For the higher and more probable estimated value of 0.10 for the structural damping, the wind-tunnel tests for the bridge with the deck completely closed, as by ice, show complete and absolute stability against vertical and torsional oscillations at all wind velocities and complete and absolute stability against coupled oscillations at all wind velocities up to 632 miles per hour for the lowest mode of oscillations, 942 miles per hour for the next mode of oscillations, and 966 miles per hour for the next higher mode of oscillations.

Accordingly, even under the worst abnormal conditions, the Mackinac Bridge is ultra-safe against any possibility of aerodynamic oscillations. The indicated critical velocities for the assumed abnormal conditions approach the supersonic range.

The highest wind velocity ever recorded in the vicinity of Mackinac is 78 miles per hour. The required "critical velocities" of 632, 942, and 966 miles per hour may be dismissed as fantastically impossible.

COMPARISON WITH OTHER BRIDGES

The outstanding aerodynamic stability achieved in the Mackinac Bridge is best shown by a comparison (Table III) with the critical velocities determined by similar wind-tunnel investigations for other notable suspension bridges.

For the prior long-span bridges, the critical wind velocities listed in the accompanying Table III are taken from published reports by Professor F. B. Farquharson in official bulletins (1954) of the University of Washington Engineering Experiment Station.

CONCLUSION

The Mackinac Bridge is one hundred per cent safe, aerodynamically, even under the most adverse conditions that may be expected to occur. It represents the achievement of a new goal of perfect aerodynamic stability, never before attained or approximated in any prior suspension bridge design.

A Progress Report on Canadian Atomic Power

I. N. MacKay, M.E.I.C.,

Manager, Engineering, Civilian Atomic Power Dept., Canadian General Electric Company Limited.

In the last few years the production of atomic power in Canada has come much closer to realization. The author discusses the main factors involved, gives an overall view of other programs, and deals particularly with the costs involved.

THREE YEARS AGO I had the opportunity of presenting to the annual meeting in Halifax some remarks concerning the possibility of atomic power in Canada. In these three years much has happened to bring atomic power closer to realization, and I would like to discuss some of the reasons for this. In particular, I would like to discuss some of the fields in which atomic power may soon find application, and also some of the technical developments which are likely to reduce the cost of atomic power to the range of conventional sources in many parts of this country.

In early 1954 a group was formed at Chalk River to study the design of a small demonstration power reactor. The group consisted of engineers and scientists from utilities, industry and Chalk River. The power range was specified between 10,000 and 20,000 kilowatts. The results of this study have been reported in the *Engineering Journal* in a paper* by Mr. H. A. Smith, of Ontario Hydro, who headed the study. As you already know, Atomic Energy of Canada Limited subsequently approached most of the principal manufacturing engineering firms in Canada and selected the Canadian General Electric Company Limited to carry out the design, and subsequently the construction of the N.P.D. power station. The Civilian Atomic Power Department of this company was formed in May 1955, with a staff of about two dozen engineers including about half a dozen from Atomic Energy of Canada Limited. During the first three weeks, a series of lectures was presented to the group by members of the Chalk River staff on various subjects associated with atomic power. The group spent most of the summer of 1955 reviewing the requirements for the N.P.D. reactor in detail and repeating many of the calculations originally carried out by Mr. Smith's group in order to familiarize themselves with the fundamental considerations of the design. During the fall, major alternatives were considered in detail; and a design which is believed to be substantially final is now progressing. Costs have been considered carefully throughout all stages of the design, and although there is as yet no cost estimate based on a final engineering design, we are in a far better position to assess the economics of this type of reactor than we were three years ago.

Let us first look at some of the power requirements in this country. The basic characteristics of atomic power plants as compared to conventional thermal power are the negligible cost of fuel transportation, the low but not negligible fuel cost, the relatively high capital cost, and the great economies attainable in large sizes. For these reasons we would expect atomic power to be used initially where hydro, natural gas, or other cheap power is not readily available. For a good many years to come it looks as though British Columbia, the Prairie Provinces, and Quebec Province will have cheap power available close to the large load centres. We can expect to see central station

*The Preliminary Design of NPD, December, 1955.

Read at the 70th Annual General and Professional Meeting of The Engineering Institute of Canada, Montreal, May 1956.

atomic power plants first in Ontario and the Maritimes.

Last January the Ontario Hydro-Electric Power Commission released some interesting figures concerning their expected power requirements over the next thirty years. Ontario consumes nearly two-fifths of the total electrical power consumed in Canada, and over the last three decades the increase has been at a rate of a little over 6½ per cent per year. However in Southern Ontario in the last five years the increase has been at a rate of 8½ per cent and last year the total load on the system increased by more than 14 per cent. By about 1965, almost all of the economically available hydro-electric power in the province will have been developed. Practically all further additions will be in the form of thermal power stations. The program assumes that by 1965 atomic power will carry base loads economically. Figure 1 illustrates approximately the expected growth of this system to 1980. You will see that the coal merchants need have no fears, but that those who manufacture waterwheel generator equipment would do well to turn their attention to much higher speed machinery. The atomic, or nuclear, power program calls for a 400,000 kilowatt station by 1965 and over 2½ million kilowatts of atomic power during the following five years. By that time the total thermal electric generation will have overtaken the hydro-electric capacity.

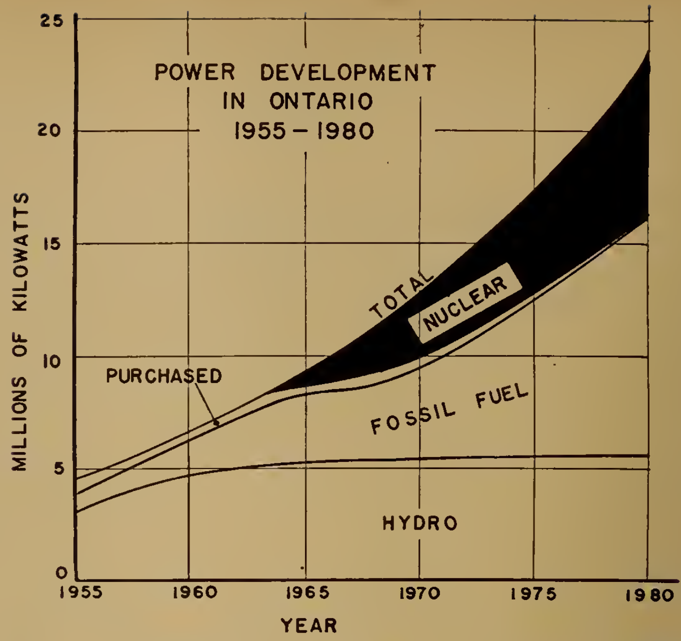

Fig. 1. Expected power development in Ontario, 1955-1980.

Growing power requirements in the Maritime Provinces call for smaller new blocks of power than in Ontario. These are smaller than the most economic atomic power unit sizes. However, due to the high fuel costs in this area, atomic power can be expected to compete in smaller units than the optimum. It would appear that the use of atomic power in the Maritimes will depend on the general rate of development there, but it could also directly affect this growth.

In addition to central station power use, there are a number of other opportunities in this country for the application of atomic power. These are based primarily on the negligible fuel transportation and storage costs. In remote communities where the cost of transportation of oil or coal is high, the cost of power may be from 15 to 35 mills per kilowatt-hour. An N.P.D. type of power plant can offer power close to the bottom end of this range. Another obvious use for atomic power is in naval ships, where it offers cruising ranges far beyond anything obtainable with conventional fuels. During its first year of operation, the U.S. Submarine Nautilus exceeded the previous record for distance travelled submerged by a submarine by a factor of more than ten. However, this type of power plant uses highly enriched fuel and is very expensive to operate. Its use in a surface ship would be difficult to justify. Although I have not gone into the question in any detail, I would doubt that power reactors could be used economically for the propulsion of naval ships of much under say 7,000 tons. By economic in this sense I refer to power plants where the operating costs would be acceptable considering the tactical advantages to be gained by their use.

The development work required to produce cheap and reliable central station atomic power plants is very largely applicable to the development of atomic power plants for other uses. With Canada's present man-power situation, it seems logical to proceed with the development of central station power plants first. This is, of course, being done and the N.P.D. reactor is intended to demonstrate the practicability of atomic power for large central stations. However, with only minor alterations, this design would provide economic power for an isolated community which is sufficiently stable to pay off the capital investment over a period of 20 years or more, with a reasonably stable load of at least 10,000 kilowatts.

A brief look at the programs of some other countries seems appropriate. Britain is undoubtedly the furthest advanced in producing commercial power reactors which will be economically attractive in that country. This is partly because their conventional fuel supply is dwindling and they can afford to pay relatively higher costs for atomic power. Their schedule calls for sixteen power reactors to be constructed by 1965 at a total cost of some $840,000,000 providing 1½ million to 2 million kilowatts. The first of these reactors is expected to be in operation this year. The first ten of these power plants are all of the same type, selected by the British Atomic Energy Authority, gas-cooled, graphite-moderated, probably using slightly enriched fuel available from the diffusion plant which was erected for military purposes. The used fuel from the reactors will contain significant quantities of plutonium. The U.S. have either under construction or in advanced engineering stages some two dozen atomic power plants of all types including those for ship propulsion. In all cases the U.S. reactors so far described publicly will use at least slightly enriched fuel. Table I shows the main features of power reactors now planned by private industrial groups in the United States. Russia expects to have two 50 Mw. reactors operating this year. Norway and France both have active atomic programs under way, and there is also a joint Dutch-Norwegian ship propulsion program.

ceivable that if the United States emphasis on enriched fuel creates a great demand for this, in the future we might prefer to sell enriched rather than natural uranium to users, and we might then erect a diffusion plant. However

Table I. Power Reactors Planned by Industry in U.S.

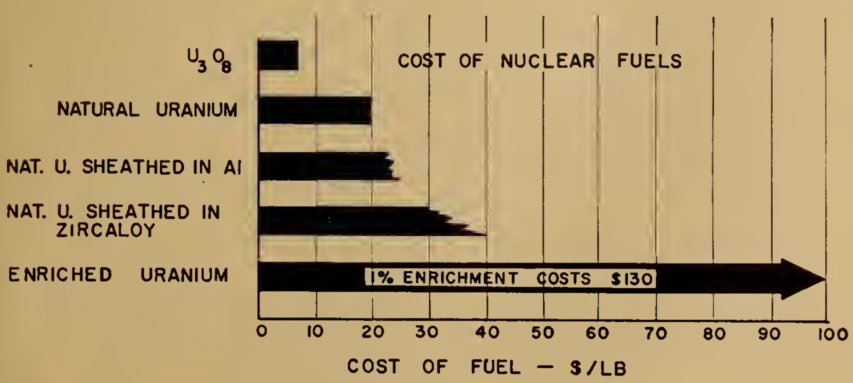
Owner	Builder	Power, Mw.	Type	Cost/kw.
1. Consolidated Edison Co. — Indian Point, N.Y.	Babcock and Wilcox Co.	236	Pressurized ordinary water	$230
2. Consumers Public Power District of Columbus, Neb.	North American Aviation Inc.	75	Sodium-cooled graphite	320
3. Detroit Edison Co. Group		100	Fast breeder	540
4. Commonwealth Edison Group	General Electric	180	Dual cycle boiling water	250
5. Yankee Atomic Electric Co.		100	Pressurized ordinary water	230

The three countries which have found it necessary to make the extremely heavy capital investment necessary to erect uranium enrichment plants are perhaps naturally using enriched uranium to fuel their power reactors. These countries are, of course, the United States, Great Britain and Russia. Although I have no information on the cost of production of U235 in the United States I do not believe that the use of enriched uranium will prove economical for central station power plants in the long run, unless a large part of the capital cost of the plants required to enrich the uranium can be charged to military expenses. I cannot imagine Canada spending very many hundreds of millions of dollars on an enrichment plant for military purposes. Therefore, unless we are to rely on imported fuel for our atomic power program, we must build our reactors to use natural uranium. As it turns out, this seems to us to be much the cheapest way of obtaining central station atomic power anyway. I suppose that it is conceivable that if the United States

if this day arrives, we can adjust our program to suit the circumstances.

Figure 2 illustrates diagramatically the relative costs of various forms of uranium fuel. The difference between the cost of U_3O_8 and of natural uranium metal is accounted for by the cost of proeessing the oxide to produce the metal. Low temperature reactors such as the N.R.U. and the N.R.X. at Chalk River use uranium metal sheathed in aluminum. The cost of this sheathing is in the order of $2 per lb. of uranium. High temperature power reactors in general use uranium sheathed in zircaloy or some other zirconium alloy. The cost of this sheathing is in the order of $10 to $20 per lb. of uranium; however as very few tons of uranium have actually been sheathed in zirconium to date, we can expect some reduction in the cost of this process. The cost of natural uranium enriched with about 1 per cent additional uranium 235 amounts to about $130 per lb., using U.S.A.E.C. prices. The P.W.R. reactor being built at Shippingport, Penn., for the Duquesne Light Company can be quoted as an example to illustrate the costs of slightly enriched fuel in a power reactor. This reactor uses between eleven and twelve tons of natural uranium plus 50 to 60 kilograms of uranium 235 in a nearly pure form. The cost of the natural uranium is in the order of $500,000, whereas that of the U235 is about three times this amount.

Fig. 2. Relative costs of various forms of uranium fuel.



A pound of U235 contained in natural uranium costs about one quarter as much as a pound of separated U235 at U.S.A.E.C. prices. Yet the former will release more energy in a reactor, and in doing so will produce upwards of three quarters of a pound of plutonium which may be had for the cost of chemical separation. However, it should be made clear that the use of enriched fuel gives the designer of the reactor much more freedom than the use of natural uranium, and may permit important economies in the capital costs of the reactor.

There are a number of ways in which the costs of natural uranium fuel may be reduced in the future. Although zircaloy is apparently the most suitable alloy for sheathing uranium for water-cooled power reactors at present, the Aluminum Company of Canada is cooperating actively with Atomic Energy of Canada Limited in the development of an alloy of aluminum and nickel which may be suitable and which would certainly reduce the cost of sheathing the fuel very greatly. Fused uranium oxide (UO_2) is currently being investigated as a substitute for uranium metal. This has several advantages including the fact that it is not acted upon chemically by the coolant in the case of sheath failure. Although its cost at present is not much different from that of metal, when large quantities are required it might be expected to cost less than the pure metal. When natural uranium is used in a heavy water reactor of the type that we are considering, for every hundred atoms of U235 contained in the natural uranium used up, something like eighty or more atoms of the otherwise inert U238 are converted into plutonium. Plutonium has properties somewhat similar to U235 and is capable of allowing the fuel to continue to be useful for a long time after all of the original U235 is consumed. Used fuel rods from reactors which operate on natural uranium contain considerable quantities of plutonium. This can be chemically separated relatively cheaply and may be used for small more or less transportable reactors where higher than normal fuel costs are acceptable. In a nuclear economy governed by military considerations, of course, plutonium has considerably higher value.

An intriguing possibility seems to lie in the use of thorium as a fuel. Thorium has properties somewhat corresponding to uranium 238, and is incapable in itself of supporting a chain reaction. However when it absorbs neutrons it produces uranium 233, which is better than either uranium 235 or 238 for fueling the kind of reactor about which we are talking. Theoretically at any rate a reactor fueled with a mixture of a small amount of uranium 233 and normal quantities of thorium would produce more uranium 233 from the thorium than is consumed. This should make possible very long irradiations from a set of fuel elements, perhaps ten times as long as from natural uranium. If proved practicable, this fuel might cost less than 1 mill per kilowatt-hour. This type of fuel could probably be used in heavy water reactor originally designed for the use of natural uranium without any other change. I understand from a prospector friend that there are large quantities of thorium associated with uranium deposits in Canada, but that extraction might be more costly than obtaining it from the Monazite sands in Brazil and India.

Figure 3 illustrates the effect of cost of fuel and also of the amount of energy which can be extracted from it in the reactor on the cost of the power from the station. Conditions are assumed to be approximately as they will be in the N.P.D. reactor. We know that we can obtain 3,000 megawatt-days per ton easily, we hope that we will be able to obtain 6,000 per ton out of the fuel for the N.P.D. reactor without chemical processing, and the graph suggests the economies that might be obtained with fuel such as I mentioned irradiated to perhaps 50,000 Mw. days per ton. Incidentally this latter figure is equivalent to more than two billion B.t.u. per pound. The heavy line at the top indicates approximately the corresponding

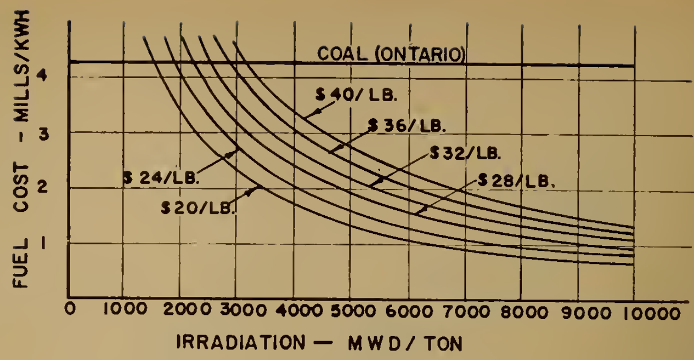


Fig. 3. Effect of the cost of fuel.

figure for the cost of coal laid down at a steam power station in say the Toronto district.

Figure 4 shows the relationship between capital and fuel costs to the total cost of power. We can see if say 6 mill power is acceptable and our fuel costs 4 mills per kilowatt-hour, then we can afford to invest only $150 per kilowatt in the plant. However if our fuel costs can be held down to say 1 mill, then we can afford a $350 investment and still obtain our 6 mill power. This diagram is calculated on the basis of capital costs being written off at the rate of 10 per cent per year. With this diagram, operating costs may be considered as part of fuel costs in order to obtain total power costs. Clearly fossil-fuelled power stations operate in the lower portion of this diagram, while atomic power plants operate in the left hand portion of the diagram.

Rapid rates of writing off capital expenditures are at present used to take advantage of the corporation tax structure. These should not be confused with the actual annual costs of equipment which can be expected to have a long useful life. In the case of atomic power plants, we are faced with relatively high capital costs, but considerably lower operating costs than coal-fired power plants. Technological advances may be expected to reduce the initial costs of future atomic power plants, but it is hardly conceivable that any development could render an atomic power plant, once built, uneconomical for continued operation. It will therefore be reasonable to write off such plants in the near future for costing purposes over 25 to 35 years. At the interest rates paid by Canadian public utilities, this amounts to no more than about 6 per cent per year.

Figure 5 is similar to Fig. 4, but using capital cost amortization at 6 per cent rather than 10 per

Fig. 4. Relationship between capital and fuel costs to the total cost of power.

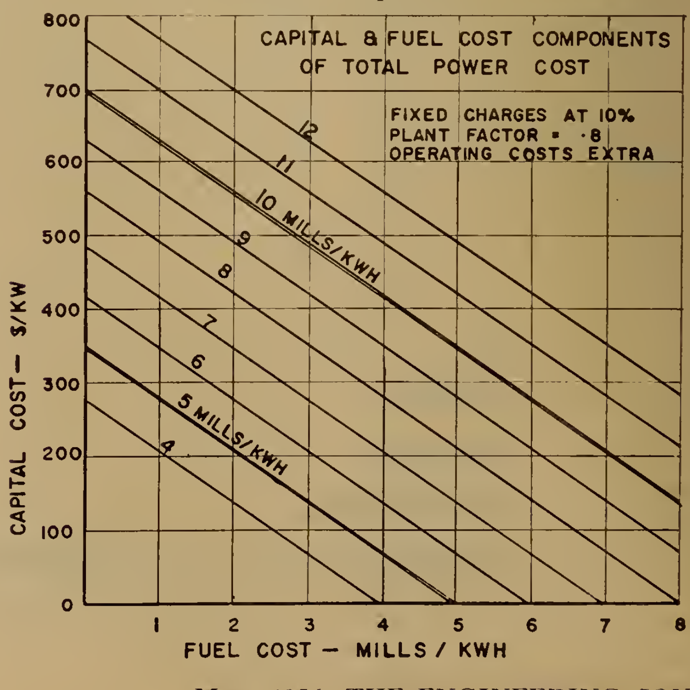

Table II. Costs for N.P.D. 20,000 Kilowatt Station

		Mills/kwh.
Capital Cost	— $750 per kilowatt installed written off at 10% per year based on 7,000 hours operation per year	10.7
Fuel	— $30 per lb. irradiated to 5,000 megawatt days per ton, overall thermal efficiency 22%	2.3
Operating Costs	— Staff (60 people at $6,000 per year to include housing subsidies, etc.); materials including heavy water make-up at $110,000 per year	3.4
	Total	16.4

cent. The effect on power costs in the examples previously quoted is obvious.

Reduction in the capital costs of any one particular kind of reactor will certainly come with experience in its design and manufacture. Particular types of reactors will almost certainly emerge as suiting certain kinds of applications better than other types of reactors. However, so far the conditions which reactors now under construction have been required to meet have varied so greatly that there seems to be no obvious pattern, at least in the United States. The N.P.D. reactor will provide valuable data on which cost reduction programs may be based and applied to large reactors of the pressurized heavy water type. An example is the use of low alloy steel piping and valves in the heavy water system. From data which we have available it appears that it is not necessary to use stainless steel piping and valves as has been the custom in the past, and that the corrosion products which may find their way into the heavy water system can be removed quite cheaply. When one considers that a sixteen-inch stainless steel gate valve may cost over $40,000, the savings are at least partly apparent. Again, it appears that it might be economical in future reactors to eliminate the very expensive pressure vessel and substitute containment of the pressurized coolant by aluminum pressure tubes operating at a little above room temperature; standard high strength aluminum alloys could be used for this purpose. Further experience with oxide fuel and long irradiations will indicate where savings may be made in instrumentation and cheaper arrangements for changing fuel. Increasing the size of the units is a very effective way of decreasing the capital cost per kilowatt. Increase in cost of an atomic power plant for given increase in power output is very much less than for a coal plant, and in general it appears that the bigger the units can be made the cheaper will be the power they produce.

It appears possible that recent developments in gas cooling may be applied to the cooling of the outer fuel elements of an N.P.D. type reactor to supply heat for superheating the steam. This would not only increase the cycle efficiency, but would reduce the cost of the turbine since this is now intended to operate on saturated steam.

After an initial period of experimentation, the cost of power from the N.P.D. station is expected to be in the neighbourhood of 17 mills per kilowatt-hour. This is made up as shown in Table II.

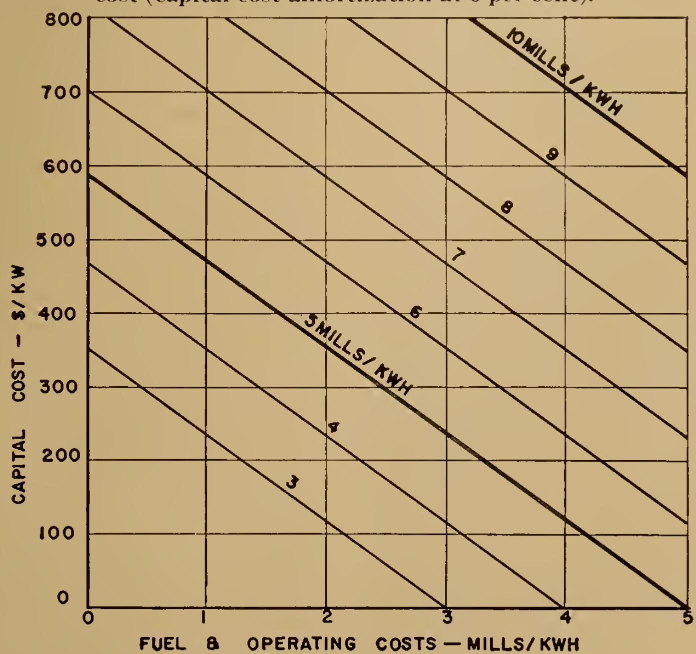
It is interesting to note how costs for a similar type of power station with a capability of 400,000 kilowatts might look. Such a station might have three units, the first of which could be ready for operation in 1962 or 1963. By virtue of the increased size of the units above, the capital cost could be expected to drop to about $350 per kilowatt. Technical developments in the next few years could reduce this figure. As previously suggested, it would be reasonable to write off such a station over say 30 years; the net cost to a publicly owned utility would be no more than 6 per cent per year. Fuel irradiated to 7,500 megawatt days per ton would reduce the fuel costs to 1.5 mills per kilowatt and there seem to be a number of ways in which this or a lower figure can be realized. A preliminary survey indicates that an operating staff of 160 people would be required, and that material costs might come to $700,000 annually. The costs would then be as shown in Table III.

Table III. Costs for 400,000 Kilowatt Station

		Mills/kwh.
Capital	— $350 per kilowatt written off at 6% per year	3.0
Fuel	— $30 per lb. irradiated to 7,500 megawatt days per ton	1.5
Operating Costs	— 160 people plus $700,000 per year	0.6
	Total	5.1

Since these costs assume virtually no technology which will not be proven by the time the N.P.D. power station has operated for a few months, we can conclude that economic atomic power from natural uranium is at hand. √

Fig. 5. Capital and fuel costs as components of total power cost (capital cost amortization at 6 per cent).



Some Aspects of Conservation and Wildlife Management

V. E. F. Solman,
Assistant Chief, Canadian Wildlife Service, Department of Northern Affairs and National Resources

A paper on wildlife may seem an unusual one for publication in the *Engineering Journal*, but we are sure that readers will enjoy this one. Many of them are hunters or fishermen, and a fair proportion of engineering works have very direct percussions on wildlife. As Dr. Solman points out, the conservationist makes use of many engineering techniques, a description of which is reserved for a possible future paper.

During man's long association with the wild creatures much has been learned about their habits. Indeed, such knowledge was vital to human survival before animals were domesticated, the better to serve man's needs.

The instincts of the hunter and fisherman are deeply ingrained in the human character. Although the need for food is no longer the main stimulus, hunting and fishing for recreation and relaxation are of increasing importance in this world of tension.

Although our knowledge of wildlife has been accumulating for centuries, it is only within the last few decades that it has become the basis for scientific wildlife management. Like many other branches of modern science, it has developed with amazing rapidity, and in consequence a large proportion of the biologists engaged in it are still young men. Some problems mentioned in ancient writings, such as predation, crop damage and "plagues" of wildlife species, are only now being subjected to intensive scientific research in the hope of finding solutions.

With the thought that members of the Institute may be interested in some of the problems and developments in wildlife management and its importance in human welfare, we discuss below a few modern ideas and discoveries regarding the subject.

Important factors in the field of wildlife management are public appreciation of the needs, public understanding of the methods and public demand for wise action. We cannot advance faster than public opinion permits, regardless of the speed or accuracy of our research.

As community leaders, engineers can perform an important public service by keeping informed of developments in renewable resource management and in endorsing and participating in wise management policies.

Many types of such management use engineering techniques. As advances are made in engineering development, wildlife management will use newer methods to do a more efficient job of water impoundment, fire control, reforestation, fish distribution and a host of other mechanized activities.

Recently fisheries research has been accelerated and rendered more accurate by the use of underwater television, the echo sounder, thermister temperature indication and more reliable and efficient outboard motors, to name only a few of the more obvious applications of modern engineering developments. The related field of terrestrial wildlife research has benefited during the same period, particularly from improvements in aircraft and helicopters and in the increased use of light-weight aluminum and fibreglass equipment of many kinds.

For many years attempts to remove animals detrimental to agricultural interests have been made in a variety of ways. One of the most popular means of achieving this end was through the payment of bounties for the head, hide or other parts of the noxious animal. The idea of paying bounties is a very old one and was brought to North America by the earliest colonists. The bounty system is based on the idea that if it is made financially worth-while, a person will exert himself to remove an animal which is causing him harm, even though it would be to his advantage to remove the animal without payment.

In some cases payment of bounty may increase the number of animals killed and help to achieve the desired purpose. In addition to this useful function, however, payment of bounty has often led to unwise, and indeed illegal practices. The unwise practices may involve the removal of animals from areas where they were doing no harm simply because they were easier to take there than in other areas, while at the same time animals were left in areas where they could continue to do harm because, in those areas, they were harder to take. The illegal practices encouraged by the bounty system include fraud and illegal transportation. Animals may be raised in captivity and offered for bounty; there may be falsification of the part of the animal offered for bounty; or old breeding animals may be left at large to continue reproduction while young are taken and offered for bounty. Animals taken in one area may be offered for bounty in a different area where higher bounty payments are made, even though the removal of the animals or parts thereof from one area to another contravenes transportation regulations. When animals under bounty have valuable pelts, bounty hunters may take them only when the pelts are prime, permitting them to carry on their harmful activities throughout the remainder of the year.

Under normal conditions only two young animals need to reach maturity and to replace their parents as breeding stock to maintain a stable population. The surplus, beyond this replacement number, is normally removed by disease, starvation, accidents and other factors. Paying bounty to remove animals which will not survive anyway has little or no effect on the population and is neither biologically nor economically justifiable.

Under a bounty system payments are made on all animals presented of the appropriate species. Many of these animals would be taken whether bounty were paid or not, but since a bounty is offered they are all presented for payment. If, in a given area, 500 wolves were taken each year before the introduction of a bounty system and it is desired to increase the removal of wolves by payment of bounty, the initial 500 each year must be paid for before the bounty serves any useful purpose in encouraging increased removal. Thus, with a $20.00 bounty, $10,020.00 would be the price paid for the first wolf effectively removed as a result of the bounty system. As the number of wolves taken under the bounty system increased the price per wolf would naturally decrease, but in any case the actual cost per wolf removed as a result of bounty payment would always be substantially higher than the bounty paid per animal.

When one considers the alternatives to a bounty system now available, it becomes immediately apparent why many game administrations have recently swung away from it. The most successful method of dealing with animals which may harm human interests, such as wolves, is to have them removed where and when necessary and in the required numbers by persons specially trained and experienced in the most effective and economical methods of removal.

In many areas poisons, such as 1080 or strychnine, can be used in meat baits set under carefully controlled conditions to take wolves or coyotes without danger to humans, domestic animals or valuable furbearers. Skilled hunters are used for control of some species. Often the work can be done at a cost per animal much lower than the bounty payment formerly offered, while at the same time removing only those individual animals which are important in causing losses. It should be realized that very many of Canada's bears, for example, do not cause damage of any consequence to human interests; a few of them, however, because of acquired tastes or undue proximity to settled areas, may do great harm to livestock, bee colonies or other property. An intelligent control program will aim at removing only the harmful animals, not at expending money and effort in pursuit of those which do not affect our economy. Employment of properly qualified predator control agents will ensure the carrying out of such a program.

The techniques for control of predators are now so well developed that it is quite possible to do too much as well as too little. Complete removal of all predators upsets the delicate equilibrium between predator and prey. For instance, when coyotes are eliminated from a certain area to reduce losses to sheep and antelope, a rapid increase in numbers of mice may result. In some places requests have been made by farmers for the cessation of coyote control so that these predators could again exert some pressure on mice.

In the Prairie Provinces the autumn of 1951 brought unfavourable harvest weather and early snow, and consequently much of the crop remained in the fields in swath through the winter. Mice lived

A Note to Branches Interested in Conservation

This paper outlines some of the interesting problems that confront the Canadian Wildlife Service. The Service has expressed its willingness to have its officers address any interested Branches of the Institute on the theme of conservation.

The staff of the Wildlife Service includes some 22 biologists, each of whom has training and experience slightly different from the other. In this way, Service speakers addressing any particular Branch would have a specialized knowledge of local conditions supplementing their overall experience. In addition to headquarters in Ottawa, offices are located at Aklavik, Yellowknife, Fort Smith, Vancouver, Banff, Edmonton, Saskatoon, Winnipeg, Kingston, Quebec, Sackville, and St. John's; a new office is to open at Whitehorse this summer.

Branches wishing to get a speaker on this subject are invited to get in touch with the Canadian Wildlife Service, Dept. of Northern Affairs and National Resources, Ottawa, Ont.

happily in the swath. In the spring when the swath dried out and was threshed by combines, mice were carried into the combines with the swath in such numbers that the machinery was plugged. Combines have two outlets, one for grain and the other for straw and chaff; but on that occasion, a third outlet for mice would have been appropriate! As far as we know, three-way combines capable of dealing with mice in quantities have not been developed.

After the crops which had served as winter mouse hotels were threshed in the spring, the dispossessed mice invaded farm buildings and granaries and even municipalities. Sometimes hundreds of mice would invade an empty granary, clean up the scattered grain in nooks and corners, and die of starvation, so that farmers had to shovel the bodies out to prepare the granaries for the next harvest. Small wonder if some farmers wished that the coyote control had not been quite so efficient, even though coyote reduction may have played only a small part in this unusual mouse plague!

There is some evidence that over-control of wolves in limited areas has been followed by the build-up of excessive populations of deer or caribou, with the result that these species have overgrazed their range and reduced its carrying capacity for years to come. Here, too much wolf control has resulted in the long run in a reduction, instead of an increase, in the numbers of deer.

To pursue this idea further, it should be realized that in a well-fed herd of deer the does have first a single fawn, then twins or triplets annually for the remainder of their productive lives. If less food is available the does may have only single fawns annually; if food is really scarce, they may have single fawns at two-year or longer intervals. Besides decreasing productivity, a reduced food supply will result in high winter losses of fawns, because they are smaller and cannot reach as high for browse as adults. We thus make the rather surprising discovery that removal of deer by predators or hunters, by keeping the population in proper balance with its food supply, results in high production and high fawn survival. Insufficient hunting or too intense predator control ultimately lowers production. The more deer killed, within limits, the more are available for future use. Some of the healthiest stands of deer are in park areas where there are also good sized wolf populations. In some cases, however, there are not quite enough large predators for the best big game production. Game animals then have to be removed from time to time to prevent over-utilization of range, with its accompanying damage to the flora, increase in erosion and loss of condition among the game animals.

Great concern is being caused at present by another phase of the conflict between wildlife and agricultural interests. Almost eighty per cent of the waterfowl which frequent North America are hatched and raised in Canada. Under the terms of the Migratory Birds Treaty between Canada and the United States, both governments are pledged to take necessary action to safeguard waterfowl so that they may be available for use and enjoyment by future generations. The major Canadian duck-producing area occupies parts of Saskatchewan, Alberta and Manitoba. These three provinces are also the "bread basket" of Canada and in some years contain more than fifty million acres under cultivation for the production of cereal grains.

Ducks and Grain

Many ducks normally feed on seeds. Certain species, particularly the mallard and the pintail, will feed on the seeds of cereal grains under suitable conditions.

Until recent years much of the harvesting of the cereal crops in the Prairie Provinces was done by cutting the grain, binding it into sheaves and placing these sheaves in stooks. After drying for a suitable time in the stook, the sheaves were threshed in the field or at some central location convenient for the storage of grain. Waterfowl do not normally land in fields of standing grain and are unable to do much damage to grain in stooks, even though they might wish to feed upon the seed. As labour costs have risen and as availability of farm labour has decreased, more complete mechanization of grain farming has become necessary. The combine was developed to eliminate the job of binding and stooking. In many areas, however, cutting the grain and threshing it in a continuous operation is not practicable. To overcome this difficulty the technique known as "swathing" was developed; in this technique the grain is cut leaving a high stubble, gathered together into narrow rows or "swaths" and left on top of the stubble. Wheat or other cereals treated in this manner dry and become ready for threshing much as when stooking was used, but with a great reduction in the cost and amount of labour involved. The ripening and drying of crops in swath prevents damage from the stem sawfly, which attacks only standing grain near maturity, and also prevents in large measure "wind shatter", which may occur when a standing crop is allowed to ripen completely before cutting. Once the swath is properly dried and ready for threshing, it is picked up by a combine and threshed in the field. Grain in the swath is not too much harmed by rain, since swaths will dry about as rapidly as stooks.

A disadvantage of swathing is that ducks and sandhill cranes may land on the swath, feed on a small amount of the grain, shell out a certain amount onto the ground and trample the swath down into the stubble where it cannot be picked up by the combine. This last type of damage is worst in wet weather, when the swath may be tramped down into the soil. Droppings accumulate on the swath and are carried through the combine with the grain and may make it unacceptable for storage in elevators.

The ducks which feed on swathed grain usually do not consume as much grain as is lost through their trampling. The grain which is shelled out and falls to the ground among the stubble cannot be gathered by any now-known agricultural operation. The mere loss of the grain on the ground, while often serious, is not the end of the difficulty. The grain which has fallen on the ground may easily take root during the following growing season and thus produce a volunteer crop in a field where there was no intention of growing grain during that year. In many prairie areas water supplies are insufficient for the growth of cereal crops each year, and the practice of leaving the land in summer-fallow in alternate years is common. A volunteer crop resulting from the trampling of ducks may be heavily seeded directly under the swath. Since the swaths are narrow and are spaced about 12 feet apart, the volunteer crop so produced may be extremely dense on narrow strips across the field. Even if it grows well such a crop is difficult to harvest. It may also offer difficulty in the further cultivation of the field, since the heavy seeding in a narrow strip may result in a dense, turf-like growth which may require special equipment to break up.

Local factors, including weather, affect the degree of crop damage by ducks. Certain areas in the Prairie

Provinces may have large duck populations without suffering much from their feeding in swathed fields. Other areas, with comparatively small waterfowl populations, may have more difficulty. Not all species of ducks have acquired that habit of feeding on cereal crops: mallards and pintails are the worst offenders.

In some areas the use of scarecrows of suitable types and at a suitable density has been effective in keeping ducks out of swathed crops. In other areas scarecrows, even when supplemented by the use of firearms, have not been completely successful either in keeping ducks out of swathed crops, or in driving them out of such crops when they had begun feeding in them.

Experience has indicated that, once the birds have become accustomed to flying from a resting area to a swathed field and feeding on the crop, it is difficult to break this habit. It is easier to discourage the first few ducks from entering such a field than to try to drive away the increasing numbers of ducks which will rapidly build up as the feeding pattern becomes established.

Control Methods

Much of the feeding activity is carried on after sunset and before sunrise. Control methods involving the use of searchlights, powerful noise-making machines, rockets and aerial bombs, and attempts to herd the birds away from cultivated areas with aircraft, have all been tried with limited success.

Ducks exhibit certain reactions when exposed to a beam from a radar transmitter. Experiments are being continued to see whether this type of reaction could be used to keep birds away from potential damage areas.

Limited studies have suggested that chemicals distasteful to birds might be used to discourage feeding. Tests of this method of control are in progress. Unfortunately, the senses of taste and smell are relatively poorly developed in birds, so the hope of success with a chemical repellent is not great. The use of grain as a source of human food offers a further difficulty in connection with the wide use of chemical repellents to control duck damage.

The source of the ducks which cause specific damage—that is whether they are locally-bred ducks or migrants—has been the subject of research during the past few years. Ducks are marked with coloured plastic neck bands in the areas where they are hatched and can then be identified wherever seen during field feeding. Conventional leg bands are also used, but then the ducks must be captured or killed to secure useful data on movements from the banding area. In some cases, birds which rest on a given water area may ignore the crops in adjoining fields and fly several miles to feed in other fields containing identical crops. In addition to this peculiarity of feeding, which is as yet not fully understood, there is the possibility that some of the damage done in the Prairie Provinces may be caused by ducks raised in other parts of the country, which may have travelled some hundreds of miles before reaching the damage area.

Other Solutions

Other approaches to the solution of this problem include the development, through plant breeding, of varieties of cereal grains which are resistant to attacks by the stem sawfly and other parasites and to wind shatter. Success along this line would furnish varieties which could be harvested by straight combine without the necessity of swathing. Elimination of swathing would greatly reduce duck damage.

Advances are being made in the technique of chemical dehydration of standing crops. This is accomplished by spraying the crops at a suitable stage of growth with a chemical which stops the translocation of water upward through the plant. The grain then dries out ready for straight combining earlier in the season than would normally be the ease. If the cost of this process can be sufficiently reduced, and if certain other present limitations can be overcome, it would be possible to use straight combining and, with the earlier ripening, to have the crop harvested before the majority of the ducks begin feeding in the fields.

There is much conjecture about the magnitude of the North American duck population and about the number of ducks killed each year. Birds which nest from the Arctic coast to the Central States and from the Atlantic to the Pacific are, of course, difficult to count accurately.

Each year summer surveys over the whole area, conducted in co-operation by biologists of the Canadian Wildlife Service, the provincial game agencies, the United States Fish and Wildlife Service, Ducks Unlimited (Canada) and other non-governmental agencies, sample all breeding areas and assess waterfowl populations and breeding conditions. Data so secured in recent years are comparable from year to year and show an upward trend in some species, despite more or less continuously liberalized hunting regulations. Accurate, comparative data are available for only a few years, so that comparisons with the early days of settlement are impossible. A series of wet years on the prairies, such as the past few, have always been followed by drought in the past; no doubt the duck populations have waxed and waned in response to water levels as long as they have concentrated on prairie nesting grounds.

It is almost axiomatic that before the present development of agriculture on more than fifty million prairie acres there were more ducks, because, in wet years at least, there were more breeding areas.

During and after the recent drought cycle in the 1930's many water areas were restored and new ones were created for agricultural purposes under the Prairie Farm Rehabilitation Act. Some of these were of direct benefit to waterfowl. Beginning in 1938 Ducks Unlimited (Canada), using dollars collected from United States duck hunters and with the co-operation of Canadian municipal, provincial and Federal agencies, restored and created many water areas specifically to benefit ducks and geese. With the return of wet years on the prairies the ducks increased as they have on similar past occasions, but during the next drought cycle the structures of the Prairie Farm Rehabilitation authority and Ducks Unlimited will retain water for ducks and help to compensate for the vast acreages of former good duck habitat now devoted to agriculture.

Opposing Interests

As long as some citizens want to see and hunt ducks and others are more interested in growing crops and putting needed food in hungry mouths, we will continue to have land drainage projects in aid of agriculture and water impoundment projects to aid ducks, often in an identical area at different times as local interests change, or in neighbouring areas at the same time.

Much attention is now being given to the idea of an upper limit to the number of ducks of certain species which can be allowed to breed in Canada and frequent the prairie agricultural lands before their southward migration. As the human population of North America increases, so in proportion do the duck hunters. The idea of imposing an upper limit on duck numbers brings the interests of the duck hunters into direct conflict with those of the agriculturists. The solution to this dilemma has not yet been achieved.

Fortunately for the future of the Canadian way of life, with its outdoor interests centering on wildlife, the apparent conflicts over land use are often solved by the gathering of more information.

Soil fertility is basic to all renewable resource development and use. Given a productive few inches of topsoil, many interests can be reconciled. Good agricultural practices protect the soil from erosion and maintain fertility. Waste grain and wise management of areas not in crop can sustain a population of game birds which will provide sport and food and, at the same time, aid in the constant battle against insect pests.

Good forest management promotes vigorous regeneration in cutover areas, which then become banquet tables for game of several kinds, to the joy of the hunter. Cottontail rabbits may multiply rapidly, provide good hunting and meat in the pot and also thin out a stand of jackpine at no cost to permit better growth of the remaining trees.

Big game can often live on cattle grazing areas without detriment to the use of the range by cattle because of different food preferences.

Management of Wildlife

In all these and many similar cases, wildlife must be as wisely managed as are the crops, trees and cattle. A population of elk can damage a poplar forest, denude a mountain slope, start soil erosion, eventually ruin a watershed and upset an economy based on river flow many miles away if not properly adjusted to the carrying capacity of the range. Almost any animal out of control can have similar disastrous effects on human economy. The rabbit introduced to Australia, free of its natural enemies and controls, is a classic example of wildlife on the rampage.

The explosive rate of population increase in most wildlife forms is often not fully realized. Three dozen pheasants were released on Pelee Island in Lake Erie in 1927. Seven years later, and annually since, a harvest of about 10,000 birds has been taken each hunting season. This sustained yield of about one pheasant per acre per year has now gone on for more than twenty years and shows no sign of reduction. All this sport and recreation takes place in addition to a very heavy agricultural development on a small island.

Most small wildlife species have a life expectancy of less than one year. With their high reproductive rates this is fortunate, or we would long since have been eaten off the earth or smothered under a blanket of mice or rabbits. Most wildlife species cannot be stockpiled. If they are not shot or trapped their numbers will be cut down by natural causes such as disease, accidents or starvation.

Even in large game such as white-tailed deer, with adequate soil fertility and deer numbers adjusted to food supplies, at least one third of the total number can be harvested each autumn on a continuous basis. For pheasants the harvestable surplus may exceed three-quarters of the late summer population. Because of these potentials, regulations governing the taking of wildlife by hunters or trappers need to be sufficiently flexible to permit an adequate harvest when the supply is available — it can't be saved for next year.

Lest this picture of high yield and quick replacement of numbers suggest a too utopian condition, it must be remembered that no area of the earth's surface can produce more than its basic soil fertility allows. Only a given number of cows can be pastured on a given field at the same time. To add more would damage the field or starve the cows. The same principle applies to all kinds of wildlife, including fish in a lake. The tendency to try to solve all angling troubles by adding fish from a hatchery often fails to achieve the desired results. Since the fish in a lake are less obvious than the cows in the field, overpopulation and food shortages are harder to detect without special studies.

The conflicts between wildlife and agriculture or other human activities have usually arisen, and will continue to arise, in increasing numbers, because of the increase in human population and the consequent utilization for the production of food and other human necessities of areas formerly occupied by wildlife.

Trans-Canada Highway Act

We record here the main points from a statement made in the House of Commons on the resolution to amend the Trans-Canada Highway Act.

The Trans-Canada Highway Act, which became law on December 10, 1949, was enacted to encourage and to assist in the construction of a continuous high standard highway following the shortest practical east-west route across Canada. The Act provides that the Federal Government may make contributions to a Provincial Government of 50 per cent of the construction costs of the highway over a period of seven years. The estimated cost of completing the highway in 1949 was $300 million and the amount voted by Parliament as the Federal Government share was $150 million.

The total length of the highway along the designated route in all ten Provinces is approximately 5000 miles. Quebec has not signed an Agreement under the statute and has not participated. The mileage in the nine participating Provinces, including Banff and Yoho National Parks, is 4580 miles.

For distances totalling approximately 2,850 miles, there is a paved highway, although to date the equivalent of only 1,600 has been constructed to the approved standard. Thus there remains approximately 1,545 miles of highway unpaved and there is 185 miles on which there is no highway of any kind.

The purpose of the Amendment is to seek authority to introduce a Bill to extend the period of construction, to provide additional funds and to alter the formula so as to enable the Federal Government to provide greater financial assistance in constructing select sections.

The Bill will seek authority for the Minister of Finance to pay a higher contribution for a portion of the highway in a Province not exceeding 10 per cent of the mileage. The Federal Government contribution for these gaps will be increased from 50 to 90 per cent of the cost of construction.

The Bill will also seek authority to extend the period for construction to December 31, 1960, and a further five months to wind up the accounting. The termination date for all contributions therefore will be set as May 31, 1961.

Authority will be sought in the Bill to increase the total amount of money authorized by Parliament for Federal contributions from $150 million to a maximum of $250 million.

DISCUSSION

Report on Investigation into the Failure of Two 100-Mw. Turbo-Generators

Sir Claude D. Gibb, C.B.E., D.Sc., M.E., F.R.S.
Chairman and Managing Director,
C. A. Parsons and Co. Ltd., England.

In the March, 1955, issue of The Engineering Journal there appeared the report of investigations into the failure of two generators at the Richard L. Hearn generating station, at Toronto. We now publish the full discussion of this paper, which aroused wide interest among engineers.

DISCUSSION IN LONDON

V. A. Pask, C.B.E., (*Member*), M.I.E.E., whose contribution was read by A. E. Hawkins, B.SC. (ENG.), A.M.I.E.E., observed that the author had rendered a signal service to both the manufacturing and utility industries in making available the results of his company's prolonged investigations in respect of the failures which had occurred to the alternator rotor end bells of two 100-Mw., 1,800-r.p.m. sets in Toronto during the previous April.

Immediately the accidents had occurred the author had notified the British Electricity Authority, other turbo-alternator manufacturers, and leading consulting engineers, adding that further information would be made available as it was obtained.

Following the preliminary examination made in Great Britain of a broken end bell from No. 1 Toronto machine, he himself had written, on behalf of the Authority, to all manufacturers, suggesting that the serious breakdowns, coupled with the fact that the Authority were contemplating machines of materially increased output capacity, indicated the advisability of the Authority and of the turbo-alternator manufacturing industry setting up a small committee to make a frank examination of the subject. He had stated that while there did not appear to be an immediate cause for undue anxiety in regard to B.E.A. plant, it would be prudent to take all reasonable steps to ensure that failures did not arise in Britain, and he had quoted the following proposals for discussion:

(1) That each firm should examine immediately the end bells of a 50- or 60-Mw. set, or sets, which had been in service for up to 20,000 hours; the examination to be in respect of both the metallurgical and mechanical condition of the steel.

(2) To consider the provision of hydraulic testing gear statically to load new end bell rough-turned forgings to some agreed percentage of the yield stress; also as an interim measure, the lowering of the yield stress from 50 to 45 tons per sq. in. on the 60-Mw. end bells in an endeavour to improve the ductility of the cold-worked material.

(3) The Authority to obtain from selected stations log sheets showing the hours in service, particularly in regard to the number of stops and starts, and how the hydrogen coolers had been operated during such periods with a view to determining the gas and metal temperatures in the vicinity of the rotor body and end bells during such thermo-cycling periods.

(4) That the Authority would consider the more widespread provision of rotor storage space having temperature and humidity control for protecting rotor end bells from possible stress corrosion conditions during the station construction period.

(5) Examination of details of the mechanical construction of the various designs of end bells and caps, having due regard to the stresses imposed by shrink fits, those caused by inertia of the end bell, and the internal pressure due to the centrifugal forces of the copper coils and supports.

Dr. C. Sykes had been invited to attend the proposed meetings.

At the first meeting of the manufacturers and the Authority held on 7th May 1954, the foregoing proposals had been generally agreed, with certain reservations in respect of the percentage of the yield stress to be imposed when hydraulically testing rough-machined forgings, and the lowering of the yield stress by 5 tons per sq. in. to 45 tons per sq. in. The Authority had agreed to return complete rotors from their stations to the manufacturers' works so that end bells could be removed for detailed examination and also re-assembled under controlled heating conditions, preferably by means of electrically heated jigs.

Dr. C. Sykes had agreed to act as chairman of a working panel, comprising metallurgists representing each manufacturer with the Authority's metallurgist as secretary, to assist and record the examinations of end bells which had been in service.

The preliminary examination of a representative number of end bells distributed amongst various

---

The paper and discussion have been published in the Proceedings of the Institution of Mechanical Engineers, 1955, Vol. 169, No. 29.

manufacturers had indicated that with very few exceptions there had been no immediate cause for anxiety. Further examinations were proceeding as and when sets could be taken out of commission, the order being based on hours in service.

Progress had also been made in the evolution of hydraulic testing gear to suit individual designs, some equipped with strain-gauge apparatus to check the hoop and longitudinal stresses imposed. Acknowledgement for originating suitable hydraulic testing gear designs should be made to Sir George Nelson and his associates.

Information obtained from the Authority's generating stations indicate that 60-Mw. sets might be subjected to some 50-283 'starts' and 'stops' per annum, and the shutdown periods varied from 6 to 36 hours, or longer. Investigation had, however, proved that by a simple adjustment of the control valves associated with the dirty- and clean-water heat exchangers respectively, the recooled hydrogen-gas temperature might be raised to 80-85 deg. F. before shutdown; further, that that temperature would not drop by more than 3-5 deg. F. during even a 36-42-hour shutdown period on a normally lagged alternator casing. Those conditions could be realized at stations located in the fresh water reaches of a river in even the coldest winter period.

The Authority were providing additional air-conditioned storage accommodation at all sites where unavoidable delays in civil construction works might involve storage of an alternator rotor.

The details of mechanical construction naturally varied with different manufacturers, as also did the obstruction or shrink fit between rotor body, carrier ring, if used, and end bell. For about the same size rotor bodies that obstruction varied between different manufacturers in the ratio of 1/2, but material reductions in the heavier obstructions were now being adopted. Consideration was also being given to the methods of effectively 'shorting' the damper strips fitted under slot wedges, and also the provision of protective relays to safeguard large machines in the event of a possible system disturbance causing single phase working.

The B.E.A. were indeed greatly indebted to the author for carrying out the long series of repeated stress cyclic tests by hydraulic pressure upon rotor end bells. The tests so clearly demonstrated that a particular pattern of holes might so appreciably reduce the fatigue strength, owing to cracks developing at the work-hardened surface of the holes, that under repeated applications of a comparatively low stress they could be propagated rapidly as a brittle fracture.

That definitely established that holes, whether for ventilation or mechanical construction, and in fact, that any form of stress raiser caused by sudden changes in section, must be avoided.

At the time that the Authority had given consideration to the use of 100 to 120-Mw. sets requiring larger diameter rotors, a definite directive had been given to manufacturers that no ventilation holes were to be drilled through the bell. In fact, a recommendation had been made that they should also be avoided on the 60-Mw. frame. In the light of the research evidence now available that decision would appear to have been a wise measure.

True engineering progress could be achieved only by a balanced compromise between the materials used, design, manufacture, and operation methods. Many of the points raised in the paper had already been given close attention.

More effective production controls were being devised for use with existing and new materials for end bell construction, improved mechanical design to ensure more uniform stressing, together with the evolution of new ventilation systems to avoid either coil shortening or arch binding, and, lastly, operation engineers in the power stations had been advised to maintain minimum hydrogen-gas temperatures of between 80 and 85 deg. F.

V. J. Vickers, A.M.I.E.E. (Stafford), said that the two disasters with which the paper dealt appeared to be identical with the failure in July, 1950 of one of the end bells fitted to the rotor of a 60-Mw., 3,000-r.p.m. machine manufactured by his company. Details of the occurrence had not been published, but the information and conclusions had been made available at the time to the main manufacturers and users in Great Britain. Fortunately the incident had taken place in an overspeed test tunnel, during balancing operations at normal speed, and before the rotor had been taken up to overspeed. The rotor itself was a complete loss, but the tunnel, which was lined with timber to form a 3-foot cavity filled with sand, completely contained the wreckage, as would be seen from Fig. 27.

Figure 28 showed the point at which the larger piece of the fractured end-bell had pierced the timber lining, releasing the sand which had enveloped the rotor. The final condition of the rotor was shown in Fig. 29, after the remains of the winding had been removed. The end bell had broken into two pieces. He was concerned only with one of the fractures, since it was clear that the second had been the result of consequential damage.

Fig. 30 showed the larger piece with the primary fracture in front.

A close-up view of that fracture (Fig. 31) showed it to be generally brittle in nature and seemingly identical in character to that illustrated in Figs. 7, 8, 9.

Fig. 32 showed clearly how the fracture commenced at the surface of the hole approximately 1 inch radially outwards from the inner surface. Fig. 33 showed the pieces on either side of the fracture brought together, and Fig. 34 clearly indicated the absence of

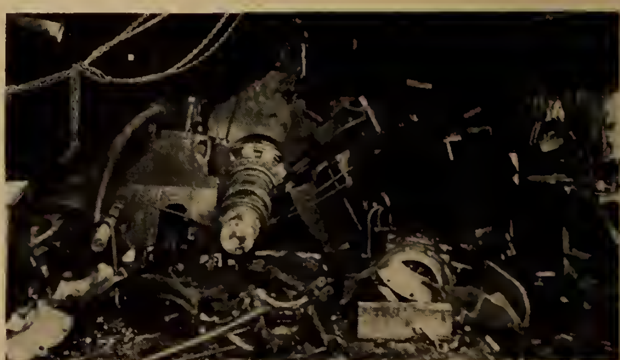


Fig. 27. General view of failure of 60 Mw. machine.

any appreciable general 'necking'. The author had said that in the immediate vicinity of the hole there was no appreciable deformation, but some 'necking' became evident as the crack extended away from it. Investigation had shown that the following were the principal factors which could contribute to a failure of that nature: first, the hole itself was a stress raiser and produced a high local concentration of stress. In addition, the work-hardening properties of that particular material, coupled possibly with a carelessly drilled hole, could produce ideal material properties for the initiation of a brittle fracture. The combined severity of those two effects would be greatly increased should such a hole coincide with a region of high residual forging stress, and also if the effects were coupled with cyclic stressing.

It was therefore abundantly clear that, while the holes might not be the complete explanation of the failure, they were a major factor. His company had therefore decided immediately to abandon the practice of drilling all end bells whether for ventilation or for other purposes. Furthermore, all machines of similar size in the course of manufacture or in service had been withdrawn. A number of smaller machines with end bells with physical properties characterized by an unduly small ratio between ultimate and yield strength had been withdrawn from service. At the same time, the policy had been adopted of not using any ring in which the ratio of yield to ultimate strength indicated inadequate capacity of the material to undergo further plastic deformation, although the ring in all respects came within the requirements of the ordering specification.

While he agreed with the author's estimate of the increase in average temperature rise of the rotor winding as the result of omitting the ventilation holes, he could not subscribe to his opinion that their retention was necessary in order to prevent coil distortion. In previously published information regarding the construction of the Toronto alternators it had been said that the coils had been wound using semi-hard silver bearing copper. It was now generally well known that the use of that material would give an ample

Fig. 28. Damage to timber lining.

margin of safety at the slightly higher temperatures resulting from the omission of the holes, particularly because the increase in temperature would be largely localized in the end turns and would not, in any case, result in a substantial increase in stress in the copper in the slots, where the forces giving rise to the stresses leading to deformation were most significant.

The investigations into the failure of the 60-mw. rotor referred to showed, as the author had remarked, that the holes *per se* were not sufficient to account for the failure, and support for that view was given by the fact that other identical rotors had already been proceeding ever since, and it had become evident at a very early stage that in any one ring very wide variations could exist in physical properties and, in particular, in the residual forging stresses arising from the method of cold working over a mandrel. That had led to the introduction in 1950 of hydrostatic testing of every forging before it was passed for use.

Fig. 35 showed the equipment set up with clock gauges to register the expansions occurring under pressure. The purpose in adopting that procedure had been twofold: first, as a further precaution, in conjunction with ultrasonic examination before and after test, to prove that the forgings were sound. That test had shown a forging defect which had not been noticed by the machinist. The second was a means of producing more uniform properties throughout the rings. For that purpose it had always been the practice of his company to produce a maximum hoop stress in the rings equivalent to 95 per cent of the lowest value yield stress obtained on any of the acceptance tests, which figure was considerably higher than that mentioned by the author. Some non-uniform permanent set invariably resulted, indicating that there had been a redistribution in stress, or that there were some areas having lower than average strength which received the necessary additional working.

Experimental results confirmed that stretching by means of internally applied pressure greatly improved the uniformity of residual forging stress distribution. There could be little doubt that any method of forging which ensured uniform working of all the material in the ring, in contrast to the step-by-step method used with the Toronto rings, and also for the rings on the 60-Mw. rotor which failed in 1950, would produce a much more uniform distribution of those stresses. One ring possessing an undesirably high ratio of yield to ultimate strength had fractured explosively while undergoing hydrostatic test.

In addition to the two major factors mentioned above, he agreed that no doubt a number of minor effects came into play. One such effect, not mentioned, might arise from the construction used, shown in Fig. 1. Experience had shown that such a construction, in which the end bell was supported at two positions on the shaft, the deflexions of which were different, had led to fretting, and in extreme cases to fatigue cracking. Fig. 36 illustrated those effects.

Fig. 37 showed that cracking had occurred over the pole where there was a sudden and significant change in section of the rotor body due to the presence of a ventilation duct. It might not be without significance that, on the evidence of Fig. 11, both fractures in service appeared to have run to points on the lip at equal, but small, distances from the pole

Fig. 29. Final condition of rotor.

centre. If those points coincided with the edge of a ventilation duct, or of the first winding slot, then a further point of locally raised stress, coupled with a small cyclic variation due to the rotation of the rotor, was introduced along a section already weakened by the three holes in line.

The author had not, as the result of his investigations to date, been able to attribute those failures to any definite causes, but he himself was interested to see and to hear that he regarded the presence of holes, particularly in material susceptible to work-hardening during drilling, and the effect of cycling and similar effects, as being major factors, which agreed with his company's conclusions.

Harry West (*Member*), M.I.E.E., said that a catastrophe of such magnitude reflected not only on the manufacturing company, but also on British industry as a whole, and critical remarks had been directed at British equipment. Had there not been a number of recent failures of Amcrican-built equipment of similar size the criticism could have reached considerable proportions.

One was faced with the fact that a material which was fairly well understood and which had an ultimate strength of about 57 tons per sq. in., and a yield point of some 50 tons per sq. in., had failed under most peculiar circumstances; yet, according to Table IV, the undrilled rings had withstood a stress of approximately 50 tons per sq. in. The drilled rings had been subjected under hydraulic test to a mean hoop stress of something between 35 and 43 tons per sq. in. and had failed.

It could be shown that the stress pattern rising when a ring was drilled was such that the surface stress could reach theoretically some three times the normal hoop stress. Therefore, it was clear that rings did fail at a low hoop stress when it was possible to have high stress on the surface of the holes, and also where material had been work-hardened and has therefore lost most of its ductility. The material would be in a suitable state for a crack to start, and once it had started the failure of the ring would follow.

The author had given the figures for working stress in the Toronto ring as 19¼ tons per sq. in., and at the nose of the bell, where it was shrunk on to the rotor body, as 26 tons per sq. in. The author did not say whether the shrink stress of 26 tons per sq. in. was that at stationary or at running conditions. In a ring of that size he would use a stress of about 20 tons per sq. in. hoop stress and a shrink stress, cold, of 16 tons per sq. in. The rings had failed at the low hoop stress because, as could be seen from Table V, under cyclic stress the failure occurred at about 27.6 tons per sq. in. in the ring. The surface stress at the holes was possibly twice or more than that, and was, he thought, an explanation of the failure.

In 1928 his company had adopted the design shown in Fig. 38. The ring was completely free from holes, notches, or any forms of stress. At the same time an attempt had been made to maintain, as far as possible, a uniform section. Since 1928 some 800 rings had been in service successfully.

Fig. 1 indicated that stresses could arise from the deflexion of the shaft. Fig 38 showed that his company had adopted a mounting of the ring on the end plate which was itself mounted on a member completely free from the shaft. That system solved the problem of shaft deflexion.

Fig. 39 illustrated the complete copper damper across the surface of the windings.

As a result of that experience his company had been able to show that their first 37-inch rotor which had been put into operation in 1935 had a hoop stress of about 20 tons per sq. in. and a shrink stress, cold, of about 16 tons per sq. in.

It was interesting that the rings had been installed in a station where, for the previous ten years, there had been two-shift working. Therefore, the rings had withstood the type of cycling which the Toronto machines had had, upward of 6,000 times, but of course they had not been hydrogen cooled but air cooled.

At the time of the Toronto failures he had visited one of the largest French manufacturers and the largest Swiss manufacturer, and had found that they had

Fig. 30. Larger piece of end bell showing primary fracture.

Fig. 31. Close-up, showing brittle nature of fracture.

adopted a ring very similar in shape to that adopted by his company with complete success. In fact the ring material specification was similar to that which his company were using. They had found that under the hydraulic test a solid ring gave a stress diagram very similar to that which could be obtained from a reasonably selective sample. He had been interested to find that the Swiss manufacturer had actually rotated a ring at high speed in order to create a very high stress, had measured the stress-strain diagram and had found the behaviour of the ring to be identical with the piece of ring material which his company had previously tested. When failures took place there was a great deal of nervousness in connexion with the materials and designs, but he himself thought that one could take heart from the fact that solid rings had behaved very well in service.

Mr. Vickers had raised a point concerning the ratio between yield point and ultimate tensile stress. In the first 37-inch rings used by his own company the ultimate tensile strengths of two samples were 65.5 and 65.1 tons per sq. in., and the yield point in the first instance was 58.2 tons per sq. in., and in the second 55.9 tons per sq. in. In view of the fact that machine sizes were increasing, and that stresses were likely to increase, it was very important to have from the manufacturers a steel which would meet the new conditions and, in fact, he believed that results with the original steel indicated that it would be safe to increase the ultimate stress and the yield point.

Professor G. W. Austin, O.B.E., M.A., M.SC. (Cambridge), said that he was not clear whether both the end bells that had failed were from the same cast of metal. In Table I was indicated one cast of metal which covered both machines.

Secondly, on the question of working on and preparing the rings, he asked whether high-temperature treatment had been carried out. Frequently, material of that description was heated to a high temperature and then quenched, and he asked whether that had happened in the present instance.

Thirdly, in regard to the very striking comment (p. 215) that the yield point of the material had been raised from 35 tons per sq. in. to 50 tons per sq. in., that was a great increase in strength. He thought, rather as earlier speakers had done, that the ductility was being exhausted. If the yield point closely approached the ultimate strength it was possible only to count on 2 or 3 per cent ductility. The rest was surely a reduction in area. The same material was used yet a very great increase had been made in the yield strength solely by cold working.

In regard to the author's reference to brittle fracture, he thought that the author had compared the present failure with the brittle fracture of mild steel. With low alloy steels there was another brittle phenomenon known as tempered brittleness, and it was possible to see in the failed material a network reminiscent of austenitic network. With tempered brittle metal the grain boundary was the weak point, and by suitable treatment it had been possible to avoid that brittleness and susceptibility to it. In the same way, by treatment and alloying, it should be possible to remove the grain boundary weakness in the end bells.

One was apt to ignore toughness and that was why he thought that the retaining of adequate ductility and the possible introduction of the notch bar test would constitute a safeguard. He would prefer a softer, tougher material to a material which had been worked to an extremely high tensile strength and was at the limit of its ductility.

Dr. Charles Sykes (*Member*), F.R.S., said that the end bells under consideration had been manufactured by his company, so that they attached great importance to the investigation. In Appendix I, attention was drawn to the differences between the properties of the end bells as defined on the test certificates and the properties actually determined from test-pieces cut from the end bells. An alteration was necessary in interpreting the curves. The acceptance figures were based on the flick yield, which was roughly 2-3 tons higher than the 0.5 per cent proof stress. Therefore the full lines in the three Figs. 21, 22, 23, should be moved towards the horizontal axis by that amount. That im-

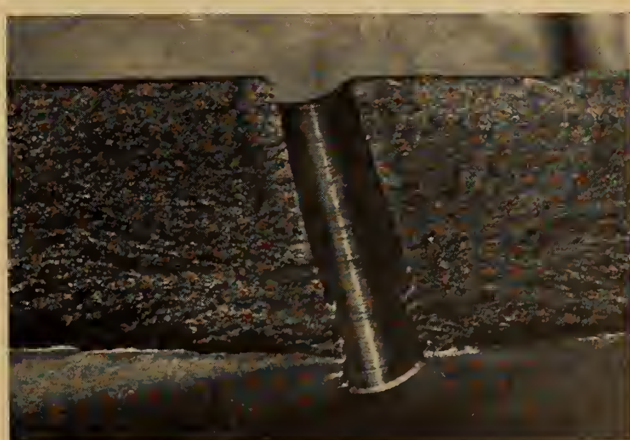

Fig. 32. Commencement of fracture.

proved the correlation. The main reason for the differences in elongation and reduction of area was associated with the fact that during the production of the rings both prior and during the cold working, some carbide precipitation took place and the degree of such precipitation was less at the ends of the rings from which the test material was taken than it was in the middle of the rings.

He would answer Professor Austin's point by saying that the material had been treated at 1,050 deg. C. prior to cold working. Subsequent to the Toronto failures his own firm had speeded up the cooling arrangements and had made them much more uniform, with the result that they had reduced the precipitation at the grain boundaries and had obtained better Izod values. At the same time, variation in ductility of the ring had been reduced.

Mechanical test figures were now available for No. 1 turbo-generator end cap which had failed after 76 cycles. It had failed at holes 39 and 39*a*. Tests had been made on the material between the two holes and the results were very similar but slightly superior to those recorded in Table IX for No. 4 machine, the exciter end. In considering the various possibilities contributing to the failures the internal stress set up in the immediate vicinity of the hole owing to the drilling should be included. While the internal stress system would be very local the stresses themselves might be very high.

Table VIII recorded a series of internal stress measurements and, while he thought that they tended to exaggerate the position, in the end rings they were variable from point to point. His firm had carried out a number of tests on rings which had been hydraulically tested in the manner described by Mr. Vickers, and the tests confirmed that that substantially evened up the internal stresses.

The forgemaster would be extremely satisfied if he could produce a type of non-magnetic material which could be hardened by heat treatment without cold working it. The cold working operation was difficult, and a good deal of time and thought has been expended on the problem of finding a heat-treatable steel. About two years previously his firm thought that they had found the solution. They had produced full-size rings with the appropriate mechanical properties and yield point, but had had to abandon the material because it had been found that the heat treatment left it in a condition in which it was much more susceptible to stress corrosion than the material at present being used. Experimental work was, of course, still going on to try to produce a material which surmounted the cold working difficulty.

The cyclic tests had emphasized the importance of the fatigue properties of end bell materials, and his firm had in hand an extensive series of fatigue tests. As the author had pointed out, under the results of Wohler fatigue tests the fatigue limit was about 21 tons per sq. in., and the ratio of the fatigue limit to the ultimate tensile strength was about 0.35 compared with 0.46 for heat-treated magnetic steels. The Wohler fatigue limit of the non-magnetic material was, however, practically the same whether the material was soft, having a yield point of 25 tons per sq. in., or whether it was cold-worked to 50 tons per sq. in. It seemed that the fatigue ratio decreased with the degree of cold working.

Mention had been made of the larger units now being contemplated, where presumably the working stress on end bells would be increased. At the same time it appeared that, owing to the very great increase in the efficiency of the cooling arrangements on those alternators, temperature fluctuations between the end bell and the rotor would probably increase during change of load. The importance of the temperature fluctuations was brought out very clearly in Figs. 25 and 26. Therefore, from the point of view of the steel maker, it appeared that shrink stresses would increase and the fluctuating stresses around shrink stresses would also increase. In view of that, he thought that the data recorded in the paper indicated that all forms of notch should be eliminated and that the shrink fit stress should be kept as low as possible in order to provide the maximum margin of safety against various types of fatigue load which would occur in service. There was an additional very important reason for keeping the shrink fit stress low. There was evidence that when stress corrosion took place it occurred when the end bells were stationary, when condensation could occur. The rate of stress corrosion probably varied exponentially with the stress, and the stress when the rotor was stationary was, of course, the shrink stress, so that it was desirable to keep it as low as possible.

L. E. Benson (Manchester), said that he had concluded on reading the paper that the ventilating holes were the major cause of disaster, also that without ventilating holes the rings would have had quite a generous margin of safety.

It was not, perhaps, realized how serious the weakening effect of the drilled hole could be in austenitic steel. The weakening effect could arise in three ways — by stress concentration, by strain hardening effect which limited the ductility of the material and, possibly, by local heating during drilling operations which, if severe, could leave the surface material in a state of initial tension when cooled.

In regard to the strain hardening effect, drilling in austenitic steel was a most difficult operation, and it was almost certain to be accompanied by severe distortion as shown, for example, in Fig. 13*b*, and by the severe strain hardening as indicated by the recorded hardness figure of up to 650 V.P.N.

Fig. 40 indicated how severe was the degree of hardening, and showed a plot of Vickers hardness against reduction in area. The points had been obtained from tensile test pieces which had been stretched, and if the graph were extrapolated up to the region of 600-650 V.P.N. it was seen that that represented a strain corresponding to a reduction in area of 90 per cent or more. At that figure the elastic limit would be very close to the ultimate tensile strength. There would be substantially no accommodation for stress concentration effects, and with a nominal working stress of, say, 20 tons per sq. in. it would be possible to have a cyclic stress locally at a hole of from nil to 60 tons per sq. in. Under those conditions it was not surprising that the material should fail.

Furthermore, in material that had been so drastically treated so much ductility had been used up that if the hole were made to deform by yielding of the material around the hole, then the material must crack. The conditions at the hole surface could be still further aggravated by roughness due to machining, and by the heat effect of drilling already mentioned.

In the absence of cold working the ability of the material to withstand repeated loadings even involving plastic strain was reasonably good. Results of fatigue tests hardly represented service conditions, but some results his firm had obtained experimentally were perhaps a better indication.

Fig. 41 showed the results of what were, in effect, fatigue tests carried out in slow bending on bar specimens of ⅝-inch by ⅜-inch section. The tests had not been carried out to simulate the effect of holes but to obtain information on the characteristics of the material. The test pieces had been strained from zero to a positive amount as shown, in tension. There was some scatter amongst the results but the general grouping of the points indicated that for 20,000 applications, which was probably as much as any coil binding ring would be likely to receive in service, the material was capable of withstanding strains above 0.5 per cent which, in the absence of serious stress concentration effects, would appear to provide an ample margin of safety. By the same token one should not expect the Parsons' ring, now being tested (without holes), to fail.

Fig. 42 showed the form of the test piece employed.

The material used for the tests had been provided by T. Firth and John Brown, Ltd. It had all been from the same cast and had been cold worked by different amounts to give the different mechanical properties indicated in Fig. 41.

Fig. 33. Pieces after fracture.

It was desirable that strain hardening effects on machining should be minimized, not only so far as the surface inside holes was concerned, but also on the outer and inner surfaces. His firm had therefore standardized finish machining conditions, i.e. tool type, shape, speed, feed, and so on. He did not claim that they had necessarily obtained the best possible conditions, but it was desirable not to have uncontrolled variations in machining with material that was so difficult to machine, or so easily work-hardened.

Apart from stress concentration effects it might be helpful to mention that his firm had evidence that machine finish, and in particular strain hardening, might affect the susceptibility of the material to stress corrosion cracking. The evidence was that with their own stress corrosion tests his firm did not obtain cracking under conditions which they understood other workers would regard as dangerous. For instance, even micro-examination at 100 diameters had not shown cracking on specimens tested at 30 tons per sq. in. in wet air and carbon dioxide for 500 hours, or at 20 tons per sq. in. in sea water for 2,000 hours. He did not suggest that machining was the answer to the stress corrosion problem, but it was important to recognize that surface condition could be a controlling factor in deciding whether or not cracking occurred or how far it occurred.

Fig. 34. Shows absence of appreciable "necking".

J. T. Moore, B.SC. (*Member*), M.I.E.E., said that he had been intimately connected with the investigations following the failure of the 37-inch diameter non-magnetic end bell referred to by Mr. Vickers, and would like to emphasize the remarkable similarity between that failure and those described by the author. Not only were the end bells of the same material, but they had also been manufactured at about the same time.

The extensive investigations following the bursting of the 37-inch end bell in 1950 showed that, while holes in the end bells had probably been not the sole cause of the failure, they had undoubtedly largely contributed when used in the particular cold-worked material, especially when the ratio of yield to ultimate tensile strength was high.

Not only had all identical end bells in service been replaced, i.e. identical dimensionally to the end bell which had failed at Rugby, but end bells in service of smaller diameter had also been replaced which, having ventilation holes drilled in them, were made of material with an unduly high ratio of yield to ultimate strength. The danger of the combination of holes drilled in end bells and a high ratio of yield to ultimate strength was confirmed by most, if not all, of the material acceptance test figures given in the paper for the different sets of end bells.

In Table I the ratio of yield to ultimate strength for the end bells for No. 1 machine was not excessively high, 89 and 86.7 per cent, for No. 2 machine 87.6 per cent and the rather high figure of 92.2 per cent, No. 3 machine 98.9 per cent (probably a rogue although indicative of unequal properties) (96.1, 93.1), and 88.4 per cent, but for No. 4 machine the ratios were both high, 91.4 and 93.4 per cent. He would have expected as a result of the experience in 1950 that the end bells on No. 4 machine with drilled holes would have been very liable to brittle fracture, and that was confirmed by the results on No. 4 end bells which the author had described.

In regard to Table IV, and the results of the hydraulic testing of the 37-inch end bells, the ratio of yield to ultimate strength on the two drilled end bells given was over 90 per cent (90.4 and 93.5) and both had failed at the holes at a not unduly high stress. On the other hand, the results on the two undrilled 37-inch end bells (with ratios of 91.4 and 94.7) would appear to show that, when undrilled, the ratio of yield to ultimate did not exercise the same importance. Nevertheless, he thought that any surface score or blemish could make such an end bell a potential danger.

From the results given in the paper and from the very similar results obtained by Mr. Vickers' company after their 37-inch end bell had failed in 1950, it would appear to be advisable to consider the replacement of any drilled end bells in service where, from the original test results the ratio of yield to ultimate strength was high. He knew that the author had had a most careful review made of all drilled non-magnetic end bells in service, and asked whether he could indicate what he considered to be the maximum acceptable ratio of yield to ultimate strength for drilled non-magnetic end bells of 37 inches diameter and less. He also wondered what was the similar maximum ratio accepted by Mr. Vickers' firm; it would be useful to have that information.

With cold-worked non-magnetic material for use in end bells the ratio of yield to ultimate strength was of vital importance, and he suggested that the various parties concerned in Great Britain, both manufacturers and users, should establish a national standard for the maximum acceptable ratio of yield to ultimate strength. All were most anxious to assist in every way in re-establishing full confidence in Britain's products and if national standards could be established for non-magnetic end-bell material, it would go a long way towards that object, and could be the forerunner of corresponding international standards.

On the assumption that an acceptable ratio of yield to ultimate was established, and that holes were not in future drilled in non-magnetic end bells of any size so that the question of the finish on the holes would not arise, a pressure test on the lines described by the author and by Mr. Vickers would seem advisable as being the only means of finding the occasional 'rogue' end bell. An end bell so tested to a reasonably high stress, and retaining its roundness without sign of failure under such a test, could be accepted with confidence, but if the end bell should go appreciably out of round under the test as a result of very unequal distribution of residual stresses, it should then be considered suspect and rejected.

As a further safeguard after machining, non-magnetic end-bells (undrilled of course) should be subjected to low-temperature annealing to remove, as far as possible, surface stresses without impairing the main properties of the material. He would welcome the views of specialists on the question of low-temperature annealing after machining.

F. Shakeshaft, O.B.E., A.M.I.E.E. (London), said that in presenting the results of a thorough investigation associated with the breakdown of the Toronto alternators, the author had made a valuable contribution at a time when large increases of plant output capacity were still in the development stage in Britain, and mainly in the manufacturing stage in the United States.

With the evolution of new cooling systems for both the rotor and stator windings, alternator output capacities of 200 Mw. were contemplated with rotor bodies of about 180-185 inches in length and around 40-42 inches diameter. As some 60-Mw. hydrogen-cooled sets had been built with rotor dimensions of about 190 inches body length, and 37 inches diameter for hydrogen pressure of 0.5 lb. per sq. in., it would be clear that the new 200-Mw. rotors were substantially the same in length, and only 8-14 per cent bigger in diameter than 60-Mw. rotors. The production of suitable rotor bodies should therefore impose no outstanding problem to the forgemaster as the increased stress level should require little or no change in metallurgical properties of the steel.

The dimensions of end bells for output capacities of 60 or 200 mw. were also very similar, the latter being only some 8-14 per cent larger in diameter. Opinions differed, however, as to the yield and ultimate strength required of the material from which the 200-Mw. alternator rings were made.

The favoured ratio between the yield and ultimate strength of materials was about 85 per cent, but the consensus of opinion was that the existing yield strength of 50 tons per sq. in. should be increased by some 10-14 per cent, i.e. to 55-57 tons per sq. in., or in about the same ratio as the increase in diameter of the end bell. That might involve a major change in the alloy used for the forgings.

A new alloy containing 18 per cent mangnese and 3 per cent chrome was being tried out on the Continent, but as little experience had so far been gained of its behaviour in practice some continental alternator engineers had named it a 'young' steel and awaited further results. It was not their intention to use the new alloy for 37-inch diameter rotors, but to adhere to an alloy similar to that now used in Great Britain.

He suggested that the problem was not one of simply designing for an increase of 8-14 per cent in rotational stresses computed under uniform temperature conditions, but of designing to avoid under service conditions, dangerous increase in compound stresses caused by temperature differences between rotor body and end bell. That problem must also be solved when aiming to achieve around 3 1/3 times the electrical output from a rotor of only some 20-30 per cent increased volume.

The experience already gained from semi-direct cooling of the winding in the rotor slots, together with the evidence made available in the paper, indicated that additional metallurgical and heat transmission research work was needed; further, that an exhaustive investigation into the mechanical design details should also be made before the fifty new large capacity alternators entered the manufacturing stage.

The application of semi-direct cooling to the rotor body winding had already shown the importance of adjusting the hydrogen flow through individual bars to avoid uneven cooling of the rotor body. If uneven cooling occurred it resulted in the bending of the rotor body and consequent heavy mechanical vibration.

Temperature differentials between the rotor body and the end bell might induce excessive combined hoop and bending stresses in the end bell. Examination of Fig. 26 showed that while the mean hoop stress in the end bell required to balance the forces imposed by the inertia of the bell and the centrifugal action of the end windings was 19¼ tons per sq. in., the maximum stress at the point of shrink fit between end bell and rotor body was about 32½ tons per sq. in. under the temperature differential quoted. That stress gave a factor of safety of around 1.5 only at normal speed on a yield stress of 50 tons per sq. in.

That raised important design matters. First, he wondered whether it would be wiser to shrink the end bell on both the rotor body and the carrier ring; secondly, whether it would be wiser to support the carrier ring on a separate sleeve either secured to the end of the rotor body or from a shaft seating adjacent to the body. One manufacturer in Great Britain and another in the United States had had satisfactory results with shrink fits as low as two-thirds of that now used when supporting the bell from the rotor body alone. That type of construction stressed the end bell more uniformly under stationary and uniform temperature conditions, and gave rise to smaller variations in stress with differential temperatures caused by service operating conditions.

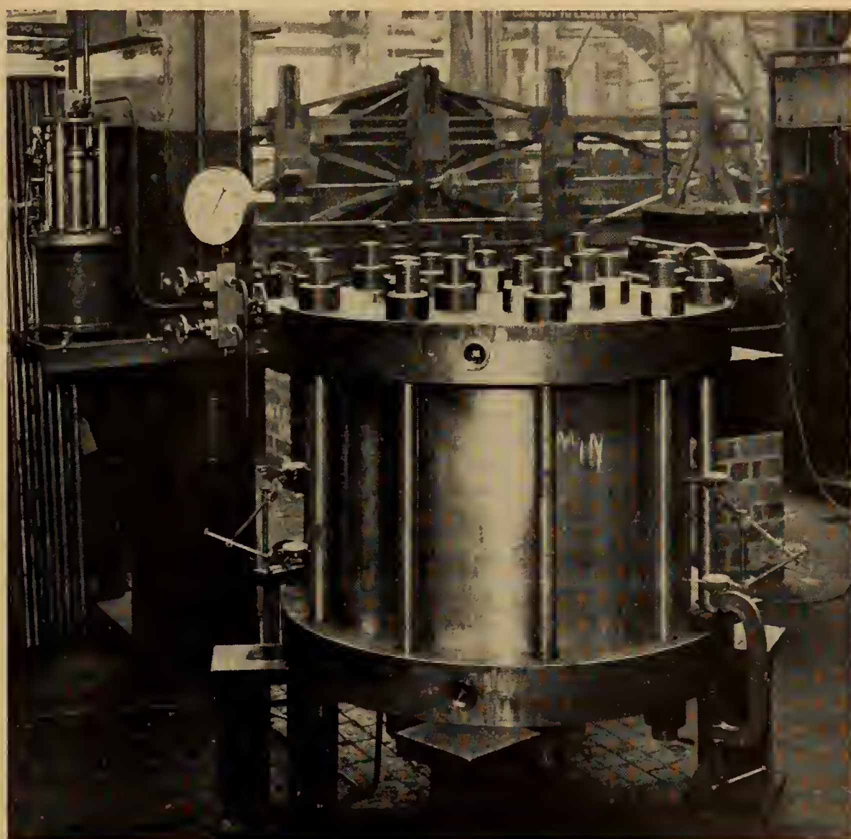
L. W. James, M.A., A.M.I.E.E. (London), said that whilst the paper dealt mainly with mechanical and metallurgical matters, there were a number of references to electrical items with which he proposed to deal.

The author had referred to the use of magnetic end-rings in place of non-magnetic rings which were more usual in Britain. One major effect in addition to those mentioned which had arisen in the past with magnetic rings had been a relatively large increase in the short-circuit stray losses particularly with full pitch and two-thirds pitch windings, giving reduced efficiencies and increased heating. Recent figures had, however, indicated that the increase with the modern involute coil of about 80 per cent pitch appeared to be very much smaller, and he asked the author for information on that effect on the Toronto machines.

In the paper the effect of holes drilled in the end rings was given as from 7 to 15 deg. C. reduction in rotor temperature and was stated to be an outstandingly helpful way of reducing temperature rise and overcoming copper distortion. It appeared, however, that for a given average temperature rise as normally measured, the actual temperature of the coil in the centre of the rotor body would be very much higher than the well-cooled end portions, and he would therefore expect that type of cooling to give, for the same average temperature rise, much more risk of copper shortening than the more normal type of rotor with a well ventilated body and slots. The new design of direct-cooled rotor was very much better from that point of view and should give a more even temperature.

The author had stated that the rotor body had a very much greater heat capacity, and therefore could follow the load changes only slowly, whereas the end bells would respond rapidly being cooled directly by the cold inlet gas. It appeared that, with a very well cooled ring as indicated, separated from the hot windings by means of fairly thick insulation, and joined to the hot body only by a relatively thin lip, the load temperatures would not be very much above the no-load temperatures, since very little heat was induced in the ring itself. He asked the author for approximate

Fig. 35. Measurements of expansions occurring under pressure.



figures for the temperature rise of the ventilated ring on load. It appeared that the use of the new direct-cooled winding with undrilled end rings would result in the rotor body and the rings having temperatures very much closer together than on the old design.

In regard to the effects of single-phase loading, while it had been fairly rare in the past to experience trouble in air-cooled machines, on most occasions when heavy unbalanced loading had occurred smoke, or the smell of hot insulation around the machine, had given warning before serious damage had taken place. It was not possible to notice in that way overheating effects of the type occurring under unbalanced loads with totally enclosed hydrogen-cooled machines and it was necessary to rely on some more accurate method for detecting unbalance. In addition, the present-day use of large numbers of main circuit breakers not having the three phases mechanically interlinked had increased the risk of single-phase loading.

Some eighteen months previously it had been agreed that all large hydrogen-cooled generators being installed on the British system should be protected against unbalanced loading by a suitable negative phase sequence relay, arranged to trip the machine off after a time delay depending on the degree of unbalance. An alarm would also be given as soon as the unbalanced loading reached such a value that there was risk of damage to the machine, so that the operators would have warning that the protection would trip the machine if no action were taken to reduce the unbalanced loading.

On the question of fire, he would be interested to know whether there had been any indication of explosion of carbon-dioxide bottles.

Dr. H. E. Davies (London) said that it would be shown that the presence of holes of relatively small size in comparison with the main section of a metallic material could give rise to a system of triaxial stresses at the holes, which could result in failure of the material by brittle fracture. The stress system at the holes was such as to inhibit plastic flow of the metal at those points, with the result that fracture took place with little or no deformation. The description and illustrations of the failure of the end bells on the Toronto machines presented evidence which indicated beyond reasonable doubt that that had been the method by which they failed.

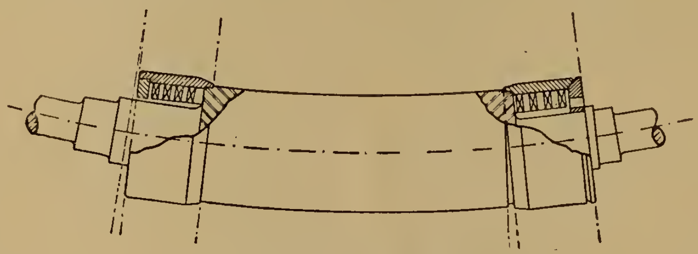


Fig. 36. Effects of rotor deflection.

Left: End bell fastened to rotor body only. No bending of end bell and no relative movement between end bell and body.

Right: End bell fastened to rotor shaft, resulting in bending of end bell and relative movement between end bell and: rotor body; windings; end cover.

Work hardening of the material, especially locally at the areas of stress concentration, also inhibited plastic flow, and increased the tendency to brittle fracture, but the stress concentration due to the presence of the holes and the fact that the material itself was cold worked throughout its mass would tend to override any tendency for fracture to commence in a hard hole as against a relatively soft one, as had been observed in one or two of the author's tests when bursting rings.

The fact that the stress conditions at the actual time of failure of the No. 2 machine end bell had not been so onerous as for the No. 1 machine end bell at its failure, should not be taken as evidence against a similar mode of failure in each case. Even brittle fracture did not necessarily propagate from initiation to final rupture in one instant under service conditions, as was evident from the number of holes showing cracks in some of the burst end bells, so that the conditions at ultimate rupture might not necessarily be so important as the previous history which initiated the crack. Presumably those conditions would be the same for both machines. The effect of that was illustrated by the cyclic tests on the end bells where failure had occurred at a stress not greatly exceeding the working stress, whereas in the static hydraulic testing failure occurred at a much higher stress value.

It seemed that the author's explanation for the overspeeding of the Venezuela end bells without mishap as being due to their much thinner section was reasonable. It had been illustrated for mild steel, under conditions propitious to its formation, that brittle fracture never occurred below a certain thickness. On the other hand it always occurred above a certain thickness, size effect being, therefore, an important factor.

Susceptibility to brittle fracture was also a property of the material itself, and he asked the author whether he had carried out tests, similar to those conducted on mild steel, which would indicate the propensity of this non-magnetic steel to brittle failure.

It seems extremely likely that in that design of end bell for a 100-Mw. machine, the limit of dimensions for the material had been passed when failure by brittle fracture would be almost certain to occur, and when it could be propagated by suitable stress raisers.

Although no indications had been forthcoming in the investigation to indicate that stress corrosion had played a part in the failure of the end bells, nevertheless that type of cracking had been uppermost in his mind when he had first heard of the disaster, since the susceptibilities of that quality of steel to that type of cracking had been amply demonstrated in the past. The British Electricity Authority, together with manufacturers, had taken active steps to examine as many end bells as possible for that type of cracking. Some seventy-four end bells had so far been examined, ten of which had exhibited stress corrosion cracking of varying degrees of intensity, some sufficient to cause rejection of the bells as being unsuitable for further service.

It was, perhaps, unfortunate that it was necessary to rely on cold working, with the resultant internal stresses in the material, to obtain the necessary mechanical properties of end-bell steel, since that condition made it more susceptible both to stress corrosion and to brittle fracture.

A. W. C. Hirst, B.SC. (Eng.) *(Member,)* M.I.E.E., said that the author and his associates had been wise in not jumping to what had been regarded by some as the obvious conclusion that the failure of the Toronto end bells was due solely to the presence of ventilating holes. The consequence was that, in casting round for other contributory factors, they had obtained a great deal of information which would be most valuable to designers who had not had similar experience, and who might now be able to avoid it.

It was suggested that if holes were used the surfaces should be carefully ground and honed, the implication being that that would substantially increase the stress at which failure would take place. He wondered whether any comparative tests had been carried out on end bells with holes treated in that way, and if so, with what results.

The problem was largely a metallurgical one, and in the present case depended very much on the amount of cold work that could be got into the material in the forging process. As with all forgings, the larger they were the more difficult they were to produce and it was hardly justifiable to compare the performance of the 7,500-kw. Venezuela end bells with the 5-foot diameter bells at Toronto.

He suggested that a series of tests on end bells of varying diameter, but otherwise generally similar in design, might yield valuable results. It was even possible that the necessary figures were already available piecemeal to individual manufacturers and steel makers, and by suitable co-ordination could be put together to form a complete picture.

He was pleased to hear the author state so categorically, in presenting his paper, that the accident was in no way due to the presence of hydrogen in the machine. On the morning following the accident the Canadian daily press had carried front-page headlines referring to a hydrogen explosion in the Toronto Power Station, and it so happened that on the reverse side of the same page there had been a picture of the Bikini atomic bomb explosion. That no doubt had given rise to an unfortunate association of ideas in the lay mind. Even today, in some quarters, there were misgivings as to the safety of the use of hydrogen for the cooling of turbo-generators and the sooner the hydrogen explosion bogey was laid, the better.

Dr. R. W. Bailey, WH.SC. *(President)*, F.R.S., said that the paper and the discussion should serve the following objects:

(1) They should ascertain the facts of the failures, nominating those most concerned, and of major significance.

(2) They should ascertain whether, and if so, what, alterations in design, materials, and manufacture would have made the conditions sufficiently less onerous as to have prevented failure.

(3) They should ascertain whether by utilizing the information disclosed, freedom from a recurrence of such a failure in future would be assured.

In varying degrees the three objects are achieved, either directly, indirectly, or derivable from the investigations and information reported, and therefore the paper rendered a valuable service to the engineering profession and to the industry.

It was possible, of course, to answer (2) and to ignore the remainder by saying that there was every reason to believe that had ventilation holes not been used the failure would not have occurred, which was virtually the conclusion reached by the investigation, but if that were done much important light upon the failure would thereby have been missed, including a satisfying explanation of it, especially in view of the author's declaration that 'previous experience and design by the same maker using end bells of similar materials, drilled with ventilation holes had been completely free from failure of the kind described in the paper'. Doubtless that fact made it difficult to unravel from apparently conflicting evidence a satisfying explanation of the failures, which on the evidence of the builder's clean record should not have occurred.

In his view the most significant feature of the failures was the fact that the fractures had been of the brittle kind. That would not imply that the material was other than normally ductile or indeed different from normal high quality material in any way, as, of course, had been amply confirmed by the many material tests made and referred to in the paper. The fact that the fractures had been of the 'brittle' kind sufficiently accounted for the catastrophic character of the breakdown and for the fact that it could occur under no more than working stresses, indeed at even lower than working stress if the conditions for setting in motion a brittle fracture were present. That heav-

Fig. 37. Cracking over pole at change of section.

ily cold-worked non-magnetic end bell steel could fail by brittle fracture was demonstrated sufficiently by the fact of the Toronto failures. But engineers and metallurgists did not possess, as a rule, an adequate appreciation of the significance of that kind of fracture which, when it occurred, caused bewilderment and alarm because usually behaviour appeared to be unrelated to the normally understood properties of the material. It was for that reason, and also for a better understanding of what occurred that he proposed to draw attention briefly to the subject.

In Fig. 43 the general stress f could be chosen so low as to be unable to support the propagation of a brittle fracture and the part would remain intact. Unfortunately, however, the threshold value of stress capable of supporting the propagation of a brittle fracture, if a ferritic steel might be taken as a guide (e.g. carbon steel), the threshold value of stress of the cold-worked end bell steel would be less than the allowable working stress in simple tension, indeed probably not more than two-thirds of the stress allowed in simple tension or for the end bell steel, say, 12.5 tons per sq. in. Thus, given the features which could initiate a brittle fracture, the destruction of an end bell under its own working stress, if as low as 12.5 tons per sq. in., would be feasible. That was analogous with the disturbing failures, by brittle fracture, of welded structures such as welded storage reservoirs and ships.

In order to remove at the outset 'fog' which might be introduced by drilled holes and cloud vision, one should be clear about the part played by the ventilation holes. It was common knowledge with engineers that elastic theory demonstrated that the stress concentration due to a small circular hole on a part under simple tension was 3, or the stress at the surface of the hole at the ends of its diameter perpendicular to the direction of the stress would be three times the stress without the hole. Or, with a tensile stress of 19 tons per sq. in.—the stress in the end bells—the stress at the hole would be 57 tons per sq. in. for elastic behaviour. The proportional limit of the steel was about 40 tons per sq. in., or 17 tons per sq. in. below the maximum stress at the hole, if the material were elastic. The elastic strain that would accompany a stress of 17 tons per sq. in. would be 17/13,000 = 0.0013. If it were assumed that plastic strain were all of that—actually it would be less—the increase in stress due to the cold work involved would be found by the stress concentration due to the hole to be 0.021, or the corresponding increase in hardness would be 0.1 Brinell. The figures for Brinell hardness at the holes given in the paper varied widely, the highest being 657. The normal hardness for the tensile strength would be around 300, and the values given by the paper were in the range 280-340. Thus the drilling had brought about a maximum increase of 357 Brinell, which compared with less than 1 which could be accounted for by the stress concentration effect of the hole. Clearly the influence of stress concentration of the holes upon hardness was negligible compared with that arising by cold work such as by drilling.

Fig. 43 showed a member in tension (it might be an end bell), containing a feature assumed capable of setting off a brittle crack when the stress f in the segment was of a sufficiently high value. When that happened a crack would shoot across the member at lightning speed (3,000-4,000 ft. per sec.) completely fracturing the part. The characteristics of the crack were revealed by the marking at the surface of the fracture, i.e. the chevron markings which were the orthogonals of the fracture front as it travelled. Those were shown in Fig. 43 for a plain member and for one drilled with two holes.

Clearly, what mattered was the feature which could set the brittle fracture on its course, because everything was over and disaster brought in a fraction of a second in a structure of normal high quality material. The feature which had brought disaster to the Toronto end bells was the drilled ventilation holes, not, in his view, by their action in causing the well-known stress concentration of a small circular hole of 3/1, but as a consequence of the increased cold working of the material imposed by the drilling of the holes.

The concentration factor of 3/1 would, of course, apply also to the strain equally with stress, but because of the high degree of deformation or cold working of the surface ductility was so lacking that under the strain concentrated by the hole, cracking of the worked skin would probably occur.

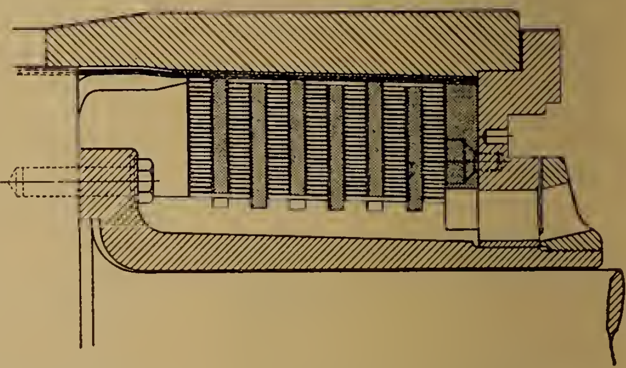

Fig. 38. Rotor end windings, end rings, and end ring support extension sleeve.

It had been amply demonstrated that a cold-worked surface, e.g. a hammered or peened surface of mild steel, for example, was a more effective source of a crack able to set off a brittle fracture in a part under stress. There had at one time been a great deal of trouble due to the fracture of anchor chains on being dropped on to decks. Heavy anchor chains, perhaps with a link diameter of 3 inches, had broken in two. Investigations made at the N.P.L. had shown that the hardened skin of the chains was capable of setting off brittle fracture, and that it was a potential source of cracking capable of setting off brittle fracture. A similar phenomenon might be expected with the drilled holes and the cracking of the surface skin would be equally suspected of being able to set off a brittle fracture. As so many holes had been drilled without resulting in disaster, one might well inquire the reason. He was inclined to think that the reason was the small depth of the hardened layer, another reason he believed was that the cracks of the skin had probably very sharp ends,

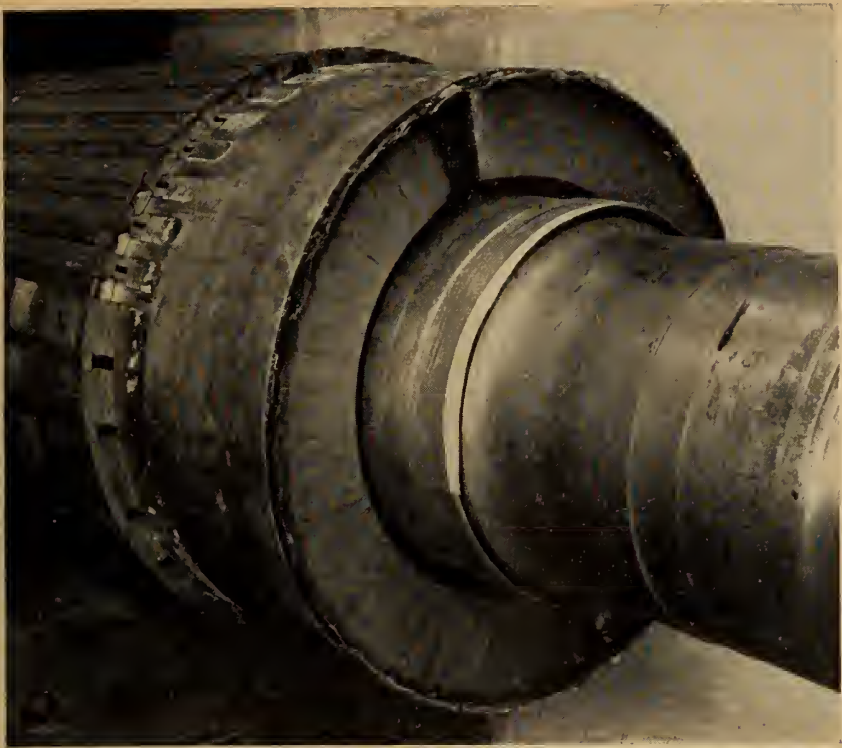

Fig. 39. Complete copper damper across surface of windings.

but if blunted failure would proceed gradually as found by the author.

With so many triggers, which might have become, with some alteration, able to set up a brittle fracture, it would seem that no significance should be attached to the fact that two rings failed in the same station.

So far he had commented upon object (1) and had nominated the work-hardened skin of the drilled hole to be, in his view, the cause of brittle fracture being initiated under the working stresses.

In regard to (2), his reading of the evidence led him to the view that any change in material would be a gamble, as insufficient was known about brittle fracture to make a change with any confidence; it was possible that all steels of the high physical properties required and of the dimensions needed would fail by brittle fracture. He would, therefore, prefer to stick to the materials known, and correct for their greatest weakness, whether or not the design involved drilled holes.

It was a well-recognized principle of the cold working of metals that the higher the degree of cold work the more rapidly softening could be effected by thermal action. Therefore, thermal treatment after machining, whether rings were drilled or not, could be made selective, softening the surface layers which had been most heavily cold worked.

COMMUNICATIONS

D. W. Puttick, (*Graduate*), G.I.E.E., wrote that he was interested in the laboratory tests carried out in order to ascertain the strength of the end bells, and asked whether they had been intended as a comparison between end-bell strength or to simulate the working conditions.

The following comments were made with the realization that what was theoretically desirable might have been found to be impossible in practice owing to the difficulty of sealing all leaks, which was essential for high-pressure testing with small-capacity pumps.

The restraints on the end bell on the generator did not appear to be exactly simulated by the hydraulic test conditions. Figures 1 and 2 showed that the end bell was constrained from moving outwards at one end by the support ring and the other end was free to move outwards under the effect of centrifugal load. In the test apparatus of Fig. 15 it would appear that both ends of the end bell were similarly constrained, both being free to move outwards. As the length of the centre piece was specified as exceeding the end bell by 0.004 inch, it would appear that the end bell was not restrained axially as it did not look possible for the end plate to distort that amount owing to the pulling down action of the outer ring of the studs. In other words, the end bell should be floating (to the extent of 0.004 inch) between the two thick blanking plates. It seemed curious, therefore, that the bursting of the end bell had caused a crack in the end plate and at the exact point of the end bell failure. He asked whether it was considered that the momentary opening out of the end bell caused it to hit the outer ring of studs which had broken the plate.

He asked how the end bell ventilating holes had been blanked. Theoretically the correct method would be a piston in the hole which would not restrain the end bell from moving outwards, being attached to the cast-iron centre piece as shown in Fig. 44*a*. Small blanking plates on inside and outside of the end bell strapped through the hole, Fig. 44*b*, would perhaps be easiest for solving leakage difficulties at 10,000 lb. per sq. in. but it was possible that the failures would not be obtained at the correct stress.

In regard to the results of the tests on the end bell he asked how the stress had been measured, or rather whether the stress had been measured by strain gauges, or by calculating them from the hydraulic pressure applied.

H. W. Puttick, (*Member*), M.I.E.E., wrote that the author had referred to the resemblance to brittle fracture on the failed end bells, and later he had referred to the thinner end bells of the Venezuela turbo-generator which had withstood successfully a serious overspeed.

He asked whether it would not be feasible to manufacture an end bell of composite material, i.e., say, a forging of 2 inches thickness of non-magnetic steel, with a shrunk-on ring of 1-inch thick magnetic steel. That would have better electrical characteristics than an end bell of magnetic steel, and would also have a much higher factor of safety than an end bell of non-magnetic steel.

R. C. Golding, M.E.I.C. (Toronto) observed that on p. 225 it was stated that the desire to have no possible chance of end bell movement when the unit was taken to overspeed to test the emergency governor, governed the design ruling that the end bell shrink should just loosen at 10 per cent above normal speed with the rotor end-bell at operating temperature. In Table II, however, it was stated that overspeed tests at 25 cycles went up to 13 per cent above normal speed. He asked whether that meant that under past conditions the bell had often lifted, and whether the new decision to decrease the shrink so that the bell would lift at 5 per cent overspeed, will worsen the position.

According to the author's statements his firm had many such end bells running on 60-Mw. machines, of 37 inches diameter, at similar stresses. However, those machines ran, he believed, at 3,000 or 3,600 r.p.m. Even with the smaller diameter, he wondered whether those smaller bells were stressed very much higher than the Toronto bells, taking into account the square law referring to speed.

H. G. McHaffie (Toronto) said that the paper summarized a notable investigation following on two regrettable mishaps. Unfortunately, however, it did not appear to have uncovered any items of metallurgical knowledge not previously familiar to those intimately associated with the turbo-generator industry. The investigation did remove all suspicion from the quality of the material used in the manufacture of the retaining rings.

His firm had used rings of this type for over twenty-seven years and in that period approximately 250 machines had been fitted with rings of that type, i.e. 500 or so non-magnetic rings were in successful service.

One solitary failure, definitely established as due to stress corrosion, had been experienced on a small, low-steamed machine which had been stored for an extended period in a salt-laden, humid atmosphere.

However, a selection of machines which had seen extended commercial service, had had their rings examined at the request of the purchasers and no traces of stress corrosion or of any incipient flaw of any description had been found. The rings had been re-assembled without modification or treatment of any description and were still in commercial service.

The material used was similar in composition to that described by the author but was not cold-worked to the same degree. Three grades had been used according to the working stress of the machine concerned. The specified properties of the grades were shown in Table A.

It would be observed that the specified ratio yield point/ultimate tensile strength in the case of grade I (as used on the largest two-pole machines) was lower than the specified ratio of 0.877 given in the paper.

Similarly the average test figure deduced from Table I showed that the ratio yield point/ultimate tensile strength for the Toronto rings was 0.912 and the corresponding figure obtained from test on grade I rings, supplied to his company, was 0.84.

Corresponding test figures for grades II and III were 0.79 and 0.73 respectively. They were convinced that the increased ductility more than offset any reduction in safety factor resulting from reduced ultimate tensile strength.

Similarly they had always avoided the drilling of radial holes in rings and other species of stress raiser. Perforated rings had never been used by the company.

They considered that the practice of supporting the ring at two points was faulty as the flexure of the shaft introduced an alternating stress. They had had a certain amount of vibration difficulty with doubly supported magnetic rings about thirty-five years previously and since then rings had been supported from the rotor body only.

His company believed that some increased difference in rate of change of temperature as between body and rings might result from the use of hydrogen as a coolant, but they could not believe that that could be sufficient to contribute to the failure.

They did, however, agree with the author that protection against unbalanced electrical loading was particularly necessary with hydrogen-cooled machines.

He regarded the results in Table IV to be most significant. It would be observed that all the undrilled rings had expanded without cracking whereas the drilled rings had either cracked or fractured.

Table A

	Ultimate tensile strength, tons per sq. in.	Yield point, tons per sq. in.	Elongation, per cent	Reduction in area, per cent	Ratio yield point/ ultimate tensile strength
Grade I	50	40	30	35	0.8
Grade II	48	35	35	40	0.73
Grade III	45	30	35	40	0.667

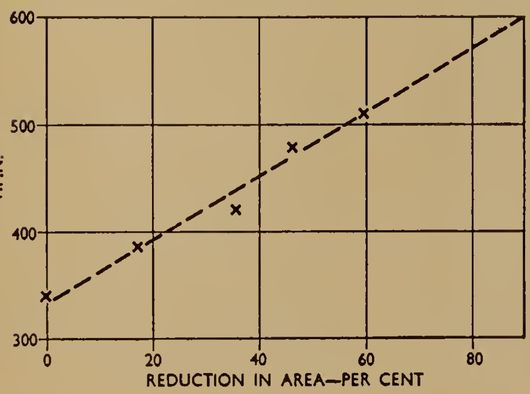

Fig. 40. Hardness versus reduction in area on tensile test. Non-magnetic steel units, ultimate tensile 55-60 tons per sq. in.

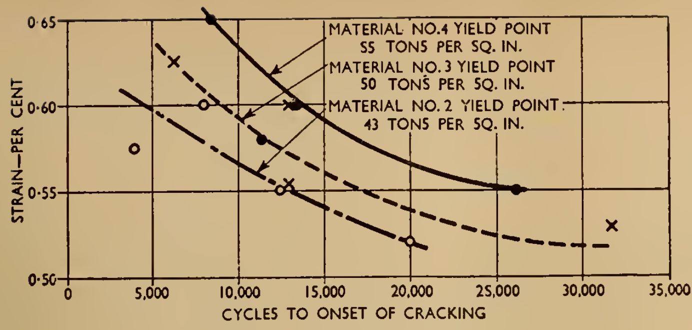

Fig. 41. Results of repeated strain tests.

A. S. Tuttle (Toronto) asked how the surface of the replacement ring was finished, and its chemical composition, having in mind the effect of surface treatment on fatigue resistance.

He also asked to what extent the electrical efficiency had been lowered by replacement of the non-magnetic ring by a magnetic alloy.

F. G. Watson (St. Catharines, Ont.) said that the paper was particularly interesting because the two failures with which it dealt appeared to be identical with the failure in July 1950 of one of the end bells fitted to the rotor of a 60-Mw., 3,000-r.p.m. machine manufactured by his company.

Details of the occurrence had not been previously published, but the information and the conclusions had been made available at the time to other British manufacturers and to users of such plant. Fortunately, the incident had taken place in an overspeed test tunnel and while the rotor was a total loss the fractured end bell parts had been recovered from the tunnel lining for examination and analysis.

The end bell fracture had proved to be generally brittle in nature commencing at the surface of a ventilating hole.

It seemed clear that while the ventilating holes might not be the complete explanation of the failure they had been a major factor. They therefore had abandoned the practice of drilling all end bells whether for ventilation or other purposes. Furthermore, all similar machines either in course of manufacture or in service having end bells with properties proved on their acceptance tests similar to those of the forging which failed had been refitted with undrilled end bells.

At the same time the policy had been adopted of keeping the ratio of yield point to ultimate strength low to permit plastic deformation.

He agreed that the omission of ventilating holes would increase rotor winding temperature, but did not subscribe to the opinion that their retention was necessary in order to prevent coil distortion. In this view the use of semi-hard silver bearing copper gave an ample margin of safety at the slightly higher temperature which, in any case, would be largely localized at the end turns.

It was acknowledged that the holes produced local stress concentrations and that, coupled with the work hardening that can and did occur when drilling, produced ideal conditions for the initiation of a brittle fracture. The danger was greatly increased should such a hole coincide with a region of high residual forging stress.

He also agreed that the ventilating holes in themselves were not sufficient to account for the failure, as the examination of many typical end bells showed wide variations in physical properties and residual forging stresses arising from the cold working of the material in the course of production.

That led his firm to introduce in 1950 a hydrostatic testing rig and subsequently every end bell has been subjected to test. With the test rig it was their practice to create a maximum hoop stress in the end bells equivalent to 95 per cent of the lowest value of the yield, taken from test pieces. Tests showed that consequent stretching improved the distribution of the residual forging stresses.

In addition to the two major factors mentioned, a secondary contributory cause could be the method of supporting the end bell at two points involving shrinking on both the rotor body and the shaft. Their experience had shown that such a construction in which the end bell was supported at two positions the deflexions of which were different, led to fretting and, in extreme cases, to fatigue cracking.

It was interesting that the author regarded the presence of holes and residual forging stresses as being major factors, as that was the conclusion arrived at by his company in 1950.

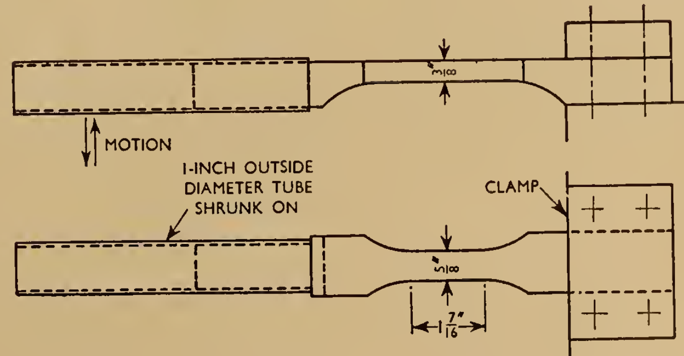
Vote of Thanks to Sir Claude Gibb

H. Fealdman, M.E.I.C., in proposing a vote of thanks to the author for his paper, said:

In rising to move this vote of thanks to Sir Claude on behalf of the Toronto Branch of the Engineering Institute of Canada, I must confess to a feeling of great pleasure mingled with a sense of humility in the presence of such a great engineer.

It does not fall to many of us during our lifetime to be present on an occasion when engineering history is made, but I am certainly of the opinion and so, I believe, is every single person in the audience, that tonight is one of those very memorable occasions.

Fig. 42. Form of test piece used.



Engineering progress can only be made on occasions such as the present, where an original mishap has caused a great deal of engineering talent and time to be concentrated on the solution of a particularly difficult problem, by the complete publication of all the relevant facts and conclusions.

In very many cases in the past this publication has not taken place, and the knowledge so obtained remains the secret of a select few. I have to congratulate Sir Claude on the full and frank treatment that he and his company have given to the subject we have heard discussed this evening. It is certain that this paper will long be a model upon which students and research workers in all branches of engineering can base their investigations and reporting.

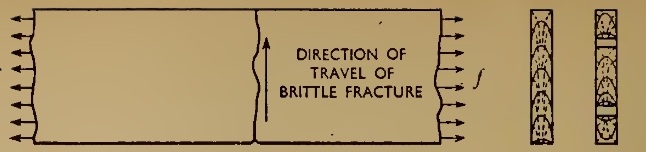


Fig. 43. Effect of general stress *f*.

I personally, have been quite fascinated by the process of deduction that was carried out prior to the solution of this problem, a process of which Miss Agatha Christie would have been quite proud. I am sure that had the effervescent M. Hercule Poirot had been here himself this evening, he would have been the first to lead the applause which, surely, has never been more merited.

I wish to extend the thanks of the Branch through Sir Claude to the very large team of engineers, scientists, and mathematicians who laboured so long and so hard to perform the work described in the paper. In conclusion I wish to thank Sir Claude specifically, not only for his work and inspiration to the team, but for the immense amount of trouble he has gone to in coming here to deliver the paper to us and for the very clear and simple manner in which the presentation was made.

I feel certain that every single person in the hall will join with me in according Sir Claude a very hearty vote of thanks.

REPLY BY THE AUTHOR

Sir Claude Gibb, in reply, wrote that as many similar points had been raised by several contributors to the discussion, it would be preferable to submit remarks extending the information given in the paper rather than to reply individually. He would, however, pay tribute to Mr. Pask and his colleagues for their interest, assistance, and forbearance in making rotors available for examination and test after long periods in service, thus to extend the scope and value of the investigation.

Had he himself considered, or the evidence led to the belief, that ventilating holes were the prime cause of the failures, the paper would never have been written and the industry would have continued in ignorance of the small margins of safety under which rotors were operating until further disasters had been experienced. It was true to state that as the result of the investigations and the researches consequent upon them, changes in forging technique, in design and in manufacture had enabled the industry to proceed with complete confidence in the manufacture and operation of generators of outputs appreciably greater than double that of the generators which had failed.

Researches into the material and methods of manufacture of end bells had continued as a matter of urgency and would continue for a considerable time. One outstanding result had been the improvement in the notched bar toughness of austenitic non-magnetic end bell material of identical composition from between 20 and 70 ft. lb. Izod at the time of the failures, to 80-120 ft. lb. at the present time.

A large number of end bells of identical composition to those of Toronto which had been in service for long periods under similar operating stresses and conditions had now been withdrawn for rigorous examination and testing. In no case had anything been found which had given the slightest cause for nervousness regarding their continued suitability for service over an indefinite period. Since the end bells had had to be replaced to enable destructive testing to be made, the replacements had been of similar non-magnetic material, but without ventilating holes.

In a cyclic pressure test carried out since the paper was presented, an undrilled non-magnetic end bell forged by a modified technique but of the same size and similar properties to the Toronto end bells had withstood, without detectable effect or damage, 1,000 cycles of a range of stress from zero to 40 tons per sq. in. At the oil pressure corresponding to a mean hoop stress of 40 tons per sq. in. seal failure had occurred after approximately every six cycles, necessitating the stripping down of the heavy bolting and flange plates and making testing so slow that the testing had been discontinued after 1,000 stress cycles. A similar end bell but drilled as the original Toronto bells, had been subjected to hydraulic pressure producing a mean hoop stress of 47.6 tons per sq. in., at which load continued stretching of the bell caused the oil seals to fail. The pressure test had been repeated after renewing the seals, and again at a mean hoop stress of 47.6 tons, expansion of the bell had caused the seals to fail without fracture of the end bell. The yield point of that bell, as shown by the acceptance tests, had been 43.5 tons per sq. in. When these test results were compared with those given in the paper for the original end bells, the advance in the quality of bells owing to changed forging techniques resulting from those investigations would be apparent and comforting to operating engineers.

Several contributors had referred to the high ratio of yield point to ultimate strength in the Toronto end bells and expressed a preference for a lower ratio. It was obvious that all designers would prefer that ratio not to exceed, say, 0.85, but the end bell had certain functions to perform while the forgemaster must have a margin on specified minimum yield point figures and for cold worked austenitic alloys that margin had long been agreed as 7 tons. Hence, when working to the specification of 50 tons per sq. in. minimum yield point, and allowing the forgemaster's tolerance, the ratio of yield point to ultimate strength could vary between 0.877 and 0.934. The latter figure was not of itself dangerous but it did indicate an increased susceptibility to brittle fracture. Furthermore, the tests taken from widely differing places in a particular end bell showed the values of yield/ultimate ratio to vary from 0.876 to 0.964. Thus acceptance tests had not necessarily been representative of the properties of a bell as a whole.

Austenitic steels were not in general susceptible to brittle fracture, but to obtain desired physical properties in end bells, the high carbon content and the conditions realized in processing resulted in the formation of a definite boundary envelope of carbide which provided a ready path for brittle fracture. Thus with the material available and the method of forging adopted up to the time of the Toronto failures, the possibility of failure has been present in many machines and only the absence of the 'triggering' combination of several factors had avoided trouble.

Whilst ventilating holes were one source of stress raiser, there were, of course, many others, and a particularly dangerous one would be a recess at the shrunk nose of the end bell which, unless the shrink was to be removed at speed, was likely to be the plane of maximum stress in the bell.

The discussion had shown the differences of experience or opinion between designers. Mr. McHaffie liked a low ratio of yield point to ultimate tensile strength, whilst his colleague Mr. West would appear to be satisfied with ratios

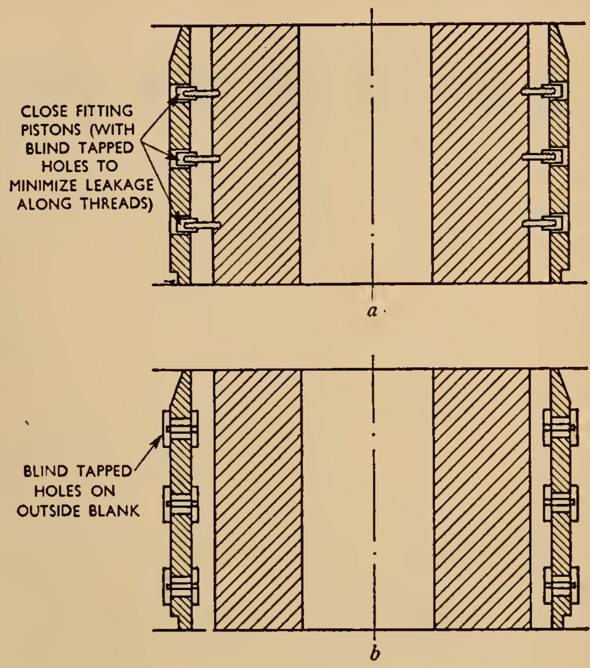

Fig. 44. Methods of blanking end bell ventilating holes.

higher than those in the Toronto rings. Those differences in the considered opinions of designers were, of course, based upon experiences, satisfactory or otherwise, of their current and past designs. His own experience would lead him to expect stress corrosion to develop between the copper damper and the end bell in the design shown in Fig. 39, but obviously Mr. West had so far not detected such an effect.

The Toronto rotors were four-pole, 1,800 r.p.m., and therefore very stiff shafts with almost uniform deflexion. No trace of fretting corrosion had been present under the nose of the cap and, as the Toronto nose had not had a stress raising recess, the cracking shown in Fig. 37 would not take place. The report referred to by Mr. Vickers and Mr. Watson was, it is believed, dated June, 1954—some three months after the Toronto failures.

Professor Austin had asked whether the two end bells which failed had been from the same cast of metal. It had now been established that they had not been from the same cast. Tensile specimens from the end bells showed more uniform extension and less necking than specimens of heat-treated alloy steel, hence the elongation figures obtained during tensile tests were a true measure of ductility. There was no other established method of obtaining high yield points in large non-magnetic forgings than by cold work.

A wide variety of alternative alloys had been tested or used for non-magnetic end bells, but all had one or more serious disadvantages, amongst them often being a marked susceptibility to stress corrosion.

No claim was made in the paper that a reduction of temperature rise of the rotor windings by the use of ventilation holes in the end bells, or by other methods, was the only way of preventing coil distortion, but it was one important factor. The use of hard drawn silver bearing copper was another important factor but it had not been established that it alone would be completely effective.

The wide interest shown in the report, both in the London and the Toronto presentations, was adequate recompense to him and his colleagues for its preparation. An advance in the science and the art of generator design and manufacture had resulted from the failures.

He wished to thank the contributors to the discussion, and particularly Dr. R. W. Bailey for his advice and assistance as well as for his valuable contribution. √

ABSTRACTS . . .

OF RECENTLY PUBLISHED ENGINEERING LITERATURE

APPLIED SOLAR ENERGY

Air Conditioning, Heating and Ventilating, v. 52, n. 12, December 1955, p. 73.

Solar energy is being harnessed directly today for heating, cooling, and for motive and electric power. A report on the World Symposium held last month in Arizona, with abstracts of those papers of interest to heating and air conditioning engineers, is presented in two parts of which this is the first.

The preliminary conference on the scientific basis of solar energy conversion was organized to permit scientists to meet and exchange ideas in advance of the World Symposium in Phoenix. Papers at the conference were in general beyond the scope of this presentation, but will be published in proceedings of the Association of Applied Solar Energy.

Dr. Farrington Daniels of the University of Wisconsin, introducing his discussion of basic principles and problems, said he thought this conference might give as much international impetus to solar power as the recent Geneva conference did to atomic energy. Dr. Daniels envisions solar power and atomic power as developing together and atomic power handling heavy loads in urban areas while solar power supplies the smaller unitary demand typical in rural areas.

At present, he said, the conversion of solar energy into usable forms costs more than conventional power sources. New technology and new ideas will be required before solar energy is widely available on a competitive basis.

Henry B. Sargent, president of the Association for Applied Solar Energy, described how the idea for the association was conceived as a result of conversations between himself and Dr. Daniels some two years ago. It seemed desirable, said Mr. Sargent, to have an association which could form a vehicle, not only to encourage further scientific and engineering work in connection with solar energy, but which could serve as a means of presenting to industry and business accurate information on the present state of the art. Accordingly, on March 17, 1954, Mr. Sargent met with a group of men from industry, agriculture, finance, and education who agreed that additional steps should be taken to meet the problem of greatly increased world requirements for energy.

A staff paper presented by J. E. Hobson, director of the Stanford Research Institute, explored the economic possibilities of solar energy. In the not too distant future, said Dr. Hobson, we will be confronted by an imminent, ominous shortage of the fossil fuels and other energy sources packaged and stored for us through action of the sun. Men of this generation must prepare today for this coming crisis.

Direct use of energy from the sun offers immediate, specific economic opportunities. Some have already been developed. Engines have been operated with solar power; water has been lifted by solar powered pumps; solar furnaces have produced exceedingly high temperatures; solar ovens can cook our basic foods; houses have been heated by solar devices. Solar cooling and direct solar electricity are physical if not economic facts of life today.

The economic advantages of large producing units do not apply to solar energy devices, because the major cost factor is in the area of the collector. That area must be doubled to double the capacity. Ordinarily the net gain from doubling the size may not be sufficient to overcome the additional operating difficulties. We may never build solar power plants with a capacity of 100,000 kilowatts, but we may well build 10,000 plants, each with a ten kilowatt capacity.

There does not seem to be an economic potential now for solar house heating in most of our eighteen selected cities, said Dr. Hobson. However, solar house heating is more economical where the cold season is long and the weather clear, since longer heating means a higher use factor. There are many locations, especially in the mountains, where solar space heating can be utilized economically today.

For a panel discussion on solar house heating, Dr. Maria Telkes of New York University reviewed research projects which have been conducted with solar heat collectors. Development and use of low cost heat storage materials is essential for the economical solution of solar heating, Dr. Telkes said.

A solar Engineering Exhibit, concurrent with the Symposium, is described in this month's News pages. Next month, the balance of abstracted papers, covering solar power, heating, cooling, water heaters, and mechanical, chemical and electrical converters will be published.

FLUID COKE — NEWEST STEAM PLANT FUEL

By F. H. Stracke and F. H. Schiffer
Power, v. 99, n. 12, December 1955, p. 102.

The power industry is showing much interest today in test burnings of a new fuel known as fluid coke. This article reviews the program of Esso Research and Engineering Company in its studies to determine the adaptability of fluid coke for steam generation, including full-scale combustion tests recently finished at the Essex Station of Public Service Electric and Gas Company.

For many years there has been a continuous increase in worldwide consumption of gasoline, heating oil, jet fuels and other light petroleum products. While the market for heavy fuel oil has increased, the rise has not been as rapid as for light products. In addition, there has been a trend toward processing heavier crudes.

About two years ago Esso became active in a project to determine ways and means of best using this new product. Because refiners who adopted the fluid coking process would be faced with the problem of moving large volumes of carbonaceous material new to the industry, a long-term development program was established. Early studies showed the material was useful as a fuel, primarily for steam generation. So we had to learn how it could best be used.

At that time the total supply of fluid coke in the world was about ten tons, from pilot-plant operations. We realized that the usual volume-burning cut-and-try technique, so familiar to the fuel industry, would not apply in this instance. So our second problem was developing this material as a fuel while having little of it to work with.

A 4-part program was established. (1) Theoretical combustion calculations were made. (2) Laboratory-scale tests were the second part of the program. (3) Pilot plant tests were proposed should lab tests bear out the calculations. (4) Last step was to make full scale tests.

These tests showed that electrostatic precipitators will function properly when handling fluid coke. Other large-scale tests indicated mechanical precipitators are somewhat more efficient handling fluid coke refuse than when handling fly ash.

Much additional information, yet to be procured, cannot be obtained until a steady supply of fluid coke is available. Based on these tests, however, Public Service has contracted for the entire output — about 170 tons per day — from the fluid-coking unit recently completed at Esso Standard Oil Company's Baltimore refinery.

Based on the laboratory and full-scale test programs, it can be said that the power industry now has a fourth fuel — fluid coke — which can economically compete with coal, gas and oil.

RESCUING DOWNTOWN AND ITS TRANSIT

By Philip M. Talbott, Woodward & Lathrop Co., Washington, in December 8th issue of *Public Utilities Fortnightly.*

Following a 9,000 mile trip through the U.S. and Canada, visiting fifteen major cities, the author contends there is nothing wrong with downtown sections of principal cities that cannot be corrected by joint action of leading citizens who have an interest in downtown areas.

It is not his opinion that downtown America is doomed. However, the problem of downtown vitalization is not merely a matter of dressing up our main streets and the buildings and stores that line our thoroughfares — it is far more than that. The problem can be solved through unified and vigorous action, properly executed.

Action should have these immediate objectives: (1) Organization of small groups of business men and civic leaders to establish a program with sole objective of an economically, culturally and socially strong downtown district. (2) Development of a program based on elimination of slum sections, better traffic conditions, rapid mass transportation, private capital for construction to vitalize the area, and promotion to bring people downtown.

No set program would fit every city. A program should be mapped out which will be effective for each particular city. Suburban developments cannot be ignored. Suburban shopping centres offer an opportunity for additional business competing more with each other than with the greatest shopping centre of all — downtown.

Many blighted downtown centres have deteriorated buildings which are the property of absentee owners. Committees should urge executors of such estates to encourage modernization. Downtown is everybody's business, everybody's responsibility. There is a job in downtown vitalization for everyone interested in his community.

WAR AND PEACE IN LABOUR RELATIONS

By Robert N. McMurray, *Harvard Business Review,* November/December, 1955.

Current labour philosophies are 'fair weather' programs. The time has come when management must set up a preventive labour relations policy to maintain the balance of power between company and unions.

The plan for labour peace through balanced bargaining power which is offered in this article is in no sense a panacea and it is not for the tender minded nor the doctrinaire. In fact, a number of companies cannot use it at all, either because of lack of sincerity or because of lack of forceful leadership. On the other hand, it may be helpful to those companies that do genuinely desire to help their people and have the kind of executive who can maintain the respect of both the union and the workers.

There is a need and place for labour unions. In large corporations some form of collective bargaining is a must: individual bargaining is impossible. But just because unions are here to stay is no reason not to try to place a check on the power and arrogance of some of them.

We must face the fact that labour peace in the sense of absolute freedom from conflict is neither possible nor desirable. The answer lies in keeping the conflict within reasonable bounds. This is best accomplished by maintaining a balance of power between management and the union.

This can be done if the business is headed by strong and emotionally healthy men capable of participative leadership. Labour problems require the same executive strength and competence as do all other aspects of business, and are not susceptive to any special quick tricks or 'gimmicks'.

TRAINING OF ENGINEERS

By Dr. E. A. Allcut, Prof. of Mechanical Engineering, University of Toronto
Modern Power and Engineering, v. 49, n. 12, December 1955, p. 52.

The problem of the shortage of engineers in Canada is an important one, because our civilization is becoming increasingly dependent on engineering and engineers — indeed our chances of survival may well depend on them. Most engineering degree courses of any repute are of four years' duration and the question therefore arises: "Could these courses be reduced to three years, or could the length of the academic year be increased, without sacrificing anything essential?"

All in all, the present four-year course appears to be of the right length. If it had not been so, we should have changed it long ago, particularly during the post-war years, when we were swamped with students. A shorter course would have been a godsend at that time.

Suggestions have been made and seriously considered, from time to time, that the length of the academic session should be increased but, for several reasons, these have not been adopted. The most important consequence would be the reduction of earning power by the students during the summer months. At the University of Toronto (and other institutions) the practical experience gained during the summer is considered to be an essential part of their training.

Lengthening of the sessions might make it impossible to get or retain adequate staffs, particularly in times like these, when they could easily leave and go into industrial work on more lucrative terms. Another factor in Canada is the prevalence of high temperatures during the summer months, which makes it almost impossible to work in laboratories that normally have relatively high temperatures and humidities.

Evening classes also have been considered, but unless budgets and staffs are greatly increased, these cannot be carried on to any useful extent.

If it be conceded that a minimum of four years is required to give suitable preparation for an engineering career, and that there is no reasonable prospect of increasing the length of the session to any appreciable extent, the problem boils down to the necessity of training a greater number of students with the buildings and facilities that may be available in the near future. We are also face to face with the practicability of reducing the failure rates in the engineering courses.

It must be assumed that there is no desire on anybody's part to reduce educational standards for the purpose of obtaining an increased "throughput". Apart from any other consideration, this panacea would be opposed by the Professional Engineering Associations as well as by the universities. I believe that both of these conditions could be met by the institution of junior engineering colleges, into which all engineering undergraduates would go for the first two years of their courses.

Those not chosen for the university course could continue in the junior college and, on graduation, could receive diplomas or certificates entitling them to practice in certain aspects of engineering work. This procedure would assuredly reduce the failure rate in the university, perhaps to a remarkable extent.

INSTRUMENTATION OF A 14-IN. EXPERIMENTAL ROLLING MILL

The Engineer, v. 200, n. 521, December 9, 1955, p. 846.

This paper describes the comprehensive instrumentation on the new 14 in. experimental rolling mill in the British Iron and Steel Research Association (B.I.S.R.A.) Sheffield Laboratories. Roll force on each side of the mill, front and back tensions and strip gauge, using the B.I.S.R.A. gaugemeter principle, are continuously indicated on high-speed servo-operated potentiometric indicators fitted with large pointers and dials. The whole instrumentation scheme is designed and laid out as a model system for industrial mills of this class. Facilities are provided for experiments with various systems of automatic gauge control. A simple system of on/off control of the existing a.c. screw motors according to the gauge deviation has been successfully operated with a tolerance of only $+0.0005$in. Facilities are also provided for switching to automatic tension control based on measured tensions as an alternative to the present method of control of coiler-motor current with correction for radius of build-up.

The system of measurement and display of roll loads, strip tension and strip gauge described in the paper has shown itself very satisfactory in service and has served as a useful model upon which industrial instrumentation schemes might be based. The rationalisation of the electronic units and the choice of a potentiometric system of display have helped greatly in getting this comprehensive scheme quickly into service.

Experiments so far carried out with a simple system of automatic gauge control by on/off control of the screw motors, using the gauge error indicator to initiate the control action, have shown that this system has considerable promise for use on some industrial mills.

$15-MILLION POWER STATION IN B.C.

From news release of British Columbia Power Commission and Canadian General Electric Company, April, 1956.

The world's largest concentration of gas turbines for the generation of electric power will be placed in operation on Vancouver Island in 1957.

The British Columbia Power Commission announced it has placed an order on Canadian General Electric Company for four gas turbine-generator units with a power capacity of 100,000 horsepower.

Site of the power station likely will be in the central section of the east coast of the island, according to Power Commission general manager Lee Briggs. Total cost of the station will be in the order of $13,000,000 to $15,000,000, depending upon final design details, location and length of related transmission facilities.

Though the initial installation will be gas turbine units fired by heavy-type oil, provision is being made for future expansion, if and when required, with steam turbine units using either coal or other fuel.

The order received by C.G.E. includes two 19,750 kw simple cycle, single shaft units, and two 18,000 kw regenerative cycle, single shaft gas turbines. The units are rated at 50° F. inlet temperature at an altitude of 200 feet above sea level.

The units will be built by the General Electric Company's Gas Turbine Department in Schenectady, N.Y.

Turbines will have tip speeds of 910 mph, and the average speed of air traveling through the turbine's compressor will be 314 miles per hour.

Each gas turbine will drive a 3,600 rpm, three phase, 13,800 volt generator which will produce 25,600 kva. of electric power at 60 cycles.

The gas turbine is essentially an internal combustion engine which directly transforms energy contained in fuel into usable mechanical energy at the coupling. However, instead of having a reciprocating motion similar to the usual internal combustion engine, the gas turbine has a rotary motion with continuous firing. The gas turbine assembly contains a shaft driven axial flow compressor which furnishes compressed air for the working medium. This compressed air is heated to the required turbine inlet temperature by burning fuel in a system of combustion chambers. The hot compressed gas from the combustion system then expands through the turbine buckets to develop rotary power to drive the air compressor and to supply shaft horsepower to drive the generator. After expanding through the turbine buckets, the gas at reduced temperature and pressure is exhausted either to the atmosphere or to a heat exchanger depending upon the cycle.

The station will be capable of furnishing enough electricity to adequately satisfy the average yearly needs of 190,000 persons. The use of the plant in large part is to "firm up" power from the Commission's hydro plants so that its Vancouver Island customers will not be threatened by "brown-outs" from time to time as load growth expands.

ASWAN HIGH DAM

A staff article in *The Engineering News Record*, issue of February 9, 1956, p. 44.

Egypt's proposed Nile river project, of current international concern, becomes increasingly interesting with this release of preliminary design details. Its maximum height, 361 feet; length, 3.1 miles; base thickness, 4,276 feet; volume of fill, 54.93 million cubic yards; reservoir capacity, 105 million acre feet; reservoir, 300 miles long, and holding four times as much water as Lake Mead.

Discussed for decades, it has been under serious investigation since 1952. In 1954 a Board of Consultants studied proposed design and construction, making recommendations now being incorporated in the final design. The estimated cost of construction is $1.3 billion. It will take ten years to build.

A construction timetable would shape up as follows: First four years, four diversion tunnels and cofferdams to Elev. 365. Fifth and sixth year would take it up to Elevation 395, including drainage ditches, grout curtains, upstream blanket and excavation of powerhouse cavern. Another four years would complete it to elevation 643 and see installation of eight hydraulic power units.

A TECHNICAL LEVIATHAN

Editorial in *Engineering*, v. 181, n. 4694, January 13, 1956, p. 33.

The opening of the Iron Curtain to specialist visitors from the West has enabled a number of people to catch a glimpse of the advances in scientific and technical education which have been taking place in Russia since the war.

The present rate of production of professional engineers and technicians in Russia, which to-day amounts to about 350,000 a year, can be compared with the numbers taking degrees and National Certificates and Diplomas in this country, which amount to about 21,000. When account is taken of the relative populations the Russian figure is over four times our own. Even if the production of university-standard graduates in all faculties continues at only the present rate, in 15 years' time there will be one graduate for every 40 of the Russian population — a staggering achievement.

Standards are certainly comparable with those in other industrial countries; while the numbers themselves, of professionals and technicians together, are comparable with those in the United States.

The question left in one's mind, after digesting the startling information provided by the report, is whether the accelerating development which it discloses must not lead to the creation of a Leviathan state impelled by blind technical progression towards world domination or its own destruction.

He would be a bold man who would say that he was certain that the Russians, if they were ever to outgrow their philosophical and political authoritarianism, would not be found to have reached that goal more successfully than ourselves.

Abstract of the report referred to: —SOVIET PROFESSIONAL MANPOWER, by Nicholas DeWitt, National Science Foundation, U.S. Government Printing Office, Washington, D.C., U.S.A. $1.25, appears on page 40 of the same issue.

Notes of the Institute and Other Societies, Comments and Correspondence, Elections and Transfers

Comparison of Salaries

Not long ago a survey of salaries of professional workers was made and issued as a confidential document. One copy has been filed with the Institute. It is full of very interesting information but in view of the confidential nature it is not possible to publish it. However, here are a few paragraphs which appear on one of the pages.

Doubtless engineers right across Canada will be interested in these observations.

"Observations"

"Canadian industry in 1955 pays its professional employees at approximately the same level as did American industry in 1952 (using for comparison figures from the Los Alamos Scientific Laboratory 1952 National Survey of Professional Salaries).

"In all countries plant operators are paid more than laboratory workers at the same level of education and with the same years of experience.

"When related to purchasing power the average Canadian salaries may not be very much greater than the British but there is no doubt that, on this basis, American rates are considerably better than either Canadian or British, especially when total lifetime earning power is considered.

"British doctors of philosophy have no advantage in starting salary over bachelors and masters. This differs from both American and Canadian practices.

"Scientists and engineers in British industry double their starting salaries in 12 years, in Canadian industry in 16 years and in American industry in 17½ + years despite the much higher level at which Americans begin.

"It is also obvious that the percentage of older people in British industry is greater than in either Canada or the United States."

Cover Picture

Launching of the new "Empress of Britain" at the Fairfield shipyard, Govan, Scotland, in June, 1955. She made her first transatlantic crossing in April and attracted considerable public interest during her stay in Montreal.

Shortages, Shortages

Recently on picking up an old number of the *Ontario Medical Review*, it was interesting to see that the medical profession also have their share of shortages.

There is therein an article which states that the report of the Ontario Health Survey Committee, which dealt with "Medical Manpower in Ontario", contained many recommendations with regard to finding new personnel for the profession.

Herewith is a quotation from the report:—

"Under the section dealing with 'Hospital Facilities and Services' the Committee recommended:

> Measures to provide training for additional hospital personnel to meet the following shortages existing at the time (1948) of this survey, i.e. — 22 pathologists, 25 radiologists, 99 laboratory technicians, 209 radiographers, 35 laboratory radiographer technicians, 176 dietitians, 91 pharmacists, 94 physiotherapists, 36 occupational therapists, 52 combined occupational-therapists, 128 medical record librarians.

"Under the 'Mental Facilities and Services' section of the Report, the Committee recommended:

> That the universities of Ontario be granted sufficient funds to train psychiatrists and other professional personnel to relieve the present shortage and to make possible the recommended mental health programme. Annual cost of this training is estimated at $500,000;
>
> That 54 psychiatrists be added to the staffs of existing mental hospitals to meet immediate needs, and that an increased number of psychologists, social workers, occupational therapists and physiotherapists be employed as they become available;
>
> That in order to make possible

the early implementation of various of these recommendations, despite the acute shortage of psychiatrists, an effort be made to employ on a part-time basis in the public service psychiatrists who are engaged in private practice."

that Canadian mill production of structural shapes and reinforcing bars be increased to overcome the serious supply problem.

There is still scope for further amendments to the NHA whereby home ownership can be extended. Moreover, many of our existing houses are substandard. As population grows and standards rise, many units will have to be improved or replaced.

Greater activity in re-housing and multiple-unit buildings will involve important policy decisions, and gives additional weight to past CCA recommendations that an advisory housing committee should be formed to provide the various groups concerned with a medium through which to co-ordinate and present their views to CMHC officials.

The increased volume of house building has been accompanied by the entry into the market of some with no experience in the building of houses and little in the way of financial resources. It is important that these aspects be borne in mind before granting them credit. Once work has commenced it should be adequately inspected to assure protection to the owner, the lender, CMHC and the reputable builders.

Pipeline Progress Reported

This *Journal* contains the first article in a new series, on "Canadian Pipeline Projects", in which we will report the progress of important pipeline developments in Canada.

The first article, on page 651, is a review of the discovery and use of Canadian natural gas, and the story of the part played by the Westcoast Transmission Company and Trans Canada Pipelines in recent years. The Westcoast Transmission Company will be transporting gas from the Peace River gas field, where the estimated reserves are 3.5 to 4.5 trillion cu. ft., and will be associated with the Pacific Northwest Pipeline Company, to serve northwestern United States. The Trans Canada Pipelines propose lines going east as far as Montreal from the southern Alberta fields, where the reserves are estimated at 15.5 to 20 trillion cu. ft. Though there is much negotiation to be done yet on this larger program, there may be news of the commencement of the western leg of the project in 1956.

Obviously these are matters of great interest to the Canadian economy and to Canadian engineers. The *Journal's* plan to follow and report our major engineering developments calls for this new series, which we hope our readers will enjoy.

Correction

Some notes on the career of the president-elect, V. A. McKillop were published on page 473 of the April issue. In the interest of accuracy it should be reported that the degree received by Mr. McKillop in 1924 was that of B.A.Sc., and not that of B.Sc., as stated.

CCA Brief to Federal Government

A submission from the Canadian Construction Association was presented to the Federal Government on February 28, 1956. Signed by CCA President A. Turner-Bone, and S. D. C. Chutter, the Association's general manager, this submission presented the statement of policy and resolutions adopted at its annual meeting. An abstract of the text follows:

A year ago hope was expressed that the volume of construction in 1955 would reach $5 billion. Preliminary estimates indicate that this figure was exceeded by a margin that more than compensated for the increased dollar total due to a 2 per cent average rise in basic construction costs. The physical annual volume of work has roughly doubled during the decade since the end of World War II.

The annual increase in the volume of construction during the entire post-war period has constituted one of the most powerful stabilizing influences in our overall economy . . . So much of the Canadian economy relies on the construction program that any sizable reduction in the amount of building activity would not only affect adversely the industry itself but also our general economy throughout the country.

Indirect action by the government influences the commencement of an even greater volume of "private works". For example, roughly half of our new houses are being financed through the National Housing Act. This amounts to about 15 per cent of the volume of construction. Losses on NHA loans have been negligible. Similarly, the federal rates set for income tax, depreciation and interest charges greatly influence capital investment decisions by private individuals, corporations and other bodies. Government policies concerning the volumes of immigration and trade also affect the volume of construction.

The prospects for 1956 are for a new record volume of construction under conditions of exceedingly keen competition. The industry's capacity has expanded so as to take care of the heavier demands. Supplies of several products — notably steel — have, however, been unable to keep pace with current demands. . . . In view of our large iron deposits and the increasing market for steel products, it is especially desirable

Highways

Despite record roadbuilding programs undertaken by the provincial governments in recent years, the backlog of road requirements has steadily increased. The benefits ensuing from investment in well-planned and well-built roads are great. Although the outlay may be large, it will bring many dividends in the form of increased economic activity and revenues resulting from development and expansion.

It is therefore again recommended that federal grants be made available to provinces for use on Canada's main highway network, and that an auxiliary joint program be carried out with regard to international connections, new access roads to undeveloped areas, approaches to national parks, railway-highway grade separations, etc.

All sections of the Association once again endorsed a policy statement advocating the "co-ordination and centralization of responsibility and control of construction projects under a general contractor". A joint meeting was held in 1955 between a CCA delegation and senior officials of Defence Construction Ltd. and the Department of Public Works to discuss tendering and contract procedures. The subjects discussed are generally applicable to all federal departments and agencies administering construction contracts.

For example, all federal agencies but CMHC require tenders to be submitted to their Ottawa office and a serious problem exists with regard to tenders arriving after the stated closing time due to delays. It is accordingly recommended that a point be designated in each province for the delivery of sealed tenders.

In a clause common to all federal tendering documents it is stated the government does not guarantee information furnished concerning subsurface conditions, and that all bidders must examine the site and make their own appraisal. It is strongly recommended that the Canadian government amend its policy by improving the calibre of and accepting responsibility for the subsurface information included in its specifications.

On private projects, subcontractors and suppliers have protection under the terms of Mechanics' Lien Acts in the event that a general contractor goes bankrupt. It is not possible, however, to take lien action against federal government property and many subcontractors and suppliers have suffered financial losses following the failure of a general contractor. It is requested that protection be provided to such firms.

Other resolutions urged that only the lowest tenderer be invited to re-bid except in the event of a major revision in plans and specifications, in which case the three lowest tenderers may re-bid; that the practice of retaining a portion of a holdback as a performance guarantee past the time limit set by Mechanics' Lien Acts requirements be eliminated; and that sole authorities be designated for both the design and supervision of construction wherever practicable.

In addition, the "Statement of Policy" reiterated long-established recommendations that unit prices on lump sum building projects should be restricted to excavation, concrete, formwork and reinforcing and that tenders should be called and opened in public except in the "secret" or emergency categories.

The Association appreciates the privilege of representation at the opening of tenders at all federal departments and at some federal agencies. Central Mortgage and Housing Corporation, Defence Construction Ltd., the Federal District Commission and the St. Lawrence Seaway Authority, however, do not conduct regular public tender openings. It is most important that the relative standing of the bids be made known without delay . . . The public tender opening principle for public projects has been long-established and adherence to it is an indication that tenders will be considered on an equitable basis.

Wintertime Construction

The Association greatly appreciates the action of the federal cabinet in issuing a directive to all federal departments and agencies requiring them to time their construction projects so as to provide the maximum amount of wintertime employment . . . It has also been encouraged by the support given by other national organizations for wintertime construction and employment. Eight national bodies representing business, designers and labour are participating with the CCA in a joint committee to publicize the feasibility and benefits of wintertime construction.

The subject is of widespread interest to the public and it is believed much has been accomplished in overcoming the belief, erroneously held by many, that work carried out in the winter months is either of inferior quality or excessive in cost or both. Further efforts by all to continue this educational and promotional campaign are recommended.

Labour Relations

The Association believes that periodic meetings of management and labour representatives can assist in improving industrial relations, and it is hoped that the National Joint Conference Board of the Construction Industry, which met over a period of years under the auspices of the Department of Labour, may once again function. Now that the TLC has agreed to amalgamate with the CCL, it may be that it will also be agreeable to sit down with the Catholic Syndicates (CCCL) on the National Joint Conference Board, thereby giving representation on a national basis to construction trade unions.

The Association has increased its staff with a view to stepping up its activities in apprenticeship promotion work. Training for engineering and management positions in the industry also should be carried out on a much larger scale to meet the industry's needs.

Immigration

It is strongly recommended that the facilities of the Department of Citizenship and Immigration be used to the utmost to encourage an orderly program of selective immigration on a larger scale than in 1955.

Federal Sales Tax

The Association has already made representations advocating the removal of the federal sales tax from the many building materials still subject to tax. These representations were supported by subsequent briefs from not only a number of specialized trade associations but also the Canadian Tax Foundation and the Canadian Manufacturers Association. There is widespread recognition of the desirability of removing the problems facing builders and tax officials alike resulting from a complex tax and a complex industry.

It is hoped, therefore, that the next federal budget will incorporate amendments whereby structural steel, plumbing and heating materials, lumber, roofing materials and other materials now only conditionally or partially exempted, will be given full exemption. It is also hoped that the placing of a number of electrical apparatus items, nails and staples, air conditioning equipment, acoustical materials and construction equipment and tools with the exempted group will receive favourable consideration. It is believed that the refund procedures recommended in connection with materials used on provincial government and public hospital projects would greatly reduce the present paper work.

Foreign Project Insurance

It has become apparent that there are opportunities for Canadian contractors to tender on overseas construction projects. It is recommended that the Export Credits Insurance Act be amended to provide insurance against non-payment on services in order that Canadian contractors may participate in overseas contracts.

Special Tariff Arrangements, Construction Equipment

Canadian contractors and manufacturers and suppliers of construction equipment are adversely affected by the special tariff arrangements concerning equipment not available in this country in that they are more advantageous to the foreign firms. While these concessions may have been desirable during World War II, it is believed that the necessity for them no longer exists.

Work on the Westcoast-Transmission Co. Ltd., gas pipeline. The crossing of the Coquihalla River, near Hope, B.C.

Canadian Pipeline Projects

Commencing with this issue, it is the *Journal's* intention to review the news and progress of the projects for piping Alberta natural gas westward to Vancouver and the Pacific states, and eastward to serve Canada's central provinces.

Two major Canadian projects, together involving an expenditure approaching $1¼ billion for transportation of natural gas from Alberta by pipeline to outside markets, are now nearing the construction stage.

Since outside of Alberta and Southwestern Ontario natural gas is little known by Canadians as a fuel, to acquaint those elsewhere in Canada with the natural gas industry the following brief history and background is presented.

History

Canadian natural gas was exported to Buffalo and Detroit as early as the 'nineties' from Ontario fields in Dawn and Welland Counties. In 1900 it was discovered in commercial quantities at Medicine Hat, Alberta. Calgary, Lethbridge and nearby towns have heated with gas for 45 years. Edmonton and surrounding areas have had it 30 years.

Growth in production in Canada has expanded more than threefold over the past decade to 163 billion cubic feet per year in 1955. About 85 per cent of this volume is used in Alberta, 10 per cent in Ontario and 3 per cent in Saskatchewan with small quantities in New Brunswick and the N.W.T. This total production would be equivalent in heating value to some 6½ million tons of good grade coal annually.

Today supplying slightly more than 5 per cent of Canada's energy requirements, by 1975 our gas production may increase a further fivefold, and by then would probably be supplying some 13 per cent of the nation's energy. That this is possible is seen by comparing the growth of production in United States, where gas furnished 13 per cent of that nation's energy in 1938 and 23 per cent in 1952.

Since 1947 discoveries in Alberta alone have increased gas reserves fourfold, and reserves in Western Canada are today conservatively estimated at 20 trillion cubic feet and optimistically at 25 trillion cubic feet, with a heating value equal to some 800 million tons of coal. Reserves are thus increasing far faster than production, while south of the international boundary supplies have been depleted from a 30-year supply in 1938 to a 23-year supply in 1952. Since little incentive to drill for gas in Canada has existed so far, few doubt that gas export will vastly spur further discoveries.

Many Pipeline Companies Sought Charters

Ever since discoveries of vast oil pools in Alberta in 1947, such as Leduc, Redwater, and later Bonnie Glen, Golden Spike and others, with their accompanying gas reserves, and of the huge Pincher Creek wet-gas field in 1947, a flood of competing pipeline companies have sought charters from Parliament to carry Alberta's natural gas to export markets outside the province. Pincher Creek field, with enough gas reserves to supply Toronto city for 80 years, plus enough propane to fuel 66,000 farm homes for 20 years and sulphur to furnish half Canada's present consumption, was first favoured for supplying the nearby north Pacific states market.

Early pipeline applicants sought to pipe southern Alberta gas to Winnipeg, and through the mountains by various routes to supply north Pacific states and Vancouver. As discoveries followed in northern Alberta and northern British Columbia however, it became apparent that the latter sources were too far distant from eastern Canadian markets.

Government policy favoured using these for Pacific Coast markets, leaving southern and central Alberta gas fields to supply local consumption and for export eastward. From the first, federal policy has supported an all-Canadian pipeline eastward north of the Great Lakes, in preference to the easier and shorter route south of the Lakes.

Gas Export Will Stimulate Canadian Economy

The impact from any new source of energy on a nation's economy is sure to be tremendous. For Canada, this has been amply demonstrated over the past nine years by the impact from the rapid growth in western oil production. So great is the predicted increase in Canadian energy requirements over the next 20 to 25 years, about double that of today, that the expected further fivefold increase in gas consumption, 3½-fold increase in electric power, threefold increase in domestic oil, still leave room for a 50 per cent increase in oil imports and considerably more imported and even domestic coal consumption than at present.

Natural gas is more economical than coal or even oil, since no space is required for storing fuel in bins or tanks. No handling, no stocking or ash removal is necessary. Dependability is another point in its favour. A supply is always available without transport by truck or tank wagon. In cleanliness and in heat value it most nearly approaches the ideal fuel. It is the most versatile of our natural resources. In some parts of Canada it can readily replace electric power for space and water heating, thus releasing electric power, where scarce, for other uses.

According to the American Gas Association, science has already developed more than 25,000 applications for natural gas in industry. Three out of every four new petrochemical plants in the United States built during the last few years are using natural gas as a raw material. Already there are large and diverse petrochemical industries growing up around Edmonton and at Sarnia, Ontario, using Alberta gas for synthesis.

Largest of these are the Canadian Chemical Company plant and The Sherritt Gordon Nickel Refinery near Edmonton. The former produces cellulose acetate from by-products of Canadian petroleum for treatment of 300 tons daily of west coast pulp. The latter uses natural gas for an ammonia leaching process of the nickel and copper sulphides, without the customary roasting and reduction. The success of this project has broad implications for the Sudbury area, where combined production of 300 million pounds a year, some 16 times Sherritt's production, may some day be largely refined by the same process, using Alberta gas from the proposed Trans-Canada pipeline.

Westcoast Wins Fight for Pacific Markets

Westcoast Transmission Company, first of the two surviving pipeline companies to reach the construction stage, had been denied Federal Power Commission approval in their first attempt to seek a permit to export, in June 1954. The company's original plan was to pipe gas from northern Alberta and northern British Columbia via the Yellowhead Pass and Kamloops, to Vancouver and the states of Washington and Idaho, U.S. cities of Seattle, Portland and Spokane.

The FPC had questioned the feasibility of the project and the adequacy of its gas reserves, pointing out the hazard of a United States market area being entirely dependent on gas supplies from a foreign country which, it claimed, could be cut off peremptorily at will.

Early in 1955 Westcoast made a deal with the Pacific Northwest Pipeline Company, guaranteed by El Paso Natural Gas Co., to join its gas reserves in northern Alberta and B.C. with these Company's reserves in the San Juan Basin, to serve market areas in Washington, Oregon, Idaho and later California. New hearings started in October, and final FPC approval of the new setup was announced on November 25, 1955.

Trans-Canada the Leading Contender for Eastern and U.S. Midwest Markets

Trans Canada Pipelines was originally backed by the Canadian Delhi Corporation, whose objective was to serve Winnipeg, Toronto, Montreal and towns and cities along the route, with a 2,200-mile pipeline starting from Princess, Alberta. Competing with it was Western Pipelines, which sought the limited objective of serving Winnipeg through an 800 mile pipeline, with branches to other prairie cities. Both of these obtained charters in 1949.

The present Trans Canada Pipelines Company is a merger of these two groups, forced by the federal government in January 1954. It is backed by C. W. (Clint) Murchison, billionaire Texas oilman and promoter, who looks upon it as his greatest undertaking. The Tennessee Gas Transmission Company who have a contract with Trans Canada for 200 million cubic feet per day delivered at Emerson, Manitoba, for serving Minnesota, Wisconsin and other central state areas, have a substantial interest in the Company. So has Canadian Gulf Oil, which will provide about two thirds of the gas for the project.

The Company proposes a 2,350-mile pipe from Princess via Winnipeg, Lakehead, Kapuskasing, North Bay to Toronto and Montreal with branches to serve Sault St. Marie, Sudbury, Ottawa and Hull. Diameter will be 34 inches to the Ontario border, 30 inches from there to Toronto, then 24 inches Toronto to Montreal with a 16-inch branch to serve Ottawa-Hull. A branch would leave the main line at Winnipeg to deliver gas to the Tennessee Gas Transmission System at Emerson. Cost of the entire project inclusive of gathering and distribution systems is estimated at about a billion dollars.

The Company now has until October 30, 1956 to show it is able to finance the project exclusive of the stretch of 675 miles across the initially unproductive territory through northern Ontario between Winnipeg and Kapuskasing, Ontario. The Federal Government and the Ontario Government propose to build the pipeline across this Ontario gap through a Crown Company, and lease to the Trans Canada for 10 years, with an option to purchase. A bill authorizing the setting up of this Crown company is now before Parliament for approval.

FPC Hearings Will Be Lengthy

Meantime the Federal Power Commission in Washington is conducting hearings regarding the project. This promises to be the most complicated and controversial legal battle in FPC history and it may be the longest. Widespread opposition has developed from many gas companies in the central States, as well as from railways, coal operators and the powerful United Mine Workers of America.

While there is little hope that a decision may be reached before the October 30, 1956 deadline, there is the possibility that Trans Canada may arrange financial assistance for building the western leg of the project as far as the Ontario border during 1956, with the assistance of Tennessee Gas Transmission and Canadian Gulf Oil Co. Such an offer, if accepted by the federal government, might result in extension of the deadline for proof of ability to finance, and thus retain the Company's permit.

Meanwhile, a rival group headed by Frank McMahon, Alberta gas and pipeline promoter, and backed by a group of US investment houses headed by Eastman Dillon & Co., has proposed to build the entire Canadian line without government assistance other than relief on sales tax and duty. This group proposes the sale of 400 million cubic feet of gas daily to four big midwestern gas producers, more than twice the export sought by Trans Canada.

Elections and Transfers

At the meeting of Council held at Headquarters, on Friday, April 20th, 1956, a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

Members:

B. Alexander, *Montreal*
D. S. Anderson, *Vancouver*
L. T. Beck, *New York*
S. H. Bingham, *New York*
J. D. Buchanan, *Cornwall*
W. F. Campbell, *Ottawa*
D. G. Edwards, *Newark*
J. Eilau, *Vancouver*
G. N. Essauloff, *Toronto*
H. A. Gadd, *Cobourg*
W. A. Horn, *Toronto*
H. V. Ievers, *Toronto*
J. H. Kila, *Sherbrooke*
H. C. Lee, *Montreal*
R. H. Magwood, *Ottawa*
L. H. J. Maile, *Toronto*
V. A. M. Robertson, *London, Eng.*
W. B. Snarr, *Ottawa*
L. W. Swain, *Guelph*
D. L. Tarlton, *Toronto*
G. F. Welter, *Montreal*

Juniors:

F. Bright, *London, Eng.*
A. Edmonds, *Montreal*
J. C. Holden, *Montreal*
J. E. Souccar, *Montreal*
E. Staible, *Yorkton*
R. T. Williams, *North Bay*

Affiliate:

J. A. Page, *Montreal*

Transferred from the class of Junior to that of Member:

L. C. Banfield, *Montreal*
J. W. Black, *Ottawa*
R. E. Crossey, *Montreal*
J. W. A. Donald, *Windsor*
G. A. Harrison, *La Tuque*
J. G. Lefebvre, *London, Eng.*
A. F. MacDonald, *Winnipeg*
R. C. McDermott, *Toronto*
K. W. Moore, *Toronto*
R. C. P. Preston, *Picton*
K. F. St. George, *Corner Brook*
R. Tetreault, *Granby*
R. E. Thompson, *Montreal*
W. M. Walker, *Winnipeg*
R. Watson, *Montreal*
G. Wood, *Toronto*

Transferred from the class of Student to that of Junior:

C. F. Adams, *Cornwall*
B. J. Ferries, *Winnipeg*
A. Long, *Montreal*

The following Students were admitted:

Queen's University

W. M. Duncan
L. O. Gloin
K. A. Methot
G. B. Miller
W. J. E. Milligan
W. D. Morgan

University of Toronto

R. J. A. Barr
D. J. Knapp
J. A. Krupicz
K. G. Linseman
R. G. Ridgeway

Royal Military College

A. V. Andrews
J. W. Beare
R. L. J. Lalancette
D. E. Stothers

Nova Scotia Technical College

G. L. Crooks
J. E. Andrews

University of Alberta

B. C. Compton
D. A. Rae

Dalhousie University

R. H. G. Mitchell
D. W. Street

McGill University

J. J. P. Larouche

University of New Brunswick

S. W. Hill

Graduate

G. Lee, Montreal, B.A.Sc., British Col. 1955

Associations

G. A. White, London, Ont., Student, Assn. P.E. of Ontario
J. H. Tonn, Student, Assn. P.E. of Manitoba

Applications through Associations:

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections have become effective:

ALBERTA

Member:

R. M. Donald

SASKATCHEWAN

Student:

A. Stuart

QUEBEC

Junior:

J. G. Kirkland

St. Lawrence Seaway and Power Project

The *Engineering Journal* reviews the progress of the St. Lawrence project.

At the Barnhart power plant, one gantry crane assists in construction of the second.

In spite of a rugged winter, good progress was made on both seaway and power developments; 1956 is the key season of the construction period, and the most important as far as progress is concerned. Seven thousand or more workers will be employed in the Cornwall-Massena area, or some 15,000 in all between Montreal and the 1000 Islands.

Progress by Ontario Hydro

Approximately 26,000 cubic yards of concrete had been placed at end of March in the permanent structures in the north end of the power-house excavation. During the month, the concrete placing operations accelerated and some 22,000 cubic yards were placed during March.

To speed up the concrete operations, three gantry cranes are to be erected on the power-house site, two on the upstream face and one on the downstream face. One has already been erected, and erection of the second was virtually completed by the end of March. It is expected that the third unit will be ready by next month.

During March, work on the St. Lawrence transformer station in the 115-kv. section was pressed to completion. This section was scheduled to go into initial operation the first week in April. At the same time, initial steps had been taken to effect the change-over of the transmission lines replacing those from the Cornwall transformer station, which is to be removed commencing in April. Many tests had been made on the new equipment during the month.

The Cornwall transformer station was being removed to make way for the new diversion canal. For that channel, earth excavation had been completed in the closure structure area, where the dyke will meet the new canal. Progress also had been started on rock stripping within the closure structure area.

Heavy snow and cold weather slowed up the house moving operations during the month. By the end of March, 115 houses had been taken to New Iroquois. At the New Town No. 2, sewer and watermain installation progressed favourably. Work was well advanced on the construction of the pump-house and the installation of the water intake. At New Town No. 1, house surveys were virtually completed. The sewer and watermain work was pressed forward despite bad weather.

In channel improvement work, progress was made in excavation on Galops Island despite unfavourable conditions. The contractor had completed part of the excavation down to grade at the west end of the Island and had exposed rock over an area of about one acre.

Generally, the month of March presented unfavourable work conditions throughout the entire project because of the severe snowstorms, high winds and sudden thaws. Total personnel employed averaged 2,875 for March.

Ontario Hydro has called tenders for the relocation of a section of the CNR line which will be affected by the seaway. This undertaking will consist of track laying, ballasting and associated work for some 39.5 miles of double-track main line. All permanent construction materials will be supplied either by the Commission or the Railway. The line must be relocated for operation by the Railway on May 1, 1957. Tenders closed on April 17, 1956.

Progress by NYSPA

Progress was retarded by a strike called on March 12, 1956, by the International Union of Operating Engineers, Local 545, causing all construction work to be shut down until March 19. Despite this delay more than one and one half-million cubic yards were excavated during the month, bringing the total to date to thirteen and one-half million yards for the entire project. At Iroquois dam 7,000 cubic yards of concrete were placed during the month, bringing the total to date to 22,000 yards in the east section of the dam and in the spillway apron.

The contractor was given an incentive rate on concrete poured before April 1. Propane gas heaters of 4 million B.t.u. per hr. capacity under canvas or paperboard panels were used for protection. Excavation to date for the South Galop channel was nearing the two million cubic yard mark.

At Long Sault dam, excavation for Cut "F" was 56 per cent completed. Excavation was started for the extension of Cut "G". Quarrying and hauling of rock to the north cableway tail tower had been started in preparation for construction of the Cofferdam "E". Long Sault dam will be the focal point of activity during the coming season. By next September progress on the gate structure will permit the spectacular river diversion of 240,000 c.f.s. flow of the river. In the power-house area, excavation, drilling and grouting of the foundation progressed, as erection of the contractor's construction plant neared completion.

At Massena intake, excavation, drilling and grouting continued concurrently with the erection of the contractor's construction plant. Approximately half of the bedrock area had been exposed. Bids were opened for the construction of water facilities, and the contract was awarded on March 21, 1956. Long Sault canal construction power line was completed and the relocated 13.8-kv. construction power line to Barnhart Island neared completion.

Work on engineering drawings and specifications continued on schedule. Specifications for tunnel diversion gates and channel improvements at Point Three Points, Leishman's Point and Ogden Island were issued. Expediting of critical items was continued. Sixteen carloads of gantry crane components, originating at Paceco, Oakland, California, have arrived for Long Sault and Iroquois dams. Total personnel employed averaged 2,165 in March.

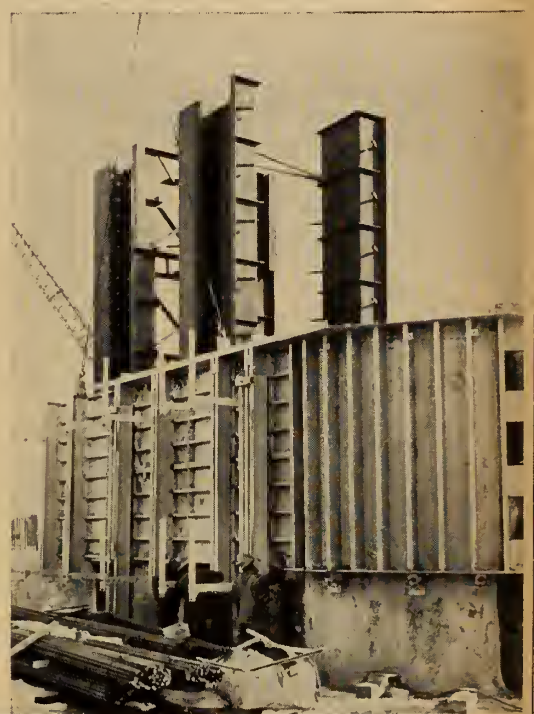
Progress by SLSA

Two contracts have been awarded for the supply and handling of fine aggregates for St. Lambert lock, in the Lachine section of the seaway. These two contracts involve a total of 205,000 tons of sand required for concrete. The contract for supply (f.o.b. siding at St. Lambert) valued at $440,750 was awarded to Standard Lime Company Limited. The contract for handling sand from the siding to the lock, valued at $88,150, has been awarded to the Carrière de Trois Pistoles, Enr.

The first construction contract in the 16-mile-long Soulanges section of the seaway was awarded March 28 to Atlas-Winston, Limited, of Montreal, the lowest of three tenderers. This contract, for first stage construction of lower and upper Beauharnois locks, is valued at $3,479,750. The second lowest bid amounted to $3,851,168, while the third lowest bid amounted to $8,077,750. Completion is called for October 31, 1956.

This contract will initiate the construction of two single locks, and their approaches, adjacent to the power development at Melocheville, whereby the junction between Lake St. Louis and the navigation channel in the Beauharnois power canal will be completed. The lift of the locks will be approximately 47 feet each, the level of Lake St. Louis being approximately 94 feet lower than the level of the Beauharnois power canal already built to the required 27-foot seaway depth.

The work includes clearing of the contract site, excavation of some 200,000 cubic yards of common excavation and of some 1,100,000 yards of rock excavation, rock grouting, cofferdam construction and unwatering, construction of service roads and the relocation of a portion



Iroquois dam. Pier forms are raised to the next lift.

Iroquois dam. Excavation operations are in progress and concrete operations continue.

of the New York Central railroad line.

A week ago (Thursday, March 22), the Authority's President revealed Authority plans to build a four-lane roadway tunnel under the Lower Beauharnois Lock which the Authority will build, to ensure uninterrupted traffic on Provincial Highway No. 3. This contract also provides for the excavation required for the construction of the tunnel.

Progress by SLSDC

Only one bid was received by the Corps of Engineers, agent for SLSDC, for the Grasse River lock near Massena. The contract was awarded to the same five-firm joint venture group already at work for NYSPA on the Long Sault dam and the Barnhard Island power-house, Perini-Walsh-Morrison Knudsen-Utah-Kiewit, for $26,800,000.

The Corps of Engineers does not customarily award a contract unless the low bid is within 15 per cent of the estimate. After due consideration, however, to the time that would be lost in readvertising in hopes of lower bids, since schedules are critical, the contract was awarded at a price some 23 per cent over the estimated cost. It was the largest awarded to date on the U.S. portion of the seaway navigation project, and includes supply and erection of two swing bridges for rail and highway traffic. Completion is called for by January, 1958.

Comment on the Seaway

Seaway Threatens Maritimes

The seaway will exaggerate the economic differential between the Maritime Provinces and the wealthier regions of Canada if the Atlantic coast ports are unable to maintain their share of port traffic, Donald J. Patton, of the University of Maryland, told the Association of American Geographers, meeting in Montreal April 3.

At present Halifax and Saint John share the Canadian Atlantic coast port traffic about equally. Fifty per cent of the total traffic comes during the winter months and 25 per cent of the remainder is local trade among the Maritime Provinces, he said. The vital interest of the Maritimes is to increase the summer port traffic. Although local traffic can be expected to remain about the same and winter traffic to increase, the seaway will give both Halifax and Saint John stiff competition for shipping during the summer.

The two Maritime ports, however, have several points in their favour. Halifax is on the direct line of the sea lane from Northwest Europe and the Mediterranean to the United States. It is therefore easy for these ships to put in at Halifax to deliver goods for Canada. Moreover goods destined for central Canada can be put off in Halifax at greater advantage than if they are carried on to New York or Boston, because of the differential tariff rates, Dr. Patton said.

Low rail rates from the Maritime Provinces to the rest of Canada also makes it possible for goods to be freighted from Halifax and Saint John to central and western Canada at lower cost than from the American ports, in spite of the shorter distances from the American ports. The direct competition for shipping between the St. Lawrence River and Great Lakes ports and the coast ports which the seaway will bring about, however, is a matter for very serious thought since, in this respect, Saint John and Halifax will have a grave geographical disadvantage, he added.

Dr. Wilbur Zelinski expressed the view that while the seaway would accelerate the booming development of the industrial heartland about the lakes, it could not seriously reduce the economic impetus of other regions. It just wasn't that big — at least compared to other projects and developments.

Professor Richard S. Thoman, University of Omaha, said foreign trade zones (free ports) had not prospered in the U.S., and cautioned against their institution on the seaway. A better idea, he observed, might be the more flexible system of bonded warehouses for storing goods during trans-shipment through a country other than their destination.

St. Lambert Protests Victoria Bridge Spur

Canadian National Railways plans for building a spur off the west or upstream side of Victoria bridge as an alternative rail route while ships are passing under the lift span over the St. Lambert seaway lock, are being vigorously opposed. This spur would be carried through the west end residential area of St. Lambert on a 25-foot embankment.

Delegates from St. Lambert and the City of Montreal were advised on April 10 by CNR President Donald Gordon that their proposed solution of building the proposed Nun's Island highway bridge to carry both trains and automobiles would not be feasible. Gradients the bridge needed to clear shipping would be too steep for locomotives unless the approaches were three or four miles long, which was not possible. Curves suitable for railway tracks would not suit the layout of the highway bridge.

St. Lambert's minimum target is to have the spur line changed to a location on the east or downstream side of the bridge. A direct appeal, supported by a petition, is to be made to the Prime Minister.

Montreal Bridge Traffic Doubles in Five Years

Montrealer's feel sufficient provision for future traffic on their bridges is not being provided for. Vehicular traffic over the Harbour bridge has almost doubled in the five-year period from 1949 to 1954. There is good reason to believe the rate of increase may be even greater the next five years.

Even without the stimulus to Montreal arising out of the opening of the seaway, predicted by Seaway Authority President Chevrier and by Transport Minister George Marler, the rate of house building in Montreal has exceeded any other metropolitan area in Canada. Moreover the rate of growth in Canada's automobile registrations is exceeding the rise in population. But the proposed Nun's Island bridge can hardly be opened for traffic before 1959 or 1960.

No Quick Fortune in Seaway Terminals

President Brooks of Toledo Marine Terminals warns that the dock operator who thinks he is going to make a quick fortune when the seaway rush starts, is in for a disappointment. All Great Lakes ports find that bulk commodities pour through specially built terminals, and packaged general cargo handling is an infinitesimally small part of the port's work.

Publicists, he contends, are "off the beam" in forecasting any large and rapid increase in the flow of general cargo the first year or so. Besides this, there is always the possibility that port authorities may move into the cargo terminal business and give privately operated marine terminals hot competition.

Metal Projects May Add Seaway Traffic

Reynolds Metals is considering aluminum plant expansions in northern New York and in Canada. The possibility of bulk shipments by seaway and of power from the New York State Power Authority are both factors in the project which is still in the nebulous stage.

The Jones and Laughlin Steel Corporation has joined in the hunt for Ungava iron ore in an area north of Sept Isles, believed to contain a billion tons of lean but easily beneficiated ore. If the project pans out the seaway will have another major customer.

Toronto Bids for Seaway Business

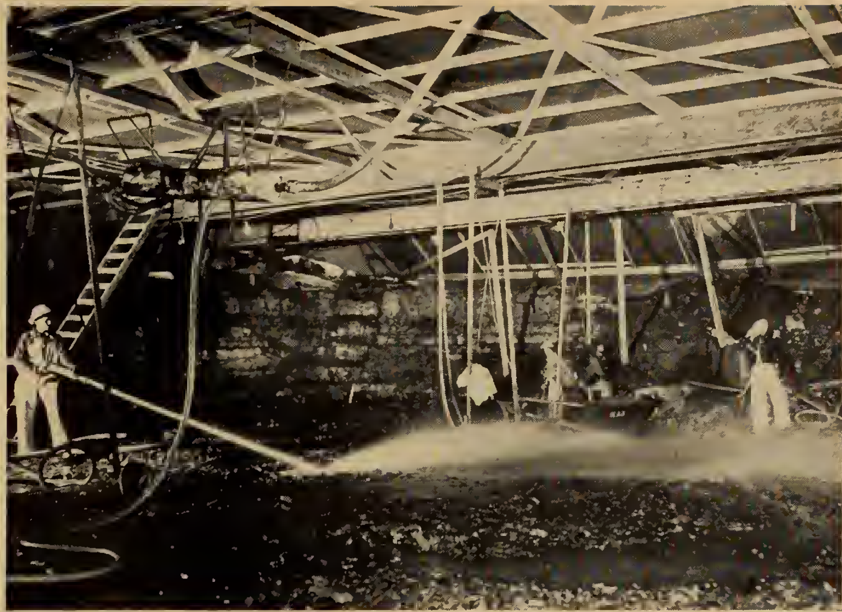
Toronto is already a seaway port, ranking fourth in Canada after Montreal, Vancouver and Hamilton, in that order. It is already handling more freight than Seattle, Marseilles, Oslo or Halifax. It has 11 miles of docks, 34 miles of waterfront railway trackage and 21 direct overseas lines operating on regular schedules with 125 vessels.

H. B. Griffith, manager of the Toronto Harbor Commission, believes many new ships will proceed to Toronto, instead of trans-shipping at Montreal. Toronto will become a turn-around point, as Montreal is today. It has one tremendous advantage. Those who direct its port are free to go out and sell the port's advantages over other ports. For this purpose it has set up a Trade Development Department.

The port of Montreal on the other hand, is under administration of the National Harbours Board. Such a government agency cannot go out and "sell" the port of Montreal to the disadvantage of other Canadian ports. Montreal needs a Trade Development Department of its own which would in no way rival the Harbours Board, but would rather supplement its endeavours. This is what the Halifax Port Commission has been doing for the past four years for the city and port of Halifax.

Operation Policy Must Encourage Use of Seaway

President Lionel Chevrier, of the St. Lawrence Seaway Authority, addressing members of the Institute of Internal Auditors on April 20, gave a progress report on the construction going forward from Montreal to Lake Erie, revealing that 30 construction contracts have been let for a total of $75 million. The value of work completed is approximately $15 million, or 20 per cent of awards to date.



Iroquois dam. Rock foundation is prepared for concrete by cleaning surface with high pressure streams of water.

"After everything is in readiness for the opening of navigation in 1959 — the Authority will be organized to carry out its permanent duties — the operation of the seaway, including the collection of tolls to cover the costs of construction and operation. In this the seaway will be operating in similar fashion to other business organizations. It will have costs to meet, revenues to collect and services to sell," he declared.

Legislation in both Canada and the United States requires that costs be amortized by the two seaway authorities over a period of 50 years. This represents a departure from long-established practice in both countries, where canals have been maintained free of tolls, he pointed out.

"It puts the seaway in the same class as the Panama and Suez canals, though the available routes for by-passing the seaway are not nearly as circuitous or expensive as they are for either of the other great canals. The seaway is paralleled by rail and highway routes, and . . . in the Middle West it will encounter competition from the Mississippi route," Mr. Chevrier said.

"These traffic considerations provide guarantees against any restrictive or monopolistic policy on the part of the two authorities. They cannot afford to take the attitude that their traffic is secure regardless of whatever policy they might adopt. Their policy must not only produce revenues sufficient to recover the costs of the project, but must also encourage the widest possible use of the seaway. The greater the volume of traffic the easier it will be to cover costs and to lighten the toll charges. This in turn will encourage greater use of the seaway."

Referring to the scale on which the seaway's locks and channels have been planned, Mr. Chevrier pointed out that with 27-foot navigation, those responsible for building the seaway felt they had arrived at what economists call the 'optimum solution.' Fundamentally the seaway is a public highway; some limiting standardization is necessary and there can be no responsibility to provide for outsize vessels, he declared.

"Certainly at the present time, the cost of increasing the capacity of the seaway beyond that now planned is out of all proportion to the probable benefits of such a step. But as the dimensions cannot be expanded every year or so to keep pace with the growing size of ocean vessels, we are naturally building for the future."

Mr. Chevrier underlined the expansion in industrial activity and markets and remarked that "the real value of the Seaway becomes correspondingly greater." We can be confident, he concluded, that the construction is taking place at a most opportune time — when it can be integrated into the existing transportation system with relative ease, and when both from the power and navigational point of view it can be said without exaggeration that it is a necessity.

Thirty-five Years Ago

Comment on the *JOURNAL* of May 1921

In 1921 argument concerning the proper use of the term "engineer" was at its height. Professional engineers, ourselves included, wanted exclusive use of it, while many labour bodies and a lot of other people could point to long established practice on this continent which gave them the right to use the word to apply to skilled artisans.

The professional engineers were beaten before they started, but seem not to have realized it, for almost every issue of the *Journal* about this time carried an editorial or correspondence bearing on the matter. The issue for May, 1921, was no exception; two correspondents fulminated, one because the International Union of Steam and Operating Engineers dared to call itself that, the other because the author of a new book was billed as a "household efficiency engineer."

It seems not to have occurred to those who were so bitter on the subject that the term "engineer" had become so thoroughly ingrained in our speech that to dislodge it was a real impossibility; as well try to get people to agree to call a child a "baby" up to, say, the age of one year and something else after that and not to use the word in any other connotation.

Provincial Associations Organizing

With the organization of the provincial associations, all in their infancy in 1921 and some not even started, most of this agitation died away. Licensed engineers became "professional" engineers by law and the term is now loosely applied by the public to all engineers eligible for registration, whether legally licensed or not.

Speaking of provincial associations, this *Journal* announced the inaugural meeting of the Corporation of Professional Engineers of the Province of Quebec, held at Institute headquarters "recently." The original officers were A. R. Decary, president; K. B. Thornton, vice-president; F. B. Brown, secretary; Arthur Surveyer, C. N. Montsarrat, J. M. Robertson, A. B. Normandin and J. E. Gibault, councillors, all members or associate members of the Institute.

The Ontario engineers' registration bill had received second reading and had been referred to a special committee, the usual practice. It was hoped that it would be passed "without material change."

Employment

The principal editorial in this issue of the *Journal* was by way of being a puff for the Institute's employment service. It was touted as being the best existing agency for bringing employers and potential engineering employees together, especially at the time of writing, when "it is undoubtedly a fact that Canada is caught in the backwash from war prosperity and the . . . business world's current watchword is 'Ca'canny' ". That our employment service was really accomplishing something was shown by the publication of a quite complimentary letter from an employer who had secured a draughtsman through it.

Engineers' Status

As long as I can remember engineers have groused about their place in society and many have been the suggestions as to how to improve it. I have my own opinions on this matter, but this is not the place to expound them and were I to do so, I should probably be banished from these pages for life. The Toronto Branch had tackled the problem in a systematic way by appointing a Social Service Committee; its first brief progress report appeared in this *Journal*. Many of the committee's recommendations were those made regularly by similar bodies. Others at least had the merit of a certain degree of novelty.

On education the committee said, "University education is weighted down with much work in the first year that should be transferred to the last year of high school." This has now been partially accomplished. But the committee member who thought that "the present method of (political) representation is faulty and it is suggested that . . . representation by occupation would produce better results", got little support for his ideas. Did he have a vague notion of Mussolini's corporate state in the back of his mind?

Technical Papers

Perhaps I have spent time enough commenting on features of this *Journal* which were really not its most important; the technical papers always occupy that position. The principal paper in this issue was a long and exhaustive treatise on superheaters — twelve pages — by H. B. Oatley of the Superheater Company. Whatever its merits, and it seemed to have many, it certainly must have disabused the reader of any idea that a superheater was merely a coil of pipe stuck into a boiler flue at some convenient place. I would imagine that, except for changes in materials, today's superheaters are not much different from those described by Mr. Oatley.

Another long and interesting paper dealt with methods of proportioning concrete, by Professor G. M. Williams, A.M.E.I.C., of the University of Saskatchewan. He critically examined three current theories of proportioning — Fuller's maximum density theory, the water-cement ratio theory and the aggregate surface area theory — and found them all wanting in some respect. His own proposal was not so much a new and radical theory as it was a logical method of procedure, what I suppose would today be called "trial-mix", as the procedures he recommended seem quite similar to those now used by concrete technicians. His main point was that the common practice of proportioning by volume was completely unreliable, often giving compressive strengths much lower than it was supposed to. For example, he refers to a 1:2:4 mix as being "standard" then for 2,000-lb. concrete, whereas many of his experimental mixes in these proportions did not reach 700 p.s.i. in compressive strength.

Frank Williams, A.M.E.I.C., spoke to the Moncton Branch on designing locomotives so that they would not be hard on track; his remarks were reported in this *Journal*. If he were speaking on the same subject today, he would hardly be so much concerned with "dynamic augment" and "impact" as he was then, neither of which can be of much importance in the design of today's diesel-electric monsters.

Work of C.S.A.

The Canadian Engineering Standards Association's main committee had just met and its proceedings were published here. They occupied only a column and a half and the matters reported on were few, but it was evident that the association was beginning to make its influence felt. Among other things, it decided to send its secretary, R. J. Durley, M.E.I.C., later to become our general secretary, to an international conference of standardizing societies in London. This was the first of many such conferences, which have helped to put Canada on the map standards-wise, and especially to bring us into closer and more friendly contact with the other standards associations of the Commonwealth.

If the Institute could point to no other accomplishment, its firm and continuous support of the Canadian Standards Association, in old form and in new, is quite enough to warrant our gratitude and that of countless others, too.

Correspondence

Engineering in Israel

One of the many pleasant things about being general secretary of The Engineering Institute of Canada is to receive interesting and newsy letters from members in far parts of the world.

A few months ago a member out in Israel wrote in at some length to tell of the work he was doing and of the many problems that were facing that new country. Permission to publish was requested and granted.

Members of the Institute, particularly young members like Mr. Shanas, may well envy him the interest and variety of his experience. On the other hand they may be happy that theirs is an easier lot. No matter what they think of the position in which Mr. Shanas finds himself they will have to admit that here we have a colourful instance in which a young member of our profession far from Canada is standing firm in his difficult place and working diligently for the good of the people who so well deserve his support. This is real nation-building and members of the Institute may well be proud to have the young man's name on their membership list. Mr. Shanas was graduated in civil engineering from Manitoba in 1947. Ed.

Dear Sir,

This past year I have been chief design engineer in the Water Department of the Jewish Agency's Negev Project. To explain this, the Jewish Agency through its Settlement Department is responsible for setting up new agricultural settlements, handing out the necessary grants and loans, planning and designing the villages in all aspects from general town planning through crop rotation and irrigation down to the financial budget of every last settler. Then too, it is in charge of building the villages, supplying the necessary equipment, implements, livestock, seeds and tools; looking after the various services as electricity, roads, water, etc.; instructing and training the settlers (all new to farming and many even illiterate and from backward countries) and in general helping with the management until the settlement is on its feet and the villagers themselves are capable of carrying on.

Our branch, the Negev Project, looks after an area of about four thousand square miles, more than half the size of all of Israel. Nearly all the settlements in the Negev, about 75 in number, are still under our care and, political conditions permitting, many more are to be established in the near future. Now in an area with an average annual rainfall (no snow at all) of between 4 and 12 inches, the key to all settlement is water. Nearly all crops have to be irrigated. The proper design of irrigation works in our highly eroded and erodable soil, as well as the general water supply for all of these settlements, has been my particular charge.

To date we have about 22,000 irrigated acres under intensive cultivation, only one-third of what is needed by the present settlements, and as I previously mentioned many new villages are to be established. This is a radically new field for me, one far from any of my studies at Manitoba or experience since, and although I originate from the "Gateway to the Golden West" it's only recently that I learned to distinguish a head of wheat from a head of barley. Therefore, I had to put in a lot of extra work and study. And if all this weren't enough to keep me busy, we have on all sides of us our neighbours continually threatening us with physical annihilation — not only a threat to destroy all that we have built and to turn the country back into the barren lifeless wastes it was but a few years ago, but also a threat against our very lives.

The recent arms shipments and the daily border incidents you read about show us that this threat, unfortunately, is all too real and actual; so no little of our time and efforts have to be spent in warding it off. And also as luck would have it, my own home, one of the aforementioned settlements, has suddenly found itself right in the center of the troubled area — immediately facing the Gaza Strip. Undoubtedly you have heard the name Kissufim in the news this past year. So all in all I am not left with much spare time, and writing letters, as my people back in Winnipeg can tell you, has always been one of my weak points.

Now that I have wandered so far away (I thought you might be interested to hear of work and conditions somewhat different to those of most engineers in Canada itself) I had better get back to the main point of this letter which was to inform you that I've decided to retain membership in the Institute for yet another year. Not that conditions as I outlined them in my letter of a year ago have changed any, but that I find that I am quite reluctant to give up the honour of being a member of the Institute and to cut the ties, weak as they are out here, with the people that gave me my start in the profession. Also the *Journal* with its regular reports of engineering progress in Canada and occasional familiar names and faces still remains among my favourite reading. In this respect, you may be interested to know that an almost complete set of the *Journal* since 1946 — the year I joined the Institute — is now on file in the library of the local branch of the Association of Engineers and Architects in Israel, in the new, old, Biblical town of Beersheba.

And now in closing, kindly accept my humble belated Season's Greetings. I hope you have had a very merry Christmas and duly enjoyed all the festivities of the past Yuletide week. With the ushering in of a new year I would like to convey my best wishes to you and, through this letter, to all the members of the Institute for a year of increased happiness and success; to the engineering profession in Canada for a year of progress and even greater accomplishments; and above all, for a year of real undisturbed peace with greater understanding and goodwill among all men.

E. L. Shanas, M.E.I.C.,
Kibbutz Kissufim,
Hanegev, Israel
January, 1956.

NEWS OF THE ASSOCIATIONS & CORPORATION

Information received through co-operation with the provincial organizations

Ontario

Professional Degrees

For some fifty years or more, the University of Toronto has had available for graduate engineers further professional degrees carrying the abbreviated titles of C.E., M.E., etc., in civil, mining, mechanical, electrical, chemical and metallurgical engineering.

In recent years, the interest in these degrees on the part of graduate engineers has declined almost to the vanishing point and a continuation of the facilities by the University no longer seems necessary.

Consequently, the Senate of the University at a recent meeting approved an amending statute which will terminate these professional degrees but with a provision whereby any applicant who can demonstrate a bona fide program already underway will be permitted, at the discretion of the Executive Committee of the School of Graduate Studies, to complete requirements for the degree up until May 1, 1957.

Nuclear Engineering Course

Announcement has been made by the University of Ottawa, whose degree in chemical engineering was recently accepted by Council of this Association, that beginning in September, 1956, a graduate course in nuclear engineering will be given by the Faculty of Science in co-operation with Atomic Energy of Canada Limited.

The course will lead to the degree of Master of Science (Nuclear Engineering) and will be open to mechanical and chemical engineers, engineering physicists, and physicists. Part of the twelve-months course will be spent at the Chalk River Plant of the Atomic Energy of Canada.

Our Senior Citizens
by Ralph W. Harris

One thing in life is just as sure as Death or Taxes. That is, that we grow older year after year. Nor can the most vigorous and aggressive of us shelter behind the belief that "It Can't Happen to Me".

The proportion of senior citizens in our population is increasing both steadily and rapidly.

The present trend in industry and business to fix unalterable rules for comparatively early retirement, the prevalence of Pension Plans, Group Insurance and Old Age Pensions recognize the fact, but multiply and emphasize certain economic inequities.

Perhaps the first of these inequities is felt by the man over forty who is barred from employment because he is too old to join the firm's Pension Plan, yet the Plan insists that a very high percentage of those of the payroll must be contributing members.

The active man who faces compulsory retirement at age 60 is presented with still more serious problems. If he is a family man he has probably been unable to build a substantial estate in any form but protective life-insurance, yet the ten year period from sixty to seventy demands a substantial sum if he is to retain a standard of living even comparable with that he has been able to establish during his peak years.

The Old Age Pension is totally inadequate to provide the barest essentials of food, shelter, clothing and fuel.

We are deliberately creating within the richest economy the world has ever known a new class of people who can, and want to be, self-supporting but who are gradually being forced into the position of economic-parasites.

Within our own Profession the problems of the "retired" and the "about to be retired" are assuming ever-increasing importance.

It is a strange anomaly that, in times when every scrap of technical knowledge, training and experience is in demand, our economic system is forcing capable engineers into idleness.

Your Association has formed a new Committee to study the problems of members in the senior age groups and to search for practicable means through which their ability and energy may be usefully employed for the common good.

Under the Chairmanship of J. Roy Gilley, this Committee on Gerontology has already done considerable organization work and preliminary study.

Sub-committees have been assigned to consider — (a) Employment, (b) Library, (c) Publicity, (d) Services (Counselling, Recreation, etc.)

The problems facing the Senior Citizen may be Economic, Social or purely Humanitarian. We believe they can be solved.

Employment

In planning its activities, the sub-committee on Employment is desirous of building up a list of the older or retired members who would be interested in full or part-time work. To this end members who are interested are requested to send to the Secretary, Committee on Gerontology, Association of Professional Engineers, 236 Avenue Road, Toronto, details of engineering experience, nature of employment desired and whether on a full or part-time basis. With this knowledge of the nature and extent of the demand, the committee will be in a position to make the information available to prospective employers as well as to develop in employers a better understanding of the very valuable fund of experience and engineering know-how which is available in the group in question.

March, 1956.

News of Members

James D. Kendall is now residing in Wanaque, N.J. and is employed by the Kearfolt Company Inc., of Clifton, N.J., as a project engineer in the company's motor laboratory. Previous to making this change in employment, Mr. Kendall was with Canadian Cutler-Hammer in Toronto.

L. W. Ward, of L. W. Ward and Associates, has announced his change in office address to Suite 15, 23 Applewood Village, 1077 Queen Elizabeth Way, Port Credit, Ont.

Peter Gelin, has established a service as consulting structural engineer at 259 Beatrice Street, Toronto. Mr. Gelin is specializing in thin shell roofs and domes, shells for industrial purposes, shell bridges and vibration problems of structures.

G. A. Urmston, has moved to Oakland, Cal., and has joined Kaiser Engineers, a division of Henry J. Kaiser Company, as service engineer. Mr. Urmston, who is an engineering graduate of Cambridge University, England, was earlier with C.I.L. 1954 Limited, Montreal, as a structural designer.

H. Hugh Mullinger was recently elected president of Columbia Engineering and Sales, Inc., of 553 Beaufait Avenue, Detroit, Michigan.

Mr. Mullinger was formerly with Canadian Breweries Ltd., following his graduation in chemical engineering from the University of Toronto in 1947. From 1950 until becoming associated with Columbia Engineering and Sales, he was an industrial sales engineer for Sinclair Refining Company, Detroit.

Harold W. Blakely has been appointed Canadian Sales Manager of York Shipley Inc., of York, Pa. York-Shipley of Canada will market its complete line of industrial-commercial package type steam generators and hot water boilers, factory-coordinated fuel-burning systems, rotary oil burners, oil — and gas — fired residential systems and air-conditioning equipment. The headquarters of York-Shipley of Canada is 215 Harborn Road, Cooksville, Ont.

A graduate in engineering and business from the University of Toronto, Mr. Blakely has been a sales engineer for the Ashland Oil and Refining Company of Cleveland and Buffalo, and assistant sales manager for Babcock-Wilcox and Goldie McCulloch Ltd.

Peter D. Stevens, has also been appointed a sales representative of York-Shipley of Canada for the Toronto-Kingston area and also Northern Ontario.

J. D. Kean has resigned his position as county engineer for Peterborough County, and has joined Curtis Bros., general contractors, as engineer. Mr. Kean's new address is R. R. No. 3, Peterborough, Ontario.

A. J. Pluhar has been appointed manager of the non-destructive testing division of Warnock Hersey Co. Ltd., Mr. Pluhar's headquarters will be in Toronto.

Mr. Pluhar graduated in civil engineering from the University of Prague in 1931, and has had many years of experience in engineering and research, as well as in the application of welding and non-destructive testing techniques.

H. W. S. Le Bel has been appointed chief engineer of the Mead-Morrison Division, Welland, Ont., according to an announcement of the United States Steel Corporation.

Mr. LeBel is an engineering graduate of McGill University of the class of 1937 and brings to his new responsibilities a broad range of experience in design and plant engineering. Latterly he has been associated with the Electro Metallurgical Company of Canada Ltd., of Welland.

Raymond F. Sherk has been named representative in Toronto and Southwestern Ontario for Spartan Air Services Ltd., and Canadian Aero Services Ltd.

Mr. Sherk is a graduate of the University of Toronto and a former R.C.A.F. pilot, and brings a background of engineering, marketing and flying to his new position.

M. W. Hotchkin of Kirkland Lake, was elected managing director of Wright-Hargreaves Mines Ltd. Mr. Hotchkin, who is president of the Association of Professional Engineers of Ontario, succeeds **Ralph L. Healy** in this position, Mr. Healy's retirement having been made necessary through ill health.

Mr. Hotchkin has been engaged in mining for some 48 years and is well known in all parts of this continent. For a number of years he was general manager of Toburn Gold Mines in Kirkland Lake, and three years ago when Toburn discontinued its operations, Mr. Hotchkin joined Wright-Hargreaves as engineer in charge of outside exploration.

P. C. Nicolle is manager of Greyhawk Uranium Mines Ltd., Bancroft, Ont. Prior to assuming this position Mr. Nicolle was field engineer with Kennco Exploration Ltd., of Toronto.

Boris A. Pazitch has moved from Windsor, Ont. to Niagara Falls, Ont., where he is employed on the engineering staff of H. G. Acres and Company. For the past three years he has been associated with Truscon Steel Company of Canada Ltd., in Windsor.

H. C. Minns and **R. H. Bigham**, of Hamilton, Ont., announce the organization of a new company, Package Air Conditioning Engineering Limited, to serve the commercial, industrial and residential air-conditioning markets. The headquarters of the company is at 500 Main Street East, Hamilton.

Mr. Minns is an engineering graduate of Queen's University, Kingston, and was formerly the plant engineer of English Electric Co. Ltd. More recently he has been manager of air conditioning installation and service for Blenkhorn and Sawle Ltd., of St. Catharines.

Mr. Bigham, after several years as application sales engineer for the apparatus division of Canadian General Electric Company Ltd., has been in charge of the Hamilton branch of Blenkhorn and Sawle Ltd.

Saskatchewan

E. J. Durnin Elected President

The new president of the Association of Professional Engineers of Saskatchewan for the year 1956 is E. J. Durnin, construction engineer with Saskatchewan Power Corporation.

Mr. Durnin was born in Dauphin, Man., and received his B.A. degree from the University of Saskatchewan. After serving for three years with the R.C.A.F. as a pilot officer, he qualified for his B.A.Sc. degree in electrical engineering at the University of Manitoba in 1928 and enrolled in the Canadian Westinghouse Company test course in Hamilton, Ont.

Upon completion of the course he returned to Saskatchewan where he accepted the position of junior engineer with the Saskatchewan Power Commission, becoming successively district superintendent and commercial superintendent.

In 1940 he joined the Royal Canadian Engineers, serving for five years in Canada, Great Britain and Northwest Europe. He was discharged at the close of the war with the rank of major, after which he returned to the Saskatchewan Power Corporation where he was named engineer in charge of construction and transmission on distribution and substation projects.

Mr. Durnin has been active in the affairs of the Association. In 1948 he was named a member of Council, and in 1955 he was elected vice-president. He is also a member of the Canadian Electrical Association and of the Engineering Institute of Canada.

Nova Scotia

C. N. Murray is Association President

C. N. Murray, general superintendent of the Dominion Steel and Coal Corporation of Sydney, N.S., is the newly-elected president of the Association of Professional Engineers of Nova Scotia.

Mr. Murray was born in Sydney and received his education at Acadia University and the Nova Scotia Technical College, graduating from the latter in mechanical engineering in 1935.

He began his engineering career with Alexander Murray and Company and afterwards joined Dominion Steel and Coal Company Ltd. as instrument clerk. In 1943 he was named superintendent of blast furnaces, subsequently becoming assistant to the general superintendent, and general superintendent, the position he now holds.

A member of the Engineering Institute of Canada, Mr. Murray is a past-councillor, as well as a past-chairman of the Cape Breton Branch.

New Brunswick Elects Council

The following are the Officers and Members of Council of the Association of Professional Engineers of New Brunswick for 1956:

President, D. R. Webb, Saint John; Past President, D. J. Brewer, Fredericton; Vice-President, W. D. G. Stratton, Moncton; Councillors, K. V. Cox, Lancaster, N.B.; L. O. Cass, Saint John; R. E. Tweeddale, Bathurst; C. E. Weyman, Fredericton; F. K. Leighton and R. L. Parsons, Moncton; and P. G. Robinson, Chatham, N.B.

The Secretary-Registrar is J. H. McKinney, P.O. Box 24, Saint John, N.B.

Manitoba

Association Office Opened

Since a full time office for the Association of Professional Engineers of Manitoba has been opened, applications for membership in the Association have increased considerably. To date these applications are well ahead of the number at this same time last year.

One of the great advantages to the membership at large in having an office operating in the downtown area, is the ability to get vital engineering information without the delays that were encountered before. It is eventually hoped that the Association will conduct an employment service which will be of assistance to the engineering employer as well as the employee. An engineering library located at this office is also a distinct possibility, which would be invaluable to many of the practising Engineers in this province.

The Late D. A. Ross

It was with deep regret that we learned of the passing of D. A. Ross on April 1, 1956. Mr. Ross was a prominent engineer and architect for the past 40 years. Until retirement he was a member of the firm of Pratt & Ross, Architects and Engineers, and also was a member of the Court of Revision for many years.

G. W. Moule

G. W. Moule, contract engineer, City of Winnipeg Hydro Electric System, a member of the Council of the Association of Professional Engineers of Manitoba for the past three years, is leaving Winnipeg to accept a position with the B.C. Power Commission. Mr. Moule graduated from the University of Manitoba in 1937 and was employed by C.I.L. from 1937 to 1945. On leaving C.I.L. he joined the Hydro and has been with them until the present time. Mr. Moule served as secretary for the Winnipeg Branch of the E.I.C. for many years and is considered to have been one of the best secretaries in the history of the Branch. Any who know or have been associated with Gerry will wish him lots of luck in his new position.

British Columbia

Three well-known members of the Association of Professional Engineers of British Columbia will be granted honorary degrees of Doctor of Science by the University of British Columbia at the Spring Convocation ceremonies on May 15.

Dr. H. J. MacLeod, former Dean of Applied Science, and member of Council of the Association in 1939 and 1940, will be honoured for his distinguished academic career in Alberta and British Columbia, which terminated with his retirement from the University of British Columbia in 1953. He is now a member of the B.C. Power Commission in Victoria. He will deliver the address to students graduating on May 15.

Also honoured will be Thomas Ingledow, and Col. W. G. Swan, both of whom are past-presidents of the Association. They will receive their degrees in recognition of their "great contributions to engineering in British Columbia, as well as to the educational and social life of the province". Mr. Ingledow is vice-president of the B.C. Electric Company and Col. Swan heads the consulting engineering firm of Swan, Wooster and Partners.

Engineers in the News

W. C. McKenzie has joined the consulting engineering firm of Choukalos, Woodburn and Hooley, and the firm has now changed its name to Choukalos, Woodburn, Hooley and McKenzie Ltd.

Mr. McKenzie has had extensive experience in administration and public works contracts and in supervision of construction and design obtained while with the Provincial Bridge Department, and more recently as resident engineer with Phillips, Barratt and Partners on the Oak St., and Granville bridges.

H. T. Libby, of B.C. Electric Co. Ltd., was recently promoted from superintendent of gas distribution to manager of the gas distribution department.

A. W. Moore, of the Consolidated Mining and Smelting Company, has been appointed to the post of assistant superintendent of the Alberta nitrogen department at Calgary. He has been at Trail as superintendent of the ammonia group.

James Atwell, of the Consolidated Mining and Smelting Company, at Trail, has been promoted from the position of superintendent of the fertilizer group to assistant superintendent of the Warfield Department, Chemicals and Fertilizer Division.

H. R. Wright will be joining the consulting firm of A. L. Swanson on May 1 and the firm will become Swanson, Wright and Co. Ltd., Mr. Wright has been chief engineer of the central engineering division of Alaska Pine and Cellulose Co. Ltd., for the past three years. Previously he had experience with C. C. Moore and Company, as Vancouver branch manager; Pacific Mills Ltd., at Ocean Falls, as electrical and project engineer; and the B.C. Electric Company, as industrial power engineer.

Art Ewans, previously with Westcoast Equipment Ltd. is now with Rosco Metal Products (B.C.) Ltd.

E. G. Tallman is another Ontario Hydro engineer who has taken a position with the B.C. Power Commission. He has been appointed to the position of senior projects engineer.

John Lamb, of Britannia Mining and Smelting Company has been promoted from assistant mine geologist to exploration geologist.

W. S. Jackson, with the Provincial Water Rights Branch at Nelson, has been promoted from assistant hydraulic engineer to assistant district engineer.

W. Nimisczeck, who has been with the Aluminum Company at Kemano, is now with H. A. Simons Ltd. in Vancouver as a design engineer.

J. A. Millican, district engineer at Nelson for the past four years, resigned his post to join Mid-West Copper and Uranium Mines Ltd., which operates the Velvet Mine near Rossland and has other Kootenay mining interests. Mr. Millican will continue to live in Grand Forks.

L. Telfer was recently elected chairman of the West Kootenay branch of the Association. Other officers are: **R. J. Armstrong,** vice-chairman; **D. Dolgov,** secretary-treasurer; and **R. Deane, R. G. McEachern, S. M. Rothman, J. W. Peck,** and **J. D. Little,** executive members.

W. T. Pound has been appointed vice-president, engineering, of St. Lawrence Corporation Ltd., and expects to make his initial headquarters at Three Rivers, Que. His services will be available to all mills and woods operations throughout the corporation. Mr. Pound was formerly with Crown Zellerbach Canada Ltd. as assistant resident manager, Ocean Falls, B.C.

G. T. J. Hughes has resigned from H. A. Simons Ltd. and has accepted an appointment as design engineer with the Consolidated Mining and Smelting Company of Canada at Trail.

J. C. Cant has accepted a position as cost engineer with Dawson, Wade and Macco. He was formerly with H. G. Acres and Co. Ltd. on the Upper Campbell Lake development.

O. E. Weightman of Kimberley, has been transferred by the Consolidated Mining and Smelting Company to its Coast Copper property.

A. W. Turnbull has accepted a position with Vancouver Iron Works Ltd. He was formerly on the staff of D. M. Drake.

R. O. Cutler is now with the Trans-Mountain Oil Pipeline Company in Vancouver.

H. Kettleson, recently at Salmo, B.C., with Canadian Exploration Ltd., has accepted a position with Algom Uranium Mines Ltd., Elliot Lake, Ont.

Peter Long is now employed by the City of Victoria. He was formerly with the Department of Highways at Chilliwack.

J. V. Sunell, previously with Reliance Import and Sales Co. Ltd. is now on the design staff of Ford, Bacon and Davis in Vancouver.

R. E. Wells has accepted a position with the Saguenay-Kitimat Company at Kitimat, B.C. He had been with Associated Engineering Services Ltd. in Vancouver.

L. Esser has taken a position with Vancouver Iron Works Ltd. He has been employed by Westminster Iron Works Ltd.

Eugene Butkov, a 1954 University of British Columbia graduate in engineering physics, and the winner of the Association Gold Medal for that year, has just won a scholarship valued at $1,200 from the National Research Council of Canada. He will undertake post-graduate work at McGill University.

E. V. Hird is now with Lenkurt Electric Company of Canada Ltd. in the application engineering department in Vancouver. He was formerly manual equipment engineer with the B.C. Telephone Company.

Ernest Peters, who is an instructor with the Department of Mining and Metallurgy at the University of British Columbia, recently accepted a permanent position with the Electro Metallurgical Company, Niagara Falls, New York, and expects to leave Vancouver about June 1.

J. F. Walker, Deputy Minister of Mines for British Columbia, has been elected president of the Canadian Institute of Mining and Metallurgy for 1956.

M. B. Hansen of the Canadian National Railways engineering department, has been promoted from division engineer at the Vancouver terminal. to assistant district engineer.

H. R. Banks, retired superintendent of the Sullivan Concentrator of the Consolidated Mining and Smelting Company, who has made his home in Kimberley for 32 years, recently left British Columbia to take up residence in Ottawa.

F. S. Foyston, formerly of Alaska Pine and Cellulose Ltd. at Port Alice, is now with Hansel Engineering Co. Ltd., Vancouver.

Professional Recognition

A man who is a large company's vice-president, industrial relations, (and also a professional engineer), said recently, "If engineers want the privileges, status and pay of professionals, they must act like professionals and accept professional responsibilities."

This statement is simple, the truth in it self-evident.

There's no argument.

Yet, ask yourself: Am I applying myself in the best way possible to the fulfilment of my professional training?

And there may be some argument there.

As a professional engineer, working in Canada, you have unlimited opportunities. This country's need for professional engineers is expanding constantly. This is happening not only in established industries, but also in a thousand new ones springing up around us in the wake of our nation's bursting growth. It is possible that the attitudes developed now towards engineers will be the attitudes of our nation's future, too. And that brings us back to that opening quotation.

The whole question of proper professional recognition of the engineer is a warmly-discussed subject right now, as you know. But no matter what the other pros and cons, it is a truth in any calling that a man to a large extent creates his own level of acceptance. That's how it is with you, too.

You have special problems. You must operate usually—in the beginning, at any rate—as a member of a big team. Yet the real fulfillment of your professional training comes in the individual contributions you make to that team. These come from training plus imagination. The training you have. But imagination is found most often in the man whose mind works beyond the narrow realm of his formal training.

Engineering training, because of its special and exacting nature, sometimes is achieved at the expense of broader education. But that needn't be important in the long pull.

The engineer who believes that his training ends the day he walks away from his university for the last time is not the man to whom this is addressed, because he has sealed his destiny before it is properly begun. The good professional engineer will use every chance he gets to expand his hard-won engineering education and preliminary professional training into something bigger. This he does not only by developing professional skill, but also by a conscious broadening of his senses of responsibility and ethics, improvement of his ability to communicate ideas, his professional conduct and personal appearance.

These things pay off.

One of the largest automotive companies decided to find out recently what had made a man in its top management group get to the top. (Incidentally, 25.4 per cent of all top management in this company were engineers by training.) A survey was made, searching for common denominators among the reasons why these men had outstripped their competition. These were the findings:

—Even when working on short-range projects, these men always had been looking ahead, preparing by study and observation for broader duties.

—Confronted with problems, they had shown daring, imagination and perseverance in exploring new means and methods.

—If any particular job had required some specialized knowledge, they had gone out and attained that knowledge.

"In these and other ways, these men were willing to pay going market price for success," this survey said.

"Others, with ability, were not willing to pay such a price and so had to be satisfied with something short of full success."

Let's quote another engineer, speaking of his profession: "Success for the practising engineer today and in the foreseeable future is predicated upon his possessing not only technical competence but also social and personal competence."

Mental honesty, self-discipline, and the ability to complete every engineering assignment to the best of one's training, experience and skill is technical competence.

What is social and personal competence, for an engineer?

Partly, it is the obligation to live, on and off the job, like a professional.

Partly, it can be expressed by saying that it is essential you realize that as a professional man you are identified as part of management. This identification should be both a challenge and a goal for you.

You, as a professional engineer, have a special role to play in economic and industrial expansion. You make judgments which other men in your company are not equipped to make. Management relies on your judgments, often to the extent of staking whole courses of action — and investment. People are hired, advertising campaigns launched, sales, efforts triggered, on the results of your work. It is a great responsibility. Are you doing all you can to fit yourself for it?

Your background and training has provided the basic tools for you to accomplish this goal. In the end it is up to you, the individual engineer, to transform the fruits of your ability into the rewards both tangible and intangible of full professional recognition.

—Prepared by the Association of Professional Engineers of Ontario, and reprinted from "The B.C. Professional Engineer," *February 1956.*

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Roy Marshall Walker, M.E.I.C., retired structural design engineer with Hydro-Quebec, died on February 25, 1956, in Montreal, Que.

Mr. Walker was born in Toronto, Ont., on January 24, 1890. He studied at the Technical High School in that city and was a 1912 graduate of the University of Toronto, with a B.A.Sc. degree in civil engineering. As a student he gained experience during the summer months with a geological survey party, with the Dominion Bridge Company, and with the Walter J. Francis Company, in Montreal, which firm he joined on graduation as as assistant engineer and draftsman. He was with the Riordon Pulp and Paper Company for a short time, in 1915, but joined Canadian Explosives Ltd., later that year as a project engineer and assistant engineer in charge of construction and repairs, and remained with the firm until, in 1921, he accepted a position with the Hydro-Electric Power Commission of Ontario, at Morrisburg, Ont. After a short time he moved to Montreal with the Montreal Light, Heat and Power Company, which later became Hydro-Quebec, and remained with the organization as assistant engineer and structural engineer, until his retirement in July 1955.

He was a member of the Electrical Club of Montreal, and the Corporation of Professional Engineers of Quebec.

Mr. Walker joined the Institute as a Student in 1910, became a Junior in 1913, transferred to Associate Member in 1921, and to Member in 1940. He was granted Life membership on January 1, 1956.

R. M. Walker, M.E.I.C.

Reginald Herbert Balfour, M.E.I.C., who retired in 1942 as sales manager of Philips Electrical Works and the Automatic Electric Company, died in Montreal, on September 17, 1955.

Born in Quebec City, August 14, 1874, and educated at Bishops College School, Lennoxville, Que., he was one of McGill University's graduates, obtaining his B.Sc. degree in mechanical and electrical engineering in 1897.

He joined the Lachine Rapids Hydraulic Power Company in 1897 and became superintendent. This company was absorbed into the Montreal Light, Heat and Power Company about 1903, and Mr. Balfour held various positions with the firm during the next seventeen years. He was assistant general superintendent of power distribution at the time of his resignation in 1914 to become chief engineer of the Montreal Electrical Commission. During his term with the Electrical Commission considerable progress was made, particularly in the financial district, with the transfer underground, of the power, light, telephone and telegraph cables.

In 1917 Mr. Balfour was offered the sales managership of the Eugene F. Philips Electrical Works, manufacturers of electrical wires and cables, and was subsequently made a director of the company. About 1933, control of the Philips Company was acquired by American interests and a sales oganization known as Canadian Telephones and Supplies was set up. This firm eventually became the Automatic Electric Company. He became district manager in 1937. At the time of his retirement he had served the company for twenty-five years.

He was a member of the Corporation of Professional Engineers of the Province of Quebec. He became a Student member of the Institute in 1899, transferred to Associate Member in 1903, and Member in 1940. In 1942 he attained a life membership.

Colonel Frank Chappell, V.D., M.E.I.C., died at his home in Oshawa, Ontario, on February 20, 1956.

Colonel Chappell was born at Cardiff, Wales, on December 1, 1883. He studied at the University College of South Wales, graduating in 1907 with a civil engineering diploma, then came to Canada where he was engaged in post graduate work in municipal engineering at McGill University. He accepted a position in Oshawa in 1909 as town engineer and superintendent of water works. In 1915 he was appointed industrial engineer with McLaughlin Motor Company and Chevrolet Motor Company. The first world war intervened and he spent three years overseas with the Canadian Engineers, CEF, in France and Belgium, where he was mentioned in dispatches.

Col. Frank Chappell, V.D., M.E.I.C.

On his return to Canada in 1920 he was appointed superintendent of the radiator plant, with General Motors, at Oshawa. He later became assistant factory manager, factory manager, and in 1934 was named public and industrial relations manager.

During the second world war he assumed heavy responsibility, being appointed commanding officer of the Central Mechanization Depot, R.C.O.C., and Mechanics Training Centre, London, Ontario. He went overseas in 1941, and in 1944, due to ill health, accepted his dicharge and retired from the Canadian Army.

Col. Chappell had been commissioned in the 34th Ontario Regiment in 1913. From 1925 to 1928 he commanded the Ontario Regiment as lieutenant colonel, and from 1932 to 1936 he was colonel commanding the 25th infantry brigade.

The community of Oshawa benefited from his untiring efforts — from 1911 to 1940 as a member of the Oshawa Hospital Board, and work with the education and library board. He was president of the Canadian Legion in 1926, and in 1938 president of the Oshawa Chamber of Commerce. In 1930-39 he was president of the Oshawa Boy Scouts Association.

He joined the Institute in 1908 as a Student, became an Associate member in 1913, a Member in 1936, and attained Life membership in 1944. He was also a member of the Military Institute.

Oliver Archibald Barwick, M.E.I.C., architect and structural engineer in Montreal for many years, died in Montreal on March 11, 1956.

Mr. Barwick was born in Montreal, on January 3, 1889. He followed a five year apprenticeship in draughting, before entering McGill University and in 1914 was graduated with the degree of bachelor of architecture.

Rejected from military service and beginning his graduate career in the opening months of World War I, Mr. Barwick soon started what was to be a valuable contribution in the field of munitions, both at that time, and in the second conflict. With Mond Nickel Company briefly in 1914, he joined Canadian Inspection and Testing Laboratories in 1915, as inspector of shell parts, and for two years, during 1916 and 1917, carried on night work in the field of microscopic experiments and tests on the manufacture of ammunition, first with the Montreal Ammunition Company, Longue Pointe, Montreal, and later with Dominion Bridge Company and Dominion Copper Products Company, Lachine, Que. He also did some private consulting work on heat treatment and calibrations for smaller plants.

The war over, in 1919, he accepted a position with P. Lyall and Sons as draughtsman on the shopwork of the new parliament buildings at that time under construction in Ottawa, and he was concerned with designing and draughting plans for the construction of the Capitol theatres in Montreal and Calgary. His services were also called upon in the plans for the expansion of the Royal Bank in the West Indies. In the next few years he had extensive experience in various architectural projects, including association with Bannigan, Armstrong and Thompson, Toronto, and James, Proctor and Redfern, Toronto. He was also in private practice in Montreal for some time and was construction supervisor of the head office building of the Royal Bank of Canada, built in Montreal during the twenties.

