While Ontario offers the best opportunities for utilizing atomic power in large units, the Maritime provinces as well will be increasingly dependent on thermal sources in the future, and nuclear sources will not be ignored. Even Saskatchewan, with its huge resources of petroleum and low grade coal, is watching progress in the field of nuclear power with interest. Smaller and isolated markets for atomic energy are probable in the high-cost power areas of the far north. The share of these markets that can be supplied from atomic sources is due for rapid growth when it is proved that nuclear power can compete with existing sources of supply.

Production of Canada's uranium ores is progressing rapidly in three major fields. 1957 production of some 125,000 tons is expected. To stimulate uranium production, Canada purchases the output of all acceptable concentrates offered, under a published price schedule effective up to March 1962. The bulk of current production is exported to the U.S. Atomic Energy Commission, though production may be retained for Canadian use when the need arises. There appears to be no doubt that Canada will have all the uranium needed for atomic power requirements for the foreseeable future.

Dr. A. J. Mooradian, Atomic Energy of Canada Ltd., in summarizing the research at Chalk River to date, states that uranium dioxide has been selected as the fuel for the N.P.D. reactor being built at Des Joachims on the Ottawa river. He also asserts that: (1) Economic fuelling of a power reactor to compete with present-day thermal power stations is possible. (2) The heavy-water reactor offers the best promise for achieving low fuel costs. (3) Practical limitation on achieving economic fuelling can be overcome, probably in the near future.

POWER IN THE NORTH

Plans were made in 1956 for the development of a new 15,000 h.p. hydro-electric station at Whitehorse, in the Yukon territory, for the Northern Canada Power Commission. This picture shows the early stages of construction and the de-watering of the cofferdam. (*Photo: Poole Construction Company*)

COMMUNICATION

NEW RECORDS were posted in 1956 for Canada's telephone industry, in capital expenditures, telephones installed and conversations. This is indicated by preliminary totals for the year based on records of the Bell Telephone Co. of Canada, which owns two thirds of the telephones in operation and accounts for 70 per cent of the employment by Canada's fifteen largest telephone systems, which together account for 91 per cent of the total for all Canada.

At the end of 1955 these fifteen systems had a total of 3,823,537 telephones in operation, eight per cent more than at the end of 1954. Cost of property and equipment at $1.41 billion was up 13 per cent from the previous year. Revenues at some $354 million exceeded the previous year by 11 per cent, while net income at $45.9 million was 7.6 per cent over the previous year. Conversations on twelve systems at 6.6 billion for 1955 exceeded the number recorded in 1954 by 11 per cent.

Record Year For Bell in 1956

In 1956, the Bell system's operating revenue rose by $29 million to $273.9 million or 12% over 1955. Net profit at $34.95 million was 9% higher than in 1955. During the year the company spent $139 million on construction of new facilities, or $10 million more than in 1955, bringing total assets to $1,183 million. The addition of 288,000 telephones raised the total installed by the company in its Quebec-Ontario territory to more than 2,766,000. This total was more than double the number installed up to ten years ago, and almost four times the number installed up to twenty years ago. Capital expenditure for 1957 is forecast at $176 million.

While the demand for new service continued to rise steadily in 1956, the company succeeded in reducing the list of waiting customers last year by 19,000 or 37 per cent. There remained at year-end some 28,000 unfilled orders for telephone service, as well as 47,000 unfilled orders for individual in place of party-line service. The number of exchanges had been increased, however, permitting individual line service as soon as ordered.

There was a sharp increase during the year in the demand for special services, including a wide variety of office and plant intercommunication systems. New fields of usefulness were developed for teletype, notably as a component of integrated data processing systems. Public services such as police and fire departments show increasing interest in the advantages of flexible communications systems tailored to meet their particular problems, and are being provided with special switchboards and private line teletype and mobile service networks.

Cross-Canada Microwave Network

Together with the other fourteen members of the Trans-Canada telephone system, Bell is building a 4,800-mile microwave radio relay network from Sydney to Victoria, including branches to Halifax, P.E.I., Moncton, The Soo, Saskatoon, Edmonton, and Lethbridge. During 1956 the Toronto-North Bay-Winnipeg section was completed, as well as part of the Maritimes sections. Construction of the remainder of the chain is progressing according to plan, and the entire network is scheduled for completion in 1958, to carry long-haul telephone conversations and provide network TV for 28 cities. This type of service has been in operation between Buffalo, Toronto, Ottawa, and Montreal for the last four years, connecting with telephone circuits and network TV all over the continent.

Network for Trans-Canada Pipeline

In co-operation with the rest of the trans-Canada telephone system, Bell is also building the communications network for control of the Trans Canada natural gas pipeline from Alberta to Toronto and Montreal. This project will knit together several communication services—private telephone lines, radio phones, and telemetering circuits—into a single integrated system.

Acting as agent for the Trans Canada system, Bell's special contract department has planned, designed, and built the mid-Canada radar warning line, which went into partial operation at the end of the year. Completion is scheduled for 1957.

