of Queen's University for a second term, at the recent annual meeting.

Today Queen's University boasts some 16,000 graduates and forty-two active alumni branches established across Canada and the United States.

Mr. Dawson is associated with The A. R. Williams Machinery Company Limited as their representative sales engineer in Hamilton and the Niagara Peninsula.

He is a past chairman of the Hamilton Branch of the Institute.

F. W. Bradshaw, M.E.I.C., has been appointed executive assistant to the president of the Consolidated Paper Corporation Limited.

Associated with the pulp and paper industry since 1921 Mr. Bradshaw joined the Corporation in 1934 and has served as chief engineer, manager of the Laurentide Division and manager of manufacturing.

He is a past-chairman of the St. Maurice Valley Branch of the Institute.

William A. Bentley, M.E.I.C., former contract engineer with Dominion Bridge Company Limited has been named sales manager of the Ontario division of the firm.

Born in Toronto and educated at Central Technical School and University of Toronto, he joined the staff of McGregor and McIntyre Works Limited at Toronto in 1927. After this company was acquired by Dominion Bridge Company Limited in 1928, he served in the drawing office, short order department and the design office.

In World War II he was resident engineer at the Sorauren Avenue munitions plant. Since 1946 he has been sales engineer in charge of mining sales. From 1951 to 1952, he was on loan to the Department of Defence Production. In 1955 Mr. Bentley was appointed contract engineer.

F. Gordon Murphy, M.E.I.C., general manager of the electric products department of Linde Air Products Company, division of Union Carbide Canada Limited in Toronto has recently been named general sales manager of industrial products with the firm.

A 1940 graduate of the University of Toronto in mechanical engineering Mr. Murphy has been on the staff of Linde Air Products and its predecessor for the past ten year, holding various positions in the Ontario and Quebec areas.

F. M. Pratt, M.E.I.C., formerly of the Anglo Newfoundland Development Company Limited, Grand Falls, Newfoundland, retired from his position as chief engineer in May 1956, after twenty-three years service with the firm. Now, resident in his native Ottawa, Mr. Pratt intends to engage in work as an engineering consultant in that city.

Mr. Pratt spent a number of years with the E. B. Eddy Company Limited in Ontario, as chief engineer, prior to 1933 when he joined the Newfoundland firm. A graduate of the University of Toronto, he spent three years overseas with the Canadian Engineers, early in his career, during World War I.

• PERSONALS

E. de Haas, M.E.I.C., **W. E. Cooper**, M.E.I.C., of the Hydro Electric Power Commission of Ontario are lecturers in a program comprising a course in nuclear energy, which began in Toronto this fall.

The two-hundred and fifty participants, mostly professional engineers, are members of the Ontario Hydro Unit of the Canadian Federation of Engineers and Scientists.

Responsible for the first five lectures, Mr. de Haas addressed the group on nuclear physics. In the five remaining talks, Mr. Cooper will deal with reactor technology.

Walter G. Seline, M.E.I.C., of Trois-Rivieres, Que., has been appointed manager of the Quebec manufacturing division of the Packard Electric Company Limited of St. Catharines, Ont., at Trois-Rivieres.

Born in Finland and educated in Winnipeg, Mr. Seline graduated from the University of Manitoba in electrical engineering in 1945. On staff at the University the following year, Mr. Seline joined the Shawinigan Water and Power Company at Shawinigan Falls, Que., in

W. G. Seline, M.E.I.C.

1947. From 1948 to the present time he was design engineer in the electrical repair department of the company at Trois-Rivieres.

Mr. Seline is a member of the Corporation of Professional Engineers of the Province of Quebec, and the American Institute of Electrical Engineers.

COURTAULDS (CANADA) LIMITED

Drummond Giles, M.E.I.C., president and general manager of Courtaulds (Canada) Limited, held office in the Institute in 1950 as a vice-president representing the province of Ontario. In 1947 and 1948 he represented the Cornwall Branch on the Council of the Institute.

Mr. Giles was appointed president and general manager of Courtaulds in 1949, having served the company since 1944. He resigned from the position of special assistant to the co-ordinator of production in the Department of Munitions and Supply, Ottawa, at that time.

Jack Morris, M.E.I.C., manager of the plant in Cornwall, is at present active in the affairs of the Institute, serving as chairman of the Branch in that city. He also held office in 1955.

Originally from England, Mr. Morris came to Canada in 1933, and joined Courtaulds in 1945 after periods of duty with the Princess Louise Fusiliers (MG) as a general staff officer and with N.D.H.Q. as assistant to the director of chemical warfare.

George van Beek, M.E.I.C., has been appointed chief plant engineer with Courtaulds (Canada) Limited at Cornwall, Ont.

Mr. van Beek joined Courtaulds in 1955 as chief services engineer, following a six-year appointment with the Howard Smith Paper Mills Limited at Cornwall as assistant chief power engineer.

A native of Holland, Mr. van Beek came to Canada in 1924 and received his education in the public and high schools of Chatham, Ont. In 1940 he enlisted in the Royal Canadian Navy, engine room branch, and served for five years. On his discharge he entered Dalhousie University and obtained a B.Sc. degree in 1948. The following year he was awarded a B.Eng. degree at Nova Scotia Technical College.

P. H. Nasmyth, M.E.I.C., of Courtaulds (Canada) Limited, Cornwall, Ont., has resigned from his position as chief plant engineer in order to return to his former home in Western Canada. Associated with the textile organization for seven years, he served as plant engineer for four years.

Mr. Nasmyth graduated from the University of British Columbia in 1942 with a B.A.Sc. degree in mechanical engineering. During the next three years he saw extensive service overseas with the R.C.E.M.E. At war's end, returning to Canada, he accepted employment with Robert A. Rankin and Company Limited, consulting industrial engineers, as a project engineer in charge of Courtaulds plant extension in Cornwall.

The Courtaulds engineering staff at Cornwall consists very largely of members of the Institute. Some of these members are as follows:

L. H. Snelgrove, M.E.I.C., planning engineer for the organization, joined the staff in 1946, following graduation from McGill University with a B.Eng. in electrical engineering in 1946.

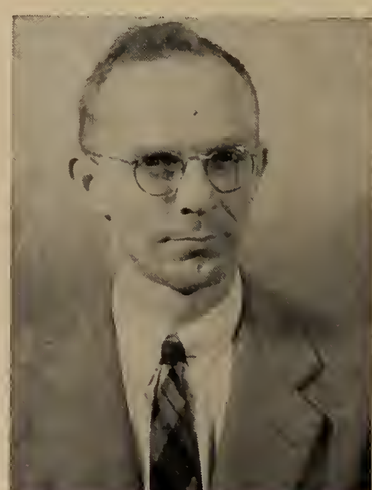
M. H. D. Broadbent, M.E.I.C., a native of England, who was awarded an A.M.I. Mech. Eng. in 1952, joined Courtaulds in 1955. He serves as an assistant plant engineer.

J. Haworth, JR.E.I.C., design engineeer on the engineering headquarters staff of Courtaulds for the past three years, is a Queen's University graduate, class of 1947, in mechanical engineering.

Donald C. McEwan, JR.E.I.C., assistant plant engineer, originally became associated with the organization in England in 1952. He came to Canada as a member of the plant engineering staff in 1953. A 1949 graduate of Edinburgh University in mechanical engineering he has previously had four years experience as a design development engineer in England.

Graham B. Wray, M.E.I.C., a design engineer on the engineering headquarters staff of Courtaulds (Canada) Limited, joined the company in 1955. A native of England, Mr. Wray received his G.M.I. mech. eng. from the Royal Technical College at Glasgow, in 1952.

James D. Buchanan, M.E.I.C., assistant plant engineer with Courtaulds for the last year is a graduate of Glasgow University, class of 1947. He has held supervisory positions in several well-known engineering firms in England.



P. H. Nasmyth, M.E.I.C.

G. van Beek, M.E.I.C.

• PERSONALS

John H. Fox, M.E.I.C., has been appointed vice-president in charge of sales with Honeywell Controls Limited, formerly known as Minneapolis-Honeywell Regulator Company Limited, Toronto.

Mr. Fox was named general sales manager, responsible for the sales activities of all divisions of the company's twelve Canadian offices in 1953.

He has been associated with the organization since 1935, working in various sales engineering and sales management capacities.

C. V. F. Weir, M.E.I.C., of Ottawa, has recently accepted an appointment with the Department of Justice as senior assistant to the chief engineer, Penitentiaries Branch.

A graduate from the University of Alberta and the University of Toronto, he worked for a number of years before the war, with the City Power plant, Edmonton, on design work and as field engineer. Returning to Western Canada in 1945, after lengthy military service, he rejoined the power plant as an electrical engineer. He was transferred to the position of assistant superintendent of the Edmonton Transportation System that year and in 1946 became superintendent of the Calgary Transit System.

Taking up residence in Ottawa in 1949, he has since then held engineering positions guiding development in the National Parks and Historic Sites of Canada and many federal projects in the Yukon and Northwest Territories. In carrying these out he has been chief of the engineering and construction service of the lands and development services branch of the old Department of Resources and Development, which later became the engineering and architectural division of the new Department of Northern Affairs and National Resources.

Lenox T. Lane, M.E.I.C., president of Lane and Lane Associates Limited, consulting engineers in Sudbury, Ont., is the 1956-57 chairman of the Sudbury Branch of the Institute.

L. T. Lane, M.E.I.C.

J. A. Drain, M.E.I.C.

A native of that city, Mr. Lane has been engaged in the consulting engineering field with his father, F. C. Lane, O.L.S., since 1945. Prior to that he served for two and a half years with the Royal Canadian Engineers following graduation in 1943 from Queen's University. Mr. Lane was awarded a civil engineering degree.

He is a member of the Association of Professional Engineers of the Province of Ontario and of the Association of Ontario Land Surveyors.

James A. Drain, M.E.I.C., has been named to the newly created post of vice-president and general manager of the mining and construction division of Joy Manufacturing Company. He will be responsible for research, engineering, manufacturing and sales of mining and construction division products.

Mr. Drain first joined the Sullivan Machinery Company, which was a predecessor of the Joy Manufacturing Company, in 1941, as assistant to the president. He served as vice-president in charge of engineering for Joy until 1948 when he became vice-president of the Canadian subsidiary, at Galt, Ont.

He is a graduate of the Massachusetts Institute of Technology and holds membership in the American Institute of Mining and Metallurgical Engineers and the Canadian Institute of Mining and Metallurgy.

H. L. Smith, M.E.I.C.

P. Laporta, M.E.I.C.

Philip Laporta, M.E.I.C., has been appointed vice-president of the J. Serrentino Construction Company Limited, Montreal.

Before joining his present firm Mr. Laporta acquired experience in management, design and supervisory functions related to the construction industry while in the employ of the City of Montreal for a period of six years, and at Canadian Vickers Limited for three years.

He graduated from McGill University in 1946.

H. Leslie Smith, M.E.I.C., has accepted a partnership in the firm of H. H. Minshall and Associates Limited, consulting engineers, at Vancouver.

Mr. Smith recently returned from San Francisco where he was employed with the power division of Bechtel Corporation as assistant project engineer on the design of the Pittsburgh and Morro Bay steam plants for Pacific Gas and Electric and the Fort Lauderdale plant extension for Florida Power and Light. While there he was also engaged on water-power development studies including those on Snake River. Prior to moving to San Francisco, Mr. Smith was employed as senior engineer with Canadian Bechtel on the Trans Mountain Oil Pipeline, as hydraulic design engineer with the B.C. Electric Company Limited on the Ruskin and Wahleach developments, and as design engineer with Western Bridge and Steel Fabricators Limited.

He graduated from the University of British Columbia in civil engineering and took post-graduate studies in soil mechanics, theory of thin shells, and vibrations of structures at the University of California.

Dan Scouler, Jr., M.E.I.C., is assistant chief engineer of the Dominion Steel and Coal Corporation, Limited, with headquarters in Montreal.

A native of Halifax, and graduate of the Nova Scotia Technical College, class

*There's been a Revolution in Rubber

Why A POLYSAR Rubber For Your Products?

Why? The answer is simple. Because *there's been a revolution in rubber. Now... with Polysar chemical rubbers and the help of Polymer's research laboratories . . . you can be sure of getting a rubber with the special properties your products demand.

Whether rubber now enters into your products or not, you owe it to yourself to investigate what Polysar can do for them. Like manufacturers in 40 countries, you'll find that there's a Polysar rubber to improve your products.

At Polymer Corporation Limited we have the largest industrial research and development division in Canada. Why not make full use of our facilities? *Write to our Sales and Technical Service Division, Sarnia, Canada.*

Here's How POLYSAR Rubbers Have Revolutionized Tires

Tires like the one illustrated—incorporating Polysar Krylene, Krynol and "S" rubbers—have enabled manufacturers to offer motorists the toughest treads in tire history, with longer mileage, greater safety and better value. These three Polysar rubbers provide high resistance to abrasion, flexing, aging and weathering; have good tensile strength; and are easily processed.

Polysar has revolutionized tires—it can revolutionize your products, too.

• PERSONALS

of 1948, Mr. Scouler was first employed with Dominion Bridge as a student and also served with the R.C.N.V.R.

He joined Halifax Shipyards Limited on graduation as a maintenance supervisor, and in 1952 was appointed plant engineer for both the Halifax and Dartmouth plants & Halifax Shipyards Ltd.

Karl Bulins, M.E.I.C., has received the appointment of senior design engineer with Bowater's Newfoundland Pulp and Paper Mills at Corner Brook, Nfld.

Previously concerned with the mechanical design of most of the major development in the firm during his first eight years at Corner Brook, Mr. Bulins came originally from Latvia, where he graduated as an engineering technologist from the University of Latvia in 1931. From then until 1944 he held various posts in Latvian industry, ending as area manager for the Latvian Electric Corporation. At this point in his career, ordered by the Germans, he was obliged to go to Germany to work for the Prussian Electricity Company in Hanover. Released in 1945 he accepted appointments with A.M.G.O.T. and U.N.N.R.A. prior to taking up his present work.

Henry B. Carter, M.E.I.C., of Corner Brook, Nfld., has been named senior electrical engineer with Bowater's Newfoundland Pulp and Paper Mills, following service with the company dating to 1946. He will also serve as consultant to the Bowater Power Company Limited.

At that time a recent graduate of McGill University, with a B.Eng. degree in electrical engineering, he worked as an electrical draughtsman. In 1954 he was promoted to the duties of electrical engineer.

He is president-elect of the Association of Professional Engineers of Newfoundland.