In 1940, after a period of service as senior assistant architect in the engineering services branch of the Department of National Defence, he was asked, on the basis of his First War experience, to take charge of the metallurgy department of Dominion Bridge Company Limited in connection with a shell plant then being put into operation in Toronto. Mr. Barwick accepted the appointment and, in the spring of 1940 travelled to Great Britain, where he observed similar projects in England and Wales. On his return to Canada he remained with the plant until production was established. He then diverted his services to include work on hull construction with United Shipyards, and was also building and equipment engineer with Wartime Merchant Shipping Limited.

He returned to private practice in 1944, although he had kept some architectural work of a private nature in operation. The following year he began an association with the Montreal firm of architects, Ross and McDonald, that was to last for ten years. About a year before his death Mr. Barwick chose to return to full-time private practice.

A resident of St. Lambert, Que., he was for a number of years chairman of that municipality's architectural commission, chairman of the by-laws committee, and member of the board of assessors.

Mr. Barwick was a member of the Association of Architects of the Province of Quebec, and of the Royal Architectural Institute of Canada.

He became a Member of the Institute in 1923, transferred to Member in 1940.

Edward Darling, M.E.I.C., president of Darling Brothers Limited, died on February 26, 1956, in Montreal.

Born in that city on October 4, 1873, he was a McGill University graduate, receiving the degree of B.Sc. in 1894. He joined the firm of Darling Brothers, founded by his two brothers, and until 1901 worked in the capacity of draughtsman. He subsequently became works manager and vice-president. From 1925 he was president and general manager, being, in all, at the time of his death, sixty years with the firm.

Mr. Darling was president of the board of management of Verdun Protestant Hospital, having served both as governor and president, and last year, despite his advanced age, accepted reelection.

E. Darling, M.E.I.C.

He joined the Institute as a Member in 1925, attained Life Membership on January 1st, 1956.

Melvin Lambeth Gale, M.E.I.C., vice-president of Turnbull and Gale Construction Company in Vancouver, died suddenly at his home in Vancouver, on February 12, 1956.

Born at De Winton, Alberta, on October 10, 1903, he followed his studies at Western Canada College, in Calgary, and at the University of Alberta, receiving a B.Sc. degree in civil engineering in 1927.

For the first three years after his graduation Mr. Gale was estimator, designer and general supervisor with the Permanent Construction Company in Edmonton. In 1930 he left the firm to operate independently as engineer and general contractor. He accepted the appointment of assessor in the Department of Municipal Affairs of Alberta in 1934, and served in this capacity for some time. After an interlude as general contractor in partnership, in 1937, under the name Gale and Allyn, he moved to Vancouver in 1938, becoming structural engineer with Armstrong and Monteith Construction Company Limited. In 1946 he was chief engineer and supervisor of construction with the firm.

Later, the organization known as Turnbull and Gale Construction Company Limited was formed.

Long active in the Boy Scout movement in Vancouver, he was in 1951 awarded the Boy Scout Medal of Merit for outstanding services, while he was serving a four-year term as assistant district commissioner.

Mr. Gale joined the Institute in 1935, as an Associate Member, and transferred to Member in 1940.

Maurice F. Carty, S.E.I.C., who graduated from the University of Alberta last year, died on February 8, 1956, following a lengthy illness.

He was born in Ottawa, on October 2, 1930, and attended Lisgar Collegiate in that city. In 1949 he enrolled at McGill University where he studied for a time. He transferred to the University of Alberta in 1953 and received a B.Sc. degree in electrical engineering from that university in 1955.

Mr. Carty worked as a student during the summer months, 1950-52, with the radio aviation section of the Department of Transport, Ottawa, with the E. B. Eddy Company at Hull, Que., in 1953 as an electrician's helper, also with T.M.C. (Can.) Ltd., Ottawa, as a project engineering assistant in 1954.

Upon graduation he was immediately accepted by the Department of Transport in Montreal as an engineer in the District Aviation Radio Office at Dorval Airport.

His father is E. G. Carty, M.E.I.C., of Ottawa, retired general executive assistant with the Department of Transport.

Real Couture, S.E.I.C., who graduated from the Ecole Polytechnique in 1955, died as the result of an accident early in September, 1955. He had been planning to go on to further studies at the Massachusetts Institute of Technology in a few weeks time.

Born at St. Joseph d'Alma, on the twenty-sixth of December, 1929, he was educated at St. Joseph College and the Academie de Chicoutimi, Que., before going on to study engineering at the Ecole Polytechnique, Montreal.

While a student in 1951 he had been employed as rodman by Pentagon Construction Company Limited.

Mr. Couture joined the Institute in 1952.

News of the Personal Activities of Members of the Institute

E. V. Leipoldt, M.E.I.C. — Shawinigan Engineering Company Ltd., announces the appointment of Mr. Leipoldt as vice-president and consulting engineer. He has been a director and vice-president of the company since 1947.

Mr. Leipoldt, a South African, studied extensively in Europe, later gained engineering experience there, in South America, and the United States. He came to Shawinigan Engineering in 1920.

He is a member of the Canadian committee of C.I.G.R.E., most active international organization in the electrotechnical field, with headquarters in Paris, and known in this country as the International Conference on Large Electrical Systems.

E. V. Leipoldt, M.E.I.C.

J. A. Burke, M.E.I.C. Another top appointment on the part of Shawinigan Engineering Company Ltd., is the recent promotion of J. A. Burke, from general superintendent to vice-president of construction.

With Shawinigan since 1937 when he was a field engineer on construction projects at Trois-Rivières, La Tuque and Shawinigan Falls, he became general superintendent in 1948 when construction of the Trenche powerhouse was started.

Mr. Burke holds degrees in both electrical and civil engineering gained at the University of Alberta.

G. R. Rinfret, M.E.I.C., whose name appeared high on the list of recent appointments in the Shawinigan Engineering Company Limited, has been named vice-president of engineering. He was made chief engineer in 1952, and in 1955 was appointed vice-president and elected a director.

Mr. Rinfret is a native of Dawson City, Yukon, and was educated at Loyola College in Montreal, the Shawinigan Technical Institute and McGill University. He joined the Shawinigan Water and Power Company in 1918 and was transferred to Shawinigan Engineering when it was organized the following year. He was resident engineer on construction of Shawinigan's Rapide Blanc development and the St. Maurice Power Corporation plant at La Tuque. After World War II he spent some time in China when the Shawinigan company took part in a study of hydro-electric sites for the Nationalist government.

J. A. Thomas, M.E.I.C., hydraulic engineer, with Shawinigan Engineering Company Limited, has been assigned to the position of chief engineer, in the civil division.

A Queen's University graduate, he joined Shawinigan Engineering in 1948, to become hydraulic engineer shortly afterwards. Since 1954 he has been hydraulic engineer in charge of civil engineering design and has been engaged in the design of various major hydro-electric developments in Canada.

J. A. Burke, M.E.I.C.

G. R. Rinfret, M.E.I.C.

R. E. Grout, M.E.I.C., since 1954, senior electrical engineer for Shawinigan Engineering Company Limited, is now chief engineer of the electrical division.

He joined Shawinigan in 1937 as a junior engineer and after doing design work on various installations he was loaned to Defence Industries Limited and participated in the electrical design of the NRX atomic reactor at Chalk River. Since then Mr. Grout has been in charge of the electrical design for a number of developments within his company and elsewhere.

W. P. Harland, M.E.I.C., will be manager of the field division for Shawinigan Engineering Company Limited, according to recent announcements made by the firm. This follows a 1953 appointment as supervising engineer.

Prior to that time he worked as resident engineer or field engineer on a number of major construction projects, including the Trenche development. He joined the company in 1948.

From Lethbridge, Alta., and a University of Alberta graduate, he also attended the California Institute of Technology where he was awarded a civil engineering degree in 1944.

W. Sharples, M.E.I.C., a long-time employee of Shawinigan Engineering Company Limited, who is carrying out special duties of an administrative nature, has been named personnel manager of the company's Montreal office.

• Personals

From Quebec City, he studied in Montreal, graduated from McGill University, then joined Shawinigan Engineering as a draughtsman. In 1933 he was assigned to the plant engineering department of Shawinigan Chemicals Limited, but returned to the engineering company in 1938 as assistant to the structural engineer. In 1941 he was assigned to Wartime Merchant Shipping Ltd., hull steel department, as assistant manager and returned to Shawinigan Engineering the following year.

Mr. Sharples is a member of the Publication Committee of The Engineering Institute.

H. T. Libby, M.E.I.C., of the British Columbia Electric Company Ltd., and superintendent of gas distribution since 1946, has been appointed manager of the gas distribution department. He has been associated with the firm for more than thirty years.

Mr. Libby is the author of several technical articles, mostly concerning gas distribution, one of which was printed in Canada, United States and Great Britain.

He is a member of the British Columbia Engineering Society, the National Association of Corrosion Engineers, the American Gas Association; the Vancouver Board of Trade, and the Association of Professional Engineers of British Columbia.

Also active in Engineering Institute circles, since becoming a member in 1947, he was in 1955 elected to represent the Vancouver Branch on the Council of the Institute.

F. L. Sparks, M.E.I.C., has been appointed managing director of McIntosh Industrial Equipment Limited and president and general manager of Refinery Vessels and Maintenance Limited, at Calgary.

The president and general manager of Steel Crafts (Alta.) Limited in Calgary in 1952, he was the following year appointed managing director.

Mr. Sparks is a 1950 graduate of the University of British Columbia.

J. G. Chenevert, M.E.I.C.

J. G. Chenevert, M.E.I.C., was recently elected president of the Association of Consulting Engineers of Canada Inc. In 1953 he was among those chosen to direct the organization.

Mr. Chenevert is a long-time member of the Montreal firm of consulting engineers, Surveyer, Nenniger and Chenevert.

He is a graduate of the Ecole Polytechnique, in Montreal.

Air Vice Marshal M. M. Hendrick, M.E.I.C., air member for technical services at R.C.A.F. Headquarters in Ottawa, last year transferred from chief of telecommunications and was promoted to his present rank. He now holds responsibility for the design and development of all Air Force equipment and facilities as well as the policies governing the procurement, storage, distribution, inspection and maintenance of all Air Force material.

With an outstanding wartime record behind him, in which he served as chief liaison officer, communications and electronics, on the Canadian Joint Staff Missions in Washington, and later was called to the A.E.A.F. signals staff and the R.C.A.F. planning staff overseas. Air Vice Marshal Hendrick has since then held a number of important posts. In 1945, as a group captain he took over the Directorate of Signals, in Ottawa and remained in charge for two and a half years. Then, in 1948, after a brief period as commanding officer of the R.C.A.F. station at Edmonton he was sent to North-West Air Command Headquarters at Edmonton, in connection with operations and training. Promoted to air commodore in 1949, he was named Air Member of the Canadian Joint Staff and Air Attache at Washington, D.C., which post he took over early in 1950.

Air Vice Marshal M. M. Hendrick, M.E.I.C.

He attended the Imperial Defence College course in London in 1952, and the following year received a posting to Ottawa as chief of telecommunications, with responsibility for the electronic activities of the Air Force. During this period these included the planning and design of the Mid-Canada Line, the bringing into service of the micro-wave communications ring to serve the Air Defence Command, the installation in Europe of the mobile micro-wave net and new high powered radars for the Air Division overseas; the reorganization and extension of the R.C.A.F. administrative tape relay communication system, based both on landline and radio teletype, and continuous planning for the improvement of our radar ground environment and the introduction of automacity therein.

Air Vice Marshal Hendrick is a member of the Canadian Aeronautical Institute. He joined the Engineering Institute in 1932 as a Student, was transferred to Junior in 1938, and to Member in 1947.

J. E. Leo Roy, M.E.I.C.

J. E. Leo Roy, M.E.I.C., chief engineer with the Quebec Hydro Commission's Auxiliary Services, has been elected president of the Corporation of Professional Engineers of Quebec.

A civil engineering graduate of Ecole Polytechnique in 1930, Mr. Roy received his electrical engineering degree from McGill University two years later. He was at one time associated with the Shawinigan Water and Power Company as sales engineer, and the Quebec Power Company in Quebec City, as assistant superintendent of the power division. In 1946 he accepted a position in the same capacity in Quebec Hydro's distribution department. In 1953 he was appointed to his present position.

Mr. Roy has very recently been elected president of the Montreal Electrical Club. He is a past secretary-treasurer of the Quebec Branch of the Institute.

G. W. E. Nicholson, M.E.I.C., is president of the Tennessee River Pulp and Paper Company which last month opened executive offices in New York.

For a number of years he was associated with the Union Bag and Paper Corporation, Savannah, Georgia, and New York, and also spent some time with the Southern Kraft Corporation, and the Bogalusa Pulp and Paper Company Inc.

Prior to 1931 Mr. Nicholson sojourned in Montreal.

A. M. Hudson, M.E.I.C., has joined the staff of the Foundation Company of Canada in Montreal where he holds the position of equipment manager.

Recently associated with Rayner Atlas Limited in Niagara Falls, Ontario, as mechanical coordinator, he has also been chief of the mechanical division, War Assets Corporation, and during the war was with the Department of Munitions and Supply in Ottawa.

Earlier, in 1934, he was with the De-

Got a lifting problem?..
then get this handbook!..*

If you have an *industrial* lifting problem, you will find our new Crane Handbook invaluable.

In it you will find information on the classification and selection of electric overhead cranes for various services; features of construction; runway design data and many other items.

partment of Northern Development of Ontario as project manager. Prior to that time he was associated with the Canadian Ingersoll-Rand Company Limited, and also participated in several railway projects in the years following his arrival from England in 1908.

Major W. A. McDill, R.C.E., M.E.I.C.

Major W. A. McDill, R.C.E., M.E.I.C., has been appointed technical staff officer with the Directorate of Engineer Development, Army Headquarters, Ottawa.

Major McDill graduated from the University of British Columbia with a B.A.Sc. degree in mechanical engineering, in 1948, and also holds B.E. and M.E. degrees from Colorado Agricultural and Mechanical College.

After completing these studies he went on to the Royal Military College of Science where he completed the sixth technical staff course, and was then, in 1954, appointed Canadian engineer liaison officer in the War Office at Whitehall.

Rolf S. Lockeberg, M.E.I.C., has recently been appointed assistant to the vice-president of R. L. Crain Limited, in Ottawa, Ontario.

Mr. Lockeberg received his B.Sc. degree in mechanical engineering from Queen's University in 1940 and served during the war years as an aeronautical engineering officer in the R.C.A.F. He later attended the Harvard School of Business Administration, receiving his M.B.A. degree in 1947. He then joined Canadian Ingersoll-Rand Company Limited in Montreal, where he served as controller from 1950 to 1954. From 1954 until the beginning of this year, he was controller of B. W. Deane and Company, in Montreal.

R. S. Lockeberg, M.E.I.C.

Jack Morris, M.E.I.C., whose name was among recent company promotions, is now manager of Courtauld's (Canada) Limited plant in Cornwall, Ontario.

Mr. Morris joined Courtauld's (Canada) Limited in 1945 as engineering division manager. He had come to Canada from his home in England in 1933 as technical representative for an English engineering company. At the outbreak of World War II he was called to active service with the Princess Louise Fusiliers (MG) serving as general staff officer and later as assistant to the director of chemical warfare, N.D.H.Q., with the rank of lieutenant colonel.

J. Morris, M.E.I.C.

He is a member of the American Society of Mechanical Engineers.

A. M. H. Norris, M.E.I.C., formerly associated with Jacques Price, consulting civil engineer in Windsor, N.S., is this year located in Fredericton, N.B., with the Central Mortgage and Housing Corporation, and is at present with the C.M.H.C. Camp Gagetown Project as service contract engineer.

Keith Dixon, M.E.I.C., superintendent of lights for the Department of Transport in Victoria, B.C., since 1949, has accepted the position of district marine agent with the Department.

A veteran of two world wars, who earned the rank of colonel, Mr. Dixon was with the Department of Transport in Prince Rupert, B.C., after the second conflict. Earlier in his career he was associated with the Esquimalt and Nanaimo Railway, at Victoria, the Ontario Department of Northern Development, and the Canadian Pacific Railway.

C. K. Lockwood, M.E.I.C.

C. K. Lockwood, M.E.I.C. Vice-President of sales is the new appointment received by C. K. Lockwood of Shawinigan Chemicals Limited, formerly vice-president, stainless steel and alloys, in Montreal.

With Shawinigan Chemicals since 1937, Mr. Lockwood was appointed sales manager of the stainless steels and alloys division in 1945 and became vice-president of the division in 1953. The following year he was elected to the board of directors of the company.

Mr. Lockwood has been active in the Alloy Casting Institute and in 1954 was named president of that organization. He was chairman of the Montreal chapter of the American Society for Metals, and has served the National Research Council. In 1951 and 1952 he was on loan from Shawinigan, working as chief of the stainless steels section, steel division of the Canadian Department of Defence Production.

T. W. Lazenby, M.E.I.C., has been elected chairman of the Kootenay Branch of the Institute.

Born in England, he received his high school education in that country, in the city of York. He then enrolled in a lengthy course in mechanical engineering, at the same time serving a seven year apprenticeship as mechanical draftsman. Later he was awarded a

T. W. Lazenby, M.E.I.C.

• Personals

scholarship, and went on to Leeds University.

Mr. Lazenby came to Canada in 1923 and was located in London, Ont., with E. Leonard and Sons, Ltd., as chief draftsman. He remained there for some time and it was not until 1936 that he transferred to the west coast to take up a position in the same capacity with the Vancouver Engineering Works, Vancouver, B.C. After five years with the Vancouver Engineering Works he transferred to his present position with the Consolidated Mining and Smelting Company of Canada, in Trail, B.C. He has been associated with the company's design office for the past fifteen years.

Mr. Lazenby's membership in the Institute dates from 1928. He was secretary of the Kootenay Branch from 1949 to 1952.

P. M. Tomney, M.E.I.C., is branch manager with Canadian Westinghouse Company Ltd., in Moncton, N.B.

A 1950 graduate of the Nova Scotia Technical College with a B.Eng. degree in electrical engineering, Mr. Tomney has been with the company for some time. In 1952 he was apparatus sales engineer for the company in Halifax, N.S.

A. P. Robinson, M.E.I.C.

Arnold P. Robinson, M.E.I.C., previously with Northwest Industries Limited, in Edmonton, has been appointed plant manager of the Inland Cement Company Limited plant at Edmonton. With Northwest Industries Limited since 1952, he had become assistant manager of the company. Mr. Robinson studied at the University of British Columbia.

Major J. H. MacLean, M.E.I.C., is officer commanding the 200 Minor Base Workshop, R.C.E.M.E., in Halifax.

He had previously been officer in charge of the unit, last year receiving a promotion to the rank of major.

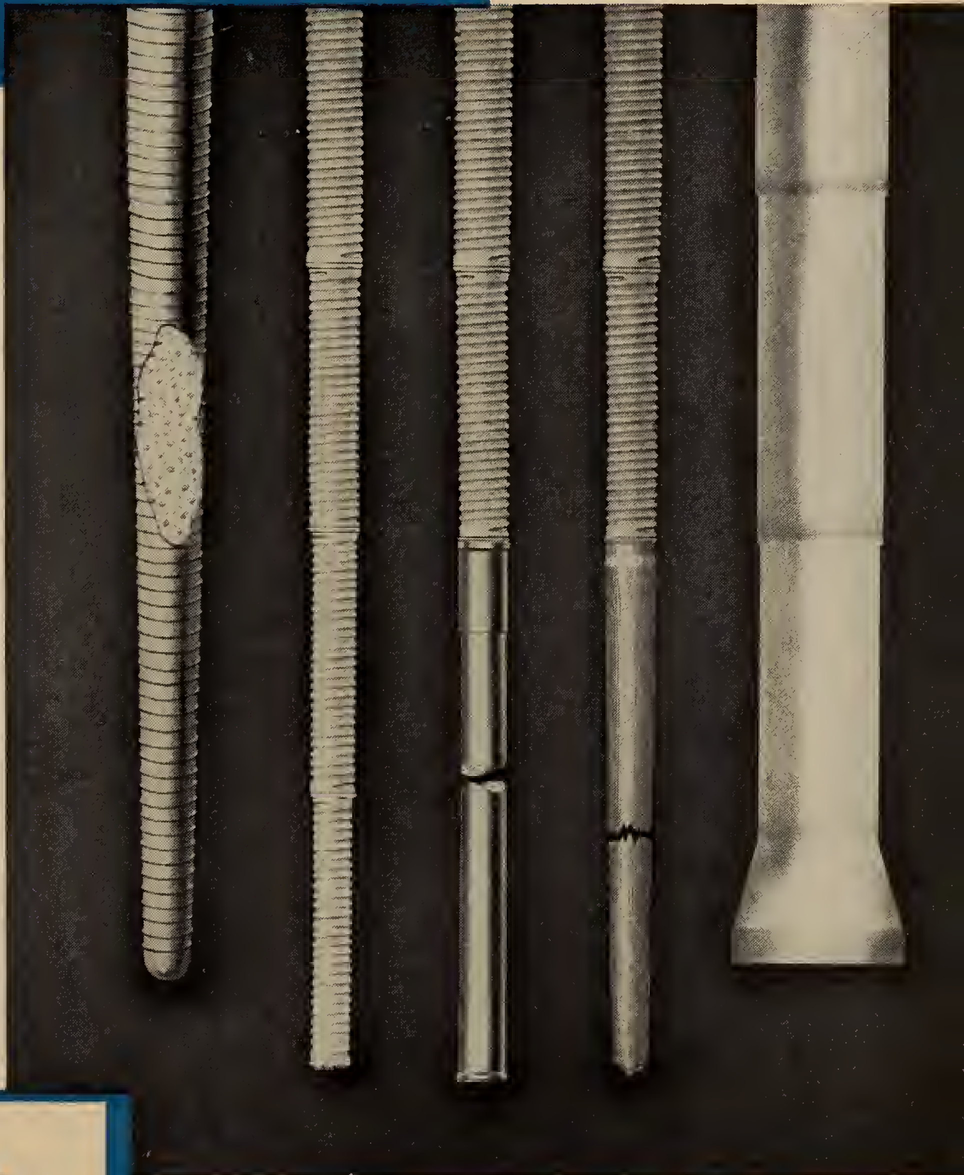
Major MacLean spent some time in Britain attending a technical staff officer course at the Royal Military College of Science in Great Britain. He returned to Canada early in 1955.

He is a University of Toronto graduate, with B.A.Sc. and M.A.Sc. degrees, gained in 1941 and 1949 respectively.

J. R. Harris, M.E.I.C., has been appointed manager of the Toronto branch of the Swedish General Electric Limited.

Mr. Harris was born in Jamaica, B.W.I., and obtained his bachelor of engineering degree from McGill University in 1946. After having attended the test course of Canadian General Electric Company Limited in 1946-47 he joined the Hydro Electric Power Commission of Ontario. He was later

J. R. Harris, M.E.I.C.



• Personals

employed by C.S.A. Approvals Laboratories as testing and equipment engineer, until joining Swedish General Electric Limited in 1953.

He is a member of the Corporation of Professional Engineers of the Province of Ontario, the Canadian Electrical Association, the Toronto Electric Club, and holds an associate membership in the American Institute of Electrical Engineers.

C. Climo, M.E.I.C., of Niagara Falls, Ontario, is temporarily located in Logan, Ohio, where he is the resident engineer on a new three million dollar plant now under construction by the Carborundum Company. It will be devoted to the manufacture of resin bonded abrasive wheels.

Mr. Climo, long-time staff member with the Carborundum Company, Niagara Falls, N.Y., expects to return to his firm at the completion of the Ohio project, in about a year's time. His permanent position is that of chief design and construction engineer.

He served as chairman of the Niagara Peninsula Branch of the Institute during 1950-51.

M. A. Burns, M.E.I.C., is with the geophysical department of Mobil Oil of Canada in Calgary, Alta.

Mr. Burns, a graduate of the University of Alberta, in mining engineering, was formerly associated with Western Geophysical Company Limited.

H. A. Cann, M.E.I.C., sales manager with the mechanical goods division of the Dominion Rubber Company since a 1952 appointment, has recently been named sales manager of the division's operations in the Prairie Provinces, with headquarters in Winnipeg.

Mr. Cann's association with the company dates from 1938 when he graduated from the University of Manitoba.

Mr. Cann joined the company in 1938 following his graduation from the University of Manitoba, and after lengthy war service with the R.C.E. returned to join the company's Edmonton branch sales staff.

H. A. Cann, M.E.I.C.

G. A. Cunningham, M.E.I.C.

G. A. Cunningham, M.E.I.C., has been elected Chairman of the Halifax Branch of the Institute.

Mr. Cunningham was born in Peterborough, Ontario, attended high school in that city and went on to engineering studies at the University of Toronto, where he received a B.A.Sc. degree in 1929. On graduation he obtained a position on the staff of Riley Engineering and Supply Company Ltd., Toronto, as chief engineer. He joined Imperial Oil Limited in 1932 and was employed as district representative in Welland, Ont., and St. Catharines, Ont. Then, in 1948 he was chosen manager of industrial

• Personals

sales for the company's maritime division.

Mr. Cunningham's affiliations with the Institute go back to 1927 when he joined as a Student. In the thirties he was active in the Peterborough Branch and served on the executive of the London, Ont., Branch, as vice-chairman in 1945 and 1946.

D. M. Jenkins, M.E.I.C.

Donald M. Jenkins, M.E.I.C., has been elected chairman of the London Branch of the Institute.

Mr. Jenkins is a native of Blyth, Ontario. He received his high school training in that province and in 1940 he went to work at McKinnon Industries, Ltd., a G.M. division at St. Catharines, Ont. In 1943, he enlisted in the Canadian Army and after his discharge in 1946, from the Royal Canadian Electrical and Mechanical Engineers, he enrolled at the University of Toronto. On his graduation in mechanical engineering in 1949, he joined the Ontario Paper Company at Thorold, Ont.

He moved to General Motors Diesel Limited, in April, 1950, as a project engineer and became senior project engineer and then assistant chief of the department. In September, 1952, he was appointed chief engineer.

K. M. Mote, M.E.I.C., has accepted an appointment as plant engineer with Messrs. Borg, Warner Ltd., of Letchworth, Herts, England.

Mr. Mote was associated with British Cellophane Ltd., Bridgewater, Somerset, England. In 1954 he went to Mexico to work with Celorey, S.A., in Monterrey. Last year he was with Procter and Gamble Company as their London, England, construction engineer.

He is a graduate of Birmingham Central Technical College.

A. J. Arens, M.E.I.C., formerly with the Materials Testing Laboratories in Lethbridge, Alta., has been named manager of Atlas Transit Mix in that city.

W. H. Hooper, M.E.I.C.

He is a 1953 graduate of the University of British Columbia.

W. H. Hooper, M.E.I.C., has been appointed manager of domestic product sales with Amalgamated Electric Corporation Limited.

Mr. Hooper joined Amalgamated Electric in 1940 as sales engineer. Since that time he has held the important executive positions of manager, of dis-

• Personals

tribution equipment, and of apparatus sales.

Mr. Hooper is a graduate in electrical engineering from McGill University. He is a member of the Association of Professional Engineers of Ontario.

I. M. Hamer, M.E.I.C., director of Dowty Equipment of Canada Limited, has received the appointment of vice-president and general manager of the company.

Mr. Hamer, who graduated from the University of Toronto in 1937 joined the parent Dowty organization in England in 1940. Since returning to this country in 1941, as chief engineer, he has been in charge of the Canadian company's engineering operations. He became a technical director in 1951.

Robert J. Griesbach, M.E.I.C., has recently been made a partner of O. J. McCulloch & Co., consulting engineers, Montreal.

He graduated from McGill University in 1942 with a B.Eng. degree in civil engineering and gained a variety of construction and design experience with the Foundation Company of Canada, and with Surveyer, Nenniger and Chenevert, consulting engineers, before joining his present company in 1950.

Wm. Rutherford, M.E.I.C., has accepted the position of oil and gas process engineer with Dutton-Williams Brothers, Engineers and Constructors, in Calgary.

He has recently held an appointment with the Foundation of Canada Engineering Corporation, and was sent to Edmonton as resident engineer on the construction of a cement plant for the Inland Cement Company Limited.

Mr. Rutherford has also been associated with the Rankin Company Limited in Montreal, as director of technical development, and was for a time with Central Mortgage and Housing Corporation in that city as construction engineer.

He is a civil engineering graduate of the University of Durham.

R. E. Stopps, M.E.I.C., is a technical officer with the Canadian Standards Association, in Ottawa. He has recently been associated with Canadian Comstock Company Ltd., in Hamilton, Ont.

Mr. Stopps began his engineering career with the department of Transport, at Ottawa, in 1944 as an assistant radio engineer. Later he worked for Imperial Tobacco Company Ltd., in Montreal, and for El-Met Parts Ltd., at Dundas, Ont.

He is an electrical engineering graduate of McGill University.

E. I. Rubinsky, M.E.I.C., district engineer with Raymond Concrete Pile Company Ltd., has been transferred from Montreal to the company's headquarters in Toronto.

Originally a graduate of the University of Beirut, Lebanon, with a B.Sc degree in civil engineering, Mr. Rubinsky received a M.Sc. degree from Harvard University, in 1951. He worked in engineering in Ottawa before joining Raymond Concrete Pile Company in 1954.

• Personals

L. P. Cousineau, M.E.I.C., has been named general manager of Cartier Construction Company in Montreal.

Associated with Angus Robertson Limited in Montreal since 1947, he was assistant chief engineer and, at the time he left the firm had become project manager.

Earlier in his career he was associated with the National Syndicate of Electricity, Marine Industries Limited, and the Quebec Streams Commission. He joined Dufresne Engineering Company Limited of Montreal in 1941, remaining with the firm until 1946. During this time he was engaged in a number of large construction projects and was for a year loaned to Quebec Shipyards Limited. In 1946 he became town engineer for the community of Val d'Or, Quebec.

Mr. Cousineau has a civil engineering degree from the Ecole Polytechnique and also studied in Paris, graduating as a welding engineer from the Ecole Superieure de Soudure Autogene, following his Canadian studies.

W. Clyde Baggs, M.E.I.C., with Bathurst Power and Paper Company since 1937, has been named general manager, mills division.

Prior to that time he held the position of chief engineer and it was in 1951 that he received the appointment of mills manager. He was transferred to the executive offices of the company in Montreal in September, 1954.

Mr. Baggs was briefly with the International Power and Paper Company of Newfoundland on his graduation from McGill University, before joining his present company. He holds a B.Eng. degree from that university.

W. C. Baggs, M.E.I.C.

Eldon V. Hunt, M.E.I.C., with the Alberta Gas Trunk Line Company Limited in Calgary as chief engineer until recently, has accepted employment in New York. His present position is that of assistant construction manager with Ebasco Services Incorporated.

He is a graduate of the University of Colorado and a member of the American Society of Civil Engineers.

J. G. Chalmers, M.E.I.C.

J. Gordon Chalmers, M.E.I.C., administrative vice-president of Bathurst Power and Paper Company Limited, with headquarters in Bathurst, N.B., has retired after forty-two years with the company, and its predecessor.

A native of New Brunswick, from Belledune, Mr. Chalmers obtained a variety of experience in the nine years which preceded his joining the Bathurst organization in 1914. An apprentice machinist with Alex Dunbar and Sons, of Woodstock, N.B., and then machinist with various firms, he had also been a marine engineer with the Northern Dredging Company. In 1915 he had already been named superintendent of the power plant and electrical department with the Bathurst Company, and five years later was general superintendent of the plant, in charge of all engineering. From 1935 to 1952 he rose from the position of mill manager to administrative vice-president.

He is a director of the company and will continue to serve the firm as resident director, in Bathurst.

William N. Wray, Jr.E.I.C., is with Dutton Williams Brothers Ltd., in Calgary, Alta.

He graduated from McGill University, class of 1954, with a B.Eng. degree in civil engineering.

E. T. Cotton, Jr.E.I.C., is with the Electric Reduction Company of Canada, at Buckingham, Que. He was associated with the Canadian General Electric Company Limited as a plant engineer in 1953, having been engineer in training with the firm previously, in Peterborough, Ont.

He graduated from Queen's University in 1950 with a B.Sc. degree in mechanical engineering.

E. G. Hazle, Jr.E.I.C., has been taken on the staff of the Canadian Arsenals Ltd., Toronto.

Previously with Canadian Gypsum Company Ltd., in Toronto as plant engineer, and with Toronto Asphalt Roofing, Manufacturing Company Ltd., he is a mechanical engineering graduate from Queen's University, class of 1948.

Paul A. Webb, Jr.E.I.C., has been sent by his firm, Phillips Electrical Company Ltd., Brockville, Ont., to Great Britain where he will spend a year with

• Personals

British Insulated Callender's Cables Ltd., at Prescot, Lancs, Eng.

Mr. Webb is a mechanical engineering graduate of McGill University, class of 1954.

E. E. Olson, Jr.E.I.C., who is on leave of absence from Canadian National Railways department of research and development in Montreal, is studying at the University of California Graduate School of Business Administration, for an M.B.A. degree.

He is a graduate of the University of British Columbia, class of 1952, in civil engineering.

Peter H. Cameron, Jr.E.I.C., has been transferred to Montreal by Canadian General Electric Company Ltd., from Toronto. In 1953 he was named supervisor of sales promotion, wire and cable division, Canadian General Electric Company, Toronto.

A 1949 graduate of McGill University, he has a B.Eng. degree in electrical engineering.

Carl A. Hennigar, Jr.E.I.C., has accepted a position with Sterling Electric Company Ltd., in St. Catharines, Ont. In 1953 he joined E. L. Dodington, consulting engineer in that city, and has also been associated with the Montreal East refinery of the B.A. Oil Company of Canada Ltd.

Mr. Hennigar graduated in electrical engineering from McGill University in 1950.

W. G. Gall, Jr.E.I.C., has accepted a position with the Hydro Electric Power Commission of Ontario, distribution department, at Niagara Falls, Ont.

Mr. Gall graduated from the University of Manitoba, class of 1954, with a B.Sc. degree in electrical engineering.

Lieut. (L) L. G. Holtby, R.C.N., Jr.E.I.C., is stationed in Belfast, Ireland, where he is a member of the R.C.N. electrical trials team, currently carrying out trials aboard the new R.C.N. carrier, H.M.C.S. "Bonaventure". On completion of the trial program he will join the ship as an electrical officer.

He was previously in Ottawa with the trials section of the Electrical Engineer in Chief of the Royal Canadian Navy.

Lieut. Holtby graduated in electrical engineering from the University of British Columbia in 1950.

Roland Dion, Jr.E.I.C., is at Knob Lake, Schifferville, Que., with Mobec Ltd. Formerly with Canadian Fairbanks Morse Company Ltd., at Loretteville and Quebec, Que., he is a graduate in electrical engineering from Laval University, class of 1951.

Francis J. McNaughton, Jr.E.I.C., has been transferred to the Ottawa office of the National Harbours Board, from St. John, N.B.

He graduated from the University of New Brunswick, in civil engineering, class of 1953, and joined the National Harbours Board at that time.

R. A. Stewart, Jr.E.I.C.

Rae Alden Stewart, Jr.E.I.C. First prize in the Bausch and Lomb Photogrammetric Awards for the most outstanding papers on photogrammetry has been awarded to Rae Alden Stewart, field officer with the Canadian Topographical Survey Department, Ottawa.

The Prize-winning paper, "The Application of the Balplex Plotter to Trimetrogon Obliques," developed new aerial mapping techniques and won him the citation plus a cash prize of one hundred dollars.

Mr. Stewart obtained an M.Sc. degree in geodetic science in 1955. He majored

• Personals

in photogrammetry at the Institute of Geodesy, Photogrammetry and Cartography at the Ohio State University.

Originally from the University of New Brunswick, he graduated with a B.Sc. in civil engineering in 1950.

M. Brault, JR.E.I.C., has been named branch development engineer with Canadian Liquid Air Company Ltd. in Montreal. He was formerly resident engineer with the company.

Mr. Brault holds a B.Eng. degree in civil engineering from McGill University. He graduated in 1952.

T. R. Walton, JR.E.I.C., has been in Jamaica since last summer with the Alumina Jamaica Ltd., where he is employed in the operating division of the plant. He was formerly a field engineer with the Ontario Research Foundation in Toronto.

Mr. Walton holds a degree in mechanical engineering from the University of Toronto, class of 1950.

D. Hicks, JR.E.I.C., has been taken on the staff of Engineering Management Inc., in San Francisco. He has been associated with Marwell Construction Company in Clearwater, B.C. Mr. Hicks is a 1953 graduate from Queen's University in civil engineering.

R. J. DiCicco, JR.E.I.C., has accepted a position as maintenance superintendent with the Asbestos Corporation at Thetford Mines, Que.

Mr. DiCicco graduated from McGill University with a B.Eng. degree in mechanical engineering, class of 1951, then joined Consolidated Paper Corporation Ltd., as a woodlands mechanical engineer at Grand'Mere, Que.

G. W. Madore, JR.E.I.C., has been named director and manager of the engineering services department of Foresteel Products Ltd.

In 1953 he was appointed manager of the air conditioning division of the firm. Earlier he was associated with the Canadian General Electric Company Ltd., heating and air conditioning departments, and with the Minneapolis-Honeywell Regulator Company Ltd., as sales engineer, in Montreal. He is a mechanical engineering graduate of McGill University.

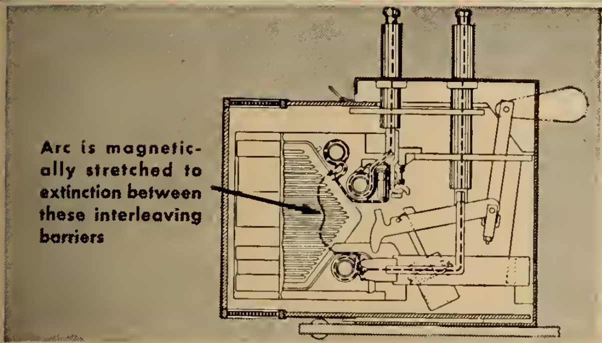
J. P. Kot, JR.E.I.C., has joined the engineering staff of the Potash Company of America, in Saskatoon, Sask.

Mr. Kot, a 1949 graduate of the University of Saskatchewan in electrical engineering, has recently been associated with Giffels and Vallet of Canada, consulting engineers in Windsor, Ont., as chief electrical engineer. He has also been with Price Brothers and Company at Kenogami, Que., as hydro engineer and the Boiler Inspection Insurance Company at Montreal.

Murray F. Pittuck, JR.E.I.C., is at present located at Chaudiere Station, Que., with the Shawinigan Engineering Company. He joined the company in 1951 and became assistant superintendent of transmission line construction the following year.

In 1955 he was promoted to the position of superintendent of that depart-

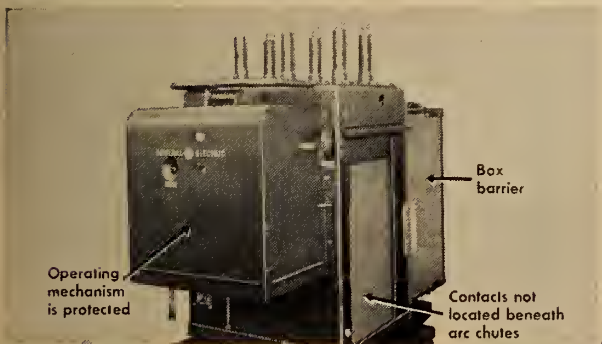
4 reasons why G-E magne-blast breakers are best for metal-clad switchgear



Most reliable operation

1

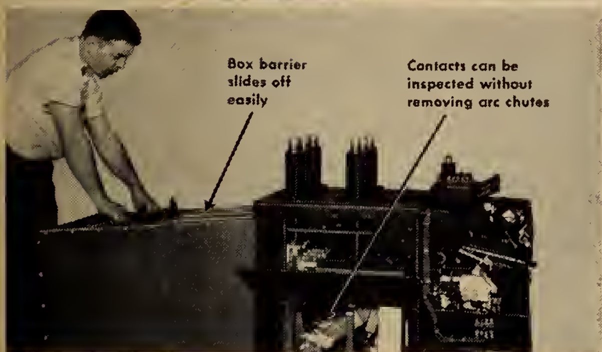
The G-E magne-blast principle of arc interruption has been proved by years of heavy duty operation in utility reclosing feeder service, high capacity motor starting applications, arc furnace control, and tough capacitor switching jobs. ALL THREE PHASES are switched simultaneously—eliminating any possibility of "single phasing" the load due to switching. Booster cylinders provide quick low current interruption—magne-blast blowout coils assure super-fast high-current interruption.



Seldom needs maintenance

2

Most causes for maintenance have been eliminated or reduced in G-E magne-blast breakers. Products of arc interruption cannot fall on the contacts because the arc chute is located *horizontally to the rear* of contacts. Box barrier, which is not open at top, helps protect arc chutes. Operating mechanism is protected by steel cover. Interrupting characteristics of arc chutes actually improve with age. The arc is magnetically stretched to extinction in AIR—eliminating oil maintenance problems.



Easy to inspect

3

All parts of G-E magne-blast breakers are readily accessible for inspection and maintenance. Contacts can be inspected *without removing arc chutes*. Lightweight box barrier *slides off* for easy inspection of arc chutes. Operating mechanism is located outside and in front of breaker—can be reached without removing breaker from housing. Although normal G-E recommendations are for inspection and maintenance once a year, many users find inspection every two or three years is adequate for their needs.

Designed for greater safety

4

Low center of gravity of G-E breakers makes them practically impossible to tip over accidentally—reducing this common hazard of breaker handling. Compare the low center of gravity (at left) with that of any other breaker on the market. And for greater operating safety—service-proved Self-X insulation, which will not support combustion, provides better *built-in fire protection* for breakers in case of trouble. ment, working at Shawinigan Falls, Que.

Mr. Pittuck is a 1951 graduate of McGill University with a civil engineering degree.

George Bird, JR.E.I.C., formerly of Regina, Sask., has been transferred to Toronto by the Canadian Bitumuls Company. With the company since 1951, he was named district manager of the Prairie Provinces district in 1954.

He is a 1949 graduate in civil engineering from the University of Toronto.

George R. W. Bliss, JR.E.I.C., who graduated from the University of New Brunswick, class of 1954, in civil engineering, now works for the New Brunswick Electric Power Commission design department in Fredericton.

Paul Vilim, JR.E.I.C., has joined the staff of the Atomic Energy of Canada, Ltd., in the engineering services division, at Chalk River. He is a graduate of the University of Manitoba in mechanical engineering, class of 1953, and has been employed by the Hydro Electric Power Commission of Ontario, in the R. L. Hearn generating station at Toronto.

William Yukish, JR.E.I.C., has accepted a position with the Foundation Company of Canada, project department, in Montreal.

In 1953 he was with the general engineering department of International Petroleum Company in Talara, Peru; and has also been associated with McKay and Cocker Construction Ltd., in London, Ont.

Mr. Yukish is a 1950 graduate in civil engineering from the University of Toronto.

John Q. Davidson, JR.E.I.C., is with Fraser Companies Ltd., New Castle, N.B.

Previously with the firm at Edmundston, he is a graduate of the University of New Brunswick, class of '53.

H. T. Abbott, JR.E.I.C., has joined Brunswick Balke Collender Company in Toronto, as a plastics engineer.

Project engineer with General Motors Diesel Ltd., in London, Ont., in 1955, he is a graduate of the University of Manitoba where he graduated with a B.Sc. degree in electrical engineering in 1950.

W. G. Dolman, JR.E.I.C., is with the Fort William Hydro Electric Commission, Fort William, Ont.

He was formerly city engineer at Selkirk, Man., and Fort Francis, Ont., and holds a B.Sc. degree in electrical engineering. Mr. Dolman graduated from the University of Manitoba, class of 1950.

G. A. Patterson, JR.E.I.C., is resident engineer with the Bailey Meter Company Limited, in Regina, Sask.

A graduate of the University of Saskatchewan, class of 1948, with a B.Sc. degree in mechanical engineering, he spent a year instructing at the university. In 1950, he joined the Bailey Meter Company Limited, and has worked as sales service engineer in Regina and Winnipeg.

"SIPOREX"*

PARTITION WALLS

fire-proof — a sound barrier — economical

Reinforced "SIPOREX" panels of various thicknesses and lengths are ideally suited for interior partitions. These precast, cellular concrete panels permit rapid construction and their dimensional accuracy permits the use of paint or thin plaster finishes. "SIPOREX" partition walls are vermin-proof, rot-proof, fireproof and provide a highly effective sound barrier. Complete information is available from any of the offices of SIPOREX LIMITED.

Left: square edge panels ready for plastering.

Right: chamfered edge panels requiring only painting.

Registered trade mark of Dominion Tar & Chemical Co. Ltd. denoting their autoclaved, lightweight cellular concrete.

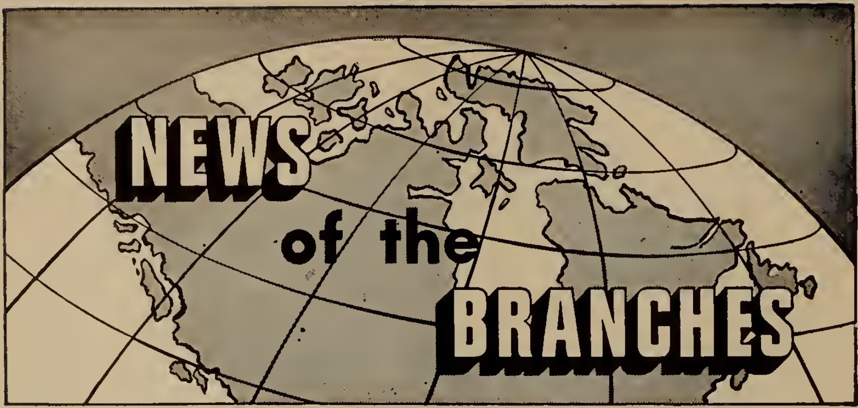
Charles R. MacFadyen, S.E.I.C., a 1955 graduate in civil engineering from the University of Saskatchewan is with the Bell Telephone Company at Dawson Creek, B.C., where he is working in the company's special contracts division.

W. J. Brice, S.E.I.C., 1955 graduate from the University of Saskatchewan, with a B.Sc. degree in mechanical engineering, is working for Schlumberger Wells Surveying Corporation, Virden, Man.

Correction
W. G. Mitchell, M.E.I.C.

In the March issue of the *Journal* it was erroneously stated that Mr. W. G. Mitchell was once professionally associated with Dominion Bridge Company. The *Journal* wishes to convey the fact that he joined the Canadian Bridge Company in 1929 and has remained with the company.



Activities of the Forty-seven Branches of the Institute

and

abstracts of papers presented at their meetings

Belleville

J. A. Grant, M.E.I.C.,
Secretary-Treasurer

Annual Meeting

The annual meeting of the Belleville Branch was held on April 9, 1956, at the Masonic Temple and 24 members attended.

The chairman called on the secretary-treasurer to read the minutes of the previous annual meeting which was held on April 18, 1955. It was moved by C. R. Whittemore and seconded by G. A. M. Bradford that the minutes be adopted as read.

Year Is Reviewed

Mr. Lusk then outlined the activities of the past year including such subjects as the Business Administration Course just completed, the B.C.I.V.S. and Quinte High School scholarships, the Branch Newsletter, the President's visit to Peterborough which was attended by several Belleville members and their wives, the Committee on Confederation and the Committee on the Admittance of Science Graduates. He outlined the purposes of the Engineering Institute of Canada and recommended that members keep these in mind.

The membership and financial reports were presented by the secretary-treasurer. It was moved by S. Sillitoe and seconded by G. B. Thompson that the reports be accepted.

The possibility of visits to the General Motors Plant at Oshawa and the St. Lawrence Power Project were discussed. The meeting was advised by Mr. Downman that due to the recent strike, plant tours of the General Motors Plant would not be possible until well on into the summer. It was recommended by Mr. Lusk that a visit to the St. Lawrence Power Project be deferred until the fall at which time the work would be advanced to the stage where a tour would be of greatest interest.

The possibility of changing the meeting time from 8.00 to 8.30 was discussed and it was decided that the present meeting time of 8.00 p.m. was preferable. C. R. Whittemore of Deloro pointed out the current shortage of engineers and urged that all members encourage high school students to enter the engineering field whenever the opportunity arose.

New Officers

The slate of officers for the coming year was presented by the chairman on behalf of the Nominating Committee as follows: A. D. Janitsch, chairman; J. A. Grant, vice-chairman; W. C. Benger, T. J. McQuaid and W. L. Canniff, committee members for a two-year term; A. E. Argue, E. Flinn and B. H. Downman, committee members completing a two-year term.

After calling for nominations from the floor, it was moved by G. A. M. Bradford and seconded by G. B. Thompson that the nominations for chairman be closed. The motion was carried and A. D. Janitsch was declared chairman by acclamation.

It was moved by W. C. Benger and seconded by B. H. C. Downman that nominations be closed for office of vice-chairman. The motion was carried and J. A. Grant elected vice-chairman.

It was moved by W. Sweet and seconded by S. Sillitoe that nominations for the three 1st-year committee members be closed. The motion was carried and Messrs. Benger, McQuaid and Canniff declared elected by acclamation.

The new officers were installed and the chairman, Mr. Janitsch, expressed his thanks for the confidence placed in him by the Belleville Branch. Mr. Janitsch advised that a new secretary-treasurer would be appointed by the new executive committee as soon as possible to replace J. A. Grant who now becomes vice-chairman.

Pipeline Film

A film was shown on the fabrication and laying of the pipeline between England and France during World War II for the supply of oil fuel to the invading forces.

The meeting was adjourned at 9.30 p.m.

Students' and Juniors' Papers Night

Three papers were presented at the annual Students' and Juniors' Papers Night by W. A. Pieczonka, J. H. Westaway, and W. A. H. Filer.

At a luncheon at Wallaceburg, Ont., on March 8, 1956, left to right, seated, William Joyce of the Wallaceburg Brass Company and Wallaceburg Singer Ltd., and J. S. Bulmer, of Dominion Die Casting Ltd.; standing, J. L. Fraser, of the Wallaceburg Brass Company; N. J. Southern, of Dura Chrome Ltd., H. B. R. Craig, consulting engineer, and L. F. Grant, Institute field secretary.

• Branch News

Nuclear Propulsion

Mr. Pieczonka addressed the meeting on "Nuclear Propulsion", as it applied to aircraft. He described three methods used, showing the superiority of the turbojet over the turboprop and the ramjet. The greatest advantage in design is long range, while the biggest disadvantage is shielding the reactor. In a mathematical study to determine the power requirements of a bomber similar to the B-47, it is necessary first to know the size of the reactor. From this, the amount of radiation may be calculated to determine the amount of shielding required. In this case it was found that 64 tons of lead would be needed.

Other problems connected with nuclear powered aircraft are those of structural and landing changes due to increased weight, radiation dangers in the event of a crash, and difficulty in controlling the reactor. These are offset, on the other hand, by extreme long range, low operating cost, and high altitude possibilities.

Mr. Pieczonka mentioned the fact that two submarines using nuclear propulsion have been built, and that the application of nuclear propulsion to locomotives is quite likely. The need here, however, is for a more efficient unit, he said.

Installing a Vertical Generator

J. H. Westaway presented the second paper on "The Installation of a Vertical Generator", in which he pointed out that there are two main types of vertical waterwheel generators: the conventional type with the thrust bearings above the rotor, and the umbrella type with the bearings below the rotor.

He then described the method of levelling the low bracket with a precision level. By using wire attached to a heavy weight suspended in oil, the parts are plumbed; the stator is then positioned; and sometimes the laminated core is stacked in the field. An experienced crew then winds the stator in the field, and the rotor, consisting of shaft, spider and rim, is then assembled. The poles are attached to the rim, and the stator is made ready to receive the rotor. The brakes that stop the rotor also serve as jacks. As the rotor is being lowered, the stator is protected by wood blocks held by a number of men.

Most waterwheel generators use Kingsbury type thrust bearings in which a wedge of oil above the pivoted shoe supports the load. There are various methods for loading the shoes equally: strain gauges may be used, and the average difference between load and no load may be measured with a dial gauge at several points.

After the shaft is checked for runout, the remaining components, such as the guide bearings, exciter, collector rings, and air coolers are assembled. The generator is then checked to prove that it is mechanically sound by driving it without electrical connections. To dry out the stator, the main leads are shorted, and the generator is run with the temperature controlled by varying the field current. Stator windings are tested with a voltage of 20,000 applied to each phase for one minute.

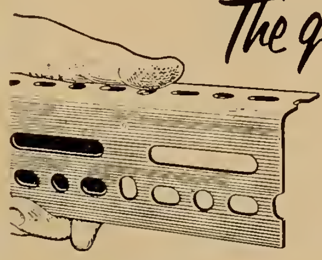
Mr. Westaway concluded his talk by summing up the advances made in waterwheel generator design through the years.

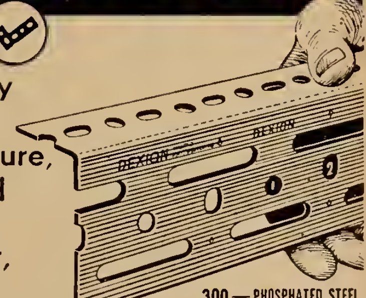
Why Professional Development?

W. A. H. Filer presented the third paper on "Why Professional Development?". He approached his subject by asking how much an employer could buy with $250,000, which is the amount paid to an engineer during his 30 years of service. This question pointed to the fact that the best way to ensure an employer a good return on his investment is the training of the young engineer.

Professional Development programs have been initiated because of the recognized need for post-graduate training of engineers, Mr. Filer said. Two spheres of influence affecting the engineer are those of industry and engineering societies.

Engineering societies do their part in assisting the young engineer to develop into a well-rounded professional man.





• Branch News

The Engineering Council for Professional Development, sponsored by engineering groups in Canada and the United States, studied the problems confronting the young engineer and issued the Monteith Report in 1950. This Report indicated that industry should contribute to the engineer's technical training, orientating him in industry, in his profession, and in community affairs.

The United States has in operation only one Professional Development course at the University of Cincinnati. Canada, under the sponsorship of the Engineering Institute, has in operation as many as 20 programs. That which is in progress in Hamilton was begun in 1951.

Professional Development is based on a liberal education. Flexibility is the keynote of the Hamilton program which is planned for the 150 members of the group, the directorate suggesting the basic outline only.

While technical competence is necessary, said Mr. Filer, it is not a sufficient condition in itself for becoming a professional engineer.

When the judges of the papers, H. E. Archibald, F. E. Milne, and W. Whetan, adjourned to make their decision, Chairman J. J. Kelly welcomed to the meeting the pre-engineering students of McMaster University. Prizes were afterwards presented as follows: J. H. Westaway, first; W. A. Pieczonka, second; and W. A. H. Filer, third.

A.I.E.E.-E.I.C. Joint Meeting

The Hamilton Branch has over a period of years shared a joint meeting annually with the Hamilton Section of the American Institute of Electrical Engineers. This year's meeting, held on April 5, 1956, in the Westinghouse Auditorium, included also the Toronto Section of the A.I.E.E.

Dr. J. A. Hutcheson Is Speaker

J. P. Skillen, chairman of the Hamilton Section, A.I.E.E. as chairman for the evening, asked J. J. Kelly, Hamilton Branch E.I.C., chairman and Professor G. F. Tracey of the Toronto Section of the A.I.E.E. to make announcements for their respective groups. He called on J. W. Kerr of Canadian Westinghouse to introduce the speaker, Dr. J. A. Hutcheson.

Lethbridge

R. D. Hall,
Secretary-Treasurer

Visit To Great Falls, Montana

On April 21, a joint meeting was held with the North Central Branch, Montana Section of the American Society of Civil Engineers. Approximately 40 members of the Branch and their wives joined the Montana Section A.S.C.E. for a combined field trip to the Malmstrom Airforce Base and tour of storm sewer installations. This was followed by a dinner meeting and dance at the Meadowlark Country Club, Great Falls.

Mayor Conklin Greets Guests

Registration was held from 12.30 to 1.30 p.m., after which Mayor Russel Conklin welcomed the Canadian visitors and delegates from other parts of Montana. Delegates were then briefed by Harry A. Balmer on construction in progress at the base and on the layout and operation of this large field.

During the tour of the base, the guests toured a large cold storage plant, permanent type masonry barracks buildings and a theatre, all under construction. Next they toured some portions of the city's 5 million-dollar storm sewer and paving projects. Upon returning to the Country Club, W. Wendland, chief resident engineer for Hoskins and Associates, consulting engineers for the city, explained details of the multi-million dollar projects.

At 6.30 p.m. the ladies joined the group for a "get acquainted" social hour.

Dr. E. W. Shilling Is Speaker

Dr. E. W. Shilling, Dean of the College of Engineering at Montana State College, Bozeman, was the featured speaker at the banquet. The title of his address was "Engineering Yesterday, Today and Tomorrow". Leyland J.

• Branch News

Walker was chairman of the meeting and A. A. Van Teylingen of Havre, was the toastmaster.

Engineer Training Trends

Dr. Shilling stated that the engineering curriculum has improved and is constantly improving. He cited examples of early engineering courses in shop and foundry work, pattern and machine shop training and detailed draughting. He suggested that the most important lesson learned from such training was that when someone was needed to do this work, a tradesman and not an engineer should be employed.

The modern curriculum places less emphasis on detailed draughting and shop work and more on blueprint reading. English and the other humanities courses are receiving more attention. Dr. Shilling stated that many graduate engineers do not know enough English to write their reports. Courses formerly only taught in post graduate work are now being taught to undergraduates and courses are becoming more technical. More stress on mathematics is needed to enable high school graduates to enter schools of engineering.

Extended Courses

For the future Dr. Shilling predicted a five-year course for engineers, and further specialization. This will lead to more graduate work, research and development. Since many are fathers upon graduation, Dr. Shilling cautioned against prolonging courses to the extent that graduates will be grandfathers.

Following the banquet, a very enjoyable dance was held in the Meadowlark Country Club.

J. A. Haberman, chairman of the Lethbridge Branch headed the Canadian delegation. Leyland Walker and E. J. Axllne of Great Falls were in charge of arrangements for the American Society of Civil Engineers.

Mr. Kerr related that Dr. Hutcheson's interest in electrical work was evident at 18 years of age when he operated his own radio repair shop. This business was so successful that he was able to help himself through college. In 1926 he entered the student training program of Westinghouse Electric Corporation, specializing in radio engineering. He was appointed manager of radio engineering in 1940 and three years later became assistant director of the Westinghouse Research Laboratories. In this capacity he attended the atomic bomb tests at Bikini as a civilian observer. Dr. Hutcheson became director in 1948 and the next year, vice-president of the Laboratories. He has been vice-president in charge of engineering of the Westinghouse Electric Corporation in Pittsburg since 1955, and was therefore able to speak with authority on the subject of "Research in the Electrical Industry".

Early Experiments

Dr. Hutcheson traced the development of the electrical industry from the early experiments in 1799 of Galvani, the biologist, who experimented with frog's muscles and by means of the leyden jar found what is now known as electricity. During the period 1800 to 1830 such great scientists as Volta, Ohm, Ampere and Faraday discovered the fundamentals which form the basis of electricity. These men did research but, in many instances, they did nothing to apply this knowledge.

Through the fifty-year period, 1830 to 1880, the inventors were busy applying the fundamental concepts of the scientists. The inventor was described as a "lazy engineer" since he was interested in applying the fundamentals with the least amount of effort. Motors, batteries and electric locomotives were some of the manifestations of the inventor's work. The first electric lamp was produced in 1878.

The third significant step in the development of this industry was the advent of the promoters, business men who were desirous of setting up companies to produce electricity first and then electrical products. Electricity for lighting was the first application of this new phenomenon which introduced the difficulty of transmitting direct current profitably. So it was that alternating current came into being with the necessity for transformers. This history forms the background which clearly indicates the prime importance of research.

Research Laboratories

Research is essentially the process of lowering the degree of empiricism by producing new scientific knowledge. The

Improved Ethylene production

offered by Canadian Kellogg

Pyrolysis process gives better yields and higher selectivity whatever the feed stock

PROVED HIGH ON-STREAM EFFICIENCY AVERAGES 95%

Ethylene demands are exceeding the limits of the existing supply produced by simple recovery from refinery gases. The engineers and contractors of one of Canada's first conventional type ethylene recovery plants, Canadian Kellogg, now offer a unique process for the manufacture of ethylene that holds many advantages over conventional systems and guarantees optimum yields and purity from economically-available feed stocks. The key is the steam-pyrolysis process developed by Kellogg and used with great success in England and on the Continent. The results of this process have been marked by excellent yields of high purity olefins, generally higher than can be obtained by conventional cracking. Equally important is the remarkable, high on-stream efficiency which permits continuous plant operation at high conversions.

Canadian Kellogg invites interested firms to review the considerable cost data on ethylene manufacture, based on pilot plant and actual commercial production, that has been accumulated.

• Branch News

value of research is demonstrated in two common products. In 1909 a 60-watt light bulb cost $1.29 to produce. Today the cost is one-tenth, or 12.9c. At the same time the life of the bulb has been extended through research on the tungsten element. It was found that the evaporation of the tungsten caused the bulb to blacken. Instead of creating an absolute vacuum in the bulb, some air was left inside, thus reducing the evaporation. A second example is the steam turbine where the efficiency has doubled through a study of the action of the materials.

Research is being carried on today by universities and industrial laboratories. Initially the universities did all the research and the industrial laboratories applied it, but industry has come to realize that it must share the responsibility for research.

Fundamental and Applied Research

The Westinghouse Electric Corporation Laboratories employ about 650 people in Pittsburg. Forty per cent of the work is devoted to fundamental research, that is toward new knowledge which has no immediate application. Such was the nuclear research done in 1936 preparatory to the atomic bomb On the other hand the remaining effort is directed towards basic research which has more immediate uses. Such knowledge would pertain to magnetic, insulating and structural materials. In many instances research is carried out not for the prime purpose of finding new materials but rather to understand the existing materials better.

Competitive Atomic Power

On the subject of atomic power Dr. Hutcheson stated that atomic energy would be competitive with existing sources of power in ten years. As available supplies of coal and water powei are exhausted the world will be forced to turn to this form of energy.

There was a brief question and answer period after which F. E. Milne, past-chairman of the Hamilton Branch. expressed the sincere appreciation of the 300 men present for a most enjoyable and stimulating address.

Annual Members' Night

Thursday, April 5, the annual Members' Night was held at the Sudbury Granite Club. The first speaker to present a paper was Kelvin Sproule of the research department of International Nickel Company of Canada Limited. His subject "Atomic Energy ABC".

Atomic Energy ABC

Mr. Sproule pointed out that atomic energy is fast becoming a major factor in both world affairs and in technology, and that it is the duty of engineers both as citizens and in their profession to obtain some understanding of it. As an aid to understanding the potentialities of the atom, the underlying theory of atomic power was viewed in simple terms.

Briefly, atomic energy involves splitting the nucleus of the atom in contrast to chemical energy where only the electrons are involved. In a nuclear reaction, one element changes into another with the conversion of a very small percentage of the matter into a very large amount of energy.

A brief outline was also given of the uses in industry, agriculture and medicine of radioactive isotopes. Examples mentioned were tracing the use pattern of phosphorus in plants, thickness gauges in the rolling of steel, and cancer treatment.

A New Mine

The second member to present a paper was George Charlap of Falconbridge Nickel Mines whose topic was "Some Problems Encountered in Starting up a New Mine".

Apart from the size, shape and depth of orebody at least partially determined by the geologists through diamond drilling, there are still the problems of financing, finding the best method of treating the ores, and deciding the

possible future demand for metals. When these have been decided upon, a working force consisting of a planning group, a field group and correlating or executive group are set up. The planning group tries to keep ahead of the field group with plans, while the correlating group plans the right job for the right time. The correlating group also looks after housing, medical accounting and purchasing. The planning and field groups in turn, are divided into such departments as geology, mining, mechanical, electrical and engineering.

Principal Requirements

Mr. Charlap then gave a summary of the principal requirements: access roads, location of headframe, yard elevation, supply of electrical power, temporary quarters close to but away from permanent buildings, type of temporary quarters, services, compressors, type of hoist and size of shaft. The depth of orebody fixes the location of crushing station and depth of shaft. Cables, shaft hardware, hoists, ventilation equipment and pumps are some of the items necessary to start a mine. A railway and mill to process the ore, have to be considered, also.

Mr. Charlap closed by saying, "With competent people, co-operation between the groups and a lot of hard work these "problems can be licked".

After an extensive question period on both papers Mr. Sproule and Mr. Charlap were thanked by Ted Fletcher.

Nuclear Radiation Detection

George Cowper of Atomic Energy of Canada Limited, Chalk River, spoke on "The Detection of Nuclear Radiation" at the Toronto Branch meeting of March 15. The topic is not a new one, but Mr. Cowper made it clear that detection is a very important phase of nuclear engineering. Accurate and reliable detection is essential if nuclear reactions are to be controlled safely.

Various Methods

Various methods of detection were discussed in considerable detail beginning with chemical analysis, which is relatively crude, and ending with scintillation counters which are capable of detecting extraordinarily small amounts of radiation.

Nuclear radiation possesses the definable characteristic that nuclei of radioactive materials are not stable, releasing charged particles and electromagnetic radiation. The change in chemical properties due to the breakdown of the nucleus in a radioactive element can be detected by the usual methods of micro-chemical analysis, and by the measurement of ionization either by electroscopes or by gas (geiger) counters.

Humble Mothball Is Used

Differentiating among the kinds of particles and radiation given off can best be done by scintillation counters and by cloud chambers. It was interesting to note that the humble mothball is used in scintillation counting.

Two points were emphasized by Mr. Cowper; first, the transistor will reduce the bulk of counting apparatus; and second, that the reliability of all components of the detection equipment must be beyond reproach.

For the uninitiated Mr. Cowper's talk was very interesting as it removed some of the mystery connected with nuclear phenomena, by putting the theoretical information on a practical basis.

Editor's Note:— Branch News Editor A. C. Davidson's "spring tonic" for the Journal staff was much appreciated. We hope he will not mind the liberties we take in publishing a part of his letter covering Toronto news this month and in sharing with others his enviable good humour:

. . . You will probably recall that Robert Benchley was once asked to write a thesis on the economics of a certain fisheries treaty which he did from the standpoint of the fish, much to the consternation of the professor who was examining him. I have been sorely tempted to write the visit to

Westeel Hollow Metal Doors and Door Frames cannot warp, swell, stick, splinter or get out of plumb. Speed and ease of installation save hours of costly labour. Every frame is custom-built to your specified size . . . every door is tailor-made to fit its frame. Both are flawless in finish. Both are products of Canada's largest all-Canadian fabricator of architectural metal products.

PRODUCTS LIMITED

MONTREAL • TORONTO • WINNIPEG • REGINA • SASKATOON • CALGARY • EDMONTON • VANCOUVER — Sales Offices also at: HALIFAX • QUEBEC • OTTAWA the Hydro steam plant from the standpoint of two lumps of coal.

However I have fought back the temptation as it might offend the sensibilities of our more staid members. The draft is appended (draft in the sense of a written brief and not in the sense of air for combustion) for your delectation and exhilaration. This will do as a spring tonic as I know your labours, like those of the rest of us, do become burdensome at times. . . .

The following is probably the result of the reincarnation of the Muse of Poetry roosting on my television mast overnight during a recent flight of wild fowl northward in the Spring migration.

Therefore, in blank verse after the manner of W. Shakespeare:

Scene I

Enter two lumps of coal on a moving belt.

1st Lump:

Hola comrade!
We meet again
Far from Pluto's regions.

2nd lump:

Aye, 'tis on a mission of great import
That we go into the outer world.
Word comes to dark Erebus' dominions
Telling that some witless wight
Is cold because his electric
Blanket is wattless.
We are to give up our energy
In one brief flash so that
He may be warm'd.

1st Lump:

Hold! Crowd not upon me so!
'Tis dark here in this great cavern.
Our friends press down upon
Us and all is gloom;
Slowly we descend
Into the bowels of some great machine
Which roars and rends,
Shaking us till our very molecules
Rattle apart.
Up we go again
Wafted on by some hot hurricane
Which carries us to a doom
Like that of the three
Who defied the great King of Babylon;
Were roasted yet did not die.
We, too, will burn but
Yet will live, yea,
We change to other form
And slowly sink to a place
From which none do return.
Farewell!

Exeunt two well sintered clinkers.

Scene II

(This could be a bit of byplay between two drops of water as they pass through the Rankine cycle, but I feel the Muse has a clearance from flight control and is off to Churchill, Man. and points North.

This might even inspire a recitative aria between two singers: a coloratura soprano and a basso profundo, the one representing the passage of steam through the nozzles at the high pressure end of the turbine, and the other, the ponderous rumblings of the generator. But this is beyond me: the blank verse effort preceding, and not very well metred at that, is about all I can manage.)

Generating Station Tour

The meeting of April 5 took the form of a plant visit to the Richard L. Hearn Generating Station on the Toronto waterfront. Plant visits are always a popular feature of the Toronto Branch meeting schedule, and this one was no exception as there were at least 150 members in the tour. The Ontario Hydro arranged the tour with one guide for every ten sightseers, and supplied coffee and doughnuts at the end of the two-hour trip. The small parties together with the congenial guides made the visit a memorable one.

Steam generating plants have been thought of by Canadian engineers as standby equipment for emergencies when hydro electric equipment breaks down. It was brought forcefully home that the generators of the Hearn station were supplying a deficiency of hydro generating equipment. On the night of this visit two machines were supplying load, a third standing by, while the fourth was stripped for repairs and inspection.

Fourth Machine Stripped

The fact that the fourth unit was taken down made the visit even more interesting as it was possible to examine the construction of boiler, turbine, generator and auxiliary equipment in detail.

The whole plant represents the latest thinking in the field of heat power engineering and shows that the professional engineers in charge of the operation are alert to trends and forward looking in all that they do.

Quoting statistics of the plant equipment or even saying that the plant is big conveys little or nothing to the reader; a visit is probably the most convincing way to demonstrate such facts. The most important point to be emphasized is that the engineers here are wringing the last available bit of energy from a lump of coal and that very soon, much sooner than anyone expects, other means of obtaining energy will have to be employed.

The thanks of all who went on the trip are extended to those in the Toronto Branch who arranged the trip and to those in the Ontario Hydro who acted as guides and answered questions.

Students' Night

The Vancouver Branch annual Students' Night dinner meeting was held in the University of B.C. Faculty Club dining room on Tuesday, March 13, 1956. Approximately 80 members and students attended with each student sponsored by a member of the Branch.

The program featured a short talk by H. N. (Dutch) McPherson entitled "Fun out of Living", followed by a competition in the form of three short presentations from the top student speakers

Participants in Students Night of the Vancouver Branch. Above, H. N. "Dutch" McPherson, and left to right: Bill Taylor, John Duerksen, and Joe West.

3M COMPANY ADHESIVES

Did you know that "3M" has developed over 1,000 adhesives for specialized applications?

These "3M" adhesives have revolutionized production methods in almost every industry. Expensive drilling and tapping operations and costly fastenings have been superseded . . . and a better product assembled in less time.

PLASTIC GARDEN HOSE

Did you know that after 25,000 motor vehicles of all sizes had run over a length of 3M's "IRV-O-LITE" Brand Hose it was still as good as new?

Tougher, higher grade plastics extruded with extra care produce a hose that stands up to the destructive effects of weather and handling. Heavier gauge fittings add extra assurance of durability.

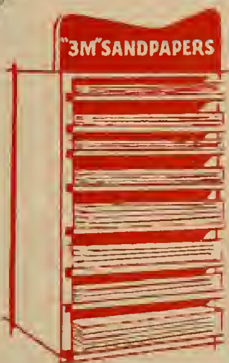
PRODUCTS OF 3M RESEARCH

SCOTCH BRAND SOUND RECORDING TAPE

Did you know that you can now put one and a half hours of recordings on a seven-inch reel of "SCOTCH" Brand Magnetic Tape?

With the world's greatest tape-research organization developing new techniques and materials, "3M" maintains a clear lead in the field of sound recording tapes.

3M COMPANY "DO-IT-YOURSELF" ABRASIVES



Did you know that "3M" uses 5 different minerals, 4 types of backings and 5 kinds of bonding materials in the manufacture of its sandpaper?

In hardware stores across Canada you'll see in operation a plan to help retailer and customer get more out of abrasives . . . easier selection of the right grade of top quality sandpapers for the home handyman.

Other "3M" contributions to industry are "SCOTCHLITE" Brand Reflective Materials, "SCOTCHRAP" Brand Pipe Insulation and "SCOTCH" Brand Pressure-Sensitive Tapes for every requirement.

selected at the noon hour seminar meetings of the University Student Branch. The latter talks, organized along the lines of a toastmaster's meeting with the Student Branch Vice-Chairman Bill Taylor in the chair, were light and amusing. Joe West gave an amusing dissertation on "The Egg", John Duerksen parodied his favourite game, "Golf", and Bev Campbell described the fictitious agricultural industry of "Macaroni Farming".

Mr. McPherson was introduced by Wilf Heslop, Branch executive member. Bill Millar, Cliff Day and Craig Clark introduced the three student speakers. Fred Shrack of the Students' Branch thanked Mr. McPherson while Larry Hunt, Shigeo Saimoto and Art Kempe acknowledged the student talks.

Prize Winners

At the conclusion of the meeting, Judges Wilf Heslop, Ron Wilkins and Pete Fratinger announced the winners of the competition, first prize going to John Duerksen, second to Joe West and third to Bev Campbell. Cheques were presented to each of the student speakers and a further presentation of Student Membership Pins was made to each of the Student Branch officers; Eskil Johnson, Bill Taylor, Murray MacKenzie, Dave Haig and Rod Haefer.

Winnipeg Electrical Section

G. L. MacDonald, M.E.I.C.,
News Editor

University Plays Host

The University of Manitoba played host to the Electrical Section for its February Meeting.

The Section toured the engineering buildings and laboratories and saw a demonstration of an impulse generator, assembled in the laboratory, with cascaded rectifiers producing about 100,000 volts.

J. P. C. McMath Department Chairman

The University made two announcements of interest to electrical engineers and to industry in Western Canada. Dean A. E. MacDonald, of the Electrical Department, announced the appointment of Prof. J. P. C. McMath, as chairman of the Electrical Engineering Department, at the university.

Prof. McMath then announced plans for the building of a high voltage testing laboratory for the University. A new building is being built to house this laboratory, and it is expected that it will be finished late this year and equipment installed and ready to operate sometime in 1957.

High Voltage Testing Bay

The building will include a high voltage testing bay, 60 ft. long by 36 ft. wide by 38 ft. high, to house the high voltage impulse generator and provide space and clearance for the testing of heavy power apparatus. The clearances provided in the test bay will permit the testing of large apparatus to about 2,500,000 volts, and the impulse generator will be capable of producing this voltage.

Testing Equipment

In addition to the impulse generator, equipment will be provided for steady state d.c. testing to about 440 kilovolts and 50 milliamps., and also a.c. testing to 250 kilovolts, 60 cycle, with about 250 kva. capacity.

A section of the laboratory will be occupied by staff of the Canadian Standards Association for approval work, chiefly on electrical apparatus built in Manitoba, or imported electrical equipment not C.S.A. approved elsewhere.

It is expected that the facilities provided by this high voltage testing laboratory will be unique in Canada at the present time, and will provide a very valuable means for training and research at the university, and for the electrical industry in Western Canada.

D. B. Brandt Guest Speaker

The Electrical Section held its March meeting in the Westinghouse Auditorium. D. B. Brandt, of the General Electric Company, Schenectady, addressed the meeting on the subject, "Planning for Simplified Relay Application". Mr. Brandt told the Section that the tremendous electric system growth facing the industry and the shortage of technical manpower will require a new approach to system relaying.

This can be achieved by the selection of an overall plan of protection for all system components, and the re-use of this plan whenever a similar component is added to the system. The plan should be flexible to accommodate new ideas, techniques and equipment. This plan will minimize application effort initially and provide the greatest flexibility in modification or additions to a system to meet load growth. Protective relaying could now be planned ahead because of advances in relaying equipment and methods, and because of better co-ordination between system planning and relay engineering.

Advances in Relay Components

Advances in relaying components have been made along the lines of increased speed, improved selectivity and greater freedom from the effect of current transformer errors. The advances have resulted from increased knowledge of the characteristics of system disturbances and system components, and improved relay design and construction. With increased knowledge of the characteristics of system disturbances, it has been possible to devise relaying equipment that is capable of distinguishing between one or more unique characteristics of each type of disturbance. Transformer differential relays, for example, may be provided with harmonic restraint to prevent operation from magnetizing inrush by using harmonics in the magnetizing current. Generator differential relays are provided with means to prevent false operation resulting from transient current transformer ratio errors during external faults.

A variable per cent slope characteristic is employed which retains the desired sensitivity under full load conditions, but which provides a rapidly increasing percentage restraint for increasing external fault current magnitudes. This increasing restraint characteristic is put under directional control, restraint being permitted to exist only when the fault current flows from the generator into the system. This overcomes the hazard of failure to operate when the system supplies high current to a generator fault. This feature is known as product restraint.

High Speed Voltage Relay

The development of a high speed voltage relay has greatly simplified bus differential relaying using bushing current transformers. Directional comparison relaying for transmission lines, using carrier current pilot or micro wave pilot and distance relays, both phase and ground, for protection of sub-transmission lines, are well suited for standardization.

Standard Relay

An example of standardized relay application was discussed for a unit type generating station, where the generator, main power transformer and station service transformer are solidly connected, and the station expands by adding additional units. In this case, the generator is protected by product restraint differential relays. The main power transformer and the station service transformer are protected by harmonic restraint percentage differential relays, and the station service transformer zone includes the low side circuit breaker. The high voltage switchgear and station service low voltage switchgear have differential protection, in the former using bushing current transformers, and in the latter, current transformers in the metal-clad switchgear.

Proper Relay Selection

A plan for selecting proper relays will bring about better electrical service at a reduced cost because the expensive system studies and relay readjustment to obtain adequate protection are reduced. Each utility should establish what is considered the proper standard relays for all components of the electrical system. These relays should reflect the best practice of the day and should be kept up to date as new relays and new methods are evolved.

BOOK REVIEW

Proceedings of the international conference on the peaceful uses of atomic energy, v.3, Power reactors. New York, United Nations, Toronto, Ryerson, 1956. 389pp., illus., $7.50 (U.S.).

The International Conference on the Peaceful Uses of Atomic Energy held in Geneva in August 1955 was the first international meeting on the subject. Consequently, the information contained in the more than one thousand papers presented there, and the discussions the papers provoked, constitute the most important and up-to-date collection of material available.

The United Nations is publishing the complete text of the Proceedings in sixteen volumes. The first of these to appear, Volume III, is entitled Power Reactors. It contains thirty papers presented at Geneva, together with a verbatim record of the discussions which took place at the six sessions.

The first two sections, comprising five papers, deal with fuel cycles and experience to date with nuclear power plants, including a description of the 5,000 kw. nuclear power station which has been operating in the U.S.S.R. for over a year.

There are descriptions of the reactors for power production which were being designed when the conference took place, and of the power reactor prototypes which were in operation or under construction last August.

Four papers from France describe primarily gas-cooled reactors; the seven papers from the United States deal with a variety of reactors; the Dutch papers consider reactors designed to use suspension of radium particles as fuel; the Russian paper describes a boiling homogenous reactor, and there is also a description of the project for a fast breeder reactor to be built at Dounreay in Scotland.

Included in the volume is a catalogue of existing and planned nuclear reactors which was prepared especially for the Geneva Conference.

The other fifteen volumes to be published in this series will cover the world's energy requirements and the role of nuclear power; various aspects of reactor design; geology of uranium and thorium; the effects of radiation; radioactive isotopes, etc. These sixteen volumes will provide the most valuable reference work on atomic energy which is likely to appear for many years.

S. C.

BOOK NOTES*

Prepared by the Library
The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

***Aircraft gas turbines.** C. W. Smith. New York, Wiley, 1956. 448pp., diagrs., $8.75.

The aim of this book is to provide for engineers a well-rounded picture of the aircraft gas turbine power plant, with somewhat greater emphasis on the theoretical aspects than on mechanical and structural details. The Brayton and other gas turbine cycles, theory of flow in ducts, nozzles, and diffusers, and the design of components are fully treated. Selected problems of stresses, materials, performance, and installation are also discussed. The book contains sufficient aerodynamic and thermodynamic theory for full understanding of the contents without recourse to other texts.

The analytical theory of heat. Joseph Fourier. New York, Dover, 1955 [c.1878]. 466pp., $1.95.

This classic work covers radiant heat, cause and reflection of heat rays, communication between internal molecules, uniform and linear movement of heat, heating of closed spaces, movement of heat in a ring, solid sphere, solid prism, and solid cube, use of trigonometric series in the heat theory, and propagation of heat in an infinite rectangular solid, etc.

Boiler house and power station chemistry, 3rd ed. Wilfrid Francis. Toronto, Macmillan, 1955. 348pp., diagrs., $10.00.

The main object of this book is to provide an account of the chemical considerations involved in the combustion of coal and in the generation of electricity. In this edition, a description has been included of the properties and preparation of alternative fuels, with methods for the rapid calculation of combustion engineering data relating to them.

Besides the chapters dealing with these two main subjects there are sections on boiler availability, methods for the cleaning of boilers, and methods for the analysis of fly ash from boiler flues and passes.

The appendix includes conversion factors, abridged Callendar steam tables, and a comparison between standard sieves.

Book of ASTM standards, 1955, including tentatives. Philadelphia, American society for testing materials, 1955. 7v. $84.00 per set.

This is the largest book of standards to date, containing some 2,150 standard specifications, tests, and definitions for materials. Each of the seven parts covers a certain area or group of areas of materials, and standards of a general nature appear in several parts.

The division by volumes is as follows: ferrous metals; non-ferrous metals; cement, concrete, ceramics, thermal insulation, road materials, waterproofing and soils; paint, naval stores, wood cellulose, wax polishes, sandwich building constructions; fuels, petroleum, aromatic hydrocarbons, and engine antifreezes; electrical insulation, electronic materials, plastics and rubber; textiles, soap, water, paper, adhesives, and shipping containers.

Each part is complete with a detailed subject index and a list of standards in numerical order. To keep the book up to date, supplements to each part will be issued late in 1956 and 1957.

Champs de vecteurs et de tenseurs. Edmond Bauer. Paris, Masson, 1955. 204pp., 2200fr.

The author of this work, a physicist, has tried to present the subject of vectors and tensors in a way which will be useful to mathematicians as well as to those in his own field.

The first three chapters deal with basic principles, while following sections apply the established formulae to the subject of electromagnetism. Included are the fundamental electromagnetic laws of Coulomb, Ampere, Maxwell and Lorentz.

The constitutional diagrams of alloys: a bibliography, 2nd ed. J. L. Haughton and A. Prince. London, Institute of metals, 1956. 323pp., £1.15.0.

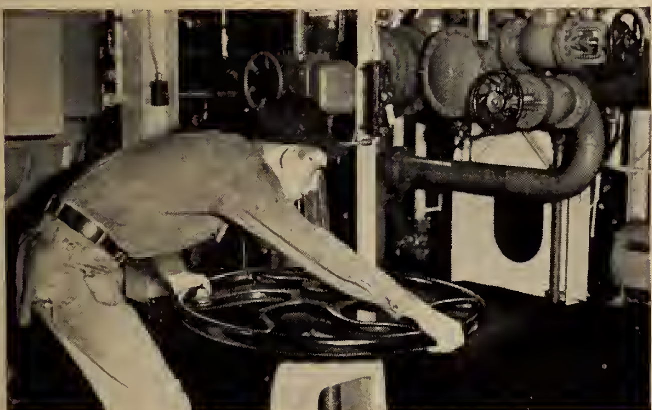
About twice as many references are found in this edition as in the first edition published in 1942 and all have been brought up-to-date.

The bibliography is divided into sections covering the binary, ternary, quinary and senary systems which are arranged in alphabetical order of the chemical symbols of the metals composing them. Under each system the references are listed in chronological order and the location of the abstract in the Institute's publications is noted. The bibliography also indicates whether the original article contained a new or revised constitutional diagram or a portion of one.

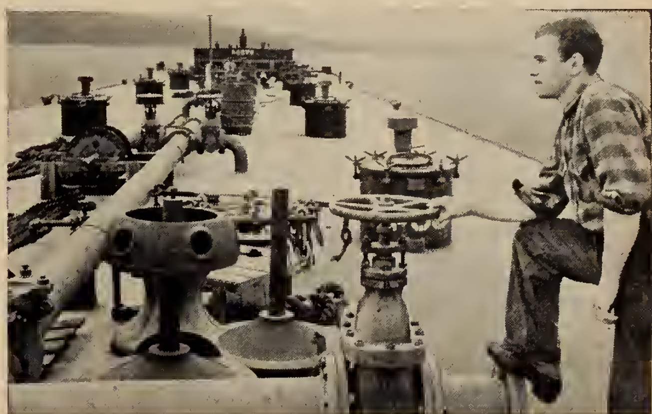
Push aplenty... but no control

Sails and rudder were not enough—only when steam power came could ships cope with the wind's will. And just as valves harnessed steam, they've been the means of steady progress at sea and of cities and industries. Today, they're basic tools for controlling all fluids—for power, processing, and utility services.

Making valves that do the job better has been Crane's main effort through years of adherence to quality manufacturing. Thrifty buyers know Crane quality for its greater dependability, durability, and lower maintenance costs in all piping services. That's why more Crane valves are used than any other make.



BIG SHIPS NEED BIG VALVES and they get them from Crane in the same wide selection as smaller sizes. The Crane Marine line is complete with valves and fittings precisely engineered and approved for piping service on all types of vessels—from small river boat to ocean liner. On water as on land, Crane quality stands for bigger value in piping equipment.



FLUID CARGOS HANDLED FASTER on barges and tankers under the safe control of Crane valves and fittings. Crane assures it—with steady refinement of design, controlled manufacturing, and complete testing. And Crane puts such quality into piping materials for every industry. See your Crane Catalogue—or your Crane Representative, Crane Branch or Wholesaler, or

***Construction planning, equipment and methods.** R. L. Peurifoy. Toronto, McGraw-Hill, 1956. 534 pp., illus., $10.20.

The purpose of this book is to show how the application of engineering fundamentals and methods of analysis can improve the quality of construction while at the same time reducing costs. The subjects covered include job planning, construction management, factors affecting equipment selection, and such fundamentals as soil compaction, the effect of altitude and temperature on engine performance, rolling resistance, etc. Considerable space is devoted to the performance, cost, and suitability of various kinds of equipment, and to drilling, tunneling, foundation grouting, and other procedures.

Diesel operation and fault diagnosis. G. B. Fox. Toronto, Nelson, Foster & Scott, 1955. 191pp., illus., $4.75.

The scope of this practical manual is wide, covering small single-cylinder units and automotive engines, as well as the larger types of diesels for marine and industrial uses. It is a detailed instruction book on the various components of the diesel engine and on the manner of diagnosing troubles.

After a brief history of the compression-ignition engine, there is a description of the fuel-injection system which includes comments on the various types of equipment now in use and their maintenance. This is followed by chapters on instrumentation, engine tuning, location of faults, pistons, rings and liners, bearings and lubrication, fuels, combustion, air compressors, starting devices, the log-book and overhauls, and supercharging methods. The last chapter describes a dozen current engines to illustrate the various classes of diesel.

Electrical measurements and measuring instruments, 4th ed. E. W. Golding. Toronto, Pitman, 1955. 913pp., illus., 40/–.

There have been many new developments in this field since the third edition of this book was published in 1950 and these have been incorporated into this new edition. Most important, perhaps, are the subjects of M.K.S. units and rationalization which are fully covered, although the author has continued to use the C.G.S. system.

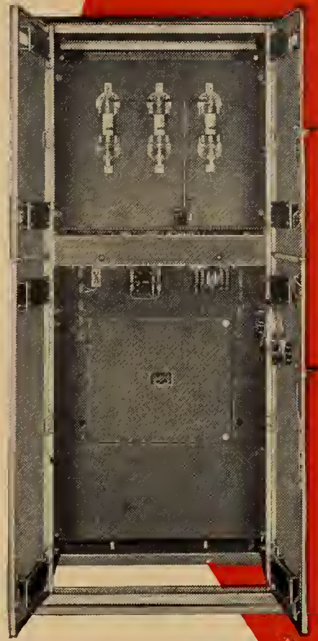
Because it is essentially a textbook the emphasis is on theory and principles but a number of worked examples have been given as illustrations. Among the subjects presented are circuit analysis, inductance, measurement of resistance, potentiometers, magnetic measurements, illumination, high-voltage measurements, wave-forms, transient phenomena, measuring instruments, the measurement of power and energy, and electronics and electronic measuring devices.

Electronic data processing for business and industry. R. G. Canning. New York, Wiley, 1956. 332pp., $7.00.

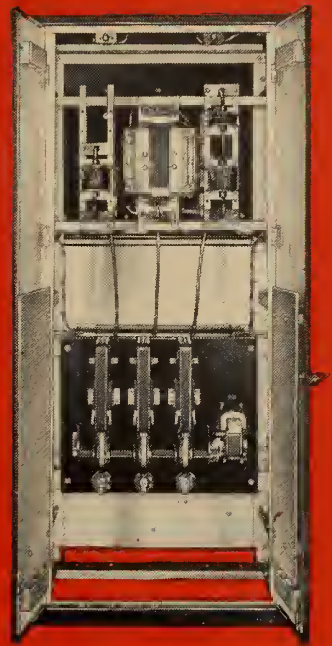
Many executives will welcome this comprehensive presentation of a most important subject. Perhaps its greatest value lies in the fact that no previous knowledge of the electronics field is

Improve protection and reduce maintenance costs with

HIGH VOLTAGE STARTERS



Front



Rear

High Voltage Starter with HRC Fuses ond Air-Breok Contactor.

HAVING THESE FEATURES:

1. **150,000 KVA INTERRUPTING CAPACITY, DISCONNECTING TYPE FUSES**
   These High Rupturing Capacity Current Limiting fuses will safely protect against short circuit conditions.

2. **FUSES HAVE SINGLE PHASE PREVENTIVE FEATURES**
   A striker pin on each fuse operotes on ouxiliary contoct in the control circuit of the main contoctor, thus completely disconnecting the motor from the line in the event of o fuse blowing. This same mechanism operates when the hook stick commences to pull the disconnect, thus ensuring that the disconnects cannot be opened under load.

3. **HEAVY DUTY AIR-BREAK CONTACTOR**
   Contacts operating in air have longer life, ore free from hazards ond dirt associated with ail.

4. **HEAVY GAUGE STEEL CUBICLE TYPE ENCLOSURE**
   Cases are standordized far grouping. There is provision for mounting main bus in tap comportment when desired.

If your floor space is limited . . .

necessary to understand the processing systems described.

The author first covers the basic operations of electronic computers and the method of instructing the machine to perform various operations. Specific applications in different types of industry are analyzed, and the appropriate electronic systems outlined.

A large part of the book is devoted to a study of the systems engineering approach to individual data processing problems. This explains how to determine the requirements of any firm then describes a method for laying out a suitable electronic system.

The connection between operations research and the various electronic systems is considered, and this chapter is followed by a description of available commercial electronic systems. The book concludes with a suggested plan of action for management to obtain a reliable system.

Encyclopédie technologique de l'industrie du caoutchouc, v.4 G. Génin and B. Morisson. Montreal, Fomac, 1956. 587pp., illus., $24.60.

The first two volumes of this series are still to be published but the third volume has appeared and covers the subject of rubber technology and its various uses. The present work discusses tires and inner tubes, and the direct uses of latex. The first section comprises eight chapters which deal with all phases of the manufacture of tires and tubes and their repair.

In the second part of the book various authors describe latex mixtures, the manufacture of such articles as latex gloves, sponge rubber, glue with latex base, the use of this material in the manufacture of paints and varnishes, the paper industry, elastic, artificial rubbers, and other pertinent subjects.

Entrepreneurs et entreprises. Paris, Moniteur des travaux publics, 1955. 202pp., illus., 2250 fr.

One of the main features of this elaborate history of some forty French construction firms is the illustrations and colour photographs. It is an interesting picture of the evolution of technology as well as of the lives, careers, and accomplishments of many famous members of the construction industry. The structures cited in the book include not only French landmarks and important public buildings but also those in other countries.

In addition to the history of each builder, there are articles by well-known authors on French building technique, the evolution of the construction industry, with its economic and social aspects, the role of the contractor in erecting civic buildings and historical monuments, the place of the contractor in the development of roads and railroads, and so on.

Factory electrification. F. T. Bartho and C. H. Pike. London, Macdonald, 1956. 398pp., illus., 35/-.

Those engineers concerned with the installation and maintenance of electrical plant will find this book of value. The authors discuss factory electrification in terms of principles, and describe representative types of equipment with their capabilities and limitations. The book does not cover special equipment such as welding plant and furnaces.

In detail, there is information on main distribution switchgear, power transformers, cables and wiring systems, a.c. induction and 3-phase commutator motors, d.c. motors, synchronous motors and power-factor improvement, and motor control gear. The last chapter provides a valuable survey of motor application.

***Fluid flow in practice.** J. R. Caddell, ed. New York, Reinhold, 1956. 119pp., illus, $3.00 (U.S.).

A concise treatment of selected aspects of the flow of fluids (including slurries) in pipelines and pumps, with some attention given to applications for gases. The volume is made up of six papers covering the following subjects: basic principles; planning piping systems; the selection of valves, pumps, and flow meters; operation and maintenance of equipment; and trends in research. This is the third volume in an "Experience in Industry" symposium series.

Function and training of the chemical engineer. Toronto, Ryerson, 1955. 85pp., $1.25.

This is a report of discussions heard at an international conference of chemical engineers held in London in 1955. The six sessions dealt with several aspects of chemical engineering, including the part played by the chemical engineer in bridging the gap between research and plant construction, his role in plant operation and management, educational courses in chemical engineering, and the practical training of the chemical engineer before and after entering industry.

***Fundamentals of press tool design.** W. F. Walker, New York, Philosophical Library, 1955. 152pp., diagrs., $4.75 (U.S.).

This book gives concise, practical information on the design of tools for over twenty different operations performed by the more commonly used types of press tools. The operations treated include blanking, piercing, clipping, shaving, matching, bending, drawing, cupping, etc., with variations of each operation illustrated by a series of drawings. Basic information on the construction and uses of the various types of tools is included, and the calculation of blank sizes and selection of tool materials are briefly considered.

***Fundamentals of transportation engineering.** R. G. Hennes and M. I. Ekse. Toronto, McGraw-Hill, 1955. 520pp., diagrs., $10.20.

Major sections of this survey of the civil engineering aspects of transportation are devoted to roads and pavements, and to airport, railroad, and river and coastal engineering; briefer sections deal with pipelines and belt conveyors. The book includes design and layout data, and planning and construction standards and procedures of value to both students and practicing engineers.

Geometry of four dimensions. H. P. Manning. New York, Dover, 1956 [1914]. 348pp., $1.95 (U.S.).

After a discussion on the history of fourth dimensions and on their foundations, the author goes on to perpendicular and simple angles, symmetry, order, motion, Euclidean geometry, figures with parallel elements, and regular polyhedroids, etc.

Handbook of drainage and construction products, 5th ed. W. H. Spindler, ed. Guelph, Armco drainage & metal products of Canada, 1955. 579pp., illus., $5.00.

The wide scope of this handbook includes chapters on strength research, strength design, durability studies, subsurface drainage, special drainage problems, and installation instructions. Each section is summarized at the beginning to save time in searching for information.

Numerous tables, diagrams and illustrations add to the value of the book. Students, as well as practicising engineers, will find it a useful tool.

Kempe's engineer's year-book for 1956, 61st ed. London, Morgan, 1956. 2v., illus., 75/-.

Since almost every engineer is well acquainted with the wide scope of this reference work, we need only mention the changes which appear in the 1956 edition. These include a new chapter on foundations and earthwork, the rewriting of the aerodynamics and aircraft propulsion sections, additions to the chapters on electrical and electronic engineering, gas and steam engineering, steam turbines, explosives, concrete, and depreciation.

Machinery's screw thread book, 16th ed. Brighton, Machinery publishing co., 1956. 224pp., diagrs.

This edition has been completely rewritten. It contains much more detailed information than previous editions, and is also completely up-to-date. The section on screw-thread measurement by the wire method is claimed to be the fullest account ever published. The present edition omits any coverage of gauge tolerances.

Among the types of screw threads included are British threads of Whitworth form, unified and American series, American translational and pipe threads, continental forms and series, and horological threads.

Nomography and empirical equations. D. S. Davis. New York, Reinhold, 1955. 236pp., $6.75.

The engineering applications of empirical equations and nomography are explained in this book, which describes the use of these tools to speed up calculations.

Part I deals with the development of empirical equations for two- and three-variable data and describes new techniques using trigonometric and hyperbolic functions and the modified Gompertz equation, as well as other devices for two-variable data. Simple methods for correlating three-variable data are included.

In the second section the theory and construction of several industrially important types of chart are described. Among these are addition charts, logarithmic, nonlogarithmic multiplication, recurrent variable, and line coordinate charts. The last chapter deals with graphical anamorphosis.

Office automation; integrated and electronic data processing. R. H. Brown. New York, Automation consultants, 1955. 283pp., loose leaf, illus., $12.50 (U.S.).

In non-technical terms this manual outlines the whole field of office automation. Written for business executives, government officials, students, and office workers on all levels, it gives the essentials of the subject with references to more detailed information elsewhere. Its scope includes the entire field of data processing.

The first section deals with the commercial aspects of office automation and this is followed by a description of the new tools and equipment in the field. The

• Library Notes

author explains how the new machines are used and what benefits can be derived from them. The sociological aspects of office automation are discussed, as well as such new scientific techniques as operations research, cybernetics, the information theory, and automatic programming. The last section covers some of the potential applications of electronics in the business field.

Personality and group relations in industry. M. P. Fogarty. Toronto, Longmans, Green, 1956. 341pp., $5.40.

Those interested in industrial relations will find this book useful background reading. In a rather unusual arrangement, its point of departure is the level of the single human personality, rather than that of the group. The author presents a psychological study of the personality and traces the changes which occur through life. He then progresses to a discussion of small, primary working groups, and includes several case histories.

In the last section of the book he deals with large working groups, studying them sociologically, economically and politically.

Practical metrology, vol. 2. K. J. Hume and G. H. Sharp. London, Macdonald, 1956. 71pp., diagrs., 7/6.

This is the second of four volumes which contain laboratory experiments in metrology with complete instructions on performing and recording them. The experiments in this book include the measurement of plug gauge, plate gauge, spur gear, pitch error of screw gauge, form and angle of plug screw gauge, the checking of a form gauge and a sine bar; and taking a cast of a small ring screw gauge.

Propagation des ondes dans les milieux périodiques. Léon Brillouin et Maurice Parodi. Paris, Masson, 1956. 347pp., diagrs., 4600 fr.

This work is based on an earlier book by Brillouin, entitled "Wave propagation in periodic structures", but contains new chapters bringing the material up-to-date.

A series of problems, ranging from electrical engineering to electromagnetism and wave mechanics of the spinning electron, are bound together by a common mathematical background. They all deal with periodic structures of various kinds, and they all lead to similar results. The general theory developed in the book also bears a close connection with many problems of applied mathematics such as the Mathieu functions and Mathieu's and Hill's equations.

Significance of tests and properties of concrete and concrete aggregates. Philadelphia, American society for testing materials, 1956. 393pp., $5.25 (U.S.) (ASTM special technical publication no. 169).

The subject matter in this new edition is divided into four general sections. The first includes papers on sampling, statistical considerations, evaluation, and needed research. The second deals with tests and properties of freshly-mixed concrete, hardened concrete, and special categories such as ready-mixed and lightweight concrete and aggregates. The papers in part 3 cover tests and properties of concrete aggregates, while the last group discuss other materials: water,

• Library Notes

curing materials, air entraining admixtures and mineral admixtures.

Standard specifications for highway materials and methods of sampling and testing, 7th ed. Washington, American association of state highway officials, 1955. 2v., $7.50 (U.S.).

In this edition specifications and test methods are published in separate volumes. There are 100 specifications, 45 of them revised, covering hydraulic cements, bituminous materials, soils, aggregates, brick, culvert and sewer pipe, bridge paints, reinforcing steel and wire rope, metallic materials for bridges, and miscellaneous materials. Whenever ASTM standards are identical with those of this Association, reference is given to the ASTM serial designation.

Part 2, on methods of sampling and testing, contains 140 methods covering the same divisions as in Part 1. There are some 60 methods added or revised since the previous edition was published in 1950.

Steel structures painting manual. Joseph Bigos, ed. Pittsburgh, Steel structures painting council, 1954-55. 2v., illus., $6.00 (U.S.) a vol.

The first volume of this manual, entitled Good Painting Practice, covers surface preparation and painting practice in various industries. The eighteen chapters are written by experts, and cover such topics as chemical surface preparation, painting of bridges, painting of steel vessels for salt and fresh water service, pipeline protection, etc.

The second volume, Systems and Specifications, contains specific recommendations for the painting of steel structures, supplementing the general recommendations found in volume I. The specifications, prepared by the Steel Structures Painting Council and having their designations, cover surface preparation, pre-treatment, paint application, paints and complete paint systems.

These volumes were prepared as part of the Council's efforts "to make more effective and more economical the protection of steel surfaces". The many illustrations and the clarity of the text will make the Manual valuable to all concerned in any way with the painting of steel structures.

Strength and elasticity of materials, v.4., part 2. W. H. Brooks, London, Macdonald, 1956. 464pp., 35/-.

This volume completes the series of solutions to London University engineering examination questions.

The solutions are grouped in sections, the subjects ranging from slope and deflection of beams, compound beams, stresses in curved bars, temperature stresses and strains, shearing stress distribution and thick cylinders, to three dimensional stress systems, periodic vibration of loading systems, and dynamic loading.

Tape recorders: how they work. C. G. Westcott. Indianapolis, Sams, 1956. 176pp., illus., $2.75.

All phases of tape recording, from the theory of magnetic recording to recommended procedures for testing recorders, are described in this book. There are chapters on the motorboard mechanisms, drive motors, volume indicators, bias oscillators, equalization circuits, and magnetic recording heads. The author explains how recorders operate, how to get the best frequency response with .owest noise level, how to avoid tape overload, and how to obtain best bias settings.

Théorie générale de l'équation de Mathieu. Robert Campbell. Paris, Masson, 1955. 272pp., diagrs., 2900 r.f

The object of the author in this work is to set forth Mathieu's equation in such a way that engineers and physicists will no longer find it a barrier in their calculations.

The first chapter deals with Mathieu functions and their characteristic equations. The next section describes functions of a secondary order, including those of Mathieu, Whittaker, and MacLachlan. The last chapter is concerned with the general theory of Mathieu's equation.

Thermal power from nuclear reactors. A. S. Thompson and O. E. Rodgers. New York, Wiley, 1956. 229pp., $7.25.

This book indicates the progress which has been made in the field of atomic energy for it deals with the practical problems faced by the mechanical engineer in designing nuclear reactors for the generation of mechanical or electrical power. Many of the advanced nuclear theories are not touched on but the author has attempted to familiarize the engineer with the current thought of physicists.

The first chapters give a concise review of nuclear fission and these are followed by a description of new concepts and methods of analysis developed for the design of reactors. Some of the problems treated are thermal stresses, transient behaviour of reactors, and distribution of gamma rays and neutrons. Engineering techniques such as numerical and dimensional analysis are applied to these problems and workable design criteria are presented.

Thermodynamics and engineering. W. E. Ranz, ed. Pennsylvania. University. Dept. of engineering research, 1955. 194pp.

This collection of papers originated at a conference on thermodynamics held in 1955 at the Pennsylvania State University. They have been separated into the three categories of science, industry, and education. In the section on science the subjects include irreversible processes, statistical thermodynamics, relaxation phenomena, electrochemistry, electric and magnetic systems, and elastomer thermodynamics. Contributions from industry concern heat engines, distillation calculations, and chemical rate processes. In the field of education the papers discuss thermodynamics as an engineering science in the curricula of the future.

Towards the automatic factory. London, Political & economic planning, 1955. (Reprint from Planning, v.21, June 13, 1955, p. 65-84). 2/6.

This little pamphlet covers some important aspects of automation. Beginning with a definition of the word, it goes on to discuss the extent of automation and prospects for the future, economic problems, and human and social implications.

The Youtz-Slick Lift slab method of construction, engineering manual. Austin, Texas, U.S. Lift slab corporation, 1955. various pagings, $5.00.

A radically new construction method which is used for vertical positioning of massive objects is described in this manual. The Youtz-Slick equipment is a portable elevator of great capacity and the lifting is done with hydraulic jacks placed on either permanent or temporary columns. Its main use to date has been to raise concrete floor and roof slabs.

The basic principles of the method are presented so that architects and engineers may study its possibilities.

The Lift slab method of construction is a trade mark of the United States Lift slab corporation, which has a licensee in Canada, where the tallest structure built by this method to date had been erected.

(*Continued on Page 735*)

Profit by the experience of operators everywhere — lubricate with *Texaco Crater*. It coats each metal strand with a durable film that fights off wear and rust. And *Texaco Crater*, with its excellent penetrating ability, gets right down to the core — assuring even longer rope life.

If you prefer the convenience of spray application for your rope and gears, use *Texaco Crater X Fluid*. It has the same outstanding adhesive and protective properties as regular *Crater*.

On open gears, *Texaco Crater* does an equally outstanding job. It cushions the shocks of extra-heavy loads, reduces noise, keeps wear at a minimum for longer gear life.

For mine car wheel bearings, use *Texaco Olympian Grease* . . . noted for its long-lasting protection, its ability to assure easier starts in any weather.

A McColl-Frontenac Lubrication Engineer will gladly help you get more operating efficiency and economy from all your equipment. Just call the nearest of the many McColl-Frontenac Bulk Stations across Canada, or write McColl-Frontenac Oil Co. Ltd., 1425 Mountain Street, Montreal 25, Que.

ENGINEERING CAREERS

CANADA

The Civil Service of Canada

It is estimated that well over 5,000 professional engineers are working for the people of Canada in the various public services, municipal, provincial and federal. Of these, nearly 2500 are employed in the Civil Service of Canada. Many others are employed in the crown corporations and federal public utilities, such as the Canadian National Railways, and as consultants.

The federal civil service is, therefore, by far the largest employer of engineers in the country. Its strength represents over 11 per cent of the number of registered professional engineers in Canada.

Engineers in the public services have an important role. A past president of the Engineering Institute of Canada said in effect that Canada's economic future, although dependent on private capital and initiative was in no small measure in their hands. He pointed out that the country's wealth of natural resources must be surveyed on a scale beyond the capacity of private enterprise, that government research and development is essential to the most effective social and economic use of these resources, and that intelligent conservation and control is necessary to prevent their wasteful exploitation.

It follows that the Civil Service Commission of Canada, along with independent agencies such as the National Research Council and the Defence Research Board, must make every effort to recruit and hold competent engineers to undertake the many pressing tasks which must be completed before private capital can be fully effective.

We shall confine our remarks to engineers in the classified service (under the Civil Service Commission) and on the staffs of the National Research Council and Defence Research Board. In so far as Crown Corporations, such as the Atomic Energy Limited, the Central Mortgage and Housing Corporation, the St. Lawrence Seaway Authority, and the Defence Construction Limited are concerned, suffice it to say here that the government's general policy on personnel matters serves to guide these agencies, but their practices tend to be more like industrial practices than would be the case if they were under the jurisdiction of the Civil Service Commission.

The scope of engineering activity in the Civil Service of Canada touches upon every imaginable engineering specialization, covers the country geographically, extends into our relationships with other countries and is unquestionably greater than it would be with any other employer. In each specialization, work normally involves applied research, design and development, construction or production and inspection. Some functions are concentrated in one departmental unit; some are dispersed administratively. The activities of various types of engineers, and the departments in which they are employed, are appended under the heading "Engineering Activities."

RECRUITING

Two basic principles underlie civil service recruiting and selection. First, there is a statutory as well as moral obligation for the Civil Service Commission to let all qualified people know of the existence of vacant classified positions which are open to public competition. Secondly, all qualified candidates who express an interest in these vacancies have a right to demonstrate their personal and technical competence before an objective examining body. These principles, inherent in the merit system, make recruiting both expensive and time consuming. On the other hand, they protect the rights of those who apply and, in a more general sense, the Canadian public which is entitled to the services of well qualified and effective civil servants.

Engineers are in short supply all over the country, and this, coupled with our expanding needs, has made recruiting difficult. Government departments had to catch up on a considerable number of projects, which could not be attempted during the war, meet those which have occurred since, and at the same time service a large defence establishment.

Our average annual intake to the Classified Service* has been about 180 engineers a year. This represents about 13 per cent of the average annual graduating class in engineering over the same period. If the intake of the Defence Research Board and the National Research Council were added the figure would be about 15 per cent. In relation to the total number employed, the civil service would be getting a fair share of graduating classes if annual intake averaged around 12 per cent. Thus, it appears that the civil service is attracting slightly more than a fair share of available engineers from the Canadian market.

Despite this, however, we have a large backlog of unfilled positions which, at the time of writing, numbers more than 300. To meet these demands it would be necessary to attract the equivalent of nearly 20 per cent of the 1956 graduating class. It is obvious that this will not be possible, and therefore, some activities which are basic to the rapid technological and economic development of the country must be curtailed.

In an effort to reduce the impact of this shortage the Civil Service Commission, in co-operation with the departments and other agencies, has made efforts to have a great deal of semi-professional technical work turned over to draughtsmen and technicians, thereby freeing the professional engineer for professional problems. Although much remains to be done in this regard, much has already been accomplished.

The Civil Service Commission has a continuous recruiting program.

Contributed by G. A. Blackburn, M.E.I.C., Assistant Director, Planning and Development Branch, Civil Service Commission.

*In the past five years.

Various kinds of descriptive literature on engineering activities and specialties have been distributed to university placement officers and professional associations and its availability is announced in professional journals. Also, through educational leave, some people already in the service are brought up to the required professional standards. To summarize, the federal government is attempting to meet essential demands for engineering personnel through general publicity directed at the profession at large, through internal re-organization to make the best use of the talent now available and through in-service training programs and educational leave provisions which are designed to develop potential.

QUALIFICATIONS

The nature of the work at the National Research Council and Defence Research Board necessitates outstanding academic qualifications and aptitude for research and development. Thus, generally speaking, these agencies insist on graduation from accredited university courses as a basic requirement for entrance to professional positions. On the other hand, the Civil Service Commission requires either university graduation or qualifications which permit membership in recognized professional engineering associations, provided candidates have successfully completed examinations approved by the Commission. There are, of course, some work areas in the classified civil service where university training of a high order is essential.

SELECTION

The selection program of the Civil Service Commission usually commences with a study of documentary evidence supplied by and on behalf of each candidate. This study is done by a board, made up of the Commission's personnel selection officers, who are frequently engineers themselves, and other engineering advisers. Following this review, a number of the most likely candidates are usually called for oral interview in order to determine which of the candidates are most suitable. In this process, the Commission relies with gratitude on the invaluable assistance of representatives of the profession.

The need to safeguard the interests of all qualified people who wish to apply, plus the preference accorded to veterans who have served abroad in time of war, make it necessary to spend more time on selection than would be the case in a private concern. As a result, the Civil Service Commission is always trying to resolve the need for quick appointments in urgent areas with the responsibilities imposed upon it by the Civil Service Act. Despite our best efforts, however, the time taken will always be longer than it is in industry. We hope the need for this will be appreciated and that prospective candidates will value the protection afforded to them by the merit system.

The National Research Council and Defence Research Board make their selections in much the same manner as the Civil Service Commission, although with variations in detail.

CAREER PATTERN

Of the 2500 engineering positions in the civil service, about 50 per cent are to be found in five departments, Mines and Technical Surveys, Public Works, Transport, National Defence, and Agriculture; and in the National Research Council. The balance are employed, in varying numbers, in fourteen other government departments.

Latterly, there has been more movement of technical personnel from department to department. The first few promotions beyond the entrance level are usually within one department but as engineers approach the intermediate and senior grades they tend to progress, quite frequently, through inter-departmental promotion competitions. Promotion from within is followed wherever possible. As a rule, senior positions are only open to the public when a high degree of specialization is required and it is unlikely that a suitable person can be found within the civil service. It follows, therefore, that most recruiting is done at the Grade 1 or Grade 2 level.

After the war there was a shortage of engineers with well-developed administrative capacity, with the result that the Commission had to go into the open market to fill some senior positions. Because the Civil Service should be more self-sufficient in future, the Commission has developed training programs in administration for junior engineers and other scientific personnel. This is supplemented at the intermediate and senior levels by courses in administration which embrace all professions. Also, some departments have initiated their own long-range executive and professional development programs.

A second training objective is to hasten the development of young engineers so that they may assume heavy responsibility at a comparatively early age. The latter is of paramount importance since the proportion of senior engineers approaching retirement is rather high as a result of limited engineering activity prior to World War II. Fortunately, the young engineers seem to be rising to the opportunity since many around thirty years of age are now assuming duties which, before the war, they would not be expected to handle until they reached their forties.

A rolling mill at the Mines Branch, Ottawa.

The accompanying table shows various engineering salary levels and the percentage of engineers at each level. The salary ranges are only approximately related to the grades in brackets because the precise salary ranges are being revised at the time of writing. Level F represents a considerable number of special classes, among them district engineers, superintending engineers, chiefs of construction, directors of branches and the like.

Table of Engineering Salary Levels

Level (Grades)	Range ($)	Percent of Engineers
A (1 and 2)	3,900– 5,800	50
B (3 and 4)	5,500– 6,600	27
C	6,200– 7,200	15
D	6,800– 8,400	4
E	8,200– 9,000	3
F (Special)	9,000–12,500	1

The recent expansion of activities and consequent increase in intake accounts for the unusually high percentage at level "A". Ordinarily, the young engineer who comes to us on graduation or shortly thereafter can expect to reach level "B" within four or five years. In other words, with the great number of positions at this level, the young engineer with initiative and ability can reasonably hope to reach $6,600 within six or seven years of graduation. This, we believe, is a satisfactory rate of progress, particularly when he can look forward to higher positions as his capacities develop.

Turnover figures seem to indicate that professional engineers are, on the whole, quite happy in the public service. The turnover rate including retirements is less than 5 per cent a year. In view of the fact that there are some areas in which no long-term careers can be offered and in which the Commission does not encourage people to settle, this turnover rate is we think, quite small.

In determining salaries, the policy, as stated by the Government, is that they should be sufficiently high to attract and retain good candidates in sufficient quantity to meet our needs and that they should be comparable to those paid by good private employers. With this in mind, the Commission's Organization and Classification Branch constantly reviews salaries in business and industry. There have been six general revisions in the past nine years. It is, of course, clear that the rather extraordinary salaries occasionally available in industry cannot be paid in the public service. On the whole, however, civil service salaries, although tending to lag behind industry a bit at the senior levels, are maintained in compliance with the government's policy.

ADVANTAGES AND DISADVANTAGES

The public service has some advantages which are proper to it. In the author's opinion, the most important of these is the personal satisfaction to be derived from playing a part in activity which is of such great consequence in the economic and technological development of the country. There are also such things as stability of employment and various service benefits which will be mentioned later. These introduce an element of security into family life which, in turn, frees the mind for creative endeavour.

On the other hand, there are a number of disadvantages. One aspiring to a very high income will not find it in the public service. Secondly, public servants are usually cloaked in anonymity and it is only at the top levels that public acclaim can be expected for outstanding achievement. Finally, some are frustrated when they find they have to subordinate their own views to those of the general public as expressed through their elected representatives.

Usually, the one who does best and is most content is the person with a strong sense of public service. He can derive great pleasure from even a minor role in the social and economic development of the country. Also, there is much satisfaction to be gained from playing a part in the creation of important policies and projects. This is particularly so at Headquarters in Ottawa and it is well known that a great many professional public servants have turned down very lucrative positions elsewhere in order to remain in the positions which they find so stimulating.

A bridge across the Mississagi River at Iron Bridge, Ontario—a link in the Trans-Canada Highway.

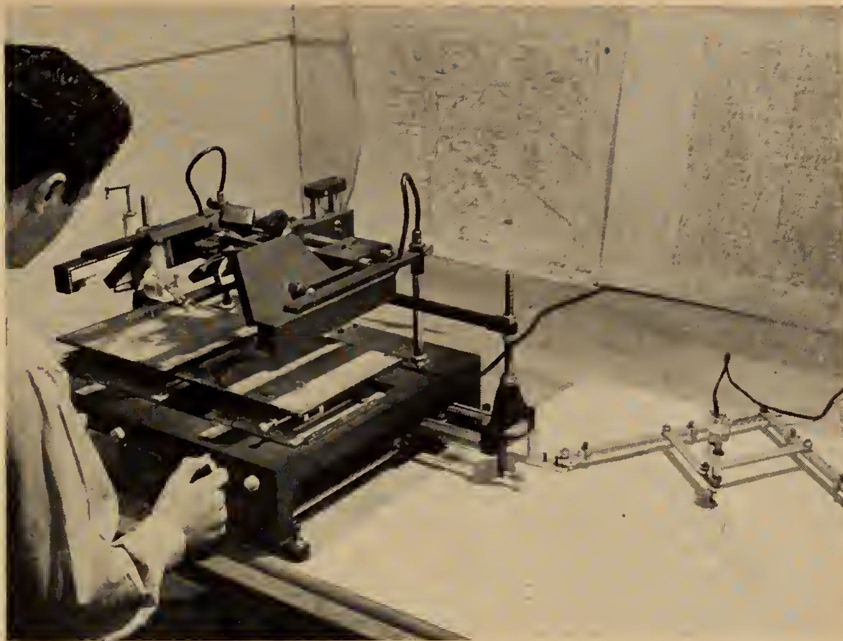
From a technical point of view, there are excellent opportunities for self-development, either through in-service training or educational leave. Some mention has been made of the in-service program and, of course, much can be learned on the job. The educational leave provisions permit leave with full pay to attend university if the added training is essential to the satisfactory performance of the duties of a position; leave with half-pay may be granted if the study will be of mutual benefit to the department and the employee; leave without pay is granted in those cases where the employee is the primary beneficiary.

The Civil Service has numerous fringe benefits among them an excellent pension plan, one of the best in the country, a form of low-cost term insurance, three weeks holidays, sick leave which, if not used, accumulates from year to year and various types of other leave, as well as ten statutory holidays. Under the pension scheme, it is often possible for a person who is moving from private employ into the government to buy back his previous time and have it count for pension purposes. Another thing worthy of note is that engineers can share in the royalties obtained on patents of commercial value, even though the invention is developed in the course of one's normal duties.

CONCLUSION

As suggested above there are advantages and disadvantages in civil service careers. For most professional people, the advantages outweigh the disadvantages. The Civil Service of Canada needs its fair share of professional people and particularly professional engineers, if it is to discharge, in a satisfactory manner, the responsibilities imposed upon it by Parliament. The Civil Service Commission and other employment agencies have set high professional standards and, where required, high technical standards for admission to the government. This we believe is justified since the public deserves the best possible service.

In conclusion, the Civil Service Commission invites the engineering profession to take an interest in the development of sound personnel policies in the government, either directly or indirectly. It would help, for example, if members of the profession would suggest to young engineering graduates that they explore the career opportunities in government, particularly if these young men demonstrate something of the spirit of public service which makes for a successful career in the Civil Service of Canada. There are few places in which they can serve their fellow Canadians to better or more direct advantage.



Topographic survey technician using a stereoscopic plotter.

ENGINEERING ACTIVITIES

An Outline of the Fields of Specialization

The federal public service employs almost every type of professional engineer. Civil engineers make up well over half of our total engineering strength of approximately 2,500; numerically the next largest groups are the electrical and mechanical engineers. Engineers with other backgrounds are employed in smaller numbers. Below are brief descriptions of government engineering activities, broken down by fields of specialization.

Aeronautical Engineers

The National Research Council provides the Canadian aviation industry with research, development and testing facilities, and with the Defence Research Board carries out research work on many problems related to flight at both subsonic and supersonic speeds. The main concern of aeronautical engineers in the Air Transport Board is research, while those in the aeronautical engineering division of the Department of Transport work on design and inspection. Those employed as civilians with the Royal Canadian Air Force also work on inspection and design but mainly in an advisory capacity. Production liaison is carried out in the Department of Defence Production. Junior appointments are unusual in this field because, in most cases, aeronautical engineers are expected to act as advisors to senior officials and must, therefore, have had practical experience before joining the civil service.

Mining, Metallurgical and Ceramic Engineers

Engineers with these backgrounds are employed almost exclusively in the mines branch of the Department of Mines and Technical Surveys. They work in modern laboratories, equipped with the latest facilities for research and development. Mining engineers test minerals and fuels, study mining methods and seek to improve the quarrying, processing and utilization of industrial minerals, including structural materials. They also investigate the processing and utilization of fuels, such as coal, peat, crude oil, natural gas, oil shales, and bituminous sands.

Engineers specializing in physical metallurgy study the physical and mechanical properties of metals and alloys and the methods of production and fabrication. Those concerned with extractive and chemical metallurgy investigate the character and treatment of ores, including radio-active ores and metallic and non-metallic minerals, and seek to improve present methods of ore processing. Others are engaged in applied and fundamental research on raw and manufactured ceramic materials. Some are assigned to field work on technical and economic studies related to markets, taxation and other factors affecting industrial development.

Chemical Engineers

They are engaged in research in the fields of chemical and extractive metallurgy, corrosion, wood utilization, sanitation and in all branches of fuel technology. Most are employed in the Department of Mines and Technical Surveys but some are also to be found in the public health engineering section of the Department of National Health and Welfare and in the testing laboratories of Public Works and National Defence. Chemical engineers are also employed extensively in defence research studies and in applied and fundamental research in the National Research Council.

Civil Engineers

As stated, civil engineers make up the largest group of engineers in the public service. They are employed in a number of departments and are engaged in many activities, including structural design, hydraulics, highway and airdrome construction, public health engineering and hydrometrics. The main employers are the Departments of Mines and Technical Surveys, Public Works, Transport, Northern Affairs and National Resources, National Defence, and the National Research Council.

In highway and airfield work, they are engaged in every facet of activity from initial exploration and location, through construction and inspection. The gamut is just as wide in Public Works where activity has to do with buildings, docks, piers and other kinds of heavy construction. Many interesting problems in design are encountered in northern construction where permafrost and muskeg present great challenges. Interesting problems in hydraulics are met in the harbours and rivers branch of Public Works, in the water resources division of Northern Affairs and National Resources, and in the canals branch of the Department of Transport. In structural design stimulus is to be found in the air services construction division of Transport, the structural division of Public Works, and the building and construction divisions of National Defence. Again, the problems of complicated communications, permafrost, and muskeg make many of the projects unique. Assisting with these and other problems, civil engineers in the National Research Council provide research services both to other government departments and to the Canadian building industry. The hydrometric work done by engineers and technicians in the water resources division of the Department of Northern Affairs and National Resources is, of course, of major importance inasmuch as it provides planning data for hydro-electric and irrigation projects.

A great many civil engineers, as well as engineers with other backgrounds, are employed in the surveys and mapping branch of the Department of Mines and Technical Surveys. These engineers, along with their technicians, have revolutionized large-scale topographic mapping practices by exploiting technical developments in other countries and creating special equipment to meet Canadian needs. Geodesists, hydrographers, topographers, and experts in map reproduction techniques provide basic data for virtually all big resource development projects in this country. A number of engineers are engaged in land surveys of Crown properties; most of these are in the legal surveys branch of the Department of Mines and Technical Surveys.

Electrical Engineers

The majority of electrical engineers are concerned with problems in electronics which have to do with research, the design and development of new equipment and the production, installation and maintenance of radiation and communications systems for both civil and military purposes. Most of this work is done in the Department of National Defence, the National Research Council, the Defence Research Board, and in the Department of Transport. In the last named department, quite a large number work on the development, installation and maintenance of aids to marine and air navigation; radio and television interference problems; and on the operation of the government telegraph and telephone systems.

Electrical engineers are also employed in considerable numbers in electric power design, and on the installation and maintenance of equipment in public buildings, airfields and military structures. They are concerned with transmission and illumination systems, standby equipment, and, in the case of canals, with electrical control mechanisms for mechanical equipment. Finally, in the Department of National Defence both electronic and power engineers are employed in connection with the production, design and manufacture of equipment for the armed services.

Mechanical Engineers

The Departments of Transport, Public Works, and National Defence are the main employers of mechanical engineers. Much of their work has to do with ventilation equipment for public buildings, mechanical equipment in dry docks and ocean terminals, lift and swing bridges, aids to navigation, railway equipment and power houses. In other areas, particularly in the mines branch and the National Research Council, mechanical engineers are engaged in research on stress analysis and the fatigue properties of materials, and on many phases of aeronautical, hydraulic, and mechanical engineering and naval architecture. Still others in National Defence and the Defence Research Board work on the development of armament and motorized transport. Production engineering is the one field in which the Civil Service of Canada offers little of interest.

Engineering Physicists

The main employers of engineering physicists are the National Research Council, the Defence Research Board, and the mines branch of the Department of Mines and Technical Surveys. All are engaged in fundamental or applied research. Problems in physical metallurgy involve the physics of metal deformation, alloy constitution and nuclear metallurgy. In this field, and in radiation, the most up-to-date equipment is provided for spectroscopy, radiation physics, thermodynamics and other areas of investigation. Quite a few engineering physicists are also engaged in the electronics work mentioned in the section on electrical engineers. In the field of communications, the engineers in military establishments have made appreciable contributions to the technology of defence.

Miscellaneous

Engineers are also employed in many other areas not normally associated with engineering. For example, quite a few are employed in the Patent and Copyright Office on work having to do with the technical and legal aspects of inventions. Some are also engaged in personnel, job analysis and management units, particularly in the Civil Service Commission, to advise on personnel and management problems arising out of technological development. Others are engaged in administration where the nature of the work is such that it requires a technical background. Also, quite a few engineers are concerned with information activities, particularly in the preparation of technical material for general distribution and in answering specific questions of a technical nature which come to such agencies as the National Research Council, the Forest Products Laboratories, and the mines branch of the Department of Mines and Technical Surveys.

STANDARDS REVIEWED

British standards, British standards institution, 2 Park Street, London, W. 1. British standards are available from the Canadian standards association, National Research Building, Ottawa.

B.S. 759:1955 — Valves, gauges and other safety fittings for application to land boilers and to piping installations for and in connection with land boilers. 4/–.

This revised standard deals with safety valves, high and low water alarms, stop valves, feed valves, blow down fittings, water gauges, pressure gauges, test connections and fusible plugs.

It does not provide for fittings for calorifiers or for certain low pressure and hot water boilers. Materials, temperature and pressure limits and methods of construction are specified, together with formulae for determining the minimum aggregate area of safety valves and the sizes of valve springs.

B.S. 775:1956 — Contactors when supplied separately or in combination with other gear. 5/–.

This revision applies to electro-magnetically and electro-pneumatically operated contactors and it covers air-break and oil-break contactors for voltages up to 11 kv. a.c. and 650V d.c.

It should be noted that this standard is closely related to B.S. 587, 'Motor starters and controllers', a new edition of which will shortly be published.

London Airport

The Construction of a Modern Civil Airport

A. R. Macrae and C. Heyes

Ministry of Transport and Civil Aviation, London

Of the world's major international airports, London Airport is probably the most up-to-date at present. Its development from a Royal Air Force project is traced by the authors, who comprehensively cover the civil, electrical, and mechanical engineering that is involved. The title illustration shows the central area at night and indicates the effective street lighting without any upward light.

London Airport is situated some 14 miles to the west of the City, a distance which takes 50 minutes by road, even in the best of conditions.

The site occupied by London Airport was selected in 1943 when it was planned to develop an airfield for Royal Air Force transport aircraft of the heaviest types proceeding to the far eastern theatre of war.

The problem of finding a site suitable for development as a major airfield which was within a reasonable distance of the heart of London, yet clear of the built up area of Greater London was, of course, very exacting. Nevertheless, although comparatively close to the built up area of Greater London the site selected enveloped a small airfield, market gardens, small farms, disused gravel pits and a small number of dwelling houses, so that comparatively little demolition of private property was necessary in the development of the site which was practically level and had very good flying approaches in the required directions.

Construction of the airfield for the Royal Air Force started in 1944 and work on the first three runways was well under way when the war ended the following year and it was decided to develop the airport for civil use. In considering the design and development of the airfield as a civil international airport due account had therefore to be taken of the fact that three runways, forming a triangular pattern had already been constructed. In the layout of runways finally adopted, as shown in Fig. 1 and now complete, two of the three original runways are included. Part of the third runway is utilized as a taxi track.

Six runways have been provided in the form of two parallel runways in each of three different directions. The triangular pattern of runways thus formed encloses the central terminal area where passenger handling buildings, control tower, administration and operational buildings are located. Access to the central area for all traffic is by a tunnel which leads under No. 1 runway into the north of the central area.

In the eastern section of the airport is No. 1 maintenance area where main hangars and maintenance bases of British Airways Corporations are situated. No. 2 maintenance area in the southern section of the airfield is to be developed primarily for airlines other than the British Airways Corporations. An area in the south west of the airfield is reserved for future development as No. 3 maintenance area if required. Along the north boundary of the airport are temporary buildings which were provided to handle passenger traffic until the permanent buildings in the central area are complete.

RUNWAYS, TAXI TRACKS AND APRONS

The major engineering works which had to be undertaken on and around the site to permit the construction of runways included: (a) the dewatering and filling in of ponds and disused gravel pits covering a total area of some 100 acres; (b) the diversion of two small rivers over a total length of 4½ miles; and (c) the construction of some 3 miles of roadway outside the boundary of the airfield to replace public roads which had passed through the site.

At the time the runways were designed the indications were that the weight and take-off loads of long distance aircraft would continue to increase and the runways were accordingly designed to carry the largest aircraft then envisaged. The runways, taxi tracks and aprons have been designed to carry an all-up load of approximately 350,000 pounds on four wheels. The actual basis of design was a load of 81,000 pounds on a single independent wheel with a tyre pressure of 120 lb. per sq. inch. The instrument runways numbers 1 and 5 are 300 ft. wide and over 9,000 ft. long.

From an engineering point of view the site selected has many advantages. It is practically level, has a stable gravel formation and is located in what is known as the Taplow Terrace gravel area. The geological formation in that area consists of gravel which is found immediately below the surface top-soil and to a depth of approximately 20 ft. Underneath the gravel is London blue clay. The gravel lends itself very well to compaction and for that reason provides an ideal foundation for the runways and other installations which had to be constructed even though in winter the subsoil water level rises to within 6 ft. of the ground surface.

The construction of the runways varies. A sub-base of high bearing capacity was attained by removing completely the top soil and brick earth and exposing the gravel, and by refilling to required levels in layers not exceeding nine inches with similar gravel. On this the 12 in. pavement quality concrete (minimum strength 4,000 lbs. per sq. in. at 28 days) was laid. Because it was only possible to carry out the compaction of gravel filling under favourable weather conditions, and to protect and seal the subgrade and so permit concreting to continue, it was decided to provide an 8 in. dry lean concrete base slab below the 12 in. pavement quality concrete. By this means continuous progress during wet weather was ensured. The concrete was, in general, laid in bays 20 ft. x 20 ft. with expansion joints every 120 ft. and these have in practice proved adequate.

A view of the central area apron at London Airport.

Stormwater Drainage

The design of the main stormwater drainage system proved difficult because of the flat nature of the site and the lack of suitable water courses into which the large quantities of surface water could be discharged. Owing to the large quantities of surface water to be dealt with, it was decided that the scheme would have to be a gravity system. In spite of the flat nature of the site this has been achieved although in some cases gradients of stormwater drainage pipes are of the order of 1 in 3,000.

The Taplow gravel is extensively used as concrete aggregate. A number of pits from which gravel has been removed exist near the airport and use has been made of some of these as balancing reservoirs; a portion of these reservoirs has been enclosed by a dam which acts as an oil and petrol interceptor. Water passes to the reservoir proper by means of weirs which are furnished with drip boards on the upstream side. Where the reservoirs discharge into rivers this is controlled by means of a weir and rectangular notch.

ELECTRICAL SUPPLY AND DISTRIBUTION

It was decided at the outset to provide an 11 kv. electrical distribution system through the airfield, but the Supply Authority network in the neighbourhood of the airfield was limited in the early days of construction, only 300 kva. being available. The civil use of London Airport increased rapidly after the opening in 1946, and it was necessary to augment this supply from another source. This, however, was only an interim stage as the new capacity was also limited, not more than 2,000 kva. being available.

Meanwhile the design of the ultimate distribution system was put in hand and negotiations opened with the Supply Authority for a permanent electricity supply up to 20,000 kva., the first stage of which was brought into use in 1951 during which year the demand rose to 2,190 kva.

The main electricity supply to the airport is obtained from the local Electricity Board through 22 kv. feeders, from two separate sources; each feeder is taken to a main intake substation within the airport boundary, with a 22 kv. interconnector between these two substations. At each, the 22 kv. switchboard controls two 5,000 kva. 22/11 kv. transformers which feed

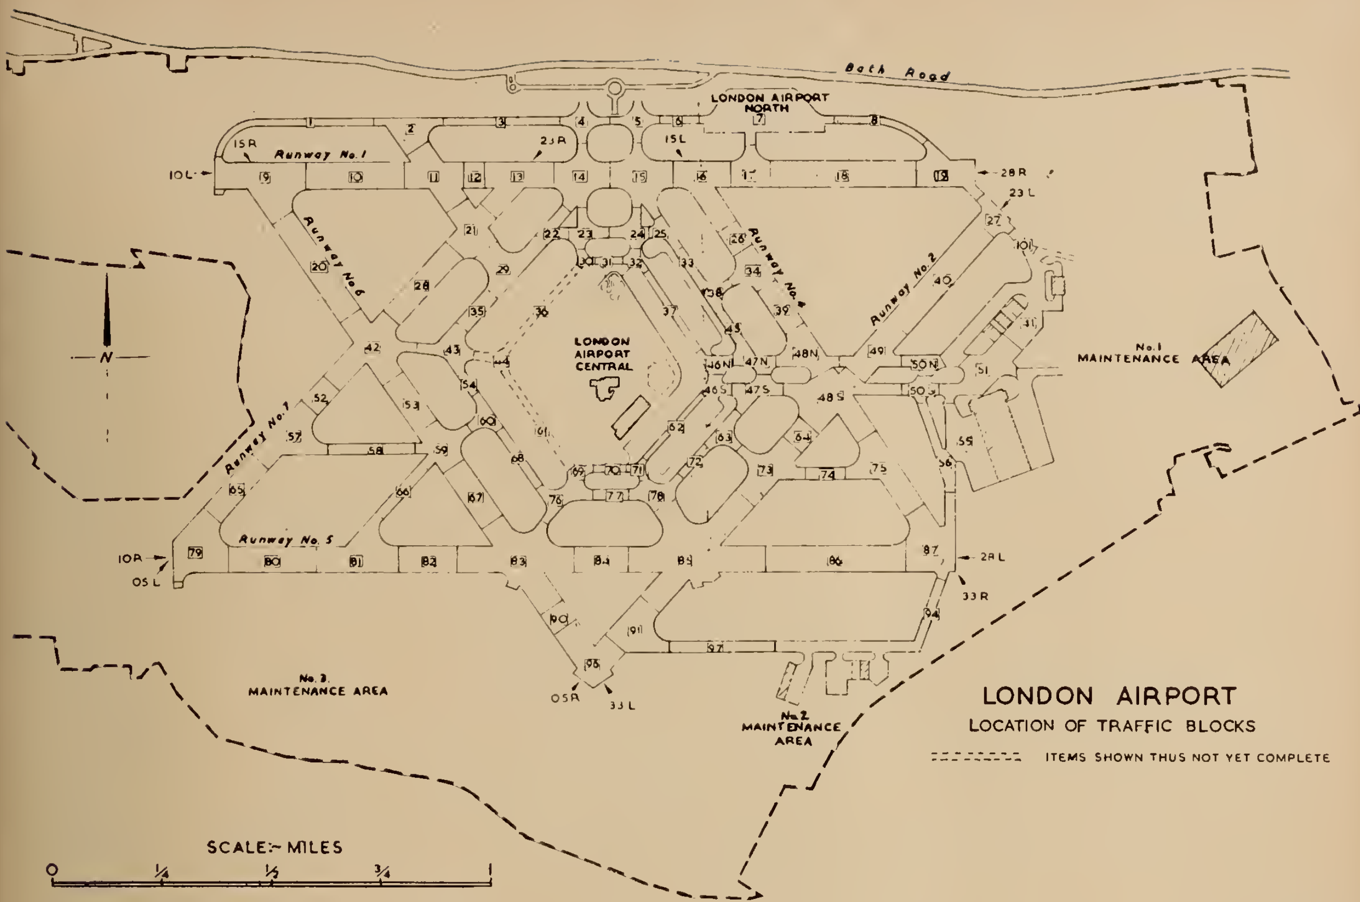

Fig. 1. Layout of runways finally adopted, showing location of traffic blocks. There are six runways.

into the 11 kv. switchboard which has duplicate bus-bars; there is thus a capacity of 10 megawatts available at each intake substation, and provision has been made for this to be extended to 20 megawatts later. The maximum demand at the airport now exceeds 8 megawatts.

Electrical Distribution

The first section of 11 kv. distribution was laid down in 1946-47, providing a supply to the future central terminal area and all three original runways. As the development plan of the airfield unfolded, so the pattern of the ultimate distribution system took shape. This was designed to take all electrical loads within the boundaries of the airport together with certain navigational aids located not more than half a mile from these boundaries. It was foreseen that the industrial load of the airport would become impressive, and the cable layout has been designed with this in mind.

The eventual apparent fault capacity of the 11 kv. system is 250 Mva., hence the majority of the switchgear has been installed to deal with this; however, in order to continue use of certain parts of the system installed in the early days, in which neither the cables nor the switchgear are suitable for this duty, reactors have been inserted at appropriate points.

A number of ring mains are provided between the two intake substations, the basic principle being that operational loads shall be separated from industrial loads, as far as practicable. Thus there are two operational rings serving the airfield proper, an outer which circumscribes the runways, and an inner which is laid outside the central area aprons. These supply power to all navigational aids. The control tower is on a third ring, but in this case all the central area buildings are supplied from the 11 kv. switchboard in the control tower, by means of radial 11 kv. feeders. There is an interconnector between this third ring and the inner operational ring, for use in emergency.

The industrial loads are taken on two further rings, and it is the intention to provide more such rings as the maintenance facilities of the airport increase.

Protection of the main 11 kv. circuits is by comprehensive balanced feeder protection, using pilot cables which have been laid with all the ring main cables, hence a fault is isolated immediately at the nearest circuit breaker on each side of the fault, whilst the rest of the ring continues to function as a spur from each of the main intake substations at which back-up overload protection is provided on each feeder. Transformer substations of which there are forty-one in number, provide the normal 400 volt, 3-phase, 4-wire local systems. These transformers are sized from 100 kva. to 1,000 kva., according to need.

Standby Sets

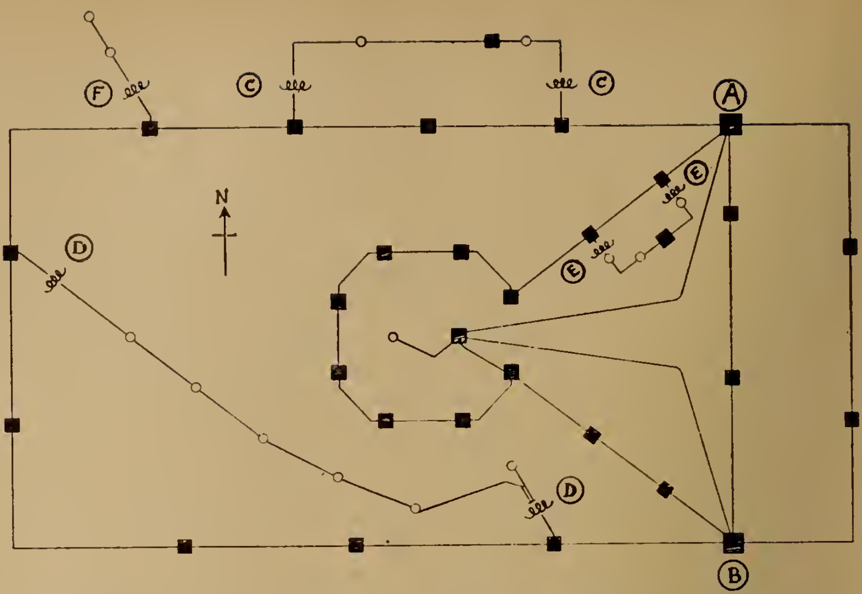
To serve the navigational aids in the event of a mains failure a number of standby sets ranging in size from 2½ kw. up to 250 kw. capable of taking load within two minutes of power failure have been provided. In practice this is usually achieved within 20 seconds by the use of automatic start diesel or petrol driven alternators located near to the aid they serve.

These sets rely on a power failure to initiate starting, consequently they do not meet the requirement for special telecommunications equipment, which will be out of use for more than two minutes if the supply is momentarily interrupted. For this reason a new provision has been continuously running generating sets, normally driven by an induction motor off the mains, but coupled to a diesel engine through a magnetic clutch which is energized from the alternator exciter as soon as a power failure occurs. A heavy flywheel on the motor shaft provides the required inertia to drive the diesel until it has run up to speed, and this is accomplished with a drop in frequency not exceeding 5 per cent.

AIRFIELD LIGHTING AND CONTROL

The first installations of runway and approach lighting were of a type which had been developed for military purposes during the 1939-45 war and represented the most up-to-date pattern at that time. The approach lighting to the main runway was in the form of a divergent funnel, each line being set outwards at an angle of 2° and extending to a distance of 4,500 feet from the threshold. The omni-directional fittings had red filters, and for bad visibility conditions a "box" of four directional sodium lights was provided adjacent to the threshold, two on each side of the runway. The runway lighting was also the wartime flare path, designed to provide the minimum useful source of light against a completely black background, and of little use against a normally lighted airport.

The approach lighting gave way to the modern line and bar system in 1949, London Airport having the first installation of this type in



The 11-kv. supply system. The diagram shows: A, B—22/11 kv. sub-stations. C—750 kva. reactor. D—500 kva. reactor. E—100 kva. reactor. F—50 kva. reactor. Circle—ring main unit and transformer enclosure. Black square—brick-built sub-station.

Great Britain. At the same time the runway lighting was changed to the latest equivalent of the contact lighting system. Taxi lighting has also been developed to meet the requirements of London Airport and so far is unique in this country.

Approach Lighting

The function of the lighting pattern is fourfold; primarily it is to show the pilot the continuation of the centre line lighting into the

The line and bar system of approach lighting; runway lights at end.

approach and across which one or more crossbars are provided at fixed distances from the threshold, these serving the three purposes of giving an indication of distance, providing a horizon by which the attitude of the aircraft can be checked, and showing the pilot that he is on the correct angle of descent. The extended centre line is illuminated to a distance of 3,000 feet from the threshold; the crossbars are also illuminated, and are of lengths proportionate to distance from threshold, so that when on his proper descent path each crossbar appears to the pilot to be of equal length. The lighting of the centre line is coded, one fitting being provided at each position in the first 1,000 feet from the threshold, two fittings in the second 1,000 feet, and three fittings in the third.

High intensity lighting is achieved by using high powered uni-directional fittings, with tungsten lamps. Although the original high intensity fittings at London Airport were comparatively heavy, the modern counterpart is of lightweight construction, about 6 lb. inclusive. On all approaches the fittings in the first 500 ft. from the threshold have been changed to lightweight type, and all fittings throughout new centre line and crossbar systems are lightweight. These fittings have a narrow beam of intensity about 20,000 candelas at full brilliancy, which can be controlled in five stages down to 1 per cent. Since they are uni-directional, such fittings cannot provide an orbiting guide for aircraft in conditions of good visibility, hence a separate system of red omni-directional lights is provided, one fitting corresponding to each position of high intensity fittings.

High intensity lighting is normally only used on instrument approaches, of which there are four at London Airport, three having six bars of lights, the fourth having three bars; in every case omni-directional low intensity lighting is superimposed. The remaining approaches used for night flying are equipped only with low intensity centre line lights, and either one, or two crossbars.

The circuits of all approach lights are duplicated and interleaved, in order that failure of one circuit shall not destroy the lighting pattern. Most of the circuits are parallel, but the newer approach systems have series circuits, which are more economical and, moreover, give uniform brilliance to all lights.

Runway Lighting

The chief criteria for runway lights are that they shall approximate in brilliance to the approach lighting, and that they shall be accurately beamed and provided with brilliancy control. Since the runways are 250 ft. and 300 ft. wide at London Airport, flush or blister type bi-directional fittings have to be used in lines spaced 150 ft. apart, hence approximation in brilliance to approach lighting cannot be attained for the maximum beam of the blister fitting is some 5,000 candelas of white light; they are, however, accurately beamed and provided with brilliancy control. A distance marker is provided in the runway fittings to advise pilots that they have reached a point beyond which it is not safe to touch down; yellow half filters are fitted to these lights, showing in the direction of approach only for the last 2,000 feet of the runway.

Two sets of threshold marking lights are provided, both green; the normal threshold consists of blister type fittings, controlled with the runway lights, but without brilliancy control; these are spaced evenly across the runway. The other threshold is made up of elevated lights, uni-directional towards the approach, and circuited with the approach lights; these are the high intensity markings, spaced at the sides of the threshold only, leaving a gap of 75 feet in the centre of the runway.

Runway lights are interleaved on constant current circuits and brilliancy control is achieved by tapped transformers with chains of contactors or, more recently, saturable core reactors. The existing blister type fittings have a projection of about $1\frac{3}{4}$ in. above runway surface, but a new type having a projection less than 1 in. is now under development.

Taxi Track Lighting

There is a complex system of taxi tracks at this airport, and aircraft may be routed along a number of alternate ways. It was therefore necessary to provide route marking by lights, with control of individual sections; this has been achieved by providing a centre line system of lighting, instead of the usual side lighting, this decision was taken because of the difficulty of seeing edge lighting on the wide tracks in conditions of low visibility.

Blister type fittings, of the same design as the runway lights, but provided with green filters, have been placed along the centre line of all taxi tracks; they are supplied by a number of series circuits, through transductors, which have tertiary windings for D.C. saturation. When a series circuit is energized, all the taxi lights will be illuminated, until D.C. is applied to particular transductors, when the corresponding lights will be extinguished. The series circuits are thus arranged in geographical order, whilst the D.C. control circuits are arranged in order of lighting sections.

The control of the taxi track system is divided into blocks, each junction forming a block on its own, with the interconnecting straight sections forming other blocks (see Fig. 1). At the dividing point of the blocks there is placed a line of red lights across the taxi track, known as a traffic bar; when these lights are extinguished an aircraft has right of passage, but when illuminated the red lights demand that the aircraft shall halt.

It was found in practice that an auxiliary aid is sometimes required to guide aircraft along the selected path, for in certain conditions of sunlight it is not easy to pick out the green centre line. To meet this contingency a system of route indicator boards has been devised, placed at the entrances to all junctions. These boards have mimics painted upon them showing the possible routes available in correct orientation, and each branch is provided with a white light, the lamp on the selected route being illuminated. There are also red lights to denote that the traffic stop bar is illuminated; control of the route lights is effected from the control tower.

A mimic diagram of airfield lighting is used in the control tower.

Control of Airfield Lighting

The fact that navigational aids are spread widely over the surface of an airfield, and indeed beyond its boundaries, had led during the 1939-45 war to consideration of an economic means of exercising control over the switching of a large number of services already growing and with unknown possibilities of expansion. It will be seen that there are many hundred circuits which require to be operated from the control tower, and that these circuits arise at many different points over a large area. To avoid the laying of heavy multi-core cables a system is used whereby almost an infinite number of switching operations may be carried out over a small finite number of telephone-cable cores. This system transmits coded pulses from the control tower, which are received at the appropriate switching centres where they operate a relay tree to effect the required switching operations. Installation was commenced in 1947 and has continued since then as new construction has called for further additions to the system.

To assist the air traffic controller, a mimic is provided in the control tower, indicating the services selected; thus a system of back indication is a vital requirement. This is achieved by the use of a current-actuated device to give evidence that a circuit is alive and current flowing, with the presumption that the lamp is alight. No visual aid depends upon a single lamp, so this presumption is justified.

The exceptionally large number of circuits to be controlled and back-indicated at London Airport has led to consideration of the best means of relieving the air traffic controller of that part of the task he now performs in checking that the control system is, in fact, in order. It has been decided that a form of electronic scanning will meet this situation in the most economical manner, and this equipment is now in the course of manufacture.

It has long been recognized that some means of pin-pointing aircraft, and vehicles, on the runways will prove of great value particularly during periods of bad visibility; to this end experimental work has been proceeding to obtain the indication by using the aircraft or vehicle to upset the coupling between oscillator and receiver coils embedded in the runways. This work is entirely separate from the scanning of the airfield by radar.

Street Lighting

When London Airport was opened as a civil airport there were no street lighting fittings specially designed to obscure upward spill which might cause confusion to pilots. This applied particularly to those lighting the main Bath Road which runs parallel to the instrument runways. These lights were therefore shielded to prevent all egress of light above the horizontal; the street lights erected at that time in the north terminal area were also treated in a like manner; but this has two disadvantages, the appearance is unpleasing and the windage stress is high.

During the past ten years new types of fittings have been evolved, but the overriding criterion insofar as the central area is concerned, is the necessity for shielding upward light completely. There are more than two hundred fittings in the central area, so the importance of shielding light from the controllers in the control tower is paramount. The fittings chosen are an adaptation of a design for street lighting, and consist of inverted troughs containing three 80-watt fluorescent tubes, with two plane mirrors behind. They are mounted on 30 ft. high standards, spaced at approximately 90 feet. The resulting uniformity and intensity of illumination is most satisfactory.

Similar fittings are used on main roads in the airport, usually mounted at 25 ft. height, whilst on subsidiary roads an aero screen type of fitting with 80-watt mercury lamp, mounted at 15 ft., is used.

Airport lighting control equipment (apparatus room).

NON-VISUAL NAVIGATIONAL AIDS

The *Instrument Landing System* enables a pilot to check his position in the approach to a runway during bad visibility, by means of radio signals. Two beams are projected from the ground, one at a fixed bearing in the direction of approach, emitted from a transmitter situated beyond the up-wind threshold of the runway, and the other at a fixed angle of elevation, from a transmitter quite close to, but offset from, the runway centre line at the touch down threshold. There are also up to three location markers which indicate the distance of the aircraft passing over them from the runway threshold. The aircraft carries equipment which indicates to the pilot any deviation to one side or the other of the azimuth beam and above or below the glide path; the markers each of which has its own distinctive signal, enable the pilot to check his height against distance from threshold and so provide a check on the glide path.

The *Ground Controlled Approach System* requires an operator to advise the pilot of his course as he sees it on the dual cathode ray tubes, which present the position of the aircraft in three dimensions. The aerials of this radar device have necessarily to be placed to align with a particular runway, and for the sake of economy the present type of equipment has been mounted in mobile caravans so that it can be moved around the runways as required. The operators have to work inside these caravans, with light excluded as far as possible, and since there is a considerable amount of heat generated by the radar equipment, it has been necessary to introduce refrigeration to cool the ventilation air through the caravans.

Another application of radar is surveillance, or approach control, which plots aircraft in the vicinity of the airfield and can be used for

The control room on the ninth floor of the control building.

speeding up movement rates by marshalling approaching aircraft into closer intervals of space than would otherwise be safely possible, and by giving early separation to aircraft taking off.

The *Airport Surface Movement Indicator* is also a radar device, which plots aircraft and vehicles on the runways and taxi tracks; this is used to assist the ground movement controllers, within the limitations of its indications.

Standard methods for communication between control tower and aircraft are installed, also direction-finding radio. Certain other radio aids are now being evaluated.

APRON SERVICES

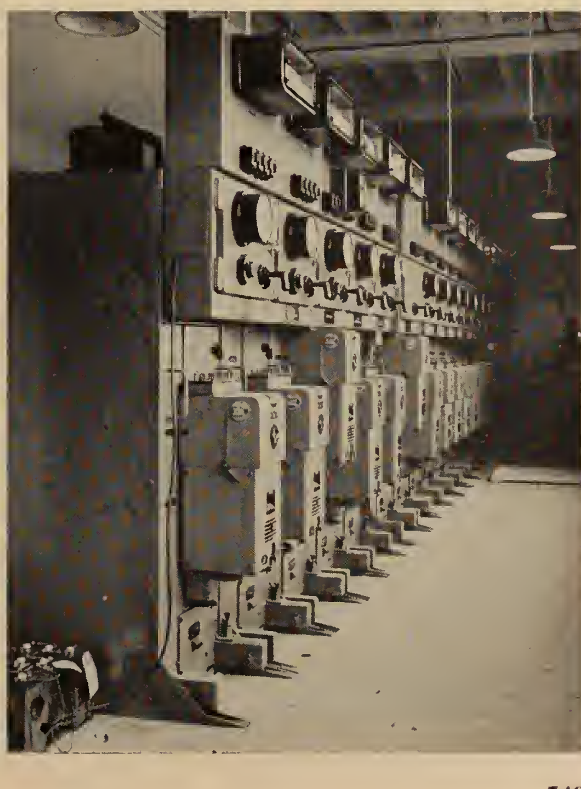
Lighting of aprons is of prime importance, not only to enable passengers and staff to find their way to, and about, the aircraft, but to reduce the danger hazard of rotating propellers. The early lighting by using floodlights at low level was not only ineffective, but dangerous on account of dazzle; this was overcome by using floodlights mounted on low towers, 35 ft. to 40 ft. above apron level, which gave a reasonable illumination to a depth of up to 200 feet.

The central area aprons, however, are nearly 600 feet across; the main taxi route runs through the centre, with parking bays on each side; there is no need to illuminate the taxi track; in fact it is better left dark, hence the problem resolved itself into lighting a strip 150 feet wide from the apron edge towards the taxi track, on both sides of the latter. The factors taken into account in fixing the mounting height were the proximity of runways and taxi tracks on the airfield side of the aprons, the architectural blending of supporting structures with the buildings, and the reduction of glare to taxi-ing pilots, and to the air traffic controllers in the control tower. The chosen height of 60 feet has provided a satisfactory solution to these problems; on each tower up to twelve floodlight fittings of a special design may be mounted, each fitting having a 1,000 w. tungsten lamp. The average intensity of illumination over the 150 ft. strip is 0.5 lumens per sq. ft. Control of the lighting may be effected from the base of the towers, or from the face supervisors control room in the passenger building; power supplies are taken from the local MV network through contactors in the apron sub-stations.

The electrical requirements of an aircraft while on the apron are growing and now represent on the average a load of 20 kw. continuously, with an addition of 60 kw. superimposed momentarily during engine starting. Since the use of engine-driven generators on trucks is expensive and wasteful, a system of mains-fed socket outlets on the aprons is now being installed. Because of the risk of petrol (gasoline) vapour in pits even if flameproof equipment is used it was decided that some form of retractable console was called for, and this has been under development for some time; the final prototype is now undergoing intensive trials.

Since there are approximately seventeen parking bays on each of the central aprons, more than half of which may require power at any one time, and since the engine-starting load is a potential source of bad voltage regulation throughout the electrical system, it was decided to put down a transformer for each pair of retractable consoles, which provide 415 volt 3-phase and 240 volt 1-phase supplies. It was not desirable to house 11 kv. high rupturing capacity switchgear in the congested spaces where the transformers have to be located, consequently a 3.3 kv. ring main has been laid round each apron, and the sub-stations housing the transformers, HV and MV switchgear are of minimum size.

At one time it was expected that



An 11-kv. switchboard in the central area control building, sub-station 23.

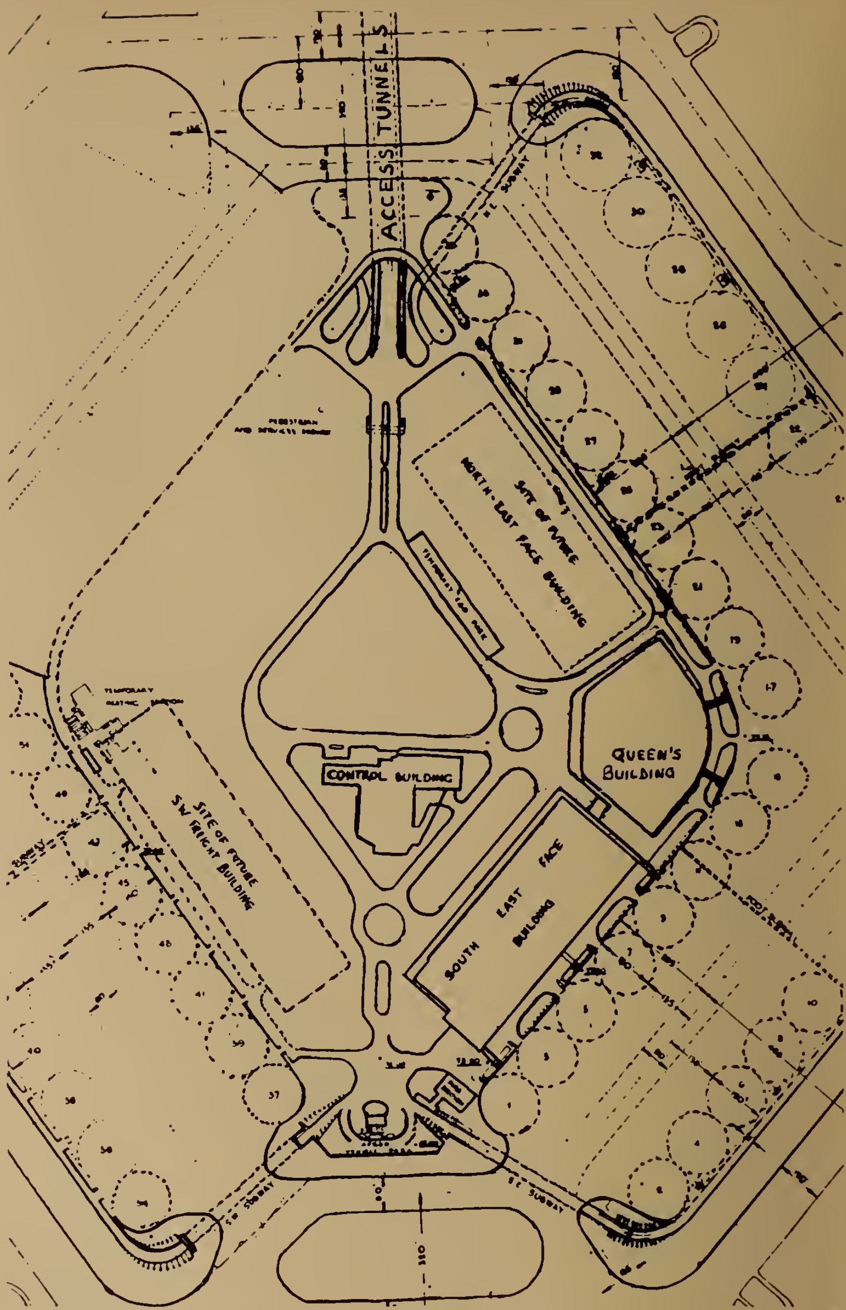


Fig. 2. The central terminal area covers some 160 acres in all.

pilots would need guidance to indicate the parking bay they were to occupy; a system of lead-in and lead-out curves was therefore provided by blister lighting fittings in the apron, and trials have been carried out with illuminated number indicators mounted about 20 feet high denoting the number of the bay. In practice, the curves of light do not seem necessary, and the value of the indicators is now being assessed.

The possibility of installing hydrant refuelling systems on the aprons is discussed in another part of this paper.

TUNNELS AND SUBWAYS

The access to the central area is by tunnel. It is constructed of reinforced concrete, 2,000 ft. long and 86 ft. wide, containing two separate 20 ft. carriageways, two separate cycle tracks and two pedestrian paths. It was constructed on the cut and fill principle and during its construction No. 1 runway was out of commission. Lighting is by cold cathode tubes throughout, the specially designed fittings being triangular in section so as to allow the lighting sources to be mounted at the junction of wall and ceiling on both sides. The lighting is graded down from the portals, and automatic differential switching is provided for day and night use to achieve the maximum economy since the connected lighting load is 130 kw. The tunnel is straight and relatively short, hence no amount of grading can fully compensate for the eye adaptation time.

Apart from the pilot lights (which are mains-supplied through independent circuits) the lighting is fed from both ends of the tunnel, the power being obtained from separate airport rings; the fittings are interleaved on these two main circuits.

The motor carriageways are ventilated from two fan chambers, one serving each way. In each fan chamber are installed two fans each capable of delivering 175,000 cu.ft./min. into the air duct which runs under the cycle subway; from this duct air is fed into the carriageway through grilles spaced at low level along one side; the air finds its own way out of the tunnel. Control of the fans is effected through an automatic gas analyser which determines the amount of carbon monoxide in the tunnel air at one sampling point in each carriageway; this is located at about two-thirds of the length of the tunnel from the entrance.

Drainage of the tunnel is by pumps which deal with the normal drainage of the sub-soil water surrounding the tunnel, which is a continuous process at low rate of flow; and storm water drainage designed to deal with the estimated flow of water into the tunnel from the approaches in the heaviest downpour expected in the district. Both sources of water flow into a common drainage system and then to the pumphouse sump, which is divided into two chambers. There are two normal pumps rated at 625 g.p.m. each, one of which is capable of pumping out the collecting sub-soil water, and four large pumps, of 1,875 g.p.m. delivery each, to deal with the storm water. The latter are brought in automatically, in cascade, on level gauge control in the sumps. In addition, two special sump drainage pumps have been installed to deal with the possibility of petrol spillage finding its way into the sumps; in this case normal pumping will be stopped and the spirit removed into containers. At the same time foam can be introduced into the sumps as a fire precaution.

For purposes of fire and damage control, a number of control points have been established at intervals along the carriageways. At each are fire alarms, telephones, water hydrants, illuminated instruction signs, and traffic lights. These are operated by fire services or police, there is also provision for remote control of the traffic lights, and illuminated signs, which bear the legends "stop" or "stop engines" as required. In ad-

Looking north from the control tower, showing the entrance to the main tunnel connecting the central area to the Bath Road (top of Fig. 2).

dition there are traffic counters at each end of the carriageways, which also indicate the actual number of vehicles in each way at any time; the traffic lights at the tunnel entrances are linked with this differential counter and will turn to red in the event of a sustained concentration of vehicles in a carriageway.

TEMPORARY TERMINAL BUILDINGS AND HANGARS

Prior to the opening of the central terminal buildings all passenger handling was done in buildings erected in a temporary terminal area along the northern boundary of the airport. All the buildings erected in that area, pending development of the central area, are of temporary construction. Temporary hangars and workshops were similarly erected in No. 1 maintenance area.

Since these buildings were constructed rapidly, in many cases from materials no longer required for wartime purposes, the heating arrangements had to follow suit; moreover the plan for the future development of the airport was not formulated. Consequently, it was not possible to design a scheme for district heating nor could the requisite equipment have been obtained at short notice. The immediate demand for heating was met therefore from a number of small boiler houses placed adjacent to the group of buildings and supplying heat by low pressure hot water or steam. The result was unavoidable but wasteful in manpower and less efficient than a large modern central heating plant could be. The arrangement has, however, been perpetuated and indeed added to from time to time to keep pace with growing demands so that today quite a number of small boiler houses exist around the airport. Meanwhile, two interesting modern installations of moderate size have been provided and are described later.

CENTRAL TERMINAL AREA

The central terminal area is diamond shaped (see Fig. 2) and covers approximately 160 acres in all. The area reserved for buildings is bounded by concrete aprons for aircraft stands. These are arranged in two parallel rows on either side of a taxiway which runs through the centre of each apron. Vehicular and pedestrian subways have been provided under each apron to enable vehicles and staff to get to and from the outer aircraft stands without having to cross the surface of the aircraft parking aprons. At the present stage of development the north-east, south-east and the south-west aprons are complete.

The buildings already constructed and to be constructed in the central area are of permanent construction. They are of structural steel framework encased in concrete and faced with hand made rustic bricks.

The electricity supply to all buildings within the central area is taken from the main sub-station at the control building by means of high voltage spur feeders. At present, feeders have been laid to a transformer sub-station constructed underground between the Queen's and the south-east face buildings. From here medium voltage (400 volt, 3-phase, 4-wire) cables are taken to the main low voltage switchboards in each building. An emergency lighting supply for essential lights is obtained from a battery in each building, rated at 30 minutes. Should the emergency last longer than this a supply can be obtained from the control tower standby generating set.

CONTROL BUILDING

In the centre of the central terminal area is the control building which is T-shaped in plan on the ground and first floors with a central tower rising to a height of 126 ft. The control building houses all the aerodrome approach control and ground movement operations rooms, telecommunications and airport administrative staff as well as staff restaurants. All movements of aircraft approaching and departing from the airport and all movements of aircraft and motor vehicles on the aircraft manoeuvring areas are controlled from this building, which is, in consequence, the focal point of a highly complex system of radio and line communication, radar and radio navigational aids, airfield lighting and ground movement control.

The tower in plan consists of two intersecting trapeziums with staircases and a central services core be-

Main access tunnel—interior view of eastern vehicle tunnel looking south.

tween them. The central services core extends to the full height of the tower and contains lifts, ventilation trunking, pneumatic message tubes and cable ducts. The control rooms have a false floor underneath in which cables and tubes are run direct from the services duct to any position in the room; thus ensuring flexibility in the layout and easy maintenance of technical equipment.

On the roof of the nine-storey control tower, in a glass fronted penthouse, is the aerodrome control room which commands an all round view of the airport and its approaches. Movement of all aircraft and vehicles on the airport is controlled from this room. Immediately below is the approach control room which is enclosed by glass on three sides. This room houses radio and radar equipment by which the controllers guide aircraft from distant radio "fixers" on to the airport approach path.

Below the approach control room in the tower are administration offices, conference room, etc. The east wing of the building houses telecommunications equipment and telephone exchange; the west wing accommodates the medical centre, while staff restaurants and rest rooms are located in the south wing.

The control tower is operationally the most important building at the airport; consequently, special precautions have been taken to ensure continuity of electricity supply. The incoming supply is taken from two transformers each of 500 kva. rating, fed from the central substation. On the medium voltage side there are two main switchboards, the division being made here into "essential" and "non-essential" services. This distinction is, of course, applicable only to emergency conditions when in the case of power failure the stand-by set is run up and connected to the "essential" switchboard only. The maximum demand of this building is of the order of 450 kva. but the essential load is about 150 kva. at present. To meet this a 250 kilowatt supercharged diesel engine generating set running at 600 r.p.m. and automatically started has been installed adjacent to the control tower. This set will run up and take this essential load in 20 seconds from a mains failure.

All electrical requirements for navigational purposes are essential loads, together with the lighting and heating of the rooms occupied by the air traffic control personnel.

The lighting of rooms in the control building, with the exceptions noted below, is of a high standard, fluorescent sources being used extensively, whilst in the staff restaurant the lighting is decorative. The exceptions are the aerodrome control room at the top of the tower which has continuous glass windows all round, and the approach control room. In the former any light source above the level of the operating personnel can be annoying by causing reflections on the glass. This has been overcome by placing the light source in a small tube with a narrow slit along one side which can be varied in width and is placed at actual desk level to illuminate instruments (where these are not self-illuminated) and writing pads. In the approach control room with its radar screens normal light is required for certain functions, whilst the viewers must have very little light. These apparently incompatible interests are still under investigation. Most of the areas are provided with forced ventilation to exclude dust and noise. Filters, fans and heating batteries are housed in plant rooms situate at convenient positions, the air systems being similar to those in the passenger building described elsewhere. In addition there is a very large solar gain in the aerodrome control room and somewhat less in the approach and control rooms immediately below. To enable comfortable conditions to be maintained in these areas, air-conditioning plant has been installed. This uses the same air system as for winter ventilation with the addition of cooling coils through which chilled water is circulated, that is, there is temperature control but no humidity control, the condition of the air being arranged to come within the comfort zone as derived from the psychrometric chart.

Apart from the warm air of the plenum systems, other heat is introduced in the building through radiators and convectors as necessary to bring the temperature to 65° F. normal. Domestic hot water is obtained through secondary systems from calorifiers. High pressure hot water is used direct in some of the kitchen cooking equipment, the remainder being electrically heated.

Two lifts have been installed in the centre of the tower proper, one used normally for passengers, having a speed of 300 ft./min., and the other for freight.

A comprehensive automatic routeing message tube system is installed between the air traffic controllers at the top of the control tower and the telecommunication and meteorological staffs below, also from the control tower to the passenger handling buildings. The master clock is housed in this building, from which a number of circuits are run throughout the building and also to the passenger handling and Queen's buildings, all of which are equipped with slave dials of various types. For use by the air traffic controllers there are also cyclometer type clocks registering at 5-second intervals, the figures being half an inch high.

The lightning protection system arranged at the top of the control tower is adequate for coverage of the other buildings at present.

The new Queen's Building from the control tower in the central area.

PASSENGER HANDLING BUILDING AND QUEEN'S BUILDING

The first passenger handling building erected in the central area is sited in front of the south-east terminal apron. The second passenger handling building will, in due course, be erected in front of the north-east terminal apron. In between these, on the eastern corner of the central area, is the Queen's building which is now rapidly approaching completion.

The passenger handling building now in use is some 600 ft. long by

250 ft. wide and three storeys high and handles all short haul passengers passing in and out of London Airport. It is designed so that passengers pass transversely through the building by a number of parallel channels each of which is self-contained with immigration, health, and customs control. Each channel is served by a baggage conveyor belt running beneath the first floor, except in the customs hall where it rises to first floor level to bring the baggage up for inspection. Passengers are thus able to pass easily and quickly through the control formalities. The main feature of the building is the large concourse which runs almost the full length of the building on the first floor. Departing passengers enter on the ground floor and are conveyed by short escalators up to the main concourse on the first floor and then through their appointed channel to customs, immigration, health, final departure waiting room, and thence by a bridge to the aircraft parking aprons. The whole of the lower ground floor of the building is given over to the handling of baggage, the accommodation of technical staff and equipment, kitchens, plant rooms, etc. The first floor is given over to passenger handling and facilities for passengers and on the second floor are restaurant, buffet, lounge, and office accommodation for operating companies. Shopping, banking and other facilities are provided in the main concourse. The roof of the building is planned to accommodate spectators who will gain access by a bridge from the roof of the Queens' building on to the roof of the passenger building.

Passenger Building concourse; line source loudspeakers and chandeliers.

The main electrical distribution cables are run from the medium voltage switchboard to sub-distribution panels throughout the building, and separate cables are taken to the plant rooms for the heating and ventilation equipment. A maximum demand of about 1,000 kva. is expected when the building is operating to its maximum capacity.

The lighting fittings in the south-east face building have been chosen primarily to harmonize with the interior architectural features. There are some very large spaces where good lighting is achieved by fluorescent tubes either concealed in the ceiling as in the main concourse or provided with pleasing fittings as in the customs hall where the level of illumination is of the order of 15 lumens per sq. ft. over the inspection benches. Some lighting is purely architectural as exemplified by the unique chandeliers in the main concourse, and an indirect use of cold cathode tubes round the circular roof lights over the balcony.

Most of the building is sealed against exterior noise; in consequence resort has been made to mechanical ventilation. The air is filtered and heated (when necessary), and the basis of design is six changes of air an hour. The main concourse has seven plenum systems introducing air at low level and extracting at ceiling. All other parts of the building are ventilated from two large plant rooms each containing a number of plenum and recirculation fans together with their heating batteries. Air supplies to kitchens are based on 20 changes an hour with total extraction.

Apart from heating by warming the air there are two large systems of floor heating, one in the main concourse and the other in the customs hall; also to a minor extent radiators are employed. The floor heating is designed to give a constant floor surface temperature of 75° F. The overall effect of heating and warm air is to attain a temperature of 65° F. to 70° F. throughout the building, the various sections being thermostatically controlled.

High temperature hot water is brought into the plant rooms and the air heating batteries are directly connected. The floor heating coils, radiators and domestic water services are all supplied at low temperature through calorifiers which are also housed in the plant rooms. Steam for kitchen purposes is raised in generators directly heated by the high temperature hot water, and in some instances the latter is used direct for heating cooking appliances.

An interesting installation is the baggage conveyors which take passengers' baggage from the ground level up to the customs hall, then drop down again to ground level. A number of endless belts form each conveyor. Provision has been made for emergency stops by customs officers and also at other positions as may prove necessary. In handling baggage of all imaginable kinds, care has been taken to make the transmission from one belt to another and also around bends as proof as is possible against accident by jamming or ripping of the fabric of the containers. In addition to the push button stops, customs have physical barriers which can be lowered by hand across the belts, and there are electric eye installations to stop the belt if an object has not been removed for examination.

Two kitchens are provided, one for the public restaurant and snack bars, and the other for the preparation of aircraft meals; for the former, food and wine lifts are provided to serve the various floors at which meals may be served. Since these lifts are handled by any of the kitchen staff and may have access from either side, care was necessary to ensure that adequate interlocking was incorporated.

The public address systems in the building are quite comprehensive, serving the three main functions of operational instructions, notices to passengers, and entertainment. There are three separate systems all subject to the overriding control of the airport management; the first, notices to passengers, in the main passenger parts of the building; second, the local systems in each of the waiting rooms where outward bound passengers have passed through customs; and third, the entertainment parts which are largely the roof spaces. The feature of interest in these installations is the first use made in this country of the "line source" type of loudspeaker for large areas. In particular the main concourse has two sets of such loudspeakers mounted in vertical line back-to-back at approximately the centre of the concourse which is 480 feet in length. Each "speaker" consists of 10 loudspeakers of 50 watts maximum loading each.

Queen's Building

The Queen's building which is located in a central position between the present and the future passenger handling buildings is designed to cater for aircraft operations and crew rooms as well as providing amenities for the visiting public. The operations accommodation will include aircraft and crew clearance rooms, meteorological forecasting, and flight planning and crew briefing rooms, etc. For the general public it will house an exhibition hall, post office, news cinema, lecture hall, grill room, and buffet. It will also provide access to the roof gardens of all the main buildings where amenities for the visiting general public have been provided. These buildings are connected with one another by bridges at roof level.

Most of the services follow lines similar to those in the main passenger building. The maximum demand on this building is expected to be 600 kva. This building is to be brought into use in the near future.

PERMANENT HANGARS

Two permanent hangar blocks have been built in No. 1 maintenance area as a first stage in the development of the permanent engineering and maintenance bases for British Overseas Airways Corporation and British European Airways. Both these buildings are entirely self-contained in that they include offices, workshops, stores, and all the facilities and services for undertaking major overhaul of aircraft.

The larger of the two permanent hangar blocks has been constructed for B.O.A.C. and measures approximately 860 ft. x 410 ft. overall. It is of reinforced concrete construction throughout and consists of four hangars, separated from one another longitudinally by an engineering hall 126 ft. wide which runs the full length of the building and transversely by stores, workshops and offices which rise to a maximum height of 66 ft. and for which lifts have been installed. Offices at one end of the block provide the main headquarters' accommodation for B.O.A.C.

Central light well in the engineering hall at B.O.A.C. headquarters.

Each hangar has a clear door opening of 300 ft. x 45 ft. and a clear depth of 140 ft. from front to back. The hangar doors are of the folding type the covering being corrugated aluminum sheeting. Normal drive is by electric motors through reduction gearing. Hand operation is also available in case of emergency. The building is constructed on the cantilever principle, and reinforced concrete cantilevers with portal girders over the hangar doors provide the main supports for the roof which is glazed. Each of the counter balance blocks to the 8 cantilevers over the hangar doors weighs 1,000 tons and the total load on the foundation of each of the 8 main pylons is of the order of 4,000 tons dead weight.

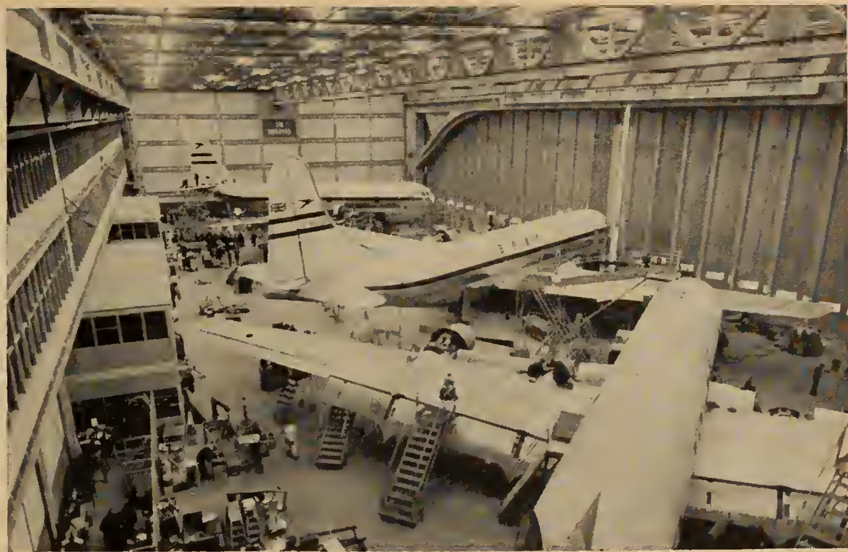
There are five electrical substations within this building, four of which are transformer substations on a ring main, the fifth being a high voltage switching point connected into the airport distribution network. Each medium voltage system is electrically separate but there is provision for linking the systems should one of the HV substations be put out of action. Considerable use has been made of bus-main trunking on the 400 volt 3-phase side to facilitate connection of machine tools and other loads which may be in temporary use. All electrical installations within the hangar pens are required to be of flameproof construction from the floor to a height of 10 feet above the maximum height of the wing of the largest aircraft which can be accepted. Included in these flameproof installations are six floor pits in each pen containing socket outlets for the tools and appliances which are used when working on the aircraft. The maximum demand at present is 2,000 kva. but this expected to rise to over 2,500 kva.

Lighting plays a big part in this building, for much of the space comprising the engineering hall is without natural light. In this area 200 kw. of cold cathode lighting has been installed, producing a minimum intensity of 20 lumens per sq. ft. at working plane. In the hangar pens, which are 55 feet high to the underside of the roof trusses, the lighting fittings combine 750 watt tungsten lamps with 400 watt mercury lamps. Each fitting comprises two inverted glass refractors which concentrate the bulk of the light downwards but allow an appreciable upward spill to illuminate the roof and thus avoid the "dark tunnel" effect. Since the mercury and tungsten lamps in each fitting are spaced within two feet of each other, the colour blending is good and the average intensity of illumination on the floor is 20 lumens per sq. ft. The lighting load in each pen is 124 kw. The remainder of the lighting is largely by fluorescent tubes, although some use is made of tungsten lighting especially in the light workshops where radio interference suppression is required.

Heating of the hangar pens is by floor coils through which flows low temperature hot water giving a design temperature of 77°F. at the floor surface. As some compensation for main door opening, a high velocity unit heater is mounted on each side of the door at 15 feet above floor level; these are brought into use as required. Provision has also been made to install high temperature radiant panels along the back wall 20 feet above floor level, should these be required in the future to provide a higher level of heat to men working on the aircraft. The majority of offices and store areas are ventilated by plenum systems giving four air changes an hour with re-circulation. In most offices there is also a low temperature convector heater to offset the loss of heat through the fabric of the building; some use is made of high temperature hot water pipes suitably guarded for this purpose also. The kitchen which serves a very large canteen is provided with cooking equipment mostly heated by high temperature hot water, and is ventilated by 20 air changes an hour.

Cranes are provided in the hangar pens covering the full depth of 140 feet. These are in two sections each bridge being independent of the other and can be used as a separate crane; the two bridges can be latched together and used as a single unit thus making possible the interchange of the load. The maximum load on any bridge is five tons under any condition of usage. There is also a five ton crane spanning 80 feet over the central workshop.

The workshop services include the provision of compressed air at 120 lb. per square inch gauge from a central plant, a limited supply of air at 3,000 lb. per square inch gauge, and a vacuum plant. Air conditioning has been provided for the radio and instrument workshop to hold the temperature of 68°F., and relative humidity not exceeding 50 percent. Public address systems, electric clocks, and fire alarms are also provided. Sprinkler and "deluge" systems which work in conjunction with the fire alarms are



Interior view of a hangar in the B.O.A.C. hangar block.

described in another part of this paper. A comprehensive lightning conductor network is provided over the roof of the building.

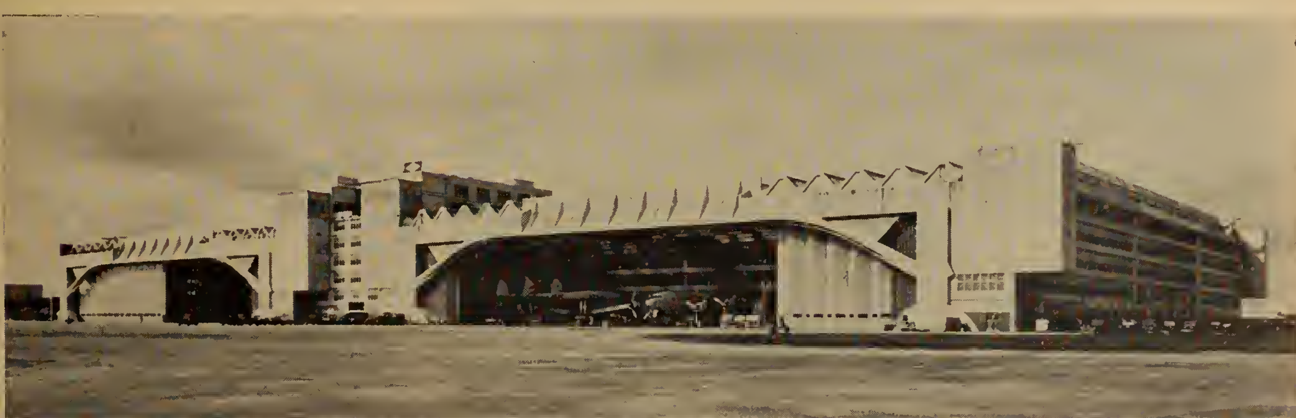
The smaller of the two permanent hangar blocks has been erected for B.E.A. and consists of two hangars each approximately 900 ft. x 110 ft. placed back to back with workshops, offices and service rooms in between. Each hangar has five separate pairs of doors which have a clear opening of 150 ft. x 30 ft. A large stores block flanks one end of the hangars and the overall dimensions of the hangar block are 1,020 ft. x 460 ft. This building is constructed principally of reinforced concrete with prestressed concrete roof beams over the hangars.

The lighting of the hangar pens has been carried out using a cold cathode installation consisting of tubes running fore and aft fixed beneath the roof trusses at 15 feet centres. The tubes are 35 feet above floor level and designed for an average intensity of 20 lumens per sq. ft. on the floor. The lighting load in each hangar (5 pens) is 225 kw. The hangar pens have partial floor heating extending from the main doors to about one third of the depth. The remainder of the required heating is supplied in the form of unit heaters placed along the back wall, these being supplied with high temperature hot water from the main heating plant. The remaining heating throughout the building is by high temperature panels and low temperature radiators and convectors, domestic hot water being obtained through calorifiers.

The electrical requirements of this building are provided through a high tension substation on one of the airport ring mains in which transformers are installed and the main medium voltage switchgear is located. The maximum demand is of the order of 1,500 kva.

HEATING SERVICES

All the buildings of temporary construction are heated by low pressure hot water or steam. The boilers are all small units fired with coal, automatic stokers being fitted to about half of them, and the heating pipelines extend less than a



B.O.A.C. headquarters and hangar block at London Airport.

quarter of a mile from any boiler house.

In 1951 the first high pressure hot water boiler plant was brought into commission to provide heat for the new permanent hangar blocks then under construction in No. 1 maintenance area. The boiler house contains seven economic type boilers, coal-fired, each rated at 10 x 10^6 B.t.u. per hour, and each fitted with an automatic stoker which feeds chain grates in four boilers and underfeed grates in the remaining three. All boilers have induced draught fans.

Water is circulated at 120 lb. per square inch gauge, and 325°F. through the pipelines to the hangar blocks, one of which is situated 400 yards to the east and the other 1,000 yards to the west of the boiler house. A base-exchange water treatment plant has been installed.

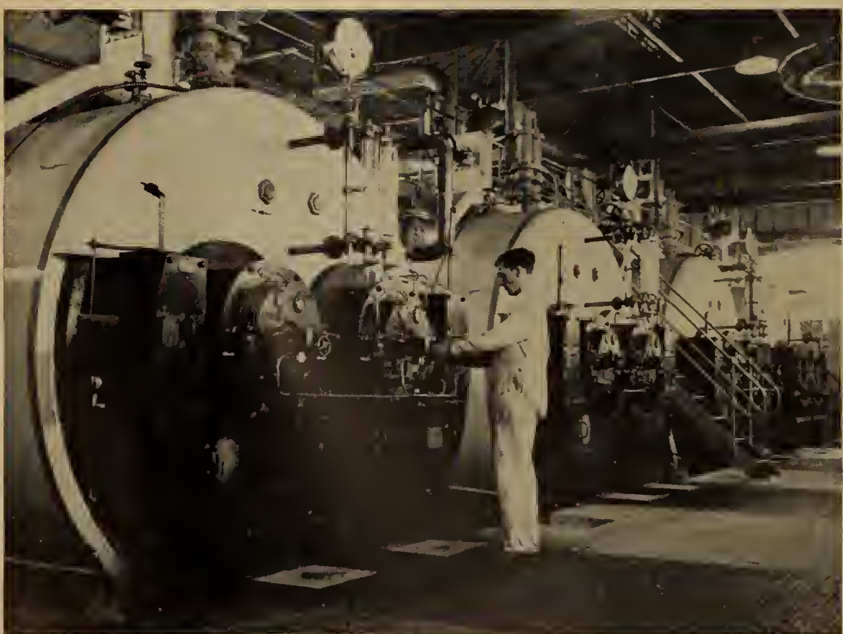
Instrumentation has been carried to the extent of providing automatic control to all boilers, hence a constant watch on efficiency is maintained. The quantity of heat is computed from the readings of the Venturi meter and temperature recorders.

This boiler house has recently been extended by the provision of three new boilers of the LaMont type, which are vertical water tube type boilers of relatively small water capacity, each rated at 10 x 10^6 B.t.u. per hour also. These feed into the common range and are oil fired using 950 seconds fuel oil.

Another high pressure hot water boiler installation has been brought into use in the central area to provide heat for the new terminal area buildings. Because the final development plan for this area was not available, the boiler house was erected in temporary construction and contains four economic type boilers each of 10 x 10^6 B.t.u. per hour, water is circulated at 165 lb. per square inch gauge, and the temperature at the boiler outlet is 350°F. This also is an oil-fired installation using 950 seconds fuel. No automatic control has been installed but instrumentation is adequate to provide a constant watch on efficiency. Induced draught fans are provided. All four boilers emit their flue gases into a common chimney. Since the boiler house is not far from the control tower, the height of this chimney was reduced to 80 feet and the density of smoke is strictly controlled and recorded on a chart. The feed water is treated in an acid softening plant. The water pumps providing the circulation through the pipelines are centrifugal type. The present length of pipeline supplied from this boiler house extends to a distance of 700 yards, and on these pipelines some of the expansion devices are of the bellows type, which have proved very satisfactory.

To meet the heat requirement for the further development of the central area, which cannot be obtained from the temporary boiler plant, a new central heating station is now being designed which will have an ultimate heat output of 100 x 10^6 B.t.u. per hour, and it is proposed that this shall be a pressurized system at 250 lb. per sq. inch gauge. This will, of course, feed into some of the existing pipelines.

A view of the boiler plant in the central area at London Airport.



FIRE SERVICES

A description is given here of the fixed installations which form part of the fire-fighting services but no account is taken of the mobile equipment and its uses since these are not engineering services.

The supply of water for fire fighting has been made completely independent of all other water usage, and the general principle adopted as the basis for design was the simultaneous requirement of fixed quantities of water at three points in the airfield, namely, the runways, the aprons, and a maintenance building.

Surrounding London Airport there are a number of very large gravel pits; some of these are worked out and remain as reservoirs into which storm water from the airport is drained, as previously described. The pumphouse was accordingly located beside the eastern balancing reservoir which is adjacent to the largest maintenance area. The fire mains extend to the central area, a route length of some 5,000 yards, and will later be extended a further 1,000 yards westwards.

The pumphouse floor is constructed below the water level in the reservoir to ensure permanently flooded suctions for the pumps of which there are eleven installed. Seven of these are the main fire pumps each capable of delivering 1,850 gallons per minute against a pressure of 130 lb. per square inch. The 325 b.h.p. driving motors are directly started through the 3.3 kv. switchboard, and are brought into operation automatically in pressure controlled sequence. There are, however, two smaller balance pumps of 100 gallon per minute delivery, which are installed to maintain a static pressure of 130 lb. per square inch in the fire mains. To ensure steady operation and provide the initial quantity required when water is demanded, a 12,000 gallon tank is connected to the delivery lines and maintained half full of water under the mains pressure by compressed air; the two remaining pumps remove any water which may collect inside the pumphouse.

The electricity supply is obtained from the airport distribution system through two 1,000 kva. step-down transformers from 11 kv. to 3.3 kv. In addition a smaller transformer steps down to 400 volts for pumphouse services. The pumphouse is normally not manned, and although the pumps are brought in automatically, they are arranged for

(*Continued on page 780*)

Automation, Men, and Machines

J. J. Brown,

President, Industrial Automation Limited, Montreal

Suppose you are the owner of a manufacturing plant and a salesman comes up to you and says he can give you a device that will operate your punch presses and other machines automatically. He offers you these operating gadgets for only $22,000 each. You are interested, but in the course of conversation the salesman has to admit that it will take a little time to get the operating gadget properly adjusted, and thereafter it will run for only two hours without a rest. Moreover, it must not be used more than eight hours a day or two thousand hours a year. There also is the drawback that the performance of this gadget varies from hour to hour, it is sometimes inoperative for days, and at least once a year it will fail to work at all for a two-week period. Finally, it turns out that the device has a maintenance cost to you of $1.75 an hour, plus miscellaneous charges which amount to another $1.25 an hour.

Now if this proposition were made seriously to you as a hard-headed plant manager, you would undoubtedly throw the salesman out the door without ceremony. As you ushered him to the door, you might take time to point out that the whole machine his gadget is to operate costs only $1,000, that the machine itself can work 24 hours a day, 365 days a year, with perhaps only 1 per cent of its cost per annum needed as a maintenance charge. Moreover, the whole machine costs only $1.00 a day to operate, including its depreciation.

Although no plant manager in his right mind would buy such an operating device today, the fact is that literally millions of such units are in use in industry. The only reason why we put up with it is that we don't realize we are paying $22,000 for each one we have in our plants.

This machine-operating gadget I have been describing is, of course, a man. Man was not designed by nature to be a machine tender. He does not work well in series with the machine.

Since man is alien to the machine, we have had to devote years of effort to easing his pain. We have large personnel, job evaluation, time study, employee relations, health, education and recreation departments—all designed to make the human machine operator feel better about his job. In the aggregate these departments cost the company more than the entire production department.

For some years I have been advocating a program for solving all these problems at one stroke, by getting the man entirely off the production floor.

Automation represents a belated recognition that to a large extent man is out of place in the factory, and should be removed, in the view of the author. The subject is defined and its history traced; the economic and social effects of automation and its status in Canada are all discussed.

Automation today represents a belated recognition that to a large extent man *is* out of place in the factory, and should be removed. This will make it possible for men to live more satisfying lives, and also allows the factory itself to become more efficient.

The main reasons why the recognition came in 1955 instead of 1935 are four: the development of new technology under forced draft during World War II, new understanding of public relations techniques, the postwar prosperity and concomitant shortage of manpower, and finally, organized labour's need for an issue suitable for boom times.

In all areas of study, psychology as well as architecture, machine design as well as economics, there is something called "cultural lag". Twenty to forty years usually pass before the carefully thought out ideas of the professors finally work their way into the public consciousness. Lord Keynes, whose ideas on monetary policy were alternately laughed at and ignored for a quarter of a century (before being universally adopted) was well aware of cultural lag. So was Sheridan, the man who vainly tried for years to sell his intake ice preventer, as aircraft continued to crash on take-off; so was Biro, the inventor of the ball-point pen; Armstrong, the pioneer in F.M. radio, and a thousand others, known and unknown.

One lesson to be learned from the long history of technology is

Read at the 70th Annual General and Professional Meeting of The Engineering Institute of Canada, Montreal, May 1956.

this: that technology alone is not enough. After the discovery is ready for the world, the world must be made ready for the discovery. This publicity, or public relations aspect of the total problem often takes just as long as the scientific aspect.

The history of the rise of automation is a classic example of the general principle I have outlined. On the level of technology, there is nothing in automation that was not known ten years ago. At the level of scientific principles, everything we need for today's level of automation was laid down over two hundred years ago. After World War II, we had available everything required for a rapid development in automation. We had a large body of technicians and engineers who, during the war, had become intimately familiar with the theory and practice of automatic control; we had analogue computers, gun laying devices, electronic controls, and a thousand other equipments refined to a high state of perfection.

And finally, we had, at the end of 1945, a successful automatic factory, (Sargrove's Electronic Circuit Making Equipment) operating in England.

What then was missing? If everything was available, why didn't we all hear about automation in 1945 instead of in 1955? How did we come to lose ten years in this vital race? The missing element, a priceless ingredient, was public relations.

The technical people in the field did not care what the public thought, so in return the public ignored their work.

When the technological history of our time comes to be written, two of the most striking episodes will be Orson Welles's "Invasion from Mars" program, which caused panic in the streets, and the spectacular rise of something called automation. What these seemingly disparate events have in common is their demonstration of the power of publicity. Without modern techniques of communication and propaganda, neither event would have happened; or at least, would not have appeared in the form it did at that particular time.

The rise of automation is a remarkable example of what is needed to arouse society's *interest* in a problem. Each year since 1949, Professor Doriot of the Harvard School of Business Administration has assigned a group to study automatism, particularly as applied to the automatic factory. In 1949 the leader of the group, Philip Zeigler, wrote me for information and a bibliography, since at that time Leaver and I were the only people who had written on automatism. Of course I had to tell him that there was no bibliography—that what we had written was fashioned from whole cloth.

The next year, the leader of the Harvard group was James Bralla, now of Princeton. His group too wrote an excellent report, which, as before, was consigned to oblivion.

But in 1951 the man appointed to lead the group was John Diebold, a man who combined the necessary engineering skills with a keen sense of the value and use of publicity. His group wrote a report that was neither better nor worse than those of its predecessors; in fact, since there was nothing new to say, it was substantially the same. But the report was promoted with remarkable skill, using all the most advanced techniques of publicity, public relations, and management consulting.

A Catchword

One thing needed was a catchword that would sum up the whole area of automatic control. In answer to this need came the word "automation" a horrendous mixture of Greek and Latin roots (thought up, I am sorry to say, by an engineer). But whatever the philologically sensitive may think of the word, it did the job. Pushed as "the latest product of American ingenuity" by the publicity departments of the great automobile companies, by 1955 the word was on everyone's lips. The missing element of publicity, once it was supplied with typical American aggressiveness and imagination, gave the subject of automatic control just the push it needed. Automation became what the general semantics people call "an OK word". Today, when speaking on automation, you enjoy the businessman's confidence. You are no longer labouring under the suspicion of being an impractical dreamer.

As a result of these activities we have today not really much more knowledge of automatism (in fact, some would say that what factual information we *had* is now buried under a mass of false or over-simplified "truths" known to all), but public awareness of the subject has reached a new high. There are three new magazines devoted entirely to automation; older magazines are trying to get into the act by adding the words "and automation" to their titles; conferences by the score have been held; editorial writers have editorialized, pundits have pontificated. By now everybody has had his say on this subject except a few obscure professors of Old Testament theology.

This spectacular change in the public attitude toward a subject in less than ten years cannot, of course, be ascribed entirely to one man. Many factors that were missing in 1945 had come to the fore by 1950.

One basic thing was a change in our attitude toward employment. In 1945 we were most of us still depression minded: we were looking for ways of providing work for everyone who wanted a job. By 1950 people were beginning to see that the labour supply was tight, and was going to remain that way for the foreseeable future. And, of course, when there is a shortage of labour, it is relatively easy to interest businessmen in labour-saving devices.

Again, the labour unions were not interested in automatism in 1945 because they were too busy with what seemed to them more immediate matters. But by 1950 most of the immediate post-war labour-management problems were well on their way to solution. With unprecedented prosperity, and talk once more of two cars in every garage, the union leaders stood badly in need of an issue. Because without a good issue on which to take a stand and make pronouncements, all members of the opinion-manipulating groups are lost. When the word automation began to enter the public consciousness, union leaders were shrewd enough to see that it was a godsend. They immediately jumped in with both feet, painting a frightening picture (à la Norbert Wiener) of thousands of men made jobless by the machine. One union executive has said: "The answer to automation is unionism". However this may be, it is clear that automation has provided the unions with a badly-needed issue, and that the revival of such ideas as the guaranteed annual wage can be traced directly to it. All this talk has been good for the union business, but it has also done much to make the public conscious of automation.

As you see, I am willing to concede that the invention of the word automation played an important role in the development of the field. It provided a convenient, (if messy) peg on which to hang a large number of seemingly unrelated notions about information handling and automatic control.

DEFINITION

But the word is now rapidly losing its usefulness, particularly among technically-trained people. Perhaps now, in 1956, the propitious moment has arrived to bring up once more the unpopular subject of definition. Defining things, so we know what we are talking about, is dull, and I am not going to bore you by any detailed description of classification schemes at this time. But what I want to suggest is that until we have good definitions, clearly understood, there is going to be an immense amount of aimless thrashing about in this important field. Leaver, Sargrove, Amber and others have published elaborate classification schemes covering the whole field of present and future automatic devices. I have even published one myself. I realize that it will take some time for reasonable areas of meaning to be assigned to key words in this field, and even more time to gain public acceptance for these meanings. But my plea is that we should start *now* to give serious consideration to the basic problem of terminology.

The problem of what automation *is* becomes particularly acute when one attempts, as I am about to do, to discuss its effect on individual men and on society. Let's say, you think that the word automation means sulphuric acid, and I think it means brown bread. We don't discuss our private definitions, but plunge immediately into a debate on its effect on the human digestive system. You can see at once that this is an impossible situation.

In view of the current confusion, let me take a few moments to outline briefly what *I* mean when I use the words automation, automatic, mechanized, automatism.

At the risk of oversimplifying a complex subject, I want first to divide all methods of handling information to provide a service, or raw materials to provide a product, into two basic classes: The first class I call mechanization; the second I call automatism, or (under protest and only in order to communicate) automation.

These two classes are characterized by different properties in almost every parameter. For example, in terms of basic design, the first class of machine is designed in terms of the product it makes, while the second is designed in terms of the function it performs. Again, when we look at the type of construction typical of the two classes, mechanization produces machines that tend to be relatively large and monolithic; automatization produces machines that are made up of many small units plugged together. In overall size, the first tend to be relatively large, the second relatively small. In terms of flexibility—the range of products the machine can make—mechanization tends to produce a narrow range; automation a wide range.

When looked at from the point of view of control, mechanization makes use of mechanical means such as cams, or of relatively simple electrical means such as limit switches. Automation, on the other hand, uses either electronic control or more complex electrical means, such as servomechanisms.

The feature that makes an ordinary machine into an automaton is programming. Programming in general is machine control moved up to a higher level of sophistication. Programming a machine consists of making available to it, in some form, the information which tells it what to do next. This information can be built into a machine in one of two ways: the machine can be told (by means of a metal cam, record, or punched tape) to do this, then that, then the other thing. Or, the machine can be made sensitive to what is going on in its surroundings, or to what its product looks like. Then it can make the changes needed to bring its operation back to normal.

This last is usually done by feedback, which might be defined something like this: if, in any manufacturing operation, the tolerances are close, so that variations in the raw material and environment become important, then the program running the machine has to be adjusted automatically from time to time to fit these variations. These program changes must be made in such a way as to keep the product the same.

The use of feedback leads to a more sophisticated type of automatism, one that is self-adjusting, as well as self-operating. For the machine, the program answers the question "what shall I do?": Feedback answers the question "how am I doing?". Feedback systems can be more or less advanced depending on whether they look at the operations themselves, or at the results of the operations, that is, the product.

It is often charged that automatic control is complicated. Far from tending toward complication, the use of feedback can lead in many cases to extreme simplification. Take, for example, a windmill. By means of a very simple feedback device (a vane placed at one extremity of the rotatable top) the blades are always kept pointing in the direction yielding best operating efficiency. Now if a modern industrial efficiency expert, working along conventional lines, came to the farm, he would realize that the farmer has to be working in the barn and fields most of the time, but also he has to be running out periodically to point the windmill into the wind. The efficiency man would gather charts showing the wind direction and velocity for the past twenty years; he would plot the farmer's steps and turnaround time between the barn and the windmill; he would plan optimum intervals between windmill adjustments; he would study perhaps twenty or thirty such contributing factors. Then, when all this was done, he would work out a more efficient system for organizing the farmer's work, dividing his available time between the barn and the windmill. That is, he would develop a complicated plan for fitting the man in with his machines.

But the expert on automatism comes along and eliminates all the above at a single stroke. He makes the simple suggestion that a tail be put on the windmill, thus eliminating the man.

U.S. AND CANADIAN INDUSTRY

To complete this catalogue of the basic differences between mechanization and automatism, let us look for a minute at the three kinds of industry in Canada and the United States today. At the top, in terms of the public's awareness of it, is mass production industry; highly-mechanized, efficiently-run plants designed to produce large runs of one standard product. At the bottom are the custom builders, people set up to make a small number of specially-designed, hand-built, hand-rubbed luxury products that are shipped out to customers in fleece-lined cellophane bags.

In between are the job shops. These comprise by far the largest group in our economy, both in capital invested and number of employees. These plants make the shorter runs of mass-produced goods, often serve the capital rather than the consumer goods market, and carry on their activities in a very large number of relatively small plants.

Of the two basic types of machine organization I have been speaking about, mechanization is the one that fits the top layer, the layer of mass-production industry. Automatism is ideally suited to the second layer, the job shops. Neither type has wide application for the custom builders, except indirectly.

But since the job shops are most numerous, and employ most of our industrial workers, I foresee a better future for automatism than for mechanization. In fact, as far as I am concerned, mechanization is a dead-end street.

This brings me to my main point, which is this: the social and economic effects of automation depend first on what kind of automation you are talking about, and second on the particular area of our economy in which it is applied. Detroit automobile manufacturers have put advanced mechanization into a large mass-production industry and are reaping one kind of social and economic consequence; the small machine tool builders are applying elementary automatism to the job shop, and will cause quite different consequences.

This is not to say that the consequences of mechanization and automatism are different in every respect. There are enough similarities, and the subject as a whole is complicated enough to make it rather easy to confuse the two.

HISTORICAL SKETCH

Only the word automation is new. The fact dates back to the time when the first user of a hand tool wished that the tool would go on performing the work, leaving its owner free to go about more entertaining business. The development of automation has taken place in orderly stages, from the primitive situation when men produced goods by hand, to the high degree of automation that I see for the future, when machines alone will produce and distribute many goods and services. Over the centuries since the invention of the wheel, the trend has been toward less and less work by men, and more and more work by machines. Such ideas as interchangeability of parts, steam power, mass production, standard screw threads, have laid a firm groundwork for the complex industrial society we know today.

The automatic factory grows from the bottom up, rather than from the top down. That is, we do not begin with a computer and then decide to what machines the computer shall feed information. On the contrary, first a few machines are made to control themselves automatically, then later these machines are linked so that the action of one machine controls another. Finally, so many machines have been linked the whole factory is integrated, and you have automatic production of goods.

This series of events has already taken place in some process industries.

Mechanization of work processes, which is the basis of automatism, goes back into pre-history. The Greeks had a form of machine gun, and other fairly high levels of mechanization can be seen in classical times in the works of Hero of Alexandria.

The mediaeval clockmakers played an important role in the advance of mechanization. With the revival of seafaring that came with the Renaissance there was a great need for a method of determining the longitude. The large rewards offered by all European governments during the 17th and 18th centuries, for a method of finding the longitude, encouraged the development of automatic devices.

The earliest example I have been able to find of an automaton that shows a sensitivity to its environment is Leroy's compensated balance wheel. He built this for his marine chronometer about 1734. Programmed automata of various kinds go back at least to the middle of the 18th century. Punched cards were used to program production tools over 200 years ago.

Partly because of the abundance of human labour during the late 18th and early 19th centuries, the growth of mechanization was arrested. If human labour is cheap, there is no particular advantage in machines. It took the Wages and Hours legislation of the early 20th century, plus the vast expansion of consumer demand, and the waste of modern methods of waging war, to produce today's need for more automatic production.

Since the beginning of the 20th century, many highly-mechanized plants have been built both in Europe and America. These automatic factories have appeared chiefly in the industries, such as petroleum, where there are processed very large amounts of a homogeneous material that is difficult to manipulate by hand. The first modern automatic factory was probably John Sargrove's ECME, which was operating in England in 1945. In the winter of 1949-50 the U.S. Navy sent a mission to look at the Sargrove machine, and as a result of this the "Tinker Toy" project came into being. From "Tinker Toy" and similar research activities, has come a long line of circuit-making equipment using printed circuit, modular, dip-soldering, and multiple-station techniques. In short, automation is here.

THEORY

Of course, it is here only in the sense that the motion pictures were here in 1912, and the automobile was here in 1890. That is to say, the essential theory, the necessary fuels and materials, and the practical enginering skills required to make these products were ready at hand. That is the position in automation today. We have enough theory, we have a valuable fund of practical experience, we have the engineering skill, the raw materials, the economic incentive to enable us to go ahead at a rapid pace.

When I say we have enough theory, I do not want to leave the impression that the theoretical side of automatism is solved. Far from it. Such basic problems as the Leaver-Brown theory of process rather than product orientation, and the unit operations concept of Professor Brown of M.I.T.

have, as yet, hardly been discussed by engineers. Such matters as these will provide subjects for debate for many years.

For example, one debate going on right now is over the question of whether the changes now coming into industry will be evolutionary or revolutionary in nature. That is, are they going to change business and industry qualitatively, or merely quantitatively?

This is a difficult area in which to make generalizations. Before I attempt it, let me give you an illustration of what I call a radical or revolutionary approach as opposed to an evolutionary approach. Montreal is a large city, and like most large cities, has a transportation problem. Unluckily, Montreal's problem is made even more horrendous by the fact that it is a northern city, and in the average winter 80 inches of snow fall in the streets. If enough falls at one time, all traffic comes to a halt. Even if the weather is kind, millions of dollars have to be spent each year on snow removal operations.

The evolutionary approach to this problem is to improve the kinds of snowblowers and other types of equipment used to remove snow. You can also experiment with chemicals, with heated sidewalks, and with other means of turning snow into a more fluid substance that will flow down drains. But in every case you wait until the snow has fallen.

The revolutionary approach to this problem is to ask: why not do something about snow before it gets underfoot? In other words, instead of looking at a part of the problem, we look at the whole problem in its social and environmental context.

Using this approach, one suggestion has been to seed the snow clouds outside Montreal, and deposit the snow harmlessly on the farmers' fields. A radically different approach, such as cloud seeding, can, if successful, play a major economic role in many important industries.

But there are problems. Conventional solutions are easier to sell to city authorities. Radical approaches, by definition, were not used by our grandfathers, hence are not proven. Weather control is still not an exact science, and when the inevitable failures come, they are more newsworthy than the steady but unspectacular successes.

Precisely these same generalizations can be made about the revolutionary as opposed to the evolutionary approaches to automation. Radical procedures would undoubtedly get us to where we want to go faster and with more efficiency, but they are less "practical" in the sense that it is very difficult to get management to try them.

For example, people in the field have realized for a long time that it is silly to expect that a product designed to be put together by hand would lend itself to automatic production. If it did, it would be just an accident. The thing to do is start from scratch, and design the product specifically for production by automatic machines. Product designers just do not think in terms of workerless factories. Until they do, we are going to continue to see evolutionary approaches to the problem of production, and many compromises.

ECONOMIC EFFECTS OF AUTOMATION

Going back for a moment to the two general classes of machinery I have described, you will remember that examples of mechanization tend to be large, monolithic, inflexible, and product oriented. Examples of automatism, on the contrary, tend to be small, unitized, flexible, and function oriented.

Since the machines are so different, it is clear that many of their economic effects will be different. For example, take the question of whether the introduction of machines that control machines will require larger capital investment, and therefore tend to close off new areas of industry from all but the largest corporations. Thinking in terms of capital investment per unit output, mechanization seems to be costing not much more than conventional systems when the production runs are very large. But for smaller runs the cost may be prohibitive. With automatism, the opposite is the case. Large runs tend to be costly because a large portion of the cost pays for machine versatility we do not need. For smaller runs, however, that is, at the job-shop level, automatism seems to require lower capital investment than either mechanization or conventional mixtures of machines and men.

The same kinds of answers might be given to the question: does automation lead to greater or less decentralization of industry? To oversimplify, mechanization tends to centralization, and automatism to decentralization. Large inflexible transfer machines, linked to form a factory of the v-8 engine type, are most efficient when they use very large aggregations of machines. Thus their use will tend to make plants larger, and such plants can be financed only by the great corporations.

On the other hand, I would argue that automatism for the first time makes it possible to decentralize efficiently.

Decentralization means integration of all aspects of the business at the lowest possible level. In the past this has been difficult to achieve because our methods of communicating with distant plants and offices were neither fast nor efficient. Today we have the means to tie everything the company owns into one communications network, and it is even possible to run machines in a dozen scattered plants (underground if you like) from a single recorded operation at the head office.

This kind of thinking, if it prevails, will almost certainly lead to decentralization of industry on a scale undreamed of today.

The point I want to make in these two examples is that both mechanization and automatism have economic effects, but these effects are not necessarily the same. In some cases they tend to nullify, and in others to reinforce each other.

Other selected economic effects of automatic control I want to discuss very briefly are: its possible effect on the rate of money flow, and on executive development, the basic problem of management.

Conspicuously missing from this list, you will notice, is the bugaboo of technological unemployment. The reason why I propose to skip this subject is that it is so full of imponderables, it carries such a high emotional charge, and so many people who are neither engineers or economists have pontificated on it, that the whole area is an almost impenetrable jungle. However, one thought is this: Professor Meier of the University of Chicago, a very careful student of the history of technology and its effects on society, has watched the development of automatism very closely for the past 15 years. His recent conclusion is that, because automation affects chiefly mass production industry, and all industry employs only 40 per cent of the total working force, the threat of technological unemployment is negligible for the foreseeable future.

A more subtle consequence of automation is its effect on the flow of money. If I understand Samuelson, the important fact about money to an economy is not how much there is of it, but its rate of flow. Although I am not competent to discuss theories of money flow, it does seem probable that automation will revolutionize it. For example, it looks as if unskilled labour will be the class of labour most seriously affected by automation. It is also well known that unskilled labour is the freest spending group, and also the most numerous single class. If the freest spenders who are also numerically the largest group suffer a loss in take-home pay, it cannot help but have serious economic consequences.

EXECUTIVE DEVELOPMENT

Management as a group is still almost completely ignorant of the techniques and potentialities of automation. Yet, because of developing automation, the day of the intuitive manager is over. Automation demands much higher levels of competence from all echelons of management. This is because it is not merely a new technology, but a new and integrated way of looking at the production and distribution processes.

At first glance, this statement may seem to contradict the remark made earlier, that automation was nothing new. The point is that old technological ideas, when combined with modern techniques of publicity, make a third entity that is different in kind from either of its components. Moreover, something the social scientists call the "self-fulfilling prediction" comes in here. On the stock market, if you predict that certain shares will soon be selling for $10 instead of $2, and then spend enough on publicity to this effect, the shares *will* sell for $10, entirely independent of whether they represent any intrinsic value. This same kind of thing happens with new technology.

This new way of looking at business as a whole has implications affecting marketing, capital investment, design, employee and public relations, accounting, inventory control—in fact, all aspects of business and industry.

With automation, managers will have to know exactly what they are doing and why. To get this result, we are going to be forced to make radical changes in our executive training programs.

AUTOMATION AND SOCIETY

In the broader social sphere, one point I wish to bring up is this: has all the talk about the danger of technological unemployment caused by automation distracted our attention from much more serious threats? For various reasons, which I shall not take time to go into here, I feel that the unemployment problem will solve itself. But I am not so sanguine about the effect of automation on the individual.

Even today, after a relatively short history of rather elementary methods of mass production, modern man is engrossed in consumership. Most of his waking hours are spent in deciding what new products and services he can arrange to consume. Carlyle's epitaph on the country squire could be applied to millions today as the sum total of their accomplishment.

This is sad, because by concentrating on being consumers, we cut ourselves off from the delights and rewards of creative activity.

But automation is going to give us a world in which mass production of products will be vastly improved. This flood of products will have to be sold, and the only way it can be done is through a stepping up of all kinds of promotional activity. Instead of being swamped in advertising and public relations propaganda only part of the time, as he is today, tomorrow's citizen will be drowned in it every waking hour. He will have to be, because with such a flood of products, the only way to get them sold will be by raising marketing and promotional activities to a fever pitch. People will have to be taught to buy, consume, depreciate, write off, and otherwise get rid of products and services at a rate unknown today. What I fear is that this consuming, at the rate needed to keep in balance with really efficient mass production, will be a full-time job. And this, I feel, will be a degrading life for most human beings.

The promise of automation is that it will give a high standard of living for very little work. This means that it will give us leisure, and with leisure we can aspire to higher levels of cultural development in both qualitative and quantitative terms. Other times in history when people enjoyed abundant leisure and wealth were marked by great cultural activity. Perhaps the main reason why the Elizabethan era was so productive of literature and fundamental science was that men had leisure to carry on these activities. They were supported by the somewhat less respectable activities of the Elizabethan freebooters on the high seas and in the colonies.

Given a reasonable basic level of education, it would seem that, on the sheer basis of probability, the more people with leisure the more likely we are to have new developments in science and the humanities. Automation can provide this leisure on a scale hitherto unknown.

It has been said that all civilization is based on slaves. As I see it, one of the great forces making for increased automation today is the fact that human slaves are getting harder and harder to find. Automation, by providing us with millions of non-human slaves to do the menial and degrading work, can provide the society of the future with the leisure for high cultural development, without the attendant degradation that comes to a society based on human slaves.

FREEDOM OF CHOICE

Although, as David Reisman has pointed out, leisure itself carries with it certain threats to the individual's psychological well-being, nevertheless, I think it is fair to say that most of us desire more leisure, or at least more freedom of choice in deciding how we shall spend our time. Automation, correctly handled, can give this freedom of choice.

It is a paradox that automation, while giving us more of one kind of freedom, may take away an even more fundamental kind. A society in which automation has come to full flower might be one in which the maverick, the individualist, and the creative thinker would have no place. One of the beauties of our rather haphazard social organization is that the great power groups: labour, the farmers, business, and the church, impinge on each other at different angles. Thus they leave spaces between them in which an individual can hide without being crushed. Higher degrees of social integration caused by a highly-mechanized society might, if not carefully handled, eliminate these important asylums.

"To reduce a man to nothing, it is only necessary to give his work the character of uselessness". So wrote Dostoevesky in *The House of the Dead.* In our country there is a growing realization of the worth of the individual human being. Political systems, social arrangements, economic advances, are nothing if they do not lead to a fuller and happier life for the individual citizen. Automation, properly directed, can do just this. It can free men forever from degrading, dangerous or monotonous toil.

The Ideal Machine

But we are not at this millennium yet. How far we are from it can be judged by comparing the ideal automatic machine with what we have today. True automatism is reached at the point where the machine's independence of man is the greatest; when the machine has the ability to go on doing its given task, cooperating freely with other automata but also enjoying the greatest possible flexibility. The highest type of automaton might be such that:

(1) its operation can be easily changed;
(2) it is easily linked to other automata and machines;
(3) it checks its own performance;
(4) it modifies its performance with the changing environment;
(5) it maintains itself or requires no maintenance;
(6) it can be modernized from time to time.

An automaton with these properties would produce maximum output with minimum attention.

We have nothing like this. Even the highest automata in use today satisfy only a few of these requirements. In other words, everything is yet to be done. I have given some suggestions on how we might go about the job of developing and applying automation in a rational way. I want to end on a note that may surprise some of my audience, namely that, in my opinion, Canada has all the requirements for leading this field.

AUTOMATION IN CANADA

Canada's status in automation today is briefly this: Examples of high degrees of mechanization can be seen in many Canadian factories. Some of our petroleum and chemical plants have highly automatic continuous-flow processes. Others use a wide variety of electronic and other devices to control specific processes.

But, if we mean by automation a qualitatively different way of looking at all aspects of the production and distribution process, from product design through marketing, then it is no exaggeration to say that automation is unknown in Canada.

This is too bad, because Canada, with her economic situation, her job-shop industry, her tax laws, her high rate of population growth, her strategic location close to the United States, and with the broad nature of her engineering education, is in many ways ideally placed to become a world leader in automation.

In Canada, the gross national product per capita is in the range of 70 to 75 per cent of that in the U.S. This means there is more room for the development of automation here.

I have pointed out that the ideal seed ground for automation is not the large-mass production industry, but the job shop. Here in Canada, virtually all our plants are job shops. Moreover, simply because its plants and businesses are relatively small, Canada provides an area in which new applications of automation to manufacturing, data processing, and so on, can be tried out on a small scale without disrupting large scale, closely-integrated operations.