Telegraphs and Cable Systems

Telegraph and cable systems operating in Canada had a record year in 1955, last year for which complete statistics are available. Earnings at $6.18 million were 49 per cent higher than for the previous year and almost 31 per cent above the previous record of $4.73 million established in 1943. Due to a decline in operating expenses, net revenues rose from $5 million in 1954 to $6.8 million in 1955.

New construction amounting to $9.66 million was reported for the year. The Dominion Government Telegraph Service, which sold the major part of its system in 1954, recorded a decrease in property and equipment of over $4 million. Western Union also reported a slight drop in its Canadian investment figure. All other companies showed increased investment and total cost of property and equipment at $124.3 million was 5 per cent higher than in the previous year. Pole line and wire mileages at 48,067 miles was higher than in 1954, largely due to an increase of some 1,900 miles in Newfoundland, and wire mileage rose to 438,692 miles. Employment rose slightly to 10,852 persons.

Telegrams transmitted at 20,067,424 were higher than in 1954 but below the peak of 21,815,800 reached in 1951. The number of cablegrams transmitted at 2,236,433 showed an increase of 6 per cent over the previous year. Money transfers established a new record with over $23 million transferred, almost 8 per cent above the previous high reached in 1953.

Overseas Telecommunication

Canadian Overseas Telecommunication Corporation was established in 1950 by the government (Department of Transport) to maintain and operate in Canada and elsewhere external telecommunication services for the public, by cable, radiotelegraph, radiotelephone, and other means between Canada and any other place, and between Newfoundland and any other part of Canada.

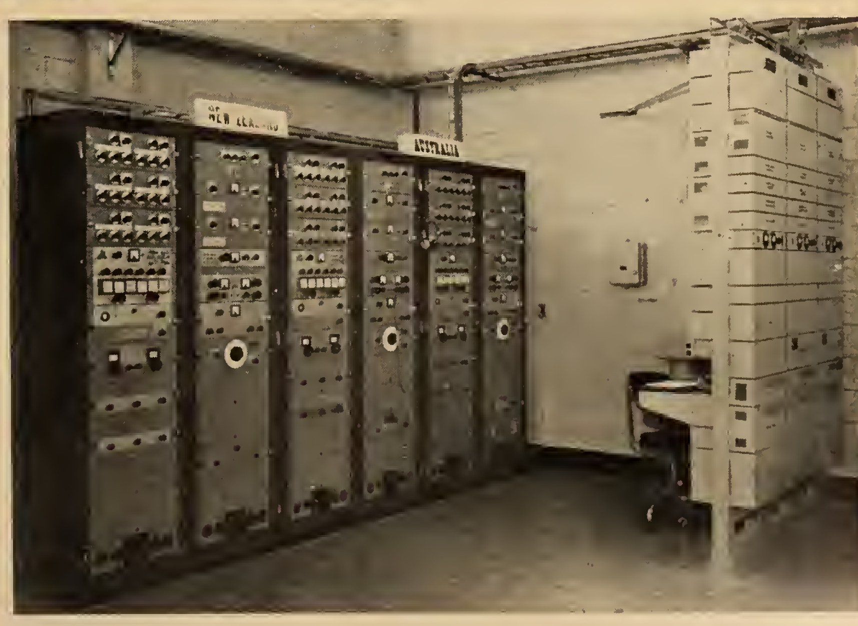
It would make use of all developments in cable and radio transmission and reception for external telecommunication service. Its objectives were the improvement of service generally and the coordination of

AT HOME

The second "4-A crossbar" installation in Canada went into operation in Montreal during 1956. Half the long distance calls in the Bell telephone system can now be dialled directly by the operators. This view is of the automatic trouble recorder associated with the installation.

ACROSS THE GAP

A high-frequency carrier system was installed by Canadian National Telegraphs during 1956 to bridge the gap between North Sydney, N.S., and St. John's, Nfld. The directional antennae at North Sydney are seen here.



OVERSEAS

Part of the installation at the Ladner, B.C., receiving station of Canadian Overseas Telecommunication Corporation. This is equipped with single side band receivers for telephone reception and special narrow band receivers for single side band telegraph. A micro-wave link with the transmitting station provides telegraph and telephone circuits.

The channel 9 antenna being removed from the CBLT tower, in Toronto, during the change-over to channel 6.

BROADCASTING

Electrical engineering and electronics are important fields in television communication. This view of the audio control room in Studio 42 of CBUT, Vancouver, also shows part of the visual control room through the window at left.

Canada's external services with the services of other parts of the British Commonwealth of Nations.

It was quickly apparent that increasing demands for overseas communications services from Canada called for the Corporation to embark on a program of expansion designed to meet anticipated requirements for the years ahead.

Perhaps the most important project under this program was Canada's participation in the transatlantic telephone cable jointly with the United Kingdom and the United States. After some months of negotiations, the Corporation on behalf of Canada, in November 1953, entered into an agreement for the construction and maintenance of a transatlantic telephone cable with the Postmaster-General of the United Kingdom and the American Telephone and Telegraph Company.