F. H. Clark, M.E.I.C., since 1954 construction engineer with Bowater's New foundland Pulp and Paper Mills, has been appointed paper mill engineer, acting as engineering assistant to the mill manager, Corner Brook, Nfld.

A graduate of the Nova Scotia Technical College, class of 1943, he holds a B.Eng. degree in mechanical engineering. Joining the R.C.A.F on receiving these qualifications, he has also been associated with Construction Equipment Limited in Toronto, and Canadair Limited, Montreal. In 1948 he returned to his native Newfoundland, to take up work with Bowater's.

Goerge P. Hobbs, M.E.I.C., chief engineer with Bowater's Newfoundland Pulp and Paper Mills Limited, Corner Brook, Newfoundland, has received the appointment of mill manager

A native of Newfoundland, Mr. Hobbs has been with his present firm since 1946, joining as assistant chief engineer, and remaining in the position until two years ago. Concerned with electrical problems, speed-up and expansion of parts of the mill, and the complete renovation of the electrical and power systems at Corner Brook and Deer Lake, he will now have the duty of operating the equipment and process for the design of which he was as chief engineer, responsible.

A McGill University graduate, class of 1940, Mr. Hobbs had varied engineering experience before taking up his work with Bowater's. In the electrical design field for the explosives factories of Defence Industries Limited, during the war, he also served as electrical superintendent of one of the plants at Nobel, Ont. At war's end, transferring his interest to the Pulp and Paper industry, he joined the Marathon Corporation. After designing the firm's new pulp mill at Marathon, Ont., and getting it into operation, he continued to work for the company as electrical engineer until he moved to Corner Brook.

Norman H. Ursel, M.E.I.C., formerly associate editor of the Engineering Digest, has joined the firm of Francis R. Joubin, consulting geologist, at Toronto. Mr. Ursel's duties within the firm will call for the correlation of the various phases in the exploration and development of mineral resources, with particular emphasis on minerals important to the applications of nuclear energy in industry.

Mr. Ursel graduated from the University of Saskatchewan in ceramic engineering in 1949 and was employed by the Department of Highways of Saskatchewan. Later he worked for the Ontario Department of Highways and the engineering division of Ferro Enamels (Canada) Limited at Oakville.

Mr. Ursel was for a time associated with the editorial staff of the Engineering Journal in 1953 and 1954.

W. Hobson, M.E.I.C., of Montreal, formerly district manager with D. M. Fraser Limited, now heads the firm of W. Hobson and Associates. The organization is one of engineering sales representation for the Esterline-Angus Company Limited, in the province of Quebec and Eastern Ontario.

Mr. Hobson graduated in electrical engineering at McGill University in 1943, and then served with the R.C.N.V.R. He was later associated with the Northern Electric Company Limited, Montreal, in 1948, prior to joining the firm of D. M. Fraser Limited.

Cornelis Boot, M.E.I.C., director of the Spero Engineering and Trading Company Inc., Amsterdam, Holland, a firm of importers and distributors for American and English firms in the metallizing field and packaging industry, is now associated with the establishment of the organization in Toronto, for European representation.

C. Boot, M.E.I.C.

Mr. Boot joined the company in Holland in 1946, after twelve years graduate experience in various engineering fields. These include periods spent with the Acoustical Laboratories of the Dutch Institution of Sound at Delft; with N. V. Philips in commercial technical work for road and airport illumination; eight years with Royal Dutch Airlines in general supervision of the radio and electrical department and training of personnel; and three years with the Provincial Power Supply Company of North Holland in special charge of the electricity rationing during World War II.

Mr. Boot attended the Technological State University in Delft, following a five-year course in electrical engineering. He graduated in 1932.

Last year Mr. Boot was on the instructor staff of the University of Toronto's laboratory of applied physics.

John C. Querido, M.E.I.C. has accepted the position of instrument engineer with C. F. Braun and Company, Alhambra, California.

Mr. Querido was formerly with the Foxboro Company Limited, Montreal. He graduated in mechanical engineering from McGill University in 1951.

Robert Herdman, JR.E.I.C., formerly assistant to the chief engineer at Bowater's Newfoundland Pulp and Paper Mills, Corner Brook, Nfld., has been named to the post of resident engineer.

With Bowater's as a student, Mr. Herdman has been a member of the graduate staff since 1950 when he received a B.Eng. degree in mechanical engineering from McGill University.

E. D. Fedryk, JR.E.I.C., formerly of Montreal, has accepted an appointment with the Canadian Westinghouse Company Limited, Hamilton, Ont., as marketing manager in the distribution ap-

• PERSONALS

paratus department, industrial products division.

Formerly a sales engineer with the Aluminum Company of Canada, both at Montreal and Kingston, Ont., Mr. Fedryk is a 1950 graduate of the University of Toronto in electrical engineering. In 1951 he followed the graduate course in business administration at the University of Western Ontario.

E. L. Littlejohn, Jr.E.I.C., of Union Carbide Canada Limited, has been appointed manager of public relations with the company.

Mr. Littlejohn joined the Union Carbide organization after graduating from the University of Toronto in chemical engineering in 1949. He spent some years in the production department of the Bakelite Company, division of Union Carbide Canada Limited, before transferring to the sales department in 1954. Earlier this year Mr. Littlejohn was appointed sales manager of thermoplastic products.

R. B. Sweet, Jr.E.I.C., formerly assistant mechnical superintendent of the Canada Paper Company at Windsor Mills, Que., has been promoted to the post of mechanical superintendent.

Mr. Sweet who joined the Canada Paper Company early this year, was previously employed by the Algoma Steel Corporation Limited, at Sault St. Marie.

He is a University of Saskatchewan graduate, class of 1949.

Michael O. Jones, Jr.E.I.C., has been transferred from the Singapore assembly plant of the Ford Motor Company of Malaya to the Ford Motor Company of New Zealand, as assistant to the general manufacturing manager.

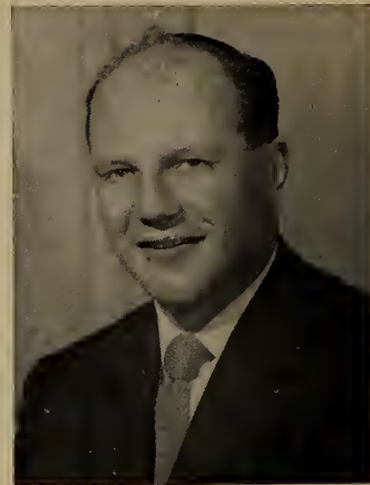
Mr. Jones graduated from the University of British Columbia in 1951 and worked with the Ford Motor Company at Windsor, Ont., shortly after graduation.

Gerard Gaudreau, Jr.E.I.C., has recently joined the firm of J. U. Moreau and Associates, consulting engineers in Trois Rivieres, Que., and is engaged in mechanical and electrical design with related structural work.

Mr. Gaudreau received his B.A. Sc. degree in electrical engineering from Laval University in 1953 and since then has been with Tasse-Sarault and Associates, engineering consultants in Quebec City.

A. F. Joplin, Jr.E.I.C. Chairman of the Central British Columbia Branch of the Institute for the 1956-57 term is A. F. Joplin, division engineer with the Canadian Pacific Railway at Revelstoke.

Born in Victoria, B.C., Mr. Joplin is a graduate in civil engineering with a B.A.Sc. degree from the University of British Columbia. Enrolling at that university in 1938 Mr. Joplin's studies were shortly interrupted by the advent of World War II. After serving with the R.C.A.F. for a period of five years he returned to Vancouver and completed his course in 1948.



A. F. Joplin, Jr.E.I.C.

With the Canadian Pacific Railway before graduation and after, he has since 1951 been employed as a division engineer.

Active in the affairs of the Central B.C. Branch since taking up residence in the Okanagan in 1950, he has since 1951 held a position on the executive. During the year 1955 he acted as vice-chairman and took over the chairmanship of the Branch when W. A. Ker accepted an appointment with the Department of Lands and Forests at Victoria.

Mr. Joplin is also chairman of the Central B.C. Branch of the Professional Engineering Society.

Maurice Paquet, Jr.E.I.C., and **Raymond Bedard**, Jr.E.I.C., have opened the consulting engineering firm of Paquet and Bedard in Quebec, Que., specializing in heating, ventilation, plumbing and electricity.

Both graduates of Laval Univerity, Mr. Paquet studied electrical engineering and obtained his degree in 1950; while Mr. Bedard, who qualified in civil engineering in 1953 was also awarded an Athlone Fellowship and has since then spent two years at the National College for Heating and Ventilating, London, Eng. Last year he was employed with Leblanc, Montpetit and Dorval, of Quebec, Que., as a heating and ventilating engineer.

Mr. Paquet has gained his professional experience with this firm also, and with Tasse, Sarault, and Associates, another group of consulting engineers at Quebec.

W. E. Jubien, Jr.E.I.C., who was last year associated with the department of civil engineering, University of Alberta, has moved to Vancouver where he will work with the firm of Ripley and Associates, engineering consultants in that city. Mr. Jubien who received his engineering training in Eastern Canada, is a graduate of the class of 1954, in civil engineering, at McGill University.

Walter H. Pent, Jr.E.I.C., a 1948 graduate in mechanical engineering of the

IN POWER STATIONS, as in every sphere of industry, the results of Metropolitan Vickers research, enterprise, and experience are clearly evident. Many advances in the design of equipment for power stations owe their origin to this great organisation.

First direct order from Canada for boiler feed pump motors received through Peacock Brothers, Montreal, for Boundary Dam Power Station. This contract covers three 700 hp. 3,600 r.p.m., type HTAS. squirrel-cage machines with twin-cooling air circuits.

Technische Hochschule in Hanover, Germany, has accepted employment with Canadian Mechanical Handling Systems Limited, Windsor, Ont. He holds the position of superintendent of engineering.

In 1952 Mr. Pent joined the staff of the National Breweries Limited, in Montreal, as a draughtsman, production division. Later he was with Dow Brewery Limited in that city as a draughtsman-designer.

Vincent Jolivet, Jr.E.I.C., has accepted an appointment as assistant professor of finance at the University of Washington in Seattle. He will teach corporation finance.

A civil engineering graduate of McGill University, class of 1952, Mr. Jolivet also holds the qualification of Master of Business Administration, received at Harvard Graduate School of Business Administration in 1954. Later he became a research assistant in financial management at the school.

F. M. Corbett, Jr.E.I.C., an Athlone Fellowship winner, has recently returned to Canada from Great Britain where he was associated with the educational department of Metropolitan Vickers Electric Company Limited, at Manchester. He is now employed with the Aluminum Company of Canada in Montreal.

Mr. Corbett formerly served with that organization in 1953, also at Montreeal. Prior to that he was with the Canadian General Electric Company at Peterborough, Ont.

R. E. Chamberlain, Jr.E.I.C., is with the Bailey Meter Company Limited in Montreal, as a production engineer.

With the firm in Cleveland, Ohio, in 1955, he was prior to that time associated with the Shell Oil Company of Canada Limited, as an exploration engineer.

He is a 1953 graduate of the University of British Columbia, with a B.A. Sc. in electrical engineering.

M. T. Rourke, Jr.E.I.C., has accepted an appointment as manager of industrial products with the Sun Oil Company Limited, wholesale and fuel oil departments, for the Montreal district.

After graduating from McGill University in metallurgical engineering, Mr. Rourke was engaged for a year in research work for a large electrical manufacturer. Since joining the Sun Oil Company in 1951 he has been industrial products department representative, for the Montreal district.

J. M. Wigham, Jr.E.I.C., a B.Sc. in civil engineering from the University of Alberta, class of 1955, is employed as an instructor, civil engineering department, at the University.

Mr. Wigham was formerly associated with the Regina, Sask., firm of Ducks Unlimited, as a field engineer.

J. D. Dunn, Jr.E.I.C., formerly with the Canadian Splint and Lumber Corporation Limited, Pembroke, Ont. has joined the staff of Consolidated Paper Corporation, at Trois Rivieres, Que.

Mr. Dunn is a Nova Scotia Technical College graduate in mechanical engineering, class of 1951.

G. E. Cotter, Jr.E.I.C., formerly of the Gartside Supply Company Limited, Granby, Que., has accepted a position with the G.M. Plastic Corporation, also at Granby.

A 1951 graduate in mechanical engineering, he received the degree B.Eng., from McGill University.

E. L. Pearson, Jr.E.I.C., has accepted employment as a division engineer with Canadian Industries Limited, ammunition division, at head office, Montreal.

Recently returned from Great Britain, as an Athlone Fellowship winner, Mr. Pearson was associated with the Fraser-Chalmers Engineering Works, a subsidiary of the General Electric Company, at Erith, Kent, Eng., for the past two years.

He is a 1953 graduate of the University of Manitoba.

R. A. McDougald, Jr.E.I.C., a University of Manitoba graduate of 1954, and Athlone Fellowship winner of that year, has recently returned to Canada, following M.Sc. studies in production engineering at the University of Birmingham.

He is now associated with the manufacturing and engineering department of the Peterborough works of the Canadian General Electric Company.

F. W. Agnew, Jr.E.I.C., formerly of the Dominion Tar and Chemical Company Limited, Toronto, has accepted a position with Commercial Alcohols Limited, at Gatineau, Que., where he is employed as a chemical engineer.

Mr. Agnew graduated with a B.Sc. degree from Queen's University in 1954.

K. M. Milne, S.E.I.C., a 1956 graduate in mechanical engineering from McGill University is working as an engineering trainee with Atlas Steels Limited, Welland, Ont.

Activities of the Forty-Seven Branches of the Institute and abstracts of the papers presented at their meetings

CALGARY

R. G. PRICE, M.E.I.C.,
Branch News Editor

Guest Speakers

The first regular evening meeting of the season was held October 4, at the Palliser Hotel. T. B. Smith, plant superintendent of the Pacific Petroleums Gas Processing and Refining Plant, Taylor, B.C., addressed the gathering on "Some Unique Features of the Peace River Gas Processing Plant."

On October 18, "What Makes Us Laugh", was the topic of John S. Peach, director of Public Relations for the Canadian Petroleum Association.

Monday Luncheon Club

The Monday Luncheon Club of the Calgary Branch held its first meeting September 10, at the Al-San Club. Seventy-five members were present. Phil Meis of Minneapolis-Honeywell Regulator Company gave a short address on automatic temperature control and regulators.

Under the direction of "Nip" Guest and "Bud" Watson, these luncheon meetings will be held every Monday throughout the winter. Visiting members of the E.I.C. are especially welcome.