Thus many Canadian plants that are subsidiaries of U.S. and U.K. companies are in an ideal position to try experimental plant and office automation here. They can draw on the parent company for funds, yet not have to meet all the conditions required for capital expansion in their home countries. Moreover, test runs in Canada would be conducted a little out of the public eye, so that if they failed (as experiments often do), the parent company would avoid bad publicity.

Automation is innovation, and innovation is risky. Canada is an ideal country for the development of inherently risky ventures, because there is no tax on capital gains, and there is a climate of opinion favouring the taking of long odds for a large potential profit.

Canada's high rate of population growth, firmly backed by great raw material resources, is another reason why automation might develop very rapidly here. Between 1939 and 1953 Canada's population increased 30 per cent, as compared with a 20 per cent increase in the U.S. Since we are going to be building new production facilities anyway, it is relatively easy for us to introduce automation.

Our strategic position close to the U.S. means that all the highly professional "engineering of consent" that goes on down there is brought to bear on us through U.S. newspapers and magazines. Reading about what the Americans are doing makes our executives stir uneasily, and wonder if they shouldn't do something too!

We Have the Requirements

Not only do we have the strategic requirements, but we have the people. Perhaps because of the British influence on our educational system, the training of Canadian engineers is somewhat less narrow than in most U.S. schools. This makes graduates more hospitable to imaginative solutions to business and industrial problems, although an offsetting factor is the fact that the Canadian engineer has a less free hand in decision-making than does his opposite number in the U.S.

Canadian scientists developed the first production tool controlled by electronic records; first enunciated the concept of recording complex human skills; published the first discussion of automatism in a national magazine. They have gained international recognition as pioneers in automation over the past ten years. Thus there is no real reason why we should be behind in this field. Quite the contrary. With natural and political advantages on our side, and with well-trained people, we could do work here that would be the wonder of the world.

Trends in Design of Electrical Distribution for Industrial Plants

N. E. Hudak, JR.E.I.C.

Amalgamated Electric Corporation Limited, Toronto

In recent years the amount of power required by industrial plants has increased immensely. Indications are that the industrial requirements have been doubling every ten years and there are no indications of any slackening in this growth. This rapid increase can be attributed to the rapid growth of industry and more extensive uses of electrical energy.

In looking back it appears that many plants tended to skimp on power facilities. Today the trend is the other way, particularly in the better new plants. Management is realizing that adequate reliable power facilities are of paramount importance to the successful operation of any plant. And management today is more prepared to invest early into a suitable distribution system rather than risk the shortcomings.

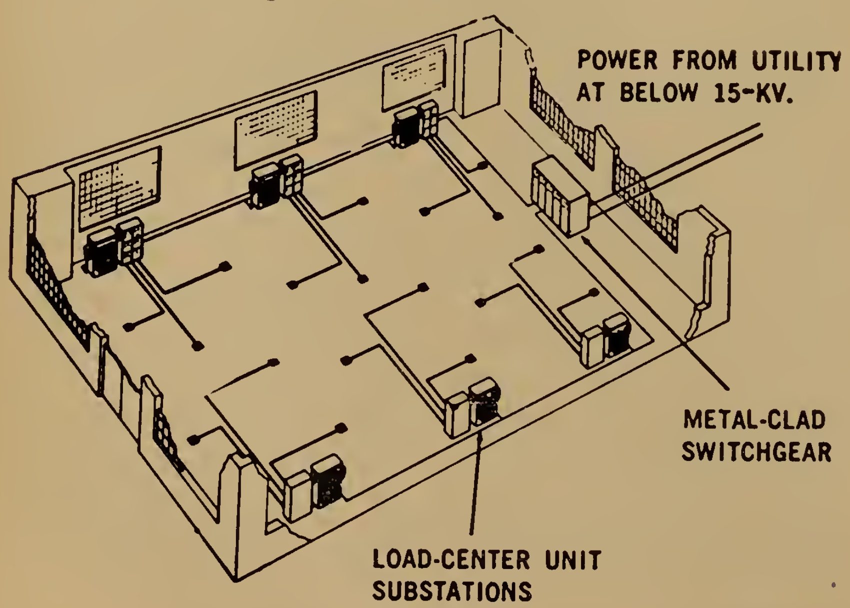
In the majority of the cases the first cost of power system is less than 10 per cent of the building cost and wise management will consider investing extra capital to get a system that is more reliable, more flexible and more economical to operate.

Planning

In planning for a new plant, the first question to be asked is, is the power to be generated or purchased, or both? In majority of the cases the power will be purchased, but in a few cases it may be generated, particularly if the electrical power becomes a by-product of the steam plant as in some chemical and paper plants. The trend, however, is away from industrial generation. Primarily because many industrialists believe that capital invested in manufacturing facilities yields a greater return. Also in many cases they feel that the problems of operating and maintaining electrical generating equipment should be left to the experts in the utilities.

If buying power, the utility should be brought into the picture as early as possible. The utility will wish to know the power demand, the load factor, the probable future growth, continuous flow processes, if any, and special services, if any, that may be required. For large plants, and plants having continuous flow processes, it is most desirable to have at least two lines of service from the utility so that in case of one supply line failure, or supply line maintenance, the plant may be switched to the other line.

Fig. 1. Load-centre distribution



Voltage

In laying out a plant distribution system there are usually three voltages to be considered. These are the plant supply, distribution, and the utilization voltages.

Plant Supply Voltage

The plant supply voltage is usually based on the ultimate plant load and the utility voltage available in the area. Each power utility has its own policy regarding the voltage for new services. For most utilities the plant supply voltages are as follows:

Volts	Loads, kva.
575	up to 75
2300/4160	75 to 300
13,800 and above	above 300

Read at a joint meeting of E.I.C. and A.I.E.E., Montreal, November 1955.

In most cases the first cost of a power system is less than a tenth of the building cost, and it is wise to consider extra investment in the power installation to get the most reliable and, eventually, economical system.

For the loads above 300 kva. the supply voltage depends pretty much upon the utility voltage in the area, the block of power to be delivered and the distance of the plant to the supply point. Some utilities such as the Toronto Hydro are attempting to standardize at 575 v. and 13,200 v., whereas utilities such as North York Hydro are standardizing on three voltage levels, 575 v., 2400/4160 v., and 27,600 v. Oshawa Hydro is providing power at 2400/4160 v. to most industrial plants, but for heavy blocks of power such as the new General Motors plant the supply voltage is 44,000. There are also areas where the supply voltages are 6,900 and 2,300.

From the foregoing it is seen that the supply voltage depends primarily on plant load, distance to supply and the available utility voltage.

Distribution Voltage

The voltage at which power is distributed within the plant is determined principally by the size of the load, the distances that the power is to be transmitted within the plant and the voltage rating of the equipment. For example, for loads of 10,000 kva. and less the common distribution voltage is 4,160, but if there should be a considerable motor load of 200 h.p. rating or higher requiring 2,300 v. it may prove more economical to distribute at 2,400 v. In many plants for loads of 10,000 to 20,000 kva. the distribution voltages are either 2400/4160 or 13,800. For loads greater than 20,000 kva., 13,800-v. distribution is usually the more economical. It is advisable to distribute at 2,400 v., 4,160 v. or 13,800 v. as these voltages permit the most economical use of standard voltage rating equipment—2.5 kv., 5 kv., and 15 kv. respectively. Voltages such as 6,900 and 7,600 offer problems in that the equipment required is on non-standard voltage rating.

In cases where the load is small, mostly lighting, small motors, and power driven hand tools, the power may be brought in and distributed at 575 v. or 120/208 v. In such cases there is no substation, but the amount of power available is usually limited and often the distribution within the plant is uneconomical.

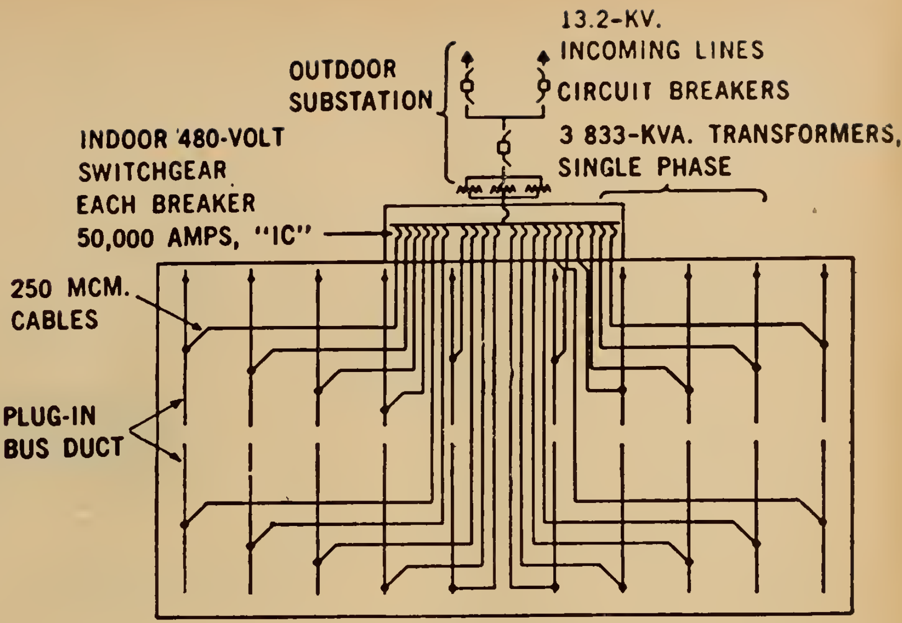


Fig. 2. Load-centre distribution

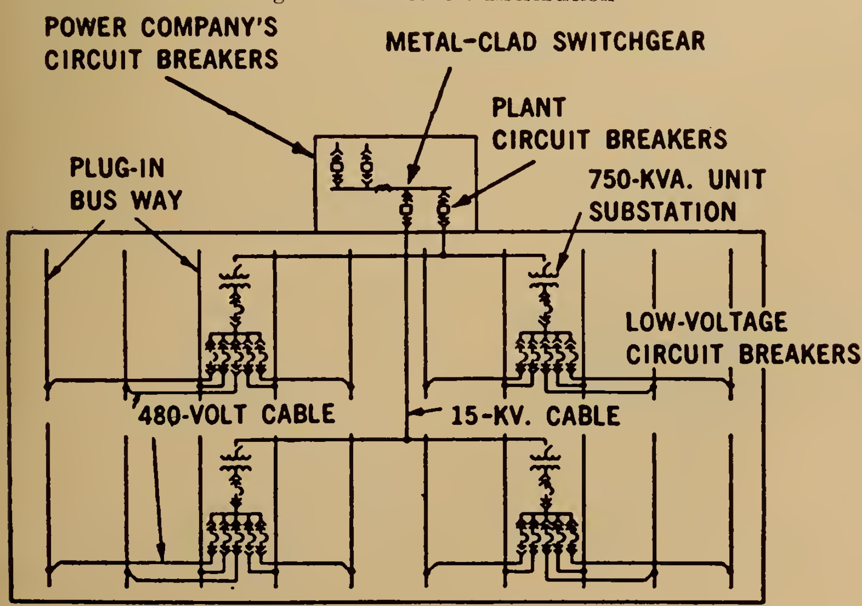

Fig. 3. Load-centre distribution

Utilization Voltage

The final phase of the plant electrical system is utilization. Most of the plant electrical equipment is rated 575 v. and less. In the United States the most common utilization voltage is 440 but the trend is toward 480/277 v. This trend permits the use of electrical equipment originally designed for 440 v. and permits the combination of fluorescent lighting circuits with power circuits. Equipment having a nominal voltage of 440 has a safety margin of greater than 10 per cent and therefore will operate quite satisfactorily at 480 v. Many American plants are taking advantage of this safety margin. Some plants, mainly the textile plant, use 550-v. equipment but the use of 550 v. is fairly well limited to plants already having 550 distribution as 550-v. equipment is not readily available in U.S.A.

In Canada some plants are favouring the American practice of 480/277 v. distribution and combining lighting and power circuits, but there are far more plants favouring the 575-v. distribution.

In recent years there have been many articles advocating the 480/277 v. system combining the power and lighting circuits, yet the number of such installations in Canada have been relatively few. However, it is expected that this trend will continue.

Load-Centre Distribution

There are two common ways of distributing power within a plant. One method is the substation method where the supply voltage is stepped down to utilization value, 575 v. or 230 v., at the incoming point and distributed throughout the plant at this value. The other method, and now becoming the more common method, is the load-centre distribution method. In this system power is distributed at higher voltage (13,800 or 2400/4160 v.) to unit substations located in the centre of the load area and the voltage is stepped down to utilization voltage at the load-centre substation. This latter arrangement enables the higher voltage to be brought nearer to the load thereby shortening the low-voltage feeder runs and permitting a considerable saving in cable cost. Also the power loss will be lower and the voltage drop will be less. In case of expansion, an additional unit substation may be added to the system without increasing the short circuit rating on the existing substations.

With the one-substation system, adding transformer capacity to the substation increases the interrupting rating on all the feeder breakers. Once the interrupting rating of the breakers has been reached additional expansion means another substation requiring a large capital investment.

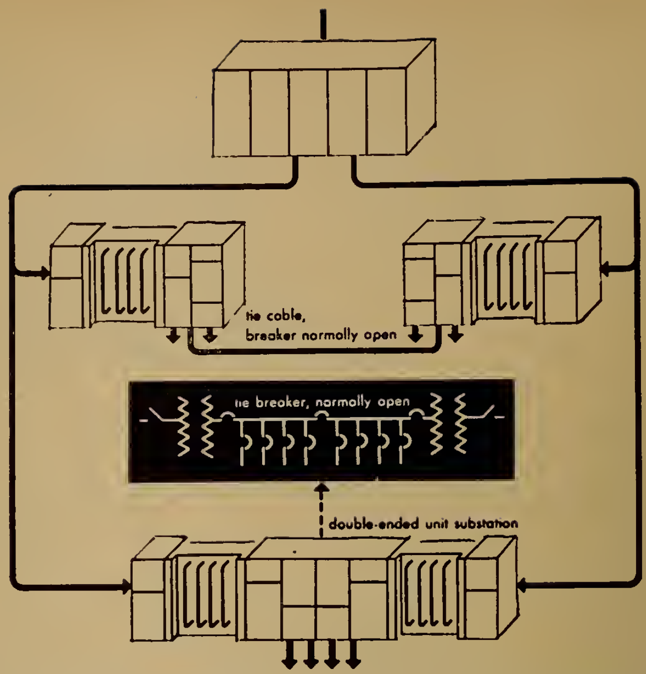

Fig. 4. Unit substations or load centres may be single-ended or double-ended. Secondary selective system.

Also the load-centre system offers greater continuity and flexibility. A substation outage affects only the area served by the particular load-centre substation and not the whole plant. In case of a load-centre outage arrangement can readily be made to have the load picked up by the other substations. (Fig. 1, 2, and 3.)

Choice and Location of Unit Substations

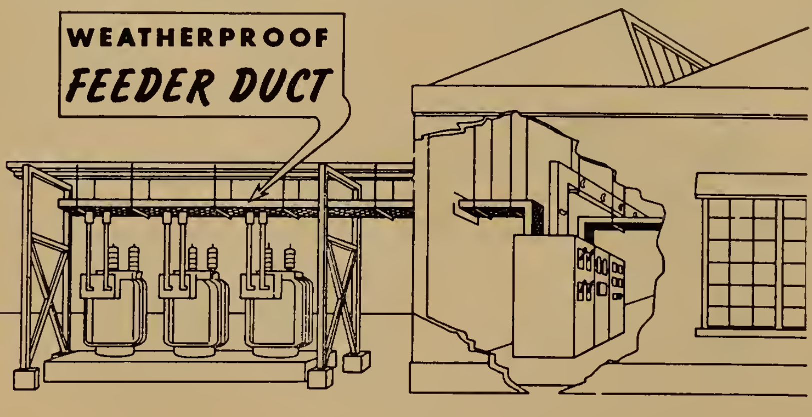
Unit substations or load centres are of two general classes, single-ended and double ended (Fig. 4). For most plants the single ended substation fulfils the requirements. The double ended substation finds use primarily in secondary selective circuits, network arrangements, and in areas where the load is heavily concentrated and the choice is between two smaller substations or one large single unit.

The choice of a substation should be based on the installed cost taking into consideration the cost of cables, bus duct, and the circuit breakers.

Circuit breakers come in five standard interrupting ratings — 15,000 amp., 25,000 amp., 50,000 amp., 75,000 amp., and 100,000 amp. The 15,000 amp. interrupting capacity breaker will conveniently carry a 200 kva. substation, the 25,000 amp. breaker a 500 kva. substation, and a 50,000 amp. breaker a 1,500 kva. station. In most cases it is not considered economical to go to unit substations beyond 1,500 kva. as this requires switchgear of 75,000 or 100,000 amp. interrupting capacity which is very costly. Often it proves more economical to install two smaller substations or a double ended substation rather than a large single unit. For example, two 750 kva. substations or two 1,000 kva. substations may in the overall analysis prove more economical than a single 1,500 kva. or 2,000 kva. substation respectively.

The ideal location of a unit substation is in the centre of the load area. This is usually not possible as the substation would occupy

Fig. 5. Transformers outside building wall, with switchgear inside.



valuable manufacturing space or would interfere with production lines. In many of the newer plants the substations are spotted on the roof and the distribution is overhead by means of bus duct. With this arrangement the substations are out of the way and close to the distribution duct. The substations can be either weatherproofed and exposed, or of indoor construction and located in penthouses. The latter is more popular as indoor equipment is less costly, easier to maintain, and less susceptible to breakdown during rain or blizzards. Roof-mounted substations have dry type transformers and air circuit breakers to permit more economical roof construction and to reduce fire hazard.

Another common arrangement is to place the transformer outdoors adjacent to the building wall and the switchgear just inside the building wall (Fig. 5). This arrangement permits the use of lower cost oil transformers and places the transformers where they do not occupy valuable factory space.

Other probable locations for unit substations may be balconies — often over washrooms, basements, and other low-value areas near the load centres.

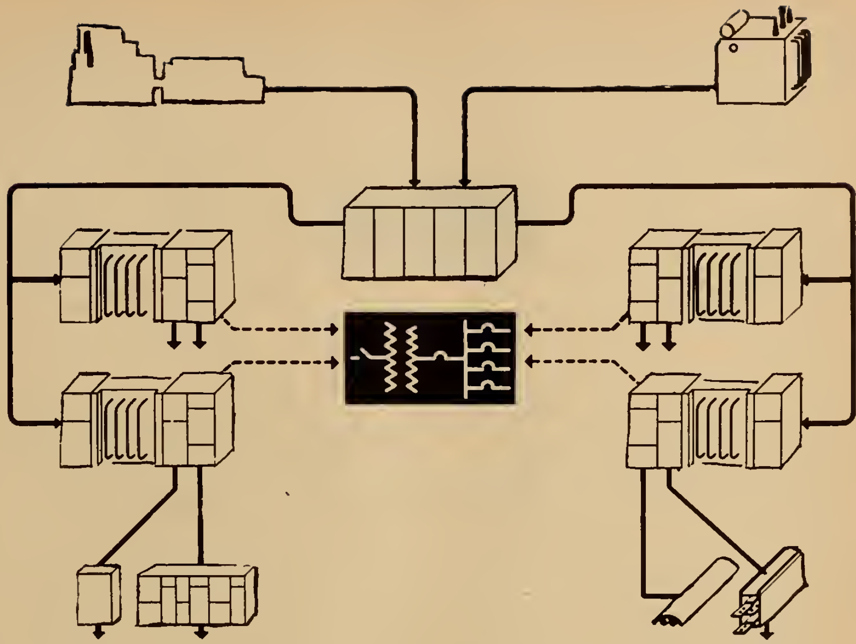


Fig. 6. Simple radial (or "tree") system is simple and low in cost.

Circuit Arrangements

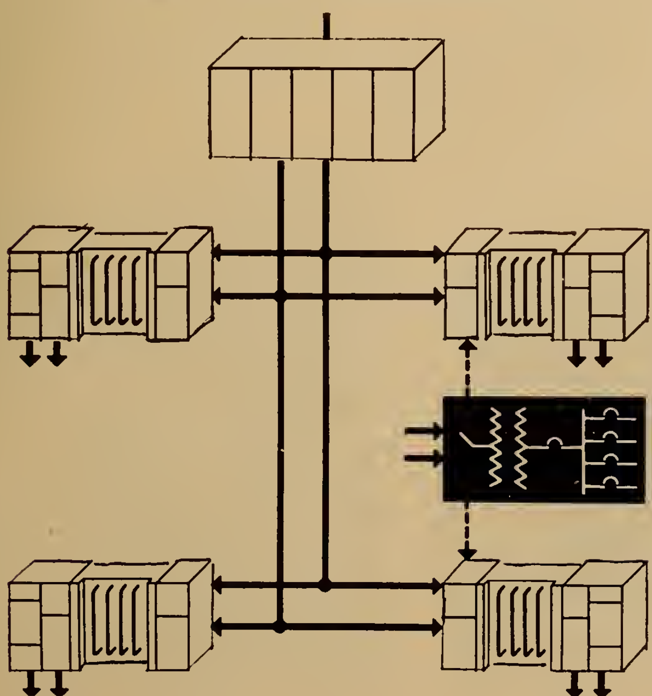
There are approximately 11 basic circuit arrangements and these range from the simple radial system to the more complex selective spot-network systems. Only the three most commonly used will be considered here. These are the simple radial system, the selective radial system, and the secondary network arrangement.

Simple Radial System

The simple radial system, or the "tree" system as it is sometimes referred to (Fig. 6), has gained maximum popularity because of its simplicity, adequate reliability, and low initial cost. The low first-cost and simplicity are derived from the fact that there is no duplication of equipment—one feeder and one transformer serve a given area.

The inherent disadvantages are lack of flexibility and service continuity. Should a fault occur on the primary feeder or transformer, the area serviced by the unit substation will be shut down until such time as service is restored or emergency arrangements can be provided. The down-time will depend upon how long it takes to restore normal service or to provide an emergency supply. Also, every time that maintenance is to be carried out on the supply equipment the load area will have to be completely shut down.

Fig. 7. The selective radial system.



Selective Radial System

The selective radial system (Fig. 7) is essentially a radial system with an alternative source. This alternative source may be either on the primary or the secondary side of the unit substation. If on the primary side of the unit substation transformer the system is called a "primary-selective" system, and if on the secondary side of the unit substation transformer the system is called a "secondary-selective" system. The primary-selective system has two feeders to each substation with either feeder capable of supplying the load, whereas the secondary-selective system may have one of several forms. But, basically, the secondary-selective system (Fig. 4) is made up of two simple radial systems with normally open tie

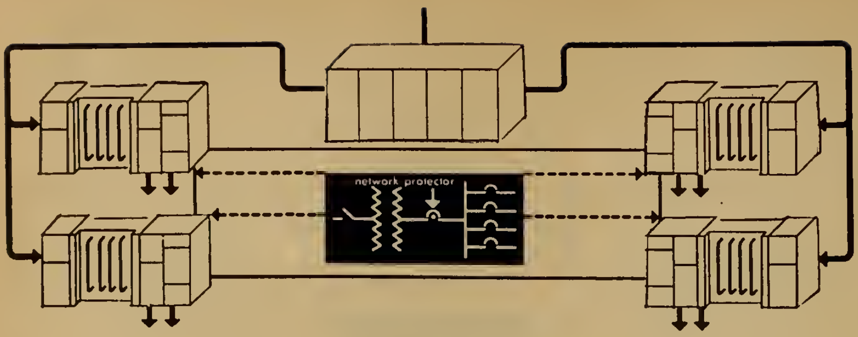


Fig. 8. A secondary network system.

breakers between them. The cost of a selective radial system is usually slightly more than the simple radial system but the selective-radial system is more reliable. In case of a fault or when maintenance is required, power can be obtained in a matter of minutes by switching to the alternative source. However, in switching to the alternative source it should be remembered to drop non-essential load in order to prevent overloading the transformer which will be called upon to service a new area as well as its own load area.

Secondary Network

Network systems are of several varieties but all are designed to provide uninterrupted service. The network systems are the most costly but offer the greatest reliability. They are used in plants where a power outage would prove exceedingly costly by disrupting an assembly line or upsetting a continuous flow process. In a secondary network system (Fig. 8) all load-centre substations have their secondaries tied together in a loop or network and each transformer feeds into the network through a network protector. In a network system all transformers co-operate so that when a load is added anywhere to the network it will be shared collectively by all the transformers. This arrangement permits the removal of any transformer or primary feeder without disrupting service to any load area. As a word of caution, the interrupting rating of the secondary breaker should be closely considered as the transformers are paralleled and the available short circuit current is high.

Bus Duct

Basically, bus duct is a system of bus bars supported on insulators and metal enclosed in standard prefabricated sections. The sections include factory assembled elbows, tees, crosses, plug-in devices, etc., which make it easy and simple to install bus duct in the field.

Bus ducts can be divided into two general types—"feeder duct" and "plug-in duct".

Feeder duct is primarily used to carry heavy currents from one point to another, whereas plug-in duct is used primarily to distribute current to many small loads in the load area. Feeder duct is commonly available in sizes from 800 amp. to 4,000 amp., whereas plug-in duct is commonly available from 250 amp. to 1,000 amp.

The bus bar arrangement of the feeder duct is considerably different to that of plug-in duct. In feeder duct there are at least two conductors per phase and the phase conductors are paired a-b, b-c, and c-a. The phase conductors are held in close proximity to one another in order to obtain the maximum flux neutralization and so keep the reactance and volt drop low.

In the "plug-in" duct, the emphasis is not on low reactance, since the currents are relatively light, but on providing readily available power outlets. Usually there is only one bar per phase and the bars are so arranged that a plug-in device may be inserted from either side of the duct enclosure. The plug-in outlets are spaced every 24 inches on either side of the enclosure thus making one power outlet available every 12 inches. The outlets are polarized so as to avoid the danger of plugging in a machine on reversed polarity.

Plug-in duct is particularly suited in machine shop areas where it is desired to frequently add or move machines to meet changing manufacturing methods, as there are no modifications required to the bus duct. Plug-in bus duct has often been termed an "elongated switchboard", and rightly so, since the plug-in devices include such equipment as circuit breakers, switches, fuses, transformers, meters, capacitors, temperature indicators, and ground detectors.

The Kaplan Turbine in Canada

G. Dugan Johnson, MEM. ASME

Chief Hydraulic Engineer, S. Morgan Smith Company, York, Pa.

The physical arrangement and blade operating mechanism of the Kaplan turbine are described, the history of its development is outlined with emphasis on laboratory research, and its outstanding performance characteristics are discussed briefly together with the attendant problems of cavitation, thrust, and runaway speed. The present use of Kaplan turbines for capacities up to 150,000 h.p. in the United States and heads up to 200 feet in Europe indicates the broad field for potential application in Canada.

To THE BEST OF the author's knowledge, a complete list of the Kaplan automatic adjustable-blade propeller turbine installations in Canada is given in Table I. The installations are in chronological order to indicate the general trend toward larger unit capacities. However, the combined capacity of all the Kaplans in operation is less than one per cent of Canada's total hydro-electric development.

By contrast, Kaplan turbines account for approximately 20 per cent of the installed hydro capacity in the United States. It is the purpose of this paper to describe the physical appearance and operation of the Kaplan turbine, to outline its development in Canada and the United States, to point out its advantages, and mention some of the problems encountered.

Propeller Turbines

The over-all arrangement and appearance of propeller turbines are quite similar to the usual vertical-shaft Francis units. From the spiral case or flume (Fig. 1), water flows between widely spaced stationary stay vanes to the adjustable guide vanes or wicket gates, which give it a whirling motion as it passes to the runner and also regulate the amount required for varying loads. In a Francis runner, the water is guided by the buckets, usually about 15, the crown and the band or shroud ring into the draught tube. By means of progressively increasing cross-sectional area, the draught tube gradually and efficiently reduces the velocity of the water discharged from the runner and converts a large portion of this residual kinetic energy into effective head by reducing the pressure against which the runner discharges.

The wicket gates, which regulate the amount of water required as the load on the turbine varies, are normally under the control of a constant-speed or tachometric governor in Canadian and United States installations. Utilizing a sensitive set of flyballs or a frequency pickup for the basic impulse, a carefully manufactured mechanism quickly opens the gates by means of servomotors operated by oil under pressure to increase the output of the turbine when the speed starts to drop as a result of an increase in load and closes the gates when the speed starts to increase due to a reduction in load on the unit.

Although they may be installed with either vertical or horizontal main shafts, practically all propeller turbines are vertical-shaft units. They differ from Francis wheels mainly in the location and shape of the runner, the intermediate head cover and discharge ring. A propeller runner has only a few, usually four to eight, wing-like blades attached to a central hub, somewhat similar to a ship propeller, with no peripheral band or shroud ring. The runner is located well below the wicket gates with a large vane-free space immediately above it. Water leaves the gates with the usual whirling motion, forming a vortex in this transition space and being guided to the runner by the intermediate head cover and the bottom ring or upper portion of the discharge ring. It flows through the propeller, essentially parallel to the shaft (axial-flow) confined by the blades, the hub and the lower portion of the discharge ring, into the top of the draught tube.

A Kaplan turbine is a propeller wheel with angularly adjustable blades, the inclination of which can be automatically controlled during operation. Physically, it is exactly like a propeller turbine except for the adjustable feature of the runner blades with the resulting changes required in the main shaft plus the blade control mechanism. The simultaneous adjustment of

Read at the 70th Annual General and Professional Meeting of The Engineering Institute of Canada, Montreal, May 1956. Published by arrangement with the American Society of Mechanical Engineers.

the blades to maintain optimum flow conditions through the runner for any position of the wicket gates results in exceptionally high part-load efficiencies and very flat efficiency-horsepower curves. In order to obtain the highest possible efficiencies under all conditions of load and head, the runner blade control system is interlocked with the wicket gate governing mechanism, so that for every position of the gates the blades automatically assume their optimum position. Load changes actuate the gate mechanism through the governor in the usual way, and the mechanical motion of the gates is simultaneously transmitted to the blade pitch control, causing the proper change in the inclination of the runner blades.

The Kaplan Mechanism

The "standard" method of actuating the runner blades also utilizes oil under pressure automatically controlled by the Kaplan or blade-control valve, which receives its actuating impulse from the governor mechanism and directs the flow of oil accordingly (Fig. 2). An oil supply head, normally mounted on top of the generator, receives the oil from the blade-control valve and properly directs its flow to and from the two concentric revolving pipes which lead down through the hollow generator shaft to the blade-actuating servomotor. The piston of this servomotor is connected to the upper end of an operating rod which moves up and down within the hollow turbine shaft and revolves with it. This rod extends down into the runner hub and its lower end is fitted with a cross-head which utilizes the up and down motion of the servomotor piston to change the inclination of the blades by means of a link and lever connection to each blade trunnion.

Complete and continuous lubrication of the various moving parts in the runner hub is accomplished by filling it with high quality oil through an opening in the hollow main shaft, conveniently located as high as possible in order to maintain some positive oil pressure inside the hub at all times. Each blade trunnion is equipped with a double seal where it passes through the runner hub to minimize the escape of oil and entrance of water. In spite of these seals, considerable leakage of water into the hub has been experienced but without detrimental effects, probably because of the formation of an emulsion by the water and the oil with its rust and oxidation inhibitors. Nevertheless, some of the larger units have been equipped with automatically-recharged air pressure tanks to maintain definite pressures inside the hubs.

The shape of the cam, which is the adjustable unit in the connection between the gate governing mechanism and the blade-control valve, depends upon the variable hydraulic conditions of each job. It is designed to obtain the maximum possible efficiency at each gate opening for any given head range, but it must be adjusted manually if the prevailing head changes appreciably. Since many of the smaller installations are not entirely homologous to the "standard" laboratory test models used for the original cam designs, it is advisable to check each cam in the field and revise if necessary, in order to obtain the absolute maximum in efficiency and smoothness of operation. A field "index" test[1] is an inexpensive method of determining the shape of the efficiency-horsepower curve and establishing the correct relationship between the blades and gates without the difficulty and expense of actually measuring the water flow rates.

The Kaplan Development

The idea of the axial-flow turbine was evidenced as early as 1865 by many patents on wheels of this type equipped with adjustable wicket or cylinder gates. Moreover, in 1867 a United States patent was issued to O. W. Ludlow for his design of an inward-flow turbine, having adjustable wicket gate type runner buckets, the wheel case being equipped only with stationary guide vanes. However, there is no evidence that the advantages of simultaneous adjustment of the runner vanes and wicket gates were realized until many years later.

Credit for the simultaneous independent development of the modern high speed fixed-blade propeller runner goes to Forrest Nagler, of the Allis-Chalmers Manufacturing Company, Milwaukee, Wisconsin, in the United States, and to Dr. Viktor Kaplan, of Brunn, Czechoslovakia, in Europe. Nagler designed his runner in 1913 and the first installation went into operation about 1917. Kaplan may have been no earlier with his fixed-blade design, but during his laboratory tests in 1913 he discovered the marked advantages obtainable by simultaneous adjust-

ment of the runner blades and wicket gates. No practical use was made of this discovery during the European war, but in 1919 the J. M. Voith Company of Heidenheim, Germany, began building Kaplan turbines under an exclusive licensing arrangement.

In 1927 the author's company acquired from Dr. Kaplan and the Voith Company exclusive rights for the United States, and in 1928 for Canada, to manufacture adjustable-blade turbines under the Kaplan patents, which provide for automatic simultaneous controlled adjustment of the runner blades and wicket gates while the unit is in operation.

The first fully automatic Kaplan adjustable-blade turbine in the United States was installed in the Lake Walk Plant of the Central Power and Light Company of San Antonio, Texas. This unit, containing a 70 inch four-bladed runner rated to deliver 1900 h.p. at 277 r.p.m. under a head of 33 feet, went into operation in 1929. As may be seen in Table I, the first fully automatic Kaplan turbines in Canada were installed in 1930 at the Tusket Falls Plant of the Nova Scotia Power Commission. Each of the three units contains a 72-inch four-bladed runner rated to deliver 1050 h.p. at 225 r.p.m. under a head of 20 feet. These first North American Kaplan wheels have been giving satisfactory service for over 25 years, with only routine maintenance.

The first large project in North America to be equipped with fully automatic Kaplan turbines was built on the Susquehanna River at Safe Harbor, Pennsylvania, in 1932. The original installation consisted of six units, each of which contains a 220-inch five-bladed runner rated to deliver 42,000 h.p. at 100 r.p.m. for 25 cycles/sec. current, or 109.1 r.p.m. for 60 cycles, under a head of 55 feet. Because of the magnitude of this development at that time, three units only were built by the author's company. The remaining three were built by the Baldwin-Southwark Corporation in Philadelphia, Pennsylvania, who had obtained a United States sublicense from the author's company in 1931, as had the Allis-Chalmers Manufacturing Company.

The highest head under which large Kaplan turbines have been installed in this hemisphere is 105 feet at the Rincon del Bonete Project on the Rio Negro in Uruguay. The 190-inch six-bladed runners of this installation are rated to deliver 40,000 h.p. at 125 r.p.m. from the design head of 69 feet up to the maximum of 105 feet, and the first unit went into operation in 1945. However, two small Kaplan wheels rated 12,800 h.p., 300 r.p.m., 116 feet head with 90-inch eight-bladed runners have recently been installed at El Oviachic plant in Mexico with a maximum head of 156 feet.

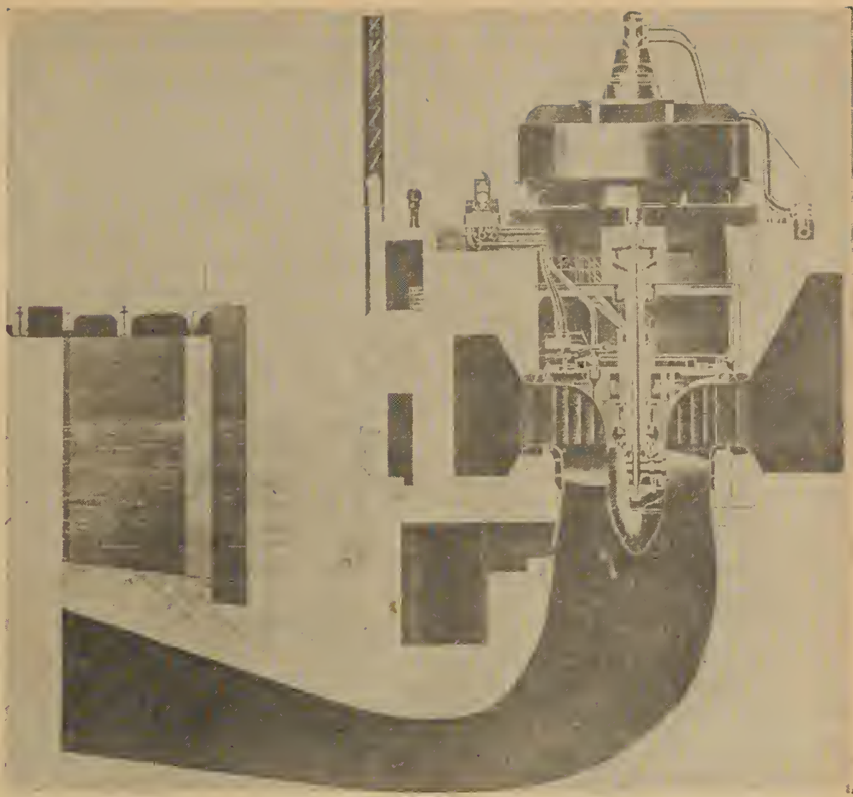

Fig. 1. Sectional elevation of Safe Harbor Kaplan turbine and generator.

The highest head Kaplan turbines operating in Canada are the two 104-inch five-bladed 13,500 h.p., 225 r.p.m., 75-feet head units in the Tobique Narrows Plant of the New Brunswick Electric Power Commission. The highest powered Kaplan turbine in Canada is the 21,600 h.p., 128.6 r.p.m., 48-feet head unit at the Bear's Paw Development of the Calgary Power Company in Alberta. It will shortly be eclipsed in capacity by the two 45,000 h.p., 109.1 r.p.m., 57-feet head Kaplans now under construction for the Beechwood Development of the New Brunswick Electric Power Commission.

Also worthy of note will be the six diagonal-flow adjustable-blade pump-turbines of the Sir Adam Beck Niagara No. 2 project, rated to develop 45,500 h.p. at 92.3 r.p.m. when operating as turbines under 83 feet head. Two 138-inch diameter axial-flow pump-turbines were furnished to the Canadian and General Finance Company of Toronto in 1938 and 1946 for installation in the Traicao plant in Brazil.

The highest capacity Kaplan units in the world were built for the U.S. Army Corps of Engineers' McNary project on the Columbia River between Washington and Oregon, where twelve 280-inch six-bladed units rated 111,300 h.p. at 85.7 r.p.m. under 80 feet head are presently in operation. A real record for capacity was established during the field tests of unit number two in 1954, which actually developed 138,000 h.p. (100,000 kw.) under an effective head of 89 feet[2]. The rated capacity of these turbines will be exceeded by the fourteen 123,800 h.p., 85.7 r.p.m., 81-feet head units now being installed for the Dalles project of the U.S. Army Corps of Engineers on the Columbia River just above Bonneville Dam, where ten 74,000 h.p., 75 r.p.m., 60-feet head Kaplan turbines also held the world record at one time for unit and plant capacity. However, another new record for unit capacity will be set when the three 143,000 h.p., 90 r.p.m., 89-feet head Kaplan turbines recently ordered from the author's company go into operation at the Ice Harbor plant of the U.S. Army Corps of Engineers on the Snake River in Washington.

No account of the development and principal features of the Kaplan turbine would be complete without some mention of the late R. V. Terry's brilliant alternative to the Kaplan patents with his automatic adjustable-blade propeller[3]. In 1928, shortly after the author's company had acquired exclusive rights to use the Kaplan patents in North America, Terry began studies and tests to develop an adjustable-blade propeller runner, so arranged that the blades would automatically adjust themselves to the optimum efficiency position for any combination of flow and head. By 1931, Terry's experiments had progressed to the point where he was convinced that his company could build runners with the blades so pivoted with respect to their centres of pressure that they would automatically follow the movements of the wicket gates and maintain the most efficient relationship for any load.

Apparently, this ingenious arrangement functioned quite satisfactorily in a number of installations, but it has never been accepted by the industry as a satisfactory substitute for the Kaplan with its positive control of the blade positions at all times. Moreover, within the last few years the company with which Mr. Terry was associated has begun to manufacture adjustable-blade turbines of the "true" Kaplan type.

Advantages of the Kaplan Turbine

The specific speed (N_s) of any hydraulic turbine may be defined as the best efficiency speed (in r.p.m.) for a geometrically homologous unit capable of developing one horsepower (h.p.) under a head (H) of one foot. It is calculated by the formula,

$$N_s = \frac{\text{r.p.m.}\sqrt{\text{h.p.}}}{H^{5/4}} \quad \ldots\ldots(1)$$

Since it involves speed, output and head, specific speed is really an index of the class to which any particular turbine belongs. In selecting the units for any installation, it is more economical to obtain the required unit output at the highest practicable speed, which permits the use of physically smaller turbines and generators with resulting savings in equipment cost and powerhouse construction.

However, the most suitable number, size and type of units for a given development depend upon the available supply of water, its distribution throughout the year and/or the amount of storage available, as well as the characteristics of the connected load. Within reasonable limits, larger machines favour lower capital and maintenance costs but single-unit plants may not provide sufficient guarantee of continuous power supply or satisfactory part-load efficiencies. For a plant with a variable load, a number of small Francis or propeller wheels would be required to obtain good average operating efficiencies, which could justify the increased costs. In this connection, due consideration must be given to the well-known fact that the average part-load efficiencies of these types decrease as the specific speeds increase.

Two of the greatest assets of the Kaplan turbine are its very high specific speed and its high efficiencies over an extremely wide load range. Because of the resulting high average operating efficiencies the use of Kaplan runners instead of Francis or propeller wheels permits a considerable reduction in the number of units in any particular powerhouse without any reduction in the total annual power output from the available supply of water.

The "index" tests of the McNary turbines (Fig. 3) illustrate

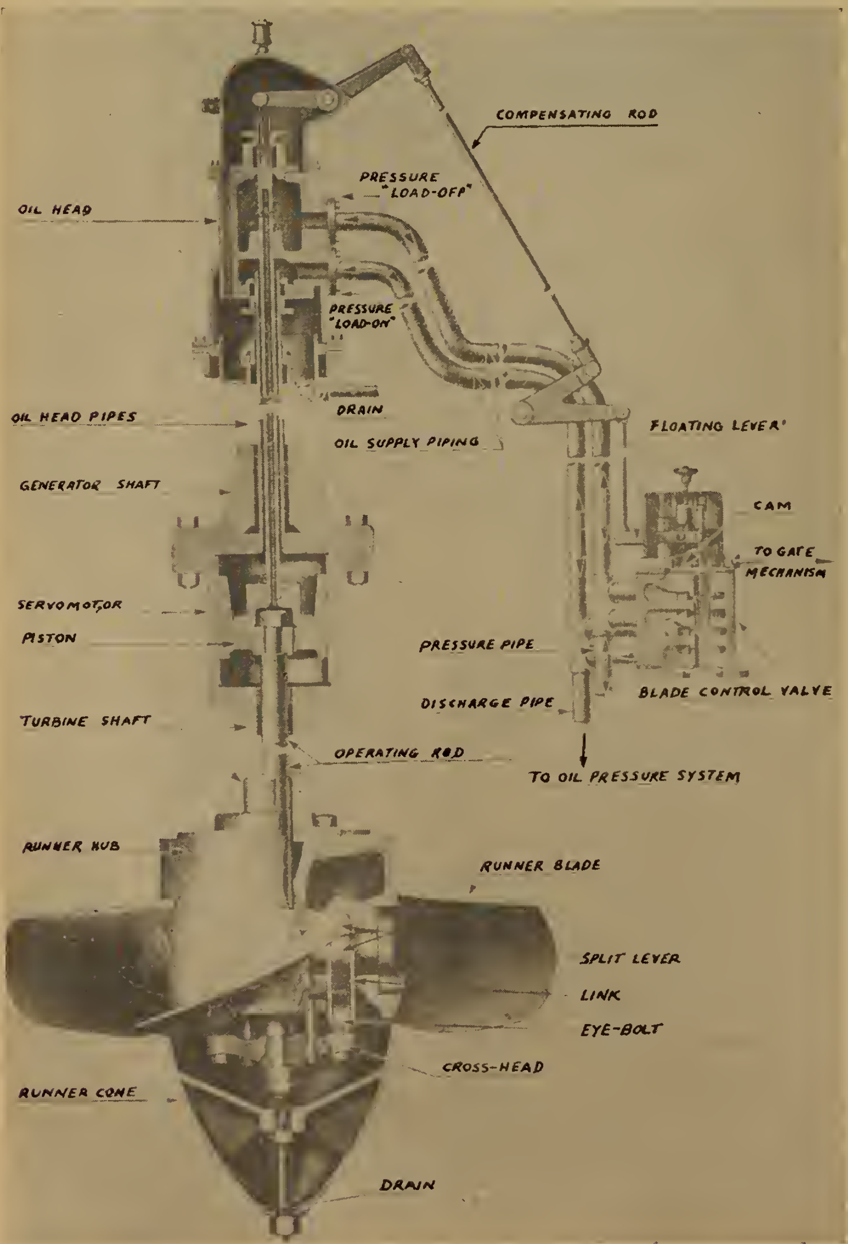

Fig. 2. Schematic sectional arrangement of Kaplan mechanism.

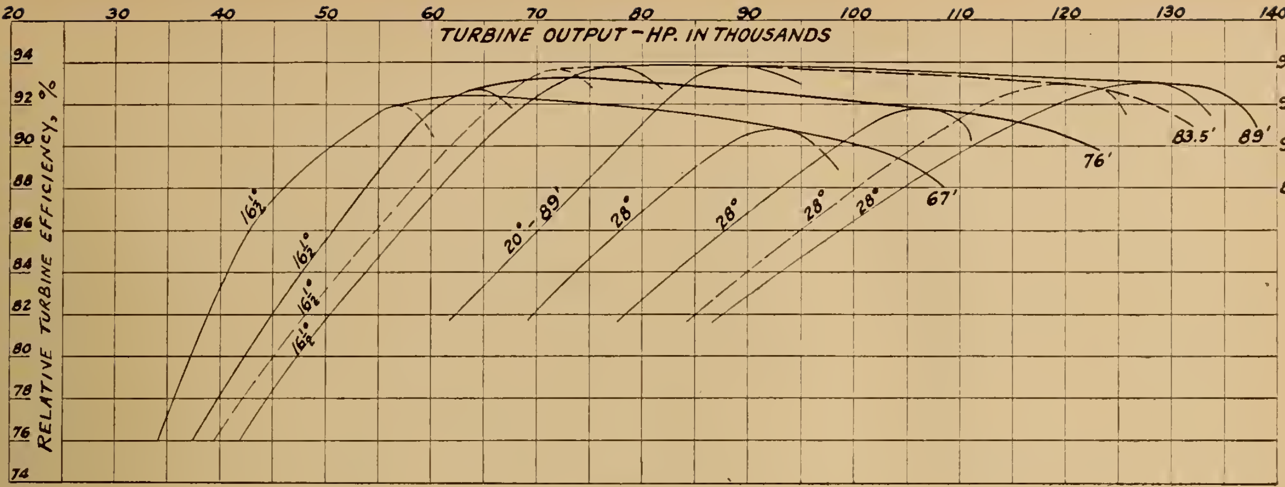

Fig. 3. Field index test curves for McNary Kaplan turbines.

the extremely flat efficiency-horsepower curves achieved by modern Kaplan turbines. The individual blade pitch curves indicate how narrow the load range is for satisfactory efficiencies with high specific speed propellers, which can therefore be used economically only where load and head variations are small or of short duration.

Another very valuable asset of the Kaplan turbine is its ability to provide high power output under heads considerably below the normal or rated head. The capacities of Francis and propeller wheels are selected for the rated heads, and their outputs under low-head high-tailwater conditions are limited. However, by increasing the pitch of the Kaplan runner blades well beyond that required for the normal rating, substantial "extra" full gate capacity can be realized under low head conditions without adversely affecting the high operating efficiencies under normal heads.

Because of its flat efficiency-horsepower characteristics and its ability to supply "extra" capacity at reduced heads, a one- or two-unit Kaplan plant, like almost all of the Canadian installations, is especially well suited to run-of-river developments with wide variations of flow and head and little or no storage. At the higher heads and lower rates of flow, the high part-load efficiencies of the Kaplans result in much greater power outputs than could be realized with the same number of Francis or propeller turbines. At the lower heads and high rates of flow, beyond the full gate capacity of the plant in most cases where efficiency has no real significance, the "full-tilt" overload capacity of the Kaplans results in further marked increases in output.

Obviously, the substitution of an equal number of Kaplans for Francis or propeller wheels of the same rating results in higher turbine costs. However, the price of the turbine equipment is only a small percentage of the complete development cost, and evaluation of the increase in yearly output, as well as in firm and peaking capacity, will usually indicate a handsome return on the increased investment.

The actual advantages of Kaplan turbines over Francis and propeller units are even greater than calculated because of the instantaneous automatic reaction of the Kaplan control to changing loads, whereas in the operation of plants with Francis or propeller wheels the attendants must distribute the loads manually, and they cannot follow the changes as closely. Even in a plant with a large number of Francis or propeller turbines operating under a moderate range of head so that the units could be operated continuously at or near peak efficiency, the total annual output can usually be increased sufficiently to more than pay for the increased cost of one or two Kaplans to take care of the small load variations automatically and at maximum efficiency.

An all-Kaplan installation is economically justified, even for a plant with a large number of units when the head range is considerable, as in a run-of-river plant with negligible storage or in a plant with considerable storage but with a sizable drawdown. In such cases, evaluation would emphasize the high average efficiency of the Kaplans leading to increased annual outputs, as well as operating flexibility and peaking capacity, especially at low heads.

The Kaplan turbine plant lends itself to automatic and remote control just as well as any other type of hydro plant. The only additional complication is the simple adjustment of the cams in the blade-control valves if the head changes appreciably; remote operation of this adjustment is quite simple, and even completely automatic control is feasible but has not yet been required in Canada or the United States.

Modernization of Existing Plants

In addition to their value for the development of new low-head power sites, the performance characteristics of the Kaplan turbine make it an obvious choice for the replacement of obsolete equipment. The increased annual power output that can be realized with Kaplan units more than pays for the changeover, even though the existing wheels may still be in fair operating condition. If such is the case, they may be retained for operation only during periods of high water flow when efficiency is not important, provided that this additional low-head capacity has sufficient value to justify the plant extension for the Kaplan installation.

Particularly spectacular are the results that have been realized by replacing groups of multiple-runner horizontal Francis units by one or two vertical Kaplans. In the early years of this century, many low-head installations consisted of two-, four- and six-runner horizontal units, each pair of wheels discharging into a common draught chest. The main reasons for such arrangements were to increase the over-all unit specific speed with resulting savings in electrical equipment and to minimize the hydraulic thrust by balancing each pair of runners.

This multiple-runner scheme was also applied to vertical-shaft machines[4] for the same reasons, although three runners on a single shaft seems to have been the limit. The combination of a vertical-shaft Kaplan turbine and a high-speed generator with a reliable thrust bearing has been the answer for many worthwhile plant improvements.

Hydraulic Laboratory Investigations

The role of carefully conducted laboratory tests in the inception and development of the Kaplan turbine has already been mentioned. The fundamentals of turbine theory, such as the Eulerian theorem (1754), are important in turbine design but in actual practice no important installation is consummated without confirming the calculations by complete laboratory tests on a homologous model. A sound theoretical basis of design cannot be dispensed with, but the complexity of flow conditions in any hydraulic turbine renders model testing necessary to assure the successful performance of the prototype installation. Current practice is to model the complete inlet and discharge water passages as well as the turbine proper.

In addition to determining performance characteristics under conservative operating conditions, critical cavitation data are also determined in all modern hydraulic turbine laboratories. Cavitation begins when the absolute pressure at any point on the back (low pressure side) of the runner blades drops below the vapour pressure of the water, resulting in the formation of numerous tiny bubbles filled with water vapour. These bubbles are carried quickly to areas of higher pressure where they collapse suddenly, producing shock pressure concentrations of terrific intensity which eventually destroy the metal surface and cause pitting.

The Thoma cavitation index, sigma (σ), may be defined as the ratio of the barometric head (H_b) minus the static suction head (H_s) at any point, usually taken for convenience as the elevation of the blade pivot axes for Kaplan runners, to the total operating head (H) on the turbine:

$$\sigma = \frac{H_b - H_s}{H} \quad \text{........(2)}$$

To determine the minimum allowable or critical sigma in the laboratory, the model is usually tested with a constant blade angle and gate opening at a constant speed under a constant head while the elevations of headwater and tailwater are lowered step by step for successive runs until a definite break or change in performance is observed. In practice, a reasonable margin of safety above this break determines the operating limit for the corresponding head and load on the prototype. When the plant sigma drops below the critical sigma for any head and load, pitting, vibration and loss of output will result, but the suction head should not be reduced unnecessarily since that would result in excessive excavation costs.

In addition to its effect on efficiency and output, cavitation also has considerable influence on the runaway speed data for Kaplan turbines. Runaway speed may be defined as the speed which the prototype turbine would attain if the generator were completely disconnected from its load and the governor failed to close the wicket gates. Prototype values for all types of turbines are calculated from the results of no-load tests on homologous models under various head conditions. Kaplan overspeeds not only depend upon wicket gate openings and runner blade angles but also vary with sigma[5].

Another important characteristic of prototype hydraulic turbines that must be determined from laboratory tests is the downward hydraulic thrust load to be supported by the generator thrust bearing. For Kaplan runners this thrust, like the overspeeds, depends upon the various runner blade angles and wicket gate openings.

Many turbine development programs include model tests without spiral or semi-spiral cases although they are required on all contract tests. However, since they are concerned with accelerating flow, losses are almost negligible in any reasonably well-designed case and corrections to the so-called open-flume tests are minor.

But the same considerations do not apply to draught tubes, except possibly for very low specific speed Francis units. Many Kaplan and propeller units are installed with the runners below tailwater level, under positive back-pressure or negative suction head, in order to exploit relatively high capacities and/or effective heads. Under such conditions, the over-all dimensions of the draught tube are of prime importance. Depth of excavation is kept to a reasonable minimum by the use of a quarter-turn elbow formed in the concrete substructure of the powerhouse. Many years of designing and testing model tubes of this type have resulted in a number of highly efficient shapes, which compare so favourably with the more expensive and complicated White hydraucone and Moody spreading tube[6] that elbows are almost universally specified for modern installations.

Because of the large rates of flow and high runner discharge velocities associated with Kaplan and propeller turbines under relatively low operating heads, an efficient draught tube capable of regaining most of the kinetic energy is especially important. Because the flow is decelerating, losses tend to be considerable and to be critically affected by the various runner discharge velocity and whirl patterns. Consequently, Kaplan and propeller models must be tested with draught tubes essentially homologous to the prototype installations in order to approximate closely to expected field performance characteristics.

Cavitation Laboratories

Dr. Kaplan's original research began about 1910 when a hydraulic turbine laboratory was established at the Technical University of Brunn, Czechoslovakia, but his open-flume testing program did not include cavitation tests. The first turbine cavitation laboratory was built in 1924 by Dr. D. Thoma as an addition to the laboratory of the Hydraulic Institute of the Technical University at Munich, Germany. Dr. Thoma's early work was concentrated on Kaplan and propeller turbine models, and it was here that he developed the universally accepted index, sigma, which permits correlation of cavitation data on models and prototypes.

The first hydraulic turbine cavitation laboratory in North Amer-

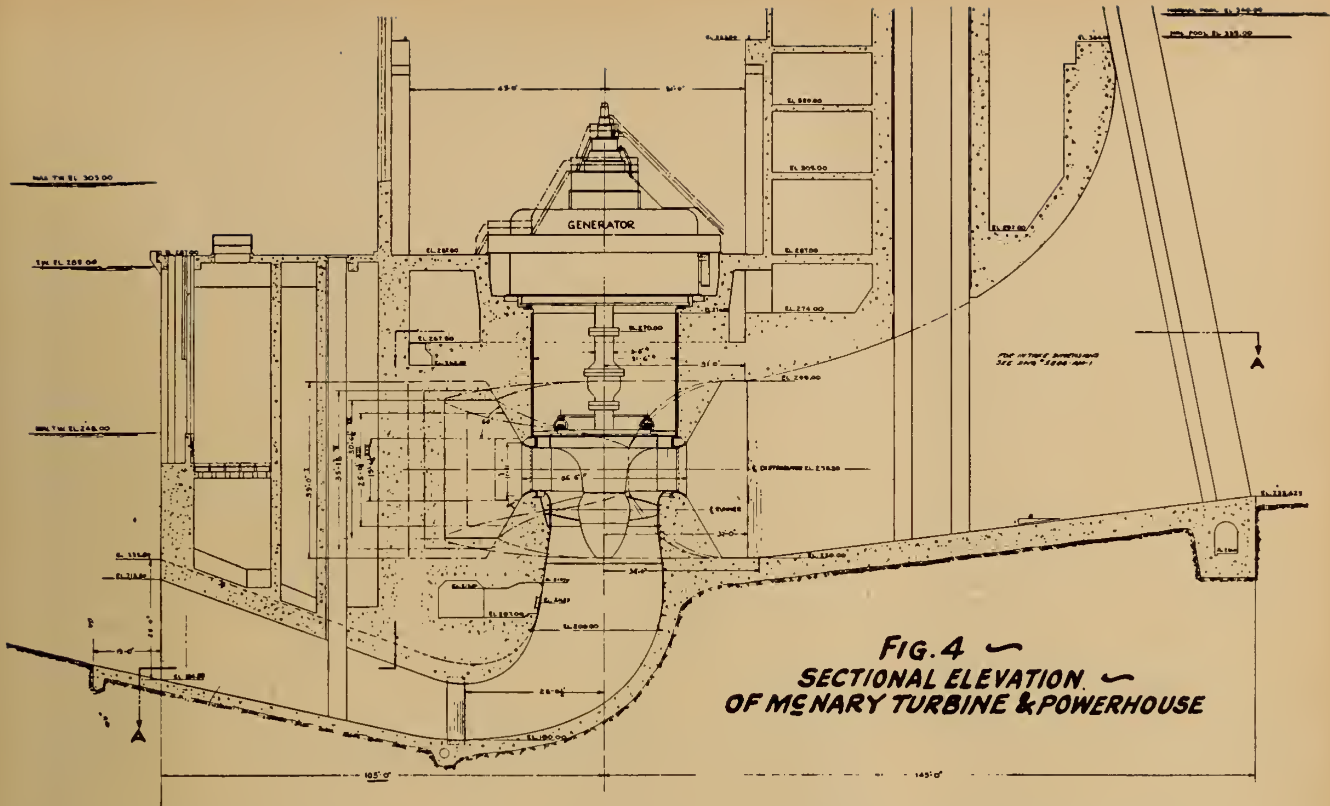

Fig. 4. Sectional elevation of McNary turbine and powerhouse.

ica was established about 1925 at the Shawinigan Falls plant of the Shawinigan Water and Power Company of Montreal, where propeller turbine models with sixteen-inch diameter runners were tested under gravity heads up to 60 feet.

The first Kaplan turbine cavitation laboratory in the United States went into operation in 1930 at the Holtwood plant of the Pennsylvania Water & Power Company. It was built to assist with the design of the Safe Harbor plant of the same company, where six 42,000 h.p. Kaplans were installed in 1932. The author's company participated in the establishment of this laboratory and, because of its proximity to the main manufacturing plant only 25 miles away, continued to utilize it for Kaplan model cavitation tests until 1940. Sixteen-inch diameter runners were tested with homologous semi-spiral cases and elbow draught tubes under gravity heads of 50 to 60 feet. The same models were also tested for comparison of performance under high sigma values in the open-flume test stand at the hydraulic turbine laboratory of the author's company which had been built in 1921.

The company built its first turbine cavitation stand in 1941 to test models for the high head (105 feet) development on the Rio Negro in Uruguay. Test heads of 30 to 50 feet were provided by pumping, and ten-inch diameter runners were tested with complete spiral cases and elbow draught tubes. In 1954, a new high head turbine test stand was installed in an extension to the original laboratory building. Utilizing centrifugal pumps to create heads up to 325 feet, Francis turbine models can be tested conveniently at very low values of sigma and ten-or twelve-inch Kaplan and propeller models can be tested under prototype head conditions with homologous spiral or semi-spiral cases and elbow draught tubes.

The only existing turbine cavitation laboratory in Canada was built in 1951 by the Dominion Engineering Works, in Montreal.[7] Sixteen-inch diameter runners are tested under heads of 25 to 80 feet provided by adjustable-blade propeller pumps arranged for two- or three-stage operation.

Contract Model Tests and Field Tests

Most large prototype Kaplan and propeller turbines operate under heads of less than 100 feet and are installed with the powerhouse forming part of the dam structure (Fig. 4). Under these conditions, the circular penstock and complete spiral case of the usual Francis turbine plant are replaced by a relatively short intake and semi-spiral case. With this type of plant, it is practically impossible to conduct a reasonably accurate field acceptance test in accordance with any approved test code.[8, 9] The effective head and the horsepower output present no special problems, but accurate measurement of the large quantities of water involved is not economically feasible.

Consequently, current practice is to specify accurately conducted laboratory tests on homologous models including inlet and discharge water passages, and the contract guarantees are based on model performance. The various turbine manufacturers make their guarantees on the basis of previous tests on similar models, but they must be confirmed on a completely homologous model before the prototype structure and turbine-generator equipment are actually processed. The major items to be settled are the draught tube and spiral case details and dimensions, the elevation of the distributor centre-line, the actual turbine design, including speed and size required to achieve the specified outputs and efficiencies under the various heads and flow rates without exceeding the critical cavitation limits, as well as the maximum runaway speed and hydraulic thrust for which the generator must be designed.

After the turbines have been installed and placed in satisfactory operation, "index" tests are conducted in accordance with the ASME test code (1953) to determine the shapes of the efficiency-horsepower curves, to confirm the guaranteed output capacities and cavitation limits under various head and tailwater conditions and to determine whether the blade-gate cams need to be modified from the shapes based on the model tests (Fig. 5). In order to draw actual prototype efficiency-horsepower curves (Fig. 3), the maximum model test efficiency is "stepped-up" to prototype size by the Moody formula[10] in Canada and the United States, and by the Ackeret formula in Europe.[11]

Only in very rare cases are Kaplan or propeller turbines installed under sufficiently "ideal" test code conditions to permit fairly accurate efficiency determinations to be made. One such case was the 81-inch manually adjustable five-bladed propeller of the Bonneville service unit, which is essentially a large model of the 280-inch main unit Kaplan turbines. It was tested by the Allen salt-velocity method in 1938 with excellent results (Fig. 6). It is hoped that more units will be installed under favourable test conditions so that they can be accurately field tested at reasonable expense for comparison with laboratory tests on homologous models.

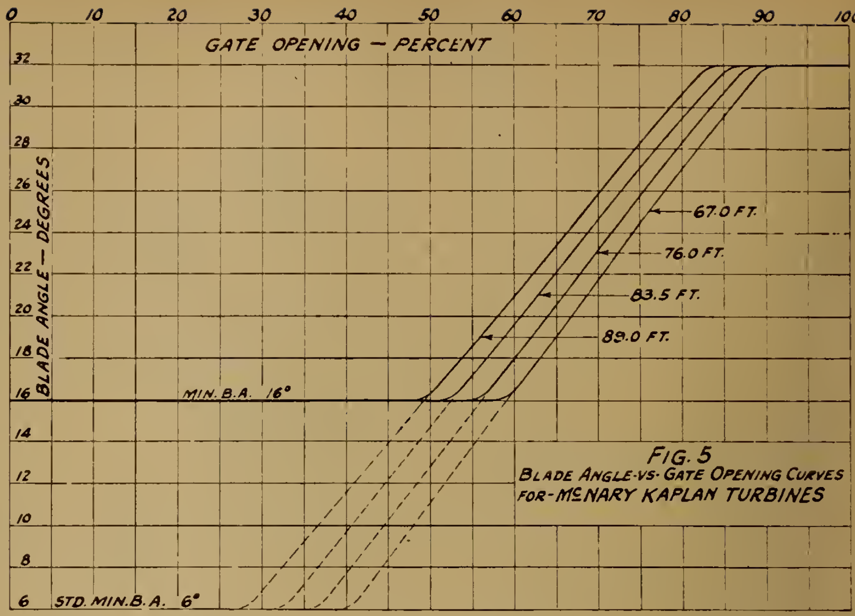

Fig. 5. Blade angle v. gate opening curves for McNary turbines.

Control of Cavitation Pitting

An interesting feature of the two 5200 h.p. units in the Ragged Rapids plant of the Hydro-Electric Power Commission of Ontario is that for the 104-inch five-bladed runners the blade surfaces were accurately machine finished to design templates. Although this is still rather general practice in Europe very few runners in North America have been so manufactured, since operating results have failed to justify the additional expense as compared to blades merely hand finished to approximate templates by chipping and grinding. This expensive machining of the water surfaces is not required for hydraulic efficiency but was considered to be of value in minimizing the inception of local cavitation damage to the mild steel blade castings.

After sufficient field experience had been obtained to establish the approximate locations of areas likely to experience cavitation pitting, even while operating above the critical sigma limits, such damage was minimized on larger wheels by precoating these areas (Fig. 7) with a thickness of one-eighth to one-quarter inch of stainless steel, which is highly resistant to pitting. This coating may be applied as a weld, deposited either manually or by machine,[12] or it may consist of small stainless steel plates or strips attached by welding. The entire periphery is also protected, preferably by means of solid stainless steel bars welded to the blade.

Because the relatively thin sections of smaller blades make these procedures impractical, the area to be protected is frequently made up of solid stainless steel inserts welded to the basic blade, and very small blades are often made as solid stainless castings. As a matter of fact, the blades of the 110-inch diameter Lower Great Brook runners of the Nova Scotia Power Commission are solid stainless steel castings. Various types of stainless steels and some non-ferrous materials, such as aluminum bronze, are suitable for cavitation prevention, their relative resistance values being the subject of numerous discussions as well as accelerated pitting tests in several laboratories.[13]

One of the greatest advantages of the Kaplan turbine is its ability to provide "extra" output capacity under low head conditions. Reduced heads frequently occur when excess water is available, as in run-of-river plants with negligible storage, and efficiency is then meaningless. The only deterrent to opening the runner blades in order to obtain absolute maximum output is general cavitation, evidenced by rough operation and vibration accompanied by reduced efficiency and eventual pitting. Depending upon the actual setting in any particular case, maximum output may be obtained at a blade pitch somewhat less than wide open because of advanced cavitation. Under these conditions, the attainment of the desired maximum output, regardless of the contract cavitation limit, should be restricted only by vibration and roughness[14]. Unless stainless steel has been used to prevent it, some pitting will occur even at outputs below the cavitation limit and any increase in pitting repair costs due to such overload operation would represent a small fraction of the revenue realized from the additional output.

Runaway Speed

The runaway speeds of propeller turbines tend to be relatively higher than Francis or impulse wheels, and Kaplan units could attain even higher relative values as a result of the blades being adjustable. The maximum runaway speed of a Francis or propeller turbine would occur under the maximum operating head with the wicket gates wide open. For a propeller or Kaplan turbine the maximum runaway speed tends to decrease as the blade pitch is increased, and with full tilt of the blades most Kaplans would not even attain a 100 per cent overspeed. At lower blade inclinations, and especially in the higher portions of their head ranges, even if the "on-cam" relationships with the wicket gates are maintained, most Kaplan wheels could attain overspeeds approaching 125 per cent. But if the "on-cam" relationships are not maintained for any reason, large wicket gate openings with low blade pitches would result in calculated "off-cam" overspeeds of 150 to 200 per cent, the higher values tending to apply where the maximum head is large compared to the design head.

"Standard" hydro-generators are designed without undue difficulty and expense for 100 per cent overspeed (twice normal speed) up to 50,000 kva. and for 85 per cent overspeed above that capacity, either value being satisfactory for normal Francis and impulse turbine installations. For large generators, specified overspeeds approaching 200 per cent would require abnormal and extremely expensive construction to maintain the usual factors of safety. Present practice seems to indicate acceptance of the idea that the generator should be designed for a specified overspeed slightly greater than the calculated maximum "on-cam" value so that there would still be a small margin of safety even if the calculated maximum "off-cam" overspeed should occur. For small and medium sized generators, design for specified maximum "off-cam" overspeeds apparently has presented no unusual difficulties, and that has been the usual practice.

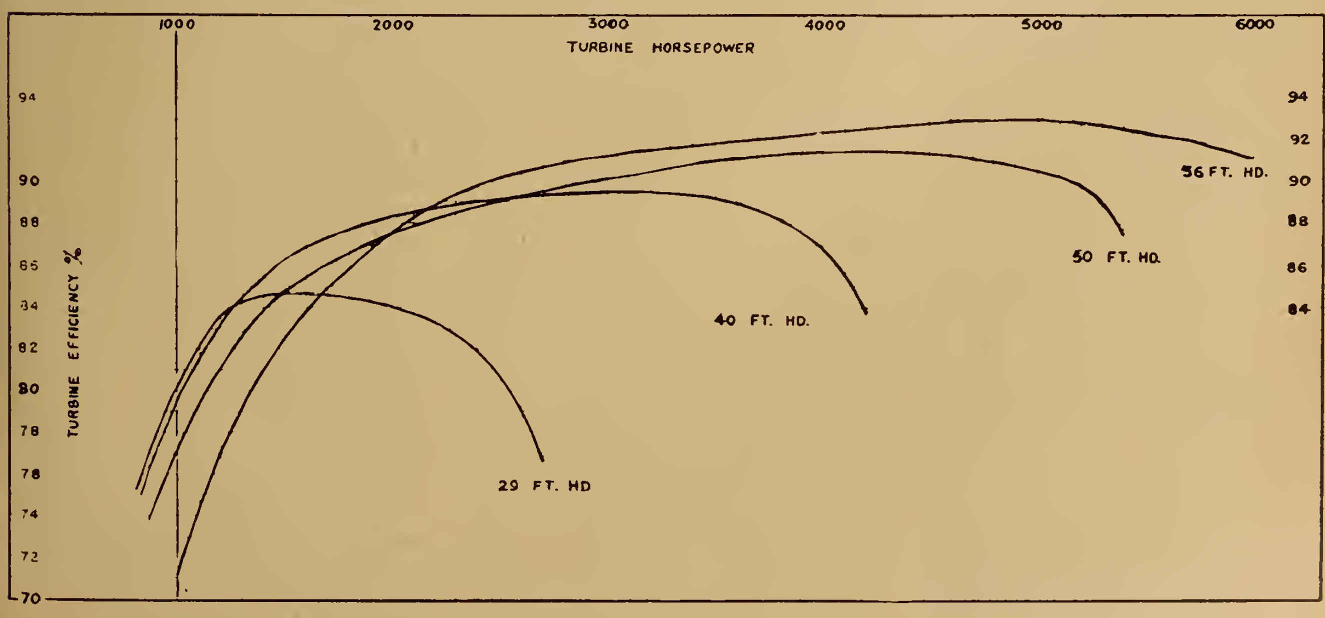
Actually, an accidental "off-cam" runaway has never been reported for a Kaplan unit, and it may be impossible for such an event to occur[5]. In normal designs, loss of governor oil pressure with the control valves "off-centre" or mechanical disconnection from the control system would allow the wicket gates to drift rapidly to a small opening and the runner blades would move rapidly to their maximum pitch position, both of which tend to reduce the overspeeds substantially.

At least two specific measures based on these tendencies have been employed to limit the maximum possible "off-cam" overspeed in actual installations[15]. One is a gate servo-motor stop-nut mechanism which automatically limits the maximum wicket gate opening as the head increases, thereby serving a two-fold purpose. It prevents dangerous overloading of the generator at the higher heads and also reduces the maximum "off-cam" runaway speed by 5 to 10 per cent depending upon the head range. The other is more positive and effective and consists of limiting the minimum blade inclination to approximately normal mid-position, which would reduce the maximum possible "off-cam" runaway by approximately 15 per cent.

This limiting of the minimum blade angle would not be suitable for the turbines in a plant with a small number of units properly sized by consideration of the minimum flow rate and the normal minimum blade position. It actually reduces the effectiveness of the Kaplan principle and should be applied only to installations where the number of units is much larger than would be indicated by low flow considerations. In some of the huge Columbia River installations, for example, the large numbers of units seem to have been determined primarily by the maximum capacity of the available generator thrust bearing designs.

Actually, some scheme to uncouple the blades from the control system when a predetermined overspeed has been attained, thereby permitting them to open and effectively limit the maximum overspeed even in the event of simultaneous loss of governor oil pressure, appears to have more practical possibilities than the addition of a separate set of braking blades as proposed by an English manufacturer.[16] The author's company has already conducted tests at several installations to determine the effectiveness of a bypass around the blade servo-motor piston for limiting the maximum overspeed. These tests indicate that rapidly opening the bypass as the unit speeds up will limit the maximum overspeed to less than 85 per cent. Canadian and United States patent applications were filed several years ago, and a very simple dependable automatic device is

Fig 6a. Field test curves for Bonneville service unit.



available that may be installed on several units now on order.

Hydraulic Thrust

Another turbine characteristic that seriously affects generator design is the downward hydraulic thrust load that must be supported by the generator thrust bearing in addition to the dead weight of the rotating elements of the turbine-generator combination. In the case of Francis turbines, especially for low specific speeds, internal construction details may be arranged to minimize this hydraulic thrust, but for propeller and Kaplan wheels no reductions are possible. Since these axial-flow runners consist only of blades and a relatively small central hub, there are no balancing chambers or areas that can be designed to limit the maximum thrust.

As in the case of overspeed for Kaplan runners, the thrust tends to increase as the blade inclination is decreased, approaching a maximum essentially equal to the weight of a cylindrical column of water of the same diameter as the runner and of a height equal to the head acting on the turbine. The normal maximum hydraulic thrust of a Kaplan turbine amounts to approximately one-half of the total load for which the thrust bearing must be designed. The design of the high capacity thrust bearing required for a large Kaplan unit is also significantly affected by the specified turbine runaway speed. Unfortunately, the same "off-cam" blade-gate relationship that would produce maximum calculated overspeed also corresponds to a continued high hydraulic thrust load as the speed increases, whereas the thrust as well as the runaway speed would be substantially reduced if the "on-cam" relationship could be guaranteed.This indicates another advantage accruing to the blade servomotor bypass devices that may be employed to minimize maximum overspeed values, since the successful design of a maximum capacity thrust bearing depends to a large extent on the specified maximum overspeed and the maximum thrust at that overspeed.

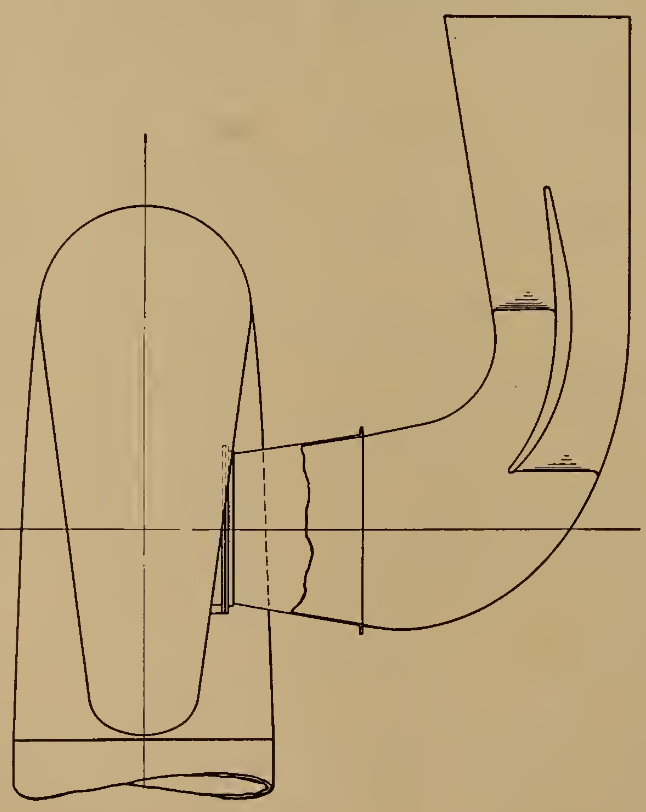
Kaplan Turbines for High Heads

Although the heads under which Kaplan turbines are operating in Canada and the United States are almost all under 100 feet, there are a number of European installations with heads approaching 200 feet and at least one with a head well over 200 feet[11]. There has been a great deal of speculation and discussion regarding the maximum head under which a Kaplan unit can be installed. Actually, there is no definite theoretical limit and the practical limit depends upon evaluation of the advantages in performance against the disadvantages of setting and expensive turbine-generator construction. As always, the detailed conditions at any particular site, as well as individual preferences, will determine whether or not Kaplan wheels are selected.

In general, Kaplans will show to advantage when a substantial variation in head exists. In addition, a well-integrated hydraulic and mechanical turbine design and arrangement is required for optimum performance at minimum cost. The hydraulic designs are improving as more and more field experience is effectively correlated with model research and analysis. Revised blade shapes and the smallest practicable hub diameters will permit higher settings than were previously feasible, but the mechanical problems of space limitations and high stresses require ingenious designs and high strength materials.

One obvious difference in the high head Kaplans will undoubtedly be the use of steel plate spiral casings instead of the very popular concrete semi-spiral casings for heads up to 100 feet.

Fig. 6b. Sketch of setting—Bonneville service unit.



Conclusion

One of the aims of this paper has been to indicate that the economically feasible range of applicability for the Kaplan turbine already extends from unit capacities of a few hundred horsepower up to 150,000 h.p. and from operating heads of 20 feet or less up to 200 feet or more. As it becomes expedient to develop more and more Canadian hydro sites with heads of 200 feet or less, the use of Kaplan turbines should receive serious consideration.

This is particularly desirable for installations with a small number of units or with a large number of units and a considerable range in operating head. Even in the case of an almost constant operating head and a large number of units, a combination of fixed-blade propellers and a few Kaplans should be considered because the automatic adjustment to load changes and the flat efficiency curve simplify plant operation and increase annual output. Similarly, the advantages of a Kaplan extension to an existing multi-unit propeller or Francis development with only limited variations in head should be investigated.

Since these low head projects tend to be more expensive than high head Francis and impulse installations, every means should be employed to reduce costs in their development. The modern trend is toward larger and larger units[17] in all types of prime movers. This indicates over-all savings by the use of a smaller number of larger turbine-generator sets for most developments. The Kaplan turbine permits effective exploitation of available water powers even with single unit installations, although a minimum of two will usually be selected to guarantee uninterrupted service, especially in isolated plants or small interconnected systems.

Optimum results at minimum cost should be realized in these large units, and in smaller ones also, by considering the turbine and generator as basic parts of the same machine rather than as two separate entities both custom-built for each particular project. Some "standardization" of physical sizes and major components, such as thrust bearings, should be feasible and can be expected to result in simplification and improvement of overall designs. However, the European scheme of locating the thrust bearing on the turbine head cover[11] is not considered by the author to have any real advantages over conventional Canadian and United States practice.

Simplification and elimination of non-essential parts in equipment designs should also be extended to powerhouse structures and operating procedures[18]. The increased use of outdoor and semi-outdoor stations as well as of automatic and remote control equipment will reduce construction and operating costs, thereby encouraging the development of otherwise marginal sites.

It is essential to realize that hydro power is not competitive with thermal power but that the two are complementary. Coordination of run-of-river and storage hydro with interconnected thermal plants has become almost a science in itself. Effective integration of the various types is just as beneficial as the installation of substantial additional capacity. The specific roles of the different plants depend upon the character of the various installations as well as upon that of the connected load and will vary in accordance with changes in these conditions. At present, thermal plants usually carry block load at best economy and hydro plants follow load changes and take care of peak requirements.

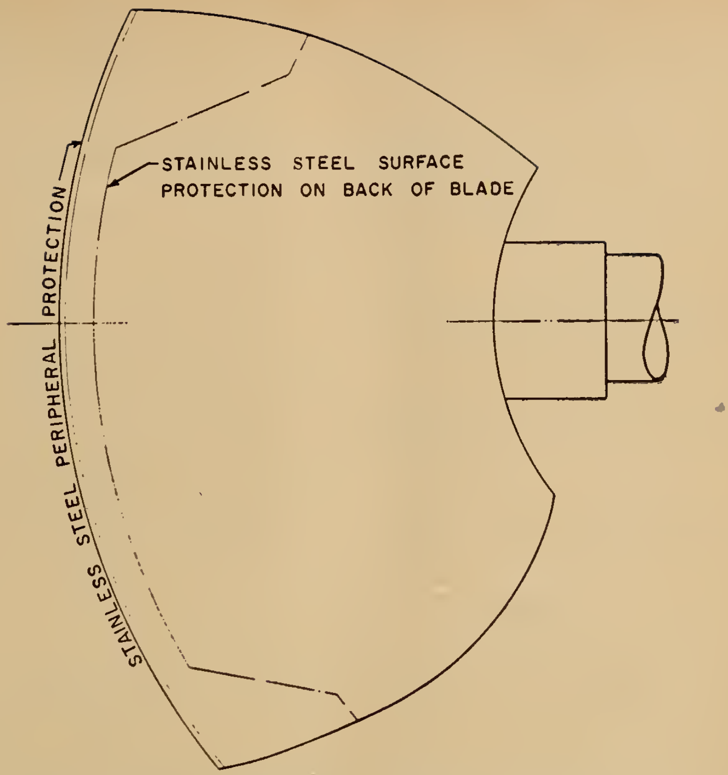


Fig. 7. Cavitation protection on periphery and back of Kaplan turbine blade.

The ability of a hydro-generator unit to be started cold and be fully loaded in several minutes eliminates the need for the expensive "spinning reserve" of an all-steam system and gives a much greater value to the hydro than its actual production or peaking capacity. A hydro unit is also capable of instantly dropping any load up to full load without damage, which adds to its "flexibility" value in a combined system.

The advent of nuclear power plants as system components will probably intensify the use of hydro for regulating to suit changing load requirements and taking care of peak demands. Any hydraulic turbine is flexible and valuable for this type of service, but the Kaplan is obviously the most flexible and therefore the most valuable. Water power is not obsolete, especially in Canada; with free fuel and efficient designs the future potential is almost unlimited, particularly for plants intended for regulating and peaking purposes. For peaking and load regulation over a wide range, the Kaplan turbine is in a class by itself; continued development and improvement of hydraulic and mechanical designs should make it economically attractive in Canada for many years to come.

LONDON AIRPORT *(Continued from page 756)*

manual shut-down. The operation of the pumps is reported back over the airport electrical control system to the control engineer when arrangements for manning are immediately made.

Water is delivered from the pumphouse into the airport proper through two 30-inch water mains. The distribution pipework is then graduated throughout the airport to hydrants. In the case of the new permanent buildings in the central area there are also hydrants fixed inside the buildings with standard hoses in readiness.

The permanent maintenance blocks are very comprehensively equipped for fire fighting. In each of the hangar pens a "deluge" system has been installed to give a drenching water supply. The "deluge" system is designed on the basis of zones, each one covering about 50 feet length of the hangar pen, and being provided with an automatic water control valve which is held closed by an air pressure of 80 lb. per square inch. The water pipelines are run at high level beneath the roof and are provided with open drencher heads evenly spaced over the zone. Two methods of fire detection are employed, one being the well-known bulb type which fractures on heating, thereby releasing the air, and the other being an electrical system in which two wires, one bare and the other insulated, traverse the zone, operation being effected by the resultant unbalance in an electrical bridge circuit when the bare wire heats up more rapidly than the insulated wire. This also reduces the air pressure and the water valve opens. The resultant water spray is as intense as very heavy rain and will contain a petrol fire and allow firemen to approach very closely with their chemical equipment. There are safeguards provided by warning devices should the air supply pressure drop to low levels. In addition to the "deluge" systems which cover only the hangar pens, normal sprinkler systems have been installed in all offices, workshops and stores in these buildings.

Alarm signals are given in the fire station of the operation of any "deluge" or sprinkler system in the permanent maintenance buildings. With the exception of the main tunnel there is no external system of fire alarms, reliance being placed on telephone calls to the fire station.

AVIATION FUEL INSTALLATIONS

The standard method of refuelling aircraft in the United Kingdom is to provide a limited storage at some remote part of the airfield to which aviation fuel is brought by tanker and from which airport or operators' bowsers are filled. The bowser itself dispenses the fuel into the aircraft tanks on the apron or in the maintenance areas. This method is still in use at London Airport hence the following description must serve to indicate proposals and not installations now in being.

It is intended that contracting oil companies shall put down tank farms at the west side of the airport, and pump aviation fuel through a number of pipelines to the west side of the central area where relatively small capacity depots will be built. These depots will supply bowsers operating in the central area. Bowsers which supply fuel to other parts of the airport will draw direct from the main tank farms, thus avoiding the necessity to run tankers through the main tunnel.

The main tank farms will have a capacity of some 2,875 tons of fuel. Pumps located here will deliver fuel at relatively low rates of flow to the central area depots through the pipelines to be laid below the surface of the ground and under runways and aprons to a number of 12,000 gallon tanks. At these depots expense pumps will fill the local bowsers.

Proposals are also under consideration to provide a piped supply of fuel to hydrants to be installed in the aprons, and the pipelines would be run beneath the concrete aprons and branches would be brought into pits in which the hydrant heads would be located. Details of this scheme have not yet been finalized. One of the principal difficulties is the location of the hydrants to suit any type of aircraft which may be using a particular parking stand.

ELECTRICAL DISTRIBUTION

(Continued from page 768)

which can be inserted at any convenient spot along the bus duct.

Usually the bus duct is suspended from the roof at reasonable height above the work area but should this arrangement interfere with the overhead cranes the duct could be supported approximately 36 in. above the floor as has been done in several recent installations (Fig. 9).

Bus duct, besides providing a highly efficient and reliable means of distributing power is easy to install, easy to expand and to re-arrange to meet changing plant conditions. Bus duct is 100 per cent salvable so that it can be taken down and moved to another area without difficulty. It is rapidly finding its way into industry replacing the cable and rigid conduit systems and also in many cases replacing the conventional switchgear and motor control centres.

In concluding it can be said that the foregoing are only a few of the trends in the electrical distribution system for industrial plants. ✓

Figures 1, 2, and 3, are taken from *Factory Management and Maintenance*, May 1953 ("Electrical Distribution"); Fig. 4 to 8 are from *Power*, Oct. 1953 ("To-day's Electrical Practice").

DISCUSSION

Is Effective Town Planning Possible?

S. D. Lash, M.E.I.C., ***Head, Department of Civil Engineering, Queen's University, Kingston, Ont.***

***The Engineering Journal,* 1956, Feb., p. 116, Discussion p. 137; Mar. p. 238.**

Author's Reply to Discussion

I am most grateful to those who have added so much to my paper by their thoughtful contributions.

A number of contributors questioned my statement that town planning in Canada has been relatively ineffective. I suppose this depends on what one means by *relatively*. There is no doubt that many Canadian towns are better today than they would have been without the efforts of town planners. On the other hand, one cannot but be aware of the tremendous amount of bad town building that has gone on during the postwar decade. In this period of unparalleled urban growth planners have had little influence in most Canadian cities. D. H. Lawrence's comment "that as builders of towns the English are as ignominious as rabbits," could surely apply with equal force to Canada. Mr. Thrift takes exception to my description of planners as a "pretty motley crew". According to my dictionary the word motley means "composed of diverse parts." There are undoubtedly many highly competent planners in Canada but it is questionable if planning has yet reached the status of a recognized profession. The Town Planning Institute of Canada is working towards this goal and there can be no doubt about its ultimate success but in the meantime the situation is confused. There are some who represent themselves as planners but who have had little or no professional training. The general public has difficultiy in separating the competent from those who are not qualified in this field.

Town Planning and Government

Possibly the most controversial part of my paper was concerned with the position of a planning agency in the structure of local government. Mr. Miller, if I understand him correctly, believes that in the smaller cities and towns planning should be regarded as an activity of the city engineer's department. In some small towns this may be the best way, but wherever possible I believe that the planning function should be independent. The planner's job involves co-ordinating proposals arising in various branches of local government. Such co-ordination is lacking in authority if the planner is too closely associated with any one department. Mr. Brown strongly supports my recommendation that the planning agency should be an integral part of local government. On the other hand Mr. Bunnell believes that "it would not seem possible for the planning agency to be a normal department of the local government". Professor Lee believes that planning will never be successful "unless we divorce the primary control from the strictly local government". In this connection I think it is instructive to consider experience in other countries. In Great Britain, planning only became a normal function of local government during the nineteen-forties. The change from special planning committees to regular standing committees was made after thirty years experience with the former had shown them to be unsatisfactory. In Sweden, planning has been a normal function of local government for many years and the system has worked well. In Puerto Rico, according to a recent book by Rexford Tugwell[1] "There is a planning agency to envisage the future. That agency is part of the governmental process". Coming back to Canada, in Edmonton and Vancouver the trend has been towards emphasizing planning as part of city government and relegating the independent planning commission to a relatively minor role.

Mr. Bunnell and Mr. Thrift take exception to my view that "Planning should be compulsory in all areas where any substantial amount of development is taking place". Compulsion is an ugly word but surely it is no great hardship to require local governments to think ahead. For example, the British Education Act of 1944 required local education authorities to look ahead and estimate their requirements for new schools during a twenty year period. It would have saved a great deal of trouble in Ontario if a similar provision had been in effect. Planning must surely lead to the more effective spending of public money and it is therefore not unreasonable to require that proper plans be made. It should be remembered that most municipalities obtain substantial revenues from provincial governments. It is generally considered that the local planning surveys and development plans required by the British Planning Act of 1947 have constituted a very great step forward towards effective planning.

Mr. Faludi and Professor Lee rightly emphasize the need for regional planning. This is the most difficult kind of planning unit to establish, largely because there are seldom any local governments at the regional level. Recent developments in Alberta and British Columbia show that progress is not impossible and we can profit from the experiences of Tennessee Valley Authority and the County of Cumberland, New South Wales.

Mr. Campeau is concerned about over-emphasis upon the aesthetic aspects of town planning. I can find little evidence of such over-emphasis in the Canadian towns with which I am familiar. It is true of course that in the City Beautiful movement at the beginning of this century too little emphasis was placed on the more practical aspects of town building but it seems to me that the pendulum swung too far in the opposite direction and that town design as an art was lost at the time when it was most needed. Frederick Gibberd[2] has recently written, "The town must work properly and be economically sound, but it should also give pleasure to those who look at it; the technical solutions to the functional problems must be fused with aesthetic feeling".

ABSTRACTS . . .

OF RECENTLY PUBLISHED ENGINEERING LITERATURE

MECHANICAL-ENGINEERING PROGRESS IN THE PETROLEUM INDUSTRY

By Emory N. Kemler, Professor of Mechanical Engineering, University of Minnesota, Minneapolis, Minn., U.S.A. from *Mechanical Engineering,* v. 77, n. 12, December 1955, pp. 1043-1046.

During the period 1915 to 1930, the petroleum industry began to employ and understand the importance and use of technology on an industrywide basis. One major step taken by the industry was the establishment of the American Petroleum Institute in 1919. This industry-sponsored Institute has been very active in the standardization of oil-field equipment. Prior to the API standards, there were over 400 sizes, styles, and types of derricks without interchangeability, whereas the number was reduced to less than 10 after standardization. During the period there also appeared in this country for the first time, technical books relating to the petroleum industry.

During this period a number of major oil companies established separate research laboratories to serve the technical needs of their industry. Companies supplying equipment and services to the industry went through similar changes. Sales and service engineers were employed by these organizations and many of them organized research departments and expanded their design and development staffs. By the start of the 1930's we find that technology had demonstrated to management of the industry what it could offer.

Recent Progress

Both the size of the petroleum industry and complexity of its operations make it difficult to evaluate its progress briefly. Since the early 1920's, the production of natural gasoline and LPG products serve to remind us that during this period the industry has made much progress in the direction of conservation. Prior to this period these were essentially waste products.

The petroleum industry's technical problems cut across many areas of science. The engineer in the industry is, in general, responsible for a technical area much broader than covered by any given professional group. The following discussion, therefore, attempts merely to point out the accomplishments, particularly in areas of general interest to mechanical engineering, but also including major areas of technological accomplishment.

Exploration

In the area associated with location of petroleum the mechanical engineer has, in recent years, been actively engaged in designing and developing new types of transportation to make it possible to explore such areas as swamps of the south and the muskegs of the Canadian plains. He also has had a part in the design of some of the instrumentation utilized for exploration work.

Drilling

The developments in drilling have been in the direction of permitting drilling to greater depth, reduced cost, increased drilling rates and, more recently, the adaptation of drilling to offshore development. The deepest well to date is the Ohio Oil Company well in California of 21,482 ft., abandoned this year. In addition to heavier-duty equipment for deeper drilling, much attention has been given in the past decade to increased drilling rates. The jet bit has been developed for Gulf Coast operations and has given exceedingly high drilling rates. A large part of the successful operation of rotary drilling for general use resulted from the development of bits for hard formations. The drilling rates for hard formations are still very low. Current developments aimed to improve rates for harder formations include rotary percussion and sonic methods, and use of magnetostriction units.

The pressures encountered in drilling are normally about ½ psi per ft., or 10,000 psi for a 20,000 ft. well. Equipment manufacturers have developed wellhead equipment to withstand these pressures. Manufacturers of casing and drill pipe also have developed alloy materials to handle these depths. The development of muds to fit a wide range of drilling conditions has likewise been an important factor without which it would be impossible to drill many formations.

Production

The basic methods in pumping show little change since the early wells. The walking-beam mechanism of Watt is still used on modern pumping methods, and sucker-rod pumping is used on most of the 514,000 producing wells requiring artificial lift. Hydraulic pumping systems have been developed which are adaptable to a wide range of production requirements. In this system power oil under pressure is transmitted to the bottom-hole pump, thereby doing away with the sucker rods.

Considerable attention has been given to automatic operations of production equipment. Automatic operation of offshore installations becomes important from a safety as well as an operating standpoint. Some consideration has been given to piping oil and gas from the well to shore before separation.

Conservation has received increasing attention. Early production practices involved getting out the oil as rapidly as possible. Superstition, lack of knowledge of how a reservoir behaves, and the desire to convert the oil to money as rapidly as possible, all lead to the use of this uneconomical practice. The development of rational conservation practices has closely followed the expansion of our knowledge of reservoir performance.

Research on the flow of fluids in reservoirs was well under way by 1930. The area of reservoir engineering has extended greatly since that time and has been the most important factor in bringing about better practices. The application of modern reservoir practices has resulted in greater recovery, lower gas-oil ratios, longer flowing life, and lower lifting costs, as well as greater conservation.

The increase in knowledge of reservoir behaviour and in the properties of reservoir fluids has also brought about other practices which lead to greater recovery. These include rational application of waterflooding, repressuring, pressure maintenance both through gas and water return to the reservoir, hydraulic fracturing of the reservoir rocks, and *in situ* combustion.

Transportation

Pipe lines and tankers, in early use in the history of the petroleum industry, continue to be the important means of petroleum transportation. The past quarter century has seen much attention being given to the transportation of products. Perhaps the most attention has been given to the automatic operation of pumping stations and in the automatic metering and control of the product at the delivery point.

The natural-gas industry has shown a tremendous growth since 1930. The development of high-yield-strength thin-walled pipe has made it possible to transport the gas economically.

The transportation of crude shows little general change, except for the introduction of automatic operation. The transportation of refinery products has expanded greatly during recent years. The handling of a variety of products in a line has necessitated developing techniques for identifying the products en route. Radio-active techniques have been successful for this purpose.

The Inter-Provincial-Lakehead crude line from Edmonton, Alberta to Sarnia, Ontario, is a recent installation which illustrates some of the problems of modern crude trunk lines. This line is 1765 miles long, the world's longest. Oil can be transported from Edmonton to Sarnia at a cost of 64 cents per barrel. The 645-mile Lakehead portion is 30-in. diam., and cost $74,000,000. It involved laying two 20-in. 21,000-ft.-long lines under the Straits of Mackinac at depths as great as 230 ft. below the surface. It requires a total of 2,800,000 bbl. of oil just to fill this 645-mile section.

Refining

The developments in refining include processes to give greater gasoline yields, lower costs, automatic operation, and generally improved products. The petrochemical industry—an extension of refining—is just in its infancy.

Cracking was first used to give an increase in gasoline yield. As demand for gasoline increased, more attention has been given to processing techniques which would give better utilization to the crude. These processes are quite complex and in general utilize a catalyst. They operate at high pressures and temperatures, i.e. pressures up to about 800 psi and temperatures as high as 1000 F.

The use of fluidized catalytic beds represents a significant development. This makes it possible to replace batch processing with continuous-flow processes. The batch or cyclic processes also have been improved through introduction of controls, and through combination with other processes to reduce intermediate storage and heat losses.

Distribution

The markets for petroleum products present a continually changing pattern. Gasoline continues to be a major one, accounting for about half the demand. Use of petroleum products for fuel purposes has been on the increase. In 1954 there were 7,600,000 homes using oil burners and 22,000,000 natural-gas customers. A total of 58,100,000 motor vehicles, together with 4,700,000 tractors were using petroleum products. The number of railroad diesels had increased to 23,700 by the end of 1954. The supplying of diesel and fuel oil for marine uses, use of fuel oil and gas for industrial plants, and supplying of road oils represent other large uses. The delivery, storage, and marketing of these products involves many engineering problems.

The Mechanical Engineer's Role

The problems of the various phases of the petroleum industry with which the mechanical engineer is associated require the application of the principles, techniques, and information from essentially all the areas of applied science. Drilling, production, transportation, and refining operating groups all need information from such areas as mechanics, applied elasticity, fluid mechanics, heat transfer, thermodynamics, machine design, automatic control, servomechanisms, electronics, electrical design, chemical-process design, instrumentation, soil mechanics, structural design, mettallography, and corrosion.

BUILDING TOMORROW'S MANAGEMENT

by Nathanel Stewart, Director Management Development Program, Government Employees Insurance Company. In *Dun's Review and Modern Industry,* January 1956.

Executive talent is not a commodity one can find in profusion on the open market, and an operating company in need of it faces a major problem. One answer is to develop abilities available in the organization.

The search for and development of executive talent should begin within a company's own ranks. The program is based on the following essentials:—

(1) Monthly series of case studies, discussions and presentations at dinner sections of the executive group.

(2) Top management's genuine interest in looking over personnel for potential executives.

(3) Participation of senior officers in the operating management team and other staff groups where problems are identified and solved.

(4) Development of a valuable executive's library.

(5) Emphasis on the man's capacity to perform as a company official in daily administration of his division.

(6) The acid test will be not what the company can do for these potential administrators but what they can . . . do for themselves, through conscious and deliberate self development and self education in the art and science of management. This investment in the development of its younger executives and managers will pay off as it enters the periods of transition and expansion.

NEW VISCOSITY CLASSIFICATION

by William S. James, Research Consultant, in *ASE Journal* v. 64, n. 1, January 1956, p. 55.

If experience with the multi-grade type of oil designation does not clarify its use, it may be wise to consider changing the viscosity classification into terms more generally understood by the car owner and service station attendant.

One way to do it would be to designate oil viscosity characteristics by two temperatures: the lowest expected temperature at which a start is desired and the temperature setting of the water thermostat in the cooling system. Both of these temperatures the car owner has.

The advantage of this system is that whenever automotive engineering or petroleum technology or both improve their products, the new oils could easily be fitted into the designation system. Car owners and service station attendants would have no need to learn a new system.

ENGINEERING PROGRESS IN BRITAIN 1955

The Engineer, v. 201, n. 5215, January 6, 1956.

The Engineer, in the January 6th, 1956 issue, gives in retrospect a summary of progress for the year under the following general headings:— Aeronautics, atomic energy, civil engineering, continental engineering, electrical engineering, national boat show, naval construction, ports engineering, Royal Navy, shipbuilding and marine engineering and turbine airliners.

Additional articles are included on "Power from Niagara Falls," and "American Water Power Schemes in 1955". Sixteen art plates illustrate the various subjects covered, as well as steam and diesel electric locomotives, automobile engineering, water-supply schemes, collieries, United States gas turbines, bucket excavators for a German lignite mine, and U.S. machine tool automation.

An editorial entitled "Retrospect," deals in a general way with railway plans, road construction, nuclear energy, automation, education, economics and labour.

The following issue, dated January 13th, 1956, gives a summary of progress in unification of standards, British Railways, coal, continental engineering II, electrical engineering II, gas turbines I, and generating plant commissioned by the C.E.A.

URANIUM IN CANADA-1955

Canadian Mining Journal, v. 77, n. 2, February 1956, p. 81/82.

The estimated Canadian production for 1955 has now been valued at the Dominion Bureau of Statistics at $23,000,000, compared with $26,467,574 for 1954. This figure came as a surprise to most people who had been led to expect something in the order of $40 million to $48 million. These higher estimates were based on the increased capacity of the Beaverlodge mill from 400 to 700 tons per day, and on the new production from the Gunnar and the Pronto mines which started up at the end of August.

The discrepancy however arises from the closing down of the Port Hope Refinery for a period of several months for the purpose of extending and improving the process. Since mine production figures are still on the secret list, calculations of uranium production are made at the smelter level which means the value of shipments of uranium products from the Port Hope Refinery. Thus with the refinery closed down, there was a considerable gap between mine production and smelter output.

1955 was a significant one in many respects for the metal which first rose to prominence as the powerful force behind the atomic bomb and which subsequently became the quest of every prospector and would-be-prospector, and caused unprecedented speculation on the stock markets. The government set a definite time limit up to which it would purchase uranium in an acceptable concentrate as agent for the U.S. Atomic Energy Commission, the ultimate buyer of our concentrates, by giving a deadline of March 31, 1956, for the signing of all purchase contracts at a premium above the regular price schedule; by insisting on reasonable assurance that production commence not later than April 1, 1957; and by stipulating that all deliveries are to be made before March 31, 1962. Provided that a concentrate has a minimum uranium content of 10 per cent by weight, it will qualify for purchase by the Government, through Eldorado Mining and Refining (1944) Limited, in accordance with the sliding scale of prices up to a maximum of $6.00 per pound of uranium until the deadline of March 31, 1962. In addition, a development allowance of $1.25 per pound is allowed during the first three years of production. To qualify for a special premium price, each contract, subject to the above-mentioned time limits, is negotiated on its own.

The end of the year saw a letting-up of the intense prospecting and staking activity which followed the original discoveries in the Beaverlodge, Blind River, Bancroft and other districts. Developments may best be described in terms of new sales contracts to which Eldorado committed itself. During 1954 a contract was signed with Gunnar Mines for the delivery of concentrates to the value of $76,950,000 and another with Pronto Uranium for the amount of $55,000,000 making a total of almost $132 million. The first units of both the 1,250 ton mill of Gunnar and the 1,500 ton mill of Pronto started production in August and were to be brought up to full capacity early in the next year. In 1955 three separate contracts were negotiated amounting to slightly over $425 million. These were for $270,000,000 with Algom Uranium, $182,250,000 with Consolidated Denison, and $38,805,000 with Bicroft Uranium. Algom's two 3,000-ton mills are scheduled for completion by mid-1956 and the beginning of 1957; the large 5,700-ton plant at Consolidated Denison should be in production by the middle of 1957; and the 1000-ton mill of Bicroft is being constructed to be ready by the end of 1956. In addition to these plants, the Beaverlodge operation of Eldorado is being expanded to handle 2000 tons per day by 1957.

Shortly after the end of the year Faraday also received a contract for $29,754,800 and is preparing for a 750-ton operation. Extensive exploration both by diamond drilling and by underground was carried on by a large number of other companies in an effort to meet the deadline, and there appears little doubt but that a number of these will also qualify either individually, or by groups. Custom mills would solve the problem for mines having insufficient tonnage to warrant individual milling plants of their own, and at least one of these in the Beaverlodge area is being planned.

POROUS SOLUTION

Flight—and Aircraft Engineer, n. 2452, v. 69, Friday, 20 January, 1956, p. 68.

Aircraft which "perspire" may prove to be the answer to heating problems at supersonic speed, according to Mr. C. E. Pappas, chief of aerodynamics and thermodynamics at the Republic Aviation Corporation. Mr. Pappas said in New York recently that he believed that within two years aircraft could by flying at a Mach number of 4 at 50,000 ft., under which conditions the airframe surfaces would heat to 900 deg. F. in not much more than a minute's flying time. For such speeds, he said, new metals would be used—and so might "transpiration." For example, water could be forced out through pores in the skin, being emitted as steam and carrying off a good deal of the heat. Mr. Pappas added that aircraft flying at 100,000 ft. at a Mach number of 10 could become a reality in five years if appropriate structural materials and power plants were developed. Temperatures at such speeds would be about 3,000 deg F, and flight could last no longer than five minutes because of fuel and temperature limitations.

TRANSISTOR CHARACTERISTICS FOR CIRCUIT DESIGNERS

by Seymour Schwartz, *Electronics*, v. 29, n. 1, January 1956, p. 161

Successful transistor circuit design requires not only familiarity with transistor equivalent circuits and characteristic curves but also an understanding of the behaviour of the parameters describing the transistor and the variation of these parameters with bias and temperature.

Tables I to VI have been compiled as a systematic presentation of data necessary for transistor circuit design. Tables indicate physical properties, maximum electrical ratings, small-signal low-frequency parameters and average characterstics for grounded-base, grounded-emitter, grounded-collector and switching circuits for 218 transistor types: 106 junction triodes, 46 high-frequency triodes, 6 tetrodes, 23 high-power units, 25 point-contact and 12 phototransistors.

The characteristics peculiar to the high-power transistor are the lower values of input resistance, output resistance and α, resulting from the higher values of bias currents employed. Bias stability techniques are used to minimize the effect of runaway due to self-heating of the collector.

DIFFERENTIAL ANNEALING

by G. A. Maeder, Aluminum Laboratories Ltd., Banbury, Oxfordshire,
in *Eng.neering* v. 181, n. 4694, January 13th, 1956, p. 48.

The author shows theoretically that a deep-drawing "circle" (i.e. a sheet-metal disc prepared for deep drawing) in which the temper varies radially in a controlled manner can be cupped and redrawn to a substantially greater extent than a uniform circle and that the resulting product is more satisfactory. The effect of variation in temper across the blank is examined in detail. A differential-annealing machine is described which has enabled the theory to be confirmed by the production of shells with 60 per cent cupping reductions.

Any shape of blank can be differentially annealed, if a suitable annealing apparatus can be developed. In fact, to anneal only the four corners of a rectangular blank does not present any great difficulties. For a heat-treatable metal, the inverse process is feasible, namely, to commence from a soft blank and heat-treat the centre portion only. No theoretical super-deep drawing alloy, however refined, can ever give the advantages of differential annealing because, for a circle of even temper, the drawing ratio cannot be exceeded, in fact it is necessary to keep well below it to allow for friction and bending.

The 70th Annual General Meeting

Sheraton-Mt. Royal Hotel, Montreal, May 23-25

A Review of the Main Proceedings and Events

"The best meeting ever held in the history of the Institute" was the opinion of at least one senior member. Certainly foremost in quantity, with a highest-ever registration of nearly 1,700 delegates and visitors, the 70th Annual Meeting lacked nothing in the quality of the proceedings. That the gathering in Montreal during the week ending 26th May was an outstanding success was also the general opinion of those who took part in the extensive program of business, technical, and social affairs. Even the unseasonably cold weather was fair enough not to mar the occasion.

The record attendance was made up not only of members of the Institute from all the Canadian territories, but was augmented by the welcome presence of members of the American Society of Mechanical Engineers and the American Rocket Society, both of which bodies were actively associated with the meeting, as well as by representatives of engineering institutions in Britain and France.

The general proceedings are recorded here, and more detailed reports of individual events will be given in subsequent issues of the Engineering Journal.

The Annual General Meeting

On the morning of 23rd May, the Annual General Meeting got under way at 10.30 a.m. to open the business program.

The president, Dr. R. E. Heartz, was in the chair and the meeting proceeded smoothly through the agenda, which included the announcement of honorary membership, the awards of honours, prizes, and medals, the reports of council, finance committee, and treasurer, reports of other committees and the branches, a report on progress towards confederation, and the election of new officers.

The medal and prize awards are only summarized here, but further biographical details and a pictorial record of the presentations will be published later.

Honours, Awards and Medals

Honorary Membership—C. E. Davies, New York, N.Y.; A. R. Decary, Quebec, Que.; F. W. Gray, Victoria, B.C.; J. A. McCrory, Montreal, Que.; H. W. McKiel, Sackville, N.B.

Julian C. Smith Medals—Maj.-Gen. Howard Kennedy, Ottawa, Ont.; Adrien Pouliot, Quebec, Que.

Duggan Medal and Prize—J. Dubuc, T. A. Monti, G. F. Welter (joint authors) Montreal, Que.

Leonard Medal—F. R. Joubin, Toronto, Ont.

Plummer Medal—M. Katz, Ottawa, Ont.

Ross Medal—G. W. Holbrook, Kingston, Ont.

John Galbraith Prize—H. J. Saaltink, Niagara Falls, Ont.

Phelps Johnson Prize—R. R. Real, Montreal, Que.

Election of Officers

The newly elected officers of the Institute were announced by the general secretary, and those present were introduced to the meeting. The induction of the new president and officers was to take place at the annual banquet.

President—V. A. McKillop, London, Ont.

Vice-Presidents—H. R. Sills, Peterborough, Ont.; G. M. Dick, Sherbrooke, Que.; H. W. L. Doane, Halifax, N.S.

Councillors—Listed below are the names of the councillors and the Branches they represent.

E. L. Hartley	Vancouver
H. L. Roblin	Edmonton
J. M. Campbell	Lethbridge
W. A. Smith	Calgary
J. B. Mantle	Saskatchewan
R. T. Harland	Winnipeg
D. C. Holgate	Sault Ste. Marie
G.G.M. Eastwood	North East. Ontario
H. C. Bates	Huronia
L. C. Sentance	Hamilton
Wm. R. Roberts	Kitchener
Paul E. Buss	Niagara Peninsula
W. M. Huggins	Toronto
A. J. Bonney	Peterborough
R. F. Legget	Ottawa
John M. Hawkes	Cornwall
Roger Brais	Montreal
C. E. Frost	Montreal
H. A. Mullins	Montreal
C. H. Boisvert	Quebec
R. C. Eddy	North. New Brunswick
M. F. K. Leighton	Moncton
D. J. MacNeil	North. Nova Scotia
O. Nelson Mann	Halifax
J. R. Wallace	Cape Breton
R. A. McGeachy	Sarnia

Confederation

Dr. I. R. Tait outlined the progress of the work that had been done by the Institute and Dominion Council committees on Confederation. A full joint report had been prepared, dealing with the major issues involved. This report had been circulated to all members of council for study and had been discussed in detail at the meeting of council on 22nd May. As a result, the report had been approved in principle both by council and by the branch officers. Dr. Tait explained that the next step was for the report to be considered at the meeting of the Dominion Council on 30th May.

A motion from the floor endorsed the action taken by council on the issue of Confederation.

Vote of Thanks to Retiring Officers

Dr. I. P. Macnab moved that a vote of thanks be accorded to the retiring president and members of council in appreciation of the work they had done for the Institute during their term of office. The motion was seconded by Dr. D. M. Stephens, and a personal note of appreciation was added by Dr. H. W. McKiel, the senior past-president at the meeting.

The Professional Meeting

The Annual General Meeting was followed by a well-attended luncheon at which Dr. Heartz, the retiring president, spoke on the future of the Institute. His address will be found on page 792 of this issue.

After the luncheon the professional meeting got under way with the first of a fine program of technical papers, which continued through the next two days. In all there were thirty-one technical papers and three panel discussions covering a wide range of interesting and timely subjects. The professional societies already mentioned as being associated with this meeting — the American Society of Mechanical Engineers and the American Rocket Society — contributed to the program of papers, as did two visitors from the United Kingdom.

The interest aroused by the subjects covered was shown by the generally good attendance at technical sessions, and many animated discussions had to be closed to keep within the program schedule. Some of the papers have already appeared in the Journal; the remainder will be published in later issues and it is hoped that further discussion will be forthcoming to round off the subjects. Except for minor details, the program of papers and panels followed that published on pp. 437-440 of the April issue.

To complete a successful opening day of the professional meeting, there was a particularly enjoyable gesture by the City of Montreal in the form of a buffet supper at the Chalet on Mount Royal. His Worship, Mayor Jean Drapeau welcomed a large gathering of delegates and ladies, who spent a delightful evening overlooking the welcoming city and even a part of the St. Lawrence Seaway development that had been discussed that afternoon.

Other Activities

On the following day, Thursday, the afternoon was devoted to a most interesting visit to the Cartierville plant of Canadair Limited, where some 600 members and other visitors were shown many of the latest developments and techniques involved in Canada's air defence program. The developments went beyond the phases of design and production —far and fast, too, in the form of an exhilarating air display put on by Canadair and elements of Air Defence Command of the Royal Canadian Air Force. Sincere thanks are due to J. G. Notman, M.E.I.C., president of Canadair Limited, and to his staff, who made this visit possible and provided an outstanding and memorable event.

The conclusion of this visit and air show was by no means the end of the day's activities. The

Dr. I. R. Tait reports to the annual general meeting on the progress made by the joint committee on Confederation. Also present, from the left, are: V. A. McKillop, president-elect; R. L. Dunsmore, chairman, finance committee; B. G. Ballard, retiring vice-president; R. E. Heartz, retiring president; L. Austin Wright, general secretary; Miss M. McLaren, E.I.C. headquarters; M. A. Montgomery, vice-president; and J. O. Martineau, retiring vice-president.

The Students' Conference was a great success. The delegates seen here are, from the left: (front row) E. J. Korhonen, Queen's University; M. A. Laughton, University of Toronto; J. F. Riel, Ecole Polytechnique; J. L. René, Laval University; L. J. Schneider, University of Alberta; G. M. Ranger, University of Ottawa; (standing) T. D. Rooke, University of Manitoba; C. Day, University of British Columbia; D. E. McKercher (observer), P. M. Arsenault, McGill University; D. J. McColm, University of New Brunswick; L. Morrison, University of Saskatchewan; K. L. McIntyre (observer), University of Toronto; D. E. Stothers, Royal Military College.

annual dinner of the Association of Consulting Engineers of Canada, at which the chairman was J. G. Chenevert, M.E.I.C., was well attended by many members and visitors who were addressed by Sir George H. Nelson, president of the Institution of Electrical Engineers.

The junior panel discussion "What can a young engineer do in developing professionally?" was held on this evening, while other members enjoyed an interesting film show. Finally, there were many who found time from all these activities to spend a sociable hour or two visiting E.I.C. headquarters, where "open house" was held, to meet friends and members of the staff.

On Friday a luncheon was held under the auspices of ASME, at which the chairman was G. Ross Lord, chairman of the Ontario section of that society. Those who attended heard a vigorous address by ASME president Dr. J. W. Barker on international co-operation among engineers.

The President's Dinner

On the evening of 22nd May, the president's annual dinner was held and was a notable gathering of past-presidents and other officers of the Institute together with such distinguished visitors as president Sir George H. Nelson and general secretary K. Brasher of the Institution of Electrical Engineers, and Joseph W. Barker, president of ASME, with Clarence Davies, general secretary.

The president of the Institute, Dr. Heartz, paid particular tribute to the deans of engineering, who were attending the special conference on engineering education. Every degree-granting Canadian university was represented at the dinner by its dean of engineering, except for one who was unavoidably absent because of convocation ceremonies.

The president also presented certificates of honorary membership to John Armstrong and de Gaspé Beaubien, who had been elected the previous year but had been unable to be present at the 1955 dinner.

In accordance with established custom, all past-presidents were called upon in turn to contribute their views and reminiscences to the occasion, and those who spoke were: F. P. Shearwood, H. W. McKiel, C. J. Mackenzie, de Gaspé Beaubien, L. F. Grant, J. E. Armstrong, I. P. Macnab, J. A. Vance, J. B. Stirling, Ross Dobbin, and D. M. Stephens.

To conclude the occasion the president-elect, V. A. McKillop,

The E.I.C. Employment Department opened a special office in the hotel for the convenience of members attending the meeting.

was introduced and made an informal response.

The Special Conferences

Starting on 22nd May, other important conferences and meetings were held. It is hoped that further reports of these, together with photographs, will be included in later issues.

These events included the annual student's conference, branch officers' conference, meetings of council, and a unique gathering of senior engineering faculty members, from every degree-granting university in Canada, at a special conference on engineering education.

It is customary for the ASME-EIC International Council to convene during the annual meetings of E.I.C. and ASME. A meeting was held on 23rd May, and will be reported later.

During the visit to Canadair Limited, J. G. Notman, M.E.I.C., president of the company, is seen with Mrs. Notman, Lady Nelson, and Dr. R. E. Heartz.

Council Meetings

At the council meeting on 22nd May the outstanding item was the discussion on Confederation. This started at the morning session and continued in the afternoon with the branch officers' conference present. The joint report of the E.I.C. and Dominion Council committees was adopted and approved in principle. A lot of useful and instructive discussion took place, and it was evident that the whole subject is paramount in the minds of a large body of the E.I.C. membership. Dr. Tait, chairman of the E.I.C. committee, stressed the point that the report submitted to council was a joint one, and identical with that to be presented to the meeting of Dominion Council on 30th May.

The feeling of E.I.C. council members present, in general, was that the committee on Confederation had done an excellent job, that their work should be endorsed, and that they looked forward to the further progressive steps to be taken—possibly by a joint committee of the E.I.C. and the Dominion Council.

This opinion was extended at the first meeting of the new council, on 24th May, when the principal item of business was the adoption of a two-point motion to the following effect: (a) that Irving R. Tait be authorized to proceed as the E.I.C. representative to the Dominion Council meeting in Saskatoon, 30th May; and (b) that council should take further steps, as appropriate, to participate with Dominion Council in the formation of a joint committee to develop further the details of Confederation, if that is Dominion Council's wish.

Some of the many members and ladies, who were the guests of the City of Montreal at a buffet supper, on the steps of the Chalet, on Mount Royal. Mayor Jean Drapeau (left of centre) speaks to Mrs. C. G. Kingsmill; to his right are Mrs. Heartz and Dr. R. E. Heartz.

A section of the group who visited the Canadair plant watch an F-86 Sabre make a slow pass overhead during the air show which was a highlight of the tour.

More details of the joint report will be published later.

The Ladies' Program

The ladies represented a considerable proportion of the record attendance at the meeting and they took part in many of the functions on the general program. However, their prime interest must have been in the excellent ladies' program arranged so successfully by Mrs. C. G. Kingsmill and her able committee.

The Banquet and Dance

At the close of the technical sessions on Friday afternoon, this annual meeting was already assured of a resounding success, but the events of the evening, the banquet, followed by the reception and dance, undoubtedly formed a climax that crowned the whole program with distinction. Certainly the gathering was distinguished, from the impressive banquet head table through the rest of the company present, and the attendance was such that tables overflowed from the huge ball room into the foyer and balcony.

The winners of awards and medals were received with real enthusiasm, and there could be no doubt that the guest speaker, Dr. David L. Thomson, of McGill University, made a vivid and favourable impression on his audience with his discourse on engineering education from a university viewpoint.

The new members of council having been introduced, the proceedings of the banquet closed with the induction of the new president, Vernon Archibald McKillop.

There followed an informal and pleasant reception at which members and guests were able to meet President McKillop and Mrs. McKillop, the retiring president, R. E. Heartz, and Mrs. Heartz, and E. D. Gray-Donald, chairman Montreal Branch, with Mrs. Gray-Donald. For many of the banquet guests, joined by numerous others who arrived later, the day ended happily to the music of the annual dance.

The Seaway Tours

Though the events of Friday evening formed the grand finale of a memorable annual meeting, there were many who took advantage of the arrangements made on the following day, 26th May, to visit the main works of the St. Lawrence Seaway development. Two tours were offered, one covering the developments in the Montreal area, and the other taking in the extensive projects near Cornwall and Iroquois (Ont.) and Massena (N.Y.). Further news of these tours should make an interesting addition to our regular reports on the seaway and power developments.

The Meeting Arrangements

There are many factors which go to make a meeting such as

C. G. Kingsmill, chairman of the annual meeting committee, and Mrs. Kingsmill, who led the ladies' committee, seem to be pleased with the progress of the meeting.

this a success. However, it is certain that a special tribute must be paid to the work of the annual meeting committee under their chairman C. G. Kingsmill. Everyone realizes how untrue is the old platitude about "everything ran smoothly"; in a program of the scope covered at this annual meeting there must be many snags and real problems. That these difficulties were all resolved with such satisfying results seems to be the best witness to the efforts of the committee and the excellent liaison established with the headquarters staff.

This annual meeting was international in scope and representation. Above, Dr. R. E. Heartz (left) greets his successor as president of The Engineering Institute of Canada, Dr. V. A. McKillop, while Sir George H. Nelson, president of the Institution of Electrical Engineers, looks on. Left, Dr. J. W. Barker, president, headed the attending members of the American Society of Mechanical Engineers, while the American Rocket Society were represented by Rear-Admiral F. R. Furth, seen (below left) with Air Vice-Marshal A. Ferrier.

Photographic Exhibition

An innovation at the 1956 annual meeting was a photographic exhibition to which Canadian industry contributed a wide selection of studies of engineering subjects. Altogether, 135 photographs were displayed and a ballot was held so that members could express their opinions of the exhibits.

On the results of this ballot, certificates of merit will be awarded to the contributors of the five photographs that aroused the greatest interest.

The results of the ballot and reproductions of the leading entries will be published in a subsequent issue of the *Journal*. A general view of the exhibition is shown here.

The Engineering Institute
What of the Future?

Address by Dr. R. E. Heartz, the retiring President, at the Annual Meeting luncheon, 23rd May, 1956

It has been my privilege to have served The Engineering Institute as its president. During my term of office I have visited 37 branches from Newfoundland to British Columbia, including Whitehorse in the Yukon, conferred with executive committees, addressed the engineering students of 17 universities, attended all 10 council meetings held in 6 cities from Charlottetown to Winnipeg, and spoken to several Rotary Clubs and other organizations.

Two weeks were spent in England visiting the Institutions of Civil, Mechanical and Electrical Engineers. Meetings of the American Societies were attended in Boston, New York and Chicago.

In discharging my responsibilities, I have travelled 32,600 miles, attended some 250 meetings and spent about 7 months of my term of office on the work of the Institute.

While such a schedule places a heavy burden on the President, it does give him an insight into the problems, the activities and the importance of the Institute, which he could not favourably obtain otherwise.

It has given me the opportunity of observing the Institute in action, of discussing its work with its leaders throughout Canada, and of conferring with engineering organizations in this and other countries. The gracious hospitality of the fine people I have met and their keen interest in the Institute have made lasting impressions. It has been a thrilling and rewarding experience.

International Relations

The Engineering Institute, in addition to being a national body, has valuable connections in other countries through which mutual interests are developed.

The Conference of Commonwealth Engineering Institutions is made up of three representatives from the United Kingdom—The Institutions of Civil, Mechanical and Electrical Engineers, the leading Institutions in Australia, New Zealand, South Africa, India, Northern Rhodesia, and The Engineering Institute of Canada. The conference meets every four years to discuss ways and means of improving communications between the parts of the Commonwealth and the members of the engineering profession. There is also an exchange of speakers and technical papers, some of which are published in whole or in part in *The Engineering Journal.*

The Institute also participates in engineering projects of an international nature. For instance, in collaboration with the British Institution of Electrical Engineers and the American Institute of Electrical Engineers, the Institute will take part in the inauguration of the new Trans-Atlantic cable next spring.

The Union of Pan-American Engineering Societies (UPADI) is made up of The Engineers' Joint Council, in the United States, the Engineering Institute of Canada, and 18 separate engineering societies from different countries in South America. Its meetings, held every two years, are attended by several members of The Engineering Institute. This is a splendid medium by which to promote better relations with the many countries in South America. Also, an organization of this kind should be able to do a lot to assist the developing of trade relations between Canada and the South American countries.

The Engineers' Council for Professional Development (ECPD) is an organization made up of eight major engineering institutions in North America, seven in the United States, and the eighth, The Engineering Institute of Canada. As you will deduce from its title, the main purpose of this organization is to promote professional development among engineers. This is a powerful body, doing work not previously attempted by any other engineering organization. Through ECPD, The Engineering Institute has made a vast number of friends and, through them, has received great help in many of the problems which we have had to face.

The International Association for the Exchange of Students for Technical Experience (IAESTE) has as its object the exchange of engineering students between nations. Its membership is made up of 22 nations, with one organization in each country. The Engineering Institute is the representative from Canada. Students are exchanged in the year preceding graduation and return to their own countries to finish their courses. Last year 5,200 students were exchanged—50 came to Canada, 11 Canadians went abroad. The organization finances itself, and is entirely free from governmental influence.

The close collaboration between some of the American societies and the Institute, over many years, has been of mutual benefit by way of exchange of views and information, special rates for each other's publications, and frequent attendance at each other's meetings. This 70th Annual Meeting of the Institute in association with The American Society of Mechanical Engineers, the co-operative agreement between ASME and EIC, and our joint participation at their conference on engineering education at Potsdam, New York, and the proposed next conference at London, Ontario, this fall, are but further indications of the valuable benefits that accrue when men of good-will get together.

The Institute also collaborates with the National Committee of The World Power Conference (WPC), The International Electrotechnical Commission (IEC), The International Committee for Scientific Management (CIOS) and with many other organizations.

With the improved means of communication and the interweaving of the interests of nations, the relations of one nation to another have become increasingly important. In this international relations development, The Engineering Institute can and does perform an important part. The work which is done by the members of the Institute, with the members of organizations in other countries in the professional field, must be a real influence in establishing and maintaining the desirable good relationships.

As an example of how our interests overlap, let me remind you that at this 70th Annual Meeting we have with us senior members of seven engineering societies outside of Canada, five from the United States, one from England and one from France. The presence of these distinguished visitors will not only add colour to our conference but, at the same time, will do something towards improving the relationships between our countries.

International Privileges

Another of the good things that has come to the members of the Institute by virtue of the Institute's international connections, is the privileges which are extended to our members in almost any country of the world when they carry letters of introduction from us to an officer of the engineering society in that country.

These international relations have been fostered to a large extent by the efforts of our general secretary. I would recommend to those who follow me that they make certain to maintain these contacts. Only those who have served as president can fully appreciate the valuable work the general secretary does, his breadth of vision, and the great volume of friends he has made for the Institute throughout the world.

I feel you should also know that the annual conference of university students, which takes place just before our annual meeting, and the conference of deans of our degree-granting engineering universities, now in progress, are his original ideas.

I would like to express my genuine thanks to Dr. Wright and his entire headquarters' staff, including Colonel Thompson, Colonel Grant, Mr. Luke, and Miss McLaren for the splendid assistance they have given me during my term of office.

Institute Problems

In planning for the future, the Institute will have to find answers to many important problems. I would like to comment briefly on three of them.

The first problem is confederation, which was discussed by Council yesterday and reported on at your annual meeting this morning. We are fortunate in having the work in the hands of such a highly competent committee. The joint report by the Institute and Dominion Council committees is an excellent indication of the close co-operation between these two groups. While progress has been good, every effort must be made to expedite the remaining portion of the work. From what the committees have reported, it will be evident to you, as it is to me, we have little need for worry on this point. As stated some time ago, I am hopeful of the outcome.

The second problem is the result of our dynamic age and its rapidly expanding technology. In order to meet the situation, Council appointed a committee on technical operations, whose report recommending a comprehensive technical programme was approved yesterday. As many of you know, technical divisions have been in operation in some branches with great success, and it is now proposed to extend them across the country. An assistant has been added to the headquarters staff to help in setting up these activities.

The success of this proposal is vital to the interests of the Institute. The committees appointed by Council and by the branches to arrange widely diversified programmes throughout Canada have a great responsibility. The enthusiastic support of our members will be essential for best results. A great number of technical papers will become available for the *Engineering Journal*. In due course it may be necessary to publish transactions to take care of them.

The third problem was pointed up by the unveiling of the memorial in Ottawa to Colonel By. The whole project was so successful, and the nationwide reaction so favourable, that we now must continue to honour engineers who have made outstanding contributions to the development of Canada. The Institute is presently obtaining prices on the cost of publishing (in book form) the biographies of two famous engineers, which I hope will be published under the auspices of the Engineering Institute. Here is a golden opportunity to carry on with the principle initiated at Ottawa so that the people of Canada may become familiar with the leading part engineers have played, and will continue to play, in the building of this Canada of ours.

Education

Many of you will recall that the theme of my talks across the country was—the great need for more and better engineers and technicians, the lack of sufficient facilities for their training and the necessity of doing something about it immediately.

The shortage of engineers is now so evident that further reference to it is quite unnecessary, but it is important to realize that it is becoming increasingly worse, in fact, there are signs that it is beginning to affect our economy.

The desirability of establishing technical institutes in Canada was ably dealt with by Dr. C. R. Young, a past-president of the Institute, in a memorandum submitted to Council in 1944. There is an urgent need for more technical institutes of the type recommended by Dr. Young.

With the great demand for more highly qualified engineers, and with the possibility of those seeking an education doubling in number within the next decade, the challenge is a formidable one for the universities.

If our institutions of higher learning are to carry out their monumental task, they must have substantially increased financial support from governments, business and industry, and individuals.

Anxious to do something constructive about the situation, the Institute, at its own expense, arranged a conference of the deans and heads of departments of all degree-granting engineering universities, to be held in Montreal before the start of our 70th Annual Meeting to discuss engineering education.

The Institute also presented a brief on the problem to the Royal Commission on Canada's Economic Prospects, which was very favourably received.

Demands for copies of the brief have come from various parts of Canada and the United States. The original 350 copies were quickly used up. Of the second printing of 250 copies, only a few remain.

The Institute is fully aware of the urgency of the problem, and is ready and willing to collaborate with other individuals or organizations in any way that will assist in alleviating the present situation.

Canada is being affected as seldom before in history by foreign competition. We must be able to compete successfully in the markets of the world if we are to maintain, and preferably improve, our standard of living. Our abundant resources, incidentally by no means inexhaustible, as some would have you think, should be processed more and more within our country. New products will have to be developed and old ones improved at an unprecedented rate. The impacts of the applications of scientific research throughout the world may affect our country considerably. Never has there been greater need for superbly trained scientists, engineers, and technicians for the continued and future welfare of Canada.

The Future

Now that I face the termination of my presidency, I have mixed feelings. As explained earlier, the post makes great demands upon one, but I wouldn't have missed the experience for anything. I am reminded of a story that is both old and widely distributed. I tell it only to remind you of it because of its appropriateness to the occasion.

The father of 15 children was being interviewed on the merits of large families. When asked how he felt about the whole experience, he replied "I wouldn't take a million dollars for any one of the 15, but I wouldn't give you a dollar for another one."

The presidency is a high office. The opportunity it gives to serve the profession is so great that no one with any sense of responsibility could refuse it. And yet, at the end of my term, as I look back, I wonder how many of the things I had in mind to do have been done. How well have I served the profession?

I don't suppose there has ever been a president who, standing where I stand now, has been satisfied with what he has accomplished. Thus it is that I realize, that here, as in other places, "Man's work is never done."

Perhaps there is more to the presidency than just the day to day details. Perhaps the greatest contribution of all is to pass along to one's successor some of your enthusiasm for the work of the organization, some of your experience to aid him and some of the inspiration that drove you so hard so that he may carry on the things you saw started, and see many of his own brought to fruition.

Don't leave it all to the president. No matter how good he may be, he is helpless without the support of the members. The responsibility of his office, the stirring challenge of the future are yours as well as his.

What will this future hold for the Institute? I see in it opportunities and problems that will tax the best minds in the organization but I see, also, new heights of activity and new achievements that will go on building new standards of service on the foundations laid by those who have gone before.

The Institute is a great organization. It was founded by the leaders of the profession, the giants of their time, and it has been blessed with the continuous support of such persons. Already it has done a work that has made it a distinguished asset to Canada, but what is ahead will be even brighter as it meets square on the challenge of the future.

To every one of you I say if you are interested in your country, if you are interested in the welfare of your profession, stand firmly back of the Institute. It needs you—and you need it.

Annual Meeting Reports

In subsequent issues of *The Engineering Journal*, reports and pictures of the principal meetings and other functions will be published to complete the record of a highly successful program.

Month To Month

Notes of the Institute and Other Societies, Comments and Correspondence, Elections and Transfers

Bigger and Better

So many times it has been said that a person never really knows the Institute until he has attended an annual meeting. It is true that the great, broad program of the Institute cannot be seen or appreciated in any other way.

The 1956 meeting just completed in Montreal must have impressed many hundreds of people, some in attendance and others who followed it in the daily press. It is encouraging from year to year to see the program improving in quality and quantity, and the members turning out in steadily increasing numbers to participate in it.

This latest meeting as far as the record or man's memory goes has broken all records. There were more people present (1700 to 1800) to hear more papers and panels than ever before. There were more representatives of sister societies, more gentlemen of the press, more ladies, more excitement and more fun than ever before. And of course there were trials and tribulations for committee members and Headquarters staff, but they were not out of proportion to the other factors.

The Institute's Important Work

This meeting proved again and with increased emphasis the importance of the Institute and its work, both nationally and internationally. One needs but to look at the program to see the importance of the subjects discussed and the high calibre of the authors and speakers to realize that the Institute has a great work in hand — work of real significance to the profession and to Canada. The members of the profession through the Institute are indeed accepting their responsibilities towards the development of the profession and of the people associated with it.

Probably nothing ever done previously by the Institute has had as great a significance as the conference on engineering education. To this conference were invited the deans and three members of the staff of every engineering degree-granting university in Canada. In fact, there were additional staff members present as observers. The Institute paid the entire cost of the conference. The deans have reported a most successful two days of meetings. There were about sixty in attendance. There has never been such a meeting before. A report in some detail will appear in a later issue of *The Engineering Journal.*

Sister Societies Participate

The Institute was fortunate and happy to have so many representatives from other societies. The American Society of Mechanical Engineers and the American Rocket Society were joint participants in the technical program. The Institution of Mechanical Engineers and the British Institute of Management also were represented by members participating in the program. As well, there were the presidents of the Institution of Electrical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the Engineers' Council for Professional Development and a representative of the Société des Ingénieurs Civils de France. It was a great meeting. Not only did it make a worthwhile contribution to the professional life of Canada, but it pointed up the usefulness and adaptability of the Institute itself. Such a showing puts further obligation on the officers of the Institute to forge ahead with Canada but also it gives the encouragement to accept the challenge.

"On the past we build the future" and so on to Banff in June, 1957, for more achievement and for more development of the profession.

Cover Picture

A touch of humour and a tribute to a well-made automobile was added to the 70th annual meeting when Mayor Jean Drapeau and Dr. and Mrs. R. E. Heartz of Montreal arrived at the Mount Royal Chalet in a 1911 Cadillac. The City of Montreal was the host at a buffet supper in the Chalet where over 800 guests were welcomed by the mayor.

Annual Meeting

1960

At the April meeting of the Council of the Institute an invitation was received from the Winnipeg branch inviting Council to hold the annual meeting of the Institute in that city in 1959 or 1960.

In view of the fact that the 1957 meeting is to be in Banff, Council felt that another meeting in the West should not take place until 1960. Accordingly the invitation was accepted for that date.

The record shows that the Institute has met twice in Winnipeg—once in 1921 and then again in 1945. Both meetings were outstanding successes and anyone who attended either one of them will be delighted to know that another one will be forthcoming shortly.

Eating our Seed Grain

In the light of today's shortage of engineers and scientists it is disturbing to realize that there are many instances of industry taking away from the universities, people who have had an important part in training engineers and scientists.

Recently an advertisement appeared in "The B.C. Teacher", which illustrates the point excellently. The advertisement is reproduced herewith.

Opportunities for Science Teachers

Young men science teachers will find interesting opportunities in the pharmaceutical field where scientific knowledge, coupled with teaching ability, are prime requisites.

A well known ethical pharmaceutical house, expanding its business, is now offering stimulating work in the presentation of new developments to the Medical Profession.

It is interesting to note that the organization refers to itself as an "ethical" organization. There are some people who might think the adjective was not appropriate under these conditions.

It is inevitable that this competition between industry and education will exist, when it is remembered that the salaries paid at universities are so much lower than those offered by industry. Nevertheless, industry should be wise enough to see that their needs in the future can never be met if they continue to take out the teachers who are solely responsible for producing the crop year after year.

Teachers Going Into Industry

The president and general secretary of the Institute were entertained at lunch by the president of one of the western universities during the visit there last November. During the course of the luncheon the president of the university stated that during the year they had lost eight of their senior instructors. Six out of the eight were going into industry and only two to other educational institutions. It is hardly necessary to explain that this was a serious blow to a university that is trying so hard to do a job of work commensurate with the demands and with the opportunities.

A Dangerous Practice

Perhaps the cure for this suicidal practice is to have the teachers paid better salaries. Certainly it would not be fair to the teachers to persuade industry never to approach them, but perhaps there could be some reasonable compromise between these two extremes. There are some instances where teachers have done better for themselves and for others as well once they got into industry. On the other hand there are a great many teachers now in Canadian universities whose presence there is vital, not only to the numbers of engineers and scientists turned out but to the quality as well. Is it too much to hope that the universities in one way or another will find enough money to pay these important people something like the salary they should be earning, and at the same time that industry will realize that its own success in the future depends upon these people remaining at the universities?

British Plan for Technical Education

From a recent issue of the magazine *Flight,* we see that the British Government is proposing to do something drastic about the shortage of engineers and technicians. The leading editorial in *Flight* contains several interesting passages. Those which relate to facts rather than to opinions are these:

"The immediate objectives of the Government's five-year plan for technical education, disclosed in a White Paper last week, are to increase by 50 per cent the output of students from advanced courses at technical colleges; to double the numbers released by employers for part-time day courses; and to spend some £100m on new buildings and equipment. The main avenue of advance to the highest qualifications will be 'sandwich' courses of alternating theory and practice; and most full-time and sandwich courses are to be concentrated in colleges of advanced technology.

"Much space in the White Paper is devoted to the task of 'selling' technical education — to parents, teachers, employers, trade unions and the general public, all of whom are urged in the national interest to support the Government's plan. A major factor if the plan is to be a success is the attitude of individual employers; the provision of facilities for any young man or woman to continue to advanced training is only one aspect of the complete and imaginative approach to the problem that is required.

"The employer's responsibility to youth is three-fold. Firstly, the practical training offered at a firm's own factory should be an effective apprenticeship, be it full, sandwich, or short-period. It should not be the casual and frustrating semivacuum experienced by so many in the past.

"Secondly, the firm's attitude towards day-release, sandwich and full-time advanced courses at colleges and universities should be an enlightened one. The firm's own short-term interest should not over-ride the line of best development for the individual concerned.

"Thirdly, the student technician's endeavours in achieving a sound education should be matched by honesty and integrity of purpose on the part of the employer after training is completed. Firms may need to be reminded that it is for them to give students good reason to join and stay with their particular organizations."

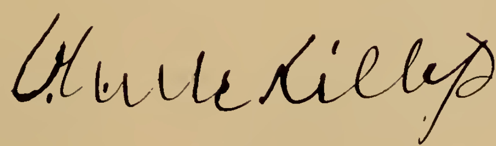
While the editorial in *Flight* is directed principally to the aircraft industry, nevertheless it has much of a general interest. Until a copy of the White Paper itself is received at the Institute, it is thought the information disclosed in this editorial will be of interest to Canadians.

Message from the President

THE privilege of serving the members of The Engineering Institute of Canada in the capacity of president is one for which I am very grateful. The long record of the Institute in the service of this country and, in fact, far beyond our borders is such that I can only consider it a real honour to participate actively in this work. The past presidents and officers have set an example in their devotion to the interests of the Institute that will be an inspiration to those who follow.

Whatever service the engineers of this country have been able to render to their fellow citizens in the past, it would appear that there will be many more opportunities in the future. The responsibility of the engineers for the welfare of the people was recognized during the war, and with peace came a new understanding of the reliance placed upon the work of the engineers by all levels of society. This dependence has become so related to our every day requirements that it is now the very basis of our way of life. Likewise, the experience and advice of engineers is essential for the wise and orderly development of our natural resources. The engineer himself, being one of those resources, should feel a special sense of responsibility to see that his time and talents are used wisely.

When we are able to adopt such an attitude toward our work and responsibility, we will then be thinking as engineers first, and as members of this or that organization secondly. Then Confederation will be an accomplished fact.



V. A. McKillop, M.E.I.C.
PRESIDENT

At the 80-ft deep excavation for the Iroquois lock at Iroquois Point, Ontario, the contractor will soon be placing concrete for the structure. Here ships will pass between the power pool or seaway lake and the upper river to enter the Thousand Islands section of the seaway.

St. Lawrence Seaway and Power Project

The *Engineering Journal* reviews the progress of the St. Lawrence project.

Progress by Ontario Hydro

In general, the wet weather and soft ground conditions during April made construction work difficult. Excavation for all features of the project at end of April totalled approximately 10,700,000 cubic yards.

Concrete placing in the north end of the power-house continued throughout the month of April on an accelerated scale. A total of 67,300 cubic yards had been placed in the "U" abutment sector and the wing wall by the end of the month.

On the diversion canal, now 25 per cent complete, the contractor had reached rock at grade in the closure structure area. This bottom will be ready early in May for concrete placing. The contractor had commenced erection of a new batching and mixing plant. This new concrete plant was expected to go into operation in May.

In preparation for the mile-long diversion canal, the Cornwall transformer station was dismounted, and the contractor had been excavating in the west end of the canal near Robinson's Creek. Meanwhile the new St. Lawrence transformer station was placed in service. It has taken over the 44-kv. and 115-kv. loads formerly handled by the Cornwall transformer station.

With the return of spring weather, dredging operations had been resumed at Chimney Island near Prescott, where dredging was about 12 per cent completed. The Canadian Dredge and Dock Company's unit "Excelsior" had resumed operations on the channel. Meanwhile, at Galop Island, excavation was more than 25 per cent complete. The contractor had reached bedrock in the northwest corner of the excavation and was using the rock produced to build the permanent training dike from the island at the northwest end. Excavation at Iroquois Point was about 32 per cent completed.

Preparations were being made with the return of favourable weather to commence work on the Cornwall dike. The Commission's highway and railway contractors also were preparing for full-scale resumption of work.

Bad weather and soft ground conditions had hindered rehabilitation work in all areas. It had been hampering excavation for sewers and water mains in all four new townsites. At Iroquois, the house moving machines had been operated in a limited way, being supported on temporary timber runways to travel over the soft ground. A total of 123 houses had been moved to the end of April. Work was started in Morrisburg on sewer and water mains. Meanwhile, this work was continuing in new towns Nos. 1 and 2.

Employment had reached a total of 2,800 men on 28 construction contracts.

Progress by NYSPA

April progress and the start of the crucial 1956 construction season were marked by the placement of the first concrete in two additional projects of the power development. April 17 was "Concrete Placement Day" at Barnhart power-house; at Massena intake it was April 24. April was also marked by a new high in employment. Excavation quantities had passed the fourteen and one half cubic yard mark, although excavation for the structures was tapering off as bedrock was exposed.

The structure of Iroquois dam was taking shape as the concrete piers rose from foundation and apron in the east section, with concrete in four piers placed to above tail-water level. Concrete in place at the end of April totalled 34,000 cubic yards. Excavation of upstream dikes had increased the total yardage to two and a half million.

Concrete placement at Long Sault dam was resumed on April 4 with 28,300 cubic yards being placed during the month, bringing the total in place to 60,000 cubic yards. Concrete had been placed to gate sill level over nearly half of the length of the dam. Excavation for Cut "F" was 59 per cent complete and erection of the cofferdam "E" cableway towers was in progress. Employment on this contract had passed the one thousand mark.

With rock excavation at its final depth in sections of the Barnhart power-house, concrete was being placed more than 80 feet below the river surface under two units near the south end. Form construction and installation of embedded items as well as continued drilling, grouting and other activities had required substantial increase in employment.

At the Massena intake, the first concrete was placed in April, some 64 feet below the water level in the canal. The structure is about 22 per cent complete.

Rock and earth excavation in the Galop Island south channel continued to progress, but a resumption of dredging in the Chimney Island area was delayed by a labour dispute.

Access roads were 85 per cent complete; land acquisition 100 per cent complete; reservoir clearing 5 per cent complete; Barnhart Island bridge 97 per cent complete and dikes 20 per cent complete.

Surveys for the Barnhart-Plattsburg transmission line were well underway. Studies were being made of docking facilities near Robinson Bay Lock for Alcoa.

The contract for channel excavation at Point Three Points—Leishman's Point—Ogden Island had been awarded. Bids were received for the electrical work at Barnhart Island power plant.

Preparation of engineering drawings and specifications continued on schedule. Purchase orders had been placed for accessory equipment including load frequency control apparatus and station lightning arresters. Employment had reached a total of 3,290 men on 26 construction contracts.

Progress by SLSA

To the end of April 1956, 32 construction contracts had been let by SLSA for a total of over $80 million. The value of work completed was approximately $15 million or 20 per cent of the work awarded to date.

Construction was actively under way in the Lachine section over the whole 16-mile stretch from deep water in Montreal harbour to within a mile of Lake St. Louis. This work is let in nine general contracts amounting to a total of $45 million, and includes the St. Lambert and Côte Ste. Catherine locks. In addition to the above nine contracts, only three others are required to complete the whole Lachine section.

Here progress is well ahead of schedule. One contract was fully completed eight months before its stipulated completion date, and all others, save one, are proceeding according to schedule. This one has been delayed because of high water, but with normal conditions again prevailing, it will catch up. At the start of the second year of construction the Lachine section was roughly 10 per cent completed by dollar value, with two and a half years to go.

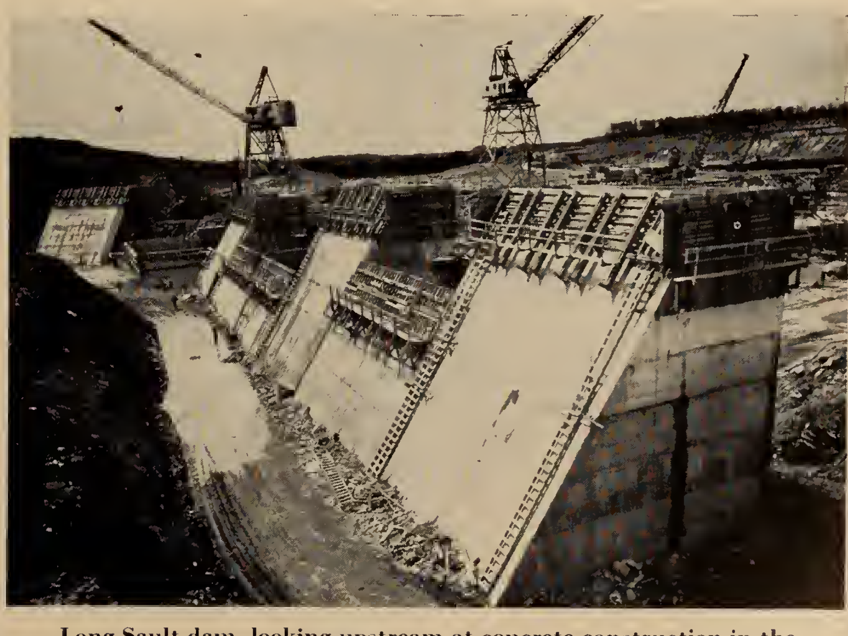
In the Lake St. Francis section which extends for some 15 miles, channels were being deepened by dredging to a depth of 27 feet where necessary. Here 30 per cent of the channel excavation work had been completed and work was ahead of schedule.

The work to be done in the Soulanges section, nearer Montreal, includes the construction of two locks separated by a three-quarter-mile intermediate pool. Also required is the construction of three lift bridges at the existing railway and highway bridges crossing the Beauharnois power canal, which will be used for navigation. No. 3 highway, which follows the shore of Lake St. Louis will be carried under the lower lock in a four-lane divided tunnel.

In this section a contract has been awarded for the first stage construction of the two locks which includes the excavation for the main highway diversion tunnel, the cofferdam, and close to a million yards of rock excavation for the channel. Work is just getting under way.

The award of two additional contracts for the supply of concrete aggregates: one for the supply and delivery of fine aggregate to a railway siding at Côte Ste. Catherine, is announced by SLSA. This fine aggregate is to be used for concrete in the Côte Ste. Catherine lock. The other contract covers the handling of sand from the siding to the contractor's bin.

The contract for the supply of the aggregate—185,000 tons f.o.b.



Long Sault dam, looking upstream at concrete construction in the southeast retaining wall.

railroad cars, is valued at $397,750 and was awarded to Standard Lime Company Limited. The contract to handle the sand at the lock site was awarded to Canamont Construction Ltee., and Canit Construction Ltd. in joint venture, and is valued at $181,300.

Tenders have been called for the excavation of the channel and the construction of a dyke in the Caughnawaga Indian Reservation, Lachine section. This contract will be the last one to be awarded for excavation and dike purposes in this section of the seaway.

The work consists of 1,200,000 cubic yards of common excavation, 1,980,000 cubic yards of rock excavation, and approximately 10,000 feet of dyke construction. In addition, it includes clearing, cofferdams, unwatering, handling and disposal of surface drainage and the disposal of materials. The work must be completed by August 31, 1958.

New Bridge at Cornwall

Cost of a new bridge for the seaway across the St. Lawrence river near Cornwall will probably be shared by Canada and the United States. A bridge now spans the north river channel from the Canadian shore to Cornwall Island. A second bridge spans the south channel from this island to the U.S. mainland. The two bridges are owned by the New York Central Railway which leases them for motor traffic to the Cornwall International Bridge Co. This company also operates a highway across the island.

Seaway shipping will use the south channel instead of the north channel. This calls for demolition of the bridge over the south channel and its relocation across the river at Polley's Gut. On May 3rd a bill to amend the St. Lawrence Seaway Act, to permit Canada's Seaway Authority to build a new international bridge at Cornwall, was introduced in the House of Commons, where it got third reading and was sent to the Senate.

The New York Central will have the right to use the new bridge. However, there are rumors that New York Central may abandon their Cornwall-Ottawa line entirely, now only used for freight service since passenger traffic was abandoned two years ago Negotiations are reported under way with the Ontario government regarding a possible purchase of the right of way for a super-highway between Cornwall and Ottawa.

Progress by SLSDC

A full year after the actual start of earth moving on the American side of the St. Lawrence at Robinson Bay lock, the hole was 95 per cent completed at the end of March, while excavation for Grasse River lock was 88 per cent done, with a further 300,000 yards remaining. Despite spring thaws and a week's strike by machine operators, contractors on locks and two canal excavation jobs had moved three quarters of a million yards for the month.

At the upper end of Long Sault canal "The Gentlemen" big coal-stripping dragline operated by Badgett Mine Stripping Co., had a completion score of 45 per cent. On the mainland portion of the 10 mile overland canal Morrison Knudsen-Kiewit showed a 9 per cent completion. At the Robinson Bay lock site the contractor had started preparing the lock foundations where rock was exposed.

With the award of contracts for building the two locks at Robinson Bay and Grasse River, the peak of the engineering design period has been passed. This effort has demanded the services of many engineers of specialized skill and experience.

Underestimating on major SLSDC contracts has resulted in total spending for the current fiscal year exceeding estimates by some $852,000. In addition, NYSPA has decided that SLSDC should pay some $20 million for dredging in the International Rapids Section. If the Seaway Development Corporation is charged with this added fiscal burden, it cannot operate within the $105 million limitation imposed by Congress two years ago, as the $18 million cushion between estimated spending and the legal limit is being rapidly used up.

A dispute with the Coastguard Service as to who should operate navigation aids has been turned over to Attorney General Brownell for a decision. Both the Comptroller General and Budget Bureau have ruled that the aids are SLSDC responsibilities, but the Coastguard has refused to accept the rulings.

Shipping on the Seaway

New Type Ships Being Created by Seaway

President Lionel Chevrier of SLSA told members of the Society of Naval Architects and Marine Engineers, meeting in Montreal May 3-4, that "The present Great Lakes-St. Lawrence system has already given rise to distinctive types of ships, each adapted to the type of service it is designed for within the limitations imposed by the route or the part of a route to be utilized, of which the laker-type bulk-carriers of ore and grain, and the canaller-type capable of negotiating the present 14-foot canals are the most familiar."

"The length and beam measurements," explained the speaker, "will be governed by the size of the new locks, being built to the same standards as those of the Welland Ship Canal. The seaway will accommodate vessels up to 765 feet long with beam measurements of up to 75 feet. Draught will be limited by the 27-foot depth of the channels and would therefore be some 25 feet."

The timeliness of the seaway in the light of economic development over the last 20 years was also stressed by the speaker. "In what I shall call the 'old days' it was perhaps natural to look upon the seaway project as a tremendous shot in the arm to a sluggish economy greatly in need of some such stimulant. Today, the patient is in robust condition and growing fast. None of our doctors in economics today would feel the need to prescribe the seaway as a stimulant; but they might well prescribe it as a much needed relief from growing pains," he concluded.

Cheap All-Water Rates May Boost Lake Ports

A boost in business for Great Lakes ports following completion of the seaway was predicted by Sydney A. Vincent, consulting architect, Newport News Shipbuilding and Drydock Co. He was addressing a meeting of the Society of Naval Architects and Marine Engineers at Montreal on May 2. The cost of moving a mixed cargo from Detroit to Antwerp by water, stated Mr. Vincent, would be half the cost of moving the same cargo from Detroit to Baltimore and thence to Antwerp by sea.

The speaker's conclusions give

inland ports like Toronto and Hamilton a yardstick by which to estimate the savings of shipping direct to and from lake ports, instead of moving cargo by rail to Montreal and thence by water to Europe. The study is one of few on the comparative costs of shipping from inland ports. It gives a firm indication of the sort of competition the port of Montreal will meet in retaining its present volume of ocean traffic.

Montreal port authorities have maintained the cheaper cost of all water traffic to and from lake ports via the seaway would be offset by factors such as congestion of the Welland canal, amount of overseas traffic destined for unloading at Montreal, and the relatively more economical movement of grain and major export cargo in lakers to Montreal for trans-shipment overseas.

Toronto Area Committee

The committee coordinating technical activities of civil engineer members in Toronto area of the Engineering Institute, the Institution of Civil Engineers and the American Society of Civil Engineers, has concluded one year's work. At an executive meeting of the Joint Area Committee, as it is named, two items were recorded in the minutes which are of interest.

The membership list of the committee is now complete and contains the names of all known members of the three parent bodies residing in the area of Greater Metropolitan Toronto. It was decided to restrict the list to this area, unless specific requests were received from members residing outside of it. Any member who has accidentally been omitted from this list, or who wishes to be included, should contact Mr. B. Hardcastle, c/o McColl Frontenac Oil Co. Ltd., 8 Spadina Road, Toronto, (Telephone Walnut 4-8711).

There will be an Open Night on the program for the 1956-57 session, for which original papers of civil engineering interest are invited from members of the Joint Committee. The tentative date selected for this meeting is April, 1957. Any member wishing to present a paper on this occasion should contact the secretary in writing, outlining his paper briefly.

Aeronautical Meeting

The Canadian Aeronautical Institute held their third annual meeting in Montreal, on May 4 and 5, 1956. For this meeting the C.A.I. had arranged a program treating aviation in its various aspects—propulsion, manufacturing, design, aerodynamics, maintenance and operations. The technical program fulfilled the purpose of reviewing Canadian aviation to date, to the extent that one paper had to be revised to avoid disclosing secrets of Canada's latest supersonic fighter. This was J. Morris' paper on "Some Performance Problems Associated with a Mach 2 Fighter". The technical program was as follows:

The Program

The Development of Rolls Royce Propeller Turbine Engines, by D. P. Huddie.

Choice of Design for an Advanced Turbojet, by F. H. Keast.

Manipulation and Control of Titanium, by L. B Gray.

Transition from Small to Large Aircraft Manufacturing, by H. L. McKeown.

Machining Approach to Aircraft Production, by H F. Young.

Design and Procurement of R.C.A.F. Ground Handling Equipment, by F/L B. D. Darling.

Lift and Thrust Creating Systems—Their Application to Short and Vertical Takeoff Aircraft, by F. C. Phillips, and K. Irbitis.

The Comet 4; Design and Operational Considerations, by R. E. Bishop and J. Cunningham.

An Experimental Investigation of the Effect of Surface Roughness on the Drag of a Cone-Cylinder Model at a Mach Number of 2.48. by Dr. J. H. T. Wade.

Some Performance Problems Associated with a Mach 2 Fighter, by J. Morris.

Boundary-layer-induced Noise in the Interior of Aircraft, by Dr. H. S. Ribner.

The Changing Aspect of Northern Flying, R. N. Redmayne.

Airline Engineering Evaluation of Transport Aircraft, by A. E. Ades.

Field Data Analysis; Some Techniques Currently Being Developed in the R.C.A.F., by S/L. J. E. Neelin and B. Larmour.

McCurdy Award

R. D. Richmond, president of the 1500-member Institute, who is chief development engineer of Canadair Limited, presided at a business meeting, and at the annual dinner.

The annual dinner provided the occasion for the presentation of the McCurdy Award for 1955 to J. H. Parkin of the National Research Council. The Hon. J. A. D. McCurdy for whom the award is named, was there to make the presentation to the Canadian judged to have achieved most for Canadian aviation during the past year. Mr. McCurdy was the first Canadian to fly a powered aircraft.

M. M. Hendrick Is Speaker

Air Vice-Marshal M. M. Hendrick, Air Member for Technical Services, R.C.A.F., speaking at the annual dinner, discussed the R.C.A.F., which in the last three years has become a jet air force using planes which are now all Canadian-built.

He mentioned some of the "tools" of the Air Force: the CF 100; the Sabre VI, used abroad, the Silver Star jet trainer, and the Pine Tree Warning Line, the electronic control network. With these tools, he said, the Air Force has created a fully operational fighting machine.

He touched the subjects of ground control and electronics, and the technical complexity of air defence and offence. The Air Force is predominantly a technical service, he said; one fifth of all its officer personnel are practising engineers. An important technique now is Operational Analysis or Weapons System Analysis, a procedure which will be recognized by engineers in industry.

The great problem facing the military in the future is how automatic to make the air defence system, the air vice-marshal said. But his opinion was that man will still fly in the plane of tomorrow. The new supersonic fighter now under design and development in Canada will carry two men to exercise judgment and to deal with the unexpected. The guided missile still must demonstrate its ability to do all the things promised of it.

Another challenging thought was the possible increasing measure of help from industry, not only to fabricate air defence facilities and overhaul them but to maintain them. However this balance between service and civilian activities for defence may come out, said AVM Hendrick, the fact remains of course that there always will be a partnership between the Air Force and the industries which support it.

Canadian Pipeline Projects

A monthly review of the news and progress of the projects for piping Alberta natural gas westward to Vancouver and the Pacific states, and eastward to serve Canada's central provinces.

Progress by Westcoast Transmission

In sharp contrast to the tangled affairs of the Trans Canada pipeline project and the noise of battle over its destinies in the House of Commons in late April and early May, Westcoast Transmission's 680-mile project to bring Canadian gas to Pacific states was well away to a good start on construction.

Westcoast Transmission construction crews were already shifting into high gear in April, with nearly a third of the expected summer employment of 2,700 men already on the payrolls, clearing right of way, building access roads for delivering the pipe, and laying pipe at river crossings. Delivery of the first 3,000 tons was made at Vancouver in February and March, out of the 90,000-ton $15-million order from Britain for the first 250 miles of pipeline. The balance of the order is scheduled to arrive in monthly lots of 6,000 tons.

Contracts had been awarded for the entire 668 miles of line from Peace River to Huntington at the International Boundary. Dutton Williams is building the northerly 110 miles from Taylor Flats in the Peace River block to the Parsnip River. Canadian Bechtel Limited construction division is undertaking the next 210 miles to just north of Williams Lake; Conyes Construction Corporation is building from there to Merritt, while Mannix Limited is doing the balance from Merritt to Huntington.

Franchises had been executed at Penticton, Kelowna, Vernon and Trail. Inland Natural Gas Company will build a lateral pipeline to serve the Okanagan Valley, tapping the main line at Savona. Other short laterals will serve Prince George, Quesnel, Williams Lake and the surrounding districts.

A contract had been awarded for construction of the $18 million natural gas absorption plant near Fort St. John, B.C. This plant scheduled for completion in 1957, is one of the first industrial operations in Northern B.C. connected with the petroleum industry. The plant is to be located on the north bank of the Peace River near the Alaska Highway bridge, and will process the gas before it enters the pipeline.

It is a three stage operation, in which raw wet gas is scrubbed and cleaned, liquid hydro carbons removed and elemental sulphur produced. The 250 to 300 tons daily of sulphur to be produced initially will be more than sufficient for the needs of the entire British Columbia pulp and paper industry. The plant may be the forerunner of many new chemical industries for British Columbia.

As well as the sulphur, propanes and butanes, the plant will produce large quantities of high grade fuel for cars, trucks and aircraft. As gas volumes carried by the pipeline grow in coming years the capacity of the plant will be increased.

Contracts for building the plant were awarded to the Marwell Construction Company of Vancouver, while the Stearns-Roger Company, which has world wide experience in building gas absorption and gasoline extraction plants, will make the installations. More than 700 men will be employed in building the plant. It will give employment to some 100 permanent workers.

Meanwhile, south of the international border, construction of the Pacific Northwest pipeline to connect up with Westcoast Transmission at Huntington was reported proceeding rapidly. At the end of March more than 750 miles of 26-inch and 22-inch pipe had been laid from the San Juan Basin to Kennewick, Washington, where the line splits into three branches, or about half of the total length of 1,487 miles. The line on the American side is being built by Fish Northwest Constructors, Inc.

A 70-well gas drilling program in the Peace River area at a cost of between $20 and $30 million is being undertaken this summer by Pacific Petroleums Limited. A new gas discovery in April, 160 miles northwest of Fort St. John by Shell Oil and Canadian Gulf Oil, found a 12 million cubic foot per day gasser from the mid Devonian horizon. Located near the centre of British Columbia's gas reserves and close to Westcoast's main source of gas supply, this important discovery is being watched with interest.

The Westcoast Transmission project, given final FPC approval in November, 1955, joins gas reserves of Northern Alberta and Northern British Columbia with the U.S. supply from the San Juan Basin in New Mexico, to supply the States of Washington, Oregon and Idaho, extending the market to San Francisco in California. The size of the pipe was raised to 30 inches in place of the 24 inches originally planned. It will supply 250 million cubic feet daily towards the 350 million cubic feet per day market in the north Pacific states by 1957.

Starting at Fort St. John, centre of the British Columbia gas reserves, it parallels the John Hart highway to Prince George, then follows the Cariboo highway and Pacific Great Eastern Railway south, swinging eastward just above the Fraser Valley to terminate at the U.S. border near Huntington, B.C., 35 miles east of Vancouver. There it will join up with the Pacific Northwest Pipeline Corporation's main from the south. A spur line will serve Vancouver, while other laterals will feed many other British Columbia towns and communities.

The British Columbia Electric Company is carrying out a $10-million program in Vancouver and the lower Fraser Valley to increase its gas distribution system, in readiness for natural gas on November 1. Meantime gas will be supplied from the Pacific Northwest pipeline. Estimated savings to domestic and commercial consumers with natural gas will range from 25 to 52 percent as compared with manufactured gas.

Progress of Trans-Canada Pipelines

Up to the middle of May, the future of the Trans-Canada pipeline project still remained uncertain and confused. The bill to authorize a Crown Company to build the 675 mile Northern Ontario gap had been introduced in the House of Commons, and though lively debates occurred at intervals no final action had been taken. Extension of the time limit allowed for Trans-Canada to give proof of its ability to finance the project had been extended by the Board of Transport Commissioners from April 30 to October 30, 1956.

Trans - Canada announced in March that the company had signed up contracts with producers which strengthened its gas supply picture to a point where only a minor portion of requirements now need to be obtained to supply present market commitments.

The percentage ownership of presently outstanding stock of Trans-Canada is as follows: Canadian Delhi, 24½%; Western Pipelines group, 24½%; Canadian Gulf Oil, 17%; Hudson's Bay Oil and Gas, 17%; and Tennessee Gas Transmission, 17%.

By mid-April, financing for the $153 million project had been completed. The Metropolitan Life Insurance Company is taking $40 million, almost half of the $83 million of the first mortgage bond issue. All told, Canadians will put up $34 million, $10½ million of which comes from Royal Bank of Canada for debentures. The company will raise over $16 million from the sale of common shares, with 55½% of it coming from Canadians.

Heading a strong group of Canadian and United States oil and gas interests, Frank McMahon, Alberta oil and gas promoter and president of Westcoast Transmission, made an alternative offer in April to build the pipeline to the central provinces, without government assistance other than relief on sales tax and duty. Four American mid-west gas utilities would import 400 million cubic feet of gas daily, or twice the amount of import proposed by the Tennessee Gas Transmission. The offer, however, was withdrawn early in May. Legislation providing a $72-million loan to Trans-Canada was introduced in the House of Commons, to enable Trans-Canada to build the western leg this year as far as Winnipeg.

Elections and Transfers

At the meeting of Council held at Montreal, Que., on Tuesday, May 22, 1956, a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

Members:

A. R. Dow, *Beaurepaire*
W. N. B. Fitzgerald, *Downsview*
A. B. Hayman, *North Bay*
G. L. Karasek, *Montreal*
A. J. LeBlanc, *Toronto*
G. F. McClay, *Lennoxville*
W. C. McKenzie, *Vancouver*
W. C. McLean, *Valleyfield*
R. T. MacTavish, *Montreal*
H. D. Morgan, *London, England*

Applications Through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

Alberta

Member:

D. P. Smith

Saskatchewan

Members:

D. A. Black	A. N. Lang
P. F. Brennan	A. P. Newell
E. F. Cybulski	R. W. Phendler
E. H. Hanson	W. J. Wankel

Students:

R. H. Bjerke	J. B. Street
W. E. Threinen	

Junior to Member:

A. E. Dawson — W. A. Schwinghamer

Student to Junior:

D. G. Matheson

New Brunswick

Junior to Member:

R. G. Cowan	L. W. MacDonald
E. C. Garland	G. C. L. McEnery

Nova Scotia

Members:

A. J. MacDonald	E. J. Smith
L. M. Smith	

Junior to Member:

D. J. Bird	J. A. G. Brown
J. B. Morrow	

The Maritime Professional Meeting

St. Andrews by the Sea, N.B.

September 5, 6, 7, 1956

Thirty-five Years Ago

Comment on the *JOURNAL* of June 1921

The most important bit of Institute news in the *Journal* for June, 1921, was buried in the fine print of the Halifax Branch report. J. W. Roland, M.E.I.C., chief engineer of the Nova Scotia Highways Board, had been dismissed without any charges having been preferred against him and without any hearing. Attempts on the part of the Halifax Branch to get at the underlying reasons for this action met with complete failure, the Board refusing to discuss the case at all.

At that time the Board itself was under investigation by a Royal Commission which went on record as saying that Mr. Roland's "honesty and truthfulness have not been questioned. . . . Neither does there appear to be any question as to his capacity as an engineer." The Minister of Highways himself in a speech in the Nova Scotia legislature said he believed Mr. Roland to "be good, conscientious, honest and competent." It seems a little odd, to say the least, that the very people who dismissed Mr. Roland, without reason so far as the record shows, should go out of their way to praise him.

And it seems even odder that no mention of this affair was made in the *Journal* until June, 1921, when the dismissal took place in December, 1920, six months earlier. One would have expected the Institute at large, not just the Halifax Branch, to have exerted every power it possessed to wring some kind of explanation for its action out of the Highway Board, and if it were convinced that Mr. Roland had been wronged, to have done everything it could to secure justice for him. He must have thought the Institute's fine words about the services it was rendering to its members personally, quite voluminous at that time, were only so much hot air.

Of course, we know only what we see in print; much may have been going on behind the scenes. But the only action announced up to June. 1921, was the passage by the Halifax Branch of a strong resolution condemning the Highway Board for the manner in which it had dealt with Mr. Roland and supporting him solidly, small solace to a man who had been so summarily and unreasonably dismissed from what was virtually a public office.

Journal Uses Cartoons

This June *Journal* unbent enough to print a page of cartoons of some sixteen more or less prominent members of the Montreal Branch, contributed by A. J. Racey, the cartoonist of the Montreal "Star". It seems strange that so many of our older and more sedate members ever looked as these cartoons show them and sad to realize that a lot of them are no longer with us.

Each cartoon was accompanied by a poem, if one may be permitted to call it that, for most of the rhymes were pretty bad, even if they did hit off the quirks of their subjects. The author of these masterpieces is unknown; perhaps it is just as well.

Civil Service Debated

The Spinney bill was before the House in Ottawa. This would have taken a good many of the top positions out from under the Civil Service Commission and left them "in the hands of the Government", i.e., made them rewards for political service.

Naturally, the Institute was opposed to any such retrogressive step and said so in a long telegram to the Hon. Mr. Spinney himself. In reply they got assurances from him that "your organization will not be exposed to any hardships by the findings of the . . . (Civil Service) committee."

A correspondent from one of the branches noted that both the University of Toronto and Queen's University had conferred honorary degrees on some of our members and suggested that McGill University ought to do likewise. What he didn't realize was that in the matter of conferring honorary degrees our universities are as independent as the Supreme Court of Canada, and that each has its own cherished methods for selecting its candidates for such honours. It would be quite believeable that McGill did *not* include any engineers in its list *because* the other two did; it was not going to be charged with merely following the procession.

Town Planning

The town planners came up in this *Journal* with three schedules of twelve lectures each, one on "general principles", one on "techniques" and one on "regional and civic surveys", which they hoped the universities might adopt. They admitted that they were probably somewhat ahead of the times. There was only a drop of engineering flavouring in any of these schedules, which gives a pretty good idea of the 1921 concept of town planning.

Technical Papers

The place of honour in this *Journal* went to "Surge Protection on Transmission Lines and Cables", by S. Cunha and G. C. Bond of Montreal Light, Heat and Power, Consolidated. Their paper may have been an excellent one; it is hard to tell. Constant reference was made to its diagrams and most of these were poorly drawn in the first place and so badly reproduced that they were quite unintelligible. In many, if not most, of the Institute's papers illustration plays a major part. They ought to be neat and precise, showing enough, but not cluttered with needless detail. On the whole, the *Journal* does a lot better than it used to, but there is still room for improvement.

J. W. Tyrrel, M.E.I.C., had a paper in this *Journal* on the "Hudson Bay Route". Already the federal government had spent about $6¼ million on trying to develop a harbour at Nelson, before coming to the conclusion that perhaps this was not the best location. They also had about $14¼ million invested in the Hudson Bay Railway by that time.

So a halt was called and a Senate Committee appointed to look into the whole matter. Quotations from its report make interesting reading even now. "Sufficient care was not taken in the selection of Nelson as the terminus . . . A new . . . examination into . . . the merits of Churchill (should be made) . . . The waters . . . teem with fish and valuable marine animals and we believe that the Bay is equally well stocked . . . The mines already discovered . . . are of sufficient number and richness to indicate the existance of great . . . mineral wealth." Well, Churchill was chosen as the railway terminus and the operations of the Hudson Bay Railway over a considerable period are now a matter of record.

F. H. Link, geologist with the Imperial Oil Co. Ltd., wrote an interesting historical paper on the search for oil in the Fort Norman area. Seepages were noted there by Sir Alexander Mackenzie in 1789. The first geological survey, a paleontological one, was made by Meek in 1867 and the first oil reconnaissance was made in 1908-09 by a geologist of the Standard Oil Co. of Ohio. On August 25, 1920, a high grade of oil was struck at Oil Creek.

We hear little of the Norman Wells field today. It has been pretty well eclipsed by more productive fields closer to civilization and to markets, but there are those who insist that Canada's greatest oil potential lies in the far north and in the "tar sands" area. The latter we know to contain enormous reserves of oil. The problem is how to extract it economically, a problem which will be solved when it becomes worthwhile.

Correspondence

City Planning, Montreal

This communication is published at the request of C. E. Campeau, M.E.I.C., director of the City Planning Department, Montreal. Ed.

To the Editor:

The director of the City Planning Department of Montreal wishes to inform builders, promoters, engineers and architects that, in future, all plans submitted to his department for erecting new buildings or for modifying existing buildings, on Sherbrooke and Dorchester Streets and on the Metropolitan Boulevard, will be submitted to the approval of a committee of the Planning Commission especially appointed for exercising an aesthetic and architectural control of construction.

At its last meeting, this Committee on Architectural Control requested the collaboration of all interested citizens so as to give a good aesthetic appearance to the major arteries of the city. In order to facilitate the work of the committee, the director of the City Planning Department requests all promoters and architects to submit preliminary sketches of their projects and to await the approval of the department before proceeding with the preparation of the detailed plans. Everybody will save time by this procedure and will also avoid unnecessary expense.

The Architectural Control Committee and the City Planning Department rely on the help of the architects', engineers' and builders' associations for bringing to fruition an initiative which is one of the first of this type on the American continent.

C. E. Campeau, M.E.I.C.
March, 1956.

Students and Scientists

The following is quoted from the *Hamilton Spectator* of December 8, 1955. Ed.

To the Editor:

What do high school students think about the idea of becoming scientists ?

Dr. Melvin Barnes, assistant superintendent of Oklahoma City schools, said a survey he conducted here indicates the youngsters have little or no desire to make science a life work.

He asked 100 high school juniors this question: Why is it more students do not take science and math ?"

"Einstein! Long hair and a sweat shirt," one youth said.

Some described scientists as "squares" and "little old men with beards working in a musty laboratory."

The majority described science and math courses as dull, that they take too much time and that they aren't taught to really "understand" the subjects.

They declared that an education in science is expensive and, after making the investment, you "wouldn't make much money." And, on top of it all, who wants to be called a "square or a brain ?"

In his interviews, Barnes referred only to advanced high school courses in math or science which students may elect to take.

"A timid, conservative shy little man," one pupil commented when asked about Dr. Jonas Salk (polio vaccine).

"A scientist is an evil genius on TV thinking up ways to torture people," another said.

"Duke Snider (Brooklyn baseball player) is one of the 10 best dressed men. If he was a scientist, would he be ?" a boy asked.

Some suggested the scientist should be "glamorized." Students see the scientist as a man who works "alone" and is not social or friendly.

The foregoing gives a realistic insight into the way a teenager views a scientist. There is no reason to believe, in this day of instant communication, that youths of Canada think any differently than those of Oklahoma City.

How to Influence Youth

While a lot of earnest work is being done to induce youth to select scientific careers, one wonders if the problem has been either fully appreciated or that measures taken have received the emphasis or organization which they deserve. It is not enough to have a local scientist annually visit the school and, somewhat extemporaneously extol the virtues of his profession. Someone has to do a real selling job. A job that is honest and gets down to the teenage way of thinking.

It may well be that one of the key factors in influencing a youth's thinking is an appeal to his sense of adventure. On this theme Her Majesty the Queen has already pointed the way in her Christmas message:

". . . For all of us each new year is an adventure into the unknown. Year by year, new secrets of nature are being revealed to us by science — secrets of immense power for good or evil, according to their use. These discoveries resolve some of our problems, but they make others deeper and more immediate.

"A hundred years ago our knowledge of the world's geography was by no means complete; today most of the blanks have been filled in.

"Our new explorations are into new territories of scientific knowledge and into the unknown regions of human behavior.

". . . In the words of our Poet Laureate:

'Though you have conquered
earth and charted sea
And planned the courses of
all stars that be,
Adventure on, for whom the
littlest clue
Has come whatever worth
man ever knew:
The next to lighten all men
may be you.'

"We must adventure on if we are to make the world a better place. All my peoples of the Commonwealth and Empire have their part to play in this voyage of discovery".

George Matthew Adams in "Voyages Into the Unknown" writes: "Adventurers are among the greatest benefactors. They have delved into the earth for its secrets. They have crossed great areas in search for homesteads and challenged the air, the sea and the untried. You will find these brave and courageous men among our inventors, pioneers and scientists. It's the unknown that men strive to discover".

While all the arts give scope for creative thinking none have more promise than science or engineering.

But convincing youth to consider science as a satisfying career is not enough. It should be backed up with something more substantial of which the following might be considered essential:

1. Assurance of approximately five months summer employment while at University.

2. Arrangements for loans for those who cannot finance their courses along with summer employment.

3. Assurance of a job by which to work his way through University by taking alternate years if he wishes to adopt this means.

4. Make available accurate information concerning rewards and remuneration received by scientists as compared with that received by persons in other professions.

5. Provide funds for enlarged facilities at universities, or establish science and engineering courses at universities where there are none.

6. Provide many more scholarships.

As education is a provincial matter it would seem desirable that all provinces agree to adopt uniform measures which would produce the results so urgently needed on an national scale. They should enlist the services of government, professional associations, educational institutions, industry, clubs and all interested in preserving our progress and way of life.

I feel we are on the threshold of the greatest period of scientific discovery and application the world has ever known.

"Ask, and it shall be given you; seek, and ye shall find; knock, and it shall be opened unto you."

Let's show the kids we aren't squares!

E. T. W. Bailey, M.E.I.C.
Hamilton, Ont.
March 3, 1956.

News of Other Societies

The Canadian Welding Bureau (1391 Yonge Street, Toronto) as a recently elected member of the International Institute of Welding, has provided Canadian welding engineers with information about the annual meeting which will take place in Spain, July 1-8, 1956.

●

The Nova Scotia Technical College announces the offer of a fellowship of $2000.00 by Bruner Mond Canada Sales Limited, Toronto, Ont. The fellowship is for the academic years 1956-57 and 1957-58, tenable at the department of civil engineering of N.S.T.C., for the purpose of studying the possibility of extending the highway construction season in Canada, to prevent freezing and promote compaction during freezing weather.

Further information may be obtained from the Registrar, Nova Scotia Technical College, Halifax.

●

The American Institute of Mining and Metallurgical Engineers held the 1956 Pacific northwest regional conference in Seattle, Washington, May 3, 4, 5, 1956.

Canadians taking leading parts in the conference were Dr. J. Gordon Parr, of the University of Alberta, and Dr. Desmond F. Kidd, of Attwood Copper Mines Ltd., Vancouver. In addition, six technical papers were presented by Canadians.

●

The International Society for Photogrammetry and the Swedish Society for Photogrammetry invite participation in the eighth international congress of photogrammetry being staged at Medborgarhuset, Medborgarplatsen, Stockholm, July 17-23, 1956.

●

The Netherlands Universities Foundation for International Cooperation offers a summer session at the University of Delft from July 20 to August 9, on the subject of "Communications in Our Shrinking Modern World".

Information about sessions and fees can be obtained from Mrs. A. F. P. Volten, secretary summer session, NUFFIC, at 20 Molenstraat, The Hague, Netherlands.

●

The Embassy of the Republic of Germany in Ottawa, has supplied information about industrial fellowships which are available from private donors in Germany for Canadian graduates in engineering.

The fellowships are for 4000.-DM each (approximately $950.) and can be used either for studies at a German university or for practical work with the donating firm.

Applications, giving some details and references as to academic abilities and character and facility in the German language should be addressed to: Presse-und Kulturreferat, Embassy of the Federal Republic of Germany, 580 Chapel Street, Ottawa.

Columbia University, New York, offers a summer session, July 29 to August 10, 1956, on the subject "What Managers Do and How They Do It". This is the fifth annual utility management workshop, with participation open to nominees from private gas, electric, telephone and pipeline companies, airlines, railroads and other transportation companies:

●

Massachusetts Institute of Technology (Cambridge 39, Massachusetts) lists subjects on the summer program as follows: Recent Developments in Fluid Power Control, July 9 to July 20; Control Systems Engineering, July 30 to August 10; Disposal of Industrial Wastes, from August 20 to 31.

●

L'Association des ingenieurs electroniciens will hold a congress and exhibition on automation in Paris from June 18 to 24, 1956. This is organized in conjunction with the main national engineering associations and its international character is pointed out by the fact that the vice-presidents are Dr. J. F. Coales of Cambridge University, and Dr. D. P. Campbell of Massachusetts Institute of Technology.

Correspondence should be addressed to: Secretariat du Colloque sur "l'Automatique", Chaire de Mécanique, Conservatoire National des Arts et Metiers, 292 Rue Saint-Martin, Paris (111).

●

Natural Resources Research Institute (University of Wyoming, Laramie). The fourth biennial briquetting conference, September 1, 2, 3, 1955, brought together speakers from Mexico, France, the United States and Canada. Canadians contributing to the sessions were E. S. Babinszki, Calgary, Dr. N. Berkowitz, Edmonton, R. P. Charbonnier, M.E.I.C., Calgary, W. A. Lang, Edmonton, C. F. J. Rozenhart, Calgary, and E. Swartzman, Ottawa. Dr. Berkowitz and Mr. Swartzman, and Mr. P. Prokopy, Calgary, serve on the executive of the Institute.

●

The Town Planning Institute of Canada (King Edward Hotel, Toronto 1). . . . A. P. C. Adamson of University of Toronto, is the president for 1956; P. Alan Deacon, Toronto, and Burroughs Pelletier, Quebec, vice-presidents; Hugh T. Lemon, Toronto, secretary-treasurer. Other officers are: A. H. Armstrong, Ottawa; C. E. Campeau, M.E.I.C., Montreal; R. Norman Dryden, Kitchener, Dr E. G. Faludi, M.E.I.C., Toronto, E. Fiset, Quebec, L. Gertler, Edmonton, Stanley H. Pickett, St. John's, D. J. Reddington, Cooksville, Ont., D. F. Taylor, M.E.I.C., Toronto, J. A. Walker, M.E.I.C., Vancouver, Murray Zides, Regina.

●

American Society for Engineering Education (Secretary, W. Leighton Collins, University of Illinois, Urbana, Ill.) will hold the 1956 annual meeting at Iowa State College, Ames, Iowa, June 25 to 29.

NEWS OF THE ASSOCIATIONS & CORPORATION

Information received through co-operation with the provincial organizations

British Columbia

Engineers in the News

H. P. J. Moorehead, chief engineer of the Powell River Company has been named vice-president of engineering.

F. G. Pearce has been appointed to the position of chief engineer of Vancouver Iron Works Ltd. Mr. Pearce has served both Vancouver Engineering Works Ltd. and more recently Vancouver Machinery Depot Ltd., as sales manager. As chief engineer, he will be in charge of hydro-electric turbines and associated equipment.

R. W. Racine has been appointed heating sales engineer for the B.C. Electric, responsible for promotion and sales of natural gas and electric space heating.

J. C. McAdam, who preceded Reg Racine as heating sales engineer has been appointed B.C.E. sales research engineer directing a staff on statistical, analytical and administrative operations.

C. G. Hewlett has been named the first winner of the Peacock Memorial Prize in mineralogy. The prize, amounting to $100.00 was recently announced by the Walker Mineralogical Club, of the University of Toronto, and is given for the best Canadian scientific paper on pure or applied mineralogy. Dr. Hewlett's paper, entitled "Optical Properties of Potassic Feldspars" was an outcome of studies made for his doctorate degree at the University of Wisconsin in 1954. He is a local graduate of 1949 and is presently with the geological staff of the B.C. Department of Mines in Victoria.

M. L. Zirul, of the Provincial Water Rights Branch has been promoted from district engineer to senior hydraulic engineer and has left Kamloops and taken up his new position in Victoria.

H. D. M. Jager, formerly chief engineer of Bralorne Mines Ltd., has been appointed chief engineer, Pioneer Gold Mines of B.C. Ltd.

B. L. McCallum has accepted a position with John Laing & Son (Canada) Ltd. He was with the Department of Transport, Air Services Construction.

J. H. Thomson has been hired by the Aluminum Company of Canada Ltd., as a field engineer on the Kitimat townsite development. He has been with Central Mortgage & Housing Corp.

R. H. B. Hebbert is now employed by Phillips Electrical Company Ltd., and has been sent to England for a one year training scheme with British Insulated Callander's Cables Ltd.

D. F. Samis has accepted a position with Sydney Roofing & Paper Company Ltd., in Victoria. He was formerly at Ocean Falls with Crown Zellerbach.

D. A. Foster has been transferred from Winnipeg to a new position as mechanical engineer for the Atlantic Region of the Canadian National Railways with headquarters in Moncton, N.B.

G. B. Ralston is now Vancouver manager of International Radiography & Inspection Services Ltd.

G. R. Wyer, executive vice-president of Canadian Fairbanks-Morse Company Ltd., Montreal, was elected a director of Canadian Locomotive Company Ltd., Kingston.

W. J. Trembath, until recently with the Trans-Mountain Oil Pipeline Co. in Vancouver has left for Maracaibo, Venezuela where he joins the Gulf Oil Corp.

F. R. Mehling has accepted a position with Crown Zellerbach Canada Ltd. at Port Alice, B.C. He was with Stanley Smith Engineering Ltd.

E. J. McKenzie and **J. E. Snowball** have entered into the partnership of Richmond Consultants Ltd., a new firm of consulting engineers with offices on Mitchell Island, Vancouver 15. Both men were previously employed by McCarter, Nairne and Partners.

D. D. Kristmanson, a '53 chemical engineering graduate of the University of British Columbia has been awarded an Athlone fellowship for two years study in England. Mr. Kristmanson was given the award as an ex-graduate with two years' practical experience in his field. He has been working as a chemical engineer at central research with the Consolidated Mining and Smelting Company of Canada Ltd., Trail. He will spend a year studying in England and another working in British industry.

D. H. Brown, with the Canadian Pacific Railways, formerly at Nanaimo, is now working in the chief engineer's office in Montreal.

Robert M. Martin, recently retired from the Indian Affairs Branch, Dept. of Resources and Development, has taken a position with the New West Construction Company of Edmonton, and will be engaged on a Pacific Great Eastern contract near Dawson Creek.

W. N. Plumb has accepted a position with Henry L. Hill and Associates, consulting mining, metallurgical and geological engineers. Mr. Plumb was formerly with Giant Mascot Mines at Spillimacheen.

E. S. Jones, scheduled to retire on May 31, will continue in his post as deputy minister of highways for another year. Provincial cabinet has approved deferment because his experience is required while the department is engaged in a complete reorganization program which will decentralize control.

Frederick Thomson, formerly with Crown Zellerbach Canada Ltd. at Port Alice, has taken a new position with Sydney Roofing & Paper Co. in Victoria.

W. R. Tracey is now employed by Trans-Mountain Oil Pipeline Co. in Vancouver. He had been with Northern Electric Co. in Montreal since his graduation last year.

M. F. Painter has taken a position with C. D. Schultz & Co. and will be project engineer in the Buttle Lake area. He had been District Engineer of B.C. Forest Service at Okanagan Mission, B.C.

J. E. Snowball has been elected District Lieutenant Governor of the Toastmasters' Club in B.C.

C. O. Brawner, of the Beaver Toastmasters' Club in Victoria recently won the B.C. district speech contest at Courtenay and competes against speakers from Oregon and Washington in Vancouver on May 26th.

Dr. C. Riley on Public Relations

The Public Relations Committee of 1956 has been divided into several subcommittees, one of which is an engineers' education committee. It would have been better to say continuing education committee because no one ever finishes either his technical or cultural learning. It was considered worth while to publish a few short articles, repeating some well-known facts regarding education of engineers.

Propaganda is repetitious but is specially effective if the same thing can be said in a different manner each time, so it was decided to retell some old tales that all of us know.

Public relations may be divided into two general classes — conscious — or deliberate, and the unconscious or spontaneous. Of the two the latter is the more effective. An example of the deliberate, of course, is paid advertising. The most obvious example of the second is the satisfied patient or the happy client. Reputations grow fastest and last longest with satisfied customers.

In the case of engineers the best public relations are those established by the individual engineer as a citizen rather than by conscious effort. As in the other professions or businesses, this is accomplished in two ways. The first is the practice of our profession and here every one of us strives for perfection. A task well done, particularly in engineering may speak out for his creator for many years, as for instance, a well-built structure. Not all can build great bridges, but minor tasks are bricks which may build reputations.

Social Contacts

The second way is our social contacts, and in the part we play as citizens. The engineer should not only participate in public affairs and in society but he should take a leading position in at least some phases of it. After all, he generally has had the advantages of university education, but the intensive courses required for engineering are of a sort only to equip the student as an engineer rather than as a citizen. That is true in a large measure for all university courses, but it is especially true in engineering.

Complete Citizen

A complete citizen should have some knowledge of the legacy left us by the great thinkers of the ages. He should have some knowledge of history, literature, philosophy, and the arts. Probably the legal profession gets more of this in university than the engineer. Certainly a greater percentage of its members appear in public affairs and in the society of man than members of the engineering profession. Therefore, the engineer should make a conscious effort to improve his cultural background and perform his duty as a leading citizen of his community. This means first increasing his general knowledge; second, fitting himself to express himself clearly and intelligently and to fit himself to move in public affairs with assurance and grace. Assuming the above discussion is valid, it is proposed to discuss later some of the ways in which the engineer can fit himself better as the leading citizen he should be.

Abstract from *The B.C. Professional Engineer,* April, 1956.

Ontario

News of the Members

Robert B. McIntyre has been appointed a director and assistant general manager of Dowty Equipment of Canada Ltd. of Ajax, Ont.

Mr. McIntyre obtained his engineering degree from the University of Toronto in 1936 and subsequently on a Massey Fellowship obtained an engineering degree from Cambridge University, England. He returned to Toronto in 1938 and lectured at the University of Toronto and for the first four years of World War II was in charge of engineering in the aircraft division of the Massey-Harris Company.

He later joined the De Havilland Aircraft of Canada Ltd., where he held a number of engineering and production positions before becoming manager of the engine division, which position he held at the time of his appointment by Dowty Equipment of Canada Ltd.

E. Czerkawski has accepted a position as electrical engineer with R. M. Way & Company Ltd., consulting engineers, 321 Bloor St. East, Toronto. Mr. Czerkawski was formerly with the Canadian Comstock Co. Ltd., Toronto.

Terence J. G. Simms is presently located in Cutler, Ont., where he is working for Noranda Mines Ltd. as a resident engineer on the construction of a new plant in that area.

G. Rozentals has ceased his employment with Armet Industries Limited, of Guelph, Ont., and has accepted a position as chemical engineer with Naugatuck Chemicals of Elmira, Ont.

John Brooke has moved from Ottawa to Chalk River, Ont., where he is employed by the Atomic Energy of Canada Ltd. Prior to this move Mr. Brooke was with the mechanical engineering division of the National Research Council in Ottawa.

Grant A. Bacchus has resigned his position with the Ontario Department of Highways to join the Metropolitan Toronto Planning Board as assistant traffic engineer in the Transportation and Services Division.

Mr. Bacchus graduated in civil engineering from the University of Toronto in 1951 and has been with Ontario Department of Highways until the recent move, latterly as traffic studies engineer.

Arthur H. Holmes is employed in the engineering department of the Hydro Electric Commission of Ontario. Previous to the acceptance of this position he was with Foundation of Canada Engineering Corporation Ltd., in Toronto.

J. W. A. Donald, of Ford Motor Company of Canada Ltd., has been transferred from Windsor, Ont., to Edmonton, Alberta, where he is resident engineer on the construction of the new parts depot in that city.

Geoffrey P. Webb, of the English firm of consulting engineers, Kennedy and Donkin, has moved from London, England, to Caracas, Venezuela, in connection with his firm's undertakings at that place. Mr. Webb left Canada for England during 1955.

J. D. Mitchell, of Dominion Engineering Company Ltd., Montreal, Que., has been appointed manager of the Power Crane and Shovel Division of the company.

Mr. Mitchell graduated in engineering from Queen's University in 1941 and following service in the R.C.N. during World War II, joined Dominion Engineering in 1945 in the capacity of sales engineer. In 1953 he was made assistant manager of the Power Crane and Shovel Division.

I. C. Percy, of Niagara Falls, Ont., has moved to Montreal, Que., where he has accepted a position in the power section of Aluminum Laboratories Ltd., of Montreal. Mr. Percy, who obtained his degree in electrical engineering at the University of Toronto in 1951, has been with the Hydro Electric Power Commission of Ontario at Niagara Falls, Ont.

G. B. Batanoff has left the Canadian General Electric Co. Ltd. and is now employed by Marshall Refrigeration Co. Ltd., at 892 Millwood Road, Toronto 17.

Prior to the change Mr. Batanoff was a sales engineer with the Canadian General Electric Company, with which he has been associated since his graduation in engineering from the University of Saskatchewan.

R. C. P. Preston has accepted the position of county engineer, County of Peterborough, and is now located in the city of Peterborough, Ont.

Mr. Preston graduated in civil engineering from the University of Toronto in 1950 and vacated a similar appointment with the County of Prince Edward in order to assume his new position.

Hugh F. Jenkins has left the Ontario Hydro with which he was employed at the Stewartville Generating Station, Glasgow Station, Ont., and is with Atomic Energy of Canada Ltd., at Deep River, Ont.

D. F. Knudsen formerly editor of "Electrical News and Engineering", Toronto, has accepted the position of manager of public relations for Computing Devices of Canada Ltd., of Ottawa.

Mr. Knudsen is a graduate in electrical engineering of the University of Toronto and prior to assuming editorial duties with the Hugh C. MacLean Publishing Company some five years ago, was associated with the Bell Telephone Company of Canada.

Victor L. Savage has joined Libby Engineering Ltd., Montreal and Toronto, heating, ventilating and air conditioning engineers and contractors. Manager of the industrial division, he is now located at the company's head offices, 7000 Park Avenue, Montreal 15, P.Q.

Mr. Savage was previously with the Quebec North Shore Paper Company and the Ontario Paper Company for eight years, latterly as steam and ventilation engineer. He is a McGill graduate in mechanical engineering, Class of 1941.

Alwyn T. Wason has been appointed executive engineer, Public Works Department, Barbados, British West Indies, and is presently concerned with the construction of a new 300-bed hospital.

Mr. Wason graduated in engineering from the University of British Columbia in 1951 and has been following his profession in the British West Indies since graduation. Latterly he has held the appointment of assistant engineer of the Public Works Department, Barbados.

V. M. Wallingford, who was formerly resident engineer for the New Brunswick Electric Power Commission on its Beechwood power project, is now resident engineer on the construction of the aluminium plant at Baie Comeau for the Canadian British Aluminium Company Limited and is located at Baie Comeau, Que.

P. R. Boon has terminated his employment with the Canadian General Electric Co. Ltd. in Peterborough, Ont., and has moved to Toronto to join Monsanto Canada Limited, 183 Front St. East, as a technical sales representative in plastics.

Ying L. K. Hope announces that the offices of Ying L. K. Hope and Associates, consulting professional engineers, have moved to 40 Irwin Ave., Toronto 5. The previous location of the organization was at 77-79 Huntley St., Toronto.

George R. Wyer, the executive vice-president of The Canadian Fairbanks-Morse Company Ltd. of Montreal, Que., has been elected a director of the Canadian Locomotive Company Limited, of Kingston, Ont.

Annual Meeting Reports

COMMITTEE ON GERONTOLOGY

J. R. Gilley, Chairman

In recognition of the desire of a number of members of the Association who have retired from full-time practice due to age, to obtain some form of employment for economic reasons or to keep active professionally, Council of the Association authorized a Committee on Gerontology at its meeting in July, 1955.

Council did not limit the Committee by any specific terms of reference and to the chairman was entrusted the task of selecting members of the Committee.

The work of the Committee to date has been almost entirely along the lines of organization and at this stage the various broad functions have been assigned to sub-committees covering:

(a) Employment
(b) Library
(c) Publicity
(d) Other services such as counselling, social life and recreation.

In addition to these four it is planned to appoint another sub-committee (e) called Preparation for Retirement —primarily for the 50 years and over group. Much data and information have already been collected in regard to this plan.

Here, I interject a timely quotation —"Useful activity is the wonder drug for the older citizen."

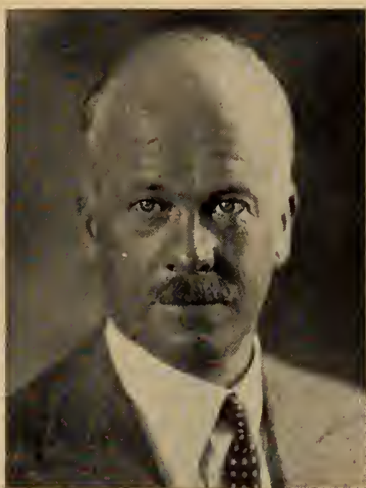
In recent years medical science has increased longevity in all the Countries of the western world—Canada is no exception. The percentage of the population in Canada over 60 years of age grows larger each year. Governments at the three levels—Dominion, Provincial and Municipal, have a real concern for the problems created by this trend in the age grouping of the population. Dr. Edward Stieglitz an eminent Gerontologist from the United States, in discussing problems of longevity, has commented that life should have breadth and depth as well as length.

The Committee on Gerontology will make every effort to provide personal service to the older age group of this Association. As far as we know your Association is the first professional organization or society in Canada to appoint such a Committee. It is obvious, therefore, that the achievements of this Committee will be studied and measured by the vast number of professional organizations in this country. Your Association now has a unique opportunity to provide leadership in the field of Gerontology throughout the Engineering Profession as well as in the other professions across Canada. May we bespeak your interest and personal support in this important new venture.

Obituaries

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

The Earl of Bessborough, former Governor General of Canada, 1931-35, and HON. M.E.I.C., died on March 10, 1956, at Stansted Park, Hampshire, England.



The Earl of Bessborough, Hon.M.E.I.C.

A man of wide international business interests, he was chairman of the board of the Unilever Margarine Corporation, De Beers Consolidated Mines and the Sao Paulo Railway in Brazil. He had also been associated with such undertakings as explosives and insurance.

Born on October 27, 1880, Vere Brabazon Ponsonby was educated at Harrow and Trinity College, Cambridge, and was called to the bar in 1903 after graduating with a bachelor of Arts. During the first World War he served in Gallipoli and France, and was attached to the headquarter staff of the British Expeditionary Force in France. He was a Conservative Member of Parliament before succeeding to the earldom on his father's death in 1920.

He arrived in Canada in 1931, his term of office following the Imperial Conference of 1926. He made the opening address at the Imperial Conference in 1932, which was called to determine the economic relations between Commonwealth nations.

One of the last official acts performed by Lord Bessborough in Canada was to dissolve the seventeenth Parliament, Aug. 14, 1935, and swear in the new ministers of the cabinet of the late Rt. Hon. R. B. Bennett.

McGill University and the University of Toronto awarded him honorary doctorates of law while he was in Canada. He accepted honorary membership in the Institute in 1931.

Donald A. Ross, M.E.I.C., senior partner of the firm of Pratt and Ross, architects and engineers, Winnipeg, died on April 1, 1956.

Mr. Ross was born in Winnipeg on October 5, 1878, attended Upper Canada College and later studied mining engineering at the University of Toronto. He started his career as terminal engineer for the Canadian Northern Railway in Winnipeg, and later became locating engineer for the Canadian National Railways. He was engineer in charge of the construction of the Pinawa hydro-electric plant, the first hydro-electric plant on the Winnipeg River. He designed and supervised the construction of the Winnipeg Electric Company steam plant in 1912. His firm was also responsible for many of the large buildings in Winnipeg and several churches, including the First Presbyterian Church, a Synagogue, and a new Catholic Church recently opened.

During the First World War, Mr. Ross was Deputy Assistant Quarter Master General, Military District No. 10.

Active for many years in the affairs of the Engineering Institute, Mr. Ross was chairman of the annual meeting of the E.I.C. (then Canadian Society of Civil Engineers) in 1910, which was the first annual meeting of the Institute outside Montreal. He continued his interest in Institute matters up to a short time before his death, taking a special part in the guidance of younger engineers.

Mr. Ross joined the Institute as an Associate Member in 1904, transferred to Member in 1910.

Maxwell V. Sauer, M.E.I.C., noted hydraulic engineer with the St. Lawrence Seaway project and alternate member of the Canadian section of the joint board of engineers, died on April 28, 1956, in Lachine, Que.

Born in Plattsville, Ont., Mr. Sauer graduated from the University of Toronto in 1901 with a degree in applied science, spent a year in post-graduate study, and was the following year a fellowship winner.

The early years of his career were marked by appointments with the Ontario Power Company at Niagara Falls, with the Niagara Falls Power Company, Niagara Falls, N.Y., in 1905, and the Iroquois Construction Company in Buffalo, N.Y.

Renewing affiliations begun on graduation, he went back to work, in 1907, with the Ontario Power Commission, and became, in 1912, mechanical engineer in charge of design, field and inspection departments. Later, working with the Hydro Electric Power Commission of Ontario, he was prominent in the design and construction of the Queenston - Chippawa power development.

Joining Canadian Vickers in 1923, Mr. Sauer was named hydraulic engineer, with headquarters in Montreal. In 1926 he accepted the appointment of vice-president of William Hamilton Limited, at Peterborough, Ont. Two years later he was designing engineer for the Winnipeg Electric Company in Winnipeg, but in 1929 chose to return to the east to join the Beauharnois Construction Company at Beauharnois, Que. Later, in 1934, he was appointed assistant chief engineer for the Beauharnois Light, Heat and Power Company.

He was hydraulic engineer and general superintendent of generating stations, with the Montreal Light, Heat and Power, and later with the Quebec Hydro-Electric Commission, receiving the appointment as consulting engineer in 1951. He retired in 1953 from Hydro-Quebec.

Mr. Sauer was closely associated with the St. Lawrence seaway project since that time. He was appointed by the federal government, pursuant to the order of the international joint commission of October, 1952, dealing with the power development in the international rapids section of the St. Lawrence River.

Recipient of the Keefer Medal of the Engineering Institute, in 1945, for his paper, "St. Lawrence River Control and Remedial Dams—Soulanges Section", he was also honoured by the University of Toronto engineering Alumni Association's award of merit in 1945.

Mr. Sauer joined the Institute as a Student Member in 1904, transferred to Member in 1913. He attained Life Membership in 1948.

Maxwell V. Sauer, M.E.I.C.

He was also a member of the Corporation of Professional Engineers of the Province of Quebec.

Leonard Galbraith McNeice, M.E.I.C., of the consulting engineering firm of McNeice Associates, Orillia, Ontario, died on March 26, 1956, in Toronto.

Mr. McNeice was born at Reay, in the Muskoka district of Ontario, on May 31, 1890. He received his secondary education at Gravenhurst, Ont., and then went on to engineering studies at Queen's University in 1913, gaining a B.Sc. degree in civil engineering. He served a short apprenticeship on Dominion Land surveying at that time and then joined the consulting engineering firm of Chipman and Power, in London, Ont. In 1917 he became town engineer at Wallaceburg, Ont., and remained there until 1931 when he embarked on a career that was to last for twenty-two years, as general manager of the Orillia Water, Light and Power Commission, as well as filling the position of town engineer for the community. He had a wide influence on the growth and development of the city. About two years ago Mr. McNeice and his son Leonard M. McNeice formed the present consulting engineering company being operated in Orillia. They had been in charge of a number of large water and sewer projects in Ontario towns.

A former executive of the Canadian Section American Waterworks Association, Mr. McNeice was also past president of the Canadian Institute on Sewage and Sanitation, past president of the Electrical Employers' Association of Ontario; member of the American Institute of Electrical Engineers and other electrical associations, and member of the American Public Works Association.

He joined the Institute as a Student in 1913, became an Associate Member in 1919, and in 1936 was transferred to Member. He attained Life Membership in 1955.

Captain William Hamilton Abbott, M.E.I.C., a member of the staff of H. G. Acres and Company Limited, Niagara Falls, Ont., died in Toronto, on April 6, 1956.

A native of Montreal, Captain Abbott was born on April 2, 1887, and studied civil engineering at McGill University. With the Canadian Field Artillery for 5 years in World War I, and discharged with the rank of captain, he was a winner of the Military Cross and was mentioned in despatches on several occasions.

He was, within the first few years of his engineering career, resident engineer with Hull Electric Company in Hull, Que., and was also associated with the Manitoba Power Company Limited, in Winnipeg, with charge of transmission of power from Great Falls to the western part of the province. From 1922 to 1923 he was on the engineering staff of the Gregory Commission on the Ontario hydro electric enquiry. He joined Beaubien, Busfield and Company of Montreal, working as principal assistant engineer from 1923 to 1927. In 1928 he joined the Foundation Company of Canada and was assistant superintendent for the company on the construction of the Ghost power development for the Calgary Power Company. In 1930 he went to St. John's, Newfoundland with the Newfoundland Light and Power Company, in connection with the Pierresbrook development.

Later, in 1945, he was associated with the Montreal firm of T. Pringle and Sons Limited, in Montreal and the Associated Textiles of Canada. Two years later he was manager of the Air Vent Sheet Metal Inc., of Montreal.

He joined the H. G. Acres Company in Niagara Falls, in 1949, which firm he continued to serve until the time of his death. In 1953 Capt. Abbott was named project manager with the company.

He joined the Institute in 1920 as an Associate Member and became a Member in 1940.

William Gray Goodeve, M.E.I.C., executive engineer with General Motors Diesel Limited, at London, Ont., died in an aircraft accident there on April 16, 1956.

A member of the R.C.A.F.'s City of London 420 (Reserve) Squadron, he had flown with the Royal Navy's Fleet Air Arm during World War II.

Born in Chatham, Ont., in 1921, he received his preliminary education there and at St. Andrew's College, then studied at Queen's University, receiving a B.Sc. degree in mechanical engineering in 1948. He was taken on the staff of Richards Wilcox, where he worked on crane design. In 1950 he chose to join General Motors Diesel Limited as a sales and service engineer.

Mr. Goodeve joined the Engineering Institute as a Member in 1952.

Personals

News of the Personal Activities of Members of the Institute

R. W. Diamond, M.E.I.C., has retired from the position of executive vice-president, western region, of the Consolidated Mining and Smelting Company of Canada Limited, at Trail, B.C. He will continue to serve in an advisory capacity.

From Campbellford, Ont., he was educated at the University of Toronto and was awarded a B.A. Sc. degree in mining and metallurgy in 1913. After several years with the Anaconda Company at Anaconda, Montana, he joined the staff of the Consolidated Mining and Smelting Company of Canada Limited at Trail, B.C., in 1917, thus beginning what was to be a career filled with achievements and honours in his field. Originally engaged to carry out research into the separation of the mineral components of the Sullivan ore, this job was accomplished in the next three years. As a direct result of this work and as superintendent of concentration he saw the Sullivan grow to become the most important lead-zinc mine in the world. He directed the development and growth of the company's chemical and fertilizer program which commenced a short time afterward.

R. W. Diamond, M.E.I.C.

Following a series of appointments to various important operational posts he was appointed assistant general manager in 1939, vice-president and general manager in 1945, and executive vice-president, western region, in 1952. He was elected to the Board of Directors of Cominco in 1945 and in 1947 was appointed president of the West Kootenay Power and Light Company Limited.

His achievements as an engineer and a business leader have been marked by recognized and have been widely the many honours from universities and professional societies which include the McCharles Medal and Award, the Leonard Medal, the Selwyn G. Blaylock Medal, the Julian C. Smith Medal of the Engineering Institute, honorary degrees, the presidency of the Canadian Institute of Mining and Metallurgy, and the Institute of Metals' Platinum Medal.

The Selwyn G. Blaylock Medal was presented to him "for distinguished service to Canada through exceptional achievement in the field of metallurgy, and for his contributions to the eminent position of the Consolidated Mining and Smelting Company of Canada Limited."

W. R. Schriever, M.E.I.C., a native of Zurich, Switzerland, has been presented with the Baker Gold Medal of the Institution of civil engineers (London), making him the first Canadian to win the prize.

In this country since 1948, when he joined National Research Council's division of building research, he is today head of the division's building design section. He was associated with the Toronto subway during the entire stages of its construction, in the capacity of resident research engineer, and his prize-winning paper, "Strain measurements on the temporary road deck for the Toronto Subway", describes some of the results of the research work carried out by the Division in co-operation with the Toronto Transportation Commission.

The Baker Medal, triennially awarded, was established in 1934 and has been presented only six times previously. It commemorates the life and work of Sir Benjamin Baker, famous designer of the Forth Bridge.

Mr. Schriever is a graduate of the Swiss Federal Institute of Technology, class of 1944, and of Harvard University, where in 1948 he concluded further studies and received the M.Sc. degree.

P. A. Dupuis, M.E.I.C., has been named president of the Association des Diplômés de Polytechnique.

Joint chief engineer with the Department of Public Works, bridge branch, for the Province of Quebec, he has held this position since 1949. He has been associated with the department since 1921.

He is also a professor at Laval University, conducting courses relative to the building of bridges.

His many professional affiliations include membership in the Corporation of Professional Engineers of Quebec, the International Road Federation, the Canadian Good Roads Association; the American Concrete Association, the International Association for Bridge and Structural Engineering, and the Federation Internationale de la Precontrainte.

Named president of the Quebec section of the Polytechnique Graduates

P. A. Dupuis, M.E.I.C.

Association in 1944, students of the Ecole Polytechnique in 1952 invested him with "L'Ordre du Mérite."

He has worked with the Quebec Branch of the Engineering Institute, serving as its chairman in 1947. He was elected honorary secretary-treasurer of the Corporation of Professional Engineers of Quebec in 1952.

J. H. Wallis, M.E.I.C. Retirement of J. H. Wallis, vice-president and manager of the power crane and shovel division of the Dominion Engineering Works Limited, after twenty-eight years of service, has been announced recently. A director of the Dominion Welding Engineering Company Limited, he remains active as president of Lakeshore Power Shovels Limited, Beaconsfield, Que.

• Personals

Returning from extensive service in the first war with the rank of major, he gained his early experience with the Canadian Creosoting Company and then spent several years associated with the pulp and paper industry. He worked as supplies engineer with the Riordon Pulp Corporation, Temiskaming, Que., as purchasing agent with the Ste. Anne Paper Company at Quebec City, and with Murray Bay Paper Company Limited at Beaupre, Que.

Named manager of the Dominion Welding Engineering Company Limited, Lachine, Que., in 1928, he became general manager of the Dominion Hoist and Shovel Company Limited, Montreal, in 1931, and manager of the Dominion Engineering Company Limited, in 1935.

In 1953 the Dominion Hoist and Shovel Company Limited, a subsidiary, was integrated into the Dominion Engineering Works as the Power Crane and Shovel Division. Mr. Wallis became vice-president of the parent organization and manager of that division.

A member of the Royal Canadian Engineers, Reserve Force, he commanded the third Canadian Division Engineers, Reserve Force, during part of the Second World War, subsequent to which he was appointed honorary lieutenant colonel of the regiment. He relinquished the command in 1955.

C. O. Maddock, M.E.I.C., is vice-president, office manager and part owner of the Nickel Belt Cement Products Limited in Sudbury, Ont.

Mr. Maddock was construction and estimating engineer with International Nickel Company Limited at Copper Cliff, Ont., for a number of years before his recent retirement. He joined the company in 1926, originally as a draughtsman.

He is a University of Toronto graduate, and a past chairman of the Sudbury Branch of the Engineering Institute, serving in this capacity in 1951.

T. A. Harvie, M.E.I.C., was the choice of the Montreal members of the Canadian Aeronautical Institute as chairman of the Montreal Branch during the year 1956-57. The election took place recently.

A McGill University graduate, class of 1941, with a B. Eng. degree in mechanical engineering, Mr. Harvie's engineering career to date has been with Canadair Limited in Montreal. First with the company in 1947, following extensive overseas service, he was supervisor of tests and developments, design engineer, and in 1953 was named to the position of development project engineer with the firm.

S. H. Hawkins, M.E.I.C. Retired to Ganges, B.C., is S. H. Hawkins, who was last year project engineer for the P.F.R.A. Red River project, while on leave of absence from his position as resident engineer for Defence Construction Limited, Penhold, Alberta.

In this country a great many years since leaving the old town of Shrewsbury, England, Mr. Hawkins worked first with the National Transcontinental Railway in a variety of positions from draughtsman and topographer on survey parties, to resident engineer in charge of plans, estimates, layouts and field work, in connection with railway construction.

Overseas with the Canadian Infantry and the Canadian Engineers from 1914 to 1919, he was the last two years captain and adjutant of the tenth battalion, Canadian Engineers.

After the war he moved to Alberta and was for many years associated with the irrigation department of the Alberta Department of the Interior. He was district engineer for P.F.R.A. at Eastend and Swift Current, Sask., and project engineer on irrigation work in Calgary before joining Defence Construction.

Mr. Hawkins joined the Institute as a Student in 1909, became an Associate Member in 1920, and transferred to Member in 1940.

George O. Saunders, M.E.I.C., vice-president of Canadian Locomotive Company Limited at Kingston, Ont., has now been named a director of the firm.

He joined the company fourteen years ago as an assistant in the plant engineering department, transferred to diesel engineering and subsequently became manager of locomotive sales, assistant to the works manager in charge of steam locomotive production, and then works manager.

He is a graduate of Queen's University in mechanical engineering.

G. W. Moule, M.E.I.C., with the City of Winnipeg Hydro-Electric System since 1945, has transferred his services to the engineering branch of the B.C. Power Commission in Victoria, B.C.

He joined the Winnipeg company as a designing engineer, and three years later, in 1948, was named contract engineer. Prior to that time he had been associated with Canadian Industries Limited and Defence Industries Limited, in Montreal and Winnipeg.

Mr. Moule will be remembered by Winnipeg Branch members of the Institute as secretary-treasurer in 1948.

D. R. Webb, M.E.I.C., has been elected president of the Association of Professional Engineers of New Brunswick.

A native of Saint John, N.B., he received his education at Saint John High School and the University of New Brunswick, from which he graduated in 1935.

Manager and consulting electrical engineer for Webb Electric Company in Saint John for many years, he has, since 1953 been associated with Kearns and Bromley, consulting engineers, also of that city.

F. A. Ritchie, M.E.I.C., has been appointed director of manufacturing engineering-manufacturing staff, of Ford of Canada Limited in Windsor, Ont.

Mr. Ritchie's career with Ford began in 1931 when he joined Ford in Windsor as a summer student employee. In 1942 he was placed on the staff as a designer in the former plant engineering department, and a year later he headed experimental test work on universal carriers, being done at that time.

Since 1948 Mr. Ritchie has held numerous supervisory positions, including those of assistant superintendent and, later, superintendent of production engineering, and assistant general superintendent, industrial engineering. Last February he was named general superintendent of industrial engineering.

He is a B.Sc. graduate in mechanical engineering from Queen's University.

L. E. Neil Carr, M.E.I.C., of Calgary, will henceforth carry out his services as consulting engineer under the name of Carr and Company Limited, at new offices in Calgary.

A 1946 graduate of McGill University, with a B. Eng. degree in mechanical engineering, he was for a time employed with Larwill Construction Company in Calgary before going into private practice several years ago.

Dr. J. D. Mollard, M.E.I.C., soils specialist, has been retained by The Photographic Survey Corporation Limited, of Toronto in a consultant capacity. He recently retired as chief of the Air Photo Analysis and Engineering Geology Division of the Prairie Farm Rehabilitation Administration to set up in Regina the firm of J. D. Mollard and Associates Limited, consulting engineers.

Dr. Mollard has been technical consultant for the Canadian Government's Columbo Plan surveys in Pakistan and Ceylon. These surveys are being conducted by PSC which has personnel now in both countries.

A civil engineering graduate from the University of Saskatchewan in 1945, he also obtained an M.Sc. degree from the Purdue University in Indiana two years later, specializing in the field of highway engineering. Subsequently for some time he was with the Indiana State Department of Highways, doing research work on airphoto mapping and engineering evaluation of soil and bedrock materials.

Dr. J. D. Mollard, M.E.I.C.

A little later he returned to Canada where he has mainly been associated with the Dominion Department of Agriculture's P.F.R.A. He took time out to obtain his Ph.D. at Cornell, where he stayed several years as research engineer and lecturer and to direct air photo studies in Newfoundland and British Columbia for various governmental bodies.

W. A. Cairns, M.E.I.C., has been named superintendent of the Consolidated Mining and Smelting Company fertilizer department at Kimberley, B.C.

A University of Alberta graduate, Mr. Cairns was previously assistant general superintendent of the Alberta nitrogen department of the Company which he

• *Personals*

joined in 1936. He worked as a research chemist at Trail, B.C., and was transferred to the chemical fertilizer operations in Calgary in 1945, as assistant superintendent of the nitrate group. He became superintendent of development there in 1946, and assistant superintendent in 1949.

J. Douglas Anderson, M.E.I.C. Transferred from Winnipeg to Montreal, with Canadian Pacific Railway Company, is J. Douglas Anderson, assistant engineer of track.

A 1945 graduate in civil engineering from the University of British Columbia, with a B.A.Sc., he shortly afterwards gained an M.S. degree from the University of Washington.

Mr. Anderson has held the position of special engineer while in Winnipeg.

R. W. Borrowman, M.E.I.C., is with the City of Ottawa Department of planning and works, as engineer in charge of planning.

He has been associated with the Metropolitan Planning Commission since 1945 and has held the position of assistant planner since 1949. Earlier he was a building and maintenance engineer of Defence Industries Limited, Winnipeg works.

He is a graduate of the University of Manitoba, class of 1940, with a B.Sc. degree in civil engineering.

R. E. Davey, M.E.I.C., for five years head of the works department for the town of Brockville, Ont., has taken up a similar position with the township of North York, Toronto.

Mr. Davey has also served as town engineer of Trenton, Ont. He is a graduate of the University of Toronto.

G. T. C. Scott, M.E.I.C., a University of London, England, graduate, class of 1947, is an associate with The Canadian-British Engineering consultants in Toronto. He came to the firm in 1953 as a representative of Sanford Fawcett and Partners.

E. L. Johnson, M.E.I.C., has been appointed manager of the factory division of The Robert Mitchell Company Limited.

Since 1949 he has been with the Mitchell Company, most recently as assistant general manager of the Mitchell subsidiary, Prowse Limited.

At one time works manager with the Dominion Ammunition Division of Canadian Industries Limited, in Brownsburg, and Defence Industries Limited, Montreal Works, he was later factory manager for the Continental Can Company of Canada Limited, in Montreal.

H. J. Gordon, M.E.I.C., assistant engineer for track with the Canadian Pacific Railway in Montreal, has been transferred to Calgary where he will take up the duties of special engineer, concerned with alterations being made to the Canadian Pacific Railway station.

With the railway for his entire professional career, since 1934, Mr. Gordon gained his early experience in the position of draughtsman and transitman. Serving with the Royal Canadian Engineers, throughout the second world war, both in Canada and overseas, it was not until 1946, discharged with the rank of captain, that he returned to the railway. Then he was assigned to the Vancouver division which appointment was closely followed by that of assistant engineer in Montreal. For a time locating engineer at La Cave, Ont., he has since 1950 been located in Montreal and from 1953 worked as assistant engineer of track.

Mr. Gordon is a graduate of McGill University.

G. J. Dunne, M.E.I.C. After ten years association with Frank W. Horner Limited, in Montreal, Mr. G. H. Dunne has been elected to the company's board of directors.

At first employed as supervisor of the fine chemical department, following graduation in 1944 from McGill University, he became production manager in 1952 and has served in that capacity until the present time.

Frank H. Hedley, M.E.I.C., has moved to Vancouver where he has accepted a position as sales manager with Okanagan Equipment Company Limited in the firm's sawmill division.

Mr. Hedley was formerly a manager of Canadian Westinghouse Company Limited in Edmonton.

S. M. Finlayson, M.E.I.C., has been elected a director of the John Inglis Company Limited, and its associated

S. M. Finlayson, M.E.I.C.

company, the English Electric Company of Canada Limited. Mr. Finlayson is President of the Canadian Marconi Company, Montreal, and also president of the Montreal Board of Trade.

W. T. Butler, M.E.I.C., has been appointed vice-president and general manager of Bauer Bros. Company (Canada) Ltd., Brantford, Ont., a newly incorporated branch of an established American pulp and paper equipment firm, now constructing a plant in Brantford.

Mr. Butler started his engineering career with Howard Smith Paper Mills Limited in 1940, as assistant mill chemist, Beauharnois division, upon graduation from McGill University; then, at the close of the war, after lengthy military service, he resumed work as chief mill chemist.

In 1947 he chose to join the Abitibi Power and Paper Company Limited as technical control superintendent, and in time became administrative assistant to the director of research.

He is a member of the technical section of the Pulp and Paper Association and the Technical Association of the Pulp and Paper Industry. In 1954 Mr. Butler was chairman for the Sault Ste. Marie Branch of the Institute.

A. H. Harris, M.E.I.C., is managing director of Regulators and Equipment Limited, a Winnipeg company recently organized to manufacture and sell Reynolds Gas Pressure regulators and associated equipment to the gas industry in western Canada.

Most recently he has been connected with the Winnipeg and Central Gas Company, as vice-president and general manager, but retired last year from active participation in the affairs of the firm, to continue membership in the capacity of consultant only. He was, for a number of years, manager of gas utility with the Winnipeg Electric Company.

Oliver Cundall, M.E.I.C., an English engineering graduate of the University of Manchester, class of 1946, has joined the staff of the C. D. Howe Company in Montreal as a design engineer.

In England, Mr. Cundall was associated with consulting engineering in London. Since taking up residence in this country he has had employment with the Foundation Company of Canada, with Preload Engineers Inc., and, most recently, with O. V. McCulloch and Company, consulting engineers in Montreal.

He is an associate member of the Institution of Civil Engineers and a member of the Association of Professional Engineers of Ontario.

F. S. Heeley, M.E.I.C., has moved from Winnipeg to Toronto where he has accepted a position with W.H. Smith and Company (Electrical Contractors) Canada Ltd.

He has been system planning engineer with the City of Winnipeg hydro electric system since returning from Brazil in 1953 after nearly two years with the Brazilian Traction Light and Power Company Limited in Sao Paulo. Prior to that time he was also with the Hydro Electric System in Winnipeg. He is a graduate of the Royal Technical College of Salford, England, class of 1947.

R. Bing-Wo, M.E.I.C., has once again been elected secretary-treasurer of the Saskatchewan Branch of the Institute. First chosen to serve in this capacity in 1952, he has repeatedly held the office since that time.

Long active in the affairs of the Institute, he has, since 1949 been continually in demand as an officer. He was at that time elected to serve a two year term as a member of the executive of the Saskatchewan Branch. Concurrently with this he was a councillor with the Association of Professional Engineers of Saskatchewan for two years. In 1952, at the time he took office with the Institute he was also appointed registrar and secretary-treasurer of the Association of Professional Engineers.

* There's been a Revolution in Rubber

Can POLYSAR Bring to Life Your Product Ideas?

Yes, Polysar *can* give reality to many product ideas, previously impractical with other materials. Why? Because *there's been a revolution in rubber. Now . . . with Polysar chemical rubbers and the help of Polymer research chemists . . . you can have a rubber tailor-made to fit the exact requirements of *your* product idea.

Whether rubber now enters into your products or not, you owe it to yourself to investigate what Polysar can do for them. You'll find—as have manufacturers in 40 countries—that Polysar can make a world of difference.

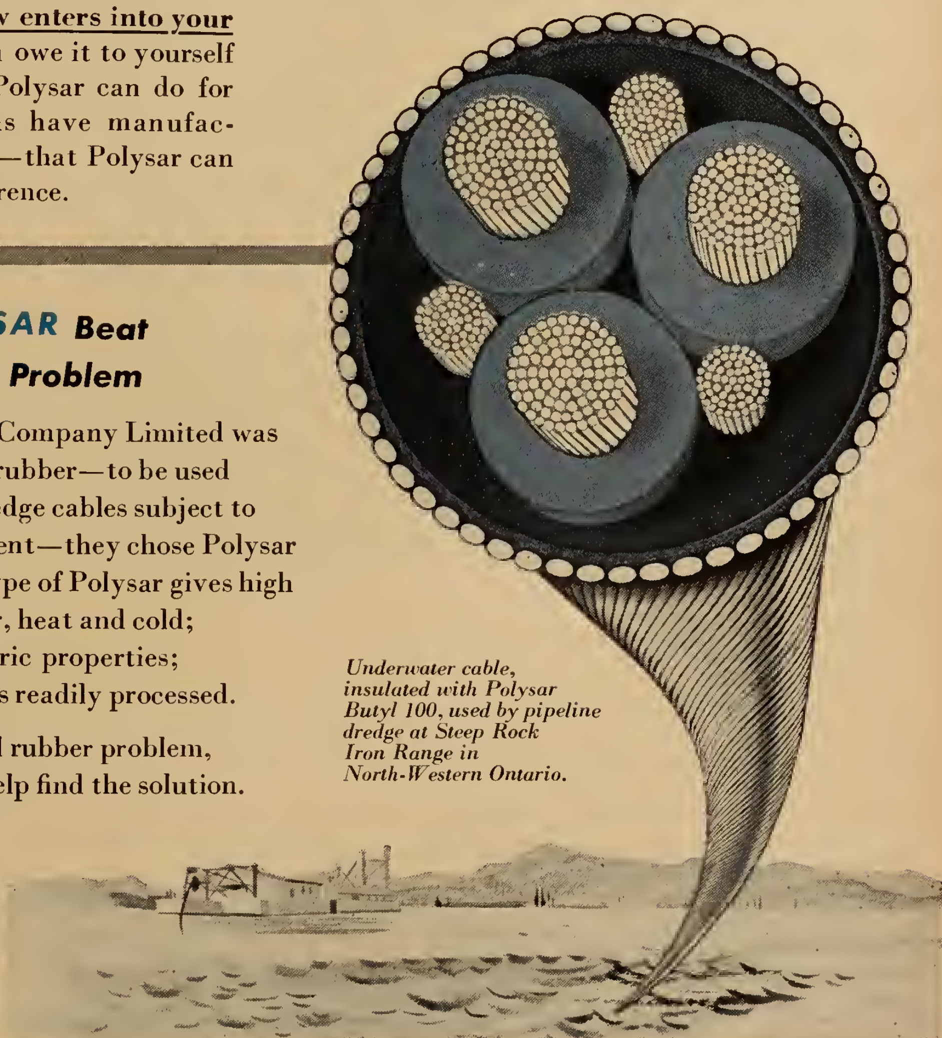
Polymer Corporation Limited, makers of Polysar rubbers, has the largest industrial research and development division in Canada. Why not make full use of these facilities and learn how Polysar can improve present products and create new ones?

Write to our Sales and Technical Service Division, Sarnia, Canada.

Here's How POLYSAR Beat a Critical Insulation Problem

When Northern Electric Company Limited was looking for an insulation rubber—to be used in underwater electric dredge cables subject to extremely rugged treatment—they chose Polysar Butyl 100. This special type of Polysar gives high resistance to ozone, water, heat and cold; provides excellent dielectric properties; has good flexibility; and is readily processed.

If you, too, have a critical rubber problem, Polymer will be glad to help find the solution.



Underwater cable, insulated with Polysar Butyl 100, used by pipeline dredge at Steep Rock Iron Range in North-Western Ontario.

Last year Mr. Bing-Wo represented the Association of Professional Engineers at the annual meeting of the Dominion Council of Professional Engineers, held in St. John's, Newfoundland.

He is an engineer in the design department of the Dominion Department of Agriculture, P.F.R.A., with headquarters in Regina, and has been associated with the Department since graduation from the University of Saskatchewan in 1943.

Austen B. Barnes, M.E.I.C., has joined the engine division of de Havilland Aircraft of Canada Limited in Toronto.

From Birmingham, England, he has, since coming to this country, included among his professional appointments a period with Phillips Electrical Works in Brockville, Ont., in 1952, with Automatic Electric (Canada) Limited the following year and the Canadian General Electric Company Limited where at Lansing, Ont., he held the position of maintenance engineer.

Zygmunt K. Radecki, M.E.I.C., has accepted a position as instrument engineer with the Aluminum Company of Canada at Arvida, Que.

A chemical engineer from the Technical University of Lwow, Poland, where he graduated before the war, Mr. Radecki's previous appointments include that of section engineer in the department of solvent recovery with Canadian Celanese Limited, at Drummondville, Que., from 1948.

V. M. Wallingford, M.E.I.C., formerly resident engineer for the New Brunswick Electric Power Commission on their Beechwood power project, is now resident engineer on the construction of the aluminum plant at Baie Comeau, for the Canadian British Aluminum Company Limited.

F. L. Fournier, M.E.I.C., formerly of Calgary, has moved to London, Ont., where he holds the position of general manager of Bluewater Oil and Gas Limited.

Mr. Fournier is a former senior geologist with Imperial Oil Limited in Calgary. He became associated later, in the same capacity with Calvan Consolidated Oil and Gas Company Limited in 1951, in that city. In 1953 the firm appointed Mr. Fournier vice-president and general manager.

He is a University of British Columgia graduate in geological engineering.

K. L. Hall, M.E.I.C., mechanical engineer with Trans Mountain Pipeline Company in Vancouver since 1953, has been transferred to Kamloops, B.C.

Mr. Hall has also been associated with McColl-Frontenac Oil Company (B.C.) Ltd., in Vancouver, as lubrication engineer. He is a graduate of the University of Saskatchewan.

D. A. G. Smith, M.E.I.C., is in Uranium City, Saskatchewan with Lake Cinch Uranium Mines.

Active in the fields of mining and metallurgy for a number of years, he has been associated with the International Uranium Mining Company Limited at Yellowknife, N.W.T., and in Edmonton. He has been mining engineer with the Winnipeg Supply and Fuel Company, which he joined in 1948, and more recently, in 1954, he was the chief inspector of mines with the Department of Mineral Resources, Regina.

Mr. Smith is a graduate of Queen's University.

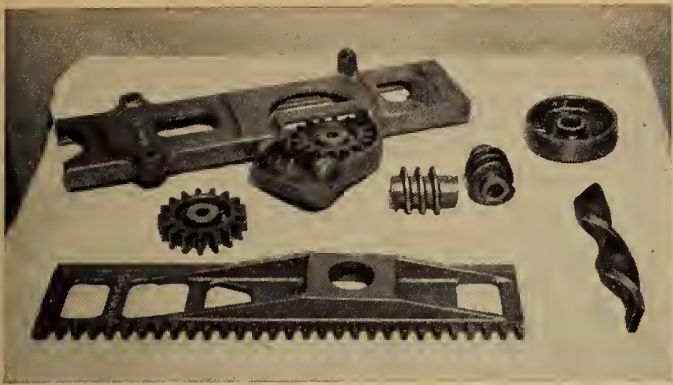
J. S. Motherwell, M.E.I.C., is with Sandwell and Company, consulting engineers, in Montreal, where he fills the position of resident engineer. He has been with the company in Vancouver and after service with the R.C.A.F. during the war was associated with the Powell River Company in British Columbia. Earlier in his career he was with the Dominion Engineering Company Limited at Montreal.

He is a graduate of the University of British Columbia in mechanical engineering.

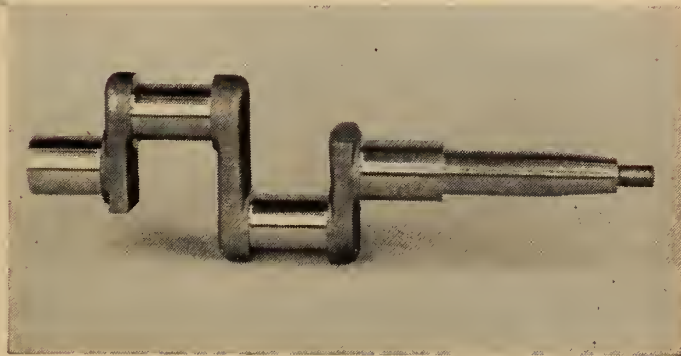
H. E. Palmer, M.E.I.C., who is a 1951 graduate in mechanical engineering from the University of British Columbia is with Westcoast Transmission Company Limited in Calgary. His position is that of natural gas engineer.

In 1953 he was assistant production engineer with the Canadian Natural Gas Company Limited in that city.

Eric Blair, M.E.I.C., is now associated with the firm of Crippen Wright Engineering Limited in Vancouver.



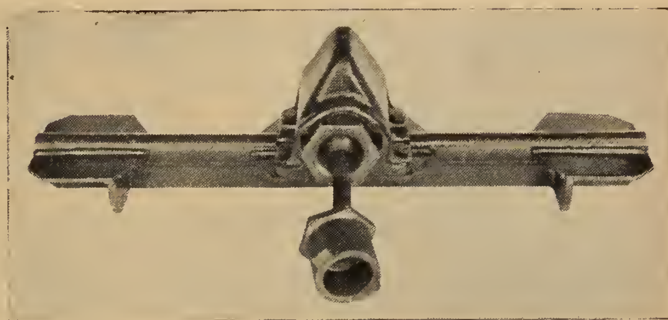
A good example of the intricate castings possible with ductile iron. These 60-45-10 type were cast by Bell Foundry Co. Ltd., St. James, Manitoba, to be used on a grain swather. Notice flat bar test piece, at right, twisted in ductility test.



A sample of an exacting casting that must be able to absorb shock, possess torsional rigidity, have excellent wear resistance and yet be readily machinable. This ductile iron crankshaft of 80-60-03 type was cast by Canada Iron Foundries, Limited, Special Products Plant, Hamilton, Ont.

Ductile Irons Prove Economy Both in First and Overall Cost

Ductile iron castings are not expensive even in the first cost. But, more important, parts made of ductile iron have proved, in many cases, extremely economical in overall or ultimate cost. The superior properties of ductile iron have enabled castings to replace more costly forgings or welded structures. Their good machinability has effected important savings in machine shop time and labour. Their resistance to wear, shock or elevated temperature frequently permits their replacement of more costly materials and enables them to perform satisfactorily for a longer time.



Ductile iron Jungle Trac, a type of equipment which adapts tandem axle trucks to half track for off-the-road service. Parts include adjustable links or "dumbells", and bushings which were cast by Otaco Limited, Orillia, Ontario, in their 60-45-10 Ductalloy.

He was formerly engaged in civil engineering, design, and construction service with the Indian Affairs Branch of the Department of Citizenship and Immigration, at Ottawa.

H. Wittnich, M.E.I.C.

H. Wittnich, M.E.I.C., has accepted a position with the Steel Company of Canada.

In 1954 he was appointed assistant to the industrial engineer of Alnee Wood Products Inc., in Montreal, with charge of production control. He has also worked for R.C.A. Victor Company in Montreal and with Canadian Allis-Chalmers Limited in Lachine, Que.

A. Gall, M.E.I.C., formerly chief draftsman with the British Columbia International Engineering Company Limited at Kemano, B.C., has accepted a position with Monarch Forge and Machine Works in Portland, Oregon.

After completing studies in engineering in England he began his career with Messrs. Head Wrightson and Company Limited in 1945, and two years later was transferred to South Africa by the firm and spent six years gaining experience in various types of engineering, with the original firm and others. In 1953 he supervised the layout, design and detailing of gold mine and uranium plants to be constructed in that country. Shortly afterwards he came to Canada to take up his position in British Columbia.

G. Arczynski, M.E.I.C., has left his position as design engineer with John Inglis Company Limited in Toronto to join the firm of Crippen Wright Engineering Limited, consulting engineers, in Vancouver.

A graduate of the Polish University College of London, Eng., he received a diploma in mechanical engineering in 1948.

J. D. Kean, M.E.I.C., has resigned from the position of county engineer, Peterborough, Ontario, after seven years' service. He will take up new work with the Curtis Bros., general contractors, in that city.

He was engineer for East Whitby township before going to Peterborough and was also junior engineer in the East York township of Ontario for a time.

He is a University of Toronto graduate.

H. Brekke, M.E.I.C., has joined the consulting engineering firm of H. A. Simons Ltd., at Kenora, Ontario, where he is responsible as inspector for all concrete work in connection with the extension of a paper mill in that district.

Mr. Brekke was for several years associated with the City of Winnipeg, first as hydraulic engineer in 1941 with the hydro-electric system, and later, in 1946, as construction superintendent.

Mr. Brekke came to this country from Europe. He is a civil engineering graduate from the German University of Prague which he attended before the war.

Yum-Hong Omen Lee, M.E.I.C., who in 1950 gained an M.Sc. degree from the University of Toronto, following a de-

gree in Lingnan, Canton, China in civil engineering the year before, is with the Ontario Hydro Commission at Toronto.

Mr. Lee was formerly structural designer with H. G. Acres and Company in Niagara Falls.

R. M. Ferguson, M.E.I.C., is now employed by Consolidated Mining and Smelting Company in Trail, B.C., as a designing draftsman.

Mr. Ferguson, who is a graduate of the University of Alberta in civil engineering, was previously associated with Dominion Bridge Company in Calgary.

Hans Streibel, M.E.I.C., has accepted a position with H. G. Acres and Company Ltd., in Niagara Falls, Ont. He was formerly a design engineer with C. J. Jeffreys in Montreal.

Mr. Streibel graduated from the Institute of Technology in the Free City of Danzig in 1936. He was awarded a diploma in civil engineering.

T. N. Davidson, M.E.I.C., is assistant superintendent, distributing house planning, with Northern Electric Company in Montreal.

A Queen's University graduate of 1941, in electrical engineering, he was during the next two years a sales engineer with the Canadian National Carbon Company. Then, at the close of the war, after three years service with the R.C.N., he joined his present firm as telephone equipment engineer.

Sean Martyn, M.E.I.C., of University College, Galway, Ireland, class of 1947, who in this country has been working for Bell Telephone Company of Canada, special contracts division, in Montreal, has moved to Val D'Or, Que., where he has accepted a position with the Fraser-Brace Engineering Company Limited.

H. Frymann, M.E.I.C., a graduate of the Swiss Federal Institute, class of 1950, has assumed the position of chief electrical engineer with the St. Lawrence Cement Company in Quebec City, following several years service as an electrical engineer with the company.

R. H. Tooley, M.E.I.C., of Sault Ste. Marie, Ontario, has accepted a position with Abitibi Power and Paper Company in that city, as assistant staff engineer, in the firm's research and development division.

He has formerly been associated with the Algoma Steel Corporation in Sault Ste. Marie, Ont., working in the capacity of assistant to the superintendent of maintenance.

In 1950, receiving a B.Eng. degree in mechanical engineering, he graduated from the University of Saskatchewan.

Mr. Tooley is secretary-treasurer of the Sault Ste. Marie Branch of the Institute.

James E. Twiss, M.E.I.C., has resigned as assistant to the electrical superintendent with the International Nickel Company of Canada Limited, in Copper Cliff, Ontario, to accept a position with R. M. Way and Company Limited, consulting engineers in Toronto. He will be assistant chief electrical engineer.

Mr. Twiss joined the International Nickel Company on graduation from Queen's University in 1947 and worked as a junior electrical engineer until 1949. In the years that followed, until his promotion to assistant to the electrical superintendent in 1954, he served as assistant chief electrician at the Copper Cliff smelter and Garson mine.

E. J. Wilson, M.E.I.C., is employed by Messrs. Racey, McCallum and Associates, Limited as a site engineer on the Mid-Canada Early Warning Defence Line.

He has previously, for several years been employed by Canadair Limited, in Montreal.

V. S. B. Corbet, M.E.I.C., has been appointed mill manager of Canadian Cottons Limited, in Hamilton, Ont.

He graduated from McGill University with a B.Eng. degree in 1944 and after a period of service with the R.C.E.M.E., joined the staff of J. D. Woods and Gordon, management consultants, where he held the position of supervisor. In

What is a "Good" Casting?

"Good" is the measure of performance. A good casting measures up—in performance—to all the requirements of its buyer and its end user.

If, during its life, it must withstand repeated thermal shocks, then it must be heat resistant; if it is going to be subjected to constant friction, then it must be wear resistant; if it comes into contact with salts or acids, then it must be corrosion resistant.

"Very true," you say, "and also very obvious. It is one thing to make fine castings to fit the job but can you make the price fit the castings? That's a requirement, too."

We can. That's where our Special Products Plant comes in. It is run by experienced men, controlled by a first class laboratory and equipped with modern foundry equipment—it's an operation that's geared to meet quality *and* price requirements.

Our electric furnace, for example, allows flexibility, versatility and far greater uniformity of composition in the production of all types of iron.

The result: the best possible assurance against being let down half way through the machining operation. Your shop investment is thus protected.

So when *you* need "good" alloy castings, delivered clean and on time, order them from:

Canada Iron

1953 he became manager of industrial engineering for Canadian Cottons, with headquarters in Cornwall, Ont.

Mr. Corbet has been an active member of the Cornwall Branch of the Institute and served on the executive for the past two years.

Dr. K. L. Pinder, Jr.E.I.C., who returned to Canada in 1955 following two years study in England on an Athlone Fellowship, has been appointed to the staff of the Pulp and Paper Research Institute of Canada. Dr. Pinder will join a special group of scientists engaged in developing a new technique, invented at the Institute, for the recovery of chemicals from industrial waste liquors.

He received a B.Eng. degree in chemical engineering from McGill University in 1951, his master's degree a year later and while at the University of Birmingham in 1954 received a Ph.D. degree in chemical engineering.

Dr. Pinder spent some time with Shell Oil Company in Calgary on his return to Canada.

J. E. Sinnot, Jr.E.I.C., has terminated his association with the Ford Motor Company of Canada Limited at Windsor, Ontario, where he held the position of electrical design engineer and has joined the staff of Pagon and Goodman in that city.

He is a University of Toronto graduate, class of 1950.

Horace Owen Moses, Jr.E.I.C., has accepted employment with Sandwell and Company Limited, consulting engineers in Vancouver.

He is a University of British Columbia graduate in mechanical engineering.

In 1953 he was associated with Canadian Industries Limited at Shawinigan Falls, Que., as a foreman.

Jean R. E. Moreau, Jr.E.I.C., has been named assistant manager of the Eagle Pencil Company at Drummondville, Quebec.

A graduate of the Ecole Polytechnique, class of 1951, in civil engineering, he has had experience with the Canadian Arsenals Limited at St. Paul L'Ermite, Que., and with Dominion Engineering Works Limited, Lachine, Que.

G. Roy Pond, Jr.E.I.C., has recently accepted the position of assistant mechanical engineer in the motive power and car equipment department of the Canadian National Railways. He is now located at St. John's, Newfoundland.

Mr. Pond was previously employed as assistant to the process development superintendent of Mersey Paper Company Limited in Liverpool, N.S., after having graduated in mechanical engineering from Nova Scotia Technical College in 1954.

J. Haworth, Jr.E.I.C., has accepted the position of plant design engineer with Courtaulds (Canada) Limited, Cornwall, Ontario.

Mr. Haworth graduated from Queen's University in 1947 and shortly afterwards went to Cornwall in connection with equipment installation in a rayon plant for Robert A. Rankin Company Limited.

He has since spent time with the firm in Dartmouth, N.S., and Montreal in 1951 and 1952.

For a time he was associated in 1949 with Stadler, Hurter and Company in Montreal.

Frank A. Kay, Jr.E.I.C., has for some months held the position of chief engineer with Quebec Iron and Titanium Corporation at Sorel, Quebec. He was field engineer with the firm in 1953.

Mr. Kay is a 1950 graduate from McGill University, in mechanical engineering.

R. A. W. Clayton, Jr.E.I.C., is working as a project engineer with Sandwell International in Montreal.

He has worked previously with Sandwell and Company Limited, consulting engineers, in Vancouver.

He is a 1951 graduate of the University of British Columbia in civil engineering.

Henry E. Parker, Jr.E.I.C., a 1952 graduate of McGill University and winner of an Athlone Fellowship that year, has returned to the university as a

• Personals

lecturer in the department of mechanical engineering.

Under the provisions of the Athlone Fellowship, Mr. Parker went to England in 1953, where he attended the College of Aeronautics at Betchley, Buckinghamshire.

L. H. J. Mooney, JR.E.I.C. From Quebec City to Paris, France, is the transfer recently accorded Mr. Mooney, district manager with Otis Elevator Company Limited for the past several years, and, at an earlier date sales engineer with the firm.

He is a 1950 graduate in electrical engineering from McGill University.

George N. M. Currie, JR.E.I.C., lately of Charles E. Napier Company Limited in Toronto has taken an appointment with Urwick Currie Limited, management consultants, in that city.

He is a mechanical engineering graduate from McGill University, class of 1951, and holds an M.A.Sc. degree, gained in 1953, from the University of Toronto. Mr. Currie is especially qualified in public health engineering.

Wallace E. Stewart, JR.E.I.C., is associated with Defence Construction (1951) Limited, in London, Ont.

With the City of Hamilton, Ont., in 1953, shortly after his graduation from the University of Manitoba, he has since then also been employed with H. G. Acres, in Niagara Falls.

Elias Blouin, JR.E.I.C., a 1954 graduate from Laval University in electrical engineering has been for some time employed as electrical engineer with the Canadian Resins and Chemicals Limited at Shawinigan Falls, Quebec.

J. Alberto Dada, JR.E.I.C., an electrical engineering graduate from McGill University, class of 1954, who was shortly afterwards working in San Salvador, El Salvador, with Dada, Dada and Company, is now employed by the Compania Alumbrado Electric de San Salvador. He holds the position of distribution engineer.

J. G. Doyle, JR.E.I.C., has accepted a position with Sperry Gyroscope Company of Canada Limited, in Montreal, as product engineer.

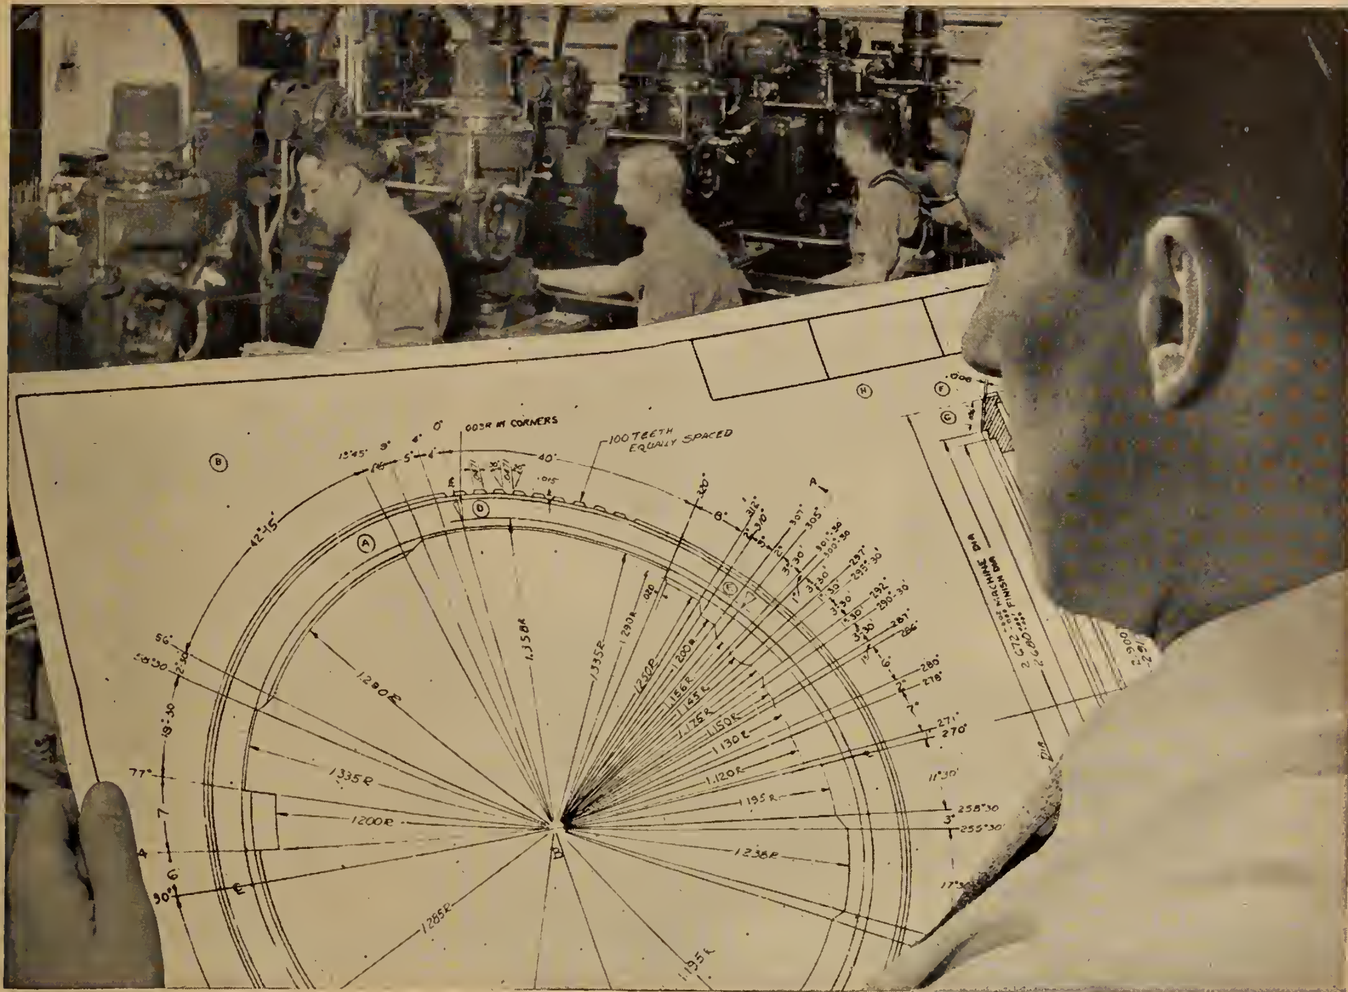
A graduate of the Nova Scotia Technical School, class of 1950, he joined the Canadian General Electric Company in Montreal the following year and has been with them in the intervening period.

J. H. Whalen, JR.E.I.C., back to Canada September last, after extensive experience overseas, is with the Canadian International Paper Company, Montreal, in the Economic Planning Department.

J. H. Whalen, Jr.E.I.C.

In Sweden in 1954, he spent some time with the Holmens Bruk Paper Company at Hallstavik, and later, at Aylesford, England, was with the Albert E. Reed Paper Company.

Mr. Whalen obtained a B.Sc. degree in civil engineering from the University of New Brunswick in 1952, then went on to the Massachusetts Institute of Technology, Cambridge to gain a master of science degree in the spring of 1954.



• Personals

Wm. G. Allen, Jr.E.I.C., has left the Canadian Army Signals Engineering Establishment, Ottawa, and has taken a position with the Atomic Energy of Canada Limited, Deep River, Ontario.

Shortly after his graduation from McGill University in 1949 with a B.Eng. degree in electrical engineering he became a lieutenant with the Canadian Signals Research and Development Establishment, Department of National Defence (Army), at Ottawa. In 1953, as chief mechanical engineer with the unit, he held the rank of captain.

Lorne A. Keyes, Jr.E.I.C., has accepted a position with R.C.A. Victor Company Limited in Montreal. He is an electrical engineering graduate of Queen's University, class of 1954.

M. S. Dubas, Jr.E.I.C., who in 1955, attained a master of science degree at the University of Alberta, has joined the staff of the Materials Testing Laboratories, in the southern Alberta city of Lethbridge.

Raymond F. Sherk, Jr.E.I.C., has been named representative in Toronto and Southwestern Ontario for Spartan Air Services Limited and Canadian Aero Service Limited.

R. F. Sherk, Jr.E.I.C.

A graduate of the University of Toronto, class of '52, and a former R.C.A.F. pilot, his more recent background includes both marketing and engineering.

Mr. Sherk is a member of the Ontario Association of Professional Engineers.

R. H. Dunn, Jr.E.I.C., is production manager with Precast Haydite Limited in Toronto.

He is a 1951 graduate of McGill University, with a B.Eng. degree in civil engineering. In 1953 he was plant engineer with Canadian Copper Refineries Limited, in Montreal.

H. E. Ryan, Jr.E.I.C., has accepted a position with the Ebasco International Corporation in Elizabeth, New Jersey, U.S.A.

Previously a staff engineer with the Nova Scotia Power Commission in Halifax, he is a 1949 graduate from the Nova Scotia Technical College.

F. D. Malloch, Jr.E.I.C., has accepted a position with the Department of Northern Affairs and Natural Resources, Ottawa.

F. D. Malloch, Jr.E.I.C.

A graduate of the RCN College, Royal Roads, B.C., and Queen's University, Mr. Malloch graduated from

the latter in 1951 with a B.Sc. degree in mechanical engineering. He has since then been employed in the Wire and Cable and plant maintenance departments of Northern Electric Company Ltd., in Montreal.

Gordon E. Smith, JR.E.I.C., who last year worked with Mathews Construction Company Limited in London, Ontario, has joined Proctor, Redfern and Laughlin, civil and consulting engineers in Toronto.

A Queen's University graduate, class of 1950, he joined the Ontario Department of Highways soon after graduation, working in Toronto and Bancroft, Ontario.

R. G. Cowan, JR.E.I.C., until recently employed by C. D. Howe Company Limited, consulting engineers, in Montreal, has transferred his services to Moore, Mainville and Cowan consulting engineers in Moncton, N.B.

Before joining the C. D. Howe Company in 1952, he was with Building Products Limited in Montreal as a foreman and was mechanical engineer with Hagan and Company Halifax Limited.

He is a 1950 graduate of the Nova Scotia Technical College.

James G. Morrison, JR.E.I.C., who has been associated with Bell Telephone Company of Canada since 1951, has been transferred from Kingston to Ottawa. For the last two years he has held the position of traffic assistant in the St. Lawrence District, with headquarters in Kingston. He now becomes traffic superintendent of the Ottawa Valley District, with headquarters in Ottawa.

A graduate of 1951 he studied engineering at the Nova Scotia Technical College.

Warren A. Trotter, JR.E.I.C., has relinquished his position as assistant commissioner of works in the Township of East York, Ontario, and has become associated with the Toronto firm of consulting engineers, Gore and Storrie.

Mr. Trotter is a Queen's University graduate, class of 1948. He has also lived in Kingston as a graduate civil engineer where he held the post of deputy city engineer.

Lieut. C. A. Millar, JR.E.I.C., has been assigned the duties of Platoon Commander, Apprentice Training Company, R.C.E.M.E. School, Kingston, Ontario.

Combining an army career with engineering since graduation from the University of British Columbia in 1953, Lieut. Miller that year became control officer with the Department of National Defence, No. 7 Coy., R.C.E.M.E., Coldbrook, N.B.

J. D. Ross, JR.E.I.C., is employed by Sherritt Gordon Mines Limited, in the chemical and metallurgical division of the company's nickel refinery at Fort Saskatchewan, Alta.

A graduate in engineering physics from the University of Saskatchewan in 1953, he has gained experience with the Schlumberger Well Surveying Corporation at Stettler, Alta., and Fort Saskatchewan.

Donald W. Blair, S.E.I.C., a Queen's University graduate of 1955, is with Geocon Limited, in Montreal.

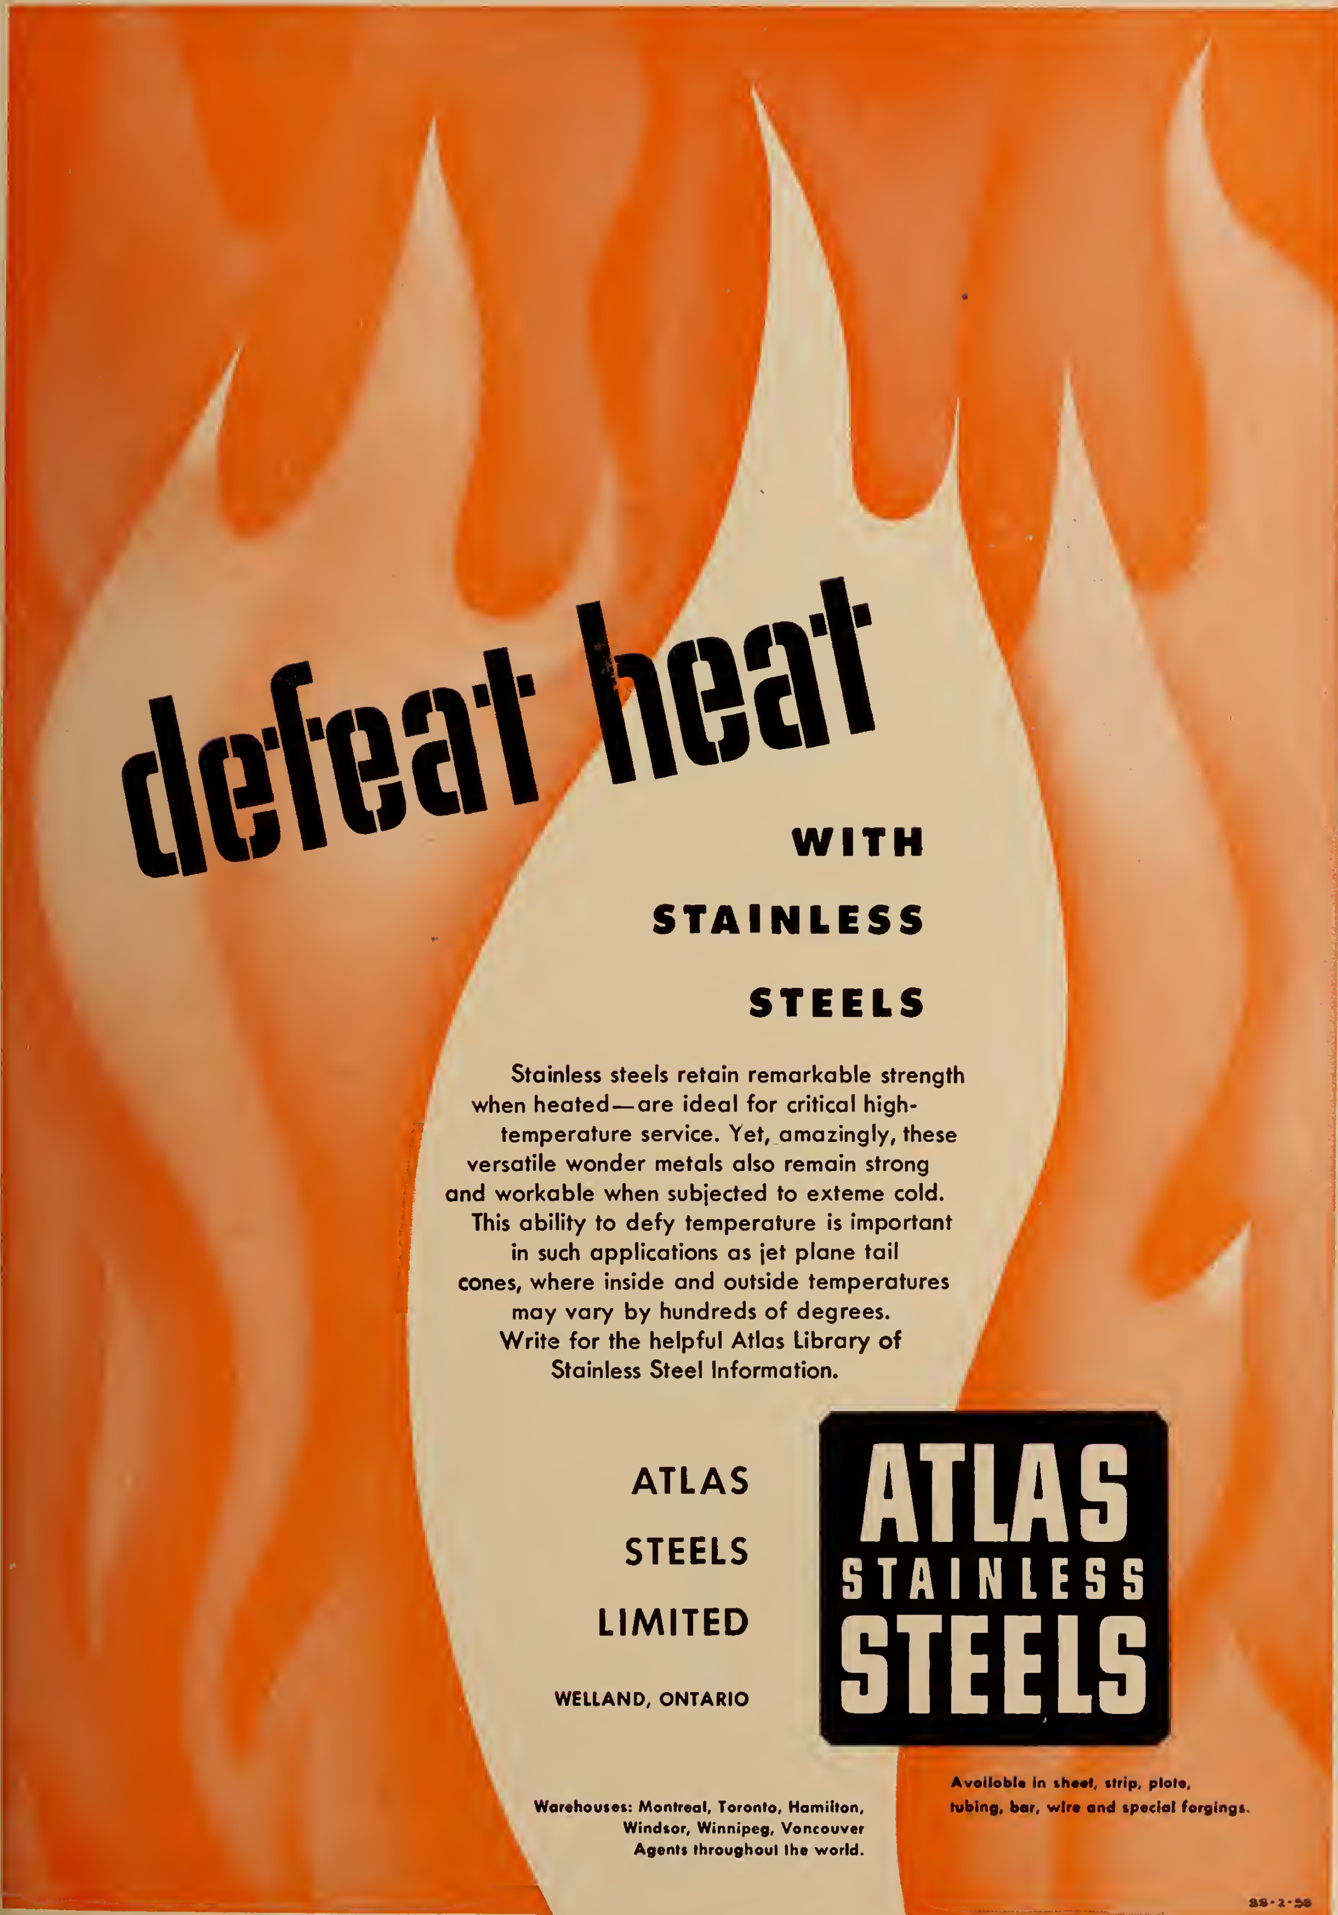
G. J. Palmer, S.E.I.C., a graduate in mechanical engineering last year, from the University of Manitoba, has taken up work with Canadian Industries Limited at Shawinigan Falls, Que.

E. J. Bliss, S.E.I.C., a 1955 graduate from the University of New Brunswick, with a B.Sc. degree in civil engineering, is employed with the Maritime Cement Company Limited, in Moncton, N.B.

C. M. Goodrich, S.E.I.C., a University of Saskatchewan graduate, class of 1955, is working with the Department of Public Works, Government of Alberta, Edmonton, where he will serve as a mechanical engineer in the architectural branch of the Department.

Since graduating last year he has been briefly associated with the Canadian Gulf Pipe Line Company and the Peace River Oil and Pipeline Company, in Edmonton and Valleyview, Alberta.

C. J. Partridge, S.E.I.C., a 1955 graduate of Queen's University who since then has worked as field engineer with the Bell Telephone Company of Canada at Knob Lake and Sept Isles, Quebec, is now employed by B. Perini and Sons at Blind River, Ontario.



defeat heat
WITH
STAINLESS
STEELS
Stainless steels retain remarkable strength when heated—are ideal for critical high-temperature service. Yet, amazingly, these versatile wonder metals also remain strong and workable when subjected to exteme cold. This ability to defy temperature is important in such applications as jet plane tail cones, where inside and outside temperatures may vary by hundreds of degrees. Write for the helpful Atlas Library of Stainless Steel Information.

Annual Meeting Held

The annual meeting of the Branch was held at the Sudbury Granite Club on May 3, 1956. Special guests for the evening were the wives of the members.

Following the dinner at 7 p.m. there was a short business meeting during which the election of officers for 1956-57 took place with results as follows: chairman, L. T. Lane; vice-chairman, J. W. Smith; non-resident committeeman, J. F. McCallum; resident committeemen, W. B. Ibbotson and R. P. Crawford.

After the meeting an evening of dancing was enjoyed.

Joint Meeting—April 19, 1956

This was a joint meeting with the American Society of Mechanical Engineers and was the final meeting of the current winter season for the Engineering Institute.

Dr. G. Ross Lord—on Flood Control

Dr. G. Ross Lord, m.e.i.c., Professor of mechanical engineering, University of Toronto, spoke on "Humber Valley Flood Control". This engineering problem is of great local interest because of the disastrous flood which occurred in the watershed caused by Hurricane "Hazel", in 1954. Although the problem is of local interest, as previously remarked, there are important conclusions which can be applied to the prevention of similar floods in drainage areas like that of the Humber.

Humber Valley Watershed

The Humber Valley watershed is approximately 336 square miles in extent.

E. V. Gage, treasurer of the Engineering Institute in 1955, spoke to the guests following the banquet.

Engineering Societies Dance

At a recent dance held by the Engineering Societies, in Shawinigan Falls. From left to right are: Mrs. A. P. Earle, R. A. Phillips, vice-president of the Corporation of Professional Engineers of Quebec, Mrs. E. E. Copping, G. H. Hoganson, speaker, and office engineer with the Canadian National Railways; E. E. Copping, dance chairman, Mrs. G. H. Hoganson, E. V. Gage, Mrs. R. A. Phillips and A. P. Earle, chairman of the St. Maurice Valley Branch of the American Institute of Electrical Engineers.

Using

DU PONT ELASTOMERS

NEOPRENE-HYPALON®

in Industry

NEOPRENE coatings last 12 times as long as acid-resistant paints on tank trucks

FOR THE TANK SPLASH AREA (shown above), a black neoprene coating (brush) is used. For the rest of the tank, a grey coating is applied (spray).

Resist caustic soda and aluminum chloride; nitric, muriatic and other corrosive acids

Chemical Tank Lines, Inc. of Downington, Pa., reports that neoprene coatings applied externally have lasted 12 times as long as the best acid-resistant paints on the dome and center-sheet area of its acid tank trucks.

The company first tried a neoprene coating on only one of its tank trucks. The neoprene coating lasted over two *years* with only minor touching up and was still serviceable. The best acid-resistant paint previously used lasted only two *months*. This cost-saving performance persuaded Chemical Tank Lines to apply neoprene coatings to all of its 64 trucks.

First cost of the neoprene coatings is higher, says Earl D. Radcliffe, superintendent of operations, but "it looks like we'll only have to do the job every other year instead of six times a year. The net result should be that we keep our trucks painted for 1/6 the materials cost and 1/12 the labor cost." Mr. Radcliffe also reports that in addition to material and labor costs he loses $100 in revenue every time a truck is brought in for repainting. This amounts to $600 a year per truck with acid-resistant paint, only $50 a year per truck with neoprene coatings. And the company expects 4 years extra service from trucks coated with neoprene, thus reducing the cost of tank depreciation by $800 per year per tank.

Neoprene coatings are only one of many neoprene products that may help you reduce your company's cost of operation. Neoprene is also used in hose, belting, gaskets and scores of other products where resistance to chemicals, oil, grease and outdoor exposure is necessary, service conditions which quickly deteriorate ordinary rubber. Ask your rubber-goods supplier about neoprene, or mail the coupon below. We'll be glad to send further information.

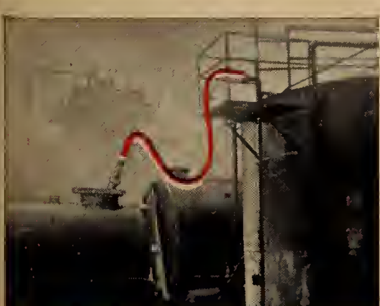
HYPALON® hose carrying 98% sulfuric acid outlasts ordinary hose 16 to 1

Four months' service from a hose that loaded three tank cars a week with 98% sulfuric acid! That's the report from one southern phosphate company after switching to acid hose with tube of HYPALON, Du Pont's new synthetic rubber.

Before the change, regular acid hose had to be replaced after only one week . . . meaning just three tank-car loadings a hose. Yet the HYPALON tube hose was still in good condition after sixteen weeks. The difference lies in the superior resistance of HYPALON to acids—especially strong oxidizing acids.

Striking comparisons like this show what happens when HYPALON products are used for those *extra-tough* service applications. Replacement costs are cut . . . maintenance is drastically reduced. HYPALON products deliver top performance under the most severe conditions. High ozone concentrations, strongly oxidizing chemicals, high temperatures—rugged HYPALON can take them all and still give long-term service.

When you need a rubber product that must have *extra-high resistance* to deterioration, it will pay you to investigate HYPALON. Clip the coupon for further information.



ACID HOSE OF "HYPALON" in action, loading 98% sulfuric acid.

• Branch News

The headwaters of the river are near Orangeville, and the river itself falls about 1200 feet in 58 miles. There is a tree cover of about 10 per cent. Approximately one-sixth of the river channel lies in the Toronto metropolitan area. Because of the population involved, there is considerable interest in its discharge of flood water. The works of man may be damaged and lives lost when the river goes on a rampage.

The kind of flood which may create conditions similar to those in October, 1954, is that generated by a decadent hurricane. Spring floods are not likely to cause such damage because present day weather forecasting gives ample warning. The flash flood generated by a summer thunder shower presents a considerable threat, but the area of the Humber watershed is above the critical value (200 sq. mi.) for such a flood to do great damage. The Great Lakes themselves ameliorate severe thunder showers. Most of these, with a duration of twenty-four hours pass to the south of the Lakes.

Hurricanes Not on Increase

Hurricanes themselves are not increasing in number, they are simply getting more publicity. Most hurricanes occur in the summer or in the fall, and there have been some twenty-five in Ontario since 1900. Altogether there have been seventy-two floods in the Humber Valley watershed since 1791, with half occurring in the period 1921-34. A few statistics will point up the fearful power of the flood caused by Hurricane "Hazel".

Year	Flow, c.f.s.
1878	9,535
1897	10,381
1946	4,800
1947	4,690
1954	45,600 (Weston gauge)
	49,000 (Estimated at mouth)

The flow over Niagara Falls at night presently is 50,000 c.f.s.

The horse-power dissipated from "Hazel" was between two million and three million over the whole watershed; the amount is almost equal to that which will be generated by the St. Lawrence seaway power development.

The engineer should consider the cost of flood control in the light of the losses incurred, both of life and property; loss of communications, road, rail and wire; health hazards, waste of water and loss of water.

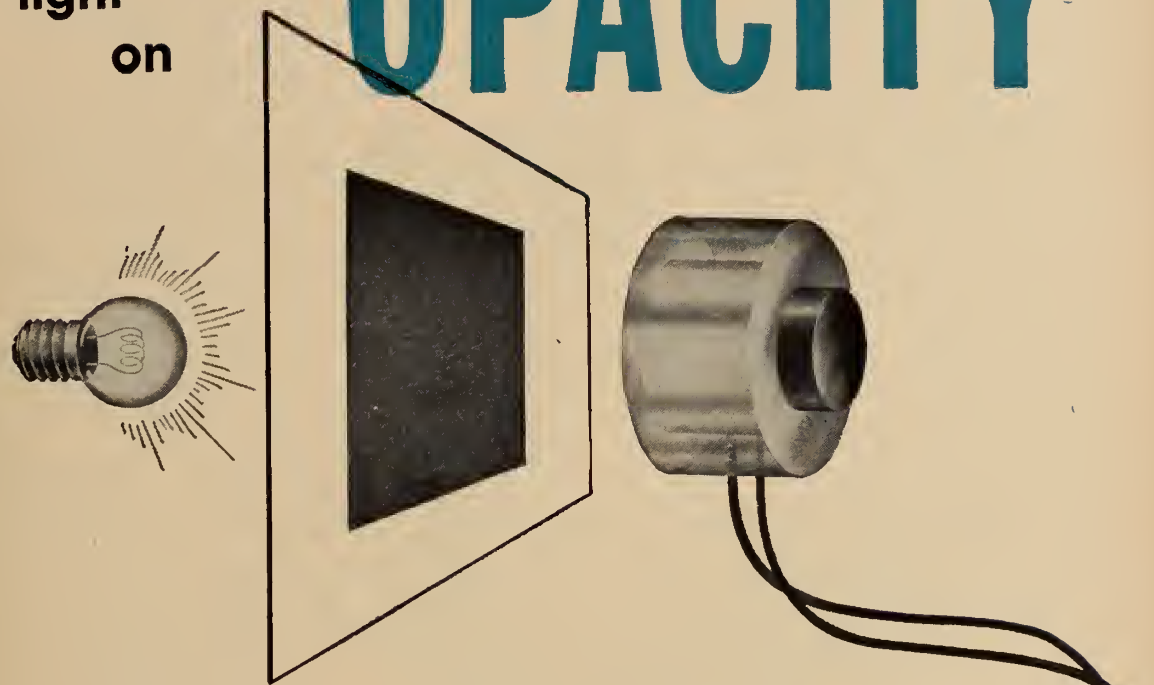
Man is encroaching on the Humber River Valley without much thought to the consequences. The watershed is being denuded, other cover is being removed, the river is being confined to its regular flow channel, housing is being built on the floodplain, agricultural drains and storm drains are all increasing the flood danger.

Not a Maximum

Is hurricane "Hazel" a maximum flow? Is it infrequent? Might another occur in fifty years? These are pertinent questions. The recorded rainfall during Hazel was 7.25 inches, corrected to 9 inches in forty-eight hours, with a

A new light on

OPACITY



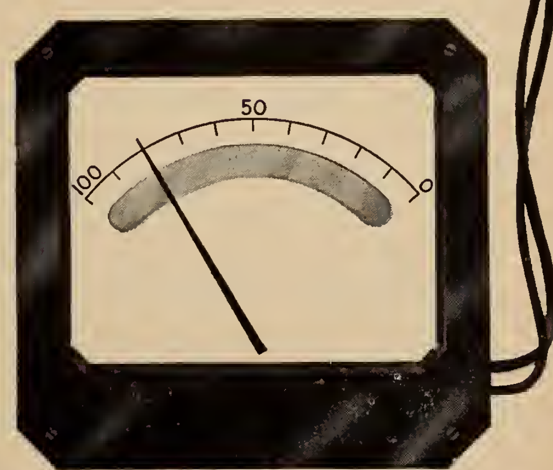
insures sharp reproduction from your TURQUOISE tracings

READ HOW, for the first time in pencil history, Eagle's laboratory measures the opacity of a pencil line with scientific accuracy. Three precision instruments are involved:

(1) Our two-ton "Pencil Sharpener" gives the test pencil a cylindrical point (as shown at left) of fixed diameter, accurate to .0001".

(2) In our Automatic Shading Machine, the pencil deposits graphite as a square of parallel strokes under uniform pressure on the paper.

(3) A Microammeter, connected to a sensitive light cell, first measures the light blocked by the chart paper, and then measures the *opacity of the graphite deposit alone* to a fraction of one percent!



Such exact measurement of every TURQUOISE degree enables us to develop and maintain maximum opacity . . . the quality that gives you perfect prints from TURQUOISE pencil tracings.

PROVE IT IN THE PRINT with a free TURQUOISE sample. Just write us, naming this magazine and the grade you prefer. Made in Canada

EAGLE PENCIL COMPANY • NEW YORK • LONDON • TORONTO • MEXICO • SYDNEY

90 per cent run-off. Investigation shows that this is *not* a maximum. Much greater might occur, possibly 15 inches of rainfall.

Obviously if worse is to come something should be done. The proposed control is balanced between building impounding resevoirs, channel improvements, and conservation, although most residents of low areas and river flood plains everywhere in the world object to dams being built. Five are proposed on the upper reaches whose capacity will reduce a flood like that following "Hazel", to half. The Great Lakes themselves form just such a series of natural reservoirs, preventing any major disasters. So do the Kawartha Lakes at Peterborough. The recreational advantages alone from the construction of such a system of dams are obvious.

To Be Built Gradually

The whole control system will be built gradually. Flood plains will be abandoned. Channel improvements are under way at Woodbridge. This improvement will pay for itself in the first major flood, like the one on the Etobicoke creek at Brampton, which cost $1,000,000 but saved Brampton, during "Hazel".

This channel control will be tied into conservation. Trees will be planted on slopes and hills which never should have been denuded of cover; strip farming, contour plowing and ponding will be encouraged. The channel will be cleaned and kept clean.

At present the Humber River is nothing but a natural sanitary sewer carrying raging floods in spring and fall, subsiding to a useless ditch in summer.

There were about ninety interested listeners who entered into a lively discussion after the talk. Two very interesting points were brought out:

1. There were $3,000,000 lost in the flood following "Hazel", versus $14,000,000 proposed cost to control the Humber.
2. A river meanders because the grade is below that for eroding the channel. If meanders are straightened by using a cutoff channel, a weir must be employed at the bottom of the cutoff, else the artificial channel may be itself destroyed by a flood.

arduous work which made them a success, are to be heartily congratulated for filling a great gap in the professional life of the civil engineer so ably here in the Toronto area.

Joint Paper Presented

L. J. Marcon and W. R. Schriever, of the building research division, National Research Council, Ottawa, gave jointly a paper on loading test on a prestressed concrete beam at Cobourg, Ontario.

Although this was only one test, from which an engineer is hardly justified in making general conclusions, both authors felt that the basic theory presently employed in prestressed concrete design is sound.

No attempt will be made here to paraphrase or even summarize the test results since it is expected that the paper will be published eventually in the technical press. However, a few salient features of the test will be described which are considered to be ingenious and novel.

Features of Test

Loading was applied by hydraulic jacks and measured with calibrated gauges. Reactions were measured with load cells. Deflections were taken with dial gauges and a wire and pulley system with a further check using a surveyor's level and rod. Both electrical resistance strain gauges were used to find strain in the steel and concrete. There was good agreement between design and empirical strain, which the authors demonstrated well.

The beam was subjected to the old National Building Code (1941) requirements for test loading. The results were very satisfactory.

Various other loads were applied, and finally the beam was loaded toward failure. Unfortunately, a jack tilted out of position at 294 tons load and the ultimate collapse load was not reached. The beam withstood D.L. + 5½ L.L. according to the calculations of the authors, and might have reached D.L. + 6 L.L.

Deflections varied with humidity, the authors found, and also the deflections varied, due to readjustments of strain in the material.

The authors are to be complimented on the painstaking care with which the tests were conducted, the data compiled and conclusions drawn.

Designer Answers Queries

Philip Benn, the designer of the beams used at Cobourg was present at the meeting and he very kindly answered many queries. This was a very interesting phase of the meeting as it is rare for a designer to have his design so thoroughly discussed and verified.

W. R. Schriever Honoured

The chairman of the meeting, Harold Fealdman, stated that Mr. Schriever had received the Sir Benjamin Baker Medal of the Institution of Civil Engineers for a paper which he had given before the Institution on tests which he had conducted on the temporary deck structure of the Toronto subway. This is a signal and well deserved honour for Mr. Schriever.

BOOK REVIEW

Design and construction of steel merchant ships. David Arnott, ed. New York, Society of naval architects and marine engineers, 1955. 494 pp., illus., $14.00 (U.S.).

For years the need for a modern, comprehensive textbook on ship design and construction has been keenly felt by students, naval architects and engineers, technical and public library users, and others interested in this field. The present work, resulting from the efforts of many outstanding members of the United States shipbuilding industry, fills this need.

Needless to say, there are limits to the subject matter which it was possible to include. Only ordinary, modern, steel merchant ships are discussed to the exclusion of warships and other highly specialized types. The practical, rather than theoretical, approach is taken, and the emphasis is more on structural design than on ship construction. Examples of the ordinary ship calculations are not included.

The book is divided into fourteen chapters, beginning with such basic design factors as hull form and power estimates. Consideration is then given to general arrangements and interior design, and to the historical background of ships' structures. The next two sections on structural design and methods of joining structural parts contain much-needed textbook information on new material specifications, and on riveting and welding in ship construction.

There is a detailed discussion of the function and design of such structural members as deck beams, machinery casings, rudders, foundations, etc., followed by a chapter on fittings. The last part of the book is devoted to specialized arrangements and equipment: cargo-handling, anchor, mooring, and towing arrangements, steering, hull piping systems, heating and ventilation, lifesaving equipment and aids to navigation, and hull preservation and maintenance.

A valuable feature of the work is the bibliographies found at the ends of many of the chapters. The Glossary of shipbuilding terms in the appendix should also be of particular interest to those new in the field.

M. R.

BOOK NOTES*

Prepared by the Library
The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

***Aeroelasticity.** R. L. Bisplinghoff and others. Cambridge, Addison-Wesley, 1955. 860 pp., diagrs., $14.50. (U.S.).

In the first part of this book which is divided roughly into two halves, the authors present analytical methods for dealing with problems of aircraft structures under load, and problems of two- and three-dimensional incompressible flow, compressible flow, and three-dimensional unsteady flow. In the second part, these methods are applied to practical problems of static aeroelasticity, flutter, and dynamic response phenomena. The theory, design, and construction of models, and experimental techniques are also dealt with briefly. The book is intended for advanced students and practicing engineers.

Air conditioning - refrigerating data book: design volume, 9th ed. New York, American Society of Refrigerating Engineers, 1956. 231 pp., diagrs., $10.00. (U.S.).

This is the companion work to the Society's Applications volume, and in it is found the fundamental data and basic engineering information relating to the theory and principles of the design of refrigeration and air conditioning equipment and systems.

The main portion of the book is divided into sections dealing with theory, physical data, application design, basic equipment, auxiliaries and self-contained units, and operation. The chapters on air distribution and controls have been largely rewritten and other revisions bring the subject up-to-date.

There is also a Classified section listing manufacturers of components and assembled units of air conditioning and refrigerating equipment.

***Les barrages en voute mince.** Jean Lombardi. Lausanne, F. Rouge & Cie, 1955. 163 pp., paper. Sw. fr. 28.70.

The author develops in a systematic manner a method of analysis for the thin arch dam in accordance with standard shell theory, with particular attention to torsion effects. Realistic examples are dealt with, and a step-by-step calculation is carried out. The general method developed is compared with the classic method of arch dam analysis.

Brazing. E. B. G. Trehearne. London. British welding research association, 1956. 27 pp., illus., 5/-.

This booklet is one of a series on welding and associated processes, methods and designs. It is a guide to available brazing methods, and to the metals and types of joints most suitable for brazing. There are sections on the treatment of metal before and after brazing, on aids to production, and on new materials.

***Chemical engineering processes and equipment.** E. Molloy and E. Carr, eds. Toronto, British Book Service, 1955. 236 pp., $3.60.

Concise descriptions of a wide range of processes and equipment are presented, supplemented, in some cases, with lists of references to more detailed information. The equipment dealt with includes ball and pebble mills, mixers, porous stainless steel filters, heat exchangers, film dryers, electrical precipitators, and automatic dust collectors. Among the processes covered are vibro-agitation, tabling, magnetic separation, elutriation, evaporating, crystallization, and heavy media separation.

Design of reinforced concrete. B. W. Boguslavsky. New York, Macmillan, 1956. 428 pp., diagrs., $7.50.

The author's purpose in writing this book was to present the student with the fundamentals of structural theory as applied to the design of reinforced concrete members, and to provide a guide for the practicing engineer in actual design work. To facilitate these two objectives, the text contains a number of formulae and methods which are new or generally unfamiliar, and also includes many illustrative problems.

Among the unusual features of the book are formulae for designing slabs and beams which automatically include their own weight, formulae for estimating the size and weight of the footings, and for estimating the cross sectional dimensions of prestressed concrete beams. The chapter headings describe the contents of the book: beams, tension, columns, slabs, footings, retaining walls, bridge arches, maximum moments in building frames, and design of a building.

MAINTENANCE
DEPT.

• Library Notes

Die designing and estimating, 4th ed. W. N. Nordquist, ed. Cleveland, Huebner, 1955. Various pagings, illus., $7.50 (U.S.).

Since the publication of the third edition of this book in 1942, several new chapters have been added, including those on press die design, the basic principles of cutting with press dies, and the selection of die materials. The remaining sections contain new and up-to-date information. In addition to the above mentioned subjects, the book covers the applictaion and design of piercing, blanking, cutting, compound, combination, drawing, deep-draw, progressive, side or cam-action, temporary and short-run dies, and lamination dies.

A special section gives procedures for predetermining die costs, and a list of practical points in die design and construction is appended.

*__Distribution of lateral forces in small buildings,__ 2nd ed. L. A. Briggs and O. M. Bloch. Glendale, Briggs Publishing Company, 1955. 89 pp., $3.00 (U.S.).

A presentation of a method of distributing lateral forces, whether earthquake or wind, into the resisting piers or walls. The subjects treated include determining forces, how elements of a structure resist forces, the proportion of the force resisted by each pier, wall rigidities, rotational analysis, and walls normal to force. Three chapters are devoted to analyses of small wood frame structure, a similar structure of concrete, and a three-storey structure.

Electric dipole moments. J. W. Smith. Toronto, Butterworth, 1955. 369 pp., $8.40.

In this book are described the techniques of the determination of the electric dipole moments of molecules. It was written for those interested in physical measurements and also for those who use the results of such measurements.

The first section presents the theoretical principles underlying the various methods of determining dipole moments, and describes the experimental procedures involved. The second part interprets the values obtained, while the third section examines some of the problems which have been solved with the use of dipole moment determinations.

In the appendix the principles of wave mechanics are outlined as much of its terminology is used throughout the book.

Electronics. A. W. Keen. New York, Philosophical library, 1956. 255 pp., illus., $7.50 (U.S.).

This is an elementary and descriptive treatment of the science of electronics, written for the non-technical reader with some knowledge of electricity and magnetism.

Among the subjects discussed are electronic conductors, control devices, beam tubes, circuits elements and processes, electronic sound, radio communication, television, computing, electronics in industry, electronic instruments and excitation.

An encyclopedia of the chemical process industries. J. R. Stewart and F. E. Spicer. New York, Chemical publishing co., 1956. 820 pp., $12.00.

Based on the 1953 edition of Stewart's Scientific Dictionary, this is a reference work covering the raw materials, processes, equipment, and finished products of the chemical process industries. It also lists definitions of technical and scientific terms used in this field.

The encyclopedia will also serve as a buyer's guide to chemists and consumers, as it lists the manufacturers and uses of a great number of trade-name and trade-marked products in the United States, although, in most cases, it does not give the address of firms.

Frequency response. Rufus Oldenburger, ed. Toronto, Macmillan, 1956. 372 pp., diagrs., $7.50.

These are the papers presented at the 1953 A.S.M.E. Frequency-Response Symposium plus ten additional articles. Beginning with a section on the fundamentals of the subject, they cover fre-

• Library Notes

quency-response aids; servo, airplane and power system applications; process control; transient response; optimum controls; nonlinear techniques; sampling controls; and statistical methods.

The editor's introduction acquaints the reader with historical developments, fundamental theory, and significant advances. Among the articles are two by Russian engineers which were hitherto unavailable to the general reader.

The golden book of management. L. Urwick, ed. London, Newman Neame, 1956. 298 pp., illus., 35/-.

In recording the work of some seventy pioneers in management this book will serve as a reference tool for students of business management. Eleven countries are represented, with the United States predominant. The special contributions, publications, careers and personal characteristics of each man are described in an average of four pages. The book is published under the auspices of the International committee of scientific management, and the editor is well known in the field.

Hi-fi loudspeakers and enclosures. A. B. Cohen. New York, Rider, 1956. 360 pp., diagrs., $4.60 (U.S.).

This book will appeal particularly to those wishing to build or assemble their own high-fidelity set. It is divided into sections on the Loudspeaker, the Enclosure, and the Room, and detailed design information is given. The appendix consists of 18 complete plans for the construction of typical loudspeaker enclosures of all types and for various speaker sizes.

High-temperature technology. I. E. Campbell, ed. New York, Wiley, 1956. 526 pp., illus., $15.00.

In this important work sponsored by the Electrochemical Society, thirty-five specialists in the field described new materials of construction for service at very high temperatures, methods used in production, and techniques for measuring properties.

Among the materials discussed are oxides, carbides, borides, silicides, nitrides, sulfides and cermets. In the section on methods of producing these materials, there are chapters on sintering, resistance and induction-heated furnaces, and arc furnaces. The last part of the book contains papers on the mechanical and physical properties of these specialized materials, and on special techniques for their measurements, e.g. high-temperature microscopy and X-ray diffraction.

In general, consideration is given to service at temperatures above 1500° C, although some of the discussion relates to processing at moderate temperatures.

Introduction to color TV, 2nd ed. Milton Kaufman and H. E. Thomas. New York, Rider, 1956. 156 pp., diagrs., $2.70 (U.S.).

The few changes in this new edition include descriptions of larger screen picture tubes and more simplified receiver circuitry. There are chapters on the NTSC color television system, tri-color picture tubes, and adjustment of receivers.

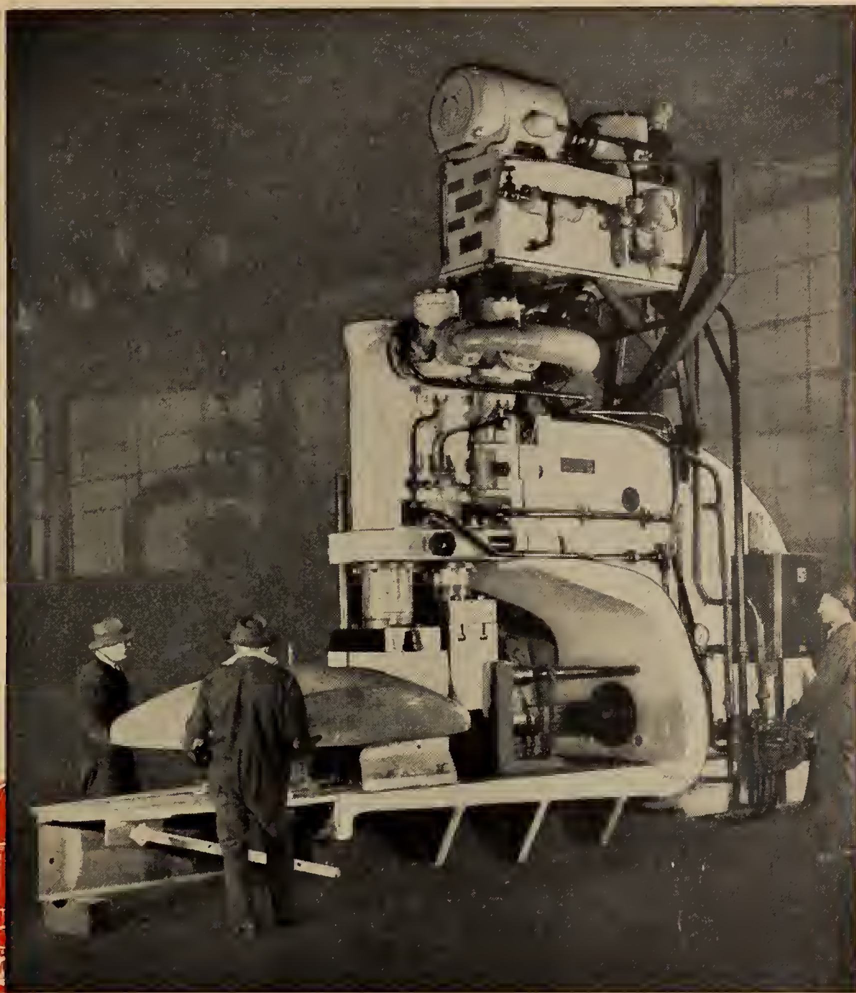
Introduction of plasticity. Aris Phillips. New York, Ronald, 1956. 230 pp., diagrs., $7.00 (U.S.).

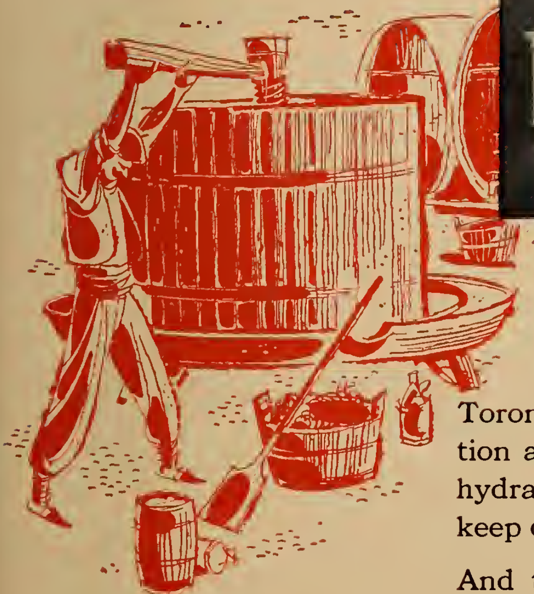
This text on metal plasticity is suitable for advance engineering students as well as for the practicing engineer. It introduces the latest methods of calculating stresses and strains in plastic materials, but uses only the minimum mathematical tools. The concept of a tensor is excluded.

The first six chapters deal with one-dimensional problems, beginning with axial loading, and going on to deflections and curved bars. The last three chapters consider problems of combined stress: stress-strain relations; collapse under combined stresses; and strain hardening under combined stresses.

Inventions and their management, 3rd ed., rev. A. K. Berle and L. S. De Camp. Toronto, Van Nostrand, 1954. 742 pp., $10.75.

This is a recognized handbook for inventors, investors, company executives and businessmen, and attorneys. Its objective is to show the aspiring inventor how to approach and manage an invention successfully, from the original idea through development, protection, and commercialization. Many test cases are





• Library Notes

presented to illustrate different procedures.

Among the vast amount of information contained in the book, there are chapters on patent laws and limitations, patent searches and study of the market, patent applications and sales, trade marks, copyrights, and accounting and taxes in relation to patents.

The appendix includes a glossary of terms connected with inventions and their management.

Legal problems in engineering. Melvin Nord. New York, Wiley, 1956. 391 pp., $7.50.

While there are a number of books available on the legal aspects of engineering, this work will be a valuable addition to such a collection because of its thorough treatment of the subject. The author has been able to include a wide field of topics by eliminating unnecessary long case histories and detailed documentary examples.

Among the legal principles discussed are contracts, sales, insurance, workmen's compensation, public utilities and labor law. This section is followed by one on the ethical responsibilities and professional registration (specifically in the United States) of engineers.

The last part of the book is concerned with construction contracts, governmental regulation, patents, and air and stream pollution.

The mathematics of physics and chemistry, 2nd ed. Henry Margenau and G. M. Murphy. Toronto, Van Nostrand, 1956. 604 pp., $8.75.

One of the main additions in this new edition is the chapter on the theory of Laplace and Fourier transforms. A number of other small changes and corrections are also found but the main plan of the book is the same.

The first section discusses the mathematics of thermodynamics, which is followed by ordinary differential equations, special functions, vector analysis, coordinate systems, and calculus of variations. There are also discussions of the mechanics of molecules, matrices, quantum mechanics, numerical calculations, linear integral equations and group theory.

Multivibrators. Alexander Schure, ed. New York, Rider, 1956. 48 pp., 90c (U.S.).

The basic principles of the multivibrator are outlined in this booklet, with particular attention given to these major types: the bi-stable multivibrator, mono-stable multivibrator, and a-stable multivibrator.

Naval boilers, 2nd rev. ed. R. F. Latham. Annapolis, Md., U.S. Naval Institute, 1956. Various pagings, illus.

Written as a textbook for midshipmen in the United States Naval Academy, this work provides an introduction to the fundamental features of a steam generating plant. It traces the history and development of steam generating units from early times to the nuclear power plant, with emphasis on marine boilers used in the U.S. Navy. The function of the boiler unit within the framework of the propulsion plant is described, including principles of heat transfer, circulation, and properties of steam.

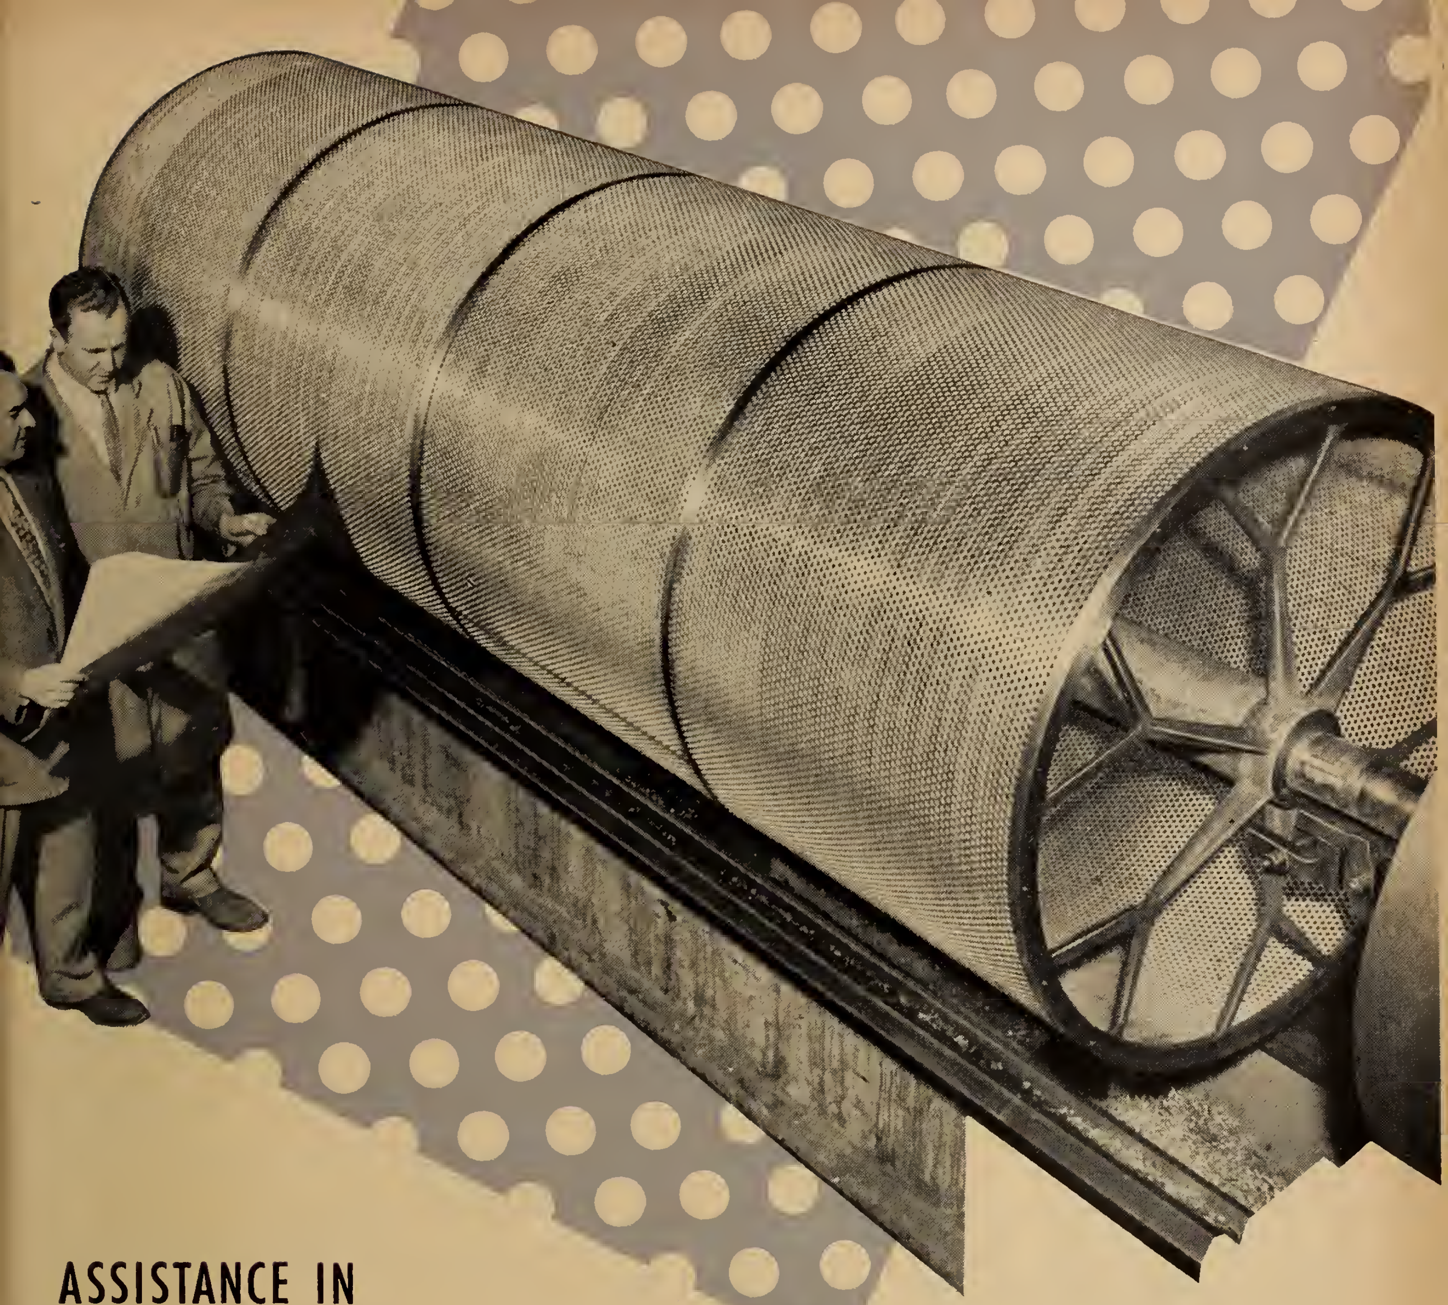
The last four chapters deal with such basic operating equipment and techniques as boiler water treatment, including types and effects of contamination. There are also sections on fuel oil, combustion, atomizers and burners used in naval boilers. The final chapter deals with basic naval power plant arrangements, and economical boiler operation and maintenance.

***Overhead line practice,** 2nd ed. John McCombe. London, Macdonald, 1955. 287 pp., illus., 25/-.

A clear presentation for engineers, foremen, linesmen, and others, of the details of the layout, design, and erection of overhead power lines. All the aspects of the work, from surveying to inspection and testing of lines are covered. In this edition there are new sections on sag-tension calculations, aluminum alloy conductors, and maintenance; the chapter on legal notices and right-of-way has been omitted.

Practical problems in soil mechanics, 2nd ed. rev. H. R. Reynolds and P. Protopapadakis. London, Crosby Lockwood, 1956. 205 pp., illus., 18/-.

The practical approach is emphasized in this book which illustrates the application of soil-mechanics methods and analyses to everyday problems.



ASSISTANCE IN METAL SELECTION

INCO Sales Engineer confers with the Works Manager of Hydraulic Machinery Company Limited, Montreal, where construction of a Stainless Steel Cylinder Mould is under way.

INCO can be of service* to you

The above scene is typical of the personal contact and technical assistance available from INCO. Through its highly qualified staff INCO puts its wide range of practical experience and accumulated background information at the disposal of Canadian Industry. If you have a metal selection problem, or need any other metal information, let us know . . . for INCO can be of service to you.

• Library Notes

Among the subjects discussed are soil properties, stability of earth slopes, embankments, retaining walls, foundations, artificial cementation and ground water lowering, soil stabilization for roads and airfields, and site exploration and soil investigations.

Many problems are fully worked out, a feature which will help civil engineers in their design work.

Proceedings of the first conference on coastal engineering instruments. R. L. Wiegel, ed. Richmond, Calif., Council on wave research, 1956. 302 pp., illus., $5.00 (U.S.).

The purpose of this conference was to present papers on many of the instruments used to obtain data necessary to the design of coastal structures, ships and seaplanes. They are too numerous to list but they include the capacitive wave profile recorder, parallel wire resistance wave meter, the thermopile wave meter, the N.I.O. wave analyzer, the storm wave force meter, shock pressure meters, Carruthers current meter and wire angle gage, and C.B.I. Salinity-temperature meters.

Proceedings of the RETMA symposium on automation. New York, Engineering publishers, 1956. 114 pp., illus., $5.00 (U.S.).

This book includes both the papers presented at the symposium sponsored by the Engineering Department of the Radio-Electronics - Television Manufacturers Association and the discussions which followed. Included are both practical and theoretical considerations of techniques and systems, economic problems, design principles, and application details.

The subject covered are: mechanization for high volume assembly; data sensing, processing and utilization; the future of automation; automation for low volume production; and redesign for automation of components and products.

Within these broad subjects there are discussions on such specific topics as automatic production of components, automatic warehousing and automatic ticket reservation systems, automation of non-circular gear cutting, etc.

Proceedings of the symposium on printed circuits. New York, Engineering publishers, 1955. 122 pp., illus., $5.00 (U.S.).

This symposium, sponsored in 1955 by the Radio-Electronics-Television Manufacturers Association and the Institute of Radio Engineers, covered all the methods of printed circuitry in present-day commercial use.

The papers deal with both theoretical and practical aspects, materials and components, design and production, testing and evaluation, and reliability and management problems. Effective methods of using new techniques are discussed, as well as the economic factors involved.

Productivity measurement, v. 2—Plant level measurements: methods and results. Toronto, Ryerson. 1956. 194 pp. $1.50.

A brief account is given of the practice in various European countries regarding productivity measurement in plants. A discussion of such practical problems as collection of basic data, interpretation and use of results, is followed by solutions actually used. The second part of the book deals with a comparison of results in different countries, with an account of difficulties encountered in making these international comparisons.

This is the second volume on the subject published by the Organisation for European economic co-operation.

***The radio amateur's handbook, 33rd ed., 1956.** West Hartford, American radio relay league, 1956. Various pagings, $3.00 (U.S.).

A new edition of a standard handbook covering the entire field from basic theory to practical construction details. Changes have been made throughout to take note of recent changes in practice, a new chapter has been added on semi-conductors, and a considerable amount of new apparatus is described in the chapter on measurement. This edition also includes design data and construction information on v.h.f. beam antennas.

• Library Notes

Rubber in automobile engineering. R. Dean-Averns. London, Natural rubber development board, 1956. 206 pp., illus., 5/-.

The aim of this book is to explain the properties and characteristics of rubber from the point of view of the automobile engineer. The greater part is devoted to engine vibration problems and suspension systems in relation to the use of rubber. There is a chapter on pneumatic tires, followed by sections dealing with the use of rubber in the clutch, drive, steering and brakes; in units attached to the body or frame; in electrical fittings, hoses and seals; in door mounting, flooring and seating.

Theodolite design and construction. E. W. Taylor. York, Cooke, Troughton & Simms, 1955. 136 pp., illus., 20/6.

This manual deals with the construction and design of an accurate and reliable theodolite. It discusses graduated circles, reading the circles, effects of eccentricity and misplaced indices, the telescope, the spirit level, the adjustments of a theodolite, the mining theodolite, and accessories for the instrument.

The theory and technique of ship design. G. C. Manning. New York, Wiley, 1956. 278 pp., $10.00.

In his preface, the author expresses the opinion that ship building is an art as well as a science and he has based the contents of his book on this philosophy. It is a study of the fundamental principles and processes used in the design of ships of all classes, with the emphasis on commercial vessels.

Beginning with a chapter on the philosophy of ship design, the book [illegible] to consider such problems as th[illegible] liminary estimate of displacement, elements of form, and of stability. There is a chapter on preliminary lines and calculations, on the design of general arrangements, on strength and weight calculations, and on contract and final design.

The appendices include the computation of righting arms from principal dimensions and coefficients, and Taylor's mathematical lines.

***Transistor electronics.** A. W. Lo, and others. New York, Prentice-Hall, 1956. 521 pp., diagrs., $12.00 (U.S.).

In this book, written for graduate students and electronics engineers, the emphasis is on a basic understanding of the circuit aspects of the transistor and on the physical principles governing transistor operation as a basis for practical circuit design.

The book begins with a discussion of transistor physics and general properties of the transistor as a circuit element, then goes on to describe stabilization of the d-c operating point, low-frequency amplifiers, power amplifiers, high frequency operation, high-frequency amplifiers, oscillators, modulation and pulse circuits. A large number of illustrated practical circuits facilitates circuit design, and the effect of various physical phenomena of transistor action on equivalent circuits is also covered.

STANDARDS REVIEWED

A.S.T.M. standards. American society for testing materials, 1916 Race Street, Philadelphia 3, Pa.

A.S.T.M. specifications and tests for electrodeposited metallic coatings. $1.85 (U.S.).

The 17 specifications here reprinted have either been developed jointly with the American Electroplaters Society, or have subsequently been endorsed by them. There are specifications for zinc, cadmium, nickel-chromium, and lead on steel; nickel-chromium on copper; nickel-chromium on zinc; and chromate finishes on zinc coatings. In addition there are recommended practices for preparation of low-carbon steel, high-carbon steel, zinc-base die castings, and copper-base alloys for electroplating; chromium plating on steels; and preparation of and electroplating on stainless steel and aluminum alloys.

A.S.T.M. specifications for steel piping materials. $4.00 (U.S.).

This 1955 edition of the compilation contains 58 approved specifications for ferrous pipe, tubes, castings, and fitting and bolting materials in their latest forms. New specifications include those for metal arc welded steel pipe for high pressure transmission service, cold drawn wrought iron heat exchanger and condenser tubes, and alloy steel castings, normalized and drawn for high pressure and elevated temperature service.

A.S.T.M. standards on cement, 1955. $2.75 (U.S.).

This compilation includes 37 specifications and methods of test of which 18 have been revised since the 1954 edition and 5 are new. The publication also contains information on analytical balances and weights, a manual of cement testing, a list of selected references on portland cement, and other data.

A.S.T.M. standards on plastics, 1955. $5.75 (U.S.).

This volume includes 143 specifications and tests on properties, analytical methods, molds and molding processes, conditioning, plates, sheets, tubes, rods and molded materials, and electrical tests. Much of the material has been substantially revised since the last compilation appeared in 1954.

British standards, British standards institution, 2 Park Street, London, W. I. British standards are available from the Canadian standards association, National Research Building, Ottawa.

B.S. 1116-1956 — Flexible trailing cables for quarries and metalliferous mines. 6/–.

In this revision of the 1943 edition the three parts have been combined. The main new features are the inclusion of 6.6. kV cables, and the incorporation of composition and test requirements for rubber insulation and for natural rubber and polychloroprene sheaths by reference to B.S. 7. The standard does not include collectively or individually screened cables, for which reference should be made to B.S. 708 — Trailing cables for mining purposes.

B.S. 1306: Pt. 1:1955 — Non-ferrous pipes and piping installations for and in connection with land boilers. 3/–.

This standard applies to the design and construction of non-ferrous pipework for connecting a land steam boiler to engine, turbine or industrial plant, and to all associated auxiliary pipework. It specifies maximum design pressures and temperatures for copper pipes and gunmetal castings used in these installations.

B.S. 1470-77:1955 — Standards for wrought aluminium and aluminium alloys. B.S. 1470 — 6/–; B.S. 1471-77 — 7/- each.

These eight revised standards deal with various wrought forms as follows:—

B.S. 1470 — Sheet and strip.
B.S. 1471 — Drawn tube.
B.S. 1472 — Forgings and forging stock.
B.S. 1473 — Rivet, bolt and screw stock for forging.
B.S. 1474 — Extruded round tube and hollow sections.
B.S. 1475 — Wire.
B.S. 1476 — Bars, rods and sections.
B.S. 1477 — Plate.

The system of nomenclature adopted throughout all standards in the earlier series has been retained; but two new prefix symbols have been introduced, 'V' for extruded round tube and hollow sections and 'B' for bolt and screw stock.

Three new materials have been introduced in the series, namely super-purity aluminium designated 1, and two aluminium-magnesium-silicon type alloys designated H20 and H30, which have been included immediately following H10 because of their similarity to that material. Alloy H20 contains an addition of copper, and also manganese, and/or chromium, while H30 is a copper-free alloy with an obligatory manganese content.

The tolerance tables in several of the series have been extended, and minor amendments made to the values specified.

B.S. 2004:1955 — Polyvinyl chloride insulated cables and flexible cords for electric power and lighting (for working voltages up to 250 volts). 6/–.

This revision incorporates an amendment providing for tinned copper conductors, with plain copper conductors as an alternative, to be supplied when specified by the purchaser. Apart from changes resulting from the introduction of tinned conductors, and a few corrections and minor editorial amendments, the text is the same as that of the 1953 edition.

B.S. 2633: 1956 — Class I Metal arc welding of steel pipelines and pipe assemblies for carrying fluids. 10/–.

Lack of uniformity in welds used in pipelines and pipe assemblies, and for securing flanges and attachments e.g. anchor plates, has resulted in a variety of practices. This standard is one of the process standards in the comprehensive series for the welding of steel pipelines and pipe assemblies for carrying fluids. It covers the shop and site metal-arc welding of steel pipelines and pipe assemblies for carrying fluids suitable for Class I conditions and in sizes up to 24 inches diameter. It covers all types of butt joints, branches and sleeve welds, in addition to qualifying tests for welders.

B.S. 2641: 1955 — Glossary of terms relating to automatic digital computers. 3/-.

The development of high-speed digital computers has produced a need for the standardization of the terms used in this technique. In the early stages, however, it was thought that methods were changing so rapidly that attempts to draft a glossary would be inadvisable and profitless, and delay was counselled. Techniques now having reached a more stable state, this glossary has been produced. It contains about one hundred entries, covering the following subjects: Fundamental terms; Coding systems; Storage techniques (mainly electronic); Programming and routines. For completeness, a few definitions relating to number representation and number scales are included.

B.S. 2642: 1955 — General requirements for the metal-arc welding of medium tensile weldable structural steels to B.S. 968 Type a. 6/-.

B.S. 2642 specifies the general requirements for the metal-arc welding of medium tensile weldable structural steel to B.S. 968, Type a, under normal conditions of manufacture and service. Details are given of the materials to be used and the design of butt and fillet welds. Graphs are included for the determination of intermediate values of plate thickness and varying degrees of preheat for rutile and low hydrogen electrodes for use with both butt and fillet welds.

B.S. 2645: Part 1: 1955 — Tests for use in the approval of welders. Part 1. Manual metal arc and oxy-acetylene welding of mild steel and low alloy steel sheets, plates and sections. 12/-6.

B.S. 2645 has been prepared to make available a series of standard tests, one or more of which can be selected for assessing or testing the capabilities of a welder. It is complementary to B.S. 1295, 'Tests for use in the training of welders'. The tests in Section 1, for which the specified material is mild steel, are for use in the preliminary assessment of a welder's skill.

The tests in Section 2 are for use in the approval of welders for specific applications.

B.S. 2688: 1955 — Dimensions of impulse magnetos (unscreened and screened) 5/6.

This new British Standard applies to the dimensions of base mounted and spigot impulse magnetos for internal combustion engines. It deals only with the dimensions of unscreened and screened impulse magnetos necessary to ensure interchangeability, and also applies to impulse starters separate from, and constituting an attachment to, standard magnetos to B.S. 1620 and B.S. 5027.

B.S. 2693: 1956 — Screwed studs. Part 1: General purpose studs. 3/6.

It is hoped that publication of this British Standard will meet a long felt need, since it is the first British Standard to give full information, including limits and tolerances for the threads, for screwed studs intended for general use. The principle adopted is that of mating an oversize stud with a standard tapped hole and the amount of oversize and the thread tolerances specified are those considered suitable for most purposes. Details are given for studs with UNF, UNC, B.S.F. and B.S.W. threads in diameters up to 1½ in. and for studs with No. 2 and No. 4 B.A. screw threads.

B.S. 2697: 1956 — Rack type gear cutters. 2/6.

This standard includes tables of dimensions and permissible errors, it indicates the method of mounting, and shows the tooth form and explains the terms used, by the pictorial method. Two appendices give details of the marking to be employed and instructions for ordering the cutters.

B.S. 2708: 1956 — Unified black square and hexagon bolts, screws, nuts (UNC and UNF threads) and plain washers — normal series. 5/-.

This is the latest addition to the range of standards for unified fasteners and it is intended to satisfy the demand for bolts and nuts with smaller hexagons for applications where precision tolerances are not required.

A table of heavy hexagon nuts in sizes from ¼ to 2 in. has been included, since users of the standard may wish to follow what is common practice in the U.S.A., where square headed bolts are often used, not only with square nuts, but with heavy hexagon nuts. The standard also includes appendices giving formulae for the calculation of sizes outside the range of the specification, details of identification marking, and tables of approximate weights of bolts and nuts.

The Pulp and Paper Industry

Canada's largest single industry is well known by the title "pulp and paper". Since pulp, the basic material of the industry, is derived from wood (with the exception of less than one per cent from other sources) it might be more appropriate to borrow the term "forest products" to describe the great range of derivatives covered by this industry. Not only paper, in its many forms, but packaging and building materials and valuable chemical products play a large part in its flourishing operations.

The pulp and paper industry is the largest single employer of labour in Canada; it also has need of professional men from all occupations, and the engineer finds his place among them in many different fields. Chemical, civil, mechanical, electrical, and forest engineers all have their opportunities in the various branches of the industry.

Forest Operations

Canada has one of the largest coniferous forests in the world that is suitable for development for the large-scale production of pulpwood. These forests must now keep the mills supplied with some 40,000 cords of pulpwood a day for an output of about 32,000 tons of pulp and paper—and the industry is developing all the time to meet an ever-growing demand for all its products.

These forests are managed scientifically and economically, so that the harvest of pulpwood may be gathered and moved to its destination by the best means, and so that the future supply is assured through proper methods of conservation.

The engineer may be needed for general administrative duties, but is more likely to work on logging operations within the forests. Cutting operations in British Columbia, where trees are large and work proceeds throughout the year, is almost entirely mechanized and uses many units of heavy equipment. There is also a definite trend towards mechanization in the eastern woods operations.

Apart from cutting and handling methods, the engineer helps to plan, far in advance of actual operations, the means of transporting the pulpwood to the mills. This involves surveys of natural waterways and routes for rail and road, and the subsequent developing and building of these channels for the ready flow of material. New areas have constantly to be opened up, and the magnitude of the operation may be judged from the fact that over twelve million cords of pulpwood are cut and moved each year.

The Mills

There are some one hundred and thirty pulp and paper mills across the continent of Canada and Newfoundland. Numerically, over 40 per cent are in Quebec, rather more than a third in Ontario, nearly a tenth each in British Columbia and the Maritimes, and the remainder (some 5 per cent) in Newfoundland, Manitoba, and Alberta.

The mills may produce pulp alone, or paper or both.

The newsprint mills form the largest group within the industry, with about 60 per cent of total production; of this total another 23 per cent is pulp for sale (largely to other mills and the chemical industry), and 10 per cent is paperboard. The remaining 7 per cent of output is made up of other types of paper.

Basically, the mills are equipped with a variety of heavy and complex machinery and require large

Newsprint spins out of the dry end of a huge paper machine. Engineering talents of all kinds are required to keep the mills and equipment in operating condition, to develop and improve products, and to do research.

amounts of power for their operation. As an example, the major mills of one leading Canadian organization consume power at the rate of 365,000 h.p. each day. Civil, electrical, and mechanical engineers are needed for the operation and maintenance of the mills and their associated equipment; chemical engineers are in demand for the work of technical control departments, where the quality of materials and products is constantly controlled, and also in the chemical pulp mills.

The two methods of making pulp are mechanical and chemical. Mechanical pulping, largely used for newsprint material, requires heavy machinery and makes great demands for electric power. Chemical pulping is a more complex process of considerable concern to the chemical engineer. Whatever the source of pulp, its conversion to paper again involves the engineer in the planning and layout of plant and the design of paper-making machinery. A single machine may be several hundred feet long and produce over 200 tons of paper a day in widths of the order of twenty feet. (Engineering departments are constantly developing such machinery, and other equipment, and working on changes and improvements in plant processes.)

In addition to the engineer's part in operating, maintaining, and improving these mill processes a considerable amount of fundamental and applied research and development work is continuously carried out by the mills.

The bottom of one of the eight digesters in a New Brunswick pulp mill. Each digester is 16 ft. dia. and 60 ft. high, made of steel with a special brick lining.

Other Manufacturing Operations

Perhaps the most rapid growth to be expected within the industry will be in the field of packaging materials. Apart from paper for bags and wrapping, there is a continuing trend to the use of boxboard and container board cartons. Both for small items and for heavier equipment the paperboard container is ever more widely adopted so that more paper and paperboard is now used for packing than all other packaging materials combined.

The design and manufacture of these packaging products and the containers into which they are made represents an increasingly important section of the industry, with its own problems and requirements for the engineer.

Similarly, hardboard and other paper products are in increasing demand as materials for building and construction, while the chemical engineer may be increasingly engaged in developing the use of pulp by the chemical industry.

Opportunities for the Engineer

The man with a basic engineering degree has many opportunities for a career in the pulp and paper industry. Usually he will start as a junior engineer in a particular branch and proceed to gain practical experience as he works on the job.

In many cases the graduate will be assigned to a task which he follows through while he receives additional training and guidance from senior engineers. As his training proceeds and he gains necessary experience the young engineer fits himself for more advanced positions.

Promotion is generally by merit, based on the combination of ability and experience possessed by the candidate.

From junior engineer on the general staff, progress will depend on the particular bent of the individual, but there are positions to be filled in the plant engineering departments of the mills up to chief engineer or to senior superintendents of process control departments. Similarly the other manufacturing divisions, for example those making containers, have their own plant and process engineers, while such positions as plant manager are frequently filled by the professional man.

The demand for engineers in the forests has already been indicated, and many are employed at administrative and managerial levels.

In several cases the president of a company or group of companies within the industry is an engineer, as also are other senior executives and their immediate staffs.

The way is thus open to the engineer with the right combination of skills and experience to proceed to the top positions in an industry that is itself a leader with a foreseeable future of rapid and extensive expansion. The industry particularly has a need for men of imagination and broad outlook.

Training Schemes

Most companies take engineering students for summer work and provide a basic training in various aspects of the industry.

As already mentioned, the young graduate joining a company is often given on-the-job training and guidance during the first year or two of his assignment. Some companies provide formal training courses for engineers entering specific divisions; for example, in all phases of plant operation in manufacturing departments such as container plants.

Salary Scales

Wages throughout the industry are generally good, and the scale of salaries for engineers are in keeping with those obtaining in other leading Canadian industries.

Junior engineers may start at a salary of $350 a month or more, rising to, say, $1000-$1250 monthly for a senior plant engineer, with correspondingly higher figures for the upper managerial positions.

Other Benefits

Paid vacations, sick leave, pension schemes, and various forms of health insurance are generally available throughout the industry.

Many of the mill towns are separate communities provided by the industry with all modern facilities for living, education, medical care, and recreation. Most outdoor sports are available to company members, and many hunting and fishing clubs are organized and run by and for employees in the pulp and paper industry, as well as excellent community recreational clubs.

Sturtevant built-to-take-it ROOF VENTILATORS

DESIGN 1 — PROPELLER TYPE — Specifically designed for light duty direct-to-outside exhaust applications, these ventilators offer dependable operating characteristics and give excellent service in every respect.

DESIGN 10R — CENTRIFUGAL TYPE — This ruggedly constructed unit has a welded steel frame and housing. The V-belt driven fan and motor are shielded from the airstream and give deliveries over a wide range of pressures. Backwardly inclined blades give high CFM discharge at low static pressure.

DESIGN 2A — AXIFLO TYPE — This strong, rigid unit can be used with or without ducts. Very high "starting-up" pressures assure positive shutter opening and give maximum air moving capacity with minimum horsepower. Built to withstand the rough usage encountered in many industrial applications.

Write for your copy of Roof Ventilator bulletin DB–C91–207 — it contains complete engineering data.

Cross Suspension System

Kemano-Kitimat Transmission Line

H. B. White, M.E.I.C.

Power Transmission Engineer, Aluminum Company of Canada, Limited

On January 26th, 1955, an avalanche destroyed three towers in the Kildala Pass section of the 49-mile long Kemano-Kitimat transmission line and thus interrupted the delivery of power to the Aluminum Company of Canada aluminum smelter at Kitimat, British Columbia. After temporary repairs had been made, and the circuits re-established, study was given to several schemes of permanent repair and relocation that would keep this section of line free from avalanche danger in the future.

Considerations of safety, time and cost led to the use of a new type of cross suspension system for supporting high voltage transmission lines. The lines, which run up a narrow valley at this point, were to be suspended from two steel wire ropes strung across the valley. The system was erected, and power was being fed over it on September 26th, 1955, eight months after the outage, and only six months and four days from the date of the decision to proceed.

Power Outage

Approximately 40 miles of the Kemano-Kitimat transmission line is of a heavy but conventional double circuit type of construction with "Falcon" ACSR as the conductor, and a nominal line voltage of 287 Kv. For the nine mile section between the valleys of the Kemano and Kildala Rivers, where the lines rise steeply up and over the mile-high Kildala Pass, an exceptionally heavy construction is used, with two single circuits strung with "Emu" ACSR conductor.[1]

"Emu" ACSR

Diam.	2.2947 in.
Stranding Al	108 x 0.1765
Stranding steel	37 x 0.1261
Alum. area	3,364,000 circular mils.
Wt. per ft.	4.760 lb.
Design ultimate strength	135,400 lb.

The two single circuits are identified as right (R) and left (L) as seen when looking from Kemano towards Kitimat. The right line is carried on steel towers of a lattice type construction and the left line on a new type of tubular aluminum tower.[2]

A new type of cross suspension system was adopted for the permanent re-location of part of the Kemano-Kitimat transmission line which was destroyed by an avalanche in 1955. The work involved is described in this comprehensive paper. The author was responsible for the project design.

On the afternoon of January 26th, a dry snow avalanche slid off the southwest slope into Glacier Creek Bowl which is just below the last rise up into Kildala Pass, and destroyed aluminum tower 113L and steel towers 111R and 112R. There was also damage to the crossarm of tower 113R, which stands above the slide area, as a result of the conductors being dragged sideways by the snow.

The conductors remained intact throughout, although severely damaged. However, they were short circuited in many places by contact with each other and with the fallen towers so that power supply to Kitimat was interrupted.

Temporary Repairs

The temporary repairs were carried out under conditions of continuous bad weather as 47 inches of snow fell during the nine days required to re-establish the left circuit and a further 75 inches fell between February 4th and February 15th, by which date the right line had also been returned to service.

Maximum advantage was taken of the few breaks in the weather to move men and material to the site by helicopters and with the assistance of the tractors that had been stored in the area, and two more that were driven up the old construction road, repairs were made that remained in service until September when the new suspension system was ready to carry power.

The aluminum towers of the left line consist of a box girder crossarm resting on five, or in some cases six, tubular leg members arranged to form A frames or tripods. The avalanche swept the legs from under the crossarm at Tower 113L, and left the crossarm, undamaged and still attached to the conductors, almost resting on the snow. The damage to the left line was limited to this and a temporary repair was made to this line first. The crossarm and insulators of tower 113L were removed, the conductor spliced and restrung through the double span from tower 112L to 114L. This was a strong repair measure, although both the design ice carrying capacity and ground clearance had to be reduced.

The repairs to the right line were more difficult as two towers had been demolished, and the conductors between towers 110R and 113R damaged beyond repair. The damaged crossarm on 113R was repaired and the gap between 110R and 113R

Read at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada, Montreal, May 1956.

was spanned with "Partridge" ACSR, which has an aluminum area of 266,-800 circular mils and a diameter of 0.642 inches. The sag in this span of 4,200 feet was only 159 feet, which resulted in a stringing tension of about 49 per cent of the ultimate strength of the conductor. This high tension was adopted to keep the conductor well above possible future avalanches to which the left line remained exposed.

It was anticipated that such a high stringing tension would result in considerable vibration and dampers were applied. In spite of them there was a pronounced vibration of the conductors, especially at the upper end of the span where strong steady winds are prevalent. Close examination of the three conductors, when they were removed after eight months' service, showed only one strand broken by fatigue.

There was little reserve strength in this small conductor to carry the heavy ice that could be expected in the area during the remainder of the winter season, but with the entire electrical load of the Kitimat smelter kept on this right line, the heating of the conductor was sufficient to prevent ice or rime formation.

Permanent Relocation

Even before temporary repairs had been completed, studies were begun to find a way of assuring that such an outage could not be repeated.

Attention was first given to the strengthening of the towers, the deflection of snow slides from the towers and the controlling of the snow movements by structures installed in the snow basins which would prevent avalanches from starting. These plans were abandoned because of the problem of controlling such a vast quantity of snow and doubt that the measures would be effective.

Several alternative routes for the tower lines were then investigated. One consisted of re-routing the lines up the ridge to the southwest of Glacier Creek Bowl and around the back of the snow basins to the Pass. A second route went only part way up the ridge to a pair of tall heavy angle towers from which long spans reaching over the slide area took the circuits to the Pass. A further scheme utilized two very tall towers just below the slide area, to permit long spans to clear the danger area to towers located near the Pass.

All the above-mentioned schemes would require between two and three years to design, fabricate and erect at a cost of between 1.5 and 3 million dollars.

The most promising possibility in terms of both time and cost was a cross suspension system with the conductors supported from wire ropes spanning transversely across the valley. Estimates indicated such a scheme would cost less than one-half of the least of the others, that it could be in service by the end of the working season of 1955 and had the prospect of greater reliability than could be claimed for any of the other proposals. On March 22nd, the decision was made to proceed with the design and construction of such a system.

Five years' experience in the Kildala Pass area has shown that winter can arrive as early as October 1st, making construction work very difficult and expensive. Therefore, the design, fabrication and erection of the system was scheduled for completion within six months.

In spite of the poor weather throughout the latter part of the season, which made working conditions unexpectedly rugged, the right circuit was energized by September 26th, and the left circuit was ready to carry power on October 5th.

Fig. 1. A retouched panoramic view of the cross suspension system from Twin Peaks with Kildala Pass in centre background.

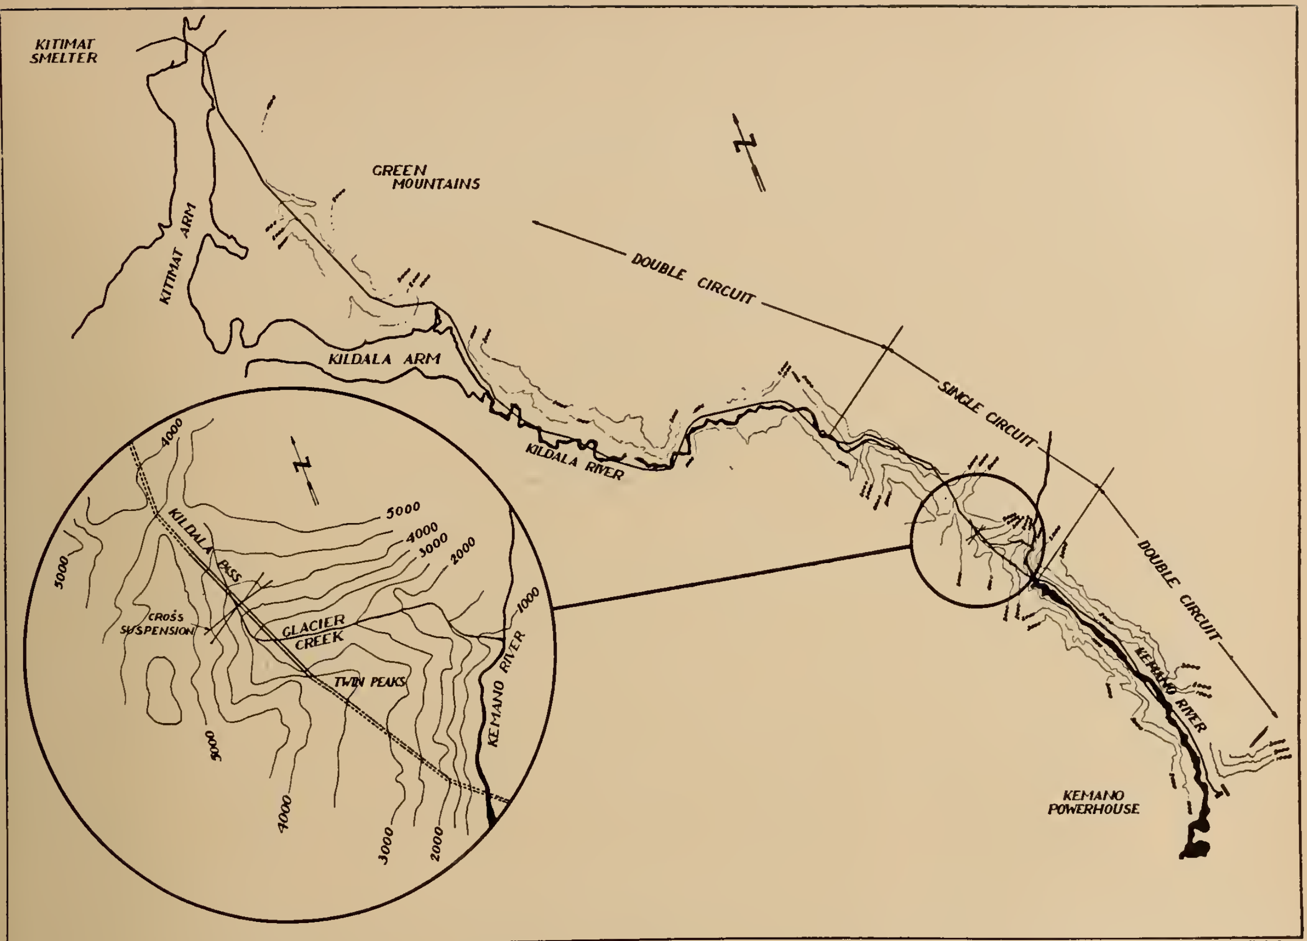

Fig. 2. Map of Kemano-Kitimat transmission line showing location of cross suspension.

Design

A choice had to be made between a suspension of the entire transmission system on one cross rope or a suspension on two or more separate cross ropes. The latter alternative was considered to be no safer than the former because the failure of any one of the ropes would drop it down across the six conductors, shorting out both circuits and damaging the conductors beyond the possibility of immediate repair.

The desired security was obtained by using two cross ropes and yoking them on each side of the centre section that supports the conductor (see Fig. 3). Thus a failure of one rope or one anchorage could drop one of the half sections of rope, but its movement would be arrested at the bridle plate. Each rope is strong enough to support the entire system with an ice loading of 15 lb. per foot on all components.

The design had to be begun while the possible anchorage sites for the cross ropes were still covered by deep snow. A study of photographs taken during previous summers revealed promising locations on both sides of the valley and the southwest anchorages so chosen proved to be satisfactory with only minor adjustments to satisfy very local rock conditions.

The location of anchorages on the northeast side of the valley was a more complex problem as this slope is traversed by many snow slides. A large canyon cuts diagonally across the lower portion of this slope and the first anchorages were located just below the protection afforded by the upper end of the canyon, at an elevation of approximately 3,800 ft. Initial calculations showed a need for back stays to maintain adequate clearances under the upper conductor spans and model tests indicated a marked tendency to severe vibration of the system, if there was even a suspicion of resonance between any of the system components. Early field investigation after the snow had disappeared showed also that the rock at this northeast anchorage would not be reliable.

Fortunately, sound rock conditions were subsequently found at a more suitable anchorage site higher up and closer to the Pass.

The system, as finally arranged, has no symmetry. All four rope anchorages are at different elevations, the wire rope lengths from the bridle plates to the anchorages are all different, the four main conductor spans are unequal and the end towers are each at a different elevation. This lack of symmetry made some of the calculations so very complex that a model (see below) had to be used to confirm stresses and distortions under the various loading conditions.

The suspension system would make use of the existing end towers and was designed to the following requirements:

1. With an ice load of 15 lb. per foot on any or all components of the system, the tension in the cross ropes was not to exceed 535 kips, or 65 per cent of the 824 kip design ultimate strength of the ropes. The maximum rope tension of 487 kips occurs at anchorage B with ice on all components.

2. Assuming the failure of a single rope or anchorage, the remaining rope must support the system with any or all of the remaining compon-

ents carrying an ice load of 15 lb. per foot. The ultimate strength of the rope is the limiting condition for this loading.

3. There must be no failure of any component of the system if an ice load of 40 lb. per foot should be applied to all components simultaneously.

4. Conductor tension under dead load only was limited to 22,000 lb. or about 16 per cent of the ultimate strength of the "Emu" conductor. Experience has shown that with stringing tensions of no more than this, the aluminum strands of the conductor are not susceptible to fatigue failure resulting from aeolian vibrations.

5. Adequate conductor-to-ground clearances must be maintained with an ice loading of 15 lb. per foot on any or all components of the system.

6. Resonance must not exist between any of the components of the system.

Conditions 5 and 6 were the most difficult ones to satisfy.

The very irregular terrain of the Kildala Pass area is conducive to localized icing and riming and it is difficult to maintain conductor-to-ground clearances when ice forms on one span of a line and not on the adjacent spans.

With a 15 lb. ice load on all conductors of the cross suspension system, the minimum clearance to ground is 65 ft. below the lower right conductors. With ice on the lower span conductors only, the minimum clearance is still about 40 ft. because as the cross ropes swing downhill into the lower span, the relatively short upper conductor spans quickly tighten up and limit the distortion of the system. With ice on the short upper spans only, the initial dead load clearance of 180 ft. is reduced to about 10 ft. over an assumed depth of 25 ft. of snow.

The problem of resonance was first encountered while investigating the dynamic behaviour of the model under loadings such as caused by the release of ice, and it was explored until there was a thorough understanding of the mechanics of the phenomena, and their application to the behaviour of the prototype.

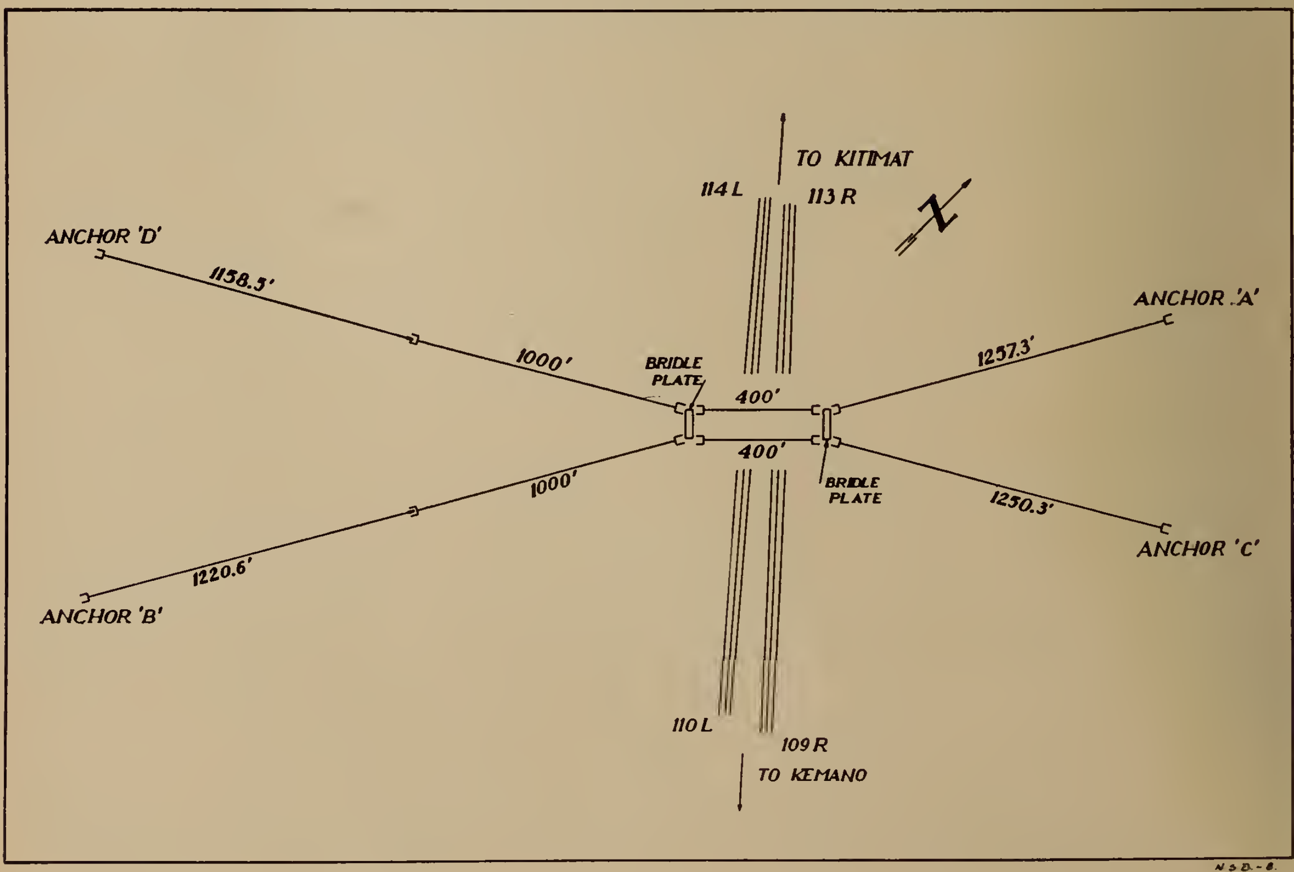
The fundamental vibration mode of the system as a whole can be described as an up and down motion of the conductors together with a pendulum motion of the cross ropes, the six conductors of one span being in phase but lower and upper spans being in opposite phase.

When the cross ropes intersect the conductors at an angle different from 90 degrees, a small "side-kick" is imparted to the conductors by the pendulum motion of the cross ropes. The tests showed clearly that when ths "side-kick" is resonant with a natural transverse mode of a conductor span, large transverse amplitudes will build up and superimpose on the vertical motion. Because of the small differences in sags of the three conductors in each span, they are bound to get out of phase so that danger of collision is imminent. When a typical case of resonance was present in the model collisions were always observed.

It was found possible to tune the system by adjusting conductor sags so that a conductor would vibrate transversely in say three loops which in fact occurred when the fundamental frequency of the lower right conductor span was 33.4 c.p.m. against a system frequency of 49.4 c.p.m. The frequency of the three loop vibrations was 99.6 c.p.m. or almost exactly 3 x 33.4 and 2 x 49.4.

As the frequency of a complete system is difficult to determine theoretically and as it was not found to change perceptibly with minor changes in conductor tensions, the model value of 49.4 c.p.m. (3.5 c.p.m. prototype) was used in the

Fig. 3. Schematic drawing showing components of cross suspension system.



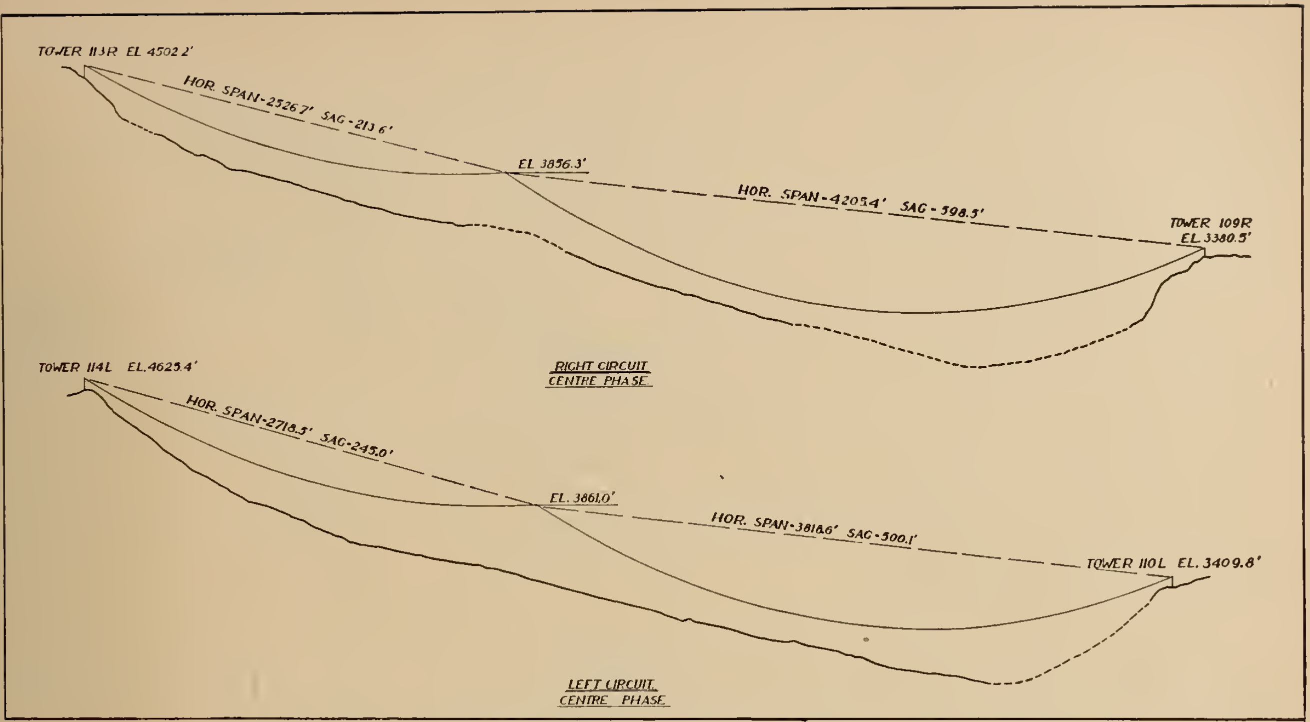


Fig. 4. Profile of conductor spans.

design of the prototype.

The conductor sags were adjusted during the final field design with regard to their frequency of swing according to the formulae

$$F = \frac{60}{2\pi}\sqrt{\frac{ag}{k^2}} \equiv \frac{60}{\sqrt{Sag}} \text{ c.p.m.}$$

where: a is the distance from the support axis to the centre of gravity of the span.
g is the acceleration of gravity
k is the radius of gyration about the support axis.
f is the conductor sag.

and set so that their frequency would differ from that of the complete system by at least 5 per cent.

The amount of "side-kick" imparted to the end of a conductor is reduced by setting the cross ropes at right angles to the direction of the conductors. The change in anchorage location described previously improved the average angle of intersection from about 81 to 87 deg.

Model Study

A model was used to verify the complex calculations necessary to determine the stresses and distortions of the system under applied ice loadings and to study the system's behaviour when subjected to dynamic loadings.

The model was built in the Testing Laboratory of John A. Roeblings' Sons, Corporation, Trenton, N.J., fabricators of the 3 inch wire rope, to a linear scale of 1:200 and as close to true elastic scale as possible. The conductors and cross ropes were represented by piano wire with lead weights added to represent the weights of their prototypes and further lead weights were added or taken off as required to represent the various live loadings.

In order to study the elastic behaviour of the prototype with a model built to a linear scale

$$l_p/l_m = r,$$

the elastic stretch - Pl/AE of all components must be kept to scale.

Thus:

$$l_p/l_m = r = \frac{H_p l_p / A_p E_p}{H_m l_m / A_m E_m}$$

from which we have

$$H_p A_m E_m / H_m A_p E_p = 1$$

We know

$$H_p/H_m = \frac{W_p . l_p . l_p / 8Sag_p}{W_m . l_m . l_m / 8Sag_m}$$

and as

$$\frac{l_p/Sag_p}{l_m/Sag_m} = 1$$

$$W_m = W_p r . A_m E_m / A_p E_p$$

Where:

r = scale factor
H or P = tension, lb.
A = cross section area
E = modulus of elasticity
W = load or weight per foot

The values of W_p, A_p and E_p of each component of the prototype were known and with the selection of a wire (A_m and E_m) for the model, the necessary weight per foot, W_m was obtained.

As such a model can portray accurately but one characteristic, in this case displacement, the characteristics of vibration and damping could only be studied qualitatively.

The model studies were of great

CHART OF MODEL CHARACTERISTICS

	Cross Ropes		Conductors

value as a means of obtaining answers quickly and with the necessary accuracy. The early studies with the first location of the northeast anchorages clearly showed the need for the backstays to maintain adequate ground clearance under unequal ice loadings. When the problem of resonance was uncovered, it became apparent that a new anchorage location was desirable, preferably one which would set the cross ropes at right angles to the conductors and also remove the need for the backstays. Fortunately such an anchorage was found when the site became accessible.

The model was frequently adjusted to accommodate new field data and after construction was finished the "as built" system was set up on the model as a double check on the work.

Anchorages

The cross rope anchors were designed to transfer the load of the ropes to the rock through anchor bolts loaded in direct tension. Sound rock was a requirement for the safety of such an anchorage. Early studies of the surface of the rock at the final anchor sites indicated satisfactory conditions and these were substantiated when the excavations were completed.

The rock at each of the four locations is essentially a hornblende-diorite-gneiss. In addition, at D anchorage, there were foot-wide bands containing biotite. The rock is jointed to varying extents at all anchorages but is very tight except for the surface rock at D. A programme of pressure grouting is planned at D to stop further loosening of the surface rock caused by the freezing of water in the cracks.

Each anchor consists of six 2½ inch diameter deformed anchor bolts 25 ft. long, upset and threaded for 15 inches at one end. They are grouted into a pattern of 4½ inch diameter holes of which three dip at 15 degrees and three at 45 degrees. In plan the six bolts are splayed up to a maximum of 30 degrees on each side of the centre line. A grout mix of 1:2:2 by volume of Embeco, Portland Cement and sand was firmly tamped in place with care taken to leave no air or water pockets. In some holes, where ground water was present, the mix was placed dry and then tamped.

Under the assumption that a failure of the rock could occur behind the block of rock picked up by the group of anchor bolts, the design assumes a frictional co-efficient of

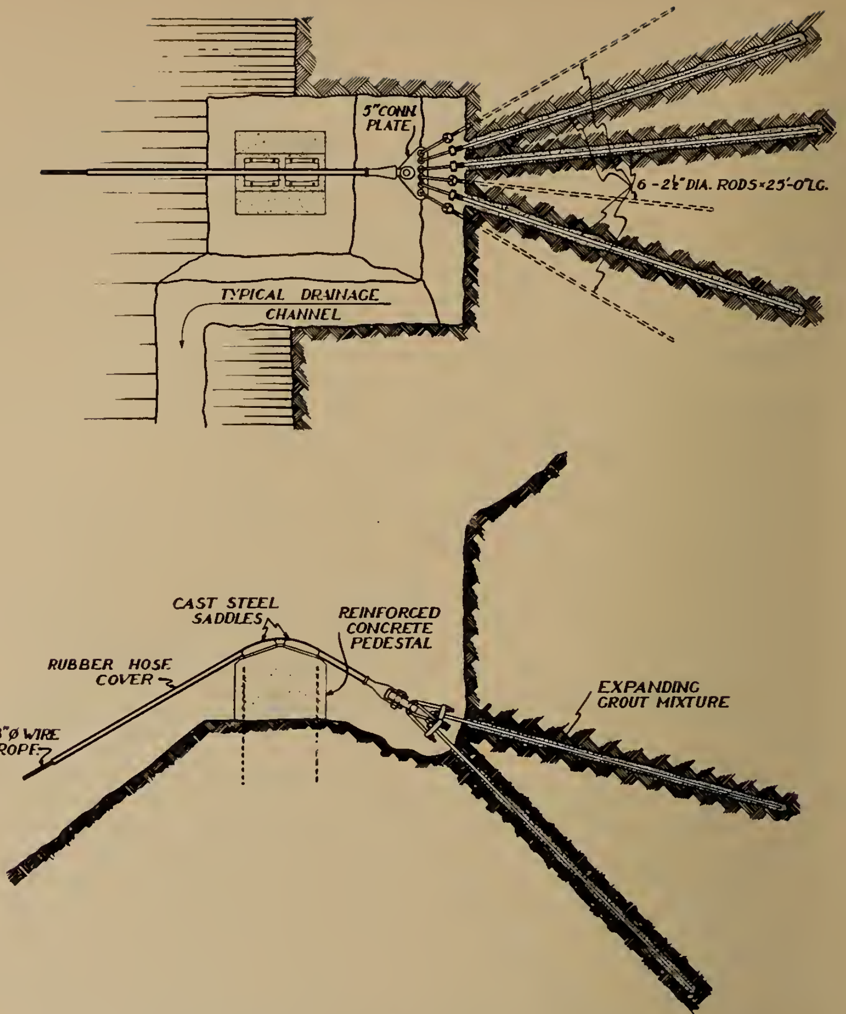

Fig. 5. General arrangement of anchorage of 3-inch suspension ropes.

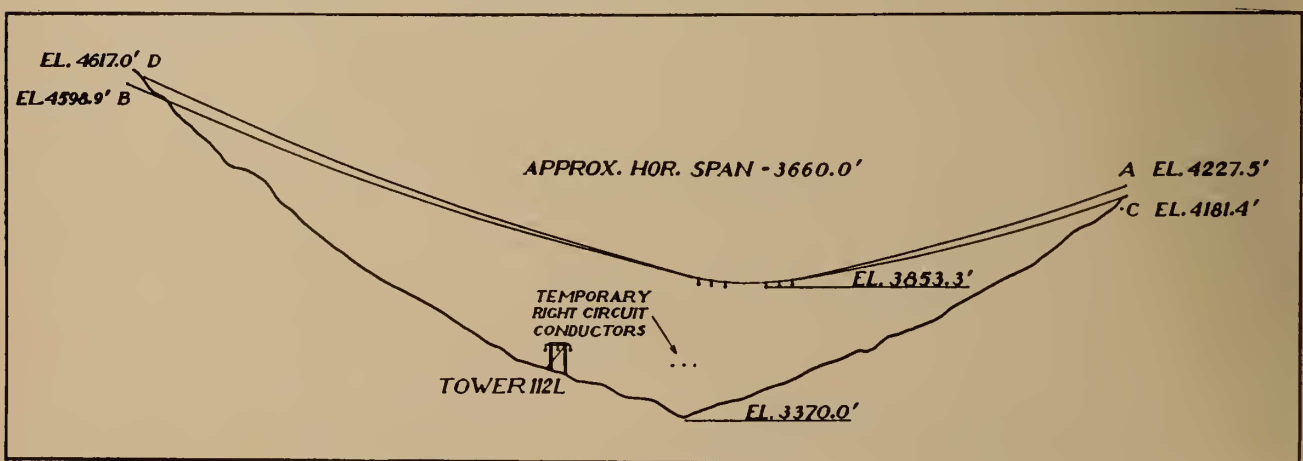
Fig. 6. Profile of cross suspension showing the existing right and left circuits.



but 0.12 on the lower horizontal plane of cleavage to prevent pull-out under the 900 kip breaking strength of the wire rope.

The six anchor bolts were yoked to a common 5 inch thick steel connector plate through an arrangement of U bolts and nuts which permitted adjustment to divide the load equally among the anchor bolts. The open socket at the end of the wire rope was pinned to the connector plate with a 5¼ inch diameter pin. The wire rope was then led up and over the cast steel saddles which were bolted to the top of the reinforced concrete pedestal.

Suspension Ropes

The 3 inch galvanized bridge ropes that form the cross suspension were delivered to Kemano warehouse area before the anchorages had been definitely located. Thus, while the two 1,000 ft. sections and the two centre 400 ft. sections could be shipped complete with sockets attached in the shop, the four closing sections, one to each anchorage, required cutting to length and the installation of one socket each in the field.

The sockets were of the poured zinc type although much larger than those usually encountered as the socket castings weighed approximately 350 lb. each. A special shed was erected at Kemano for the field socketing and close attention was given to the detailed socketing specification.

Galvanized Bridge Rope Characteristics

Diameter	– 3 in.
Stranding	– 7 x 28
Wt. per foot	– approx. 15.11 lb.
Design ultimate strength	– 824,000 lb.
Test strength	– 900,000 lb.
E	– 20 x 10^6 p.s.i.

The wire ropes were prestressed to 120,000 lb. after fabrication, measured and then cut to length. Those four sections to be cut in the field were marked every fifty feet over given lengths so that field measurement would be simplified. The longest single length of rope on its reel weighed about thirteen tons.

Catwalk

Several means of permitting inspection and maintenance of the erected system were studied. The scheme adopted employs a catwalk suspended from the main wire ropes for the centre 400 ft. section between bridle plates. Access to the catwalk is by a cable car, which is run down from anchorage C.

The catwalk is of 12 ft. sections of Irving type aluminum grating coupled together to form a flexible decking. The 3 inch wire ropes are the "handrails". Shorter removable sections of grating immediately over each conductor suspension point permit direct access to the insulator assemblies. Furthermore, if a conductor requires maintenance, it can be lowered by rigging, run down through the opened grating.

The components of the catwalk were designed to support an ice load of about 600 lb. per linear foot as the catwalk may be subjected to very heavy snow, rime or ice accumulation.

A 25 h.p. gasoline engine, with a single drum, reversing gear and brake, hauls the cable car, which is also equipped with its own emergency brake. The hoist is located immediately in front of the pedestal at anchorage C. No component of the cable car weighs more than 150 lb. so that it can be dismantled by two men for storage beside the pedestal during the winter. Climbing to the hoist at anchorage C will be difficult when deep snow covers the north slope and at such times the helicopter will be the only practical means of access.

End Transmission Towers

Although three transmission towers were removed from each line,

Fig. 7. Socket being lowered for attachment to anchorage at C.

Fig. 8. Final closure at anchorage A.

the static loadings on each of the end towers 109R, 110L, 113R and 114L have been reduced. The cross suspension carries more of the conductor weight than the six replaced towers had supported, and the more direct route between Twin Peaks and the Pass has resulted in a decrease in line angle at all four towers.

Although all structures have been removed from the areas swept by avalanches, the very strong air blast (estimated at up to 200 miles per hour) that accompanies an avalanche, could strike the conductors where they pass over the slide slope. The model was used to study the loadings on the end towers when the system was subjected to such severe dynamic loadings.

It was found that the suspension system absorbed energy and distributed shock loads very effectively. The impact loadings on the end transmission towers were only about one third of those recorded at the ends of similar spans which were fixed at each end.

A further improvement in the capacity of the system to absorb dynamic loads was made by converting towers 114L and 113R from strain type to suspension.

Erection of Cross Suspension Ropes

The ropes had to be raised over existing extra-high voltage power lines while these were supplying the aluminum smelter at Kitimat; and aluminum production procedures dictated that power interruption would have to be limited to three hours duration. However, only one interruption of 44 minutes was required, and the raising could possibly have been carried out with no interruption to the power supply at all, had this been necessary.

When erected the suspension ropes would cross the power lines about 200 feet northwest of tower 112L, at which point the temporary "Partridge" conductors of the right line were already about 170 ft. above the ground. (Fig. 6)

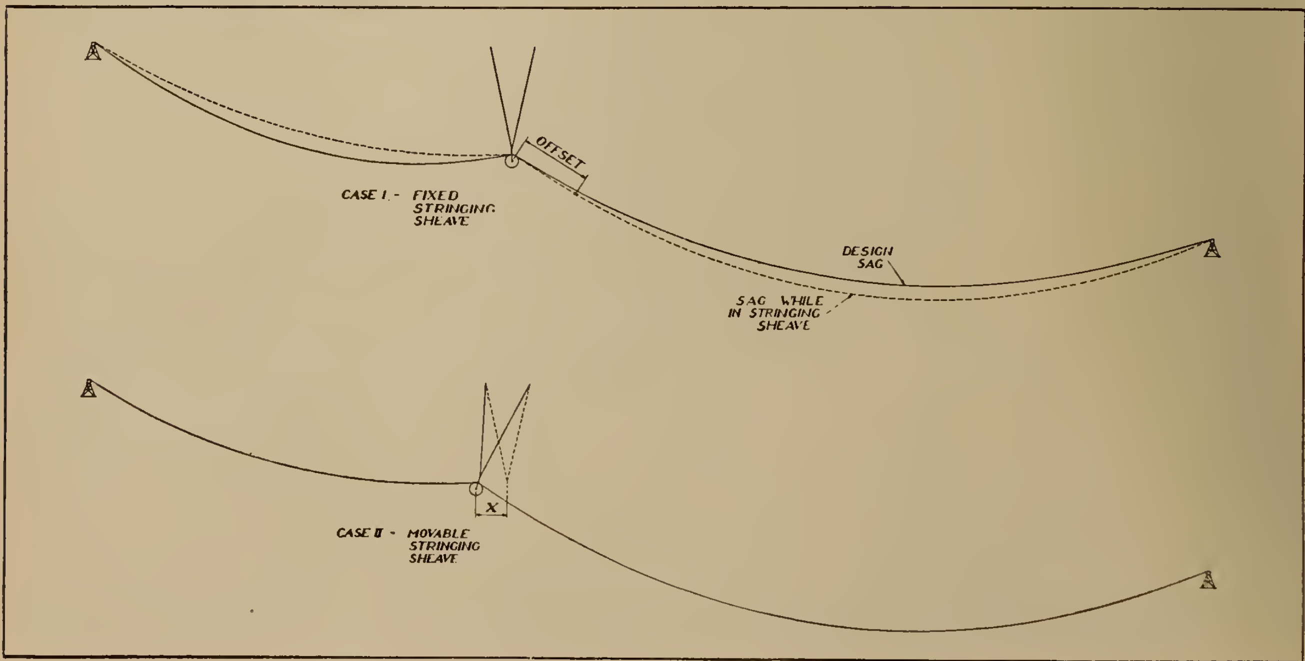
The erection procedure was as follows:

1. The power was transferred to the left line and slack taken out of the 4,200 ft. "Partridge" span in the right line to increase its ground clearance to about 200 ft.

2. The power was switched back on the right line and the conductors of the left line were lowered to the ground at tower 112L. Trestles were built to permit the 3 inch wire ropes to pass over these lowered conductors without damage to them.

3. The wire ropes which had been pulled up to anchorages B and D to the southwest from the reels located near tower 112L, were passed over the lowered left line conductors on the trestles.

Fig. 9. Illustration of the use of "offsets".



4. The 400 foot centre sections together with the sections for the northeast end of the suspension were pulled across the bottom of the valley and for a sufficient distance up the north side to allow the 6 part closing tackle to be connected.

5. With power supplied to the tackle by a hoist at the road heading 900 feet below, the cross ropes were raised clear of the ground and the catwalk was installed.

6. The cross suspension ropes were raised further by the closing tackle to a position where they passed some 45 feet below the live right line conductors and passed over the left line just above the level of the crossarm of tower 112L. A 12 ton weight suspended from the cross ropes at a point immediately below the right line helped to provide these clearances.

7 The left line conductors were raised and clamped in position at tower 112L.

8. Power was switched off the right line (both lines were now dead) and the cross ropes raised up and into the right line conductors, resulting in a clearance of about 45 feet over the left line conductors at tower 112L. Power was then returned to the left line.

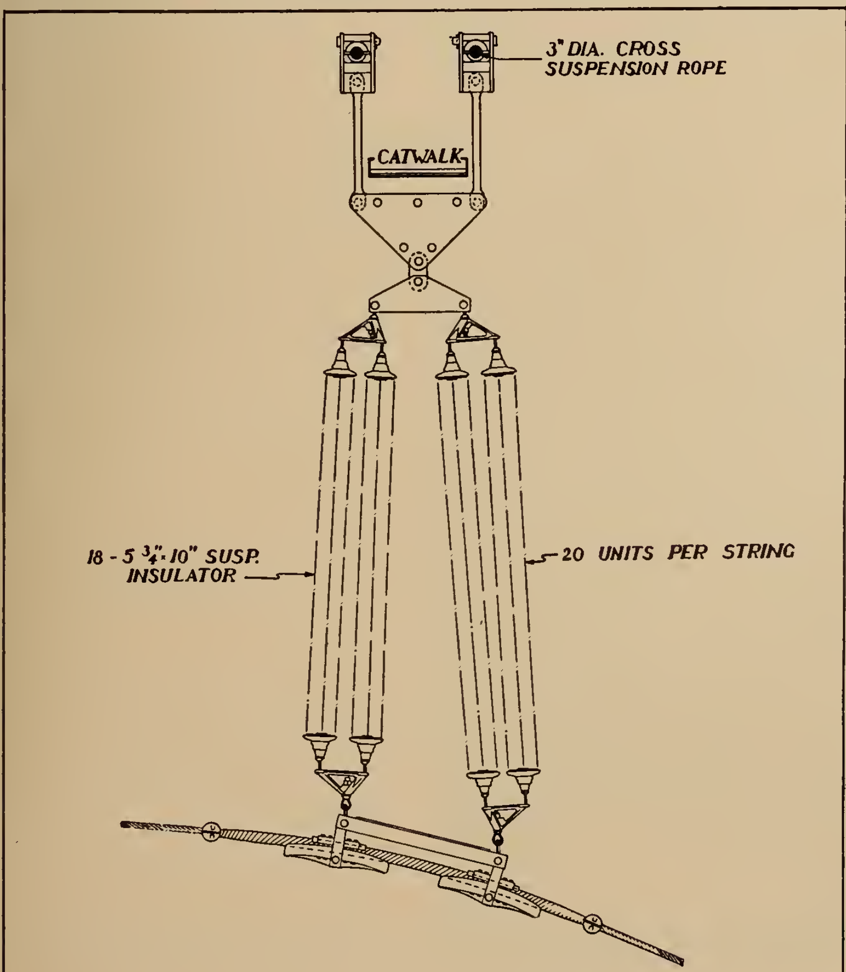
9. The "Partridge" conductors on the right line were disconnected at tower 110R and dropped to the ground as the cross ropes were pulled up to final closure at anchorages A and C. Power was carried on the left line until the right line conductors were raised to the cross suspension.

With the wire rope threaded above one circuit and below the other, its raising had to be carefully controlled. All equipment locations and control points in the area were linked by field telephone and during critical phases of the raising, radio equipped jeeps were used to supplement the telephones. When power was completely shut off, the clearances to proceed were obtained from and returned to Kemano by radio and during this period clear communication was ensured by prohibiting the use of radios elsewhere on the project.

Attention was given to the dangers of working close to charged extra-high voltage lines. Of particular concern was the possibility of the buildup of a voltage on a length of wire by induction from a nearby live conductor. A grounding network was established running across and up and down the valley and every length of rope and each major piece of stationary equipment was carefully grounded. Even with these precautions, it was possible to feel an appreciable shock when touching a wire rope several hundred feet from the live conductors if its grounds were too far apart.

Fig. 10. Conductor and insulator assembly being raised for attachment to cross suspension system.

Fig. 11. Six string insulator assembly and hardware for attachment to cross suspension.



Conductor Stringing

The problems of stringing the right line conductors were in general different from those of stringing the left line although one serious difficulty was common to both. When conductor is being strung on transmission towers in hilly country, the conductor tends to run downhill while it is still in the sheaves, so that although the correct amount of conductor may be in place between the end strain towers, the slack will tend to accumulate in the lowest span.

This condition is usually overcome by calculating the distances by which the clamps are 'offset' from the towers (Case I, Fig. 9) so that when the conductor is taken from the sheaves and clipped in, the horizontal component of tension in each span is the same, the insulator strings hang vertically and the sags in each span are as designed.

When the usual tower support for the sheave is replaced by a cross suspension that will itself tend to swing uphill, it becomes necessary to calculate both the 'offset' and the position of the sheave relative to the final position of the clamp (distance "x" in Case II). As the suspension system is not symmetrical and as the system would change as each conductor was clipped in, the calculations involved in computing both the values of "x" and the 'offsets' become impossible for all practical purpose and measurements of these values of sufficient accuracy could not be made on the model.

This problem was overcome by calculating the exact length of conductor required for each phase of each span, measuring out the necessary conductor length of each span, positioning and applying the armour rods and clamps to the conductor while on the ground and then raising the conductor and attaching the clamp directly to the cross suspension.

Where new conductor was used, as between towers 110R and 113R, it was measured and marked as it was pulled from the reels. The existing conductor in span 109R to 110R of the right line and all the conductor in the left line was reused. The lengths of the existing conductors were obtained by measuring the existing sags and spans and calculating the lengths of the catenaries. All such conductor lengths were adjusted for temperature and tension.

The average error of the twelve conductor spans between design sag and "as built" sag was 1.1 per cent, the maximum being a 2.4 per cent error in the middle phase of the upper left span. This is a finer degree of accuracy than that obtained by usual sagging methods during the initial stringing of the line.

Fig. 12. View from catwalk looking towards north-east anchorages during hook-up of last conductor. Cable car can be seen at far end of catwalk.

New conductors for the right circuit between Towers 110R and 113R were pulled over timber lagging which was used to keep the conductors off the rocks. The existing conductor in the 2,500 foot span from 109R to 110R was swung down from tower 110R and joined to the new conductor, the armour rods and suspension clamps were installed and the conductor raised to position.

The restringing of the left line was perhaps the most spectacular item of the entire project. Even though the existing conductor was to be used, the conductor raising was much more difficult and involved than on the right circuit. Length adjustments had to be made in each conductor to obtain the desired final sags but in addition, the conductors had to be removed from tower 111L, a strain type tower, and from tower 112L, a suspension tower.

To assist in this operation, two blocks had been placed on the 3 inch ropes in such a position that when the cross ropes were raised, a "sky hook" existed, ideally located about 300 ft. above tower 112L. The conductors were then lowered to the ground from tower 112L and the crossarm was removed. By using the "sky hook", and with suitable hold backs to take care of the rather large line angle that existed in the old line, the conductors were raised out of and clear of tower 112L.

This method, however, could not be repeated at tower 111L, a strain type tower. Here, wire rope straps

Fig. 13. Sikorsky S-55 helicopter ready to drop 850-lb. load of two 2-1/2-in. dia. x 25-ft. long anchor bolts at platform near north-east anchorages of cross suspension.

were run over the crossarm and clamped to the conductor some distance out from the dead end clamps. Conductor tension was transferred to the straps, the insulator assemblies were removed and the conductors were in effect left resting on top of the crossarm. Each conductor in turn was then swung over and lowered to the ground nearby, where the strap was removed, final length adjustment was made, and the conductor then raised to its final position on the cross suspension.

Transport

The old construction road that runs from the Kemano Powerhouse to the project site and then on to the Pass was easily re-opened by removing accumulated slide debris, and with a minimum of maintenance the road served as a principal means of access to the work site throughout the working season. There was road access to all towers except 109R and 110L on Twin Peaks.

A section of new road around the head of the valley to a position some 900 feet below the northeast anchorages brought men and equipment as near as possible to this working site. Some material, including the 3 inch wire ropes, was dragged or high-lined up to the anchorages by lines running up to blocks at the top and then down to a hoist located at the road heading below.

In general, however, the principal means of access to the anchorages was by helicopter. Twelve foot square landing platforms were erected at Camp 10, located just below the slide area, and at the two anchorage sites; and two helicopters shuttled between these platforms, moving the workmen, sand, cement, blasting powder, lumber, rigging and all the other materials and equipment necessary to complete the anchorages. It is of interest to note that on one exceptional day one pilot made 52 round trips between the landing platform at Camp 10, elevation 3,000 feet, and the anchorage sites which were from 1,200 to 1,700 feet higher.

Fig. 14. Installation of rigging in preparation for raising of sixth conductor.

When the single loads exceeded 300 lb., which is the capacity of a Bell helicopter at these elevations, a Sikorsky S55 helicopter was used. It carried its load by sling from Kemano direct to the platforms at the anchorages, where the loads were dropped from a height of several feet. Landings were considered to be both hazardous and unnecessary.

Compressed air had to be provided at the anchorage sites for drilling the anchor bolt holes. Suitable compressors could not be flown in to the sites, neither could they be dragged up from the valley. The problem was solved by placing diesel compressors at the nearest road headings and delivering the air from these points to the anchorages through 20 foot sections of 3 inch light wall aluminum alloy tubing joined by a flexible type of quick coupling. Pipe friction and leakage were negligible even though the distance up the north face was some 1,200 feet and the pipe line up and across the south face was about 2,700 feet long. Over a period of three months maintenance was negligible and recovery of the pipe and couplers after completion of the work was more than 90 per cent.

Survey

The early studies of the suspension system were hampered by the lack of accurate topographical data of the area. A stadia survey of the old tower sites, aerial photographs and an aerial map of one side of the valley, was all that was available during the initial planning. A rough aerial map of the whole area was made in April, but it was not until the end of June that the disappearance of much of the snow and the cessation of slides permitted a stadia survey of several of the anchorage sites then under study.

Following this, a grid, accurate to within 1:50,000, was established by triangulation and survey monuments

Canada's Economic Prospects

H. Carl Goldenberg, O.B.E., Q.C., *Barrister-at-Law, Montreal*

CANADA'S economic prospects have been very much to the fore for the past few months. A Royal Commission has crossed the length and breadth of Canada and has received many representations on the subject. It expects to present its findings to the Federal Government by the end of this year. It would be presumptuous for me to try to anticipate its conclusions.

I propose for the purposes of this talk to point to certain features of Canada's past economic growth, to examine its present economic position, and to look at the direction which its further growth may take. If I venture to make any forecasts, it is not in the role of a prophet.

Canada's economic growth has in the main been associated with the development of its natural resources. Wheat was the principal stimulus in the first quarter of this century which saw the building of our wheat economy and the settlement of the West. Our large investment in railways and in storage and grain-handling equipment is associated with wheat. While considerable progress had been made by the end of the 1920's in mining, pulp and paper manufacturing, and hydro-electric power development, agriculture was still the centre of our economic structure. Its importance was very evident in the 1930's when a combination of low wheat prices, successive years of drought and declining export markets destroyed the basis of national prosperity.

Comparing the Canadian economy of to-day with that of twenty-five years ago, we note marked changes. While wheat continues to play a major role, it does not dominate the economy to the extent that it did as recently as twenty-five years ago. The stimulus since then has been provided chiefly by our forest resources, our minerals, our hydro-electric power and by related manufacturing industries. These industries have reached their present status at different times and by varying rates of growth. Wars and depressions have led to an uneven expansion in the twentieth century.

Periods of Growth

The 1920's represented a period of rapid growth; the 'thirties showed scarcely any net increase in production; the early 'forties saw a great expansion particularly in industries whose products were required for war purposes. The expansion since the end of the war has been phenomenal and is continuing. I do not propose to burden you unduly with details but a few statistics will illustrate our recent economic history.

Gross national product, that is, the dollar value of all goods produced and services rendered—the most basic and comprehensive measure of our economic position — has risen from $12 billion in 1946 to an estimated $26.6 billion in 1955. While the rise in non-farm gross national product was from $10.9 billion in 1946 to an estimated $25.2 billion in 1955, accrued net income of farm operators from farm production increased in the same period from $1.1 billion to $1.4 billion. These figures are illustrative of the relative change in the position of agriculture in the Canadian economy.

While measurements in terms of dollars exaggerate the actual expansion because of the rise in prices which has taken place, volume indexes show that it has been very large. The index of industrial production (basis 1935-1939 = 100) rose from 171.9 in 1946 to an estimated 265.9 in 1955, of mining production from 97.1 to an estimated 242.4, of manufacturing production from 189.9 to an estimated 270.1, and of electricity and gas production from 157.8 to an estimated 275.7. These are a few selected economic indicators.

The volume of production is determined by the effective demands of individual consumers, government, investors and foreign buyers. Exports and capital investment are the most dynamic determinants of the level of national prosperity. Being subject to sharp and wide variations, they exert an influence on general economic activity out of proportion to their actual size. In the economic climate which has prevailed since 1946, both of these factors have served as a

---

Read at a meeting of the Engineering Institute of Canada, Montreal Branch, March, 1956.

powerful stimulus to expansion. In terms of current dollars, capital expenditures on new construction, machinery and equipment rose from $2.5 billion in 1947 to $6.2 billion in 1955; the forecast for 1956 is $7.5 billion. In terms of 1949 constant dollars the increase was from $2.9 billion in 1947 to $4.8 billion in 1955.

Value of Exports

Canada's exports have risen in value from $2.4 billion in 1946 to $4.35 billion in 1955; in 1939 they amounted to $900 million. It is of interest to note that 60 per cent in value of our total exports in 1955 went to the United States while 73 per cent in value of our total imports of $4.7 billion came from that country. Our principal exports to the United States were forest products, base metals, chemicals, iron ore and petroleum, while our principal imports from this source were iron and steel products, engines, machinery, aircraft and electrical apparatus. In 1955 our total foreign trade reached the record figure of more than $9 billion.

I have said that exports, which in 1955 totalled $4.35 billion, and capital expenditures or investment, which totalled $6.2 billion, are considered to be the most dynamic determinants of economic activity because they are subject to sharp fluctuations. Another determinant of increasing importance is government expenditures on goods and services, which in 1955 rose to $5.2 billion. By far the largest expenditure, however, is represented by personal expenditures on consumer goods and services. These have risen from $7.9 billion in 1946 to $16.8 billion in 1955, in terms of current dollars. This constitutes the largest single claim on our production and is determined by population, the distribution of income and the apportionment of disposable consumer income between spending and saving.

Canada's remarkable growth and development in the twentieth century has been associated with the increase in its population. The relative increase has been among the largest in the world; its population of 15.8 million is three times as great as in 1900. It increased by about one-third since the end of world war II and the trend continues upward.

This is Canada's position to-day: a population of approximately 16,000,000 and still rising; a gross national product of $27 billion and still rising; rich, vast and varied natural resources being profitably developed, new resources in process of discovery, and large undeveloped resources; a large industrial plant which continues to expand; a growing domestic market and an almost insatiable foreign market, particularly for the products of its natural wealth; and a growing economic maturity as the frontier is being pushed back. Knob Lake and Seven Islands, Blind River, Beaverlodge, Leduc and Pembina, and Kitimat — these and many others reflect our economic transformation.

Future Economic Growth

And now, what of our future economic growth? The first major factor to be considered is population. Projecting present trends in the annual rate of natural increase, which has always accounted for the greater part of our population growth, and assuming a continued high level of economic activity, which will mean a continued flow of immigrants, it may be forecast that Canada's population will be 26 or 27 million by 1980. Whether this figure will be attained depends on a number of factors. The effects of another war could not be forecast. A major economic depression would, as in the 1930's, reduce the birth rate and immigration. I venture to predict, however, that, while moderate and short recessions may and will occur, for example, because of a temporary decline in foreign demand, a major depression like that of the 'thirties will not recur. Society has gone a long way since then and has learned how to use fiscal and monetary policy to prevent a major depression. President Eisenhower's most recent economic message to Congress shows that even the Republican Party is now firmly of the opinion that the Federal Government must intervene in the economy of the country to help smooth out or to prevent violent fluctuations.

The author indicates certain features of Canada's past economic growth, examines her present economic position, and views the direction which further expansion may take, without, as he says, making forecasts in the role of a prophet. The paper is much to the point and comes at a time when the findings of the Royal Commission on this subject are being deliberated.

Stabilizing Factors

In addition to fiscal and monetary policy which can be used to promote economic stability and expansion, our economy now has certain "built-in" stabilizers. These provide a supporting floor which, with few exceptions, did not exist in the 'thirties. We have guaranteed minimum prices for certain basic commodities. We provide a minimum income for the aged through old age pensions and for the unemployed through unemployment insurance and unemployment assistance. Other welfare measures provide family allowances, disability pensions, forms of health insurance, widows' allowances, and so on. These are now an integral part of our economic system and of our way of life. If they make us a welfare state, we need have no fear. The state after all exists primarily to promote the welfare of its citizens. Why should we fear measures which promote this end? Fiscal and social policies which effect a wider distribution of income among low income families, apart from other considerations, are in the national economic interest since they enlarge the market for goods and services.

It has been suggested that, since Canada is so dependent on foreign markets for the sale of a very large part of the products of its natural resources, a prolonged weakness of world demand for such products may retard our growth. In my opinion, while occasional moderate recessions arising from a decline in foreign demand are probable, a prolonged period of decline in such demand is unlikely in the foreseeable future. It is important to remember that while we anticipate an increase of 10 or 11 million people in Canada over the next 25 years, the United States anticipates an increase of about 60 million in the same period with a correspondingly greater increase in consumption in that country. This is of major importance to Canada.

Future of Basic Materials

The Paley Commission, which reported to the President of the United States in 1952, assessed future consumption and imports of basic materials. It forecast that the consumption of such materials in the United States in the decade from 1970 to 1980 will be two-thirds greater than in 1950 and that about 20 per cent of this much larger consumption will have to be imported as compared with 9 per cent of the consumption imported in 1950. This will have a marked effect on the development of the Canadian economy and will further increase the dependence of the United States on imported materials from Canada. The Paley Report forecasts that the production of copper, lead, zinc, nickel and iron ore in the free world outside of the United States in 1975 will have to be approximately double the production of 1950 and that much larger increases will be required in petroleum and aluminum. When it is considered that the United States was virtually self-sufficient in copper, zinc and lead only 20 years ago, it is striking that the Report forecasts that in the 'seventies it will be importing half of its copper and zinc and three-quarters of its lead. In other words, in these and in other materials the United States faces an increasingly large deficit position. Having regard to Canada's actual and potential resources, the prospective increasing dependence of the United States on Canada as a source of supply points to very favourable long-term prospects in the demand for the products of our natural wealth. It is, of course, probable that the almost untouched resources of Asia, Africa and South America will be opened up to meet not only demand from the United States but the growing demands from other countries in the free world with rising populations and living standards and with increasing industrialization. If these untouched resources are not developed, there is bound to be an even greater acceleration in the rate of development, and, therefore, of exhaustion, of Canada's resources, particularly in minerals. Conservation policies now become all-important.

Productivity

I have spoken of population as the first factor in economic growth. The other major factor is the productivity of the economy. Productivity per man employed, that is real output per capita, has over the past 25 years risen by 1¾ per cent to 2 per cent per annum. This accounts as much as population growth for the doubling of our national production. With continued technological improvements and innovations, which are the basis of higher productivity and rising living standards, it is conservative to forecast a continued annual rate of growth of at least 2 per cent in real output per capita. On this basis a gross national product of about $65 billion, at present prices, is forecast for 1980.

The implications of the expansion which is forecast — a population of 26 or 27 million and a gross national product of $65 billion by 1980 —are vast. I shall only refer to a few. The first consequence that comes to mind is the great increase in the home market. For the Canadian farmer it would mean that he would be independent of export markets for some of the products now presenting serious marketing problems. Increased production of meats, dairy products, vegetables and fruits would be necessary. This would call for the opening up of new agricultural areas, such as the Peace River district and the Mackenzie Basin. Canada would, however, remain a major exporter of wheat. For the Canadian manufacturer, while the enlarged domestic market would still not compare with the mass market of the United States, it would be large enough to enable many more industries than at present to operate on an efficient and competitive basis and would require the expansion of others. It would also reduce dependence on export markets.

While exports as a proportion of the gross national product will decline — it has been estimated from about 24 per cent to 20 per cent— they will continue to be a major influence in the economy and to offer by far the largest outlet for our basic industries. Canada is essentially a producer of raw and semi-processed goods. These now account for about 85 per cent of our exports. Our economic prospects are in very large part based upon the further development of our natural wealth. As our population increases and as we improve the efficiency of our manufacturing operations, I anticipate a large expansion in manufacturing industries. We must, nevertheless, face the fact that we shall continue to be a major exporter of basic materials. We should process these at home to the extent that we can do so on an economically competitive basis. It would be unsound, however, to restrict the development of our primary industries in order to build up secondary industries which could only be maintained at an unduly high cost to the Canadian economy.

Population Increase

The prospective increase in Canada's population will not only enlarge the market for consumers' goods and services but will also require a capital investment programme of very large proportions. It is anticipated that the population increase will be concentrated very largely in cities and towns. In 1871 less than 20 per cent of the Canadian population was urban; by 1951 the figure rose to more than 57 per cent; the forecast for 1980 is as high as 75 per cent. The implications in terms of requirements for housing and social capital are clear. Enormous sums will have to be invested in the construction of schools, hospitals, roads, water and sewerage systems and other facilities. Provincial-municipal investments in social capital in Ontario alone are estimated at $7 billion to $8 billion over the next decade. In addition to social capital, a continued high rate of housing construction in Canada is inevitable. I have already pointed to the importance of capital investment as a dynamic factor in determining the level of economic activity. The public and private capital investment which will be required to meet the demands of a population and an economy expanding at the rates which have been forecast will, therefore, play a major role in sustaining that economy and stimulating its further expansion.

Long-term Prospects

The long-run economic prospects of Canada are bright indeed. While occasional set-backs must be anticipated and many problems—social, economic, financial, and political— will arise and will require solution, I am confident that they will be faced with the maturity which we are acquiring. We will face them more successfully, however, if we have regard to the fact that the expansion of our economic output is not an end in itself. The end is the improvement and development of our human resources. It is urgent that we keep pace with the technical and scientific requirements of economic growth, and in this the engineer plays a major role. It is also urgent that we concern ourselves with living standards not only in our own country but in other countries, particularly where the masses are only now awakening. The full realization of our economic prospects will not be determined by ourselves alone; events in far-off countries can and will affect us very seriously. Economic self-interest as well as humane considerations make it urgent that we assist more effectively in developing under-developed countries and raising the living standards of the masses of humanity which are still submerged. In the modern world economic prosperity, like peace, is indivisible.

Moving-Bed Processes

E. H. Lebeis, *Catalytic Construction Company, Philadelphia, Pa.*

TWO of the earliest industrial processes which are still in use today are the manufacture of iron in vertical blast furnaces and the calcination of limestone in a vertical shaft kiln. Modern blast furnaces and lime kilns differ from early models primarily in size and mechanical refinements. Basically, the processes and equipment have undergone relatively little change. In recent years, however, the mode of solid-fluid contacting characteristic of these units has been extensively modified to adapt it to other and more complex processes. This paper deals with some of these complex adaptations, which have been termed moving-bed units to distinguish them from simple vertical shaft furnaces.

At the outset, the distinction between moving-bed processes and fluidized-solids processes should be clearly stated. In a moving-bed process relatively large solid particles, generally larger than one-tenth of an inch, gravitate through one or more reaction chambers in essentially straight line flow. In a fluidized-solid process, fine powders are usually fed, and these particles are constantly moved in all directions by the "boiling" action of the fluid stream. This distinction is shown pictorially in Fig. 1 and 2.

In a moving-bed the solids flow at a density slightly lower than the bulk density at repose, whereas in a fluid-bed a larger percentage of voids is created between the particles by "boiling" action. The existence of large gas bubbles in fluid-beds has been well established. Efficiency of contact between solid and gas is hindered by bubble formation.

Probably the biggest difference between the two types of process is the kind of contact achieved between solid and fluid. In a moving-bed process the fluid can flow in a direction opposite to the direction of solids flow as shown at the top of Fig. 1. This is true countercurrent contact. It is also possible to achieve true concurrent flow with both solid and fluid flowing in the same direction, as in the bottom portion of Fig. 1. By inspection of Fig. 2 it is clear that in a fluid-bed the solid and fluid are quite intimately mixed and that the type of contact is neither true countercurrent nor concurrent. If a number of fluid beds are arranged in series, a partial approach to true countercurrent or concurrent contact can be achieved. Providing a number of fluid-beds in series would also minimize the tendency for some of the feed to short-circuit to the discharge points.

In a fluid-bed unit the fluid rate cannot be decreased below the value at which fluidization stops. On the other hand, the fluid rate cannot be increased above the value at which the dust loss is excessive. This means that the gas or liquid feed rate to a fluid-bed unit cannot be varied far from the design value. For many processes, this in turn fixes the solid feed rate within rather narrow limits. In contrast with this, a moving-bed unit can be operated over a wide range of feed rates. It should also be noted that dust losses may be quite high in fluid-bed units operated at design rate; these losses increase rapidly at rates higher than design. Other distinctions between the two processes will become apparent in the course of the discussion.

The moving-bed technique has achieved widest usage in the petroleum field, mainly for the catalytic cracking of selected fractions to produce optimum yields of high quality gasoline. To illustrate some of the features which may be found in a modern moving-bed process, a schematic diagram of a recently erected Houdriflow catalytic cracking unit is shown in Fig. 3. Fig. 4 is a photograph of one of these units shortly before it was placed in operation.

Starting at ground level, catalyst particles are conveyed by a pneumatic lift to the lift disengager at the top of the unit. In the disengager, the particles lose their upward velocity component and fall to the lower portion of the vessel. From the disengager, the catalyst gravitates through a pipe called a seal leg into the top of the reactor vessel. Here the heavy hydrocarbon charge is introduced, part as liquid and part as vapour. The liquid portion is vaporized on contact with the hot catalyst particles. The vaporized feed and catalyst flow vertically downward concurrently at a temperature in the neighborhood of 900 degrees F., with the hydrocarbons cracking and undergoing molecular rearrangement. Carbon is deposited on the catalyst during the cracking operation. The cracked vapours are separated from the solid catalyst at the bottom of the reactor. These vapours flow to distillation equipment for fractionation.

The catalyst particles next flow through a section in which hydrocarbon vapours are stripped or desorbed from the particles by a countercurrent flow of steam. The steam-hydrocarbon mixture flows upward

Read at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada, Montreal, May 1956.

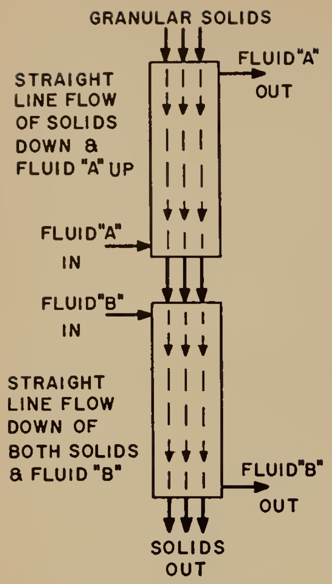

Fig. 1. Moving-bed process

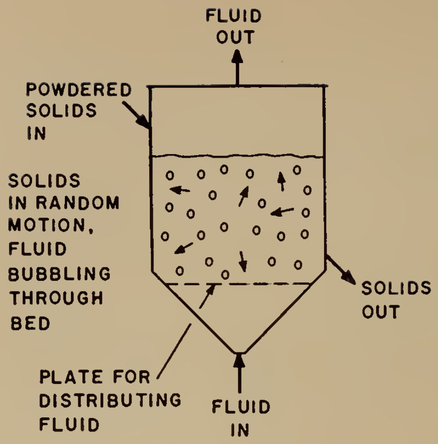

Fig. 2. Fluid bed process

into the bottom of the reactor to join the cracked vapours. From this purge section, the catalyst gravitates through a number of "seal pipes" into the regenerator, or kiln.

In this part of the unit, the carbon deposit formed during the cracking reaction is continuously removed by burning with air at temperatures in the range of 900 degrees to 1100 degrees F. Burning is accomplished in two or more stages, with cooling zones between stages. Cooling is usually accomplished by flowing the catalyst over horizontal coils through which water is pumped at a high rate. The steam generated is used for driving the regeneration air blower and various pumps.

In order to maintain the catalyst in a highly active form, it is imperative that the temperature be kept below a maximum value. The regenerator is engineered so that substantially all of the carbon deposit is removed without exceeding this maximum temperature. Air flow is generally countercurrent to the solids flow in the regenerator, although in some units one or more of the zones may be operated concurrently.

Catalyst leaving the regenerator at about 1100 degrees F. flows into one or more lift engagers whence it is returned to the top of the unit by a hot gas stream. Part of the hot flue gas leaving the regenerator is used for lifting following a moderate amount of recompression in a steam jet thermocompressor. The number of lift pipes employed varies from one to as many as 12, and lift pipe diameters vary from 8 in. to 19 in. I.D., depending upon the size and requirements of the unit. As an indication of lift capacity, 12 in. pipes are usually designed to move about 50-60 tons per hour per pipe.

Despite the rapid recirculation of catalyst through the unit and the high velocities attained in the lift pipes, loss of catalyst by attrition is remarkably small. To prevent choking of the unit with fines, part of the catalyst steam is continuously diverted to an elutriator. Another portion of hot flue gas from the regenerator is used for elutriation. The large particles are returned to the system and the fines rejected. The particle size of the catalyst in the unit is generally beween 0.08 and 0.20 inch, averaging about 0.13 inch.

One of the interesting features of these units is the way in which combustible hydrocarbons and air are handled in adjacent vessels interconnected with piping, containing no valves. The keys here are close attention to pressure balances and the use of steam as a sealing medium.

The hydrocarbons in the reactor are under a pressure of 5 to 10 pounds gauge. The lift disengager contains oxygen-bearing flue gas and, furthermore, is vented to the atmosphere. Steam is introduced at the top of the reactor. Part flows down into the reactor and the major portion flows up the pipe, or seal leg, connecting the disengager and reactor. The quantity of steam is controlled so that the pressure drop of the upflowing steam is always greater than the static pressure in the reactor. This ensures a downflow of steam into the reactor, so that there can be no upflow of hydrocarbon vapours.

A similar steam-sealing system prevents hydrocarbon vapours at the bottom of the reactor from coming in contact with oxygen-bearing flue gas at the top of the kiln. By coupling modern instrumentation with sound engineering design, these steam-sealing systems have been developed to a virtually foolproof point.

The advantages of the moving-bed cracking system can best be illustrated by comparison with the fixed-bed reactor system which it supplanted. In the fixed-bed system, three or more reactor vessels were required. In each reactor the following sequence of operations took place. First, hydrocarbon vapours were admitted for cracking. Then the hydrocarbon flow was stopped and the vessel was purged by evacuation and steaming. Next, air was admitted to regenerate the catalyst by burning off the carbon deposit. After another purging operation, oil vapours were again admitted.

To allow continuous operation, one or more banks of three reactors were used. While one reactor was in cracking service, another was purging, and the third was undergoing regeneration. Complicated piping manifolds and valving were required, together with an ingenious cycle timer for opening and closing valves in such a way that oil and air were never mixed.

Because the cracking reaction absorbs heat and the regeneration reaction liberates heat, molten salt was circulated through tubes in the bed to supply heat during cracking and absorb heat during regeneration. To add to the reactor complexity, other tubes were necessary so that hydrocarbon and air could be admitted to and withdrawn from the vessel.

The moving-bed process made possible great simplification in piping and reactor internals. By circulating the catalyst at a high rate a large amount of heat capacity is available in the solid, so that the heat necessary for cracking and the heat absorption in regeneration can be supplied by relatively small changes in solid temperature. This eliminated the necessity for the molten salt heat transfer system. Among other advantages is the elimination of downtime to empty fixed-bed reactors and recharge with fresh catalyst periodically.

Applicability of The Moving-bed Technique

For convenience the applicability of the moving-bed technique will be discussed under three different categories. These categories are as follows:

1. Systems in which the fluid flow is countercurrent to the solids flow.
2. Systems in which the fluid flow is concurrent with the solids flow.
3. Systems in which the fluid flow is perpendicular to the direction of solids flow, or cross-flow systems.

Countercurrent Systems

The applicability of countercurrent moving-bed systems may be illustrated by analogy with tubular heat exchange systems. Tubular exchangers are operated in counter-flow to achieve the closest temperature approach between the two fluids at one or both ends of the exchanger. This permits the closest approach to the theoretical maximum amount of heat exchange. From a heat transfer standpoint, a countercurrent moving-bed system is directly comparable.

The pebble heater shown in Fig. 5 is an illustration of a countercurrent moving-bed heat exchanger. The pebble heater derives its name from the fact that ceramic pebbles circulating through two moving-bed vessels in series are used to heat gases to very high temperatures above the range where metallic exchangers are feasible. In the upper vessel, the pebbles flow countercurrent to a stream of hot combustion gases admitted at, say, 2400 degrees F. The pebbles are heated to a temperature close to the gas temperature, 2380 degrees F. for example.

The pebbles at this temperature flow into the lower vessel through which the gas to be heated (air in the illustration) flows upward countercurrent to the pebbles. Let us assume that the air enters at 60 degrees F. The air will leave the top of the vessel at a temperature close to the entering pebble temperature, or 2000 degrees F. in the example shown in Fig. 5. The pebbles also closely approach the inlet air temperature and leave the vessel at 200 degrees F. They are then continuously elevated to the top of the unit by mechanical or pneumatic means and fed to the top of the upper vessel.

It can be seen that the solid and gas temperatures approach each other closely at each end of each vessel. Aside from radiation loss the only heat rejected from the system is in the flue gas stream which is shown leaving at 300 degrees F., or 100 degrees F. above the entering pebble temperature. It is clear that the thermal efficiency of the process is extremely high.

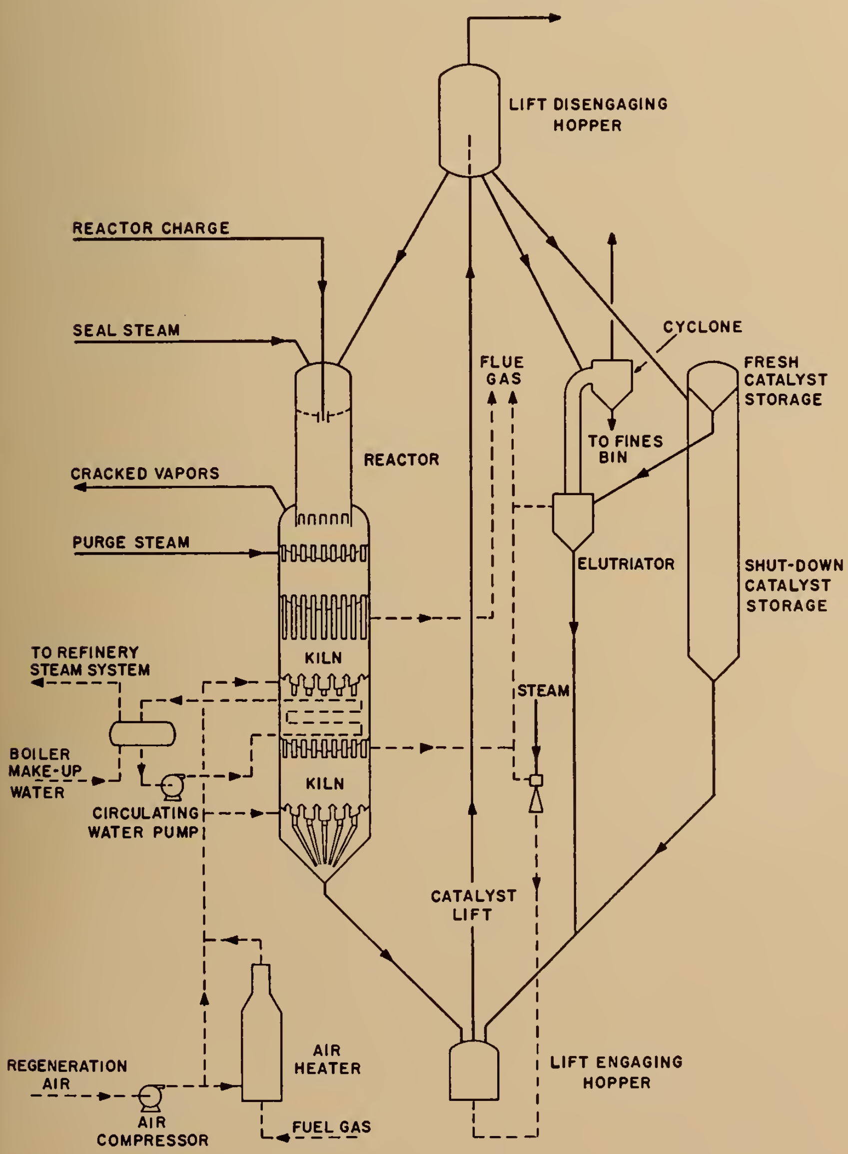
For some processes the most desirable pattern of temperature gradients can be achieved using countercurrent operation. In the heat treating or calcining of catalysts and other solids it is possible to exercise precise control over the maximum temperature reached by the solid by operating countercurrently. In this operation air or air-steam mixtures heated to elevated temperatures are admitted to the bottom of a vertical shaft calciner. The operating conditions are so selected as to make possible very close approach of solid and air temperatures at the bottom of the unit. The maximum solid temperature is thus controlled by the inlet air temperature.

The rate of temperature change of the solid depends upon the ratio of the product of weight flow rate of fluid and specific heat of fluid to the corresponding product for the solid. If this ratio is close to 1.0 the rate of solids temperature change will be very gradual, with the solid temperature approaching the gas temperature only near the bottom of the contacting zone. This is illustrated in Fig. 6.

If, on the other hand, a high weight ratio of gas to solids is employed, the solids will be heated very rapidly and will remain at a temperature close to the gas temperature throughout most of the contact zone, as shown in Fig. 7.

The temperature profile most desirable for the system can be established by selecting the proper "heat capacity" ratio. In many cases involving gases and solids, the specific heats of the two phases are essentially equal, so that the weight ratio of the two streams can often be used.

Fig. 3. Flow diagram of Houdriflow catalytic cracking process.



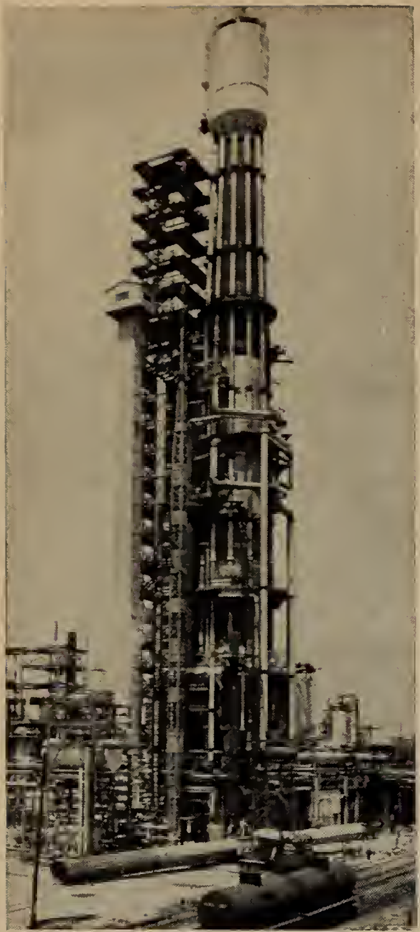


Fig. 4. A Houdriflow catalytic cracking unit.

When mass is transferred in countercurrent systems, concentration gradient patterns are established which are similar to the temperature gradient patterns in counterflow heat exchange. The same advantage accrues: the closest approach to the maximum possible amount of mass transfer is achieved. This advantage of countercurrent moving beds is utilized in Hypersorption units and moving-bed ion exchange units. In these cases, the last contact of the effluent fluid is with a solid which is freshly "regenerated" and has the maximum removal capacity. Therefore, the concentration of the component being removed can be reduced to a very low value.

If an ion exchange operation is performed in a fixed-bed, only a small portion of the bed is in actual use at any instant. The zone of "active solids" moves through the bed. As this imaginary zone approaches the effluent end of the apparatus, the efficiency falls off and increasing amounts of unwanted components appear in the product. To avoid excessive product contamination, it is necessary to switch over to a freshly regenerated bed.

By contrast, all of the bed is in use in a moving-bed unit. Efficiency is high and the composition of the liquid effluent is unvarying.

In the regenerators of Houdriflow catalytic cracking units, mass transfer, heat transfer, and generation of heat within the solid occur simultaneously. Countercurrent contact enables very close control over temperatures in this case.

The factors of prime importance are carbon concentration on the catalyst, oxygen concentration in the gas, and temperature. The burning rate is directly related to all of these variables. The carbon concentration is at the maximum at the point where the solids enter the regenerator. However, at this level the temperature is lowest and the oxygen concentration is lowest. The latter two factors offset the tendency toward too rapid burning because of the high carbon concentration.

As the solids progress downwards, they contact gas which is progressively richer in oxygen. At the same time, the solid temperature progressively rises because of the heat liberated by combustion. The increase in temperature and oxygen concentration offsets the tendency for the burning rate to fall from the decrease in carbon content. The air admitted to the upper zone is restricted in amount to keep the solid temperature rise within well-defined limits.

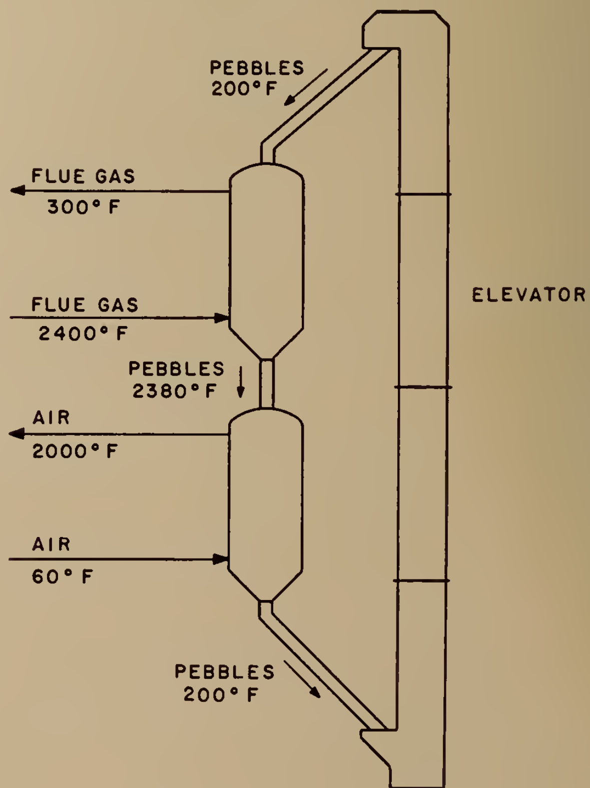
The incompletely burned solids leaving the upper zone flow through a cooling zone. The solids, now at a lower temperature, flow into the lower regenerator zone where the remainder of the carbon is burned off under essentially the same conditions as before. Throughout the entire operation, close control over solid temperature is made possible by the true countercurrent contact of the gas and solid. The same type of control can be achieved in other combustion reactions, such as the roasting of ores and concentrates.

Concurrent Systems

Just as it is sometimes preferable to operate shell and tube heat exchangers in concurrent or parallel flow, it is also sometimes desirable to operate moving-bed units concurrently.

There is no limit to allowable fluid velocity in concurrent flow, whereas in counterflow the fluid velocity is limited to a value below that at which lifting of the solid particles will occur. The corresponding limiting pressure drop is generally of the order of about 8 to 20 inches of water per foot of bed depth. Lifting of the bed occurs when the pressure drop in pounds per square foot per foot equals the solids bulk density in pounds per cubic foot.

Fig. 5. Pebble heater for heating air.



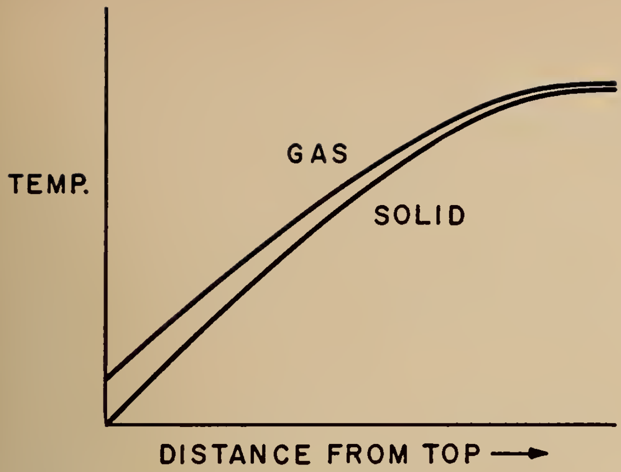


Fig. 6. Heating curve, low gas rate.

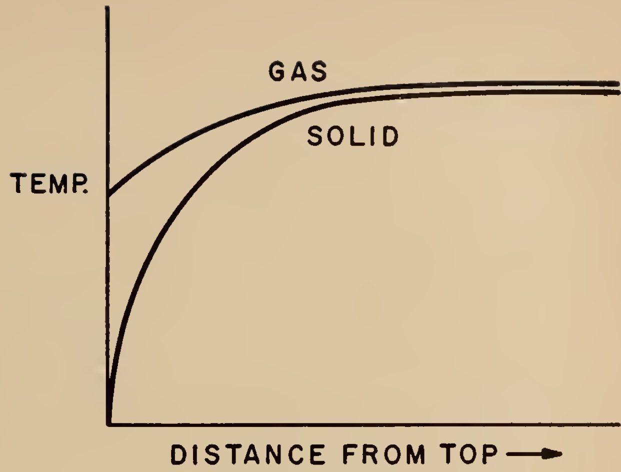

Fig. 7. Heating curve, high gas rate.

Houdriflow units operate with concurrent flow in the reactor. The regenerated catalyst enters the reactor at a temperature in excess of the temperature at which the cracking is to occur. The excess sensible heat content of the catalyst is used to vaporize the liquid portion of the feed. If, as in earlier cracking units, the reactor is arranged for counterflow, all of the feed must be in the vapour state. In the concurrent scheme, vaporization of liquid feed in the reactor has the advantages of removing part of the cooling load from the regenerator and removing some of the heating load from the feed preparation system.

Cross-flow Systems

The cross-flow technique has been utilized on a commercial scale to a limited extent, mainly for drying. A large-scale installation for the drying of clay catalyst pellets has been described which employed the cross-flow technique because large volumes of water had to be evaporated into the drying air stream and it was not possible to evaporate this quantity of water with countercurrent or concurrent flow. The difficulty here is that the drying air is cooled by the evaporation of the water. The more the air is cooled the lower its saturation humidity becomes. By blowing air through a number of cross-flow units in parallel it was possible to evaporate a large quantity of water at the rather low temperature level required to produce catalyst of satisfactory physical properties.

In this installation, the drying air was blown horizontally through the downwardly gravitating solids. The solids were confined by louvres to beds which were rather thin in the direction of air flow.

Limitations

In this section some of the limitations which must be considered in determining the applicability of the moving-bed technique to a new process will be outlined.

Solid Properties

One of the first solid properties which should be considered is particle size. Moving-bed units can be designed to process very small or very large particles. The factor which plays the biggest part in determining the optimum particle size is fluid pressure drop. Fluid pressure drop is an inverse exponential function of particle diameter. The power required to move the fluid through the bed increases, in turn, with pressure drop. In order to keep power costs low, it is obvious that the particle size should be as large as possible.

In many cases, pelleting or other preforming operations are indicated for fine materials. Several techniques are available — briquetting, extrusion and nodulizing in drums or pans. In some cases, more expensive casting or tableting procedures can be justified. There has been a large growth in the use of pelleting techniques in recent years, with the result that a variety of dependable equipment is now available. Low cost binders, such as those derived from sulphite waste liquors, are available in quantity. Pellets formed by any of these techniques are quite porous, so that mass transfer into and out of pellets is usually not unduly hindered by aggregation.

It is desirable that the range of particle sizes be kept as small as possible in order to avoid segregation problems. This is ordinarily not too burdensome a limitation, especially if the feed is pelleted.

The solids must have sufficient strength to pass through the unit without undue breakdown or attrition. Fortunately, the pressures exerted upon a particle are not large and the solids velocity in the gravitating bed is usually quite low, often being measured in inches per minute. Many materials which would be too weak to withstand repeated recirculation, as in a catalytic cracking unit, can be processed in a once-through operation with little breakdown. If some fines are formed they are generally trapped between the larger particles so that the loss in effluent gas streams is low. If rapid temperature or composition changes will occur, it is important to determine that these will not result in excessive breakage.

Temperature

This factor can affect the investment cost of a moving-bed unit quite markedly. The devices for engaging and disengaging gases are generally fabricated of metal. As the operating temperature is raised, the allowable stress decreases and costs increase. Above about 1400-1500 degrees F., refractory construction will usually be more economical.

The walls of high-temperature units are generally lined with firebrick or castable refractory and no particular problems are encountered here.

Pressure

Although moving-bed catalytic reforming units have been designed to operate at several hundred pounds pressure, fewer complications are involved at low or moderate pressure levels. Since the feed will enter and the product will leave at atmospheric pressure, sealing devices must be provided to maintain the desired pressure within the unit. At low pressure levels, this is easily accomplished by the use of fluid seals of the type described earlier. At higher pressure levels, longer seal legs and/or more sealing fluid is required. At some point it becomes more economical to use mechanical sealing devices such as lock hoppers or rotary valves.

Heat Transfer

If strongly exothermic or endothermic reactions are involved, heat transfer problems may arise. Heat may be added or removed by flowing the solids over horizontal tubes, preferably staggered at adjacent levels. The overall heat transfer coefficients from the bulk solid to the tube are in the neighborhood of 15 B.t.u. per hour, square foot of exchanger surface, degree Fahrenheit.

If the heat transfer surfaces are oriented vertically, the mixing effect of the staggered tubes is lost. In this case, heat transfer coefficients of the order of 5 to 10 B.t.u./(hr.)(sq. ft.) (degree F.) are obtained.

If a substantial portion of the heat addition or removal is by a change in the heat content of the solids, the specific heat of the solids becomes a factor of importance. The specific heats of solids vary widely on a weight basis. However, the specific heat is generally inversely proportional to the density, so that specific heats are remarkably constant on a volume basis. The volumetric specific heat of most solids will fall between 15 and 30 B.t.u./(cu. ft.) (degree F.).

This means that with a reactor of given volume and a process which requires a certain residence time, relatively little change in heat absorption or liberation by the solids can be achieved by changing the solid composition. However, the heat change of the solids can be increased by adding an inert diluent provided the reactor volume is increased to maintain the required residence time for the active material.

Considerable heat can be absorbed or given off by the fluid stream. In order to handle high fluid mass rates, a compromise design must be developed which considers both pressure drop and fluid flow distribution. It is possible to lower pressure drop by increasing the bed diameter and decreasing bed height. At the same time, this gives the fluid more opportunity to channel through certain parts of the bed. It is advisable that the bed depth be at least equal to the bed diameter to avoid channelling problems.

History

As mentioned earlier, blast furnaces and vertical shaft lime kilns have a long history. The gas producer has also been in use for many years. It was not until the late 1930's that the moving-bed technique was adapted to the first of many petroleum industry applications. The Thermofor kiln was developed in 1939 by Socony-Vacuum Oil Company for the regeneration of percolation clay used in oil refining. In 1942 the Thermofor catalytic cracking process was commercialized. The Houdriflow process described earlier is an outgrowth of the Thermofor process. Among the many process refinements which it incorporated was the substitution of pneumatic lifts for the bucket elevators used in the early units. The pneumatic lift was also adopted by Socony in its TCC Airlift design.

The pebble heater for high temperature heat exchange applications was developed in 1946. The pebble heater has been proposed for a number of processes, including the pyrolysis of selected hydrocarbon fractions to obtain valuable products such as acetylene.

In 1946 the moving-bed technique was adapted to an adsorption process for the separation of light hydrocarbon gases. In this Hypersorption process, activated carbon is circulated through the unit and recirculated by a pneumatic lift.

A moving-bed coking process has been developed which is novel in that the petroleum coke formed in the reaction is deposited on a circulating stream of coke particles. The rate of withdrawal of coke from the unit is balanced against the production so that a constant inventory results.

Several moving-bed catalytic reforming processes for the upgrading of selected gasoline fractions have been developed in the past several years.

Moving-bed catalytic cracking, as exemplified by the Houdriflow unit described earlier and by Socony TCC Airlift units, has enjoyed the greatest commercial success. About 100 moving-bed crackers are in operation, processing a total well in excess of one million barrels of feed per day. The largest of these units has a feed rate of 27,000 barrels per day (35 Imperial gallons per barrel). Two units are installed in Canada, one with a daily feed rate of 16,000 barrels and one with a daily rate of 11,500 barrels.

Outside of the petroleum field, moving-bed applications have been relatively few to date. Shaft furnaces have interested metallurgists for many years. Much research has gone into their utilization in such fields as the production of sponge iron. This process was brought to commercialization by Wiberg in Sweden in 1941 after 20 years of development.

Beneficiation of low grade iron ores has been given intensive study in recent years. It is reported that Erie Mining Company will utilize the moving-bed principle for hardening 20,000 tons per day of pelleted taconite concentrate. This decision was apparently dictated primarily by the extremely high heat economy that can be achieved.

Future Applications

One of the deterrents to wider use of the moving-bed technique has been insufficient knowledge concerning the fundamentals of solids flow, especially in the presence of gases or liquids. In a number of cases experimental work on promising moving-bed applications has been terminated prematurely for this very reason. An impressive amount of information has been accumulated in the field of solids flow in recent years, so this is no longer an obstacle. In addition, new materials of construction and new instruments can make feasible many processes which formerly defied commercialization.

One of the very promising fields is ion exchange. This unit operation has grown by leaps and bounds in recent years. Because true countercurrent contact affords so much advantage over conventional fixed-bed operation, it is probable that many installations will be converted over to moving-bed operation. This has received a lot of study, especially in the field of extractive metallurgy.

Another promising field is pyrometallurgy. Because of the high degree of heat economy and temperature control achievable in moving-beds, a large increase in the use of moving-bed roasters of various sorts is foreseen.

Last, but not least, a host of chemical and metallurgical reactions involving solids and fluids will be adapted to moving-bed processing. Oxidation, reduction, halogenation, dehalogenation, and decomposition are a few of the chemical reactions for which the technique is admirably suited.

Geothermal Energy

With Special Reference to New Zealand

NUMEROUS people have suggested that use should be made of the heat resources of the New Zealand thermal area, and two papers, in the early thirties, dealt with the matter in some detail outlining "the future of the recent developments in the utilization of subterranean heat, with a view to emphasizing the great possibilities of this source of natural energy." They reviewed the use made of thermal heat in Iceland, at Larderello in Italy, and in California.

In a later publication, about 1943, it was suggested that subterranean heat might possibly be experimented with on a comparatively small scale as a commencement in some of the following directions:

(1) Heating of glasshouses, production and ripening of out-of-season vegetable, salad and fruit crops.

(2) Heating of soil in frames, Dutch lights, open beds and tree nursery beds.

(3) Heating of homes and buildings as well as for various other domestic purposes, such as laundering, baking, and home drying of vegetables and fruit, etc.

(4) For dehydration and drying, including the drying of timber, wood pulp, eggs, wool, meat, milk, vegetables, fruit, fertilizers and manures.

(5) The recovery from natural steam or hot springs on a small scale of certain chemicals and gases, e.g., sulphur, boric acid and carbon dioxide.

(6) Production of power in a small way for purposes of study. A small geothermal plant would answer this purpose.

(7) The use of natural heat sources near the sea for evaporation of salt water to make salt.

(8) Heat processes for the synthetic production of phosphatic fertilizers.

Developments in Italy

The geothermal area in Tuscany occupies some hundred square miles to the south of Pisa on the west coast of Italy. Powerful steam jets (soffioni) occur and form, by condensation, pools of water known as lagoni. The lagoni contain boric acid, which has been exploited commercially since early last century. Bruce and Shorland state, "Towards the end of the eighteenth century attempts were made to recover the boric acid by evaporating the lagoni waters with the aid of ordinary fuel. In 1827 Larderello greatly improved the method by employing the steam from the soffioni to evaporate boric acid."

A condensed version of an address by W. M. Hamilton, D.Sc., assistant secretary of the New Zealand Department of Scientific and Industrial Research, to the Cawthron Institute, Nelson, N.Z.; published here through the courtesy of the author and of the *New Zealand Electrical Journal.*

Following 1899 Prince Ginori Conti made a substantial advance by sinking wells to tap the steam at depth. The recovery of boric acid developed into a large-scale industry and was the chief source of the world's supply for nearly a century.

Conti showed "as early as 1904 that cylinder steam engines could be worked directly from the soffioni steam with entirely satisfactory results." In 1913 the first steam turbine, driving an electric generator of 250 kw., was installed at Larderello. About 1916 three units, each of 3,000 kw., were added.

At the end of 1944 the installations for electric powered generation totalled 135,000 kw. and the total output of electric energy in 1943 was 908 million kwh.

During the retreat of the German forces through Italy the installations at Larderello were wrecked and many of the wells destroyed. Since the end of the war the area has been vigorously redeveloped with improved techniques.

Progress in Iceland

Some use of the natural hot waters from the thermal areas in Iceland has been made from the earliest times because of the great scarcity of fuel. A small thermal area on the outskirts of Reykjavik has been used for laundering from the earliest times, and this was also the first area to be harnessed for hot water reticulation. The system of hot water reticulation now in use was conceived in 1928, when the city water board suggested that the nearby volcanic springs should be used for central heating. A small scheme installed at this time proved a success and a much larger scheme was commenced in 1934.

The nearest source of sufficient size lay at Mosfellssveit, about ten miles to the east of Reykjavik. The natural flow being about 1,320 g.p.m. this was augmented by boring operations. The diameter of the holes ranges from 4 in. to 8 in. and the borings, which cover an area of less than 160 acres, descend to 450 to 1,200 ft. Boring not only increased the flow but also increased the average temperature of the water from 80° C. to 87° C. The wells are cased for only 7 to 10 ft., the casing being suitably secured to a concrete anchor-block. The water is piped to insulated holding tanks from which pumps deliver it through two 14 in. insulated pipes to the main holding tanks above the city. From these holding tanks there is gravity feed to the city, with booster pumps brought into action when the load is heavy. The temperature drop from the springs to the consumer is only 5° to 6° C.

Extensive use is also made of natural heat for greenhouses for growing vegetables, flowers and fruit.

Developments in New Zealand

At various times during the thirties there were discussions on the possibility of utilizing natural heat in the thermal areas and an investigation was considered by the Council of Scientific and Industrial Research early in 1940. They recommended that steps be taken to investigate the problem of utilizing natural heat. S. H. Wilson of the Dominion Laboratory surveyed the possibilities and thought the most promising outlet for volcanic steam would be for power generation. At that time, however, it was considered that the North Island was well provided with water resources for power generation and there was little need to consider the possibility of natural heat power generation for some considerable time.

At the same time in Rotorua, where heated ground water could be tapped at relatively shallow depths, a number of wells had been sunk for space heating and hot water services. Modriniak estimated that in 1944 fifty wells had been sunk in the Rotorua area for this purpose and this number has now greatly increased.

Approval for a general programme of investigation in the thermal area was given in 1946. Arrangements were also made for engineer officers of the armed forces in Italy and Japan to collect all information available on the utilization of thermal resources in those countries.

It also became evident that the demand for electric power was growing more rapidly than had been realized and that the hydro-electric resources of the North Island would, within the foreseeable future, be inadequate to meet the rising demand. With this in mind the present Commissioner of Works and the Director of the Geological Survey visited Larderello in Italy in 1948 to examine developments there. Following the return of the Director of the Geological Survey, a meeting was held to formulate a programme of investigation on geothermal power and a small inter-departmental committee was established to supervise the general programme and policy associated with the investigations of geothermal energy in New Zealand.

A programme estimated to take five years was drawn up and the programme was approved by Cabinet in November 1949. Before it became fully operative, however, as the power situation became more pressing, it was decided that the search for geothermal steam should be speeded up and that exploratory drilling should be undertaken simultaneously with the scientific investigations. With this in mind it was decided to concentrate the scientific effort on an area approximately 13 miles square at Wairakei, since this seemed one of the most promising areas.

Steam Production

The heat escaping at the surface in the Wairakei zone is assumed to have its origin in a mass of intruded cooling magma at depth. The steam and gases given off from the magma rise through fissures in the basement greywacke into the more permeable volcanics filling the graben. As yet we have no evidence of what type of beds fill the graben below the ignimbrite sheet into the permeable Huka beds above. These permeable surface beds are saturated with ordinary ground water which is heated by the rising steam and gases. The number or location of the feeding fissures from the magma below is not known, but the hottest areas at the surface appear to be associated with northeast trending faults.

Chemical analysis of the geothermal steam and waters for various constituents enables deductions to be made concerning the ultimate source of the steam and the layers through which it has passed. Practical problems associated with the utilization of the steam also require determination of the amounts of gas remaining after condensation and of constituents likely to be corrosive to turbines and valves.

Comparison With Larderello

The geological conditions at Wairakei differ substantially from those at Larderello. At Larderello the magmatic steam is trapped under an impermeable cap rock. Surface temperatures are low until the drill nears the lower edge of the confining rock cap. The steam produced is dry and often with a substantial degree of superheat. At Wairakei, drilling takes place through beds of permeable volcanic material at temperatures approaching the boiling point for depth, thus adding substantially to the difficulties of drilling.

It is now clear that production of natural steam at Wairakei may be possible from three entirely different types of sub-surface accumulations:

(1) Production, as at present, from the surface layer of permeable volcanics.

(2) Production from a permeable layer below a cap rock structure, if such can be located. This condition might be realized near the west end or in the vinicity of Karapiti.

(3) Production from the deeper rocks lying between the ignimbrite sheet and the greywacke basement.

Only the first of these possibilities has so far been explored.

Utilization of Steam

The demand for electric power in the North Island has been increasing rapidly in recent years. Even with restrictions in force during the war and post-war period consumption doubled in ten years. With removal of restrictions the growth of demand has been much more rapid and it is obvious that the limit of hydro-electric capacity to meet the demand will be reached within the next decade unless restrictions are again applied.

The urgency in geothermal development has therefore been to evaluate its role in the future power supply situation. To this has been added the request from the United Kingdom that the possibility of producing heavy water in conjunction with power development should be considered.

Power Potential

As mentioned the production of natural steam at Wairakei may be possible from three different types of sub-surface accumulations. At the present time we are using only the heated ground water from the surface layer of permeable volcanics and on this basis it is conservatively estimated that the central area at Wairakei can provide the equivalent of approximately 33,000 kw. of power from shallow bores, and including flash recovery, the estimated power production is 62,600 kw. By harnessing other areas in the Wairakei vicinity it is estimated that a further 72,000 kw. could be obtained, making a total for the Wairakei area of approximately 134,600 kw. The full utilization of geothermal resources at Wairakei would almost certainly

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

DOCTORS AND ENGINEERS STUDY BONE AND METAL SPLINTS

Electrical Engineering, 1956, v. 75, n. 2, February, p. 209.

Two Yale faculty members, one a medical authority on bones and the second an engineering expert, have joined forces in a unique study of "bone engineering".

The materials used in studying the problem of splints are bone and metal. Bone splints in use today are made of vitallium or stainless steel, and are fastened to bones by screws inserted in holes drilled into the bone on opposite sides of the fracture.

But, few doctors are convinced of the complete success of this type of operation. It has been found in the engineering lab that drilling holes in bones reduces strength by as much as one third.

Supported by a grant from the Erdle-Prange Foundation, the study of bone and of metal behaviour is being made. In the laboratory of the civil engineering department, bones are subjected to a variety of tests, before and after drilling, to determine the inherent strengths.

University civil engineers and medical researchers have also found that it is extremely difficult to design and install a bone splint which can absorb the same stresses as the bone to which it is attached. For example, a person standing on one leg imposes on the corresponding hip joint a weight two and a half times his body weight; thus, a 200-pound mant standing on his right foot bears 500 pounds on his right hip. This is because of "body engineering" with various interconnections between the bones and muscles of the body.

The bones of the leg have a safety factor of about 30; that is, they will withstand pressures 30 times those caused in normal use, so that designing and installing a lightweight brace with the same safety factor is not easy.

"Bones are remarkable structures as far as design goes," says the Yale doctor, "and nature won't let you tamper with them to any great extent." But even with their remarkable "economy of design", bones fortunately are the strongest where the pressures on them are the greatest.

However, bones pose engineering problems of no small scale. Bone substance has an amazing amount of flexibility—up to a point. Beyond that point bones are exceedingly brittle. Then too, if abnormal constricting pressures are applied to the bone, it disintegrates in a very short time.

Thus, any type of splint must be applied only on one side of the bone —and this increases the difficulty of designing splints strong enough to provide the needed support, yet light enough to avoid complications. Engineering investigations found, for example, that narrowing the centre section of a particular splint weakens it severely, but routing out the centre section of the same splint actually strengthens it.

The Yale doctors and engineers have also found that if the screws used to fasten the splint to the bone are small enough to avoid weakening the bone appreciably, they may be too small to withstand normal pressures.

The problem of bone splinting is one that cannot be ignored or avoided, because bone splints are necessary on fractures requiring considerable length of time to heal. A fracture of the thigh bone may require as much as six months to one year to heal completely; if the entire limb is enclosed in a cast for that length of time, permanent stiffness is a "definite possibility".

Casts probably will always be used for some fractures, especially minor ones, but more serious fractures do require bone splints for successful healing.

A SIMPLE RELIABLE IMPACT TEST

Modern Plastics, 1956, v.33, n. 8, April, p. 149.

For years the designer of load-bearing parts has had almost no fundamental data on which to base a choice of materials for impact service. Now an inexpensive, simple, unambiguous tensile-impact test is available, which uses standard Izod equipment modified to hold a variety of specimens so that they are tested in pure tension rather than bending. Both stiff and limp materials may be tested.

Notched-Izod is Traditional

The notched-Izod test, popular because the required apparatus is relatively inexpensive, has long been accepted for testing metals. However, the design of metal parts is usually based on keeping the metal within its elastic limit; a slight degree of plastic flow is often fatal. Thus elastic modulus and yield strength, on the basis of weight of material used, are far more important design criteria for metals than notched-Izod (or other) impact measurements.

As plastics came into use, they were not used for structural parts of bridges, buildings, and heavy machinery because they had insufficient rigidity per unit cost. They did, however, find wide acceptance in housewares, toys, machine parts, electrical apparatus, and packaging. In these uses they were often subject to severe and sudden mechanical loads, and soon the notched-Izod test was in wide use as almost the only official measure of impact strength for plastics. Another measure is the area under the stress-strain curve in the standard tensile test. But plastics are very sensitive to the time rate at which the load is applied, and the standard tensile test is run at a rate of loading thousands of times lower than is encountered in normal service impacts. The Izod test offered the advantage of applying load at a reasonably high rate.

Izod not Reliable

It was soon realized that the results of this test and the actual field performance of plastic materials under impact loads corresponded only coincidentally. But, any high-rate test is better than none, so notched-Izod has continued in wide use as a basis of design even though it estimates an ill-defined and changeable combination of material properties. Mostly it appears to measure the notch-sensitivity of materials under the influence of a high-rate, three-dimensional system of assorted stresses. For the more flexible materials, like polyethylene, the test is meaningless since these materials are not broken, but twist aside and escape the brunt of the impact.

Basis of New Test

Most impact failures begin because somewhere in the specimen there is a too-high tensile stress. Thus, we should attempt to measure the ability of plastics to withstand sudden tensile loads. This kind of measurement would have the additional advantage that, since more is known about the analysis of tensile stresses than any other kind, the results would be more widely applicable to objects of various shapes. Apparatus to do this has been built but it is expensive and complicated. Test pieces must be carefully prepared in a particular shape, and testing is relatively slow.

Measures Impact in Tension

The new tensile-impact test changes all this. At the Cleveland S.P.E. meeting, Dr. Chester Bragaw (Du Pont Polychemicals Dept.) showed how anyone can alter Izod equipment to make impact measurements in pure tension. The new method also permits the tester to measure notch-sensitivity directly. A wide variety of shapes may be tested and specimens can be moulded, cut from sheets, machined from rods, or cut out of commercial products. Materials need not be stiff. In thin-film form they may be tested by cutting a number of strips from the film and stacking them together for the impact blow. The gauge-length and cross-sectional area under stress of the test specimen are accurately known, and the stress has the same value over the entire cross-section being stressed.

Results indicate that tensile-impact measurements correspond well with failure of various plastics in several types of impact service.

COMMERCIAL HIGH OCTANES FROM COAL

Chemical Engineering, 1956, v. 63, n. 2, February, p. 130.

The world's first commercial plant for making high-octane gasoline from coal has started up near Vereenining, South Africa. Representing the first large-scale use of the M. W. Kellogg fluidized-bed version of the Fischer-Tropsch process, the plant is owned by the South African government's SASOL organization, bent on freeing the country from dependence on foreign petroleum. The plant will produce 55 million gal. per year, one-sixth of the country's requirements.

Justification for the $90 million spent on the project rests on economic as well as strategic grounds. From thick seams of coal at shallow depths located 1½ miles away, raw material can be delivered to the plant at a remarkably low 70c per ton. And Kellogg claims economic advantages for its process over other versions of Fischer-Tropsch: the high octane of its gasoline product; high over-all conversion efficiency; lower initial investment.

The Kellogg process uses powdered iron catalyst which, after separation from reaction products, is recycled to the fluidizers. Catalysis products are recovered, separated and purified by conventional oil refining techniques. Interestingly, light hydrocarbons recovered are in so little demand in South Africa that they are reformed to carbon monoxide and hydrogen (with steam and a nickel catalyst), then recycled to the fluid unit.

Besides the Kellogg fluidized-bed reactor, a fixed-bed unit—the new German Arge version of Fischer-Tropsch—has been installed at SASOL. However, its main product is high-boiling wax for export. Because high octane gasoline is South Africa's main concern, the Arge unit hasn't yet been started up. Both the fluidized and fixed-bed processes give diesel oil as a minor product.

High-purity oxygen is made in six Linde-units—1,800 tons per day total. At full production, 3,200 tons of coal will be gasified daily in eight Lurgi units to give 4.25 million cu. ft. per hour of purified synthesis gas. Alcohols, ketones, aldehydes and acids are plant by-products which will be consumed domestically.

HOW RUSSIAN PLAN TO HEAT ARCTIC HITS CANADA

The Financial Post, March 3rd, 1956.

Co-author W. R. G. Cameron is an economist who has devoted special study to announced Russian plans to change the northern hemisphere. His article is based on Russian announcements and on the interpretation thereof by Canadian scientists.

Damming of the Ob and Yenisei rivers in northern Russia is now under way to provide water and power for the vast Russian farmlands near the Caspian Sea. Probable completion date is 1975. The Russians also plan to close Bering Strait between Siberia and Alaska, to block off cold arctic waters from the north Pacific. Building of atomic power and heating stations on Arctic islands is also planned to counteract the effect of the added flow of cold water past Canada's eastern seaboard and Europe's west coast once the two dam projects are completed.

Warm winds will blow over Siberia, Alaska and Northwestern Canada, creating millions of acres of new farmlands. But scientists believe the Bering dam will result in an increased flow of arctic water across the top of North America to augment the icy Labrador current down Davis Strait and the Maritimes coast, thus adding to early frosts and storms in the fall, perhaps tying up Halifax and St. John's as winter ports.

Disruption of the delicate climatic balance over Europe by melting of Greenland ice may bring longer more severe winter weather, and bring an estimated five foot rise in the world's ocean levels, flooding parts of London, New York, the Netherlands, and many other Canadian and American coastal lands, and causing a shorter growing season. Implementation of the plan involves three giant steps over a 50-year period.

THE CANADA-INDIA REACTOR

In April 1955, under the Colombo Plan, Canada offered to India a high-powered atomic research and experimental reactor similar to the NRX reactor at Chalk River, Ont. This offer was accepted and, just a year later, an inter-governmental agreement on the project was signed in New Delhi. Costs of the joint enterprise will be shared, Canada contributing some $7.5-million of the total $14-million, and final control of the completed project will pass to the Indian Government.

The reactor will be erected at the government nuclear energy establishment at Trombay, near Bombay, and will be housed in a rotunda consisting of a hermetically sealed steel shell, about 135 ft. high by 120 ft. diameter. Surrounding buildings will contain auxiliary equipment and laboratories.

Canada is designing and providing the reactor and the steel rotunda, and will be responsible for the engineering and erection; most of the construction will be done by Indian contractors and labour.