First social event of the season was a barbecue held September 13, at Colpitts Ranch, southwest of Calgary. More than three hundred people, including E.I.C. members, families and guests enjoyed a successful evening under the joint chairmanship of P. S. Grant and R. S. White.

CORNWALL

L. SNELGROVE, M.E.I.C.,
Secretary-treasurer

The Colonel Magwood Bursary

The Cornwall Branch takes pleasure in announcing the institution and operation of the Colonel Magwood bursary for students in first year engineering. Named after Colonel William Herbert Magwood who served the City of Cornwall for many years as chief engineer, and has a distinguished record as soldier, engineer and citizen, the bursary will assure that the successful candidate will be able to continue to a higher education.

Administered by the Cornwall Branch, the bursary committee consists of Messrs. Drummond Giles, M.E.I.C., W. P. Nesbitt, M.E.I.C., John Hawke, M.E.I.C., and Branch chairman, J. Morris, M.E.I.C. This committee reviews applications and makes the choice of the successful candidate, which receives final approval by the Branch executive.

Funds for the bursary are obtained from local industries. While it is hoped that there will be a number of industries participating in the future, for the present, those concerned in supplying the funds are Courtaulds (Canada) Limited, and Howard Smith Paper Mills, Cornwall.

Applicants must be residents of the United Counties of Stormont, Dundas and Glengarry, must have attended high school in that area, and fulfilled the scholastic entrance requirements for the first year of the engineering school of a recognized Canadian university.

However, while scholastic ability must be sufficient to cope with an engineering course, this will not be the sole basis used in judging the fitness of candidates. The committee will endeavour to select the person who in their opinion will make a good engineer. Such things as character, perseverance, integrity and finances will be given careful consideration.

Further information may be obtained on writing: L. Snelgrove, B.Eng., M.E.I.C., Secretary, Cornwall Branch, Engineering Institute of Canada, c/o Courtaulds' (Canada) Limited, Cornwall, Ont.

Half Century of Service

The bursary honors a man who has devoted a half-century of service to the municipality of Cornwall and whose career exemplifies the highest principles of the engineering profession. Born in Perth County in 1870, he was educated at local schools and in Peterborough. He joined No. "D" School of Infantry at London, Ont., in 1891 and completed partial engineering training. Later he took a military staff course at R.M.C. In 1897 he began his career in Cornwall with the engineering staff of the Ottawa and New York Railway, as an instrumentman, and on completion of this section of railway, remained in Cornwall and was engaged in municipal work. In 1902 he commenced work for himself, doing municipal work for several municipalities. Three years later he began his work as town engineer, and served continuously until his retirement in 1954, apart from a period of active service with the Canadian Expeditionary Force during World War I.

Visit Hydro Development

On Sunday, October 14, 1956, Branch members and their wives motored to the site of the New Brunswick Electric Power Commission's $50,000,000 hydro electric power development at Beechwood, New Brunswick's largest. An enjoyable luncheon, served in the contractors' cook house was followed by a talk by J. L. Feeney, M.E.I.C., chief engineer of the New Brunswick Electric Power Commission, introduced by Branch chairman Ira M. Beattie, M.E.I.C. Mr. Feeney gave a very informative talk on the steps leading up to the construction of the Beechwood power dam and the progress to date.

A documentary film, compiled by the public relations department of the Power Commission was also presented. R. E. Tweedale, assistant chief engineer of the Power Commission provided explanations of the film as it was run off.

Later, the group was taken on a conducted tour and various phases of the work were explained by the job site engineers, acting as guides.

Fredericton Branch members returned to their respective homes with a much better understanding of New Brunswick's largest power development.

KINGSTON

D. I. OUROM, JR.E.I.C.,
Secretary-treasurer

Brig. C. D. Quilliam — Guest Speaker

The first meeting of the 1956-57 season took place October 23, at the R.C.E.M.E. officers' mess in Barriefield.

The guest speaker for the evening was Brig. C. D. Quilliam of Kingston, a veteran of some thirty years in the British Army and subsequently Middle East correspondent for the London Times. He has in recent years been engaged in book selling and lecturing in Canada.

His topic was "Some Notes on Terrorism" in which he discussed the social and economic conditions which foster unrest and which in the extreme may lead to terror activities by the more radical element of a society. The pattern of terrorist acitivity since the early 1930's, particularly in the Near and Middle East, was traced and the methods employed by various terrorist groups was discussed. In conclusion, Brig. Quilliam posed the question of what Canadian engineers, in particular those who travel and work in international fields, can contribute towards an understanding and solution of the problem.

An especially lively question period followed which dealt with such things as recent terrorist activities in Cyprus and Israel and the significance of the seizure of the Suez Canal by Egypt.

Some fifty members and guests attended the meeting at which Col. C. W. Jones presided.

LETHBRIDGE

October Dinner Meeting

A monthly dinner meeting of the Lethbridge Branch was held on Saturday, October 27, in the El Rancho Banquet Room, Lethbridge. About 30 members were in attendance.

Pleasant dinner music was provided by Mr. and Mrs. George Brown, followed by an enjoyable sing-song led by Mr. G. S. Brown.

Two distinguished guests for the evening were Dr. J. C. Sproule, M.E.I.C., vice-president and Mr. A. E. MacDonald, executive secretary of the Association of Professional Engineers of Alberta. Dr. Sproule gave a short address and presented Mr. R. J. D. Gardiner with his A.P.E.A. membership certificate.

Guest Speaker on Town Planning

Guest speaker of the evening was Mr. Sam Lurie, M.R.I.A.C., A.R.I.B.A., director, Lethbridge and District Planning Commission, who spoke on the subject "Town Planning". Mr. Lurie gave an insight into the requisites of a town planner, but pointed out that while town planning is now emerging as a profession, much of the present town planning is still done by laymen using common sense and an intimate knowledge of the town and its problems.

Before planning can begin, Mr. Lurie explained, a detailed survey of the district must be made; not only of its geographical features, such as location, soil, water supply, drainage, minerals, and climate, but also of its population trends, economics, governments, employment, and the shopping habits of its people.

This survey is followed by a development period in which detailed engineering surveys, including studies of highways, sewage, and architecture are carried out.

Mr. Lurie went on to explain that the third step is to lay out a program. This procedure requires an intimate knowledge of law, government, and administration to ensure that the suggestions pro-

posed by the planner will be acceptable to the community as a whole.

Mr. Lurie concluded with a brief discussion of the Town and Rural Planning Act of Alberta and the chief problems facing the Town Planner in the City of Lethbridge.

Mr. Lurie was introduced by Mr. C. S. Clendining. Mr. W. B. Thomson thanked Mr. Lurie on behalf of the members present for his informative and interesting address.

NIPISSING and UPPER OTTAWA

G. R. KARTZMARK, JR.E.I.C.,
Secretary-treasurer

J. Field Guest Speaker

The Nipissing and Upper Ottawa Branch held the first meeting of the season at Temiskaming, Que., on Sept. 26. J. Field, guest speaker, formerly of C.I.L., delivered an interesting address on "the manufacture of nylon."

The annual fall field trip of the Nipissing and Upper Ottawa Branch was held at Falconbridge, Ont., on Oct. 27, with a visit to the Falconbridge Mines.

After the tour, conducted by various top personnel at Falconbridge and members of the Sudbury Branch, the visitors were entertained by the management at a social hour, held in the directors lodge.

Later, proceeding into Sudbury, a dinner meeting, also arranged by the Sudbury Branch was held at the Granite Club.

KOOTENAY

G. T. HUGHES, M.E.I.C.,
Branch News Editor

Dean A. Macdonald, Guest Speaker

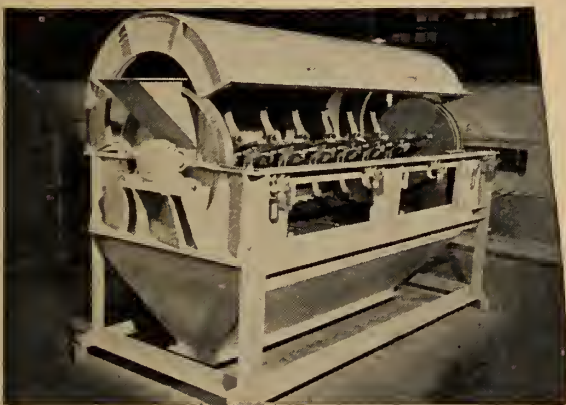
Members of the Kootenay Branch welcomed Dean A. E. Macdonald of The University of Manitoba at a luncheon meeting in Trail on September 27.

Dean Macdonald dealt with the problems confronting the universities arising from the shortage of engineers and he gave a brief account of the National Conference on Engineering. Scientific and Technical Manpower which he attended and emphasized the value of the meeting.

Dean Macdonald commented that as far as the University of Manitoba was concerned, the era of the dedicated teacher was passed. The attraction of high salaries offered by industry was a constant drain upon the resources of academic teaching; though it was also true that certain universities could compete in this sphere.

Bursaries and scholarships partially solved the problem of assistance in the

• Steel box section weighing over 40 tons for a mining company.

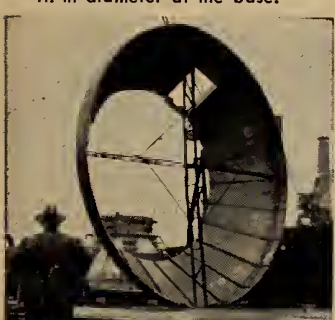


• Ore grading machine built for a mining company.

• Fabricated steel pump and motor base to support a de-watering pump and 6,000 H.P. motor.

• 1¾" tank shell for a high pressure steam drum for an oil refinery.

• Prefabricated sections of tank 80 ft. in diameter at the base.



• Canical section for high pressure reactor.

Whatever you need in BIG OR SMALL STEEL FABRICATION

call DAVIE

for fast service and reliable work

In the course of over 100 years of building ships, Davie Shipbuilding Ltd. has mastered the shaping, fabricating, welding and handling of steel in large or small sizes.

The recently-formed General Engineering Division of Davie has inherited this know-how and is using it in fashioning steel for industry. Whatever your requirements, large or small, Davie Shipbuilding Ltd. can fill the bill. Send us your inquiries.

DAVIE Shipbuilding LTD.

P.O. BOX 130 LEVIS, QUE.

training of engineering graduates. Dean Macdonald cited the forward step of Goodrich Rubber in their Waterloo plan proposal of thirteen weeks' employment alternating with thirteen weeks' study for classes of undergraduates, and remarked that this could be a successful undertaking for a city like Detroit. It would be almost inapplicable to a province like Manitoba where long distances would hamper such a scheme.

Dean Macdonald felt that the press could be more cooperative in their reporting of university policy and illustrated his point by reading an excerpt from his local press unfairly criticising the university in its procedure regarding failures.

Dean Macdonald concluded by reading extracts from the Bulletin issued by the National Employment Service published September 1956 concerning the placement of graduates, recognizing the shortage and suggesting that engineers should be usefully employed.

Engineers' Ball

The seventh annual Engineers' Ball was held on October 5, in the Century and Burgundy Rooms of the Fischer Hotel. More than four hundred guests attended this popular event, to enjoy the delightful informal atmosphere which prevailed throughout the evening, and the fast-moving variety of entertainment afforded. Favours were received by the ladies and several lucky winners took home door prizes and special dance prizes. Receiving the guests at this gay social event were J. J. Kelly, chairman of the Hamilton Branch, and Mrs. Kelly, A. F. Barnard, secretary-treasurer of the Hamilton Branch and Mrs. Barnard, and members of the ball committee. Many prominent personalities were presented as invited guests. These were M. V. Hotchkin, president of the Association of Professional Engineers of Ontario and Mrs. Hotchkin, of Kirkland Lake; M. A. Montgomery, vice-president of the Engineering Institute, and Mrs. Montgomery, of Kitchener; Mrs. J. R. B. Carruthers, president of the Women's Auxiliary of the Hamilton Branch, E.I.C., and Mr. Carruthers; H. E. Thomson, president of the Hamilton Construction Association, and Mrs. Thomson.

"Get Acquainted Smoker"

The Hamilton Branch enjoyed a "Get Acquainted Smoker" on October 18, at the Royal Hamilton Light Infantry officers mess. Affording an opportunity for renewal of friendships and the developments of new ones, this informal type of meeting is an important phase of Institute activity which should not be overlooked.

H. G. Gerber Speaks on Hilton Mines

The demand for high grade iron ore has made it economical to develop low grade deposits. The mystery of this anomaly was explained by Harry G. Gerber, superintendent of the Hilton mines at a luncheon meeting of the Ottawa Branch, on October 4, 1956.

The Hilton mines, known to old timers in the Ottawa area as the Bristol mines, are located a few miles from the

Mr. and Mrs. M. V. Hotchkin, left, chat with Mr. and Mrs. J. J. Kelly, at the seventh Annual Engineers' Ball, held recently at Hamilton.

capital, and their redevelopment is being followed with much interest locally, due to the methods employed and the re-vitalizing effect on the area.

Concentration of Iron Ore Important Factor

The efficiency of a blast furnace is dependent upon the concentration of iron ore charged to it. The use of high grade foreign ores during the war proved economical and presented a challenge to the old established mines.

Ore from the Mesabi Range assaying 51 per cent had been accepted by the steel mills for forty years. Now ores of 60 per cent iron and more are being demanded and produced. As natural deposits of these high grade ores are rare it has become necessary to concentrate the lower grades in beneficiating plants. It is this concentrating process that has made it economically possible to develop such deposits as were abandoned at the Bristol place.

The Hilton mine will produce a 66 per cent concentrate from a 25 per cent ore. The crude from the pit will be ground to particles the size of tooth powder. By a process of magnetic separation the iron is then taken from the waste rock. This finely ground and concentrated ore must next be prepared for blast furnace use.

The concentrate is rolled in a drum and pellets about one inch in diameter are formed, these pellets are then introduced into an oxidizing atmosphere of about 2400 degrees F. The final product is a dense cluster of pellets looking somewhat like a bunch of grapes. In this form the ore will be shipped to steel mills in Hamilton and the United States.

Mr. Gerber was introduced by W. B. Pennock, chairman, and thanked by councillor R. E. Hayes. Others at the head table were: Alan Brown, vice-president, Gatineau Power Company; B. H. Goodings, Ontario Association of Professional Engineers; R. J. Hawkinson, Pickands Mather & Company; H. I. Marshall, chairman, Ottawa Branch of the Canadian Institute of Mining and Metallurgy; and W. H. Norvish, assistant director of the Mine Branch, Department of Mines and Technical Surveys.