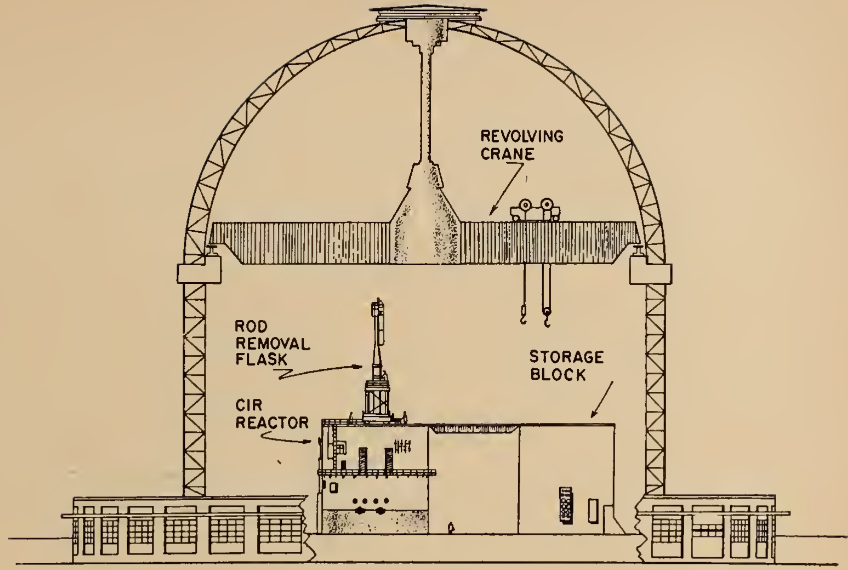
Work is already under way on the foundations and basement of the reactor, and the steel rotunda should be nearly complete by the end of 1956. It is hoped to have the reactor in full operation by the middle of 1958.

Selected Indian scientists and engineers will visit Chalk River for training and experience, under the normal Canadian technical assistance program. First-hand knowledge of reactor operation will be obtained by working with the Canadian design staff.

The Canada-India reactor is designed as a fundamental research tool for nuclear energy, and will produce radioactive isotopes for use in medical therapy, agriculture, and industry, and for tracer element research studies.

In particular, the reactor is specially suited for engineering studies and research on reactor materials, which can be tested under conditions of high neutron intensity. This will enable advanced engineering experiments to be made in connection with the design of future power reactors.

India has offered the experimental facilities of the reactor to approved scientists from other countries, including those belonging to the Colombo Plan in south and south-east Asia.



Cross-sectional diagram of the Canada-India Reactor building and the reactor proper, which is a modified version of the NRX research reactor of A.E.C.L., at Chalk River.

INDUSTRIAL ACCIDENT PREVENTION IN BELGIUM

Though one of the smaller European countries, in area, Belgium is highly industrialized and is well equipped to maintain a proper standard of machine design and industrial safety, to judge by the work of the Association des Industriels de Belgique.

This non-profit organization, which has been operating for over 65 years, has as its aim the supervision of industrial establishments from the point of view of safety from accidents, occupational diseases, and fire. This is carried out by plant visits, literature, instruction with visual aids, training courses, and through physical tests in well-equipped laboratories.

The laboratories can carry out most of the accepted proving methods and investigations in the fields of non-destructive testing, metallography, corrosion, physico - chemical testing, and so on. The mechanical testing equipment is of particular interest to the engineer, and the Association has recently issued an illustrated record of the work that can be done on their large installation (known as G.I.M.E.D.), which is used for dynamic and static tests on large units and structures. Loads may be applied in any direction, and it is possible to obtain complex combinations of static (tension and compression) and vibratory loads by the use of auxiliary equipment. The maximum static single loads obtainable are 300 tons vertically or 200 tons horizontally; fatigue tests may be carried out up to 100 tons (vertically) at 250-500 cycles/sec. The base of the machine is of heavy reinforced concrete with a planned system of anchor-points and fixtures to which the test piece and auxiliary test equipment can be secured.

Some of the tests shown as examples are: simple and complex beam loadings; static and dynamic proof of drill pipe; stresses in concrete structural shapes; multi-directional loading of a pylon; a nine-point dynamic test of a steel rail bogie; and other interesting indications of the work of the Association in this field.

SURPLUS POWER FROM NUCLEAR TEST PLANT

Canadian Isotope Newsletter, 1956, v. 5, n. 4, April

Holyoke, Massachusetts, and Ilion, New York, have contracted to purchase excess electric power from the United States Atomic Energy Commission's prototype submarine reactor at West Milton, N.Y. The municipal hydro systems have to transmit the power from West Milton. They will pay three mills per kilowatt-hour, but no guarantee has been made as to the amount and timing of available power, because of the experimental nature of the West Milton nuclear plant.

BRITAIN'S TECHNOLOGICAL SHORTAGE

EMC-SMC Newsletter, 1956, n. 89, Feb. 14.

Great Britain's Advisory Council on Scientific Policy, through its Committee on Scientific Manpower, has issued a "Report on the Recruitment of Scientists and Engineers by the Engineering Industry" that indicates an earlier appreciation of specialized manpower needs in that country than in the United States. In 1946 the Committee "recommended that the immediate aim of the universities, aided by the University Grants Committee, should be to double their existing output of scientists and technologists. This was in fact achieved by 1950. But the demand continues unabated. Any fears there may have been about the overproduction of scientists and engineers have been completely dispelled by events."

The report reveals that, for all its recruiting efforts, the engineering industry obtained only 75% of the men it needed. Complaints about the caliber of the recruits were numerous, and the decline in the quality of graduates was attributed in part to rapid postwar expansion that enabled the universities to double their output. The impression that quality has been sacrificed to quantity is widespread.

"That there is an urgent need to increase the number of graduates is obvious. The demand for such men is rising all the time with the increase in the general level of industrial activity . . . The gap between supply and demand is thus bound to grow unless the steps now being taken to increase the volume and quality of engineering education become even more vigorous than they are."

The industrial firms surveyed prefer first-degree graduates to men with graduate training, and some expressed the fear that the expansion of university programs and enrolments is merely drawing off the brighter boys who would normally have gone into the student apprentice program and for whom there is equally urgent need in apprenticeships. The Committee on Scientific Manpower reminds industry that, even with the doubled output of graduates, the engineering departments of the universities are not meeting current demand. In appealing to "those who influence the choice of careers, particularly parents and masters," to steer more young people into industrial science and technology, the Committee reveals that it has not succeeded in discovering any sure way of closing the gap between supply and demand.

Cross Suspension System, Kemano-Kitimat

Transmission Line *(continued from page 910)*

were set. This degree of accuracy was necessary as the wire rope lengths had to be calculated, measured, cut and socketted to ±0.1 foot if the system was to be placed in space with sufficient accuracy and if the tensions in the almost parallel pairs of ropes were to be close to designed values.

Once the anchorage rock was proven and the anchor positions established, the anchorage working lines and the saddle locations were tied into the grid and this data was used to calculate the rope lengths.

After completion of the project, the erected system was re-surveyed to determine the "as built" condition and the bridle plates at each end of the catwalk were found to be within 15 inches of their designed locations.

The cross suspension system has been observed closely during the eight months that it has been in service. It has behaved in a very docile manner through what was apparently a normally severe winter. Observations were made several times of its reaction when large amounts of heavy rime fell from the conductors. The conductors bounced in a completely normal manner and the system vibrations died away in a minute or two.

Acknowledgments

The Saguenay-Kitimat Company, a subsidiary of the Aluminum Company of Canada, were the general contractors, Mr. F. T. Matthias, General Manager and Mr. W. Richards, Field Superintendent.

The erection of the cross suspension ropes was contracted to the Dominion Bridge Company, Limited and carried out by their erection department at Vancouver, Mr. H. Minshall, Erection Manager and Mr. R. Harris, Erection Engineer.

Dr. D. B. Steinman, Consulting Engineer of New York City, N.Y., was consultant on the design of the suspension system and supervised the construction and test programme of the model.

Engineering and construction were under the direction of Mr. J. S. Kendrick and the writer was responsible for the project design.

Geothermal Energy

(coninued from page 922)

cause all surface thermal activity to cease, as it has at Larderello.

These estimates are based on obtaining maximum yields from the surface layer of permeable volcanics. The possibility still remains that if drier steam could be obtained from beneath a cap rock structure, if such can be located, or from deeper sources beneath the ignimbrite sheet, then the above estimates might be substantially increased, though to what degree must remain a matter of speculation until test wells have been drilled.

On the basis of experience at Wairakei a careful estimate has been made of the present natural heat escape from other thermal areas. Including flash recovery from the hot water these could run to an estimated 475,000 kw.

However, unless production greatly exceeds current estimates, geothermal energy cannot provide sufficient power to satisfy the long-term requirements of the North Island. Eventually they must look to steam generating stations, nuclear power or other sources to meet the rapidly rising demand for electricity, a demand which on past experience doubles in less than ten years. This is not to belittle the contribution which geothermal power can make. Its full utilization, as an alternative to coal-fired generating stations may well mean a saving of £5 million per annum. It represents a resource of high potential value. Its possibilities should be explored resolutely and boldly.

DISCUSSION

The editor invites discussion of papers appearing in the Journal.

Readers may contribute to this section by sending appropriate comments to the editorial office.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Progress By Ontario Hydro

Construction work on Ontario Hydro's half of the St. Lawrence Power Project geared up during May for peak summer operations. In the month, activity had been hampered somewhat by extensive rains and frost coming out of the ground. However, in this period, contractors started moving more equipment on to various sections of the development, ready for speeding up of construction activity. Work on the power-house section proceeded with scarcely any interruptions, despite the unfavourable weather conditions during the month.

A total of 100,000 cubic yards of concrete had been placed by the month end in the north sector of the power-house area in the "U" abutment, wing wall, and No. 1 ice sluice sections. The structure was 35 per cent completed. Rock foundation had been prepared for No. 2 ice sluice and for No. 1 generating unit. Excavation of earth had been carried out in the top lift right to the international boundary.

During the month, work was resumed on Cornwall dike, No. 2 highway, and on channel dredging operations, after the winter shutdown. Meanwhile, scrapers commenced work on the west end of the diversion canal, beginning full-scale excavations in that area. In the main part of Cornwall dike, now 12 per cent complete, the contractor had pumped out last season's excavations which were dried sufficiently to permit work over them.

Several houses had been moved from the north end of the dike area to give free access to the contractor for extending the dike structure. The entire fleet of scrapers was completing the stripping and resuming dike building between the present Canadian National Railway line, now 66 per cent complete, and old No. 2 highway. Concrete placing had started in the dike closure structure. Stripping also had commenced in the power-house sector of the dike.

Work commenced in May on the second section of No. 2 highway from Moulinette area west to the vicinity of Dickinson's Landing. This consisted mainly of fencing the right-of-way and in grubbing, in preparation for grading. In the third sector of the new highway from Dickinson's Landing west to the county road north of Aultsville, clearing had begun.

At the beginning of the month, two dredges were back for channel improvement work in the vicinity of Spencer Island and a third was in position. On Galop Island, excavation work continued and the contractor was concentrating on rock removal in the northwest section of the island. Building of the upstream rock dikes also was in progress in that section.

House moving operations in Iroquois were suspended for part of May because of soft ground conditions. Progress was made however on sidewalk building and construction of permanent roads. Erection of the new community's water tank proceeded favourably.

Sewer and water main installations in new towns No. 1 and 2 progressed well during May. In town No. 2, installation of the power distribution system was completed. During the month, in Mille Roches and in Moulinette, preparations advanced for the early moving of houses to new town No. 2 site.

Throughout the month, construction progress was affected considerably over the entire project because of the wet conditions. The work force during May was increased to a total of 3,400 employees.

Progress by NYSPA

May progress was keyed to concrete placement operations as four major structures rose from solid rock

Barnhart power plant. This general view of the power-house construction shows the curving draft tube forms being assembled.

foundations reached after months of excavation below river level. Concrete in place at end of May exceeded a quarter of a million cubic yards. Some sixteen and one-half million cubic yards of material had been removed and excavation operations began tapering off in structure areas. With expanding construction operations demands for manpower had increased employment to 4,700.

Final stage excavation at Barnhart power-house and clean up of rock for the eight units at its south end moved toward completion. Form work, placement of reinforcement and concreting operations continued in the intake structure and ice sluice. Draft tube base slabs had been poured for 8 of the 16 units.

At Long Sault dam, with structure 27 per cent completed, the rising structure of the 275-ton permanent gantry crane and placing of concrete in piers give a preview of the completed structure's impressive size. Concrete in place exceeded 100,000 cubic yards, and compacted backfill was being placed behind abutment and wingwall. Excavation at Cut "F" was more than two-thirds complete as four million cubic yards had been removed.

Piers were increasing in number at Iroquois dam as forms were transferred to new locations and placing of concrete continued; the structure was 39 per cent completed. Consolidation foundation grouting for Stage 1 was completed. Excavation equipment was creating a new channel for the river with removal of two and one-half million cubic yards of material through May.

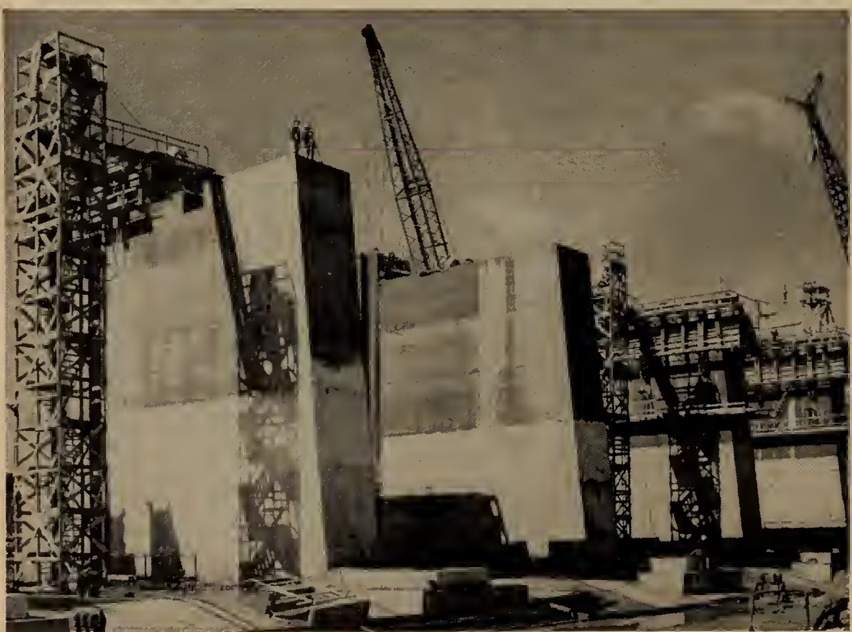
Concrete placement at Massena intake continued as the structure took shape in what was formerly a muddy excavation far below the river. To the end of May, 25,000 cubic yards of concrete had been placed. Water facilities for Alcoa and Massena progressed as grading of the right of way moved forward and large sections of pipe were distributed along the bank of the canal. With concrete deck and sidewalks in place, the Grass River bridge was opened for traffic.

With excavation approximately 20 per cent completed, work continued on five channel improvement contracts requiring the moving of 35 million cubic yards of material. Work was started on the Waddington sewage disposal system as required by one of the major channel improvement contracts.

Surveys for the Barnhart- Plattsburgh transmission line were progressing. The Massena town beach and recreation area near Louisville Landing was reconditioned and extended during the month.

The design work continued on schedule. Specifications were issued for the trash racks, stop logs and lifting beams and the contract for the electrical work at Barnhart Island was awarded. Bids were received May 29 for the main switchboards.

Iroquois dam. Sluiceway blocks are reaching their full height.



Progress By S.L.S.A.

Tenders were called on May 16 for two of the most important contracts in the building of the seaway. These are for the two locks which will enable ships to be raised or lowered the 85 feet between Lake St. Louis and the Beauharnois power canal. Tenders were called for the supply and erection of two rolling lift type bridges, one at Cote Ste. Catherine and the other at Iroquois lock, near Iroquois, Ontario.

Features will be the temporary diversion of the New York Central Railroad during construction, the building of a four-lane highway diversion tunnel to carry Quebec highway No. 3 under the lower Beauharnois lock, the construction of a cofferdam in Lake St. Louis and dredging in the Beauharnois canal. The highway diversion is to receive priority in the progress of the work.

Excavation over the two-mile extent of the two lock contracts will require the removal of some 1,110,000 cubic yards of overburden and 2,621,000 cubic yards of rock. For construction there will be required some 9,000 tons of iron and steel and some 3,200,000 bags of cement. Work for the upper Beauharnois lock must be completed by November 30, 1958, and for the lower Beauharnois lock, by October 31, 1958.

The bridges for which tenders are called are to be completed, respectively, at Iroquois lock, March 31, 1957, and at Cote Ste. Catherine lock, December 31, 1957.

Controversy Over Dredging

The United States has declined to meet Canada's wishes for deep sea dredging on the north side of Cornwall Island, apparently fearing it may lead to an all-Canadian seaway and American-Canadian competition for seaway traffic. The U.S. wants to dredge a 27-foot channel on the south side of Cornwall Island, but further dredging will be needed on the north side so river levels and flow will not be unduly disturbed.

Canada has reserved the right to build all the seaway channel on her side of the river if future traffic or friction with the United States should warrant it. Both countries agree some dredging must be done on the north side, but the U.S. maintains it need not be done to a depth of 27 feet, while Canada insists that it should.

Under the Boundary Waters Treaty of 1909 neither country can undertake construction in international waters without the other's consent if it will result in changing flows or water levels. Canada feels it would be best to obtain consent to 27-foot dredging now rather than to have to open negotiations later.

However, authorities state the problem is getting high priority from both governments. Further discussions will be held at an early date. They are convinced it will not delay completion of the power and seaway project scheduled for the opening of the navigation season in 1959.

SLSA President Addresses Queen's Graduates

President Lionel Chevrier of Canada's Seaway Authority, addressing the graduates of the faculty of science of Queen's University, at Kingston on May 18, told them that they should "retain the clarity and open mindedness on which your scientific knowledge is based; but retain also with that a lively awareness of the social consequences of your work". He then underlined the importance of engineering in civilized society, stressing particularly the marked effect this profession has had upon the destinies of Canada.

Mr. Chevrier pointed to the seaway as one of the greatest achievements in the heart of Canada, and as one where the engineer finds the opportunity to put into action all the resources of his skill. In the mind of the speaker, however, the aspect to be stressed on the occasion was that graduates are to leave the university "with a balanced view of their society".

Progress by SLSDC

Dedication ceremonies took place on June 3 at Massena, New York, for the Dwight D. Eisenhower lock, one of the two United States locks on the seaway now under construction, formerly referred to as the Robinson Bay lock. Assistant Army Secretary George H. Roderick gave the opening address in the community sponsored ceremony and a new lock site marker was unveiled. Lewis G. Castle, SLSDC administrator was also present. The ceremonies formed part of a 1½-hour TV program entitled "The St. Lawrence Story".

Tenders have been called for the supply of trash racks, stoplogs, lifting beams and gate suspension metalwork for the U.S. half of the Barnhard Island power plant, Long Sault dam and Massena intake, amounting to some 1200 tons of fabricated steel metalwork. Bids closed on June 15 and were not restricted to American manufacturers.

Seaway Ports
Facilities or Traffic First?

Professor John L. Hazard of the University of Texas, who served as economic consultant to the SLSDC, places the probable total traffic potential of the seaway at 36½ million tons by 1959. He believes if Great Lakes port cities provide adequate facilities and don't hamstring their port authorities with local restrictions, a traffic total of 52 million tons by 1965 is possible.

About half the seaway supporters believe direct overseas commerce will expand steadily after 1959, he states. The remainder think there will be startling surges in 1959, with some levelling off thereafter. Various estimates of non-bulk overseas seaway commerce average up to 1.8 million tons for 1959 and about six million tons by 1965. The general expectation is for a cumulative average growth of 15 per cent yearly to 1959, 40 per cent a year for 1960-61 and then a slow tapering-off.

Since last summer, local ardour for the project has cooled somewhat. In some Ohio and Michigan communities there is a strong tendency to wait and see before providing new and enlarged waterfront facilities, reports Prof. Hazard. Some leaders in these areas question the wisdom of installing large new facilities for general cargo handling. Nor are they keen to give their port authorities control over their waterfronts.

The opposite school, bankers, utility managements and the like, who see vast economic benefits for general foreign commerce, contend facilities must be provided before overseas trade will come. Port authorities must co-ordinate the entire waterfronts, so that industry which does not make a direct contribution to port activity cannot stymie building plans.

American Lake Ports are Preparing

Chicago, Milwaukee, Detroit, Cleveland and Toledo expect seaway benefits to be substantial, according to a recent Seaway Supplement in the *New York Journal of Commerce* dated April 25. These cities have long been leaders in interlake tonnage. The New York Port Authority predicted last year that the seaway would divert three to four million tons of cargo yearly from New York to Great Lakes ports. New Orleans thinks it may lose six million tons of its commerce to lake cities.

Chicago is generally conceded to have geographic and economic advantages which should make it the number one ocean port on the Great Lakes. Milwaukee too has been alive to the possibilities of a seaway for twenty years. It is far and away the best prepared community in the lakes from standpoints of business and understanding of what the seaway will mean to it. Milwaukee's modern port facilities and machinery can handle lifts up to 90 tons. Its port authority estimates it will develop at least a million tons of new highgrade cargo within 10 to 20 years following 1959. Between now and 1959 the city will spend some $4.7 million to deepen harbour slips, build a new pier and terminal and access highways and expand its harbour railroad system.

Milwaukee has confidence in its future as a lake port. But it recognizes many seaway problems cannot be solved by mere building of additional berths and shed capacity. It is the first lake port to have succeeded in establishing export rates as an inducement to use of the port by inland shippers.

Duluth, already one of the world's two busiest ports, is in excellent condition to tap the commerce and industry of the upper tier of midwest states. Seventy-five million tons of bulk cargo, including 80 per cent of the iron ore used in United States passes yearly through Duluth-Superior. Over a million tons of taconite ore were shipped from Minnesota ports last year. By 1971 mining engineers estimate 35 million tons yearly will be shipped. Though most of it will load at nearby Two Harbors, Duluth, which will also benefit, looks forward to a slow and steady growth of direct foreign commerce, though it does not expect an overnight boom.

Detroit and Cleveland, while not overlooking the possibilities of increased overseas commerce, point out that the deeper harbours and expanded port facilities would have strong appeal for chemical manufacturers, and for producers and consumers of bulk cargoes in search of cheaper transportation within the lakes areas. Detroit authorities foresee a yearly import-export commerce of some millions of tons after 1959. The port of Detroit, which handled 23 million tons of cargo last year, will remain Michigan's No. 1 port. Detroit does not claim to be ready for the seaway yet, but hopes private enterprise will provide the needed waterfront development. If not, the Port Commission will step in. The commission is now seriously considering a $20 million port development, to accommodate 30 to 40 ocean going vessels including slum clearance action on some 140 acres of sub-standard housing.

Cleveland also believes the greatest foreseeable benefit will be the development of commerce and industry in Ohio and other lake states. It has no port authority. Cleveland's port plans are progressing slowly. An independent engineering report last year estimated 1959 overseas traffic potential at over 2½ million tons. By 1970 more than 4½ million tons were predicted, of which a million tons would be general cargo. But the most ardent seaway boosters foresee not more than 200,000 tons of overseas cargo by 1959. Cleveland's total port traffic amounted to 15½ million tons in 1954, including 41,300 tons of general export-import cargo. Construction is proceeding on a new waterfront terminal and additional improvements are expected later.

Other upper-lake ports deserving of mention include Muskegon, with its large well-equipped terminal which handles nearly a million tons bulk cargo yearly; Escanaba with its natural harbour and 5 million tons of iron ore shipments per year; Manistique with a proposed harbour deepening project; and Bay City, Saginaw and Port Huron, all of which have plans for benefiting from the seaway.

Along the 1700 square mile area sitting along the southern shore of Lake Erie are other ports which will be regular ports of call for the heavier draft vessels, such as Erie, Ashtabula, Fairport, Conneaut, Toledo, Oswego and Buffalo.

Erie, Pennsylvania, like its larger competitors Cleveland and Buffalo, is looking forward to becoming a deep water port. During the decade up to 1953, Erie handled some 7 million tons of cargo yearly, all of it bulk, chiefly iron ore, coal and pulpwood. Port interests believe the city could generate a quarter of a million tons of traffic yearly and double that in 25 years.

Toledo expects nearly 60 million tons of traffic through its port by 1980, including 1½ million tons of general cargo. It is presently Ohio's largest port from the standpoint of tonnage, having handled more than 34 million tons in 1955.

Oswego has a good natural harbour and a nucleus of terminal and pier facilities adaptable to deep water shipping at modest expense. It has functioned as a port for more than 200 years. Its waterborne commerce amounted to over three million tons in 1953, of which two million tons of various commodities such as coal, grain, pig iron, cement, pulp and petroleum. It is formulating an active port development program and setting up an Oswego Port Authority.

Buffalo, long the seat of determined opposition to the seaway, has undergone a change of heart. It now visualizes the whole Niagara frontier as one of the chief beneficiaries of the deep waterway. Seaway traffic in exports of general cargo is expected to reach more than 667,000 tons by 1960. The port is expected to have a potential of 800,000 tons of coal in 1960 and a million tons a decade later, for shipment to Canada.

Canadian Pipeline Projects

With construction of Westcoast Transmission's pipeline from the Peace River and Northern B.C. areas well under way, as reported in our last issue, favourable weather conditions are permitting excellent progress on all sections of the project.

The British Columbia Public Utilities Commission has authorized Inland Natural Gas Company to distribute gas in 25 communities of the Cariboo, Okanagan Valley and West Kootenay areas. Authorization was also given this company to sell gas to the Prince George Gas Co., which will distribute the gas when approval is given by the municipality. Some $22 million will be spent by Inland Natural Gas between now and the fall of 1957. Orders have already been placed for some of the pipe.

Meantime, attention was focussed during the month of May on Parliament at Ottawa and the debates on the proposed legislation respecting the trans Canada pipeline. Here, observers saw history reversing itself. Arguments between government and opposition resembled those in the fight over the Canadian Pacific seventy five years ago.

But this time the parties were in different "corners" of the ring. Conservative opposition leader George Drew now assumed the role of liberal opposition leader in the "Eighties", Sir Richard Cartwright, who had predicted the C.P.R. 'would not earn enough to pay for axle grease'. If history should repeat, they predicted, Canadians some years hence would be indeed thankful for the pipeline.

Legislation authorizing an $80 million 5-per cent loan to Trans Canada, repayable by April 2, 1957, to enable it to build the 575-mile western leg of the line to Winnipeg during the coming summer, and for setting up a Crown company—The Northern Ontario Pipeline Co., to build from Winnipeg to North Bay, was finally passed by Parliament and Senate and received Royal Assent early in June. The company must complete the line to Winnipeg by December 1, 1955. Default on the loan would give the government the option of expropriating the company's assets.

In the course of the debates at Ottawa, the Hon. C. D. Howe expressed the hope that Trans Canada would be able to complete the 2200-mile pipeline in two construction seasons. It was necessary to get things moving, he observed, and so assure prospective customers they would have the Alberta gas they wanted. Contracts were coming along well, he reported, and already some 75 per cent of the sales contracts needed to enable Trans Canada to survive its debt were in sight. In other words the question of whether the line could be fully financed without export of gas to the United States was pretty well answered.

But this legislation, and the granting by the Board of Transport Commissioners of a permit on May 25, make it appear that Trans Canada Pipelines is not required to show capacity to finance any portion of the line beyond Winnipeg. However, it is evident the western leg alone cannot stand on its own feet unless joined with markets either in Canada's central provinces or in the United States.

Vast Construction Program will Result

An early start on the pipeline from Alberta to Winnipeg may touch off an expenditure of about $150 million this year in addition to Western Canada's estimated investment of some $680 million for exploration and development, land purchase, refineries, new construction and expansion of pipelines for oil and gas, along with scrubbing plants and other facilities which are definitely earmarked for 1956.

The start of Trans Canada's western leg will call for expenditures of some $118 million on the pipeline, gathering and distribution systems. The major portion will be the $80 million for the main line itself. Opinions vary as to the possible 1956 outlay for a drilling program, an expenditure of some $20 million being predicted in some quarters, while elsewhere the view is held that gas wells already drilled and capped are adequate for production during the early stages of the project.

Another king size project in Alberta to be commenced soon after a start on the western leg will be the Alberta Trunk Line Company's system, designed to gather and deliver gas to Trans Canada at the inlet 'gate' near the Alberta-Saskatchewan boundary. The estimated cost of this project alone is $47 million to be spent over three years, with some $23 million being required the first year.

Pipe Purchased Total $116 Million

Trans Canada announced the award in May of a $32 million contract with the South Durham Steel and Iron Co. Ltd., for 636 miles of 30-inch-diameter pipe for the northern Ontario section of the national gas line between Winnipeg and North Bay, Ontario. This is the British firm which is already supplying 30-inch pipe for the West Coast Transmission project. First deliveries will be made in a year's time with completion of the contract by July, 1959.

A further $45-million order for 878 miles of 30-inch pipe for this northern Ontario section to Toronto was placed at the end of May with the Welland Tube Company. This company, formed by Steel Co. of Canada and Page-Hersey Tubes, Ltd., is now building a new mill at Welland, Ontario, for the manufacture of seamless pipe in sizes up to 34 inches in diameter. The contract calls for delivery during 1957 and 1958. This is said to be the largest order for pipe ever placed with one supplier at one time.

These orders, which complete pipe requirements for the main pipeline from Alberta to Toronto, are in addition to the order placed last October by Trans Canada with the United States Steel Corporation for more than 200,000 tons of 34-inch pipe at a cost of $30 million for the western leg to Winnipeg. They are also in addition to the $9-million order placed last fall for 24-inch and 20-inch pipe for the extension of the Niagara Toronto line to carry a further 90 million cubic feet of gas daily to the Montreal and Ottawa-Hull market areas and cities and towns along the route.

Most of the pipe needed for gathering and distribution systems are of sizes that can be rolled in Canada. Already several pipe mill groups are preparing for filling these requirements. Alberta Phoenix Tube and Pipe Co. Ltd., recently completed a $6-million mill near Vancouver and another mill at Edmonton is being built by the company to produce 150,000 tons yearly in sizes from 3½ to 12¾ inch diameters. Hoesche Werke Aktiengesellschuft is putting up a $3 million mill at Regina for 3-inch to 20-inch pipe. Mannesmann Tube Co. is building a $20-million seamless pipe plant at Sault Ste. Marie to make smaller diameter pipe for feeder lines.

Bigger Market in Northern Ontario

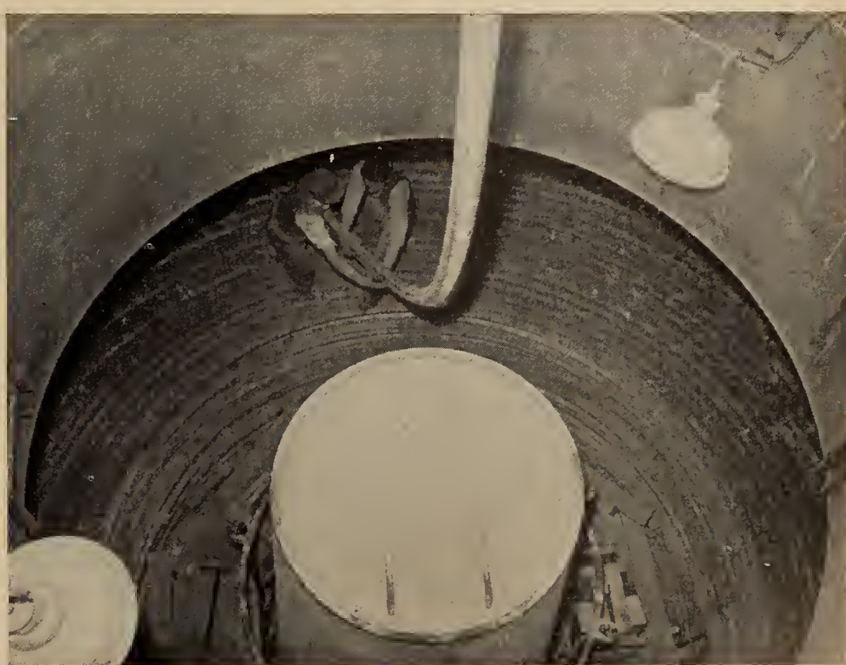
Meantime, the gas marketing outlook in northern Ontario is reported to be proving better than pipeline officials previously estimated. This is the area to be served by the 675-mile line from the Manitoba border to North Bay, the gap to be constructed by a federal-provincial Crown company.

Between Kenora and North Bay the outlook is for sales of 100 million cubic feet of gas daily in the third year of pipeline operation. Long term gas sales contracts have recently been concluded by Twin City Gas Co. with Fort William, Port Arthur and Sudbury. In May the Ontario Fuel Board will consider company applications to serve these areas.

Long term sales contracts are signed by Northern Natural Gas Company, with 21 municipalities between Hearst and North Bay, and Fuel Board "Letters of Convenience and Necessity" are granted to construct the facilities for service. Northern Natural Gas is also negotiating with Orillia, while Northern Ontario Gas and Consumers Gas are competing for the right to serve Barrie. Northern Ontario is also negotiating with Bracebridge, Gravenhurst and Huntsville.

Submarine Power Cable

This cable will link the high voltage supply system of the British Columbia Electric Company in Vancouver Island with the hydro electric resources on the mainland. Ninety miles of 138,000-volt gas-pressure type cable was manufactured at British Insulated Callender's Cables Limited, England, during the past two years. Loading started early in May on the cable ship "Ocean Layer" by means of a purpose-designed power operated gantry system.



Month to Month

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE ELECTIONS AND TRANSFERS

Progress Report on Confederation

The Institute's Committee on Confederation presented an interesting progress report at the annual meeting in Montreal. First it was presented to the meeting of Council held on Tuesday, May 22, then in the afternoon of the same day, to the Branch Officers' Conference. On the following day it was brought before the annual business meeting of the Institute and on the day following that it was discussed at the first meeting of the new Council. On all these occasions the report was approved unanimously.

The chairman of the committee, Dr. Irving R. Tait, in response to the invitation from Dominion Council, was requested by Council to attend the annual meeting of that body to be held in Saskatoon, so there could be free and full discussion of the report and Confederation. This Dr. Tait agreed to do.

Dr. Tait reports that the discussion at Saskatoon brought out many expressions of opinion, but that no decision was made as to the report itself. It was agreed however that it should be submitted to each provincial association with the request that they study it and report back to Dominion Council.

There the matter rests for now. It is understood that the associations will give the report their early attention so that the minimum of delay will result.

It is of interest to note that the report is a joint one submitted by the special committee of the Dominion Council and the special committee of the Institute. Under these circumstances there is a reasonable prospect that it will be as well received by the councils of the associations as it was by the Council and members of the Institute.

There are twenty-three pages in the report, and as it is only an interim or progress report and as it has not yet had the approval of the associations, it is not proposed to print it in full in the *Journal.* However in view of the wide interest in the subject shown by members right across Canada, and at the suggestion of the chairman of the committee, an attempt will be made to summarize it.

Members are reminded that these proposals in many instances are compromises between the two committees, and are not final or as yet binding on anyone. It may well be that further study and further discussions will bring about changes in the present recommendations.

Also it should be kept in mind, that no undertaking on Confederation can be agreed to by the Council of the Institute until a final proposal has been submitted by ballot to every member of the Institute and has been received favourably.

Herewith is the summary.

It is recommended jointly by the committees that the functions of the national body be described as follows—

1—Perform the present work of Dominion Council.

2—Perform the present work of The Engineering Institute of Canada.

3—Provide a recognized voice for all professional engineers in Canada.

4—Promote and effect relations and activities with non-Canadian engineering bodies.

Membership

1. Engineers will be members of the national body by reason of their provincial registration.

2. All members of the national body will be eligible for membership in the branches of the national body for which there will be a separate fee. It is contemplated that branch membership may be voluntary unless the provincial body decides that in the best interests of that province it should be compulsory.

3. Provision will be made to take care of students, juniors, affiliates, etc.

Fees

In the report there are seven pages of figures compiled by the Institute's committee, which show that with a confederated set up and greatly increased membership substantial reductions can be made. It is expected that under the same circumstances, reductions can be made, at least by some of the provincial bodies. Therefore with these varying conditions no attempt can be made now to set down a specific fee for joint membership. It is safe to say however, that in the minds of the two committees, there should be really worthwhile reductions under Confederation. It is possible that the reduction in the Institute fee may be even greater than that now applying in those provinces where there is a co-operative agreement between the Institute and the Association.

Cover Picture

The cover picture is related to the paper "Cross Suspension System, Kemano-Kitimat Transmission Line" on page 901 of this issue.

It is a view, during the construction, from the northeast anchorage during pull to final closure. Towers on Twin Peaks are visible to right and Kemano Valley is in the centre.

Organization

The national body would be managed by a National Council made up of one member elected by each provincial body (10), one elected by members of the national body in each province (10), plus the immediate past-president, the president, the vice-president, a representative of affiliated technical societies and a treasurer.

The Council would meet three times a year and have their expenses paid.

There would be an Executive Committee made up of the president, vice-president, chairman of finance committee and three other members of the Council. They would meet not less than four times a year and their expenses would be paid.

Committees

There would be the following additional committees—

1. Affiliated Technical Societies.
2. Uniform Standards for Professional Registration.
3. Public Relations
4. Publications
5. Professional Status
6. Engineering Problems
7. House and Library
8. Honours and Awards
9. Ethical Review
10. The Engineer in Industry
11. Legislation
12. The Young Engineer
13. Finance
14. Nominations

It is hoped that this summary will put each and every member "in the picture". As details become settled the membership will be informed. It is expected that the president Vern A. McKillop will discuss the subject with the executive committees and the members of all the branches he visits during his term of office. The members may be assured that no decisions will be made without their support.

A Great Loss

The profession and the Engineering Institute lost a distinguished member in the recent death in Montreal of Roger DeLand French. He was known to engineers both old and young from coast to coast, and was held in high regard by them all. For forty years he was on the teaching staff of the engineering faculty of McGill University.

Professor French was never one to compromise with principles. He had an unusually alert mind, and usually was well informed not only on the things related to his teaching, but on the practical things of the world as well. This background made him a wonderful person to consult on a great variety of subjects. There was never any doubt as to where he stood on any question, and he did not hesitate to give expression to his convictions when it was useful to do so.

He was a strong character with fear of no one. His alert mind was served with a quick and clever tongue. On committee work he was a tower of strength to his associates. He never spoke unless he was informed on the subject, but he seemed always informed, and in a few short words he could sum up and dispose quickly of a discussion, to everyone's relief and satisfaction.

These qualifications made him unusually valuable to the Institute. Not many members know it, but for about fifteen years there has not been an issue of *The Engineering Journal* that has not been influenced in one way or another by Roger French. For that period of time he has been vice-chairman of the Publication Committee and has done a great variety of editorial work. He has written original articles, edited papers, and handled almost wholly by himself two of the best departments of the *Journal*.

It was he who month in and month out did the articles about *The Engineering Journal* titled "Thirty - Five Years Ago". It was he who read dozens of periodicals and books every month to produce the material for the "Abstracts" section.

It was characteristic of the man that he would have ready at the time of his death a whole series of twelve articles for "Thirty-Five Years Ago". These will be published over his initials throughout the next twelve months. It was part of this same characteristic that permitted him to have on hand at the Institute, enough Abstracts to carry on for several months.

In his latter years Professor French was seriously crippled with arthritis so much so that he could walk only with a cane and crutch, and yet this man almost never missed a meeting of the Publication Committee and never stopped using his typewriter. His conquest over his handicap, his resourcefulness and his will to work, made him outstanding in any company and endeared him to his many friends and associates.

The *Journal* will miss him terribly, not only will his copy never be available again, but his advice, his comments and his counsel are gone forever. The profession has lost a great man, the *Journal* a great contributor and those on the staff who knew him well, a great friend.

"I shall not look upon his like again."

An obituary of Professor French will be found on Page 942 of this issue.

Early Engineering

In some way not known to the present generation, the Engineering Institute of Canada some time ago came into possession of two original letters that are of considerable interest to engineers and historians. One is dated February 26, 1841, signed by George Stephenson, and is addressed to T. Gooch, Esq. The other is dated September 18, 1841, and is signed by Robert Stephenson. It is addressed to T. L. Gooch.

Here we have interesting and early communications from the man who invented the steam locomotive and from his son. From the context of the letters it would appear that Mr. Gooch had charge of the operations of the trains and their crews. Our research in the Institute library has indicated that at the time in question Mr. Gooch was joint principal engineer for the construction and operation of the Manchester and Leeds Railway.

It is interesting to note that in 1841 speeds of 26 to 28 miles an hour were not considered excessive. It seems hard to realize that they could have been running as high as 50 miles an hour, as complained of by Mr. George Stephenson.

These valuable documents have been in the Institute's possession for some time, but unfortunately the Institute has never developed any museum for such things or other means of taking proper care of them and for making them available to interested parties. Hence it was agreed at a recent meeting of Council that in appreciation of the hospitality extended by the Institution of Mechanical Engineers to the president of the Institute when he visited there in October of last year, these two letters be presented to the Institution.

Recently word has been received that the Council of the Institution of Mechanical Engineers will be happy to receive the letters which will be added to their outstanding collection of documents of all kinds relating to the two Stephensons, both pioneers in the field of mechanical engineering.

The letters read as follows:

Tapton House
February 26, 1841

My Dear Sir:—

I have drawn up a few observations about the Tunnel. Look it over and see if it will do to be attached to your report. Let Mr. Gile see it and if he can put in any better words about you let him interline it. I should advise you to cause the Locomotive Engineer to go slower, certainly not exceeding 26 or 28 miles per hour until the road gets consolidated. At the speed you are now running you will destroy both rails and engines. I believe I came along the other day at the rate of 50 miles per hour.

I am, my dear sir,
Yours truly,
(Signed—G. W. STEPHENSON)

T. GOOCH, Esq.

Westminster
18 September 1841

Dear Sir:

You will oblige me by permitting the Bearer, Mr. England, to inspect the Locomotive depot of the Manchester and Leeds Railway.

Yours sincerely,
(Signed—ROBT. STEPHENSON)

T. L. GOOCH, Esq.

The Institution of Mechanical Engineers has, since receiving and studying the original letters, referred the following information to Headquarters, which will be of further interest:

"Both these letters are, undoubtedly, addressed to T. L. Gooch, who was a contemporary of the Stephensons and is well known to us. Thomas Gooch, as he was known then, was appointed chief draughtsman under George Stephenson during the construction of the Liverpool and Manchester Railway. He became engineer to the Bolton and Leigh, and later to the Manchester and Leeds Railway. He was brother to Sir Daniel Gooch who became locomotive superintendent of the Great Western Railway, when he was only twenty-one, at the commencement of that line. Thomas Gooch made most of the drawings during the construction of the Liverpool and Manchester Railway, and was secretary to Stephenson.

"The address at the top of George's letter is Tapton House, which was a brick built mansion just outside Chesterfield where George Stephenson resided from 1837 until his death.

"You may possibly be aware that we have an excellent collection of original letters of George Stephenson housed in the Institution, most of which were presented by one of our past presidents, the late Colonel S. John Thompson, and we are indeed very happy to have these further additions which you have so kindly sent to us."

What Do You Expect Now?

This issue of the *Journal* has been prepared by a new and different printer, as some of you are now aware if you noticed the announcement in April "Month to Month". The different format for some of the section headings will also arouse suspicion that something queer has happened.

The change-over of printing establishment from Montreal to Toronto will obviously seem like a capital idea to many Ontario readers, but we hasten to assure you that neither geography nor politics had anything to do with it. Improved service and a better price were the objectives of the new contract.

It seems to some of us here in the editorial department that it should be a time for wiping clean of slates, and rededication of purposes, with maybe a search for some fresh ideas. But we must confess that with the arrival of summer our thoughts are liable to veer sharply toward golf, fishing, and the washing of new automobiles. This will never do.

On the serious side, we can hope that our new printing facilities will give us scope to produce a still better *Journal.* It should never remain static for very long—except in purpose. We will do our best, and members can help. Another readership survey will be launched in October. If one of the cards comes to you—please complete it and mail it back. But no one needs to wait for a survey card. Send us your suggestions now, and complaints too if you wish. These are life blood to a successful publication, and the Institute would never be satisfied with anything less.

Invitation to Banff

These Westerners came to Montreal for the annual meeting — the new councillor for the Calgary Branch W. A. Smith (left), and the Calgary past-councillor J. J. Hanna. They lost no opportunity to boost the 1957 annual meeting at Banff, June 12, 13, 14. Here they are shown at the Wednesday luncheon promising a Western welcome.

THIRTY-FIVE YEARS AGO

Comment on the Journal of July, 1921

During World War I Canada went into the production of ships in a relatively large way for a country so small in population and inexperienced in ship building. Its success was a little intoxicating and led a good many Canadians to think that their country was well on the way to regaining the place among the maritime nations of the world that it had held in the 50's, 60s and 70's of the last century.

It was only natural, then, that the two principal papers of the July, 1921, issue of the *Journal* should be concerned with ship building. One, by H. R. McClelland, A.M.E.I.C., dealt with the general design of ships, the other, by T. C. Phillips, M.E.I.C., with their propelling gear. Either paper would bring home to a 1956 reader how far we have come in only thirty-five years and how unsafe it is to venture on prophecy.

Mr. McClelland thought there would be no more luxury liners, like the *Aquitania* and the *Imperator*, for one reason, because "the use of aircraft may have developed to such an extent that the thoughts of transportation . . . then will be . . . (of) hangars rather than . . . of wharves and freight sheds." His speculation as to transocean air travel came true, but he did not foresee that there would still be a good many travellers who would prefer the comparative stability of a ship's deck to the more skittery aircraft.

Mr. Phillips' paper traced the development of marine propelling machinery from the slow speed, single cylinder steam engine, operating at 3 or 4 p.s.i., and driving a pair of clumsy paddle wheels, to the modern steam turbine with geared or electric drive. Incidentally, he noted that John Molson's *Accommodation* that made the trip between Montreal and Quebec in thirty-six hours, was the second steam driven vessel to be built in America; she had a 6 hp. engine.

The author's opinion of the diesel engine was to the point. He thought it would become a strong contender of the steam turbine, because of the small space it occupied and because of its high efficiency. Even in 1921 there were upwards of sixty vessels powered with diesels, one of which had been operating successfully for eight years.

Salaries Considered

The matter of salary scales for engineers was very much alive in 1921; it will never die. Not much had been heard of it in the *Journal* for some months, but this number published a report by a committee of the Halifax Branch which felt that its report ought to receive careful consideration by Council. It was a sensible document. In essence it said that no schedules, United States or Canadian, so far suggested were good enough to be adopted as official by the Institute.

The branch committee thought that there was too much variation in the classifications; that most of the schedules appeared to have been made up to suit local conditions; that there was not enough differentiation between positions bearing the same titles, but involving quite different duties and responsibilities; that there was generally little or no recognition of executive ability; and that intangible qualifications, like good judgment, personality and leadership were often not considered at all.

These were all important points, but trying to include every one of them in a schedule might well have led to the use of a sort of rating system like that so dear to some personnel people—a hundred points for ideal experience, another hundred for perfect personality and so on—rank and salary to be determined by the applicant's score on this basis. This scheme never works too well, except for preliminary purposes; the final choice of any employee, certainly in the "top brass", is usually based on reputation and all-around fitness for the job, generally determined mostly from personal interviews.

The first annual meeting of the new Cape Breton Branch, seven months old, was held in Sydney on May 26, 1921. The Institute's general secretary made a special trip from Montreal to attend and to talk to the branch about Institute affairs in general. He received a courteous and attentive hearing, but the real event of the day was the address of the branch's own retiring chairman.

He bore an Irish name, which probably accounted for some of the wit of his remarks, but some must also have come from his Nova Scotia environment — the dry, somewhat dour, matter of fact, inclined to be skeptical atmosphere we have learned to associate with the Maritimer. We need traits like these to keep our national character in balance, to stir the self-contented people of the central provinces out of their complacency and to offset the ebullience of the westerner.

Professional Recognition

The chairman's subject was the perennial one, professional recognition for the engineer and why he deserved it. His views were not so different from those which had already been expressed by many others, but his language was more positive and direct.

"Up to a few years ago there were only three professions . . . the doctor, the preacher and the lawyer. The doctor officiates at our entrance into this . . . world, the parson (tries to) to ensure our safe passage into the next and the lawyer, having read of the difficulties which a rich man encounters in his efforts to attain the celestial kingdom, does his best to remove any surplus wealth which we are in danger of accumulating . . .

"If the doctor mixes up the wrong decoction . . . and your widow has to cash in your life policy, the M.D. is always there with . . . (an) excuse . . . When the jury decides against you in a case you 'can't lose' . . . the lawyer is there with his story of miscarriage of justice . . . and a bill . . . which would make a plumber green with envy. If . . . you find that your road across . . . the mapless land leads in a direction opposite to that which you intended . . . you can't come back to argue the case, (but) you may rest assured that your spiritual adviser will not accept any of the blame for your misdirection.

"The fact is that the only certain profession is that of the engineer. If you build a bridge it must carry its load, if you lay a pipe line it must carry the water; . . . there is no getting by—your work is there to answer for itself. In the language of the day you must 'deliver the goods'

. . . The world today is . . . looking to the engineering profession to drag it out of the chaos with which it is threatened . . . A devotion of our best talents to the betterment of living conditions alone will obviate this and it is to the engineering profession that we must look for the solution of the questions which daily present themselves."

Thoughts of this kind were no doubt running in the minds of many in 1921 and still are in 1956—but it is seldom that anybody states them so frankly and in such positive language. Most of us keep them under our hats for fear of stirring up a row, something each succeeding generation seems more and more reluctant to do. R. DeL.F.

A.W.A. Meets Again

The Aviation Writers Association held their eighteenth annual meeting at San Francisco from May 27 to June 3. There were about three hundred including about twenty from Canada. The locale was the Mark Hopkins Hotel.

It is always surprising to find so many women writers at these meetings, and what is even more surprising is that there are about nine thousand women who have been licensed as pilots in the United States. Practically all the ladies attending this conference were licensed fliers, including some from Canada. It was an education to hear them discussing a plane or a flight, with the assurance and the vocabulary of the expert, which of course they are.

The new deadline for *Journal* copy made necessary by the arrangement with the new printer makes it impossible to get a complete report ready for the July issue. This then is just an introduction with more to follow in the August issue. It was a most noteworthy meeting and it is hoped that a more detailed account will interest many readers.

When it comes to packing a program, in all probability the first prize should go to the Aviation Writers' Association. They surely set themselves a task that none but the hardy, the enthusiastic and the dedicated could follow. Starting with a reception on Sunday night, the program plugged its way through a solid week of papers, speeches, plant visits, fly pasts, demonstrations, breakfasts, lunches and dinners, sufficient to make a full agenda for at least three conferences for any other organization.

In looking back over those seven hectic days it is difficult to straighten out one's thinking, and to know where and when certain newsworthy events took place, in addition to which it is difficult to determine which items should be included in a general statement and which should be featured later. Perhaps some pattern will emerge as we plough through the releases and photographs that were issued in gigantic quantities, and the notes made in the enthusiasm of the moment which at this later date seems to have lost some of their meaning and significance.

The Aviation Writers' Association annual meeting has many features not found in other meetings. One of the most noteworthy is that, in this instance at least, members were flown "for free" all the way to San Francisco and back, seven planeloads of them. Another helpful feature is that all meals—three a day for six days—are "sponsored" by various industries in the aviation field. As if this were not enough, other industries provide refreshments before every lunch and every dinner reminiscent of "Muriel's Room" hospitality at its best.

The program placed great emphasis on the armed services in the air. Trips were taken to distant air fields to see what the army could do, and the navy, and of course the air force. Top officers addressed the group to tell them not so much of their achievements but of their hopes and their problems (frequently political) that faced them in the achievement of these hopes.

It was surprising to the Canadians to hear so much about the troubles, the failures of top people at government level to see what should be done for and between the services. The comment was made frequently by Canadians and Americans, too, that if the administrative officials at Washington were as sensitive as the Minister of National Defence at Ottawa proved to be at last year's A.W.A. meeting in Toronto, all three services would be losing their senior officers. Nothing has happened yet so apparently the Secretary of Defense can take it better than can the Canadian minister.

The theme adopted by the U.S. Air Force seems to be "Peace through strength". Over and over again A.W.A. members had it impressed on them, that the great bases they were visiting, the great fleets they were seeing were there to deter other nations from going to war, and not to make war. One air base had over the door to the main building "A decade of security thru global air power 1946-1956".

Such a meeting surely brings home to Canadians the extent of the aviation and associated industries in the United States—with dozens of companies manufacturing all or parts of a plane, with three services requiring planes and with each service requiring a great variety of planes, the scene is quite confusing. Add to this, the constant change in basic requirement, the never-ending series of improvements and the increasing demand for more and better planes, and it is quickly evident that "confusing" is a modest word for it.

Impressive Organization

The organization of the United States forces was most impressive. They are surely not playing with the issues. They are well organized and equipped, and operate from permanent bases that should be efficient in their work and thoroughly acceptable to the men who work there. If Canadian service men could see these working conditions they would indeed be envious.

To a neighbor and an ally, it was a comfort and satisfaction to see the fine calibre of persons occupying the senior posts in all three services. From generals down they were an intelligent-looking lot of men, with uniforms of fine material and excellent fit, and pressed up to the n'th degree. It would seem that the Canadian forces could improve their appearance a great deal by observing what has been done to the south of us. What is more these U.S. officers not only looked like leaders but they acted like them, and their smart appearance was no small aid in bringing this to pass.

It was disappointing to a writer from a technical publication, to find so much of the program given over to the activities of the services. However, there were some technical papers given at breakfast, lunch or dinner and there was the visit to the Ames Aeronautical Laboratory of the National Aeronautical Research Establishment at Moffett Field. These all merit some mention in later issues of the *Journal.*

ATLANTIC PROVINCES MEETING OF PROFESSIONAL ENGINEERS

Sponsored by the Atlantic Provinces branches of the Engineering Institute of Canada and the Associations of Professional Engineers of Nova Scotia, Prince Edward Island, Newfoundland and New Brunswick.

SEPTEMBER 5, 6, 7, 1956

The Algonquin Hotel, St. Andrews-By-The-Sea, New Brunswick

THE PROGRAM

WEDNESDAY, SEPTEMBER 5

2.00 P.M. Meeting of Council

5.00 P.M. Informal dinner

THURSDAY, SEPTEMBER 6

10.00 A.M. Professional Sessions:

"High Voltage D-C Transmission"

E. V. Leipoldt, Vice-President, Shawinigan Engineering Limited.

"Sub-surface Foundation Exploration by the Seismic Method"

Emery Holzl, Chief Engineer, S.E.M. Prospecting Limited.

12.30 P.M. Opening Luncheon

2.00 P.M. Cruise on M.V. "Grand Manan" through proposed Passamaquoddy power project area.

7.30 P.M. Banquet

Speaker: Brian M. Colquhoun, Engineering Adviser to the International Bank for Reconstruction and Development.

FRIDAY, SEPTEMBER 7

10.00 A.M. Professional Sessions:

"Recently Developed Metallurgical Techniques as Applied to New Brunswick Minerals"

Dr. Marvin Udy, Consulting Engineer.

"Utilization of Nuclear Fuels for Power Production"

Dr. A. J. Mooradian, Superintendent of Engineering and Development, Atomic Energy of Canada.

1.00 P. M. Luncheon

Speakers: Mrs. T. P. Lusby, "The Role of the Engineers Wife".

2.30 P.M. Golf Tournament

7.30 P.M. Banquet

Speaker: Rt. Hon. C. D. Howe, Minister of Trade and Commerce of Canada. "The Professional Engineer and Expanding Economy".

10.30 P.M. Grand Ball.

SATURDAY, SEPTEMBER 8

9.30 A.M. Breakfast

TRANSPORTATION

Special 21-day return tickets are available from local agents. Delegates are encouraged to inquire at local C.P. agencies about the S.S. "Princess Helene".

HOTEL

The entire hotel is reserved, at rates of $12.00 and $14.00.

Reservations should be requested from:
J. B. Eldridge, M.E.I.C.,
P.O. Box 38, Saint John, N.B.

Mass Transportation in Cities

On 25th May the annual meeting proceedings included a panel discussion on traffic problems. A similar panel had proved highly successful the previous year; this year's discussion was a further development of the theme, and a most interesting one.

Chairman of the panel was George S. Mooney, director of the St. Lawrence Municipal Bureau, Montreal, and the panel members were: Col. H. S. Bingham, M.E.I.C., (retd.) late administrator, Board of Transportation, New York City; C. E. Campeau, M.E.I.C., City Planning Director, Montreal; W. E. P. Duncan, M.E.I.C., general manager, Toronto Transportation Commission; Arthur Duperron, M.E.I.C., chairman and general manager, Montreal Transportation Commission.

Mr. Duperron opened the discussion by stating City transportation generally had more than doubled over the last decade. He pointed out that Montreal's street traffic was almost paralyzed today, with speeds no better than fifty years ago. Montreal's population, he predicted, would double by 1981, while the number of vehicles using city streets would quadruple. The only solution lay in utilization of high speed mass transit, with free car parks at City approaches. Many more would use public transportation if faster service could be provided. Meantime buses would entirely replace trams within the next 5 years.

Mr. Campeau, explaining modern trends in City Transportation, said 60 per cent or more of those going to work daily rely on public transit, and this would be the case for the foreseeable future. Every device had to be used, he said, in order to save the centre areas of our cities. Only community planners had the means to co-ordinate the use of highways, expressways and city transit services. It was only common sense to make fullest use of the investment in transit services already provided.

Mr. Duncan emphasized that modern cities need every means of transportation, used at the right time and place. Buses occupy only a tenth of street space per passenger as do

(Continued on page 991)

The Junior Panel Discussion

Those who attended the junior panel discussion (some sixty members and visitors) obviously took a considerable interest in the subject "What can a young engineer do in developing professionally?", to judge from the lively open discussion and the many questions asked from the floor.

Co-chairmen of the panel were N. J. Viehmann, A.M. ASME, Jones and Lamson Machine Company, Springfield, Vt., and G. L. MacLean, Jr. E.I.C., Geocon Limited, Montreal. The members of the panel were: R. W. Honebrink, General Electric Company, Schenectady, N.Y.; W. R. Thompson, A.M. ASME, United Engineers and Constructors, Inc., Philadelphia; J. F. Harris, M.E.I.C., consulting engineer, Toronto; and Guy Savard, M.E.I.C., Canadian Liquid Air Company, Montreal.

Each of the panel members spoke of his experience in the field of professional development, and enlarged on the subject during subsequent discussion. Many contributions to the proceedings were made by members of the audience, who expressed their views and particular interest. Notably, Colonel L. F. Grant, the E.I.C. field secretary, outlined the professional development courses carried out by the various Branches.

Altogether this was a stimulating and valuable evening session, and a more detailed account of the proceedings will be published in a later issue of the Journal.

Seen during the junior panel discussion are (from left): Guy Savard, M.E.I.C.; J. F. Harris, M.E.I.C.; G. L. MacLean, Jr. E.I.C., co-chairman; N. J. Viehmann, A.M. ASME, co-chairman; W. R. Thompson. A. M. ASME; and H. W. Honebrink.

Events at the Annual Meeting

On these pages are further reports and scenes from the Annual Meeting.

The Annual Banquet

Top picture, from left: C. G. Kingsmill, M.E.I.C., chairman, Annual Meeting Committee; E. D. Brown, M.E.I.C., president, Mining Society of Nova Scotia; J. Hoogstraten, M.E.I.C., president, Association of Professional Engineers of Manitoba; Mrs. Olive S. Morrison; Georges Demers, M.E.I.C., president, Dominion Council of Professional Engineers; Mrs. H. G. Burchell; Colonel E. H. Webb, Canadian Army; Madame Leo Roy; A. J. C. Paine, M.E.I.C., president, Royal Architectural Institute of Canada; Mrs. E. D. Gray-Donald; Wing-Commander R. R. Hilton, Royal Canadian Air Force; Mrs. A. Turner Bone; J. G. Chenevert, M.E.I.C., president, Association of Consulting Engineers of Canada.

Mrs. O. B. Thornton; V. A. McKillop, M.E.I.C., president-elect, the Engineering Institute of Canada; Mrs. G. Ross Lord; J. A. McCrory, Hon. Member and past-vice-president, E.I.C.; Mrs. H. W. McKiel; Francis W. Gray, Hon. Member and past councillor, E.I.C.; Mrs. Thorndike Saville; M. D. Hooven, president, American Institute of Electrical Engineers, Mem. ASME; Msgr. I. Lussier, rector, University of Montreal; Lady Nelson; Joseph W. Barker, president, American Society of Mechanical Engineers; Dr. David L. Thomson, vice-principal, McGill University; R. E. Heartz, M.E.I.C., Hon. Mem. ASME, the President.

Sir George H. Nelson, president, Institution of Electrical Engineers; Mrs. R. E. Heartz; Dr. F. Cyril James, principal and vice-chancellor, McGill University; Mrs. V. A. McKillop; Dr. Thorndike Saville, president, Engineer's Council for Professional Development; H. Dolisie, Société des Ingénieurs Civils de France; A. R. Decary, past-president and HON. M.E.I.C.; Madame Georges Demers; H. W. McKiel, past-president and HON. M.E.I.C.; Mrs. J. Hoogstraten; C. E. Davies, HON. M.E.I.C., secretary, ASME; Mrs. Joseph W. Barker; R. Gaudry, president, Chemical Institute of Canada; Mrs. A. J. C. Paine.

Bottom picture, from left: O. B. Thornton, chairman, Executive Council, Canadian Chamber of Commerce; Mrs. E. D. Brown; J. S. Cameron, M.E.I.C., president, Canadian Standards Association; Madame J. G. Chenevert; A. Turner Bone, M.E.I.C., president, Canadian Construction Association; Capt. H. G. Burchell, M.E.I.C., Royal Canadian Navy; Mrs. C. G. Kingsmill; G. Ross Lord, M.E.I.C., chairman, Ontario Section ASME, past-president, Association of Professional Engineers of Ontario; Mrs. R. Gaudry; Leo Roy, M.E.I.C., president, Corporation of Professional Engineers of Quebec; Mrs. E. H. Webb; E. D. Gray-Donald, M.E.I.C., chairman, Montreal Branch, E.I.C.

The ASME Luncheon

At a luncheon held during the Annual Meeting under the auspices of the American Society of Mechanical Engineers, many members heard a vigorous address by ASME president Dr. J. W. Barker. Seen here are the guests at the head table.

Above, from upper left: G. M. Dick, vice-president-elect, E.I.C., Mem. ASME; M. A. Montgomery, vice-president, E.I.C.; C. W. Parsons, M.E.I.C., Mem. ASME; J. O. Martineau, vice-president, E.I.C.; R. L. Dunsmore, vice-president, E.I.C.; W. H. Byrne, vice-president, ASME; General the Hon. A. G. L. McNaughton, M.E.I.C., Hon. Mem. ASME; V. A. McKillop, president-elect, E.I.C.; Dean Thorndike Saville, president, Engineer's Council for Professional Development; Sir George Nelson; J. W. Barker, president, ASME.

Below, from upper left: R. E. Heartz, president, E.I.C., Hon. Mem. ASME; M. D. Hooven, president, American Institute of Electrical Engineers, Mem. ASME; Dr. Lillian M. Gilbreth, Hon. M.E.I.C., Hon. Mem. ASME; Professor A. G. Christie, M.E.I.C., Hon. Mem. ASME; Dr. D. F. Galloway; Dr. W. G. Van Note, Mem. ASME; T. H. Wickenden, Mem. ASME; H. R. Sills, vice-president-elect, E.I.C.; B. G. Ballard, vice-pres., E.I.C.; W. K. Brasher, secretary, Institution of Electrical Engineers.

In the chair at the luncheon was G. Ross Lord, M.E.I.C., chairman of the Ontario Section, ASME.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

DOMINION COUNCIL

National Office for Dominion Council

A national office is to be established in Ottawa by the 30,000-member Dominion Council of Professional Engineers, it was announced at the annual meeting of the Council held at Saskatoon last week.

Durnin Elected President

The new president of the Council, which represents the 11 provincial engineering associations, including the Yukon, is *E. J. Durnin,* of Regina. He succeeds Georges P. Demers, of Quebec City. Other members of the Council's executive are: C. N. Murray, Sydney, N.S., vice president; Prof. W. O. Richmond, Vancouver, executive member; and J. Murray Muir, Toronto, secretary-treasurer.

Confederation Discussed

The meeting saw the circulation of a brief to all councils on the plan for unity which would provide a confederation of all engineering bodies in Canada. After consideration by them, the brief will be studied by the Dominion Council's special committee on unity for further action.

Other matters discussed at the three-day meeting included; consideration by each of the provincial associations of changes in their respective legislation; and the existing federal legislation governing the free entry into Canada of engineering plans from other countries.

E. J. Durnin, M.E.I.C.

Yukon Joins Council

Newest member of the Dominion Council is the Association of Professional Engineers of the Yukon Territory which was represented at the meeting by Lieut.-Col. M. C. Sutherland-Brown, Whitehorse, provisional vice-president.

Also attending as observers were officials of the two U.S. engineering bodies; L. R. Durkee, Seattle, Wash., vice-pres., National Society of Professional Engineers, and Bruce Williams, Joplin, Missouri, president of the National Council of State Boards of Engineering Examiners. Representatives of other technical societies in Canada were in attendance, including G. A. Blackburn, of Ottawa, who represented the Civil Service Commission.

It was announced that the 1957 meeting of the Dominion Council would be held in Nova Scotia. Actual meeting place will be announced at a later date.

QUEBEC

Pierre Bournival, M.E.I.C.

Sécretary-general of the Corporation of Professional Engineers of Quebec is Pierre Bournival, a Laval University graduate in geological engineering, class of 1948. The appointment was made early this year.

He joined the Quebec Roads Department shortly after graduation, working first as a soils engineer. In 1949 he headed a land surveying party on the mapping of rivers and lakes for the department.

Later in 1949 he accepted the appointment of assistant registrar of the Corporation of Professional Engineers of Quebec. He has since served as registrar and assistant general secretary.

He is a native of Shawinigan Falls, Que.

Results of the December, 1955 Salary Survey

In accordance with a practice established some years back, at the Corporation, a salary questionnaire was sent out to the membership in early January. Survey forms were forwarded to approximately 5,700 members and of this number 2,230 completed and returned their forms, thus providing the Remuneration Committee with a fair cross-section of the salary conditions prevailing as of December 1, 1955. The response indicated above represents 39% of the membership which is somewhat better than the 29% return achieved in 1953 but still below the 50% high recorded the year before.

Pierre Bournival, M.E.I.C.

The three charts which were printed in the March 1955 issue of the Bulletin have been reconstructed using the new salary survey figures; the results are presented herewith.

Although the curves are self-explanatory, some of their features are worth commenting upon:

1) Generally, engineers' salaries have been subjected to an upward pressure. It can be seen, for instance, that 50% of the members who responded were earning more than $6,700 per year as compared with $6,400 in 1954. As to the current year's graduates, their median income was $4,100 which compares with $3,900 in 1954.

2) This year again, the survey shows that administrative positions top the salary scale with supervisory functions and non-supervisory work following behind.

A complete tabulation of the results of the December 1955 survey will be made available upon request.

Abstracted from the Bulletin *of the Corporation, June 1956.*

ONTARIO

Russia's Bid

Much has been written regarding the educational program now being carried out in Russia to train engineers, scientists and technical workers. Some arresting facts and impressions of a well known Canadian industrialist, James S. Duncan, C.M.G., are presented in this issue. They are based on a recent and extensive tour of Russia and provide food for serious thought by the peoples of the Western World.

Western Appraisal

Western appraisal of Russian engineers and scientists of some twenty years ago was not very high. Today's reports suggest that the older ideas must be revised for it is evident that by 1955 the progress of technical education has left the entire Western world lagging behind. Mr. Duncan has emphasized the possible Western error of regarding the lower standards of living of the Russian people as signs of backwardness, and of the proneness to underestimate the power, drive and vitality of the U.S.S.R. He also underlines the real danger in cold war which springs not only from Russian Communism but from the ambitious, relentless, uncompromising and expansional policy of Russia's State Capitalism and a totalitarian government.

Discipline in Education

With the Russian education system we must remember that several generations have been brought up to accept the doctrine that the Russian leaders know best and that such is their sense of discipline that the policies of the leaders are accepted without question.

Little Ivan's dream to become a second Shostakovitch has nothing to do with his future. The powers that be will tell him what he has to do and, depending on his abilities he may become an engineer, a scientist, a technician or one of the many skilled laborers. Starting at the age of seven he goes to school, six days a week, and many more weeks in the year than his Canadian fellow being. He'll study mathematics, physics and chemistry whether he likes or not and when and if he is allowed to complete his higher education he will go to work where he is told.

Expansionist Dreams of Progress

We have had a number of years to consider the expansionist dreams of the U.S.S.R. and to witness the progress. We are becoming alarmingly aware of the part education is playing in this plan and are able to compare the Russian education system with others. We are fairly well convinced that we must not let down our own guard and must continue to match Russia's growing industrial and military strength with our own. We realize that much of our own well-being is dependant upon markets abroad and that the shadow of a determined competition is not imaginary. With all this before us it also might be wise to remember that it is much later than we thought.

Abstracted from The Professional Engineer, *May, 1956.*

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Roger DeLand French, M.E.I.C., retired professor of engineering at McGill University, died in Montreal on May 23, 1956.

Born at North Brookfield, Mass., on August 20, 1885, he was educated at Worcester Polytechnic Institute, earning a B.Sc. degree in 1905, and three years later the degree of civil engineer. After graduation he was for a time located in Louisville, Kentucky, where he was employed by the Commissioners of Sewerage, and later by the National Concrete Construction Company of that city.

Established in Canada in 1911, he became the principal assistant engineer with R. S. and W. S. Lea, consulting engineers of Montreal, and did work on water supply, sewage disposal, and various municipal projects for Montreal, Ottawa, Quebec, and other large cities. In 1917 he transferred his services to the consulting engineering firm of Arthur Surveyer and Company of Montreal, and continued this association for three years. Since his arrival in Canada he had carried on, with his other duties, as a lecturer on highway and municipal engineering at McGill. He was made professor in 1920. At that time he was also awarded the Gzowski Medal by the Engineering Institute for a paper on the design and construction of reinforced concrete covered reservoirs. He was awarded the King's Jubilee Medal in 1935.

Serving on the Lignite Board created by the Dominion government, Professor French was instrumental in devising methods of increasing the availability of Saskatchewan's low-grade coals as a domestic fuel. For three years he was a member of the Committee on the Fire Resistance of Roofing Materials of the Dominion Fire Prevention Association. For some time he was a member of the Metropolitan Town Planning Board of Montreal, and during World War II became a member of the Advisory Board Wartime Bureau of Technical Personnel.

At McGill University he held the duties of chairman of the engineering faculty's highway and municipal engineering section, and was secretary of the faculty for over twenty years. He was one of the eight members of the university's placement board. He retired from the university in 1951.

In addition to his many accomplishments Professor French was the author of numerous technical articles, and his facility with the written language was regularly called upon to provide some of the best material for the pages of this Journal.

A member of the American Society of Civil Engineers, he also belonged to the Canadian Institute on Sewage and Sanitation.

His greatest hobby was stamps — postage and revenue. It is stated that his collection of Canadian revenue stamps is the finest in existence. Not only was he among the foremost collectors of stamps but he was an expert consulted frequently by other collectors, estates and universities.

Professor French joined the Institute in 1913, as an Associate Member, became a Member in 1918, and was elected to Life Membership in 1948.

R. DeL. French, M.E.I.C.

Major James Henry Brace, M.E.I.C., president of Fraser-Brace Engineering Company Limited, Montreal, died on April 10, 1956, in Westmount, Que.

He was born in 1870 at Sheridan, N.Y., near Buffalo, but the family later settled in Lone Rock, near Madison, Wisconsin. He attended the University of Wisconsin and graduated in civil engineering, in 1892.

Major James H Brace, M.E.I.C.

For eleven years after graduation, Major Brace was mainly engaged in work on waterways and power schemes in the Great Lakes and upper St. Lawrence River areas. This work included projects for the Chicago Drainage Canal Authority; Chicago Park Commission; United States Board of Engineers on Deep Waterway; New York State Barge Canal Authority; and Michigan-Lake Superior Power Company, Sault Ste. Marie, Michigan. During these years, he worked on surveys, estimates, designs and construction projects for water supply and other municipal services, hydro-electric power developments and a deep waterway canal from the Great Lakes to the Atlantic Ocean.

Proceeding to New York City in 1903, he became assistant to Mr. Alfred Noble, who was the consulting engineer on the construction of the Pennsylvania railroad tunnels under the East River into Pennsylvania Station. On this project he was associated with Mr. Charles E. Fraser, and in 1908 they formed a partnership founding the construction firm of Fraser, Brace and Company. Three years later a third associate, Mr. George C. Clarke, joined as a partner in the company.

This was the commencement of a half-century of activity during which Major Brace, as vice-president, directed the construction activities of Fraser-Brace companies in both Canada and the United States. In this capacity, he was responsible for the construction of many important hydro-electric power developments and extensive industrial projects.

The hydro-electric developments constructed by Fraser-Brace under Major Brace's direction have a total installed capacity of over 2,000,000 h.p., which is approximately one-eighth of the total hydro-electric power developed in Canada up to 1954.

In addition to these electric projects Major Brace directed the construction of some of the largest chemical and metallurgical plants built in Canada. Some of these are as follows: more than fifty projects for the International Nickel Company of Canada Limited, in the Sudbury area of Ontario, numerous chemical and explosive plants for Canadian Industries Limited and the Du Pont Company of Canada Limited, for the manufacture of diversified chemicals and chemical products.

During the first and second world wars, Major Brace contributed all his time and energy to wartime projects. He supervised the construction of the Cedar Rapids power development for the Montreal Light, Heat and Power Company, from 1913 to 1917, and was instrumental in pushing through to completion this pioneer of Quebec's hydro-electric power industry in time to furnish the required power for a substantial portion of Quebec's industrial contribution to World War I.

In 1917 he joined the United States Army as a Major in the U.S. Engineers Corps. 4th Batt., 22nd Engineers, and served with them in France.

In World War II, at the age of seventy-five, Major Brace came out of semi-retirement and contributed unsparingly of his time and energy to supervise in both Canada and the United States many large construction projects having a total value of more than a half-billion dollars.

In the United States the projects supervised at this time by Major Brace, comprised many large ordnance works for the U.S. Government.

In Canada, during the same war period, Major Brace further extended himself to supervise the construction of some of Canada's largest ordnance plants for Defence Industries Limited—a wartime subsidiary of Canadian Industries Limited, including T-N-T cordite plant at Nobel, Ontario; a Cordite plant at Transcona, Man.; Hexachlorethane and P.D.X. plants at Shawinigan Falls, Que., and the first Canadian Atomic Energy plant at Chalk River, Ont.

In addition, under his general supervision, Fraser-Brace constructed several aluminum pot lines for the Aluminum Company of Canada at Shawinigan Falls, La Tuque and Arvida, Quebec, at a time when the production of aluminum had top priority on the allied wartime production program.

Another World War II project of considerable magnitude was United Shipyards Limited, where, in association with the late W. F. Angus, then president of Dominion Bridge Company Limited, Major Brace, as vice-president of United Shipyards Limited, headed up a wartime joint venture which constructed and operated at Montreal, one of the largest shipyards in Canada.

Following the retirement of Mr. Fraser, Major Brace was elected to the presidency of Fraser-Brace in 1946 and guided the affairs of the company during the following eight years.

He was a member of the Corporation of Professional Engineers of the Province of Quebec; A Life Member of the American Society of Civil Engineers of New York, and of the Western Society of Civil Engineers of Chicago.

Major Brace joined the Institute in 1916 as a member, and was elected to Life Membership in 1947.

Robert Wilson, M.E.I.C., general manager of the telephone contract division of the Northern Electric Company Limited, Montreal, since 1953, died on April 12, 1956.

Mr. Wilson was born in Clydebank, Scotland, on September 12, 1897. He attended Clydebank High School and Technical School and on graduation from the latter in 1915, joined the British Army, serving in France and Belgium. He was awarded the Distinguished Conduct Medal. After the war, in 1919, he enrolled at the Royal Technical College, Glasgow, as a student of engineering.

At the conclusion of his studies, in 1922, he moved to Canada. The following year he was taken on the staff of the Northern Electric Company Limited in the capacity of equipment draughtsman. Other positions held, over the years, were dial equipment engineer and supervisor, manual and toll equipment engineer, assistant chief equipment engineer, telephone engineer, chief engineer, installation superintendent, manager of engineering and installation, and acting sales manager of the company's communications equipment division. In 1952 he was named to the post of assistant manager of the telephone contract division.

Robert Wilson, M.E.I.C.

Mr. Wilson was a member of the Corporation of Professional Engineers of the Province of Quebec. He joined the Institute in 1943 as a Member.

George Skiffington Grimmer, M.E.I.C., of Chamcook, N.B., died in St. Stephen, N.B., on April 30, 1956.

Mr. Grimmer was born in St. Andrews, N.B., on Sept. 17, 1887. He attended St. Andrews Grammar School, and then studied at the University of New Brunswick, gaining degrees in 1910 and 1911, in both forestry and civil engineering. He won the City of Fredericton Gold Medal in these subjects.

Following a varied career in engineering, his first professional appointment was that of resident engineer in charge of construction, in 1911, with the Canadian Sardine Company in Chamcook. He was engaged in survey work between New Brunswick and Quebec in 1912. Later, in 1914 he decided to go into private practice as a land surveyor. Within the next few years he was concerned with the development of two large eastern plants. In 1918 he moved to the United States and until 1926, was responsible for a great deal of construction work in the city of New York. Appointed president of the Bachman-Veghte Company, fuel and building materials suppliers, the Fuel Oil and Supply Company and the Elizabeth, New Jersey coal exchange, he remained in the United States until 1953.

It was at this time that he returned to Canada to take up residence at Chamcook, for many years his summer home.

Mr. Grimmer was elected a Member of the Institute in February of this year.

Institute Honours and Awards

Presented at the Seventieth Annual General Meeting

President R. E. Heartz makes awards to J. A. McCrory and A. R. Deca

HONORARY MEMBERSHIPS

Five honorary memberships were awarded this year to distinguished members of the profession: Clarence Ebenezer Davies, M.E., D.ENG., secretary, The American Society of Mechanical Engineers, New York; Albert R. Decary, M.B.E., D.SC., formerly superintending engineer, Province of Quebec, Department of Public Works, Quebec; Francis William Gray, LL.D., formerly assistant general manager, Dominion Steel and Coal Corporation, Victoria; James Alexander McCrory, B.SC. (mechanical engineering), D.SC., engineering consultant, Shawinigan Engineering Company, Montreal; Harold Wilson McKiel, B.Sc., LL.D., vice-president, Mount Allison University, Sackville. Citations accompanying the awards were as follows.

Clarence Ebenezer Davies, HON.M.E.I.C.

Clarence Ebenezer Davies was born in Utica, N.Y., and graduated from the Rensselaer Polytechnic Institute with the degree of Mechanical Engineer in 1914.

Following graduation he entered the production department of the Smith Premier Works of the Remington Typewriter Company in Syracuse, N.Y. In 1917 he became an assistant production superintendent at the Frankford Arsenal of the United States Army and a year later was promoted to superintendent of its fuse shop. At the conclusion of the first world war Dr. Davies returned to the Remington Typewriter Company and shortly after became production superintendent at their Syracuse Works.

In 1920 he joined the staff of the American Society of Mechanical Engineers as associate editor. He has remained with that great organization ever since and has been its executive officer since 1931.

When the United States entered the second World War, he was called to the post of chief of the Control Division in the office of the Chief of Ordnance of the War Department in Washington, with a rank of colonel. For these services he was awarded the United States Legion of Merit.

Colonel Davies was one of the organizers and the first secretary of the Engineers' Council for Professional Development, of which our own Colonel L. F. Grant has been president for the past three years. For two years he was president of the Newcomen Society of England, the first and only person outside of England to hold this office.

He joined the Engineering Institute of Canada as a member in 1937, and is, as well, a fellow of his own society and of the American Association for the Advancement of Science, a member of the Institution of Mechanical Engineers, of the Society of Automotive Engineers, of the American Management Association, and a number if other organizations.

Colonel Davies was awarded honorary doctor of engineering degrees by Clarkson Institute of Technology in 1948 and by Drexel Institute of Technology in 1950.

Probably no other American engineer in our generation has done more to promote mutual understanding and practical working relationships among the engineering societies of the Western World, and particularly between The Engineering Institute of Canada and The American Society of Mechanical Engineers.

The characteristics that have made Clarence Davies a great secretary and a great servant of our profession are imagination, vision, perception, dynamic and persuasive leadership and the ability to plan and carry out great projects. He is a great secretary, a great friend and a great man.

Albert R. Decary, HON.M.E.I.C.

Albert R. Decary was born in Montreal, in eighteen hundred and seventy-five. He received his education at St. Mary's College in Montreal and at the Ecole Polytechnique in Montreal. He was with the Department of Public Works of Canada on hydrographic work on the St. Lawrence River, between Kingston and Quebec, from 1900 to 1905. At that date, he was appointed district engineer at Quebec, which office he held until 1913, when he became superintending engineer, having jurisdiction over the Province of Quebec.

He was intimately connected with all the important river and harbour works made by the Dominion Government since 1900, including the Champlain dry dock at Quebec, and the new Esquimalt dry dock in British Columbia; in connection with this latter undertaking, he was chairman of the board of engineers specially entrusted with the design and preparation of plans.

Dr. Decary joined The Engineering Institute of Canada in 1900. He was a councillor from 1914 to 1924, when he became vice-president. In 1925 he was elected president of the Institute.

When the Quebec Branch of the Institute was formed in 1907, Dr. Decary was among its principal promoters; he was a charter member and a member of the first executive committee, an officer of which he has remained ever since. He was chairman of the branch for eight years; in 1913 and from 1919 to 1925. Upon retiring from the chairmanship, the Quebec members made him their honorary chairman for life.

He was largely responsible for the establishing of the Corporation of Professional Engineers of Quebec. He was elected the first president in 1920, which office he held until 1938.

Dr. Decary is also a member of the Province of Quebec Association of Architects, a fellow of the Royal Architectural Institute of Canada, and holds membership in the Quebec Board of Trade, the Permanent International Association of Navigation Congresses, the Canadian Institute, the Quebec Geographic Society, the Canadian Forestry Association, the Canadian Club, the Quebec Garrison Club, the Engineers' Club of Montreal, the Quebec Golf Club, the Royal St. Lawrence Yacht Club of Montreal, the Quebec Yacht Club, the Cercle Universitaire Laval and the Cercle Universitaire Montreal.

In 1927 he was given the honorary degree of doctor of applied science by the University of Montreal and in 1949 the same degree from Laval University.

He was made a Member of the Order of the British Empire in 1943.

Francis William Gray, HON.M.E.I.C.

Francis William Gray was born in Yorkshire, England, and graduated from Sheffield University in 1899. He came to Canada in 1904, to work with our own past president, George Herrick Duggan. His professional and business life was spent entirely in the Cape Breton area with the Dominion Steel and Coal Company and its various affiliated enterprises. In 1928 he became assistant general manager of Dosco, a position which he held until his retirement in 1945. In some way or other during these busy years he managed to fill the posts of editor of the *Canadian Mining Journal* and *Iron and Steel of Canada* from 1919 to 1921. Like so many other wise men from the east, after retirement he moved to Canada's garden spot of Victoria, British Columbia.

Dr. Gray was an outstanding authority on mining coal under the sea. He introduced oxygen breathing apparatus for fire fighting in coal mines in Canada, and has served as consultant in both technical and labour boards in the West.

Dr. Gray has been active in several engineering organizations including the Engineering Institute of Canada. He has been president of the Canadian Institute of Mining and Metallurgy, and the Mining Society of Nova Scotia, and is an honorary member of the Association of Professional Engineers of Nova Scotia. He has been a member of the Institution of Mining Engineers of Great Britain for fifty-two years.

His character and achievements have been recognized formally by several organizations. Dalhousie University awarded him the honorary degree of doctor of laws, the Canadian Institute of Mining and Metallurgy their Barlow Medal and the Engineering Institute of Canada their Leonard Medal in 1923, and their Julian C. Smith Medal in 1940.

He joined the Engineering Institute of Canada in 1921 and served as councillor in 1942.

Dr. Gray is one of those rarer types, who successfully and respectfully live a double life. All through his workaday life he has been a patron and a producer in the field of the arts. He is distinguished as a painter, a sculptor and an author in both prose and verse.

He is the sort of fully developed man who so many people bemoan does not exist. He gives the lie to those uninformed and prejudiced persons who say the engineer has no culture.

We are grateful to him for this service to our profession. He is an ornament to our calling.

F. W. Gray

H. W. McKiel

C. E. Davies

James Alexander McCrory, HON.M.E.I.C.

James Alexander McCrory was born in Pittsburgh, Pa., and graduated from Pennsylvania State College in 1907 with a B.Sc. degree in mechanical engineering.

He came to Canada in 1910, joining the staff of the Shawinigan Water and Power Company as an assistant engineer. When the Shawinigan Engineering Company was formed in 1918, he was appointed office engineer, in which capacity he served until 1935, when he was made vice-president and chief engineer. He became president of the company in 1949 and chairman of the board of directors in 1951, continuing in the latter post until 1953, after which he served as engineering consultant until 1955, when he retired.

Mr. McCrory is probably best known for his contribution to the development of the great power resources of the St. Maurice River. In recognition of these services he was awarded the Julian C. Smith Medal of the Institute in 1950 and the honorary degree of doctor of science by McGill University.

Joining the Engineering Institute of Canada in 1921, Doctor McCrory served it for many years. He was chairman of the Montreal Branch in 1929 and a member of Council from 1930 to 1935. In 1937-1938 he was vice-president and chairman of the finance committee.

Doctor McCrory was president of the Corporation of Professional Engineers of the Province of Quebec in 1942.

Dr. McCrory is a conspicuous example of the all too few instances where Canada benefits greatly by the immigration of highly educated, intelligent men from our great neighbour. This is the sort of invasion which we like to encourage.

Harold Wilson McKiel, HON.M.E.I.C.

Harold Wilson McKiel was born in Gananoque, Ontario, and graduated from Queen's University, Kingston, with a B.A. degree in chemistry in 1908, after which he continued his studies to obtain a B.Sc. with honours in chemical engineering in 1912. In 1913 he was appointed professor of mechanical engineering at Mount Allison University. He held this position for seven years and served at the same time for most of the period as secretary and registrar of the faculty. In 1920 he was made Brookfield professor of engineering, becoming dean of the faculty in 1934. In 1949 he was appointed vice-president of the university.

Dean McKiel served in a consulting capacity with a number of prominent maritime industries for many years and also devoted considerable time to professional development and engineering education. He was given the honorary degree of doctor of laws by Mount Allison in 1943.

Doctor McKiel joined The Engineering Institute in 1919. He was made a Life Member in 1955. He served as a councillor in 1927, becoming vice-president in 1936-1937. In 1939 he was elected to the presidency of the Institute—the first to be chosen from the Maritime Provinces.

Doctor McKiel is a fellow of The Canadian Institute of Chemistry, having served as a councillor, chairman and vice-president of the Maritime Section. He is a past president of the Association of Professional Engineers of New Brunswick. For almost twenty years he was a member of the board of governors of the Nova Scotia Technical College at Halifax. He has been an active Rotarian throughout his life, and successively held the positions of district governor, Canadian director and vice-president of Rotary International.

It is fitting, Sir, that his betters and his equals in his calling here assembled should recognize his contributions to the profession by making him an honorary member of the Institute.

JULIAN C. SMITH MEDALS

Two awards were made this year: to Howard Kennedy, C.B.E., M.C., B.SC. (civil engineering), consulting engineer, Ottawa; and Adrien Pouliot, B.A.SC., C.E., M.SC., L.SC., LL.D., dean of the faculty of science, Laval University, Quebec. The citations are as follows:

Howard Kennedy, M.E.I.C.

Howard Kennedy was born in Dunrobin, Ontario. He was graduated in civil engineering from McGill in 1914; immediately he immersed himself in military affairs, a field in which he acquired great distinction, rising through two wars to the rank of major general, and being awarded the Military Cross, and in 1944 a C.B.E.

His professional career in civil life has been spent almost wholly with the forests and their products. He has been associated in a senior capacity with the E. B. Eddy Company, Quebec Forest Industries Association, Ontario Paper Company and the Quebec North Shore Paper Company. In 1946 he was appointed a one-man commission on forestry in Ontario, and in 1954 chairman of a Royal Commission on Forestry in Newfoundland. Also he was chairman of the Eastern Rockies Conservation Board.

General Kennedy has been a staunch supporter of institutions associated with his profession, such as The Engineering Institute of Canada, the Canadian Pulp and Paper Association, the Quebec-Ontario Industries Association, the Association of Forest Engineers, the Forest Insect Control Board, and the Canadian Forestry Association.

In military circles he has been active in the Military Engineers Association. He was made honorary colonel of the Fourth District Royal Canadian Engineers in 1945 and the Tenth Field Engineers Regiment in 1953.

His military record is a notable one. Starting in the first World War with the Canadian Engineers he went overseas with the rank of captain. In 1917 he received the Military Cross. At the outbreak of the second World War he went overseas again, this time with the rank of major in command of the Third Field Company of the Royal Canadian Engineers.

In 1941 he returned to Canada to take charge of training schedules, and methods of officer selection for the Royal Canadian Engineers. He occupied successively the posts of general staff officer in charge of trades training, adjutant general, and quartermaster general.

In 1953 he was recalled to the army to serve as chairman of a board of enquiry into conditions in the reserve army.

He joined The Engineering Institute in 1921, and in 1956 attained life membership. In 1946 he served as chairman of the Institute's Rehabilitation Committee for Armed Forces Personnel.

Howard Kennedy

Adrien Pouliot

Morris Katz

Adrien Pouliot, M.E.I.C.

Adrien Pouliot was born at Saint-Jean, Island of Orleans, Que. He received his B.A. degree from Laval University in 1915, and his B.A.Sc. degree from Ecole Polytechnique in 1919. In 1928 he obtained both his M.A. degree from Laval and his L.sc. from Sorbonne in Paris; the following year undertaking postgraduate study at the University of Chicago. Dr. Pouliot also holds an LL.D. of the University of Ottawa, an honorary D.Sc. of the University of Montreal, doctorates d'honneurs of the University of Poitiers and Rennes, France, honorary doctorate in philosophy of Milan, Italy, and a doctorate in letters of St. Joseph's University, Moncton.

In 1919 Dr. Pouliot was employed on the engineering staff of the Department of Public Works in Quebec, and at the same time lectured in mathematics at Laval, becoming professor of mathematics in 1928. Ten years later he was appointed secretary of the faculty of science. In 1940 he was named dean of the faculty of science, serving as director of the department of mathematics until 1950, and since then as director of the department of civil engineering.

He was appointed vice-chairman of the board of governors of the Canadian Broadcasting Corporation in 1955, having served as a member of the board since 1939. He is a past-president of the French-Canadian Association for the Advancement of Sciences, of the National Congress of Mathematicians, the Quebec Society of Mathematicians, and the Corporation of Professional Engineers of Quebec, of the Graduates of Ecole Polytechnique, of the Conseil de la Vie Francaise en Amerique and of the Societe du Parler Francais au Canada. He served as vice-president of the Canadian Committee on the Council of Reconstruction, through UNESCO, in 1948. He is an honorary and life member of the Engineer Doctors of France, and a member of the Scientific Research of Quebec; the Mathematicians Society of France, member of the Societe des Ingenieurs Civils de France, the American Mathematical Society, the American Association for the Advancement of Science, the Mathematicians Association of America, and the Canadian Institute of Mining and Metallurgy.

He is a Knight of the Legion of Honour, a Commander of Saint Gregory the Great, a Knight of the Latin Order, Officer of the Academy and Laureate of the Academie Francaise. He has also received the Medal of Honour from the Universities of Turin, Brussels and Liege and from the City of Dieppe and the Medal Archambeau for 1955 from the ACFAS.

He joined the Engineering Institute of Canada as a Member in 1942.

DUGGAN MEDAL AND PRIZE

The Duggan Medal and Prize, awarded for papers dealing with the use of metals for structural or mechanical purposes, was awarded to three authors of the paper "Fatigue Life of Steel I-Beams at Normal and Sub-zero Temperatures". They are Julien Dubuc, B.A.SC., C.E., M.A.SC., JR.E.I.C., associate professor, Ecole Polytechnique, Montreal; Thomas A. Monti, B.SC.A., D.SC.A., M.E.I.C., consulting engineer, Montreal; and Georges A. Welter, B.A.S.C., D.ENG., M.E.I.C., professor of applied mechanics, Ecole Polytechnique, Montreal. This paper was published in *The Engineering Journal May, 1955 issue.*

Julien Dubuc, JR.E.I.C.

Professor Julien Dubuc was born in Quebec, Canada, and received his engineering degree in 1947 from Ecole Polytechnique of Montreal, where he became assistant in the strength of materials laboratory.

He received his master of science degree in 1949, and for the next two years he carried on postgraduate studies at the Federal Polytechnic Institute in Zurich, Switzerland.

He is now associate professor at Ecole Polytechnique in Montreal.

Mr. Dubuc joined The Engineering Institute as a Student in 1944, transferring to Junior in 1949.

T. A. Monti, M.E.I.C.

Dr. T. A. Monti is a past chairman of the Junior Section of the Montreal Branch of the Engineering Institute, and a former member of the executive of the Branch. He has also been a vice-president of the Corporation of Professional Engineers of Quebec.

His engineering degrees were gained from Ecole Polytechnique, Montreal — B.A.Sc. in civil engineering in 1941, and D.A.Sc., in 1947 with specialization in strength of materials. He has earlier been awarded Institute prizes—the Ernest Marceau Prize in 1941 and the Keefer Medal in 1951.

Dr. Monti was employed by the Dominion Bridge Company, Lachine, from 1941 to 1943, as a steel structures and bridge engineer. During his doctorate studies, 1943 to 1947, he worked as a consulting engineer. Completing his studies, he joined the National Research Council staff as a regional representative, and in 1949 became district engineer for the Canadian Institute of Steel Construction for Quebec and the Maritimes. Since 1952 he has practised as a consulting engineer in Montreal, in the firm Letendre, Monti and Associates.

Dr. Monti joined the Engineering Institute in 1938 as a Student, transferring to Junior in 1946, and to Member in 1949.

Georges Welter, M.E.I.C.

Dr. Georges Welter studied engineering at the University of Charlottenburg, Berlin, Germany, receiving a B.A.Sc. degree in mechanical engineering and metallurgy in 1914, and that of D.Eng. in 1916. He was born in Luxembourg.

From 1918 to 1931 Dr. Welter performed research work on Light, Ultra-Light and Antifriction-Alloys at the research laboratories of the Metallgesellschaft at Francfort on Main. He was chief of the mechanical and technological departments of these laboratories.

He became a professor at the faculty of chemistry and metallurgy, in the Polytechnical Institute of Warsaw, Poland, working there from 1931 until 1939. During this time he also organized a new governmental institute for metallurgy and scientific research work at Warsaw. He was made a vice-director of the Institute of Metallurgy and Metallography.

In 1941 he joined the staff of Ecole Polytechnique, Montreal as professor of strength of materials and head of the metallographical and mechanical testing laboratories. Here much research work was done for the National Research Council and at the request of such agencies as the Carnegie Corporation, the British Air Ministry, the Department of Mines of Quebec, the Defence Research Board, the Welding Research Council and others. Results of this research have been compiled and in many cases published.

Altogether since 1920, over a hundred scientific publications have been contributed by Dr. Welter to English, French and American technical periodicals.

THE LEONARD MEDAL —

The Leonard Medal, awarded for papers on mining subjects submitted either to the Canadian Institute of Mining and Metallurgy or to The Engineering Institute of Canada, was presented to Franc R. Joubin, B.A.SC., M.A., M.C.I.M, for his paper "Uranium Deposits of the Algoma District".

Franc R. Joubin, M.C.I.M.

Francis (Franc) R. Joubin was born in San Francisco, California, in 1911 and was brought to Canada in 1912. He became a naturalized Canadian in 1918.

Receiving his early education in Victoria, he studied also at the University of British Columbia, obtaining a B.A. degree, majoring in chemistry (1936) and an M.A., majoring in geology (1942).

He has worked in the field of geological exploration throughout Canada and in several Central American countries. He has written and lectured widely on Canadian exploration methods for technical journals and societies in Canada and abroad. Among his better known works is the paper entitled "Modern Methods of Mineral Exploration in Canada" prepared by him at the request of the Canadian Institute of Mining and Metallurgy for presentation to the Fourth Empire Geological Congress (Oxford, 1949), his contributions to the "Structural Symposium on Canadian Ore Deposits"; and his several recent papers including that on "Uranium Deposits of the Algoma District, Ontario", presented through the American Geological Institute to the Nuclear Engineering and Science Congress in Cleveland in December, 1955.

It was in 1948 that Mr. Joubin turned his attention to exploration for uranium deposits. Under his leadership a small group of geologists, engineers and metallurgists have discovered, developed and have readied for production at least eight uranium mines in the Beaverlodge district of Saskatchewan, in British Columbia and in the Algoma District of Ontario. The developments in the Algoma field directed by Mr. Joubin will establish Canada as a world leader in the production of uranium.

Mr. Joubin has been generous with his service to professional societies of which he is a member, acting on committees and presenting technical papers. The associations to which he gives his support are the Canadian Institute of Mining and Metallurgy (member of the committee on applied field geology and member of the executive of the Toronto Branch); the American Institute of Mining and Metallurgical Engineers, the Geological Society of Canada, and the Associations

Franc R. Joubin

of Professional Engineers of British Columbia and Ontario.

He has served until recently as managing director of Pronto Uranium Mines, Rix Athabasca Uranium Mines, Rexspar Uranium Mines, Lake Nordic Uranium Mines, Spanish American Uranium Mines; as a director of Preston East Dome Mines and as president and managing director of Algoma Uranium Mines.

PLUMMER MEDAL

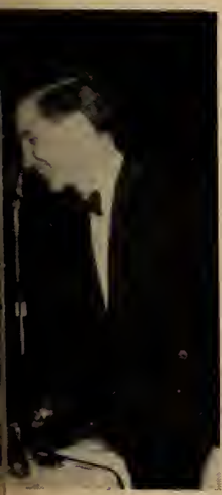
The Plummer Medal, for papers on chemical and metallurgical subjects, is awarded this year to Morris Katz, B.SC., M.SC., PH.D., M.E.I.C., consultant on Atmospheric Pollution; chairman, Technical Advisory Board on Air Pollution, Department of Health and Welfare, Ottawa. His paper "The Nature, Distribution and Dispersion of Contaminants in the Urban Environment" was published in the April, 1955 issue of *The Engineering Journal*.

Morris Katz, M.E.I.C.

Dr. Morris Katz is a graduate of McGill University with the degrees of B.Sc. in chemical engineering, 1926, M.Sc. in 1927 and Ph.D. in 1929; with early specialization in organic and biological chemistry and later in physical chemistry. While at McGill he also served as a demonstrator in various branches of chemistry.

Late in 1929, he was called in to investigate the international problem of smelter fumes at Trail, B.C.; in 1931 he returned to Ottawa as a member of the research staff, Chemistry Division, National Research Council. In 1934, there was another flare-up of the fume problem at Trail, and he was appointed officer-in-charge of field and experimental work on the effects of sulphur dioxide on vegetation, soil and water supplies and other aspects of the problem. This research was completed in 1937.

Julien Dubuc



Thomas Monti

Georges Welter

In 1939, the National Research Council published a book entitled, "Effects of Sulphur Dioxide on Vegetation", based on the experimental and scientific investigations of Dr. Katz and his co-workers at Trail and Summerland. This book is considered a classic in its field and is still widely used.

During World War II, as consultant to the Directorate of Chemical Warfare, he undertook the development of more effective catalysts for the oxidation of carbon monoxide, in addition to respirator and personnel protection problems. When the chemical warfare studies were transferred to the Defence Research Board in 1947, Dr. Katz was taken on staff of the Board as a research scientist and occupied this position until joining the Department of National Health and Welfare in January 1956, as consultant on atmospheric pollution. He holds world patent rights on a new type of oxidation catalyst and has perfected an improved type of carbon monoxide indicator.

Since 1949, Dr. Katz has been chairman of the Canadian Section of the Technical Advisory Board on Air Pollution, International Joint Commission, and in this connection he has been in charge of all field and experimental work relating to the Canadian part of the International Detroit-Windsor air pollution problem.

Dr. Katz is the author of about seventy-five scientific papers in the fields of high polymers, kinetics of heterogeneous reactions, catalysis, toxic gases and their effects on plants, measurement, identification and control of atmospheric pollution.

ROSS MEDAL

The Ross Medal is awarded for papers on electrical engineering subjects. George William Holbrook, B.SC., M.SC., M.E.I.C., head of the department of electrical engineering, Royal Military College of Canada, Kingston, won this award for his paper "Design of a Wide Audio Band", which was published in the November, 1955 issue of *The Engineering Journal.*

George William Holbrook, M.E.I.C.

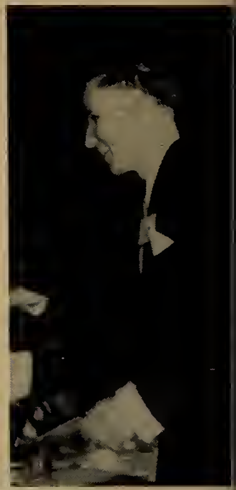
Prof. Holbrook is originally from Asquith, Saskatchewan. He studied at the University School in Hastings, Sussex, England, and at London University (Woolwich Polytechnic), receiving the Woolwich engineering diploma, and a B.Sc. degree in electrical engineering in 1938. In 1948 and 1949 he studied at Queen's University, Kingston, after which he obtained the degree of M.Sc. in electrical engineering.

His professional training and experience began in London, England, with four years as an accredited engineering student with Standard Telephones and Cables, and one as a laboratory engineer in the transmission laboratory of the company.

He became a signals officer in the Armoured and Airborne formations, for the British Army (Royal Signals) in 1939, retiring in 1946 with the rank of major. He transferred to the Canadian Army in 1946, and serving in the Royal Canadian Signals, was chief instructor at the Royal Canadian School of Signals, and head of the department of electrical engineering, Royal Military College of Canada. He retired with the rank of lieutenant colonel in 1951.

H. J. Saaltink

G. W. Holbrook



R. R. Real

Since 1951 he has been a Civil Service professor and head of the department of electrical engineering, R.M.C.

Prof. Holbrook has completed many research and development projects during this time, as well as the one on which his prize-winning paper was based. Some of the subjects were resistance capacitance oscillators, speech scrambling system, harmonic measuring set.

He is an associate member of the Institution of Electrical Engineers, and a member of the Association of Professional Engineers of Ontario. Among his present publications are papers on "Variable Gain Amplifier", published in *Electronics;* and "High Frequency R.C. Oscillator", *Electronic Engineering,* Vol. 25.

JOHN GALBRAITH PRIZE

The John Galbraith Prize is awarded for the best paper by a Junior in the Province of Ontario. It was won by Hendrik Jan Saaltink, JR.E.I.C., engineer, hydraulic Department, H. G. Acres and Company, Niagara Falls, Ont., for his paper "In the Wake of Hurricane Hazel" written in collaboration with R. L. Clinch and published in the August, 1955 issue of *The Engineering Journal.*

Hendrik Jan Saaltink, JR.E.I.C.

H. J. Saaltink was born in Semarang in the Dutch East Indies in 1923, and received his early schooling and secondary education alternately in the Netherlands and in the Dutch East Indies.

From 1941 to 1950, he served in the Engineering Corps of the Royal Dutch East Indies Army in the Pacific, lastly with the rank of first lieutenant. In 1952 he received his degree in civil engineering from the Technological University in Delft, The Netherlands.

Upon his arrival in Canada in May 1952, he joined the staff of H. G. Acres and Company Limited, consulting engineers, and has since been engaged in various phases of engineering, mainly in connection with hydro-electric developments.

He is a member of the Association of Professional engineers of Ontario.

PHELPS JOHNSON PRIZE

The Phelps Johnson Prize is awarded for the best paper by an English Junior in the Province of Quebec. Roderick Roy Real, B.ENG., JR.E.I.C., is awarded this prize for a paper "Over the Hill and Line of Sight", which is a treatise on the propagation of electromagnetic waves from radio to microwave frequencies.

Roderick Roy Real, JR.E.I.C.

Mr. Real is an electrical engineering graduate of the University of Saskatchewan, class of 1953, with the degree of B.Sc. in electrical engineering. At present he is one of seven engaged in graduate studies in communications, leading to the degree of M.E., electrical engineering, at McGill University.

He was earlier for two and one-half years in the power cable testing and design division of Northern Electric Co. Ltd., Lachine, Que.

His graduate studies will extend to May, 1957. He has been on the electrical engineering staff of McGill as a laboratory demonstrator for the 1955-1956 session, and this will be repeated in the next session. He is also the recipient of a National Research Council grant for his research project. This is one of a series of noise and acoustics problems, of concern to industry, being conducted by Dr. F. S. Howes, professor of electrical engineering at McGill.

In addition to his association with The Engineering Institute, Mr. Real is a student member of the Institute of Radio Engineers, and is associated with the Society of Sigma Xi, for the promotion of research in the sciences in North America.

Personals

News of the Personal Activities of Members of the Institute.

T. Ingledow, M.E.I.C., president of the B.C. Engineering Company Limited, in Vancouver, has been awarded an honorary degree from the University of British Columbia.

A native of Cumberland, England, and a graduate of the University of Glasgow, he was named president of B.C. Engineering Company Limited in 1954, at the same time holding the appointment of vice-president and executive engineer with B.C. Electric Company Limited.

B. G. Ballard, O.B.E., M.E.I.C., vice-president (scientific) of the National Research Council of Canada and director of its division of radio and electrical engineering, recently received the degree of doctor of science from Queen's University, Kingston, Ont.

Dr. Ballard was born in 1902 at Fort Stewart, Ontario, and graduated from Queen's University in 1924. Following a Westinghouse graduate course in electrical engineering in 1924-25, he joined the staff of the Westinghouse Electric and Manufacturing Company, East Pittsburg, Pa.

In 1930 he was appointed to the National Research Council of Physics, and

B. G. Ballard, M.E.I.C.

throughout the following ten years built up the electrical engineering section of that Division.

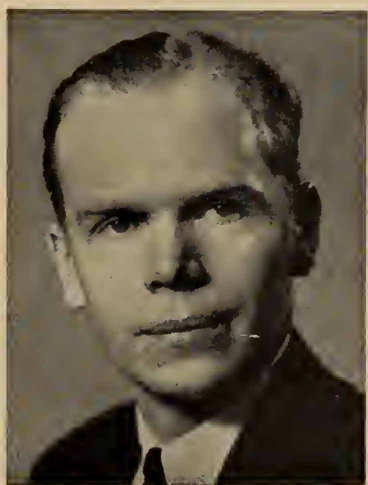
For his wartime efforts, which included the development of mine sweepers and other means of protecting ships against enemy magnetic mines, Dr. Ballard was awarded the Order of the British Empire.

In 1946 he was named assistant director of the division of physics and electrical engineering, and in 1948, a full division of radio and electrical engineering was established, with Dr. Ballard as director. He was named vice-president in 1954.

R. A. Emerson, M.E.I.C., vice-president of operations and maintenance with Canadian Pacific Railways, has been elected treasurer of The Engineering Institute.

From Manitoba originally, Mr. Emerson received his schooling at Morden and then went on to engineering studies at the University of Manitoba from which he graduated in 1930. Three years later he was honoured in being chosen a Strathcona Memorial Fellow and in the term 1933-34, carried on further work at Yale University.

Mr. Emerson's association with Canadian Pacific Railway dates back to 1935. His first appointment with the company was at Revelstoke, B.C. He spent the next nine years in various railway positions across the Prairie Provinces, and in 1944, then a division engineer, he received an appointment to Vancouver as assistant district engineer. Within a short



R. A. Emerson, M.E.I.C.

time he was district engineer for British Columbia.

In 1948, named to take over the system office of the engineer of track in Montreal, he left Western Canada and has remained in the eastern city to the present time, rising in three years to the position of chief engineer of the company. He received his most recent appointment in 1955.

Mr. Emerson is a member of the Corporation of Professional Engineers of Quebec and the American Railway Engineering Association.

C. K. McLeod, M.E.I.C. Following the annual meeting of Walter Kidde and Company of Canada Limited, it was announced that C. K. McLeod had been elected president. Mr. John F. Kidde remains as a director. Mr. McLeod has

C. K. McLeod, M.E.I.C.

been associated with the company for thirty years, and has been the managing director for the last sixteen.

Karl Ewart Whitman, M.E.I.C., consulting engineer of Halifax, N.S., was awarded an honorary degree of doctor of engineering at the annual convocation of the Nova Scotia Technical College held recently.

Mr. Whitman is a native of Advocate Harbor, N.S., and a graduate in civil engineering from the Nova Scotia Technical College, class of 1914.

He returned to Nova Scotia in 1923, having worked in other parts of Canada, and it is in this province that most of his engineering work has been done. He was, at first, associated with the Avon River Power Company, and later, in 1925 and 1926, was assistant professor of civil engineering at the Nova Scotia Technical College. In the succeeding twenty years, he did a great deal of work with the Department of Highways of Nova Scotia, the Avon River Power Company, and the Nova Scotia Power Commission. Since 1947 he has been in private practice. Over a period of thirty years Mr. Whitman has been concerned with the structural or hydraulic design of most of the hydro-electric developments.

K. E. Whitman, M.E.I.C.

A member of the Association of Professional Engineers of Nova Scotia, he is also a member of the American Society of Civil Engineers, the American Concrete Institute and the Association of Consulting Engineers of Canada.

T. M. Parr, AFFIL. E.I.C., of Canadian Ingersoll-Rand Company Limited, Toronto, has been appointed manager of the firm's central region, responsible for the operation of branches at Toronto, Kirkland Lake, Timmins, Sudbury and Winnipeg. Geographically the central region covers Manitoba, Northern and Western Ontario, the mining area of North Western Quebec and Southern and Central Ontario as far east as Kingston.

Born in Morden, Manitoba, Mr. Parr was educated at St. John's College Winnipeg, and the University of Manitoba. After a few years service with the Canadian National Railways in Western Canada, he joined Canadian Ingersoll-Rand Company Limited in 1927 and on completion of a training course at Sherbrooke, Que., was transferred to head office in Montreal, working in the compressor, pulp and paper and general sales divisions. In 1928 he joined the sales force at Toronto, specializing in industrial and construction sales work. During the next three years Mr. Parr handled mining, construction, railway and industrial sales at Kirkland Lake, Winnipeg and Calgary.

In 1931, Mr. Parr returned to Toronto and, after gaining broad experience in mining, construction, petroleum and various industrial fields, he succeeded the late G. R. Southee as branch manager in 1940. In 1951 he was appointed regional manager, Toronto.

Mr. Parr is a member of the Canadian Gas Association, Canadian Institute of Sewage and Sanitation, American Water Works Association, Canadian Section, and a past chairman of the Toronto Branch of the Canadian Institute of Mining and Metallurgy.

For information about appointment of three regional managers of the company see "Business and Industrial Briefs."

Dr. Harold W. McKiel, M.E.I.C. Among those receiving an honorary degree in 1956 convocation exercises in Canada this spring was Dr. Harold W. McKiel, vice-president of Mount Allison University, Sackville, N.B. He was awarded the degree of honorary doctor of engineering at graduation exercises held recently at Nova Scotia Technical College, Halifax, N.S.

Dr. Charles A. Robb, M.E.I.C., Montreal consulting engineer and retired professor of mechanical engineering at McGill University was recently awarded an honorary degree from Mount Allison University, Sackville, N.B.

A graduate of McGill University, the Massachussetts Institute of Technology, and John Hopkins University, he was

Dr. Charles A. Robb, M.E.I.C.

professor of mechanical engineering and resident engineer at the University of Alberta for twenty years. He has also taught engineering at the M.I.T.

During the early days of World War II he was engaged by the Canadian government as power consultant to the Department of Munitions and Supply. From 1942 to 1945 he was with the Aluminum Company of Canada as a power expert and was concerned with steam and hydro power costs and with power resources.

At the end of the war Dr. Robb took office as chairman of the department of mechanical engineering at McGill University. He taught thermal power plant design. It was in 1953, on leaving the university staff that he became established as a consulting engineer.

Dr. Robb joined the Institute in 1908, as a Student, transferred to Associate Member in 1913, and to Member in 1923. He attained life membership in 1948.

L. C. Sentance, M.E.I.C., has been named manager of the new defence apparatus division of the Canadian Westinghouse Company Limited.

Mr. Sentance joined Canadian Westinghouse in 1937 following his graduation as a mechanical engineer from the University of Saskatchewan and two years spent as a lecturer at that University. After serving his engineering apprentice course he joined the apparatus division as a design engineer, and in 1951 was appointed manager, manufacturing department, apparatus division. In 1952 he was made manager, manufacturing department, electronics division.

Mr. Sentance was this year elected to serve as councillor representing the Hamilton Branch of the Engineering Institute.

W. L. Hutchison, M.E.I.C., has returned to Canada after several years' service in Great Britain with Remington Rand Limited. He has accepted the appointment as general works manager of Moffats Limited, a division of Avco Manufacturing Corporation, in Weston, Ont.

Mr. Hutchison was responsible for setting up the manufacturing facilities for the noiseless typewriter in Scotland, and later became supervisor of production in the company's United Kingdom operations. In New York, in 1953, he held the position of assistant director of European production in the International division of Remington Rand Inc.

He had, in 1946, while still in Canada, been working as plant manager for the company in Hamilton, Ont.

Prior to that he held the position of general superintendent of the Hamilton Bridge Company Limited, in that city.

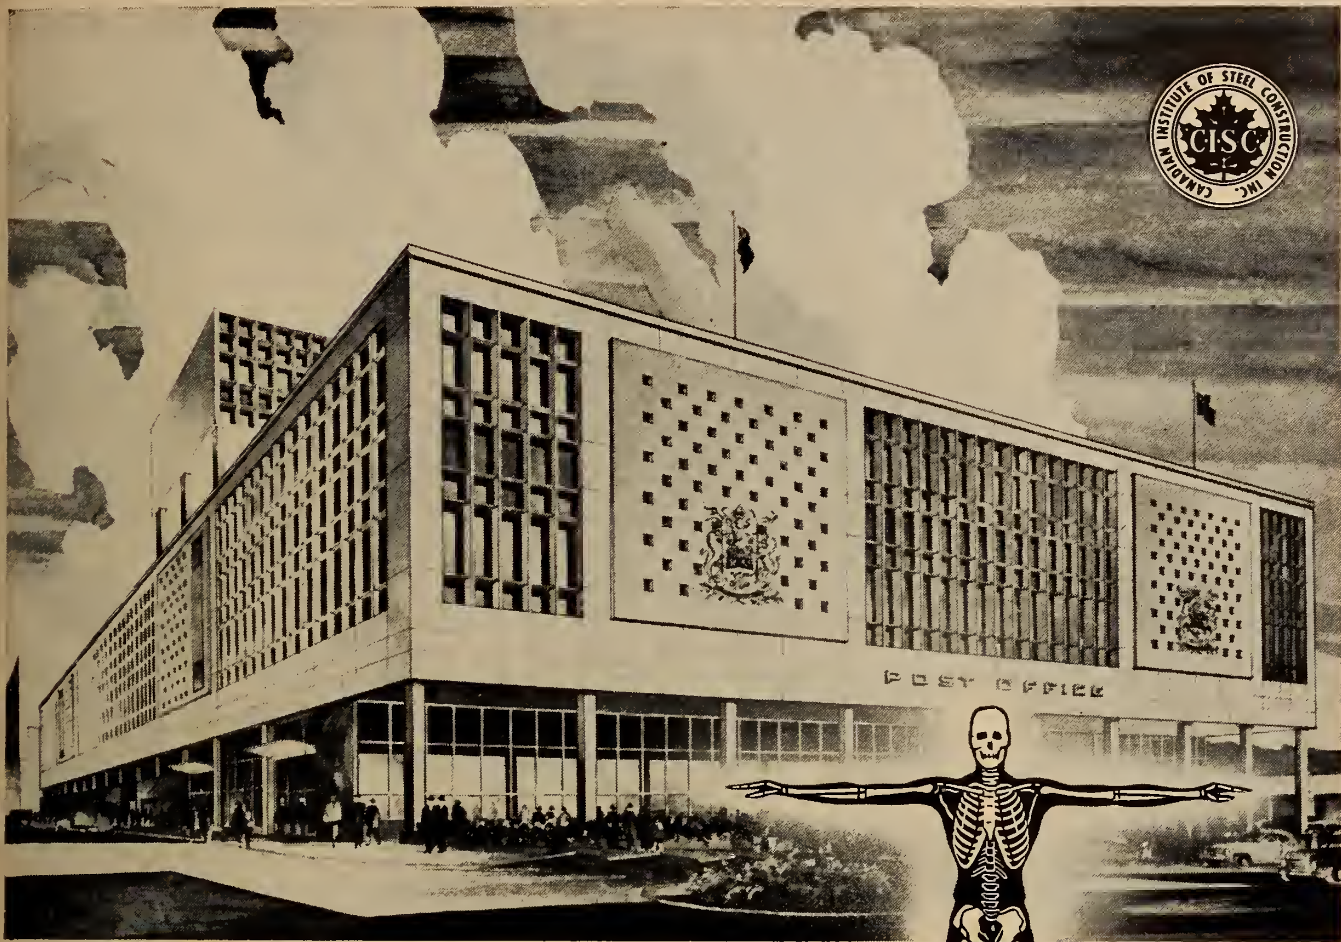
Mr. Hutchison is a McGill University graduate.

Percy L. Climo, M.E.I.C., plant engineer with the Ontario Paper Company in Thorold, Ont., has been elected chairman of the Niagara Peninsula Branch of the Institute. Known in engineering circles in Temiskaming, Ont., where he

Percy L. Climo, M.E.I.C.

worked prior to 1952, Mr. Climo was active in organizing the Nipissing and Upper Ottawa Branch.

A native of Cobourg, Ontario, he attended schools in that community, studied engineering at Queen's University,



CANADIAN INSTITUTE OF STEEL CONSTRUCTION INC.
CISC
POST OFFICE

and obtained a bachelor of science degree in 1932. Shortly after graduation he became municipal engineer on sewer construction for the Town of Cobourg, and remained in this position until 1934. Moving to Timmins, Ont., he was six years with the Hollinger Consolidated Gold Mines Limited.

In the next ten years he was associated successively with the Gaspesia Company Limited at Chandler, Que., which firm he joined in 1940; with Armstrong Wood and Company in Toronto, and with the Canadian International Paper Company at Temiskaming, Que. He joined the latter firm in 1947 and remained with them until he accepted his present appointment in 1952.

Mr. Climo has, for two years occupied a seat on the Grantham Township Council, a municipality close to the City of St. Catharines, Ont.

Mr. Climo joined the Institute in 1928 as a Student, was transferred to Junior in 1934, and became a Member in 1940.

F. A. Bain, M.E.I.C., recently named superintendent of the Sun Oil Company refinery at Sarnia, Ont., has been chief refiner at the company's Canadian installation since 1953.

His previous professional experience has been gained with Imperial Oil, Polymer Corporation and Canadian Industries Limited.

He is a McGill University graduate.

Col. W. G. Swan, M.E.I.C., 1955 winner of the Engineering Institute's Julian C. Smith award, has been conferred an honorary degree by the University of British Columbia.

Col. W. G. Swan, M.E.I.C.

A long-time resident of British Columbia, Colonel Swan was born at Kincardine, Ont., and studied engineering in that province, being graduated from the University of Toronto in 1906. In 1911 he won the degree, C.E.

Col. Swan served overseas during World War I, was awarded the D.S.O., the Croix de Guerre, and earned the rank of Colonel.

He has been for many years a consulting engineer in Vancouver.

With the onset of another war Colonel Swan was director of construction for the War Supply Board; then served as chief engineer with the Pacific Command of the R.C.E. He was, in 1945 awarded an O.B.E. Two years later he was recipient of the Alumni Medal of the University of Toronto.

L. A. Dokken, M.E.I.C., has accepted a position at Concord, California, as chief engineer with Martin Brothers Incorporated.

With Piggott Construction, Edmonton, as general manager and director in 1951, he was earlier associated with Industrial Maintenance Limited, in Montreal as president and general manager, and was for a time in 1949 president of the Dokken Pipe Line Construction Limited in Edmonton. Prior to that he worked with Edmonton Cottons Limited and Imperial Oil Limited in Regina and the Montreal East refinery.

Mr. Dokken is a 1942 graduate of the Univesrity of Saskatchewan.

S. Charles Moseley, M.E.I.C. Representing his firm overseas is S. Charles Moseley, senior plant engineer with Rolland Paper Company at St. Antoine des Laurentides, Que. While in Great Britain he will oversee the plans and specifications in the manufacture of the new 160-inch fine paper machine being installed by his company, as well as visit some of the important paper mills in England and on the continent.

He is a member of the Corporation of Professional Engineers of Quebec, and the Association of Professional Engineers of Ontario.

S. Charles Moseley, M.E.I.C.

Mr. Moseley is a McGill University graduate.

W. G. Seline, M.E.I.C. An award has been made to W. G. Seline, electrical engineer with the Shawinigan Water and Power Company repair department in Three Rivers, Que., for a paper submitted to the American Institute of Electrical Engineers, St. Maurice Valley Section. The paper dealt with the rewinding of alternating current generators.

He is a graduate in electrical engineering from the University of Manitoba, class of 1945.

William P. Kerr, M.E.I.C., has been appointed assistant chief engineer with the Department of Highways, Province of Nova Scotia.

A graduate of Mount Allison University, 1946, he also holds a bachelor of science degree in civil engineering, obtained from the Nova Scotia Technical College two years later.

Mr. Kerr joined the staff of the Department of Highways at that time and from 1948 to 1950 was a resident engineer on highway construction. From 1950 to 1952 he was assistant division engineer for Halifax and Hants Counties, and since 1952 has held the position of division engineer for Lunenburg County.

Jack C. Dale, M.E.I.C., general manager of Canadian Utilities Limited, has been named president and general manager of the company.

Mr. Dale started his career in the utility field in 1933, joining Northwestern Utilities Limited, in Edmonton, on graduation from the University of Alberta. Two years later he joined his present firm, working on design, drafting and estimates. In 1940 he left the company for service overseas, as a major with the 13th Field Regiment, R.C.A. He returned in 1945 to the Calgary office and became assistant to the superintendent and responsible for construction of electric transmission lines and distribution systems in towns. In 1951 he received the appointment of general manager of the company.

He has been active in the work of the Association of Professional Engineers of Alberta.

E. Gordon Tallman, M.E.I.C., has been appointed senior projects engineer with British Columbia Power Commission. His headquarters will be in Victoria.

With the Hydro Electric Power Commission of Ontario since 1937, Mr. Tallman has, among other appointments within the firm held those of project engineer of the hydraulic generation branch, and hydrometric and topographic survey engineer.

Mr. Tallman was for some time Canadian representative of the International Association of Hydrology.

Secretary - treasurer of the Toronto Branch of the Institute, 1946 and 1947, he also served on the executive, in the succeeding years 1948 to 1950.

He is a graduate of the University of Saskatchewan.

S. P. Slinn, M.E.I.C., of Vancouver is in private practice as a consulting mechanical engineer. He is at present engaged in the designing of mechanical services, for the Oakridge Shopping Centre of Woodward stores, Vancouver.

A mechanical engineering graduate of the University of British Columbia, class

of 1949, Mr. Slinn was in 1954 associated with H. F. Clarke and Company, Calgary, as manager.

R. E. Davey, M.E.I.C., holds the position of senior engineer, roads and bridges department, with the Township of North York, Willowdale, Ontario.

Experienced in this field, Mr. Davey has served as town engineer for the Town of Trenton and the Corporation of Brockville, both in Ontario. He accepted the Trenton appointment in 1948, the latter in 1951.

At an earlier period in his career he was with the Toronto Transportation Commission, rapid transit department, and in 1946 was divisional manager of Canadian Oil Companies Limited, in Montreal.

Stanley S. Copp, M.E.I.C., sanitary engineer with the Department of National Health and Welfare in Edmonton, since 1950, has been transferred to Vancouver.

A 1943 graduate of the University of British Columbia, he worked with Imperial Oil Limited in Calgary and spent three years in geological and geophysical oil exploration in Alberta and Colombia, South America. He spent nine months with the engineering department of the City of Vancouver, before taking up work with the Public Health Engineering Division of the Department of National Health and Welfare, as district engineer in the Edmonton Office.

Stanley S. Copp, M.E.I.C.

A few years ago Mr. Copp took time out from active engineering practice to prepare for a master's degree in sanitary engineering at John Hopkins University, which award was made in 1951.

D. E. Peatfield, M.E.I.C., has accepted employment as civil engineer with Noranda Mines Limited. He was formerly associated with C. J. McCulloch and Company, consulting engineers at Point Edward, Sydney, N.S. He held the position of resident engineer in the construction of Seaward Defence Base.

Earlier, after receiving a civil engineering diploma from Loughborough Engineering College in 1950, he was on the staff of H. K. Ferguson Company Ltd., in Midhaven, Ont., as area engineer.

M. J. Hassell, JR.E.I.C., is on the staff of Dominion Tar and Chemical Company in Montreal.

A B.Sc. graduate in electrical engineering, two years ago, from the University of New Brunswick, he has also worked in Montreal with the Montreal Engineering Company.

Martial Quesnel, JR.E.I.C., has accepted employment at Eastman, Que., with the Quebec Copper Corporation Limited.

Mr. Quesnel is an Ecole Polytechnique graduate in mining and geology, class of 1954, and has gained experience with the Iron Ore Company of Canada at Knob Lake, Que., since that time.

F. H. M. Ridley, JR.E.I.C., has been named manager of the installation field engineering section of the Canadian General Electric Company Limited's electronic equipment and tube department in Toronto.

On receiving a B.A.Sc. degree in mechanical engineering from the University of Toronto, he joined the Canadian General Electric Company Limited as methods engineer in 1949.

Oliver Y. Barde JR.E.I.C., has left C. D. Howe Company in Montreal to join the

JOY

AIRVANE

NEW ROTARY *PORTABLE* COMPRESSOR

—EXCLUSIVE FEATURES !
—DEPENDABLE, EFFICIENT OPERATION!

Joy RP-600 Airvane Rotary Portable Compressor furnishing air for a Joy Challenger drill.

JOY engineers started with all accumulated rotary information—then went on from there to produce, we believe, the best rotary compressor available today. These JOY developments contribute materially to a superior machine:

- **THERMAL BY-PASS** Heats oil quickly, keeps it flowing into compressor at correct temperature —*under all weather conditions.* Efficient oil circulation system provides immediate lubrication (no dry starts).
- **SPLINE COUPLING** Does away with a clutch, gives greater power-transmission efficiency. It's light, takes little space, is virtually indestructible.
- **TWO-STAGE FILTER-SEPARATOR** Removes oil from air and returns it to circulation system so efficiently that oil consumption becomes a minor item.
- **ECONO-MISER** load control automatically selects most efficient engine speed, maintains steady pressure, saves fuel, increases compressor life.
- **SHORTEST TURNING RADIUS** Compact design and low center of gravity give the shortest turning radius of all rotaries. With light weight, this spells *maneuverability.*
- **OTHER FEATURES** (often overlooked) Body is waterproof—tool box and fuel tanks can be locked—doors stay open without props—three lifting rings support entire machine—push-button uses ether-capsule for cold weather starting.

Write for descriptive bulletin A-58.

JOY CANADA

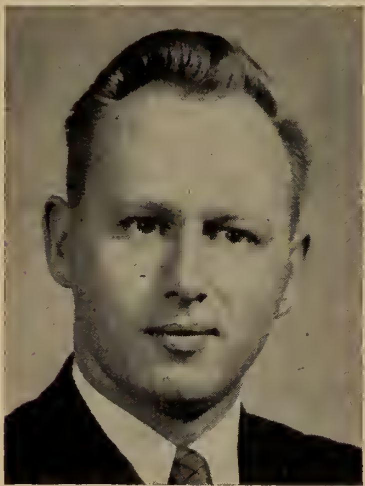
SALES AND SERVICE FROM COAST TO COAST

JOY MANUFACTURING COMPANY (CANADA) LIMITED — GALT, ONTARIO

ST. JOHN'S • SYDNEY • FREDERICTON • MONTREAL • KIRKLAND LAKE • TORONTO • SUDBURY • WINNIPEG • CALGARY • VANCOUVER staff of Key Construction Limited in that city. In 1955 he held the position of resident engineer with the former concern.

He is a 1948 graduate of the Swiss Federal Institute of Technology.

Jon G. Mydral, JR.E.I.C., a University of Manitoba graduate, class of 1951, is now at work in Vernon, California. He holds a position with the power division of Bechtel Corporation, engineers and constructors, as electrical engineer in charge of the electrical design of hydroelectric power plants.



Jon G. Mydral, Jr. E.I.C.

On graduation Mr. Myrdal joined the firm of E. G. Eggertson Inc., consultants, of New York and Winnipeg. He was employed in the design of two hydro-electric power plants in Iceland, and immediately following the completion of these projects joined International Engineering Company, designers, of San Francisco, California. Shortly thereafter, he was transferred to the parent company of Morrison-Knudsen Company, as an electrical engineer on construction of the underground powerhouse for the Aluminum Company of Canada, at Kemano, B.C. Later, on completion of this work, he returned to International Engineering Company, becoming a part of their hydro-electric design department.

Michel Gendron, JR.E.I.C., a 1954 graduate of Laval University, in Great Britain recently on an Athlone Fellowship, has returned to Canada and is with Eastern Mining and Smelting Corporation Limited, in Chicoutimi, Que., where he serves as assistant to the works manager.

Under the Athlone Fellowship scheme, Mr. Gendron spent one year at the Imperial College of Science and Technology. From September 1954 to June 1955 he did post-graduate work in structures, and, under Dr. J. Sutton Pippard, studied structural analysis, obtaining the D.I.C. degree on presentation of a thesis entitled, "Domes Analysis".

M. Gendron, Jr. E.I.C.

Later, through the Federation of British Industries, he was given the opportunity, in the summer of 1955, to visit many of the country's industrial works.

Mr. Gendron then concluded his stay in Great Britain by spending a few months in association with a firm of consulting engineers.

J. W. Johnson, JR.E.I.C., who was last year in Edmonton with the Joint Services

Number <u>three</u> of a series . . . . ADVANTAGES OF RAYMOND CONCRETE PILES

uniform bearing capacity

THE COMPLETE FLEXIBILITY of Raymond Concrete Piles as to length permits all piles to be driven to a uniform resistance regardless of variations in depths of bearing soils. Raymond Piles are available in an endless variety of lengths through combining step-taper sections of different lengths or joining step-taper sections with pipe or wood lower sections. Because the piles are cast-in-place, time is saved (and cost reduced) by eliminating the driving of test piles to predetermine lengths, as well as eliminating the delay due to casting and curing of precast piles.

RAYMOND STEP-TAPER PILES, AVAILABLE IN SUITABLE LENGTHS, ARE DRIVEN TO UNIFORM RESISTANCE AND BEARING CAPACITY REGARDLESS OF SOIL CONDITIONS.

• PERSONALS

Operational Research Team, serving as a Defence Research Technical Officer, has received a posting to Ottawa. He is now employed in the capacity of Defence Scientific Service Officer, and is instead, attached to the Canadian Army Operational Research Establishment.

He is a University of Alberta graduate in civil engineering, class of 1954.

P. Van Vliet, JR.E.I.C., of Regina, formerly employed as a machinist with the White Motor Company of Canada Limited now holds the position of switchman on the automatic exchange in connection with the Government Telephones in that city.

H. F. Pragnell, JR.E.I.C., was recently appointed project engineer with the Eddy Match Company Limited, Pembroke, Ontario.

Mr. Pragnell graduated from the Royal Military College in 1942 and is a civil engineering graduate of McGill University. Since graduation in 1949 Mr. Pragnell has been employed in construction and design work with the Foundation Company of Canada Limited in Montreal and Chalk River, Ontario.

Camille Cauchon, JR.E.I.C. Recently transferred from Montreal to Quebec City is Camille Cauchon, of the sales engineering division of Minneapolis-Honeywell Regulator Company Limited.

He is a native of Quebec City and

Camille Cauchon, Jr. E.I.C.

a graduate in electrical engineering from Laval University, class of 1951.

Lorne Rispler, JR.E.I.C., has been transferred to Ottawa from Montreal by the Minneapolis-Honeywell Regulator Company Limited. He is responsible for sales in the commercial division of the Ottawa office of the company.

Lorne Rispler, Jr. E.I.C.

He is a graduate of the University of Alberta, class of 1951.

G. A. C. Eby, JR.E.I.C., is now chief engineer, of the reinforced plastics division of the Brunswick Balke Collender Company in Toronto.

First a laboratory supervisor with Dominion Alkali and Chemical Company in 1949 and then associated with E. B. Magee Limited in Port Colborne, Ont., in 1951, he has also worked with Dominion Rubber Company, in Kitchener,

Ont. Concluding his studies at McGill University in 1949, he was awarded a B.Eng. degree in chemical engineering.

F/O H. R. Hyslop, JR.E.I.C., combining his profession with an air force career is at present stationed at Air Force Headquarters, Ottawa, in the procedures section of the Directorate of Construction Engineering.

F/O Hyslop graduated from the University of Saskatchewan in 1953. He was awarded a B.Eng. degree in civil engineering.

D. M. Murray, JR.E.I.C., is with the operational research section of the Defence Research Board, Ottawa, following a period of work with the division of radio and electrical engineering, National Research Council of Canada.

A 1951 graduate of the University of Manitoba, Mr. Murray has held positions with the Dominion Rubber Company of Canada shortly after his graduation, with Poole Construction in Edmonton, in 1953, and the engineering department with the City of Edmonton a year later.

Albert Rodney Sandall, JR.E.I.C., has accepted a position with the Ste. Anne Paper Company at Beaupre, Que., following a term of service with the National Street Car Corporation, in Hamilton, Ont. With this firm since 1954, he has also been employed in the same general field as materials inspector, with the Ontario Northland Railway, at North Bay, Ont., in the mechanical department.

Mr. Sandall completed his engineering studies at the Nova Scotia Technical College. In 1950 he was awarded a B.Eng. degree in mechanical engineering.

In 1953 he held the position of design engineer with the Bathurst Power and Paper Company Limited, Bathurst, N.B.

R. S. Jermyn, JR.E.I.C., has taken up employment with Dominion Electrohome Industries Limited in Kitchener, Ont., as mechanical engineer.

Most recently he has been working in the capacity of sales engineer with Magna Metals Limited, in Toronto, and has also had employment with the Canadian Westinghouse Company Limited in Hamilton, Ont.

He studied engineering at the Nova Scotia Technical College and gained a B.Eng. degree in mechanical engineering in 1952.

James R. Young, JR.E.I.C., with Canadian Westinghouse Company since 1950, has received a transfer from Hamilton, Ont., to Edmonton. Serving in the company's apparatus sales office, he will be largely concerned with the oil and mining companies of the area.

Mr. Young has spent the whole of his engineering career to date with the Canadian Westinghouse Company, beginning with a two-year engineering training at the company plant in Hamilton, following his graduation from the University of Alberta. On conclusion of the course he was moved to Montreal where he was employed in the apparatus division, dealing with shipbuilding and suppliers of marine and naval equipment.

James R. Young, Jr. E.I.C.

C. G. Forberg, JR.E.I.C., has received the appointment of London, Ont., township engineer, following three years' work of a similar nature as municipal engineer at Wallaceburg, Ont.

A veteran of the second world war,

HAWAII FOR PINEAPPLES...

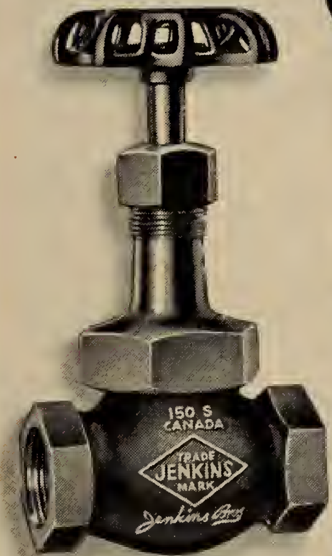
JENKINS FOR VALVES!

It pays to deal with specialists

Throughout the years, Hawaii has built a reputation for the world's finest pineapples . . . a reputation which is guarded today by the most exacting of standards.

In just the same way, for *generations,* Jenkins Bros. Limited have enjoyed a reputation for the world's finest valves . . . a name built on careful manufacture and complete concentration on this *one product.*

That's why you can be completely confident of trouble-free service when you order Jenkins . . . the valves made by *specialists.*



Making Quality Valves is Our Business — Our Only Business

he served overseas with the R.C.A.F. After the war, returning to his home in Ontario, he studied at Queen's University and there obtained a civil engineering degree in 1949.

Mr. Forberg's graduate engineering career began with an appointment as assistant city engineer at St. Thomas, Ont., where he remained until his Wallaceburg appointment in 1953.

Jacques Lapointe, JR.E.I.C., is field engineer on the construction of an electro-metallurgical pilot plant being built by Fraser-Brace Engineering Company Limited, Montreal, at Niagara Falls, Ont.

Mr. Lapointe graduated from McGill University in 1950, and immediately joined the Canadian General Electric Company Limited for a one-year test course in Peterborough, Ont., and later spent six months with the company's transformer design section in Toronto.

In 1951 he accepted a position with Fraser-Brace Engineering Company Limited as assistant electrical superintendent on the construction of the Dupont Nylon plant at Maitland, Ont. He remained with the firm, at that time, until 1954, rejoining in November, 1955.

In the interim Mr. Lapointe was service engineer with Thompson Electrical Works Limited, in Montreal.

MacKenzie Dickson, JR.E.I.C., has become vice-president and sales engineer with Separator Engineering Limited, in Montreal.

Earlier in his career, after a 1950 graduation from McGill University with a B.Eng. degree in chemical engineering, he was in 1952 employed with Merck and Company Limited at Valleyfield, Que.

He has also worked as sales engineer with the Delaval Company Limited in Peterborough, in 1953.

G. W. Morgan, JR.E.I.C. The position of chief engineer with Coast Steel Fabricators Limited, in Vancouver, is held by G. W. Morgan, the former chief design engineer of Standard Iron and Steel Works Limited plant in Toronto.

Shortly after graduating from the University of British Columbia in 1950 his address was Lambton Mills, Toronto.

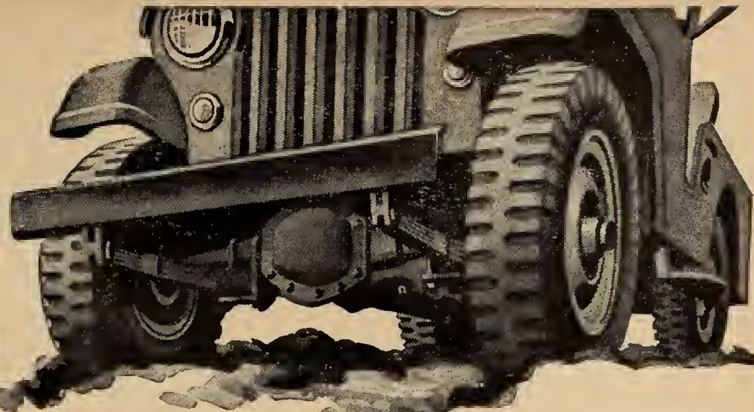
J. Hode Keyser, S.E.I.C., a 1955 graduate of the Ecole Polytechnique has been accepted for the position of soil engineer with the City of Montreal.

Mr. Keyser obtained a B.A.Sc. degree in civil engineering.

Jean Morin, S.E.I.C., has joined the staff of Canadian Fairbanks-Morse Company Limited as an estimating engineer in the firm's pump and electrical department.

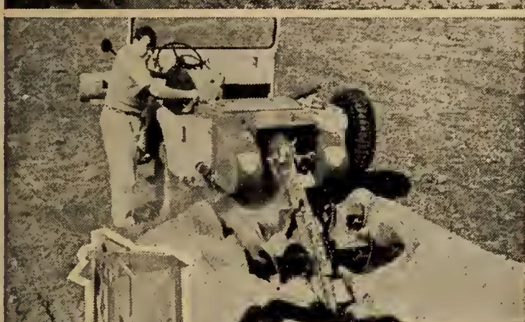
He is a 1955 graduate of the Ecole Polytechnique, where he studied mechanical engineering. While an undergraduate he won one of the student prize memberships, awarded by the Institute in 1954.

Traction



and Action anywhere!

'JEEP' BACKHOE



'JEEP'-A-TRENCH

'JEEP'-A-DRILL

'Jeep'®

4-Wheel drive VEHICLES

Internationally recognized for their go-anywhere mobility and rugged service, 'Jeep' 4-wheel-drive vehicles are proving in practically every industry a sensational ability to slash costs on an ever widening range of jobs.

Economical transportation in two or four wheel drive on or off roads; with mobile "take-off" power ready for delivery *anywhere.*

'Jeep' vehicles supplement heavy-duty equipment, spread their costs over an amazing variety of jobs, give extra savings through long life and low maintenance costs.

A 'JEEP' VEHICLE CAN HELP YOU *CUT* JOB COSTS!

There are over 50 pieces of special equipment for 'Jeep' vehicles, with applications in every industry dependent on mobile power. You'll find the working potential of your 'Jeep' vehicle unlimited.

NEWS OF THE BRANCHES

Activities of the Forty-Seven Branches of the Institute and abstracts of the papers presented at their meetings

BELLEVILLE

E. T. HILBIG, JR.E.I.C.,
Secretary-treasurer.

General Meeting

The final meeting for the 1955-56 season of the Belleville Branch of the Engineering Institute took the form of a conducted tour of the Marmoraton Mine, located near Marmora.

All phases of the iron mining operation as it occurs at Marmora were seen. The magnetite type of ore is obtained from an open pit, being hauled by huge 22-ton Euclids, to the north end of the pit where it is dumped into skips. A balanced arrangement of inclined hoists raises the loaded skip, while simultaneously lowering the empty skip.

The ore is subjected to the usual crushing processes, emerging from the ball mill as fine powder. Of considerable interest is the separation of the magnetite from the tailings by means of revolving magnetic drums, under which the emulsion of ore and water is conveyed. The final operation consists of "pelletizing" the beneficiated ore. In this form, the ore is suitable for refining in the blast furnaces at Buffalo, to where it is shipped by rail and boat.

The Belleville Branch are greatly indebted to Mr. H. O. Olson, the mine manager, and his assistant, who personally conducted the tour.

A. D. CRONK, JR.E.I.C.,
Secretary

T. F. HADWIN, M.E.I.C.,
Branch News Editor

International Invasion

At the invitation of the Seattle Section of the American Society of Civil Engineers and their Ladies' Auxiliary, a group of members of the Vancouver Branch of the Engineering Institute of Canada and their wives were royally entertained in Seattle on May 26, 1956. The invading party headed by the Branch chairman, S. S. Lefeaux and ably supported by the organizing Secretary, A. D. Cronk, made their headquarters at the Vance Hotel on May 25 and were greeted by their hosts led by Hanford Thayer, chairman of the Seattle Section, Mrs. Elmer Ginnute, chairman of the Ladies' Auxiliary and Mr. and Mrs. Edward Greathouse in charge of arrangements. The hosts then distributed copies of a carefully prepared program for the following day.

Inspection Trip

On May 26, while the ladies shopped, the men were taken on a bus tour which included many points of interest, but placed prime emphasis on two unusual construction projects. The first was the new First Avenue bridge which will span the Duwamish Waterway. This bridge of the bascule type is constructed on a silt bottom too deep for piles and the idea was conceived of precasting a concrete base long enough to support both leaves of the bascule, floating it into position and sinking it on a prepared bed. This was successfully accomplished, and at the time of the inspection, both leaves of the bascule were almost complete. Frank Culp, project engineer, illustrated and described the engineering features.

The second unusual engineering project was the supersonic wind tunnel at the Boeing plant in south Seattle. Here Gordon Cheney, supervisor of wind tunnel design, conducted the group to the two 38 foot diameter spheres which will supply the air blast, giving supersonic speeds of Mach Number 4. The centrifugal compressors with air dryers and the exhaust towers with sound supressing baffles posed many problems of engineering interest.

Lunch and Dinner Dance

Lunch for the engineers and their wives followed the tour at a waterfront seafood grill and the afternoon was spent at private homes of Seattle engineers. The climax of the trip was a smorgasbord and dance at a private club. There, the host and visiting chairmen expressed the hope of all concerned that the alternation of annual visits to Vancouver and Seattle would continue indefinitely and foster the interchange of ideas and professional fellowship across the border.

VANCOUVER ISLAND

Engineers Wives Association

Organizing to form an association, the wives of the professional engineers of Lower Vancouver Island met recently to elect a president and executive.

Mrs. T. A. J. Leach became president by acclamation, Mrs. A. B. Sanderson and Mrs. R. C. Thurber were elected first and second vice-president and the duties of corresponding and recording secretary went to Mrs. W. G. McIntosh and Mrs. A. F. Paget. Other officers elected were Mrs. C. Errington, treasurer, Mrs. J. Bowering, social convenor, Mrs. F. Slaney, program convenor, and Mrs. J. B. Hicks, membership convenor.

ATTENTION PLEASE!
E.I.C. BRANCH EXECUTIVES

Several months ago you were written to by headquarters' staff on the subject of new developments in your area of Canada, and the desirability—almost the necessity—of getting Journal papers to describe them. There is so much going on now, in so many places, that ordinary methods of keeping abreast of the engineering news may fail us. We hope not, but you can help us to be sure. Please organize your branch this year so as to cover these two things:—

1. When you hear about a new development in your vicinity, in engineering or technology, get a few facts together, plus the names of some of the principals, and send this information to the editor. We will take it up from there, if you wish.
2. When you have a paper delivered before your branch, if it is a reasonably worthwhile effort TRY to get a manuscript of it and send it to the editor. Some of our finest technical presentations are lost forever because of this lack, and no record exists beyond the memories of the comparative few who heard the speaker.

HELP THE EDITORS TO KEEP IMPROVING OUR JOURNAL

News of Other Societies

International Society of Aviation Writers

The International Society of Aviation Writers, a new worldwide body to encourage high standards of aviation writing for peaceful ends throughout the globe, was formed in San Francisco. The organization was formed as the result of the expressed interest in and need for wider exchange of aviation information and with the aim of increasing goodwill among the nations of the world.

The permanent headquarters of the new organization is Montreal, Canada, the site of the International Civil Aviaion Organization, U.N. Agency. I.C.A.O. Council Chambers will be used as a meeting place.

Leading writers and information people are behind the organization from the following countries: United States, United Kingdom, Canada, France, Italy, Denmark, Norway, Sweden, Belgium, Netherlands, Spain, Portugal, Switzerland, Greece, Argentine, Brazil, Mexico, India, Burma, Hawaii and Australia.

Officers of the new organization are announced as follows: President, Arthur Riley, the Boston Globe; Vice-Presidents, Sydney Cooper, The International Civil Aviation Organization; Erik Bergaust, American Aviation, Washington, D.C.; Peter King, The Bristol Aeroplane Co., United Kingdom. The Secretary-General is Ross Willmot, Hunting Associates, Toronto. Other directors include: Verne Haugland, Associated Press; Boyd Ferris, Air Industries and Transport Association, Ottawa; Neal MacDougall, The Aeroplane; Niels Beck, Union of Burma Applied Research Institute, Rangoon; Stanley Brogden, Royal Australian Air Force, Victoria, Australia; Maximillian Garavito, Revisto Aerea Latinoamericana; Gunnar Kristiannson, Stockholms-Tidningen.

The first general meeting of the International Society of Aviation Writers is planned to take place in the Montreal Headquarters later this year. Another meeting is to be held at the same time as the Society of British Aircraft Constructors' Show, at Farnborough, England in early September.

Canadian Chemical Institute Meets at Montreal

The thirty-ninth annual conference and exhibition of the Chemical Institute of Canada was held in Montreal, May 28 to 30, 1956, with some 1500 delegates in attendance. His Worship Mayor Jean Drapeau opened the exhibition and welcomed delegates to the city. Dr. Raymond V. Lemieux of the University of Ottawa presented the Merck Lecture on the subject "The Significance of the Half Chain Conformation in Carbohydrate Chemistry".

Dr. Clifford B. Purves, chief of the wood chemistry division, Pulp and Paper Research Institute, Montreal, was elected president of the Chemical Institute for 1956-57, with Dr. Osman J. Walker of the University of Alberta as vice-president. E. A. Crockett, chief chemist, Polymer Corporation, Ltd., Sarnia, was elected chairman of the board of directors, together with 12 new councillors.

The Chemical Institute of Canada Medal, awarded yearly for outstanding contributions to Canadian chemistry, was awarded to Dr. Leo Marion, F.C.I.C., of the National Research Council, in recognition of his great contribution in the field of alkaloids.

The opening luncheon meeting on Monday was addressed by F. C. Pace, of the special weapons section, Civil Defence Services, Ottawa, who spoke on "Medical Planning in Civil Defence". Describing the effects of nuclear explosions and radiation therefrom, and the three main devices for detection, he stated the Canadian plan for civil defence was really a huge effort in preventive medicine.

A symposium on "Problems Confronting University Educators" was held in the afternoon. Dr. C. A. McDowell of U.B.C. drew attention to the increased employment and lack of teachers and equipment. F. A. Demarco of Assumption College, Windsor, urged courses in social sciences and liberal arts be included in curricula. Louis A. Madonna of the University of Ottawa pointed out that the theory required from the students was continually in a state of change in our fast developing world. Only by mutual cooperation can Universities know what is actually desired in industry and alter courses accordingly.

The second luncheon meeting on Tuesday was addressed by L. G. Cook, director of the chemical and metallurgical division, Atomic Energy of Canada, Ltd., Deep River, Ont., whose subject was "Our Relation to the Technicians". He told of the need for more technicians to give professionals more time to think.

The Montreal Medal of the C.I.C., established earlier this year for award to the Canadian showing the most significant leadership or making the outstanding contribution to the profession of chemistry or chemical engineering, was awarded during the luncheon meeting to R. R. McLaughlin of the University of Toronto by President Roger Gaudry.

Earlier in the conference, T. H. C. Raikes of Howard and Sons (Canada) Ltd., stated that the chemical industry, employed 60,000 workers and had a gross product exceeding $1 billion. It was as inventive and progressive as any in the world. The only drawback was a shortage of chemists and chemical engineers.

Tuesday afternoon was devoted to a symposium of the division of chemical engineering on "The Financing of the Chemical Industry in Canada", with P. W. Blaylock, president, Shawinigan Chemicals, Ltd., Dudley Dawson, president, Dawson Hannaford, Ltd., H. B. Fewkes, associate treasurer, Sun Life Assurance Co. Ltd., and Selwyn Irwin, president, McArthur Irwin, Ltd., as panel members.

Conclusions reached were that the Canadian public can expect increasing opportunities to invest in Canada's chemical industry because of its current rapid expansion, and because with the publicity now being given to the high rate of foreign investment in Canada, foreign companies may give Canadians a larger opportunity to participate in their subsidiaries. So far most of the industry has financed its expansion internally, but due to expansion, outside capital is becoming necessary. Expected capital investment needed this year is $80 million.

Dr. Louis Frederick Feiser of Harvard University delivered the Leroy Egerton Westman Memorial Lecture, his subject being "Hooker Oxidation". This was followed by the conferring of an honorary degree on Dr. E. W. R. Steacie, president of the National Research Council, by the Université de Montréal, and a reception by the Société de Chimie de Montréal.

Plastic Design of Steel Structures

Some sixty structural engineers from across Canada attended a five-day course in Plastic Design of Steel Structures during the week of May 28. The course was arranged by the Royal Military College and Queen's University of Kingston, Ontario, with the support of the Canadian Institute of Steel Construction, Inc.

(Continued on page 970)

• NEWS OF OTHER SOCIETIES

Professor J. W. Dolphin, head of the civil engineering Department at R.M.C., Professor H. M. Nelson, assistant professor of civil engineering at R.M.C. and Doctor D. T. Wright, M.E.I.C. assistant professor of civil engineering at Queen's University were the lecturers.

The course was geared to meet the needs of the practising structural engineer rather than a group interested in pure research only. For this reason considerable emphasis was placed on practical problems, such as joint details that will be encountered when plastic design methods are used. The results of research in this field seem to indicate that structural joints will be simpler and more functional in appearance but that fabrication and erection procedures will have to be changed somewhat from present day practice in order to achieve full economy.

The course began by developing the simple plastic theory of flexure and applying it to the design of structures. Modifications to the basic theory were introduced in order to cope with such familiar problems as shear, axial load and local and lateral instability. Laboratory tests on full-sized structures demonstrated the accuracy of the procedures advocated.

Dr. Bruno Thurlimann of Lehigh University was guest speaker at a luncheon.

Dr. Thurlimann pointed out that the current practice of designing continuous structures by the stress theory was somewhat of a fallacy, as in nearly all structures of this kind stresses exist that are not taken into account in design. Such practices as welding, cambering, crimping and aligning of members, and even cutting and shearing, create residual stresses that may be extremely high, so that the yield stress may be reached in some parts of the material before any design load is put on the structure. The question arises as to just what is keeping such a structure from collapsing. Plastic behaviour appears to be the only answer. Elastic analysis is only a beginning in the actual problem of steel design. We are now ready to consider the more logical method of taking plastic behaviour into account and making full use of its desirable characteristics.

In effect, plasticity is that property of a continuous structural member which permits it to transfer moment by the formation of plastic hinges at points of maximum moment. This ability allows the member to carry considerably more load than has been previously thought possible. The whole basis of plastic theory is based on the ductility of structural steel (i.e. the ability to strain without increase of stress). In order for a designer to correctly understand this method of design, it is necessary for him to forget the stress concept and to concentrate on actual load carrying capacity. Of course there are still several problems involved in plastic design. One of these problems which is extremely important is lateral stability of the structure and another is column design in high buildings, where a high axial load occurs; but the outlook is very bright and Dr. Thurlimann believes that a solution is imminent.

Dr. Thurlimann strongly believes that the factor of safety, as we know it today, should be re-appraised. A safety factor of 4 was originally devised in France in 1820 and was based on actual ultimate load tests measured in existing buildings in Paris. From that time until now the factor of safety has been reduced to a figure of 3.25 on ultimate load. Under the new theory a designer will be able to predict accurately the exact load at which real structural failure will occur. These predictions have been verified by actual tests of full-scale models. He suggests, therefore, that a more realistic factor of safety be determined.

As far as practical considerations are concerned, plastic design will provide a marked tendency to more continuous structures, and the present waste of material involved in simple span framing will be largely eliminated. Since rigid connections are an absolute necessity, welding will be used far more, and new techniques will have to be evolved. It is quite clear that just by using less structural material the actual economy of structures may not be immediately reduced because shop fabricating costs for the type of connections required will be higher until the necessary experience is gained. The trend will likely be to more shop welding with splice connections being made in the field by use of high-tensile bolts.

Presently in England the British Standard for the design of steel building frameworks incorporates a clause on fully rigid design that enables the designer to use the plastic design method. Upwards of two hundred building frames embodying this principle have been erected.

In the United States a committee of the A.S.C.E. has been established which will publish simple design procedures and test results for the use of practising engineers. The American Institute of Steel Construction is presently preparing a design manual for the plastic design of low buildings. Because research is still engaged in the design of columns with high axial loads, only one- or two-storey buildings will be included in the scope of this manual. It is generally felt that in a matter of one or two years plastic designs throughout the range of buildings will be made in the United States.

In Canada the theory of plastic design has been in the curriculum of at least six Canadian universities during the past year and it is expected that additional courses either for graduates or under-graduates will become available for the coming semester.

Mining Congress

The Canadian Institute of Mining and Metallurgy, and the Canadian committee of the Sixth Commonwealth Mining and Metallurgical Congress in 1957, have announced that the president of the congress will be R. W. Diamond, M.E.I.C., of Trail, B.C.

Mr. Diamond will direct a nation-wide organization appointed from the Canadian mineral industries to plan and prepare for this major mining event in the fall of 1957. The congress plans call for a cross-country inspection tour of important Canadian mining operations by 500 delegates from all parts of the Commonwealth. Three special trains and six chartered aircraft will take the delegates on their tours from Vancouver to Halifax and through the north country. Major meetings of the Congress will be held in eight Canadian cities, commencing in Vancouver on September 8-9-10, 1957.

The Congress General Committee is headed by Robert A. Bryce of Toronto. Co-chairmen are H. L. Roscoe, for Eastern Canada, and H. R. Banks for Western Canada. John S. Proctor of the Imperial Bank of Canada is honorary treasurer. Committee members are Dr. John Convey, F. V. C. Hewett, and C. C Huston. C. H. Mitchell is excutive secretary for the general committee of the Congress, with headquarters at 507 Metropolitan Building, Vancouver 1, B.C.

Forestry Conference

A national forestry conference will be held in Winnipeg, September 17-19, 1956, under the sponsorship of the Engineering Institute of Canada, the Canadian Chamber of Commerce, the Canadian Institute of Forestry and the Canadian Forestry Association.

Secretary of the program committee is J. L. Van Camp, of the Canadian Forestry Association (4795 St. Catherine Street West, Montreal 6).

BOOK REVIEW

Rideau waterway

Robert Legget. Toronto, University Press; 1955. 249 p., $5.00.

When an author is in love with his subject, a better than ordinary book is pretty sure to result. One needs to read only a few pages of "Rideau waterway" to realize that Mr. Legget is indeed an enthusiast on the waterway and that he must have spent many hours not only in digging into the data on which much of this book is based, but also a good deal of his spare time in travelling up and down the waterway itself.

The first six of the even dozen chapters are historical. They tell why, how and by whom the waterway was built and are necessarily a biography of Lt. Col. John By, R.E., the genius behind the project. Perhaps Lt. Col. By was our earliest distinguished engineer. As such, he has lately attracted increasing notice from today's members of his profession, to the extent that a memorial to him was recently unveiled in Ottawa, thanks largely to the efforts of our Ottawa branch.

But Mr. Legget also pays tribute to the work of By's associates—his principal assistant, John MacTaggart; the junior engineers, e.g., Lieuts. Pooley and Denison; the contractors, among whom we find names still familiar to us—Drummond, McKay, Phillips, White and Redpath, for example. Parsons and politicians, lawyers and merchants pop in and out of these chapters, making them veritably a brief history of the Rideau area from its early days to the present.

These chapters will be of more direct interest to the engineer than to the general reader, written as they are with the touches necessary for technical clarity yet they should be quite intelligible to anybody. They bear witness of By's ability and good judgment in the face of conditions inherent in the time and place, which would have discouraged a less talented and determined engineer.

Having got the waterway built and in operation, Mr. Legget follows its fortunes from its official opening in 1832 to the present. Never used for military purposes under stress of war, it contributed much to the development of the area which it served, until driven out of the commercial picture by the competition of rail and road. Given over today almost exclusively to tourist traffic, the waterway justifies its continued operation by bringing into Canada many more dollars than it takes from the taxpayer's pocket.

The last five chapters of "Rideau waterway" are a log of a trip through it from Kingston to Ottawa and a short account of the founding and development of Ottawa. There is much gossipy comment on and anecdotes of people and places, past and present, along the way. If the general reader has even only a partly developed sense of history, he cannot fail to be intrigued by these chapters.

There are sixteen pages of excellent illustrations, mostly from the author's own photographs, a few line cuts in the text and adequate maps. The book ends with a list of references; a list of superintending engineers — By himself served from 1826 to 1832; information on maps, charts and fishing; a table of mileages, lifts and clearances; and a good index.

This writer thoroughly enjoyed "Rideau waterway". It should give any Canadian pride in his national heritage and ought to convince any engineer that there is an historical tradition behind him. It is pleasant to feel that Mr. Legget, director of the division of building research of the National Research Council and an active member of the Engineering Institute of Canada thought it well worth while to devote some of his time to this kind of writing, though it will probably add little to his professional reputation. Would that others able might follow his example! We need biographies of other Canadian engineers—the Shanlys, Sir Casimir Gzowski, T. C. Keefer and Sir John Kennedy, to mention only four.

R.DeL.F.

BOOK NOTES

Prepared by the Library
The Engineering Institute of Canada

* Review provided through the courtesy of the Engineering Societies Library in New York.

Alternating-current circuit theory, 2nd ed.

M. B. Reed. New York, Harper, 1956. 589 p. illus., $6.50 (U.S.)

The advent of television and computers has created more complex systems in the electrical engineering field, and these in turn demand greater precision in the mathematics and physics needed. The second edition of this textbook takes into account these developments by revision of some of the material, or by the presentation of new approaches to problems e.g. the *m*-derived approach to filter design has been replaced by the time-tested method based on the symmetric lattice.

The first section of the book covers such basic principles as sine wave and vector representation of an alternating current, the algebra of complex numbers, the parallel and series-parallel electric circuit, Fourier series, and transients. The remainder of the book deals with specialized topics, among them three-phase wye- and delta-connected power distribution systems, symmetrical components, steady state operation of a transmission line, and electric filters.

***Analyse dimensionnelle et théorie des maquettes.**

H. L. Langhaar. Montreal, Fomac, 1956. 230 p.

This work is a translation of the author's "Dimensional analysis and theory of models" and is devoted to the principles of dimensional analysis which treats the general form of equations that describe natural phenomena. The first four chapters deal with basic principles and develop them mathematically. Chapter five covers the theories of similarity and model testing. The remaining five chapters treat specific applications of dimensional analysis. A knowledge of the principles of physics and engineering

DURING THE SUMMER MONTHS
THE LIBRARY IS OPEN FROM
9 TO 5, MONDAY TO FRIDAY

usually presented in the first three years of an engineering curriculum is assumed.

Analysis of electric circuits.
W. H. Middendorf. New York, Wiley, 1956. 306 p., diagrs., $6.00.

The author has attempted in this book to present in detail the basic principles and problems of circuit analysis. A variety of numerical examples is used to assist the student in understanding the subject matter.

The first section of the book is entitled "Basic circuit analysis" and includes chapters on basic laws, types of voltage and current variations, notation, the algebra of complex numbers, impedance and admittance, circuit parameters, equivalent series, locus diagrams, resonance phenomena, and magnetic field coupling.

The second part is more advanced and considers such matters as nonsinusoidal waves, and network simplifications and theorems. The last section of the book deals with polyphase and communication circuits.

***Annual report on the progress of rubber technology, volume 19, 1955.**
London, Institution of the rubber industry, 1955. 15B p., 21/–.

A critical review of the literature covering advances in cable and electrical insulation, synthetic rubber, testing and equipment, machinery and appliances, processes and materials, and in the manufacture of various types of rubber goods. One section deals with the use of rubber as a road surfacing material.

Les applications de l'explosion thermonucléaire.
Camille Rougeron. Paris, Berger-Levrault, 1956. 307 p., 600 fr.

In this work the author discusses the possibilities of harnessing thermonuclear power, and expresses his belief that the solution to the problem lies in underground explosions.

The author believes thermonuclear power could be used in excavations for large dams, for electric power, and in the chemical industry. He also suggests that by using this type of power it would be relatively easy to keep navigation in the St. Lawrence-Great Lakes open all winter.

There are also chapters on naval, air and land warfare.

Applied electricity, 3rd ed.
A. W. Hirst. Glasgow, Blackie, 1956. 39B p., diagrs., 25/–.

The M.K.S. system of units has been used in this revised edition. Other new material is included in the sections on parallel operation of transformers, double cage rotors, strain gauges, transducers, closed loop control systems, and photoelectric cells.

The boik contains material on direct current machines, alternating current circuits, transformers, alternators, induction motors, the conversion of a-c to d-c, illumination, instruments and measurements, and the elements of thermionics.

Architectural construction, 2nd ed.
Theodore Crane. New York, Wiley, 1956. 433 p., illus., $10.00

The new edition of this valuable reference work will be welcomed by students in architecture and engineering, and by those practicing in these professions. It is an up-to-date resume of the better types of construction in use in the United States, with recommendations concerning their specific applications. The reader is given a procedure for determining the type of building frame, foundation, floor, roof and wall construction most suitable to meet the requirements of a special structure. The book also discusses the choice of the best type of building materials.

The first chapter deals with building codes and design standards. Included in the new material in this edition are descriptions of modern coliseums, hangars and parking garages, and contemporary fireproofing details for steel assemblies.

Beton-Kalender; Taschenbuch für den Beton-und Stahlbetonbau.
Berlin, Ernst, 1956. 2 vols., 16 DM the set.

In this forty-fifth edition of the handbook all aspects of concrete construction are dealt with, as well as all types of cement and concrete. Each chapter has been written by a specialist, and topics covered include the analysis of structures and parts, foundations, rigid roofs, machinery etc.

There are many graphs, tables and diagrams, and throughout the handbook reference is made to the German standards for steel and other construction materials.

The Canadian petrochemical industry.
Shell Oil Company of Canada. Chemical division. Toronto, Ryerson, 1956. 154 p., illus.

The petrochemical industry in Canada is only about fifteen years old but a great deal of progress has been made in this short span. The Shell Oil company has attempted to define the term "petrochemical" and has devoted a chapter to each of the major products in this class. Within each chapter the work of the most important developing company has been described.

The ten chapters include synthetic rubber; glycols, polystyrene and other chemicals; carbon black; ammonia; sulphur; petrochemicals and cellulose acetate; polyethylene; isopropyl alcohol, acetone and phenol; glycols; and formaldehyde and pentaerythritol.

Circular cylindrical shells.
Dieter Rudiger and Joachim Urban. Leipzig, Teubner, 1955. 270 p., tables, 24 D.M.

In the last decades many types of structures have been used for enclosing large spaces economically without supports, and of these cylindrical shells have become important, both because they are relatively simple to calculate and construct and because they can be used for roofing rectangles.

The main body of the book is devoted to tables for the calculation of cylindrical shells, and solutions are given for 48 parameter-values, from 0.03 to 0.90.

There is also a short introduction giving the theory of circular cylindrical shells, and the basic equations used. Several pages of worked examples are given. The text is arranged with German and English in parallel columns.

The control of quality in the production of wrought non-ferrous metals and alloys. Part III—The control of quality in heat-treatment and final operations.
London, Institute of metals, 1955. 104 p., $2.50. (Monograph and report series no. 17).

The papers published here were presented at a symposium held in London in March, 1955. The six papers are followed by a general discussion of the reports.

The subjects covered range from an assessment of quality of wrought products; the production of rolled, extruded, and drawn aluminium and its alloys, of copper and aluminium rod and wire, and of copper and copper-base alloys; to the production of light-alloy drop-forgings, and the heat-treatment, inspection, and testing of wrought nickel and nickel alloys.

***Engineering in history.**
R. S. Kirby and others. Toronto, McGraw-Hill, 1956. 530 p., illus., $10.20.

This is a general introduction to the subject, devoted to recording the most significant achievements in certain branches of civil, mechanical, electrical, and metallurgical engineering. Engineering history is integrated into general history with the intent of showing how social conditions influenced engineering advances and how these in turn influenced the development of Western civilization. Selected references are listed after each chapter, and a general bibliography is given at the end of the book.

50 years' boundary layer research.
H. Gortler and W. Tollmien, eds. Braunschweig, Vieweg, London, Maxwell, 1955. 499 p., diagrs., $13.50.

It was in 1904 that Ludwig Prandtl gave a lecture at Heidelberg which established the theory of boundary layers. This volume, containing forty-four papers written by leading scientists from all over the world, has been published in commemoration if that event.

However, the book is not an historical survey, but rather the authors have presented the findings of the latest research on the subject. It should therefore, be of interest to all those connected with fluid dynamics, aeronautics, shipbuilding, etc.

Among the topics considered are turbulence, the boundary layer in the electron stream, the laminar boundary layer on a rotating sphere, the growth of the boundary layer behind a shock wave, the profile drag of biconvex wing sections at supersonic speeds, etc. With one exception the papers are all in English or German.

The Financial post survey of oils, 1956, vol. 14.
Toronto, Financial Post, 1956. 372 p., $3.00.

This is the most comprehensive survey of its kind, covering 600 oil producing, refining, pipeline and drilling companies in Canada. Its reports on individual companies give data on production, reserves, earnings, dividends, acreage interests and management.

A special section contains up-to-date maps of important oil fields, including some 1956 information.

The volume also provides a five-year price range of oil stock movements, among other statistical material, and lists inactive and defunct companies.

Germanium diodes.
S. D. Boon. Eindhoven, Philips, Houston, Elsevier, 1956. 85 p., illus., $1.95 (U.S.)

The germanium diode is one of the new "semi-conductors" and this small book describes its properties and uses. Sufficient theory is given to enable the reader to analyze the most common diode problems and to design diode circuits, but the book is mainly practical. There is a detailed treatment of the electrical properties of germanium diodes, and various examples of practical applications of this device are provided.

***Heating ventilating air conditioning guide, volume 34, 1956.**
New York, American society of heating and air-conditioning engineers, 1956. 1696 p., $12.00 (U.S.)

The new edition of this standard guide to current practice in the field has been brought up to date by additions or changes in sections devoted to heat transmission of building materials, cooling load, chimneys, estimating fuel consumption, central systems for air conditioning, automatic control, automobile air conditioning, and a number of other subjects. As in past years, the contents are presented in seven main sections dealing with fundamentals, human reactions, heating and cooling loads, combustion and consumption of fuels, systems and equipment, special systems, and instruments and codes. A manufacturers' catalog data section is again included.

High-speed combustion engines, 16th ed.
P. M. Heldt. Philadelphia, Chilton, 1956. 805 p., illus., $12.00 (U.S.)

This new edition of the classic text book on combustion engines covers design, production and tests.

New developments since the previous edition was published in 1951 have made it necessary to include material on the properties of liquefied petroleum gases used as motor fuels. There is a new chapter on the thermodynamics of the combustion engine, and the chapter on engine tests has been enlarged.

The general plan of the book remains the same. Each component of the combustion engine is discussed separately: engine cylinders, crank case, pistons, connecting rods, engine valves, carburetor, ignition equipment, bearings, manifolds and muffler, etc. There are also sections devoted to the problems of balancing the engine, torsional vibration, water- and air-cooling, speed control and power output.

• LIBRARY NOTES

Introduction to electrical engineering.

Walter La Pierre. New York, Harper, 1956. 339 p., diagrs., $5.25 (U.S.)

This textbook is designed to give new students of electrical engineering a broad view of the field and, at the same time, some detailed knowledge of it. The first part of the book deals with electric circuits and basic electromagnetic relationships, including capacitive and polyphase circuits. The last twelve chapters describe the generation, use, and control of electric energy. Within this broad range, there are chapters on the polyphase synchronous machine, industrial power distribution, production of direct current, lighting, and electrical instrumentation.

There is also some discussion of the economic, industrial, and social aspects of electrical engineering, within the United States.

Job evaluation, 2nd ed.

J. L. Otis and R. H. Leukart. New York, Prentice-Hall, 1954. 532 p., $6.50 (U.S.).

Here is a comprehensive treatment of a fairly new aspect of industrial management. The aims of the first edition—to present the principles of sound wage and salary administration based upon job evaluation — have been retained. The authors have increased the number of practical illustrations and mechanical details of job evaluation, and have included case problems at the end of each chapter.

The book is divided into six large sections, beginning with an introducion to job evaluation. This is followed by a detailed description of nonquantitative and quantitative evaluation systems, and by chapters on methods of analyzing and evaluating jobs. The last two sections are devoted to the procedures used in establishing the pay system, and to the principles of wage and salary administration.

Melfort looks ahead. "A guide for community development."

Regina, Dept. of municipal affairs, Community planning branch, 1956. 74 p., mimeog., plans.

This is an example of what a small town can do in the field of town planning. The sub-title of the book is "A guide for community development" and it might well be used as a guide by other towns faced with the same problems of expansion.

The problem is divided into sections such as regional considerations, economic aspects, and population forecasts. The actual planning is considered in regard to residential, business and industrial districts, schools, public buildings, recreational areas, public utilities and roads.

Suggestions are also given for ways in which the recommendations may best be implemented.

Modern marine engineering.

D. W. Rudorff. New York, Philosophical library, 1956. 154 p., illus., $4.75 (U.S.)

In this book we find a concise review of various types of propulsion plants used in marine vessels. These include steam boilers, condensers and reciprocators, geared steam turbine drive, turbo-electric propulsion, and gas turbines.

There are also chapters covering the use of electricity on ships, and refrigerating techniques. Detailed treatment of technical matters is avoided; the book gives instead a broad descriptive view of modern trends in marine engineering.

Office work and automation.

H. S. Levin. New York, Wiley, 1956. 203 p., $4.50.

The tempo of change in office management is rapidly accelerating and the executive will welcome any book which attempts to keep him abreast of this change.

The central theme of this book is information handling—in three phases: first the initial handling of the great quantity of information flowing into an office, with discussions centering around the common-language concept.

The next chapter deals with electronic computers and their impact on business data processing. Various problems arising from the introduction of computers into an office are discussed.

• LIBRARY NOTES

The end result of office automation is the use of the information thus obtained, and this is described under the term "operations research". The last chapter deals with some of the changes which arise from these new developments.

A pocket-book for mechanical engineers, 6th ed.

D A. Low. Toronto, Longmans, 1956. 778 p. diagrs., $3.80.

Since the publication of the previous edition of this concise reference work in 1948 there have been new developments which necessitated the revision of some material. New editions of certain British standards have also caused some changes. The main alterations and additions are in the sections on iron and steel, non-ferrous alloys, wood, unified screw threads, bolt-heads and nuts, pipes and pipe joints, ropes, chains, and sand-blasting.

As in former editions there is a good deal of space devoted to the proportions of machines and machine details, with numerous rules and tables given.

Principles of turbomachinery.

D. G. Shepherd. New York, Macmillan, 1956. 463 p., diagrs. $10.00 (U.S.)

The originality and value of this text-book lies in the fact that the author has correlated the use of turbomachinery in pumps, fans, compressors, and steam, gas, and hydraulic turbines. There is no attempt to present design from the mechanical standpoint. Rather, the emphasis is on a general treatment of all forms of turbomachinery, including such aspects as dimensional analysis, energy transfer, thermodynamics of compressible flow, and the flow of fluids in the passages and over the blades of turbomachines.

These principles are then applied to the individual types of machines and a general description of design methods is given so that the reader is able to understand performance factors.

Early in the text attention is given to basic energy quantities and to the rather difficult problem of notation, to avoid confusion as much as possible.

°Resistance of materials, 4th ed.

F. B. Seely and J. O. Smith. New York, Wiley, 1956. 459 p., diagrs., $6.50.

Part I of this standard text consists of the basic topics usually included in the subject: relations among loads, stresses, and deformations; stresses in beams; statically indeterminate members; dynamic loads, etc. Part II deals with such additional topics as composite beams, unsymmetrical bending, continuous beams, and elastic vibration of load-resisting members.

Route surveys and construction, 3rd ed.

Harry Rubey. New York, Macmillan, 1956 282 p. illus., $6.25 (U.S.)

The tables contained in this reference book are for use in the survey, design, and construction of highways, railroads, airways, conveyor belts, canals, pipe lines and transmission lines. Some of the tables are not easily found elsewhere, for example, eight place natural sines and coisines.

In this edition there is more emphasis on professional engineering, engineered construction, professional management, contracting, and practical photogrammetry.

Sistemi elastici piani; metodo dell'incognita principale.

Attilio Linari. Naples, Pellerano del Gaudio, 1956. 2v., diagrs., tables, 3000 lire.

In these volumes the author presents new methods for calculating continuous beams, frames and Vierendeel beams, beams with various moments of inertia and continuous parallel beams.

The second volume is composed of tables of the various functions required in the calculations.

Stability functions for structural frameworks.

R. K. Livesley and D. B. Chandler. Manchester, University press, 1956. 33 pp., 6/—.

The tables in this pamphlet are for use in determining the critical loads of elastic rigid jointed structures, and were worked out on the electronic computer at Manchester university. As the functions are still unfamiliar to many engineers, examples are given of some of their methods of use.

Technology of heat.
H. W. Baker. Toronto, Longmans, 1956. 427 p., diagrs., $6.50.

The author's object in writing this book was to provide the engineering student with a fairly complete understanding of the technology of heat.

Following a general introduction to the subject there are chapters on actual working fluids and fluid mixtures; elementary working cycles for transforming heat into mechanical work; reversibility and entropy; fuels and combustion; the theory of air compressors and motors; steam engines and turbines; heat pumps; heat transference by radiation, conduction and convection; waste heat recovery and heat balances.

°Theory and practice of lubrication for engineers.
D. D. Fuller. New York, Wiley, 1956. 432 p., diagrs., $10.50.

In the first half of this book, fundamentals of viscosity and flow are dealt with, and the hydrodynamic and hydrostatic theories are developed from simple and readily understood principles. In the last half, two chapters are devoted to journal bearings, and single chapters to typical industrial bearings, materials, air-lubricated bearings, dry friction, and boundary friction. Many bearing designs are given, including those for machine tools, generators, rolling mills, and centrifuges. The book is intended both for class room use and for practicing engineers.

• LIBRARY NOTES

alysis; fibers; textiles made of asbestos, bast and leaf fiber, cotton, glass, rayon, acetate, silk, and wool; and warp knit, pile, and unwoven fabrics. Twenty-two of the standards are new or revised since the previous edition was published in 1954. 761p., $5.75 (U.S.)

British Standards, British standards institution, 2 Park St., London W.1. British standards are also available from the Canadian standards association.

B.S. 602, 1085:1956—Lead pipes for other than chemical purposes.

For the first time these two standards have been included under one cover, as pipes complying with both standards mainly serve the same applications for other than chemical purposes, and they are made by the same extrusion presses.

In the revised B.S. 602 for some applications lighter weight pipes are permitted, and this has necessitated the introduction of additional tables, as the heavier weight pipes are still recommended for service underground. In the revised B.S. 1085 a slight amendment has been made to the composition.

The tables in both standards specify the minimum weight to be used for each application. When sizes above the minimum are required, the new standard specifies that they should be chosen from the list of standard bores and weights given in an Appendix in order to limit the number of sizes of pipes demanded. 6/-.

B.S. 2591: 1956 Glossary for valves and valve parts (for fluids) Part 2—Safety valves and relief valves. Part 3—Plug valves and cocks.

Part 2 defines types of, and parts for, the following types of ordinary safety valve: direct spring loaded; direct weight loaded; lever and weight loaded; lever and spring loaded; 'Ramsbottom' type. There are seven illustrations of typical safety valves.

Part 3 defines types of, and parts for, the following types of plug valve and cock: lubricated plug valve; non-lubricated plug valve (including lift plug and split plug types); plug cock; gland cock; compound gland cock; packed cock. There are six illustrations of typical plug valves and cocks. 6/- each.

B.S. 2654: Part 1: 1956—Vertical mild steel welded storage tanks with butt-welded shells, for the petroleum industry. Part 1: Design and fabrication.

This new British Standard specifies the materials, design and fabrication of vertical cylindrical tanks, with butt-welded shells, for erection above ground. The tanks are of the following types: a. Non-pressure fixed roof tanks (all sizes); b. Pressure fixed roof tanks (up to 128 ft. diameter only); c. Open top tanks (all sizes).

Tanks with floating roofs are excluded. Reference is made to mountings, stairways and handrailings. There are numerous tables and twenty-two illustrations. 15/-.

Canadian standards, Canadian association, National research building, Ottawa.

C92.2-1956—Canadian standard practice for street and highway lighting.

This code is based on the American Standard Practice for Street and Highway Lighting as sponsored by the Illuminating Engineering Society and approved by the American Standards Association.

It is believed that all improvements that are economically practicable should be made as soon as possible since it has been definitely established that adequate lighting results in a decrease in crime and in traffic accidents. The installation of adequate lighting costs the community less than the accidents caused by inadequate lighting and it is evident that the elimination of lighting inadequacies will not only remove the cause of a great loss of life and will reduce crime, but would also permit a more expeditious movement of traffic. 50 cents.

The Automotive Industry

This article covers the main fields of industry in Canada that offer scope for the automotive engineer and his associates. More specifically, these fields concern the production of automobiles, trucks, and buses, and the maintenance of large operating fleets, particularly of public service vehicles.

There are certain specialized applications and equipment, such as those used in the construction industries — special vehicles, earth-moving equipment, mobile cranes and other materials-handling units — that might be considered as coming into the province of the automotive engineer, but these concern a minority of such engineers and will be more appropriately dealt with in further articles on industries using such equipment.

In general, the mechanical engineer predominates in the industry, but there is also a demand for electrical and some civil engineers. Many senior production and administrative posts are filled by engineers, and several of the industry's top executives are engineering graduates.

The Automobile Industry

All the leading American automobile makers have manufacturing facilities in Canada, mostly located in Ontario, but with smaller plants in other provinces. The extent of these operations naturally varies, but covers the production of engines, chassis, bodies, and their assembly into the finished vehicle. Some British and European makers have engineering facilities in Canada, which may well be extended in the drive for the Canadian export market.

Annual production of passenger cars in Canada during the 1950's has approached 300,000, while the total number of male salaried employees has steadily increased to a present figure of some 5000 in the motor vehicle manufacturing industry. Although there is some seasonal fluctuation of employment in the industry as a whole, this does not affect those positions filled by the engineer.

The highly competitive nature of the North American automobile industry results in an exceptional degree of advanced planning for model changes, and the design engineer has a major role to play. Even minor modifications to engine or body style involve considerable work for the tool designer and for the production engineer, since this is a mass-production industry and there must be complete interchangeability of components made at high rates of output.

Design of tools and plant, in fact, is quite as important as the design of the actual automobile, and there is a similar division of other duties between engineering for the product itself and for the production plant, so that two separate departments may be, and often are, necessary.

Vehicle Engineering

The department responsible for the engineering of the product will usually have need of metallurgical engineers to deal with the many applications of ferrous and non-ferrous metals and alloys to be found in the modern motor vehicle. Project engineers are required for engine, chassis, body, and accessories and other equipment; here, also, the services of electrical engineers are needed.

This vehicle engineering group may range from junior project engineer, through senior and supervisory grades, to chief engineer.

Production Engineering

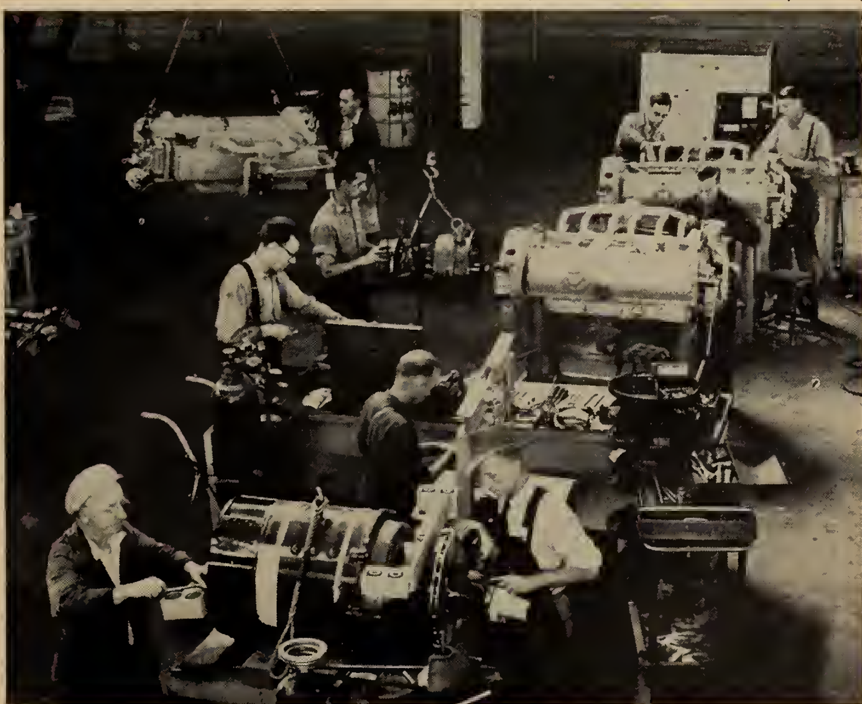
As already mentioned, the industry is generally based on mass-production, and efficient plant engineering is all-important.

When a major change in a car model is planned, new tooling and dies must be designed, made, and installed together with other necessary new production equipment in a short period limited by the demands of current production and starting the new run to meet sales demand.

Tools, dies, and patterns have to meet high standards, since all components and spare parts must be completely interchangeable. Furthermore, this accuracy must be maintained over long production runs, both for reasons of economy and for maintaining continuity. This is the field of the tool engineer, and some idea of its scope may be gathered from the fact that tooling costs for a new model may run into several million dollars.

A constant check must be kept on the quality of materials and products,

Assembling engines and electrical traction motor units
(Photo—Canadian Car and Foundry Limited)



and a staff of quality control engineers operates in the production departments.

Mass-production in this industry involves the use of much complex machinery including fully automatic transfer machines for the production of finished engine and other components from original stock. Maintaining the mechanical installations in a production plant requires the services of plant engineers, with an electrical engineering staff to look after the power supply systems and other electrical equipment.

The production field offers opportunities for engineers in the departments mentioned, and further to senior management positions.

Trucks and Buses

There are several truck manufacturing plants in Canada, again mainly in Ontario, a large Canadian bus manufacturer in Manitoba, and other bus plants.

The requirements for engineers are much the same as found in the automobile industry, both for product and production engineering, with the same high standards for tooling and interchangeability of finished parts.

Opportunities for advancement to senior engineering and management positions are also open to the engineer.

Maintenance Departments

Most of the major centres of population across Canada operate public transportation systems, mostly using buses.

The conditions of service of these vehicles are particularly severe under normal conditions and become even more so during the winter. Consequently, a heavy load is placed on maintenance facilities.

The larger transportation systems operate maintenance shops with mechanical engineers on the staff; some electrical engineers may also be required, and civil engineers may be called upon for the construction and extension of the system's roads and premises. (Naturally, the systems that also use street-cars and trolley buses have a greater need for electrical engineers, but these systems are not considered in detail here.)

Many of the shops use systems of preventive maintenance, which may be designed and applied by the engineering staff.

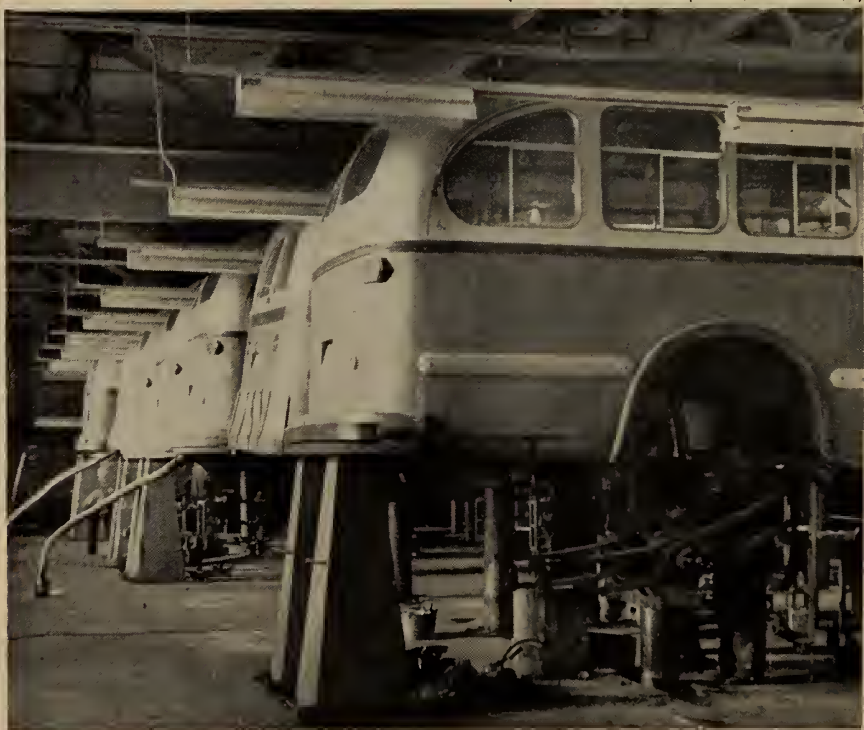
Although the practical engineering staffs of these undertakings may be small compared with those in other parts of the industry, there are opportunities for the engineer to enter the fields of administration and management in the transportation systems.

To a lesser extent there may be some need for engineers in the operating and maintenance departments of large users of trucks and other vehicles.

There is also an intermediate field of operation in which engineers are required to follow up on problems that may arise in the use of a manufacturer's vehicle or components or in servicing and maintenance.

Preventive maintenance is essential for large users of vehicles. Maintenance departments often need engineers.

(Photo—Montreal Transportation Commission)



Training Schemes

Manufacturers and maintenance departments take undergraduates for summer work to a limited extent.

The manufacturers generally provide the newly-joined recently-graduated engineer with training courses to suit the specialized requirements of the industry. Such courses may extend up to two years, initially, during which time the engineer is on salary and studies both theory and practice of all the industry's operations.

Salary Scales and Benefits

Engineering salaries are in line with other leading Canadian industries.

Paid vacations, pension and health schemes, and some bonus schemes apply. The automobile manufacturers may offer special terms on the purchase of new cars and components.

mine and mill conveying equipment, to huge post installations for stocking and transferring such basic raw material as gypsum and iron ore. Location Ontario. File No. 5756-V.

CIVIL OR MECHANICAL ENGINEER preferably early thirties to act as project engineer, and as such would have liaison work to do between construction jobs and chief engineer, and therefore must have a knowledge of construction, both structural phases in concrete, structural steel etc. and in erection of equipment. The salary can be mutually arranged and will be satisfactory. All usual benefits are available, such as pension plan, group insurance etc. File No. 5757-V.

ASSISTANT PUBLIC HEALTH ENGINEER required by B.C. Civil Service Department of Health & Welfare, Victoria, B.C. Salary $420.00 rising to $500.00 per month. To assist in supervising policy of sanitation, approving plans for water and sewerage systems and related work. Eligible for professional registration in B.C. preferably experience in public health engineering. British subject. Apply Chairman, Civil Service Commission, Parliament Buildings, 544 Michigan Street, Victoria, B.C. File No. 5758-V.

JUNIOR INTERMEDIATE AND senior engineers for the design and development of and field representation on: navigational aids, transistor application, fire control systems, air data systems, ice detection and production equipment, photographic processing equipment, optical plotting and measuring devices, armament control equipment and other forms of servo-mechanisms and computors. File No. 5759-V.

MILL SUPERINTENDENT. Metallurgical or chemical engineer, to take charge of privately owned uranium mill in Saskatchewan. Must be experienced in the operation of ore milling and hydrometallurgical plants. Will have a staff of several engineers and total crew of 60-70 men operating crusher, mill, acid manufacturing plant. Excellent housing available for family. Apply giving details of education and experience to File No. 5763-V.

A SPECIALIST in aircraft engines and propulsion is required to undertake studies and analyses for defence requirements; to evaluate research and development projects and plan test facilities in support of these; to be responsible for technical supervision of extramural research projects; to carry out liaison with research laboratories and the services on development projects. Candidates must be Canadian citizens or British subjects, and graduates of a recognized university in aeronautical or mechanical engineering or engineering physics with a good academic standing. Some pertinent experience is essential. Initial salary is dependent on qualifications and experience. Employee benefits include a five-day week, generous provision for vacation and sick leave, medical-hospital insurance plans, and an attractive pension scheme. Excellent opportunity for advancement.

Inquiries are invited from interested candidates. Write, outlining briefly your qualifications, to: Director of Personnel, Defence Research Board, Ottawa, Ontario. Please refer to 56-DRB-2. File No. 5787-V.

Mass Transportation in Cities

(Continued from page 938)

automobiles in motion, and one twentieth of the space when stopped. Trams and buses on Toronto's Bloor Street handle 9500 people per hour. Automobiles bumper to bumper could carry only 2000 people per hour. Trams would serve on Toronto streets for a long time yet, he predicted.

Comparing capacities of Toronto thoroughfares, he stated that before the subway was opened Yonge street carried 13,000 passengers hourly. The subway carries 40,000 passengers per hour. An expressway for bus and auto traffic combined could carry 2500 per hour, and with auto traffic alone could carry only 600 or less per hour. The subway costs $11 million per mile. The average street costs $5½ million per mile uptown and $8 to $10 million downtown.

Colonel Bingham explained that the basic problem was to open a way for people and commerce through streets now choked with automobiles. Transit, he said, was safer and relatively cheap, and would be faster if not impeded by autos, though in rush hours it was more crowded and uncomfortable.

Montreal, he said, was entering a period of accelerated growth due to the impact of the Seaway, and new problems were arising. Mass transit was the only alternative and must be encouraged by society and governments. Improvement of transit equipment had to be studied.

Montreal would need a subway soon, he predicted. Another solution might be the use of the newly designed monorail such as is now in service at Houston, Texas. Costing only $700,000 per mile as compared to $12 million per mile for subway construction, it could be designed for use underground with double track at a cost of $11 million per mile.

There was need to distinguish between the advantages of each type of service and to co-ordinate all systems to the maximum benefit of the city. Planning, he emphasized, should be along lines to take care of the predicted volume of traffic 20 years ahead.

Microwave Radio Project

of the Trans Canada Telephone System

J. A. Groleau, M.E.I.C.

Area Chief Engineer, The Bell Telephone Company of Canada

Chairman, Engineering Committee, The Trans Canada Telephone System

Read at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada, Montreal, May 1956

By mid-1958 the Canadian continent will be crossed by a microwave radio system now under construction by the Trans Canada Telephone System. This is the largest such undertaking by the commercial companies, and will materially enlarge long-distance facilities and provide television network under contract to the Canadian Broadcasting Corporation. The electrical and constructional engineering problems involved are challenging, and the techniques are described here.

AT THE 1954 annual meeting of this Institute, Mr. A. G. Lester, M.E.I.C., presented a paper tracing the history of telecommunications in Canada and outlining some of the developments expected in the future. This present paper covers a current project of major importance, the construction of a transcontinental microwave radio system by the Trans Canada Telephone System. This undertaking will provide for a material enlargement of long distance facilities and for the provision of network television facilities under contract to the Canadian Broadcasting Corporation. This is the largest project ever undertaken by the commercial communication companies, and it is making large demands on Canadian engineering, construction and manufacturing skills.

There are seven principal administrations responsible for the provision of local and long distance telephone service in Canada. These are the Maritime Telegraph and Telephone Company, The New Brunswick Telephone Company, The Bell Telephone Company of Canada, the Manitoba Telephone System, the Saskatchewan Government Telephones, the Alberta Government Telephones and the British Columbia Telephone Company. Each of these administrations provides the plant and equipment required to furnish service in its own territory. About 25 years ago these seven administrations formed the Trans Canada Telephone System for the purpose of developing long distance communications on a national scale. The Trans Canada Telephone System is not a corporation, but rather is a co-operative undertaking in which the seven administrations agree to provide adequate facilities between provinces and to work to uniform standards of service and transmission with the objective of supplying long haul telecommunications adequate to the country's needs.

Figure 1 shows the circuit mileage devoted to the handling of interprovincial and long haul business, excluding that between Ontario and Quebec, from the beginning of the Trans Canada System until the present time. The expansion in Canada's economy since the end of the war has been accompanied by very rapid growth in long haul communications, and the circuit mileage and volume of business has doubled each five years.

Except for the heavily settled sections of Ontario and Quebec, the long haul circuits of the Trans Canada System are developed on open wire lines equipped with carrier systems, supplemented in the Maritime provinces by a microwave radio system of limited circuit capacity between Halifax and Saint John. About three years ago, it was apparent that with further growth the capacity of the existing structures would soon be exhausted and that major construction would be required to obtain additional facilities across most of the country. Long range studies were undertaken to determine if relief should be provided by the construction of more open wire lines, by the provision of cable, or by the construction of a major microwave radio system. The Bell Telephone Company of Canada already had under way a microwave radio system connecting Buffalo, Toronto, Ottawa, Montreal, and Quebec.

Looking well into the future, microwave was a very attractive solution. It is the most modern and flexible means of long haul communications. It has inherently a large capacity for future growth, and has the particular attribute of being suitable for the development of facilities required for network television service. In addition, it provides storm-free plant, a factor of major importance when one considers the vast distances and wide range of climatic conditions in Canada. Early in 1954, the Bell Telephone Company and the Manitoba Telephone System decided to proceed with the construction of such a system between Toronto and Winnipeg, and studies were continued for the rest of the country. At about that time, the Canadian Broadcasting Corporation invited tenders from the principal telecommunications companies for the provision of network television facilities on a transcontinental basis, and the Trans Canada Telephone System was awarded this contract in competition with the other carriers. Early in 1955 work was started on the construction of a microwave system through the rest of the country.

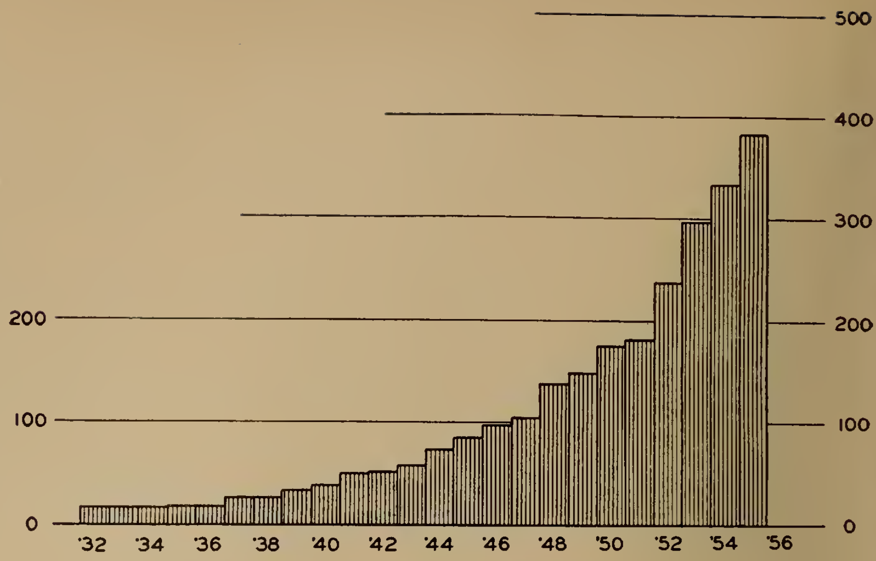

Fig. 1. Circuit mileage of the Trans Canada System.

The TD-2 Radio Relay System

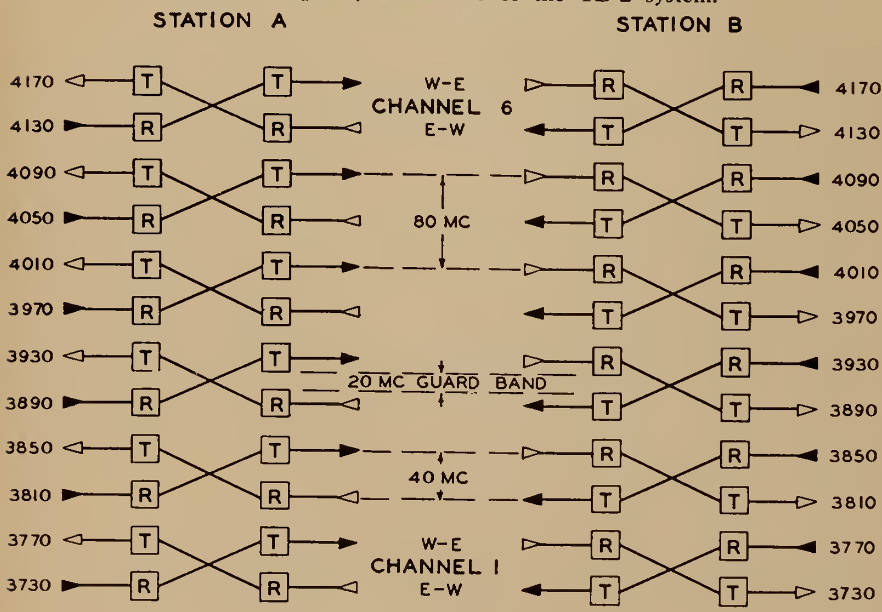
The project is using what is known as the TD-2 radio relay system. This is the type of system that has been in service between Buffalo, Toronto, Ottawa and Montreal for the last three years. It is designed to carry large quantities of high grade telephone circuits and network television over the long distances encountered on this continent, and many thousand channel miles of it are in satisfactory operation in the United States.

Transmission Design

It operates in the 4000 megacycle band with a corresponding wave length of approximately three inches, and the system has capacity for six radio channels in each direction. One radio channel can handle 600 telephone circuits or a black and white or colour video signal. Under certain conditions, a channel can handle a video signal and a limited number of telephone circuits as well. Channels may be equipped one at a time and the system can be readily expanded to care for growth. Of the six pairs of channels, one is normally reserved for protection purposes, and electronic devices switch the protection channel in to replace any regular channel on which transmission becomes unsatisfactory.

Although much has been achieved in the last few years in the transmission of microwave signals well beyond the horizon using tropospheric scatter propagation, this type of operation is not satisfactory where very large quantities of voice circuits or a video signal must be carried long distances. Consequently, the TD-2 system requires conventional line-of-sight transmission paths between repeater stations. The transmission design assumes an average repeater spacing of about 30 miles, with a corresponding free space transmission loss of about 135 db. Sufficient transmission margin is available to allow a limited number of repeater sections to be somewhat in excess of 40 miles and still provide adequate protection against propagation fades. This basic design parameter of about 30 miles checks out well with the practical limitations imposed by terrain, and it is the usual experience that the average repeater spacing on systems of this type is between 28 and 30 miles.

Fig. 2. Frequency allocations of the TD-2 system.



The frequency plan of the TD-2 system is shown in Fig. 2. The 12 channels occupy the spectrum between 3700 and 4200 megacycles. Channels are placed 40 megacycles apart, with 20 megacycles used for the channel proper and 20 megacycles as a guard band between channels. Alternate frequencies are used for opposite directions of transmission, providing an 80 megacycle separation between channels transmitting in the same direction, thus simplifying the design of filtering arrangements at transmitters and receivers. The frequencies assigned to a pair of channels are transposed by 40 megacycles at each repeater station. In this way, like frequencies are at about the same transmission level at each repeater point thereby reducing the problem of interference between antennas.

Terminal and Repeater Schematic

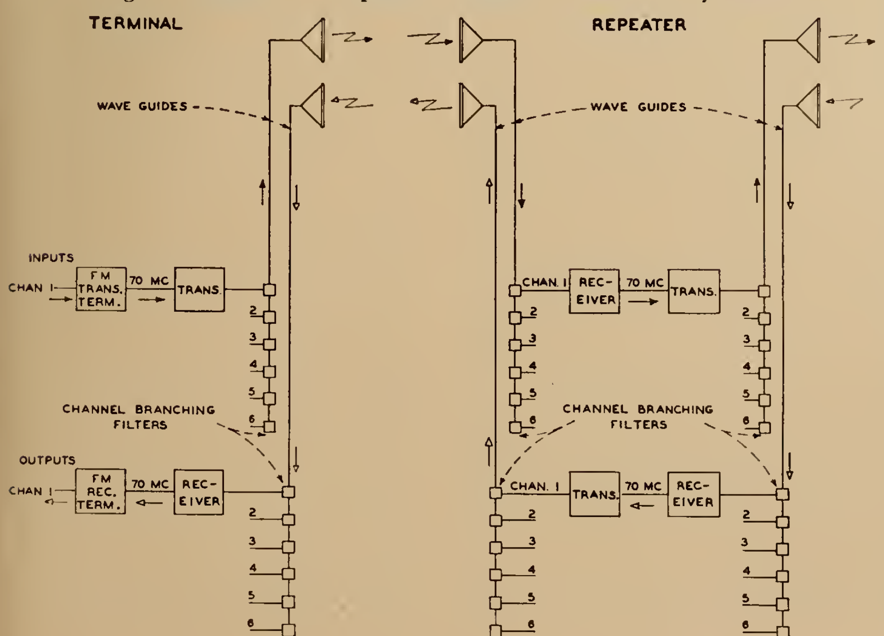
A block schematic of the terminal and repeater arrangements of the TD-2 system is shown in Fig. 3. The base band signal from either the telephone multiplex equipment or the video system is applied to a frequency modulation transmitter and the product is a 70 megacycle intermediate frequency. This is heterodyned with the microwave transmitting frequency in the 4000 megacycle band and supplied to the antenna through the waveguide. At the repeater station the line frequency is heterodyned in the microwave receiver, the product being the original 70 megacycle intermediate frequency. Amplification is provided at this intermediate frequency which is then heterodyned again with a line frequency 40 megacycles transposed from the received frequency and applied to the transmitting antenna. At the receiver the incoming signal is brought down to 70 megacycles and the frequency modulation receiver output is the original telephone multiplex or video signal.

Antennas and Waveguide

This radio system operates at very low power levels, the output of the individual channel to the antenna being in the order of one-half watt. Because of this, antennas with highly directional characteristics are required to focus the energy into a narrow beam. The type of antenna being used over most of the Trans Canada route is of a new design known as the horn reflector. The geometry of this antenna is shown in Fig. 4. The antenna is a combination of an electromagnetic horn capped by a section of a paraboloid of revolution. The apex of the horn coincides with the focal point of the paraboloidal reflector. In the side of the antenna opposite the reflecting surface, the horn is cut away to form an aperture of about 64 square feet through which the energy passes to the next station. As shown in Fig. 5, the antenna is a large device about 20 feet high and 11 feet wide, and weighs about 1700 pounds. Great accuracy is required in the manufacture of the reflecting surface as its contour must be accurate to within one-sixteenth of an inch. The antenna is highly directive, providing a gain of 40 db. over what the signal would be if it were radiated in all directions, and thus between the receiving and transmitting antennas there is a power gain ratio of 100 million over an isotropic antenna system. The radiated beam is very narrow and the power falls off to half the level of the main signal with a deflection of only one degree. This imposes some severe design requirements in the supporting tower structures.

The antennas are connected to the radio equipment by low loss copper waveguide. Circular waveguide, having a loss of 0.004 db. per foot and with an internal diameter of 2.812 ± 0.003 inches, is used for the long run from the antenna to the level of the entrance to the building. Rectangular waveguide is used for the entrance to the building and connection to the equipment, and an appropriate coupler is provided between the vertical run of circular waveguide and the horizontal run of rectangular waveguide.

Fig. 3. Terminal and repeater schematic of the TD-2 system.



Waveguide must be manufactured to great precision and erected with care as irregularities of the internal surface act as impedance irregularities at microwave frequencies. The waveguide and antenna system is kept under low pressure of dry air and compressor-dehydrators are provided to supply it.

With a fully developed TD-2 system, separate antennas are required for transmitting and receiving in both directions from a repeater station. When only a few radio channels are equipped, it is possible to use one antenna for both transmitting and receiving by resorting to cross polarization of the energy in two directions.

416B Electron Tube

One of the interesting features of the TD-2 radio system is the 416B electron tube used in the modulator and in the transmitting amplifier. It is a planer type triode and because it operates at 4000 megacycles, the elements and interelectrode spacings are very small indeed. The grid wire is 0.0003 inches in diameter and is wound at 1000 turns per inch. The cathode to grid spacing is 0.0006 inches and the plate to grid spacing is 0.01 inches. Very precise control is required in the manufacture of this tube and it is a remarkably satisfactory device. When one considers that some 5000 tubes of this and other types are involved in the transmission of a signal across the country, the extreme need of high reliability in the performance of these tubes is apparent.

Power Supply

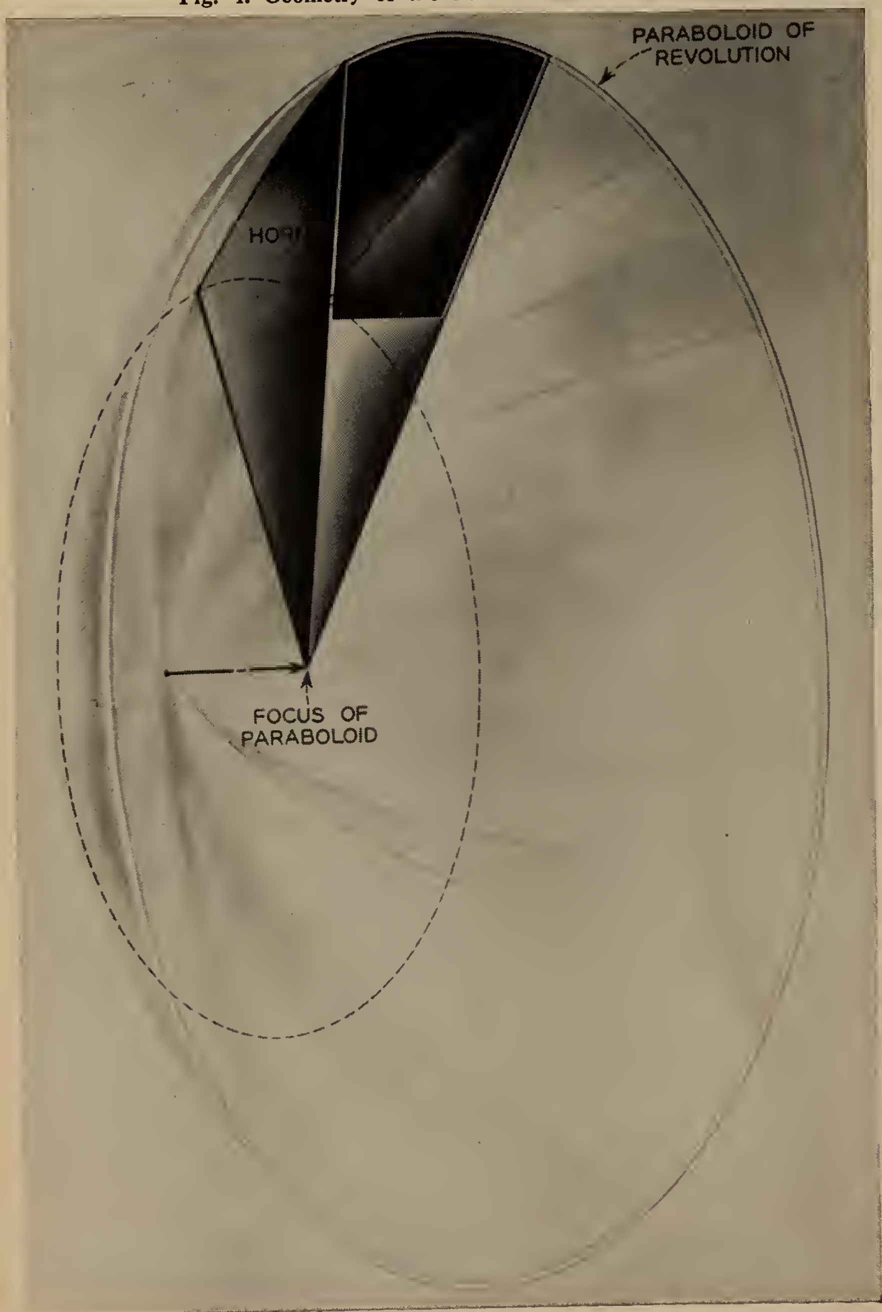
The radio equipment requires direct current power supplies at 12, 130 and 250 volts. A small supply of 24 volts is required for various items of control apparatus in the station. At the small repeater stations, the 12 and 250 volts supplies are normally obtained from rectifiers driven directly from the available alternating current source, with the rectifiers being provided on a per channel basis. No batteries are provided for these voltages. The 130 volt supply is from a battery normally floating across a rectifier. A 10 kilowatt diesel driven alternator arranged for automatic start is provided at each station for use in the event of failure of the incoming a.c. supply. This engine will take over the station load in a two to five minute period after power failure, and during this interval the 12 and 250 volt rectifiers derive their a.c. supply from vibrators operating from the 130 volt battery. Because of the lightning exposure involved at elevated sites with high towers, grounding arrangements must be particularly good, and tower, waveguides, and equipment are well bonded and connected to the power neutral if such is available.

At repeater stations where it is not economic to build out to the nearest available commercial power line, a large diesel plant designed for continuous operation is provided. Two 20 kilowatt engine alternators arranged for automatic timed changeover are supplied.

Equipment Assemblies

The equipment is designed for maximum shop assembly, wiring and testing of the radio, power, and miscellaneous bays. Through the use of fixed floor plan arrangements, cable racking and power cables can be cut in the shop before shipment, thus minimizing the installation effort at the many repeater stations on the route. A photograph of a transmitter-receiver radio bay is shown in Fig. 6.

Fig. 4. Geometry of the horn reflector antenna.



Selection of the Route

The major part of the engineering of a microwave system is the detailed selection of a route connecting the desired service points. Many economic and physical factors must be assessed if satisfactory transmission is to be obtained at minimum cost. Among the factors are the number of repeater stations required, the cost of access roads, the height of the antenna towers, the availability of commercial power and of communication facilities required for alarm purposes, and the physical aspects of the sites as affecting the cost of building and tower foundations.

As already mentioned, the system requires clear line-of-sight transmission paths between stations and these paths should average about 30 miles over a long system, although individual links can be well above this if required. Consideration has to be given to the nature of the terrain between repeater points, as microwave energy can be reflected off the ground and reach the receiving point in such phase relationship with the main signal that it can be either helpful or harmful to transmission.

Preliminary selection of the route is made from office study of topographical maps with at least 25 foot contour intervals. Diagrams similar to that shown in Fig. 7 are drawn for prospective paths, showing the topography in relation to the curved surface of the earth. From study of these diagrams, an assessment can be made of the probable transmission conditions and the tower heights that would be required at the repeater locations. A complicating factor in the selection of sites and paths is the fact that the route must be staggered in a planned manner so that energy will not be transmitted from one station and received several stations down the line, thus causing interference. In laying out the route across Canada, many hundreds of possible sites and combinations of paths had to be reviewed before starting field work.

For such a large country, Canada is very well mapped and the only sections for which adequate topographical data were not available were those between Orillia and the Manitoba border, and through the mountains of Alberta and British Columbia. For the section through northwestern Ontario, some general conclusions were reached from study of available maps and arrangements were made to take stereo aerial photographs of a narrow band through which a satisfactory route appeared feasible. Topographical detail was developed from the stereo photographs with very satisfactory results. The problem of selecting a route through the mountains was somewhat different as it had to do principally with obtaining adequate clearance over particular peaks in a proposed path. Preliminary study was conducted from large scale topographical maps and from reconnaissance in the field both on foot and from the air. Subsequently, heliograph tests were made between selected sites to ensure that adequate clearance was available.

When tentative sites had been selected from the office study, engineering teams made field visits to assess the suitability of the sites from the transmission aspect, and to evaluate the physical problems involved in construction. If the survey party found a site suitable, arrangements were made to obtain a rental option on a parcel of land about 800 feet square, as well as rights for the necessary access road from the existing public road. A contractor was then employed to clear sufficient of the land to provide access for path testing work.

Fig. 5. Preparing to install the horn reflector antenna.

Radio Path Testing

The suitability of the sites and paths selected from office study is verified by means of radio tests using portable microwave testing equipment. The microwave receivers and transmitters and associated transmission measuring apparatus are mounted in specially designed bodies on four-wheel-drive trucks and V.H.F. radio is provided for intercommunication between receiving and transmitting crews. The test equipment set up includes portable aluminum towers of special design that can be erected to a height of 200 feet in less than a day. Parabolic antennae mounted on carriages can be raised or lowered on these towers by means of winch lines. The antenna carriages also carry a microwave transmitter or receiver and two remote control motors, one for azimuth and one for vertical adjustment of the antenna.

Although the radio testing equipment and towers are normally taken in to the site location by means of trucks, there were two locations in the Rocky Mountains where it appeared impractical to provide roads for path testing purposes. At one site a temporary aerial cableway was erected and, at the other, helicopters were used to transport personnel, towers, and test gear.

A series of antenna height versus path loss tests are made as predetermined from experience and from study of the intervening terrain from the topographical maps. The results of these tests are plotted in diagrammatic form as shown in Fig. 8. The Fresnel zones shown are caused by the radio energy reaching the receiver over two separate paths. One of these is the direct line-of-sight path between the antennae, and the other is via an obstruction or reflecting surface in the terrain between the two sites. This second path varies in length as the height of the antenna is changed, and hence the energy arriving at the receiver over this path is alternately in phase and out of phase with the energy arriving over the direct path. Consequently, it alternately adds to and subtracts from the direct path energy, resulting in peaks above the computed free space loss and in valleys below the free space loss. A series of tests is run for various combinations of antenna heights and the results are analyzed to determine that there are no obstructions or conditions on the path that have not been determined from the study of the topographical data. This analysis also assists in arriving at decisions in respect of the optimum tower heights.

It is interesting to note that although a line-of-sight path is required between adjacent towers, actual line-of-sight transmission over this distance is seldom in a straight line. This is due to the fact that the atmosphere is not a homogeneous medium because its temperature, pressure and humidity vary with height above ground and with general weather conditions. This non-homogeneity is one of the causes of radio fading, as it is also the cause of mirage phenomena experienced with the transmission of light. For the majority of the time, there is a slight curve in the radio path as it tends to follow the circumference of the earth. Under certain atmospheric conditions, the wave can have what is called inverse bending and thus tend to go into the surface of the earth rather than toward the distant antenna.

Consequently it is necessary to allow more clearance over obstructions in the path than would be indicated from considerations of straight line propagation.