Visit to SKF Plant

On September 27, 1956, a visit was made to the Canadian S.K.F. assembly plant on Eglinton Ave., Scarborough. It is always interesting to see how any specific industry operates, adapting fundamental techniques to its own requirements. Since grinding operations predominate in the manufacture of ball and roller bearings it was not surprising to find

ꞃOBLEM:

To anneal steel, cast iron and non-ferrous alloys in an economical set-up.

ƆLUTION:

G-E Continuous or Batch-type Furnaces which anneal metals in flat or special shapes in one pass, at lower cost.

: Bell Furnaces installed at Peterborough Works of ıadian General Electric are designed for annealing copper : in reels or coils up to 36″ in diameter and 60″ high. The allation includes two Bell Furnaces and six loading bases ı a capacity of 4000 pounds each. The bases employ new ı velocity fans and high temperature gradients to assure ı heating rates and uniform temperature throughout. :em will complete both heating and cooling cycles in roximately 8 hours. The protective atmosphere equipment ıres a bright anneal finish for all sizes of wire. With auto- ic control and safety features, only one man is required to rsee the complete, one-pass operation.

ADDITION TO PRODUCT QUALITY here are other ad- tages you receive when you deal with C-G-E on heating ›lems.

TECHNICAL KNOWLEDGE — Continuous research and product development assures the latest information on processes and installations.

EXPERIENCED USER — A large number of G-E Furnaces are installed in C-G-E plants. This permits a close check on performance and product quality.

(3) **EXPERIENCED BUILDER** — C-G-E offers more than 25 years of experience in the industrial heating field, building all types of furnaces for a wide range of applications.

(4) **APPLICATION HELP** — plus installation supervision, assures you the most efficient furnace and system installation.

(5) **MAINTENANCE SERVICE** — C-G-E maintains trained service men who can be on the job immediately should service be required.

(6) **FOR FURTHER INFORMATION** contact Industrial Heating Sales, Canadian General Electric Co. Ltd., 940 Lansdowne Ave., Toronto, or 5000 Namur St., Montreal, P.Q.

these techniques being used in the plant machine shop instead of the basic techniques of planing and milling. Although not entirely displaced, these latter two techniques were employed in a more or less secondary role.

It was a pleasure to see the clean air conditioned area in which designers and draftsmen worked, using modern office equipment and drafting machines. The S.K.F. company are to be complimented on this aspect of personnel relations.

After touring the plant the visitors had a well-prepared light lunch and a bottle of vitamin packed amber fluid to refresh them. A movie of operations in the company's parent Swedish plant rounded out the program. Both the S.K.F. executive and members of the E.I.C. Toronto Branch executive, Messrs. Young and Norgrove, are to be thanked for a pleasant and instructive evening. About one hundred members visited the plant.

Freshmen's "Initiation"

During the Freshmen's "Initiation" on September 25, all embryo engineers were treated to coffee and doughnuts in the great hall of Hart House, through the courtesy of the Engineering Institute, both the Toronto Branch and the Toronto Field Office assisting. Col. L. E. Grant, Hon. M.E.I.C. and Mr. Harvey Self, M.E.I.C., ,were present and explained to the freshmen what the Engineering Institute could do for them. The idea behind sponsoring a part of the Freshmen's reception at the University of Toronto was to make the students aware of the Institute. It was felt that the students are showing considerable interest in the Institute as a Canadian body of professional engineers. About five-hundred and fifty freshmen were entertained.

E.I.C. - I.E.E. Meeting

Mr. Ivan Widdifield reported that the Joint Committee Engineering Institute — Institution of Electrical Engineers group held its first meeting in the Electrical Building on the University of Toronto campus, Tuesday, October 9, in the evening. Mr. W. E. Cooper, liaison engineer for nuclear power, Ontario Hydro, was the speaker.

This photograph, taken at the election dinner of the Eastern Townships Branch in June, shows, left to right: Mrs. Champagne, Mrs. Mawhood, Mrs. Dick, Mrs. Masse, Mrs. Phillips, Mrs. Lemieux, Mrs. Cote; standing, G. Cote, M.E.I.C., B. Lachapelle, M.E.I.C., R. Phillips, M.E.I.C., J. Lemieux, M.E.I.C., G. Masse, M.E.I.C., R. D. Mawhood, M.E.IC., G. M. Dick, M.E.I.C., and J. P. Champagne, JR.E.I.C.

• BRANCH NEWS

Reviewing some of the basic concepts relating to nuclear reactors and the fission process generally, the author lists the basic components of the NPD reactor presently being built by Ontario Hydro, Canadian General Electric and Atomic Energy of Canada Limited, at Des Joachims, Ont.

The reactor core is a cylindrical steel pressure vessel 11½ feet in diameter and 36 feet high, with hemispherical bottom and removable top. Coolant enters the lower header, flows up the tubes and collects in upper header. Around the tubes is the moderator space and inside the tubes the fuel rods are inserted. Lower or fuel ends and upper or plug ends of rods are separable. After irradiation rods are removed and fuel and plug ends are separated. Plug ends are then decontaminated and used with new fuel ends, while spent fuel ends are sent to Chalk River for reprocessing.

The moderator is heavy water, and without it in the core, NPD does not react. The main coolant circuit flows past the fuel rods. The coolant is also heavy water pumped into the lower header, which flows past the fuel rods, picking up heat and gives up the heat to the heat exchanger.

Discussing the unique control system of NPD in detail, and how the moderator level is controlled, the author then describes the plant layout, consisting of—

1. the main section housing reactor, heat exchanger, turbine, generator and auxiliaries
2. the maintenance wing
3. the control wing
4. the office wing.

Reasons for the choice of the site were

1. ample supply of cooling water
2. land was owned by Ontario Hydro
3. accessibility of site by road and rail

The accompanying photograph was taken at the annual E.I.C. - A.P.E.O. dance held at Prudhomme's Garden Centre, Vineland, Ont., on Sept. 28. Shown below, left to right, back row, are: Col. T. M. Medland, I. L. Colquhoun, V. A. McKillop, and T. C. Keefer. Front row, left to right: A. W. F. McQueen, P. L. Climo, J. H. Fox, and D. M. Jenkins, chairman of the Niagara Group of the A.P.E.O.

S&L

4. electric power developed is easily connected to Hydro's southern Ontario system

5. foundation conditions were suitable and

6. proximity of machine shop and stores facilities at Chalk River.

Summarizing, the author points out the joint project is being undertaken for the benefit of Canada. Canada has abundant supplies of natural uranium such as will be used by NPD. Not only will the electrical industry benefit if NPD is a success, but also the mining industry and indeed everyone who uses electricity.

Prof. H. Macklin Guest Speaker

On October 11, Professor Harold Macklin M.E.I.C., of the Department of Civil Engineering, University of Toronto, gave an evening talk on modern mapping methods, in the mechanical building of the university. Professor Macklin was introduced by W. M. Treadgold, M.E.I.C., professor emeritus of surveying and geodesy at the University of Toronto. Professor Treadgold contrasted the days when he worked in the field using heavy instruments and pack horses with the present, where the airplane and machine plotting methods had supplanted the plane table and laborious hand plotting of stadia notes.

Professor Macklin traced briefly the history of surveying up to the present. Today the surveyor is called on to produce cheaply topographic maps which are the best possible in the shortest time,

Maps in the Toronto Metropolitan area will often be at a scale of one inch equals forty feet. In the fringes of the metropolitan area the scale may vary from one inch equals one hundred feet to one inch equals one thousand feet, with contour intervals running from two feet to ten feet. Because of the high accuracy required, the surveyor must use air photography and machine plotting methods.

Professor Macklin described the methods of photography and the costs of obtaining maps by these methods.

Progress in Surveying Instruments

Professor Macklin discussed the progress made in surveying instruments during post war years. The most noteworthy achievement is the Zeiss NI 2 level. This type has no level bubble as such, only a small bull's eye type for preliminary setting of the instrument. A prism suspended in the instrument by wires always gives a level sight to the operator. The instrument is capable of second order accuracy and can be set up in one half to two thirds the time required for the ordinary bubble type of level.

Electronics is being used to an increasing extent for measuring long distances. The Geodectic Survey of Canada is using Shoran to set up geodetic nets. Between 1949 and 1953 about 600,000 square miles of Canada's northland have been covered by a net and some 325 lines of an average length of two hundred miles have been measured with an accuracy of one in sixty thousand. Shoran is a radar type of device whose accuracy depends on the atmospheric conditions prevailing during its use. Better knowledge of the meteorology of the atmosphere will improve accuracy to one in 100,000. Even for the short time of use, the Shoran method is proving a remarkable time saver.

For distances ranging between one and fifty miles, two devices are available for very accurate measurement, one, called a geodimeter, made in Sweden, is capable of first order measurement, but is bulky though portable and quite expensive. The operation is based on the use of modulated light sent out from a fixed station, and reflected to a modulated photo electric call receiver. The successful operation of the equipment depends on intervisibility and clear weather. Another device called a Tellurometer is

being developed in Johannesburg, South Africa, which uses radio waves of 10 cm. wave length. It is expected that this apparatus will be capable of an accuracy in the neighbourhood of one in 200,000 over a 35-70 mile range.

In conclusion Professor Macklin remarked that the chainman was still the most valuable equipment for measuring distances less than two thousand feet.

About seventy members enjoyed the paper and the question period which followed.

Panel on Engineer Shortage

On October 25, a panel discussion was held in the mechanical building of the University of Toronto with the subject "The Engineering Manpower Shortage." Under the expert guidance of the chairman, Dean R. R. McLaughlin of the University's faculty of applied science the panellists developed their themes, beginning with Mr. Ira Needles, president of B. F. Goodrich, Canada, Limited, Kitchener.

Plan for Education

Mr. Needles talked of the plan called Waterloo College Affiliates, telling what is proposed for the Kitchener-Waterloo area. Briefly it is a plan for educating young men so that they will take up engineering or become technicians. The plan alternates a quarter of a year in business or in industry with a quarter of a year completing grade XIII. Two years will be spent this way. A third year may be added to the first two. It is not a terminal course and not an apprenticeship but the key to higher education. Mr. Needles felt that young people growing up in an industrial town have little or no motivation toward higher education because of family environment. The environment is not bad, simply that the youngster sees his father working in a factory and acquiring the material things of life quickly so the youngster wants to do likewise.

Not all will be allowed to enter the course. Selection by counselling and prestudy of the individual it is hoped, will prevent large numbers of disastrous failures.

Foundation to Evaluate Needs

S. H. Deeks, chief of engineering, Orenda Engines, followed. He explained first that he was on leave from Orenda Engines and is presently executive director, Industrial Foundation on Education. His topic was, "The Background of Canada's Science and Engineering Shortage." One of the first moves for the Foundation would be to assess the shortage in the light of the demands of the Canadian economy and then in the light of the demands of world economy as it affects the Canadian economy.

There is now, Mr. Deeks said, a world revolution in scientific discovery and progress. Nations which lead in discovery and progress will control the world.

So that Canada would not be left behind in the advance, the Foundation would evaluate Canada's economic and military needs as far as engineers and technicians were concerned, establish a course of action based on this evaluation, and then increase teaching staffs at the universities and technical schools to produce the necessary graduates.

The shortage of engineers could be alleviated by more technicians who would do the routine work which engineers presently do. The co-operative training scheme such as the one proposed in Kitchener-Waterloo was being viewed very favourably.

As the Foundation presently saw it, there would be a rise in the number of scientists and engineers of about four times, and ten times in the number of technicians over the the next twenty years. Presently Canada can supply one quarter of the demand. We may fall behind in Canada.

• BRANCH NEWS

Definition of Engineer

Colonel J. K. Bradford, the director of the placement service at the University of Toronto spoke briefly on the topic of "Define Your Terms." Colonel Bradford hoped that someone at the meeting would define for him the term "Engineer." After running over some statisics on the probable future needs for engineers in the U.S.A. he remarked that the engineering specialty fields now short of help were the metallurgical, electrical, heat, chemistry, mechanical design and aircraft. There will, said the colonel in conclusion, be an expanded utilization of the engineer who will move into a position in our technological economy where he will displace the lawyer from management.

Wastage — Not Shortage

D. R. Abbey of the Underwriter's Laboratories of Canada, took the view that there was a wastage of manpower rather than a shortage. Engineers should be taken out of the routine jobs of time study, order and pricing departments and other routine technical assignments. There should be proper utilization of present talent and development of future talent.

Small industries should retain consultants rather than attempt to hire engineers, and employers in large industries should train engineers themselves.

Mr. Abbey feels there is a trend toward a general type of engineering course rather than as presently, courses in a number of different specialties.

At the present time there is an artificial shortage created by competitive bidding due to the sudden expansion of the economy in Canada.

Mr. Abbey summed up his arguments by suggesting that engineers should develop themselves; that engineers were not part of the management team, just advisers, and finally that we in Canada should try living within our technical manpower means.

"The Head Hunters"

Mr. McMullen, manager of technical personnel, of Canadian General Electric, discussed the intriguing title, "The Head Hunters." He described the trials of a personnel manager trying to obtain technologists and technicians in Europe. Norway forbids any recruiting on her soil. Germany skims off the good ones for work at home.

Mr. McMullen brought out two very interesting points: There is no distinction between the professional (degree engineer) and the non professional (technical school grdauate) in Europe; and there is not much incentive spread between the salary earned by a man of little experience and a man with a great deal of experience.

Will the European source dry up? It will, because opportunities in Canada are difficult to sell, and the requirement of the degree will increase the use of the technician.

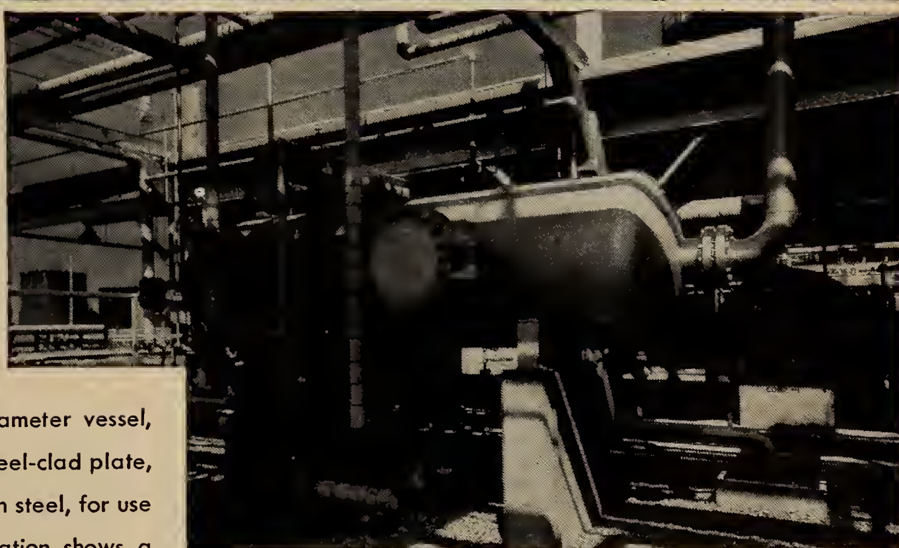
The discussion from the floor was lively. Mr. Needles emphasized that an engineering education was the finest which could be secured, the engineering trained man usually made the best executive material, and finally that young people could be inspired to enter the profession in high school, instead of drifting into industry.

Colonel Bradford felt that he had no stockpile of engineers on hand and considered the flow of engineers to and from the United States a two-way street. Both countries could benefit.

All panellists stood up bravely under fire from the floor and were thanked on behalf of the eighty members present by Lou Bresolin, Toronto Branch secretary.

PRESSURE VESSELS

- CARBON STEEL
- ALLOY LINED
- SOLID ALLOY



Top illustration shows a 10 ft. 6" diameter vessel, 127 ft. long fabricated in stainless steel-clad plate, Monel "Smithlined" plate and carbon steel, for use in an oil refinery. The lower illustration shows a suction drum for 700 p.s.i. pressure at 150° F. It was hydrostatically tested to over 1200 p.s.i. pressure.

In the fabrication of big pressure vessels Inglis applies the unique experience and equipment built up to supply the needs of industry and defence. In oil refining, pulp and paper, chemical and rubber industries, pressure vessels built by Inglis are carrying a large share of the load. These illustrations demonstrate our ability to satisfy a wide variety of requirements.

Stanley Park Pavilion

Social Evening

In its unequalled setting, Stanley Park pavilion, Vancouver, was ideal for a social evening of games and dancing, held on Ladies' Night, October 13.

F. Cazalet, M.E.I.C., and E. S. Hare, Jr.E.I.C., conducted the games and the absence of a house percentage was particularly pleasing to the winners. John Emerson's orchestra played for the dance and was ably assisted with vocal numbers by the hitherto unknown vocalist and chairman, S. S. Lefeaux, M.E.I.C.

The varied program was unusually successful in making members better acquainted with each other and in promoting a feeling of good fellowship.

Field Trip

The 1956-57 executive of the Vancouver Branch have been very successful in promoting activities that tend to weld the Branch into a family unit as well as make the members feel they are getting something available only to members. Recent examples are field trips organized to go through one of the most modern breweries on the continent, September 27 and October 25. Sicks' Capilano brewery was designed with every facility for efficient production and demonstrated what architects and engineers can do to reduce production labor costs, keep equipment maintenance to a minimum and make sanitation easy. With tiled floors and walls, copper and brass vats and the special fermentation tanks, the visitor is impressed with the emphasis on cleanliness. Any day can be visitors' day. D. McRoberts, M.E.I.C., is chief engineer of the company and D. Bloxham, engineer of the inspected plant.

J. T. Madill Paper Presented

While many papers are written on the design features of engineering projects, few are written on construction details and the operating problems that follow completion of a project. The Vancouver Section was very fortunate on October

News of Other Societies

Commonwealth Mining and Metallurgical Congress

At the invitation of the Canadian Institute of Mining and Metallurgy and with the approval of the Commonwealth Council of Mining and Metallurgical Institutions, the Sixth Commonwealth Mining and Metallurgical Congress will be held in Canada during the period from September 8 to October 9, 1957.

The Program

Arrangements for the Sixth Congress program are well advanced, with major meetings scheduled as follows:

Vancouver, B.C., Sept. 8, 9, 10
Edmonton, Alta., Sept. 16, 17
Winnipeg, Man., Sept. 19, 20
Toronto, Ont., Sept. 27, 28
Ottawa, Ont. Sept. 30, Oct. 1
Montreal, Que. Oct. 2
Quebec, Que., Oct. 3, 4
Halifax, N.S. Oct. 8, 9.

Programs and tours are being designed to include virtually every aspect of Canada's tremendous complex of mineral exploration, development, beneficiation, manufacture and marketing; or government administration, research and scientific investigation.

The Technical Programs Committee has decided that technical information will be most advantageously presented by means of plant visits, subsequent forum and panel discussions, and in specially prepared descriptive literature which will be obtainable during the congress by means of Technical Volumes.

There are special tours of Canada being arranged by Thos. Cook and Son, official travel agent for the Sixth Congress.

The "Second Brochure" of the Congress, now available, contains general information, tour plans and application forms. The Canadian Committee is requesting that completed application forms be delivered by January 31, 1957, to The Executive Secretary, Sixth Commonwealth Mining and Metallurgical Congress, 837 West Hastings Street, Vancouver 1, B.C.

Canada on Display

R. W. Diamond, M.E.I.C., president of the Sixth Congress, in a message to the 3000 interested persons in 70 countries, writes: "Every effort is being made to ensure for all delegates an unequalled opportunity to visit Canada under the best possible auspices. The Government of Canada, the Governments of the Canadian Provinces, The Canadian Institute of Mining and Metallurgy, The Canadian mineral industries and the people of Canada look forward with keen anticipation to the privilege of placing our country and its great mineral industries on display for you next year."

International Welding Institute

The International Institute of Welding, organizing the international annual assembly for 1957 at Essen, Germany, June 29 to July 6, will be supported by a Canadian Committee.

Membership in the I.I.W. for Canada is shared by the Canadian Welding Society, the Canadian Welding Bureau and the Department of Mines and Technical Surveys.

I.I.W. in Canada

In order to expedite and direct the activities of the I.I.W. in Canada the members have elected a provisional executive to act until the formation of a Canadian Council. Rules and regulations have been formulated to govern the operations of the Canadian Council.

R. A. Dunn, general sales manager, Canadian Liquid Air Company Limited, Montreal, (representing the Canadian Welding Society), is the provisional chairman, and R. W. Stickney of the Canadian Welding Bureau, Toronto, is the provisional executive secretary.

Other members of the provisional executive include: E .A. Gill, manager industrial heating, Canadian General Electric Company Limited (representing C.W.S.), H. J. Nichols, chief welding metallurgist, Department of Mines and Technical Surveys, W. P. Campbell, Department of Mines and Technical Surveys, C. H. Elsley, supervisor of automatic welding equipment, Dominion Foundries and Steel Company Limited (representing C.W.S.), and R. M. Gooderham, Canadian Welding Bureau.

The interim executive accepted the duty of informing Canadian industry and individuals of the 1957 assembly in Essen. Details of this meeting were published in the November 1956 issue of the Journal.

Adequate Wiring Program

The Canadian Adequate Wiring Bureau (126 Davenport Road, Toronto) will launch a program in 1957 designed to influence home owners to improve overloaded electrical systems and to demand high standards for systems in new homes.

The estimate is that there are 2.5 million inadequately wired homes in Canada. The results are inconvenience and fire damage, as well as constriction in the market for electrical products.

The Canadian Electrical Manufacturers Association supports the Bureau financially, while other national organizations participate in its work, with electrical utilities, contractor associations and Electric Service Leagues. The executive committee is headed by R. E. Bailey, chairman.

Its objective is to advance the installation of wiring which will be sufficient to increase the use and usefulness of electricity and electrical products in homes and other structures and wherever the better use of electrical equipment depends on the adequacy of the wiring system.

The CAWB acts as a liaison with related U.S. programs, also. Arrangements are being made within the industry to hold the annual Electrical Week in Canada at the same time as it is observed in the United States, the second week in February.

Col. Robert Dickson Harkness, M.E.I.C. of Montreal was elected president of the Canadian Electrical Manufactuers Association at the annual meeting in October. Col. Harkness is president of Northern Electric Co. Ltd.

C.I.S.S. Convention

The 23rd annual convention of the Canadian Institute on Sewage and Sanitation was held in Windsor, October 29 to 31, 1956.

The president of this Institute was C. G. Russell Armstrong, M.E.I.C., past-chairman of the Border Cities Branch of the E.I.C. and a past vice-president of the Institute.

• NEWS OF OTHER SOCIETIES

There were 528 registrations for the convention, which included papers and discussions on the modern science and practice in refuse disposal, public sewerage systems, air pollution, control, oxidation ponds, sewer laying and maintenance, sewage treatment plants for small municipalities, and reviews of specific provincial and local programs, plans and problems.

L. B. Allan, M.E.I.C., commissioner of roads for Metropolitan Toronto, assumed the presidency at this meeting. A. E. Berry, M.E.I.C., is secretary-treasurer of the C.I.S.S. He is general manager of the Ontario Water Resources Commission.

Calendar

Management

The Canadian Management Council will hold the annual general meeting in Montreal, on January 14, 1957.

Concrete Products

The eighth annual convention of the National Concrete Products Association will be held at the Sheraton Mount Royal Hotel in Montreal, January 17-19, 1957.

Metals Engineering

G. MacDonald Young of Montreal has been elected vice-president of the American Society for Metals, the first Canadian to hold an executive office in this society. Mr. Young is technical director of the Aluminum Company of Canada, Limited.

Standards

The Laboratories of the Canadian Standards Association are now known as the CSA Testing Laboratories. The change was made in October.

A new district office of the laboratories was opened in Winnipeg, at that time, with M. Lasko appointed as Winnipeg district engineer.

Heating and Air Conditioning

The 63rd annual meeting of the American Society of Heating and Air Conditioning Engineers (62 Worth Street, New York, 13) will take place in Chicago, Ill., February 25 to 28, 1957.

Steel

The 55th annual meeting of the Steel Founders' Society of America (606 Terminal Tower, Cleveland 13, Ohio) is scheduled for March 18, 19, 1957, at the Drake Hotel, Chicago, Ill.

Plant Maintenance

Advance registration cards for the eighth Plant Maintenance and Engineering Conference, to be held in Cleveland, at the Public Auditorium, January 28-31, can be obtained from Clapp & Poliak, Inc., 341 Madison Ave., New York 17, N.Y.

Tool Engineering

An invitation has been issued to Canadians to submit papers for the 26th annual convention of the American Society of Tool Engineers to be held in April, 1958. Papers submitted for the 1958 convention will be accepted for consideration until May 1, 1957. ASTE membership is not required. Each proposal should include an outline of the paper, the author's name, his title and affiliation. This information should be submitted to L. S. Fletcher, Progress Director, American Society of Tool Engineers, 10700 Puritan Avenue, Detroit 38, Michigan.

The program for the 25th annual convention, the silver anniversary meeting of ASTE, is completed. This meeting will take place in Houston, Texas, in March, 1957.

Road Show

Discussion of the roadbuilding market and new engineering techniques will dominate the 1957 convention and road show of the American Road Builders' Association, taking place in Chicago, January 28 to February 2, 1957.

Canadians may register for this meeting through the Canadian Good Roads Association (270 Maclaren St., Ottawa, Ont.)

Publications of Engineering Societies
1957 Subscription Rates

Exchange arrangements exist between The Engineering Institute of Canada and engineering societies in the British Empire and the United States whereby members of the Institute may secure the publications of these societies at special rates which, in most instances, are the same as charged to their own members. A list of these publications with the amounts charged is given below. Subscriptions should be placed at E.I.C. Library, 2050 Mansfield St., Montreal 2, Que. These prices are subject to change without notice, so no remittance should be sent until an invoice has been received.

BOOK REVIEW

Man's role in changing the face of the earth.

W. J. Thomas, ed. Toronto, University Press, 1956. 1193p., illus., $12.50.

In 1955 a symposium was held in Princeton: the topic discussed by the seventy participants was man's role in changing the face of the earth. An attempt was made to evaluate man's capacity to transform his environment, and to assess the cumulative and irreversible alterations man has made on and to the earth.

The symposium was sponsored by the Wenner-Gren Foundation which was created in 1941, two of its objects being the application of techniques developed in other fields to the solution of anthropological problems, and the dissemination of the results of anthropological research in an attempt to win more public support. It was felt that a symposium of this type would further the work of the Foundation, attempting as it did to survey a topic of interest to many different disciplines.

The book is divided into three sections the first of which, Retrospect, provides the background for the study, and traces the changes wrought by man from his first use of fire, through the influences of the food-producing populations in different areas and at different eras, to the present period of urbanization.

The second section, and to the engineer that of the greatest interest, is entitled Process, and describes the ways in which man has made the changes on the earth. Some of the topics considered are the effect man has had on seas and waters; the alteration of climatic elements; erosion and soil changes; pollution; and urban and industrial demands on the land.

The final section, Prospect, considers the effect man's actions have had on the habitability of the earth and on man's own evolution. Also considered are the material and ideological limitations which man may have produced for the future.

This is a very readable book, and is well-documented for those wishing to pursue further any particular topic. The engineer has contributed to so many of the changes which have been made in the past, and will be responsible for so many future developments that we feel this book will be of interest to many of our members. s.c.

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

BOOK NOTES

Prepared by the Library The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

***Achitectural graphic standards 5th ed.**

C. G. Ramsey and H. R. Sleeper. New York, Wiley, 1956. 758p., $18.50.

This reference volume for architects, builders, civil engineers, and others interested in building gives the standards and facts needed to deal with a wide range of types and phases of construction. The new edition has been thoroughly revised, and it has been rearranged into twenty-three sections covering such topics as foundations; wood, steel, concrete, and masonry construction; hardware; interior finishes; mechanical equipment; and landscaping. New material on a number of subjects has been added, including furniture; the design of plank and beam framing; curtain walls; pneumatic tubes; elevators; and escalators.

Building code requirements for reinforced concrete.

American concrete institute. Detroit, The Institute, 1956. 73p., $1.00.

The code covers the design and construction of buildings of reinforced concrete and may be incorporated verbatim or adopted by reference in a general building code. Among the subjects covered are: quality of concrete; allowable stresses; mixing, placing, curing and cold weather protection of concrete; forms; reinforcement; pipe and conduits; joints; general design considerations; flexural computations; shear and diagonal tension; bond and anchorage; flat slabs; columns and walls; footings; and precast concrete. The quality and testing of materials used in the construction are covered by reference to the appropriate ASTM standard specifications.

Circuit theory and design.