The Trans Canada Route

The final route selected across the country is shown in Fig. 9. Cities shown by circles are those at which either television or telephone use is to be made of the system. The total route including spurs is about 4800 miles long, and there will be some 160 repeater points, only a few of which are associated with existing telephone installations. Between Sydney Mines, N.S. and Saint John, N.B. the facilities of the Trans Canada System will be carried on the microwave system being built by the Eastern Telephone and Telegraph Company in co-operation with Canadian Overseas Telecommunications Corporation for the purpose of extending the Trans Atlantic cable circuits inland from the cable head at Sydney Mines. The spur routes to Halifax, Charlottetown, and Moncton will be built by the telephone companies concerned. It is likely that additional connections with the United States microwave network will be required within the next few years on new routes southward from Saint John, Montreal, Winnipeg and Vancouver.

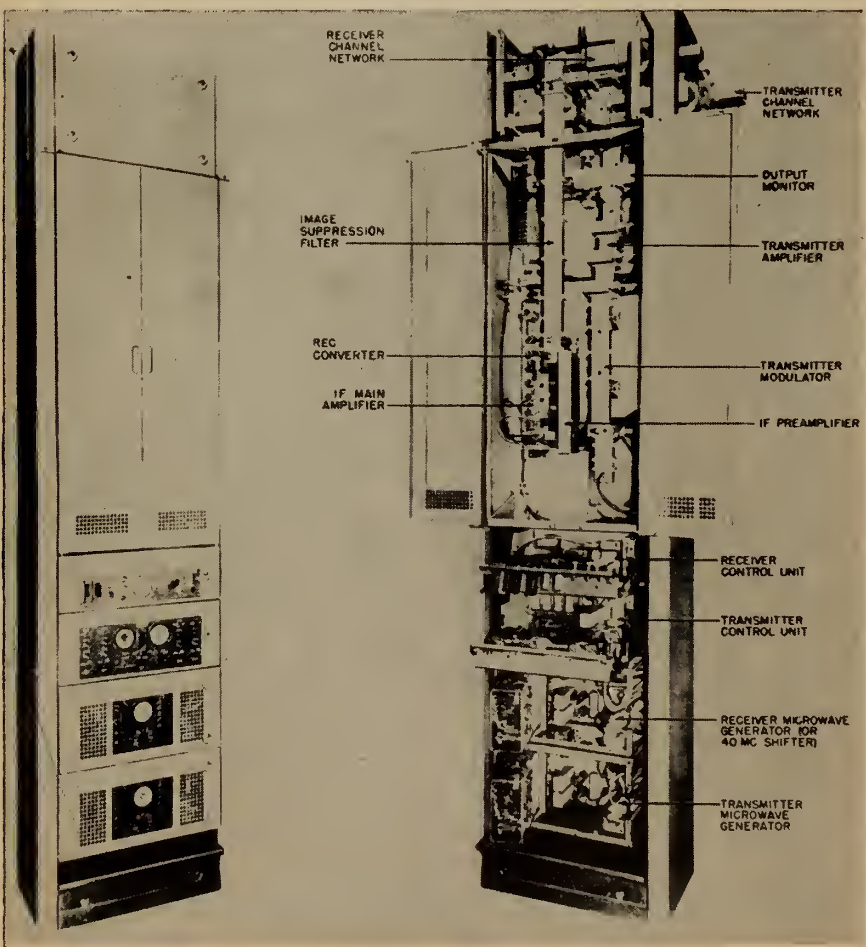
Construction of Relay Sites

Many engineering and construction problems are encountered in the development of the large number of repeater sites on this project, many of them in quite remote areas. Each site involves access roads, towers and footings, and buildings, and at most of them, construction is required to bring in commercial power and regular land line communications. Wide variations are encountered in terrain and soil conditions, including the Laurentian shield across the top of Lake Superior, the gumbo soils of Saskatchewan, and the particularly rugged conditions encountered in the Rocky Mountains where the highest site will be about 7000 feet above sea level.

Access Roads

In laying out the route, every endeavour was made to choose repeater sites close to existing roads, but, due to the need to take advantage of elevated ground, road construction is involved at almost every site, ranging from a few hundred feet to as much as 12 miles. At one site in the Rocky Mountains, it has been considered uneconomic and impractical to provide access by road, and an aerial tramway will be used. The line will be in seven spans totalling 11,800 feet, and the vertical lift will be 4400 feet.

Fig. 6. A TD-2 transmitter-receiver radio bay.



While the finished roads can be quite rough, they must be of sufficient quality to provide access at all times of the year for maintenance vehicles and fuel trucks. A final effective width of not less than 16 feet is required and, to obtain this, it is necessary to make the original road about 20 feet wide to allow for erosion. Because of the elevated nature of the sites, special attention has to be provided to grades, which have in general been limited to 10 per cent, and to the provision of adequate drainage and culverts to prevent washouts. In areas where snowfall is heavy, adequate space must be cleared beside the road to allow for disposal of snow by pusher type ploughs.

Towers and Footings

In laying out a microwave route, economic factors generally favour the use of high towers for the purpose of reducing the number of repeater stations required. On the Trans Canada route, a great many of the towers are in excess of 200 feet with a few as high as 350 feet.

The highly directional characteristics of the antenna require very stiff tower construction with design limits set at a one degree deflection under 100 miles of wind. This results in the use of very heavy steel and extensive cross bracing. The towers employ a modular design with 12½ foot panel modules. In the larger towers, the base legs are 8 in. x 8 in. x 1⅛ in. angles, the largest size rolled. On the very tallest towers, this is further strengthened by the use of a welded plate to provide a 1⅝ in. angle. The 350 foot tower weighs in the order of 120 tons. The steel is galvanized, and it is essential that this be a high quality job and that there be no damage to the surface in erection. Because of the galvanizing, rivets are not used in field assembly and erection and members are bolted using galvanized ribbed bolts. Close inspection of the work in progress and of the finished tower has been found very desirable.

Special design features include the antenna mounting arrangements, the waveguide supporting and restraining members and the arrangements at the bottom of the tower where the circular waveguide is coupled to the horizontal run into the building. Rest platforms are provided at 50 foot intervals, and the towers are painted and lighted to meet the requirements of the Department of Transport.

Because of the height of the towers and the heavy wind loading, footings have to be designed for large uplift. For this reason, large spread footings at suitable depths are required so that there is an adequate load of backfill to provide the necessary anchorage. The type of footing and pier is shown in Fig. 10. For a 350 foot tower, each footing requires an excavation of approximately 175 cubic yards, and the footing and pier require about 43 cubic yards of concrete. Because of the solid rock conditions encountered at many of the sites, consideration was given to a rock anchor type of construction and this was tried at two sites. It did not prove economic and was abandoned in favour of the pier type footings at all locations.

Over much of the route in southern Saskatchewan gumbo soil conditions are encountered. This is a peculiar soil of great depth that tends to be very liquid for some feet below the surface during the spring period of the year. While the regular spread footings were used, they were placed well below the frost line and each footing was tied to four reinforced concrete piles about 15 feet long constructed in holes drilled into the gumbo. The piles serve as friction devices only as they are not carried to bed rock.

Buildings

In the interest of overall efficiency and cost, a standardized layout has been adopted for the radio, power, and auxiliary equipment in the small repeater stations. This layout is sufficiently flexible to care for necessary minor variations in equipment provision at different sites and provides for growth for a reasonable future period. As shown by the floor plan in Fig. 11, the building is approximately 35 x 21 feet. The radio equipment, rectifiers, batteries and control equipment are located in the large room, and a smaller room houses the engine alternator and the compressor-dehydrator. At locations where locally generated power is required, a separate building is provided for the larger engine plant.

Various types of construction are being used over different sections of the route, including brick, concrete block and partially prefabricated metal buildings. A metal building has been used between Toronto and Winnipeg and has been found very satisfactory. It employs modular panels with corrugated aluminum outside and steel inside, with suitable insulation between. The same panel is used for the hipped roof which has been specially strengthened to protect against damage from ice falling from the adjacent tower. Experience with the erection of these buildings in isolated locations over many hundreds of miles and with a great deal of work done under severe weather conditions against a tight schedule, has been most satisfactory, and required a minimum of field supervision on the part of the owner. The foundations and floor slabs were put in by the contractor doing the tower footings. Erection of the buildings was by the supplier, with one crew erecting the structural frame and a second placing the roof, walls and ventilating hoods. A separate electrical contractor followed to install the service entrance, conduits, lighting and related items. A photograph of a completed building and the associated tower is shown in Fig. 12.

As the electronic equipment dissipates large quantities of heat, provision is made for thermostatically controlled forced air ventilation for use during the warmer seasons of the year. During the winter months, the temperature is maintained in the low 40's by means of thermostatically controlled heaters. Electric heaters will be used over most of the route, but in some sections where winter temperatures are severe and electric power costs are high, oil heating will be used. Sufficient capacity is provided that the temperature can be raised to a satisfactory point

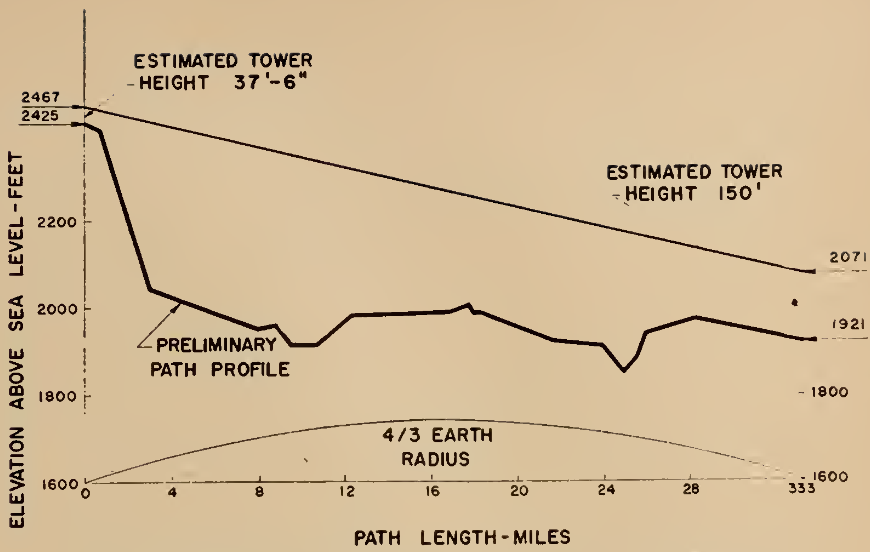


Fig. 7. Typical path profile relates topography to the earth's curvature.

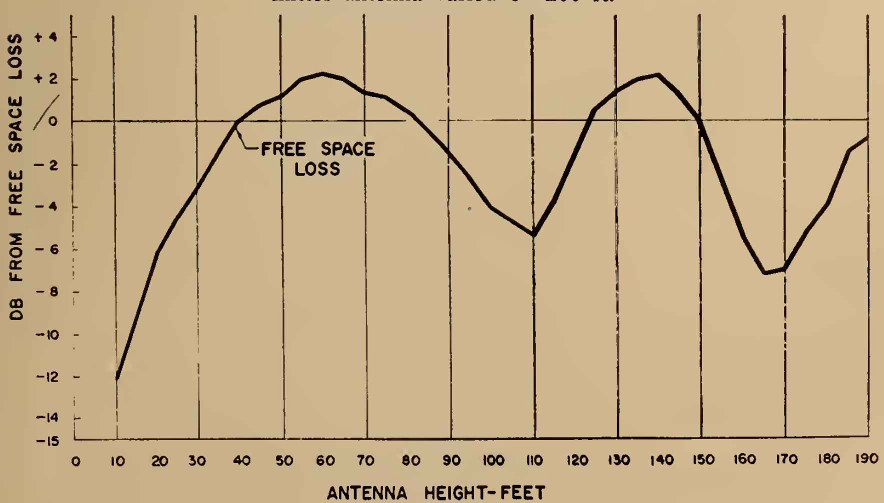

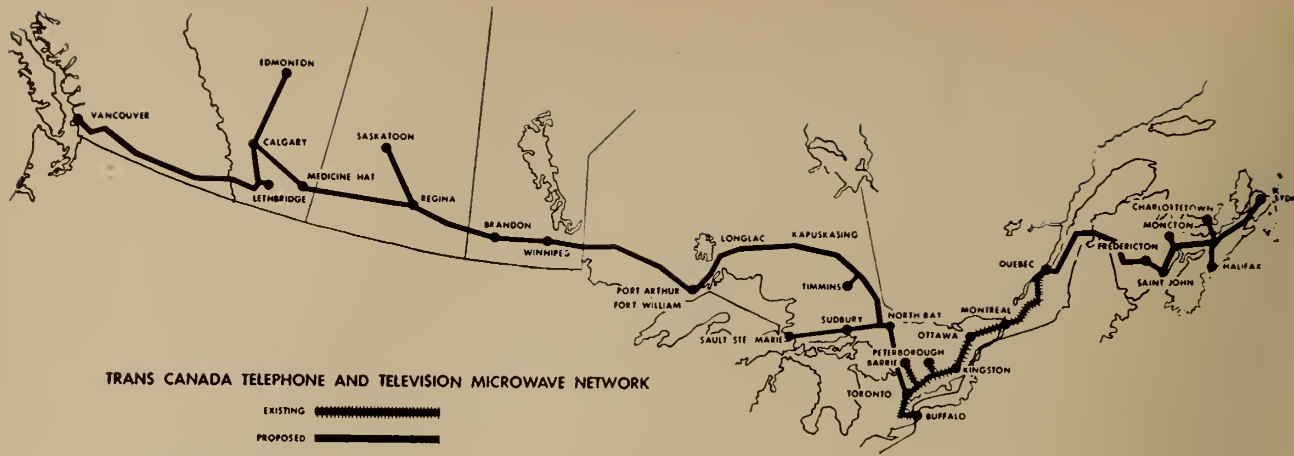

Fig. 9. Trans Canada microwave route.

when personnel are in the building.

Power and Communication Services

Arrangements are made with the various power utilities for the construction of run-offs to bring commercial power to the repeater sites. It is the practice to bring in commercial power whenever economically possible rather than rely on local diesel plants, and there have been several long builds required, the longest being about 18 miles. There are few locations where local diesel plants will be necessary.

Connection with the regular land line communication system is required for station alarms and controls. This has normally been established by building from existing open wire or cable routes, usually on a joint use basis with the power utility. In a few remote locations, radio is used to bridge the gap to the existing communication system.

Operation and Maintenance of the System

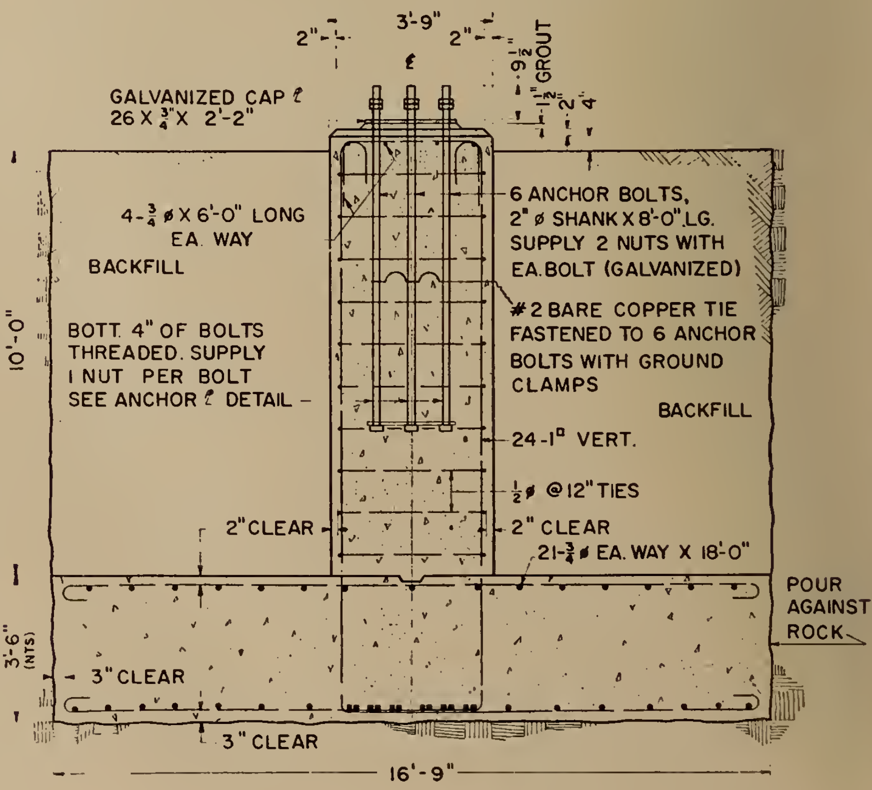
Because of the importance of the microwave system in the country's communication network, extremely high reliability in its operation is imperative, and the paragraphs that follow discuss certain of the steps taken to ensure this reliability of operation and to facilitate maintenance.

Electronic Protection Switching

Even with components of the highest quality and with a conservative approach to the transmission engineering of the route, some individual channel failures due to breakdowns and to radio propagation conditions are inevitable. As previously mentioned, to protect against these failures, one pair of channels on the route is reserved for the protection of the channels carrying the telephone and television signal material. The route is divided into protection switching sections of about 10 repeater sections each. Electronic devices at the receiving end continuously check the noise level on the radio channels. If the noise level on a channel rises above a predetermined amount, the electronic device calls for the protection channel. A signal is sent to the transmitting end, identifying the channel in trouble, and the protection channel transmitter and receiver are bridged to the regular channel. When this has been accomplished, the regular channel is disconnected. The interval from the time unsatisfactory transmission is recognized until the switch takes place is between 20 and 40 milliseconds and an additional 5 to 10 milliseconds is required to complete the switch. When transmission conditions on the original channel again become satisfactory, this is recognized by the switching system, and the original channel is restored to service and the protection channel returns to normal standby condition.

It is of interest in this connection that the system design is such that propagation conditions causing severe fading with resulting high channel noise will rarely affect more than one channel of the system at a time. Consequently, the provision of one protection channel on the route provides

Fig. 10. Typical tower footing.



a very susbtantial increase in the reliability of the system as a whole.

Alarm and Control Facilities

As the small repeater stations are operated unattended, provision must be made for the transmission of alarm information from the unattended points to master stations where maintenance forces are in continuous attendance. This is done by tying in the repeater stations to the regular land line communication system, and a maximum of 12 stations may be bridged to one set of alarm and control facilities. When trouble arises, the unattended station affected identifies itself to the master station by means of selective signalling frequencies. The attendant at the alarm centre can then dial up the station involved and the alarm system automatically scans conditions in the station and reports its findings on a visual display at the master station. As many as 42 alarm conditions can be scanned in this manner. Certain types of trouble can be corrected from the master station by means of orders sent over the control facilities, thus making it unnecessary to dispatch a maintenance man until later.

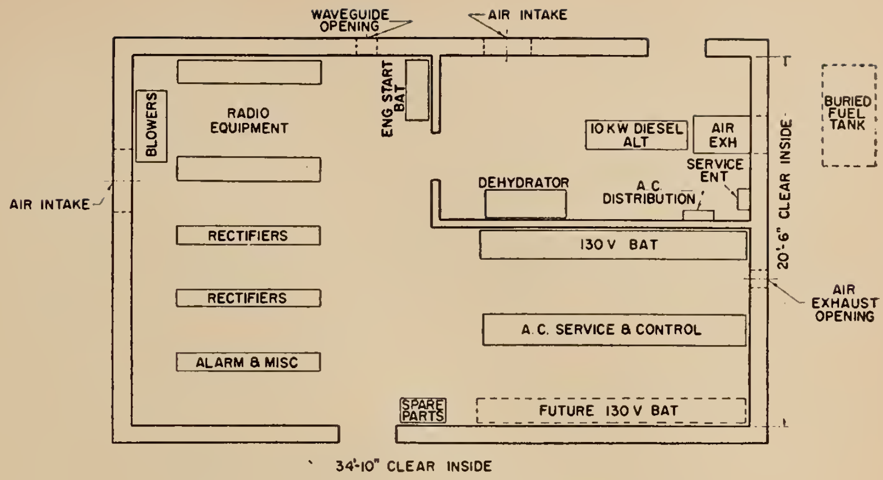


Fig. 11. Floor plan of a typical repeater station.

Maintenance Features

The system has been designed so that only routine inspections and minor maintenance operations will be carried out at the repeater stations. Because of the large volume of communication handled on the radio much of this work can be done without removing the system from service. Units that may require extensive readjustments are arranged so that they may be easily replaced and transported to maintenance centres where complete test bench equipment and trained personnel are available for these more extensive maintenance operations.

Fig. 12. View of part of the completed repeater station building and the associated tower at New Liskeard.

Telephone Multiplex and Video Transmission Equipment

At the telephone and television service points across the country, there will be large installations of telephone multiplex and video transmission equipment.

Telephone Multiplex Equipment

The telephone multiplex equipment employed is the well established Type L carrier telephone system. The basic 3400 cycle telephone circuit occupies a band of 4000 cycles, and 12 circuits are modulated to form a group in the band between 60 and 108 kilocycles. Five groups of 12 are then again modulated to form a supergroup between the frequencies of 312 and 552 kilocycles. The supergroups in turn are shifted in the frequency band to their appropriate place between 64 kilocycles and approximately 3 megacycles, and then this signal is superimposed on the frequency modulation transmitter of the radio system.

Video Transmission Equipment

The video or picture signal requires a bandwidth extending from zero cycles to approximately 4 megacycles. This signal is usually transmitted to the studio or television station over 16-gauge shielded pairs using polyethylene insulation. The attenuation-frequency characteristics of this type of facility are such that extensive use must be made of amplification and precise equalizing de-

Control of Air Pollution in England

S. G. G. Wilkinson,
Ministry of Housing and Local Government, London, England

Read at the 70th Annual General and Professional Meeting, the Engineering Institute of Canada, Montreal, May 1956

This paper gives an account of the legal and administrative measures proposed for the control of air pollution in England, as seen from the viewpoint of an officer of the central Government. Sound administration will be required to implement these measures, together with the co-operation of the public, whose opinion now seems ready for action.

I PROPOSE in this paper to give a short account of the legal and administrative measures, past, present, and prospective, for the control of air pollution in England, as seen from the viewpoint of an officer of the central Government. It is not my purpose, and indeed it would be beyond my competence, to discuss the scientific or technological aspects of the subject, or to deal with details of local administration; the object of this paper is rather to present the problem as it appears to us at the centre of Government, and to outline the policy and general principles of our control measures.

In the immediate foreground of the picture three features stand out in prominent relief. First, the severe smog — perhaps the most serious incident of its kind that has ever occurred — which covered London for four and a half days in December, 1952, and caused no less than four thousand deaths. Second, the appointment by the Government in the following year of a committee to enquire into all aspects of the problem of air pollution, including causes, effects and methods of prevention, and the publication of the committee's report towards the end of 1954. Third, the adoption by the Government of a national "clean air" policy, in line with the committee's recommendations, and the introduction of legislation last year to implement that policy.

Before describing these events in detail, a few words about the background of the picture. It is an extensive background, receding far into the distance. We have been making laws to control smoke for something like seven hundred years. In the year 1273 the use of coal in London was prohibited as being prejudicial to health. A few years later, in 1307, a Commission was appointed to

> "enquire of all such who burnt sea cole in the City or parts adjoining, and to punish them for the first offence with great fines and ransoms, and upon the second offence, to demolish their furnaces."

At about the same time, it is believed that even direr penalties were imposed, and that at least one unfortunate was actually executed for burning coal illegally in London.

Even such drastic remedies as these were evidently ineffective, for it is known that the coal trade of London grew and prospered throughout the 15th and 16th centuries. But not without occasional protests. In 1578, we find Queen Elizabeth the First objecting to the burning of coal by the brewers of Westminster; and a little later, it is recorded that

> "the nice dames of London would not go into any house or room where sea coles were burnt, nor willingly eat of the meat that was roast with the cole fire."

Even that, apparently, was not sufficient to deter people from burning coal, and no doubt making smoke, in ever-increasing quantities. Wood fuel was becoming scarce, whereas the exploitation of the nation's coal resources had barely begun. But the real demand for coal came with the industrial revolution, and in particular, the development of steam-power from the latter part of the 18th century. Abundant supplies of coal were available not only to feed the furnaces of industry, but to supply the heating needs of a rapidly expanding population. Coal production increased six-fold between 1800 and 1850. The production of smoke must have increased proportionately. The fact that coal was plentiful and cheap afforded little incentive to economy or efficient methods of combustion, and the amount of fuel wasted in unnecessary smoke was of little consequence. Indeed, by a strange inversion of values smoke became a sort of index of production, the pall of smoke hanging over an industrial town being commonly regarded as a sign of its prosperity.

By the middle of the 19th century, however, smoke pollution was coming to be recognized as a social evil and a potential danger to health. The early public health legislation approached the problem with caution. Some general requirements were laid down for the design of furnaces, but emissions of smoke were dealt with in much the same manner as other public health "nuisances"; action could be taken only if it could be shown that the smoke from a particular chimney caused a nuisance in the locality. No serious attempt seems to have been made to deal with the overall problem of smoke pollution.

Separate legislation, beginning with the Alkali Act, 1863, was passed to control pollution by gases from the chemical industries. Here the approach was quite different. Certain gases were recognized to be inherently dangerous, and were controlled accordingly, regardless of the degree of local nuisance that might be caused. The industries to which these Acts applied were required in certain cases to keep the concentration of gases discharged within prescribed limits, and in others to use the best practicable means to render the discharges harmless. Further, whereas responsibility for enforcing the legislation against smoke was vested in the local authorities, that is, the councils of towns, and urban and rural districts, the enforcement of the Alkali Act was made the responsibility of a corps of inspectors, the "alkali inspectors", appointed by and responsible to the central Government. These differences stemmed logically from the conception that whereas smoke abatement was primarily a matter of enforcing the law for the prevention of local nuisances, the chemical gases were inherently obnoxious and should be strictly controlled, under the supervision of specially qualified inspectors, wherever the source.

Current Legislation

The pattern of our general legislation to-day reflects this distinction and is still fundamentally the same, although the earlier Acts have at various times been brought up to date and supplemented in detail. The control of local nuisances from smoke, grit and dust is the responsibility of the local authorities, while the central Alkali Inspectorate, which is now a branch of the Ministry of Housing and Local Government, is responsible for the control of emissions from the chemical industry and allied processes. The processes supervised by the Alkali Inspectorate now include virtually the whole of the heavy chemical industry, tar distilleries, the extraction of zinc and lead, petroleum refineries, cement works, and the manufacture of chemical manures.

All the legislation described so far has been general in scope, that is to say, it applies to the whole country and gives the same powers to all the local authorities. In recent years however a number of individual local authorities have been obtaining special smoke control powers supplementary to those available under the general law, by promoting local Bills in Parliament. The most important of these local powers is one which provides for the establishment of "smokeless zones", or areas in which the emission of smoke is entirely prohibited. Several of the larger local authorities have made a start with establishing these zones and gradually extending them. In Manchester, for example, there is now a very successful smokeless zone which embraces some 400 acres in the centre of the city. The City of London has now gone smokeless too, under a special Act of Parliament which came into force in October last year. This of course covers only the City proper — the square mile or so that lies between the Temple Bar and the Tower of London, but it is the heart of London, and we hope that the adjoining boroughs will follow suit before very long.

This brings us right into the foreground of the picture again, and to the three events which I have mentioned earlier. At the beginning of December, 1952, the whole of London was blanketed by a fog of unusual density. The fog lasted for 4½ days, and it was established beyond all reasonable doubt to have been the cause of approximately 4,000 deaths. That figure was computed by comparing the number of deaths which occurred during and immediately after the fog with the average for the preceding weeks, and also with the average for the corresponding period in previous years. Between 80 per cent and 90 per cent of the deaths were found to have been due to respiratory or heart disease or a combination of both; 90 per cent of the victims were over the age of 45, and the majority over the age of 65. Most of those who died had previously been suffering from respiratory or cardiac disorders and, so far as is known, there were no deaths attributable to the fog among normally healthy people.

Investigations to determine the particular element in the fog which caused the deaths were inconclusive. It was noticeable that the number of deaths rose sharply during the first two days of the fog, that is, *before* the maximum concentrations of pollution were reached. Further, the maximum recorded concentration of sulphur dioxide during the fog never came anywhere near to what is normally accepted as the safe limit for prolonged exposure to SO_2. After an exhaustive examination of all the evidence, the investigators found it impossible to state that any one polluting agent was the cause of the deaths. Their report[1] did however suggest that the interaction of SO_2 with moisture and with solid particles in the fog may have been responsible.

The Beaver Committee

In the following year, a comprehensive inquiry into the whole question of air pollution, embracing causes, effects, and methods of prevention was set on foot by the appointment by the Government of a committee of inquiry, commonly known as the Beaver Committee, after its distinguished chairman, Sir Hugh Beaver. This committee produced a factual interim Report[2] in December, 1953, and its final Report[3] in the following November. The final Report dealt with all aspects of the problem. It started by laying stress on the fact that abnormal fog episodes such as the London fog of December, 1952, were but manifestations in an acute form of the more or less chronic incidence of air pollution, and that it is this — the continuing level of pollution, rather than the occasional extremes—that needs to be tackled.

The committee's report dealt separately with visible pollution by smoke, grit and dust, and with pollution by sulphur oxides. It recommended sweeping reforms in the law for the control of visible pollution not only from industrial sources, but also from domestic chimneys. It proposed that the emission of dark smoke, that is smoke as dark as, or darker than, shade 2 on the Ringlemann chart, should be made an offence, without proof of nuisance. It also recommended that measures to arrest grit and dust from industrial furnaces should be made obligatory wherever practicable.

The report showed that domestic fires were responsible for nearly half of all the smoke in the atmosphere, and concluded that the problem of domestic smoke would have to be tackled, despite the difficulties, if any worthwhile advance was to be made towards cleaner air. For us, this presents some quite formidable problems, owing to the somewhat peculiar arrangements for domestic heating that are traditional in England. Because our climate is variable and we seldom suffer from prolonged spells of cold weather, comparatively few houses are equipped with central heating. The great majority have open coal-burning fires which heat, or are supposed to heat, single rooms. There may be two, three or more such fires in a house, and sometimes a coal-fired cooking stove or water-heater as well. These open fires are lit as and when required, and they are usually let out, or go out, at night. Most of those now in use date, in the fundamentals of design, from the days I have described, when coal was plentiful and cheap and nobody bothered much about the amount of smoke in the air.

Nevertheless, the open fire is still a cherished feature of millions of homes. Now, it is impossible to burn bituminous coal in fires of this kind without making smoke; and our supplies of natural smokeless fuels are very limited. The elimination of domestic smoke would therefore entail a minor revolution; it would mean replacing the house coal now used by gas, electricity and manufactured smokeless fuels. For various reasons, gas and electricity are only likely to fill the gap to a limited extent, and the main substitute must be coke. As a measure of the problem, some 19 million tons of coal a year would have to be replaced in the larger urban areas alone, and greatly increased supplies of coke would have to be found, from increased production and by diversion from other uses, to enable this to be done.

Then there is a further obstacle—those fires again; the kinds of open fire most commonly in use are not constructed to burn coke. You cannot get a sufficiently high temperature to ignite the coke and keep it burning. Therefore, not only must the coal be replaced by smokeless fuels, but the existing fireplaces must also be replaced by more efficient types of appliance in order to enable the smokeless fuel to be burned. So it will be clear that the abolition of smoke is not going to be a quick or simple process. The Beaver Committee envisaged a long-term program of some 10 to 15 years to deal with the large urban areas of the country alone, and they recognized that the operation would involve major problems of finance and administration as well as of supply and re-equipment.

The committee devoted a lot of attention also to pollution by sulphur oxides, but were forced to the conclusion that in the present state of technical knowledge practicable means of prevention were not yet in sight, except at very large fuel-burning plants such as power stations, where it would be worth while to put in gas-washing equipment. They recommended that this should be done at all new power stations in or near built-up areas as soon as an efficient technique could be developed. The committee also recommended intensified research on other means of prevention which would be of more general application, including the removal of sulphur from the fuel before use, and methods of preventing the sulphur in the fuel being released with the combustion gases.

Damage by Air Pollution

Apart from its recommendations, the most important feature of the Beaver Committee's report, to my mind, was their assessment of the damage done by air pollution. The report showed beyond doubt that pollution is a dangerous enemy of human health. It also contained an estimate, certainly the most comprehensive and thorough so far attempted in England, of the economic cost. The estimate was built up from all the evidence that could be obtained both of the direct costs, including such items as cleaning, laundry, repairs and redecoration of buildings, damage to goods, the replacement of corroded metals, additional lighting and extra medical services; and of the economic loss or loss of efficiency resulting from, for example, damage to agriculture, interference with transport, and the loss of working efficiency due to ill-health. Aggregating all these items, the Commitee arrived at the staggering total of £250 million per annum. That, in their view, was the size of the bill, in terms of money alone, which the nation is now paying year after year for air pollution. That figure might seem incredible until one has studied the detailed account of how the estimate was arrived at. Further, it stands comparison with figures which have been obtained elsewhere; the estimate for Pittsburgh in 1952, for example, produced a figure equivalent to £14.10s.0d. for each inhabitant, whereas our £250 million represents £5 per head over the population of the country as a whole.

The Government lost no time in announcing their acceptance of all the committee's main recommendations, and legislation to implement them was introduced in the summer of last year. The "Clean Air Bill", as it is called, is now on its way through Parliament and it may have become law by the time this paper is read. It repeals almost all the present legislation about smoke pollution, comprised in twelve different Acts ranging in date from 1845 to 1939, and substitutes a single new code, the main features of which are as follows:—

(1). The discharge of "dark smoke" from any chimney is prohibited, subject to some limited exceptions and to short emissions which may be unavoidable on occasions such as the lighting-up of furnaces from cold. The prohibition will apply also to dark smoke from railway locomotives and ships. "Dark smoke" is defined as meaning smoke which is as dark as, or darker than, shade 2 on the Ringlemann chart. The Bill makes it clear that the Ringlemann chart is to be used as a standard of darkness rather than as means of proof in a court of law, that is to say it will not be necessary to produce evidence in proceedings that an actual comparison with the Ringlemann chart was made in each case. Again, we are in accord with practice across the Atlantic; I see that in the United States a little while ago a court judgment affirmed the competence of a trained observer to record violations of the law, even though he did not have a chart in his hand. As the judges remarked, it is not necessary to hold a colour chart in your hand in order to recognize "a red flower, a blue sky or a black bird."

(2). Any practicable means that may be available must be used to minimize the emission of grit and dust from furnaces. All new furnaces which are to burn pulverized fuel, or solid fuel at more than a specified rate, must be equipped with plant approved by the local authority for arresting grit and dust. The local authority may also require measurements to be made of grit and dust passing through the flues, and the results of the measurements furnished to them, in the case of furnaces burning pulverized fuel, or solid fuel at more than the specified rate.

(3). The foregoing provisions, which will of course mainly affect industry, will operate over the whole country. Enforcement will be the responsibility of the local authorities, who will be empowered to prosecute offences summarily.

(4). Smoke from other sources, including domestic smoke, is dealt with somewhat differently, and on a local, and in a sense voluntary, basis. The Bill empowers local authorities, by means of orders requiring confirmation by the central Government, to establish "smoke control areas" in which the emission of smoke from buildings, or from specified classes of buildings, will be entirely prohibited. Householders in these smoke control areas will be entitled to grants towards the cost of converting or replacing their heating and cooking appliances, where this is necessary in order to enable smokeless fuels to be burnt; 30 per cent of the cost will be borne by the local authority, and 40 per cent by the central Government, leaving the householder to bear 30 per cent. We thought that this was a fair distribution of the cost, having regard to the relative interests of the individual, the local community and the nation at large in the prevention of smoke.

When making orders to establish these smoke control areas, local authorities must give public notice of their proposals and anyone affected will then have the right to object to the Minister of Housing and Local Government if he wishes. The Minister must consider any objections made, and hold a public local inquiry, before deciding whether or not to confirm an order.

(5). The Bill does not disturb the present arrangement whereby the control of pollution from special processes is the responsibility of the central Alkali Inspectorate; indeed it envisages an extension of this system to some further industries in which the prevention of smoke, grit and dust presents special problems. The purpose is, of course, to ensure effective technical supervision of the "difficult" processes and to stimulate the development of improved methods of control.

The Bill also contains a number of supplementary provisions dealing with, among other things, the design of new furnaces, the provision of smoke density meters and recorders, the height of new chimneys, and pollution from colliery spoilbanks.

The administration of the Bill, when it comes into operation, will therefore rest on a division of labour, the local authorities having the major tasks of securing that the general standards required by law are complied with, and of initiating action to control domestic smoke in their area, while the central Inspectorate will be responsible, over a more limited field, for enforcing the most effective methods of prevention in those industries in which control still presents special difficulties. The administrative burdens will be heavy. Many local authorities are at present short of qualified smoke inspectors and are not yet fully prepared for the responsibilities the Bill will place upon them. There is a little anxiety lest the new measures should lose some of their force by starting off, as it were, at half-speed. That is one of the disadvantages of introducing reforms on a national basis; we cannot be sure that everybody will be at the starting gate at the right time, yet we do not want to delay the start. But we have, of course, no intermediate unit of administration between the central Government and the 1,500 or so local authorities, large and small, who make up local government.

Good Administration

The success of the measures now contemplated will, however, depend on the manner in which they are administered. It would be, I am sure, a profound mistake to think of administration only in terms of enforcement, that is to say, of detecting and prosecuting infringements of the law and exacting the appropriate penalties. The law must depend for its effectiveness upon voluntary compliance by the majority, rather than on compulsion against the minority. The real responsibility for the prevention of air pollution must, after all, rest with those who control its sources — the industrialist, the man in the boiler-house, and the householder; and the most important task of the administrator, whether in central or in local Government, is to win and maintain their co-operation. He cannot afford to rest on legal sanctions alone, but must go out and get goodwill by publicity, advice and the personal approach.

This element of goodwill is going to be all-important, indeed indispensable, when we come to apply the measures we have in view for reducing domestic smoke. We shall be asking a lot from householders in the first smoke control areas. They will be expected to give up the fuel they are used to and change their fireplaces and stoves, and to put their hands in their pockets for at any rate a part of the cost; all for a benefit which may in the early stages seem intangible and somewhat uncertain. They may well feel that they are being asked to buy an unripe nut, and an expensive one at that. The establishment and administration of these smoke control areas will therefore be a delicate exercise in democratic government, and a challenge to the skill and enterprise of the local authorities and their staffs. In the early stages, progress is likely to be tentative and gradual. But I think it very likely that the process will gather momentum as administrative experience is gained, and as people become familiar with smoke control and recognize the advantages of living in smoke-free surroundings. After the initial steps, it seems probable that progress will be governed more by the supply of smokeless fuels than by unwillingness to use them.

These, in short, are our plans for a new attack on visible pollution by smoke, grit, and dust. They will be accompanied by further research, and we hope technical advance, on methods of controlling invisible pollution, particularly by the sulphur compounds. At the moment, they are no more than plans; their execution lies in the future. But we believe that they are workable and that there is a general desire to put them into effective practice. Public opinion seems ready for action. There is, I believe, a growing realization in people's minds that air pollution is not only an evil, but also an unnecessary one, and that although the cure will entail difficulties and sacrificies it will be worthwhile in the end. People no longer accept "smog" with its inconvenience and discomforts as something inevitable; they want to do something to stop it. That action is needed has been demonstrated. If I may quote, once more and for the last time, from the report of the Beaver Committee:

"Enough has been said to prove that air pollution as it occurs in this country to-day is a social and economic evil of the first magnitude. It not only does untold harm to human health and happiness; it is also a prodigal waste of material resources. Expenditure on curing it would be a fraction of the savings which would result from the cure. The case for preventive action is overwhelming."

Automating the Engineer's Task

J. Kates, M.E.I.C.
President, KCS Data Control Limited, Toronto

Read at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada, Montreal, May, 1956

Following a sketch of the history of industrialization and automation this paper shows that the principles of automation are applicable to the tasks of the professional engineer, particularly to the processes of engineering analysis. The digital electronic computer is one of the most important tools for automatically carrying out engineering tasks.

WHEN discussing the automation of engineering tasks it is useful to reflect for a minute on the nature of engineering itself, how engineering has brought about automation and then how automation techniques may affect engineering techniques.

Engineers might well appropriate to their art the invention of the wheel, the early metallurgy of copper and brass, the fashioning of various tools, and so on. We could discuss the construction of the pyramid, the design of Phoenician ships, the war contraptions of Leonardo da Vinci, the experiments of Galileo and Newton. But in those early days engineering was not a separate profession and the men who noticeably advanced the art of applied science were usually a combination of artists, writers, scientists, medical practitioners, alchemists and architects.

Engineering as a separate profession, which requires the entire devotion and skills of an individual and which is marked by a body of disciplines, an educational curriculum, professional organizations and accepted public status, grew out of the increasing technical tempo of the industrial revolution (19th century).

Engineers have been concerned with the conversion of nature's raw materials and energy potentials into goods and services for mankind. Engineering deals not only with the development and design of a wide range of goods of increasing utility, but also with the more efficient production and wider distribution of those goods. Items which were once luxuries have quickly become household necessities. This lowering of the real price of goods, motivated by economic laws finding their expression in marginal profit returns, has been a prime achievement of the engineer.

Just as the industrial revolution was marked by the substitution of mechanized power for human or animal power, so the mass product of today is made possible by the introduction of interchangeable parts and the assembly line. It is the assembly line which enables society to exploit to the fullest the increase in efficiency which accompanies division of labor.

When an overall operation is broken down into a number of simple steps machines are frequently able to perform them more economically, more precisely and more reliably than human operators. There emerges a moulding together of productive and assembly processes in which a sequence of machines, gauging and transporting operations is carried out with little intervention of the human operator. This has been dubbed automation. It is interesting to reflect how much controversy, how much writing, how many speeches we would have been spared, had a Ford executive in Detroit in 1947 not added this one word to the dictionary.

The increasing replacement of man by the machine in production and distribution, coupled with the increasing complexity of goods and machines, is placing a growing emphasis on the part that engineering takes in our economy. The total number of engineers is rising, the ratio of engineers to other workers is quickly increasing, engineering is taking a bigger and bigger bite of the consumer's dollar. For example in 1945 Ontario had 4,291 engineers, in 1955, 14,000 engineers, and the Association of Professional Engineers of Ontario forecasts 26,000 engineers for 1965. This means that the working force per engineer has fallen from 368 in 1945 to 145 in 1955 and is expected to fall to 100 in 1965. In the United States about one engineer is required for every 75 production workers, whereas one engineer used to suffice for every 200 production workers. Shortages of engineers are developing in many areas. Our economy seems to be headed into a bottleneck; an engineering one.

Engineers have no vested interest in inefficiency. They alone can provide the answer to this rapidly growing problem, an answer which lies partly in the application of the engineer's methods to his own art. No longer can we look at the rest of humanity blessed with methods and efficiencies generously dispensed by engineers, while engineers themselves carry on from specification to end product as in the days of old, from slide-rule to drafting board, from approximation to pilot model. In short, if, for better or worse, we are to continue our present rate of material progress, engineers will have to automate some of their own tasks.

There appears to be agreement on two chief characteristics of automation. These are (1) that automation involves processing of information as well as processing of materials, and (2) that automation involves the performance of lengthy and complex sequences of operations without human intervention.

If we look closely at engineering techniques we find that in essence they involve lengthy and complex sequences. The process of meeting a specification by means of a design is essentially an information-processing problem which involves bringing together the data of the specification with data about materials, performance data of machines and experimental facts. The processing of these data with the know-how and experience of the designer eventually results in a design, a blueprint, a production or a distribution method. The automation of such processes will require information processing machines. Engineers have provided us with these in the form of high speed computers, and the automation of engineers' tasks will to a large extent involve the application of computers by engineers to their problems.

Electronic Computers

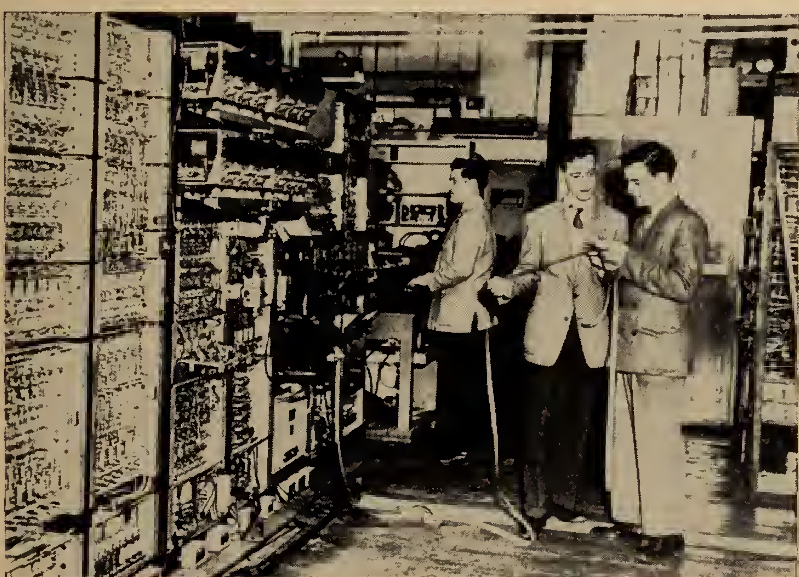
In some engineering fields such as nuclear and aircraft engineering, where engineering has always been the major bottleneck, computers have already been accepted as an essential part of the engineer's tool kit. While computers have also been applied successfully to almost every other engineering endeavour, we believe that the surface has still only been scratched and that fuller utilization of computers in engineering is bound to follow when there is intensive training and deeper understanding not only of computer essentials but of the scientific and mathematical basis underlying each engineering discipline.

The concept of a machine capable of performing long chains of calculations automatically is over 100 years old but electronic computers have become a practical reality only during the last decade and they are being introduced as a business and management tool during even more recent times. Ten years ago computers were only gleams in the eyes of research workers at Universities. The first prototypes were designed and built painstakingly and more often than not were maintained by the original designers (Fig. 1).

Today these machines are rolling off assembly lines and are achieving enviable reliability, while whole new categories of technical personnel such as computer maintenance engineers, coders, programmers and analysts are emerging.

A safe estimate indicates that electronic computers have already carried out more basic arithmetic operations than have been done by all humanity since Adam and Eve, including all the calculations that have been carried out by ancient and modern astronomers, by money lenders and by traders in the market place, all the counting of sheep done by shepherds or insomniacs, and all the painful arithmetic lessons we and our forbears were subjected to in school. Investment in computers in North America has passed the half-billion dollar mark and is rapidly reaching towards one billion dollars (Fig. 2).

Fig. 1. Computer research at the University of Toronto in 1950.



There are two classes of electronic computers, digital and analogue. The former works essentially on a sequence of digits or numbers, the latter by measurement. The abacus could be cited as a simple digital computer, the sliderule as an analogue computer.

While well before the days of the digital machine the analogue computer was applied to engineering problems, especially those involving the solution of ordinary differential equations, and while the analogue computer will always remain an engineering tool of first rate importance, the digital computer surpasses it in flexibility, in accuracy and in ability to handle large complex sequences automatically. For this reason we shall confine our discussion to the digital computer.

Essentials of Electronic Computation

Three essentials are required before an electronic calculation can begin. These are, (Fig. 3): (i) an electronic computing machine; (ii) a program; (iii) input data in mechanical form.

The general purpose digital computer is a device consisting of four main parts:

(1) The input unit, which feeds information into the computer — the eyes and ears of the machine.

(2) The storage unit, which stores information and makes it available to the other parts of the computer—the memory of the machine.

(3) The processing circuits, which process the information according to a previously adopted plan — the brain of the machine.

(4) The output unit, which furnishes us with the results of a computation — the voice of the machine.

When a computer is installed in an office or a laboratory it is at first useless and its store or memory is as empty as the mind of a newborn child. To convert this mass of aimless circuitry into a powerful tool we must feed into it a series of detailed instructions called a program. This program breathes life into the computer and unlocks the door to its tremendous possibilities.

Into a program can go man-weeks, man-months or man-years of preparation, but once a program is completed it can be fed into the machine in a few minutes, and may thereafter be used year after year. Moreover as many programs as required may be developed for the same machine and by means of these different programs it may produce a payroll at 9. a.m., a structural analysis at 10. a.m., the design of a motor at 11. a.m., a management analysis at 12. a.m. and so on. Not only is such versatility possible but this is precisely the way a computing machine should be used for greatest efficiency.

We may embody into a program many years of the know-how and training of an engineer, accountant, economist or statistician. When the program has been completed the application of this know-how becomes an automatic procedure and the electronic computer becomes the equivalent of a battery of engineers, accountants, economists, mathematicians or statisticians. Engineering has been automated. The original professional worker's skill and energies can be released for the programming of further tasks or for the carrying out of tasks which cannot be automated or where automating does not pay.

At this point it should be made clear that the programming of engineering tasks requires that they be analysed and defined with a degree of clarity, which is often absent where engineering tasks are carried out by human organization. This analysis of engineering problems for automation by computers promises to be an exciting and rewarding engineering task in itself.

Programming involves the following sequences of operations:
(i) Definition of the objective. (ii) Analysis. (iii) Flow Diagramming. (iv) Checking of the flow diagram. (v) Coding. (vi) Checking the code. (vii) Punching the program onto cards or tape. (viii) Checking the program in the machine by means of trial cases. (ix) Final release of the program for useful application.

Due to errors, or discovery of better methods, programmers often repeat the earlier steps in the above sequence after partially completing later steps.

Techniques for Applying Computers

Many practical engineering situations which heretofore have been tackled by approximate techniques or by scale models defy analysis. Fortunately techniques have been developed which greatly extend the application of computers beyond those which can be described by a neat mathematical formula. Direct simulation of a physical process or statistical sampling methods — called Monte Carlo methods — are two important methods which have been widely applied in cases which defy elegant formulation. These methods are illustrated and contrasted with the analytical approach for a trivial example in the Appendix.

Simulation involves the step-by-step carrying out of a process. In an optical problem this would involve the tracing of every ray rather than using formulae which relate objects and images, in a traffic problem the tracing of every vehicle, in a diffusion problem the tracing of every particle. The great speed and storage capacity of computers has made simulation methods quite practicable in many cases.

Some simulation problems, however, are of such magnitude that they would be quite impractical even with electronic computers. For these problems the Monte Carlo method has been developed. This is essentially a statistical sampling method by means of which a relatively small number of samples can give results to limited but predictable accuracies. For instance, the entire simulation of a diffusion process might involve the tracing of many billions of particles, but a random sample of 100 such particles might supply a 10 per cent estimate of their distribution.

We have already mentioned that automation of production processes requires the automatic carrying out of lengthy complex processes. Similarly automation by computers becomes more economical the longer the sequence which has to be programmed.

A good example is the analysis of a grid type bridge which is illustrated in Fig. 4. Such an analysis requires the determination of symmetries of the structure in order to reduce the computational effort, following which one must determine the moments of inertia of all the members of the grid and then families of deflection curves for each member of the structure. These deflection characteristics must be combined into equations. A series of matrix inversions, matrix multiplications and matrix additions are required for the determination of the interaction forces between members of the grid. These interaction forces can be used for the computation of shear and moment influence fields which, in turn, can be used to determine the effects of subjecting the structure to typical loads such as trucks rolling through lanes or a line of cars parked on a bridge.

Manually each of these computations is quite lengthy and would be considered a separate assignment. But with an electric computer it is considerably more economical and faster to leave the results of each step in the computer and let the computer proceed automatically to the next step in the calculation, printing eventually only the worst stresses encountered and the conditions under which they are encountered. A program of this nature has been developed recently for a consulting structural firm and it has made practical an analysis which previously would have been quite prohibitive in cost and time.

Wide Range of Application

Among the engineering projects to which computers have already been applied with great success are:—

- Structural analysis
- Traffic analysis
- Nuclear engineering
- Analysis of air frame stresses
- Analysis of turbines
- Hydrodynamical calculations — seaway design
- Motor and generator analysis
- Interference analysis of broadcast antennae
- Antenna field computations
- Analysis of oil refinery processes
- Electrical network calculations
- Design of radio tubes

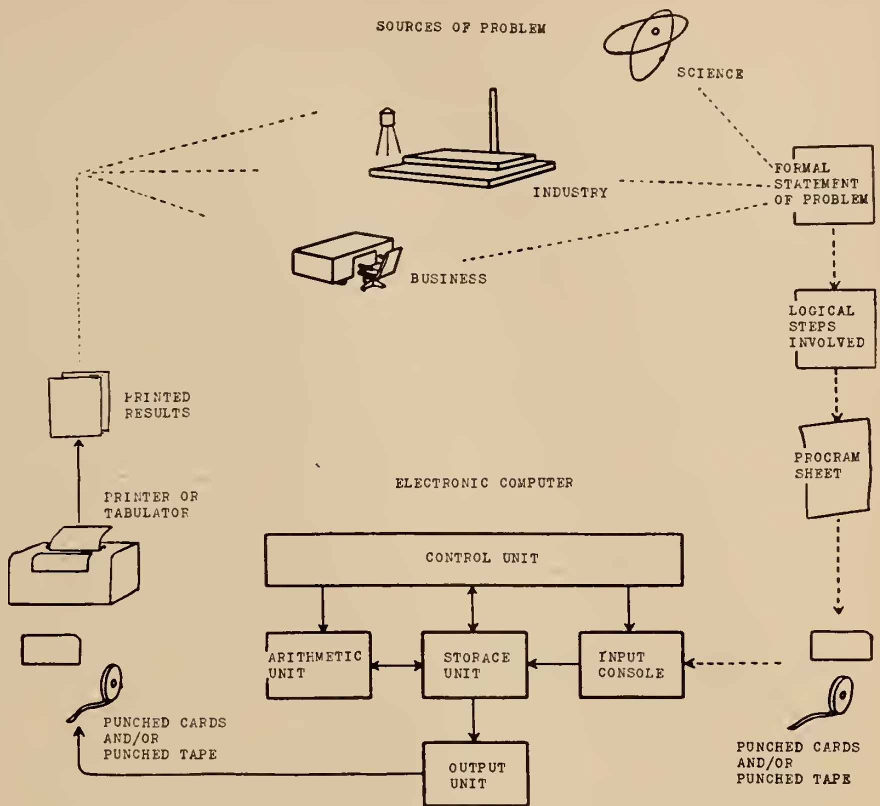

Fig. 3. The essentials of an electronic calculation.

In this brief list the word analysis predominates. This is no accident.

Many engineering tasks have the following pattern. A specification is laid down. Experienced designers make a synthesis, that is, they propose a design which will probably come close to satisfying the specifications. This proposed design is then analysed and if the analysis shows discrepancies between the forecast performance and the specifications, the design is altered slightly and analysed again until the specifications are met. In this sequence the synthesis carries most of the glamour and leans most heavily on engineering imagination, know-how, judgement, and experience; analysis on the other hand is typified by much of the drudgery, cost and time delay in arriving at a satisfactory design. For instance, the bridge analysis referred to above must be preceded by a design proposal. Here the structural engineer uses his experience to propose the number of longitudinal and transverse members to be used, their shapes and the positions of supports. This initial design proposal can then be subjected to analysis and evaluation. At present so many factors seem to enter the formulation of the initial design that it would probably be entirely uneconomical, if not impossible, to entrust this part of the engineers' work to the computer.

For this reason most computer applications have concentrated on analysis, whereas synthesis in the majority of projects will for a long time remain the prerogative of the engineer. It has proved quite difficult and usually quite uneconomical to feed varied and wide experience and engineering know-how into a computer. Compared to the human memory the memory of even the largest machine is quite minute. In other words we can reach a point of no return even with computers. On the other hand analysis usually requires the carrying out of some specific calculations for which the computer is very much faster, more reliable and more flexible than the human operator. It follows that the best use of computers will result where the experienced engineer teams up with the computer and the computer is entrusted with the carrying out of the lengthy routine sequences. Since most engineering techniques do not fall by themselves into such a happy combination of sequences (which involve experience, imagination, and know-how, followed by lengthy routine analytical procedures) efficient application of computers to engineering problems will require considerable analysis and regrouping of techniques if the fullest benefits are to be obtained. Experience to date shows quite conclusively that this ar-

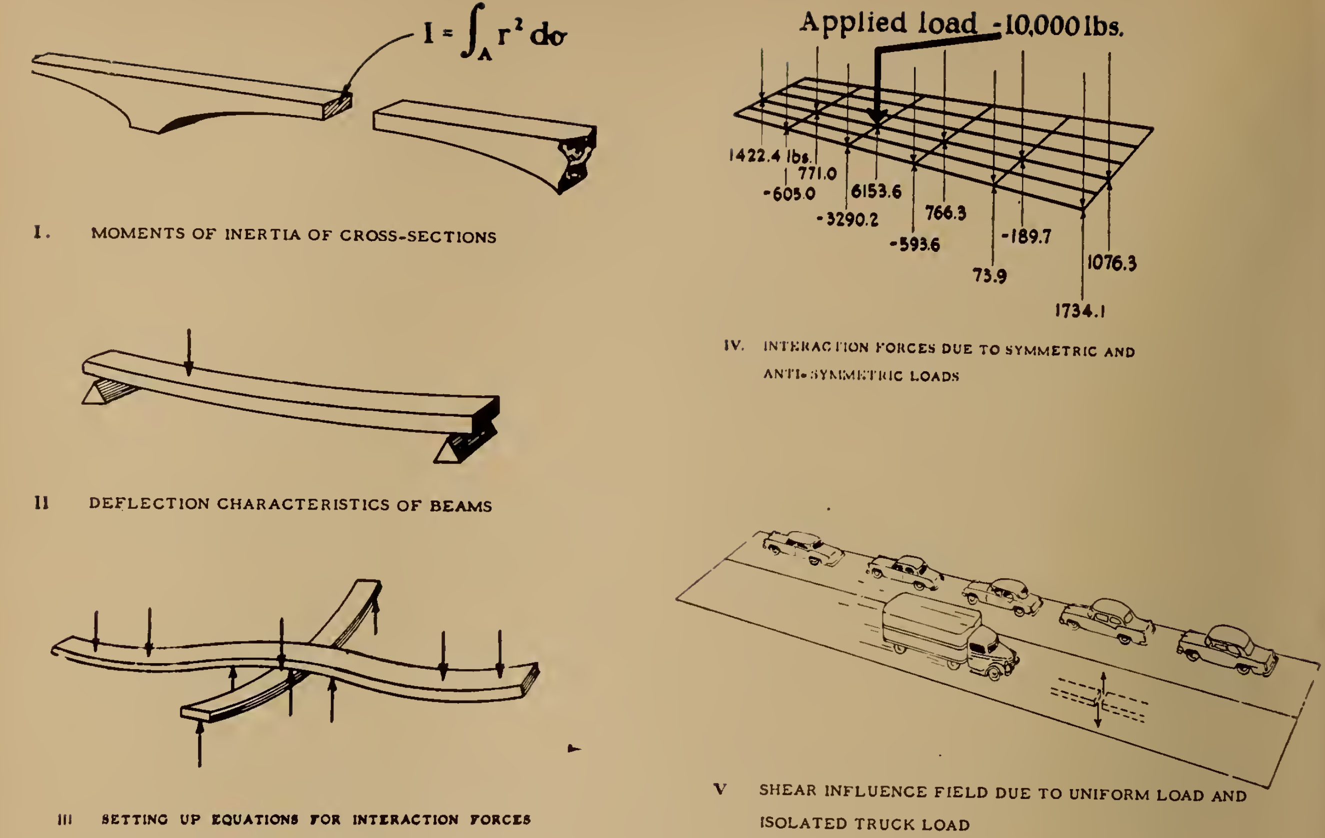

Fig. 4. Grid bridge structure analysis.

rangement of engineering techniques can have very effective results in speeding up and lowering the overall costs of projects. In addition, such analysis often results in a deeper understanding of the engineering application studied.

The division between analysis and synthesis is, of course, not rigid and immovable. On the contrary, if automatic methods are to be fully exploited, continuous effort will be needed to develop analytical procedures in replacement of synthetic procedures, to standardize, to make routine, and to refine existing routines even further.

It is typical that most engineering applications of computers to date have not been merely replacement of identical techniques carried out manually before the introduction of computers. For instance the type of stress analyses described above have been quite impractical to do manually and the testing of structures had to be done previously by building and loading scale models. So we do not find many instances where an engineering function has been replaced exactly by the computer. Rather computers are used to a large extent for the carrying out of analyses and refinements which would have been impractical previously.

It should be mentioned that, though a computer can be used for quite short sequences, the longer the sequence for which a computer is put to work the greater the economy effected. If we plotted manual and computer costs against problem complexity we would obtain curves such as shown in Fig. 5.

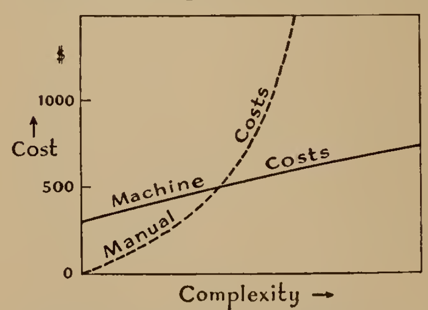

Fig. 5. Manual and machine costs *v.* problem complexity for medium size computing installations.

With the computer there is always an initial outlay on programming time which may make computer use more costly for very small problems occurring only once. If, however, the total cost of a calculation exceeds a few hundred dollars then the use of computers is indicated. This holds for lengthy isolated calculations as well as for very short repetitive calculations. In one instance traffic forecasts are made for 11½ cents a forecast. The number of forecasts required each month justify the use of an expensive computing machine. Similarly computers are used for a motor analysis which could be done by slide rule in a few hours. Cost, speed, reliability and more efficient use of engineering personnel justify such applications.

The present era is not only the era of automation but also the era of the team. The increasing complexity of modern life requires specialists teaming up on the solution of problems.

The computer is not an engineering tool alone. In the computer room the engineer will meet the manager, the accountant, the methods and procedures man, the scientist, and the statistician. In analysing situations for computer applications the engineer will often find it wise to get together with these other members of the industrial team. Production efficiency is tackled at present under two labels; industrial engineering, in the factory and, in the office, systems and procedures. Both disciplines finally lead into more general problems, the systematic solution of which has been labelled Operations Research. Operations Research has as its chief object the most effective utilization of men, machines and raw materials; it draws from engineering and accounting techniques and leans heavily on mathematical methods which often require computers.

It is interesting to note that computers have been received by engineers with enthusiam rather than with the suspicion and barriers which are often thrown up against new techniques and machines. In most instances engineers have been quick to realize that computer techniques open up new opportunities rather than displacing engineers. Engineering groups provided with such potent tools display unmatched zeal and intensity. Programming itself is one of the first tasks to be automated by engineer-programmers; the means that programs are developed by means of which the computer carries out automatically much of the burdensome coding and checking required for further programs. One might consider this as the automating of automation.

It should now be clear that electronic computing techniques can be used to automate those functions of the engineer which can be made routine; and in automating these functions engineers can be freed for other functions in the performance of which the human being far surpasses the machine. Naturally the increased engineering productivity which will accompany automation ought to increase the engineer's standard of living just as rising productivity has increased living standards of the population in general.

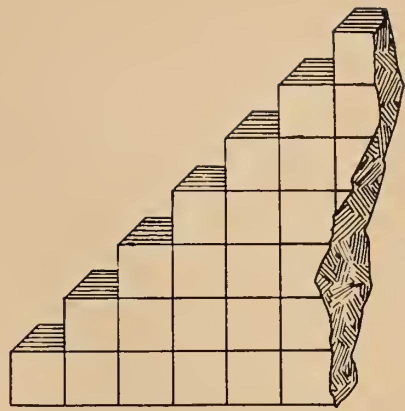
Above all, technical competition between industries, and competition from abroad whether economic or political, whether friendly or hostile, requires that each industry and this country as a whole see to it that technical personnel be used as efficiently and effectively as possible. In times of boom or times of war programmed computers will be an invisible reverse which will go a long way towards alleviating critical personnel shortages.

In reviewing ten years' developments in this field, and recalling some of the dire predictions which have been made, one thing becomes clear. Man may fashion ever more powerful tools for the harnessing of nature's forces; yet it is plain that these tools will never simulate so closely man's infinite variety and versatility that they will become more than a tool. They can never take the place of man himself. We will always need engineers.

Appendix

Three typical methods of attacking a problem are illustrated below by a trivial example which is intended as a sketch of the techniques rather than as a rigorous presentation. This problem might have arisen as follows:

In ancient Egypt Pharaoh decided to build a pyramid as high as possible and yet having provision for easy ascent. He had a supply of 400,000 blocks and he decided that the design shown below would meet his requirements:



Two-dimensional pyramid

He asked his court mathematician how high the pyramid would be. The mathematician unrolled his parchment and proceeded to analyze the situation as shown in the table.

The Mathematician's Analysis

$$1\text{ bl.} + 2\text{ bl.} + 3\text{ bl.} \ldots + n\text{ bl.} \sim 400{,}000\text{ blocks}$$

or

$$n\text{ bl.} + (n-1)\text{ bl.} + (n-2)\text{ bl.} \ldots +1\text{ bl.} \sim 400{,}000\text{ blocks}$$

Adding

$$(n+1)\text{ bl.} + (n+1)\text{ bl.} + (n+1)\text{ bl.} \ldots + (n+1)\text{ bl.} \sim 800{,}000\text{ blocks}$$

There are n terms on the left side, and therefore

$$n(n+1) = n^2 + n = \text{(approx.) } 800{,}000$$

Adding ¼ to each side to form a perfect square

$$n^2 + n + \tfrac{1}{4} = (n + \tfrac{1}{2})^2 = \text{(approx.) } 800{,}000.25$$

$$n + \tfrac{1}{2} = \text{(approx.) root } 800{,}000.25 = 894.4$$

$$n = \text{(approx.) } 893.9$$

$$n = 893$$

Thus the analysis of the mathematician showed that the pyramid would be 893 blocks high.

However, the mathematician being a pure scientist could not be rushed in this analysis and so Pharaoh turned for an answer to a young engineer who was used to getting things done. The young engineer attacked the problem directly. He took his staff and wrote in the sand:

The first step adds	1 block	= 1
The second step	2 blocks	= 3
The third step	3 blocks	= 6
etc.		
	+4	=10
	+5	=15
	+6	=21
and so he continued on and on	+300	=45,150
	+301	=45,451
	+302	=45,753
	+303	=46,056
	+891	=397,386
	+892	=398,278
	+893	=399,171
	+894	=400,065

Finally the engineer also concluded that the pyramid would be 893 blocks high. This was the brute force approach which is nowadays termed simulation.

However, while the engineer scribbled figures slowly in the sand, which was frequently blown away by the wind, a court gambler happened to pass by and enquired as to the nature of the problem. After the engineer explained the court gambler asserted that he would obtain an approximate answer by picking a few numbers at random. As a matter of fact the court gambler offered 20:1 odds that he could determine the height of the pyramid with an accuracy of 10 per cent if he were allowed to pick 100 numbers at random.

He first guessed that the pyramid would be 1000 blocks high, and he picked 100 random numbers between 0 and 999 inclusive. (See p. 1040)

The average of these random numbers was 468 and the gambler reasoned that there would be approximately

$$n \times 468 = 400{,}000\text{ blocks}$$

or that the pyramid would be

$$n = 400{,}000/468 = 854\text{ blocks}$$

(Continued on page 1040)

The Influence of Tropical and Sub-Tropical Features on the Design of Thermal Power Plants

W. K. Carruthers, M.E.I.C.

Chief Mechanical Engineer, Montreal Engineering Company, Limited.

THE objective of this paper is to evaluate some of the requirements of good tropical design in the hope that some measure of improvement might be achieved in lower capital costs, better efficiencies, lower maintenance costs and higher continuity of service.

The writer's experience with power plants in the tropics is limited to the Central American and Caribbean areas. In these regions there are few influences which might be considered as peculiar, but a good many which, although not unique, are much more severe in intensity than in more temperate zones. Both types will be discussed under the following headings:

(1) Types and choice of thermal plant; (2) ambient temperatures; (3) humidities; (4) precipitation; (5) winds & weather; (6) water supply; (7) topography; (8) load characteristics; (9) staff; (10) plant control.

Types and Choice of Plant

Fundamentally and inevitably the choice of plant type depends entirely on economic conditions, and the plant which can produce the required number of kilowatt hours and meet the expected kilowatt peaks for the least annual total cost, should be the one selected.

As elsewhere, steam, diesel, and more recently and much less extensively, gas turbine thermal plants, are the familiar types to be found. The relative advantages of these vary with the type of fuel available, the quality and quantity of water supply, and the ambient conditions of temperature, humidity and weather. These will be briefly discussed for each type of plant.

Steam Plants. Steam plants can burn any type of fuel, but as coal is generally very limited in supply in the tropics and quite expensive, oil, which is fortunately quite abundant, and natural gas are the usual fuels. As cooling waters are usually quite warm, exhaust pressures are seldom less than 6.25 cm. Hg absolute and some 4.5 litres per minute per kw generated are required. High wet bulb temperatures generally preclude the use of cooling towers, except in the dry portions of Mexico. Heat rates therefore are relatively high and vary from 3520 to 4530 kg. Cal. per kwh. (14,000 to 18,000 Btu/kwh.). Other types of generation are favoured for loads less than 10,000 kw., as the smaller sizes of steam units are less efficient and not available in the higher temperatures and pressures that modern high efficiencies demand.

Diesel Plants. Diesel plants require a higher grade of fuel than steam plants, but where transport costs are high, this is an asset rather than a liability. Only about 20 per cent of the cooling water required for a steam plant is necessary, and as approach temperatures to the wet bulb temperature are in the region of 15 deg. C., various types of air and evaporative cooling are feasible. Plant sizes are not recommended in excess of 10,000 installed kw., but even for small units thermal rates of from 2520 to 3020 kg.Cal. per kwh. are easily obtainable (10,000 to 12,000 Btu/kwh.). However, the costs per installed kw. are considerably higher than for steam units or gas turbines, which tend to offset the thermal advantage.

Gas Turbine Plants. Gas turbine plants require a relatively high grade of fuel if blading troubles are to be avoided, and for highest efficiencies low temperature inlet air, high barometric pressures, plenty of cold water for compressor inter-cooling and system demands which will permit continuous full loading of the units. The heat rates possible, subject to the limitations mentioned above, vary from 3280 to 6300 kg. Cal. per kwh., (13,000 to 25,000 Btu kwh.) and these are only for units fully loaded. At lesser loads the efficiencies drop off sharply. Site preparations are simple and transportation and installation problems are usually not significant.

Ambient Temperatures

Probably the most familiar climatic feature of the tropical region is that of very high ambient temperatures. In British Guiana for example, temperatures below 26 deg. C. are rare,

Canadian National Committee presentation at a sectional meeting of the World Power Conference, 1954, Rio de Janeiro.

whilst any over 35 deg. C. are likewise unusual. On the other hand, in Venezuela, the shade maximums often reach 40 deg. C., and in the sun 60 deg. C. are not uncommon. These temperatures are not nearly as severe as those to be experienced in the Persian Gulf for example, but they are of sufficient magnitude to influence design.

Power plant buildings must be very open affairs, and allow for a maximum of natural air movement throughout. Any more or less unavoidably confined areas should be, if possible, open at each end, or failing that, air conditioned. Control rooms would fall in this last category. Whilst open as much as possible, care must be taken that sides are blanked off, where necessary, to protect vital equipment from rainfall or excessive wind. In other words, when temperatures are high the avoidance of draughts as opposed to natural and slow movement of large bodies of air, is of the utmost importance. Steel supported asbestos cement for roof and side walls has been found to be satisfactory and economical.

The physical location of thermally actuated relays is rather critical. Cases are on record where unnecessary outages have resulted from relays being placed in "dead air" areas where the temperature build-up was above the normal plant average. Again false interruptions have been caused by improperly ventilated relay cases. The remedy would seem to lie in better ventilation of thermal relays, both inside and out, by natural means where possible, and artificially induced by fan, if not. In extreme cases it might be necessary to use the next higher rating of thermal element in a relay, but this method is not favoured as it reduces the amount of electrical protection afforded to its associated equipment.

All motors must be conservatively rated, particularly well ventilated, and the tendency is now to specify such vital motors as those driving feed pumps, fans or circulating water, to be water cooled, unless it be that the supply of such water would in turn set up too much of a problem. The only other answer, in that case, would be to employ unusually large shaft mounted self-cooling fans, in order to achieve the necessary heat transfer.

Bearings on driven equipment, such as ID fans, and also FD fans, particularly those employing re-circulation of FD air to combat cold end air heater corrosion, must be adequately protected against heat. It is necessary that heat flingers or other heat absorbing devices be liberally designed. Required factors of safety in this respect might well be considered as varying as the square of the temperature involved. Heat insulation on piping is not materially different from that in any ordinary plant, but the placement of lines can warrant special attention. These lines carrying steam or hot fluids should be in well ventilated areas so as to cause as little super elevation of ambient temperature and interference with adjacent lines as possible.

The question of sun and shade quite naturally falls into the category of high ambient temperatures. Obviously in tropical regions the sun is hot and right overhead at noon. Shaded areas have to be provided, and also means employed to cut down the glare, even from normally mat or uneven surfaces. In any consideration of the so-called outdoor plant these aspects would have to be included, as it has been found that personnel are quite sensitive to these comfort features. The establishment of a relatively pleasant, cool place to work is usually very worthwhile.

The author discusses the tropical and sub-tropical regions of the Caribbean and Central America, of which he has first-hand experience. The choice of plant should be determined by economic considerations, and the various types are discussed in the light of conditions that may be met. The effects of the climatic and other physical features of these regions are presented, together with particular considerations of load characteristics, staff, and plant control.

Humidity

Whilst by no means unique in tropical regions, the relative humidities there found are generally higher and of longer duration than in more temperate regions. This means that the general corrosion problem is much more severe and that particular care must be taken to protect relays, meters, switchboard wiring and sensitive mechanical equipment (boiler meters, etc.) which are not in themselves adequately rust protected against moist tropical atmospheres. The use of drying lamps and even small heaters will be found to be worthwhile, when equipment is not in use. Good design would incorporate in such equipment the means to keep it relatively dry, particularly when not in use, and therefore deprived of any heat which might accrue from normal usage. Good circulation of air will also be highly beneficial.

Electrical insulation should be not less than Class "B" (AIEE Std. No. 1, June 1940). Where feasible, totally enclosed, self and externally cooled motor construction should be employed, if freedom from excessive maintenance is sought. In cases where this type is not justified or available, particular care should be used in specifying insulations when ambient temperatures are apt to exceed 40 deg. C.

Where ample cooling water is not naturally available, high tropical humidities greatly limit the capacity and effectiveness of cooling towers. This capacity is limited by the closeness with which the tower effluent must approach the wet bulb temperature. This approach temperature in our experience seems to have an economic minimum of about 11 deg. C. which pretty well precludes the use of cooling towers for steam plants except in the drier regions.

Due to the much higher approach temperatures of about 15 deg. C. usable in a diesel installation, cooling towers are quite feasible, provided, of course, that ample make-up is available, and that expensive chemical treatment is not required to prevent jacket water scaling or corrosion. In this case a closed cooling system using radiator or evaporative coolers is satisfactory, resulting in lower total annual costs, despite the somewhat higher capital investment.

Precipitation

Again, rainfall is not unique to tropical regions, but perhaps the amount of it is. Plants should be designed to cope with rainfalls up to 3.5 cm./hr. and 25 cm./day, oftentimes with accompanying winds. This means that equipment in pits, unless completely unaffected by water or protected by adequate sump pumps, is to be avoided. Generally speaking, it is safe to say that the entire plant should be on at least ground level or above. This means that a problem exists for those engineers who like to have positive suction heads on their horizontal centrifugal circulating water pumps, as such installations are usually in sunken pits. Surface flooding is a constant menace, and good design should recognize this and plan to be independent of surface floods.

Tropical rainfall is generally very sudden in addition to being of considerable proportions. From the maintenance viewpoint this feature tends to make the selection of an outdoor plant a more significant problem. At this stage it might be well roughly to summarize the position of this type of plant.

Opinion is still well divided as to the respective merits of enclosed and outdoor installations. At first glance it would seem that the latter type is ideally suited for tropical regions, but actually there are advantages each way. The main difficulty with an outdoor installation is the difficulty of carrying out routine maintenance and emergency repairs in the open, irrespective of weather conditions. If shelter for such operations is envisaged, then it should be of such type as to permit the operation of the gantry type crane, either through it (with the main hook) or underneath it. If shelter comparable to the enclosed design is to be achieved, this shelter would have to be of such proportions as to cover both the turbo-generator area and the maintenance bay, and to permit free movement of the gantry crane inside it. If weather conditions are sufficiently stable and uniform, as perhaps in Texas, doubtless some less measure of shelter can be justified, and advantage therefore may be taken of reduced building costs inherent in the outdoor plant. If not, and this has proven so to be in our experience, a reasonable compromise may be taken by enclosing the turbine room and boiler fronts only, as these are the portions requiring the most maintenance, and leaving the rest outdoors. This method has been employed with excellent results in our construction in Demerara and Venezuela.

Winds and Weather Hurricanes

To the layman, hurricanes are almost invariably considered a feature which is peculiar to tropical regions, but this is not strictly true. In the mid-western States, tornadoes and twisters are on record which rival in velocity and severity any tropical hurricane. The fact that they are generally less frequent, does not indicate that good design does not have to take them into consideration. It will be found that in the regions we are considering, as in the north, structures may have to be designed for winds up to 250 km./hour. Fortunately available records define very well the relative dangers of the various areas and structure design practice can be modified to suit.

However, the "prevailing wind" so evident in some tropical regions can be made quite useful in achieving good draft free ventilation. The N.E. trade winds in British Guiana are a good example of this type. They rarely cease and generally blow steadily from the N.E. at velocities ranging from 7 to 20 km./hr. with gusts up to 30 km./hr.

Water Supply

Water, in the tropics, is usually more of a problem than in the temperate zones. Sometimes it is a question of quantity, there being either too much or too little. Then again some of it is so hard that, as one wit once stated, it wouldn't go around a long radius elbow without groaning. Invariably, what water there is is rather warm, which of course, in the case of circulating water, materially increases the size of condensing plant and auxiliaries.

With feedwater, the problem is generally one of scarcity of supply, rather than treatment, for fortunately there are adequate systems available for any water—it just being more difficult in some cases than others. The best answer would seem to be water reclamation from all possible sources, rigid control of all water usage, and adequate storage.

With circulating water of a tidal sea water source, problems exist with respect to shellfish, mussels and marine borers and the deterioration of surfaces which are alternatively wet and dry. It is not believed that the last two conditions are any more severe in tropic regions, but it would appear that shellfish and mussels might be more controllable. These types of marine growth seem to be very sensitive to temperature change in the South, as sea temperatures are very uniform, whereas their cousins in the temperate regions are quite used to the relatively slow seasonal variations experienced there. This means that if advantage can be taken of the rise in circulating water temperature through steam turbine condensers, shellfish and mussels can be given a systematic treatment of temperature rise and fall, which is most effective in destroying them. This is amply borne out by the fact that cooling water discharge mains are free of such growth, whereas in force mains the problem is most difficult. The answer lies in a system of flow reversal whereby pipe lines are alternated in function between force and discharge mains, with the resultant temperature changes being sufficient to kill all such growth in both groups.

If of river origin, water in the tropics oftentimes carries a large amount of silt, algae, or contaminants, involving expensive and constant filtering and chemical treatment. Although good revolving screens can usually be depended upon to screen out most of the debris, it is the wise designer who provides for a reversal of flow in his condensers to allow rapid clearing of tube sheets. There are several good types of three and four way valves on the market which will accomplish this very nicely. In addition, the condensers themselves can be arranged to permit this feature, with internal flat type valves of their own. Tube sheets can therefore be kept nicely clean in this way. The problem is, of course, not essentially different than the one existent in temperate regions, except in the quantity of suspended and entrained material. Tropical regions are usually densely vegetated, and there is a high proportion of leaves and grass to be found. Pumping equipment, heat exchangers and valves should be specified to handle silt in suspension, and of erosion-resisting materials. Where tidal or flow levels permit, screens should be of the cup type, which do not employ any bearings or wearing surfaces below water level, except easily replaceable seals.

In the case of brackish water it seems that cast iron attack is more severe than in either fresh or sea water. High-silicon cast irons, being more dense than the ordinary type, give better results. Where valves are concerned it is better to avoid dissimilar metals when cast iron bodies are used, the best trim being ordinary 18-8 stainless steel.

To conclude with respect to these problems, for both feed and circulating water, the solutions are, generally speaking, no more diverse or difficult than in Northern regions. Cases are rarely found anywhere that some form of feed water treatment is not required, and in fact, with the advent of higher temperatures and pressures, waters which a few years back would have been considered excellent in their natural raw state, would now be totally inadequate. As to circulating water, silt is always a problem and may be found anywhere, although due to the nature of some tropical soils and the heavy downpours of rain that take place, the tropical problem may be greater on occasion.

Topography

Again, topographical features represent a problem which varies only in degree from those experienced in Northern regions.

Tropical areas were never subjected to ice erosion and therefore little rock is exposed, but much earth. This results in a difficult erosion and debris problem due to the high intensities of rainfall so characteristic of the tropics. During a recent flood in Salvador lasting only a few hours a riverside plant was flooded and shut down for over a week.

It is probably safe to say that the greater part of the coastal areas of the Caribbean regions under discussion are on the sea side of a belt of delta, and therefore the disposal of circulating water must be carefully watched. Fortunately in these areas either tidal currents exist, or the prevailing winds help to such an extent, that normally a fixed position of intakes and discharges is possible.

In interior regions, whilst topography may effect transmission lines emanating from thermal plants, this is not truly within the strict scope of this paper. Generally the greatest inland problem is water, which is fundamentally due to (provided the area has sufficient rainfall) improper features for natural reservoirs, or a soil, such as those of volcanic origin, which permits the rapid percolation of large amounts of water through it. Lastly topographic features may make the supply of fuel to a plant difficult, if not totally impractical, for economic reasons. Sometimes poor roads, small tunnels or other barriers may exist to preclude the transport of equipment over a certain specified size to a plant site. This means that it is possible for a designer to be rather limited in his choice of equipment size, when other more normal considerations would indicate larger sizes of prime movers or steam generators.

Tropical systems, except in highly industrialized and progressive areas, are inclined to be independent of each other, and not infrequently consist of only one plant. In this case, assuming a uniform quality of service, the designer has to take extra measures to ensure continuity of supply, which would not be essential if the plant were one of two or more in the system. To be more specific, means must be provided for a separate source of station service, even to the extent of a gas or diesel driven a.c. generator. Ample spare equipment must be carried and duplicate auxiliaries for each main unit provided. Perhaps if a unit system of one-boiler/one-turbine is used, and this is certainly the modern tendency, then it likely follows that each generator has its own transformer, and if this be the case a tertiary station service winding can be employed in this transformer for station service. However, this method may not be adjudged safe, unless it is quite apparent that there will never be less than two machines on the bus at any one time. A further proviso is that the tertiary winding must be, in each case, large enough to service at least two machines, and preferably more, depending on the size and nature of the other units existent.

Load Characteristics

One of the most significant features of tropical loads is the effect brought about by the lack of a normal twilight period. For example 7 degrees north of the equator in British Guiana, it is dark ten minutes after the sun goes down. This means that lighting is necessary within two or three minutes after sundown, and this produces a very sharp evening peak condition. To be more specific, in Georgetown some 2500 kw. is added in from 10 to 15 minutes to produce a peak of 5300 kw. Approximately one hour later, the drop-off of some 4100 kw. to night loads begins at a rate which is almost as fast as the build up rate. Fortunately the loads which bring on these peaks are essentially lighting or cooking loads, and therefore the power factor is not adversely effected. In the more industrialized areas, the growing use of air conditioning equipment is tending to reduce the effect of this lighting peak and raise the annual system load factors to well over 50 per cent. The existence of this sharp evening peak quite naturally effects the method of plant operation but this is not significant. However, it is felt mostly in the designer's choice and timing of additional equipment. These peaks must be met, but since they are so sharp and usually of such short duration, the use and retention of normally obsolete or inefficient equipment is usually obligatory.

Staff

The problem of staffing a modern thermal plant in tropical regions can be a rather difficult one, compared to the situation further north. The high cost of fuels in the areas under discussion make it economically necessary that a relatively modern type of design be employed, which means of course subscribing in part at least to the present trend towards higher pressures and temperatures. Even in low cost fuel areas like Venezuela, medium pressures and temperatures (60 kg./cm². and 482 deg. C.) are easily justified. It therefore follows quite naturally that it would be most desirable for plant staffs to have had operating experience with similar plants elsewhere. This is not always possible, for economic reasons, and this means that intensive training programs will likely be necessary, in order that operators, workmen and technicians may be trained in plant operation and maintenance. Such training schemes are playing a very necessary and integral role in the supply of plant staff the world over, even where adequate trade and manual training schools exist, for it seems that practical, specific, on-the-spot instruction is needed to augment the general technical foundation learned at schools.

Unfortunately, not all tropical areas are as fully developed with respect to trade schools as they might be, or indeed as they no doubt will be. This fact makes such utility training schemes more important than ever, but none the less successful, except that probably the number of trainees produced will likely be somewhat reduced. This set of circumstances usually results in more and more automatic and remote control appearing in plant design.

The efficient operation of a steam plant demands the presence on each shift of a capable well trained shift engineer, sufficiently experienced to act wisely in a crisis. However, on the shift also are boiler tenders, water tenders, oilers and machine drivers, all of whom must be trained to a certain extent—it being physically impossible for the shift engineer to be available to each of them at all times. It is this factor that makes it usually desirable for the designer to include automatic equipment, whenever possible, for plant operation. This practice should not be limited to the automatic operation of boilers and turbines, or those processes which are normally controllable, but also the automatic cut-in of "back-up" devices. For example, if a feed pump fails, it should be so arranged that the spare pump should cut in without delay and without any human hands being required in the process. This same feature should be applied to extraction pumps, circulating water pumps, priming devices (when continual in nature), etc. It is questionable whether boiler fans could reasonably be included, for their failure would probably be electrical in nature, rather than because of the air being handled, and this is not likely. As an alternative to the "back-up" device, spare units remotely controlled from a central control room have much merit, and generally tend to make the system less complicated technically, but more difficult to actually operate. The choice should depend on the quality of operating staff and instrument men available.

A staff training program has been established in one case that is working out very well indeed. It was started off by the employment, for two months, of an expert from Consolidated Edison, New York, who concentrated on teaching the supervisory plant staff how to teach shift and maintenance personnel. A precis in Spanish was made up covering all pieces of equipment in the plant, with a complete description of how each worked, what operating steps were necessary in order to bring it into operation, and what maintenance and repair steps could be expected. Copies of this precis were mimeographed and placed in the hands of the plant staff. A regular series of lectures, twice weekly was then set up and the precis covered in detail. A goodly amount of time was allotted to questions and answers. This precis, by the way, consisted of some four hundred pages of standard 8 x 11 in. paper, of single space typing, and provided with a profusion of illustrations. It is too early at time of writing to evaluate the results of this policy, but the interest being displayed is high and genuine progress is being made. In this particular case it was not even necessary to provide any additional incentive other than the opportunity to learn, so it would seem that what has been achieved here can be duplicated almost anywhere—for of all the important prerequisites to learning, desire is by far the most important.

Plant Control

Probably the most important aspect of power station operation is that of the control system, for it is here that uniform and maximum efficiencies for a given set of equipment may be achieved, and continuity of service best maintained without jeopardizing unduly the safety of operation. The components of a control system are many and inasmuch as they are all integral parts of what might be termed the plant's nervous system, absolute reliability, simplicity of operation, and ease of maintenance are prime requisites. The problem is, of course, not confined to tropical areas, and a good many of the ideas expressed below would be good practice anywhere. However, an attempt to differentiate between the regions under discussion would be rather involved, so for the sake of continuity some of the principles which we have found desirable are mentioned, without regard to geography.

Electrical relays, contractors, timers, switches, and assorted equipment of like nature should be as airtight as possible, even to the use of hermetical seals, except where normal heat generated within would preclude this. Mechanical assemblies should be treated similarly and, if possible, lubricated for life.

Too much thought cannot be devoted to the control room and placement and grouping of instruments and controls. Gauges, and other means of indicating temperatures, pressures, levels, quantities, velocities and other pertinent items should be small in size, and grouped so that when one changes any others that are affected are reasonably near the one causing the variation. It also follows, if such control is to be understandable and easy to operate, that wherever the means of measurement exist there also should exist the means of control, so that adjustments may be made and the results easily interpreted. Quite obviously, the means of changeover from automatic operation to hand operation should be capable of being carried out rapidly and simply, for when this operation is necessary it is usually at a time of some stress, if not crisis.

Ample and extensive use should be made of line diagrams and charts associated with the various instruments and their means of control, for in this way it is possible to set up the process in natural cyclic form, which would make it simple and logical to follow. This method, whilst normal in electrical layouts, is also capable of being employed on the flow cycle of a modern plant. It makes it possible for new personnel to pick up the details of the plant much faster than would otherwise be possible. Colour coding of piping, both on charts and drawings and as actually installed, should be used.

The use of annunciators should be considered very carefully. The tendency is to use audible annunciation whenever anything, however small, goes wrong. This has the double fault of being unable to discriminate between cause and effect, and also as a corollary of this failure, the audible trouble signal has not got the warning and action-producing effect on staff that it should have. To be effective there should be distinct discrimination between cause and effect, making the annunciation, as such, visual and audible respectively. In other words, the variation of any quantity beyond reasonable limits, which is not in itself immediately damaging, other than the contributory effect it has on other more important quantities, should be visually indicated, so that means for correction may be started without any audible alarm. An example of this would be a low surge tank level, or a low machine vacuum — not in themselves necessarily damaging, unless left unattended. However, the end result of any inattention to these contributing causes, such as dangerously high bearing temperatures, machine winding temperatures, high superheat or low steam pressure, should be both audible and visual. Oftentimes, it would be desirable to arrange it so that on some quantities the visual signal should come whenever any variation takes place, and an audible one whenever that variation has exceeded preconceived and reasonable bounds.

It is felt that the control room itself should be air conditioned for the comfort of the operating staff and the protection of instruments and controls against excessive humidities and varying ambient temperatures. The economic advantages for so doing are almost impossible to evaluate accurately in any units, but good judgment seems to indicate that a happy staff and adequately cared for instruments constitute a worthwhile investment.

The Alexander Graham Bell Museum

S. L. Roberts, *Editorial and Information Division*

Department of Northern Affairs and National Resources

"Don't keep forever on the public road, going only where others have gone. Leave the beaten track occasionally and dive into the woods. You will be certain to find something you have never seen before. Of course, it will be a little thing, but do not ignore it. Follow it up, explore all around it; one discovery will lead to another, and before you know it you will have something worth thinking about to occupy your mind. All really big discoveries are the results of thought."

These are the words of Alexander Graham Bell, inventor, scientist, teacher, and humanitarian. They sum up simply his philosophy towards research. Bell did not follow the "public road"; his intellectual excursions into the unexplored territories of science yielded many "little things" that advanced human knowledge tremendously. His most popular and most successful invention was the telephone but many other branches of science attracted his searching attention. To medicine, aeronautics, marine engineering, genetics and eugenics, electricity, and the science of speech, Alexander Graham Bell gave generously of his intelligence and energy.

This month, August, the Alexander Graham Bell Museum at Baddeck, N.S., is to be opened to the public by the Department of Northern Affairs and National Resources. This museum will be of interest to many engineers, since it contains much material and records from Bell's researches. This article summarizes the main work of Alexander Graham Bell and the examples that are shown in the museum, of which a general view is published on this page.

Bell's remarkable scientific achievements are being presented in their full scope to the public at the Alexander Graham Bell Museum at Baddeck, Nova Scotia. Displayed here are many experimental models and documentary records of his work. These relics, which will be of great interest to modern engineers, have been donated to the federal government by Mrs. David Fairchild and Mrs. Gilbert Grosvenor, both of Washington, D.C., the inventor's daughters.

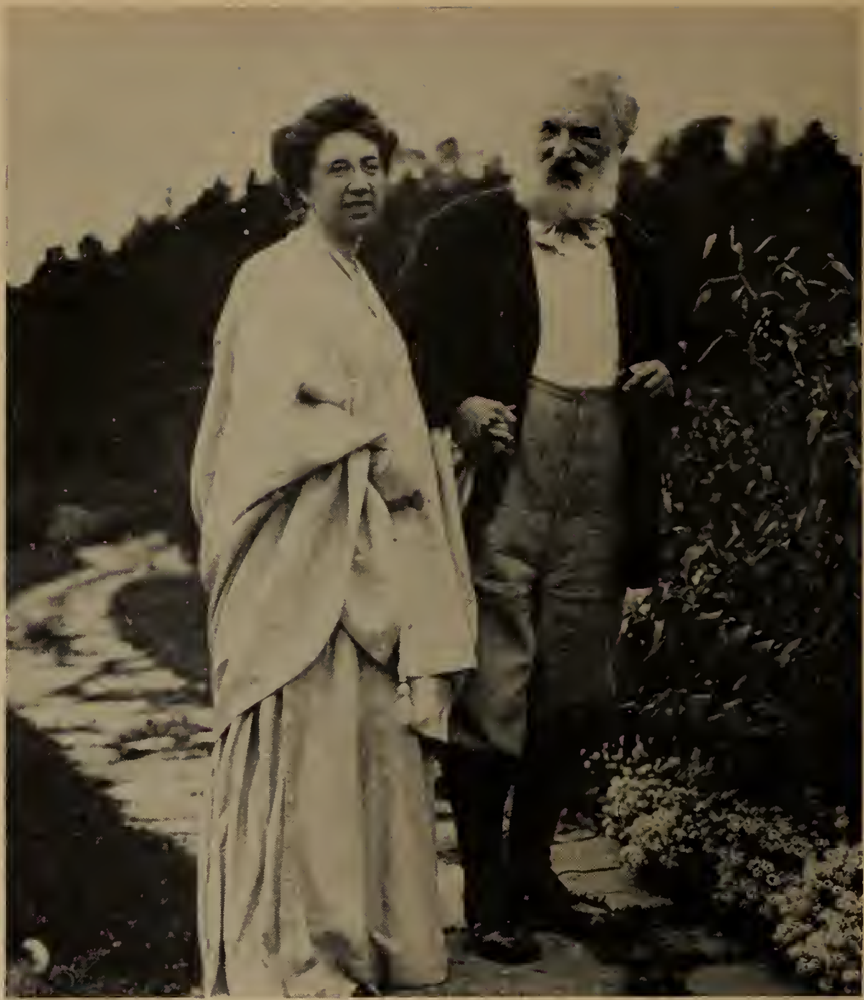
The museum has been established by the federal Department of Northern Affairs and National Resources and will be administered and maintained by the National Parks Branch of that Department. Built mainly of native Cape Breton sandstone and laminated wood, the museum's dominant architectural motif is the tetrahedron, the design Bell used for the cells of large kites, some of which were strong enough to carry a man. The tetrahedral design is repeated in a canopy over the entrance, the display cases, the large window areas, and details of the museum design. Architects for the building were O. H. Leicester and A. Campbell Wood and Associates, of Montreal.

Within the 4,300 square feet provided for display area in the triple-level building are displayed propellers, kites, ailerons, early telephones, an early hydrofoil boat, an experimental iron lung, and other scientific devices developed by Bell. Bell's research office at Beinn Bhreagh, the Baddeck summer home of the inventor, has been reconstructed within the museum and furnished with authentic furniture and personal belongings of the inventor. An unusual touch is the sketches from Bell's laboratory notes that are reproduced in black ceramic enamel on the large plate-glass doors leading into the vestibule.

Baddeck is one of the places most closely associated with the inventor's life. From 1892 until his death in 1922, he spent his summers at his beloved estate, "Beinn Bhreagh", which stands on a headland across the bay from Baddeck. To the laboratory and workshops he established in his estate, he brought his experiments and at Beinn Bhreagh in 1907 was formed the Aerial Experiment Association. The aeronautical research carried out by the Aerial Experiment Association under Bell's leadership is important in the history of aviation development in the world; from it came the aileron, the controllable tricycle undercarriage, floats for seaplanes, and many successful aircraft, one of which made Canada's first flight from Baddeck Bay on February 23, 1909.

Bell's research led him into many fields. His first investigations were directed toward a harmonic telegraph that would send multiple Morse messages over a single line. At the Volta Laboratories, which he established at Washington with the aid of the financial grant associated with the Volta Prize awarded by the Republic of France for his telephone invention, Bell and associates experimented with selenium in a "photophone" that would carry speech in the form of light waves. The Volta Laboratories also improved on Edison's gramophone, developing its own "graphophone" that used wax cylinders which were the ancestors of modern records. Bell also conducted research into genetics and such medical techniques as the iron lung, the use of radium for deep-cancer therapy, and surgical probes that would locate pieces of shrapnel or bullets embedded deep in wounded men. He experimented with the use of sound waves to reveal the presence of icebergs and in measuring the ocean depths.

In aeronautics, Dr. Bell was a pioneer. Before the nineteeth century ended, he had experimented extensively with kites. To achieve human flight in a powered heavier-than-air machine, he developed the tetrahedral cell, a geometric type of construction that would combine lightness and strength in the cells of his experimental kites. The tetrahedron, the design of Bell's kite cells, is revived in the design of the Alexander Graham Bell Museum.



Dr. Alexander Graham Bell and Mrs. Bell in the garden of their home, Beinn Bhreagh, at Baddeck.

(Photo Dr. Gilbert Grosvenor, National Geographic Society)

Although a giant tetrahedral kite built by Dr. Bell was flown by Lieut. Thomas E. Selfridge, the U.S. Army's aviation expert, in 1907, the design offered too much wind resistance for successful development.

An important chapter in the development of aviation was written by the five men who founded the unique Aerial Experiment Association at Beinn Bhreagh on October 1, 1907. Banded together under the leadership of Dr. Bell and with the moral and financial support of Mrs. Bell, four young men pledged their united efforts to construct an aircraft that would fly under its own power carrying a pilot.

F. W. "Casey" Baldwin, mechanical engineering graduate of the University of Toronto and superb athlete, Glen H. Curtiss, the young American engine expert whose motorcycle plant at Hammondsport, New York State, provided an alternative site for the experiments, J. A. D. McCurdy, the daring Nova Scotian engineer and pilot, Lieut. Selfridge, the U.S. Army's first aviator and later international aviation's first victim of powered flight — these formed the Aerial Experiment Association.

At Baddeck and at Hammondsport, the Association built "aerodromes", a name that Bell consistently applied to the frail flying machines that took to air. Their first craft, the "Hammondsport Glider" was flown successfully in 1907. Later came the "Red Wing", their first motor-propelled aircraft, and the "Baldwin's White Wing", the first aircraft in the world to achieve control by the use of hinged ailerons and to make a self-propelled take-off from land. The "Silver Dart" flown by McCurdy made the first recorded heavier-than-air flight by a British subject in the British Empire in 1909.

When the Aerial Experiment Association dissolved in 1909, under the terms of its agreement, it left a legacy to aviation. It had shown what could be accomplished by a

research team working under the leadership of a brilliant inventor. It passed on to others the aileron and the tricycle undercarriage and in Bell's notes are records of other theoretical devices which have only been developed in recent years. Bell visualized rocket-powered missiles, helicopters with jet-propelled rotors, and other advanced aeronautical designs.

Although the Aerial Experiment Association had ended, Dr. Bell and his group remained at Baddeck to form an aircraft manufacturing company. They built five aircraft, of which two were very successful. The aileron from one of these aircraft, the "Baddeck II", is on display in the museum and it is probably the oldest aileron left in the world. Failure to develop a market for their production ended Bell's association with his young experimenters but Baldwin stayed with the inventor to experiment with hydrofoil boats.

Dr. Bell believed a boat could be built to carry heavy loads at great speed if the driving force of air propellers was harnessed. To avoid the opposition of the water, he and Baldwin devised hydrofoils, sets of small wings attached to the sides of the boat. Working first with models and later with small boats, the two men developed the hydrofoil, a boat that rose on its hydrofoils like an air craft when it attained speed. In 1919, the "HD-4", their fourth full-sized experimental hydrofoil boat, sped over Baddeck Bay at the record speed of 70 miles an hour, a mark that was not equalled for many years.

The hydrofoil boat was the last great inventional accomplishment of Dr. Bell. Three years later, he died at Beinn Bhreagh, leaving the world richer. His research is perpetuated today in the achievements of modern scientists and inventors, who have extended much of Bell's basic research into practical machines to serve mankind.

Members of the Aerial Experiment Association shown here are (from left): Glenn Curtis, J. A. D. McCurdy, Dr. Bell, F. W. ("Casey") Baldwin, and Lieut. Thomas E. Selfridge, U.S. Army. (Photo—Dr. Gilbert Grosvenor, National Geographic Society)

DISCUSSION

of Technical Papers

MICROWAVE RADIO PROJECT OF THE TRANS CANADA TELEPHONE SYSTEM

A. J. Groleau, M.E.I.C., *Area Chief Engineer, Bell Telephone Company of Canada*

The Engineering Journal, 1956, Aug., p. 1001

J. E. Hayes, M.E.I.C.[1]

Mr. Groleau's paper has been a most interesting and worthwhile presentation, not only because of the lucid description of a very large and complex engineering enterprise, but also because it deals with a subject which goes beyond the sphere of engineering. A microwave network capable of carrying television pictures from coast to coast in Canada, represents a major step in the development of the nation, and might well be compared with the linking of the East and West by the first transcontinental railway.

Just as the railway provides the physical means for transporting materials from one end of the country to the other, so also the microwave system provides the technical facilities for carrying ideas in the form of words and pictures from one coast to the other; and, as the value of the railway is dependent on the importance of its cargo, so the value of the microwave system is proportional to the importance of the information it carries.

The Canadian Broadcasting Corporation has found from years of experience in radio broadcasting that the smooth functioning of a broadcasting network depends on close co-operation and co-ordination between the broadcaster and the communications companies. To this end, joint engineering committees have been formed, through the medium of which the technical and operating problems, which arise from time to time, may be thoroughly discussed and solved.

During the first year or so after the commencement of the television network service, a large number of problems arose which required the attention of the Bell-CBC committee. As solutions were found to these problems, and systematic operational procedures were established, the committee's work decreased considerably. The committee has already set up methods of reporting faults so these may be traced and corrected as quickly as possible, and it is now working on a standard terminology which will speed up the passing of information concerning specific troubles, and reduce the possibility of misunderstandings. The CBC has done a considerable amount of work on the development of over-all test procedures, and the results of this work have been reviewed by the committee. It is planned that, very shortly, the CBC will supply from its TV master control centres in major cities a test signal which can be sent out in less than one minute, and which will give fairly complete information with respect to system performance when received at stations along the network.

It may be of interest to mention briefly the relationship between a TV master control and a TV microwave network. As an example, I might refer to the TV master control at the CBC Montreal television studios. At this particular location, there are eight incoming and outgoing network feeds, plus ten local circuits. It is the function of the master control operator to see that the correct programs are sent out on the correct networks at scheduled time, and also to accept incoming programs from the networks, as required by the schedule. In this particular location, the TV network and local connections are as listed in the accompanying table.

Most of the listed feeds are on facilities provided by the Bell Telephone Company, but the French network feeds to and from Eastern Canada (items 7 and 8) are on facilities provided by the Canadian National and Canadian Pacific Telegraph Companies. Items 11 and 12 are circuits to master control from a CBC microwave receiving point on the transmitter site on Mount Royal, and item 18 is a circuit from a similar

microwave receiving point on top of Radio Canada Building. These are used for relaying local pick-ups.

This complexity of network terminations results in a type of operaiton which is considerably more complex than that normally carried on by any of the large broadcasting companies in the United States. Many of the problems that arise must be solved by our own methods and it is only by close co-operation and understanding between the TV broadcaster and the communications companies that satisfactory solutions are found.

I believe that we may be justly proud of the technical quality of the television network service which has been achieved in so short a time, and as techniques improve we may, with confidence, anticipate still further expansion and improvements in the future.

I am sure that Mr. Groleau and his associates, and all of us in the television broadcasting industry, are looking forward eagerly to the day, which is not far distant, when the last link in the transcontinental microwave relay circuit will be put into operation. All those who have worked on this project will then have the satisfaction of knowing that they have participated personally in an important contribution to the development of Canada.

AUTOMATING THE ENGINEER'S TASK

J. Kates, M.E.I.C., *President, K.C.S. Data Control Limited*

The Engineering Journal, 1956, August, p. 1014

J. C. Scrimgeour[1]

Dr. Kates has presented an interesting and worthwhile paper on the application of digital computers to engineering problems.

There are many people who believe that the development of automatic digital computers which has taken place in the last 10 to 15 years will prove equal in importance to, or even greater than, the first industrial revolution or the discovery and control of atomic energy. Certainly it will rank as one of the most important developments in the history of mankind.

The distinction drawn by Dr. Kates between design by analysis and design by synthesis is an important and valid point. In the past most design has been done by analysis and most computer applications to date still follow this approach; that is, a configuration or set of parameters is determined by human thought and presented to the computer, which calculates the performance which would result. A few choices or decisions may be made by the computer but for the most part they are established beforehand by human judgment. Only a few applications have been described in the literature where the computer chooses all the parameters for a given configuration (or even chooses the configuration) which are required to meet a given set of performance characteristics. This may be done by an iterative solution of the equations formerly used for analysis or in some cases these may be solved so that a direct solution can be made with the required performance characteristics as a set of simultaneous conditions which must be met. Dr. Kates has stated, synthesis will not be possible in many applications —at least until the engineer states in exact form the basis on which this has formerly been done mentally; and apparently often by intuition. I believe eventually that this will be done and the great decision-making power of automatic digital computers truly put to use.

An interesting question in engineering ethics and the acceptance of responsibility can be posed in connection with some computer applications — particularly where a previously written computer program is used repetitively to solve the same engineering problem. The question is, "How much of the operation and theory behind the program must the user understand in order to accept responsibility for the results?"

Once the computer program has been checked out, its operation can usually be accepted as correct but the results obtained can only be as good as the input data provided. This in turn is open to human error or even complete misapplication of the program in an extreme case. The engineer must find the point which permits delegation of routine operation of checked out programs to less skilled personnel and yet keep close enough contact to permit him to accept true responsibility for results.

Dr. Kates has given examples of three different approaches to a sample problem; by direct analysis, by simulation, and by a statistical approach. I believe a fourth approach may be added; namely, solution by iterative analysis. This could be applied to his sample problem in the following manner. We might attribute this approach to a second engineer.

Second engineer's solution

Inspection of the pyramid diagram shows that the top row contains one block and the bottom row contains n blocks. The average row therefore contains (n + 1) /2 blocks. The total number of blocks is consequently n (n + 1) /2. This must be slightly less than 400,000, i.e.

$$n\,(n + 1)/2 \sim 400{,}000$$

or $$n\,(n + 1) \sim 800{,}000$$

It is only necessary now to solve this equation for n. The second engineer reasoned that if he tried n = 800,000 for a first approximation it would surely be just a little too large. As a first approximation he should then try

$$n = \sqrt{800{,}000} - 1 = 894$$

$$\text{check: } 894\,(894 + 1) = 800{,}130$$

This is too large, so as a second approximation try n = 893

$$\text{check: } 893\,(893 + 1) = 798{,}432$$

The pyramid may therefore be built with 893 rows and 1658 blocks left over for wastage, spoilage and so on.

Leo J. Lacey[2]

In this paper Dr. Kates is discussing a topic which should be of the greatest interest to all engineers who are interested in improving the science of their profession. Computers have been and are being applied to engineering problems, but up to the present they have only nibbled at the edges of the vast area of possible applications which seem to be waiting for them in the engineering field.

At the Ontario Hydro I have been associated since early in 1953

[1]Advance Engineering Section, Peterborough Engineering Laboratory.

[2] Chairman, Data Processing Team, Hydro-Electric Power Commission of Ontario.

with the computing centre, equipped with a small electronic machine, which was established to assist the engineering staff in computational work. Since the centre was established there has been a gradual increase both in the number and the variety of applications which have been brought to the machine. Power system analysis, hydraulic calculations, survey work, and a variety of statistical studies are just a few examples of the type of work which has been handled at the centre.

It has been noticeable that the increasing number of applications has followed a steady education of the engineering staff, not so much in the intricacies of programming, but in knowing the general capabilities of the equipment and in being able to recognize where it can be of service to them in their work.

Probably the biggest barrier to be overcome in achieving more widespread use of computing equipment in engineering, is that of bringing together the computing specialists, who can solve the problem when he knows what the problem is, and the engineer who knows the problem. Unless engineers in general become computer conscious, many problems will never be brought to machines.

The Author

I agree entirely with Mr. Lacey's and Mr. Scimgeour's remarks. Certainly, as Mr. Lacey points out, it is very important for the engineer to realize the capabilities of computers. As Mr. Scrimgeour points out, it is also important for the engineer to understand exactly what a specific program does or does not. The fact that a specific program carries out a given task exactly has advantages as well as disadvantages.

As Mr. Scrimgeour has pointed out, if an engineer does not fully realize the nature of a specific program he may misinterpret the results which he receives from the computer. This is partly due to the fact that two human beings rarely deal with the same complex design situation in exactly the same way. On the other hand, if a group of engineers and computer experts *can* agree on how a certain program is to deal with any of the situations that will be incurred, there should be little further difficulty in interpreting the results. The fact that we can mechanize lengthy sequences of operations and be certain that these sequences of operations will always be carried out in the way in which we intended them to be carried out has proved one of the greatest advantages of electronic computation.

MOVING-BED PROCESSES

E. H. Lebeis, *Catalytic Construction Company, Philadelphia, Pa.*

The Engineering Journal, 1956, July, p. 915

Discussion at the Meeting

Chairman (W. H. Gauvin): Can you tell us whether the moving-bed technique produces greater attrition than fluidized-bed methods?

E. H. Lebeis: On the contrary, attrition in the former case should be considerably less because of the absence of the violent boiling action present in a fluidized bed.

T. W. Hoffman (McGill University): Could Mr. Lebeis tell us whether heat and mass transfer rates are comparable with fluidized-bed technique?

E. H. Lebeis: Mass and heat transfer rates are generally lower in moving-bed processes, primarily because of the larger size of particle that is handled. However, for most industrial applications which we have studied, mass and heat transfer rates in moving-bed processes are not unduly limiting.

N. Themelis (McGill University): What is the optimum particle size for moving-bed operation?

E. H. Lebeis: Particle size considerations are quite important. Higher rates of heat and mass transfer can be achieved with small particles than with large. On the other hand, the pressure drop of the fluid passing through the bed is higher with small particles. The optimum size will vary from process to process. In catalytic cracking the particle size is about one-eighth of an inch. For other processes, the optimum will usually be somewhere between one-tenth of an inch and one inch.

Chairman: For equal capacities, could you give us an idea of the relative plant costs of fluidized-bed and moving-bed equipment?

E. H. Lebeis: For equal throughputs, the two plants would be roughly of the same order of cost, the moving-bed plant being possibly somewhat more expensive. However, operating and maintenance costs must also be considered as well as ease of operation. In catalytic cracking, many plant operators feel that moving-bed units are easier to operate. Any general statement on relative investment costs can be misleading, especially when one has no specific process in mind.

F. R. Archibald [1]

The Catalytic Construction Company and Mr. Lebeis are to be congratulated, firstly for actively renewing and extending development of a valuable engineering principle and secondly for bringing it to the general attention of engineers by presentation of this paper. My particular interest lies in the application of moving-bed techniques to metallurgical processes and the mechanics of carrying them out. A number of considerations prompt examination of the possibilities in the field of extractive metallurgy at this time and it is hoped that Mr. Lebeis might follow the present paper with a guiding analysis of developments in solids flow, materials of construction, instrumentation, and ion exchange which he has briefly mentioned under "Future Applications".

Among the considerations that make the idea attractive in the metallurgical field are: (a) the increasing cost of fuels and the consequent emphasis in heat economy of furnaces; (b) the increasing awareness and use of solid state reactions and solid-vapour reactions such as those at which he hints in his last paragraph; and (c) recent developments in pelletizing and briquetting techniques which permit the preparation of finely-ground materials for "moving-bed" treatment.

John M. Mortimer [2]

I would like to congratulate Mr. Lebeis for his presentation which, for

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

RADAR RESEARCH IN A BIRD SANCTUARY

The late Jack Miner became internationally known through his work for conservation and his bird refuge at Kingsville, Ont. Now, eleven years after his death, this bird sanctuary has been used by the Defence Research Board, Ottawa, as a radar research station to determine effects of mass bird flights on radar screens.

In the spring of 1955 four radar towers were erected, two at the sanctuary, one ten miles away, and one forty miles away. Observations were made of the effects of flights of birds at various distances from the towers, and specialists in the field of radar research from the United States were also invited to attend.

The results of the trials have not been made public, but Dr. O. M. Solandt, then chairman, Defence Research Board has referred to them as being very successful. Jack Miner would doubtless be delighted, though perhaps a little surprised, at the contribution his life's work had made to science. The experience of his sons has apparently proved invaluable in the basic preparations for the trials and in the interpretation of results. Certainly, few other men could have made large flocks of Canada geese fly on pre-arranged schedules and otherwise predict their movements, as they seem to have done.

In such ways is the work of the physicist and the engineer helped by the knowledge of those in a vastly different field.

ENGINEERS AND INDUSTRY IN BELGIUM

A report to the general meeting, in April, of the Société Royale Belge des Ingénieurs et des Industriels gives an insight into some of the problems of productivity and technical manpower in Belgium.

Conditions are generally favourable and there is a tendency to full employment, with shortages of labour in some fields. Belgium is handicapped by a relatively high level of wages and social security contributions, the average hourly wage in Belgium of 31.50 francs comparing with about 27.50 francs in Germany and France, and 21.80 francs in Holland. Although this gap has tended to diminish, wage demands may annul any potential improvement.

Substantial investments have helped towards increased productivity and hence to meet foreign competition, but the report forsees a tightening of revenue authority concessions and further problems in disposing of the increased production.

Some of the industrial achievements include complete mechanization of coal cutting, with marked improvement in output, air-conditioning in deep mine workings, and the recovery and industrial use of firedamp. The thermal efficiency of electrical power stations has been increased some 20 per cent over prewar days; rating of individual units has risen from 50,000 kva. in 1949 to 115,000 kva. in 1955. Basic steel production has been improved by the introduction of oxygen-process plants. Progress has also been made in various fields of mechanical engineering, electronics, and petroleum.

The good financial results of 1955 have not been regarded in their true relation to the overall economy by the trade unions, who have claimed an appreciable reduction in working hours without any reduction in wages. Though many of the working class are considered to be exceptionally able, and therefore deserving of due recognition, the general adoption of a major labour reform could well prove dangerous to a country that must export 40 per cent of its production, especially if its competitors did not reform similarly.

It is apparent, however, that this risk will have to be run, and it is hoped that all will turn out well; inevitably the country's engineers and industrialists "will be called upon once more . . . to devise new solutions adapted to the changed circumstances."

Scientific training and research are ever more essential; more skilled engineers are needed. With this object in view, the society created a scholarship fund twelve years ago to assist men of ability who could not afford higher technical studies. The society is very conscious of the universal importance of engineering training and would like to see more attention paid to the young person in secondary school, who should be told what possibilities there are in technical fields and how they may be entered. Particular emphasis should be placed on pure research and the value of team work.

Better use should be made of available engineers. Observation of employment notices and recruitment regulations of the civil service and public bodies indicates a certain lack of flexibility in the employment of engineers, due to increased specialization and strict age limits; these rules should be relaxed. The engineer must be prepared to adapt himself to new techniques and industries, in which he may be invaluable, even if they are outside his original field of training and experience.

Before ending on an optimistic note, the report views with some caution the burst of activity, particularly in the building industry, connected with the 1958 Brussels Exhibition. Some of the projects are described as grandiose, and it is regretted that the program was not intiated earlier to avoid a rush that may result in harmful labour demands and may also encourage some industrialists to expand facilities unduly, so that they will be over-productive under normal conditions.

MAN-CARRYING CENTRIFUGE FOR AVIATION MEDICINE

United Kingdom Information Service

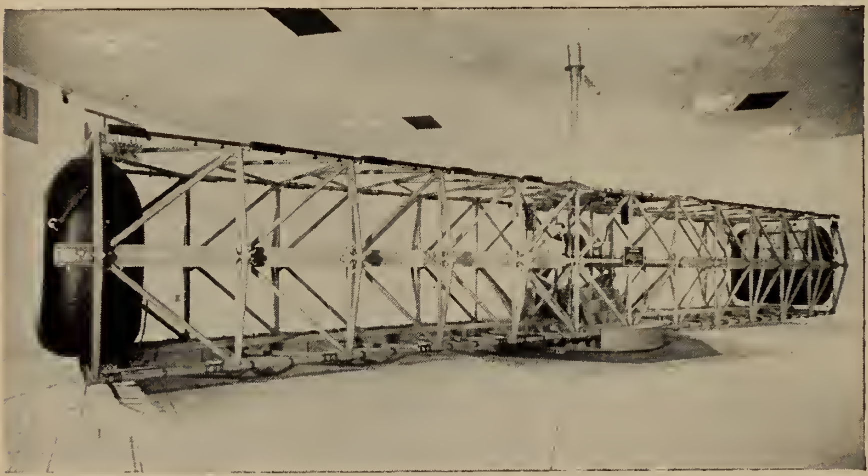
To facilitate medical research into the reaction of high speed flight on the human body, a man-carrying centrifuge has been designed and installed at Britain's Royal Air Force Institute of Aviation Medicine. A communication system enables the subject to describe to an observer what happens during a test.

The centrifuge is basically a horizontal arm rotating under a controlled cycle of acceleration and deceleration. The 60-foot arm has a car suspended on trunnions at each end, and is mounted on a 12-ton flywheel attached to a vertical spindle driving-motor in a central pit in the centrifuge chamber.

Complex design problems were involved in the design of the structure. The cars are subject to an acceleration in the direction of the axis of rotation proportional to the square of the angular velocity and the effective radius of the arm; the rate of change of acceleration is governed by rate of change of motor speed.

At maximum motor speed of 53 r.p.m. and at full radius of 30 feet, an acceleration of about 30 times gravity can be produced.

Main contractors were M. B. Wild and Company Ltd., Birmingham, and electrical and control equipment were installed by the General Electric Co. Ltd., London, England.



Man-carrying centrifuge at Britain's Royal Air Force Institute of Aviation Medicine.

WILL FUTURE TRANSPORTS BE TOO FAST FOR CONVENIENCE?

Canadian Aviation, 1956, v. 29, n. 4, April.

During the first world war, the average speed for an aircraft was 100 m.p.h. Now we consider 300 m.p.h. slow and fully expect to be able to travel at 500 to 600 m.p.h. within the next four or five years.

Many technical problems must be solved before commercial operations can be carried out at speeds above the sound barrier. However, in terms of speed alone, it is possible to assess some interesting passenger reactions on possible air schedules.

Supersonic speeds of the future may not offer the gain expected and may even become embarrassing.

Even today a traveller can make a trip between two cities by air in one hr. 10 min. Yet many people find it both convenient and comfortable to take a night train with sleepers.

Once 200 m.p.h. has been reached, so much time is used up driving out to the airport, waiting to embark, etc., that the time spent on the ground often exceeds the time in the air.

Take the Montreal-London route. The present-day aircraft can make one revenue trip during a 24-hour period. The 500 m.p.h. aircraft could accomplish two revenue trips per day, the 1,000 m.p.h. aircraft four trips, and 3,000 m.p.h. 10 trips.

A further study shows that the 500 m.p.h. flights have convenient departure and arrival times, especially the 9 p.m. service eastbound from Montreal which would allow a certain amount of rest during the normal night period before arrival in the U.K. However, as speed increases, the difficulty and inconvenience of several of the services becomes very apparent. At 3,000 m.p.h. you can leave Montreal at 1 a.m. and arrive in London at 7 a.m. having had less than one hour rest during the night period.

A basic feature in an average passenger's idea of comfort stems from the local mean time of his place of departure. To illustrate this point, take the passenger who leaves London at 8 a.m. on the 3,000 m.p.h. schedule and arrives in Montreal at 3 a.m. What will his reactions be?

A quick study of the world's time zones shows that on east-west routes, high speed flights are definitely inconvenienced by the changes in local time. On north-south routes, high speeds can provide services with the maximum of convenience.

The tendency of present air line operations over long routes, such as Vancouver-Australia, is to give the passenger a rest during his journey somewhere en route. The futuristic trend, evident in the BOAC Comet operation, is to rush the passenger through to his destination with only short refuelling stops.

This may suit certain people in a hurry, but not everybody.

Disorganization in a passenger's meal schedule occurs on east to west flights, especially trans-world flights.

On the trans-world services, although you arrive at your destination quicker at 3,000 m.p.h. you cannot, in most instances, take any useful advantage of the fact.

It will obviously be of paramount importance to an operator of supersonic aircraft to minimize unnecessary time spent on the ground.

There is every possibility that the operator who finds that 3,000 m.p.h. equipment is available, will endeavour to sell high speed services to the travelling public. The argument will be that high speeds give greater earning potential which will, in turn, reduce the travel cost per mile. Economizing of the over-all operation might easily encroach on comfort and convenience of the average traveller.

Speed must be regarded in its proper perspective and an overall assessment of the whole trip must be made before any advantage can be given to travel around 3,000 m.p.h.

COAL MINERALS AND BOILER DESIGN AND OPERATION

Combustion, 1956, v. 57, n. 11, May.

In the second of two articles Dr. Wilhelm Gumz, of Essen, Germany, provides a report of research being conducted by the West German coal mining industry to investigate the behaviour of coal minerals at the high temperatures encountered in boiler operation. The effect of silica compounds upon boiler fouling is discussed.

The situation as outlined in Part 1 of this article calls for a new approach to the problems of boiler surface fouling. Recently activity in this field has been revived in the U.S.A. and in Germany. In England the Boiler Availability Committee has taken successful steps toward a solution, the main points being coal selection and mixture.

The many open questions have incited the Steinkohlenbergbauverein, Essen, a research organization of the West German coal mining industry, to investigate the behaviour of coal minerals at high temperatures (in the presence of coal) to supplement current analyses of field samples from shutdown boilers.

This work has begun with the study of behaviour of single minerals which are the major component of the inorganic matter of coal and proceeded to the mixture of "synthetic coal minerals" and "pure" coal (extremely low-ash coal, 0.4 per cent ash content) at various temperatures and rates of heating.

From the laboratory tests it may be concluded that a partial melt rich in silica is required to volatilize the silicon as monoxide and that the concentration of SiO_2 is an important factor. The residue is a silicate glass with mullite, corundum, magnetite or hercynite ($FeAl_2O_4$) and α-iron depending upon the material used and the temperature reached.

These results demonstrate that the flue gas of a high-temperature furnace carries two types of material, entrained slag in the order of magnitude of 5 microns (and also much larger), and an extremely fine aerosol of silica with diameter of 0.1-0.2 micron (and sometimes a few larger particles). Deposit formation starts by the accumulation of these fine particles which, as shown in microscopic studies, are not always of a smooth surface but may show some protruding material or rough skins or deformations. It is supposed that these deviations from the spherical shape are due to products of sublimation of alkali compounds at the surface of the spheres which may act as an additional binder between the spheres. This hypothesis will be studied further and it is hoped that by studying the sublimation products new light will be shed on the problem of fouling.

THE LURE OF THE DOLLAR

Engineering, 1956, v. 181, n. 4708, p. 421

There is a grave danger that the cream of British technological students will be lost to the United States unless something is done to induce the students to return to Britain after getting scholarships or jobs in the U.S.

Lord Chorley, general secretary of the Association of University Teachers, speaking in support of a resolution calling on the Government to grant permanent deferment from national service to science and technology graduates, did not consider the students' decision to get jobs in the U.S. was a deliberate intention to evade national service. "When they . . . get offered salaries equivalent to £2000 a year it is a great attraction for a man of 24 or 26 to stay."

The conference of the Association at which Lord Chorley spoke supported the resolution calling for permanent deferment, and was strongly in favour of higher salaries and better prospects for technologists. Salaries for university teachers should compete with those outside.

It has been stated that (in 1952, in Britain) over a third of the public companies of the engineering industry had no technically qualified voice on the board, and that more than two-thirds of the directorial oligarchy were without technical qualifications.

The article concludes that there lies the major weakness of British industry; in this light the reluctance of the promising graduates to return, after furthering their education in the U.S., can be understood. The remedy is to raise their status as well as their pay and to give tangible proof at all industrial levels that the young technologist will not be led up a blind alley while his university friends who followed one of the so-called liberal professions climb the carpeted stairway to the boardroom.

AMERICAN CONCRETE INSTITUTE BUILDING

A new building, designed for the American Concrete Institute by Minoru Yamasaki, features a folded-plate reinforced concrete roof system. The roof, cantilevered front and rear from concrete interior corridor walls, projects over the exterior walls of precast concrete panels and glass; shorter end walls are shielded by perforated screens of coloured concrete pipe sections. The building, to be started early 1957, in Detroit, will house the society's technical activities.

TELEVISION AS AN AID TO BOILER CONTROL

Engineering, 1956, v. 181, n. 4708, June 1.

The observation of furnace conditions tends to become more difficult as the size of boilers, especially the large pulverized-fuel units which are now being installed in power stations, is increased. The combustion chambers can no longer be inspected from one, or even two, levels and a tour of inspection may take as much as half an hour.

Moreover, the plain mirror periscope, which has been in use for this purpose for many years, has its limitations when remote control of the boilers is installed, while with pulverized-fuel firing it is important that a close watch should be kept on combustion conditions.

These considerations have led to the development of periscopic television equipment which has been installed on a 400,000-lb. pulverized fuel-fired boiler at Barking C power station and which incorporates optical principles which enable the whole of the burner wall and the burners themselves to be observed from a single position, and to be televised thence to any part of the station.

The periscope, which is completely water-cooled and is also provided with an air blast arrangement to prevent fly ash from settling on the lens windows, is mounted on the pneumatically operated carriage.

The camera is of the standard Marconi industrial type which measures 5¼ in. by 4 in. by 8½ in. and weighs only 4½ lb. It incorporates a Vidicon pick-up tube, the signal from which is capacity-coupled to a three-stage video amplifier and fed thence to a mixer stage.

The periscope which has just been described, is normally used only during lighting up. Under stable operating conditions it is withdrawn and monitoring is effected by a photo-electric cell.

ALUMINUM AND ALUMINUM ALLOYS FOR PRESSURE VESSELS

The Welding Journal, 1956, v. 35, n. 6, June

This paper reviews the properties of the aluminum alloys that are especially desirable for pressure vessels and certain chemical and processing equipment. Aluminum alloys are resistant to the chemical action of many materials and, for those materials where there is some action, the resulting products are colourless; hence, they produce no discoloration. They also show remarkable resistance to atmospheric corrosion.

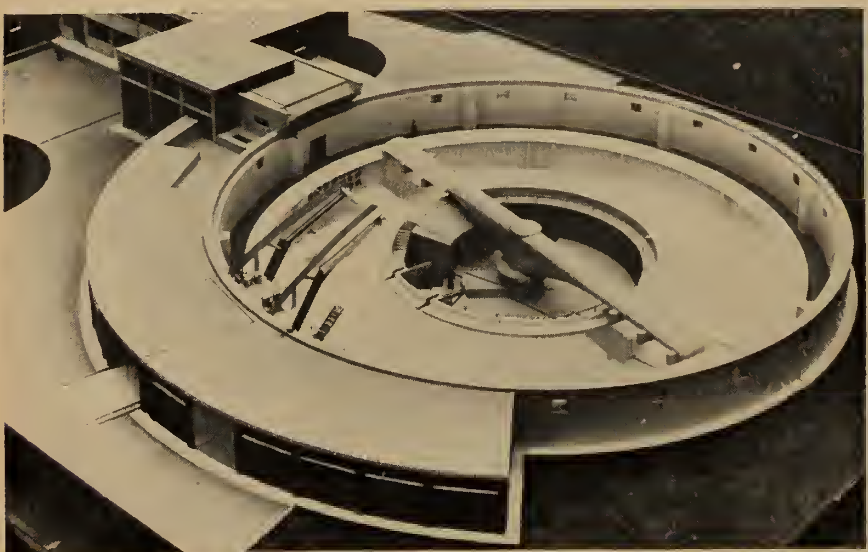
Aluminum alloys are non-magnetic and non-sparking. Conductivity ratings for heat and for electricity are relatively high. Commercially available alloys suitable for pressure vessels represent a wide range of tensile strength. Ten of the alloys in the form of plates covered by ASTM Specification B178-54T have specified tensile strengths in the annealed condition from 9500 to 30,000 psi.

Aluminum alloys do not show a decrease in ductility with depressed temperatures as does mild steel; in fact, the tensile strength, yield strength, elongation and impact resistance of most of the alloys discussed show a distinct increase as the temperature decreases to -420 deg. F. They are readily workable and easily welded.

The service record of aluminum alloys is outstandingly satisfactory. The leading producers have, as a result of many years of experimentation and experience, published much data and prepared handbooks that may be consulted for answers to specific questions.

HYDRODYNAMIC RESEARCH LABORATORY

This is a model (with dome removed) of a 60-ton rotating beam at a new underwater hydrodynamic laboratory at Teddington, near London, England. The purpose of the beam channel and a complementary water tunnel is to discover the behaviour of such missiles as torpedoes at speed. The building which houses the rotating beam is a striking engineering design with a dome 160 feet in diameter, larger than the domes of St. Paul's Cathedral, London, or St. Peter's, Rome.



MATHEMATICS FOR DECISION MAKERS

Harvard Business Review, 1956, May-June.

Modern business has "discovered" statistics and mathematics. In this article the authors discuss the application of mathematical techniques to such areas as inventory and productivity analysis. Apart from these specific uses, however, there seems to be confusion over the general role of mathematics in management. On the one hand, executives seem to underestimate the opportunities for using mathematical methods of one kind or another; on the other hand they tend to overestimate the amount of mathematics they need to know themselves in order to supervise work in the new methods. The article should help businessmen to see the problem in clearer perspective, and it should give them some ideas also as to what to do about it.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

Canadian Pipeline Projects

With close to 2000 men employed, Westcoast Transmission had reached the peak construction period in June. The bulk of the clearing of right of way through heavily timbered areas had already been done, with a view to avoiding the danger of forest fires during the hot dry summer. Some 17 ships are due at Vancouver by the end of September to complete deliveries for 30-inch pipe coming from Britain.

Inland Natural Gas Co. Ltd., has renegotiated its gas purchase contract with Westcoast Transmission Co., and will now take 48 million cubic feet daily instead of the 32 million feet originally contracted for. This represents an increase of 50 per cent from the originally anticipated needs, and follows the recent successful efforts in lining up markets in interior British Columbia communities.

Inland Natural Gas will build laterals from Westcoast main pipe to service Prince George, Quesnel, Williams Lake and Merritt, and will build a major pipeline from Savona to Kamloops, thence to Osoyoos, and Grank Forks. Air surveys have already located the pipeline routes. Financing will be carried out in September and contracts will soon be let, which will employ 600 men this summer and 150 permanently. Orders for pipe are placed for the pipelines and distribution lines. Completion is called for the summer of 1957.

El Paso Natural Gas Company president Paul Kayser sees a market for at least 100 million cubic feet of gas daily more than already contracted for by the time the Westcoast line starts operating next fall. El Paso is already constructing facilities that will boost deliveries by a further 650 million cubic feet a day.

Current estimates of gas reserves in the Peace River fields, of 3½ trillion cubic feet will have to be added to over the next few years to supply the growth in this biggest untapped market on the continent. Under terms of the contracts Pacific Northwest Pipelines, B.C. Electric, and Inland Natural Gas Co. have all reserved the right to purchase substantial additional quantities of gas when they become available.

Pacific Northwest Progress

Meantime the Pacific Northwest Pipeline Corporation has been building at the average rate of three miles per day on its 1487-mile main from the San Juan Basin to connect up at Huntingdon, 45 miles east of Vancouver, with Westcoast Transmission. When the deal was made with Westcoast a year ago, the design of the pipe was changed from one resembling a funnel with the large end at San Juan Basin, to one like an hour-glass, 26 inches diameter at either end, reducing to 22 inches in the centre. This is because the gas comes from either end, with main markets in the centre.

The pipeline passes through Monticello and Moab, Utah; Rangely, Colo.; then through the mountains in Idaho and Oregon via Pocatello and Boise to Pendelton, Oregon. Here it forks in three directions, the main going via Portland, Tacoma and Seattle to join Westcoast at the Canadian border, and branches serving the Yakima and Spokane areas. It crosses the Columbia River in three places, the Snake twice and the Colorado once. The project, costing some $217 million, is due for completion late in 1956. By the middle of May 1000 miles of main and 800 miles of laterals were laid. Gas was expected to reach Portland early in August.

Trans Canada Pipelines

Within a few hours of final passage of the government's Pipeline Bill 298 by Parliament and Senate and the granting of Royal Assent on June 7, official signing of the agreement took place between officials of Northern Ontario Pipeline Crown Corporation, which will advance an $80 million treasury loan, and Trans Canada Pipelines, Ltd., which is to build the Alberta-Winnipeg section. This put the company in a position to start work immediately. The western leg must be completed by December 1, 1956.

By mid-July Trans Canada had contracts awarded for most of this western leg and already had delivery of enough 34-in. pipe to lay the first 120 miles of line. How much of the pipe for the balance of 455 miles to Winnipeg would be delivered this year was in some doubt on account of the steel strike in the United States. Unobtainable in Canada, this pipe had been ordered from U.S. Steel Corporation and A. O. Smith Corp.

Trans Canada has until April 2 next year to repay the treasury loan with 5 per cent interest. Default would permit the government to seize all the company's assets including the gas line itself. With repayment on time, the Crown Company, financed by the Federal and Ontario governments, can build the $118 million Northern Ontario section from the Manitoba border to Kapuskasing, Ontario, leasing it to Trans Canada with an option to purchase. First, however, Trans Canada must prove ability to finance all other parts of the line.

The Crown Corporation will be headed by D. A. Golden, deputy minister of defence production, as president. Directors are Marc Boyer, deputy minister of mines and technical surveys; M. W. Sharp, associate deputy minister of trade and commerce; R. G. Johnson, president and general manager, Defence Construction, Ltd., and H. R. Balls, Department of Finance. William Mulock of Defence Production is secretary, and Col. M. W. Kynch is treasurer.

Way Cleared For Immediate Start

Trans Canada has already optioned easements on most of the 60-foot right of way required for the western leg. The land can be worked and cropped by the land owner but no building may be erected thereon within 20 feet of the pipe. Company officials estimate 120 construction days will be needed, including allowances for bad weather and other delays.

Under terms of the government loan, should the line not be completed to Winnipeg by December 1, Canada may take over Trans Canada's entire assets at 90 per cent of cost. However, there is little chance of default, since interference with progress due to "force majeure" such as floods, riots, or strikes would automatically extend the time for completion.

Financing Possible Without U.S. Market?

Federal Power Commission hearings on the export of Canadian gas to the United States, opened at Washington last February, are currently recessed for the summer. But forces opposing import of gas by the U.S. met early in June in Chicago to map future plans for their battle before FPC. More than 40 coal producers, railroad representatives and labour executives discussed 'development of the opposition case' at a private meeting. They oppose importation of gas because of the possible "displacement of the coal and rail interests and their employees". They will determine the best approach for fighting the case.

But Federal Trade Minister C. D. Howe contends that the proposed export of surplus Canadian gas to the United States is no longer so important a factor in Trans Canada's ability to get private financing for the project. After the first year of the Canadian line's operations the company would be able to carry all debt charges without U.S. export. He believes repayment of the $80 million loan may be made within a few months through private financing by Trans Canada.

Trans Canada officials have set themselves a formidable objective: to negotiate sufficient long term Canadian sales contracts this summer and fall to support the necessary $250-million financing of the entire line with exception of the Northern Ontario gap to be built by the Crown Company.

Even without FPC approval of import by the United States, company officials feel there is a good chance of doing this on Canadian business alone by the end of 1956. Loan institutions would require sales revenue the third year to clear all fixed charges and the bulk of operating expenses. An overall profit would have to be shown by the fourth year.

Faster Canadian Market Build-Up Seen

There are several reasons for this new optimism. Trans Canada's latest market survey shows a potential market for 150 billion feet of gas in Canada for the third year of operation. Under a new contract with Union Gas Co. of Canada, Trans Canada will now supply a maximum of 12½ billion feet of gas in the first year, increasing to 64 billion cubic feet in the thirteenth year. Because of underground storage facilities, two thirds of this gas will be delivered during the summer months when the general load is at a seasonal low level. The contract which runs 20 years will bring Trans Canada a total revenue of $300 million during its life, or almost four times the revenue from the previous contract.

Another year of load building in Consumers Gas territory, where the Toronto market has expanded throughout Metropolitan Toronto, east of Oshawa and Whitby and west to Port Credit and Streetsville, now shows a potential market that covers more than a quarter of the population of Ontario. A $10 million debenture issue has been marketed by Consumer's Gas Co., to finance the expansion.

Further west, Northern Ontario Natural Gas Company has signed a 20-year contract for 100 million cubic feet daily, beginning at 57 million the first year, and building up to 100 million feet daily the fifth year. This company and its affiliate Twin City Gas Company have permits to serve the entire Northern Ontario area. Some 13 pulp mills are major industrial customers. The market also includes processing gas sales to International Nickel, but excludes the potential 40 million feet daily for nickel smelting.

Winnipeg and Central Gas Co. has authorized $24 million for capital expenditure for a 5-year expansion program with the Canada Cement plant at Fort Whyte, requirements for which will be between 10 and 15 million feet daily in summer and between 5 and 10 million feet daily in winter.

Ultimate Export Inevitable

At the same time, the prospect of export to the United States is by no means being written off. Delivery of Canadian gas to the Tennessee Gas Transmission Co. at Emerson, Manitoba, appears to be ultimately inevitable for the rapidly growing midwest United States market. An early FPC approval of the case enabling U.S. companies to import Canadian gas, would of course immediately solve all the problems of financing.

Alberta Gas Trunk Line Co. Ltd.

Earlier plans contemplated a 547-mile gathering system in Alberta to feed Trans Canada Pipelines, 219 miles of which were to be built in 1956. A further 328 miles would be built the following year, all connecting with the main near the Alberta-Saskatchewan border. This system will require 120,000 tons of pipe; 74 miles of 34-in. pipe west of the "gate", and a few hundred miles in varying sizes from 30 in. down to 8 in. The estimated cost runs to $52 million.

Due to Trans Canada's current schedule to build as far as Winnipeg only this year, however, it is reported Alberta Gas Trunk Line Company plans will be now modified to building only 30 miles this year from Bindloss. This is due to the smaller volume of gas needed for the first year of operation, which will be of the order of 10½ million cubic feet daily. This field has dry, sweet gas with a field pressure sufficient to push it right through to Winnipeg.

Meantime a start has been made on B.A. Oil's new sulphur plant 13 miles southeast of Pincher Creek with a crew of some 150 workers. Operation is scheduled for about October 1, this year, for production of 225 long tons of sulphur and 2200 barrels of concentrate daily. Capacity will be doubled when the Trans Canada Pipeline reaches the eastern market, while ultimate capacity will be 780 tons of sulphur, 1230 barrels of propane, 1300 barrels of butane, 1020 barrels of natural gasoline and 7810 barrels of condensate.

During the first year's operation prior to completion of the pipeline the residue gas will be recycled back into the Pincher Creek field. Later, residue dry gas will be sold to Trans Canada at 1 million cubic feet daily for the first year and 1.7 million feet daily in subsequent years.

Bar Harbour — Yarmouth Ferry

The "Bluenose", the new car and passenger ferry operating between Bar Harbour, Maine, and Yarmouth, Nova Scotia, made her way up Yarmouth Harbour on June 9, completing the first official run and inaugurating the year-round ferry service.

Built by the Davie Shipbuilding Company of Lauzon, Que., the five million dollar vessel can carry 500 passengers and 150 cars and trucks. Some of the specifications are: service speed, 18½ knots; gross tonnage, 6,419 tons; registered tonnage, 3,341 tons; service draft, 16 ft. 7 in.; engines, six 2000-hp. diesel, developing 200 r.p.m.; total shp. 11,160; six decks to bridge, welded structure with super-structure of welded aluminum; over-all length, 345 feet; moulded breadth, 65 feet; moulded depth to promenade deck, 45½ feet.

The "Bluenose"

Ripple Rock, B.C.

An unusual project of great interest to British Columbians and to shipping interests is under way in the Strait of Georgia, some 100 miles north of Vancouver, where a tremendous explosion will be set off some time late in 1957 or early in 1958, to remove the hazardous Ripple Rock from the navigation channel.

This obstacle to navigation, located in Seymour Narrows, between the craggy shores of Vancouver Island and Quadra and Maud Islands, has always been a menace to ships plying the 'Inner Passage' which separates Vancouver Island from the B.C. mainland. Here over the past 80 years fourteen ships and more than 100 smaller vessels have been wrecked, while the loss of 114 lives has been recorded.

Right in the middle of the Seymour Narrows where the channel is reduced to a width of half a mile from its usual two-mile width, stands Ripple Rock, 3000 feet in length and 1500 feet wide at the base, tapering off to a ridge more than 300 feet in height with pinnacles nine to twenty feet below low tide level. Currents at the speed of 10 knots and sometimes 15 knots an hour past the rock, make passage extremely dangerous for shipping, excepting during the 20 to 40 minutes at slack tide twice a day.

Governments have been besieged with demands for years to have the rock removed. In 1942 the federal government, fearing for the fate of ammunition and supply ships bound for Alaska and the Aleutians during the war insisted something must be done.

In 1943 and again in 1945 attempts to drill holes in the rock from an anchored barge failed. The Department of Public Works offered $1.8 million to anyone who would guarantee a completed job. Suggestions were even made for blowing it away with an atom bomb. Then a fourth year physics student at U.B.C. conceived the plan for tunnelling under the water from nearby Maud Island and blowing it up from below.

The tunnelling scheme was handed to Dr. Steacie, director of the National Research Council, for a report on its feasibility. The underwater rock was examined for possible fissures and dangerous faults, and a TV camera was lowered to examine the underwater rock bed. Boyles Bros., internationally known diamond drilling contractors, were engaged to drill from Maud Island during the winter of 1953/54 and no dangerous faults were disclosed.

Early in 1955 Dr. Victor Dolmage, an eminent British Columbia geologist, was given charge of the project, estimated to cost some 2½ to 3 million dollars, for sinking a 500-foot shaft from a point 50 feet above water level on Maud Island and for driving a tunnel some 2400 feet in length under the channel to a position under the rock, with branches upwards 300 feet to points under each of the two pinnacles. When completed, the tunnel will be loaded with 550 tons of nitrone, a new and powerful explosive. Ten pounds per cubic yard will be used compared with the normal loading of ½-lb. per yard. The objective is to entirely remove the rock pinnacles to a depth of some 40 feet below low tide water level.

In order to furnish electric power for the tunnelling work, British Columbia Power Commission engineers this year undertook the difficult operation of spanning the Seymour Narrows with an aerial power line.

Now power is being supplied over a 3000-foot span for rock drills and for removing the blasted rock from the tunnel and raising it through the shaft to the surface. Before the blast is set off all residents of the area within 25 miles of the operation will be moved out for safety.

The people of Victoria and other cities and towns on Vancouver Island, who have been dreaming for years of a highway to connect the Island with the mainland, fear this means an end to their hopes for spanning the narrows with a highway bridge. But shipping interests in Vancouver, Seattle, San Francisco, whose boats travel the Inner Passage on their way north to Prince Rupert, Skagway and other ports in Alaska, will be indeed happy to see this hazard to navigation removed. So will lumber and paper mills along the B.C. coast, as well as the Aluminum Co. of Canada, whose ore boats use the channel for bringing Jamaica bauxite concentrates to Kitimat.

St. Lawrence Seaway and Power Project

Progress by Ontario Hydro

With favourable weather, construction work forged ahead at an accelerated pace during June. Noticeable progress was made in the power-house section, where a total of 135,000 cubic yards of concrete had been placed at month end in the "U" abutment, wing wall, ice sluices, and for generating units one, two and three. The wing wall was completed during the month and some of the concrete blocks in the "U" abutment have been finished to full height. At unit No. 1, assembling of the draught tube form got underway and it was expected that first concrete would be placed around this form early in July. The work force for the month reached a total of 3,600 persons.

The new access tunnel under the diversion canal was ready for use at the end of the month. The concrete roadway in the tunnel was completed, and the banks of the canal over the tunnel had been built up.

At the diversion canal closure structure, a total of 15,000 cubic yards of concrete had been placed in the wing walls and in the center block. The contractor also was progressing with excavation work in the west end section of the canal towards lock 20.

Dike work got underway on a major scale during June, and the work program accelerated in section three of Cornwall dike between No. 2 highway and Toll Gate Road. Here the contractor was placing and compacting material. In sections one and two of the dike, stripping was in progress to take the dike to the present Mille Roches area where it will terminate.

Railway relocation work was resumed and all three contractors had been busy on grading operations. Track laying and ballasting were proceeding rapidly from the west end in the vicinity of Iroquois. At the east end, track laying had been going on in Cornwall area on the new right-of-way out toward Nine Mile Road.

During the month, channel improvement work progressed, with rock excavation being carried out by the contractor at Galop Island, the rock being used to build cofferdams at the west end of the island enclosing the channel as far as Tick Island. Earth that was being excavated was being placed on the south side of the island. Near Chimney Island, four dredges were working on channel excavation work.

House moving operations commenced in Morrisburg during June. Seven houses were moved to make way for the new shopping center and were placed on new foundations in Morrisburg.

At Iroquois, a total of 138 houses had been moved at month end, which is almost the completion of house moving operations in that village. Steel was being erected for the new modern shopping center for Iroquois. Construction of the town's elevated steel water tank was well advanced, and work had also progressed well on the pump-house and sewage disposal plant.

In new town No. 2, building of permanent roads, sewers, and water mains had been completed in one section. Power distribution and phone lines also had been installed. Work was beginning to be accelerated in new town No. 1 where laying of sewers and water mains was progressing favourably.

Progress by NYSPA:

During June construction was accelerated as the unusually wet spring weather gave way to much dryer, improved working conditions. Concrete in place at end of June exceeded 410,000 cubic yards; excavation had reached 19 million cubic yards and employment averaged 5,600 for the month.

Gate guides and sills were being placed at Long Sault dam, piers were at an impressive height and concrete was being placed in apron blocks. Concrete in the structure totalled 145,000 cubic yards. Earth excavation in the main section of Cut "F" between the upstream and downstream plugs was complete and overall excavation was more than 75 per cent completed. The cofferdam "E" cableway was nearly ready for cable stringing.

Concrete placement in the Barnhart power-house had reached 103,000 cubic yards as drilling, grouting and excavation operations continued. Excavation for the switchyard had been started and construction of the south forebay dike had been resumed as dryer conditions permitted placing of filter material and embankment.

Eight piers at Iroquois dam had reached their height to the top of the dam. Concrete in one section of Massena intake was as high as the canal water surface, as 51,000 cubic yards had been placed to date. Construction of a temporary bridge for construction traffic and for supporting water lines had been started downstream. A detour of route 37B around the west end of the dike was being built. Pipe laying for Massena and Alcoa water supply had resulted in 1,000 feet of 48-inch and 4,400 feet of 30-inch line in place to date. About half of the concrete in the valve house had been placed.

Excavation on the main channel side of Lotus and Lalond Islands had been completed and was continuing in the south channel. An additional dredge added downstream from Chimney Island had increased production in that area. At Sparrowhawk Point, a rim dike had been built around the point and excavation was proceeding in the main section. On the Ogden Island contract, clearing was in progress, construction facilities were being built up and construction of the Waddington sewage treatment plant was continuing. Excavation under the five major channel improvement contracts was 25 per cent completed.

Production of construction drawings and specifications continued on schedule. Specifications were issued during the month for reservoir clearing between Point Three Points and Red Mills Point.

Progress by SLSDC:

A third contracting firm has defaulted on the American side of the St. Lawrence navigation channel construction. Dutcher Construction Corporation of Maryland, gave up its $2.2 million excavation contract for the Grass River lock last April with some 91 per cent of the job completed. The firm then took a sub-contract for the joint venture group known as Grass River Constructors, which undertook to complete the excavation without alteration of its $26.7 million contract for lock construction. Now Dutcher has stopped work on this sub-contract.

Progress by SLSA

A contract amounting to $1,508,520 has been awarded to Canadian Vickers Limited, Montreal, for the supply and installation of operating machines for lock gates at locks of the St. Lawrence Seaway. A second contract has been awarded to Bridge and Tank Company of Canada Limited, Hamilton, Ontario, the lowest bidder for the supply and erection of Cote Ste. Catherine lock bridge, and Iroquois lock bridge, (rolling lift type bridges). The value of the contract is $873,421.

The award of a contract was announced on June 29, for the supply of stop logs, pick-up booms, etc., for locks of the seaway to Montreal Locomotive Works, Ltd., Montreal, valued at $2,210,400. Also announced was the award of a contract for the supply and installation of unwatering pumps and sump pumps at locks of the St. Lawrence Seaway to Canadian Ingersoll-Rand Company Ltd., of Montreal, valued at $387,516. This firm was the only tenderer.

Miron et Frères, Ltee., of Montreal and Mannibec Construction Company Limited, in joint venture, have been awarded a contract for excavation of some two miles of overland channel and a dyke from the South Shore end of the Honoré Mercier Bridge to Lake St. Louis, in the Lachine section, at a total estimated cost of $5,843,750. The work will extend upstream from the Honoré Mercier Bridge through part of the Caughnawaga Indian Reserve to the dredged channel in Lake St. Louis.

The work consists of 1,200,000 cubic yards of common excavation, 1,980,000 cubic yards of rock excavation, and approximately 10,000 linear feet of dike construction. All the work must be completed by August 31, 1958.

Awards of the two largest contracts to date by the St. Lawrence Seaway Authority were announced on June 15, for two locks on the Beauharnois canal. United Waterways Constructors, Limited, was lowest bidder for construction of the Upper Beauharnois lock and approaches, at a price of $14,440,000. Canit Construction, Limited, was the successful bidder for construction of the Lower Beauharnois lock and approaches, at a price of $11,199,925. Atlas Winston Limited was second lowest bidder on each of the contracts at $14,860,200 and $12,879,800 respectively.

The two locks will raise or lower ships some 85 feet between Lake St. Louis and the Beauharnois canal, at a point near Melocheville. Thus contracts for all of the five locks to be built by Canada's Seaway Authority have now been awarded. Work on the upper Beauharnois lock must be completed by November 30, 1958 and for the Lower Beauharnois lock by October 31, 1958.

Award of these two contracts brings to some forty the number of contracts awarded by SLSA, for a total value of approximately $120 million.

Changes To Montreal Bridge

Federal Minister of Transport George Marler announced on June 15 that $30 million would be spent on construction of the Nuns Island highway bridge between Montreal and the South Shore. A plan to connect the City and St. Lambert by either a tunnel or a high level bridge had been ruled out by federal authorities because of excessive costs, and because of the disruption either would cause in St. Lambert. The National Harbours Board plans to build modern approaches with separation grades at the south end, at a cost of $1½ million, he stated. There would be underpasses and overpasses of the most modern nature, designed to eliminate traffic congestion and to accelerate movement of traffic entering or leaving the bridge.

Mr. Marler also announced that Victoria bridge would be modified by building lift spans over each end of the seaway lock. Eight million dollars would also be spent on the Honoré Mercier bridge, for a ramp at the south end rising to a height of 120 feet over the seaway channel and descending by a complex but modern system of approach roads, to provide a junction with existing highways and a separation from the railway facilities of the C.P.R. The Seaway Authority's contribution here would amount to $6,750,000.

No part of the Jacques Cartier bridge would be demolished, he reported. The south end would be raised to provide 120-foot clearance but the present spans would be lifted or jacked up to a higher level. A new span would be built over the channel itself on false work, opposite the old span. Then the old span would be rolled out of place and the new one rolled in. The operation would involve only a short interruption to traffic across the bridge.

Other Seaway News

Federal Transport Minister George Marler, speaking at Quebec City on June 6, said the United States would benefit by a larger increase of overseas traffic than Canada, once the seaway is built. Canada could also expect an increase in traffic, but the U.S. rise would be greater because of its larger population. One reason an increase in U.S. traffic through the seaway could be anticipated was the recent declaration by the U.S. Maritime Commission that the inland waterway is essential to the American trade and economy. This would enable ships of U.S. registry to collect operating subsidies, making American shipping competitive with other shipping now operating at lower costs. No vessels of Canadian registry were operating on the route at the present time, he said.

Piers of the Jacques Cartier Bridge are being enlarged.

Lake Ontario Level

The International Joint Commission made public recommendations on July 3 involving regulations of the water level of Lake Ontario. The proposals were released simultaneously in Washington and Ottawa after a meeting of the IJC in Montreal. They have been accepted by the Canadian and United States governments.

Highlights of the recommendations concern maintenance of Lake Ontario level between 244 and 248 feet during the navigation season. They also prescribe regulation of the outflow from the lake and flow through the International Rapids section of the St. Lawrence. An eventual plan of water regulation is envisaged which will take place under the international St. Lawrence River Board of Control.

Microwave Radio Project of the Trans Canada Telephone System

(Continued from page 1009)

vices to obtain the very flat frequency response required for a satisfactory picture signal. Colour television introduces particularly severe requirements in these facilities. At television service points across the country, television operating centres will be established, equipped with picture monitors, oscilloscopes and other devices that will allow continuous monitoring of the quality of transmission. At main points on the network, comprehensive switching arrangements are provided so that the network may be reversed or rearranged to meet the program requirements of the broadcaster.

Conclusion

The section of the transcontinental network extending from Buffalo, through Toronto, Ottawa and Montreal to Quebec City has been in service for some time. The long section between Toronto and Winnipeg is scheduled for service in October 1956, to be followed a few months later by service between Saint John, Halifax and Sydney. Westward extension to Regina and Saskatoon will be completed about the middle of 1957 followed in September by the extension to Calgary, Edmonton and Lethbridge. The Maritime Provinces will be connected into the central part of the network by completion of the section between Quebec City and Saint John about the end of 1957, and the entire transcontinental system will be available with the completion of the difficult section between Lethbridge and Vancouver in the second quarter of 1958.

Upon completion of this undertaking, Canada will have as modern a communication network as any country in the world and one that will have the inherent capacity for expansion to meet future increasing telecommunications requirements.

MOVING-BED PROCESSES

(Continued from page 1030)

many of us, enlarges our knowledge of moving-bed solid-fluid processes. The members, I am sure, will find the author expertly capable of answering any additional questions on the principles or application of the process.

It is of interest to note in the paper the high degree of proficiency and engineering skill that the petroleum industry has utilized in this process. This is not only a challenge to other industries but an indication to the engineer of the opportunities that may lie in further application of the principles and knowledge in kilning, drying, ion exchange and solid-fluid chemical reactions.

My interest in the moving-bed process has been with respect to the field of metallurgy: I was privileged to be associated with the author in pilot plant work on ore roasting in moving-bed units. What has intrigued us most in this application is the mechanical simplicity of operation of a moving-bed unit, the large capacities, high thermal efficiency, and the reaction control that is possible.

The Author

I would like to thank the discussers for their comments and questions. With reference to the question by T. W. Hoffman, I would like to amplify my remarks on heat and mass transfer rates. When heat is transferred between the solids and the gas or liquid flowing through the bed, higher transfer coefficients are achieved in fluid-bed units. The main reason for this is that the solid phase resistance is lower for fine particles than for coarse.

However, other factors besides transfer coefficients must be considered. As an illustration, let us assume that a solid is to be calcined at 1000° F. If this is done in a single-stage fluidized system, the calcining gas will leave the bed at a temperature close to 1000°F. because of the very nature of that system. If this same operation is performed countercurrently in a moving-bed system, the gas will transfer almost all of its heat to the solids and leave the bed only slightly hotter than the entering cold solids. Here is a case where thermal efficiency is of much greater importance than heat transfer coefficients.

Automating the Engineer's Task

(Continued from page 1019)

high. This was the gambler's first estimate but he noted that in arriving at this estimate he had used random numbers exceeding 854. He therefore improved his estimate by averaging the first guess with the first estimate and he obtained a second estimate of 927 blocks. Now the gambler proceeded to check this estimate by averaging only those random numbers below 927. These resulted in a new average of 438 and a new estimate of

400,000/438 = 913 blocks

This estimate was within 2 per cent of the exact answer and so the gambler had proven his claim. Those were the beginnings of modern statistics and since the gambler's method is based on chance, or random sampling, this technique was dubbed the Monte Carlo method.

Month to Month

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE
ELECTIONS AND TRANSFERS

Education Conference

In the Month to Month section of the June *Journal* reference was made to the Conference on Engineering Education which was held as part of the annual meeting of the Institute in Montreal on May 22 and 23.

Since that short report was made a resolution has been presented to Council which was prepared by the Education Conference. It reads as follows:

Conference Resolutions

RESOLVED: that this E.I.C. Conference on Engineering Education (1956) express to the Council of The Engineering Institute of Canada its deepest appreciation for making the conference possible. We wish to say that we consider that the Institute is to be very sincerely commended for its vision in sponsoring the conference and for its generous assistance and cooperation in making it an accomplished fact.

The beneficial results will perhaps be intangible and will not lend themselves well to being set forth on paper for all to see. But we are convinced that this valued meeting of the minds of those in whose hands lie very largely the responsibilities for meeting and solving our Canadian problems in the training of our future engineers, cannot help but exert an important and beneficial influence on our collective and individual thinking.

AND RESOLVED that this resolution be transmitted to the Council of The Engineering Institute of Canada.

When this resolution was presented, Council considered future action and after considerable discussion approved the following resolution — "That Council go on record and so inform the special committee of the Education Conference that the Institute is planning for a further conference a year hence. If the committee feels that the conference should not be held until two years hence Council would agree to it". This motion was approved unanimously and has since been transmitted to the special committee.

There can be no exaggeration of the importance of the conference. With approximately sixty people in attendance representing with but few exceptions the leading people in engineering education in Canada, something good was bound to result. The president and other officers of the Institute were congratulated by almost every delegate attending the conference, and without exception they spoke in glowing terms of the opportunities they had had to discuss the important problems that were facing them.

R. E. Jamieson is Chairman

The conference was opened informally by a dinner held at the University Club at which the president presided. This gave the delegates an opportunity to meet with each other and with some of the senior officers of the Institute. During this dinner the delegates elected Dean R. E. Jamieson of McGill as chairman for the conference.

The stenotypist who attended throughout the conference reported that it was one of the biggest tasks she had ever undertaken. Just recently her transcription has been received at headquarters and is approximately 1 inch in thickness. There is a Herculean task ahead of the special committee in digesting this into some form of minutes and into a program for an agenda for the next conference.

In view of the great bulk of material to be reviewed by the committee it will not be possible to send minutes to those who participated in the conference for some time yet. However, the committee has the task in hand and proposes to send the minutes as soon as possible.

Following is a list of those who were in attendance:

University of British Columbia

J. F. Muir, civil; W. O. Richmond, mechanical; Frank Noakes, electrical; L. W. Shemilt, chemical; L. G. R. Crouch, mining.

University of Alberta

Dean R. M. Hardy; J. A. Harle, electrical; G. W. Govier, chemical and petroleum; R. N. McManus, civil; L. E. Gads, civil, and secretary of the faculty.

University of Saskatchewan

Dean I. M. Fraser; W. E. Lovell, electrical; A. H. Douglas, civil; J. B. Mantle, mechanical.

Cover Picture

One of several special jigs developed for fabricating post sections of radar towers for the DEW Line in the Arctic. The accuracy achieved eliminated pre-assembling, reaming, and match-marking in the shops. The methods used also permitted interchangeability on all the towers, which ranged in height from 100 to 400 feet.

University of Manitoba
J. Hoogstraten, civil; J. P. C. McMath, electrical; N. M. Hall and R. E. Chant, mechanical.

University of Toronto
Dean R. R. McLaughlin; G. F. Tracy, electrical; C. F. Morrison and W. M. Huggins, civil.

Queen's University
Dean H. G. Conn; D. M. Jemmett, electrical; J. S. Campbell, mechanical; S. D. Lash, civil; A. C. Corlett, mining.

University of Ottawa
Dean Pierre R. Gendron; L. A. Madonna and E. A. Levergne, chemical; L. A. Beauchesne, electrical.

McGill University
Dean R. E. Jamieson; D. L. Mordell and J. B. Phillips, mechanical; J. U. MacEwan, metallurgical; R. A. Chipman, electrical; J. L. deStein, civil.

Ecole Polytechnique
Dean Henri Gaudefroy; J. C. Bernier, electrical; Raymond Boucher, hydraulic; Roger Brais, mechanical; Jacques Laurence, electrical, and executive secretary.

Laval University
Dean Adrien Pouliot; Lionel Boulet, electrical; L. P. Bonneau, mechanical.

University of New Brunswick
Dean Earle O. Turner; Ira M. Beattie, civil; E. E. Wheatley, mechanical; J. O. Dineen, electrical.

Nova Scotia Technical College
M. L. Baker, mechanical; G. H. Burchill, electrical; G. G. Meyerhof, civil; E. Lee Cameron, mining.

Expansion at Western University

A full four-year engineering course will be in effect at the University of Western Ontario in 1957. The first and second years of the program are already being given. The third year will be offered this fall and the fourth year will be available the following year. At present the freshman intake into engineering at Western is limited to 25, but this will be increased in September to 50, and by the fall of 1958 to 150.

Western is preparing now to provide facilities and staff for a doubling of its student enrolment by 1960, Dr. Edward Hall, president and vice-chancellor of the university has announced.

It was explained that the course in engineering is not the traditional type with major specialization in one of the fields of engineering. A program has been worked out which is believed to be a realistic approach to the education of engineers in today's and tomorrow's Canadian economy. Dr. Hall has commented, "We believe that it is both educationally and philosophically sound. Economically it is, additionally extremely attractive." The plan is as follows:

Some 20 per cent of the time, 5 hours per week for four years, will be devoted to the humanities and social sciences; the course includes a three-year program in mathematics, a three-year program in physics and a two-year program in chemistry. The first and second years are common program years. A common core runs through the third and fourth years.

Dr. Hall acknowledges the help of industries in London and Western Ontario which permit the use of their facilities for major laboratory work. He cites the activities of the Ontario Government in assistance to the universities.

The enlargement of the engineering faculty is part of a larger development throughout the university in academic and physical capacity.

An engineering science building, accommodating 500 engineering students, will be ready for occupancy in the fall of 1958. A new geological and biological science building will house several departments, allowing expansion of other departments in the natural science building.

A new arts college is in the plan; it will be called Middlesex College. Thames Hall, Stevenson Hall, and Somerville House, built during the past few years provide gymnasium and swimming pool, library expansion, and the great hall of 500 seating capacity. Another new building will be ready for 1957, the Richard Ivey School of Business Aministration.

With the completion of the long-term program only very briefly summarized here, Western will be able to provide university educational opportunities for some 5000 full-time intramural students in keeping with the great demands with which it will be faced, Dr. Hall has said.

Delegates to the E.I.C. Conference on Engineering Education, Montreal, May, 1956

Three people familiar to members of the Institute. They have been key figures in the E.I.C. activities for some time. Photographed with Colonel H. G. Thompson (left) at a farewell party, were Miss May McLaren of Headquarters, and Dr. L. Austin Wright, master of ceremonies for the occasion.

H. G. Thompson Retires

Colonel H. G. Thompson who since September 1951 has been assistant general secretary of the Institute, retired from this position on June 30, because of ill health.

During these five years Colonel Thompson has done a magnificent piece of work for the Institute and for the profession. No one could have been more loyal, industrious, or intelligent in the execution of his work than was he.

Colonel Thompson possesses to an unusual degree a happy combination of determination and good humour. He manages to get things done in spite of the evident difficulties, and yet he antagonizes no one in the process. To anyone familiar with society affairs it will be readily evident how useful this qualification is in work of this kind.

Around the office he endeared himself to everyone. It was to him that members of the staff went for counsel and advice on issues both large and small, personal and professional.

H. G. Thompson, and gift painting from the staff.

Indicative of the esteem in which he is held, was the "party" given by the staff on the eve of his departure. The Institute staff is always holding "get togethers" of one kind or another but never before was there one like this. There were presentations from the staff, from Council, and from officers of the Institute who during the course of their office learned something of the sterling qualities of this man. Above all it was a tribute to a fellow worker, a friend and a gentleman.

Colonel Thompson for almost all his life has been known affectionately as "Spike". It is doubtful if any engineer in Canada is more widely or more favourably known. Now on the occasion of his retirement he inherits the respect and affection which he has earned for himself all these years in his many capacities. His friends and associates will wish him the best of health and happiness in the long holiday which he has so fully merited.

What's New in Aviation?

All the things that were seen and discussed at the 18th annual meeting of the Aviation Writers Association (A.W.A.) in San Francisco recently were not necessarily the newest, but they were still new and some of them were even the newest. In the July *Journal* there was a short general account of the meeting, and it is the purpose of this article to fill in some details.

On Monday, May 28, after a 7.45 A.M. breakfast at which officers of Lear Inc. told of their products, the party went by bus to Palo Alto to see the plant of Hiller Helicopters. It was a beautiful day and sitting comfortably in the temporary grandstand, bathed in the lovely California sunshine, it was not difficult to persuade oneself that the speakers were not talking of war and the machines were purely for peace time purposes.

There is a lot of interesting work going on here. The company has specialized from its beginning in 1941, on rotorcraft, and today they rank third in unit production on a world wide basis. Demonstration flights were made to show three different models.

It was at Hillers that the sensational "flying platform" or "flying manhole cover" was developed and flown. This is indeed a switch in aviation development although history shows that the idea of wingless flight has been around for a long time. In fact the British flew a similar machine dubbed "the flying bedstead" in 1954, before the Hiller machine hit the front pages.

There are two vital differences between the United States and British machines. The United States platform is powered by two horizontally placed ducted fans which rotate in opposite directions at the base of the structure. The British effort is powered by jet engines. Direction is maintained in the United States machine by the operator tipping the platform by shifting his weight. In the British, the outlet from the jet engines can be changed in position to alter or maintain direction.

The platform was not flown for the visitors but it was there on the ground for inspection. It is an extremely simple affair with two relatively small air cooled piston engines mounted so that their shafts are vertical. This permitted a single V belt drive system to be used, with one engine for each propeller.

The company officials were not very talkative on details of the design. However that was not surprising in view of the fact that this is purely an experimental model. While the development work has been done for the Office of Naval Research, the machine has great possibilities for the Army. The company is now working on a new contract with ONR for the development of a "rotorcycle" or a one-man portable helicopter. The specifications call for a machine that can be collapsed into a small package for easy transport or a parachute drop for use by the Marine Corps.

By the way, the company is now in production on a small model of this platform. It is about 8 ins. in diameter, made of plastic, and it really flies. We saw it. The engine weighs one ounce. It is now being distributed to retail stores to be sold to the young inquiring minds of the nation at about $12.00.

The engineers in this company seem to be full of imagination. While it was only a model that was shown, there seems to be an interesting future for vertical take-off and landing (VTOL) designs. Hiller has a new idea or two in this field. For instance they are proposing a plane in which the wings tilt to the vertical for take off and landing, and move to the horizontal for forward flight. It looked very reasonable in the models which showed planes with two engines and with six. Perhaps this is the answer to VTOL.

The "Flying Platform" (left) of Hiller Helicopters, which uses ducted fan for lift and propulsion.

New concept of flight on the horizon. Artist's drawing shows a design using the principle of tilting wings and propeller units to eliminate need for long runways.

The company is working also on a helicopter with wing tip jet engines. Already they have a ram jet engine certified by the Civil Aeronautics Administration. It is a surprisingly small affair about 24 ins. long and 10 ins. outside diameter. A small number of helicopters so equipped are being manufactured for the Army and the Navy, purely for field evaluation purposes. Apparently the tip powered "egg beater" has many advantages.

National Advisory Committee for Aeronautics

After a delightful luncheon at the Moffett Field Naval Officers club, Hal Hibbard vice-president of the Lockheed Company spoke on what the future holds for air travel. His picture showed supersonic airliners, highly useful earth satellites and earth spanning automatic mail services, faster than the present telephone service.

He envisaged commercial transport planes travelling at almost 700 m.p.h. at altitudes of over 35,000 feet. Also he made public reference for the first time, to a rocket "we have been flying for some time". He thought "we will see mail rockets that will cross the country or travel around the world quicker than today's long distance telephone call".

Also he spoke of rockets for quick express service that, working with an automatic pilot could deliver almost anywhere in a matter of minutes. In conclusion he prophesied that shortly we would have watch pocket television, instant communication with almost any place you may wish, robots doing house work and possibly "new sources of power, new sources of knowledge of man and his behaviour, a new lease on life itself".

Later a fly past of all the latest aircraft used by the Navy was presented, and a briefing in this was given by Rear Admiral John B. Pearson, Jr. of the Navy Bureau of Aeronautics.

Research and Development

Then the group moved to the Ames Aeronautical Laboratory adjacent to Moffett Field. To this writer the most interesting thing here was the story of high speed, up to 10,000 miles per hour. This fantastic rate of travel was achieved by a sphere in a new high velocity lightgas gun developed in the NACA laboratory. The set up is arranged in such a way that photographs at one ten millionth of a second can be taken of the projectile at different positions in its flight, lighted by its own incandescence.

This almost meteoric speed is reported as the greatest ever achieved. Studies such as this aid in the collection of much needed information on high temperature associated with flight at very high speeds. It is understood that NACA proposes to build soon another gun that will develop speeds up to 16,000 m.p.h.

Picture of 10,000 miles per hour. The sphere was shot from a new high velocity Light-Gas Gun developed at NACA Ames Aeronautical Laboratory. Shadowgraph picture, made at one ten millionth of a second, shows the strong shock waves formed by the speeding model.

A Day with the Commercial Airlines

Tuesday, May 29, was taken over by the commercial air transport people. Breakfast was followed by a talk from the Hughes Aircraft Company. Then the group enbussed for the United Air Lines maintenance base to see and hear about their jet air age projects. In the afternoon there was a tour of the new San Francisco airport, which is said to be the last word. However, there is no last word in aviation and while the facilities of the airport were impressive, better ones will be built shortly. Let us hope that some of them find their way into Canada before long.

Dinner was sponsored by the Air Transport Association, and its president Stuart Tipton talked about the industry and its relationship to government and government controls. It was evident that the companies and the authorities do not agree on every issue. Here are some extracts from Mr. Tipton's address to illustrate this point.

"My thesis tonight is a very simple one. It is this: There need never be any debate on the subject of American civil airpower as represented by the scheduled airlines of the United States: there need never be any question as to whether American civil airpower is paramount and will remain paramount — unless our own government somehow manages to undermine our own air transport system. This country can continue to have the greatest airline system in the world if only our own government, which has life-and-death powers over the industry, recognizes the great public issues with which it is dealing — recognizes the disaster that can come from errors, the national benefits that can flow from sound policy.

"This is not the time, if there ever was or will be a time, when the government should be arrayed against the industry or the industry against the government. Nor is this a time when the government should be required to apologize for sympathetic or realistic consideration of the industry's problems. The airlines have too much to do, and great issues hang on their ability to do it.

"The Civil Aeronautics Board and members of the industry have greatly exasperated one another from time to time, and we have every reason to believe that they will do so again. But, by, and large, a record has been written in which the airlines, the government and the country can take pride.

The B-52 Stratofortress and the KC-135 Jet Stratotanker.

"It is enough to observe that compared to 1946, speeds of airlines have doubled, and the number of persons using air travel has more than tripled. Volume of available air service has more than quadrupled. And with all of this, the average fare level stands today just about where it was in 1938, despite such increases in costs as reflected in a rise of 235 per cent in airline wage levels and an increase of over 90 per cent in consumer's prices.

"Service to the postal service is also provable through an array of statistics. Here is the one of which we are the proudest. The post office department, which did so much to get air transportation off the ground, today gets more than 5 cents of every six-cent airmail stamp. For handling the mail we get less than 1 cent. In addition to the carriage of priority airmail, the industry and the post office department are today conducting an experiment in moving first-class mail by air in order to expedite delivery. That experiment will expand because the public will demand it. (Canada has had this for years. Editor).

"Let me simplify the story at the outset. After a lot of lean years we finally made a profit. The first thing that happens is that the government moves in and takes 52 per cent of it. Then we sit down and figure out how little of the remainder we can give our stockholders, and still maintain our credit. We give it to them, and then we take the rest and buy airplanes. When we get the airplanes we call the military department and contribute them to the Civil Reserve Air Fleet to be called up on 48-hour notice. Scheduled air transport is the biggest bargain the government or the public ever had.

"And over the next ten years the scheduled airlines are expected to spend some three billion dollars for new airliners and related equipment."

The Satellite Program

The breakfast speaker on Wednesday was Captain A. B. Metsger, deputy chief, Office of Naval Research, and his topic was the Vanguard Satellite Program. He did an awfully good job of it, but a paper quite similar to it on the same subject was presented to the annual meeting of the Institute by F. R. Furth, Rear Admiral U.S. Navy, so no further reference will be made to it here.

Luncheon and the afternoon were devoted to the "Convair Project", with particular reference to rockets and guided missiles. Some interesting exhibits helped round out the program.

That night the whole delegation were entertained at dinner in Chinatown as guests of the Douglas Aircraft Company.

A Day with USAF

Thursday was Air Force Day. After a 7.15 breakfast as guests of the Boeing Airplane Company, the busses were on their way by 8.30 *en route* to San Francisco's International Airport where two Convairs and two Globemasters of the USAF waited to convey the group to Castle Air Force Base in Merced County.

Here there was a great static display. Most attention was paid to the new Boeing B-52 bomber which is now the pride of the Air Force. Great things are claimed for it and it has been in service long enough for a thorough test. It is powered by eight jet engines in the 10,000-lb. thrust class. Its wing span is 185 feet, length 156 feet and height 48 feet. Its gross weight is over 350,000 lb. Its ceiling is over 50,000 feet and its range over 6000 miles, and its speed is better than 650 m.p.h.

Also on display both on the ground and in the air was what the USAF call "the most powerful fighter in the world". It is the McDonnell F-101 A, now dubbed the Voodoo. It is powered by two Pratt & Whitney J-57 engines each developing 10,000 lb. thrust. Incidentally this is the only two engine supersonic fighter in production in the United States.

The luncheon speaker was General Curtis E. Le May, commander in chief, Strategic Air Command (SAC). He had a lot to say about the troubles of trying to maintain an adequate supply of manpower, particularly in view of some of the things being done by the top authorities in Washington. It was interesting for a Canadian to hear so straightforward an account of the trouble and problem of an arm of the service. It was interesting also to hear a top officer lay the blame for these things at the feet of the mighty. Here are some abstracts from the address:

"The personnel situation in SAC is critical, reenlistment will fall 50 per cent short of what is needed to maintain a first-class nuclear striking force. The first need is for a realistic pay structure. The Armed Forces are still operating under an antiquated idea that one man in uniform is worth as much as another. This simply is not true today, when highly technical skills are required by modern military equipment. Practically all our Air Force technicians have civilian counterparts who are being paid at rates well above those we now pay. We decidedly are not in competition with other branches of the military service for man power—we are in direct competition with industry and we are losing out."

Cost of Living

"An airman cannot use his patriotism to pay his bills. It is not negotiable," he remarked, and added, "it is time that we started placing the proper premium instead of increasing penalties, on the patriotism of the people who defend this country of ours."

Pays Tribute

SAC cannot go on providing a potent striking force without a solution to its manpower problem. From January 1953, to January of this year, his command had a 35 per cent increase in combat wings and a 77 per cent increase in air bases — with a 20 per cent boost in man-power.

General Le May emphasized that with a realistic program costs would be reduced greatly, stating as a possible saving the amount of $2,500,-000,000.

It was something to hear!

The afternoon was given over principally to a fly-by. In the show were the B-52 heavy bomber, the Voodoo, the B-47 medium bomber, the Thunderbird strategic fighter, and the B-36 bomber. There was a demonstration of refuelling in flight when the giant KC-92 tanker refuelled a Voodoo fighter using the "flying boom" system.

Once again into the "air lift" and back to the airport at San Francisco, for a reception in the plant of the Rick Helicopter Company. A feature of this function was that two helicopters were on hand to give a short ride to anyone wanting it. We did.

Luncheon on Friday was sponsored by General Electric Company and at its conclusion one of their metallurgists, Dr. Herbert Halloman, spoke of the so-called "wonder metal" molybdenum. The tremendous strength at red-hot temperatures makes this metal one of the important materials for tomorrow's jet engines.

A peculiar quality of the metal is that it simply goes up in smoke when it gets hot and is in the vicinity of air or oxygen in any form. However, the research laboratories of General Electric are working on a special protective coating that will survive the rough handling "moly" would get in actual service.

Dr. Halloman said, "Molybdenum with a proper coating may be the key to the door through that horrible bogey called the 'heat barrier' ". He also suggested that eventually jet engine parts including the critical buckets may be made of "cermets" — a metal-ceramic combination or even ceramics themselves. He thought that an age of forgeable pottery was a possibility, explaining that non-brittle ceramics would go a long way towards answering the problem of finding materials for use beyond 2500 degrees Fahrenheit.

Dr. Halloman concluded his talk by telling of work General Electric has done on producing perfect iron. Already they have produced tiny whiskers of iron with tensile strength up to 1,900,000 pounds per square inch, which appear to be a world's record for strength of metals. Theoretically metals are ordinarily from 10 to 1000 times weaker than they should be because of imperfection in the crystals that constitute their basic structure. If metal crystals can be produced without imperfection, then metals will achieve strengths approaching those indicated by theory. It is something to ponder.

(Part three of the report will appear in the September issue).

James Newby Visits Us Again

The Cunard liner "Carinthia", on her maiden voyage to Montreal, July 3, brought to Canada a large party of about thirty British engineering students for summer employment under the current exchange plan. It is known as IAESTE, which is the short form of International Association for the Exchange of Students for Technical Experience. The Institute acts as the Canadian agency for all arrangements under this organization.

Taking advantage of this occasion to visit us again was James Newby, of Imperial College, London, England, who travelled with the party. He remained long enough to renew several old acquaintances, and see something of our industrial and university life. Mr. Newby is the British secretary for IAESTE and, prior to this year, was general secretary for the whole international plan. It was in this capacity that he was here four years ago when Canadian participation in the exchange was being set up. He was particularly interested, while in Canada this time, in starting action to establish some industrial bursaries to help Canadian IAESTE students with their travelling expenses. Initial response to this proposal has been good.

The illustration shows the group of young British engineers on the boat deck of the "Carinthia" while she was docking at Montreal. Mr. Newby is kneeling in front centre.

More information about the 1956 activities of IAESTE, in Canada and abroad, will be found in the September issue of the *Journal.*

E.I.C. Awards of Merit for Photography

The photography display which was a feature of the annual meeting this year was an outstanding success. The industries contributed views of their engineering operations which graphically portrayed their work in the development of Canada.

The members attending the meeting received the exhibit with enthusiasm and by ballot indicated a wide diversity of interest and opinion as to the quality of the 150 entries.

Six photographs have brought Awards of Merit to the following organizations:

- Avro Aircraft Limited, for the entry titled, "Flight Testing Avro CF-100's";
- Shawinigan Water and Power Company, "Testing Penstock Welds at Trenche Development, June, 1955";
- Dominion Steel and Coal Corporation, "End Hardening Rails";
- Dominion Engineering Co. Ltd., "Ball and Rod Mills";
- The Fluor Corporation of Canada Ltd. "Fluid Catalytic Cracking Unit".
- Department of Highways, Province of British Columbia, "Southern Trans-Provincial Highway on Anarchist Mountain".

The collection will receive further attention when it is sent across Canada for public display, particularly in the universities where engineering is taught.

Many of these pictures will be presented in future issues of *The Engineering Journal.*

THIRTY-FIVE YEARS AGO

Comment on the Journal of August, 1921

It is always interesting, sometimes instructive and frequently amusing to reread something one wrote in the days of one's flaming youth. And sensations are sharpened if one's authorship has been entirely forgotten.

The writer of these reminiscences finds himself this month, not in the position of the forgotten author, but of the author of a forgotten paper. The *Journal* for August, 1921, published an effort of his called "What about Western Coal?", a subject which he would now say he never dared to touch. Yet there is the evidence; he not only wrote four pages of text, suitably embellished with maps and diagrams, but he had the temerity to make some rather novel suggestions as to the means which might perhaps be used to extend the market for western coal and reduce importations of the United States product.

When first he spotted this paper in the *Journal,* he felt much as anybody does who thinks he has made a fool of himself, but his equanimity was pretty well re-established by the opening paragraph — "All the statements made here and figures quoted are . . . from sources available to anyone and the conclusions are . . . only . . . such as might be arrived at by anyone . . ." Be nothing if not cautious.

The writer has decided not to be ashamed of his brain child nor of the illustrations, which he obviously drew himself. The subject, a live one at the time, has lost most of its importance in these last thirty-five years. The west is no longer so vitally interested as it was in its coal—oil and gas are in the limelight there now—but sometime coal will come into its own again, unless it is put completely out of the running for ever as a source of power by the atom, by the sun or by something else of which we are ignorant today.

Prairie Provinces Water Power

C. H. Attwood, A.M.E.I.C., discussed the water powers of the prairie provinces. It must have come as a bit of a shock to some in the east that there were any. To the average Torontonian, say, the prairie provinces were treeless and as flat as a billiard table, blistered by heat in the summer, with an occasional hail storm or tornado by way of accent, and frozen by terrible blizzards in the winter. Their only business was to produce the wheat for his daily bread and some of his beef. How surprising, then, to find that these three provinces contained undeveloped water power estimated at some 4,200,000 hp. as a minimum and at over 7,000,000 hp. as a maximum. The developed power in the area amounted to 141,465 hp. in 1921, mostly on the Winnipeg River.

The potential power was largely in the north and its development would have to await a market; this is still true. Some, of course, has been developed, but most of it is as yet just water falling over the rocks. However, it is an asset that the provinces rightly cherish.

Western Highways

The western provinces were beginning to worry about their highways. As for mileage, they had too much —384 miles for each nine-mile square township. As described by C. W. Dill, M.E.I.C., in this *Journal,* Saskatchewan had divided its system into three classes — main, interurban and trunk — and one gathers that if a road did not fall into one of these three it was sent to limbo so far as provincial interest in improving it was concerned.

Mr. Dill believed in strict control of highway use by the 77,000 motor vehicles then registered in the province—nearly all passenger automobiles; the roads were too poor for trucks—and quoted with approval the then recent New Brunswick regulations.

Northern Development

Dr. R. C. Wallace, the Commissioner for Northern Manitoba and later the principal of Queen's University, told the Saskatoon meeting something about what was needed to develop the Canadian North, with the usual good sense and Scottish caution characteristic of him. In only one minor way did he fail to foresee what has actually happened: "As far as passenger traffic is concerned, the hydroplane . . . (may) replace the canoe in the north, (but) it does not seem probable . . . that air service will be in a position to quote a freight rate for many long years which will compete with . . . motor trucks."

Strictly speaking, Dr. Wallace was probably quite right; air transport in the north does not compete with trucks. Its advantage is that it is not so dependent on ground conditions as are tractor trains and that it can reach some areas that they cannot. Imagine trying to build DEW without air service. We owe more than we know to the bush pilot and his machine.

Notes on Brazil

The whole correspondence section of this *Journal* was filled by a long and delightful letter from H. K. Wicksteed, M.E.I.C., the father of the Mount Royal tunnel and of the Canadian Northern Railway terminal development in Montreal, whom many members will remember with respect and affection.

Mr. Wicksteed had just returned from four and a half months in Brazil on a "railway assignment". He didn't say what it was, but one may suspect that it might have had something to do with an attempt to untangle the confusion of railway gauges there. The nearest approach to a "standard" gauge seems to have been 5 ft. 3 ins., but there was also a lot of metre-gauge track and quite an assortment of other gauges. Newfoundlanders may appreciate better than most of us the handicap such a condition imposes on business.

Although Mr. Wicksteed apparently did not speak Portuguese, he managed to meet and talk with a good many Brazilian business men and officials. And he kept his eyes open; much of his letter is that of an extra-observant traveller. But he was glad to sight the snow on Chebucto Head on his return via England.

The Branches

A good many of the Montreal Branch members had attended a complimentary dinner tendered by the local branch of the University of Toronto Alumni Association, the "Toike Oikes", to Drs. T. Kennard Thompson, G. H. Duggan, R. A. Ross and J. M. R. Fairbairn. These gentlemen had only just received their honourary degrees from their alma mater and it was said that they were the only engineers so honoured by her. Dr. Fairbairn was the sitting president of the Institute, Drs. Duggan and Ross were ex-presidents and Dr. Thompson was deeply interested in engineering society affairs in the United States.

R. DeL. F.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

NOVA SCOTIA

Recently a committee of senior members of the Association was set up to study and report to Council on the " . . . desirability of instituting an annual award for which members of this Association who have contributed outstandingly to the welfare of this province would be eligible. This contribution having been made possible by virtue of the recipients technical knowledge . . .".

It has been suggested that the award be named the "F. H. Sexton Award", in memory of the late Dr. F. H. Sexton, first president of the Nova Scotia Technical College and an outstanding engineer who contributed much to the welfare of his adopted province. The award would be made once annually, but not necessarily each year.

Changes in Council Representatives

Professor M. L. Baker, a past-president of the Association has been appointed the Association's representative on the E.I.C. Council to complete the unexpired term of the late A. E. Flynn.

J. D. Dexter of Bridgewater has been for Queen's County to replace **G. S.** named chairman of the zone committee Sherman who found it necessary to resign due to ill health.

C. N. Murray, president of the Association, has been appointed Dominion Councillor for the Nova Scotia Association replacing **J. E. Clarke.**

J. D. Fraser,, a past-president of the Association, has been appointed a member of the Council, and of the executive committee, to complete the unexpired term of **R. F. Titus** who has recently been transferred to Ontario.

Councillor R. F. Titus Resigns

Mr. R. F. (Tiny) Titus has been appointed manager of Standard Paving Limited, Toronto, Ontario, and recently resigned as councillor of the Association and as a member of the executive committee of Council.

Mr. Titus was born in Moncton, New Brunswick, and received his engineering education at Mount Allison University and the Nova Scota Technical College. He graduated from "Tech" as a civil engineer in 1950.

His education was interrupted by his naval service during World War II, when he specialized as a "frogman". His activity in this work proved useful in civilian life especially at the time of the 1950 Winnipeg flood when he assisted in rehabilitation work.

Since graduation Tiny has been construction engineer with Standard Paving Maritime Limited. He was vice-president of the Nova Scotia Road Builders Association and very active in accident prevention work in the highway construction industry.

In his new position as manager of Standard Paving Limited, he will supervise his company's activities in Ontario.

Life Membership Awarded R. J. Bethune

R. J. Bethune, president of the Association in 1930, a councillor for seven years and an active supporter of both the Association and the Engineering Institute was recently honoured with the award of life membership in the Association. Mr. Bethune has recently retired from active engineering practice.

R. J. Bethune, M.E.I.C.

Mr. Bethune was born in Baddeck, Nova Scotia, and graduated from Dalhousie University in 1907 with the degree of Bachelor of Engineering (civil).

During the next eight years Mr. Bethune was engaged in railroad construction. He started as an instrumentman with the Transcontinental Railway in New Brunswick, advancing quickly to resident engineer on the Edmonton high level bridge, the Jasper Avenue subway and other construction work in this area. In May 1913 he was resident engineer for the C.P.R., on the construction of the Kootenay Central Railway in B.C.

Mr. Bethune returned to Nova Scotia in 1915, being employed by the Nova Scotia Provincial Roads Department in various counties, as county road superintendent. In 1920 he became divisional highway engineer and during the next nine years held this position in various divisions throughout the province.

From 1929 to 1931 Mr. Bethune returned to railway engineering with the Guysboro Railway in Nova Scotia, on location and construction work. In 1932 and 1933 he was associated with a gypsum company in Cape Breton.

Mr. Bethune returned to highway work toward the close of 1933 as divisional engineer with the provincial Department of Highways. He resigned this position on his retirement.

A member of the Engineering Institute of Canada, he joined as a student in 1910.

BRITISH COLUMBIA

Engineers in the News

W. H. Smith, assistant chief engineer of B.C. Electric's engineering division for the past nine years, has been appointed assistant general manager of the company's subsidiary firm, B.C. Engineering Company Limited.

E. A. Sears, of the Packard Electric Company Ltd. has recently been transferred from the head sales office in Toronto to their Vancouver office as sales engineer. Mr. Sears graduated from the University of New Brunswick in 1950 in electrical engineering. He was with Hollinger Consolidated Gold Mines, Timmns, Ont., and Spruce Falls Power and Paper Company at Kapuskasing, before joining Packard in 1954.

F. T. Brown, of Calgary has been appointed chief engineer for the B.C. highways department. Mr. Brown has been chief estimator for Mannix Limited, and was previously chief engineer with Brown and Root Limited in Edmonton. Other appointments he has held include: —chief construction engineer at Goose Bay for the federal department of transport; construction and maintenance engineer for Imperial Oil Limited at Montreal; resident engineer for the Aluminum Company of Canada Ltd. at Arvida, Que.; structural engineer in charge of construction and contracts for the Toronto subway.

Geoffrey Leach recently entered into the partnership of Carlberg, Jackson and Leach, architects and engineers, with offices at 774 Columbia St., New Westminster. Mr. Leach, had been in private practice and was previously employed with Marwell Construction Co. Ltd. which he joined after coming to Canada from England in 1950.

E. D. **Sutcliffe** has been appointed executive assistant to W. C. Mainwaring, president of B.C. Power Corporation's new subsidiary, Western Development and Power Ltd. Prior to his appointment, Mr. Sutcliffe was executive assistant to the general manager of B.C. Electric's transportation division.

F. B. Baker, of American Fabricators Limited, was recently appointed vice-president, engineering, and elected to the board of directors.

J. C. Timmer of H. A. Simons Ltd. has left for an extended vacation in Holland. He will return to Vancouver next fall.

M. H. Campbell, has accepted the position of municipal engineer for the corporation of the district of Powell River. Mr. Campbell was formerly with the engineering department, city of Vancouver.

A. T. Wason, a 1951 civil engineering graduate of the University British Columbia has been appointed executive engineer, Public Works Department, Barbados, British West Indies, and is presently concerned with the construction of a new 300-bed hospital. Mr. Wason had previously held the position of assistant engineer in the same department.

C. G. Walley, formerly with Marwell Construction Company is now general superintendent for Barker Construction Company, Limited and will be working on the suspension bridges for the gas pipe line at Shelley, Quesnel and Savona.

M. H. French has accepted a position with Canadian General Electric in their Atomic Energy Division in Peterborough, Ont. Mr. French had been in Vancouver for the past year with H. A. Simons Limited.

P. A. Boving, who has been associated with the agricultural engineering division of the Swift Current, Sask., experimental farm, recently accepted a research position with the California Experimental Station drainage department, Davis, Calif.

B. C. Finerty of B. D. Bohna and Company, Limited, has left for Fort St. John, B.C. He will work for Marwell Construction in connection with a plant on the natural gas line.

R. E. Sinke, who is with Sprostons (Jamaica) Limited, has been transferred to Kingston, Jamaica in the capacity of assistant construction manager.

Ralph Sultan, 1956 mechanical graduate of the University British Columbia and past president of the EUS — has sent word that he is now with Linde Air Products Company in their new products division at Toronto. He expects to spend some time in the development laboratories in Tonawanda, New York and then return to the Toronto area in sales.

H. H. Fickel is in Revelstoke, B.C. where he is resident engineer with the Department of Highways.

J. A. Cowlin, on the engineering staff of the Corporation of the District of Saanich, is now assistant engineer.

B. R. MacFarlane, has accepted a position with C. D. Schultz and Co. Ltd. He was previously with MacMillan and Bloedel.

W. F. Miles, of the B. C. Electric was appointed assistant chief engineer (operations) division. Mr. Miles has been with the B.C. Electric since 1946 and until recently was acting supervisor, protection and communication engineering.

G. F. Green, formerly superintendent of protection and communication engineering, B.C. Electric, is now executive assistant to the chief engineer.

E. G. Oldham, is now in Mexico as woods manager of the Tuxtepec Pulp and Paper Co. Ltd. Mr. Oldham had been with the B.C. Forest Service in Victoria.

H. D. Currey, is now with the A .P. Green Firebrick Company in Vancouver. He had been with General Appraisal Company until recently.

P. T. Christoffersen, of Read, Read, Jones and Christoffersen conducted a seminar on "Model Analysis in Concrete" before the annual assembly of the Royal Architectural Institute of Canada at Banff this month.

G. A. van Exel has left the B.C. Telephone Company to take up a new position with B.C. Engineering.

E. G. Craigen has retired from the position of electrical superintendent, Powell River Co. Ltd., Powell River, B.C.

H. E. Harlos, has announced that he has set up at 1398 West 73rd Ave., Vancouver, B.C., as consulting engineer for machine design. Mr. Harlos has been with Canadian Ingersoll-Rand Company and will continue to serve them on a consulting basis.

F. H. Chapman, of the Anglo American Corporation of South Africa, Northern Rhodesia, passed through Vancouver recently on a business trip, travelling in Canada and the United States. Mr. Chapman was executive-secretary of the Association in 1949 and dropped into the office to discuss the changing times.

A. C. Mullen, of the Powell River Company, formerly project engineer on the number nine paper machine and finishing room is now assistant plant engineer.

J. S. Goulding, also with the Powell River Company has been appointed project engineer, sulphite mill.

J. S. Ball, chief engineer of Shell Oil Company of British Columbia Limited has been promoted to the position of chief engineer of Shell Oil's refinery at Montreal, taking up his new work in July.

H. D. Dawson, municipal engineer of Saanich will retire at the end of this year.

E. L. Bartlett, assistant plant engineer, Columbia Cellulose Company, Prince Rupert, B.C. has been promoted to the position of mill engineer.

Allan Gall, recently joined Monarch Forge and Machine Works, Portland, Oregon, on leaving Letson and Burpee Limited of Vancouver.

R. G. Harvey, highway engineer, Nanaimo, has been appointed regional maintenance engineer for the department.

ONTARIO

Engineers in the News

Lieutenant Colonel William Alton of Ottawa, has been given the new appointment of Technical Staff Officer, Grade 1, in the Army's directorate of electrical and communications development at army headquarters in Ottawa. His earlier appointment was with the directorate of signals at the same headquarters.

D. E. Peatfield, of Montreal, has recently accepted the position of civil engineer for the newly formed project engineering group of Noranda Mines Limited. The first project of the group is the construction of a new tube mill for Noranda Copper and Brass Limited, at its plant in Montreal East.

J. A. Hansford, has been appointed supervising engineer on the Mid Canada Line of Bell Telephone Company of Canada, headquarters at Ft. McMurray, Alta.

Ronald C. Getty, is employed by B. Perini and Sons (Canada) Ltd., and is at present a project engineer for Can-Met Explorations Ltd., at Uranium Mine, near Blind River, Ont.

Joseph Dennis, of DuPont Company of Canada Limited, has been transferred from Kingston to the company's plant at Maitland, Ont., where he is technical development supervisor.

Robert E. Austin, field engineer for The Denison Engineering Company, Columbus, Ohio, is now the company's direct representative in Canada and is located at 70 Leisure Lane, Richmond Hill, Ont.

Mr. Austin, who is a Toronto graduate in mechanical engineering of 1944, joined The Denison Engineerng Company in 1954 and replaces the previous Canadian sales representatives for the company's line of multipresses.

W. R. Cantelon, is at Arvida, Que., with the Aluminum Company of Canada Limited. It is located at the company's ore plant No. 1. Prior to this move Mr. Cantelon was in Toronto and employed by Dominion Tar and Chemical Company as a project engineer.

W. M. Metcalfe, has been appointed town engineer of Brockville, Ont. He is located in the Victoria Building, Brockville. He graduated in civil engineering from the University of Toronto in 1949 and previous to undertaking his new responsibilities with the Corporation of Brockville, was on the engineering staff of the City of Peterborough.

G. O. Saunders, vice-president in charge of manufacturing, with the Canadian Locomotive Company Limited, Kingston, Ont., has been elected to the organization's board of directors. A graduate in mechanical engineering of Queen's University, Kingston, Mr. Saunders has been with the Canadian Locomotive Company since 1942 when he joined as assistant plant engineer.

Roy J. Brown. Announcement has been made of the appointment of Roy J. Brown, as vice-president in charge of engineering Moloney Electric Company of Canada Ltd., Toronto.

Mr. Brown took the test course of Canadian Westinghouse Company Ltd. He subsequently was on the staff of the department of electrical engineering at the University of Toronto and in 1941 was appointed an assistant professor. During the Second World War he was with the Canadian General Electric Company at its Davenport Works in Toronto. In 1944 he joined the Maloney Electric Company as chief engineer.

Eric A. Brown, of Polyfiber Limited, Renfrew, Ont., ahs been appointed vice-president in charge of sales and engineering.

Mr. Brown has been with Polyfiber Limited since its folmation in 1950.

Bernard W. Wittig, is works manager of B and W Precision Heat Treating Company, Kitchener, Ont.

Mr. Wittig graduated in metallurgy from Queen's University in 1944 and has been with the Morrow Screw & Nut Company of Ingersoll, Ont., for some time, latterly as metallurgical engineer.

S. A. M. Robertson has recently been appointed sales manager for the central district and the province of Ontario with Canadian General Electric Company Limited's motor and control department. His office will be at 1350 Castlefield Avenue, Toronto.

R. C. Satchell, has severed his employment with the Goodyear Tire and Rubber Co. of Canada Ltd. and has joined Hinde and Dauch Paper Company of Canada Ltd., 43 Hanna Ave., Toronto, where he is material handling engineer.

John A. Howard, has retired from Frost Steel and Wire Company Limited of Hamilton, where he was works engineer. Mr. Howard joined the company in 1918 and has been with it ever since.

W. Frank Sutherland. At the end of May 1956, W. Frank Sutherland, retired from the Toronto Hydro-Electric System, where he was director of industrial relations for the Commission, and is engaging in private professional practice.

Mr. Sutherland entered his engineering carreer in 1913 with Toronto Hydro and for a time was employed with the MacLean-Hunter Publishing Company on their technical trade papers as editor of "Power House", and with the Deloro Smelting and Refining Company as assistant chief engineer. He later returned to Toronto Hydro as chief designing engineer of the station construction department. During the thirties he engaged in economic research having to do with electricity supply and utilization, and in 1942 was assigned to industrial relations work of the system.

Mr. Sutherland has been a member of the Association since 1923 and for many years has been active in the affairs of the Association, particularly in respect to remuneration of the salaried engineer.

Leonard H. Harper, of Defence Construction (1951) Limited, has moved from Algoma Uranium Mines at Algoma Mills, Ont., to the RCAF Station at Uplands, Ont., where he is employed as assistant project engineer.

E. A. Sears, of Package Electric Company Limited, has been transferred from the company's Toronto office to the Vancouver office, 709 Dunsmuir St., Vancouver, B.C.

Gordon D. Campbell, has received the degree of Doctor of Philosophy from Purdue University, at LaFayette, Indiana, and is employed by the Canadian Good Roads Association, Ottawa, Ont. In this position he will act as Canadian observer on the $12 million test road to be constructed at Ottawa, Illinois; by the American Association of State Highway Officials and the Highways Research Board.

Mr. Campbell graduated in civil engineering from the University of Manitoba in 1951 and the following year obtained his Master's degree from Purdue University. Prior to proceeding on his doctorate work he was with the Trans-Canada Highway Division of the Resources and Development, Ottawa.

A. H. R. Smith, has been appointed a professor of engineering on the staff of the University of California, Los Angeles.

Prof. Smith is a graduate of the University of Toronto and following his graduation spent several years in the United States. From 1940 to 1942 he was with the National Research Council, spending much of this time in London, Eng., as a scientific liaison officer. On his return to Canada he became associate professor of electronics in the engineering faculty of Rutgers University at New Brunswick, N.J. and in 1943 began private consulting work in Ottawa.

H. F. Pragnell, has recently been appointed project engineer with the Eddy Match Company Limited, Pembroke, Ont.

Mr. Pragnell graduated from the Royal Military College, Kingston, Ont., in 1942 and in 1949 obtained his degree in civil engineering from McGill University. Since graduation he has been employed in construction and design work with the Foundation Company of Canada Limited, in Montreal, and in Chalk River, Ont.

K. C. Cox, of Toronto, has been elected to the board of directors of Dravo of Canada Limited, 159 Bay St., Toronto. Mr. Cox has been chief engineer of Dravo of Canada Limited since 1953 and previously had served with the company at Pittsburgh, Pa., for more than thirteen years in various capacities.

Mr. Cox graduated in civil engineering from Iowa State University in 1937 and two years later obtained his Master's degree at Lehigh University.

ALBERTA

Officers for 1956

President of the Association of Professional Engineers of Alberta for the term 1956-57, is J. G. Dale, of Northwestern Utilities Edmonton. Mr. Dale succeeds T. D. Stanley of Calgary Power Limited.

The office of vice-president is held by Dr. J. C. Sproule, Calgary.

Councillors whose terms expire in 1957 are E. H. Davis, Calgary, J. C. Neufeld, Lethbridge, and L. Schofield, Edmonton.

Holding office for two years are E. K. Cumming, Edmonton, K. F. Huff, Edmonton, Dr. D. R. Stanley, Edmonton, and L. C. Stevens, Calgary.

Terms expiring in 1959 are those of councillors J. W. Gregg Prof., of the University of Alberta, Edmonton, J. E. Poole, Edmonton, K. W. Mitchell, Calgary, and G. H. Sissons, of Medicine Hat, Alta.

Named Dominion Councillor was J. J. Hanna, Calgary; E.I.C. councillor, P. M. Sauder; and Faculty council representative, J. G. Dale, who will hold the two offices jointly.

Elected deputy registrar was L. Schofield of Edmonton while the office of registrar was accorded J. F. McDougall, of Edmonton.

A. E. McDonald is the 1956 choice of the Association as executive-secretary.

NEW BRUNSWICK

Election of Officers

Members of the Association of Professional Engineers of New Brunswick, for the session 1956-57 named D. R. Webb, Saint John, as their president, replacing D. J. Brewer, retiring from office. W. D. G. Stratton of Moncton will serve the Association in the capacity of vice-president, while the duties of secretary-registrar went to J. H. McKinney, resident of Saint John.

Chosen councillors for the district of Saint John were K. V. Cox, Lancaster, and L. O. Cass, Saint John.

Frederiction district representatives as councillors are R. E. Tweeddale, Bathurst, and C. E. Weyman, Fredericton.

F. K. Leighton and R. L. Parsons of Moncton were elected to serve that district, while P. G. Robinson was the Association's choice for Chatham district.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Tom Percival Strickland, M.E.I.C., of Melbourne, Australia, died in March, 1955. He was a former chief engineer of the Melbourne Tramways Board and one as an S.E.C. commissioner.

Mr. Strickland was born in Sydney, and on winning a science research scholarship, came to Canada for further study at McGill University. There he was awarded an M.Sc. degree in 1899.

Remaining in this country briefly, he was known in connection with the Charlottetown Sewerage Construction and the Dominion Iron and Steel Company. In 1902, once again in Australia, Mr. Strickland practiced engineering with the New South Wales Railways & Tramways. He remained in this work until 1921.

In 1938, Mr. Strickland went into private practice as a consultant, covering a wide range of engineering fields. He served in an honorary capacity on the council for Scientific and Industrial Research, and later, during the war, was a member of the Board of Business Administration.

He served as an S.E.C. Commissioner for a four-year period extending through the war years and into the post-war era and was concerned with plans for more extensive utilization of coal resources.

Mr. Strickland joined the Institute as a Student Member in 1898, transferred to Member in 1910, and was granted Life Membership in 1942.

C. W. Boast, M.E.I.C., chief engineer with the Spruce Falls Power and Paper Company Limited, at Kapuskasing, Ont., died May 23, 1956, at Sherbrooke, Que.

Mr. Boast was born at Richmond, Que., on December 25, 1893, and in 1917 attained a B.Sc. degree in civil engineering. For the next few years, he was concerned with varied civil and mechanical engineering projects in Canada and the United States, principally in design and construction of industrial buildings, concrete storage and power dams and materials handling equipment.

In 1921, first associated with the pulp and paper industry, he joined Orbison and Orbison, consultants of Wisconsin, to work on projects for Kimberley-Clark Corporation. In 1924 he joined the latter organization, at Neenah Wis. Two years later he was transferred to Spruce Falls Power and Paper Company Limited, at Kapuskasing, Ont. Appointed chief engineer early in 1945, he had been plant engineer for some time.

Mr. Boast was a member of the Board of the Sensenbrenner Hospital, having served in this capacity since 1929.

He was a member of the Association of Professional Engineers of Ontario.

On the Council of the Institute during 1954 and 1955, Mr. Boast joined the Institute as a student in 1917, transferred to Associate Member in 1922, and in 1940 was named a Member.

Jerzy Stanislaw Korwin-Gosiewski, M.E.I.C., former vice-president of Devoe Electric Switch Company Limited of Montreal, founder and first president of the Association of Polish Engineers in Canada, died on May 20, 1956, in Montreal.

Born in Poland, on October 5, 1886 he took a degree in mechanical and electrical engineering at the University of Mittweida, Saxony, Germany, in 1909.

His first work was the designing of small power stations and electrical installations.

From 1909 to 1915 he gained experience with the Siemens - Schuckert Werkes, a Warsaw firm, in the same type of work, having supervision over most of the important power projects built during that time in Poland.

J. S. Korwin-Gosiewski, M.E.I.C.

Concerned with electrification and modernization in the Donetz Basin, from 1915 to 1919, Mr. Korwin-Gosiewski was technical manager of a coal mine.

Later, forming an alliance with a French firm, represented in Warsaw, he was for an additional eight years, engaged in power installation work.

Joining the Swiss firm of Brown Boveri Limited, in Warsaw, he was appointed manager of two factories, and responsible for the manufacture of electrical machines and devices. Extensive technical studies marked this phase of his career with Brown Boveri in Switzerland, Italy, Germany and France. He remained with the firm until 1936.

In the brief years remaining before World War II, he held the office of president and general manager of the Zaklady Elektro Co. in Upper Silesia.

Among those evacuated by the Polish government to France in 1939, Mr. Korwin-Gosiewski worked there briefly until at the fall of France. He was moved to England, where in 1940 he became Adviser to the Polish government exiled in London.

In 1941, by that time located in Canada, he was employed with the Aluminum Company of Canada, at Montreal, in connection with the Shipshaw Development Project. Other appointments held within the next few years were those of works expert and supervisory engineer in the field of industrial engineering with George S. May Company, in 1943; chief industrial engineer with Fairchild Aircraft Limited Longueuil, Que., in 1944, and with H. V. Lea, consulting engineer in Ottawa.

Finally joining Devoe Electric Switch Company Limited, in Montreal, the firm with which he was to remain until the end of his career, he was in 1952 named general manager of the organization. Appointed vice-president in 1954 he held this position until illness forced him to relinquish it.

A member of the Corporation of Professional Engineers of Quebec and the Association of Professional Engineers of Ontario, he became a Member of the Institute in 1945.

William L. Waters, M.E.I.C., retired consulting engineer of Montreal and New York, N.Y., died on March 13, 1956.

Born in London, Eng., on September 7, 1877, Mr. Waters obtained his engineering training there. He attended London University, graduating in mechanical and civil engineering in 1898.

Embarking on his graduate career, Mr. Waters' first appointment was with the L. and S. Railway, London, Eng., from 1898 to 1901. At that time he moved to the United States where he gained employment with the National Brake and Electric Company, Milwaukee, as chief engineer. This association was of four years duration. In 1905 he left this work to become a consulting engineer with Westinghouse Air Brake, Canadian Westinghouse and Westinghouse Electric Manufacturing companies, at Pittsburgh.

However, in 1913, Mr. Waters entered private practice as a consulting engineer, which field he continued to serve throughout his career. He became known as a partner in the firm of Bury and Waters, consulting engineers of New York and London, England, with Sir George Bury, formerly a senior vice-president with the C.P.R.

Mr. Waters was a member of the American Institute of Electrical Engineers, the American Society of Mechanical Engineers and the American Society of Civil Engineers.

A Member of the Institute since 1918, he was elected a Life Member in 1949.

James Thomson Turnbull, M.E.I.C., retired district highway engineer for St. John Country, N.B., died at Red Head, N.B., on June 20, 1956.

Born in Paris, Ont., on April 22, 1884, he began his career with a period of railway service. Rodman and transitman with the Canadian Pacific Railway, he took part in location and construction revision, and the survey work done in the early days around North Bay, Sudbury, Cap Rouge, Grand'Mere and other eastern districts, and was for a time attached to the old Canadian Northern Railway.

From 1914 to 1926 he gained experience in various fields. In private practice with David R. Smith, surveyors and engineers, St. John, N.B., he was later associated with the St. John Drydock Company and from 1920 to 1926 worked with the City of St. John on a survey concerning the sewerage system. He also embarked on highway construction engineering with the St. John firm of G. G. Murdoch, workng on the Lancaster highway.

Appointed district provincial highway engineer in 1926, he continued to carry on his work in this capacity until his retirement in 1954, after twenty-eight years of service.

Mr. Turnbull accepted a temporary position as parish engineer with Simonds Parish, on a part-time basis in 1955.

A great supporter of the sport of curling, throughout his life, Mr. Turnbull was, as chairman of the building committee, instrumental in the erection of the Thistle Club curling rink in Portland Place, completed n 1947.

A charter member of the Association of Professional Engineers of New Brunswick, he was president of that body in 1939.

Mr. Turnbull joined the Institute in 1927 as an Associate Member, being transferred to Member in 1940.

George Bromley, M.E.I.C., consulting engineer in the firm of Kearns and Bromley, of Montreal and Wolfville, N.S., died on May 25, 1956.

Mr. Bromley, who was born in Petrograd, Russia, on March 1, 1916, received his early schooling both at King's School, Canterbury, Eng., and in rural Manitoba. In 1932 he entered the University of Manitoba, obtaining in 1936, a degree in electrical engineering.

Between that date and the beginning of his service with the R.C.N.V.R., in 1942, Mr. Bromley was associated with the Canadian General Electric Company test department at Peterborough, Ont., and Toronto, 1936 to 1938, the Aluminum Company of Canada, at Arvida, Que., from 1938 to 1940, and the Canadian Comstock Company, at Montreal and Halifax.

After the war, in 1945, Mr. Bromley joined A. D. Ross and Company, an electrical construction firm in Montreal, as a consulting engineer. The following year saw the formation of the firm of Kearns and Bromley, consulting engineers, in Montreal. By 1949 a branch office was in operation in Wolfville, N.S., where, for some time, Mr. Bromley had been carrying on his work.

He joined the Institute as a Member in 1946.

Lawrence Frederick Train, M.E.I.C., former sales engineer with Canadian Johns-Manville Company Limited in Toronto, died in June, 1955.

A native of Orillia, Ont., Mr. Train was born there on June 19, 1916. He attended the University of Toronto, graduating with a B.A.Sc. in metallurgical engineering in 1939.

With Canada Electric Casting Company Limited at Orillia, Ont., as a chemist, during part of his student days, he later joined the firm for a short time, on graduation, working as a metallurgist and sales engineer. In 1941 he was associated with John Bertram and Sons, and Pratt Whitney of Canada, Dundas, Ont., as a metallurgical engineer.

Named manager of the research department of Craig Bit Company, at North Bay, Ont., that year, he remained with the organization until 1948 when he became superintendent of the Toronto firm of Engineering Castings Limited.

In 1949, on joining the staff of Canadian Johns-Manville company limited, he was commodity manager, electrical refractory products. Later, as sales engineer in 1954 he held responsibility for industrial products sales within the Sarnia, London and Windsor area of Ontario.

Mr. Train became a member of the Institute in 1954.

Paul S. Cheese, JR.E.I.C., a member of the engineering staff of Molson's Brewery Limited in Montreal, died on May 18, 1956, in that city, following an accident.

Mr. Cheese was born in Montreal on October 14, 1921. He received his education at Westmount High School, Montreal, then served as a flying officer with the Royal Canadian Air Force during the second World War. He later attended McGill University, and in 1950 obtained a B.Eng. degree in chemistry.

For the past six years Mr. Cheese had been associated with Molson's Brewery Limited and at the time of his death held the position of assistant brewmaster with the company.

He became a Student Member of the Institute in 1948 and was transferred to Junior member in 1952.

Leonard Jasechko, JR.E.I.C., formerly special projects manager with Rogers Majestic Electronics Limited, Toronto, died on April 20, 1956, in that city, following a lengthy illness.

Born in Poland on April 13, 1920, and brought to Canada at an early age, he had his schooling at Kelowna, B.C., and at Hepburn, Sask. He attended normal school and then became a student of engineering at the University of Saskatchewan; in 1950 graduating with a B.Eng. degree in electrical engineering.

Within a short time Mr. Jasechko joined the staff of Rogers Majestic Electronics Limited, communication division, and in 1952 served in that position which he held when his untimely death occurred.

Mr. Jasechko joined the Institute as a Student in 1949. He was transferred to the status of Junior Member in 1952.

John J. Gorkoff, S.E.I.C., a University of British Columbia student who had completed two years study toward a degree in engineering, died in an accident on July 13, 1955, at Nelson, B.C.

Born at Brilliant, B.C., on Jan. 16, 1933, Mr. Gorkoff attended school at Blewett and Nelson, B.C., and then went on to further education at the university.

J. J. Gorkoff, S.E.I.C.

Combining engineering studies with an interest in diverse subjects, he was known also for his philatelic endeavors, and for his collection of material, in English and Russian, on a number of topics.

Mr. Gorkoff joined the Institute in 1952.

Minutes of the 70th Annual General Meeting

The seventieth annual general meeting of The Engineering Institute of Canada was convened in the Champlain Room of the Sheraton-Mount Royal Hotel, Montreal, on Wednesday, May 23, 1956, at ten thirty a.m. with President R. E. Heartz in the chair.

The president presented two communications, one a telegram extending best wishes from the president and council of The Royal Architectural Institute of Canada, and an air mail letter from Councillor-Elect R. F. Legget, of Ottawa, expressing his regrets at being unable to attend the meeting and conveying greetings and best wishes from the Institutions of Engineers in Australia and India and from the Institution of Civil Engineers of Great Britain.

The minutes of the sixty-ninth annual general meeting, as published on pages 964 and 965 of the July 1955 *Journal* were taken as read and approved.

Nominating Committee

The membership of the Nominating Committee of the Institute for the year 1956 is as follows:

Chairman ..... J. F. Harris, Toronto

Branch	*Representative*
Amherst	J. N. Ritchie
Belleville	C. R. Whittemore
Border Cities	C. G. R. Armstrong
Brockville	J. S. Waddington
Calgary	K. W. Mitchell
Cape Breton	G. W. Ross
Cent. Br. Columbia	R. L. Bigg
Corner Brook	H. B. Carter
Cornwall	B. T. Yates
Eastern Townships	Marcel Bourque
Edmonton	N. J. Allison
Fredericton	D. J. Brewer
Halifax	A. R. Harrington
Hamilton	N. A. Eager
Huronia	B. C. Lamble
Kingston	S. H. Rochester
Kitchener	A. J. Girdwood
Kootenay	W. K. Gwyer
Lakehead	W. Donald MacKinnon
Lethbridge	E. A. Lawrence
London	D. M. Jenkins
Lower St. Lawrence	Marcel Lanouette
Moncton	G. E. Franklin
Montreal	R. F. Shaw
Newfoundland	G. E. Knight
Niagara Peninsula	C. G. Cline
Nipissing and Upper Ottawa	J. Millar
North Nova Scotia	R. S. Morrow
North Eastern Ontario	C. R. McIntyre
Northern New Brunswick	G. P. Milton
Ottawa	T. Foulkes
Peterborough	B. Ottewell
Port Hope	W. S. Raynor
Prince Edward Island	
Quebec	Jean St. Jacques
Saguenay	O. Gislason
Saint John	H. P. Lingley
St. Maurice Valley	A. H. Watier
Sarnia	J. W. Graeb
Saskatchewan	Allan Tubby
Sault Ste. Marie	R. A. Campbell
Sudbury	R. L. Snitch
Toronto	C. D. Carruthers
Vancouver	W. O. Richmond
Vancouver Island	Jack Alton
Winnipeg	T. E. Storey
Yukon	H. L. Meuser

Honorary Memberships

The general secretary reported that the following had been elected to honorary membership in the Institute and that certificates would be presented at the annual banquet of the Institute on May 25:

Clarence Ebenezer Davies, M.E., D.Eng., Secretary, American Society of Mechanical Engineers, New York, N.Y.

Albert R. Decary, M.B.E., D.Sc., formerly Superintending Engineer, Province of Quebec, Department of Public Works, Quebec, Que.

Francis William Gray, LL.D., formerly Assistant General Manager, Dominion Steel and Coal Corporation, Victoria, B.C.

James Alexander McCrory, B.Sc., (Mech.), D.Sc., Engineering Consultant, Shawinigan Engineering Company, Montreal, Que.

Harold Wilson McKiel, B.Sc., LL.D., Vice-President, Mount Allison University, Sackville, N.B.

Awards of Medals and Prizes

The general secretary announced the various awards of the Institute as follows stating that the formal presentation of these would be made at the annual banquet on May 25th.

Julian C. Smith Medals—"For achievement in the development of Canada"; to Howard Kennedy, M.E.I.C., consulting engineer, Ottawa, Ont.; and to Adrien Pouliot, M.E.I.C., dean of the Faculty of Science, Laval University, Quebec, Que.

Duggan Medal and Prize—"For papers dealing with the use of metals for structural or mechanical purposes"; to joint authors Georges F. Welter, M.E.I.C., professor, and Julien Dubuc, JR.E.I.C., associate professor, Ecole Polytechnique, and Thomas A. Monti, M.E.I.C., consulting engineer, Montreal, for their paper "Fatigue Life of Steel I-Beams at Normal and Sub-Zero Temperatures".

Leonard Medal—"For papers on mining subjects"; to Franc R. Joubin, consulting engineer, Toronto, Ont., for his paper "Uranium Deposits of the Algoma District".

Plummer Medal—"For papers on chemical or metallurgical subjects"; to Morris Katz, M.E.I.C., consultant, atmospheric pollution, Occupational Health Division, Department of National Health and Welfare, Ottawa, Ont., for his paper "The Nature, Distribution and Dispersion of Contaminants in the Urban Environment."

Ross Medal—"For papers on electrical engineering subjects"; to George William Holbrook, M.E.I.C., head of the Department of Electrical Engineering, Royal Military College of Canada, Kingston. Ont., for his paper "Design of a Wide Audio Band".

John Galbraith Prize—"For the best paper by a Junior in the Province of Ontario"; to Hendrik Jan Saaltink, JR.E.I.C., engineer, hydraulic dept., H. G. Acres and Company, Niagara Falls, Ont., for his paper "In the Wake of Hurricane Hazel".

Phelps Johnson Prize—"For the best paper by an English Junior in the Province of Quebec"; to Roderick Roy Real, JR.E.I.C., post-graduate student at McGill University, Montreal, Que., for his paper "Over the Hill and Line of Sight".

Report of Council, Report of Finance Committee, Financial Statement and Treasurer's Report

Mr. Dunsmore, vice-president, and chairman of the Finance Committee, pointed out that the complete report and financial statement were in the annual report of Council, copies of which had been distributed at this meeting.

These reports were complete in themselves but he pointed out that substantial amounts had been put into reserves during the year. These reserves have been invested conservatively and the Institute was in an excellent position.

On the motion of W. B. Pennock, seconded by H. C. Bates, it was resolved that the report of Council, the report of the Finance Committee, the financial statement and the treasurer's report be accepted and approved.

Reports of Committees

Speaking on the matter of committee reports, the president stated that he wanted to thank the members of every committee for the splendid work they had done throughout the year. Some of the most important work done by the Institute was done through the committees, and Council was greatly indebted to them.

On the motion of R. E. Hayes, seconded by T. Foulkes, it was resolved that the reports of the following committees be taken as read and accepted: Admissions, Board of Examiners, Life Members' Committee, Professional Interests, the Young Engineer, Employment Service, Prairie Water Problems, Library Report, Library and House, Papers, Publication, Legislation, Membership, Report of Field Secretary, Ontario Division, Canadian Chamber of Commerce and the Canadian Standards Association.

Branch Reports

On the motion of C. D. Carruthers, seconded by Norman Ursel, it was resolved that the reports of the various branches be taken as read and approved.

Committee on Confederation

At the president's request, Dr. I. R. Tait, chairman of the Institute's Committee on Confederation, presented a summary of his report. He explained that the same report had been presented the day previously to the meeting of Council and to the branch officers conference, and had been approved unanimously by both groups.

Dr. Tait explained further that a copy of the complete report had been sent in advance of the meeting to every member of Council so that he would be familiar with it when it came up for discussion at the annual meeting of the Council.

Dr. Tait inquired as to whether or not there were any questions from the audience. The president explained that before any final form of agreement would be agreed upon it is likely there would be several changes and adjustments.

Mr. Johnston of the Saguenay Branch inquired about branch fees. Dr. Tait replied that that angle of the subject would have to be given further study before a fixed recommendation could be made.

Mr. Paterson of Toronto, proposed that the meeting should express an opinion either for or against the report so that Dr. Tait's committee would know where they stood.

Mr. Ross of Sydney, stated that he felt the meeting had full confidence in the committee and in the Council of the Institute. He thought excellent progress had been made considering how difficult the issues were.

Mr. Paterson moved that this annual general meeting endorse the action taken by Council with regard to confederation. This was seconded by Mr. J. W. Macdonald of Halifax, and approved unanimously.

Election of Officers

The general secretary presented the list of the newly elected officers of the Institute as follows:

President

V. A. McKillop, London, Ont.

Vice-Presidents

H. R. Sills, Peterborough, Ont.
G. M. Dick, Sherbrooke, Que.
H. W. L. Doane, Halifax, N.S.

Councillors

Vancouver Branch	E. L. Hartley
Edmonton Branch	H. L. Roblin
Lethbridge Branch	James M. Campbell
Calgary Branch	W. A. Smith
Saskatchewan Br.	J. B. Mantle
Winnipeg Branch	R. T. Harland
Sault Ste. Marie Branch	D. C. Holgate
North Eastern Ontario	G. G. M. Eastwood
Huronia Branch	H. C. Bates
Hamilton Branch	L. C. Sentance
Kitchener Branch	Wm. R. Roberts
Niagara Peninsula Branch	Paul E. Buss
Toronto Branch	W. M. Huggins
Peterborough Br.	A. J. Bonney
Ottawa Branch	R. F. Legget
Cornwall Branch	John M. Hawkes
Montreal Branch	Roger Brais
	C. E. Frost
	H. A. Mullins
Quebec Branch	C. H. Boisvert
Northern New Brunswick Br.	R. C. Eddy
Moncton Branch	M. F. K. Leighton
North Nova Scotia Branch	D. J. MacNeil
Halifax Branch	O. Nelson Mann
Cape Breton Br.	J. R. Wallace
Sarnia Branch	R. A. McGeachy

The president congratulated the newly elected officers and wished them every success in their arduous duties during the coming year.

Dr. Ira P. Macnab took much pleasure in expressing the thanks not only of this meeting but of all the members of the Institute all over Canada for the work which has been done by the president, vice-presidents and councillors during the past year. He had some knowledge of the magnitude of the work that had been accomplished and he moved a hearty vote of thanks to Dr. R. E. Heartz, the retiring president, to the retiring vice-presidents and councillors and to all other members of the Institute for the work which had been done. Dr. D. M. Stephens seconded the motion which was carried unanimously.

Having some idea of the enormous amount of work involved, particularly in view of the tremendous growth of the Institute in the past few years, Dr. H. W. McKiel wished to add his own personal appreciation and thanks for the contribution which the retiring Council has made. He felt that he could speak also for all members of the Institute.

Dr. Heartz thanked them all for their kind remarks, not only personally but on behalf of the retiring officers without whose strong support it would have been impossible for him to have carried on with what had turned out to be a strenuous year. It had been a pleasure and an honour to serve the Institute and he hoped that those who carry on will have the same enthusiastic and loyal support which he had had.

The meeting adjourned at eleven forty-five a.m.

Presentation at McGill University

"What's the matter with old McGill!" The president calls on the principal. Left to right: R. E. Jamieson, dean of engineering, R. E. Heartz (president 1955-56), and Dr. Cyril F. James, principal of McGill.

The Institute's prize was won this year by Robert L. Wright, S.E.I.C., who is shown receiving it from the past president while Dean Jamieson (left) and John J. Gillman, S.E.I.C., (right) look on.

Personals

News of the Personal Activities of Members of the Institute.

D. E. Blair, M.E.I.C. Retired recently as consulting engineer with Montreal Transportation Commission is D. E. Blair, long-time transit worker, and one-time president and general manager of the Montreal Tramways.

Mr. Blair has worked a total of fifty-three years with Montreal Street Railway, Montreal Tramway Company and the Montreal Transportation Commission.

A native of the province of Quebec, he completed studies at McGill University and then spent six years in the service of the Quebec District Railway and the Quebec Railway, Light, Heat and Power Company.

In 1903 the Montreal Street Railway named him assistant general superintendent. Other appointments which followed were those of superintendent of rolling stock, general superintendent and general manager.

In 1942, remaining as general manager, he became vice-president of the Montreal Tramways Company. Seven years later, in 1949, he retired from these positions but remained with Montreal Tramways Company in a consulting capacity, when the Montreal tramways Company property was acquired by the Montreal Transportation Commission.

In the earlier days of the city's growth, in 1928, Mr. Blair was active in the organization of and work of the Montreal Metropolitan Planning Board.

A past president of the Canadian Railway Club and the Canadian Transit Association, he holds life membership in the Corportion of Professional Engineers of Quebec, and the Engineering Institute. Mr. Blair joined the Institute in 1904 as an Associate Member, in 1927 transferred to Member.

D. E. Blair, M.E.I.C.

Charles E. Garnett, M.E.I.C., has been re-elected to office as chairman of the Board of Great Northern Gas Utilities Limited, and Plains Western Gas Utilities Limited. He is also president and managing director of Gormans Limited and the Edmonton Elevator Service Limited.

Mr. Garnett has been prominent in activities of the Canadian Chamber of Commerce in Alberta. He is a past-president of the Association of Professional Engineers of Alberta, a past-chairman of the Edmonton Branch of the Engineering Institute and a past vice-president of the Canadian Institute of Mining and Metallurgy.

R. F. Legget, M.E.I.C., director of the Division of Building research of the National Research Council of Canada, has been named a Fellow of the Royal Society of Canada.

Mr. Legget graduated from the University of Liverpool in 1925 and in 1927 he received the degree of master of engineering from the same institution.

He came to Canada in 1929, and was engaged in heavy construction engineering until 1936, when he joined the staff of Queen's University. He went to the University of Toronto in 1938, remaining there as associate professor and consultant on soil and foundation problems until 1947. He was then invited by the National Research Council to start the new Division of Building Research, of which he has been director since that time.

R. F. Legget, M.E.I.C.

Mr. Legget was elected an Honorary Fellow of the Royal Architectural Institute of Canada in 1953 and is a Fellow and Councillor of the Geological Society of America. He is a member of the Institution of Civil Engineers and the American Society of Civil Engineers.

J. M. M. LaForest, M.E.I.C., assistant engineer recently retired from the National Harbour Board, after forty-three years' work at the Port of Montreal.

Shortly after graduation in civil engineering from Queen's University in 1913, Mr. LaForest joined the Harbour Commission of Montreal as an engineer's assistant.

Assigned to the Department of Munitions, Ottawa, during the first World War, he was deputy inspector for the manufacture of fuses and cartridges in Canada. He also saw a term of duty as

J. M. M. LaForest, M.E.I.C.

liaison officer in London between the British War Mission and the inspection department of the Ministry of Munitions. This duty kept him in London until after the war.

Returning to Monreal in 1920 he immediately took charge of the construction of the cold storage warehouse at the port, which was finished two years later. In 1922 he became resident engineer, taking part in the major development of the waterfront. The appointment of assistant was conferred in 1947.

Mr. LaForest's work at the Port of Montreal brought him into contact with

various agencies such as the Shipping Federation, the railways and navigation companies, the City of Montreal, and adjoining municipalities.

M. McMurray, M.E.I.C., previously sales manager of Dominion Bridge Company Limited's Ontario Division in Toronto, has been given the head office appointment of assistant to the vice-president and managing director.

Mr. McMurray is a metallurgical engineering graduate of the University of Toronto. At the beginning of his career, a demonstrator in mining engineering, he joined Dominion Bridge in 1940, shortly after graduation, and spent the next five years as a metallurgist and chief inspector of munitions. Since then he has held a number of positions in the fields of engineering, production and sales.

In 1954 Mr. McMurray received a Master of Commerce degree in Business Administration from the University of Toronto.

He is a member of the council of the Engineering Institute and a past-chairman of the Toronto Branch.

H. F. Finnemore, M.E.I.C., chief electrical engineer since 1945, with the Canadian National Railways in Montreal, has recently retired.

On recieving a bachelor of science degree at the beginning of World War I, he joined the Canadian Engineers.

Demobilized in 1918, he spent the next five years with the Canadian Government Railways. It was in 1923 that he went to the Canadian National Railways mechanical department in Montreal. He eventually became chief electrical engineer.

Mr. Finnemore has been actively engaged in the development of electric motive power and installations, and the introduction of air-conditioning on the Canadian National passenger euqipment.

He served the Engineering Institute for several years on the Library and House Committee, and was a member of the Council from 1948 to 1950.

H. R. Finnemore, M.E.I.C.

M. McMurray, M.E.I.C.

Dominion Bridge Appointments

P. E. Savage, M.E.I.C., formerly erection manager of Dominion Bridge Company Limited's eastern division has received the head office appointment of assistant to the vice-president and managing director.

Mr. Savage graduated from McGill University in 1934, with a M.Eng. degree in civil engineering. Awarded a Strathcona Memorial Fellowship he also carried out advance studies at Yale University. He was employed with Dominion Bridge Company while still a student, and in 1934 joined the structural design department of the organization at Lachine. Since then he has been associated mainly with the engineering and erection departments.

Robert Chambers, M.E.I.C., for nineteen years a member of the staff of Shawinigan Engineering Company Limited in Montreal, has transferred his services to the B.C. Engineering Company Limited in Vancouver. His position is that of assistant superintendent of construction.

Mr. Chambers was last year named superintendent of power developments in the construction division of the eastern company. He has over the years done extensive work in surveying and in the design and construction of transmission lines.

He is a University of Alberta graduate.

Dr. D. B. Steinman, M.E.I.C. The famous Brooklyn Bridge, built in 1869-1883 by Roebling in the days of "horse and buggy" traffic and reconstructed 1950-1953, by Dr. D. B. Steinman, with wider roadways for modern highway traffic, has been honoured by the American Institute of Steel Construction with a special artistic bridge award as "A pre-eminent example of the adaptability of the steel bridge" to expanding traffic needs.

An international authority on design and construction of long-span bridges, Dr. Steinman has been identified with 300 bridges on five continents. He has received international honours and decorations from 12 countries.

P. E. Savage, M.E.I.C.

E. A. Ford, M.E.I.C.

E. A. Ford, M.E.I.C., whose name appeared in a recent list of head office appointments in the Dominion Bridge Company Limited, at Lachine, Que., has been named assistant to the vice-president and managing director.

Mr. Ford has, since 1952, been engaged as a contract eng'neer with the Western Division of the firm in Winnipeg.

Following a 1927 graduation from the University of Manitoba, he joined Dominion Bridge as draughtsman. He has spent most of his business life with the company's western division, in manufacturing and sales.

W. C. Wilkinson, M.E.I.C., resident of Australia for the last five years, has accepted a position with the Amalgamated Television Services Party Limited, in Sydney, Australia. He will undertake the duties of senior television engineer.

Mr. Wilkinson, who studied at the University of New Brunswick gained a degree in electrical engineering and then spent more than ten years in the communications field in Canada. He held the position of transmitter development engineer with the Canadian Marconi Company in Montreal for four years. During the war, he was with the National Research Council in Ottawa as research en-

*There's been a Revolution in Rubber

Why Is POLYSAR Used The World Over?

Why is Polysar specified by manufacturers in every continent? Because *there's been a revolution in rubber. Now . . . with Polysar *chemical* rubbers and the help of Polymer's research technicians . . . manufacturers are able to offer products with the superior qualities needed to meet today's exacting requirements.

Whether rubber now enters into your products or not, it will pay you to inquire about the possibilities of Polysar. You'll find—as have manufacturers in 40 countries—that Polysar rubbers can greatly improve present products and enable you to create new ones.

Polymer Corporation Limited—makers of Polysar rubbers—has the largest research and development division in Canada. You are invited to make full use of these facilities.

Write to our Sales and Technical Service Division, Sarnia, Canada.

Here's Why POLYSAR Rubber Is Used In Oil Seals

Manufacturers of oil seals and many other products specify Polysar Krynac rubbers because they give the best balance of good processibility, low-temperature properties, oil resistance, and physical properties. For different product needs and applications, Polysar Krynacs are available in four oil-resistant types.

Polysar rubber has improved oil seals—it can improve your products, too.

gineer. He was named vice-president and chief engineer of the Wired Radio Company of Canada Limited, from which company he resigned in 1946.

Mr. Wilkinson has also been associated with the Department of Transport in Ottawa, working in conjunction with the Radio Interferences Section. He was with the Snowy Mountain Hydro Electric Authority in Australia in 1950.

L. Pallas, M.E.I.C., now residing in Bermuda, is resident engineer of Castle Harbour Hotel, Bermuda, B.W.1.

In 1953 he was general superintendent of the North York and York Incinerator in Toronto.

He is a member of the Institution of Electrical Engineers of Britain.

A. J. Nowakowski, M.E.I.C., has been at work for some time in the experimental department of Canadair Limited, Montreal. He was formerly associated with the Dominion Engineering Works Limited, at Lachine, Que.

Mr. Nowakowski is from the Polish University College of London, Eng., class of 1950.

John Bathurst, M.E.I.C., a University of London, Eng., graduate, class of 1947 who has been living in Victoria, B.C. for some time, has left his position with the Department of Public Works, Province of British Columbia. He has joined the federal Department of Transport in that city.

K. C. Martin, M.E.I.C., has joined the staff of the Canadian British Aluminum Company Limited at Baie Comeau, Que., where his position will be that of divisional engineer.

A McGill University graduate, class of 1950, he was formerly associated with the Department of Public Works of Canada in Charlottetown, P.E.I.

W. A. Marshall, M.E.I.C., has been elected a director of Canada Iron Foundries, Limited. Mr. Marshall is president of Dominion Structural Steel Limited.

A graduate of Queen's University class of 1937, in civil engineering, he was with the Dominion Structural Steel Limited at an early date, employed as designing and detailing engineer and estimator. Apart from five years service with the R.C.E.M.E., during World War II, he has been continually associated with the company.

W. A. Marshall, M.E.I.C.

A. B. Yates, M.E.I.C., was elected chairman of the Yukon Branch of the Institute for the year 1956-57.

A. B. Yates, M.E.I.C.

Mr. Yates, whose home is England, first went to the North West Territories in 1950, as a regular officer of the Royal Engineers, British Army, on exchange to the Canadian Army. He was posted as assistant highway superintendent, Whitehorse.

In 1953 he obtained a discharge from the service and took up residence in the Yukon as a technical officer, works department, with H.Q., N.W.H.S., at Whitehorse.

With the Royal Engineers from 1942 to 1953 he saw extensive war service, then later enrolled in engineering studies at London University. In 1950 he received a B.Sc. degree.

Frank A. Ross, M.E.I.C., has accepted a position as assistant to the manager, power equipment sales department, with the Amalgamated Electric Corporation Limited, in Toronto.

Former professional associations held in Canada by Mr. Ross include those with BepCo Canada Limited, in Montreal, where he was assistant chief estimator, and with the British Elecrical Company of Canada Limited, also in that city.

J. G. Dale, M.E.I.C., has been elected president of the Association of Professional Engineers of Alberta.

Mr. Dale, a native of British Columbia, received his engineering degree from the University of Alberta in 1934. He immediately joined North-western Utilities Limited and has remained with the firm to the present time. Among his various appointments with the firm are those of combustion engineer in 1946, and utilization engineer and chief salesman, the following year. In 1953 he was named to his present position of manager of sales and service.

Mr. Dale first joined the Association of Professional Engineers of Alberta in 1941. Two years later he was named registrar and served the organization in this capacity until 1947. The following year he was chosen as Councillor which office he filled for four consecutive years. In 1952 he became the Association representative at the Faculty of Engineering Council, University of Alberta, and continues as such. Previous to his

J. G. Dale, M.E.I.C.

election as president this spring, he was the 1955 choice as vice-president.

Stuart S. Lefeaux, M.E.I.C., was elected chairman of the Vancouver branch of

S. S. Lefeaux, M.E.I.C.

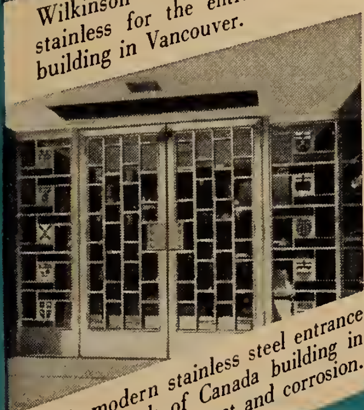
the Institute for the term 1956-57.

Born at Victoria, B.C., he attended

Entrance to the Fairbanks-Morse building in Winnipeg.

The rich, neutral luster of the metal contributes to handsome architectural effects as illustrated in the Albert G. Baker Limited building in Quebec City.

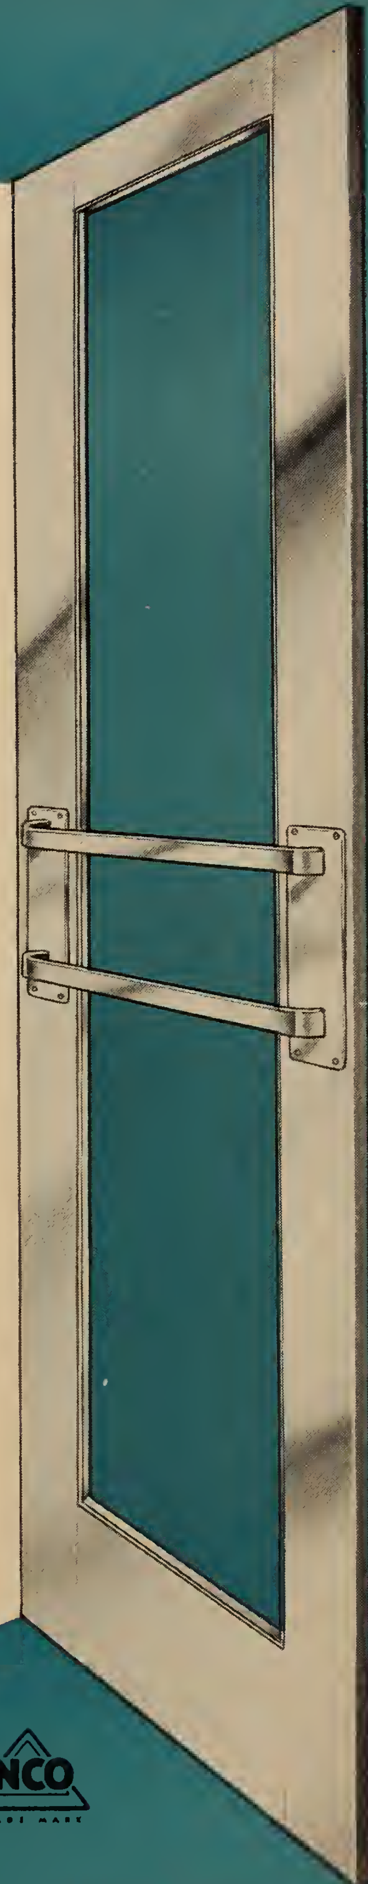
Wilkinson Company Limited chose stainless for the entrance to their building in Vancouver.



This modern stainless steel entrance to the Bank of Canada building in Winnipeg resists rust and corrosion.

From coast to coast... entrances to be proud of...

...with nickel-containing stainless steel



THE RICH, NATURAL BEAUTY OF STAINLESS IS LONG LASTING—ECONOMICAL TO MAINTAIN

Architects and designers have found that stainless steel is an enduring construction material that does not deteriorate with age and exposure. Stainless is easy to keep clean, cuts maintenance time and costs. But, above all, stainless steel is a decorative material that gives buildings grace and dignity . . . pleasing and unobtrusive beauty.

South Burnaby High School in Vancouver, and went on to the University of British Columbia where he graduated with a B.A.Sc. in civil engineering in 1945.

A short career with the Royal Canadian Engineers followed. Prior to this Mr. Lefeaux had spent his summers with the Department of National Defence on airport construction in British Columbia.

He joined the Board of Park Commissioners, Vancouver, in October 1945 as assistant superintendent of parks and has continued in this work to the present time. He has, since then been named deputy superintendent and engineer.

Mr. Lefeaux is a Fellow in the American Society of Park Executives and a member of the Association of Professional Engineers of British Columbia.

With the Vancouver Branch of the Institute he was for two years Branch News Editor and also served as Secretary to the organization for two years.

E. W. R. Butler, M.E.I.C. The appointment of vice-president of the Bailey Meter Company, Montreal has gone to E. W. R. Butler, formerly assistant manager with the firm.

E. W. R. Butler, M.E.I.C.

Mr. Butler joined the organization in 1924, shortly after graduating from McGill University, and held the position of manager of the firm's Winnipeg office from 1928 to 1952.

A. L. Stewart, M.E.I.C., has been named president of the Bailey Meter Company Limited in Montreal following recent elections within the company.

A. L. Stewart, M.E.I.C.

With the firm since 1921, Mr. Stewart has held the position of vice-president and manager since 1928.

He is a graduate of the University of Toronto and a member of the Corporation of Professional Engineers of Quebec.

Lt.-Col. W. Alton, M.E.I.C., who has spent five years with the Directorate of Signals, Army Headquarters, Ottawa, was

"My reputation is at stake"

"...just can't afford slip-ups"

"...it's my job to choose the right subcontractors"

Another engineer realizes there is no substitute for know-how. So—like many others these days—he plays safe and calls in Eastern Steel. Whenever a blueprint indicates a piece of equipment that needs to be custom-fabricated in sheet metal or steel plate, it is only natural to insist on complete assurance that any sub-contractor selected is fully equipped to do a satisfactory job. Accuracy is vital, of course, but you also require delivery on the appointed date—and a *competitive price*. Eastern Steel can satisfy you on all three counts.

We have recently completed orders for such diversified products as transformer casings, steel breechings, and smoke stacks, tote boxes, underground storage tanks, bins and hoppers, and oil loading racks.

recently appointed technical staff officer, grade I (TSOI) in the Army's Directorate of Electrical and Communications development, D.E. and C.D.

He is a graduate of Queen's University, Kingston.

P. L. Strigner, M.E.I.C., holds the position of assistant research officer with the National Research Council, Ottawa.

Last year Mr. Strigner was refinery chemist with Trinidad Leaseholds (Canada) Limited, at Port Credit, Ont.

He is a 1949 graduate of Queen's University.

Milton MacRitchie Uloth, M.E.I.C., has been elected chairman of the Peterborough Branch of the Institute.

Originally from Nova Scotia he was born in New Harbour and had his schooling there and at St. Mary's College, Halifax. Proceeding on to the Nova Scotia Technical College he was in 1942 awarded a B.Eng. in electrical engineering.

Immediately joining the Canadian General Electric Company in Peterborough, Ont., he attended the test course. Afer a year in design engineering he saw service with the Directorate of Electrical Engineering, R.C.N.V.R.

He returned to design engineering at the end of the war, and held several engineering assignments in Peterborough and Quebec City. Mr. Uloth is supervising engineer in the motor and generator division of Canadian General Electric Company, Peterborough.

M. M. Uloth, M.E.I.C.

C. S. Phelps, M.E.I.C.

C. S. Phelps, M.E.I.C., of Sarnia, Ont., is chairman of that Branch of the Institute for the term 1956-57.

Born in Sarnia, educated there and at the University of Toronto, he obtained a Bachelor of Science degree in 1934.

Following graduation he joined the Canadian General Electric Company Limited on a students test course and served the company in various head office divisions until 1942. At that time he became associated with the Canadian Kellog Company Limited on construction of the Polymer Corporation Limited.

• PERSONALS

He was for some time assistant electrical engineer at the steam and power plant, and was later promoted to electrical engineer of the Polymer plant.

In 1949 Mr. Phelps joined the Sarnia Hydro Electric System as assistant manager. His present appointment as manager dates to 1952.

A. M. H. Norris, M.E.I.C., is service contract engineer with the Central Mortgage and Housing Corporation, Camp Gagetown Project at Oromocto, N.B.

A native of London, England, and former student of the London Polytechnic class of 1949, he came to Canada in 1953, and was for a time engaged as senior engineer with Jaques Price, consulting civil engineer, in Windsor, N.S. He also held a position with Central Mortgage and Housing Corporation in Fredericton, N.B.

Ralph M. Ferguson, M.E.I.C., latterly of Trail, B.C., where he was employed in the design office of the Consolidated Mining and Smelting Company, is now in Lethbridge, Alta. He is associated with the firm of Meech, Mitchell, Robins and Associates, architects and engineers and is engaged in structural engineering.

Mr. Ferguson was also known in Calgary where he was on the staff of Dominion Bridge in 1955.

He is a graduate of the University of Alberta, class of 1946.

S. A. Milner, JR.E.I.C., has left the Inland Natural Gas Company Limited in British Columbia to take on the duties of executive vice-president of the Canadian Chieftain Petroleums Limited in Edmonton.

Mr. Milner, a graduate of the University of Alberta, class of 1951, was with Perforating Guns of Canada, shortly after receiving his degree. He was with the Inland Natural Gas Company in Vancouver in 1953, and later became construction field superintendent with the organization.

James Anderson Aitken, JR.E.I.C., has been taken on the staff of the National Steel Car Corporation Limited at Hamilton, Ont.

He is a graduate of the University of Manitoba, class of 1950, in mechanical engineering.

Mr. Aitken is known in Montreal where he was associated with Combustion Engineering Corporation Limted, which firm he joined in 1951.

John Kurelek, JR.E.I.C., is employed with Standard Tube and T. I. Limited, Woodstock, Ont.

He is a graduate of the University of Manitoba, class of 1951, and has been associated with the Northern Engineering and Supply Company Limited in Fort William, Ont., at an earlier date.

Roland Collins, JR.E.I.C. has accepted employment as construction engineer with Canadian Petrofina Limited in Montreal.

He has been associated with the Defence Research Board at Valcartier, Que., in 1952, in the year following his graduation from Laval University in chemical engineering, and later, in 1953 was design engineer with the Board in Carde, Que.

W. W. Serrick, JR.E.I.C., a 1952 graduate of McGill University in civil engineering, has taken on the duties if Public Health engineer with the Province of Newfoundland, at St. John's, Nfld.

Mr. Serrick was previously employed with the Water and Sewerage Corporation of Greater Corner Brook, at Corner Brook, Nfld.

G. W. Easter, JR.E.I.C., has moved from Shawinigan Falls, Que., to North Bay,

Ont. He has joined Du Pont Company of Canada Limited in works concerned with the production of commercial explosives. His position is that of process control and development supervisor.

Mr. Easter was formerly with Canadian Industries Limited. He is a graduate of the University of Toronto, class of 1949.

J. Raymond Roy, JR.E.I.C., who was appointed assistant Trade Commissioner, Department of Trade and Commerce, Ottawa, in October 1955, he received a posting to Brussels where he will serve as assistant commercial secretary with the Department's Foreign Trade Service.

A graduate of the University of New Brunswick in electrical engineering, class of 1952, Mr. Roy has since then, as winner of a Rhodes scholarship, been engaged in studies at Oxford University.

In 1955 he was awarded a B.A. degree in the Honour School of Philosophy, Politics and Economics.

Before leaving Canada for his position abroad, Mr. Roy carried out an in-

J. R. Roy, JR.E.I.C.

tensive three month cross-Canada tour of industry.

J. M. Watson, JR.E.I.C., has been appointed sales representative for the Montreal office of the Permutit Company of Canada Ltd. Mr. Watson is a graduate of McGill University where he received his degree in chemical engineering. After

J. M. Watson, JR.E.I.C.

graduation in 1950 he joined the Permutit Company, working out of their Montreal office in an assistant capacity.

He is a member of the Corporation of Professional Engineers of the Province of Quebec.

Jean C. Garneau, JR.E.I.C., with A. Janin Company Limited in Montreal in 1955,

we'll soon be bagging 'em with both barrels!

now serves the company in Kenogami, Que., where a hydro-power development is underway for Price Brothers.

Mr. Garneau's professional experience has included work with the Quebec Department of Roads, and with the firm of A. Jolill Company Limited, in Montreal.

He is a McGill University graduate, class of 1953.

C. Rex Burke, JR.E.I.C., a 1953 graduate of the Nova Scota Technical College is working with Defence Construction (1951) Ltd., as zone engineer at Camp Gagetown, N.B.

He was formerly with the civil service at H.M.C. Dockyard, Halifax, N.S., employed as a civil engineer.

David A. Foster, JR.E.I.C., has been transferred by the Canadian National Railways from Norwood, Man., to Moncton, N.B., where he will fill the position of mechanical engineer for the Atlantic Region. He is a 1951 graduate of the University of British Columbia.

L. H. Harper, JR.E.I.C., in 1955 associated with the Algoma Uranium Mines, at Algoma Mills, Ont., has accepted the position of assistant project engineer with Defence Construction (1951) Limited at the R.C.A.F. Station, Uplands, Ont.

He is a Queen's University graduate in civil engineering, class of 1951. Shortly after obtaining his degree he was associated with Gore and Storrie, consultng engineers, in Toronto.

D. W. Murray, JR.E.I.C., works in the capacity of design engineer with the Montreal Engineering Company Limited, Montreal. He has recently been located in Edmonton.

Winner of a fellowship for study abroad, he gained an M.S. degree in civil engineering at the University of London, Eng. in 1954.

Mr. Murray obtained his first degree in engineering from the University of Alberta, class of 1952.

L. H. Fransen, JR.E.I.C., who graduated with the class of 1952 in civil engineering from the University of British Columbia, is at work in the North West Territories. He holds the responsibility of assistant branch superintendent of maintenance at Con Mine in that locality.

J. B. Woods, JR.E.I.C., is with Canada Iron Foundries Limited at Oakville, Ont.

Formerly at Lynden, Ont., he was also known in engineering circles in Hamilton, Ont. in 1953, where he was employed as a sales engineer with Gartshore, Thomson Pipe and Foundry Company.

A civil engineering graduate from Queen's University, he obtained his degree in 1951.

W. E. Boresky, JR.E.I.C., has joined the staff of Swan, Wooster and Partners in Vancouver. He was formerly structural draftsman with H. A. Simons Limited in that city, and earlier was junior engineer with the Int. Pacific Salmon Fisheries in New Westminster.

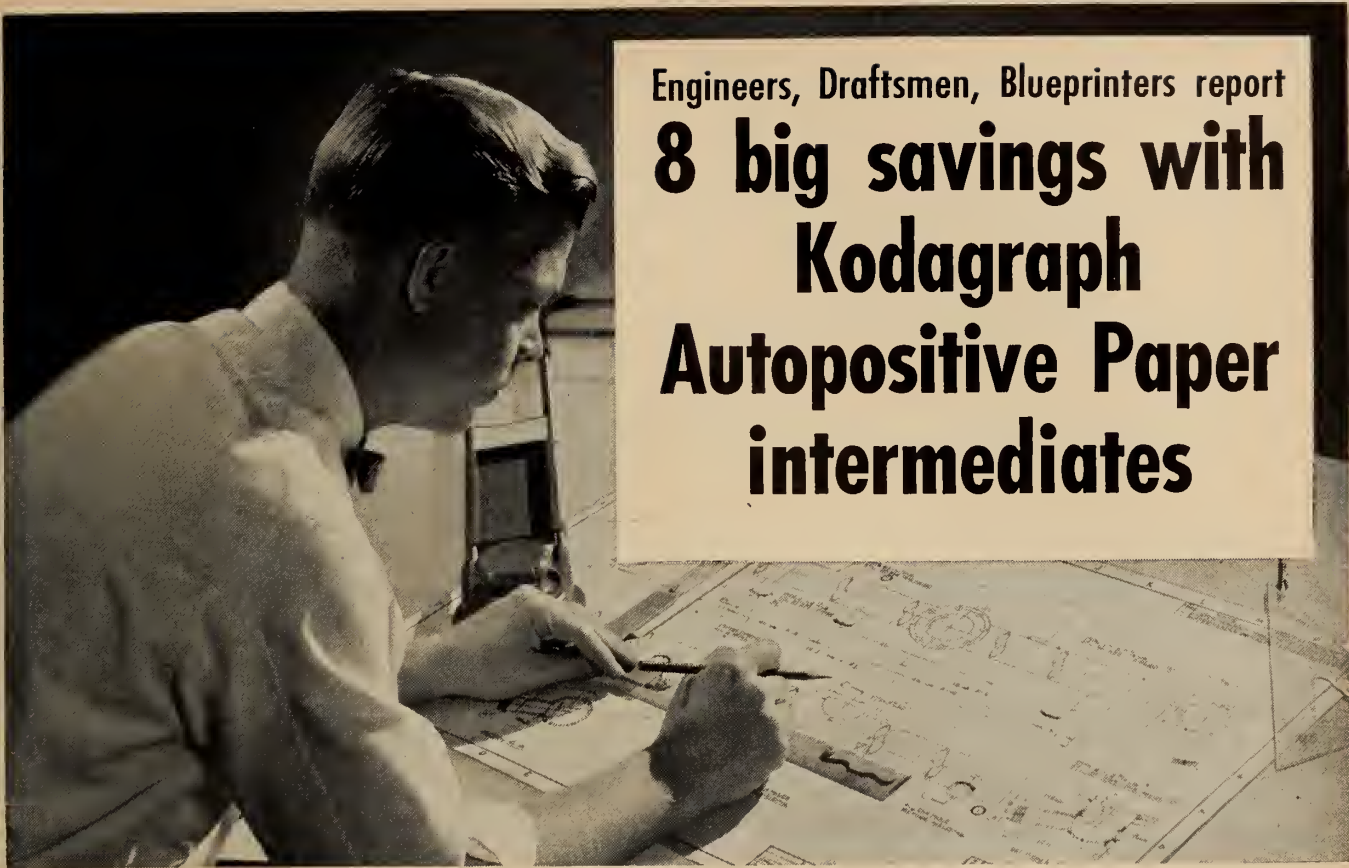
He is a 1953 graduate of the University of British Columbia in civil engineering.

A. M. Ibrahim, JR.E.I.C., a 1953 graduate of the University of Alberta, employed with the Department of Highways in Picture Butte, Medicine Hat and Edmonton in 1955, has been transferred to the town of Olds, Alta.

Colin B. Fairn, JR.E.I.C., formerly at Port Hastings, N.S., in connection with his work as engineer on the Strait of Canso lock, has accepted a position with Pentagon Construction Company Limited a Iroquois, Ont. He will be project engineer on the lock and canal.

Mr. Fairn is a Nova Scotia Technical College graduate of 1952.

William Bobbie, JR.E.I.C. Resigned recently from his position as plant engi-



Engineers, Draftsmen, Blueprinters report

8 big savings with Kodagraph Autopositive Paper intermediates

Revolutionary **Kodagraph Autopositive Paper,** which produces positive photographic intermediates *without a negative step or dark room handling,* brings these savings to drafting rooms large and small.

1. Protects original drawings. Low-cost Autopositive Paper intermediates are used instead of valuable originals in printmaking, reference, mailing, and making revisions.

2. Reclaims drawings which are old, worn, or soiled. Reproducing them on Autopositive Paper cleans up backgrounds, strengthens line detail . . . eliminates redrafting.

3. Improves legibility of prints. Blueprints or direct-process prints made from Autopositive Paper intermediates are consistently easier to read than prints made from original drawings.

4. Reproduces "unprintable" originals. When extra copies are needed of blueprints, drawings on opaque stock, two-sided originals, and other "unprintables," just reproduce them on Autopositive Paper *and you have your printmaking masters.*

5. Speeds revisions of drawings. A popular short cut is to cut out or eradicate detail on an Autopositive Paper intermediate . . . and then add the new detail to this print or one made from it.

6. Eliminates redrafting standard component designs. From a file of standard component designs made on Kodagraph Autopositive Film, select the ones needed and attach to drawing form with translucent tape. Then reproduce on Autopositive Paper, add new detail and the job is done.

7. Simplifies print distribution. Instead of shipping bundles of production prints, send Autopositive Paper intermediates. Mailing costs are saved. Required number of prints can be made at other end. No overstocking this way . . . or running short of prints.

8. Provides photo-lasting copies. Autopositive Paper intermediates, with dense black photographic lines on a translucent white paper base, will not turn yellow or become brittle in the files; will produce sharp, legible prints whenever needed.

Kodagraph Reproduction Materials

"The big NEW PLUS in engineering drawing reproduction"

- **Kodagraph Autapasitive Paper Extra Thin** for high-quality photographic intermediates at lowest cost.
- **Kodagraph Autopositive Film** for very fast printing intermediates of highest quality.
- **Kadagraph Autapositive Paper Translucent** for faster printing, more durable easier-to-revise intermediates.
- **Kadagraph Contact Paper Translucent** for fast-printing durable, very high-quality intermediates.
- **Kodagraph Repra-Negative Paper** for black-line intermediates from negative-type originals.

neer with Dunlop Canada Limited in Whitby Ont. He has accepted an appointment as industrial engineer with B. F. Goodrich Canada Limited, at Kitchener, Ont.

Mr. Bobbie, a University of Toronto graduate, was at one time associated with Plibrico Jointless Firebrick Limited, at New Toronto and with the Goodyear Tire and Rubber Company of Canada Limited, at that address also.

W. E. Currie, JR.E.I.C., has been transferred by the DuPont Company of Canada from the Kingston works to Montreal. In his new appointment he holds the position of equipment buyer in the purchasing and traffic department.

He is a mechanical engineering graduate of Queen's University, class of 1952.

B. J. Ferries, S.E.I.C., a University of Manitoba graduate in mechanical engineering, class of 1955, joined the staff of the Amalgamated Electric Corporation Limited, in Winnipeg early in 1956.

D. E. Eby, S.E.I.C., who was among the electrical engineering graduates of the University of Manitoba, class of 1955, has gained employment in Toronto. He is a junior engineer-in-training with the Ontario Hydro-Electric Power Commission.

John D. Brunt, S.E.I.C., is employed as a management trainee with the American Can Company of Canada Limited in Simcoe.

He received a B.Sc. degree in mechanical engineering at Queen's University this spring.

Garland Laliberte, S.E.I.C., a 1956 graduate in agricultural engineering from the University of Saskatchewan is with P.F.R.A., at Vauxhall, Alta. His work is in connection with the drainage division.

A. R. Black, S.E.I.C., a 1955 engineering graduate from the University of Toronto, has accepted an appointment with B. Perini and Sons Canada Limited, at Spragge, Ont. He is at work on the Consolidated Denison Mine Project.

Keith S. Preston, S.E.I.C., a University of New Brunswick graduate in mechanical and civil engineering, class of 1954 and 1955, has been taken on the staff of the Montreal Engineering Company Limited. He holds the position of power plant engineer.

Claude Hotte, S.E.I.C., a 1955 graduate of the Ecole Polytechnique is with Lachute Lumber and Millwork Limited, Lachute, Que.

Gerald C. Burtt, S.E.I.C., who was among the graduates of the University of New Brunswick, class of 1955, in civil engineering, has accepted a position with the Corporation of the City of Ottawa. His duties are those of assistant roadways engineer with the department of planning and works.

Bernard Roy, S.E.I.C., of Laval University, class of 1956, in civil engineering, is with Perini Quebec Inc., in Montreal.

Mr. Roy is employed in the capacity of training engineer.

K. Linn MacDonald, S.E.I.C., a 1956 graduate from the University of Manitoba, and winner of the University Gold Medal, has found employment with the Ontario-Minnesota Pulp and Paper Company. He is located at Fort Francis, Ont.

W. L. Sharpe, S.E.I.C., a 1955 graduate in engineering and business from the University of Toronto, joined the staff of the Aluminum Company of Canada, at Arvida, Que., early this year working at the caustic-magnesium plant.

In the June issue, personals section, it was wrongly stated that **H. Frymann**, M.E.I.C., had been appointed chief electrical engineer with the St. Lawrence Cement Company in Quebec City. The Journal wishes to make it clear that Mr. Frymann is, instead, chief mechanical engineer and head of the mechanical department at the company's new headquarters, Clarkson, Ont.

Activities of the Forty-Seven Branches of the Institute and abstracts of the papers presented at their meetings

KINGSTON

D. I. OUROM, JR.E.I.C.
Secretary

Prof. S. D. Lash

Preservation of scenic beauty along Highway 33 from Collins Bay to Adolphustown was the subject of a brief presented by Prof. S. D. Lash at the annual meeting of the Kingston Branch.

The affair which took the form of a dinner and dance was held at the Royal Electric and Mechanical Engineers Officers' mess. More than one hundred persons were in attendance.

Guests, visitors and wives were welcomed by chairman Professor A. V. Corlett, who also gave a brief account of the activities of the organization throughout the past year.

Annual Report

E. C. Reid presented the annual report, stating that membership now totalling 217 members had given rise to eight well attended meetings during the year. The sum of $200.00, to be received by the branch is to be used in furthering the interests of the E.I.C. among the undergraduates of the Royal Military College and Queen's University.

I. H. Jenks, of Aluminium Laboratories, winner of the Plummer Medal for the best paper in metallurgical and chemical subjects published in the Engineering Journal, accepted the award from Col. L. F. Grant.

Officers elected for the forthcoming year were: Chairman, Col. C. W. Jones; vice-chairman, E. C. Reid; executive, J. W. Dolphin, W. B. Rice, S. D. Lash; secretary-treasurer, D. I. Ourom.

Branch News Editor

Field Trip

A very successful field trip to the manufacturing plant of Boyles Bros. Drilling Company in Vancouver was attended by about 40 members and friends of the Vancouver Branch on June 20, 1956.

Mr. P. Bland, vice-president of the Branch, made all arrangements with plant manager J. W. Booth, of the company and all phases of bit and drilling machine manufacture were seen by the visitors.

Diamonds

Ungraded industrial diamonds in large quantities are sorted, weighed and positioned in carbon molds. A copper alloy is melted in the mold to fix the diamonds in position and for the diamond bit. An interesting feature was that bits worn in service are returned to the plant, the diamonds dissolved out and again sorted and reused. The bit customer only pays for the labour and diamond wear.

Drilling

Drilling machines are made in all sizes to suit all purposes and an extensive machine shop shapes the required gears and other parts. The complete assemblies are shipped to all parts of the world.

The procedures in core drilling were described with the various devices used to determine and change the direction of the drilling at depths up to a mile. A drill can be directed over almost any route.

Diamond drills are used only for core drilling whereas the majority of drilling is done for blasting and for this purpose Throw-Away-Bits are used. The Boyles Company manufactures these bits and the process was observed from the stock

Colonel L. F. Grant is shown presenting the Plummer Medal to I. H. Jenks.

MONTREAL · TORONTO · CALGARY · VANCOUVER to the finished bit. These bits are shipped by the thousand to all parts of the world, since their efficient manufacture in Vancouver makes them competitive in all markets.

For engineers not dealing with drilling problems, the field trip was an eye-opener and will permit the more intelligent reading of mining reports. The Boyles Company, including Mr. P. B. Hall, its president, were thanked for their courtesy and tour organization.

Inspection of the Duwamish bascule bridge at Seattle by Vancouver Branch members. This visit was reported in the July issue. In this group: Ed. Greathouse and Hanford Thayer, Seattle. Frank Culp, project engineer, with Hubert Lillie, A. eebles, and T. F. Hadwin of the Vancouver Branch.

WINNIPEG

Electrical Section

W. H. DICKINS, M.E.I.C., *Reporter*

Final Spring Meeting—May, 1956

For the final spring meeting, the Electrical section, Winnipeg, inaugurated what it is hoped will become an annual event. An informal social evening and smorgasbord for engineers and their ladies was held at the Assiniboine Hotel on May 30th. An invitation was extended to all members of the E.I.C., A.I.E.E. and I.E.E. In spite of the lateness of the season, approximately 100 people were present, half of whom were ladies.

W. K. Brasher—Guest Speaker

A distinguished guest, W. K. Brasher, secretary of the Institution of Electrical Engineers of Britain, was present. Mr. Brasher gave an informal but very informative talk on the shortage of engineers and an account of what steps are being taken in Britain to remedy the shortage. A film, "The Enquiring Mind," was produced by the Institution of Electrical Engineers, with the express purpose of attracting youth to electrical engineering. The film outlines the progress of electrical engineering through the centuries and gives an excellent presentation of the careers and opportunities available in the industry.

• BRANCH NEWS

Engineering Education

A discussion period followed, in which Mr. Brasher gave an outline of methods of engineering education in Britain, where two means of arriving at professional engineering status are employed.

a) 3 or 4 years university and following graduation, 2 years of practical and/or specialized training in industry.

b) A new scheme, whereby a youth graduating from high school may spend 6 months in practical factory training alternated with 6 months in college, for a total of 5 years.

This latter scheme is a development of the Higher National Certificate courses, which Mr. Brasher indicated had served a useful purpose in the past, but which offered limited study hours.

Mr. Brasher was in possession of up-to-date factual information on engineering education methods in Soviet Russia, a number of his colleagues having recently returned from that country. Mr. Brasher said that it must be admitted that the Russians were oudistancing the western nations in numbers of technical men and that he was afraid they were surpassing the western nations in quality also. While there was no outright direction of Soviet youth into engineering, the inducements offered were considerable. An engineer in Russia enjoyed an outstanding financial and social position and for this reason the most promising young people tended to gravitate towards engineering. Mr. Brasher hoped to visit Russia later this year.

The ladies present were intrigued at the sight of a number of women engineering students shown in the film. Mr. Brasher regretted to tell them that out of the total institution membership of some 40,000 only 70 were women. However, their training schemes were open equally to girls and boys.

Mr. Brasher was a most accomplished speaker and was obviously thoroughly familiar with his subject. The discussion period was lively and had in fact to be halted for lack of time.

Following Mr. Brasher's talk, the film "Power and Passage," produced by the Canadian General Electric Company Limited, was shown. This was an interesting and most informative film on the St. Lawrence Seaway.

New fertilizer plant to meet growing needs

These are a few of the companies with whom Canadian Kellogg has worked—

British American Oil Company Ltd.
Canadian Oil Companies Limited
Canadian General Electric Co. Ltd.
McColl-Frontenac Oil Company Limited
Nova Scotia Light & Power Company
Babcock-Wilcox & Goldie-McCulloch

Even the rich Canadian prairie lands must be fertilized to be farmed efficiently and to produce the maximum yields per acre. Soon the new Northwest Nitro-Chemicals Limited fertilizer plant will take natural gas from the prairies of Western Canada and manufacture it into fertilizers for our Western farmers. Canadian Kellogg has been assigned the responsibility of designing, engineering and constructing the ammonia plant and other important sections of this large facility.

Based on its vast experience and background in the petro-chemical industry, Kellogg can now offer four basic processes for producing ammonia, the starting point for manufacturing most nitrogen bearing fertilizers. These four basic processes can utilize a variety of gas, refinery off gas, crude oil, coke oven gas and other hydrogen bearing materials. A booklet on these processes will be sent on request. Your inquiries on ammonia and other petro-chemical or petroleum projects are invited.

Uniform Traffic Control

At the request of the Institute, W. D. Hurst, M.E.I.C., attend the special meeting of the Joint Committee on Uniform Traffic Control Devices for Canada, sponsored by the Canadian Good Roads Association and the Canadian Section of the Institute of Traffic Engineers, held at the Royal Alexandra Hotel in Winnipeg on May 7, 1956. This is his report of the proceedings. Editor.

Philippe Ewart, traffic engineer, Department of Highways, Province of Quebec, was the chairman pro-tem of the meeting and Jacques Barriere, JR.E.I.C., was the secretary pro-tem.

Between 30 and 40 persons attended the meeting, representing various levels of government, industry, and various technical associations.

The chairman explained that the meeting had been called under the sponsorship of the referenced bodies to discuss the possibilities of the joint sponsoring of a manual for uniform traffic control devices for Canada, similar to the one in existence in the United States. For this purpose a joint committee was to be set up consisting of not more than 40 persons from the following groups:

Provincial Governments (one representative each)
Federal Department of Public Works (one representative)
Cities of Vancouver, Ottawa, Hamilton, Toronto, Winnipeg, Regina, Edmonton, Calgary, Montreal, Quebec and Halifax (one representative each)
Canadian Good Roads Association (five representatives)
Canadian Section of the Institute of Traffic Engineers (five representatives)
Engineering Institute of Canada (one representative)
Canadian Highway Safety Conference (one representative)
Canadian Standards Association (one representative)
Conference of Commissioners of Uniform Legislation in Canada (one representative)
Royal Canadian Mounted Police (one representative)
Association of Chiefs of Police (one representative)
Board of Transport Commissioners (one representative)
American Association of Motor Vehicle Administrators (one representative).

The next question arising was, who would set the necessary machinery in motion: Should it be a federal body like the Canadian Standards Association, or, should the CGRA, together with the Institute of Traffic Engineers (Canadian Section) be the sponsoring bodies? In any event it was very important to have this work commenced at once because the Province of Ontario had just finished a manual on traffic control devices. This manual, followed generally the U.S. manual, but departed from it in some respects, and before the manual had received complete acceptance it was desirable to have a uniform policy across Canada.

It was ascertained from the meeting that generally speaking the United States manual was widely used in British Columbia, Alberta, Saskatchewan and Manitoba and the Maritime Provinces; but it had not come into general acceptance either in Ontario or Quebec. After some extended discussion it was decided that the CGRA and the ITE (Canadian Section) should sponsor the manual.

It was decided that the Joint Committee as constituted should remain but that an executive committee should be set up with the responsibility of preparing the manual in the next 18 months.

The following were selected for the executive committee:

Co-chairman: W. Q. Macnee, Ontario Department of Highways, and Philippe Ewart; Editor: H. F. Bruns, JR.E.I.C., A. D. Margison and Associates Limited, Toronto; Associate Editor: Jacques M. Barriere, JR.E.I.C., city traffic engineer, Montreal; Secretary, R. A. Draper.

At this point the joint meeting went into executive committee session and Mr. Macnee assumed the chair.

The appointment of sub-committees was discussed, and it was suggested that the following working subcommittees be set up: Signs, Markings, Signals, Islands, Research (a continuing sub-committee), Translation, Editing.

Chairmen and secretaries for these committees were to be selected preferably from central Canada in order to facilitate the work. The chairmen asked that regional representatives supply lists of suitable technical personnel for membership in the various subcommitees. The subcommittees would then be selected by the executive committee.

Following is a list of chairmen and secretaries:

Signs. chairman, R. B. Campbell, Ontario Department of Highways; vice-chairman, J. O. Martineau, M.E.I.C., Department of Roads, Quebec; secretary, Lucien Delisle, Dept. of Roads, Quebec.

Markings: chairman, J. R. Walker, Toronto Parking Authority; secretary, Larry Forrester, Ontario Dept. of Highways.

Signals: chairman, Samuel Cass, Metropolitan Toronto; secretary, W. W. Rankin, traffic engineer, Ottawa.

Islands: chairman, John Connolly, Department of Roads, Quebec; secretary, W. Biddel.

Research: chairman, Allan K. Hay, M.E.I.C., Canadian Good Roads Association; secretary, H. M. Edwards, M.E.I.C., Queen's University.

French Language: chairman, Jacques Barriere, JR.E.I.C., traffic engineer, Montreal; secretary, Lucien Delisle.

Editing: Chairman, H. F. Burns, M.E.I.C., A. D. Margison and Associates Ltd., Toronto; secretary, E. F. Gillies, M.E.I.C., Minnesota Mining and Manufacturing Company, Toronto.

It was decided that the next meeting of the Joint Committee would be held on Friday, October 5, 1956, in Quebec City at the time of the annual meeting of the Canadian Good Roads Association.

CEA Meets at Murray Bay

The annual convention of the Canadian Electrical Association was held at the Manoir Richelieu, Murray Bay, Que., June 18-20, 1956 with a total attendance of 616. A. C. Abbott, vice-president, distribution, Shawinigan Water and Power Co., Montreal, was elected president of the Association for the year 1956-57. V. A. Ainsworth, of Newfoundland and J. C. Dale of Edmonton were re-elected vice-presidents. N. T. Smith of Halifax was also elected a vice-president.

CEA President J. A. Pagé told delegates Canadians used more power last year than ever before. Generating capacity at 13.9 billion kilowatts, was 41 per cent more than in 1951. The estimated percentage change from 1955 to 1959 is 39 per cent and from 1951 to 1959, 96 per cent. Firm energy requirements in 1955 were 72.633 billion kilowatt hours, which, it is forecast, will reach 101.508 billion kilowatt hours by 1959, an increase of nearly 40 per cent.

Current planning of new projects still centered largely on hydro, he stated, with central electric stations expecting to spend some $634 million on capital growth this year.

The solid base for Canada's competitive position would always be hydro

power, he predicted. No 'breakthrough' was expected by nuclear scientists that would make obsolete any efficient hydro development. The big question mark was the role atomic energy would play. Nuclear fired plants would not cut the cost of electricity in half; it would replace the boiler end, but investment in that kind of equipment was only 13 per cent of the total.

While industrial Canada might have to pause to catch up with proposed plant expansion in late 1956 and in 1957, Canada's future growth would always depend on the ability of its electric utilities to provide the power and energy needed in sufficient quantities at the right time and place, he concluded.

A. C. Abbott, M.E.I.C., President

Enough Hydro Power for Next Fifteen Years

Addressing delegates at the first afternoon session, McNeely DuBose, M.E.I.C., president, Saguenay Power Co. Ltd., speaking of Our Heritage of Water Power, pointed out that this heritage was a great one, but it was largely behind us. Remaining sites would be more expensive to develop. Today coal burning plants use one pound or less of coal per kilowatt hour compared with three pounds thirty years ago. Coal at the mine was now cheaper than it was seven years ago, due to increased output with improved machinery.

If Canada's present rate of increase in energy production continued, another ten years would see half of our undeveloped water potential used up, provided it could still undersell steam power, he pointed out. A further five years would bring us almost to the end of our hydraulic resources.

We must therefore give consideration to atomic fuel and atomic boiler plants. Those in the newsprint, metal reduction or heavy chemicals industries may continue to advantage to follow elusive water power to more remote sites, but even these would be keeping their eye on steam, he added. "Let us not be caught napping, lulled by the complacency we cannot help but feel as a result of our heritage of water power."

New Farval spray panel lubricates gearing automatically, efficiently, inexpensively

FARVAL—
Studies in Centralized Lubrication
No. 183

HERE'S how to do a better job of greasing gears and save a lot of lubricant and labor besides. Just install Farval Spray Valves. They can reduce oil and grease consumption and oiling labor as much as 95%. Then you can throw away the oil can and grease bucket, and put your oilers on other constructive work.

Shown at right is a new Farval Spray Valve System developed for large-diameter wide-faced gears. Installed on a panel mounted on the gear housing are Dualine valves, spray valves and reversing valve. An automatic air-operated barrel pump supplies the lubricant.

Farval Spray Valves are completely flexible as to arrangement and operation. They can be used alone or as part of a Dualine System—wherever a supply of compressed air is available. As with standard Dualine valves, the spray can be operated as often or as infrequently as needed to deliver any desired amount of oil or grease, on gears, sliding bearing surfaces or other areas needing lubrication. There is no waste or mess. Quantity of air used is limited to the exact amount required to spray each delivery of oil or grease.

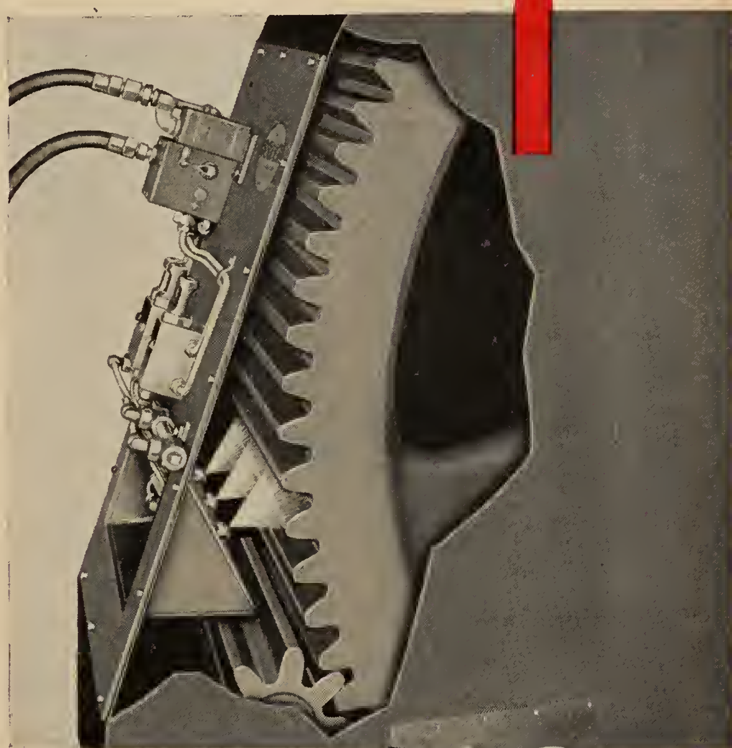
Hundreds of Farval Spray Valve Systems are now in use in many industries. Why not investigate this simple, inexpensive method for your own plant equipment? Tell us the type of gearing or machines for which you would consider automatic spray lubrication. One of our field representatives will be glad to recommend the Farval system best suited to your needs. Write for Bulletin 26-R. Peacock Brothers Limited, P. O. Box 1040, Montreal 3, Quebec. Branch offices in Sydney, Toronto, Sudbury, Winnipeg, Edmonton, Calgary and Vancouver.

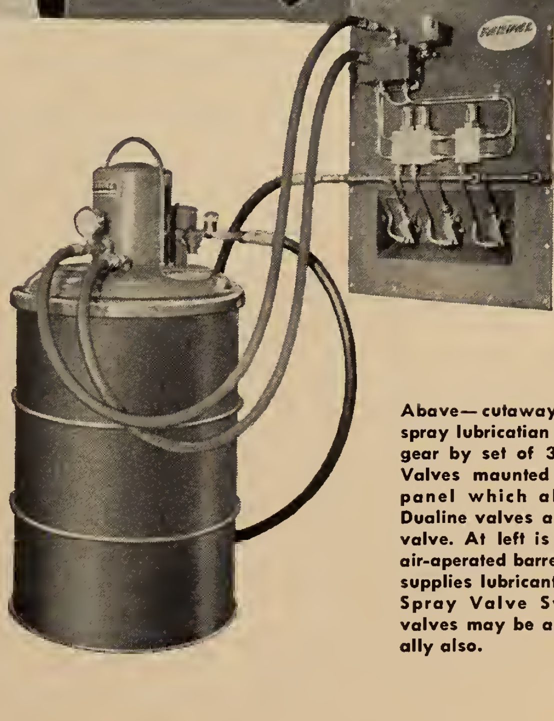
FARVAL CENTRALIZED SYSTEMS OF LUBRICATION

Sold in Canada by . . .

TRADE MARK REG'D.

PEACOCK BROTHERS LIMITED





Above—cutaway view shows spray lubrication of wide-faced gear by set of 3 Farval Spray Valves mounted on a special panel which also carries 3 Dualine valves and a reversing valve. At left is the automatic air-operated barrel pump which supplies lubricant to the Farval Spray Valve System. Spray valves may be operated manually also.

• NEWS OF OTHER SOCIETIES

During a CEMA panel discussion chaired by CEMA president H. M. Turner at the morning session the third day, John J. Deutsch, secretary to the Treasury Board, Department of Finance, Ottawa, spoke on The Position of the Electrical Manufacturing Industry in the Canadian Economy. Describing recent developments in Canada with a view to indicating the extent of the opportunities available and the progress achieved, he pointed out that gross value of output of electrical manufacturing industry had increased fourfold over that period, compared with two and a half times for the manufacturing industry as a whole.

Turning to the future, he predicted the role of electrical manufacturing would be one of the most vital in our economy. Its products were both producer equipment and consumer appliances, through which our huge resource of energy is put to use. Thus the industry held the key to the increasing productivity of the economy. Canada, he warned, must remain fully abreast of developments and changes in the technique of production, through a more general application of automatic and electronic devices, in order to maintain our competitive position.

Mr. Deutsch was followed by Walter Gilson, president, Eastern Power Devices, and O. W. Titus, vice-president and general manager Canada Wire and Cable Company.

While utilities usually operate by franchise, the manufacturing business did not lend itself so readily to any broad monopoly type of operation, Mr. Gilson pointed out. During the past two years Canadian electrical manufacturers had made an average net profit after taxes of 3.1 per cent on total sales.

During the past decade the industry had been meeting a 17 per cent per annum increase in demand production but had been running into steadily lowering net profits. An average net profit not less than 4½ per cent on production must be achieved to maintain a favourable financial climate for adequate growth. In this case, the utilities undoubtedly should have an enlightened self interest in the financial welfare of the manufacturers. The utilities and the electrical manufacturers were partners in the electrical business in Canada, he said, and as such had many mutual responsibilities.

That Canada must decide whether the nation's trading policy should be based on disposal of primary products and products of extractive industries, or upon a closer internal balance between manufactured and non-manufactured products, and between manufactured imports and exports, was declared by Mr. Titus. Manufacturing, he pointed out, was the area into which the greatest amount of population growth must move for a livelihood.

While early U.S. expansion was materially aided by foreign capital, this was mainly by debt financing, so that the ownership remained in the U.S. To a much greater extent present Canadian policies were resulting in equity financing by foreign capital, so that ownership would remain permanently outside of Canada. He suggested Canadian companies should be permitted to make such profits as would enable them to retain control of their equities in Canadian industry while expanding their facilities.

National Forestry Conference

The National Forestry Conference to be held in Winnipeg, September 17-19, 1956, will be sponsored by the Canadian Chamber of Commerce, the Canadian Institute of Forestry, the Canadian Forestry Association, and The Engineering Institute of Canada.

Some of the highlights of the program are as follows:

Welcome by the Lieutenant Governor of Manitoba, J. S. McDiarmid.

Theme address: Forestry in Canada's Economy, by Chairman Walter L. Gordon of the Royal Commission on Canada's Economic Prospects.

Address by The Hon. Jean Lesage, minister, Department of Northern Affairs and National Resources.

Discussion: The Outlook by the Forest Industry, by R. M. Fowler, L. R. Andrews, W. J. Leclair.

Discussion: Forest Protection (stressing Public Education); The Provincial Forest Protection Outlook, presented by speakers from Newfoundland to British Columbia; a panel and open forum on How Can Forest Conservation be Most Clearly Shown to the Canadian Public?

Papers: Youth Education, by W. F. Myring, Alan Beaven, W. G. Mackie, and J. A. Breton; Tree Farmers, by Gordon Godwin.

Royal Commission Forestry Summaries, statements and briefs.

Banquet. The speaker, Rt. Hon. Louis St. Laurent.

Secretary of the program committee is J. L. Van Camp, secretary, Canadian Forestry Association, 4795 St. Catherine St. West, Montreal 6, Que.

Calendar

The Federation of Sewage and Industrial Wastes Associations (4435 Wisconsin Ave., N.W., Washington 16, D.C.) have arrangements complete for the 29th annual meeting at Los Angeles, California, October 8-11, 1956.

The third International Technical and Industrial Exhibition will take place in Charleroi, Belgium, Setpember 20 to 30, 1956.

The American Public Health Association (1790 Broadway, New York City) will hold the 84th annual meeting, and meetings of 40 related organizations at Convention Hall, Atlantic City, N.J., November 12 to 16, 1956.

The Chemical Institute of Canada (18 Rideau Street, Ottawa 2) will hold two meetings in September 1956: s symposium of the organic chemistry division, a Guelph, Ont., Sept. 6-7; and the third western regional conference, Edmonton, Alta., Sept. 13-15.

The Community Planning Association of Canada (77 Maclaren Street, Ottawa 4) announces the 1956 national planning conference for October 29-31, 1956, at the Chateau Laurier, Ottawa.

There will be a Canadian convention of the Institute of Radio Engineers in Toronto, on October 1,2,3, 1956.

Information can be obtained from the convention manager, 745 Mount Pleasant Rd., Toronto 12, Canada.

The Institution of Electrical Engineers (Savoy Place, London W.C. 2) has announced a convention on ferrites to be arranged by the committees of the Radio and Telecommunication and Measurement and Control Sections of the Institution during the week beginning October 29, 1956.

Six sessions will deal with such subjects as: theory preparation and properties of ferrites, microwave applications, square loop applications, radio and television applications and carrier frequency applications.

The tenth session of the International Geological Congress, will be held in Mexico from September 4 to 11, 1956.

Information can be obtained from the general secretary of the executive committee, Balderas 36-302 A, Mexico 1, D.F.

There will be a meeting of the American Institute of Chemical Engineers (25 West 45th Street, New York 36) in Baltimore, Maryland, Lord Baltimore Hotel, September 15-18, 1957.

The Institution of Engineers, Australia, (Gloucester Street, Sydney) has extended to E.I.C. members an invitation as follows:

"As you are aware, the 1956 Olympic Games will be held in Melbourne in November.

"It seems quite possible that some of your members may be attending as competitors, officials or visitors, and the members of this Institution would be very glad of the opportunity to extend hospitality to them. Should any such visitors desire to inspect engineering works or industries in the state of Victoria, we will be very pleased to make the necessary arrangements to enable them to do so."

Information can be obtained from the Hospitality Officer, The Institution of Engineers, Australia, Kelvin Hall, 55 Collins Place, Melbourne.

You can depend on air hose with cover and tube of Du Pont NEOPRENE...

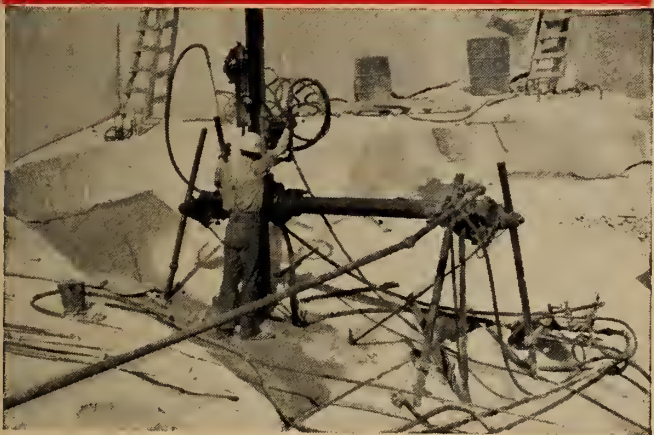
TO RESIST OIL AND GREASE . . .

Oily machine-shop floors have little effect on the sturdy Du Pont neoprene hose cover. Lubricating oil in the air stream won't crumble the Du Pont neoprene tube.

TO WITHSTAND HEAT AND ABRASION . . .

Out at a dam site, jagged rocks tear into the hose cover under a blistering sun—but rugged Du Pont neoprene refuses to chip, crack or soften.

TO RESIST SUNLIGHT AND WEATHERING . . .



Reflected sunlight bakes the hose in a quarry, yet the sturdy Du Pont neoprene cover remains firm, free from cracks. The smooth Du Pont neoprene tube keeps air stream clean.

TO RESIST FLEX CRACKING . . .

An impact-wrench operator in a shipyard yanks and tugs air hose as he works. Rough duty for any hose except a flexible Du Pont neoprene hose—it stays smooth.

No wonder you have fewer replacements of air hose made with cover and tube of neoprene, Du Pont's chemical rubber. Du Pont neoprene resists oil, grease, abrasion, heat and weathering—the very things that shorten the service life of ordinary hose.

Ask your rubber-goods supplier about air hose made with Du Pont neoprene. Whatever you need, you can count on hose with neoprene cover and tube for dependable performance and lower maintenance costs from the first day it's installed.

FREE! The Neoprene Notebook. Each issue is filled with interesting case histories about neoprene . . . tells how it improved old products, developed new ones. Clip coupon to get on mailing list.

BOOK REVIEW

Proceedings of the International conference on the peaceful uses of atomic energy.

New York, United Nations, Toronto, Ryerson; 1956.

The publication of the proceedings of the first truly international conference on atomic energy is probably one of the most important events of the century in the field of scientific literature. The sixteen volumes contain the thousand and more papers submitted at the conference, the text of the oral presentations, and the verbatim record of discussions. Bibliographical references accompany most papers, adding to their value.

This series forms the most comprehensive work available on the peaceful uses of atomic energy.

Volume I, The world's requirements for energy: the role of nuclear energy.

The main topics covered by this first volume of the series are the world's estimated power needs over the next fifty years, and the possible ways in which nuclear power can be used to overcome energy shortages.

The papers presented at the first session discussed world energy requirements in general, conventional and unconventional sources of power, and the need for a new source of energy.

At the next session the estimated requirements of individual countries and potential sources of power were discussed. The final sessions considered the role nuclear power will play in the next half-century, the capital expenditure involved, and international co-operation. (479p., $8.00)

Volume 7, Nuclear chemistry and effects of irradiation.

The problems of the effects of neutron and gamma radiation on the properties of structural and fuel materials used in nuclear reactors are discussed in this volume. The problems of handling radioactive materials are considered, as is the fundamental chemistry of the various materials associated with nuclear energy. (691p., $10.00).

Volume 8, Production technology of the materials used for nuclear energy.

This volume deals with the chemical and metallurgical processes involved in the preparation and processing of such fundamental materials of nuclear energy as uranium, thorium, beryllium, zirconium and heavy water. Production techniques are described as well as many such basic physical facts as phase digrams of materials, their alloying chemical characteristics, etc.

Because many of these materials are comparatively unknown, both chemically and metallurgically, the information in this volume in many cases corrects errors in previous literature. (627p., $10.00)

Volume 9, Reactor technology and chemical processing.

We find here collected all the papers and discussions on the fabrication of fuel elements, the chemical reprocessing of spent fuels, the chemical recovery of new fuel produced in a breeder reactor, the separation and isolation of fission products, etc.

The thirteen sections, made up of papers given by scientists from many nations, also include such subjects as waste disposal in the ground, the sea and air, the metallurgy of thorium, uranium and their alloys, handling liquid metals, liquid metal heat transfer, and corrosion in liquid metal systems.

This is one of the most important books in the series. (771p., $10.00)

Volume 15, Applications of radioactive isotopes and fission products in research and industry.

The papers in this volume will be of particular interest to engineers in industry, presenting as they do the uses of radioactive isotopes in research, and in control and technology. These include tracers, thickness guages, radiography and inspection, etc.

Fission products can be used to promote chemical reactions, to sterilize food, and to convert radiation into electricity. (326p., $7.50)

Other volumes in the series will cover reactors, uranium and thorium, medical uses of radioactive isotopes, the biological effects of radiation, and legal and safety aspects of the large scale use of atomic energy. S. C.

BOOK NOTES

Prepared by the Library The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

ASME handbook: Engineering tables.

Jesse Huckert, ed. Toronto, McGraw-Hill, 1956. Various pagings, $14.40.

This valuable collection of tables of recognized design standards, which are not usually found in handbooks, is a companion volume to the ASME publications on the design function in metals engineering and on metals properties. They are meant to save the engineer time and to make design calculations easier.

There are fifteen sections in the handbook, grouping together tables which apply to the design of such specific machine elements as bearings, various types of gears, keys, bolts, serrations and splines, nuts, springs, tubing, and gaskets. A single source is usually given for a table although identical data is sometimes available from several sources. Each section is preceded by an index.

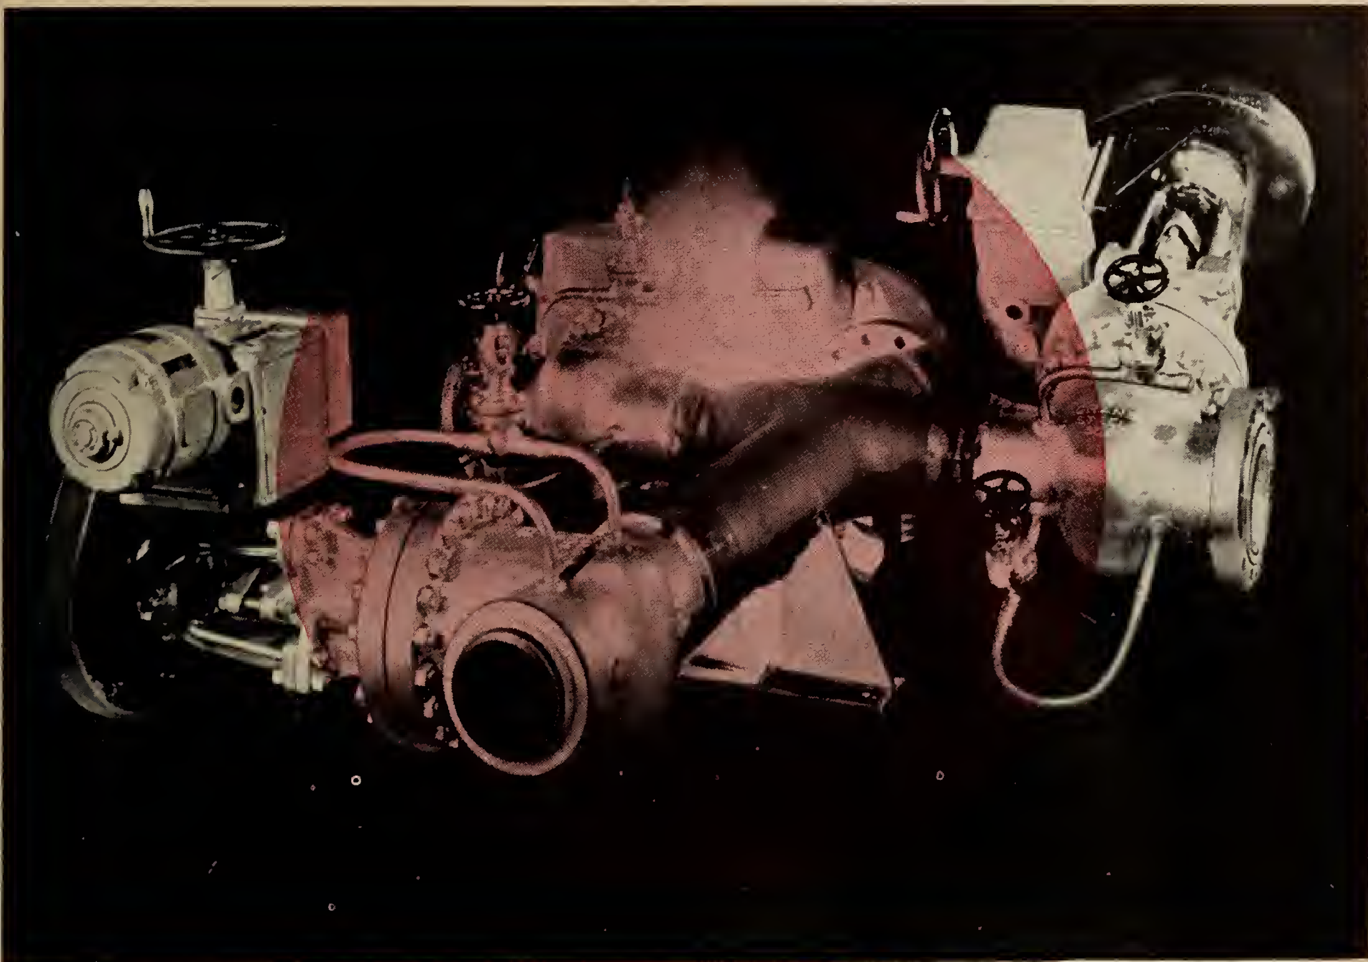
Some of the tables, which were previously hard to locate, cover involute functions, methods for finding the loads in ball bearings, and data on bars and tubes suitable for reworking into gears, levers, shafts, or screws.

Aircraft production methods.

G. B. Ashmead. Philadelphia, Chilton, 1956. 293p., illus., $7.50 (U.S.)

This book on developing aircraft designs into production is in the nature of an illustrated tour through the plants of many of the largest producers in the United States.

DURING THE SUMMER MONTHS THE LIBRARY IS OPEN FROM 9 TO 5, MONDAY TO FRIDAY



What's CRANE cooking up here?

Big Piping Savings for You . . .

The man behind the mask above is a *unit fabrication* specialist with a talent for saving you time, trouble—and dollars—in the long run.

He's part of a crew of experienced mechanics in the Crane Pipe Shop, where piping units like this 8-inch assembly are built *precisely* to specification.

And it's a complete as well as a quality service, for Crane takes over at the blueprint stage; supplies all valves and component parts—makes the pipe bends—does the welding. Right at hand are the best facilities for heat-treating or stress-relieving, radiography, etc., to assure uniform strength and dependability. The finished unit is pre-tested and proved in advance, ready for quick installation in your piping system.

You take no risk—you pay for no spoilages, and your erection crew is spared many a major headache. Why not let your Crane representative review your piping layout and help you decide where Crane Unit Fabrication will be to your advantage?

CRANE QUALITY COSTS NO MORE

For detailed information on any items from the complete Crane line of Valves, Fittings and Piping, ask your Crane representative, or Crane Branch—or write

CRANE LIMITED

CRANE VALVES • FITTINGS • PIPING
PLUMBING • HEATING

NATION-WIDE SERVICE THROUGH BRANCHES, WHOLESALERS and PLUMBING AND HEATING CONTRACTORS

• LIBRARY NOTES

Commencing with the master plaster pattern, successive chapters consider sheet metal preparation and forming, tooling, welding, machining, plastics, etc. As the aircraft industry does not operate on a mass production basis, techniques vary from one manufacturer to another. These different methods are compared, although the majority of the examples are drawn from the Douglas Aircraft Company with whom the author is presently associated.

The analysis of structures.
N. J. Hoff. New York, Wiley, 1956. 493p., $9.50.

The aim of this book is the presentation of structural analysis as a logical and unified theory based on a small number of first assumptions, rather than as a series of unrelated formulae, rules and procedures. Although prepared from lectures used in a graduate course, any mathematics used beyond the level of elementary calculus are explained in detail so that recourse to other texts is not necessary.

The four sections of the book cover the principles of virtual displacements; the minimum of the total potential; the calculation of buckling loads and complementary energy and least-work methods. Bibliographical references are collected in an appendix to which there is an author index.

Applied automation.
J. R. Custer, ed. Philadelphia, Chilton, 1956. 236p., illus., $7.50 (U.S.)

The seventy-five articles comprising this book all appeared in the periodical "Automotive industries" during the last four years. Unfortunately in this reprinting they are not dated.

The object in preparing this compilation was to present a review of the applications of automation in automotive and aircraft production. Many illustrations are included in the articles which cover such topics as car assembly, engine assembly and manufacture, painting, plating, transmission and welding.

This is a useful review of a subject which is today attracting a great deal of attention.

Automatic data processing conference. Proceedings.
R. N. Anthony, ed. Boston, Harvard university, Graduate school of business administration, 1956. 194p., $3.50 (U.S.)

In September 1955 a conference was held at Harvard on automatic data processing as one way of attempting to overcome the language barrier between scientists or engineers and businessmen.

The proceedings are divided into five parts, the first of which is an introduction to the subject. Part two considered the merits of centralized or decentralized data processing for multiplant companies. The remaining sections discuss developments in equipment, the selection of applications for automatic data processing and the relations between operations research and data processing.

Bibliography of monolingual scientific and technical glossaries, v.I. National standards.
Eugen Wuster. Paris, UNESCO, Toronto Ryerson, 1955. 219 p., $2.50.

A companion volume to the "Bibliography of interlingual scientific and technical dictionaries" this bibliography lists standardized technical glossaries issued by standards associations in various countries.

The entries are arranged according to the Universal decimal classification, and for each entry is given in addition to author, publisher, etc., language, whether terms are arranged alphabetically or sytematically, and whether terms are explained by definition or illustration, or both.

There are subject, language and author indices, the latter also containing a list of standards and similar organizations, arranged by country.

British scientific instruments, 1956.
London, Scientific instrument manufacturers association of Great Britain, 1956. 268p.

A directory of the products of the members of the British Scientific instruments manufacturers association, this handbook is divided into two sections. The first is a classified list of products manufactured by members of the S.I.M.A., and includes French, German and Spanish glossaries of the terms used. The second section lists the members of the S.I.M.A. alphabetically, showing the products they manufacture.

*** The casting of steel.**
W. C. Newell, ed. New York, Pergamon Press, 1955. 599p., illus., $15.50 (U.S.)

Prepared by a group of authorities from the British steel casting industry, this book provides a balanced view of the whole subject, from basic principles and their applications to practical problems in the foundry. The opening chapters deal with the properties of molten steel, solidification, the melting process, and refractories. Detailed descriptions of pattern making, mold preparation, and of the casting process are included, with separate chapters devoted to centrifugal and investment casting. The last part of the book covers heat treatment, properties, specificiations, and testing.

Development of power cables.
P. V. Hunter and J. T. Hazell. London, Newnes, 1956. 150p., illus., 25/—.

The authors of this work, themselves cable makers, have been collecting the data on which the book is based for over twenty years. They rescued many examples of early cables from destruction, and these now form the Hunter-Hazell Collection in the Science Museum, South Kensington. The majority of the excellent illustrations in this book are taken from items in this collection.

The history of cables is traced from the seventeenth century to the present, and the use of high-volage cables, of cables under the ocean and various manufacturing advances.

All the royalties accruing from the sale if this book are being given to the Institution of Electrical Engineers Benevolent Fund.

Now add *Beauty* to low-cost, maintenance-free roofs and sidewalls

with *Colour Galbestos*

After decades of research and more than seven years of exhaustive tests by the Robertson organization, Robertson-Irwin Limited is proud to announce Galbestos roofing and siding in four attractive new colours—red, green, buff, gray. Galbestos in black and maroon has long been the standard of perfection among protected metal roofing and siding materials for its maintenance freedom, long-life resistance to fire and corrosion, and ability to withstand extreme weather conditions. Colour Galbestos has proven itself equal or better in every respect.

With Colour Galbestos you now can have coloured roofs and sidewalls at a lower cost than possible by any other means. These new colours in Corrugated, Mansard, or V-Beam profiles, open a new field of decorative treatment for industrial and commercial structures. Use coupon to write for literature.

Galbestos . . . now in maroon, gray, red, black, green and buff.

• LIBRARY NOTES

*** Economic geography of industrial materials.**
A. S. Carlson, ed. New York, Reinhold, 1956. 494p., illus., $12.50 (U.S.)

In this book the economic, technological, and geographic conditions of key industries are explained and analyzed to show how various factors determine the location of plants, mills, and factories for efficient production. Among the twenty industries discussed, each in a separate chapter, are the coal, petroleum, electripower, iron and steel, aluminum, copper, titanium, glass, textile, and food industries, with consideration given to such factors as climate, soil, water resources, fuels, labor, capital, and markets. Two introductory chapters deal with the influence of world population and resources on industrial development and with transportation in the United States.

Electronics and electron devices.
A. L. Albert. New York, Macmillan, 1956. 5B2p., diagrs., $8.00 (U.S.)

This third edition of "Fundamental electronics and vacuum tubes" incorporates the new information on semiconductors which has become available since the second edition was published in 1948. The edition has been largely rewritten, but has retained its original purpose as a textbook on an undergraduate level.

Topics covered include electron tubes, vacuum-tubes, semi-conductor electron devices, transistor amplifiers, modulators, magnetic amplifiers and cathode - ray tubes. One new chapter covers wave-shaping and control circuits. The author follows the standards of the A.I.E.E. and the I.R.E. throughout. There are extensive bibliographies at the end of each chapter.

*** Essentials in problem solving, 2nd ed.**
Zuce Kogen. New York, Arco, 1956. 119p., $3.00 (U.S.)

The essential element in solving problems, as the author, a consulting engineer, sees it, is the development of general methods of approach that can be adapted to specific cases. In this small book, he discusses the formulation, adoption, and utilization of a number of approaches he has found useful and selects four for amplification and illustration. These are: for more without adding, utilize fully; to detach, attach something else; when continuity fails, alternate; and when the direct way fails, try the opposite.

Famous problems of elementary geometry.
Felix Klein. New York, Dover, 1956. 92 p., $1.00 (U.S.) pa.

These lectures discussing in the light of modern research the three famous geometric problems of antiquity — the duplication of the cube, the trisection of an angle, and the quadrature of the circle—were first presented in 1894. It is a tribute to the author that they are now being reprinted in translation over fifty years later.

Foundations: design and practice.
New York, Wiley, 1956. various paging, diagrs.; tables, $16.00

This work is destined to take its place as a valuable reference book with the author's "Data book for civil engineers". It provides up-to-date information on all aspects of foundation work, including subsurface exploration, inspection, foundation reports, specifications, estimates, contracts and design.

The design of simple elements such as plate footings is discussed first, followed by details of complex designs and allied problems. Various types of structures are discussed, ranging from concrete buildings to bridges, embankments and paving.

The book is intended for both practicing and student engineers, and its value lies in the clarity of presentation, the numerous references and tables, and the lists both of items to which particular attention should be paid and of danger signals to watch.

How to select and use your tape recorder.
Davis Mark. New York, Rider, 1956. 140 pp., $2.95 (U.S.)

In non-technical language this text describes the way in which a tape-recorder works and discusses various uses which may be found for it in the home and office. The chapter on the selection of a tape-recorder includes an up-to-date buyer's guide.

Introduction to the theory of groups of finite order.
R. D. Carmichael. New York, Dover, 1956 [c. 1937] 447 p., 2.00 (U.S.) pa.

In this work Professor Carmichael explains the theory of groups and examines fundamental theorems and their application. He discusses sets, systems, permutations, isomorphism, etc., then considers the various types of groups. A knowledge of higher mathematics is not essential to an understanding of the book.

Metal industry handbook and directory, 1956.
London, Iliffe, Toronto, British Book Service; 1956. 492p., 15/–.

This is a comprehensive reference book for all those engaged in, or connected with, the non-ferrous metal industries. It contains up-to-date information on the properties of the newer as well as the more familiar metals, and an extensive section is devoted to summaries of British standard aircraft material, D.T.D. and Admiralty specifications. Also included are sections on the chief metal finishing processes and data regarding all the common rod, bar, sheet and strip products, while a new feature in this year's edition is a section giving tables dealing with the weight of titanium alloys in sheet rod and tube.

The Directory for Buyers gives a very wide range of producers, stockists, and factors of all basic metal products, metal working machinery and tools, and metal finishing equipment.

*** Modern brickmaking, 4th ed.**
A. B. Searle. London, Benn, 1956. 734p., illus., 90/–.

This revision of a classic in the field, is a detailed exposition of all the better-known processes, machines, and equipment in use in Great Britain and Europe, with some reference to American prac-

tice. Chiefly intended as a guide to the selection of plant and production methods, the book emphasizes practical considerations in dealing with clays and non-clay materials; digging and preparation of clays; selection of factory site and manufacturing processes; hand and machine molding; the stiff-plastic, semi-plastic, and dry processes; kilns; and the manufacture of special types of bricks. Numerous revisions have been made to take into account advances made in recent years.

Modern workshop technology. (Part I—Materials and processes) 2nd ed.
H. W. Baker, ed. London, Cleaver-Hume, 1956. 511p. illus., 35/–.

The second part of this new edition will appear next year and will deal with machine tools and metrology. This first part covers the states and properties of the common engineering maerials and those processes which produce either deliberate or accidental changes in these materials.

The scope of the book is wide, including discussions of iron and steel, casting processes, powder metallurgy, forging, high tensile steel wire manufacture, welding, and of aluminium, magnesium, nickel and copper, and their alloys. The last two chapters, on plastics engineering and mechanical testing and inspection of engineering materials, have been greatly revised.

Molecular flow of gases.
G. N. Patterson. New York, Wiley, 1956. 217p., $7.50.

Recognizing the importance of molecular approach to the subject of gas dynamics, the author, the Director of the Insitute of Aerophysics at the University of Toronto, has written his book for engineers and physicists. He does not attempt to cover completely either gas dynamics or the kinetic theory of gases but rather helps the reader make a transition in outlook from the continuum to the molecular viewpoint. To illustrate and develop the molecular approach there is material included from both the kinetic theory of gases and fluid mechanics.

In this work the characteristics of a gas flow are determined from an assumed molecular model and the distribution of the velocities of the molecules. It opens with a chapter on the fundamental equations of molecular motion, then goes on to consider isentropic flow, basic equations for nonisentropic flow, and mechanics of rarefied gases. The mathematical development in the book is complete only for a monatomic gas.

Nouvelle conception de la résistance des matériaux.
Paris, Génie Civil, 1956. 78 p., diagrs., 800 fr.

In this work, reprinted from *Génie Civil*, the author expounds his theory of the strength of materials, based only on the isotropic tensile strength and the internal angle of friction.

The first chapters underline the discrepancies between experimental facts and the classical elastic theory. Then the author establishes from his initial assumptions the basic formulas which should govern the rupture phenomena. In all cases, it seems that the formulas proposed check satisfactorily, qualitatively and quantitatively, with the experimental results obtained elsewhere.

The author concludes by expressing his belief that it is the basic assumption of the elastic theory, i.e. the equilibrium both internal and external and the reality of an elementary volume, which is wrong, philosophically and practically. The whole elastic concept, and its consequences becomes then invalid, and the theoretical security coefficients derived from it, meaningless.

The last chapter looks into the validity of the continuity assumptions in reinforced concrete design.

The theory of sound.
Lord Rayleigh. New York, Dover, c. 1945. 2v., $1.95 (U.S.) per vol.

Another of the Dover reprint series, this edition of Lord Rayleigh's classic work on sound contains an historical introduction by Professor R. B. Lindsay, of Brown University, and a bibliography on the history of acoustics.

The thirteen books of Euclid's elements.
New York, Dover, 1956. 3 vols., $1.95 (U.S.) per vol.

This is a reprint of the second edition of the book published in 1926 by Sir Thomas L. Health, and contains in addition to Euclid's text all Sir Thomas's critical notes and commentary.

The detailed index to each volume includes references to all those who had issued earlier editions of, or commentaries on, Euclid.

Practical solution of torsional vibration problems. (Vol. I: Frequency calculation.) 3rd ed.
W. K. Wilson. Toronto, British Book Service, 1956. 704p., $18.00.

A new feature of this third edition is the rearrangement of the text to make each of the two volumes self-contained. Volume 2 will appear later and will deal with such subjects as the calculation of torsional vibration amplitudes and stresses in the design stage, and means for avoiding excessive vibratory stresses in operating speed ranges.

The book has been brought completely up-to-date but has retained its original purpose, that of being a comprehensive and practical reference work. Volume I contains new material in the sections on geared systems and systems containing distributed mases, as well as many other additions.

The Introduction contains some historical material on torsional vibration. This is then followed by detailed chapters on the subjects of simple and multi-mass systems, frequency tabulations, coupling effects in geared systems, effective inertia method, coupled torsional and flexural vibration in engine systems, and equivalent shafts. Examples are included throughout from marine, electrical, aeronautical and automobile engineering practice.

° The running and maintenance of marine machinery, 4th ed.
Various authors. London, Institute of marine engineers, 1955. 231p., diagrs., 17/3.

A completely rewritten edition of a standard British text intended both as an introduction to the subject for junior engineers and as a review of the best current practice for senior engineers. Various authorities have contributed the separate chapters which deal with boilers, fuel, steam reciprocating machinery, steam turbines, electrical machinery, diesel engines, refrigerating machinery, pumping arrangements, and steering gears.

Theory of games and linear programming.
S. Vajda. London, Methuen, Toronto, British Book Service, 1956. 106p., $1.45.

In this account of a new branch of applied mathematics, based on algebraic concepts, only a fairly elementary knowledge of algebra and linear analytic geometry is assumed.

The argument is developed from first principles, the first three chapters covering the theory of games and its connection with linear programming. This latter has drawn its stimulus from problems in economics, and deals with problems which cannot be solved by methods of calculus.

Examples worked out in detail are given of situations where linear programming methods have proved useful. There is also a bibliography of some thirty-one references on the subject.

Transistors I
Princeton, RCA laboratories, 1956. 676p., illus., $4.70 (U.S.)

Of the forty-one papers by members of the RCA staff in this volume, thirty-one have not previously been published. The Corporation decided to issue this compilation in order to make known recent research and development work on semiconductors, transistors and their applications.

There are two introductory papers, and the remainder are divided into five groups: materials and techniques; devices; fluctuation noise; test and measurement equipment; and applications. To complete the picture, there are abstracts of forty-six papers already published in technical periodicals.

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Aircraft

Safety through steep gradient aircraft. R. M. Woodham. (Guggenheim aviation safety center at Cornell University)

Concrete

Cracking in reinforced concrete flexural members. A. P. Clark. (American iron and steel institute)

• LIBRARY NOTES

Investigation of the moisture - volume stability of concrete masonry units. J. J. Shideler (Portland cement assoc. Bull. D3)

Method for determining the moisture conditions of hardened concrete in terms of relative humidity. C. A. Menzel. (Portland cement assoc. Bull. D4)

Nature of bond in pre-tensioned prestressed concrete (and discussion) J. R. Janney. (Portland cement assoc. Bulls. D2 and D2A)

Education

Engineering enrollments and degrees, 1955. (U.S. Office of education)

Report on American methods of training in industrial engineering and management in universities and industrial plants. T. B. Worth.

STANDARDS REVIEWED

British Standards, British standards institution, 3 Park St., London W. 1. Also available from the Canadian standards association.

The following British Standards have been received:

2A.102—Steel bolts (Unified hexagons and Unified threads) for aircraft. **6/-.**

2A.103—Steel nuts (Unified hexagons and Unified Threads) (ordinary thin, slotted and castle) for aircraft. **3/-.**

2A.104—Corrosion-resisting steel bolts (Unified hexagons and Unified threads) for aircraft. **5/-.**

2A.105—Corrosion-resisting steel nuts (Unified hexagons and Unified threads) (ordinary, thin, slotted and castle) for aircraft. **3/-.**

2A.107—Aluminum alloy nuts (Unified hexagons and Unified threads) (ordinary and slotted) for aircraft. **2/6.**

2A.108—Steel bolts (Unified hexagons, Unified threads and close tolerance shanks) for aircraft. **5/-.**

2A.111—Cadmium plated seel bolts (Unified hexagons, Unified threads and close tolerance shanks) for aircraft. **5/-.**

2A.113—Steel mushroom head bolts (Unified threads) for aircraft. **4/-.**

2A.114—Corrosion-resisting steel mushroom head bolts (Unified theads) for aircraft. **4/.**

2A.169—Aluminum alloy bolts (Unified hexagons and Unified threads) for aircraft. **5/-.**

2A.170—Aluminum alloy mushroom head bolts (Unified threads) for aircraft. **3/-.**

2.G.113—British standard for manifold pressure gauges for aircraft. **2/-.**

S.P.115 to 117—British standard for hydraulic surface-check type lubricating nipples for aircraft. **3/-.**

Canadian standards, Canadian association, National research building, Ottawa.

HC66—1956—Seamless copper water tube and drainage tube.

This third edition replaces the second published in 1950. It covers seamless copper tube especially designed for plumbing purposes, underground water services, drainage, etc., but also suitable for copper coil water heaters, fuel oil lines, gas lines, etc.

As with the first edition, this specification was prepared as a National Standard to which reference could be made in the plumbing and heating section of the National Building Code. The third edition includes further revisions to bring this Specification into substantial agreement with current American practice and to add certain drainage tube sizes which have now been adopted. 3rd ed. $1.00

0132.1-1956—Wood sash and screen frames.

"This Specification covers the requirements for materials and construction of wood sash, and screen frames. It sets forth the quality and species of lumber which may be used, minimum construction requirements, preservative treatment, glazing requirements, certification, marking and inspection, and shows standard opening sizes and designs of pairs of sash, single sash, storm sash, and screen frames." 50 cents

The following Canadian standards have also been received:—

Canadian electrical code, Part II, essential requirements and minimum standards covering electrical equipment.

C22.2 No. 0—1956—Definitions and general requirements, 4th ed. **75 cents.**

C22.2 No. 3—1955—Construction and test of electrical equipment for oil-burning apparatus, 3rd ed. **$1.00.**

C22.2 No. 29—1955—Construction and test of panelboards and panelboard enclosures, 2nd ed. **$1.25.**

C22.2 No. 52-1955 — Construction and test of service-entrance cables, 2nd ed. **$1.25.**

C22.2 No. 57—1956—Construction and test of pull-off plugs for electro-thermal appliances, 2nd ed. **$1.00.**

C22.2 No. 81—1956—Construction and test of electric flat-irons. **$1.00.**

Business and Industrial Briefs

A DIGEST
OF INFORMATION
RECEIVED BY
THE EDITOR

Appointments and Transfers

C.G.E. Manager in Ottawa—C. A. Morrison, vice-president, Canadian General Electric Co. Ltd., announces the appointment of Archie M. Doyle as manager of the company's district office in Ottawa, succeeding Gilbert J. Doane who has retired after 37 years in that position.

Shell Oil Appointment — A. L. Wilson, vice-president, marketing, Shell Oil Company of Canada Limited, has announced the appointment of J. M. Boyd as his executive assistant, Mr. Boyd will be succeeded as manager, head office marketing operations, by H. L. Hinchcliffe.

Standard Wire and Cable—Edmund S. Rose, president of Standard Wire and Cable Limited announces the appointments of Donald A. Campbell as secretary-treasurer; G. V. Taylor, plant manager; G. W. Vogan, sales manager.

W. S. Kirkpatrick

Cominco Officers — The Consolidated Mining and Smelting Company of Canada Limited announce the appointment of W. S. Kirkpatrick as executive vice-president, and of R. D. Perry as a vice-president.

Canadian Arsenals Limited — The appointment of G. W. Hunter, assistant deputy minister of the Department of Defence Production, as a director of Canadian Arsenals Limited, has been announced by the Right Honourable C. D. Howe, Minister of Defence Production.

Canadian Vickers Board Changes—At the first annual meeting since Vickers Limited, of England, took over control of Canadian Vickers Limited, certain changes in the board of the Canadian company were announced. New directors are: The Viscount Knollys, board chairman of the British firm; Maj.-Gen. C. A. L. Dunphie, chairman of Vickers-Armstrong Limited; Lewis J-B. Forbes, president of Pilkington Bros. (Canada) Ltd.; and J. B. Hatcher, secretary of Canadian Vickers Limited. Re-elected to the board were: O. H. Barrett, president; F. H. Brown; C. L. Dewar; R. M. P. Hamilton; J. Edouard Labelle, chairman of the board; R. K. McConnell; and Jean Raymond.

Canadian Aero Service — Michael S. Reford is appointed geophysicist for Canadian Aero Service Limited, Ottawa.

R. D. Perry

Copper Mill Appointment — J. P. Sutcliffe is appointed plant manager of the Western Copper Mills Ltd. plant in Vancouver, according to Richard M. Reiner, president and managing director.

Canadian Locomotive Directors — New directors elected to the board of Canadian Locomotive Company are G. O. Saunders, M.E.I.C., vice-president, manufacturing; G. R. Wyer, executive vice-president, The Canadian Fairbanks-Morse Co. Ltd.; and William B. Morse, Fairbanks, Morse & Co., Chicago.

T. J. Bell

Fiberglas Canada President — W. E. Phillips, vice-chairman, Fiberglas Canada Limited, has announced the appointment of T. J. Bell as president of the company. Mr. Bell was made executive vice-president last August.

Dominion Bridge Head Office—Recently announced are four new appointments all as assistant to the vice-president and managing director, to the head office staff of Dominion Bridge Company Limited. These are: Ernest A. Ford, M.E.I.C.; Palmer E. Savage, M.E.I.C.; MacKenzie McMurray, M.E.I.C.; and Robert J. A. Fricker. All were previously senior officials in their respective divisional headquarters.

Canadian Westinghouse Changes—Four new departments within the industrial products division of Canadian Westinghouse Company Limited are announced. Associated new appointments are: W. A. Eskil, manager, industrial control and panelboard; Stanley Thurgar, manager, distribution apparatus; T. B. Lounsbury, JR.E.I.C., manager, meters, instruments and relays. Manager of the small motors department is to be announced later.

General Motors Diesel—Staff changes announced by General Motors Diesel Limited include: A. G. Shugg, district manager in Vancouver for diesel engine sales; N. D. Love, engine distribution manager at London, Ont., for engine sales; G. M. Lynch, district service engineer for the territory British Columbia to the Manitoba-Ontario border.

● BRIEFS

Dominion Chain Officers — Officers of Dominion Chain Company Limited announced at the recent annual meeting are: W. F. Wheeler, chairman; F. C. Cullimore, president and general manager; C. N. Johns, vice-president; J. R. Hamilton, secretary and treasurer.

Canada Iron Group — Recent appointments within Canada Iron Foundries Limited include: W. A. Marshall, M.E.I.C., president of Dominion Structural Steel Limited, a director; G. D. Turnbull, P. M. Draper, and J. E. Rehder, vice-presidents; S. A. Williams, special assistant to the president.

Among other companies of the Canada Iron group: C. D. Marshall and H. N. Magnan become directors of Disher Steel Construction Company Limited, and W. J. H. Disher, president of that company, is made a director of Dominion Structural Steel Limited.

New Equipment and Developments

Radio and Television — Canadian General Electric Company has recently introduced several new items of equipment in the fields of radio and television broadcasting. A simplified and improved 50,000-watt broadcast transmitter for AM radio stations uses germanium rectifiers for high-voltage power supply and reduced tube requirements, using only 13 tubes against the 40-odd in existing units.

A new television broadcast transmitter, available in the last quarter of 1956, will enable prospective VHF broadcasters to take advantage of low power TV channel allocations. Equipment for the 400-watt transmitter will be in packages, and can operate unattended directly from network or with facilities of a key network production centre. Another new line is the "Ultracon" remote control equipment, designed for the unattended operation of television broadcast transmitters. The company's tube department has a new line of television receiving tubes which will reduce series-string heater power 25 per cent, drawing 450 ma. heater current, and designed for portable receivers.

Direct Link to Europe — Canadian Overseas Telecommunication Corporation inaugurated in May a new direct high-speed radio telegraph link between Quebec City and Paris.

Radioisotopes at C.N.E. — The use which Britain is making of radioactive isotopes for industrial purposes will be one of the features of the United Kingdom stand at the Canadian National Exhibition, at Toronto, 24 Aug. to 8 Sep. Four display panels will show some of the industrial applications. One will show the use of radioisotopes for radiography of castings and other parts; all welds in Britain's current nuclear power station construction are checked by this method.

The second panel will show how leaks in oil and water pipes are detected by filling the pipe with an active solution under pressure, flushing out, and checking for residual radioactivity which will be found where the solution has leaked out. The third application has been used to reduce the cost of dredging estuaries and harbours by tracing tidal movements with active isotopes dropped into the water. This has been used by the Port of London Authority. Finally, thickness gauging will be shown — a technique already quite widely used in Canada.

A model of the nuclear power station at Calder Hall, Cumberland, will also be on display.

Dominion Electrohome Industries Limited, of Kitchener has announced an engineering scholarship for a graduate of the Kitchener-Waterloo Collegiate and Vocational School. The Electrohome Electronics Award is to be available this year and will amount to $1,600 on the basis of $600 for the first year, $400 for the second year, and $300 in each of the third and fourth years. The company wish to encourage students to study radio physics, electrical engineering, engineering physics or physics with electronics option at a Canadian university. The scholarship winner will be selected by both the company and the Scholarship Committee. In announcing the scholarship award to the students of the school the company stated they hoped this gesture would lead other firms to awarding scholarships which would help alleviate the national problem of a shortage of personnel with engineering training.

Telephone answered automatically — Pye Canada Ltd. has announced its telephone answering machine, an instrument designed to answer a telephone automatically in the absence of a subscriber. This instrument answers the calls with a recorded message of up to 50 seconds duration then records the caller's message which can be as long as three minutes. On completion of the recording, the line is cleared automatically. Total recording time is one hour and automatic erasion allows the recording tape to be used indefinitely. Should insufficient recording time remain available, the machine will not answer the caller, avoiding partially recorded calls.

During playback, the machine is disconnected from the line and recorded messages are reproduced via a loudspeaker or headset. A wide range of recording levels can be reproduced successfully to cover local and long distance calls. The machine operates from normal a.c. mains; 100-150 or 200-250 volts 40/60 cps.

High Temperature Alloys — Two new high temperature alloys for aircraft and industrial gas turbine applications are announced by the International Nickel Company. The first, Inconel "700" age-hardenable nickel-cobalt-chromium alloy, contains approximately 50 per cent nickel and 30 per cent cobalt. This modification of Inconel "X" was developed for air-

craft designers who were seeking adequate strength for forged aircraft gas turbine blades at temperatures up to 1650 deg. F. A metal was required that could be operated at a working temperature approximately 150 deg. F. higher than the Inconel "X" alloy. The mechanical properties of the Inconel "700" alloy at 1650 deg. F. are very similar to those of Inconel "X" at 1500 deg. F. The second new product, Incoloy "901" nickel-iron-chromium alloy, has been developed for use in aircraft and industrial gas turbines for those components requiring high creep and rupture strength in the temperature range of 1000 deg. to 1400 deg. F. An important physical property of the new alloy is its low co-efficient of thermal expansion. Containing approximately 40 per cent nickel, it is close enough to ferritic alloy steels to permit the two materials to be joined without special provision for thermal expansion. Incoloy "901" is expected to find wide application for use in turbine rotor and compressor discs and structural parts calling for an intermediate temperature range of 1000 to 1400 deg. F.

Canadian Machines for U.S.– A battery of four special purpose bearing-torque machines is nearing completion at the Toronto plant of Standard-Modern Tool Company Limited for one of the leading automobile manufacturers in Detroit. Each multi-station machine automatically pre-loads and torque tests the bearing lock nut of the pinion shaft in an automobile rear end assembly. Narrow torque limits are 18 to 24 in.-lb. The machine tightens the lock nut, then checks the pre-load torque on tapered roller bearings during a 5-second run-in period. Three stations on the continually rotating machine turn out 240 assemblies per hour, or one every 15 seconds.

Change of Location – Head office and manufacturing facilities of Micanite Canada, Ltd., recent acquisition of Minnesota Mining and Manufacturing Company, have been moved from their former location at Granby, P.Q. to the 3M plant at London, Ont.

Rotary Unscrambler – The Line-O-Flex rotary unscrambling table is designed to unscramble cylindrical containers such as bottles, jars, and cans. This unit is usually installed as the first operation on production lines for single lane transfer to washers or cleaners, fillers, cappers and labellers. Available in 3 standard sizes to suit any discharge angle, and speeds up to 200 per minute. Accumulating table similar to the unscrambler is available. Both these machines are designed and manufactured by Specialty Manufacturing & Distributing Co. Ltd., Toronto.

Hydraulic Oil Coolers—A line of air type and water type oil coolers for industrial hydraulic systems is now available from Vickers-Sperry of Canada Limited. The coolers feature a high rate of heat transfer per unit of space occupied. Designated Series OCW, Vickers water type oil coolers are available in single unit sizes for oil flows up to 100 g.p.m. and for continuous power removals up to 37 h.p. (based on 85 deg. F. entering water temperature). Greater requirements can be met with two smaller coolers of equal size used in parallel.

New Plant – The Packard Electric Company Limited, of St. Catharines, Ont., is to build a plant at Three Rivers, Quebec, at an estimated cost of $225,000 for the manufacture of transformers and watthour meters. The plant is expected to start production early in the fall.

Industrial Fans—A new line of industrial fans designed for high efficiency is now available from Canadian Sirocco Company, Ltd. Designated series 106, the new standard industrial fans are available in sizes 11 through 37 with adjustable discharge in V-belt driven arrangements 1 and 9 for the full range, and in direct-connected arrangements 4 and 8 for limited sizes. Series 106 fan sizes 11 through 37 permit a choice of three types of wheels: AH (air handling), MH (material handling) and LS (long shavings). In sizes 41 through 60, the new units are available with fixed discharge in arrangement 1 with choice of two types of bearing supports. Series 106 fans sizes 41 through 60 can be obtained with either of two types of wheels, AH or MH.

The new series 106 packaged industrial fan, a modification of arrangement 9, is a completely self-contained unit, eliminating the need for a separate motor foundation and minimizing floor area requirement. Packaged industrial fans are available in sizes 11 through 26 with adjustable discharge housings. MH wheels only are standard with the new packaged units; AH or LS wheels can be furnished on special order.

Safety Awards – For the first time a single Canadian company has won both first prizes awarded by the National Safety Council for outstanding safety records in the wood preserving industry in North America. Canada Creosoting Company Limited, a subsidiary of Dominion Tar & Chemical Company, Limited, won the award for plants operating more than 60,000 hours and also for plants operating less than 60,000 hours during the year 1955. The first award was won by the Delson, Quebec, plant, the second by the North Vancouver plant. The awards were made for a complete accident-free year. Four other awards were won by other subsidiaries of Dominion Tar & Chemical Company, Limited, making a total of six National Safety Council awards won by this company for 1955.

Air Conditioning Units – A new line of complete central-station, cabinet-type air conditioning units for industrial and commercial applications is now available from Canadian Sirocco Company, Ltd. Capacity range in all types is from 600 to 48,000 cu. ft. per minute. Three basic types of units are included: (1) air conditioning units, (2) sprayed coil conditioner units and (3) multi-zone conditioner units. The air conditioning and sprayed coil conditioning units are available as either horizontal or space-saving vertical arrangements, both with horizontal air flow through the cooling coils. Multi-zone conditioner units are made in one arrangement for either horizontal or vertical air flow. Manual or automatic controls can be provided for temperature, multi-zone or ventilation control.

Plant Expansion — J. Gilchrist, managing director of Ex-Cell-O Corporation of Canada, Limited, announces that a $200,000 administration and engineering building is to be erected at their plant in London, Ont.

Portable Cutting Machine — Canadian Liquid Air announce the introduction of a new, lightweight, portable and inexpensive motor-driven cutting machine, known as the L. A. Handicutter. Weighing only 16 lb., the Handicutter easily performs the tasks met with in the general repair shop or plant. It cuts steel from ⅛ in. to 4 in. in thickness, in straight line, square (90 deg.) or bevelled (plus or minus 45 deg.); and circles from 1½ in. to 45 in. in diameter. A limited degree of hand-guided cutting for slow curves and single irregular outlines may also be performed.

Turbine for Laurie River – Sherritt Gordin Mines Limited have ordered a 7000 h.p. water turbine from the English Electric Company of Canada for installation on the Laurie River in Manitoba. one hundred miles north of Sherridon. The unit is a vertical shaft reaction (Francis) turbine and has an operating net rated head of 55 ft. The rate output is 7000 b.h.p. with an operating speed of 163.6 r.p.m. The turbine is to be built for English Electric by its associate company, John Inglis Co., Toronto, and delivery is planned for early 1957.

"Packaged" Program on Concrete – The Master Builders Co. Limited has announced an informative "packaged" program on concrete that should be of interest to program chairmen. Comprising two short coloured films with sound together with the services of a qualified speaker for a following question and answer period, the program runs between 1½ and 2 hours.

The first film produced by the American Concrete Institute in conjunction with the Portland Cement Association is entitled "Placing, Finishing and Curing Quality Concrete". The second entitled "The Man With The Trowel" deals with the problems of controlling the variables that affect not only the quality but also the cost of concrete in place. The question and answer session is directed towards answering questions related to specific field problems.

Bookings are now being made for fall and winter meetings and interested program chairmen should communicate with The Master Builders Co. Limited, 95 Ingram Drive, Toronto, Ont. Telephone Cherry 1-8641.

Mould Release Emulsion – An improved silicone mould release emulsion, designed to give finer surface detail, better surface finish, and greater economy in emulsion system operation, is available from Canadian General Electric's chemical materials section. It is designated as SM-62 in the department's product line. Product data sheets may be obtained by writing to Chemical Materials Sales, Canadian General Electric Co. Ltd., 1601 Davenport Road, Toronto.

Copper for Electrical Conductors — Information on the electrical properties and uses of copper and copper alloys, bus conductor shapes, wire, cable, and conduit, and special shapes, is given in Publication C-25, which is comprehensively illustrated with pictures, diagrams, and tables. The publication is obtainable from Anaconda Brass Limited, New Toronto, Ont.

British Aluminum Contracts—Canadian British Aluminium Company has awarded the contract for construction of its new aluminum smelter at Baie Comeau, P.Q., to Anglin-Norcross Corp. Ltd., and Atlas Construction Co. Ltd., as announced by P. T. Ensor, general manager. Construction is to proceed in two stages. The first is to be completed in the fall of 1957, and the second at the end of 1958.

Stage I will comprise two furnace rooms (pot rooms), each of which will have two furnace lines (pot lines). The furnace rooms will each be 1710 feet long and 78½ feet wide, with an elevated operational floor about 10 feet above yard level. Other buildings to be built, he said, include a rectifier house, casting shop, workshop and furnace lining building, a boiler and compressor house and a carbon factory. There will also be alumina and coke silos, a laboratory and an office building. The schedule calls for power to be connected with the stage I furnaces in November, 1957.

Stage II, to be finished in 1958, will add two more furnace rooms of the same capacity, more alumina and coke silos, and necessary extensions to the rectifier house and casting shop.

Hydro Standardization — Quebec Hydro-Electric Commission have awarded a contract to the Canadian Westinghouse Company for frequency standardization at Beauharnois station No. 1. The order calls for one 150,000/200,000 kva., 3-phase, 60-cycle, 230/120 kv., 55 deg. C. rise, type ONS/ONP, surge protected auto-transformer. This transformer is equipped with on-load tap changing equipment in the LV winding.

In addition, the company will supply six 50,000 kva., type OFW outdoor surge protected step-up transformers 120/13.8 kv., and sixteen 138 kv. oil circuit breakers with a 5000 Mva interrupting capacity, and 3 cycle interrupting time.

Another frequency conversion job is a contract to rebuild the generators at the Masson station of the McLaren Quebec Power Company.

It calls for the conversion and replacement of all parts needed to convert four 2000 kva. waterwheel generators for 60 cycle operation.

Wide Band Modulator — A wide band modulator, the FR-1, has been introduced by the telecommunications engineering department of the Canadian Westinghouse Company. It produces an I.F. signal in a frequency range between 5 and 100 Mc/s. This signal can be frequency-modulated with modulating frequencies of 10 kc/s - 5000 kc/s, to produce an r.m.s. deviation of 8 Mc/s. For a typical deviation of 1 Mc/s, both the second and third harmonic distortions are of the order of 60 db. It can also be used as a low distortion driver and modulator for a wide band communication system, by heterodyning the output up to any R.F. carrrier frequency.

Change of Address.—The Toronto office of Spartan Air Services Limited and Canadian Aero Service Limited is now at 347 Bay St. (Empire 6-2233).

New Headquarters.—The headquarters and Montreal division office of Racey, MacCallum and Associates Limited has moved to the Professional Arts Building, 5890 Monkland Ave., Montreal (Hunter 9-4941).

Tool Company Purchase.—It is announced in a joint statement that Remington Arms Company, Inc., Bridgeport, Conn., has entered into an agreement to purchase the Mall Tool Company, of Chicago; this agreement includes the Canadian subsidiary, Mall Tool Limited, of Toronto.

Company Merger.—Effective July 1, 1956, Standard Sanitary and Dominion Radiator Limited changed its name to American-Standard Products (Canada) Limited. Standard-Dominion is a leading Canadian manufacturer of plumbing and heating products and is a subsidiary of American-Radiator & Standard Sanitary Corporation, maker of American-Standard plumbing and heating products in the United States.

At the same time two other affiliated Canadian companies will become a part of American-Standard Products (Canada) Limited. These are Canadian Sirocco Company, Limited of Windsor, manufacturers of air handling and air conditioning equipment, and Kewanee-Ross of Canada Limited, Toronto, engaged in the industrial heat exchanger and steel boiler business. Their assets and business will be transferred to American-Standard Products (Canada) Limited, and will continue to produce and sell the same products as at present. American-Standard Products (Canada) Limited will have three plants in Toronto and one in Windsor, employing a total of 1800 people.

Clarence W. Johnson has been elected president of American-Standard Products (Canada) Limited. Mr. Johnson is now president of Canadian Sirocco. Other officers of American-Standard Products (Canada) Limited are George C. Crawford, chairman of the board; Albert O'B. Andrews, vice-president; Thomas B. Cooper, vice-president, secretary and treasurer; Arthur R. MacCallum, vice-president, comptroller; and Alex Pirrie, vice-president, manufacturing.

ENGINEERING CAREERS

The Electrical Industry

In this article the parts of the electrical industry to be considered are those concerned with the manufacture of heavy and light electrical equipment, instruments, telecommunication systems, and electronic devices, together with associated research and development facilities.

The electrical power industry, concerned with the production and distribution of hydro-electric, thermal, and nuclear power, will be dealt with in a subsequent article.

The electrical industry is not only of interest to electrical engineers, since design and development work, particularly in the heavy equipment field, has need of graduates in mechanical engineering and engineering physics.

Heavy Equipment

The heavy electrical industry is largely concerned with supplying the power facilities with generating and distributing equipment. For this and other industrial power requirements the items produced include generators and motors, transformers, rectifiers, capacitors, switchgear and fusegear, circuit breakers, and so on.

Another important operation is the manufacture of wire and cable.

Increasing demand for power supply and the growth of Canadian industry generally provide a large potential market for heavy electrical equipment. It is a highly competitive market, and Canadian electrical manufacturers are constantly trying to improve productivity to reduce the cost of the equipment. This calls for efficient engineering departments both for design and for production. For example, in the production of a large generator, components weighing several tons have to be machined and assembled, probably to a tight schedule. The production or industrial engineering department would be concerned with such problems as minimizing the handling operations involved.

In general, the heavy equipment industry requires engineers in design, production, development, and sales departments, and supervisory and management positions in these departments are often filled by engineers.

Apparatus Industry

The electrical industry also produces equipment and appliances for industrial and domestic use. These items are often mass-produced, again calling for production engineers. To meet a competitive market, design and productivity are important features.

Instrumentation and Control

Modern industry is turning more and more to automatic control, and new applications are constantly being found. Automatic control is at present probably most advanced in the process industries, such as petroleum and chemical, in which large and complex plants are run continuously by a few operators, often from a central control room.

Instruments are required for recording and controlling variables throughout the process, such as temperature, pressure, flow rates, and so on, and also to operate motors, pumps, valves, and other electrical and mechanical equipment by remote control.

Recording and control instruments are constantly being improved and developed to meet new applications, and there is considerable scope for the engineer in this side of the electrical industry.

Expansion in the field of electronics in recent years has been among the greatest for any industry. Part of one major electrical manufacturer's electronic engineering program is this analogue computer; one of the largest in Canada.

Telecommunications

From the early days of the telegraph, telecommunications have developed into a vast network, using the telephone, radio, and television. This represents a large industry, ranging from the manufacture of a trans-Atlantic cable to the design of an electronic circuit for a closed industrial television system.

Engineers are needed for the design and manufacture of telecommunication equipment, in which certain Canadian companies specialize, and are also required for the installation and maintenance of systems that are the province of the operating companies.

As an example of some of the work involved in this field, we would refer to the article "Microwave Radio Project of the Trans Canada Telephone System" in this issue of *The Engineering Journal.* This is a transcontinental project, but the industry is equally concerned with small internal comunications systems.

As with other manufacturing operations, design and production engineers are required for the equipment manufacturers' plants.

Electronics Industry

The so-called electronics industry, of which instrumentation and communication equipment may also be considered a part, has expanded enormously in the past ten or so years, mainly through the industrial application of developments made during the war years and the continued extension of military programs.

There has been a correspondingly great demand for electronic engineers, which is likely to continue for some time. This is to be expected, since the demand occasioned by a vast new industry, using new techniques and developing new applicaitons, has far outgrown the supply of graduates trained in the necessary principles.

Despite this intensive demand for the specialist electronics engineer and engineering physicist, the prospective graduate should not lose sight of the opportunities that exist in the broader fields of the electrical industry.

Automatic control and instrumentation of industrial processes has been mentioned above. Aviation, both civil and military, is developing rapidly and on a large scale. Aircraft instruments and navigational equipment are being widely developed by the electronics and electrical engineer, and this work is even more specialized in the field of guided missiles.

In many industrial fields there is considerable interest in the application of electronic computing devices, which are being developed on a considerable scale.

Behind all these developments, there lies a great amount of fundamental research work, in which the engineer plays a large part, together with the physicist and mathematician. This work is carried out by academic and pure research organizations and by industry.

The electronics industry, like other branches of the electrical industry, employs electrical, electronic and mechanical engineers, and engineering physicists, in departments of pure and applied research, design, production (manufacturing), and sales. There is also very good scope for the engineer to advance to management and executive positions.

At the opposite end of the scale from electronics is the heavy electrical equipment side of the industry. Here, a transformer coil is being clamped to size before drying and treatment.

Qualification and Training

For employment in an engineering department, most organizations in the electrical industry require the candidate to be a graduate engineer. Most companies also offer summer employment to undergraduates.

Training schemes vary in detail, but the recent graduate joining a company will have ample opportunity of further training to suit the particular needs of the industry he is entering. Courses may include on-the-job training, financial support for post-graduate courses, specialized technical training by the company, and facilities for attending special courses provided by external technical and management organizations.

Salary Scales and Benefits

For the graduate engineer in an engineering department, salary may range from about $4000 a year to $10,000 a year, according to age and experience, with higher salaries available to the man who progresses to management and executive positions.

Paid vacations are customary, and most companies offer pension and health benefits. In some cases bonuses are paid; for example, in certain field operations. Other benefits may include discounts on the purchase of company products.

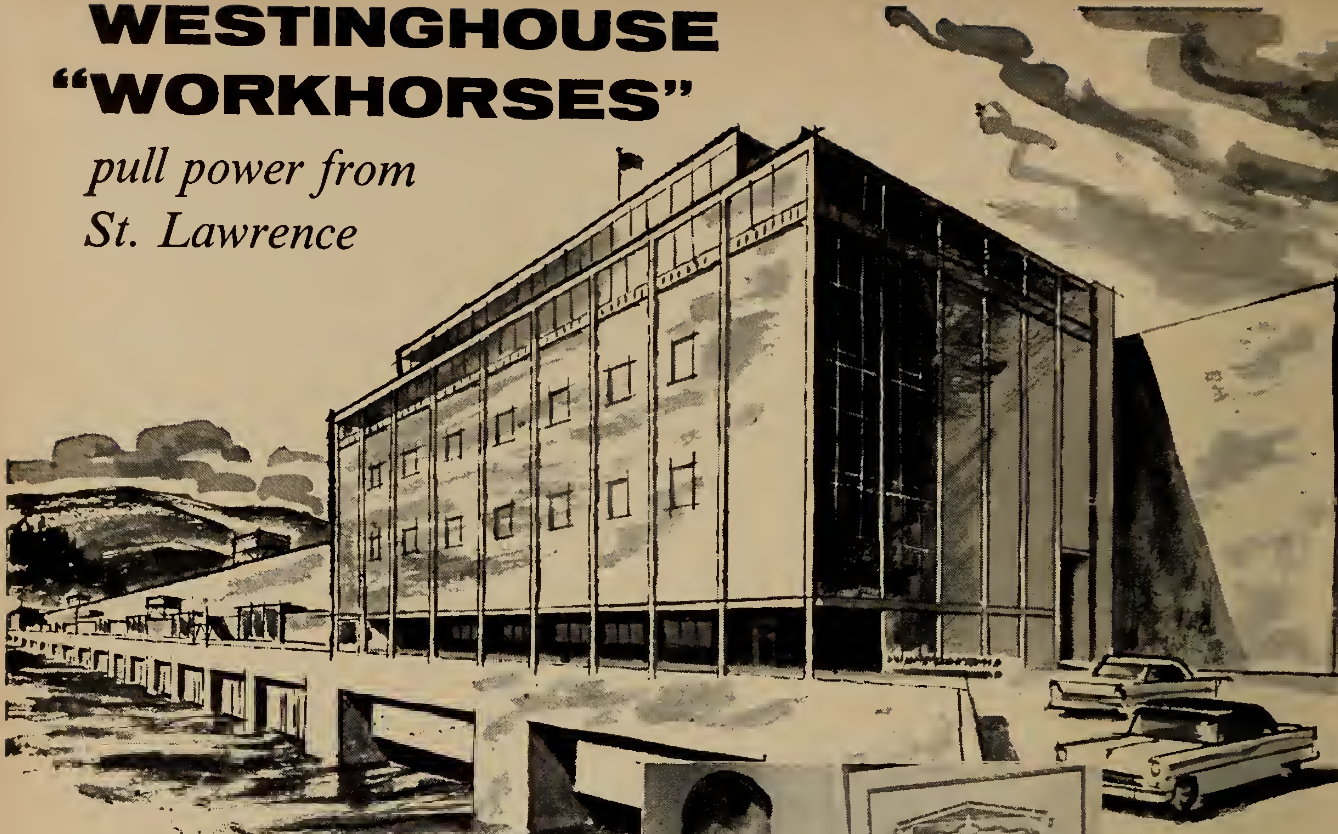
WESTINGHOUSE "WORKHORSES"

pull power from St. Lawrence



WESTINGHOUSE SUPPLIES GIANT GENERATING AND TRANSMISSION EQUIPMENT FOR VITAL ST. LAWRENCE POWER PROJECT

Model of giant outdoor geoerators, now being built by Westinghouse, will help feed 820,000 Kilowatts of new power to Ootario.

Mid-1960 will bring 820,000 Kilowatts of new Hydro power to Canadian homes and industries—vitally needed electricity from Ontario Hydro's mighty St. Lawrence Power Project.

Eight massive Westinghouse generators, each two storeys high, will handle half this giant power job. The project's entire output will pass through Westinghouse step-up transformers; and Westinghouse Jetaire circuit breakers help protect the multi-million dollar investment in heavy equipment.

More than half Canada's hydro power already comes from Westinghouse generating equipment. On the St. Lawrence, Westinghouse engineering skill and equipment will contribute still further to Canada's already highly electrical way of living.

Huge Westinghouse step-up transformers like this are now being built at Westinghouse for the St. Lawreoce Geoerating Station.

Arriving at the St. Lawrence Transformer Station, Westinghouse Jetaire circuit breakers will protect power equipment on the Hydro system.

CANADA

THE ST. LAWRENCE SEAWAY AUTHORITY

OTTAWA, July 9th, 1956

OFFICE OF THE
PRESIDENT

Dear Doctor Wright,

The Engineering Journal has been bringing to its readers many good articles concerning the progress of works for the St. Lawrence Seaway and Power Project. The September issue, devoted to featuring the project and including the texts of several excellent papers concerning the work, should be of lasting interest to professional and lay reader alike.

This is an engineering project but furthermore it is a social achievement for the lasting good of the peoples of Canada, the United States and of many other countries throughout the world. To the completion of this monumental enterprise, an example of the power of man over the face of Nature, the engineer has been an essential and prime contributor.

At this time I wish to take the opportunity of commending the editors of the Engineering Journal on their careful coverage and particularly on the production of this record of the Seaway progress.

Yours sincerely,

Lionel Chevrier

Dr. L. Austin Wright, M.E.I.C.,
Editor - The Engineering Journal,
2050 Mansfield Street,
MONTREAL 2, P.Q.

Reproduced above is a letter received by The Engineering Journal from the Honourable Lionel Chevrier, President of the St. Lawrence Seaway Authority. When Mr. Chevrier heard that a special Seaway issue of the Journal was in preparation he kindly gave his endorsement in the thoughts expressed here.

An Historical Review of the Seaway

With particular reference to the contributions made by members of the Engineering Institute of Canada

IT MAY justly be claimed that the 'seaway', more properly termed "The Great-Lakes St. Lawrence Deep Waterway and Power Project", would never have become a reality were it not for the part played by many members of The Engineering Institute of Canada. No other great national undertaking has held such a prominent place in their dreams, or has absorbed so many hours of their time in the scientific studies of all its aspects, and finally in the planning, design, and in the carrying out of its construction.

Statesmen of the two participating nations, the United States and Canada, many members of Parliament, Congress, and two Senates, prominent jurists and members of the legal profession, public servants, scientists, statisticians, economists, publicists and many authors have all played their part in bringing the dream to reality. But to Canada's leading engineers is due the credit for first conceiving the idea of a 'deep waterway' and for their persistent efforts over some sixty years in finding the right solutions to the many physical and economic problems involved.

First Conceived a Century Ago

As early as 1825 the Honourable John Young, of Montreal, began agitation for a St. Lawrence Seaway, and this was supported in 1832 by a widely-publicized article "The Concise View on Inland Navigation of the Canadian Provinces". However, from the point of view of the engineer, probably the story of the "seaway"[1] ". . . has its beginning in the dreams of Thomas Coltrin Keefer, M.E.I.C., first president of the Canadian Society of Civil Engineers (1887), later The Engineering Institute of Canada. Born in Thorold, Ontario in 1821, throughout his life he insisted upon the mystic and indissoluble union of Canada with its parents, Great Britain and France. At eighteen he was an engineer upon the Erie canal; he soon returned to Canadian waterways, to become their protagonist

1 The Engineering Journal, 1954, Dec., p. 1637

and special pleader for the remainder of his long life. In 1845 he was chief engineer of the Ottawa River works, in charge of the log chutes and skidways which expedited the passage of timber to ports of lading.

"Eight years later he was Chief Harbour Commissioner of Montreal. But he never was chair-borne for very long at a time. Throughout the sixties and the seventies he planned and supervised scores of waterway projects, mostly for the improvement of traffic conditions upon the Canadian rivers. He became the Grand Old Man of Canadian Engineering and honours were heaped upon him, not only by Canada but also Great Britain and the United States. He died in 1915.

"The prolific period of his life lay between 1848 and 1863. In the former year he lost his job through a change of government. Whereupon he took up the pen; in a series of books and in scores of pamphlets, articles and addresses he hymned his devotion to the bounty of nature as revealed in Canadian lakes, streams and rivers. The St. Lawrence was to him a broad passage into the heart of a virgin continent, whose commerce sooner or later must take to the Seas.

"In so far as natural obstacles were concerned on the St. Lawrence system — falls, rapids, and portages— he had one sovereign remedy—to cut more and more canals, until there was uninterrupted navigation for a thousand miles to the west, so that the ships of all nations could pick up cargoes at every cove on the Great Lakes. He fought vehemently for this particular waterway. To his sorrow it never came to pass in his lifetime."

In 1895 the Governments of the United States and Canada created an international waterways commission called the International Commission, and instructed it to report on the feasibility of a deep channel from the Great Lakes to the sea. The Canadian commissioners, appointed on 30 November 1895, were O. A. Howland, chairman, T. C. Keefer, and Thomas Monro. The United States commissioners were Dr. James B. Angell, John E. Russell, and Lymen E. Cooley. The first joint meeting was held on 17 January, 1896.

Thomas Coltrin Keefer, first president of the Canadian Society of Civil Engineers (1887), which later became the Engineering Institute of Canada. He was a great protagonist of the Canadian waterways.

International Joint Commission Formed

In 1900 a board of engineers appointed by the U.S. Senate recommended to the President of the United States the construction of a canal of 21 ft. depth along the American side of the International section of the St. Lawrence. In December 1903, at the suggestion of the United States, the International Waterways Commission was established with three members each for the broad purpose of reporting upon the use and protection of the Great Lakes. Canadian members were James P. Mabee, K.C., W. F. King, M.E.I.C., Chief Dominion Astronomer. and Louis Coste, M.E.I.C.,

Mr. Mabee resigned on 21 November, 1905, and was succeeded by George C. Gibbons, K.C., (afterwards Sir George). Dr. King resigned in March, 1907, and was succeeded by William J. Stewart, Dominion Hydrographer, on 13 April, 1907.

The International Waterways Commission reported to the Governments of Canada and the United States from 1905 to 1913. The Commission's work covered studies on Niagara power, St. Lawrence power levels, the regulation of Lake Erie, the Chicago drainage canal, the St. Mary's River (Sault Ste. Marie), etc. The engineering and other reports filed with the two governments were the first reports ever prepared on boundary water disputes between the United States and Canada and pointed out the need for the adoption of definite principles to be followed by the two countries in settling these disputes.

During his period in office as chairman, Mr. Gibbons brought this view before the Prime Minister, Sir Wilfrid Laurier, and in due course at Sir Wilfrid's direction Mr. Gibbons conferred with James Bryce, then British Ambassador to the United States, on the matter. Subsequently the Hon. Elihu Root, Secretary of State of the United States, and Mr. Chandler P. Anderson, worked with Mr. Bryce and Mr. Gibbons in drafting various versions of what became the Boundary Waters Treaty of January 11, 1909. The International Joint Commission was established under Article VII of the Treaty of 1909 and the organization meeting was held in Washington in January, 1912. The first Canadian commissioners appointed in November, 1911 were Th. Chase Casgrain, K.C., Henry A. Powell K.C., and Charles A. Magrath, HON. M.E.I.C.

First Report of Joint Board

From 1909 until the end of World War I the subject of the Seaway received little public attention, though a number of commissions and boards in the United States made studies and reports on a deep waterway. On 21 January 1920 the Governments of the United States and Canada referred to the International

Joint Commission certain questions relating to the improvement of the St. Lawrence River between Lake Ontario and Montreal for navigation and power.

Included in the reference was a letter of instruction to the board of engineers created by the two governments to report to the Commission on the engineering features of the proposed improvements. Lt. Col. W. P. Wooten was appointed by the United States Government and W. A. Bowden was appointed by the Canadian Government. With competent staffs at their disposal these two engineers made a thorough study of the St. Lawrence River and in June 1921 made their report to the International Joint Commission.

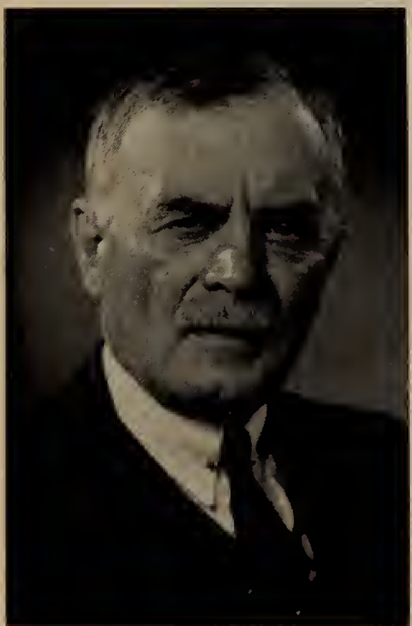
After holding extensive hearings and receiving many briefs on economic and other aspects of the project, the International Joint Commission on 19 December, 1921 replied to the various questions of the reference and recommended that a treaty be entered into between the governments of Canada and the United States for a scheme of improvement of the St. Lawrence River between Montreal and Lake Ontario. The commission also recommended that before any final decision was reached that the report of the board and other documents filed with the commission be referred back to the board enlarged by other leading members of the engineering profession. Canadian commissioners at this time were C. A. Magrath, HON. M.E.I.C., chairman, H. A. Powell, K.C., and Sir William H. Hearst. The secretary of the Canadian section was Lawrence J. Burpee.

The recommendation of the commission in regard to further studies was accepted and the Joint Board of Engineers was increased to six members. Those appointed for Canada were D. W. McLachlan, M.E.I.C., Department of Railways and Canals, Olivier O. Lefebvre, M.E.I.C., chief engineer, Quebec Streams Commission, and Brig. Gen. C. H. Mitchell, C.M.G., C.B., M.E.I.C., Maj. Gen. Edgar Jadwin, Col. William Kelly, and Lt. Col. George B. Pillsbury, all of the Corps of Engineers, U.S. Army, were the American members.

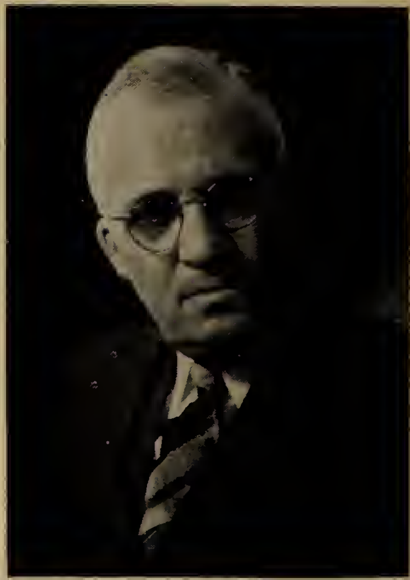
The Hon. G. P. Graham, Minister of Railways and Canals (Canada) was chairman of a National Advisory Committee appointed by the Government of Canada, and the Hon. Herbert Hoover, Secretary of Commerce (United States) was chairman of the United States St. Lawrence Commission. Both bodies studied the broader national aspects of the project.

A statement and engineering report on the development of power on the St. Lawrence river was submitted to the International Joint Commission in 1925 by the Hydro-Electric Power Commission of Ontario, whose chairman at the time was Sir Adam Beck; F. A. Gaby, M.E.I.C., was chief engineer, with H. G. Acres, M.E.I.C., as hydraulic engineer and R. S. Lea, M.E.I.C., as consultant. This report proposed three alternative schemes for development, giving estimated costs for each, and noting that extensive markets existed for power, gave the opinion that St. Lawrence power could produce energy at rates that were competitive and commercially attractive within radius of 300 miles.

General the Hon. A. G. L. McNaughton, M.E.I.C., chairman of the Canadian Section, International Joint Commission.



J. G. G. Kerry, M.E.I.C., made extensive studies of ice conditions and proposed a national power project and waterway.



Guy A. Lindsay

Report of 1926 and Treaty of 1932

In 1926 the Joint Board of Engineers submitted a comprehensive report, which may with justice be looked upon as the engineering corollary of the 1921 report of the International Joint Commission. It recommended a 25 ft. waterway (the Canadian majority favouring a 27-ft. depth) with a 30-ft. depth over the lock sills. In 1931 the board reconsidered these recommendations and revised its proposals to a 27-ft. depth. The board, which had raised the Wooten-Bowden estimates considerably after a two-year study, recommended that the new Welland canal be absorbed into the project, and set the probable cost of the whole project excluding interest charges for both power and navigation at some $850 million, about one-third of it payable by Canada and two-thirds by United States. The cost for power alone, they said, would reach $500 million. Annual charges on the Canadian share would be $9.6 million.

With a channel depth of 27 feet, they estimated the capacity of the waterway at 24,000,000 tons yearly after certain locks were "twinned". As of the year 1941, they estimated Canadian seaway traffic would amount to 7,675,000 tons, more than half of it grain and flour, on which the saving in transportation would amount to over $10 million yearly.

Tolls were discussed but no definite recommendation was given. Estimated length of the construction period was eight years and might take 16 years. The Canadian section favoured a two-stage development, in the International section of the St. Lawrence, while the American members preferred the single-stage.

A treaty between Canada and the United States, based on the 1926 report, was signed in July 1932, but failed of ratification by the U.S. Senate in 1934 after months of debate. This treaty had recommended the harnessing of 2,200,000 horsepower in the International section in two stages, one powerhouse at Chrysler Island and one at Barnhart Island. The cost would be divided equally between the two countries with credits allowed to each for any work previously done.

Other Developments on Seaway Route

Meantime, two projects which would ultimately form part of the completed seaway were being undertaken in Canada, namely, construction of the new Welland ship canal, and the development of power at Beauharnois in the Soulanges section. The former was being built by the Canadian Government, while the latter was undertaken by the Beauharnois Light Heat and Power Company with the proviso that the power canal would later be improved and deepened and widened to the dimensions necessary for use as a navigation channel for the Seaway.

Robert H. Saunders, chairman of Ontario Hydro from 1948 until his death in 1955.

The new Welland ship canal, fourth and largest of a series of four canals built in Canada to connect lakes Erie and Ontario, was commenced in 1913. Work was suspended in the fall of 1916 but was resumed after World War I and completed in 1932 at a capital cost of $130 million. The last eight miles of channel are now being deepened to 27 feet.

This new canal was designed by the Department of Railways and Canals at Ottawa, under W. A. Bowden, M.E.I.C., chief engineer. Dr. Alexander J. Grant, M.E.I.C., was engineer in charge of construction during the life of the project, with W. H. Sullivan, M.E.I.C., as principal assistant, and F. E. Sterns, M.E.I.C., in charge of designs. E. G. Cameron, M.E.I.C., was principal assistant during the later stages. Col. A. E. Dubuc, D.S.O., M.E.I.C., succeeded W. A. Bowden, M.E.I.C., as chief engineer in the mid twenties.

It was Mr. R. A. C. Henry, M.E.I.C., then chief engineer of Beauharnois Light, Heat and Power Company, who made the imaginative and far-sighted proposal that the difficulties of power development in the Soulanges section should be overcome by the construction of a canal between Lake St. Francis and Lake St. Louis to take the full flow of the St. Lawrence.

The Beauharnois development of the Beauharnois Light, Heat and Power Company, now owned and operated by Hydro-Quebec, is one of the largest plants in Canada with 1,350,000 hp. at present installed. When completed it will produce over two-million horsepower. Located in the Soulanges section, it was commenced in 1929. The power canal is 16 miles long and is now being dredged to a 27-foot depth throughout. Two locks are at present being installed by Canada's Seaway Authority. The initial development was designed by a board of consulting engineers composed of Dr. T. H. Hogg, M.E.I.C., W. S. Lea, M.E.I.C., and F. B. Brown, M.E.I.C., Construction was done under the direction of F. H. Cothran, M.E.I.C., vice-president and general manager, with D. F. Noyes, M.E.I.C., as superintendent and M. V. Sauer, M.E.I.C., as hydraulic engineer.

Two More Treaties Failed to Get U.S. Approval

In 1936 proposals for a new treaty were discussed with the United

R. A. C. Henry, M.E.I.C.

States, but without success. Following the request by the Hydro-Electric Power Commission of Ontario to divert additional Niagara water equivalent to the volume diverted from the Ogoki watershed into Lake Superior, negotiations were opened between the two countries, resulting in the establishment of a new joint board of Canadian and American engineers.

Representing Canada on this board were: Guy A. Lindsay, M.E.I.C., Dr. T. H. Hogg, M.E.I.C., Olivier O. Lefebvre, M.E.I.C., and M. C. Hendry, M.E.I.C. Representing the United States were Brig. Gen. T. H. Robins, U.S. Army, Roger B. McWhorter, and Gerald V. Cruse.

A Canada-U.S. agreement of March 19, 1941 was based on the report of this newly constituted joint board, presented in January of the same year. It called for the establishment and maintenance by both governments of a Great Lakes-St. Lawrence Basin Commission, which would prepare a combined project for navigation and power on the International section. Each government would have the obligation to carry out construction of various works within its own territory. The agreement bestowed exclusive right to the use of any waters diverted from any other watershed into the St. Lawrence Basin. The single-stage development for power in the International section was agreed upon.

The attack on Pearl Harbour on December 7, 1941 caused the seaway project to give way to more

The Hon. Lionel Chevrier, president of The St. Lawrence Seaway Authority.

urgent defence matters. Once the war was over, interest in the matter was resumed, but the U.S. Congress was not disposed to approve the agreement.

Engineering Studies Continued by Canada

During this period further study of the project, which had been proceeding under the direction of D. W. McLachlan, M.E.I.C., as engineer in charge, was transferred to a newly formed general engineering branch of the Federal Department of Transport at Ottawa. D. W. McLachlan, and later Guy Lindsay, M.E.I.C., were in charge of this work under the general direction of R. A. C. Henry, M.E.I.C., chairman, Air Transport Board, as consulting engineer. Concurrently the Hydro-Electric Power Commission of Ontario carried out further studies of the power aspects in the international section, under the successive direction of Dr. T. H. Hogg, M.E.I.C., Robert H. Saunders, and Dr. R. L. Hearn, M.E.I.C., as chairmen; with R. L. Hearn, M.E.I.C., as chief engineer and assistant chairman. Later Dr. Otto Holden, M.E.I.C., was appointed manager, engineering.

A board of engineers was appointed in September 1947 by the Canadian Government to determine whether the scheme for improvement of the Lachine section of the Seaway as recommended by the Joint Board of Engineers in 1926 was practical; what alternative schemes, if any, would be better adapted to the ends desired; and what would be the revised estimate of costs. Members were R. A. C. Henry, M.E.I.C., Dr. Arthur Surveyer, HON. M.E.I.C., Guy Lindsay, M.E.I.C., and C. W. West, M.E.I.C., director of canal services, Department of Transport.

With the co-operation of Hydro-Quebec, its manager René Dupuis, M.E.I.C., and its chief engineer, F. P. Rousseau, M.E.I.C., this board made exhaustive studies of several alternatives in the Lachine section. Their report in October, 1948, stated that the scheme for navigation alone prepared by Guy Lindsay, M.E.I.C., of the Department of Transport was the most suitable, the cost of which was estimated at $87,300,000.

For combined navigation and power the report proposed a navigation channel on the south side of Laprairie basin and along the south shore of the St. Lawrence opposite the port of Montreal, a dam and a powerhouse at alternative locations below Victoria bridge, built to develop 1,200,000 horsepower, with retention of Victoria bridge. The total cost was estimated at $256 million with an additional $19 million if the bridge was replaced by a tunnel. With the powerhouse located at an alternative location 3500 feet below the bridge the estimated cost would be $266.3 million.

Canadian Government Report of 1949

A report was issued by the Department of Transport in Ottawa in June 1949 on the entire Seaway project. This report proposed dredging navigation channels to a depth of 27 feet from Prescott to Montreal, as well as the balance of the channel through the Welland ship canal. It advocated adoption of a controlled single-stage project as agreed upon between Canada and United States representatives in 1940, with an installed capacity in the International section of 2,200,000 h.p.

It also proposed a control dam at Iroquois and a dam at the Long Sault rapids, built on the American side, as well as a navigation channel on the American side with two locks; rehabilitation of the towns of Iroquois and Morrisburg; deepening of the Beauharnois canal and provision for two locks thereon; and improvement of the navigation channel in the Lachine section by Canada as recommended in the 1948 report.

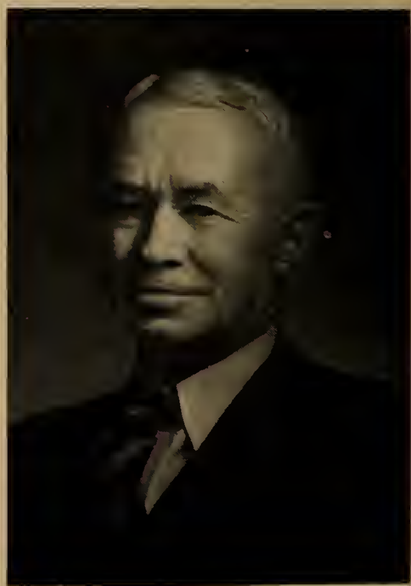
The estimated cost of completion, based on improvement of the Lachine section for navigation only, was given as $336 million for Canada and $470 million for the United States, a total of $806 million. These figures inluded work to be done by the United States in the Upper Lake section, as well as all monies already spent by both countries both there and on the Welland ship canal and in the Thousand Islands section.

Canada Proposes all-Canadian Seaway

Up to this time the proposal for the completion of the St. Lawrence "Seaway" had been based on the conception that these facilities would be toll free. However, in the 1940's the idea that the Seaway should be self-supporting had gained a wide measure of acceptance since it was evident that both in the power and navigation aspects, the St. Lawrence project could be organized on a self-liquidating basis.

In 1950, despite the support of President Truman, the 81st Congress, hindered by the U.S. Senate's reluctance, adjourned without approving the agreement of 1941. The Canadian Government, anxious to get the project started, then notified the United States that, if need be, Canada would undertake the navigation part of the project alone and bear the whole cost, subject to tolls to defray charges for operation, maintenance and amortisation. In this proposal the power works in the International section would be constructed at the cost and for the benefit of the Hydro-Electric Power Commission of Ontario and of an 'entity' to

Dr. Richard L. Hearn, M.E.I.C., who has been chairman of the Hydro-Electric Power Commission of Ontario since 1955.



be named by the Government of the United States.

In 1951 the Canadian Parliament at Ottawa passed the St. Lawrence Seaway Act, setting up a St. Lawrence Seaway Authority to undertake the work, to be composed of three members, whose mission was to carry on the necessary construction for the navigation portion of the project, locating the channel entirely through Canadian territory. The staff of the general engineering branch of the Department of Transport was moved to Montreal in 1953.

Until 1948 intensive efforts had been made to obtain Congressional approval of a combined power and Seaway project. In 1948, however, New York State applied to the U.S. Federal Power Commission for a power licence separate from the Seaway, believing this course could more quickly resolve both projects. This was blocked by the United States authorities until 1952 because of continuing efforts to obtain approval of the combined seaway-power project.

Applications to IJC, 1952

Under date of 30 June 1952 the International Joint Commission received the applications of the Governments of Canada and of the United States for an order of approval of the construction of certain works for development of power in the International Rapids section of the St. Lawrence River. Extensive public hearings were held by the Commission at cities and towns on the St. Lawrence River and on Lake Ontario in Canada and the United States.

The Commission issued an order of approval of the power project on 29 October 1952 in Montreal. This project was to be carried out by the Hydro-Electric Power Commission of Ontario and an 'entity' to be named by the Government of the United States. The conditions of the order provided that the works to be constructed by the power entities would assist and facilitate the addition of the works required for navigation.

The order also provided for the coordination of design and construction in the International section by an International St. Lawrence River Board of Engineers and most importantly for the regulation of the St. Lawrence on the completion of the project by the International St. Lawrence River Board of Control established by and responsible to the International Joint Commission.

Members of the Canadian Section, International Joint Commission at this time, who had been closely associated with Seaway negotiations over the past several years were General the Hon. A. G. L. McNaughton, M.E.I.C., Colonel J. Lucien Dansereau, M.E.I.C., and Dr. George Spence, AFFIL. E.I.C. The United States members were Hon. A. O. Stanley, chairman, Roger B. McWhorter, Eugene W. Weber, and Jesse B. Ellis, secretary.

In July 1953 the United States Federal Power Commission issued a licence which was accepted by the Power Authority of the State of New York in November 1953. Actual work was however held up by litigation in the New York State Courts. The navigation project was given approval by the United States Congress through passage of the Wiley-Dondero Act on May 13, 1954. This Act authorized a U.S. Government agency, the St. Lawrence Seaway Development Corporation, to undertake the navigation development in the International section on the American side.

On June 7, 1954 the U.S. Supreme Court finally handed down a decision refusing to review a decision of the U.S. Circuit Court of Appeals, District of Columbia, adverse to the Lake Ontario Land Development and Beach Protection Association, Inc., which had sought delay on the basis of a claim its members would be damaged by raising the levels of Lake Ontario.

On June 10, 1954, state legislation clarifying the New York State Power Authority's right to condemn property and to issue notes for temporary financing was obtained at a special session, and the first contract for cofferdams at Long Sault dam was advertised. Construction was started simultaneously by both countries on August 4, 1954.

The Four Authorities

Improvements to navigation between Lake Erie and the Port of Montreal on the Canadian side are being built by the St. Lawrence Seaway Authority, president of which is the Hon. Lionel Chevrier, with Charles Gavsie and C. W. West, M.E.I.C., as directors. A. Gordon Murphy, M.E.I.C., and Lawrence H. Burpee, M.E.I.C., are chief and deputy chief engineers respectively. (Mr. Burpee is a son of the late Lawrence J. Burpee, who as the then secretary of the Canadian Section, International Joint Commission, had carried a major responsibility for the preparation of the Commission's 1921 report to the governments of Canada and the United States on the St. Lawrence.)

Improvements to navigation in the International section on the American side are being done by the St. Lawrence Seaway Development Corporation, Inc., with Lewis G. Castle at Washington as administrator, M. W. Ottershagen, deputy administrator, W. S. Chapin, general manager, and Raymond F. Stellar, chief engineer.

At ground-breaking ceremonies in 1955 marking the start of the power project were Prime Minister Louis St. Laurent, the Hon. Thomas E. Dewey, Governor of the State of New York, the Hon. Leslie M. Frost, Prime Minister of Ontario, and Robert H. Saunders, then chairman of Ontario Hydro.

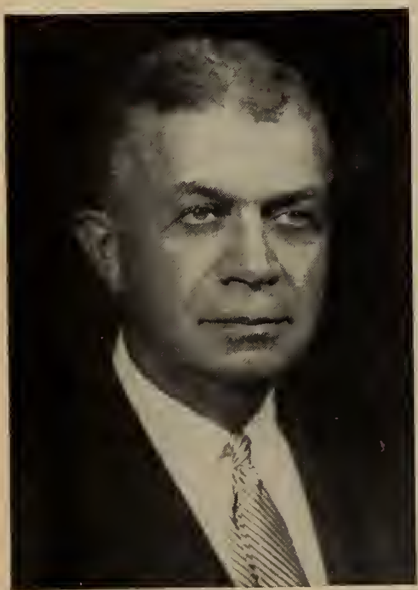
Design and contract awards are by the Corps of Engineers, U.S. Army. Uhl, Hall & Rich, of Boston, are consulting engineers.

Development of power is being undertaken jointly by the New York State Power Authority and the Hydro-Electric Power Commission of Ontario. Chairman of the Commission is Dr. Richard L. Hearn, M.E.I.C., Dr. Otto Holden, M.E.I.C., is assistant general manager and chief engineer. Gordon Mitchell, M.E.I.C., is project manager. Chairman of the New York State Power Authority is Robert Moses, with William Wilson vice-chairman, while J. Burch McMorran is chief engineer.

Supervision and Control

Supervising and co-ordinating the engineering of the four "Authorities" on the International Section is the St. Lawrence River Joint Board of Engineers, established by the two governments in accordance with the recommendations of the International Joint Commission. Representing Canada are the Hon. G. C. Marler and Hon. Lionel Chevrier. Alternates are H. W. Lea, M.E.I.C., and George Kohl, M.E.I.C. The late Max V. Sauer was an alternate member of the St. Lawrence River Joint Board of Engineers until his death in April 1956. U.S. members are the Hon. W. M. Brucker and the Hon. Jerome K. Kuykendall, with Maj. Gen. C. G. Holle and Francis L. Adams as alternates.

Responsible to the I.J.C. for the regulation of the flows of the St. Lawrence is the International St. Lawrence River Board of Control, with T. M. Patterson, M.E.I.C., of the Department of Northern Affairs and National Resources as chairman, and J. B. Bryce, M.E.I.C., of Ontario Hydro, and Dr. René Dupuis, M.E.I.C., of Hydro-Quebec, as members of the Canadian Section. G. A. Hathaway, U.S. Corps of Engineers is chairman, and Francis L. Adams, chief, Bureau of Power, Federal Power Commission, and Bertram D. Tallamy, New York State Department of Public Works, are members of the United States Section.



Lewis G. Castle, Administrator, the St. Lawrence Seaway Development Corporation, Inc. (Washington, D.C.)

Supplementary Order, IJC, July 1956

On 2 July 1956 the International Joint Commission met in Montreal and issued a supplementary order to the order of approval of 29 October, 1952 in the matters of development of power in the International Rapids section of the St. Lawrence River and the regulation of the level of Lake Ontario.

The principal effect of this supplementary order is to give precision to the methods to be followed in the regulation of the levels of Lake Ontario and the flow of the St. Lawrence River.

At this time the Hon. Len Jordan, formerly Governor of Idaho, had replaced Hon. A. O. Stanley as chairman of the U.S. Section of the Commission, and Ames W. Williams had replaced Jesse B. Ellis as secretary.

Many Members Have Made Contributions

Besides the Institute members whose names have been already mentioned herein as occupying executive positions on various boards and commissions, or in charge of planning, design or construction, are many members, and junior and student members, occupying responsible intermediate or junior positions, the work of which has contributed substantially to the end results. The total would be numbered in the hundreds.

Beyond these are many prominent Institute members who from time to time have contributed scientific, economic and statistical research studies connected with the project or have been engaged as consultants. Many other members have made valuable contributions in the form of engineering studies, addresses or articles. A partial list of these includes the following.

William Hamilton Merritt, C.E., of Hamilton, Ontario, was one of the earliest advocates of a Welland canal (circa 1821).

Lt. Col. John By, of the Royal Engineers, who built the Rideau canal in 1828-32, did much to make Canadians aware of the advantages of a Great Lakes-St. Lawrence Seaway. With the Rideau canal system completed ships could sail up from the sea via the Ottawa River, thence through the Rideau canal to the Great Lakes. This first 'seaway' became a commercial reality in 1841. Colonel By was consulted regarding the building of the early Welland and Grenville canals. The system of construction he developed on the Rideau was followed on the early Welland canals.

Walter Shanley, C.E., and **T. C. Clark**, C.E., made reports on the proposed Georgian Bay ship canal project in 1858.

John Page, C.E., chief engineer, Federal Department of Public Works, made a report on the St. Lawrence ship channel in January 1869.

F. C. Capreol, C.E., made a series of reports in 1871 on the proposed Huron and Erie ship canal.

George F. Swain, M.E.I.C., made an appraisal for the Royal Commission on Railways and Transportation in Canada (Drayton Acworth Report) in 1931/32. This appraisal and the report which followed it in 1932 had a direct bearing on the economic aspects of the proposed deep waterway.

Arthur V. White, M.E.I.C., consultant to the Commission of Conservation for Canada, in 1918, in the Commission's 9th annual report called for retention of St. Lawrence power for use in Canada, rather than allowing it to pass into the hands of powerful private interests who would export much of it for those in the United States. Mr. White also published a special report "Long Sault Rapids, St. Lawrence River" (Com. of Conservation, 1913).

Hugh L. Cooper, M.E.I.C., internationally known hydro-electric engineering consultant of New York City, made a report on the St. Lawrence waterway as a consulting engineer in 1920.

Dr. Howard T. Barnes, M.E.I.C., of McGill University, an expert on ice problems, conducted extensive studies during the 'twenties of ice problems and of the types, formations and removal of ice in the St. Lawrence ship canal, the St. Lawrence River, the Great Lakes, and at the port of Montreal.

J. T. Johnston, M.E.I.C., director, Water Power and Reclamation Service, Ottawa, in the twenties, contributed extensive hydraulic studies on stream flow and on hydro-electric power development in Canada.

F. W. Cowie, M.E.I.C., presented a paper before the Montreal Branch of the Institute in April 1923 entitled "Transportation Routes in Canada".

E. A. Forward, M.E.I.C., consulting engineer, in a paper read before the Montreal Branch, Engineering Institute of Canada, in October 1923, proposed a regulating dam at Rapide du Plat, a dam opposite Morrisburg from Clarks Point to Mariatown, a Canadian powerhouse on Canada Island and an American powerhouse on Clarks Island. He also advocated a waterway up the Ottawa to North Bay.

Studies by **C. V. Christie,** M.E.I.C., and **P. T. Davies,** M.E.I.C., on the cost of electric power were published in *Transactions, Engineering Institute of Canada,* 1924, vol. xxxv.

Frederick B. Brown, M.E.I.C., was the author of a report for the Beauharnois Light, Heat and Power Co., on the proposed hydro-electric power development on the St. Lawrence between Lakes St. Francis and St. Louis, in May, 1927.

Frank H. Keefer, M.E.I.C., in 1927 published a pamphlet on the St. Lawrence developments, entitled, "A Corollary to the Duncan Report".

Lesslie R. Thomson, M.E.I.C., consulting engineer of Montreal, presented a paper entitled "The St. Lawrence Problem" before the 43rd General Professional Meeting of the Institute in 1929. This paper embodied a complete history of the project from its earliest stages and dealt in detail with its economic aspects in relation to both navigation and power. Many maps, graphs, tabulations and appendices were included, as well as a complete bibliography of reports, articles and papers to date on the subject.

Beaudry Leman, M.E.I.C., was a member of the Royal Commission of Railways and Transportation in Canada (Drayton Acworth Report) in 1931-32.

J. L. Busfield, M.E.I.C., addressing the Montreal Branch of the Institute in March 1936 on the subject of the St. Lawrence Ship Channel, recommended the construction of a submerged regulating dam at Cap a la Roche, and a 300-ft. wide "control channel", as invented by **DeGaspe Beaubien,** HON. M.E.I.C., and himself, to eliminate undesirable features of the standard lock.

Max Sauer, M.E.I.C., hydraulic engineer and general superintendent, generating stations, Montreal Light Heat and Power Co. Cons., for many years, who in the early forties designed and built the remedial works in the St. Lawrence river for the Beauharnois project, presented a paper before the Montreal Branch, Engineering Institute of Canada, in October 1943 on this project. Mr. Sauer was also a Canadian member for the St. Lawrence River Joint Board of Engineers until his death in April 1956.

J. G. G. Kerry, HON. M.E.I.C., consulting engineer, devoted years of study to ice conditions, particularly in relation to the St. Lawrence. He had long held the vision of an 'all season' Seaway, kept ice-free by means of the latent heat in the deep waters of Lake Ontario. Mr. Kerry also advocated in 1951 a wholly national power development and waterway, diverting Canada's share of water from a point near Galop Island across the Eastern Ontario lowlands into the Ottawa River at Point Fortune, as first proposed by **Noulan Cauchon,** M.E.I.C., about 1920, and reviewed and supported by **W. F. Coutlee,** M.E.I.C.

Mr. Kerry also made extensive studies of ice conditions in the St. Lawrence estuary and gulf, and maintained winter navigation could be made possible on the ship channel below Quebec by a dam or barrage across the Ile au Coudres channel, cutting off the tidal flow and controlling a flow of relatively warmer water to ride over the saltier waters of the estuary.

Robert Moses, Chairman of the Power Authority of the State of New York.

George Washington Stephens, past president of the Montreal Harbour Commission, wrote a comprehensive work entitled "The St. Lawrence Waterway Project" published by Louis Carrier and Company in Montreal and New York in 1929.

The late **Robert H. Saunders,** chairman of the Ontario Hydro-Electric Power Commission in the early 1950's, was a vigorous promoter of the "seaway". Though not himself an engineer, his interest in public affairs and public relations, combined with his tireless energy and diplomacy, was instrumental in advancing the project to a reality.

Probably the longest continuous connection with the St. Lawrence project of any of those at present serving under the Government of Canada is that of Miss Elizabeth Sutherland, at present the secretary of the Canadian Section, International Joint Commission, who became the secretary to C. A. Magrath, M.E.I.C., then chairman of the Canadian Section, I.J.C., in 1912.

In so far as has been possible, names of Canadian engineers who have contributed their services in connection with the project have been gathered from available official reports and records.

Inevitably, however, the names of some will be found to have been unintentionally omitted. To them the Engineering Institute of Canada offers its sincere apologies. *The Engineering Journal* will be grateful to hear from the membership of any further names which should be added to the list.

General Design of The St. Lawrence Seaway

D. M. Ripley, JR.E.I.C.,

Senior Assistant Engineer (Hydraulic), The St. Lawrence Seaway Authority

Read at the 70th Annual General and Professional Meeting, The Engineering Institute of Canada, Montreal, May 1956

This paper deals generally with the design and inter-relationship of the main features of the St. Lawrence Seaway. A brief history of the development and mention of the power projects are followed by a description of the principal features of the Seaway from the Welland canal to Montreal. The author concludes with a note on the material requirements of the project and the progress made.

FROM the Canadian point of view the St. Lawrence Seaway may be defined as the works necessary to provide and maintain, either wholly in Canada or in conjunction with works undertaken by an appropriate authority in the United States, a deep waterway between Lake Erie and the Port of Montreal. The object of this development is to place the Great Lakes ports in direct communication with the lower St. Lawrence River and ocean transport. Fair and reasonable tolls are to be established to place the project on a self-liquidating basis.

Navigation Standards

The standards adopted for the St. Lawrence Seaway conform to those of the Welland Ship Canal, which, although completed in 1932, was constructed to dimensions that anticipated the early extension of deep-draught navigation facilities eastward to Montreal and the increase in traffic that would result.

As at the Welland Ship Canal, the St. Lawrence Seaway will have locks 80 feet in width and 859 feet in length. The length of the locks between breast wall and gate fender will be 765 feet, which gives a practical usable length of 715 feet. The depth over lock sills at minimum low water conditions will be 30 feet.

The controlling channel depth will be 27 feet. The bottom width of navigation channels and canals will be not less than 200 feet where flanked by embankments on both sides, not less than 300 feet where flanked by one embankment and not less than 450 feet where both banks are submerged. These widths are to be increased where cross currents make navigation more difficult or where required to reduce current velocities to those suitable for navigation. In general, average current velocities in channels to be used for navigation will not exceed 4.0 feet per second. Somewhat lower current velocities will be provided at lock entrances and in similar locations where vessels will be required to reduce speed. The minimum radius of curvature for navigation channels will be 5,000 feet with a minimum distance between bend reversals of one quarter mile.

The minimum vertical clearance provided at bridges will be 120 feet.

History of Development

The St. Lawrence Seaway project will provide a standardized and integrated plan of development for deep-draught navigation of the Great Lakes — St. Lawrence River system from Lake Erie to Montreal Harbour. This development, together with the improvement of the Great Lakes connecting channels by the United States, will provide the final necessary links in a continuous waterway, 2,200 miles in length, across half a continent from the head of Lake Superior to the Atlantic Ocean.

Canada has been building canals in the St. Lawrence River for over 100 years, but, except for brief periods, the navigation facilities on and between the Great Lakes have been more advanced in the scale of progress than those in the 114-mile portion of St. Lawrence River above the port of Montreal. The present St. Lawrence River Canals, in this section of the river which accommodate vessels of 14-ft. draught, fell well behind with the opening of the Welland Ship Canal in 1932, and their obsolescence has been hastened by the continued improvement of the St. Lawrence Ship Channel between Montreal and the sea to the present 35-ft. depth.

The St. Lawrence Seaway — or Deep Waterway as it has been called — is not a new idea. Comprehensive studies were begun by the International Joint Commission in 1919 and these led to the establishment of a Joint Board of Engineers. This Joint Board of Engineers did their work so well that their report, which was submitted in 1926, may still be considered to be a standard reference document on the St. Lawrence project. The recommendations of the 1926 Joint Board of Engineers were embodied into the 1932 St. Lawrence Deep Waterway Treaty. This treaty failed of ratification. Again, with the St. Lawrence Basin Agreement in 1941, efforts were continued to have the project approved but without success.

Up to this point provision for a deep waterway from Lake Erie to Montreal had linked with it proposals for the development of power in the International Section of the St. Lawrence River. The many difficulties encountered in obtaining approval of such an integrated project led to the adoption of a new approach by Canada in 1951. Briefly, this new approach would enable the power aspect of the project to be developed separately from the Seaway by the entities most appropriately concerned, namely, the Hydro-Electric Power Commission of Ontario and a power development entity to be designated by the United States. To ensure continuation of navigation under these circumstances, Canada agreed to construct concurrently with the power works such navigation works necessary to provide a 27-ft. canal system on the Canadian side of the river between Montreal and Lake Erie which was referred to as the All-Canadian Seaway.

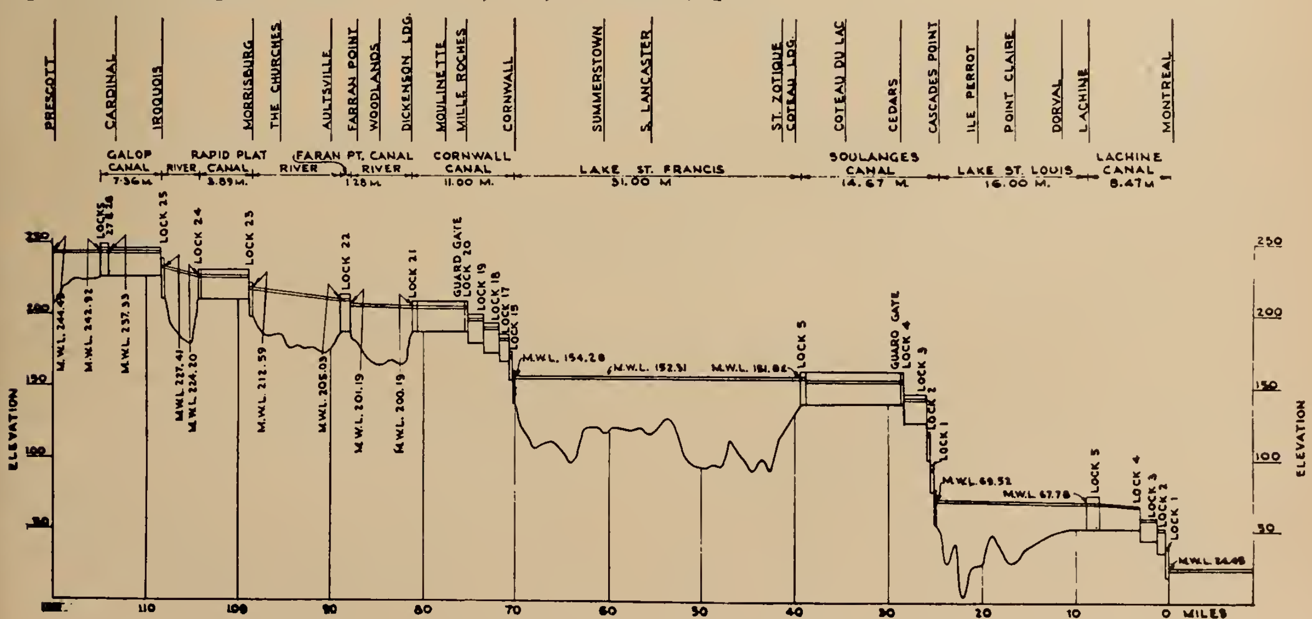
The matter of the power development in the International Section of the St. Lawrence River by the Ontario Hydro-Electric Power Commission and, as eventually arranged, by the Power Authority of the State of New York, received the approval of the International Joint Commission in October 1952. From this point events moved quickly. In May 1954, President Eisenhower signed the Wiley-Dondero Bill, an act passed by the Congress of the United States authorizing an American agency to construct navigation works on the United States side of the St. Lawrence River between Cornwall Ontario, and Lake Ontario. Corresponding legislation in Canada, the St. Lawrence Seaway Authority Act, which was proclaimed in force in July 1954, authorized the St. Lawrence Seaway Authority to proceed with the seaway construction, according to Section 10 of the Act, "either wholly in Canada, or in conjunction with works to be undertaken by an appropriate authority in the United States." The close cooperation between Canada and the United States, which has prevailed in all matters relating to boundary waters, resulted in the construction arrangement for the seaway that is now in effect. While acknowledging the right of each country to construct seaway facilities on its own side of the river, Canada initially will construct the seaway locks and canals at Iroquois, Ontario, and at Beauharnois and Montreal, Quebec, together with the channel work in Lakes St. Francis and St. Louis, and Montreal Harbour, and the deepening of the Welland Ship Canal. The United States agency, the Saint Lawrence Seaway Development Corporaton, will construct navigation locks and canals from Lake St. Francis to above the Barnhart Island Powerhouse and the channel deepening on the United States side of the international boundary in the Thousand Islands section. In all, Canada will construct five locks with connecting canals and channels, and the United States will construct two locks with connecting canals and channels.

Because of the interest focused on the construction in the International Section of the river as a result of the many international negotiations and discussions leading to the final agreement on the seaway and power project, it is not generally realized even today that a major share of the seaway work is being carried out in the Canadian section of the river. Actually, of the seven new locks being constructed, four of them are near Montreal and, of the total expenditure to be made on Seaway construction, the St. Lawrence Seaway Authority will provide approximately two-thirds, chiefly on works in Canada. In fact, the project now under construction differs from the so-called All-Canadian Seaway only near Cornwall, Ontario, where two locks and connecting canals on the U.S. side of the river have replaced for the present the similar structures it was proposed to build in Canada.

Power Developments

Concurrent with the construction of the St. Lawrence Seaway is the large-scale development of power on the St. Lawrence River at two sites, and possibly three. The development of power in the International Section of the river near Cornwall, Ontario, will make available to the Province of Ontario and the State of New York equal shares of some 2,200,000 horsepower. This power development will facilitate the navigation improvement as a result of the creation of a lake-like reach extending from the Barnhart Island powerhouses to Iroquois, Ontario, at which point the Iroquois Control Dam, a structure to be used to regulate the outflow and levels of Lake Ontario, will be located. Enlargement of the

Fig. 1. Present navigation facilities - Prescott, Ont., to Montreal, Que.



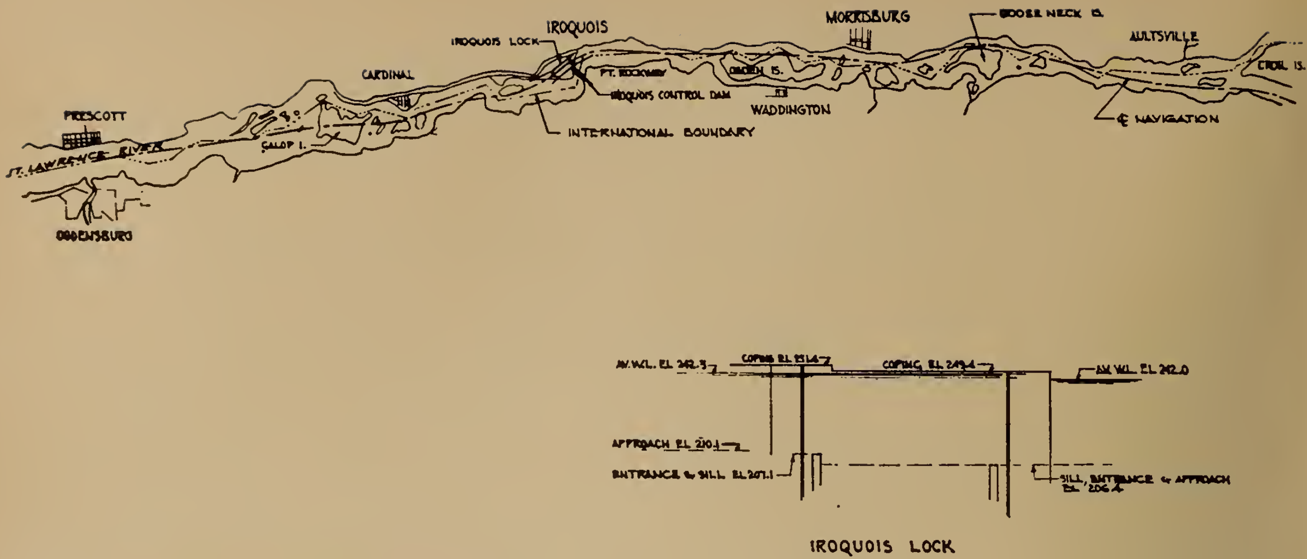


Fig. 2. Location and profile of the Iroquois lock.

river above the Iroquois Dam by the power entities will provide satisfactory navigation channels.

The second of the power developments, the Beauharnois plant of Hydro-Québec, was begun in 1932 and has been under continual expansion since that time. The present Beauharnois plant develops about 70 per cent of the more than 2,000,000 horsepower potential at that site, and the broad deep headrace canal which diverts water to the powerhouse from Lake St. Francis will provide a navigation canal in a 600-ft. wide portion along its north shore.

At Montreal, the Lachine Rapids will provide at least another 1,000,000 h.p. When this power potential at the Lachine Rapids is developed the St. Lawrence Seaway will tie in with the construction and operation of the power works in a manner to be described later.

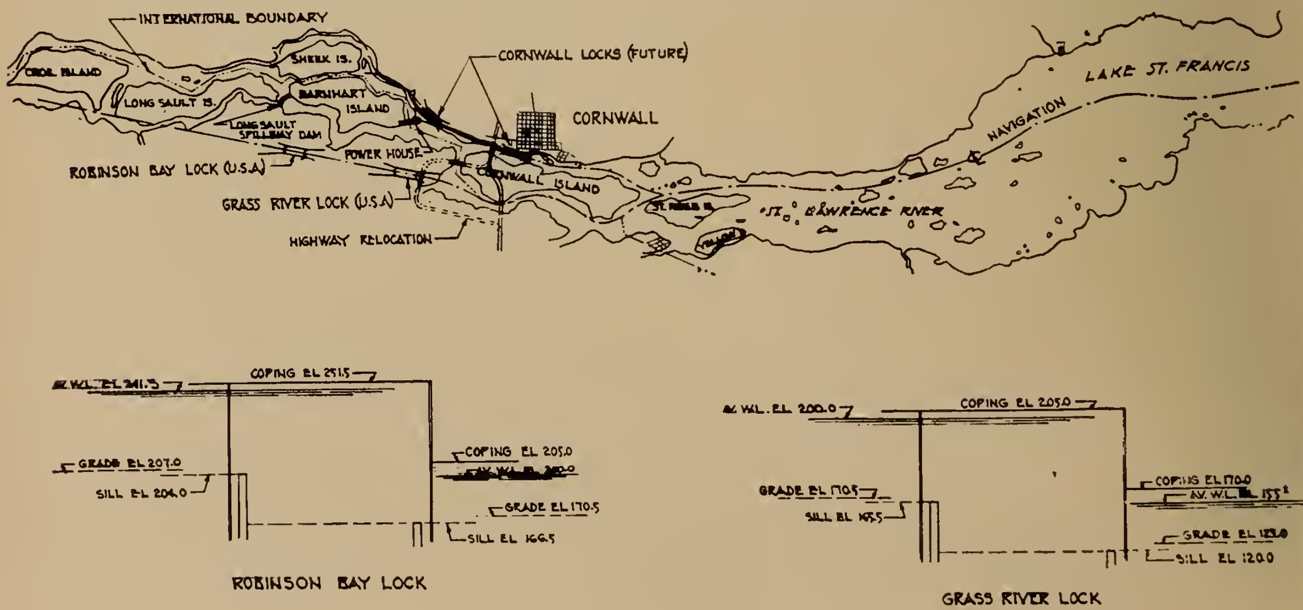
Present Navigation

Figure 1 illustrates the present navigation facilities of the St. Lawrence canals in profile. The significant features of this present system are the 14-ft. available depth at low water on the lock sills and the 22 locks require to overcome the rapids reaches of the river. The controlling lock dimensions, other than depth, are: length 255 feet, width 43.7 feet, and overhead clearance 94.8 feet. Of the 114 miles between Montreal and Prescott, 47 miles are spent traversing locks and canals and 67 miles traversing river and lake reaches. It may be of interest to note that the present 14-ft. canals system has been constructed to conform to the natural regime of the river.

Principal Seaway Features

The major works of the St. Lawrence Seaway are located in the 114-miles portion of the St. Lawrence River between Montreal, Quebec, and Prescott, Ontario. Relatively minor dredging above Prescott, through the Thousand Islands and in the reaches between the locks in the Welland Ship Canal complete

Fig. 3. Location and profile of Robinson Bay and Grass River locks. Future Cornwall locks are indicated.



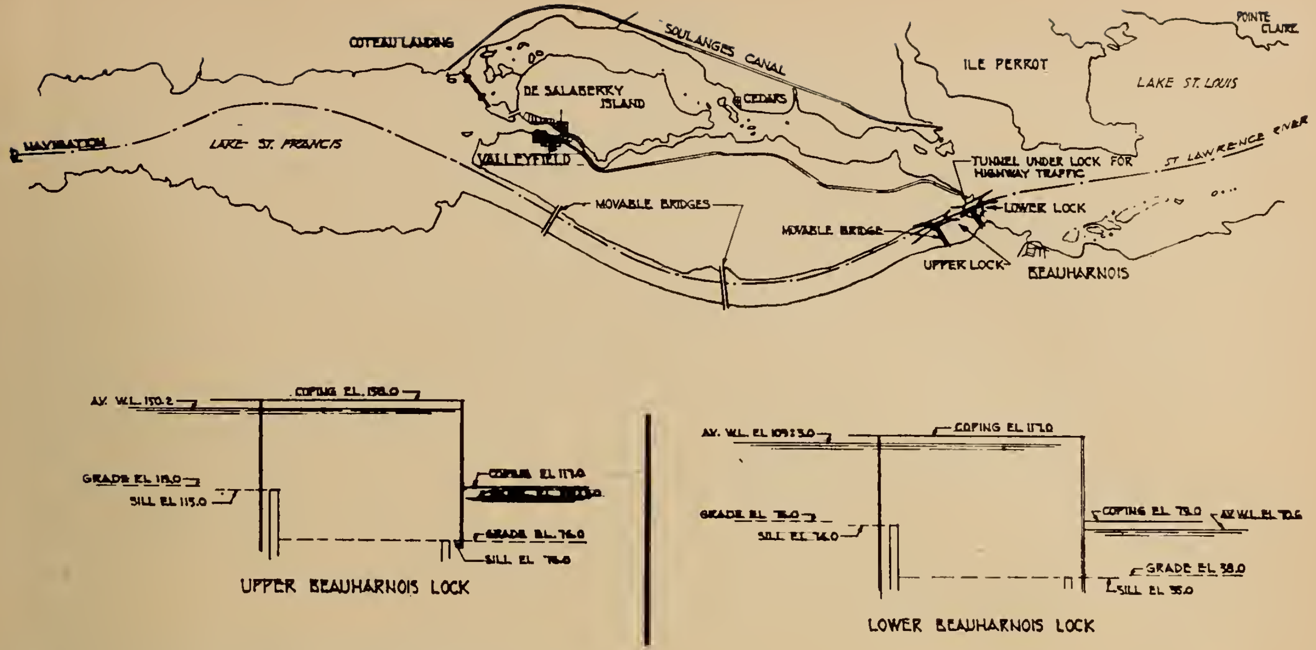


Fig. 4. Location and profile of Beauharnois locks.

the standardization process.

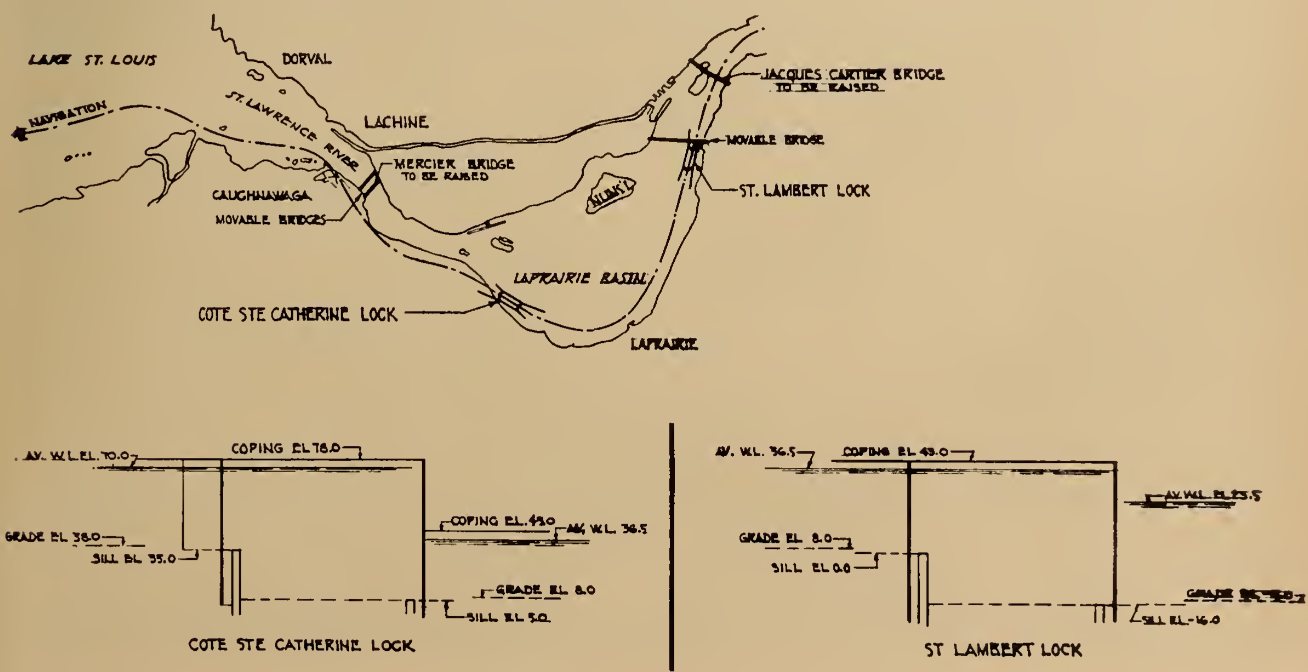
The navigation works that are to replace the present obsolete locks and canals are illustrated in plan and profile in Figures 2 to 5. It may be noted that the twenty-two old locks are to be replaced by seven new locks having a minimum depth over sills of 30 feet. The lock dimensions, as previously described, are similar to those of the Welland Ship Canal. All Seaway features are being so located and designed that extension of navigation facilities, including twinning of the locks, may be accomplished with a minimum of difficulty to meet traffic demands in the future.

Compared to the 47 miles of canal reaches of the present St. Lawrence Canals, the Seaway canal reaches will be reduced to 40 miles. Of more importance, the number of lockages will be reduced to 7 from the present 21. The resulting saving in time of passage from Kingston to Montreal will be at least 12 hours. Another significant comparison is the increased capacity of the seaway canals. The present canals accommodate vessels carrying 3,000 tons, whereas the seaway canals will handle ships carrying over 20,000 tons. All these improvements will result in an increase in annual tonnage capacity from the present 10 million tons to over 60 million tons.

Welland Ship Canal

Downbound vessels from the upper lakes when passing through the Welland Ship Canal will find the

Fig. 5. Location and profile of Cote Ste. Catherine and St. Lambert locks.



controlling channel depth increased from the present 25 feet to 27 feet. The existing canal will be widened in places to 350 feet to facilitate passing. The contracts for this work, which call for excavation in the dry during the winter months from Thorold to Lake Ontario and dredging from Thorold to Lake Erie, have been awarded and the work is in progress. Dry excavation in this latter portion of the canal is not possible because of the necessity for continuance of a diversion of water down the canal from Lake Erie for domestic and power purposes.

The Welland Ship Canal will be otherwise unaffected; in fact, as mentioned above, this canal provides the standard for the Seaway features elsewhere. Experience gained in construction and operation of the Welland Ship Canal has been, and continues to be, an invaluable aid in the design of the St. Lawrence Seaway. The St. Lawrence Seaway Authority is fortunate to have on its staff several engineers formerly employed on construction and operation of the Welland Ship Canal.

Port Weller to Prescott

From Port Weller the vessel track is 120 miles across Lake Ontario to Kingston where shipping enters the St. Lawrence River. Below Kingston the first navigation improvements encountered will be the enlargement of the present navigation channel through the Thousand Islands. Although the channel from Kingston through the Thousand Islands to the National Harbours Board elevator near Prescott is now in regular use by the largest of the upper lakes bulk carriers, it will be widened and deepened by dredging to conform to the seaway navigation standards. The work in this section of the river on the Canadian side of the international boundary will be carried out by the Seaway Authority and that on the United States side by the Seaway Development Corporation.

Prescott to Cornwall

Beginning at a point 4 miles downstream from Prescott, navigation will encounter a complete change of circumstances in comparison with those now existing. At the Galop Rapids, which form the natural outlet control of Lake Ontario, the power works begin in the form of a series of large hydraulic cuts specified in the Order of Approval of the power project. The navigation channels will be located to take advantage of these channel enlargements. The Order of Approval requires that the average current velocities in the cross section of the channels to be used for navigation must not exceed 4.0 feet per second at any time during the navigation season. The design and construction of these channels is primarily the responsibility of the power entities and exhaustive studies of these works are being made by Ontario Hydro at their Islington, Ontario, Hydraulics Laboratory. The design has now been accepted by all concerned and at the time of writing requires only the final approval of the St. Lawrence River Joint Board of Engineers, the approving agency of the Canadian and United States Governments. Briefly, the navigation standards have been met with a channel of 600-ft. minimum width. Curvation is moderate and the hydraulic model studies indicate no objectionable cross currents.

About 15 miles down river from Prescott (see Fig. 2) will be located the Iroquois Control Dam, the structure required to replace the natural outlet control for Lake Ontario that will be removed by the Galop Rapids excavation. Construction of the Iroquois Dam by the power entities is well advanced. This may be seen to the right in Fig. 6. To the left in Fig. 6 may be seen the exca-

Fig. 6. Iroquois lock and dam sites.

Fig. 7. Cote Ste. Catherine lock site.

vation for the Iroquois Lock, the navigation feature required to by-pass the dam.

The Iroquois Lock is being constructed by the St. Lawrence Seaway Authority. The contract for the lock was awarded in January 1955 and completion is scheduled for opening of navigation in 1958. The unique feature in the design of this lock is the use of sector gates; filling and emptying will be through the gate openings rather than the more conventional culvert filling system. The application of hydraulic model studies to lock design generally and the sector gate design in particular will be covered in another paper.[1]

The current velocities that will be experienced at the approaches to the Iroquois Lock have been studied on the Ontario Hydro river models at Islington, Ontario. These and other model tests undertaken by Ontario Hydro have provided the data for the establishment of the sill elevations and gate heights at the Iroquois Lock.

The normal lift at the Iroquois Lock will vary from a few tenths of a foot, when the Iroquois Dam is fully open, to 5.5 feet during the period when the water level above the Barnhart Island Powerhouses is at a maximum elevation 238.0, for a test period as required by the Order of Approval. The Iroquois Lock is being designed also to permit its use by 14-ft. navigation for a short time during the construction period, when the water level above the Iroquois Dam will be raised and the river below the dam kept as under present conditions. Under these circumstances the lift at the Iroquois Lock may be as much as 24.5 ft. Provision for such a lift will also permit use of the lock at 14-ft. draught should emergency circumstances arising after the seaway and power projects have been placed in operation require lowering of the pool between the Barnhart Island Powerhouses and the Iroquois Dam.

Proceeding below the Iroquois Lock, shipping will pass through the lake-like section created by the raised level at the Barnhart Island Powerhouses. Channels of at least the standard set out above will be available in this portion of the river. At Croil Island, 20 miles below the Iroquois Lock, vessels will enter the Long Sault Canal. This work, which is being undertaken by the Saint Lawrence Development Corporation, will provide an access canal 10 miles in length to the Robinson Bay and Grass River Locks (see Fig. 3). These locks divide about equally the lift required to overcome the fall of 87 feet at the Barnhart Island Powerhouses. The Robinson Bay and Grass River Locks are separated by an intermediate pool which is to be controlled at about elevation 200.0. Basically these locks are similar in dimension to those at the Welland Ship Canal.

Immediately downstream from the Grass River Lock will be undertaken an extensive channel enlargement designed to lower the current velocities in the South Cornwall Channel to the 4.0 feet per second required by navigation. Compensatory excavation will be done concurrently in the North Cornwall Channel to maintain the flow distribution to either side of Cornwall Island either as in nature or as agreed upon by Canada and the United States. A necessary requirement of this compensating excavation is that it will be so located and designed as not to preclude or make more difficult the future development of navigation on the Canadian side of the river near Cornwall, Ontario. The location of the

[1] "The use of hydraulic models in the St. Lawrence Seaway planning and design" by D. McIntyre, M.E.I.C., published on p. 1154 of this issue.

future 27-ft. navigation locks on the Canadian side of the river may be seen in Fig. 3.

In the Cornwall area the Seaway encounters the first vehicular crossing. A combined railway and highway bridge, the Roosevelt Bridge, at present crosses the North Cornwall Channel at Cornwall and the South Cornwall Channel about two miles below the Grass River Lock. Improvement for navigation will require the relocation of the south span of this bridge. This will be accomplished by a new movable bridge across the Grass River Lock with a new fixed span across Polly's Gut. The north span at Cornwall will remain unchanged for the present.

Cornwall to Beauharnois

Below the head of Lake St. Francis, a few miles downstream from Cornwall, the St. Lawrence River lies wholly in Canada and from this point to Montreal the seaway construction is being undertaken by the Seaway Authority.

Across Lake St. Francis the navigation channel follows a practically direct course for 30 miles to the Beauharnois power canal. Dredging required to deepen and widen the navigation channel at Fraser Point, Lancaster Bar and near the power canal entrance is now in progress.

The upper entrance to the Beauharnois Locks will be provided by the Beauharnois Power Canal. Under the terms of the Order-in-Council authorizing the diversion of water for power purposes at Beauharnois, the power canal has been constructed to include a 600-ft. wide navigable portion of adequate depth along the north bank. The layout of this feature may be seen in Fig. 4.

The Beauharnois Locks, to be located as shown in Fig. 4, will be very similar to the Robinson Bay and Grass River Locks in relation to each other. The fall from Lake St. Francis to Lake St. Louis of about 82 feet will be overcome by two locks separated by an intermediate pool having a controlled water level at elevation 109. These locks are equipped with mitre gates and a conventional side-filling and emptying system. The usual guard gate for ensuring retention of the upper pool in case of a gate failure resulting from collision by a vessel has been replaced by an emergency sector type gate, which may be closed against a head of water should a gate failure occur. A considerable saving in the time for a vessel to traverse the canal is thus affected. Contracts were awarded recently for the preliminary work on the Beauharnois Locks construction.

In the 15-mile length of the Beauharnois power canal there are a railway bridge and two combined railway-highway crossings. The three present bridges — one near Valleyfield, another near St. Louis, and one near the Beauharnois Powerhouse — will be replaced by vertical lift bridges. Highway No. 3 will be carried under the locks through a tunnel, thus eliminating any possible interruption of highway traffic.

Beauharnois to Montreal

Proceeding down-river from the Beauharnois Locks the navigation channel follows the naturally deep water in Lake St. Louis for 10 miles until above St. Nicholas Island, from which point the channel comes close to the south shore. A dredged channel 600 feet in width leads to the canal entrance near Caughnawaga. Dredging of this channel has been in progress since early in 1955.

In the past there have been many proposals for the improvement of the Lachine Rapids section for navigation. Some of these proposals were to be carried out concurrently with a power development. Although at the time of writing no power development appears likely in the Lachine Section

Fig. 8. St. Lambert lock site.

in the immediate future, the St. Lawrence Seaway will be so constructed in the Lachine Section that the power development may be carried out at a later date.

An overland channel of 250 feet minimum width and eight miles in length is being excavated through rock from Caughnawaga to Cote Ste. Catherine, where a lock is now under construction (Fig. 7). The Cote Ste. Catherine Lock will have an average lift of 33 feet. It will be equipped with mitre gates and a side-filling and emptying system. As at Beauharnois, an emergency operating sector type gate will be installed to ensure retention of the upper pool in case of a gate failure.

From the Cote Ste. Catherine Lock the navigation channel will be isolated from Laprairie Basin bv a continuous dyke throughout the eight mile length of the channel down to St. Lambert. The pool formed by the dyke will be controlled during the navigation season initially to elevation 35.0. Figure 5 shows the location of the Cote Ste. Catherine and St. Lambert Locks and the centre line of the canal from Lake St. Louis to Montreal Harbour.

At St. Lambert the lower lock of the St. Lawrence Seaway will be constructed. The lock location in relation to topographic features is shown in Fig. 8; the approach channel below the St. Lambert Lock and the dyke that separates the channel from the river may also be noted.

Fig. 9. Approach channel below St. Lambert lock during construction.

The approach channel is being excavated in rock with finished side slopes at 1.5:1 as shown in Fig. 9. The Seaway construction actually will terminate in Montreal Harbour where a turning basin is being dredged to facilitate entrance to and exit from the seaway canal without undue interference with port traffic.

Because of the wide variation in river stage experienced in Montreal Harbour during the navigation season the St. Lambert Lock, which will have an average lift of 13 feet, must handle shipping at river stages requiring lifts varying from 20 feet at low water to only 2 feet at high water.

Fig. 10. Longueuil water supply intake being placed below the St. Lambert lock approach channel. The Jacques Cartier bridge is seen in the background.

Integration with Municipal Services

The integration of the Seaway features with municipal and other facilities in the Montreal area raises many interesting problems. These problems arise because of the many service facilities intercepted by seaway construction such as highways, railways and water and sewerage systems.

At Longueuil and St. Lambert new water supply intakes are being constructed to replace those removed or interfered with by the seaway construction. In Fig. 8 and 10 may be seen the preliminary construction of the Longueuil water supply intake. Similar facilities are being continued and improved upon where required throughout the length of the seaway canal.

The bridges in the Lachine Section are being raised where possible, This is the case with respect to the Hon. Mercier Bridge and Jacques Cartier Bridge, both of which will be raised to give 120-ft. clearance. Modern traffic interchanges will be constructed at the southerly end of both of these bridges. Grade limitations, however, necessitate the installation of movable bridges at Victoria bridge and at the Canadian Pacific Railway bridge at Caughnawaga. The latter bridge will be provided with a vertical lift span.

Because of the traffic density — both railway and highway—on the Victoria Bridge, the Seaway Authority, in co-operation with the Canadian National Railway, is making every effort to avoid delays resulting from the seaway operation. Figure 11 illustrates how the Seaway Authority has proposed to handle the traffic problem, although at the time of writing the matter is still under study. The Victoria Bridge is a double-track railway bridge with a 16-ft. wide highway traffic lane on the upstream bracket. The Montreal and Southern Counties Interurban Railway line has been removed from the downstream bracket and another highway lane has replaced it.

A combined railway and highway lift span crossing the lower end of the St. Lambert Lock, an additional highway rolling-lift bridge crossing the upper end of the lock, and a traffic distribution system will enable highway traffic to continue to use Victoria Bridge without interruption during passage of vessels through the St. Lambert Lock.

At Cote Ste. Catherine a rolling-lift bridge across the lock will complete the bridge picture in the Lachine Section. However, provision for an additional rolling-lift bridge may be made at Cote Ste. Catherine, having in mind the need for increased traffic capacity should a power development near Heron Island be undertaken in the future.

Integration with Lachine Power Development

When the Lachine Rapids power development is carried out, presumably with a powerhouse located near Heron Island, a considerable enlargement of the Lachine Rapids will be required to reduce the current velocities to the 2.0 feet per second considered necessary to permit an ice cover to form in the river above the powerhouse. Hydro-Québec have indicated that a channel enlargement in the Lachine narrows to a 120,000 square feet cross-sectional area is the economic limit. This means that a Lake St. Louis outflow of 240,000 cubic feet per second can be handled in the river during the ice-forming period. The more recent plans for regulation of Lake Ontario call for a maximum river flow at Lachine of 280,000 cubic feet per second during the ice-forming period. To enable such a plan of regulation to be put into effect the Seaway Authority has agreed to make available the seaway canal from Caughnawaga to Cote Ste. Catherine as a by-pass canal during the non-navigation season. Under this arrangement, which will also require discharge works into the river below the future powerhouse near the Cote Ste. Catherine Lock, the Seaway canal will carry the 40,000 cubic feet per second discharge in excess of the river capacity.

Seaway Construction Will Not Affect Water Levels

It is natural that those who own property or operate businesses on the shores of the St. Lawrence River, Lake St. Francis, Lake St. Louis or Montreal Harbour, should express some concern regarding the water level conditions that will obtain after the Seaway is completed. The Seaway Authority is taking steps to ensure that the construction of the Seaway features will not alter natural conditions. The St. Lawrence River discharges will be influenced by the regulation of Lake Ontario which will be carried out as recommended by the International Joint Commission and approved by the Governments of Canada and the United States. Studies of Lake Ontario regulation are continuing under the direction of the International Joint Commission, but it has now been established by approval of the Canadian and United States Governments that Lake Ontario, which has ranged in the past between elevation 242.6 to elevation 249.3, will be regulated within a range of stage 244.0 (navigation season) to 248.0, as nearly as may be.

These continuing studies of Lake Ontario regulation will recognize the requirements of the downstream interests and the plan finally approved for operation will ensure that circumstances at least as favourable as those of record will be maintained.

Except for the river reach from near Prescott, Ontario to the Barnhart Island Powerhouses, where there will be a substantial change in river levels resulting from the power development that must be provided for, the Seaway project has been designed to conform to the present river regime.

Geological Conditions

In general, the geological conditions prevailing along the Seaway

Mechanical Design Features of the St. Lawrence Power Project

O. Holden, M.E.I.C., *Chief Engineer*

P. Pemberton-Pigott, *Assistant Mechanical Engineer*

The Hydro-Electric Power Commission of Ontario

Read at the 70th Annual General and Professional Meeting, The Engineering Institute of Canada, Montreal, May 1956

The St. Lawrence Power Project, now being constructed jointly by the Ontario Hydro and the Power Authority of the State of New York, requires a wide range of mechanical equipment. This paper describes the design features of the items to be installed in the various structures with particular attention being paid to hydraulic gates and cranes. A reference is also made to the variations between some of the equipment in the Canadian and American powerhouses.

THE INTERNATIONAL Rapids section of the St. Lawrence River extends some 40 miles from Prescott to Cornwall, Ontario. It is in this stretch of the river that the St. Lawrence Power Project is currently being constructed. This involves the building of five main structures, which are:

(a) The powerhouse, which is a single structure, combining both the Canadian and American powerhouses.

(b) Long Sault dam

(c) The canal closure structure

(d) Massena intake

(e) Iroquois dam

The maps, Figs. 1, 1a, and 1b show the location of the main structures required for the generation of power and for maintaining the water levels for navigation, both during and after construction. Referring to Fig. 1a, item "A" indicates the American and Canadian powerhouses located about four miles upstream from Cornwall, these being combined into a single structure spanning the International channel of the river from the Canadian shore to the north side of Barnhart Island. The International Boundary passes through the centre of the channel geographically dividing the structure into two halves, each in its respective country.

On the south side of Barnhart Island is the Long Sault dam, shown as Item "B". This is the main spillway structure and during construction it is the key item of the whole project, as it is from here that the river levels up to the Town of Iroquois are controlled at their natural elevations during the various stages of river diversion.

On the north side of the powerhouse is the canal closure structure, shown as item "C". This structure permits 14-foot navigation to continue on the Canadian side until the last stage of river closure.

Next, going up river, is the Massena intake, shown as item "D". This structure ensures the continuance of a water supply to the Massena power plant during construction, and later for the supply of process water to the Alcoa plant.

Lastly, there is the Iroquois dam, spanning the river between Iroquois and Point Rockway, Fig. 1b. This dam permits the control of the outflow from Lake Ontario.

The mechanical design features of the project will be outlined by discussing the main structures one at a time with a brief description of the main items of the equipment involved.

Iroquois Dam

The Iroquois dam shown in Fig. 2 consists of 32 sluices, each 50 feet wide, with the sill only a few feet above the rock bed of the river; at each end, bulkhead sections join up to the supporting contours. Each sluice is provided with a single section fixed-wheel roller gate 48 feet high. A second gate slot is located upstream of the main checks for use with a set of stoplogs during maintenance work on the main gate. The gates are handled by 350-ton capacity gantry cranes and are held in the raised position by "dogs" located at deck level.

The maximum head on the Iroquois Dam will occur during the construction period when the water level above the dam will be raised to assist dredging operations, while the water level below the dam will remain at its natural elevation. At this time the differential head on the dam will be of the order of 24 feet, and this has been instrumental in establishing the design criteria for both the structure and the gates.

Due to the almost complete submergence of the gates at certain periods, provision for their heating presents an unusual problem. The final arrangement adopted was for a light downstream skin plate to be added to the gate, in effect forming a box section. The space thus enclosed becomes filled with water as the gate is lowered and is heated by electric tubular type heaters placed inside vertical pipes which run the full height of the gate. The heaters themselves are divided into two sections and are so arranged that either the top half or the bottom half of the gate may be heated at any one time. This arrangement reduces the connected heating load to 60 kilowatts per gate. The portion of the gate to be heated will, of course, depend upon the position of the gate in the water.

In addition to the gate body heating, gain heaters are provided for the main service checks.

Two gantry cranes will be provided, each of 350-ton capacity. Particular attention has been paid to the appearance of these cranes, and the architectural treatment given to them results in the main hoist machinery trolley and the upper girders of the crane being completely enclosed in a sheet steel housing as shown in Fig. 3. The housing is 46 feet long by 42 feet wide and about 18 feet high and the overall height of the crane from rail to roof is about 75 feet. Thus it is readily appreciated that these cranes will be the most outstanding feature of a long, low structure like Iroquois Dam.

The cranes are designed to lift the gates at a speed of seven feet per minute and to travel along the deck of the dam at 75 feet per minute. The hoist is of the double drum, double hook type, and will handle the gates through a semi-automatic lifting beam. The crane is provided with normal wound rotor motor control with thruster brakes on the hoist drive. For fine control of the positioning of the crane, the first point of the bridge travel controller will be a drift point. The crane may then be brought to rest by use of hydraulic brakes controlled from the cab rather than with the solenoid operated brakes connected into the travel motor circuits.

Massena Intake

In order to limit the length of this paper, detailed description of the mechanical equipment, consisting of control gates for the intake for the Massena power canal and a pumphouse for the water supply to the nearby Alcoa plant and the town of Massena have been omitted. Data about these gates, however, are included in the material given in Tables III and IV.

Long Sault Dam

The Long Sault dam which, with the powerhouse, will maintain the forebay level, is located between

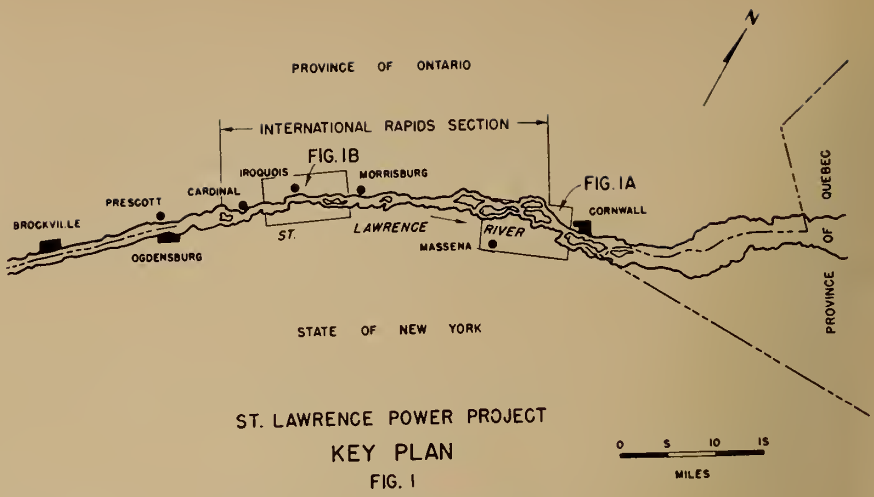

Fig. 1. St. Lawrence River, International Rapids section.

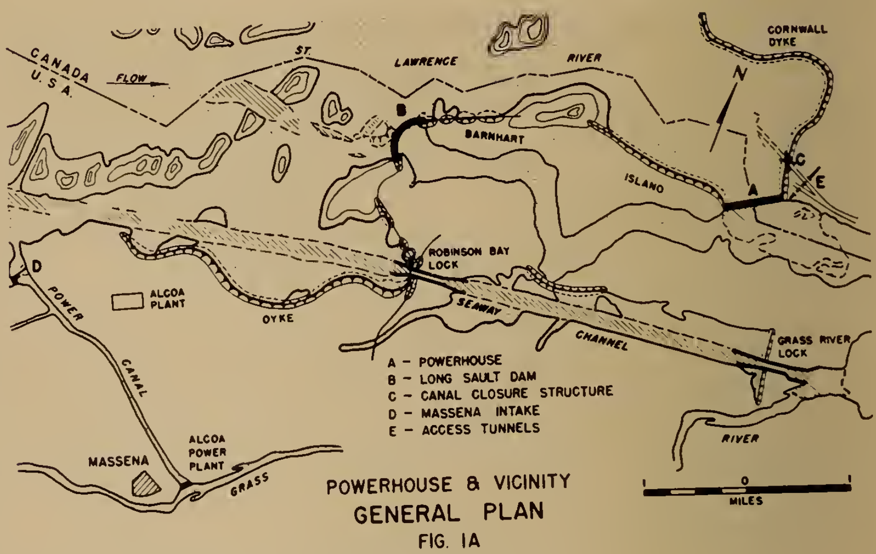

Fig. 1A. St. Lawrence power project, powerhouse area.

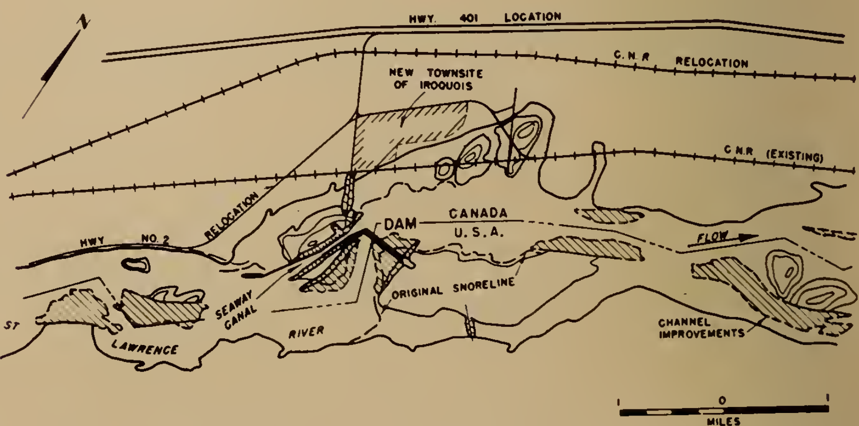

Fig. 1B. St. Lawrence power project, Iroquois area.

Barnhart Island and the American mainland. It is curved in plan although designed as a gravity section and is shown as Fig. 4. As will be seen, it consists fundamentally of a rollway surmounted by 30 spillway gates with a bulkhead gravity section at each end.

Each of the spillway gates is 50 feet wide by 30 feet high. Eighteen of these gates are provided with fixed towers and hoists, and the remaining twelve are operated by the means of two gantry cranes.

These thirty gates provide discharging capacity of several times the maximum river flow. The eighteen gates associated with the fixed hoists are made in two sections with semi-automatic couplings being provided between the sections. The upper section may be raised for the sluicing of ice or the whole gate can be raised as one unit.

The two gantry cranes at Long Sault (Fig. 5) are similar in design to those at Iroquois Dam. Each crane has a hoist capacity of 275 tons and a hoisting speed of two feet per minute. The main difference is that the Long Sault cranes are designed to allow the main hooks to reach 12 feet in front of the upstream rail for use during construction operations. A 10-ton auxiliary hook is added to the main hoist trolley for use in general maintenance work.

The architectural treatment given the cranes is similar to that applied at Iroquois dam. In this case, however, the cranes are even more massive being 79 feet long from bumper to bumper and 64 feet high. The machinery housing is 70 feet long by 64 feet wide and 21 feet 6 inches high and the weight of each crane without counterweight is estimated at 750,000 pounds.

During construction Long Sault dam provides the diversion course of the river. The first stage of construction at Long Sault provides 13 sluiceways with sills at elevation 165, the rollway portion being left out at this time as shown in Fig. 6. The water is passed through these openings during stage 2 construction and

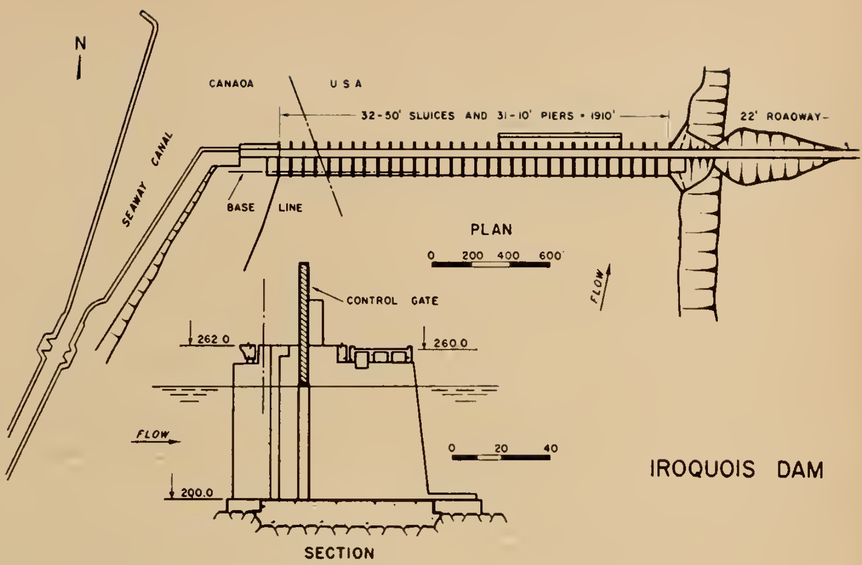

Fig. 2. Iroquois dam, general arrangement.

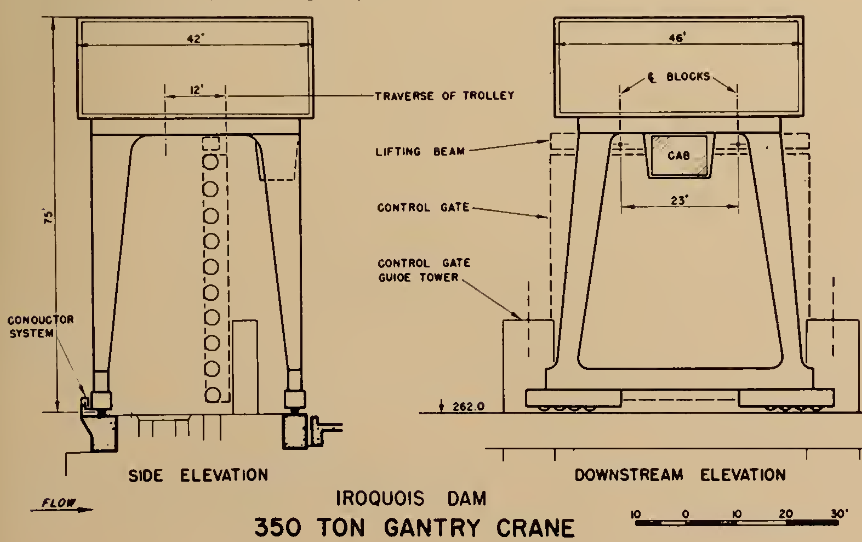
the water level is controlled to maintain the natural level at lock 21 on the Canadian 14-foot canal, thereby avoiding interference with present navigation. In order to provide this flow control, portions of the spillway gates are bolted together to give a gate 50 feet wide by 45 feet high. These are handled in their location on the upstream side of the dam by the two 275-ton gantries.

In the portion of the dam constructed during stage 2, Fig. 7, thirty-four ports, each 16 feet by 19 feet high, are provided. During the final stage of closure, these ports handle the entire river flow. Fixed roller gates are provided to close off these ports as required for closure flow control and for concreting operations.

During the closure process, the thirteen 50-foot wide diversion sluices are closed and concreted first, the river flow being progressively diverted to the closure ports. This does not affect the water level at lock 21 and permits 14-foot navigation to continue. The final operation is to close off the diversion ports.

Fig. 3. Iroquois dam, 350-ton gantry crane.