J. L. Stewart. New York, Wiley, 1956. 480p., diagrs., $9.50.

Intended as a text for either undergraduates or graduates, this book applies modern network theory to the understanding of vacuum tubes and feedback systems. The author uses pole-zero design methods to develop design methods for a variety of circuits, both with and without vacuum tubes, and for systems with and without feedback.

Following a review of steady-state circuit analysis, poles and zeros and their relation to networks are discussed, as are R-L, R-C and L-C networks and their canonical forms. Other topics covered are the approximation problem, network synthesis, image matching, vacuum-tube linear equivalent circuits, low-pass and band-pass amplifiers and feedback devices.

Suggestions for further reading and background material are included in a bibliography which is keyed to the different chapters.

Chemistry of cement and concrete, 2nd ed.

F. M. Lea. London, Arnold, Toronto, Macmillan, 1956. 637p., illus., $14.00.

This second edition has been largely rewritten to incorporate the knowledge of the chemistry of cement and the performance of concrete which has accumulated in the last twenty years. The book deals with the chemical and physical properties of cement and concrete and their relation to problems arising in use.

Some of the topics covered include the raw materials used in the manufacture of portland cements, their properties and the changes they undergo during manufacture; the cementing qualities of cement compounds and their atomic structures; hydration; setting and hardening; pozzolanas and pozzalanic cements; cements made from blastfurnace slag; high alumina cement; concrete aggregates; the resistance of concrete; and the examination of concrete failures.

As the author, the director of building research of the British department of scientific and industrial research, states in his preface, much of the information on the chemistry of cements is also available in other texts. He has therefore devoted more of the book to the problems arising in the use of concrete, as much of the information available in this phase of the subject is not available in printed form.

*Closed-circuit and industrial television.

E. M. Noll. New York, Macmillan, Toronto, McClelland & Stewart, 1956. 230p., illus., paper, $4.95.

The first chapter includes brief descriptions of a number of uses of closed-circuit television as a monitoring device in steel mills, power plants, railroad yards and other locations, and as a means of communication in schools, hospitals, business, etc. Seven chapters deal with the technical aspects of systems, cameras, viewers, circuits, installation, and servicing, and the last chapter presents construction details for a small inexpensive camera.

Currents, fields and particles.

Francis Bitter. New York, Wiley, 1956. 599p., diagrs., $8.50.

The objective of this text for undergraduates is "to give the student an appreciation of one of the great achievements of man—the development of a series of abstract concepts which make it possible to see deeply into the nature of creation." It is also intended to lay a groundwork for the understanding of the laws of nature.

Some of the topics covered include basic electrical quantities, electric and magnetic fields, optics, the experimental basis of atomic physics, wave mechanics, atoms and electrons, and atomic nuclei and nuclear radiations.

Parts of the text are in small type, indicating those sections which are supplementary to the main argument, and which may be used in advanced courses, or by those students wishing to gain a more thorough understanding of the subject. Similarly, certain of the problems are intended for the more advanced student. Many of the problems require several steps in their solution, and serve to review earlier portions of the text.

The author is professor of physics at M.I.T., and has worked in the fields of magnetism, magneto-optics and nuclear properties.

Codetermination in the German steel industry.

W. M. Blumenthal. Princeton University, Industrial relations section, 1956. 115p., $3.00 (U.S.)

The policy of codetermination was introduced into the German steel industry in 1947. It was designed as a solution to the problem of the struggle between management and labour which in the United States and other countries has been solved by collective bargaining. Under the law, labour is given equal representation with management on the board of supervision, and a labour director appointed to the board.

This report, based primarily on the experiences of ten steel companies, considers the operation of the policy, which, as the author points out, resulted in basic changes in management. The findings make interesting reading, but it seems certain that codetermination is not likely to flourish on this side of the Atlantic.

*Electronic components symposium proceedings, 7th session, 1956.

New York, Engineering Publishers, 1956. 240p., illus., $5.00 (U.S.)

These proceedings contain forty-three papers grouped into the following sections: general; progress with materials; theory and operating principles; instruments and measurements; electron tubes and solid state devices; and passive components. Typical subjects covered include ferrites for use in S-band microwave components; glass in high temperature components; effects of nuclear radiation on components; automatic testing; high power silicon transistors; metal film resistors, and manufacturing subminiature tubes. Several of the papers deal with problems of equipment reliability.

*Handbook of chemistry, 9th ed.

N. A. Lange, ed. Sandusky, Ohio, Handbook publishers, 1956. 1969p., $8.50 (U.S.)

In preparing the present edition of this standard handbook for chemists and engineers, the editor has rearranged and rewritten the material of the previous edition in order to make room for new subjects and still keep the volume of convenient size for quick reference. The additions cover such varied topics as composition and properties of non-ferrous alloys, sodium and potassium alloys, and plain carbon and low alloy steels; efficiency of drying agents; physical properties of the earth and its atmosphere; and luminescence. Formula weights of inorganic compounds, and gravimetric and volumetric factors have been recomputed to conform to the values in the 1955 International Atomic Weight Table.

Handbook of chemistry and physics, 38th ed.

C. D. Hodgman, ed. Cleveland, Chemical rubber pub. co., Toronto, Ambassador, 1956. 3206p., $12.00 (U.S.)

In this thirty-eighth edition of the Handbook, the general arrangement remains the same, but many corrections have been made, and new material added. This includes an expansion of the calibration tables for thermocouples; tables listing heats of formation of inorganic oxides, miscellaneous properties of refrigerants, mean specific heat of liquids and salts, and the thermal conductivity of liquids.

The various sections of the Handbook include all the usual mathematical tables, tables of properties and physical constants, brought up-to-date, general chemical tables, data on the specific gravity and properties of matter, heat and hygrometry, sound, electricity and magnetism, light, quantities and units, etc.

The aim of the editors has been to include in a condensed form as much information on all branches of chemistry and physics as would be useful. Many of the tables and much of the information have been compiled especially for the Handbook from different sources, and the whole forms a compact volume, printed as it is on india paper.

*A handbook on belt conveyor design.

Compiled in association with Hewitt-Robins, Inc., New York. Erith, Kent, General Electric Company, 1956. 148p., 30/-.

Detailed explanations and calculations for the design of individual conveyors are given in this handbook. The first section of the book deals with the factors to be taken into account in the design of conveyors for specific purposes, and the following sections take up such essentials as idlers, drive equipment, trippers, brakes, and shaft design. Sample calculations for several types of conveyors are included, and tables of data are provided.

Introduction to solid state physics, 2nd ed.

Charles Kittel. New York, Wiley, 1956. 617p., illus., $12.00.

An introductory textbook in solid state physics, this book presupposes a general familiarity with modern atomic physics, while a knowledge of quantum mechanics is required for an understanding of the advanced topics developed in the appendices.

The emphasis in the book is on the areas of the subject which can be discussed in terms of simple, concrete, and well-developed models.

This second edition includes fuller explanations of the basic concepts of the subject, especially in the areas of crystal symmetry and energy band theory. New material is included on alloys, semi-conductors, photoconductivity, luminescence, and imperfections in solids.

• LIBRARY NOTES

Introduction to printed circuits.

R. L. Swigget. New York, Rider, 1956. 101p., illus., pa. $2.70 (U.S.)

Automation in the electronics manufacturing field has been made possible by the development of printed circuits, as they provide a system of making electrical interconnections without wires.

The various types of circuit found in electronic equipment are described, including ceramic based printed circuits, and etched and plated circuits, discussing the characteristics, functions and manufacture of each type, and their effect on servicing devices containing them. Other chapters cover components for printed circuits, assembly systems and the servicing of printed circuits.

Irrigation engineering, v. II.

I. E. Houk. New York, Wiley, 1956. 531p., illus., $14.00.

The first volume of this work discussed the agricultural and hydrological phases of irrigation. Based on information obtained from federal irrigation projects, the Bureau of Reclamation, published material, and the author's own experience, this volume considers irrigation projects, circuits and structure.

The first four chapters discuss irrigation projects, their feasibility and planning, and the study of project lands and water. The author considers the various methods of conveying irrigation water, and their different components: linings in canals and ditches, flumes, pipes, tunnels, diversion dams and intakes, storage dams, spillways, gates and valves, and fish protection.

This study gathers together information previously found only in periodical literature, and with the first volume provides very good coverage of the subject. Its value is increased by the bibliographies found at the end of each chapter.

Long-distance gas transport in the United States.

Paris, O.E.E.C., Toronto, Ryerson, 1956. 183p., illus., $1.50.

In the interests of promoting more efficient gas transport in Europe, this report was prepared by an O.E.E.C. technical assistance mission to the U.S.A. Some of the subjects covered include gas treatment before transport, transport networks, underground storage, treatment during transmission, pipe line operation and control, government inspection, sales and company organization. Considerable attention is given to materials specifications, and economic and political factors which affect this industry.

Management for tomorrow.

Society for the advancement of management. Philadelphia, Chilton, Montreal, Wallace, 1956. 179p., $6.75.

A report of the eighth annual conference held by the Philadelphia chapter of the Society for the advancement of management, the papers included consider such topics as the internal audit, opinion surveys, developing managers, control by incentives, integrated data processing, and the relations between management and labour.

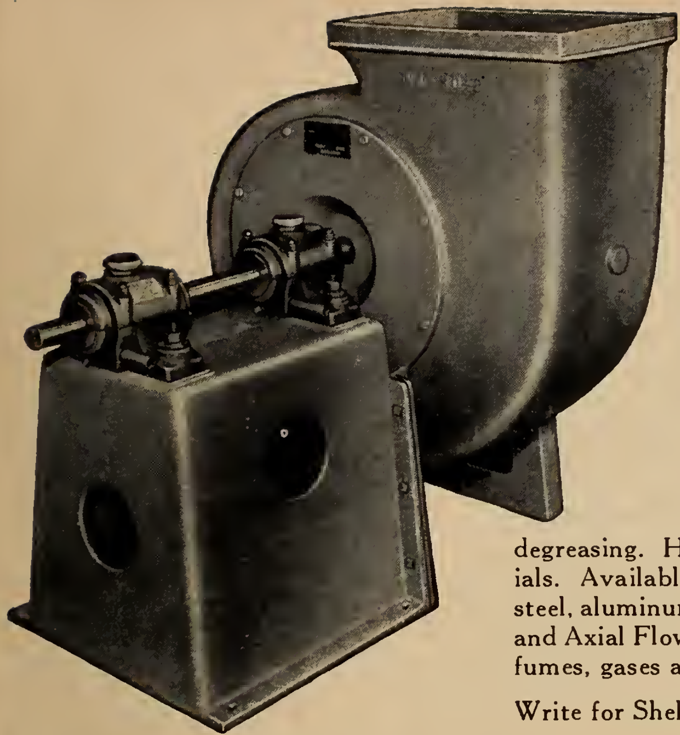
All the speakers were executives in various fields, and so able to illustrate their talks with examples drawn from their own experience.

Manual of departments and agencies of the Government of Canada.

R., J. H. and R. Quain. Toronto, Butterworth, 1956. 313p., $10.75.

A guide to the 20 departments, 40 boards and over 25 crown corporations comprising the Federal Government, this Manual is essential to anyone having any dealings with the government, and these days that includes just about everybody.

The various government agencies are considered under the headings of taxes and duties, government contracts, government services to business, transport



Sheldon

FUME EXHAUST FANS

This Sheldon Unit with cast iron housing is designed specifically for applications in metallurgical, pharmaceutal and powder plants, also in manufacturing processes such as etching, metal plating, galvanizing and degreasing. Handles corrosive fumes and withstands abrasive materials. Available with forward or backward curved wheels of stainless steel, aluminum, Monel metal or Everdur bronze. Sheldon Bifurcators and Axial Flow Fans widen selection range when problem of exhausting fumes, gases and vapors is encountered.

and communications, and miscellaneous. This latter embraces such diverse agencies as the National film board, the St. Lawrence seaway authority and the Atomic energy control board.

Included in the appendices are charts showing the organization of various departments, a directory of sources of official information, the countries entitled to the most-favoured-nation tariff, etc.

The authors, a lawyer and two chartered accountants, give information on whom to approach in a government department, on appealing a ruling made by a government official, on the workings of the income tax department, and on many other topics of interest to businessmen, lawyers, accountants, executives, etc.

Supplied with each copy of the manual is a copy of the 1956 Government telephone directory giving the address of every department in Ottawa, and the telephone number of every official of any importance.

Modern welding.

H. G. Taylor. London, British welding research association, 1956. 64p., illus., 4/-.

The series of Cantor lectures delivered before the Royal society of arts in 1956 is reprinted in this publlication. Present day processes such as argon arc and resistance welding are described, as well as the tools and uses of welding. The need for further research in this subject is emphasized because of its very important part in modern industy and constuction.

Nachrichten aus dem Karten-und Vermessungswesen. Reihe 1, Deutsche Beiträge und Informationen.

Frankfurt, Institut fur Angewandte Geodâsie, 1956. 73p.

The first of a series on mapping and surveying, this volume deals with Germany.

The first section of the book deals with maps of Germany published under the auspices of ICAO, with a scale of 1:500,000 with aeronautical information superimposed on an ordinary topographical map. A map of the Frankfurt area is enclosed as an example.

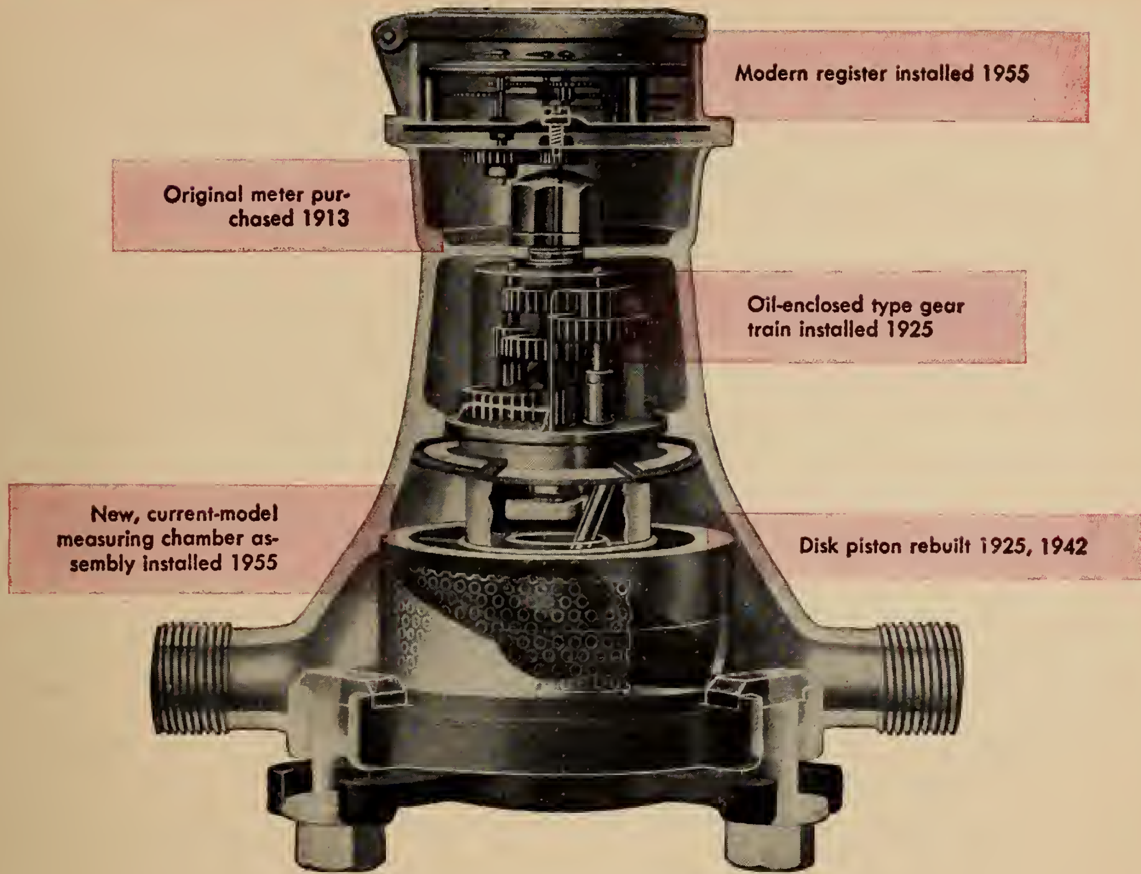
Other sections, by different authors, deal with aeronautical charts and flying safety, including tne work of ICAO and the ICAO aeronautical charts, and the map collection of the Institut für Angewandte Geodasie.

There is a bibliography listing several specifications for compiling maps, and aeronautical charts already published.

Nomographisches Rechnen.

Fritz Kieszler. Essen, Girardet, 1956. 190p., 9.80 DM.

This book on nomography is divided into two parts the first of which deals with the relation between two variable numbers, and the various systems of coordinates. The second part considers the relations between three variable numbers, networks etc. There is a brief bibli-



How NEW is this Meter?

It was built in 1913 . . . but it's almost as new as 1956. Over the years, working parts have been replaced. Its performance matches every standard of modern metering practice.

The parts used to repair this meter at its last overhaul are identical to those used in the latest Trident meters. They embody every thoroughly tested advancement known to the science of metering.

Designing modern parts to fit "old" meters has been a rigid Neptune policy for over 50 years. It is just one of the extra advantages that make Tridents a better buy . . . both for today and for the years to come.

Oxidation resistant silicon aluminium steels.

E. A. Brandes. Stoke Poges, Buckinghamshire, Fulmer research institute, 1956. 40p., tables, 10/6.

This report presents the date on tests of steels containing up to 4% silicon and 3% aluminum. Those containing 2-3% silicon with 0.5-1% aluminum are comparable in resistance to oxidation with 18% chromium, 8% nickel austenitic steel. The results of mechanical tests are also given.

These steels are considered to be useful alternatives to the highly alloyed steels now used for heat exchangers and electric furnaces, etc.

Photoconductivity conference.

R. G. Breckenridge, ed. New York, Wiley, 1956. 653p., $13.50.

The 1954 Conference on Photoconductivity was sponsored by the University of Pennsylvania, the Radio Corporation of America and the Office of Naval Research. The purpose of the conference was to advance the science of photoconductivity through discussion. This volume presents the latest information available at the time of the conference and is arranged in five sections, the first of which deals with the phenomenological theory of photoconductivity. The second section discusses aspects of the problem of interaction of a photon with a crystal lattice. The six papers in the section on electron processes are concerned with the fate of charge carriers poduced by the incident photons. The two final sections deal with the properties of photoconducting materials and with various recent developments.

Many of the discussions which took place at the conference are included with the thirty papers. The volume serves as an introduction to the subject as well as a text for workers in the field, containing as it does review papers on major topics, detailed papers on specialized topics and brief reports on current research.

Power production; the practical application of world energy.

Hans Thirring. London, Harrap, Toronto, Clarke Irwin, 1956. 309p., $5.25.

The author believes that one of the greatest problems facing the world today is the provision of an adequate power supply. His aim in this book is to give a comprehensive survey of all possible means of present and future power production, the available sources of energy, and the merits and drawbacks of the different methods.

After a brief discussion of power, energy and heat, and a survey of the sources and uses of power, the author considers the different engines used in power production: steam and internal-combustion engines, gas turbines, heat pumps and electricity.

The second part of the book is devoted to a discussion of the sources of energy: coal, petroleum and natural gas, fuels from vegetation, wood, etc., water power, solar energy, and atomic energy, including chapters on nuclear reactors and thermo-nuclear reactions.

Pofessor Thirring points out that the world consumption of energy is increasing by more than two percent perannum, and that in a relatively short period there will be a shortage of fossil fuels. He believes that increasing use will be made of nuclear fuels, which will help conserve the supply of coal, oil etc.

There is a three page bibliography, increasing the value of this very interesting work.

tices in the field of industrial research. They deal especially with industry's policies regarding research personnel. The recruiting, motivation and evaluation of research scientists and engineers are discussed in an examination of the all-important human element which plays such a large part in a successful research program.

Smoley's four combined tables for engineers, architects and students.
C. K. Smoley. Chautauqua, Smoley, 1956. 4 v. in 1, $12.00 (U.S.)

The four sets of tables comprising this one volume may also be purchased separately.

The first volume, Parallel tables of logarithms and squares, contains in addition tables of angles and trigonometric functions for levels to 12" by 32nds", and multiplication tables for rivet spacing and spacing of lattice bars. Book two contains all the usual five figure logarithmic and trigonometric tables, including circumferences, lengths of arcs for radius 1, areas and circumferences for diameters in units and fractions, and constants, formulas and decimal equivalents.

The third volume contains tables of slopes and rises, and the last segmental functions.

All the tables are clearly printed and very legible; in the new tables spaces are used instead of vertical and horizontal lines. The book is thumb-indexed for easy reference, and will be a valuable addition to any engineer's reference shelf.

***Strength of materials, part II. Advanced theory and problems, 3rd ed.**

S. Timoshenko. Toronto, Van Nostrand, 1956. 572p., illus., $8.00.

The second volume of the revised edition of this standard work for graduate students, designers, and research engineer includes a considerable amount of new material. Major changes have been made in the chapters devoted to torsion, plastic deformation, and the mechanical properties of materials. In the latter chapter, information for the proper selection of working stresses has been presented in considerable detail. New references, figures, and problems have been inserted throughout the text.

Supervision of scientific and engineering personnel.

J. T. Lloyd and R. D. Gray, comps. Pasadena, California institute of technology, Industrial relations section, 1956. 82p., $8.75 (U.S.)

This publication is an outline in the form of lists, definitions and questions and answers on the many topics pertinent to an understanding of successful professional supervision. Eleven sections cover: characteristics and development of the professional employee, building and maintaining a good technical team, appraisal of performance, the supervisor's role in professional development, policies for salary administration, benefit plans, handling complaints and grievances, unionization of professional employees, communications, organization of a professional work group, and what professional workers expect of their supervisors.

An excellent manual for those interested in a comprehensive survey of the principles of professional supervision.

• LIBRARY NOTES

Traffic department organization.

J. H. Wallace. Philadelphia, Chilton, Montreal, Wallace, 1956. 142p., $6.75.

The traffic department is of great importance to industry today, as transportation may take as much as twenty-seven percent of a company's sales volume, and is the largest single item remaining in controllable costs.

In this book the author discusses the functions of the traffic department and its place in an organization. He considers such problems as central traffic control, individual plant responsibility, unification of scattered traffic activities when a firm operates in different parts of the country, transportation cost control, the assignment of responsibilities and the functional division of activities.

Dr. Frederick illustrates his book with examples drawn from the experiences of many companies which have solved traffic problems.

Water power resources in Yugoslavia, v. I.

Belgrade, Institute of hydraulic engineering, 1956. 456p., illus., maps.

The Yugoslav National Committee of the World Power Conference decided after the war that the information available on the power resources of their country was incomplete and, in many cases, unreliable. It was therefore decided that a complete survey should be made. The results of the survey, commenced in 1948 are to be published in three volumes, of which this is the first, and considers the available hydro resources. The other two volumes will give information on the possibilities of utilizing water power, and on the hydro power plants already in operation.

The first part of the volume, by Dr. V. M. Yevdjevic, is subtitled Investigation methods of water power resources, and considers various aspects of hydro-electric power including its potentials and the amount available for economic use. Other chapters cover the data needed for estimating hydro potentials; topographical and hydrological data, discharge curves, rainfall fluctuations etc.

The second part of the volume lists the actual water power resources of the country, the information given being divided into the different drainage areas. There are many charts and maps, and beautiful photographs of the Yugoslav countryside.

The text is in parallel columns of Serbo-Croat and English, and there are summaries in French, Russian, Spanish, German and Italian. This is a very interesting publication, and the Yugoslav National Committee is to be congratulated on its preparation.

STANDARDS REVIEWED

British Standards, British standards institution, 2 Park St., London W.1. Also available from the Canadian standards association.

B.S. 468:1956 Solid rolled steel railway wheels and disc wheel centres

Authorized by the Iron and Steel industry standards committee, B.S. 468 is part of a general revision of British standards for railway materials. Each specification includes requirements for the quality of the material and for marking and identification, tensile and falling weight tests, and test procedure in general. The specification for disc wheel centres permits the deflection test as an alternative to the falling weight test. The form of the tensile piece is given in an appendix. 3/-.

(Continued from page 1758)

24 in the presentation of a paper entitled "Installation and Operating Experiences with the 2500 foot head Kemano Impulse Turbines".

This paper was prepared by J. T. Madill, M.E.I.C. manager of power operations, B.C. and F. P. Gordon, S.E.I.C. master mechanic of the Aluminum Company of Canada, at Kemano. Mr. Gordon presented the paper to the meeting, and exhibited a great many slides of the construction stages from the setting of the bottom plate to installation of the scroll cases. Since machines of three different manufacturers were involved, scroll case assembly details differed and the merits of each could be judged from a construction viewpoint.

The three runners were of considerable interest, one being integrally cast, another with bolted buckets and the third integrally welded.

Following installation all three turbines were tested for efficiency by the same method so that the relative results were highly accurate.

During the initial period of operation, cavitation was a serious problem but full co-operation with the manufacturer in changing material and bucket contours brought it well under control.

The meeting was well attended by seniors in the hydro-electric field who considered the paper a valuable contribution.

J. T. Madill, M.E.I.C.

Cristel, and Leo Scharry. Bottom. G. N. Martin, publication committee chairman, at right, with Lucien L'Allier and P. E. Morrissette.

ENGINEERING CAREERS

Primary Metals and Metallurgical Industries

CANADA IS particularly fortunate in her great natural resources of power, forests, and mineral ores. Large industries have grown around these resources, all of them offering wide scope for engineers who play a large part in the development of the industries.

Possible careers for engineers in the power and forest products industries are outlined elsewhere in this series; this article will deal with the primary production of metals up to semi-finished products. The metal fabricating industries will be considered further in another article.

Non-Ferrous Metals

Among the principal producers of the world, Canada is second in output of aluminum metal, with some 19 per cent of the world total in 1955. Bauxite, the ore from which aluminum is extracted, is not one of Canada's major natural resources, but is imported; however, aluminum production requires abundant electric power, which is available in Canada at economic rates — in fact, the aluminum industry has itself developed several of the country's major hydroelectric power resources.

On a mine basis, Canada is the world's leading producer of nickel, with some 65 per cent of total production in 1955. Also on a mine basis, Canada is second in the world in production of zinc, fifth in copper, and fifth in production of lead. The greater part of all this production, including aluminum, is exported, and imports of these metals are virtually non-existent.

Other non-ferrous metals are also playing an increasing part in the Canadian economy. These include cobalt, magnesium, titanium, uranium, zirconium, and others, many of which may be used in the development of alloys for special applications.

Iron and Steel

One of the most impressive developments in the Canadian economy has been the enormous increase in output of iron ore in the last few years, largely as a result of opening up hitherto inaccessible deposits. The world's steel industries are continuously expanding, and there is an ever more urgent demand for high-grade iron ores. Canadian production rose from some 7.3 million tons in 1954 to 17.4 million tons in 1955, or from seventh to fifth largest producer in the field. Soon Canada will have moved up to third place as a producer of iron ore, behind the U.S.A. and USSR; already she is the largest exporter of this material in the world.

As a result of this great expansion, the Canadian iron and steel industry has received considerable encouragement to expand by making better use of existing capacity and introducing new techniques. At the end of 1955 steel furnace capacity was estimated at some 5.5 million tons, of which Ontario had over 70 per cent, Nova Scotia about 18 per cent, and Quebec nearly 7 per cent. Actual production of steel ingots was about 4.4 million tons; it is estimated that steel production will reach 11 million tons in the next twenty years.

Expansion

In both the non-ferrous metals and the iron and steel industries only major expansion can be foreseen in the next decade or so. Not only will this expansion be in the fields of primary production, but there is a greatly increased awareness of the need to develop a strong secondary industry to process the primary resources into finished products. At the same time the metals producers are expanding their facilities for making the semi-finished products, such as plate, sheet, strip, bar, wire, and other extruded and cast shapes, which are all an inherent part of major importance to the industries considered here.

All in all, therefore, the metals

A typical scene during smelting operations in one of Canada's more recently developed metallurgical industries. Among the mechanical equipment, two 60-ton cranes serve the furnaces. Plant must be designed for severe operating conditions.

industries in Canada face a period of major expansion in all fields; to accomplish this expansion they will need increasing manpower, particularly engineers and scientists.

Engineering Fields

In the metals industries there are several well-known very large organizations of international scope which operate in every field from mining to the manufacture of finished products; there are also many smaller firms that may specialize in a particular metallurgical field. Between them they offer opportunities to engineers in all branches of the profession in most parts of Canada and sometimes abroad.