For maintenance of the sluice gates, a second set of checks is provided just upstream of the main service checks. A spare sluice gate is provided which may be lowered into this position to allow one sluice gate at a time to be taken to the gate maintenance shop located in the dam abutment. For the gates equipped with fixed towers and hoists, the hoists are arranged so that they can be removed, permitting the gates to be lifted out by the gantry cranes.

Protection against icing is provided by direct electric heating of the gate checks together with an air bubbler system (Fig. 8). Provision is also being made for the interior heating of the gate bodies. Heating of the gate sills is also provided by hot oil being circulated through a pipe attached to the sill beam. The electric heat exchangers and circulating pumps for the sill heating are located in the service gallery.

Powerhouses

As previously noted, the powerhouse consists of two structures located so as to meet at the International boundary (see Fig. 9). Each powerhouse contains sixteen 75,000-h.p. fixed-blade propeller turbines to which are directly connected 60,000 kva. vertical generators.

Although the equipment in both sections of the powerhouse is similar in capacity and function, there are variations between comparable items in order to meet the individual requirements of the two constructing entities. The exterior appearance of both sections of the powerhouse has been made identical and the cranes and other service items have been made interchangeable.

The powerhouses are of the semi-outdoor type with an enclosed erection bay located at each shore. The spacing between machines is 80 feet, giving a total powerhouse length of 3120 feet and a plan area of 13½ acres. In addition to the 32 generating units, there are six ice chute sluices located within the plants; two of these are at the centre astride the International Boundary, and the others pass under the erection bays located at each shore end. The generators are arranged with the top of the stator just a few feet below the powerhouse deck level, as shown in Fig. 10, and removable covers are provided over the generators to give a weather-tight housing for each unit. Crane service is provided to the powerhouse by two 300-ton totally enclosed gantry cranes. These cranes can be moved over a unit to provide a weather-tight area over the machine during maintenance.

Each turbine is arranged with a three-conduit intake and each individual water passage is provided with a 17-foot wide headgate. The headgates are operated by individual hoists located in pockets below the level of the headworks deck. Removable covers are provided over the hoist pockets to allow the headgates to be removed for maintenance.

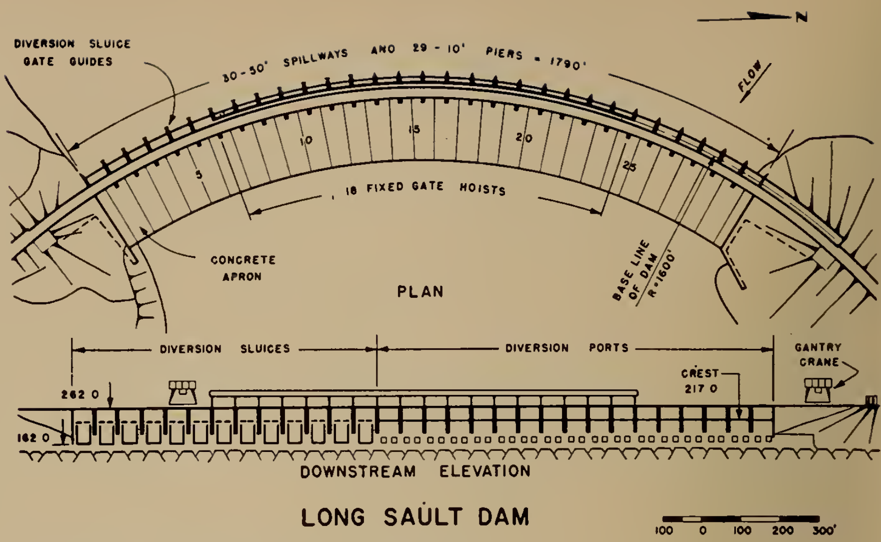


Fig. 4. Long Sault dam, general arrangement.

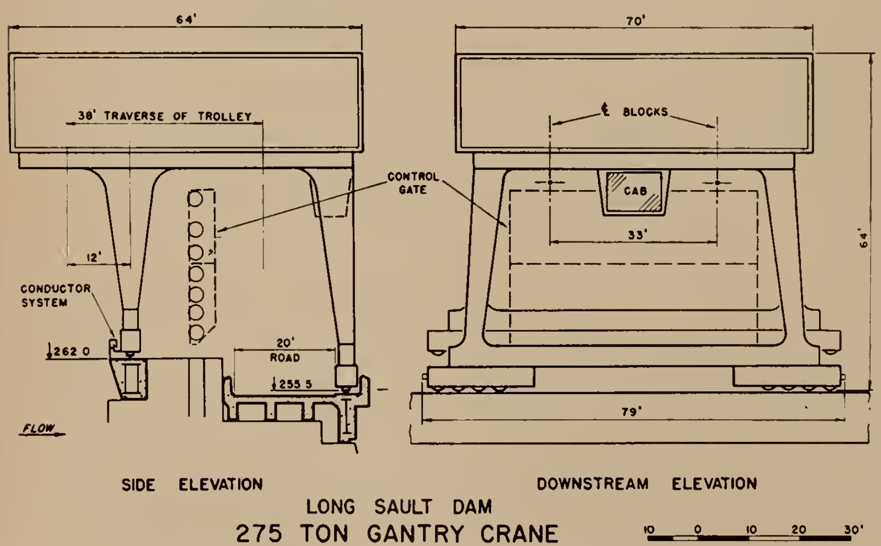
The headgates in the Canadian powerhouse are removed by being traversed forward into a cut-out in front of the hoist and then being hoisted vertically out of the gate pocket. To move the gate forward it is suspended from hanger links attached to a lifting beam. When moved forward, the lifting beam and links are disconnected from the headworks gantry crane and the bare hook block is connected to the gate for its transportation. While this change is being carried out the gate rests on the floor of the gate pocket.

The headgate hoists are designed for a hoisting speed of 5 feet per minute and a lowering speed of 10 feet per minute. The gates are lowered without power being supplied to the hoist motors, the speed braking effect being obtained from a fan brake which consists of an overloading type fan. During the normal hoisting motion, the fan absorbs only about five per cent of the horsepower absorbed when running in the reverse direction at twice the speed.

A solenoid-operated holding brake is fitted on the motor shaft, the coil being energized to release. The coil is designed for a 115-volt, d.c. supply and, during normal service, it is energized from the hoist supply circuit through a rectifier. In the event of an emergency involving failure of the normal station service supply, the brake may be released by energizing the coil from the station control batteries.

This arrangement of fan brake and d.c. holding brake is made for a particular reason. The fitting of fan brakes to headgate hoists is standard within the Commission's modern plants and the fitting of the d.c. holding brake is currently being adopted as a standard. The reason that this is done is that it is considered of paramount importance that it shall be possible to lower the headgates of a plant under any condition whatsoever, be it fire, loss of station service or turbine runaway. Thus, the fan brake is fitted as it permits the gate to be lowered without the hoist motor being energized. Its function is, of course, to restrict the rotational speed of the motor within safe limits, i.e., within 2½ times normal speed. The holding brake is fitted with a d.c. coil as this permits the provision of an "emergency lower" circuit supplied from the station control batteries — the most reliable source of electrical power. Should this source fail at the same time as the station service circuit, it is always possible to release the brakes manually with a

Fig. 5. Long Sault dam, 275-ton gantry crane.



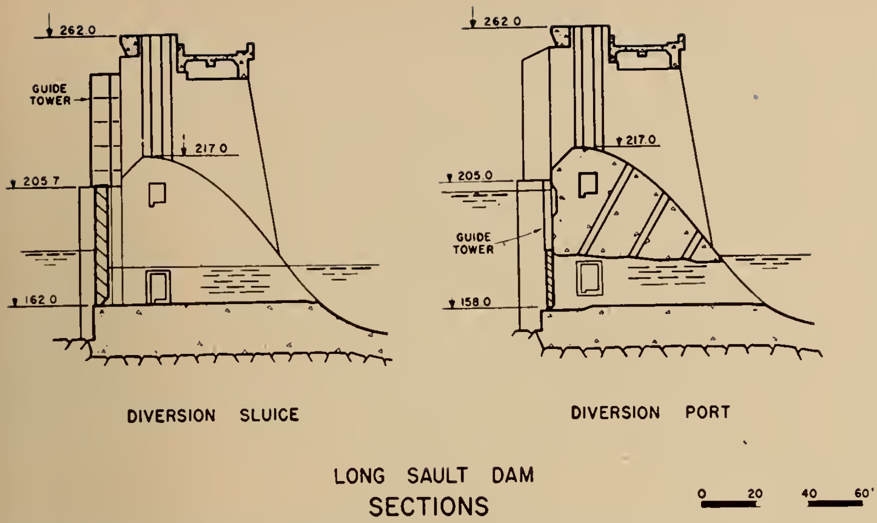


Fig. 6. Long Sault dam, diversion sluice for use during stage II construction.

Fig. 7. Long Sault dam, diversion port for use during final closure.

suitable lever or crowbar. This may be done in absolute safety as the fan brake will restrict the hoist motor speed as described above.

The capacity of the headgate hoists has been checked by model tests carried out in the hydraulic model laboratory of the Ontario Hydro at Islington, Ontario. A complete model of the intake structure and the gate was built to a true scale of 1:36. The actual test procedure used was one developed and refined during the past few years and consists essentially of supporting the model gate in such a way that all the horizontal hydraulic forces on the gate are balanced, allowing the vertical forces to be accurately weighed. This technique was proved in the design of the two large tunnel portal gates installed in the intake to the Sir Adam Beck-Niagara generating station No. 2 at Niagara Falls, Ontario.

Similar tests have also been carried out for the gates for Iroquois and Long Sault dams and also for the Massena intake. In the case of the diversion port gates at Long Sault, it was possible to reduce the hydraulic downpull to as little as one-third of the downpull found with the original design. The importance of such tests cannot be underestimated and their value to the gate designer is worth many times their cost.

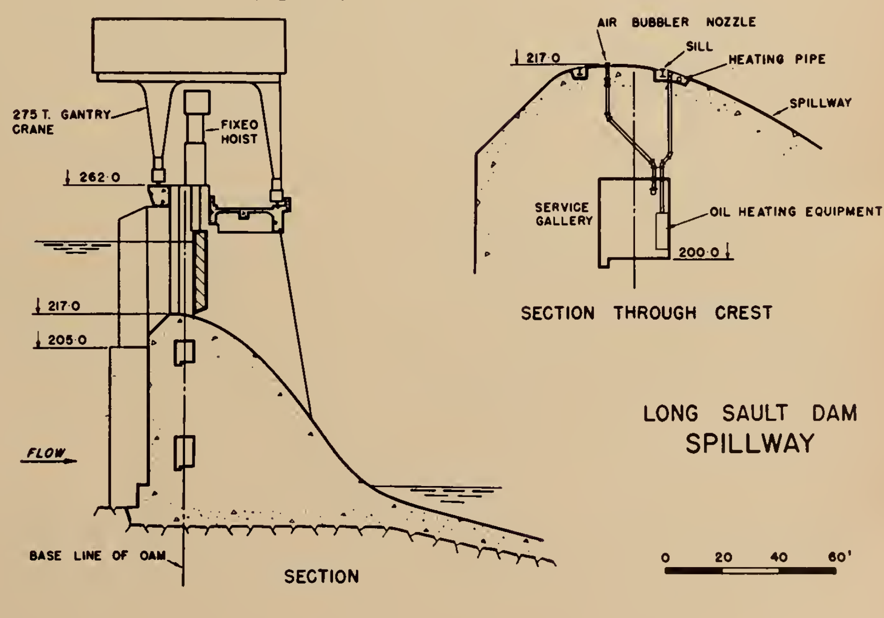
The two headworks gantry cranes are each of 90-ton capacity and their arrangements are shown in Fig. 11. Due to the difference in the arrangement for handling the headgates, the American gantry is of the double - drum, double - hook type, while the Canadian gantry is provided with a standard single hook. The only unusual feature of the cranes is the auxiliary jib hoist located on one of the upstream legs of each crane. These jibs service the stoplog checks and the trash racks. The jibs are arranged on the two cranes to face each other so that together they will handle the ice chute service gate frame. This frame is just under 80 feet long, and communication between the crane operators and their foreman for the closely co-ordinated motions that must be made, will be by short-wave radio. For maintenance of the headgates, a working area is provided at each shore abutment.

The ice sluice gates form one of the main features of the headworks block. The gates themselves will be of the hydraulically-operated drum type. Of the six gates installed, four are 75 feet long and the other two 50 feet long. The profile of the gate drum was determined from model tests conducted in a "plexi-glass" flume, as was the arrangement of the extended bucket portion under the erection bay (Fig. 12).

During the tests conducted for design of the gate profile, particular attention was paid to the manner in which passing floes of ice struck the rollway. The final results incorporated two protrusions on the upper skin plate of the drum. These had the effect of tending to destroy the horizontal velocity component of the flow passing over the gate, pulling the nappe upstream. This ensures that the ice is placed on the upper curve of the rollway instead of being dumped into the bucket at elevation 154.

The gates themselves will be raised or lowered hydraulically by adjusting the relative positions of two butterfly valves located in the valve chamber at elevation 191, under each gate pocket. One valve admits water at headpond pressure into the chamber under the drum; the other valve controls the flow from this chamber to the tailrace. The resulting water pressure within the chamber determines the elevation at which the drum gate will remain. Considering the extreme cases, if the outlet valve is closed the gate will rise to its fully closed position. If the inlet valve is closed and the drain valve opened the gate will move downwards to the fully open position. The control of the gate position will be initiated from a control

Fig. 8. Long Sault dam, spillway.



box located on the headworks deck. A position sensitive device controlling the position of the butterfly valves ensures that the gate will remain in the required position.

Electric heating of the interior of the drum, the side seal armature plates, and upstream and downstream seals is provided to prevent the formation of ice on the gate or the surfaces over which the seals pass during operation. Heating of the discharge valve line outfall is also provided. The heaters are controlled from the control point at deck level and the heating load for each gate totals about 275 kilowatts.

One service gate frame is provided to enable the ice sluice gates to be dewatered for inspection and maintenance. The frame is constructed so that it may be adjusted to fit across either the 75-foot or the 50-foot wide opening. Once lowered into position in front of the gate to be dewatered it is made into a watertight bulkhead by the use of steel stoplog sections normally used for unwatering the headworks. These are lowered into slots or checks in the frame, the whole handling operation being carried out by the 15-ton auxiliary jib booms of both headworks gantry cranes.

The decision to install the hydraulically-operated drum gates was made only after careful study. It was found that restrictions in space for locating the very large hoisting machinery required for any other type prove prohibitive. The upstream and downstream space available for the gate was also extremely limited. The drum gate has the advantage of forming part of the rollway in its lowered position and this, after modifications in profile determined by model testing, was a final factor in the decision.

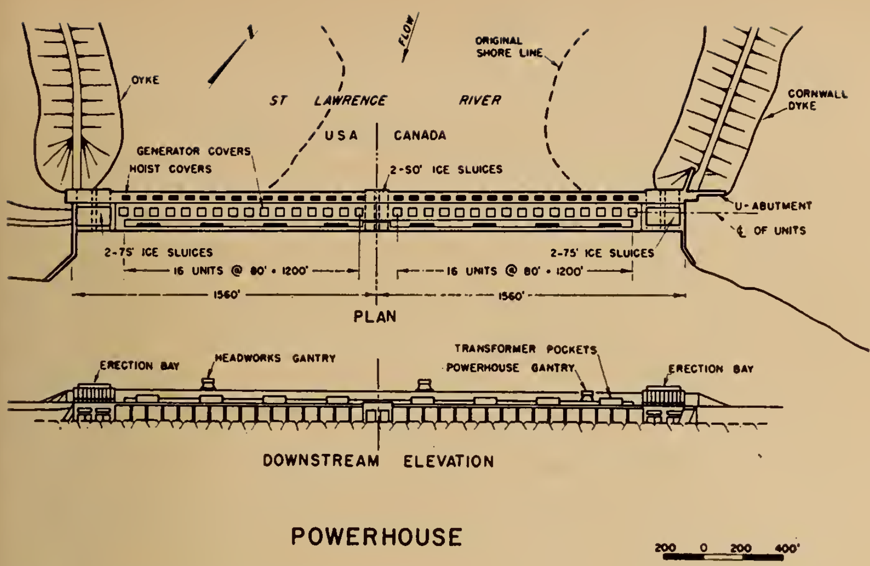

Fig. 9. Powerhouse, general arrangement.

city. This is achieved by two 80-ton cranes which can be used as one 150-ton unit by connecting their hooks with a lifting beam (Fig. 13). These cranes have the rather unusual feature of an auxiliary hoist outboarded to one side of the main crane girder, allowing the cranes a very close end approach. In fact, the auxiliary hook may be placed within a foot and a half of the end wall of the erection bay. This makes for greater use of the erection bay floor area and also enables the crane to reach down to the lower service galleries through a hatch in the erection bay floor.

In the end of the erection bay, adjacent to the powerhouse, is a vertical sliding door some 60 feet wide by 58 feet high. This door permits the main powerhouse gantry crane to enter the erection bay to pick up or set down its loads. The door is power-operated and will be capable of being raised in less than a minute. The lower level of the erection bay is used for a variety of purposes such as storage and the installation of auxiliary equipment.

Figure 10 shows a typical cross-section through one of the generating units in the Canadian powerhouse. As the various items of equipment for the 32 generating units are being supplied by several different manufacturers, variations exist from unit to unit. However, a typical unit comprises a fixed blade propeller turbine of 75,000 horsepower at 81 foot head and running at 94.7 r.p.m. The distributor centre line is at elevation 154, which is also the minimum tail-water elevation. The de-

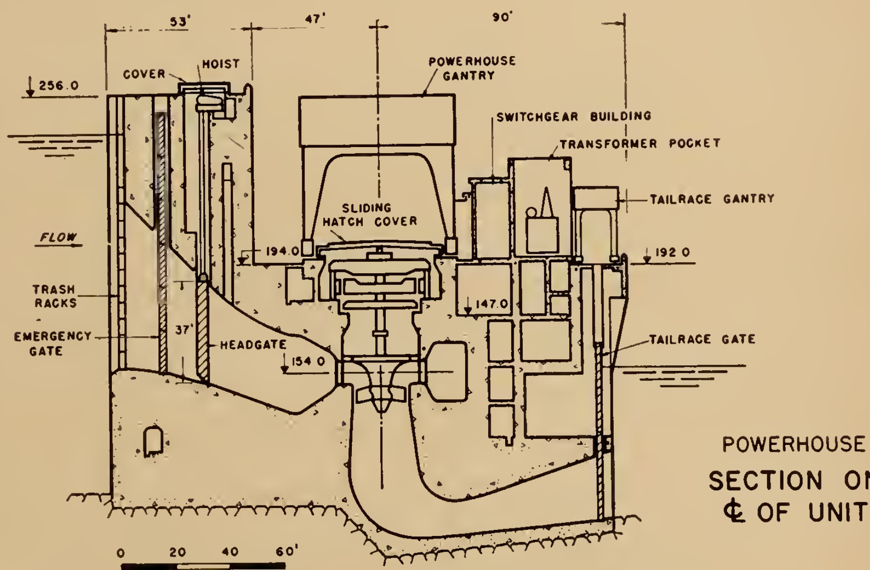

Fig. 10. Canadian powerhouse, typical cross-section through a unit.

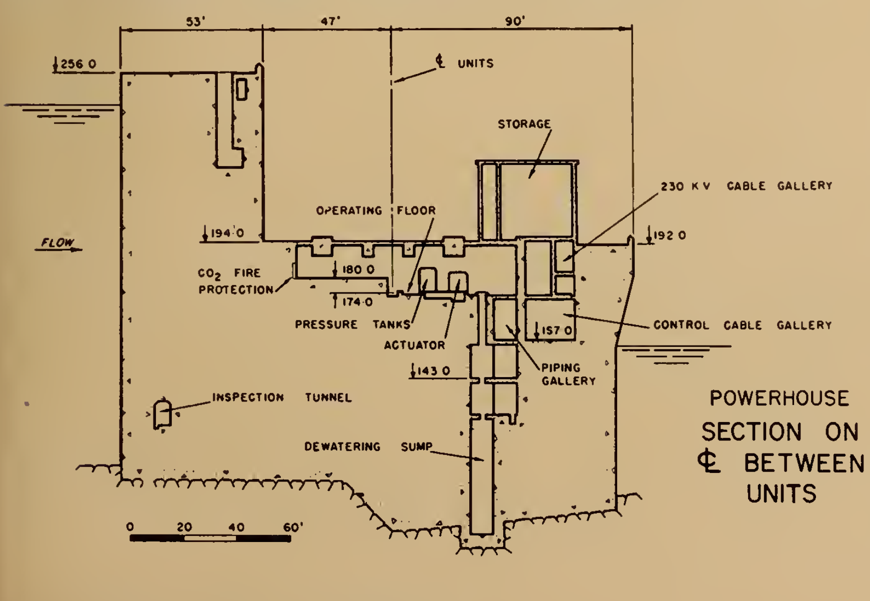
Fig. 10A. Canadian powerhouse, typical cross-section between units.



tails of the various machines to be installed are shown in Table I.

The turbine pit liner is extended up to the generator foundation, which has been set as low as practicable to give a minimum overall height to the powerhouse. The generators are rated at 60,000 kva. at 95 per cent power factor. The covers over the generators are designed to split in the centre and are rolled back to permit maintenance work to be carried out on the units. The covers are some 46 feet wide by 43 feet long and are designed to be moved by electric power.

Between each pair of turbines at the 174 level is located the governor actuator cabinet. The actuators are of the twin unit type and include the governor mechanism, pressure

[3] 85,000 pounds of concrete ballast extra

[4] Stoplogs are interchangeable between intake and draught tube

system pumps, and the sump tanks for two units. The governor pressure tanks are located on the same floor behind the actuator cabinet.

Two auxiliary turbine driven emergency governor pumps are installed on the 143.0 floor of the Canadian powerhouse. These units draw their water supply from the scroll cases of units 4 and 12 and are each capable of supplying the governor oil pressure necessary to operate one main generating unit, providing an emergency standby for the electric-motor driven governor pumps located in the actuator cabinets of those units. The auxiliary governor pressure pumps will give complete reliability for starting of the main generating units even in the event of the complete electrical isolation of the plant, as it will always be possible to start up one or two units to restore normal station service to the plant.

Two totally enclosed 300-ton gantry cranes are to be supplied, one for each powerhouse. These cranes are identical in external appearance and have the same general architectural treatment that was applied to the gantry cranes at Long Sault and Iroquois dams (Fig. 14). The upstream and downstream sides of the cranes are sheathed with aluminum, and rolling doors at each end complete the enclosure. Once the crane has been centred over a unit and the generator cover has been rolled back, the doors will be lowered to give a weatherproof working space, enabling maintenance of a generating unit to be carried out under any climatic conditions.

The cranes run on a common track

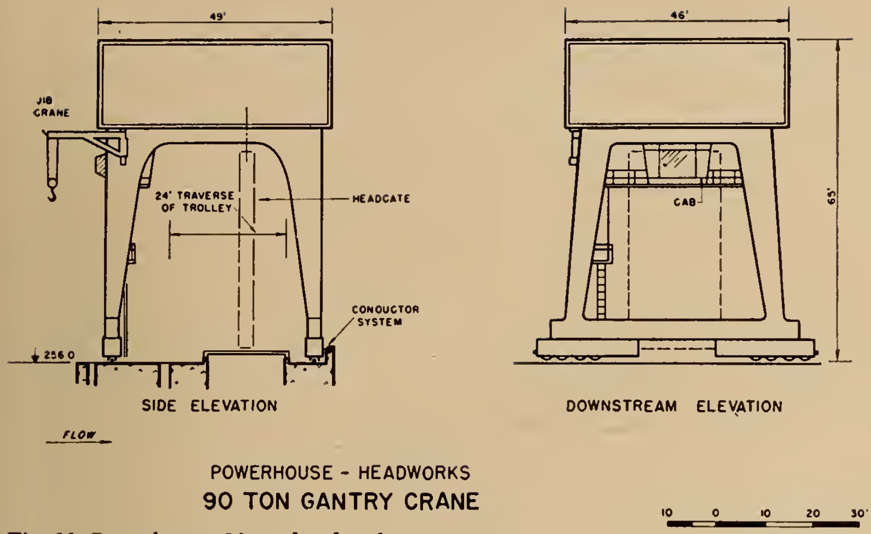

Fig. 11. Powerhouse, 90-ton headworks gantry crane.

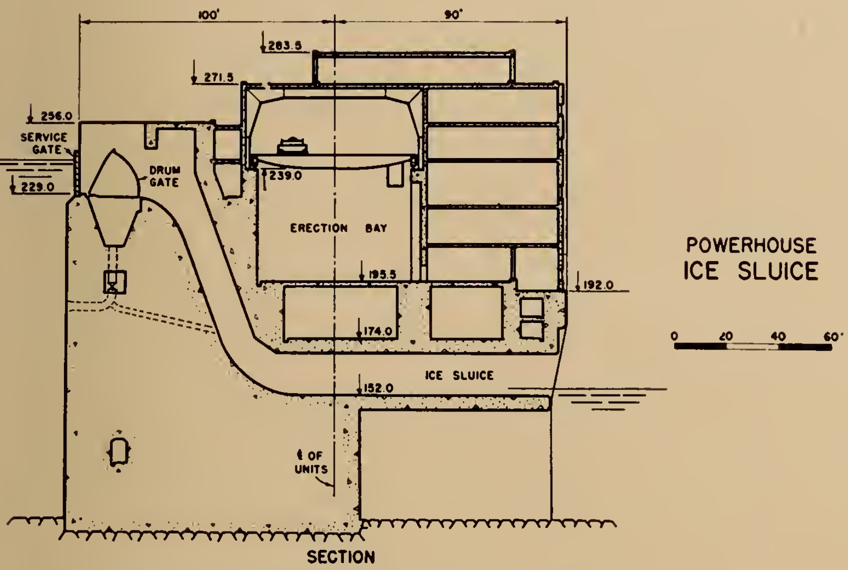

Fig. 12. Powerhouse, section through shore ice sluice and erection bay.

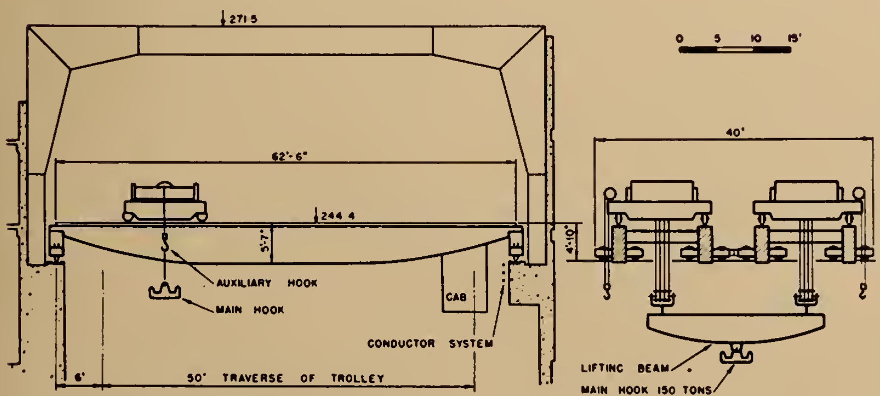

Fig. 13. Canadian powerhouse, 80-ton erection bay cranes.

with the rails set 53 feet apart. This track extends from the shore end of the Canadian erection bay to the shore end of the American erection bay. This arrangement permits the cranes to service any unit and to carry the parts into either erection bay. Thus, in an emergency both cranes could be used in one powerhouse to minimize delay and thereby shorten the outage time of the units under repair.

Each crane has a single hook 300-ton hoist and an arrangement for auxiliary hook service. Within the Canadian crane there are two 15-ton auxiliary jib cranes which are mounted on the underside of the main hoist bridge girders. These jibs are designed to rotate the full 360 degrees and give complete coverage of a unit without any travel motion of the gantry. They may place loads on the roadway immediately upstream of the crane by passing their booms through a door in the side sheathing of the crane. This feature eliminates the necessity of having to travel the gantry crane to set down minor loads.

The Canadian crane is provided with a speed-load compensating d.c. drive. The hoist control is arranged to give a speed limitation varying with load in both the hoisting and lowering directions. The unloaded main hook speed is about 18 feet a minute and this is reduced to six feet a minute if the hook is fullv loaded. The control svstem also allows the operator to "float" any load. The hoist brake may then be set or released without the load changing position. The controls and drive are so selected, that they mav be connected either to the main hoist motor or to the travel motors. The auxiliary jibs within the crane are provided with normal a.c. wound rotor motor drives and control.

Due to the size of the powerhouses a radio communication svstem is to be installed between the main cab of the gantry cranes and the powerhouse telephone switchboards. Walkie-talkie type sets will be provided for communication to the jib crane operators.

The main power transformers for the station are located on the tailrace deck. Two transfer trucks are provided to handle the transformers in and out of their pockets and, when necessary, to carry them to the erection bay, the truck for one powerhouse being available to the other during maintenance work. As a re-

sult, it will be possible to reduce outage time resulting from a transformer fault. Power supply for the operation of the trucks is obtained from the tailrace gantry conductor system located in the downstream parapet wall.

Two 15-ton capacity tailrace deck gantry cranes will be used for handling the steel stoplog sections required to close off the draught tube exits when a unit is to be dewatered. The hoisting speed will be 60 feet per minute and it is anticipated that both cranes will be used together during maintenance in order to reduce the time required for transporting and setting the gate sections. The details of the auxiliary systems in the two powerhouses are shown in Table II.

The powerhouse drainage and draught tube dewatering arrangement in the Canadian powerhouse is arranged on a two-unit basis, a sump being provided between each pair of units which takes all drainage below tailwater level. A main cooling water header runs the length of the plant and is fed from take-offs on each scroll case, and additional take-offs are provided on alternate scroll cases.

The station air compressors are located in the lower level of the erection bay, while those for the air blast breakers are located at units 4 and 12. The oil handling equipment is located under the gate maintenance area in the U-abutment at shore end of the headworks block. Automatic CO_2 fire protection is provided on a four-unit basis for the generators and a separate CO_2 bank is provided for the oil room.

The heating system for the Canadian erection bay and control building areas is based on two large capacity heat pumps. These units are located in the lower level of the erection bay and will provide a heating effect of 5,390,000 B.t.u. per hour or a cooling effect of 239 tons of refrigeration. The source of heat for these units is the generator cooling water. Temperature control valves are fitted on the discharge lines from the generators and three transfer pumps are used to deliver the discharged cooling water to the erection bay. This heating system will not only supply the control area but will also be used to heat the entire erection bay. The installation of this arrangement enabled the 550-volt station service rating to be reduced by some 1000 kilowatts.

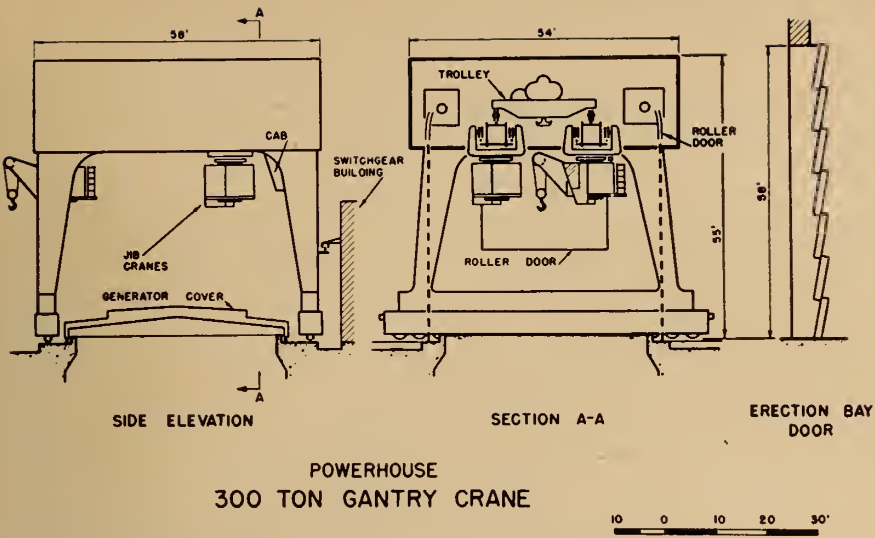

Fig. 14. Canadian powerhouse, 300-ton powerhouse gantry crane.

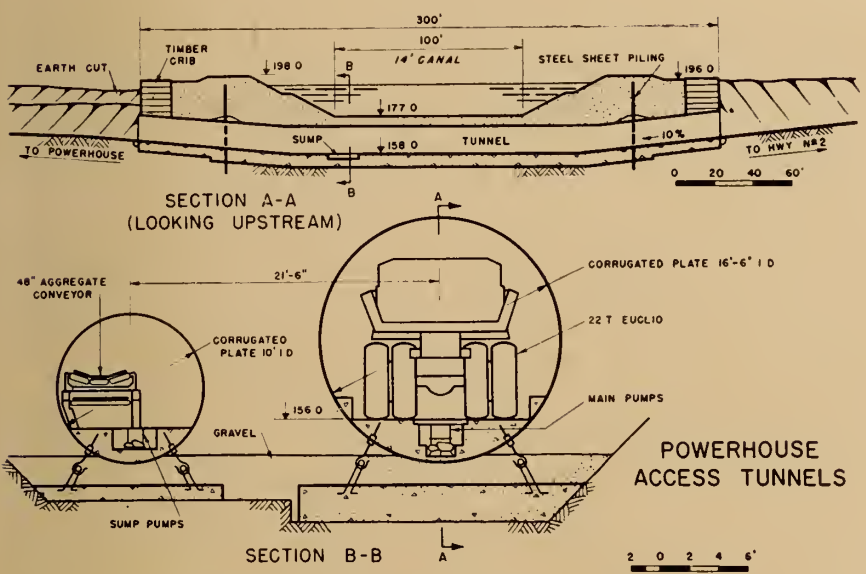

Fig. 15. Access tunnel under 14-foot navigation canal.

Access Tunnels

One unusual feature of the access to the Canadian side of the project is the tunnels under the 14-foot navigation canal and its diversion cut (Fig. 15). The one with the larger diameter provides ready and rapid access to the dewatered powerhouse site for heavy construction equipment, and the smaller tunnel is for personnel and a conveyor system. The problem of providing a pumping system to drain these tunnels was quite considerable as it was considered inadvisable to pierce the corrugated steel tunnel liner. A concrete roadway was poured in the larger tunnel to a maximum depth of three feet and it was within this concrete block that the pumping system was located. The final arrangement for the larger tunnel was for four submersible pumping units, operating under sequenced electrode control, placed in a shallow trench or sump on the centre line of the roadway. Each unit has a capacity of 250 gallons per minute and the sump has a depth of only 30 inches. The sumps are covered with a very substantial reinforced floor plate designed to take the wheel load of a loaded 15-ton truck. Electric heating of the roadway has been provided to ensure continuous access to the powerhouse area even under the severest weather conditions.

The conveyor tunnel is protected from water draining down the approach cuts and is provided with two small sumps. A domestic type submersible pump is installed in each sump to transfer leakage water to the sump in the larger tunnel.

The Use of Hydraulic Models in the St. Lawrence Seaway Planning and Design

D. McIntyre, M.E.I.C.,

Hydraulic Engineer, The St. Lawrence Seaway Authority

Read at the 70th Annual General and Professional Meeting, The Engineering Institute of Canada, Montreal, May 1956

IN SCOPE and intensity the hydraulic model study work, in various stages of completion, being carried out in connection with the St. Lawrence Seaway planning and design, is probably unsurpassed in the history of engineering. This huge model study program has been made necessary not only by the number and complexity of engineering problems which must be solved in the limited time available, but also because of the multiplicity of interests affected by Seaway works. Parties vitally concerned in any changes in the natural state of lakes and river channels along the Seaway route run the full range from individual property owners to Federal Governments. The international, interprovincial, and interurban character of the St. Lawrence Seaway makes it essential that the effects of all development work be predicted accurately, and that the best engineering design procedures be used.

In discussing the use of hydraulic models in the St. Lawrence Seaway planning and design it is convenient to separate them into two groups according to whether their purpose is to develop plans for river channel improvements, or to provide design information for hydraulic structures. In so far as possible the models discussed in this paper will be limited to those connected with the development of a Seaway channel as opposed to those relating to power development. Hydraulic structures for which models have been built can be divided quite easily into those, such as locks and guard gates typically associated with navigation channels, and those, such as dams and spillways, typically associated with the power project. However, most river channel improvements affect both power and navigation so that practically all river models have yielded information useful to both power and the navigation interests.

It has been necessary to undertake a large program of model studies to solve many of the complex engineering problems inherent in the Seaway works and because of the multiplicity of interests which they affect. A broad picture of the use of models is given here, without detailing the mathematical aspects.

Since the author has not been directly associated with river model work, little more than a brief description of each river model, together with a list of the more important engineering data required from each can be given. The hydraulic structures models are dealt with somewhat more fully, an attempt being made to show how these models are used to develop design improvements. Due to the fact that several different organizations are involved in model study work a brief description of methods used to co-ordinate the model study program is also presented.

River Models

Laboratories conducting river model studies relating to the St. Lawrence Power and Navigation Project include the Waterways Experiment Station at Vicksburg, Miss., the Ontario Hydro-Electric Power Commission Laboratory at Islington, Ontario, and the National Research Council Laboratories at Ottawa, Ontario. Additional model studies are to be made in a new hydraulic laboratory now under construction at Montreal, Quebec.

Organizations directly responsible for Seaway design are the United States St. Lawrence Development Corporation, which has delegated the U.S. Army Corps of Engineers to design and construct the American portion of Seaway works, and the Canadian St. Lawrence Seaway Authority. Those responsible for power development works include the Power Authority of the State of New York and the Hydro-Electric Power Commission of Ontario.

The fact that river model studies are being conducted by or for the different organizations concerned with navigation and power development at widely separated points has called for close co-operation between these organizations to prevent excessive duplication of effort. Integration of the model study program is attained through frequent meetings between representatives of all groups concerned with design and model study work. Basic data such as water and river bed elevations are exchanged as well as test results from the models. Considerable model study work is also done on an exchange basis so that the most efficient use may be made of all models. When a model belonging to one group is being used to obtain test results of general interest, other groups are privileged to maintain one or more engineers at the laboratory concerned. These engineers report model test results to their home offices and, in general, look after the interests of their respective organizations. This method of co-operation has worked out so well that there has been no call for the setting up of a special committee to co-ordinate model study work.

Generally speaking, improvement of the river channel between Lake Ontario and the Barnhart Island power house is considered primarily a power requirement, although this improvement is beneficial to navigation. This is largely due to the fact that power requirements limit the maximum mean flow velocity in river channels to 2.25 feet per second during the freeze-up period in order that an ice cover will be formed, while maximum mean velocities of four feet per second may be tolerated in navigation channels. River improvement works upstream from the power house have, therefore, been allotted to the power interests with the stipulation that these works must also satisfy the needs of navigation. As a result of this arrangement, all models for this section of the river have been constructed by the Hydro-Electric Power Commission of Ontario. These models will be dealt with first, beginning with those representing upstream reaches of the channel.

All river models are of the fixed bed type built of concrete, the method of construction varying somewhat at different laboratories. With one exception these models are built to a distorted scale, distortion ratios of 1:1.6, 1:3 and 1:5 being used.

(1) The Galop Rapids Reach

In the Galop Rapids reach of the St. Lawrence River is located the control section for outflows from Lake Ontario. The plan for improvement of this reach calls for increasing the channel cross-section, thus transferring the control of river discharge to a dam now under construction at Iroquois. The model used to develop a final plan for improvement of the Galop Rapids reach was built by Ontario-Hydro at the Islington laboratory. The entire reach from Prescott to Iroquois was reproduced in this model, as shown in Fig. 1, the scale ratios being 1 to 100 and 1 to 500 in the vertical and horizontal directions respectively.

The purposes for which a model of this reach was required were:

(a) To develop the most economic channel improvement plan in the way of excavation and spoil bank locations to best serve the interest of power and navigation.

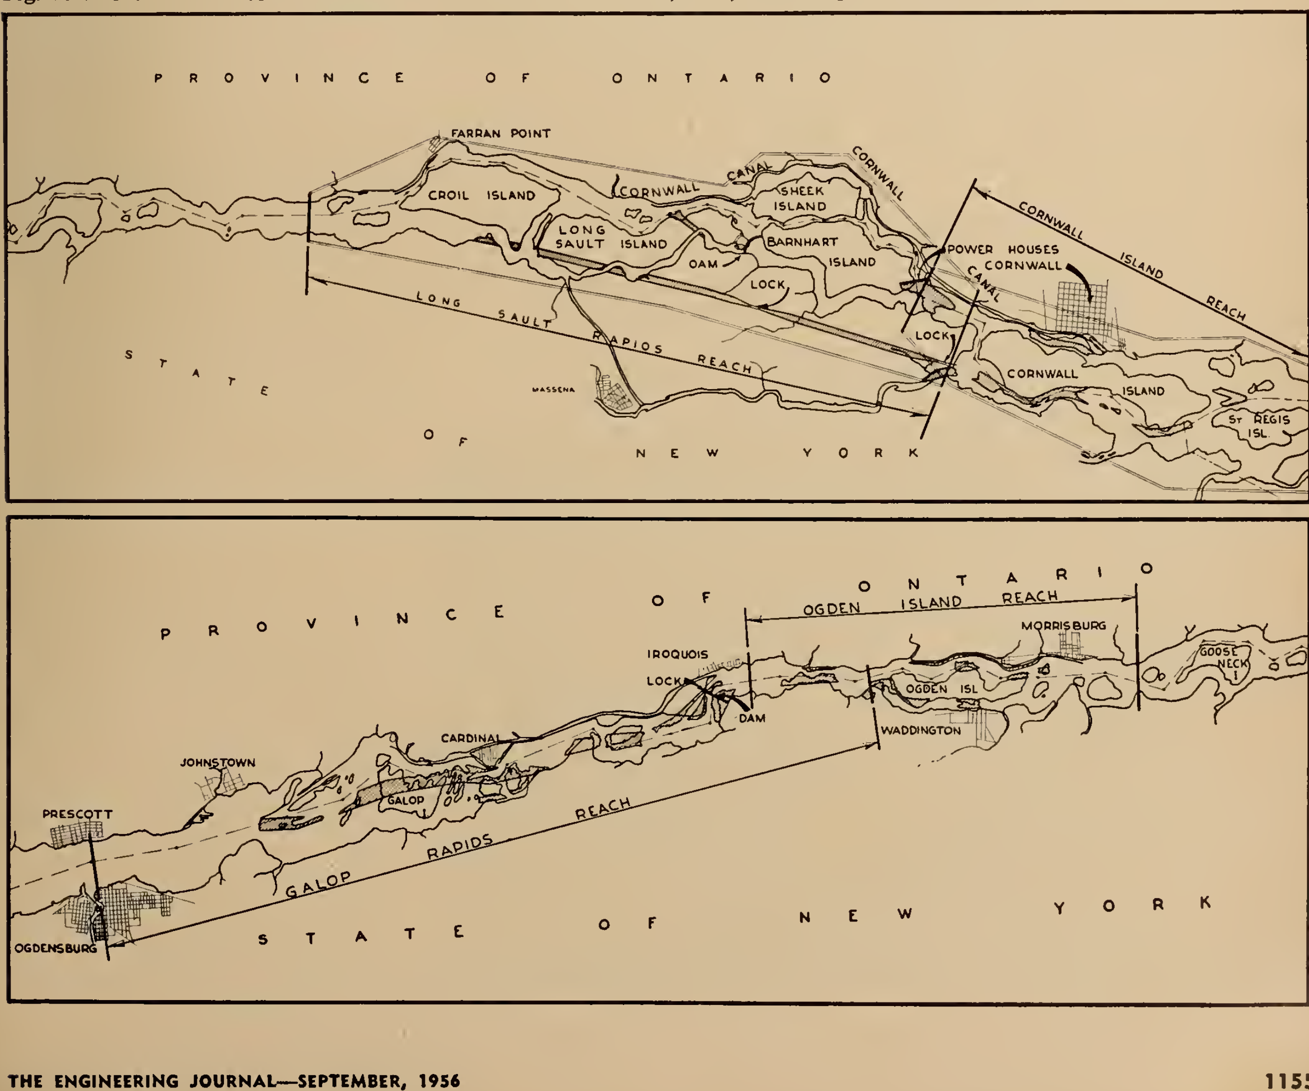
(b) To find the best location and alignment for the new Iroquois lock and approach channels.

(c) To help work out a construction program to prevent serious alterations in river discharge characteristics during the construction period.

(d) To determine the effect of proposed improvement features on water levels and flows.

Of these, only the first two are

Fig. 1. The St. Lawrence River between Prescott and Cornwall, Ont., indicating the various reaches.



directly related to Seaway design and will be elaborated upon more fully.

The problems of determining the most economical location for upstream channel excavation and of best alignment for Iroquois lock are related to the extent that it is desirable to maintain a straight navigation channel wherever possible. Where a straight alignment is not practicable a wider channel must be provided, and the minimum radius of curvature has been set at 5000 feet. For the Galop Rapids reach, where considerable channel excavation is required in the interest of power development, an extensive model study program has been carried out to develop an improvement plan which satisfies both power and navigation interests.

A proposed plan for works to be constructed by the Canadian Seaway Authority, including Iroquois lock and the approach channel upstream as far as Toussaint Island, was supplied to Ontario-Hydro by the Seaway Authority. This plan was reproduced in the Galop Rapids model together with the plan proposed by power interests for improvement of the entire reach upstream as far as Prescott. To determine the adequacy of provisions made by this plan for navigation the following information was obtained:

(a) Water depths and the direction and velocities of currents in lock approach channels as well as in the navigation channel upstream as far as Prescott.

(b) The effect on flows of proposed spoil bank areas for material to be excavated from lock approach channels.

(c) Water levels governing sill and coping elevations at Iroquois lock.

(d) The range of lifts at Iroquois lock which will obtain under various operating conditions of the St. Lawrence Power Project.

In working out details of the improvement plan for the Galop Rapids reach, it has been necessary to provide for control of Lake Ontario levels in accordance with a generally adopted scheme of regulation. At the time of writing this paper, such a scheme, suitable for design purposes, has been agreed upon by all parties concerned and model tests are in progress to determine final adjustments required in the improvement plan for the Galop Rapids reach.

To complete the story on models for the Galop Rapids reach relating to Seaway design, one other study will be mentioned briefly. This was made by the U.S. Army Corps of Engineers at the Waterways Experiment Station at Vicksburg, Miss., during the period 1943 to 1945 in connection with a scheme of river improvement very similar to that developed in the Islington model. Basic data compiled for the earlier model, as well as much of the test data obtained, were helpful in the more recent studies.

Fig. 2. Model of Cornwall Island reach at the National Research Council laboratories in Ottawa, Ont.

(2) Ogden Island Reach

The river immediately downstream from the Town of Iroquois, termed the "Ogden Island Reach", is characterized by narrow channels with velocities rather higher than the maxima specified for power and navigation. The required model was built and tested by Ontario-Hydro at their Islington laboratory, model scales being 1 to 100 and 1 to 500 in the vertical and horizontal directions respectively.

Information supplied by this model was as follows:

(a) The most economical locations and cross sections of channel excavations required to satisfy the needs of power and navigation.

(b) The proper balance of excavations in north and south channels at Ogden Island required to maintain flow distribution as in the natural state.

(c) The delineation of spoil dump areas for excavated material.

(d) The effect of temporary and permanent construction works on water levels.

(e) The development of a construction program such that the present 14-foot navigation will not be disrupted during the construction period.

The model study for this reach has been completed with the development of an improvement plan essentially satisfactory to both power and navigation interests. This plan calls for excavations at Point Three Points; in north and south channels at Ogden Island, and the removal of the Morrisburg canal bank, as indicated roughly in Fig. 1.

(3) Long Sault Rapids Reach

A model of the Long Sault Rapids reach was also built by Ontario-Hydro at the Islington laboratory, and reproduces the river channel from a point upstream from Croil Island to Massena Point downstream from the Barnhart Island Power House, as shown in Fig. 1. Model scales are the same as those used in the Galop Rapids and Ogden Island models.

The main purpose of this model was to develop a program for diversion and closure operations involved in the construction of Long Sault Dam and Barnhart Island Power House. At the time of writing this paper the diversion and closure problems had been successfully worked out, and the model was being used to

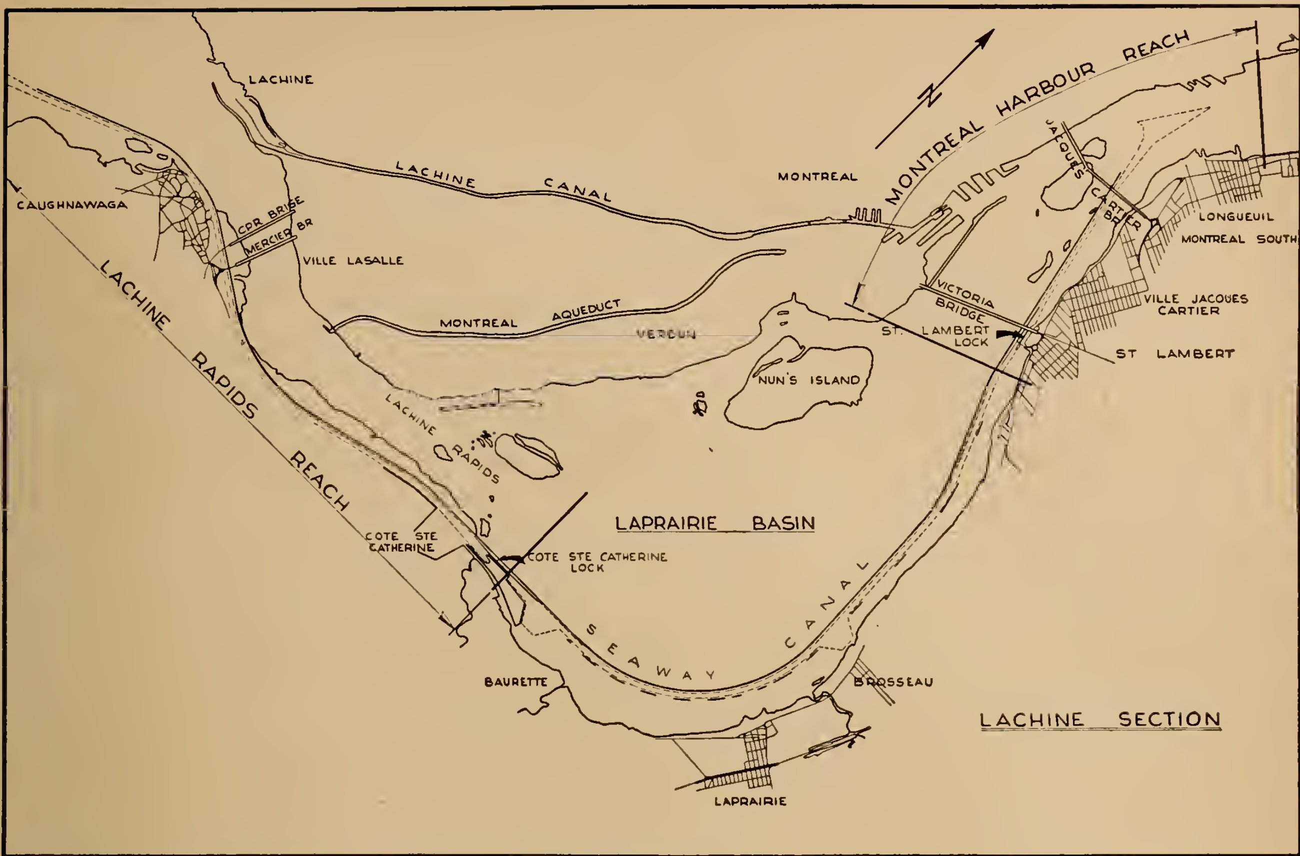


Fig. 3. The St. Lawrence Seaway; general plan of the Lachine section.

study the direction and velocity of currents which will exist in the reservoir south of Croil and Long Sault Islands at the head of the navigation channel.

(4) Cornwall Island Reach

Three models have been used in working out an improvement plan for the Cornwall Island Reach of the St. Lawrence River. Two of these were constructed by the U.S. Army Corps of Engineers at the Waterways Experiment Station at Vicksburg, Miss., and the other at the National Research Council Laboratories in Ottawa, Ont., for the Canadian Seaway Authority.

Of the Vicksburg models, one reproduces the river from Massena Point to approximately the middle of Cornwall Island at an undistorted scale of 1 to 100. The other reproduces the entire reach from the foot of Barnhart Island to the foot of St. Regis Island. (Fig. 1), with vertical and horizontal scales of 1 to 100 and 1 to 300 respectively.

The undistorted scale model was used to work out corrective measures for high-velocity cross currents in the navigation channel opposite the exit to Polly's Gut. These corrective measures will be in the form of rock dykes and a spoil bank located opposite the exit to Polly's Gut and along the shore line below Massena Point.

The distorted scale model of the entire reach was used to obtain the following information:

(a) The most economical locations and cross sections for excavations required to provide channel depths and flow velocities required for navigation;

(b) The delineation of spoil bank areas in the river channel south of Cornwall Island;

(c) The most economical form of compensating works required to maintain the natural state distribution of flows in north and south channels at Cornwall Island;

(d) The effect of channel improvements in the Cornwall Island Reach on water levels in the tailrace at Barnhart Island Power House.

At the time of writing this paper a satisfactory improvement plan for the South Cornwall Island channel had been developed with the aid of this model. Proposed compensating work in the form of a short length of excavated channel north of Cornwall Island was also developed in the Vicksburg model.

The Cornwall Island Reach model built at Ottawa for the Canadian Seaway Authority has been used to study various improvement plans in the interests of power and navigation. With reference to power development, it has been used extensively to determine the effect of various factors on water levels in the tailrace at Barnhart Island Power House. The factors referred to include:

(a) Various excavations in the tailrace area at Barnhart Island Power House.

(b) Various improvement plans for the downstream river channels.

(c) The regulation of water levels in Lake St. Francis at various elevations.

Data from these studies were supplied to the power interests on an exchange basis for model test data on navigation channels obtained from Ontario-Hydro models.

Information obtained from this model in the interest of navigation includes data on water depths and the direction and velocity of currents in proposed navigation channels in both the north and south channels at Cornwall Island. At the time of writing, the model was being used to develop an improvement plan for the North Cornwall Island channel to be used in place of the compensating excavations worked out in the Vicksburg model. This work is being done in support of the contention of the Canadian Seaway Authority that excavations in the North Cornwall channel should take the form of an improvement for navigation in anticipation of the future development of Seaway locks on the Canadian side of the river at Cornwall.

Figure 2 is a photograph of this model taken from a downstream location with the south channel in the foreground. Gauging stations are indicated by metal posts erected to support point gauges, while metal strips used to represent roughness may be seen in the beds of channels. This model was prefabricated in sections approximately two feet square and assembled on concrete blocks laid on the laboratory floor.

(5) Lachine Rapids and Montreal Harbour Models

A contract has been let by the Canadian Seaway Authority to Neyrpic, Canada, Limited for the construction and testing of models of the Lachine Rapids and Montreal Harbour sections of the St. Lawrence River channel. The general location of the reach to be reproduced in each model is indicated in Fig. 3.

Figure 4 shows a floor plan of the laboratory being built to house these models, indicating how the models will be fitted in and the general dimensions of the building required. The scales of both models are to be 1 to 125 and 1 to 200 in the vertical and horizontal directions, respectively.

Information relative to Seaway design required from the Lachine Rapids model is as follows:

(a) The effect of Seaway works on flows and water levels in the vicinity of Caughnawaga. If an increase in water levels as a result of Seaway construction is indicated, the model will be used to determine the extent and most economic location of compensating excavations,

(b) The directions and velocities of currents at the entrance to the Seaway channel at Caughnawaga. If undesirable current conditions are indicated, the model will be used to develop corrective measures,

(c) The effect on water levels in Lake St. Louis of older construction works, such as the bridges at Caughnawaga and the present Lachine Canal entrance pier.

The Montreal Harbour model will be used to obtain the following information:

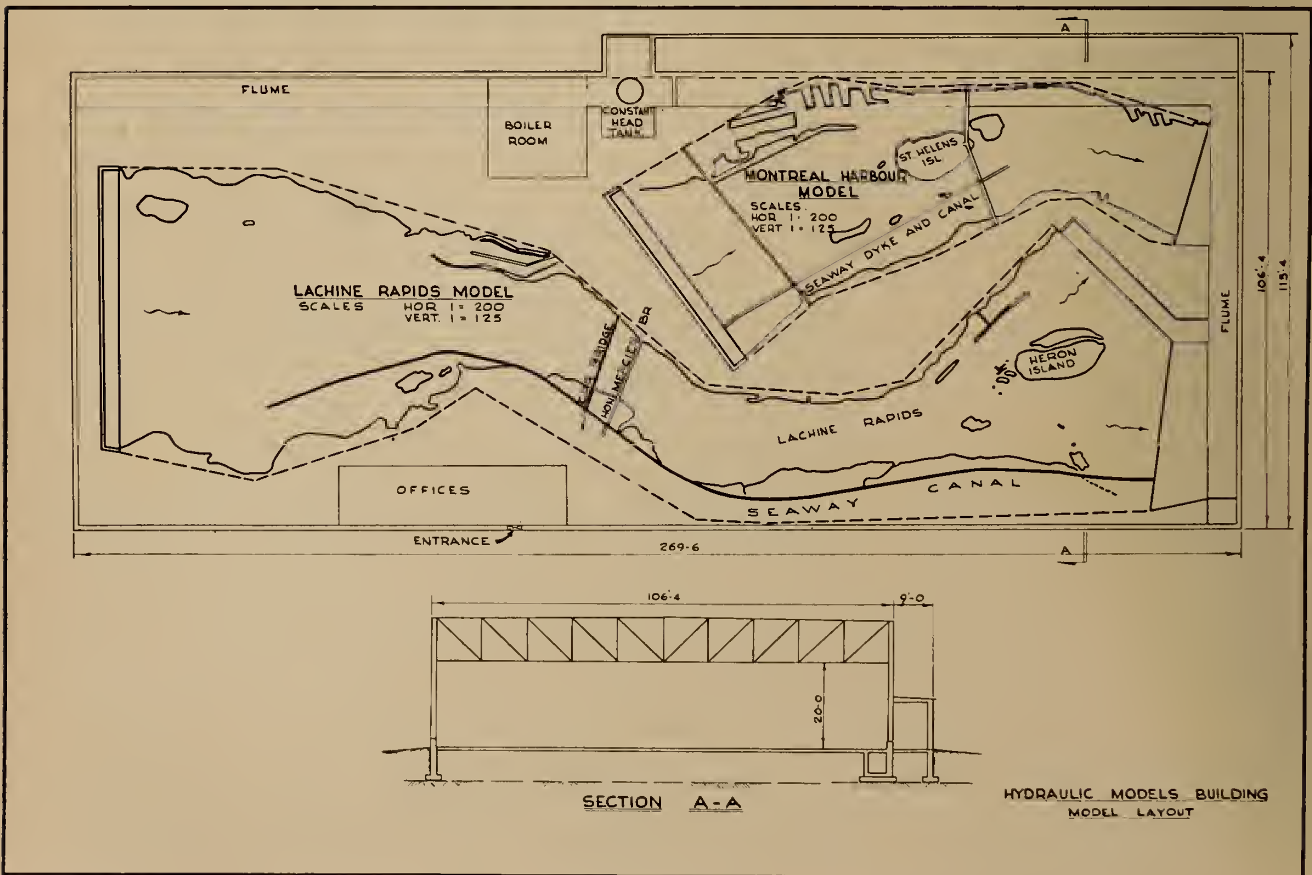
(a) The effect of Seaway works on flows and water levels in the Longueuil—St. Lambert area, and the most economic location for compensating excavations if these are required.

(b) Current directions and velocities at the canal entrance below Jacques Cartier Bridge. If undesirable current conditions are indicated, the model will be used to develop corrective works.

(c) The effect on water levels in Montreal Harbour of previous works dating back as far as 1870. These include excavations at various locations, the construction of Mackay Pier and other harbour works, and Jacques Cartier bridge.

It is understood that the Lachine

Fig. 4. Floor plan of the hydraulic models building, showing the model layout.



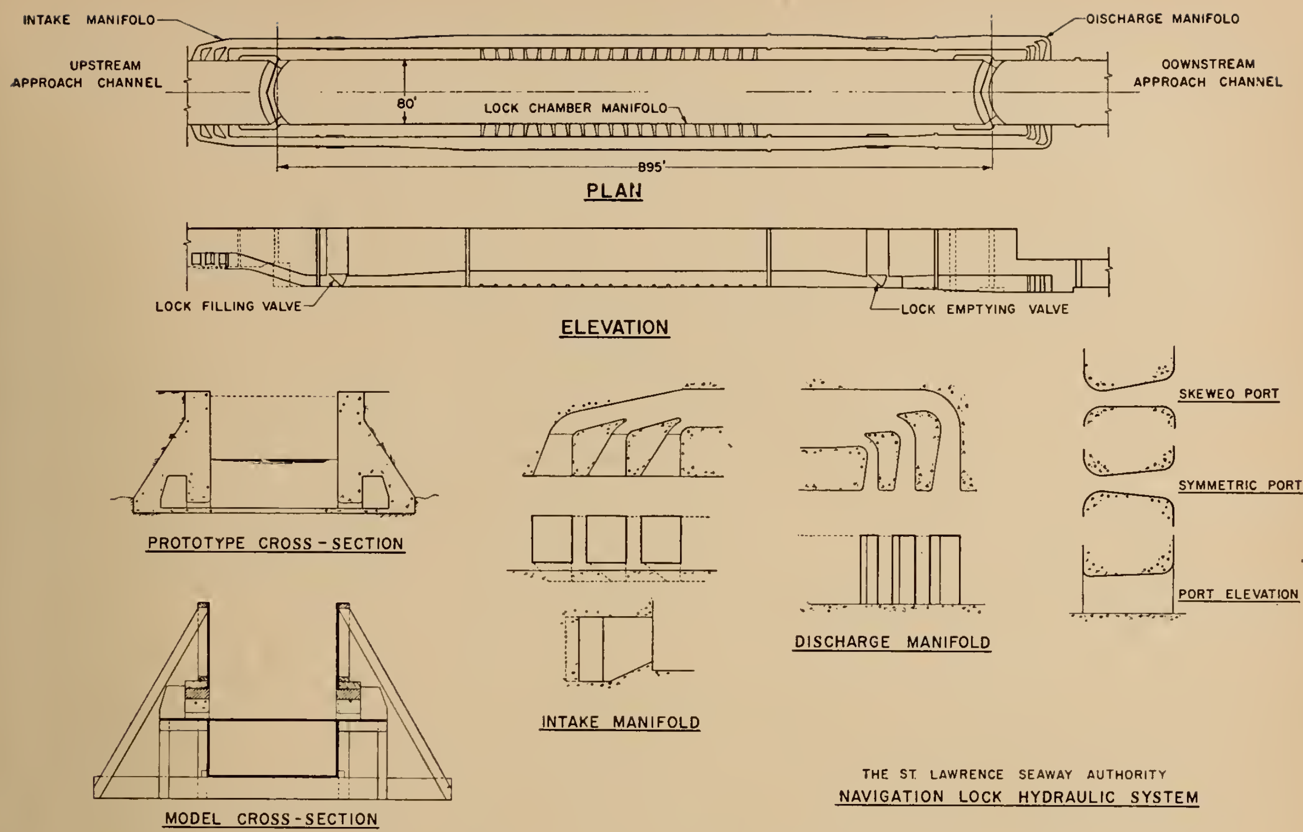


Fig. 5. Plan and elevation of filling and emptying system for use in Seaway locks.

Rapids and Montreal Harbour models may be placed at the disposal of the Quebec Hydro-Electric Commission for the study of plans for power development in the Lachine section of the St. Lawrence River. They may also be placed at the disposal of municipal planning groups wishing to develop improvements such as harbour extensions, bridges and recreational facilities in the Montreal area.

In summary, it may be stated that river models are playing a large and indispensable part in planning and design for the St. Lawrence Seaway project. They have proven to be efficient tools for solving complex design and construction problems and have made a notable contribution to the development of an integrated plan of river development which is in the best interests of both power and navigation.

Hydraulic Structure Models

Hydraulic models have been used to obtain design information on filling and emptying systems for Seaway navigation locks, and on the operating characteristics of guard gates. Models of both locks and guard gates were constructed by the U.S. Army Corps of Engineers at the St. Anthony Falls Hydraulic Laboratory at Minneapolis, Minn., and also for the Canadian St. Lawrence Seaway Authority at the National Reasearch Council Laboratories in Ottawa, Ont. As will be more fully explained later separate models were required by the United States and Canada to develop special design features to take best advantage of foundation conditions encountered at the different lock sites. Co-operation between the Corps of Engineers and the Seaway Authority in the matter of hydraulic structures design has taken the form of an agreement on governing dimensions for locks and an exchange of ideas on lock design and model work. In this connection, it is acknowledged that the U.S. Army Engineers, because of their very considerable previous experience in the design and construction of navigation locks, were able to contribute important leads to lock design improvements, particularly during the early stages of model study work. There has been little exchange of information on guard gates since the Corps of Engineers have designed a vertical-lift, fixed-roller type of gate, while the Seaway Authority design consists of a pair of vertically-mounted sector gates.

Dealing first with lock models built for the Canadian Seaway Authority, the chief purpose of these has been to develop improvements in the filling and emptying system selected for use in Seaway locks. This system, shown in plan and elevation in Fig. 5, was chosen as the simplest, most economical arrangement which could be made to perform satisfactorily in large locks with lifts ranging up to about 50 feet as required for the Seaway project. It consists, essentially, of intake manifolds, lock chamber manifolds, and discharge manifolds (see enlarged details, Fig. 5), joined by culverts through which flow is controlled by sector-type valves. Since all ports and conduits are located in the walls of the lock and approach channels, this is known as a "side-wall" system.

To fill a lock, the downstream or emptying valves are kept closed while the upstream, or filling valves are opened. Water from the upstream approach channel enters through the intake manifolds and flows into the lock through ports of the lock chamber manifold. During a lock emptying operation, filling valves remain closed, while emptying valves are opened. Water leaves the lock chamber by flowing through lock chamber ports in the reverse direction to that taken during a filling operation, and is emptied into the downstream approach channel through discharge manifolds. Under maximum lift conditions, more than 3,000,000 cubic feet of water will enter or leave some Seaway locks during filling or emptying operations. The locks are designed for filling or emptying in less than eight minutes, requiring maximum flows of about 10,000 c.f.s. in the lock hydraulic systems. Improvements in lock design are concerned with the reduction of disturbances caused by these flows in the lock chamber, and in upstream and downstream channels.

Construction began on the first lock model for the Seaway Authority during the summer of 1953. At that time the United States Government had not completed plans for participation in the Seaway project, so this model represented a lock which was to be constructed on the Canadian side of the St. Lawrence River near Cornwall. The original model was modified early in 1955 to represent a lock to be located at Cote Ste. Catherine on the south shore of Laprairie Basin near Montreal. At the time of writing this paper, the model was undergoing a second modification to reproduce one of the locks to be constructed at the downstream end of Beauharnois power canal. A scale of 1 to 30 has been used for these lock models.

A cross section of the Cote Ste. Catherine lock model, indicating some construction details, is shown in Fig. 5. All culverts and manifold are removable to facilitate design changes. The chamber space below culvert level was used in the Cornwall lock model because of the great depth to rock foundation at the Cornwall site. A false bottom just below culvert level represents the floor of the Cote Ste. Catherine lock.

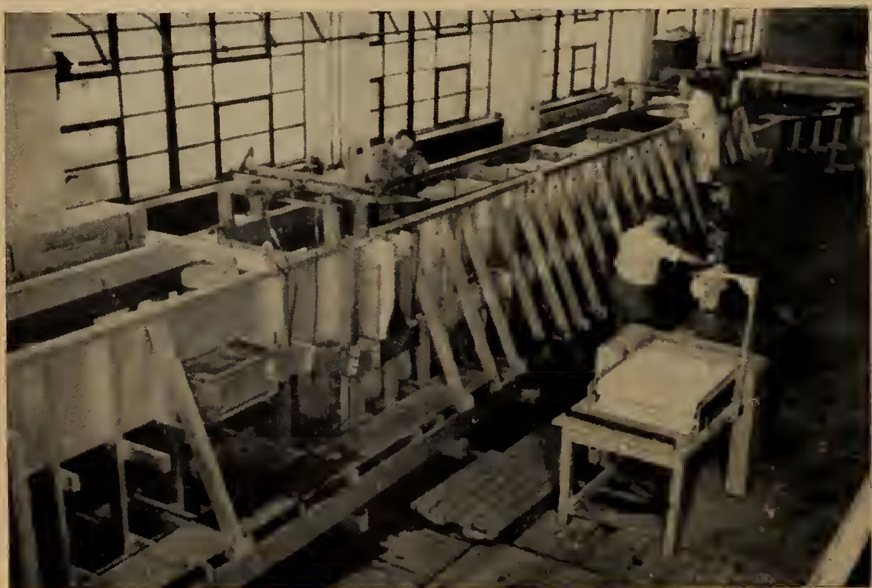
A pen-type recording instrument built by the National Research Council gives a continuous record of water levels in upstream and downstream approach channels and in the lock chamber as well as a record of filling and emptying valve motion. Hydrodynamic forces on a model ship in the lock chamber are transmitted to strain gauges and recorded by a chart recording oscillograph.

Figure 6 is a photograph of the Cote Ste. Catherine lock model taken from an upstream location. Instruments used to record model test data are shown on the right.

Figure 7 gives a qualitative graphical representation of the mechanics of flow in a lock filling system, and will be used to explain improvements in design developed through model studies for St. Lawrence Seaway locks. A simplified system is used for this purpose with only three ports in the lock chamber manifold, whereas 20 ports will be used in each wall of the Cote Ste. Catherine lock chamber.

At the beginning of a filling operation, when filling valves start to open, water in the lock chamber manifolds receives an accelerating impulse from water under higher pressure upstream from the valves. The magnitude of this impulse is proportional to valve opening rate. Due to inertia of water in the culverts, acceleration is greatest along the shortest paths between the valves and lock chamber. Flow through upstream ports builds up much more quickly, therefore, than that through downstream ports, as illustrated by the rising portions of port discharge curves shown in Fig. 7. When water in the culverts is in motion each port of the lock chamber manifolds has the effect of a sudden expansion in culvert area. Loss of water through the port results in a sudden drop in flow velocity and a corresponding rise in pressure as shown by the graph of culvert pressure head. Friction loss in the culvert between ports is less than the pressure rise at each port, with the result that culvert pressure and port discharge tend to increase in the downstream direction. This condition is intensified when deceleration of water in the conduit system begins, due to rising water level in the lock chamber. Due to inertia of water in the culverts, deceleration also is greater along the shortest paths between the lock chamber and upstream channel. As a result of increasing culvert pressures downstream caused by deceleration and the expansion effect of ports, discharge through upstream ports drops off before maximum discharge is attained at downstream ports. Discharge from downstream ports soon becomes greater than that from upstream ports, and remains so for the balance of the filling operation. Rapid deceleration of water in upstream portions of the conduit system may result in a reversal of flow in upstream lock chamber ports, as indicated by port discharge curves in Fig. 7.

Fig. 6. Model of the Cote Ste. Catherine lock at the National Research Council laboratories. Recording instruments are shown in the foreground.



The build-up of flow at downstream ports may be reduced slightly by proper port design. Graphs of discharge and head-gain coefficients are shown in Fig. 7 for ports of the type used in Seaway locks. These curves indicate that the discharge coefficient increases, and the head gain coefficient decreases in the upstream direction for all excepting the downstream two or three ports. However, this effect of port design on discharge is much too small to prevent a shift of maximum flow to downstream ports.

Effects of the above described phenomena on lock filling and emptying characteristics are:

(*a*) Discharge through upstream ports at the beginning of a filling operation causes water level to rise in the upstream end of the lock chamber. This

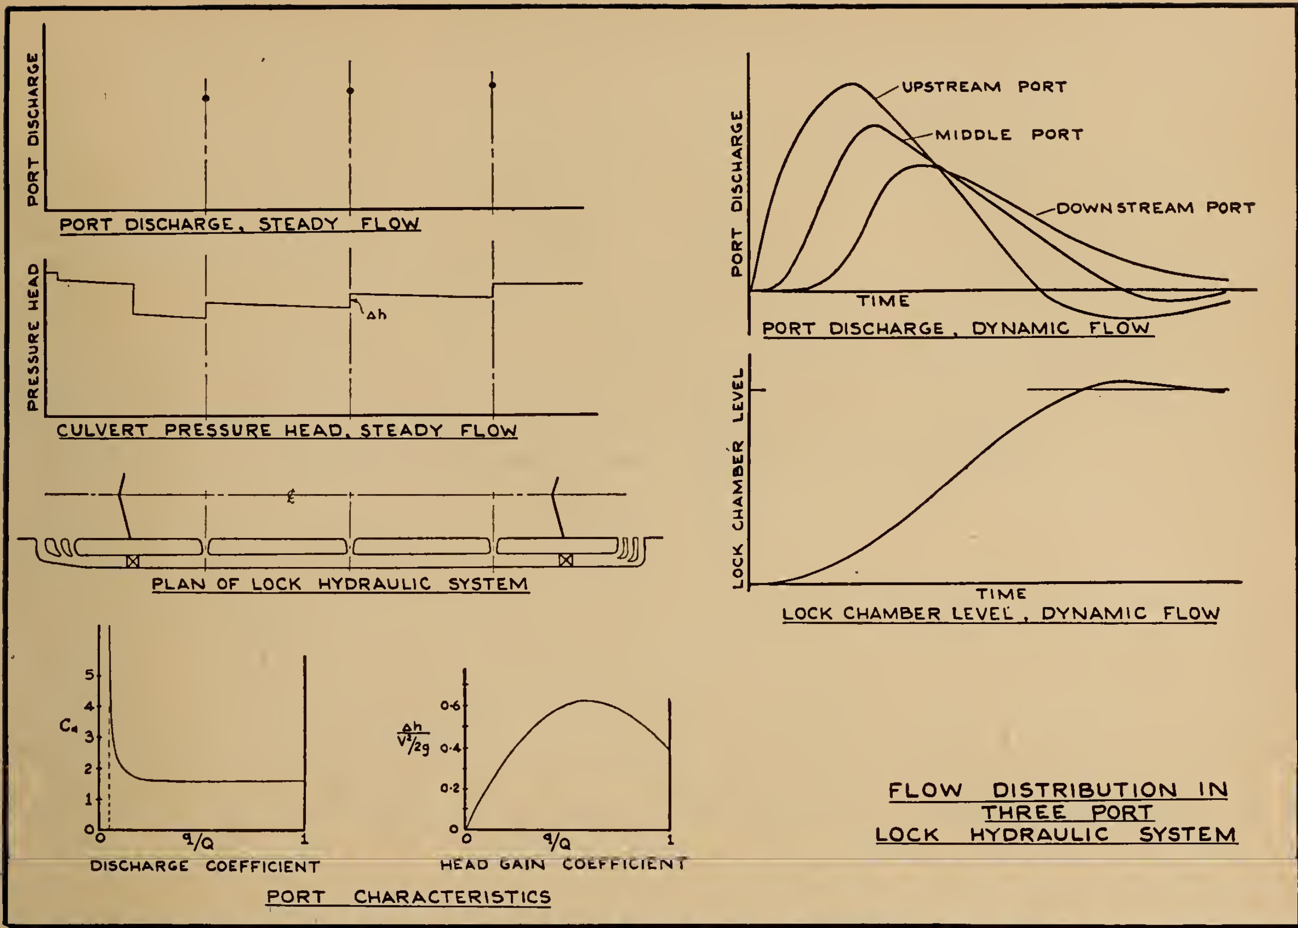


Fig. 7. Graphs of discharge and head-gain coefficients for ports of the type used in Seaway locks.

sets up a surge wave which travels from end to end of the lock for the remainder of the filling operation.

(b) The shift of maximum flows to downstream ports causes water level at the downstream end of the lock chamber to remain generally higher than that at the upstream end during the latter portion of a filling operation.

A ship in the lock chamber during a filling operation is forced first toward the downstream gates, then toward the upstream end of the lock. Forces on a ship are greatest during early stages of the operation because ports are then discharging under maximum differential head, and because water in the lock chamber is shallow, and therefore subject to greatest disturbance from port discharge.

The first lock model had lock chamber manifolds of the usual design, consisting of culverts of uniform cross section running full length of the lock, and symmetric, venturi-shaped ports. A number of modifications were made in this design with the aid of models which resulted in significant improvements in lock performance. The first of these modifications was an enlargement in the culverts of lock wall manifold as shown in Fig. 5. These were expanded from an area of 168 square feet at the filling and emptying valves to an area of 294 square feet throughout the length occupied by lock wall ports. The increased culvert area gave lower flow velocities, reducing the acceleration and deceleration effect in culverts as well as the pressure rise at ports. This resulted in a more uniform distribution of flow through lock wall ports which speeded up the lock filling operation and lowered forces on a ship in the lock. The accompanying table of test results interpreted from lock model data indicates the improvement in lock performance brought about by enlarging the wall culverts. It also shows the very important effect of valve operating speed on lock performance.

Test Results from Lock Model Data

Wall Culvert Area (sq. ft.)	Valve Opening Time (min.)	Lock Filling Time (min.)	Maximum Hawser Force (24,000-ton Lake Freighter) (Tons)
168	2.0	8.15	23
294	2.0	7.10	17
294	4.1	8.15	7

A second modification, developed in the Cote Ste. Catherine lock model, was a change in lock chamber port design from a symmetrical to a skewed shape as indicated in Fig. 5. A few upstream ports were skewed to direct flow toward the downstream end of the lock. This arrangement directs initial port discharge away from the upstream end of the lock chamber, thus reducing surge and the resulting initial downstream force on a ship. All remaining ports of the lock chamber manifold were skewed to direct flow toward the upstream end of the lock chamber. This reduced the build up of downstream water level and tended to set up a downstream surface current in the lock chamber, thus

Fig. 8. Model of one leaf of a sector gate, showing framing details.

reducing upstream forces on a ship during the latter portion of a lock filling operation. By installing the proper proportion of upstream and downstream directed ports, upstream and downstream forces on a ship during a filling operation were made approximately equal, and the maximum force was substantially reduced. The use of a skewed port arrangement in lock chamber manifolds resulted in an improvement in lock performance comparable to that obtained with an enlarged culvert section.

Other modifications in design of the lock hydraulic system were made for the purpose of decreasing lock emptying time. The emptying time for Cote Ste. Catherine lock was reduced by as much as one and one-half minutes by increasing the throat area of lock chamber ports by nearly 40 per cent. The corresponding reduction in lock filling time was approximately 0.6 minutes. Another reduction in emptying time of 0.3 minutes was obtained by modifying the discharge manifolds. The original discharge manifold design contained four ports separated by three vanes. The ports were so designed that there was a continuous expansion in flow through the 90 degree bend from the culvert to the lower approach channel. This resulted in considerable separation of flow from downstream sides of the vanes. An improvement in this condition was obtained by producing a slight contraction in flow in the bend section as shown in Fig. 5.

A somewhat modified form of side wall filling and emptying system was developed for the American locks. Although the lock chamber manifolds are very similar to those designed for Canadian locks, ports of intake and discharge manifolds are located in the floors of upstream and downstream lock approach channels. The reason for this difference in design is the greater depth to foundation rock at American lock sites which makes it possible to install intake and discharge works below channel grade level without excessive rock excavation.

In summary it may be stated that the hydrodynamic forces affecting flow in a lock hydraulic system, and the relation between these forces and those on a ship in the lock chamber are too involved for satisfactory mathematical solution. Over the past twenty years lock model studies have brought many improvements in lock design, and studies for Seaway locks constitute another step in this process. There is little doubt that future model studies supplemented by extensive mathematical investigations will produce further very substantial advances.

Guard Gate Models

The purpose for which guard gates are to be used requires that they be capable of closing under any condition of flow which may exist in the Seaway channel due to failure of a downstream structure. Models were used to determine the hydrodynamic forces for which these gates and their operating machinery must be designed in order that safe closure may be made in flowing water.

As previously mentioned, the U.S. Army Corps of Engineers has designed a vertical-lift, fixed roller type of gate, whereas the Canadian Seaway Authority has elected to use a sector gate design. As in the case of locks, the chief reason for this difference in American and Canadian design is the greater depth of overburden on foundation rock at the American site. A vertical lift submerging gate, therefore, provides the more economical construction in the American channel.

The U.S. Army Corps of Engineers design calls for a gate roughly 83 feet wide by 46 feet high to be lowered into a slot in the channel floor when not in use. A hydraulic model was built to a scale of 1 to 33-1/3 to study forces on the top and downstream side of the gate when it is raised in flowing water.[1]

[1] For further details see Engineering News Record, 1955, Oct. 27.

Guard gates designed by the Canadian St. Lawrence Seaway Authority consist of two leaves in the form of 60-degree sectors cut from a cylinder approximately 98 feet in diameter and 41 feet high. These gates fit into recesses in the channel walls and are moved outward into the channel when closed. The gates swing on hinges located at the apex of the sector and rest on rollers located near the circumference.

A 1 to 20 scale model was built to study operating torque due to hydrodynamic forces on gates of this type when they are closed in flowing water. Figure 8 is a photograph of the model of one gate leaf showing the framing and general construction. Figure 9 is a view, looking upstream, of the completed model in operation with each gate 5 degrees open, and Fig. 10 is a view of the model taken from an upstream position.

The torques required to hold a gate leaf in position with various flows in the model were measured for gate openings of up to 50 degrees, and model flows ranging up to 14 c.f.s. Torques were read from a deflection gauge attached to a calibrated torque arm which was used to hold a gate leaf in position.

In the original model, based on the Strait of Canso lock gate design, the skin plate was wrapped around the inner or mitring nose of the gate and extended back along radial frame members a distance of about three feet. It was found that water flowing between the gates tended to cling to the radial portions of the skin plates as indicated in Fig. 11,

Fig. 9. Downstream view of the sector gate model in operation.

similar to the action of air flowing over the upper surface of an aeroplane wing. Differential pressure on the radial plates due to high velocity flow on one side and relatively calm water on the other produced large closing torques on the gates. This torque varied with gate position, being a maximum at a 30 to 40 degree opening.

The original design was modified, the change consisting essentially of the removal of about two feet from the radial plate section. This modification reduced gate closing torque by about 40 per cent. The radial plates were then removed almost entirely, leaving sharp edges at the gate mitring noses. This reduced gate closing torques to approximately 38 per cent of those measured for the second gate design. The remaining maximum closing torque, estimated at 1220 kip feet under the worst operating conditions expected at the prototype guard gates, appeared to be partially due to circulation of water through gate members downstream from the skin plates.

In the model only top and bottom hinges at the apex of the sector were used, and these were made as frictionless as possible so that only torques due to hydrodynamic forces were measured. This torque fluctuated erratically in all gate positions, and the quoted torque value of 1220 kip feet is the maximum indicated. Rollers used to support the prototype gates near their outer circumferences are expected to dampen out the torque fluctuations. Maximum torque values measured in the model should not, therefore, be attained in the prototype.

In addition to their use as guard gates, sector gates are also to be installed in Iroquois lock in place of mitre gates as used at other locks. Since the lift at Iroquois lock will be less than five feet most of the the time after the pool above the Cornwall power house has been raised, this lock can be filled and emptied safely through the gates, eliminating conventional filling and emptying conduits. The model was used to obtain gate discharge coefficients for lock filling and emptying computations. These coefficients were also used to compute the rates of increase in gate discharge corresponding to different rates of gate opening. From this information it was possible to compute the height of surge together with forces produced on a ship by these surges in the lock chamber corresponding to various gate opening rates. It was then possible to recommend gate opening rates to be used in lock filling and emptying operations.

The mathematical aspects of model study work have been purposedly avoided in this paper so that a broader general picture of the use of models in Seaway design and planning could be presented. This broader picture could not be entirely complete at the present time since some models are still in operation while others are merely in the planning stage. It is to be hoped that, as Seaway work progresses, other papers will be forthcoming on various details of model work and the conformity between model and prototype performance.

Discussion of technical papers in this issue is published on the following pages. The Editor invites written discussion of other technical papers that are published in *The Engineering Journal.*

DISCUSSION

of Technical Papers

GENERAL DESIGN OF THE ST. LAWRENCE SEAWAY

D. M. Ripley, JR.E.I.C. *The St. Lawrence Seaway Authority*

The Engineering Journal, 1956, September, p. 1134

G. H. Kohl, M.E.I.C.[1]

Mr. Ripley is to be congratulated in presenting in the short time available a very comprehensive description of the St. Lawrence Seaway.

A decade ago Canada foresaw the need for improvement in the canals in the Montreal-Prescott reach which became more urgent with the development of iron ore in northern Quebec but it was only in 1952 that the international difficulties were overcome and the project could be commenced. The actual construction began in 1954.

1926 Report — Mr. Ripley has referred to the 1926 report on the project including the development of power and it is indeed a tribute to those responsible for its preparation that the project as now being carried out is basically the same as then proposed for navigation and power.

U.S. Participation — Until 1954 Canada was proceeding to construct the project alone, from Montreal to Lake Erie, utilizing the channels to be constructed in the International Rapids reach by the power entities but in that year the United States exercised their right to partake in the work in the international section and undertook to construct a canal around the Long Sault dam. This relieved Canada of part of the cost of the deep waterway but increased the length of this canal by some five miles. As Mr. Ripley has said Canada bears now two-thirds of the cost of the Seaway but of course will share to a proportionate extent in the tolls. I have been somewhat repetitive here but perhaps these points bear repetition.

Excavation Quantities — The quantities of excavation indicated in Mr. Ripley's paper are impressive, and if to this is added the work being done by the power entities in the International Rapids section it is found that close to 200,000,000 cu. yd. must be removed, which alone would entitle this project to rank amongst the largest modern engineering undertakings. The construction program indicates this excavation to be substantially completed by the summer of 1958, when the schedules call for raising the power pool.

Dykes-Cofferdams—Wherever possible excavation is being removed by land based equipment in many cases working from or behind protective dykes.

These dykes are constructed by end dumping. In the Lachine section, friable shale has been used faced on the wet side with till. In the Cornwall—Chimney Point section the natural dense till from the excavation is utilized. This till weighs up to 150 lb./cu. ft. with natural moisture of about 7 to 9 per cent. It is difficult to excavate, scrapers are ineffective, and resort has been had in most cases to drilling and blasting and removal by shovel or dragline. Although this has made for high excavation costs, this material has been found very suitable for secondary cofferdams. It has been dumped in water up to 20 ft. deep and with velocities up to about 5 ft./sec. and compacted only by the passage of equipment. No rip-rap is required except at critical points.

When excavation within the dyke has been completed, and the draglines have excavated to grade on the river side of the dyke, they are removed by the same draglines. Much work which was originally planned to be done by dredging is being excavated in this manner at a considerable saving in cost.

In its natural state this till stands on steep slopes (about 1/1) and work has been carried on in one case, immediately adjacent to the Massena Canal, 64 ft. below water level in this material.

Excavation Equipment — The excavation equipment assembled on both sides of the border for this combined power and seaway undertaking, which is planned to be substantially completed in four years, at present includes: 143 shovels and draglines (shovels to 6 cu. yd.; draglines to 15 cu. yd. capacity); 260 dozers; 500 heavy trucks, up to 30 cu. yd. capacity; 11 dipper dredges, 6-12 cu. yd. capacity.

The earth moving equipment in the International Rapids reach alone is valued at $40,000,000.

Channels Provided by Power Entities — The part played in the Seaway by the power entities, Ontario Hydro, Hydro-Quebec, and the Power Authority of the State of New York, is of interest.

At Beauharnois the 15 mile power canal is to be used for navigation. From Croil Island to Canada Island near Morrisburg the raising of the river levels by the power dams will provide sufficient depths for navigation.

At Ogden Island a hydraulic channel is being provided on the south side to carry 40 per cent of the river flow and to reduce the maximum velocities in the navigation channel on the north side to the required 4 ft./sec.

In the vicinity of the Iroquois dam, and at Toussaint Island and Sparrowhawk Point, channels are being substantially straightened out, while at Galop Island the main channel passes through the centre of the island with hydraulic cuts north and south of Lalone and Lotus Islands.

[1] Chief Engineer, Canadian Section, St. Lawrence River Joint Board of Engineers, Montreal.

Ice Cover — With these channels completed and ultimately with power developed at Isle Heron a fairly continuous ice cover may be expected to form from Lachine to Lake Ontario with the exception of a few short stretches of open water in the vicinity of Iroquois dam and in the Galop channel. The reduction in the formation of frazil ice should consequently be substantial with beneficial results in winter water levels.

River Control and 14-foot Navigation — Once the natural weir near the head of Galop Island has been breached, control of the river will pass to the Iroquois dam, which will then be operated to maintain so far as possible the normal outflows and levels of Lake Ontario, until completion of construction.

Also, during construction, 14-ft. navigation must be maintained in the International Rapids reach, and the work has been integrated with great care by the power entities and scheduled accordingly.

I am going to ask Mr. Ripley to tell us of some of the problems involved in maintaining 14-ft. navigation during the construction period.

S. Hairsine, M.E.I.C.[2]

Mr. Ripley has given us an excellent word picture on the development of the St. Lawrence Seaway project and of the problems involved in its construction. One point that impresses me is the reduction in the number of locks between Cardinal and Montreal harbour which, as he states, will be reduced to 7 from 21, with a resulting saving in passage time from Kingston to Montreal of several hours. Actually the time saved will presumably be between Montreal harbour and the locks above Cardinal, Ontario, and will be more noticeable on upbound passages because downbound vessels now run the river from above Cardinal locks as far as the entrance of the Cornwall canal, if the water on the lower sill of the river lock at Cardinal is 2 feet greater than the draught of the ship. This saves about 5 hours time for downbound vessels, 30 minutes of which is a saving in lockage time. By comparison, the approximate times required to navigate this distance between Cardinal and the entrance to the Cornwall Canal are —

Downbound — 3 hr., 19 min.; an average speed of about 9.67 m.p.h.

Upbound — 8 hr., 19 min.; an average speed of about 3.75 m.p.h.

2 Electrical and Mechanical Engineer, The St. Lawrence Seaway Authority, Montreal.

At the present time, upbound vessels making this passage have to move through 4 locks upbound compared to one lock when downbound. When the Seaway is completed, both up bound and downbound vessels will have to pass through only one lock, requiring about 10 minutes lockage time, and with the pool below the lock raised to normal elevation to reduce the current velocities to less than 4 feet per second, the passage time for vessels travelling in each direction will be about the same, or about 7 miles per hour. Perhaps Mr. Ripley would like to tell us something more about, say, the times required for vessels to travel through the existing 14-foot lower main line canals and the anticipated times required to pass through each section of the new canals.

The Author

In his discussion Mr. G. H. Kohl has raised a very important question regarding the continuance of present or so-called 14-ft. navigation during the construction of the St. Lawrence Seaway and Power Projects.

There is no problem in this regard in the river below Cornwall, Ontario. In the Lachine section the new canals and locks are entirely separate from the present system and the same is true for the Soulanges or Beauharnois section. The new navigation facilities in these sections will be ready for shipping by the opening of navigation in 1959. Aids to navigation will be established and the changeover may be made with no delays. The old canals will continue to function until no longer required by industry located along the canals, particularly at Montreal.

In the river between Prescott, Ont., and Cornwall the situation will be quite different. In this section the present 14-ft. canal system will be flooded out when the pool upstream from the powerhouses is raised, also, shipping will be subjected to some relatively minor inconveniences during construction. The chief problem is one of raising the pool elevation and keeping to a minimum the delays to vessel movements. It is now expected that the pool will be raised in September 1958, which is in the middle of the navigation season, so that delays of any duration would be undesirable.

It is proposed to handle the change-over in the International Rapids section roughly as follows. By late 1956, construction in the river near Iroquois will have progressed so that navigation must use the canal in both directions between Iroquois and Cardinal instead of the river below lock 28 for downbound shipping as at present. The Department of Transport have provided passing points and additional tie-up facilities in the canal in anticipation of the increased traffic. No appreciable delay to navigation is expected.

Shortly after April 1957 the water level above Iroquois dam will be gradually raised and the river brought under regulation. The regulation "rule" at that time will be as in the state of nature. This means that natural Lake Ontario levels and outflows will be kept while under artificial control. The raising of the water level above Iroquois dam will keep pace with the enlargement of the river upstream, particularly at the Galop Island cut. The canal banks of the present system will be raised where necessary to retain the water in the canal reaches at present levels. During 1957 the seaway lock at Iroquois may be brought into service for 14-ft. navigation. At that time the water levels above the Iroquois lock will be close to the ultimate while the water level below the lock will be at natural condition or slightly lower. This means that the lock may be required to operate at a head of about 24 feet and it has been designed to do so. The limitation of the use of the Iroquois lock for 27-ft. navigation during this period is the limited depth on the lower sill. As the pool is raised above the powerhouses the lock will be available for vessels of full seaway draught.

Until July 1958 the river and canal sections between Iroquois and Cornwall will be used as at present. A diversion canal and dyke closure structure are being constructed at the north end of the Barnhart Island powerhouses and these facilities will be put into use in November 1957. The main dyke may thus be properly constructed across the present Cornwall canal, and when the time comes to raise the pool, stop logs may be quickly placed in the closure structure, thereby closing off the 14-ft. canal.

The two locks on the U.S. side will be ready for seaway shipping when closure is made and the pool raising begins. It is essential that a continuous flow of water be maintained in the river at all times to protect the downstream power and navigation interests and it is proposed, therefore, to raise the pool by a transfer of water from Lake Ontario. The quantity of water required to fill the pool (500,000 acre feet) will not affect Lake Ontario to an appreciable extent. At the present time it appears that a rapid raising of the pool to elevation 235 will present the least difficulty to navigation and the delay that will result will not be more than four days. This proposal for changeover procedure depends on the stage of Lake Ontario at the time the pool is to be raised.

Reply to Mr. Hairsine

As Mr. Hairsine has said, the average time now required for a downbound vessel to travel from the head of the Galops canal to the head of the Cornwall canal, by river, a distance of some 30.73 miles, is 3 hours and 19 minutes. Upbound vessels require 8 hr. 19 min. for the same distance.

The average time required for a vessel to pass downbound to Montreal harbour through the remainder of the distance, according to D.O.T. statistics, is 23 hr., 43 min. and is made up of the following:

(1) Cornwall canal — 11 miles; 5 hr. 40 min. for an average speed of 1.95 m.p.h.

(2) Foot of Cornwall canal to head of Soulanges canal — 31 miles, 3 hr. 59 min. for an average speed of 7.75 m.p.h.

(3) Soulanges canal — 14.67 miles, 6 hr. 35 min. for an average speed of 2.23 m.p.h.

(4) Foot of Soulanges canal to head of Lachine canal — 16 miles, 2 hr. for an average speed of 8 m.p.h.

(5) Lachine canal — 8.74 miles, 5 hr. 30 min. for an average speed of 1.59 m.p.h.

With the improvements made in the design of the lock culverts, it will be possible to reduce the present filling and emptying times of the locks by some 50 per cent. This, together with the reduction in the number of locks on the Seaway from 21 to 7, and the improvements with canals and channels which will permit greater average speeds, accounts for the some 12 hours saving in passage time between Montreal and Kingston.

figures will be generally the same for British and American machines.

The hydraulic design of gates and hoists furnishes still another example of successful joint international undertaking. In this connection (in fact throughout the hydraulic design of the entire development) the work of the HEPCO laboratory at Islington has been invaluable in determining the optimum contour and ventilation of the bottom girders of the gates so as to reduce hydraulic downpull and consequently hoisting capacity to the practicable minimum.

As a result of such outstanding laboratory work and the constant close cooperation between the two engineering staffs, together with the competence, energy and vision of the officers of the two Commissions, the overall project design reflects a general unity and coherence with only such differences in minor detail as would naturally be expected to arise from the individual preferences of Canadian and American engineers.

MECHANICAL DESIGN FEATURES OF THE ST. LAWRENCE POWER PROJECT

O. Holden, M.E.I.C., and P. Pemberton-Pigott

The Engineering Journal, 1956, September, p. 1143

George R. Rich,[1]

The authors have presented an interesting and valuable paper with pertinent data conveniently summarized for reference and comparison. The engineering design of the project affords an outstanding instance of international cooperation between the constructing entities, The Hydro-Electric Power Commission of Ontario and The Power Authority of the State of New York.

At the earliest inception of the planning work all interested European and American manufacturers of turbines and generators were invited to attend an open meeting with the combined staff of HEPCO and PASNY to establish principal substructure dimensions, general waterway outlines, and turbine speeds and ratings that would be acceptable to all concerned as a basis for competitive bidding and yet would not place any undue restriction upon the design practice of any prospective bidder. For example the turbine runner diameter and detailed contour of the waterways were two of the design features left open to the individual manufacturer as elements of competition. The desired agreement was readily reached at the conference with the result that the American and Canadian halves of the Barnhart Island powerhouse are substantially identical in the structural, mechanical, and electrical features.

With respect to the author's Table I, "Turbine Data", it should be explained that: (1) it is standard practice in the United States to base efficiency acceptance of propeller turbines upon the stepped-up performance of laboratory model tests; and (2) in the United States turbine manufacturers have a trade agreement not to guarantee efficiencies greater than 90 per cent. This accounts for the obvious discrepancy between the guaranteed performance of the British and American turbines. Present plans contemplate prototype tests of all turbines by the Gibson method and it is anticipated that these prototype performance

1 Partner, Uhl, Hall & Rich, Boston, Mass., U.S.A.

R. H. Findlay, M.E.I.C.[2]

I would like, in the first place, to congratulate the authors on their paper. In the course of the next year or two, undoubtedly, many papers will be given on the design, construction, and operating features of this equipment. The authors have shown considerable reserve in limiting their remarks to brief outline descriptions of the equipment involved. Their paper, therefore, forms a very good introduction to the series of more detailed descriptive papers which will follow.

W. G. H. Holt, M.E.I.C.[3]

An inspection of the plans of the various hydraulic regulating gates will show that they are all of welded construction except the Canadian head gates which are riveted. Before we submitted our tender on these gates, we considered both alternatives. In fact, three different welded designs were worked out, one with a normal thickness of skin plate, one with a minimum allowable thickness of skin plate based on a membrane theory, and one with an extremely thick skin plate with an absolute minimum of stiffeners.

2 Consulting mechanical engineer to Dominion Bridge Company Limited, and the St. Lawrence Seaway Authority, Montreal.

3 Mechanical engineer, Eastern Division, Dominion Bridge Company Limited, Montreal.

No appreciable economy was apparent between these designs. What finally decided the issue was that it became clear that, on a quantity of 48, a greater saving would be realized by riveting than by welding.

In Table III of the speaker's paper, it will be noticed that the Canadian head gates and the Iroquois control gates have self-lubricating bronze bushed wheels, whereas the wheels for the balance of the gates are equipped with anti-friction roller bearings.

We have used graphite insert bronze bushed gate rollers with nickel chrome steel pins almost exclusively for the past forty years, with negligible replacements. Recently, a gate was pulled out of its slot which had been literally submerged 27 years and the bearing and pin were in good working order. Canadian utilities practically always specify self-lubricating bushings.

Roller bearings have been used extensively for gate work in other quarters but we feel there is an awkward sealing problem to keep the water out of the bearing grease; if water were to get in, it would be ruinous to the roller bearing. This especially concerns us in the case of head gates which are left submerged in water.

Exponents of anti-friction bearings always point out the great saving that can be realized in the capacity of the hoist because of the low coefficient of friction of roller bearings. There is not as much to be gained here as would appear at first thought. Take, for example, the hoists for the Cornwall headgates. Considering combined weight of gate and friction, the hoist capacity could be reduced about 50 per cent, but taking into account the hydraulic downpull, the capacity may only be reduced about 25 per cent.

Even though we have built gates with roller bearings because of the reasons just mentioned, and also the paramount fact that a roller bearing assembly is far more expensive than a plain bearing assembly, we have a preference for plain bearings.

It was mentioned that the holding brake on the head gate hoist is normally energized through a rectifier. This is a recent development and was made possible through the introduction of low cost selenium rectifiers. Formerly, a solenoid brake with a combination a.c.-d.c. coil was used when it was desirable to lower on a battery circuit.

Table IV of the speaker's paper gives much data regarding the gantries, cranes and hoists. Whereas the motors are all normal machines designed for crane duty, there seems to be some variety in the control equipment for these machines. The selection of the different types of control was dictated by various factors.

Four different types of control for the hoists will be found.

(1) Squirrel cage motors with across-the-line starters and fan lowering brakes. This type of motor is used on the head gate hoists because the rotor can readily be made to withstand the 2½ times synchronous speed when overhauled for fast, fan-controlled lowering.

(2) Wound rotor motors with manual drum controllers and mechanical load lowering brakes. Manual drum controllers are the most economical. They are available up to 100 h.p. size. The mechanical load lowering brake, in conjunction with the motor, governs the equivalent lowering speed to a little under synchronous speed.

(3) Wound rotor motors with magnetic control and mechanical load lowering brakes. This type of control gives superior performance but is more expensive. It must be used for motor sizes above 100 h.p. The mechanical load lowering brake functions as previously described.

(4) Direct-current variable voltage motors with magnetic control and regenerative braking for lowering. With this type of control, the light hook speeds can be made about twice the full load speed, thus considerably reducing the operating cycle time. This is particularly advantageous on large capacity hoists. Better inching is procurable when required for accurately placing heavy loads. There is also an inherent load limiting characteristic.

Practically the same reasoning applies to the trolley and bridge travel motions, but load lowering brakes are naturally omitted because there is no overhauling torque. Semi-magnetic or full magnetic control is required for adequate control of four motors at one time when mounted on each of four trucks of a gantry crane.

Conclusion

Our speakers have mentioned how, architecturally, the Canadian and American powerhouses are identical. It is phenomenal how different the designs of some of the components of the combined powerhouse really are. In my opinion, the main reasons for these differences are:

(1) The vast background of operating experience of the Canadian utility which guided them in designing their own equipment.

(2) The concept of the Canadian utility that 50 per cent of the value of the handling facilities provided at a power dam is for purposes of installation.

The Authors

The authors would like to thank the contributors to the discussion for their constructive and interesting comments. Two points are raised that are interesting to note as they highlight two fundamental design issues.

Mr. Rich's comments on the turbines are interesting and the dimensions fixed to enable the general powerhouse substructure design to proceed certainly permitted a wide variance of proposals from the turbine manufacturers.

Mr. Holt's comments on the gate bearings are, from our point of view, very interesting as they are backed by Dominion Bridge's many years of gate design and manufacture. With reference to the fabricating method used to make the various gates it should be noted that the ice sluice drum gates to be installed at the powerhouse are of partially welded and partially rivetted design. They too will be equipped with self-lubricating graphite insert bearings.

The most interesting comment of Mr. Holt's concerns the Commission's tendency to design for installation and to place a high value on the handling equipment during the construction period. This undoubtedly arises from the fact that the majority of the Commission's powerhouses have been built by their own construction division. The fact that the design staff work closely with the construction forces and the operating staff is bound to have an effect on the design and selection of equipment to be installed at a development.

In conclusion the authors would like to take the opportunity of thanking all those who helped in compiling the data, checking the wealth of detail, etc. which, by necessity, must be included in a paper of this type.

THE USE OF HYDRAULIC MODELS IN THE ST. LAWRENCE SEAWAY PLANNING AND DESIGN

D. M. McIntyre, M.E.I.C., *St. Lawrence Seaway Authority, Montreal*

The Engineering Journal, 1956, September, p. 1154

W. J. Weymark, M.E.I.C.[1]

The comments in this paper by Mr. McIntyre are the first presentation before an engineering body of the details of procedure used in planning and design of the St. Lawrence Seaway and Power Project. It is to be hoped that further details pertaining to specific features will be made available in the near future, so that the engineering profession will gain the benefit from the advancements achieved in engineering this tremendous project.

As noted in Mr. McIntyre's paper, models were indispensable in the design of the various features of the St. Lawrence Seaway-Power Project, and selection was not on the basis of relative economic advantage or as an adjunct to other engineering techniques but rather in several instances, as the sole basis on which design of hydraulic features of the various structures was based. This stems from the diverse interests, international and national, reflected in the basic reference document, the Order of Approval of the International Joint Commission, and the number of controlling boards and committees established to supervise and advise on the development and operation of the project. Consequently, models presented the only method by which presentation and solution of the various problems could be made. Because of the complex nature of the various problems that were investigated, it is note-worthy that tremendous advances were made in the use of models in carrying out engineering studies related to large scale hydraulic projects.

Although Mr. McIntyre did not treat with the basic considerations or procedures used in design and operation of hydraulic models, it is considered that this was not essential as basic relationships of similitude on which models are based and studies conducted are well established. However, as is well recognized in conduct of such investigations, achievement of complete similitude, geometric, kinematic and dynamic, is impractical, nor is it mandatory since pertinent transference ratios may be applied to relate prototype behaviour. This procedure was adopted by the various groups conducting model tests.

Perhaps some comments should be requested on techniques developed in the design of some of the models, especially those by the Ontario Hydro and the National Research Council for the river channel models; also, their achievements made in developing special instrumentations using recent electronic applications should be presented for record purposes.

The river channel models, those constructed and operated by the Ontario Hydro and National Research Council, and the one under construction by the Seaway Authority in Montreal, are all of the fixed-bed distorted-scale type. Although the primary problems studied related to determinations of flow patterns, velocities and current direction; governing water surface elevations and depths are features which are usually considered not amenable to distorted model investigation. This limitation was overcome, however, within acceptable tolerances through the use of appropriate modifications.

The following are some of the outstanding problems which were analyzed: *(a)* determination of controlling water surface elevations in the various reaches of the river related to the proposed method of regulation of Lake Ontario; *(b)* the relating dimensions of hydraulic and navigation channels in compliance with the requirements of the governing criteria set out in the International Joint Commission Order of Approval; *(c)* preservation of existing flow splits under improved conditions in various reaches of the river; and *(d)* the determination of the sequence of construction for the various structures in line with the requirements of the Order of Approval which specified that, during the construction period, (i) Lake Ontario levels were not to be adversely affected, (ii) continuance of 14 ft. navigation would be assured, and (iii) downstream interests were not to be affected.

It is to be appreciated that all the studies have not been completed at this date in regard to river channel improvements, or for river control during construction and operation. It is noteworthy to review, also, the purpose of the intensive tests to be conducted in the Seaway Authority model at present being constructed in Ville LaSalle which involve Seaway and power problems in the vicinity of Montreal.

Perhaps special mention should be made of some of the pre-project studies and work which played an important part in the design of the models and related investigations. New techniques were used by the Ontario Hydro in obtaining field data and determining backwater characteristics which were used in the fabrication and verification of the various models, and comment should be made on the availability of long-term records of flows and levels in the various parts of the St. Lawrence River and Lake Ontario collected by various Canadian and U.S. governmental bodies. All of these contributed to the successful investigation of the various hydraulic problems in the models.

Although Mr. McIntyre limited his comments pertaining to the structural models used in developing hydraulic design of the Seaway Authority structures, it should be noted that many types of models were used in investigating hydraulic structures of the project. These included a glass flume for spillway and conduits, and natural scale models for the locks, dams, energy dissipators, gates, powerhouse units, and ice sluice investigations. The studies for the power entities were conducted by the Ontario Hydro; those for the Seaway Authority were undertaken by the National Research Council, McGill University, and the Ontario Hydro. The SLDC had tests conducted at St. Anthony's Falls, Vicksburg, and Ontario Hydro.

In specific reference to the test conducted by the National Research Council for the Seaway Authority, relating to the design of lock structures, it is apparent that several noticeable advances were made. These resulted in improved performance characteristics relative to previous lock designs and effected economies in the cost of construction.

As Mr. McIntyre has pointed out, the critical considerations, from a hydraulic standpoint, in the design of lock structures are those relating to: *(a)* the design of ports and conduits, *(b)* provision of uniform flow conditions in the lock chamber and, *(c)* development of adequate gates and

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

INTERNATIONAL ATOMIC CO-OPERATION

Engineering, 1956, v. 181, n. 4707, May 25

If the most profitable use of atomic energy is to be made throughout the world, it will be necessary to devise effective means of distributing and exchanging knowledge and nuclear materials. This pressing need for co-operation has spawned a large number of different plans, some of which seem to overlap, and at least two international organizations carry out or co-ordinate research. Perhaps the most important consideration in connection with these schemes concerns the supply of nuclear fuels, since these are the *sine qua non* of any atomic power programme and must precede any decision by a private company to undertake nuclear power station construction.

Agencies for the supply and exchange of nuclear materials have been planned by three principal bodies: the Organisation for European Economic Co-operation; the Messina or "Little Europe" group, comprising the members of the European Iron and Steel Community (France, Belgium, the Netherlands, Luxembourg, Italy, and Germany) whose agency is to be known as Euratom; and the United Nations, which at the end of April published a draft statute for an international atomic agency. The statute, which has been approved by a twelve-nation committee including Britain, the United States and the Soviet Union, will come before a general conference of the United Nations and its specialized agencies in September.

Shortly after the publication of this statute an announcement was made concerning the Brussels plan for a collective European atomic energy commission. The plan, which provides for the establishment of the agency Euratom, may be the basis of a treaty and is expected to form part of a more comprehensive "federal" scheme of economic co-operation, which already covers coal and steel.

The commission is to set up a research centre and a college, and is likely to build a uranium 235 separation plant as one of its initial projects. The agency will have first claim on nuclear fuels produced by member countries (the Belgian Congo has considerable ore deposits) and these will remain under its control whether hired or purchased.

The diversity of plans for international co-operation in the field of atomic energy seems at first sight confusing, but there is as yet no reason to prevent all schemes from proceeding simultaneously. Either Euratom or the O.E.E.C. proposals, or both, could fit into the United Nations project, much as individual countries would take part, though Euratom could probably more easily be accommodated in this way.

It can be regarded as almost certain that, in the case of nuclear energy, the pressure of the "have-not" nations — who vastly outnumber the "haves" — will ensure that some effective system of distributing atomic knowledge, equipment and materials will finally emerge.

ULTRASONIC MACHINING OF BRITTLE MATERIALS

Electronics, 1956, v. 29, n. 1, January, p. 132.

Slicing or cutting germanium, silicon, quartz, ferrites, glass-bonded mica and other materials at high speed by impact grinding results in greater precision and makes possible a great variety of shapes.

Impact grinding offers a number of advantages, the most important of which are:

(a) The cutting tools are rugged and usually inexpensive.

(b) Attaching tools to the machine is simple. The setup is readily changed from one tool to another, providing great versatility.

(c) The operating principle ensures sharp edges on every cut, as well as perfect duplication of the tool shape in the workpiece.

(d) Since tool shape is duplicated in the workpiece, there are no restrictions on the shape to be cut. Tools can be round, square, triangular or any other shape.

(e) Because lapping grades of abrasive are used to do the cutting, a fine surface finish is produced which requires a minimum of subsequent surface lapping.

Designers of magnetic cores for high-frequency transformers, electronic computer switches and microwave transmitting devices can now explore the advantages offered by the electrical and magnetic properties of ferrite crystals.

By means of impact grinding, this material can readily be shaped in one piece with sharp corners and precisely oriented sides. Moreover, the core is not subjected to stress during machining.

Glass-bonded mica, like other hard abrasive materials with a strong grain structure, is difficult to machine by conventional methods. By the use of impact grinding this material is readily machined with no danger of hidden damage.

The transducer design problem is the central one in impact grinding. Cutting rate varies directly with frequency and amplitude of vibration, and so it is desirable to have these as high as possible.

Further development of ultrasonic impact grinding equipment will be directed toward the achievement of higher machining speeds and larger areas.

Higher speeds will require higher power (more amplitude) which will require stronger materials. Larger areas will also require higher power, but may also enforce the use of lower frequencies. Sonic impact grinders operating at high power levels in soundproofed rooms may prove both necessary and entirely practical.

Much investigational work remains to be done on the actual mechanism of cutting, reduction of the tool wear by variations in tool design, and methods of supplying abrasive.

GAS TURBINE TEST BUILDING AND PROPANE FUEL PLANT

One of the few gas turbine test shops in which six turbines can be tested simultaneously on various types of fuel has been built at Lincoln, England, by Ruston and Hornsby, Ltd., who also produce industrial gas turbines.

Particular attention has been paid to the use of cheaper lower-grade fuels, such as natural gas, sewage gas, blast furnace gas, producer gas, gas oil, residual fuel, creosote pitch, carburetted water gas tar, and pulverized peat. Long-term development is being undertaken on the more promising of these fuels. Work is also being done to develop turbines which can burn two fuels, e.g., gas oil and natural gas, simultaneously in varying proportions.

Coal tar fuels are of particular interest in the United Kingdom, and for these a refractory-lined combustion chamber has been developed.

The test shop was largely designed around the company's standard 1300 b.h.p. turbine, but two of the six test beds can handle much larger units. Beds are also available for heat-exchanger sets, arranged so that most site conditions can be reproduced on test.

A large area of the shop is lined with acoustic fire-resistant tile which lessens reverberations in the working area. Heating is by high-pressure hot water radiant panels, and the heat from the turbines under test can be fully utilized. All services are placed below ground level.

Filtered atmospheric air is used for the inlets. Twin exhaust ducts lead from each turbine to a permanent outside stack, which is made of mild steel. These stacks are used to test various external finishes, particularly at the high temperatures obtained when no heat exchanger is fitted.

In view of the importance of high calorific value gaseous fuels, such as natural gas which is abundantly available in many parts of the world, a plant has been installed to provide a mixture of propane and air to simulate the various gases which may be used at site.

Bottled methane was previously used to some extent, but was expensive and not readily available. To meet the need, liquid propane (25 tons) is stored in two pressure vessels. The propane is supplied by road tankers fitted with transfer pumps.

A gas mixture can be supplied to the turbine room at heating values between 600 and 1200 Btu./cu. ft. Liquid propane flows from a storage vessel to a steam-heated evaporator, and vapour delivery is controlled at a constant pressure of 150 p.s.i.g. The mixing station is a pneumatically operated automatic ratio control system with a rapid response to load variations. Protection is afforded against the propane-air mixtures exceeding explosive limits, and a high velocity exhaust system prevents accumulation of propane in service trenches.

This industrial gas turbine installation at Cortemaggiore, N. Italy, operates on natural gas. The set has run for over 6000 hours; continuously for 3500 hours.

THE MANAGER'S SPAN OF CONTROL

Harvard Business Rev., 1956, May-June.

The trend in American business towards narrowing the "distance" between the top executive and the members of the organization he supervises has put too much of an overload on the manager, with damaging results to efficiency and morale, says the author, Lyndall F. Urwick. A superior's authority should extend over no more than six subordinates whose work interlocks, he believes. His challenging advocacy of narrowing the span of control *under today's conditions* should be of interest to every reader — particularly since he is the man who first applied the idea to business some 18 years ago.

THE MAHI BRIDGE IN INDIA

The Mahi Bridge near Vasad (in Baroda, India) shown in the accompanying illustration is now nearing completion. The prestressed concrete construction consists of 16 spans each of 110 ft., giving a total length of 1760 ft. Each span consists of two 110 ft. span pre-cast beams 9 ft. deep, with a poured in place reinforced concrete deck slab 9 in. thick.

To avoid the need of falsework because of the height above the river, the prestressed beams were transported and placed by a pair of specially made erection girders 182 ft. long which travelled out by cantilevering to the next pier and thereafter supported the pair of prestressed beams to be rolled out on tracks on them. The process was then repeated, as shown in the diagram. The photograph was taken just when the erection girders had completed their work and they may just be discerned in the last span.

The prestressing steel in each beam consisted of 15 No. 1⅛ in. dia. Macalloy high tensile bars (known as Stressteel bars in North America) supplied by McCalls Macalloy Ltd., of Sheffield, England, the total length of high tensile bars being approximately five miles. Hindustan Construction Company of Bombay were responsible for the construction. Mr. M. V. Joglekak, M.I.C.E., chief engineer, and Mr. Donovan Lee, M.I.C.E., consulting engineer, London, were responsible for the prestressed concrete design and the design of the erection girders.

WHAT A RESEARCHER DREAMS ABOUT

Railway Age, 1956, v. 140, n. 11, March 12, p. 46.

Instead of reviewing past and present research, the writer does a little dreaming about what lies ahead in track and structures research.

Rail is the primary component in our rolling way. It receives the wheel load and transmits it to the track or to the structure. No substantial change in the cross-section design of the rail is foreseen. It is functional for the purpose it serves. The present 115, 132, and 140-lb. RE designs are ideally proportioned for use in jointed track.

Potential improvements in rail metallurgy, however, are intriguing. Wheel bearing pressures and the internal shearing stresses and direct stresses resulting therefrom are a problem from the standpoint of the development of fatigue failures, of which shelling and detailed fractures from shelling are typical examples.

We know too little about the fatigue strength of steel. The writer believes that physicists will develop steel having much greater fatigue strength than that of which the rail is now composed.

The present batch method of making steel heats, ingots and rails is cumbersome. Probably not too far ahead is a continuous melting furnace with subsequent casting and rolling of the rail in a continuous ribbon.

Immediately ahead we must explore the apparent advantages in high-silicon rail. We must determine its receptivity to welding, either for joining rails into continuous lengths or building up battered rail ends, and to heat treatment of the rail ends.

Plastic Crossties

The presently used treated wood crosstie is doing a wonderful job. Nevertheless, it has certain disadvantages.

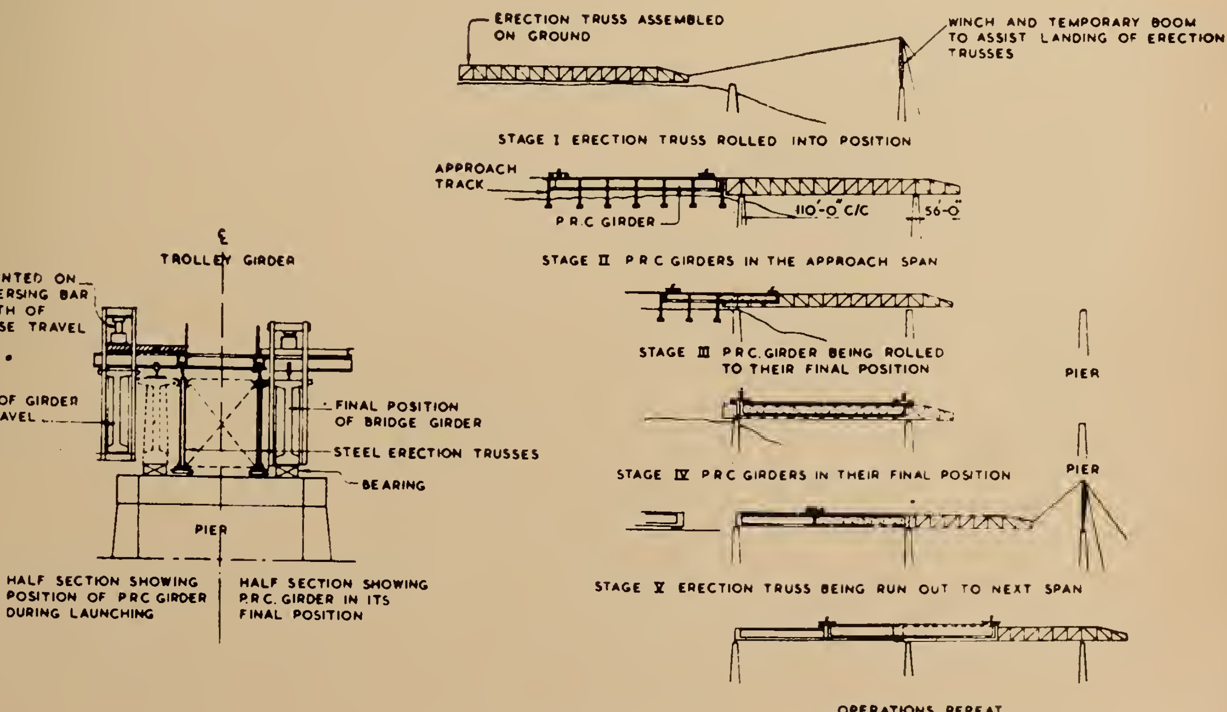
What other materials can we consider for ties, materials over which we can exert control during the manufacturing process? Neither steel nor concrete possess the inherent qualities, which include compressive and flexural strength; resistance to oil, water, various fungi, and brine; sound absorbing and electrical insulation properties; frictional resistance with the ballast; light weight and economy in first cost.

Plastics are now available that have all of these requisites except moderate cost. The dream includes a research chemist developing a competitively-priced plastic, suitable for a crosstie, from some of our more abundant materials.

The design might correspond to the trough section of the steel tie used abroad, and the provision of a

The Mahi Bridge, India, nearing completion.

Diagrammatic representation of the construction of the Mahi Bridge.



canted rail seat and restraining shoulders on the tie itself, with perhaps clamps similar to the GEO construction for securing the rail to the tie, thus dispensing with the need for tie plates and anchorage.

Different Kind of Ballast

Ballast is a component of track structure upon which far too little research has been done, probably because one of the prime requisites has been the availability of a satisfactory material. Is the present ballast, utilizing loose pieces and particles of a durable material, ideal for the purpose?

Recognizing the desirability of a dry subgrade it does not seem logical to provide for the passage of water to the subgrade. This water should be interested on the surface of the ballast section and drained away before reaching the subgrade. A further advantage would be to prevent other substances from filling the voids in the ballast, which results in a pocket forming around each tie, producing erosion and a sloppy track appearance.

Therefore, the ballast section should be a cohesive mass and ties should not be tamped, disturbing the already compacted tie bed. Instead the void between the compacted tie bed and the underside of the tie, formed bv elevating the rail, should be filled by pumping.

No Desire for a Nightmare

The dream does not include an entirely new design of the track structure, since it should not become a nightmare, as it might if a different design were envisioned.

Much has been accomplished in research into roadbed stabilization, but we have only scratched the surface of what can and will be done.

One might stabilize the present heterogeneous supporting structures by mechanical compaction, chemical treatment, and electromosis, ultimately to attain a stable roadbed, with little trouble from slides, subsidence, heaves, and slippage.

Control of vegetation on right of way and roadbed is expensive maintenance. Much progress has been made in the use of chemicals and oils for this control.

All-welded Bridges

Most railroad bridge structures now have a long life and we should have to look many years ahead for radical and extensive changes in structures. Concrete is resistant to corrosion and eliminates maintenance painting. It lends itself to attractive designs and, with prestressed or post-stressed reinforcement, can much more effectively resist flexure than ordinary reinforced concrete. It seems certain in the dream ahead that a large portion of railway structures will be of concrete.

Probably far more use will be made of all-welded steel structures than at present. Labour cost for welding is now the principal deterrent. With increased knowledge of welding techniques and weld strength; and use of automatic welding procedures, all-welded construction of new bridges may be the general practice.

Corrosion and painting costs are two important disadvantages of steel bridges. Corrosion resistant steels are at present too expensive for bridge construction, but one may envision the economical production of structural elements with outer surfaces of corrosion-resistant alloys.

ANALOG COMPUTERS FOR THE ENGINEER

Electronics, 1956, v. 29, n. 6, June

Development of new aircraft, guided missiles and automatic control systems for industry further nourishes a $10 million business in the U.S. Manufacturers offer electronic computers of varying size and complexity, ranging from desk-top to room size.

There are about 400 analog computers presently in use. The industry derives much of its present impetus from defence production. Computers are also used by petroleum companies, atomic energy plants and laboratories and other research and development activities. Vast potential applications lie in the field of industrial process control, automobile design and other metal trades products, even in automatic highway traffic control. Sales estimate for 1956 approaches $8 million.

Though computers are available at under $1,000, a commonly used rule of thumb for pricing is $1,000 an amplifier, including associated equipment. They can cost $250,000 and up, depending on research and development costs. The average computer uses 36 to 48 amplifiers, while one with 72 amplifiers or more may be considered large. One class of computer is the network analyser used by electric utilities to solve problems in the distribution of electric power. A relatively few companies manufacture general purpose problem-solving computers. A tabulation accompanying the article lists manufacturers, models, description of computer, price, accuracy, power used, size and other characteristics.

LIGHT GAS TURBINE

Engineering, 1956, v. 181 n. 4707, May 25

Aero-engine and large-scale industrial applications of the gas turbine have tended to overshadow its development as a light-weight prime mover, so that its more modest use in fire pumps, auxiliary generators and similar equipment is often overlooked. However, with the advent of the gas-turbine car the position may be changed. Recognizing the need for a light simple engine, Mr. D. D. Budworth, of David Budworth Limited, Harwich, Essex, has developed a small 45 to 60 h.p. gas turbine, approximately 16 ins. in overall length and weighing only 45 lbs., without reduction gearing, for applications ranging from pumping to the propulsion of high-speed boats.

Since the prototype was started in 1950 gradual refinements in all the component parts have been made, but it was not until last year that the full output of 60 h.p. was achieved. As with all gas turbines the engine is now capable of a very great temporary increase in power over that at which it is rated.

The turbine unit consists of an annular combustion chamber surrounding a radial compressor and turbine mounted back-to-back on the same shaft.

A low-pressure fuel system is used, such that the fuel pressure is only a few lb. per sq. in. higher than that of the combustion chamber.

Any distillate fuel may be used and the consumption of gas oil is between 10 and 12 gallons per hour.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

At the end of July 1956, with less than half the construction period elapsed and with all but a very few contracts awarded by all four 'Authorities' and work under way, seaway officials give assurance that construction is 'up to schedule'. Though progress on some contracts is ahead of schedule, on others it has not been up to expectations. Some of the work awarded late in 1955 and in 1956 has not yet reached the stage where progress begins to pick up speed and catch up on the inevitable delays in getting started.

The construction industry bore the brunt of steel shortages due to the steel strike, particularly in plate and structurals. But with much of the permanent steel equipment and material on order since last year, excluding steel for bridges, the possible effect of the strike on seaway work should be limited. Structural steel for the new bridges at Montreal and Cornwall, and for modifying four existing bridges at Montreal, might be retarded as much of it must be imported.

It is probably still too early to assess how much the overall cost will exceed official estimates. Many early contracts were underbid due to severe competition and the desire of many contractors to cash in on the publicity value of being associated with the project. This resulted in losses to successful bidders and a few defaults. On the more recent awards, due to a greater volume of work offering and thus less competition, bids were fewer and prices more realistic.

However, the continuing upward trend of the construction cost index inevitably lessens the chances that total cost will come within estimates made in 1949 or even under those made two years ago.

Employment by all four authorities as of the end of June exceeded 13,000 men. This total will grow considerably during the peak summer months.

Progress By Ontario Hydro

Throughout July good weather favoured construction work in all sections of the project. The total force employed by Ontario Hydro and the various contractors totalled approximately 4,100 persons.

Concrete was placed around the draught tube forms for Unit No. 1 and much progress was made on the power-house foundations during July, Rock excavation was completed for 4 units and well ahead for the remaining 12 units. Placement of concrete by the end of the month in the U-abutment, wing wall, ice sluices, and for the bases of five generating units amounted to 177,000 cubic yards. Concrete in place for the entire project exceeded 235,000 cubic yards, and excavation passed 17 million cubic yards.

Assembly of the second wooden draught tube form was completed for unit No. 2 in July. Preparations were being rushed for placing concrete around this form. The two forms will be used successively for each of Ontario Hydro's 16 generating units. Work in the U-abutment section of the power-house was completed during the month. All three gantry cranes operating there were moved into positions for placing concrete for the power units.

Aided by favourable weather, the dike contractor made outstanding progress in placing material on sections 2 and 3 of Cornwall dike. Some 14,000 cubic yards of material were being placed and compacted each day when weather conditions were suitable. About 24 per cent of the earth fill had been placed. This four mile dike, 40 ft. to 60 ft. high will carry part of the proposed scenic highway. Sixteen tractor-hauled, 16 and 20-yard scrapers are in use.

At the Cornwall dike closure structure, concrete placing was slightly in advance of schedule. The blocks of concrete for the wing walls were almost up to ground level from the excavation. A total of 52,000 cubic yards of concrete had been placed. Canal excavation was being continued at the west end for diversion of Cornwall canal. This canal must be ready for the 1957 navigation season. When traffic is diverted the dike will be built across the old canal. Though the closure structure is being built for 27-ft. draught, the diversion canal is being dug only 14 feet deep.

Good weather favoured work on the relocation of the double track of the CNR and the rebuilding of No. 2 highway between Cornwall and the Iroquois-Cardinal area. The railway contractors had laid a total of 32 miles of single track. Principal track laying extended from Cornwall west and from Cardinal east. In the Cardinal area, tracks had been ballasted. Grading was in progress in Sections A and B to Mile 26, near Morrisburg. In Section C, which continues to the Cardinal area, nearly all grading had been completed.

All clearing for No. 2 highway relocation had been completed. About 80 percent of the grading had been completed in the Moulinette west section and was ready for paving.

Channel improvement work was speeded up during the month in both Galop and Chimney Island sections. The contractor at Galop Island had removed an estimated 4,500,000 cubic yards of earth, and 165,000 cubic yards of rock.

First houses were moved into new town No. 2 during July. These homes were transported by a special float and placed on new concrete block foundations in the town site. At Iroquois, house moving operations were completed. Water mains and sewers for the new shopping center were almost completely laid. The steel work had been completed on the shopping center and the roof was over the entire center. Twelve houses were moved during the month in Morrisburg.

In all rehabilitation areas, work was accelerated. The laying of sewers, water mains, and construction of basements in new town No. 1, and new town No. 2 were well advanced. Progress was made on the sewage plants and the pumping stations of new towns No. 1 and No. 2.

Progress By NYSPA

July construction continued to forge ahead rapidly as working conditions remained good. Concrete in place by July 31 exceeded 560,000 cubic yards; excavation for all features had passed 21 million cubic yards and employment averaged 5,900 for the month. With July progress, the project as a whole was over 35 per cent complete.

Nine gate guides and sills were in place at Long Sault dam, piers were approaching their final height and the spillway bucket was over half completed. Two gantrys are set up in the dry ready to roll onto the deck of the dam. Concrete in the structure totalled 200,000 cubic yards. Excavation for cut "F" was 81 per cent complete and cofferdam "E" cableway was being erected. Cofferdam "DU" was being constructed as piles for cofferdam "A" were being removed.

Rock excavation for all 16 units was practically completed on the Barnhart power-house. Concrete placement at end of July totalled 166,000 cubic yards. Excavation for the switchyard and placement of embankment in the south forebay dike continued.

Iroquois dam was in its final stage 1 construction as gate sections were being placed and cofferdam cells were being removed. Embankment placing continued behind the east abutment and excavation progressed within the cofferdam area. Concrete placement totalled 88,000 cubic yards.

At Massena intake, 83,000 cubic yards of concrete had been placed to July 31. Construction of the dike was well underway and pipe laying for the Massena-Alcoa water supply was on schedule and two-thirds completed. Intake will open in 1957.

Excavation under the five channel improvement contracts was 30 per cent completed, as work at south channel of Galop Island progressed to 80 per cent completion. At Sparrowhawk Point, excavation was in progress on both Toussaints Island and on the mainland.

Bids were opened for clearing the reservoir areas between Point Three Points and Red Mills and specifications were being prepared for all remaining reservoir clearing, as well as the relocation of state highways 37 and 37B.

Approximately 65 per cent of the survey work was completed for the Barnhart - Plattsburgh transmission line. Studies are continuing by Alcoa for docking facilities. This marine terminal will permit ocean going vessels to deliver alumina from one of their Gulf Coast bauxite refineries and would also make possible water transportation to and from Massena and other Great Lakes ports.

Progress by SLSDC

At the Robinson Bay lock, now renamed the Eisenhower lock, earth excavation was complete for the lock structure but not for the approach channels and guide walls. Rock excavation was down to bed grade for the lock structure and concrete was being placed for foundations under lock walls.

Somewhat similar progress had been attained on the Grasse River lock. Here less trouble had been experienced with excavating the stiff marine clay found at the Eisenhower lock, but slides had occurred last spring, causing some delays.

On the Long Sault channel, besides the 15-yard coal stripping dragline known as 'The Gentleman', three additional 13½-yard machines were operating. Clearing was proceeding in readiness for building the 10 miles of canal dike.

Progress by SLSA

Though work on the Iroquois lock appeared to be somewhat behind schedule, most of the earth excavation was completed; the upstream approach channel was done, and a start had been made on pouring the lock approach walls. The bottom pours were made for six sections or about 300 feet of length and steel frame for moving wall forms was in place. Rock excavation was down to grade on the lock proper and was under way for the downstream gate.

Dredging contracts for the channel through Lake St. Francis were proceeding on schedule, while the 4-million-yard dredging contract with Marine Industries Ltd., in Lake St. Louis was actually ahead of schedule.

At the Beauharnois locks, Atlas-Winston Ltd., contractor for the first stage, had opened up about 1200 feet of the highway tunnel under the locks. The tough sandstone being encountered in digging the rock foundations made it necessary to change drill-bits every 12 hours. The excavation contract calls for completion in October this year. Work on the contracts for the locks themselves, awarded in June, had barely been started.

At the lower end of Lake St. Louis, Miron-Frères-Mannibec Construction had just started on two miles of overland channel containing three million yards, for completion by August 1958. On the adjoining contract downstream, Northern Construction-Stewart had recently started on their 3-mile, 7½-million-yard overland channel contract near the Mercier bridge. Below it Miron Frères Ltée. had completed their ¾-miles of overland channel and rock cushion last spring, eight months ahead of schedule.

Immediately downstream from the Miron contract is the Côte Ste. Catherine lock. Awarded to Canamont Construction-Canit Construction last year, its four million yards of excavation and the placing of concrete in the lock is due for completion in July 1958. Washouts delayed the work in early stages, but the contractor was catching up with the schedule by working three shifts. Pouring of concrete had been commenced on the lock floor and walls.

Below the Côte Ste. Catherine lock are some 10 miles of channel and dike due for completion by August 1958. Northern Construction Co. has 3.7 million yards to move on 3 miles of channel, while Walsh-Canadian Co. has 7 million yards over a four-mile length. Work was close to schedule on these two jobs, with excavation four miles apart at present and due to meet this fall.

On the St. Lambert lock, McNamara - Pigott - Peacock - McQuigge, in joint venture, had excavation completed for the lock itself and several foundation blocks poured for the lock walls. On the downstream approach channel, excavation was down some 70 feet below top of dike for about 2500 feet of length. The upstream approach channel was not yet started. Completion is called for by August 1958.

The same joint venture group has the contract for 1½ miles of channel between Victoria and Jacques Cartier bridges, to be completed by June 30, 1957. This work was 43 per cent done last fall and was still well up to schedule.

Below the Jacques Cartier bridge

Miron Frères Ltée have a mile of channel for completion by November 1957. Excavation was down to channel bed below the Jacques Cartier bridge, while upstream it was down to grade for part width over most of the distance between the bridges. Approximately half of the contract had been completed.

Downstream from the Jacques Cartier bridge, Marine Industries Co. Limited have a 3-million-yard dredging contract to complete by August 1958, on the last stretch of channel adjoining the St. Lawrence ship channel, with turning basin. Awarded last March, work on this contract was already well under way.

Atlas Construction Co. has the contract for widening, strengthening and raising piers 1 to 11 of the Jacques Cartier Bridge, to permit ramping the approaches to the new high level span over the navigation channel between piers 9 and 10. The existing bridge spans are being raised an inch at a time as the piers are enlarged and raised.

Gantry placing concrete for first section of the mile-long walls of Iroquois locks. Crane swings bucket of concrete over forms. Work is now well advanced.

SLSA Contract Awards

Contracts were awarded on June 29 for Beauharnois canal locks as follows: construction of upper lock and approaches, to United Waterways Constructors, Ltd., Montreal, for $14,440,000; construction of lower Beauharnois lock and approaches, to Canit Construction Co. Ltd., Montreal, for $11,199,925.

On June 8, a contract for some two miles of excavation for the seaway channel adjacent to Lake St. Louis, together with accompanying dike, was awarded to Miron et Frères Ltée, and Mannibec Construction Co., of Montreal. Bridge and Tank Co., Ltd. of Hamilton were awarded a contract for supply and erection of Côte Ste. Catherine lock bridge and Iroquois lock bridge, at a price of $810,221.

These contracts bring the value of some 45 contracts awarded by SLSA in various sections of the seaway to $122 million, involving excavation over a distance of some 21 miles. To complete the channel requires excavation of a total of some 48,400,000 cubic yards of earth and rock. Dredges will remove a total of some 12,700,000 yards of overburden, rock and gravel from Montreal harbour, Lakes St. Louis and St. Francis, from shoals and reaches along the way, and from the Welland ship channel.

A contract for permanent raising of the Jacques Cartier bridge and replacement of a 248-foot deck span by a new through truss span, was awarded on July 16, to Dominion Bridge Co. Ltd., at a price of $6,895,750, for completion by October 31, 1958. The only other bidder quoted a price of $8,123,295. Purpose of the modification of the bridge is to provide a minimum clearance for shipping of 120 feet above high water level in the channel, to be located between piers 9 and 10.

The work includes replacement of an existing 248-foot deck-truss by a new through-truss span, elevation of 14 spans at the southern end, and will follow the raising of existing piers to suit. It also involves raising the existing southern abutment, building a 65-foot abutment to the south, and a new steel deck girder span between the two.

The new through-truss bridge span over the channel will be erected on falsework beside the present span, and the operation of replacing the new for the old span will be accomplished with a total interruption of between four and six hours.

To maintain uninterrupted vehicular traffic during construction, two temporary Bailey bridges and platforms will be installed on each side of the bridge between span 3 and temporary roadway embankments to be built at the south end of the bridge. The contract calls for purchase of some 822 tons of structural steel, and about 2500 cubic yards of concrete for decks and abutments.

Other contracts awarded in July were: a pipeline to supply municipalities of Longueuil and Jacques Cartier, to Miron et Frères Ltée, for $535,200; deepening some four miles of the Welland ship canal to 27 feet, to McNamara Construction Co. Ltd. and Canadian Dredge and Dock Co. Ltd., of Toronto, in joint venture, for $11,623,200; 106 electrical cubicles for power supply at five seaway locks to Northern Electric Co. Ltd., at $313,165.

Cornwall Bridge

At a meeting of officials of the two seaway authorities concerned with navigation, held in Montreal on July 19, it was agreed that a high level highway bridge would be built over the south channel of the river at Cornwall. The division of cost, estimated at about $5 million, will be based in proportion to the length of the structure in each country. Can-

(*Continued on page 1180*)

Looking downstream at Galop Island south channel; excavation complete and area flooded. Cleaning up at downstream end is seen still in progress.

Stage I construction at Iroquois dam (left). A gantry crane may be seen being assembled in the foreground.

Looking north at stage I construction of Long Sault dam. First apron block is at right end of the structure. (below, l.)

Construction of concrete approach wall to Iroquois lock, most westerly of the new Seaway locks. Wall is 47 ft. high.

A Pictorial Record of the Seaway and Power Projects

Long Sault Dam construction seen through the legs of one of the permanent gantry cranes (right).

Wooden forms for draught tubes are seen in position beneath the first two generating units of the Canadian powerhouse (centre left). Forms will be re-used for total sixteen units.

Placing and compacting till is in progress behind the "U" abutment section of the powerhouse main dam (centre right).

Panoramic view of the powerhouse site shows excavation and concrete-placing operations in the dewatered area behind the downstream cofferdam which runs between Barnhart Island and the Canadian shore in the background (bottom picture).

Relocated in the foreground is the new Iroquois townsite. The old town is on the north shore of the river.

Large crater near centre of picture at left is excavation for the Cornwall diversion canal closure structure.

Dredging near Spencer Island, where channel improvements are being made to provide suitable depths and velocities. Capacity of these dredges is 6 cubic yards per lift.

Excavation for Beauharnois locks (bottom right). Here, tough sandstone has made excavation difficult.

St. Lawrence Seaway

(*Continued from Page 1175*)

ada will build the substructure, while the United States will build the superstructure.

The negotiations took place because of the necessity for removing the south span of the existing Roosevelt road-rail bridge to make headroom for the passage of vessels. The original U.S. plan for a two-purpose bridge at Polley's Gut on the western tip of Cornwall Island was part of a proposed six mile relocation for rail and road traffic which would also have crossed the Grasse River lock.

It was the only feasible alternative to a prohibitively expensive two-purpose high level bridge. But New York Central's preference for abandoning their line from Helena, N.Y., to Ottawa made a high level highway bridge much more attractive financially. The railway will apply to the Transport Board and to the Interstate Commerce Commission for Authority to abandon its line from the United States to Ottawa.

NYSPA Chairman Robert Moses immediately protested the decision in telegrams to the International Joint Commission and the Ontario Hydro, claiming the plan would delay the seaway opening and delivery of power by a full year.

Great Lakes Channel Dredging

The Corps of Engineers, U.S. Army, will soon be launching a huge channel deepening job on the Great Lakes that may tax the dredging industry's capacity to the utmost. The overall project, involving 44 million yards at an estimated cost of $150 million, was authorized by Congress last spring. It includes considerable dredging yet to be done on St. Mary's and Detroit Rivers under the Rivers and Harbors Act of 1946.

The three main areas for channel deepening are: St. Mary's River and Soo locks; St. Clair River and Lake St. Clair; and the Detroit River. The total job is divided as follows: 16 million yards of hydraulic dredging; 24 million yards to be removed by dipper or bucket dredges, and 4 million yards of ledge rock.

Though not primarily a part of the seaway project, basically the Great Lakes channel deepening is vitally connected with the seaway. The program will compete strongly with the seaway for dredging capacity and equipment. But speed will not be an important factor. Completion will probably be called for by 1962. Mostly medium size dredges will be used. In general, upbound channels will be deepened about six feet, downbound and two-way channels from two to four feet. Present plans are to take bids first for the Amherstburg channel on the Detroit River.

Moderate Tolls, More Investment Needed for full Benefits

"Improvement of the St. Lawrence will justify itself because Canada is growing rapidly, and because navigation is a by-product of the power developed. But there is no reason to think of it as an immediate source of huge profit." This is what J. L. McDougall, professor of economics, Queen's University, recently told the Canadian Manufacturers Association in addressing their 85th annual meeting held in Toronto in June.

There would be a development period in which the economy would gradually alter as it absorbs this new facility into its natural life. If unduly high tolls are set up in early years it may hinder rather than help in that process.

Great as our investment will be before the project is finished in 1958, he warned, we must be ready within reason to make further investments, in additional accommodation for grain in the lower St. Lawrence, and in whatever may be required to keep traffic moving through the Welland canal. Otherwise we shall fail to draw the full benefits possible from the money now being spent.

Grain transfer elevators at Canadian lower lake ports will become obsolete. To even the flow of grain through the lower St. Lawrence there must be additional construction at and below Montreal to take the place of this 20 million bushel capacity. Unless big 'lakers' can unload and turn around quickly there, costs will pyramid and we may be little better off with the new canals than we were with the old, he predicted.

The grain movement . . . has always been highly irregular. Allowance must be made for very high peaks, especially in the fall. Canada was only one country selling grain among a number and it must stand ready to make delivery quickly or sales would be lost, he observed.

A substantial movement of iron ore upbound would mean a better balancing of cargo movement, but it would create a problem too, the speaker pointed out. All movement expected through the new canals from Prescott easterly originates in or is destined to Lake Erie and above. Thus it must be superimposed upon traffic now moving through the Welland canal, which is now approaching saturation. We probably should be prepared for a substantial investment to increase its capacity if there is to be any real hope of significant additions to the volume to be handled through it.

Ecole Polytechnique

The Ecole Polytechnique, the faculty of applied science and engineering of the University of Montreal, will be in new quarters within 18 months, according to information received from Henri Gaudefroy, M.E.I.C., dean of the faculty.

New building for Ecole Polytechnique, Montreal.

With the help of a $6-million grant from the Quebec Government, announced in June 1954, the faculty is enabled to erect and establish itself in a new building on the campus of the University, leaving behind the now overcrowded classrooms and laboratories on St. Denis Street, which this French Canadian engineering school has been using since 1905.

The university anticipates an increase in enrolment in this faculty to 1500 students, within the next ten years, doubling the present enrolment. This progressive step will have a far reaching effect on the development of the engineering profession in the Province of Quebec. It is a step toward the solution of a very pressing problem: the great shortage of French speaking engineers in Canada, and toward meeting the demand of young men for technical and engineering education.

The problem of space at Ecole Polytechnique was noted many years ago. Preliminary investigations were made in 1948, at the time of the 75th anniversary of the school. It was realized then that the solution of this problem could only lie in the erection of a building on a new site. In 1952, preliminary studies were made of a building providing adequate facilities for the estimated large increase in enrolment. As a result, Premier Maurice Duplessis promised forthcoming help. The announcement made in June 1954 gave the green light. Final architectural details were worked out and during the winter of 1954-55, excavation was started.

The responsibility of the construction program was given to Gaston Gagnier, a Montreal architect. The engineering team was made up of Lalonde and Valois, consulting engineers in structures, Pierre-Paul Vinet, M.E.I.C., head of the Department of Mechanical Engineering for heating and ventilation, and Fernand Leblanc, M.E.I.C., head of the Electrical Engineering Laboratories, for electrical services and lighting. The contract was given to Quemont Construction of Quebec and Montreal owned by Arthur Laplante, M.E.I.C.

The new building more than doubles the space presently occupied on St. Denis street. It will have a floor space area of 460,000 sq. ft. and a cubage of six million cu. ft. It is being built on Mount Royal to the southeast of the University of Montreal and, as the illustration shows, contains a north wing, 460 feet in length, to be occupied by administration offices, the library, student quarters, and most of the classrooms. The south wing, running parallel some 200 feet to the south, will be 590 feet long, accommodating the heating plant, the departments of mechanical engineering, hydraulics, metallurgy, and part of the department and laboratories in chemistry and chemical engineering, physics and geology. Two transverse wings joining the main wings will provide space for the electrical engineering department, soil mechanics, public works and civil engineering, and will be also partly devoted to the laboratories of chemistry, physics and geology.

The accommodations provide additional space not only for classrooms, but will permit much expansion in the different laboratories both for teaching and research. It is a very sound policy in view of the rapid technical developments which will undoubtedly increase the importance of scientific experimentation in the solution of technical problems to come. The space being provided, the Board of Governors will see that it is properly used and will authorize the purchase of a large amount of new scientific apparatus.

From the architectural point of view the building will fit in with the present university buildings. The brick facing will be the same, but plans incorporate the latest improvements and allow a very modern architectural treatment.

Ecole Polytechnique was founded in 1873. During the past fifty years many extensions were built to the original building, and the school has developed at a very fast rate.

It is expected that the establishment on Mount Royal will mark a new era in the expansion and development, due to the added space and facilities, these coming at the time of spectacular technological advances in all fields of applied science.

Beaumont Power Development

The shores of the St. Maurice River a few miles above La Tuque, Que. are gradually taking on a different look as men and machines push ahead with work on The Shawinigan Water and Power Company's new 256,000 kilowatt hydro-electric development at Rapide Beaumont.

Construction crews of Shawinigan Engineering Company, a subsidiary of the power company, moved into the area this spring to start work on the modern, semi-outdoor type project which is scheduled to deliver power from the first of its six generating units late in 1958.

A modern construction camp on the river bank, with accommodation for some 800 men and containing a hospital, offices, workshops and dining hall, has been largely completed. Bulldozers were busy during the early summer clearing an access road to the site over which construction materials can be moved from a railway siding built near Fitzpatrick.

As well, to run the construction machinery a temporary 33,000-volt power line has been erected from La Tuque power-house 10 miles away.

At the construction site itself 540,000 cubic yards of rock are being excavated from the river bank to form a by-pass channel through which the waters of the St. Maurice will be diverted during construction of the dam and power-house. At present, about 30 per cent of the by-pass which will be over 1,000 feet long, 125 feet wide and an average of 80 feet deep, has been excavated.

Since the new development will raise the river level some 110 feet the CNR transcontinental main line which follows the west bank of the river at this point will be diverted to the eastern shore for a distance of some nine miles. A new bridge, just over three miles above Rapide Beaumont, will replace the present one located downriver from the site. Cofferdams for piers of the new bridge have just been completed and sinking of steel caissons is under way. A cable-way has been erected at the bridge site to transport material and erect steel. Grading of the new railway road bed on the east bank has just been started by Kennedy Construction Limited and Campbell Brothers and Thompson Limited, working in a joint venture as contractors for Shawinigan Engineering.

Cost of Shawinigan's Beaumont development, including a new 230,000 volt transmission line to Trois-Rivières, a little more than 100 miles to the south, is expected to reach $56,000,000.

Beaumont Power Development. White lines show approximate location of the by-pass channel through which the St. Maurice River will be diverted.

Canadian Pipeline Projects

Westcoast Transmission

Progress on the Westcoast Transmission pipeline, which had been retarded somewhat in the Fraser Valley and Sumas Prairie sections by rain and wet ground last spring, which cut progress to ½ mile daily, is attaining a two-mile-a-day clip under more normal conditions. Early in July the company had 372 miles of pipe on hand, or enough for 1956 construction. Final deliveries of pipe ordered from Britain will be completed by October first. Mannix, Ltd., has the contract for building the 45 miles of 18-in. and 20-in. line from Huntingdon to serve Vancouver area.

Across the International Boundry, the Pacific Northwest project had most of their pipe laid by July first. Steel pipe for this pipeline is being supplied by the Kaiser Steel Co.

Inland Natural Gas Co., Westcoast's distributors for interior British Columbia communities, had completed air surveys for the major portion of their $28 million distribution system. By mid-July, helicopters had covered the route from Osoyoos to Savona and 25 miles had been staked in the Kamloops area. Right-of-way purchase will be well advanced this year, with clearing underway this fall.

Kamloops rate payers had voted on a franchise for Inland, the city council had approved the agreement, and approval had been obtained from the Public Utilities Commission. Inland Gas Company officials were reported to be unconcerned over the steel strike, as pipe was ordered early this year. Financing will be completed in September. Ford, Bacon and Davis, Canada, are engineers and supervisors for the pipeline.

Trans Canada Pipelines

By mid July contracts had been awarded for four of the seven 'spreads', with Canadian Bechtel Ltd. and Majestic Contractors actually at work. Canadian Parkhill Stringing, Ltd., has the stringing contract for the entire section to Winnipeg. Despite heavy July rains in Saskatchewan, good progress was being made. By the end of July, 56 miles of right-of-way had been cleared and graded and 39 miles of pipe strung on spread 1 to the Saskatchewan border. On spread 2 through Saskatchewan, 75 miles of right-of-way had been cleared and graded and pipe strung for 17 miles. Construction offices had been opened at Swift Current, Regina and Brandon, and Canadian labour was being used as far as possible.

Trans Canada officials expect progress of one mile per day from each of the seven spreads when all are in action. Ninety days is believed to be sufficient for laying the pipe, and on this basis if there should be no hold-up in the deliveries of pipe by September first, the line could be completed by the December first deadline.

By late July, however, with steel shortages cutting drilling activity sharply, U.S. observers close to the steel situation believed effects from the steel strike might be felt more deeply after the strike settlement, with long delays on deliveries in the third quarter, and elimination of half of fourth quarter allocations.

Trans Canada would have had a bigger pipe stockpile on hand but for the shutdown early in May of the Tennessee Coal and Iron Co. platemill, which turns out plate for National Tube Mill at Orange, Texas, —one of the pipe suppliers. Early in August Trans-Canada officials, denying reports that no gas would reach Winnipeg and Brandon before the summer of 1957, stated they were "hopeful, but not assured", that the Prairie Section would be completed by the year-end deadline. It all depended on the steel situation.

With FPC approval of the import of Canadian gas by Tennessee Gas Transmission still many months away, possibly not before 1958, Trans Canada must arrange its financing on the strength of Canadian sales contracts only. Only by doing so will the company be able to repay its government loan and redeem its present stock from Government trustees before the April deadline provided for in the loan agreement. T. S. Atkinson, former general manager, Royal Bank of Canada, who was recently made a director of Trans Canada, now heads a finance committee working on a financing plan on the basis of Canadian markets.

Great Northern Gas Utilities has received certification to distribute gas in the Brandon area by the Public Utilities Board of Manitoba. This will be the largest distribution system built and serviced by Great Northern between Sault Ste. Marie and Fort St. John. To be built at a cost of $1½ million it will distribute gas at the lowest rates obtaining in the province. And Northern Ontario Natural Gas is planning a $32-million distribution system to serve its various markets in Northern Ontario.

Alberta Gathering System

Alberta Gas Trunkline Co. is obtaining a $3,690,000 loan at 4½ per cent from the Alberta Government to finance the building of its gathering system this year. $2½ million was advanced July 1, with the balance to come in August and September. Bailey Selburn Oil and Gas Co. Ltd., will drill five wells in the Bindloss field. 'Baysel' will supply 7 million cubic feet per day or a third of the first year's requirements to Winnipeg, from this field, in which it holds a 56½ per cent interest.

Welland Mill Soon In Operation

Welland Tubes Ltd., the company that will produce pipe in sizes up to 30 inches diameter for the Trans Canada and Crown Pipeline Companies, commenced erection of structural steel on their mill building at Welland, Ontario. The building, 684 feet long, 317 feet in width at one end and 260 feet wide at the other, covers about five acres. Rolling of the first 878 miles of 30- inch pipe will commence early in 1957.

Products Pipeline Projected

A products pipeline system, from Alberta to eastern Canada, is awaiting approval from the Board of Transport Commissioners and the Alberta Conservation Board. This project, to be integrated with the Trans Canada pipeline, would move large quantities of liquid hydrocarbons from the 'wet gas' fields of Alberta, which are removed from the gas before it enters the gas pipeline. Being a 'common carrier', this pipeline would also move refined gasoline from Edmonton refineries to Winnipeg.

Besides the natural gasoline recoverable from wet gas fields, such as Pincher Creek, to be delivered to refineries along the route, propane and butane would be carried in liquid state under pressure and sold as heating fuels to distributors and industry along the route.

Exclusive of its own gathering system in Alberta, the 8-in. and 6-in. pipeline itself will be 800 miles long from Alberta to Lakehead, and will be provided with underground and above ground storage facilities along the route. Terminating at the Lakehead cities of Fort William-Port Arthur, it calls for the addition of eight or more specially built pressurized Great Lakes tankers to move the fuel from Lakehead to eastern markets along the Canadian side of the Seaway.

Hydro Carbons Pipeline, Ltd., a subsidiary of Canadian Hydro Carbons, Ltd., and Superior Propane Ltd., is sponsor of the project. The former propose to build the line as far as Winnipeg. The estimated cost of the combined project, including the eight tankers, is estimated at from $55 to $60 millions.

Northern Research Laboratory

The northern research laboratory of the NRC Division of Building Research at Norman Wells, was opened on June 23.

The Advisory Council of NRC toured the northern part of Canada beginning at Uranium City on June 20 and returning to Edmonton on June 28. The purpose of the tour was to give the senior officials of NRC an opportunity to gain first-hand knowledge of northern problems. They inspected scientific and engineering developments in Uranium City, Yellowknife, Whitehorse and Fort Simpson.

The words "National Research Council" actually refer to the advisory Council of 21 members. Most of these men are eminent scientists from all across Canada; others represent labour and industry. They are responsible to a committee of seven cabinet ministers. The members of Council, serving without salary, select the NRC staff, award scholarships and grants in aid of research, and are responsible for the general direction of the laboratory work.

The National Research Council's laboratories are organized in nine divisions at Ottawa and two regional institutions, the Prairie Regional Laboratory at Saskatoon and the Atlantic Regional Laboratory at Halifax.

Design of Frobishers Yukon Project

The economic feasibility of the Frobisher-Ventures Ltd. metallurgical and power development in Northern British Columbia and the Yukon is now confirmed, according to a progress report recently issued by Frobisher Ltd., one of the participating companies. This $700-million project is expected to reach the design stage during the current year, while construction on the first stage, namely, development of 337,500 kw. of power on the South Nass River may be commenced by 1958.

The much larger Yukon - Taku scheme, announced some five years ago, to harness the Yukon's system of inland waterways and to develop close to four million horsepower, has been temporarily stalled due to international complications. Construction of this vast project is not likely to be undertaken until Canada and the United States forge out an agreement on an international power policy.

In spite of this delay however, the Frobisher company evidently feels confident of its eventual approval. Design for both the smaller Nass development and the larger Yukon-Taku project is being commenced this year on the dams and the turbines, with orders to be placed in 1957.

The Nass project can either be operated independenty or integrated with the big northern unit. Frobisher has already spent some $1 million on engineering studies to determine the dependable flows, pick out sites for the dams and for field surveys, test-pits and diamond drilling for foundations.

Would Take Seven Years to Complete

The Yukon-Taku is a power and ore-smelting and refining undertaking of startling proportions, using waters of the Yukon River as a source of cheap power. Originally conceived by Thayer Lindsley, past president of Frobisher Ltd., and Ventures Ltd., it would take some seven years to complete. $270 millions would finance the initial stage of development of 880,000 horsepower, together with the incidental smelters and refineries. Ultimately the scheme would utilize some 4 or 5 million horsepower.

In brief outline, a dam on the north flowing Yukon River some 800 miles north of Vancouver, as first proposed would divert part of its flow southward into a vast lake-studded watershed east of the coastal range of mountains, extending south-eastward more than 200 miles to a point about 80 miles south of the Yukon-British Columbia boundary line. Water stored at an elevation 2200 feet above sea level would drop through tunnels south of Atlin Lake to the generating plant. From here power would be transmitted 45 miles to Taku, where smelters and refineries would be built at tidewater on an ocean inlet from the Lynn canal a few miles east of the Alaska Panhandle border.

Patterned After Kitimat

Following the example set by the Aluminum Company of Canada at Kitimat, of bringing ores by ship to the site of cheap electric power, Lindsley planned metallurgical and chemical industries on a scale never before seen. Nickel and cobalt concentrates would be brought from Indonesia and New Caledonia. Iron ore would come from British Columbia and Alaska, other ores from South America, West Africa and Uganda. He visualized Taku as another Swansea, Wales, where Welsh coal has been the magnet for drawing world-wide ores to coal fired smelters there for over a century.

At the end of Taku Inlet salt water penetrates to within a short distance from the Canadian border. On Canadian soil at Tulsequah, B.C., Canadian surveyors found what appeared to be a promising industrial site, that could be made accessible to shipping by dredging out the Taku River for a distance of a little more than 10 miles. But engineers for American metal interests allied with the project preferred alternative sites further down the inlet on Alaska territory, partly with a view to avoiding collection of customs duties, by Canada on ores entering Canadian territory, but mainly to build up a profitable American industry in U.S. territory with access to cheap Canadian hydro-electric power.

First hearings were held in August 1955 at Atlin, B.C., a small interior British Columbia village with a population of around 500 residents, many of them Indians. British Columbia's Controller of Water Resources, A. M. Paget, presided. Residents conceded that the major development of raising the level of Atlin lake by 20 feet was in the best interests both of the province and the district. They were assured they would be adequately compensated for their properties and would be supplied with electric power. Company officials promised a

General Design of the St. Lawrence Seaway.

D. M. Ripley, JR.E.I.C.

(Continued from page 1142)

route are favourable for seaway construction. In the Montreal area, bedrock consists of Lorraine and Utica shales; at Caughnawaga these formaitons give way to Trenton limestone. Bedrock is Potsdam sandstone at Beauharnois and dolomitic limestone at Iroquois. The overlying soils are mostly glacial in origin and consist of a very dense till, which occurs in deposits up to 100 feet in depth, and scattered deposits of marine clay principally near Beauharnois. The sedimentary rocks are excellent for foundation for the lock structures and rock fill. The glacial till is a satisfactory material for dyke construction but presents many excavation problems due to its extreme density.

Concrete aggregates for the lock structure at Iroquois are being produced from a clean dolomitic limestone being quarried about three miles west of Iroquois. Three contracts were let recently for concrete aggregates for Beauharnois, Cote Ste. Catherine, and St. Lambert Locks. These aggregates will be produced from local sources. In general, all concrete aggregate must meet all A.S.T.M. and C.S.A. Specifications.

Construction Materials and Estimated Cost

The accompanying table of materials going into the project will furnish some idea of its magnitude.

The estimated cost of the Canadian and United States features is $320,000,000. This amount is made up of $215,000,000 for the works being constructed by the St. Lawrence Seaway Authority and $105,000,000 by the Saint Lawrence Seaway Development Corporation.

Table of Materials for Seaway Construction

		Canada	U.S.
Dry Excavation:	Rock	16,000,000 cu. yd.	60,000 cu. yd.
	Common	36,000,000 cu. yd.	25,000,000 cu. yd.
Wet excavation:	Rock	7,000,000 cu. yd.	270,000 cu. yd.
	Common	15,000,000 cu. yd.	4,600,000 cu. yd.
Fill and dyke construction		11,500,000 cu. yd.	10,100,000 cu. yd.
Concrete		2,000,000 cu. yd.	1,030,000 cu. yd.
Reinforcing steel		14,000 tons	2,500 tons
Sheet steel piling		6,000 tons	6,150 tons
Structural steel		27,000 tons	11,235 tons

Progress and Completion Date

Progress in the seaway construction to date has been satisfactory. Twenty-four general construction contracts aggregating $75 million have been awarded by the Seaway Authority for practically every type of construction that will be carried out. Major contracts yet to be awarded relate to the construction of the Beauharnois Locks, the Caughnawaga—Cote Ste. Catherine canal, dredging near Cornwall and steel structures such as bridges and lock gates.

The completed seaway is scheduled to be in use with the opening of navigation in 1959. The Iroquois Lock and the United States locks at Robinson Bay and Grass River as well as other seaway facilities upstream from Lake St. Francis will be ready to operate in time to permit generation of power at the Barnhart Island Powerhouses in July 1958.

Acknowledgment

As with all large-scale projects, The St. Lawrence Seaway represents the culmination of many years of patient and careful study, and we engineers of the Authority are not unmindful of the contribution of those engineers of the governmental and other agencies who fashioned the firm ground work for the project during those years of discussion and negotiation.

The Seaway Authority is most appreciative also of the co-operation and assistance extended to us by the engineers of our counterpart the Saint Lawrence Seawav Development Corporation and those of the Hydro-Electric Power Commission of Ontario and Hydro-Québec.

THE USE OF HYDRAULIC MODELS IN THE ST. LAWRENCE SEAWAY PLANNING AND DESIGN (Discussion)

(Continued from page 1168)

valves. On the basis of the model tests, the resultant design apparently gives a short balanced filling and emptying time; ports which permit relative steady flow conditions during filling and emptying, with a low order of hawser forces; and development of a satisfactory valve and gate design in which the effects of different site conditions were taken into consideration. If there is time, perhaps Mr. McIntyre or a representative of the National Research Council would comment further on the development of the port design used for the locks under construction relative to that used previously at Welland, and the differences between the intake and discharge systems adopted by SLDC and SLSA in the design of locks. Comment would also be appreciated on the design of the lock gates, contrasting SLDC selection with the ones developed by the Seaway Authority. In this regard, it might be considered that the only similar features between the referenced Welland lock built 25 years ago with the new structures, are the effective inside lock dimensions.

It seems fitting to close this discussion with reference to the close cooperation which has prevailed throughout conduct of the model tests between the various agencies; i.e., the work conducted by the Ontario Hydro, National Research Council, Vicksburg, and such institutional facilities at the Universities of Toronto, McGill, and Minnesota. The spirit of cooperation and free interchange of information, data and facilities is a hallmark in engineering. This has played an outstanding part in the development and construction of the St. Lawrence Seaway-Power Project.

A Chat With the Employer

The following article has been prepared by the Field Secretary L. F. Grant. He was prompted to write it by the many instances he encountered in his travels wherein young engineers had pleaded for a better professional recognition from their employers. (Ed.)

Everybody knows there is a shortage of engineers. One of the contributing reasons for it is that so many young engineers get out of engineering to become salesmen. What are the reasons for this? In some cases higher pay, but undoubtedly in some other cases a feeling of frustration because they are treated as super labourers rather than as professional men. Beginning with the young engineer whom you will be engaging shortly or have engaged, are you going to treat him as a professional person? Are you going to show him how your organization works, the place engineers fill in it, and more particularly, the place he himself will fill?

Are you going to let him think he is designing a gadget, or are you going to show him that he is helping to produce some great machine or structure that will benefit the user, and that the company's success and to some extent his future, depend upon how well this is done?

One company has a practice of having heads of departments address the young engineers, each afternoon during one week when they first join the company, telling them the place of his department in the organization of the company, and finally what the company is trying to do and some of its problems. Surely the young engineers in question are more likely to feel part of the team than they would without such talks.

In his obligation to the profession the young engineer has undertaken not to grudge his time, thought or care towards the perfection of what he is producing. He is ready for the inspiration that comes from feeling he is doing something worth while, and is not just a cog in the machine. If you wish him to continue his work as a professional man with a professional man's sense of obligation to his work and to his employer, you must treat him as such. If you compel him to punch a time clock, or treat him as a super labourer, you should not be surprised if he adopts a labour point of view.

This is not primarily a matter of salary, it is much more a matter of attitude. True enough the young man does not always appreciate this. Is it not your business to make him appreciate it so that his value to you may be increased? The attitude of these young men to your company a year, five years, or ten years hence will be very much influenced by how they are treated when they first enter your employment.

UPADI Meets Again

The Union of Pan-American Engineering Societies will hold its fourth meeting in Mexico City on October 7th to the 12th.

It is expected that the Institute will be represented by a strong delegation, which will include the president.

This Pan-American organization, known familiarly as UPADI, is made up of representatives of engineering organizations in eighteen different countries, sixteen of them being in South America, plus the United States and Canada.

The American member is the Engineers' Joint Council, whose membership is made up of the leading engineering societies in the United States, including the four founder societies.

Past president James A. Vance is a director of the organization, representing the Engineering Institute of Canada. He has attended previous meetings in Cuba, New Orleans and Brazil. He plans to attend the 1956 meeting.

Vern King of Woodstock also has attended the same three meetings that Mr. Vance has attended and it is hoped and expected that he too will be with this year's delegation. Dr. I. R. Tait of Montreal and C. M. Anson of Sydney also will be there to represent the Institute.

It is not part of UPADI's program at the moment to present technical papers at these conferences. The business is related to engineering problems of an international nature and the promotion of better international

Cover Picture

The cover picture is reproduced from an artist's impression in "The St. Lawrence Seaway, The Realization of a Mighty Dream", published by Distillers Corporation-Seagrams Limited.

Based on engineers' drawings and aerial photography, the picture indicates what the International Section will look like when work has been completed.

This area of a few hundred square miles will contain two giant storage dams, a huge power-house and two ship canals.

relations among the engineers, and the engineering organizations.

Following the meeting a detailed report will be made in the *Engineering Journal* covering the business transacted and other features as well.

IAESTE Report, 1956

With the summer now definitely "round the bend" it is possible, and timely, to take a look at the results of our fourth year of participation in IAESTE. Once more, and maybe for the last time, we should explain to readers that those letters stand for the International Association for the Exchange of Students for Technical Experience. The Institute is continuing to act as the Canadian agency for arranging these exchange visits.

Again, for the benefit of those who may not be familiar with IAESTE, it is an international association of nations for the purpose of arranging employment abroad for engineering students during the summer preceding their final year. This year 21 nations are participating, and it is expected that nearly 6000 students will have had jobs found for them in other countries.

By comparison the extent of the Canadian share in this plan appears to be small. However, judging by last year's figures, the volume of European students coming to Canada this season is satisfactory and shows a 100 percent increase. We have had 91 land on our shores from abroad, from 7 countries, and representing nearly all branches of engineering. Last year we were hosts to 46. This is good, and indicates a rate of growth that is about as rapid as the Institute and the Canadian Committee are presently equipped to handle. The jobs were made possible through the co-operation of 35 Canadian firms, or other employing organizations such as public works departments.

But it is supposed to be an exchange, and movement of our own students in the opposite direction continues to be disappointing. Only 9 have taken advantage of the plan this year, distributed as follows:—France 3, Sweden 2, Germany 2, Great Britain 1, and Switzerland 1. The snag, so far as the young Canadians are concerned, is still the matter of financing. They are unable to earn enough dollars, or their equivalent, to pay for their train and steamship travel without running into a deficit. Many a likely Canadian inquiry dies at this point in the preliminary conversations. We are glad to report, however, that some cure for this situation appears to be in sight, as a result of a visit from the IAESTE secretary for Great Britain, Mr. James Newby.

We had Mr. Newby with us, in the Montreal and Toronto area, from July 3-20, and his presence and enthusiasm for the plan were most encouraging. Those who watch "Tabloid" on television will remember seeing our visitor interviewed in Toronto, and heard him explain his mission so capably. Besides renewing his contacts here with industry and university life, he came over with the idea of starting to establish some Canadian industrial bursaries—for the definite purpose of assisting our own IAESTE students with their travelling expenses. Present indications are that Mr. Newby was successful, even beyond his own expectations, and funds available next year through this medium should make a big difference in boosting Canadian undergraduate participation.

It is safe to say now that IAESTE in Canada is established on a solid foundation, that it will continue to grow in size and importance, and that it should expect the support of every Institute member. Further information concerning the plan is readily available from E.I.C. headquarters, Montreal.

E.I.C. reception for James Newby and the IAESTE Committee. From left, Mr. Newby, R. L. Dunsmore, vice-president of the Institute; Henri Gaudefroy, chairman of the committee; R. E. Jamieson, dean of engineering, McGill University.

Thirty Years of Service

V. C. Blackett has just been re-elected to the position of secretary-treasurer of the Moncton Branch. With this appointment he completes thirty years of service to the branch in that capacity.

This is indeed an unusual record for a person serving in a voluntary office. The Moncton branch is indeed fortunate to have such steady service in this all-important office.

It is of real assistance to a branch, particularly a smaller one, when a member is willing to serve as secretary-treasurer for a substantial period of time. It takes a year or two for one to catch on to all the details of the office and frequently it is a loss when an experienced man retires to make way for a new man.

Another way of looking at it is that the work is a form of training for a young man and therefore it may be desirable that more persons be given an opportunity to profit thereby. However, in small branches it becomes difficult to find a continuing stream of persons who will serve. Under these circumstances Mr. Blackett's performance has been most valuable to his branch.

This period of service was brought to the attention of the Council of the Institute and it was agreed unanimously that a resolution of appreciation should go forward to him.

Appointment at Headquarters

A new appointment on the headquarters staff of the Institute is that of H. P. Gatin as assistant general secretary. He was among the applicants for the position, which was advertised in the February *Journal.*

Mr. Gatin has been administrative assistant to the general manager with

H. P. Gatin, M.E.I.C.

the Saskatchewan Power Commission, Regina, for the last three years.

Brought up in Manitoba, Mr. Gatin attended school in Western Manitoba, and with the beginning of World War II joined the Canadian Army, Active. He served with the R.C.A. and the R.C.E.M.E. until the end of hostilities. For the next five years he attended the University of Manitoba, working with the Manitoba Power Commission during the summer months. After graduation in 1950, in electrical engineering, he accepted an appointment with the Saskatchewan Power Corporation, first as special studies engineer, then as operating supervisor. Since becoming assistant to the general manager, Mr. Gatin has had considerable experience in management and administrative committee work within the organization and has also been active in community and welfare work around the province.

An asset in his new work, he is fluently bilingual.

Mr. Gatin's addition to the headquarters staff was caused primarily by the retirement of Colonel H. G. Thompson, which was announced in the August *Journal.*

The duties relinquished by 'Spike' Thompson have been taken over by E. C. Luke, who now becomes the senior assistant secretary.

The Kelvin Medal

Sir John Cockcroft, K.C.B., C.B.E., F.R.S., who has directed Britain's Atomic Energy Research Establishment for the Ministry of Supply since 1946, has been awarded the Kelvin Medal in recognition of his distinguished service to engineering.

His outstanding contributions have been toward the advancement of pure and applied physics, particularly in the field of nuclear physics, and in the solution of the engineering problems of the peaceful uses of atomic energy.

Tenth winner of this major award for scientists and engineers, Sir John was born in 1897, and was educated at the University of Manchester and Cambridge University.

He was Jacksonian Professor of natural philosophy at the University of Cambridge from 1939 to 1946. He is an honorary Fellow of St. John's College, Cambridge.

Through the war years, from 1941

Sir John Cockcroft

to 1944, he held the responsibilities of chief superintendent of the Air Defence Research and Development Establishment of Great Britain. Canadian scientists will recall that Sir John directed the Atomic Energy Division of the National Research Council of Canada from 1944 to 1946. In 1952 he was appointed chairman of the Defence Research Policy Committee, and scientific advisor to the Ministry of Defence.

Dominion Council Meets

The Dominion Council of Professional Engineers held its annual meeting at the Bessborough Hotel in Saskatoon on May 30 to June 1. Here is the group of distinguished engineers: Front row, L. O. Cass, L. R. Durkee, of NSPE, Seattle; N. Stewart, C. N. Murray, President-elect E. J. Durnin, President Georges Demers, W. O. Richmond, Past-President W. L. Sagar, C. T. Carson, G. A. Blackburn. Centre row, J. A. Merchant, M. C. Sutherland-Brown, W. G. McKay, W. R. Staples, R. Bing-Wo, A. E. McDonald, N. S. Bubbis, C. A. Knight, Pierre Bournival, E. D. Brown. Back row, J. H. Legere, J. L. McDougall, C. S. Landon, Bruce Williams, president of NCSBEE, E. Lee Cameron, R. A. Phillips, J. G. Dale, I. R. Tait of E.I.C.; J. B. Mawdsley, of C.I.M.M.; J. J. Hanna, T. M. Medland, J. M. Muir.

Among the honours conferred on Sir John, one of the most notable was the Nobel prize for physics (with E. T. S. Walton) in 1951. A foreign member of the Royal Swedish Academy, foreign honorary member of the American Academy of Arts and Sciences, and winner of the Hughes Medal of the Royal Society, he has also received the United States Medal of Freedom (Golden Palms) and the J. A. Ewing Medal of the Institution of Civil Engineers. In 1950 the French government conferred on him Chevalier de la Legion d'Honneur.

Sir John holds honorary D.Sc. degrees in a number of universities including Oxford, London, Sydney, Canberra, Manchester, Cambridge, and honorary LL.D. degrees at Toronto, Glasgow and Melbourne.

Chosen a Fellow of the Royal Society in 1935, he was in 1944 named Commander of the Order of the British Empire, and created a Knight in 1948. Three years ago he was invested as Knight Commander of the Bath.

Sir John is the author of various papers on nuclear physics in proceedings of the Royal Society, and on technical subjects for the journal of the Institution of Electrical Engineers.

The Kelvin Medal, founded in 1914, principally by British and American engineers of nineteen societies is an international memorial to commemorate the achievements and lifework of Lord Kelvin in those branches of science which are especially applicable to engineering.

The Kelvin Award Committee consists of the presidents of the following engineering institutions, after they have considered recommendations from similar bodies in all parts of the world; the Institutions of Civil, Mechanical, Electrical, and Mining Engineers, the Iron and Steel Institute, the Institution of Naval Architects, of Mining and Metallurgy and the Institution of Engineers and Shipbuilders in Scotland. The Engineering Institute of Canada is one of the organizations asked to make or support nominations for the Medal.

Lord Kelvin, mathematician, natural philosopher and engineer, the most famous British physicist of the nineteenth century, was born in Belfast in 1824, and was for over fifty years professor of natural philosophy at Glasgow University.

Although founded in 1914, the Kelvin award was not presented until 1920 due to difficulties encountered during World War I. Since its inception the medal has once been awarded to a Canadian. Dr. C. J. Mackenzie, chairman of the Atomic Energy Control Board, retired president of Atomic Energy of Canada Limited and former president of the National Research Council was the ninth scientist so honoured in 1953. Dr. W. C. Unwin, British physicist, was the first to receive it, in 1920. The name of Marconi, the inventor of radio was added to the list in 1932. Other award winners include Dr. Elihu Thomson, American physicist, in 1923; Sir Charles Parsons, British inventor of the steam turbine in 1926; Andre Blondal, French physicist, in 1929; Sir John A. Fleming, British engineer, in 1935; Sir J. J. Thompson, British physicist, in 1938. A further delay in the award of the Medal occurred during the Second World War, and for 1947 the Committee decided on an award to Air Commodore Sir Frank Whittle, Hon.M.E.I.C., inventor of the jet engine. In 1950 the committee's choice was Professor Theodore von Karman, aeronautical engineer at the California Institute of Technology.

Toronto Civil Engineers

The annual report was issued this summer for the Joint Area Committee for Toronto civil engineer members of the Engineering Institute, the American Society of Civil Engineers and the Institution of Civil Engineers.

The report, included in the Branch News section of this issue, shows four meetings at which subjects of civil engineering interest were treated. The attendance was good, averaging approximately 100, or 12½ per-cent of potential.

The response of the members in Toronto and the results of the committee's special negotiations to arrange cooperation among groups with common interests would tend to encourage similar activities where they may be necessary. The Institute commends this heightened concern with specialized technical advancement.

Contributions to Colonel By Memorial

At the first meeting of the new Council of the Institute on May 24, it was reported that twenty-one branches had made substantial contributions to meet the cost of erecting the fountain in Ottawa in memory of Colonel By of the Royal Engineers.

While it is known definitely that other branches are contemplating contributions when their programs begin in the fall, it is thought it would be of interest to members now to know of the branches that have already contributed and the amounts.

It would be interesting to members to know also that seven members of the Institute each contributed $123,00 to the fund.

The support of the branches is indeed encouraging. There is no doubt that the Ottawa Branch will be very happy to have this information and to know that the project which originated with them met with the approval of so many other centres across Canada.

It was always the idea of the Ottawa committee that the memorial was a national one and had nothing particularly to do with the city of Ottawa. Ottawa itself, is the capital of the Dominion, and therefore it is reasonable that projects of this kind in that city should be regarded as national in character. Contributions from these twenty-one branches indeed indicate clearly that the same idea is held right across the country.

Herewith are the details as to the branches and their contributions, and may it be pointed out again that some of those branches whose name are not here now have indicated their intention of making a contribution later.

Calling European Engineers

Recently the office of the Institute has been informed that at least fifty qualified engineers, graduates of recognized Institutions in Europe, are now in Canada doing work of a non-professional nature.

It is suggested that the reason they are doing work of this class is because of language difficulties, remoteness from large centers and desire to work and to make no fuss.

In view of the serious shortage of engineers it would indeed be a serious thing if these men were unwillingly doing work below their capacity. With this in mind this article is being published to suggest that any such person who desires a position of greater engineering responsibility should write immediately to the general secretary of The Engineering Institute of Canada, 2050 Mansfield Street, Montreal 2, Quebec.

There is a great scarcity of engineers in all fields and if any of these people are properly qualified there is little doubt but that they can be placed advantageously and without delay.

Do We Want the Students' Conference?

From time to time the question has been raised whether we should continue to hold a students' conference in connection with the annual meeting. Are we repaid in any recognizable way for the time, energy, and money spent in bringing these young men together?

The following three letters have been received recently at Institute headquarters, and are rather typical of the student delegates' reaction. They answer the above questions eloquently.

Dear Doctor Wright,

I wish to thank you and your staff on behalf of the University of Toronto Engineering Society for the hospitality shown to Keith McIntyre and myself at the students' conference and annual meeting last week.

Many ideas were exchanged and plans made between delegates that should prove of value to the respective student societies. It is my personal conviction that more plans were made than indicated by the minutes because they were worked out after the conference had ended and were not concerned with the E.I.C., directly.

Contact with the other student engineering societies aroused enthusiasm within me for the strengthening of inter-university bonds, and the contacts with the senior members of my chosen profession deepens my respect for the profession more than I can adequately express. I hope to be able to convey some of these feelings back to the students at Toronto.

MICHAEL A. LAUGHTON,
Delegate,
University of Toronto

Dear Sir,

I should like to thank the Institute through you, for making it possible for me to attend the annual convention in Montreal. The student's conference was a good opportunity to meet and talk with student bodies across the country, and I feel certain that much benefit will result from it, both to our own organizations and to the Institute. The technical papers, speeches and tours which followed gave a good insight into the profession into which we students are entering and showed well the part which the E.I.C. plays in this profession.

What impressed me most of all, however, was the warm hospitality which was extended to us. No matter how busy you all were, you always seemed to find time to talk to us and make sure that our stay was an interesting and enjoyable one.

Thank you once again,

E. J. FORHONEN,
President,
Queen's Engineering Society

Dear Doctor Wright:

I wish to thank you and the Engineering Institute of Canada for making it possible for me to attend the conference in Montreal.

The conference was a tremendous experience for me and I am deeply grateful to you. The E.I.C. has much to offer to the young engineer as well as everyone concerned with it.

This coming year at Tech I hope to get across to the students the importance of this organization. Even now I am telling everyone I meet of this great wish to thank you on behalf of my wife and myself. I hope that in the years to come I shall be able to repay the E.I.C.

JOHN E. ANDREWS,
President,
Student's Union,
Nova Scotia Technical College

I.E.E.—E.I.C. Agreement Revised

The terms of the reciprocal arrangement between The Engineering Institute of Canada and the Institution of Electrical Engineers for the waiving of entrance fees in some circumstances have been revised this year. This arrangement, which was first announced in the *Engineering Journal*, September, 1954 issue, applies to members of one Institution when resident in the country of the other and elected to its membership.

The effect of the revision is to cover members of all grades and, in particular, Students of the Institution who might qualify as Junior Members in The Engineering Institute of Canada. The following is the revised arrangement:

No entrance fee will be payable

On election to The Engineering Institute of Canada, if the applicant

Is a member of The Institute in good standing, permanently resident in Canada, and

Makes application within twelve months of his taking up residence in Canada or, if already resident there, within twelve months of the first appearance of this notice.

On election to the Institution, if the applicant

Is a member of The Engineering Institute of Canada in good standing, permanently resident in Great Britain including Northern Ireland, the Isle of Man and the Channel Islands, and

Makes application within twelve months of his taking up residence in Great Britain or, if already resident there, within twelve months of the first appearance of this notice.

It has been agreed between the two Societies that where election to the host Society is in a grade of membership for which no entrance fee would in any case be payable, the oversea entrant shall, provided he is still a member in good standing of his mother Society, pay no entrance fee to the host Society when he is transferred to a higher grade of membership, irrespective of the time at which such subsequent transfer takes place, or of his grade of membership at that time in his mother Society.

Industry and Education

Engineers, chemists, physicists and other pure and applied scientists have been in short supply for some years. There is a possibility that they may be even scarcer before enough become available. Failure to secure as many recruits as it would like from recent university graduating classes is perhaps the impelling motive behind industry's increased interest in scientific and technical education in particular and in all college education in general. Additional impetus is provided by the realization that Russia's technical and scientific manpower is growing in numbers at a rate greater than that of the West.

Industry's interest in education originated longer ago than most of us realize. One of the oldest industrial scholarship schemes is that of the Canadian Pacific Railway Company, now in its fortieth year. Under this scheme two C.P.R. employees or sons or daughters of employees are sent to McGill University each year by the company and maintained there until they receive their first degrees, i.e., for four or five years. Thus there are eight or ten of these scholarships in existence at any one time. Graduates are not bound to accept employment with the company; in fact, only a minority have done so.

No doubt the incentive to establish an industrial scholarship is tinctured largely by self-interest and by the feeling that charity might as well begin at home. Each sponsor hopes that it may eventually receive into its business family a fair proportion of those to whose educational expense it is contributing.

There are disadvantages in drawing scholarship material from a limited field, say the employees of a particular company, and other disadvantages in binding graduates to enter the service of the concerns whose scholarship holders they were. A limited field of selection means that the scholar chosen will not always be of the high calibre desired. At times, there may not be any qualified candidate. To feel that one must go to work for one's sponsor may be a very real handicap; it may divert the student's interest from a career for which he is eminently fitted to one for which he has no overwhelming talent and in which he will do less well and be less happy.

Corporations Accept Responsibility

However, most of today's corporations, especially the larger ones, have a keen realization of their responsibilities to the community and are becoming less and less restrictive in their demands. They are content to contribute to a worthy cause and to leave it to the good sense of the recipients to use their contributions wisely. This policy is reflected by the conditions under which most industrial scholarships are now awarded. Industry puts up the money and the university chooses the scholar, whose future is mortgaged by no commitments.

Over the past few years industry seems to have come to the conclusion that its major recruiting headache is not so much finding graduates with bachelors' degrees for its scientific and technical staffs as it is in filling posts whose occupants should possess graduate degrees. Masters and doctors are conspicuously scarce, especially in some fields of great and increasing importance. It is natural, then, that some concerns should have revised their scholarship schemes to apply to the graduate student and that others have instituted new schemes for the same purpose.

As an example of how these "fellowship" schemes work, let us look at that of the Shell Oil Company of Canada, instituted in 1945. We hold no brief for this particular scheme — there may be better ones — but it appears to have worked well and we happen to have the data at hand.

Fifty-five fellowships have been awarded to date. Seven have been available each year and there will be an eighth in 1956-57, tenable at the University of New Brunswick. The seven existing fellowships are distributed among the University of British Columbia, the University of Alberta, McMaster University, the University of Toronto, Queen's University, McGill University and Laval University. They are tenable for a year by a candidate aiming at an M.Sc., M.Eng. or Ph.D. degree in chemistry, chemical engineering, geology, geophysics, mechanical engineering or physics. Fellows are chosen by a committee composed of representatives of the company, the National Reseach Council and the universities. Each fellow receives $1,200 for fees and living expenses during an eight-months' session, $1,800 if he works the full year.

In addition to direct grants to fellows, the universities at which they are studying will receive $500 each for them from 1956 on. This grant-in-aid is designed to help make up the difference between fees and the real cost of education. We do not know of any case where a Canadian student pays more than about half of what he costs his university. The difference is universally made up by drawing on investment income, sorely needed for other purposes.

Besides these eight fellowships, Shell supports two for study in Great Britain. These amount to $4,000 each, spread over two years. They are currently held by a graduate of the University of Manitoba at Oxford and by a graduate of the University of British Columbia at Cambridge.

Perhaps the outstanding feature of these fellowships is the recognition that any student is a financial liability to his university and the provision of grants-in-aid to make him less so. Some schemes also provide small sums for the purchase of equipment and supplies, for the payment of technicians, for publication costs and the like.

There are many scholarships and fellowships similar to Shell's. All aim at turning out more and better engineers and physical scientists. What help is available for the boy or girl who wishes to become a lawyer, teacher, doctor or dentist, or who wishes to go into commercial life? Unfortunately, not much. Every university has some scholarships and fellowships of its own tenable in various fields, but there are never enough and they are often not well distributed; there are too many in some areas of learning and too few in others.

Often founded by well meaning benefactors with a hobby, or an axe to grind, they may be hedged about with almost impossible conditions of award. A good example is one for a French-Canadian student intending to proceed into the ministry of a particular Protestant sect; we hear that it has been awarded only once in nearly fifty years.

And such scholarships and fellowships are generally too small to be of great help today. Founded when the dollar was worth a dollar in gold and when both fees and living expenses were low, they were most useful then. We once heard an old graduate remark that he had an $80 scholarship during the full four years of his course and that it paid his fees and most of his living expenses. Today it might pay 20 or 25 per cent of a student's tuition only.

There are a few scholarships and fellowships for medical and dental students, supported by pharmaceutical concerns and the like, but they are not at all numerous. The odd school commission offers help to those intending to be teachers, usually with the string tied to it that the holder shall work for the commission for some minimum period after graduation.

Help is required here — in the liberal arts particularly — as much as in engineering and science, but industry has been slow to realize that an improvement in the educational level of its rank and file non-technical and non-scientific staffs might in the long run redound as much to its advantage as improvements on the technical and scientific side, to which it stands pretty well committed.

Help From The Government

The universities and colleges of Canada, large and small, with the possible exception of those supported directly by the provinces, simply cannot give the ever increasing flood of capable students the training of all kinds which they want and must have if we are to progress scientifically, technically and culturally, unless educational resources are increased. There seem to be only two possible sources of additional income for our institutions, government and industry.

There is little or no hope of large gifts from the Rockefellers and Carnegies of the future; there won't be any such people. Our tax laws discourage the accumulation of large fortunes and if one is fortunate enough to leave a large estate on one's death, the bite of succession duties sometimes leaves hardly enough to support the widow and children in decency. There will continue to be private gifts to education, but not on the scale of the past.

Most educators dislike the idea of government subventions, fearing that they may be the thin end of the wedge of political domination. So far as we know, our limited experience of them in Canada does not show them to be particularly dangerous, but they might become so in future.

If industry is to contribute more freely to the support of education in Canada, it would be well if that support were a little better organized. Scholarships, fellowships, and grants-in-aid are all very well, but the universities and colleges need money for the expansion of facilities, the replacement of buildings and equipment, the institution of new courses to keep up with the times and particularly to establish a more equitable scale of salaries for their teaching staffs.

Campaigns for Universities

A campaign seems to be the favourite device for raising funds for capital expenditure. A large number of people give their time and energy to the business of soliciting gifts, another large number takes care of the endless paper work involved. There is much enthusiasm and excitement as the campaign nears its end and it becomes apparent that it is going to be a success, and corresponding gloom and depression if it promises to be a "bust". All work is not finished when the campaign is over; pledges must be collected periodically and slow payers prodded. There will be some who will not keep their pledges. A good deal of energy is wasted and there is always conflict with other campaigns; over fifty are scheduled in Montreal alone in 1956.

It is only fair to say that industry has always been a generous contributor to such campaigns, but we have been told that many concerns would prefer to contribute a smaller amount each year than to make one large donation every five or ten years.

This leads us to suggest that the Canadian Manufacturers Association, our most comprehensive organization of industries, might poll its members to inquire how much each is prepared to contribute annually to an educational fund over a term of, say, ten years as a minimum. Having collected several million dollars (we hope!), the CMA would then distribute it once a year to the qualified universities and colleges. A list of eligible institutions would have to be set up. This should not be too hard a job, though it might be accompanied by some pretty acrimonious discussion.

A more difficult task would be to determine the basis of distribution. Some of the factors to be considered would be number of students, type of instruction — a medical school obviously needs a greater income per student than the small liberal arts college — and other sources of income.

These donations from industry should be given without any strings attached. The recipients can be trusted to use the money wisely. They are not and cannot be extravagant; ask any faculty member who has tried to get an appropriation for a pet project. For one that is granted, there are a dozen refused for reasons which seem good and sufficient to the holders of the purse strings.

Alternative Plans

Suppose the universities and colleges do not accept government subventions if offered, and industry does no more for education than it is now doing, plus the modest increase to be expected with growth, what are the alternatives?

One of our major universities has already announced that it proposes to hold its registration down to relatively modest figures by raising standards of scholarship all along the line from entrance to graduation. This will make little difference to the outstanding student, but what about the merely good one? After all, few are geniuses, yet we like to think we contribute something to the good of mankind and most of us do. The merely good student might find himself denied a college education if this policy were universally adopted.

We think that requiring very high academic ability for the privilege of entering college and staying there is of doubtful value. We would like to see standards raised to the point where withdrawals for academic reasons were reduced to the minimum and so, we think, would the universities. Our engineering schools are making some progress in this direction. It must be remembered that a good many withdrawals from college are because students discover they are not college material, others for family or financial reasons and still others as the result of disciplinary action. No scholarship standards, high or low, will salvage those who withdraw for these or similar reasons.

We would not set academic standards any higher than necessary to guarantee, so far as this can be done, that every student who worked faithfully would graduate and not by any means all with honours, either. We have seen too many poor students who managed to get through college and who subsequently became able and prominent in their own fields and leading citizens, to have implicit faith in academic standing as the only means of judging ability.

Apparently other Canadian universities are planning to raise their

(Continued on page 1326)

Aviation Writers' Association

Being Part 3 of an Account of the Annual Meeting.

Most of the morning of Friday, June 1, was taken up with a business meeting but the luncheon and the afternoon belonged to General Electric.

J. S. Parker, general manager, Aircraft Gas Division of General Electric gave quite an address after luncheon. His subject was "The Heat Barrier Under Attack" and he surely put it and a lot of other things under attack before he had finished.

He started out by saying: "In recent months, I have become disturbed by an undercurrent of opinion, which has, in a sense, infiltrated all discussion and opinion of airpower. This undercurrent is not restricted to those of us intimate with airpower, but rather it has taken hold nationwide. Although it is a behind-the-scenes type of opinion, it still pervades all intelligent conversation or written matter concerning airpower.

"I am referring to the subtle joining of two rather common — but unlike — words as being synonymous. These two words are 'airpower' and 'problems'.

"I have attempted to analyze that sudden realization. I came to the conclusion that everyone closely concerned with airpower has been so conscious of its importance to the free world's security — and so immersed in the search for progress in the air — that no one has had time to discuss successes adequately. The search is continuous and sometimes frantic to reach one more success in the race for 'higher, faster, farther'. While self analysis and self improvement are critically needed, we still must acknowledge current progress.

"You and I know that the best in airpower is essential. I sincerely believe and advocate that those of us concerned with airpower must do more than face up to the challenges posed. And you, the members of the Aviation Writers Association, can do more than any other group concerned to establish a healthy public attitude towards airpower. Certainly, there are problems, but we have no right to be complete skeptics.

"Certainly, the possibility of failure stares us in the face, but doesn't it always? Remember this, the combined efforts of the military and industry have never failed, and this is no time to believe they will.

"The key to the 'best' in airpower is, without question, constant and extensive research and development. We all know what superhuman efforts were needed after research and development funds were drastically reduced following World War II. It set us back approximately five years. This cannot and must not occur again.

"Today, one of the primary targets of attack is a not-too-aptly titled one . . . namely, the 'heat barrier'. I state 'not-too-aptly titled' since, first, it is not a barrier, and secondly, it is not a new problem. The team of Daedalus and Icarus had a slight heat problem some centuries ago, when Icarus lost his wings flying too close to the sun — and those who traverse the skies have faced heat problems in one form or another ever since.

"The 'barrier' idea is also false! It is not one hurdle to cross. Rather it resembles a long avenue without street lights. We are all trying to string the wire and implant the light fixtures one by one so that we can see our way.

"We know the ogre of the too high temperature pretty well. We know what happens to many of the various components of the airframe and engine. For example, we know that at certain mach numbers high friction temperatures cause a nightmare of failures: electronic tubes start to malfunction . . . nylon and rayon fittings disintegrate . . . fuels begin to boil away . . . and metallic components common to all aircraft begin to lose their required properties. As we go faster there tends to be a dissociation of air particles which results in strange phenomena such as metal burning before it melts, transient condition buckling failures and so on. These failures are not all in the future; some are occurring now in supersonic areas. We are already exceeding normally limiting temperatures of many materials."

Mr. Parker went on to tell of the great expenditures in plant and equipment made by his company. He emphasized their confidence that some day success would attend their every effort. He gave some interesting facts and figures, such as the following:

"Temperature limits of turbine bucket are critical to jet engine operation. This is an area of high priority, for a very understandable reason: higher turbine inlet temperatures mean greater engine thrust out of the same jet engine package. A jump of 200 degrees Fahrenheit from 1500 to 1700 degrees increases thrust 10 per cent. And if we can increase the temperature to 2000 degrees, we have an increase in thrust of approximately 40 per cent. This could mean, for instance, that a basic production jet engine might have 40 per cent more thrust with a 2000 degree bucket. As the envelope re-

Hamilton Air Force Base, Calif. The new vertical plotting board recently installed in the 28th Air Division Air Defence Control Centre serves to plot the positions of all aircraft flying within the Division's operational area.

mains the same, the implications are obvious.

"For the future, a great percentage of our work in metallurgy has centered on a certain group of high temperature metals, that include: molybdenum, columbium, chromium, cobalt and nickel. All offer promise of growth to meet the needs in turbine buckets, turbine wheels, various hot-end sheet metal parts, and high-temperature bearings."

He concluded on a note of optimism and confidence.

"I have every confidence that the capabilities of the aviation industry's research and development efforts in metallurgy and in the related areas pertinent to the so-called "heat barrier" problems will soon put them behind us. I am so confident that I don't hesitate to predict the advent of manned aircraft flying at speeds in excess of 2000 miles per hour as an operational condition within a few short years. I have no hesitancy in predicting altitudes for aircraft above 100,000 feet.

"These new operating parameters will be in good part, the direct result of improved metals, incorporated in both airframe and powerplant. These metals will be able to withstand temperatures from minus 400 degrees to something akin to 4000 degrees in the combustion area."

This writer came away with the feeling that Mr. Parker knew a lot more than he was telling, and that some of these problems would be "licked" by General Electric or someone else shortly.

Banquet

The annual banquet was staged for Friday night. The main speaker was General Thomas D. White, vice-chief of staff, U.S. Air Force. He talked about the desirability, if not the necessity, of closer collaboration between the three armed services. Apparently this collaboration is not present now to the degree that is desired. The same things may exist in Canada but if so they are surely kept better hidden from the public than they are in U.S.A.

After explaining that he deplored these inter-service arguments and would take no part in them, he said, "Controversy can rock the national defense boat at a time when we need continued stability."

He spoke strongly on the need of unification in the services, saying—

"I believe that our military services will move toward more complete unification. We need a military organization that will help us all to be free of conflicting service loyalties and confusing influences.

"One step could be to more closely integrate existing forces. The continental Air Defense Command is an example of what I mean. Units of the Army, Navy and Air Force are united in a common effort — the air defense of the United States. Further integration of our forces into joint commands oriented toward one mission might be effective.

"Another step toward more complete unification would be the free transfer of men between the services. Perhaps this would allow the men in each of the three services to think a little more objectively about the requirements of defense and less about gaining or keeping weapons, and missions for their own particular branch.

"With the passing of time, the roles and missions of all the services seem to overlap more and more. Conceivably, if these trends continue the day could come when, for all practical purposes, all three services would have the same weapons, the same capabilities and limitations, and all attempting to do the same jobs. If that happens, perhaps we certainly would find it advisable to standardize uniforms and streamline the organization."

To the Canadian, and doubtless to many Americans too, this was a startling thing to hear — and yet on pondering the matter later it appeared more and more reasonable. Maybe we would do well to think about such things for Canada.

His closing paragraph summed up the whole purpose of the talk. He said: "I have mentioned the 'long pull' in defense several times tonight. All of us who are directly concerned with defence, and I include all the industries which support the military as well as the Army, the Navy, and the Air Force, and particularly you communicators who link us all together — each of us must remember that if the long pull is to insure continued peace — we must pull together."

Last Day

Saturday, the last day of the conference, proved to be one of the most interesting and pleasant. The sponsors of the breakfast were Hoffman Laboratories and the speaker was Colonel J. Francis Taylor, Jr., Air Navigation Board, U.S. Department of Commerce. He spoke on "The Status of Tacan" (Tactical Air Navigation) and he thought well of it. It seems there are some differences of opinion as to the qualities of Tacan compared to another type of air navigation system. There was no doubt in Colonel Taylor's mind as to the superiority of Tacan.

Solar Power

The air borne portion of Tacan is manufactured by the Hoffman Laboratories and is one of their principal products but they have many others in the electronic field. H. Leslie Hoffman, President, spoke at some length about other products. One is the silicon solar cell which gives practical amounts of electrical power directly from the sunlight. To demonstrate the work of the cell he referred to the plane model standing nearby where four propellers were rotating solely from solar power.

He observed that this was only a model and would not fly, but he was sure that some day a plane would rise and fly with only power from the sun. Also he believed that solar shingles on the roof of a house would soon develop all the electrical power needed to operate all the equipment in the house.

Hamilton Air Force Base

After breakfast buses were loaded for the nearby Hamilton Air Force Base. It was a delightful drive on a beautiful day and over the famous Golden Gate bridge. On arrival the delegates were addressed by Major General William E. Hall, assistant chief of staff for Reserve Forces. As would be expected he spoke of the reserve force, their purposes, plans and problems. The problem of maintaining a base near a large city was a difficult one to solve. The reservist living in the city had to have a field nearby, but the civic officials in general, wanted the field some place else and were saying so in terms that could not be ignored. He said, "This is a grave and disturbing situation. If we are to have an acceptable degree of combat capability in our Reserve Forces, for which a mobilization requirement has been firmly established, we must somehow achieve wider public understanding and acceptance of the Reserve Forces' requirements."

A tour of the station followed. This is a large establishment that looks much like a well settled city, with its permanent buildings looking like apartment houses and its streets lined with palm trees, and green grass everywhere.

An unusually interesting feature of the tour was a visit to the control center and an explanation and demonstration of how it works. In the center (see illustration) is a transparent board divided cross sectionally to cover the surrounding area. The operators or markers work behind the board using color paints and writing backwards so the record can be read from the front. The markers can be seen back of the board in the illustration as ghost-like figures or smudges. They work on platforms at three levels. The board is about 20 ft. by 30 ft.

Every plane that was sighted on the many radar screens in the rooms also appeared on the board and its position was recorded all the time it was in the operational area covered by the plotting board. The data for the board was transmitted constantly to some "higher-ups" for decision as to action. This is a 24-hour-a-day activity.

The static display was very elaborate including almost every type of plane in service and some rockets as well. A good show was presented in removing a jet engine from a plane, putting in a replacement and flight testing. It all took 13 minutes.

Another demonstration was a "scramble". Two crews were called out to man two jet fighters, and in a hurry! In a matter of seconds they were in the air. Such crews stand ready 24 hours every day for emergency calls up and down the coast.

A delightful luncheon was served at the officers club, after which bathing in the pool was offered or an immediate bus ride back to San Francisco.

That concluded the program of the eighteenth annual convention of the Aviation Writers Association. Sunday morning at 7 a.m. the buses left the Mark Hopkins Hotel for the airport and once again MAPS "air lifted" the group back to New York.

It was a really great week. The services and industry certainly extended themselves to show their wares — and they had a lot to show. No one could fail to be impressed with what these great United States have accomplished and have under way for the future.

Funds for the Needy

Recently a senior member of the Institute died and left $25,000.00 to the Institute with the stipulation that the interest hereon be used to assist needy engineers.

This is by far the most substantial contribution the Institute has ever received, and it is indeed appreciated.

Under existing conditions there are not many needy engineers, but under different conditions which may develop in the future this fund will become a most useful and valuable one. It is nice to have a reserve set aside for such a contingency.

Elections and Transfers

A the meeting of Council held at Headquarters, on Friday, July 20, 1956, a number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected:

Members

W. P. Armstrong, Toronto
J. W. Barker, New York
C. Boot, Toronto
L. M. Boyd, Montreal
B. D. Elderkin, Goose Bay
R. N. Harrison, North Bay
E. E. Heaton, Montreal
G. D. Hendry, Toronto
A. W. Henschel, Toronto
G. T. J. Hughes, Trail
A. T. Klassen, Toronto
A. F. Mundy, Montreal
Z. F. Oszter, Toronto
R. J. Penman, Montreal
S. M. Peterkin, Toronto
L. S. Piper, Trail
O. Reich, Montreal
H. E. Rentsch, Toronto
M. T. Seguin, Montreal
G. C. Smith, Hamilton
P. W. Trafford, Ottawa
R. J. White, Whitehorse

Juniors

I. A. Andressen, Brownsburg
J. G. Bulleid, Toronto
M. Erdstein, Montreal
J. A. Rotgans, Montreal
A. E. Spence, Dartmouth

Transferred from the class of Junior to that of Member

R. G. Armstrong, Whitehorse
R. E. Chant, Winnipeg
E. R. J. Dupuis, Mackenzie, B.C.
T. Fell, Port Arthur
E. J. Gilbert, Montreal
A. Kofman, Montreal
S. S. Lazier, Kingston
J. C. Querido, Montreal
R. C. Short

Transferred from the class of Student to that of Junior

J. Allan, Dartmouth
J. M. Wigham, Regina

The following Students were admitted:

R. M. Bright, B.Sc.Mech. Queen's 1956
T. A. F. Brookes, Univ. of Toronto
C. D. Burton, B.Sc. Civil Alberta 1956
P. G. Cockburn, Univ. of Toronto
C. T. Courtney, B.Eng. Elect. N.S.T.C. 1955
H. M. Dokken, Diploma, R.M.C. 1956
S. K. Henry, B.Eng. Chem. N.S.T.C. 1956
B. B. Kubow, B.Eng.Elect McGill 1956
U. Luksep, Univ. of Toronto
J. P. Maley, B.Sc.Mech. Queen's 1956
H. R. McGinn, B.A.Sc. Elect. Toronto 1956
J. J. O'Connell, Nova Scotia Tech. College
F. W. D. Shannon, Univ. of Toronto

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members

D. E. Aitken
Z. D'Amico
J. M. den Hartog
W. H. Denier
R. C. B. Jarvis
N. Koslovsky

Professional Development in Canada

W. A. H. Filer, Jr.E.I.C.

Past Director, Hamilton Branch

Professional Development Program

Canada is a land of boundless opportunity, a young country for young people. We hear this on every hand, and we are told that the greatest potential lies in the field of engineering. How fortunate are we young engineers! Nevertheless, we must realize that with increased opportunity there is increased responsibility, both to ourselves and to our fellow men. The passage of time clearly indicates how little we know, and that a formal university education is simply the foundation on which to build.

Problems Studied

Professional societies in the United States and Canada have been studying the problems of the young graduate in an attempt to ascertain what might be done to help them attain full professional stature. The two-fold result will be the advancement of both the individual and the profession. They have determined that the most difficult, and probably the most critical stage in the engineer's career is the transition between college and industry. During this period he is endeavouring to set professional goals, gain confidence in his own ability, as yet unproven, and to find his place in industry. Possibly he is assuming the responsibility of a family on a modest salary. Any one of these is a major undertaking, and generally all are being established during the first five years after graduation. How successful he is in adjusting himself will determine his future welfare and his usefulness to his employer.

Professional development programs have grown from the realization that these first five years after graduation are the most difficult. The two spheres of influence which must assist the engineer are industry and engineering societies. Whether or not there is a formal training program in industry, technical advance is taking place. In order that the graduate will not become merely a technician, as opposed to a professional man, progress is necessary in broader interests: interests which because of a concentrated university course he has not been able to pursue. This is where engineering societies take their place beside industry.

Engineers' Council for Professional Development

The Engineers' Council for professional development is an amalgamation of the work of eight large and influential engineering bodies in the United States and Canada. Probably no other profession has so many well-established societies. Of these, the American Society of Civil Engineers was founded in 1852, and the Engineering Institute of Canada in 1887. They have contributed in large measure to the industrial advance of our country. Recently these groups have banded together to form the Engineers' Council for Professional Development, specifically for the purpose of counselling would-be engineers in high school, the examination and accrediting of various engineering schools' curricula, and development of the young graduate.

The Monteith Report

For a number of years little progress was made in the search for what the profession might do for the young engineer. In 1949 Dr. A. C. Monteith, of Westinghouse Electric Corporation, was chosen to make a survey and submit a report from which a program could be designed and implemented. The importance of this report can be understood since, if a program could not be implemented from its findings, the Engineers' Council for Professional Development would consider that such an undertaking was beyond its powers. Dr. Monteith gathered a group of engineers together who were interested in assisting the rising generation of engineers to "attain full professional stature". During the ensuing year this committee systematically surveyed the training given by fifty-four companies in the United States, from those who employ five engineers each year to those who employ hundreds. The Monteith Report, presented at the annual meeting of the Engineers' Council for Professional Development in October 1950, confined its remarks in general, to the first five years of professional development under the following headings:

a) Orientation and Training in Industry
b) Continued Education
c) Integration into the Community
d) Professional Identification
e) Self-Appraisal
f) Selected Reading

Consider very briefly, some of these aspects. We are all well aware of their existence, but possibly we are not fully aware of their importance. Orientation and training are largely the responsibility of industry. An engineer often enters an organization at a relatively high level and has not had an opportunity to become familiar with its problems. Of course, the engineer must do much on his own initiative whether or not there is a formal training program. He should be alert and inquisitive in his own department, and should have the opportunity to visit other departments in order better to appraise the work in which he is engaged.

Education is a continuing process, but there is an anticlimax upon graduation when the external compulsion to learn is removed. The individual must, therefore, exert his own initiative to continue his education. In this fast-moving world of technical advance, if he is not keeping abreast of new ideas he is falling behind. A truly professional man realizes this and builds on the firm foundation he established at university.

Responsibilities and Recognition

Engineers, with their advanced education, have a responsibility to their community growing out of this privilege. A professional man should assume certain obligations in municipal, provincial and federal affairs. Yet how many engineers are vitally interested in their community's activities? We, as engineers, want to be considered as professional men, but we are not ready to assume our full share of the responsibility. Until we are ready, our professional acceptance by society will not be forthcoming to the extent that we desire.

An important phase of the engineer's development is the attainment of professional recognition through his affiliations with professional associations and engineering societies. Initially registration in a professional association could be purchased, whereas today it is a privilege to be earned. Academic standards are constantly being raised, thus enhancing the status of the profession. These professional associations are the governing bodies for practising professional engineers. The Engineering Institute of Canada provides the op-

(Continued on Page 1199)

THIRTY-FIVE YEARS AGO

Comment on the Journal of September, 1921

The *Journal* of thirty-five years ago was not as attractive externally as it might have been. At its birth it had adopted a muddy brown jacket to which it adhered for many years, in fact, even today there are traces of it in our covers. It seems to have become fixed by tradition. But a complete job of cover redesign has brightened up our dress and cover illustrations add a lot to our good looks, until now we compare favourably with other similar periodicals. We have nothing of which to be ashamed, though we still think there is room for some improvement.

Saskatoon Meeting

This *Journal* was wholly given up to papers and reports from the Saskatoon professional meeting of August 10-12, 1921. Some of the papers were mentioned here last month. The meeting seems to have been a successful one; 102 members registered and there was a lot of discussion on subjects of most interest to the western provinces.

M. A. Lyons, A.M.E.I.C., had some positive ideas as to road policy for the prairie provinces "(A) committee (may) draft the policy, but there is little more to it than writing out a nice reading (one) . . . After the policy is drafted it is of no use unless it is put into effect and the money found for carrying it out."

The matter of the disintegration of concrete in alkali soils was very much to the fore at this meeting, as well it should have been. It was without doubt the most important and troublesome question then facing prairie construction engineers and contractors. In spite of much investigation and experimental work, not much was really known as yet as to its causes and how to offset them.

Groups from Calgary, Saskatoon and Winnipeg had their say in this discussion. They agreed in general, but there were some arguments over minor details of their findings and the language in which these should be expressed. Methods of making concrete with the best possible alkali resistance were recommended—in essence, "Make the best concrete you can of the best available aggregates with the least possible water."

But even such concrete was not proof against deterioration, so it was suggested that coatings and admixtures should be thoroughly investigated; a little work of this kind had already been done.

The water supply of southern Saskatchewan, both for domestic purposes and for irrigation, was discussed at length "under the direction of the Alberta branches", perhaps because some of their members had had much irrigation experience. The conclusion was that which had been arrived at before; the salvation of this part of the province lay in the South Saskatchewan river, a conclusion which still holds good. As early as 1912 two members of the Institute had told the cities of Regina and Moose Jaw that if they wanted water supplies adequate for their future growth, they would have to go to this river. It took the cities forty years to make up their minds to implement this advice; only recently have they inaugurated a joint supply from that source.

Institute Affairs

One session of the Saskatoon meeting was given over to a discussion of Institute affairs. The general secretary was present, of course, and this gave all the grousers, both individual and collective, an opportunity to take pot shots at him, as representing the entrenched powers. He had a busy time.

The session opened on a note of harmony and self - congratulation. With the help of the Institute seven provinces had enacted some kind of engineers' registration law. Those still outside the pale were Prince Edward Island and Saskatchewan itself, whose 1920 act was declared "unsatisfactory". Some local members were constrained to apologize for this condition, which seems to have been largely due to provincial politics. At least, it couldn't be blamed on socialism; it was still to be many years before the C.C.F. was to take over the provincial government.

Then the members present turned their attention to their own status and incomes and found both poor. They wanted immediate adoption of a schedule of positions and salaries; "live publicity . . . of the true nature, character and extent of engineering services"; and, finally, "that a permanent committee be appointed . . . to keep in touch with all matters respecting this branch of the work."

In none of the discussions on status or salaries, at Saskatoon or elsewhere, does there ever seem to have been any hint that perhaps the individual member could accomplish at least a little by climbing a few steps under his own steam, instead of waiting for somebody else to kick him up the whole flight. The lack of personal pride in the profession and of much feeling of personal responsibility may be among the reasons why engineers do not rank as professionals in the public eye with doctors and lawyers, for example, who possess such qualities in marked degree, instilled into them during their college years.

Three members from Vancouver had a number of suggestions for boosting the Institute: "An energetic campaign should be undertaken . . . to increase membership . . . Surely (twelve associates) are not . . . enough . . . We (are) missing a . . . great opportunity of improving our relations with the business . . . interests by failing to have as associates . . . employers, manufacturers, ministers . . . of public works . . . general managers and presidents of railway companies and a score or more of other . . . . classes . . . which are interested in engineering."

"The present would be a most inopportune time to increase . . . dues . . . By a substantial increase in membership a reduction . . . might . . . be affected . . . The best interests of the Institute can be served by granting more power to the branches . . . The work done by the branch secretary warrant(s) . . . remuneration . . . amounting to one dollar for each corporate member in good standing.

"It has been said of the Institute that it was run for the glorification of a few . . . We do not believe any such statement can be fairly made today . . . (but) offices are occupied too long and too frequently by individual members, no doubt . . . frequently because no one else would act . . . It would be a step in the right direction to have a large number of members hold office."

Actually this was a more powerful blast than is suggested by the excerpts above. It was received without action by the meeting, but we shall have to wait to see if it had any effect on the imperious and stubborn men in Montreal who were imagined by some members to run the Institute pretty much as they wished. Of course, there never was any such clique. R. DeL. F.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

ONTARIO

Engineers in the News

W. J. Farago, of Canadian Comstock Co. Ltd., has been named manager of the manufacturing division of the company in St. Catharines, Ont.

An engineering graduate of the University of Saskatchewan, Mr. Farago has been plant superintendent of the same division for the past four years.

Noel B. Montagnon has moved from Arnprior, Ont., to Ottawa, where he is employed by Computing Devices of Canada Ltd., as development engineer in the special projects department of the company.

Franklin P. Buchanan has left the field engineering department of the International Nickle Company at Copper Cliff, Ont., and is employed in the department of works, City of Toronto.

Paul A. Berube has left Canadian General Electric Co. Ltd. at Peterborough, Ont., and has moved to Rochester, N.Y. where he is employed as an electro-mechanical engineer in the telephone division of the Stromberg-Carlson Company.

K. S. Boorman has recently joined Isotrope Products Ltd., Oakville, Ont., in the position of sales engineer.

Mr. Boorman was formerly engaged in sales engineering with the engineering electronics division of Canadian General Electric Co. Ltd. in Toronto.

Ian L. Jennings has been appointed vice-president, supply division, with Standard Paving and Materials Ltd., and also manager of its subsidiary company, Consolidated Sand and Gravel Ltd., Toronto.

Mr. Jennings was formerly the general superintendent of Consolidated Sand and Gravel Ltd. at Paris, Ont.

A. C. Northover, formerly waterworks engineer of Etobicoke Township, has joined J. S. L. King, consulting engineer, 1216 Yonge St., Toronto, as chief engineer.

Mr. Northover has specialized for ten years in municipal engineering, including township projects, in Newfoundland, the West Indies and the Pine Tree line. He graduated in civil engineering from the University of Toronto in 1937 and in 1947 gained the professional degree of C.E. from the same university.

J. R. O. Walli has moved to Saskatchewan from Keno Hill, Yukon Territory, and is chief engineer of Gunnar Mines Ltd., at Uranium City, Saskatchewan.

Arthur E. Smith of Electro Metallurgical Company, a division of the Union Carbide and Carbon Corporation, Niagara Falls, N.Y., has been appointed chief project engineer in charge of the supervision and direction of the engineering department.

A graduate of 1934 in mechanical engineering from Queen's University, Kingston, Ont., Mr. Smith joined the Electro Metallurgical Company in 1936 at Welland, Ont., and successively held the positions of maintenance engineer, process engineer and works engineer. In 1952 he was trasferred to the general engineering department, where he has acted as project design engineer and project engineer. In the latter position he was responsible for the engineering of Electromet's new titanium sponge plant, recently constructed at Ashtabula, Ohio.

The election of **Stephen R. Knott,** to the board of directors of W. Fearnehough (Canada) Ltd., Toronto, has been announced by the parent company, W. Fearnehough Co. Ltd., of Sheffield, England.

Mr. Knott graduated in engineering from the University of Toronto in 1940 and served with the R.C.A.F. during World War II. He was named general manager of W. Fearnehough (Canada) Ld. in 1955.

Stanley M. Roberts is now located in Hamilton, Ont., and is manager of power rectifiers, of the Canadian Westinghouse Co. Ltd. in that city.

Prior to this change in employment, Mr. Roberts was assistant electrical superintendent of Price Bros. & Co. Ltd., Kenogami, Que.

Ross L. Clarke has been named works commissioner for the municipality of Metropolitan Toronto, thus permitting Leslie B. Allan to devote his whole attention to Metropolitan Toronto roads. Prior to this change Mr. Allan directed both the works and roads activities.

Mr. Clark is a native of Toronto and obtained his degree in civil engineering from the University of Toronto in 1937. During the period 1937 to 1942 he was with the engineering department of the Consumers Gas Company of Toronto. In 1942 he joined the R.C.A.F., and served throughout the war. In 1946 he joined the department of works, City of Toronto. He was appointed Metro's deputy works commissioner in 1953.