Civil engineers are needed for construction, design and project engineering. Some of the projects in the industry are in remote areas in which whole new communities are established as the country's resources are developed. Engineers may have to design and build anything from a small plant extension to a whole new town.

Electrical engineering plays a large part in these as in other industries and, in addition, major electric power developments are directly associated with metals production, particularly in the aluminum industry. Here, the field ranges from the design of instrumentation for the control of metallurgical processes to 50,000-ampere switchgear, and transmission lines that cross mountain ranges.

Chemical processes are involved in much of the basic production of metals, and furthermore many chemical by-products arise from the industries. Consequently, there is a demand for chemical engineers in several fields.

In the primary industries, mechanical engineers are required to design, operate, and maintain machinery and equipment for ore, chemical, and metals processing, and for materials handling. In the field of semi-finished products a wide range of equipment is installed, for example, from steel rolling mills to fine wire-drawing machinery. Mechanical engineering staffs are engaged in many activities connected with the design, construction, and operation of this plant and equipment, including industrial engineering.

Other engineers find opportunities in metallurgical research and development, testing, quality control, alloy improvement, and so on. The industries frequently incorporate modern research laboratories in which processes, products, and fabricating methods are some of the fields fundamentally investigated.

As in other industries, various levels of production supervisors are in charge of different phases of the industry. Frequently these supervisory positions are held by engineers experienced in plant operation. There are thus opportunities for progress within purely engineering departments, or in production and other fields; in the industry generally there is no limit, up to the head of the organization, to the progress that can be made by a graduate engineer with the right qualifications. Indeed, many of the top positions in the metals industries are now filled by professional engineers.

It has been stated that the metals industries in Canada are expanding and that they are also major exporters of their products. The domestic and world markets are highly competitive, however; for example, plastics are competing seriously with metals in some structural fields, and aluminum conpetes with copper in electrical applications, while all the time the producers of other countries are striving to gain markets. Many engineers are needed to strengthen technical sales departments and to develop both new materials and new industrial applications for existing products.

An aerial view of the aluminum smelter at Kitimat, in northern British Columbia. Developments such as this call for engineers to contribute to the design, construction, and running of new towns, power projects, and industries in undeveloped areas.

Training

The industry generally follows the logical course of training the newly-graduated engineer by giving him experience of the operations through working in different plants and departments, and further specialized training to fit him for the field to which he is best suited.

In addition to many training programs, opportunities are frequently available to technical staffs to benefit from specific outside courses, some of which are sponsored by organizations in the metals industries.

Although not alone in such work, these industries make generous contributions to education in the form of grants to schools and universities, and scholarships to students.

Salaries and Benefits

Starting salaries are in line with those prevailing in other major Canadian industries. Prospects for advancement, as indicated in this article, are good.

Benefits to be generally expected include pension and health insurance schemes, and paid vacations. Bonus payments are made in some parts of the industries, and other advantages that may be offered are loans, grants towards further education, and facilities for obtaining company stock. One company has a well-known profit sharing scheme for its employees.

BAILEY CONTROLS

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Canadian Car & Foundry Company Limited. — The appointment of E. G. Burgess to the position of vice-president, planning and development, has been announced by Allan C. MacDonald, executive vice-president of the company.

Jaeger Machine Company of Canada Limited. — R. D. Macdonald, formerly general manager, has been appointed vice-president of the company.

Trans-Canada Pipe Lines Limited. — N. E. Tanner, president of the company, has announced the appointment of Robert C. Berry as treasurer; Mr. Berry will be located in the company's Toronto office.

Honeywell Controls Limited. — W. H. Evans, president of Honeywell Controls Limited, recently announced the following appointments: L. F. Wills, formerly works manager, will be vice-president in charge of administration and production; John H. Fox, M.E.I.C., becomes vice-president in charge of sales; Carl A. Anderson will be vice-president of the company's aeronautical division; C. J. Hooks, formerly comptroller of the company, has been named treasurer.

Canadian Marconi Company. — C. P. McNamara, manager, commercial products division, has announced the following changes: J. A. Hammond has been appointed general sales manager, commercial products division, and J. H. Martin has become sales manager of the standard lines department of the division

The International Nickel Company of Canada Limited.—Aubrey S. Tuttle, a member of the Canadian development and research division of the company for eleven years, has been transferred to Calgary to open a Western Canada technical field section.

Peacock Brothers Limited.—J. J. Hillen has been appointed general sales manager, and D. S. McCann assistant general sales manager.

Frank E. Miller

Bertram A. Wilson

J. Carl Wilson

J. A. Wilson Lighting & Display Limited. —J. A. Wilson, of J. A. Wilson Lighting & Display Limited, Toronto, and J. A. Wilson Lighting and Display Incorporated, Buffalo, N.Y., announces the following reorganization: J. Carl Wilson becomes president and general manager of the Canadian company; Bertram A. Wilson becomes president and general manager of the American company; Harry R. Yates has been elected a director and vice-president of the Canadian company.

Linde Air Products Company. — The appointment is announced of Robert G. Leckey as manager, advertising and sales promotion, of the company (Division of Union Carbide Canada Limited).

Monsanto Canada Limited.—It has been announced that R. M. Beaugrand has been promoted to the position of operating superintendent - plastics, and T. P. Foley to the newly-created position of traffic superintendent.

The Pressure Pipe Company of Canada Limited.—The company has announced the appointment of Frank E. Miller as Ontario manager in charge of their new

New *Cordon Circuit Breaker. *Provides, in one integral unit, positive protection for your complete network. No wider, no deeper and, at the most, only 3 inches longer than standard frame sizes.*

*CORDON . . .

a revolutionary new molded case breaker that provides short circuit protection to 100,000 rms AMPS

The new CORDON circuit breaker solves a serious problem for designers and users of low voltage electrical distribution systems (up to 600 volts A-C) who are faced with ever increasing short circuit loads due to high concentrations of power.

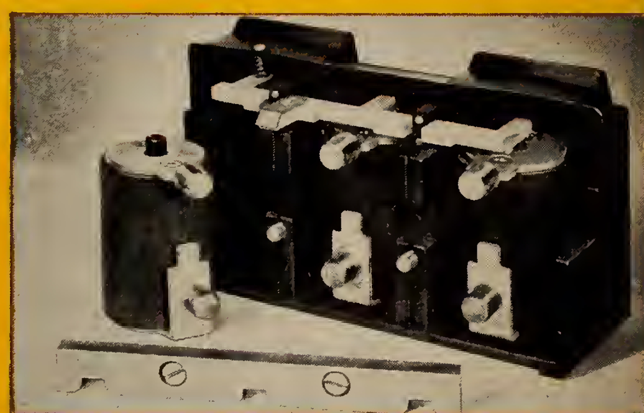
The CORDON breaker combines a standard moulded-case circuit breaker with a specially designed current-limiting device called Amp-Trap. This entirely new approach extends short circuit protection from 25,000 to 100,000 rms. amperes—while retaining all circuit breaker automatic operational advantages!

The standard section of the CORDON circuit breaker contains a conventional thermal trip for minor overloads and instantaneous magnetic trip for all faults below extreme short circuit currents.

The new Amp-Trap current limiting device takes over the interrupting duty at a value below the maximum interrupting rating of the breaker and is designed to minimize arcing even under unusually high short circuit currents. It will positively interrupt short circuit currents in a quarter of a cycle. Thus, all magnetic stresses and heat produced by the short circuit are kept well within the capacity of the breaker.

The CORDON circuit breaker is available in four frame sizes with continuous current ratings of 100, 225, 400 and 600 amperes. Its standard features include interchangeable thermal magnetic trip units, choice of rear-connected studs, plug-in mounting or front-connected terminals for switchboard mounting, special features are also available.

For full information on this entirely new CORDON circuit breaker, write or call EPD.



The Amp-Trap (*which extends short circuit protection up to 100,000 rms. amperes*) *remains extremely cool under rated load current and does not affect conventional thermal trip operation for minor overloads. The spring-loaded plunger in the centre of each fuse is released when subjected to high fault currents thus providing a visual indication of the phase that shorted. In addition the projected plunger actuates a common tripper bar, opening all three phases of the circuit breaker.*

5513-R

**Cordon* (*Definition Webster's*) (*Military*) *A chain of forts—A line of sentinels protecting an area, or a body of men.*

New Cordon Circuit Breakers are the sentinels that protect your electrical equipment!

plant in Toronto; until the end of this year Mr. Miller will be located at the company's head office in Montreal.

A. D. Margison and Associates Ltd. — Harold B. Johnson is a newcomer to the company from the consulting engineering firm of Merz and McLellan in Great Britain. The latter firm is now allied with A. D. Margison and Associates Ltd. Toronto.

Canadian Resins and Chemicals Limited. —The company has announced the following appointments Arthur G. Pinard as sales supervisor, resin and chemical products; Edward A. Clout as sales supervisor, granular products; Maurice F. Malone as sales development supervisor, industrial products division. James C. Bacon has been appointed a technical representative, industrial products division, Toronto office.

The British Thomson-Houston Co. (Canada) Ltd.—H. G. McHaffie, general manager, announces the following appointments: B. N. Callaghan, manager, apparatus department, and J. Grant, manager, industrial products department, both with headquarters in Toronto; J. R. Platts, sales manager, Quebec and Maritime Provinces, with headquarters in Montreal.

Sun Oil Company Ltd. — A. G. Galoska has been appointed sales representative for the industrial products department of the company in the Montreal area.

Alcan Chief Engineer. — Franklin T. Matthias has been appointed chief engineer of the Aluminum Company of Canada Limited. He succeeds W. L. Pugh, M.E.I.C., who is retiring after many years of service, but who will continue to act as consultant to the company.

Air Reduction Canada Limited.—Allan F. Smardon and Ernest Ehrhardt have been appointed technical sales representatives for the company.

Department of Public Works, Canada.— The following senior staff changes at headquarters, Department of Public Works, have been announced in Ottawa by Major-General H. A. Young, Deputy Minister: Robbins L. Elliott, formerly assistant director, property and building management branch, becomes the new chief of the personnel division; H. G. Hunt, former chief of the personnel division, is the new chief of the purchasing and stores branch; R. G. McFarlane, who was chief of the purchasing and stores branch, takes over as assistant director, property and building management branch.

News of Business and Industry

Federated Consultants Limited.—Twelve consulting engineering firms and individual consultants, combined to form an organization, Federated Consultants Limited, will be able to provide services in nearly every major engineering field. Since its formation the organization has been engaged in major operations in Canada and internationally.

The member firms are: Hunting Technical & Exploration Services Ltd.; T. O. Lazarides, Lount & Partners; Karel Rybka & Associates; and Milner Naismith. The associated consultants are: Gordon S. Adamson, consulting architect; Stanley R. Frost, M.E.I.C., consultant on heavy industrial engineering; R. A. Hanright & Co., consultants on thermal power engineering and various aspects of heavy industry; Jens C. Holm, consultant on cement production and cement plant engineering; G. Ross Lord, M.E.I.C., consultant on projects involving hydraulics and fluid mechanics engineering; Norman D. Wilson, M.E.I.C., consultant on public transit and traffic studies; and Clyde Wynant and Associates, consultants on pipeline engineering practice. Federated Consultants was established as a private company incorporated under Dominion charter in November, 1955. All members retain their individuality and private practices.

Dugald Cameron Associates. — It is announced that Dugald Cameron, M.E.I.C., has as of October 30, 1956, resigned from his position, as vice-president and managing director of Dexion (Canada) Ltd., in order to devote his full attention to the expanding business of Dugald Cameron Associates Ltd., Malton, Ont. The latter firm has, since 1946, manufactured office and factory partitions and engaged in general steel fabrication, including welding, marketing under the trade name of Fur-Nail Steel Products.

Hydro Project in Pakistan. — An order for the supply of two 9,000 h.p. Kaplan turbines for the Shadiwal canal hydro-electric development in Pakistan has been awarded to Dominion Engineering Company, Limited. These turbines were ordered on behalf of the Colombo Plan Administration of the Government of Canada. Dominion Engineering is also manufacturing four 55,000 h.p. Francis type hydraulic turbines and other equipment for the Warsak development in Pakistan, also to be supplied under the Colombo Plan. H. G. Acres and Company Limited of Niagara Falls, Ontario are acting as consulting engineers for the two projects.

Canadian Representation. — Pacific Division, Bendix Aviation Corporation, of California, announce complete sales, engineering, and service for Bendix-Pacific Electro-Span digital remote control and telemetering equipment in Canada, through recent association with Computing Devices of Canada Limited, in Ottawa.

Change of Address. — R. M. Way & Company Limited, consulting engineers, have moved (from 696 Yonge Street) to 321 Bloor Street East, Toronto.

Early Aerial Surveys. — Records of the earliest aerial surveys in Canada were exhibited at the recent opening of new quarters for Photographic Surveys (Quebec) Limited, at 8375 Bougainville Street, Montreal. The company's predecessor, Interprovincial Airways, was formed in 1923 as Canada's first commercial air survey organization. Photographic files have been maintained since 1923.

Fifty-year Celebration. — A. R. Williams Machinery Western Limited, recently celebrated 50 years' operations in western Canada with a machinery show in the company's head office in Vancouver.

Canadian Carborundum Expansion. — The silicon carbide plant of Canadian Carborundum Co. Ltd., at Shawinigan Falls, Que., is to be enlarged and modernized. Some 20,000 sq. ft. of additional floor space will accommodate new furnace units and will be equipped with the latest materials handling equipment. It is planned to have the new plant in operation in September, 1957.

New Montreal Plant. — Federated Metals Canada Limited has opened a new plant for non-ferrous metal fabrication and processing. The 40,000 sq. ft. plant is in Lachine, near Montreal. Another plant was recently opened in Scarborough, near Toronto.

Wire and Cable Developments. — Western Canada's first telephone cable plant and a wire and cable factory were recently opened at Fort Garry, Manitoba. Both plants are operated by Canada Wire and Cable Co. Ltd. but the telephone cable is produced by Telecables and Wires Ltd., a new company in which Canada Wire has the majority share interest; minority holdings are owned by the General Cable Corporation, of the United States, and the Telegaph Construction and Maintenance Co. Ltd., of London, England. Among other products the Canada Wire plant will supply soft copper wires to Telecables.

Federal Public Works Contracts. — Public Works Minister Robert Winters has announced that contracts involving expenditures totalling $4,873,006.66 were awarded by the Federal Department of Public Works during October, 1956. The amount for new works is $3,531,964.25; for the repair and maintenance of existing structures, $1,000,785.41; and for dredging $340,257.00.