The laying of the first section of the cable started from Clarenville, Newfoundland, in June 1955, and the whole system was completed in August 1956. The cable was placed into service on 25 September, 1956. Total cost of the project amounted to some $40 million, of which the Corporation's share was about one-tenth. The quality of voice transmission and reception has been exceptional and public acceptance of this improved facility has been far beyond expectations.

The Corporation constructed a new headquarters building in Montreal (to which operations were transferred in March, 1957). Other recent developments include new trans-Pacific radiotelephone and radiotelegraph services to and from Australia to New Zealand. This required erection of transmitting facilities at Cloverdale, B.C., a receiving station at Ladner, B.C., and the erection of a two-storey building in downtown Vancouver. The new trans-Pacific operations commenced on 1 November, 1956, and for the first time Canada now has direct voice communications with Australia and New Zealand.

It also became necessary to augment overseas radiotelegraph facilities at Yamachiche and Drummondville, Que., owing to the expansion of existing services and the introduction of new direct radiotelegraph circuits between Canada, Germany, and France.

In December, 1956, the Corporation initiated and brought into service International Telex. This is an overseas teleprinter switching system by means of which the user can teletype directly from his own office into that of his correspondent. Service is made available across Canada by means of connections to the Corporation's International Telex switchboard in Montreal and provided by Bell Telephone Company, Canadian Pacific, and Canadian National Telegraphs.

Canadian Broadcasting Corporation

At the beginning of 1956 the Canadian Broadcasting Corporation had the following transmission facilities: radio broadcast stations, 22; frequency modulation, 5; low-power relay stations, 54; television stations, 8. Broadcasting on the International Service was carried out on nine frequencies with a power of 50,000 watts. In addition there were short-wave facilities for national service.

During the year a new combined studio and transmitter plant was constructed to replace the obsolete plant at Gander, Newfoundland.

Modifications were made to two existing television stations. The power of CBFT, Montreal, was increased to 100 kw. E.R.P. visual, 49 kw. E.R.P. aural, and the channel of CBLT, Toronto, was changed from 9 to 6, with power increased to 99.5 kw. E.R.P. visual, 53.9 kw. E.R.P. aural.

New television studios were built or additions made in Halifax, Ottawa, Winnipeg, Vancouver, Montreal, and Toronto.

Three variable frequency drive units were installed to facilitate frequency changes at the International Service transmitters at Sackville, N.B. Many other improvements and studies were made during the year.

RAILWAY TRANSPORT

ɴ Spite of the high level of busi-
ɪess and industrial activity in Can-
ıda during 1956, railroads have not
ɔeen sharing in the general pros-
ɔerity of the Canadian economy.
Though the volume of traffic has
ɔeen high, net financial returns have
ɔeen disappointingly low.

Over the first three quarters of he year 1956, revenue ton miles of reight, the main source of revenue or the railways, increased by some 2 per cent over the same period f 1955. The poor showing in net evenue, in spite of increasing traffic nd the 7 per cent rate increase uthorized last June, was due to apidly growing operating costs. Be-ides the increasing cost of materials, his was also due in large measure ɔ awards for wage increases.

Beyond this, however, it points to ıe need for relaxation of the obso-escent system of regulation by hich the railroads are governed, if ıe industry is going to be able to ıeet increasing competition and pro-ide the service which business, in-ustry and the public expect of it ı Canada's expanding economy.

Passenger traffic during the first ine months of 1956, on the other and, dropped below that of the ame period of 1955 by some 10 per ent. Here, regulation must share the lame with rapidly increasing com-etition from airlines, bus lines and ıe automobile.

anadian Railways in 1954

In 1954, the last year for which omplete statistics have been pub-shed, Canada's thirty railways had ,132 miles of single track, 31 miles ss than for the previous year. Their vestment in road and equipment nounted to $4,550 million. The ımber of locomotives in service ere 3586 steam and 1152 diesel, a total of 4771, compared with 19 in 1953. At the end of 1954 ere was a total of 189,351 freight rs and 6648 passenger cars owned. otal employment at 196,307 persons as 7.4% lower than the 211,951 per-ons employed in 1953; 60,000 of ese were transportation employees, mpared with 63,100 the previous ar.

During 1954, freight carried nounted to 143.2 million tons compared with 156 million in 1953. Locomotive miles operated totalled 160 million against 177.6 million in 1953. Fuel consumed (coal and oil) amounted to 10.3 million tons compared with 11.7 million tons in the previous year. Revenue ton-miles at 57.55 billion, compared with 65.27 billion the previous year. Revenue passenger miles amounted to 2.86 billion (2.98 billion in 1953). Gross earnings in 1954 were $1,019.5 billion; net earnings at $75.9 million were down from the total net of $105.5 million in 1953.

Canadian Railways in 1956

Though up-to-date figures are not yet available for all the Canadian railways, it is possible to record a substantial measure of Canadian rail operations for the year just passed from statistics of Canadian Pacific and Canadian National, which between them account for about 90% of the nation's railway traffic.

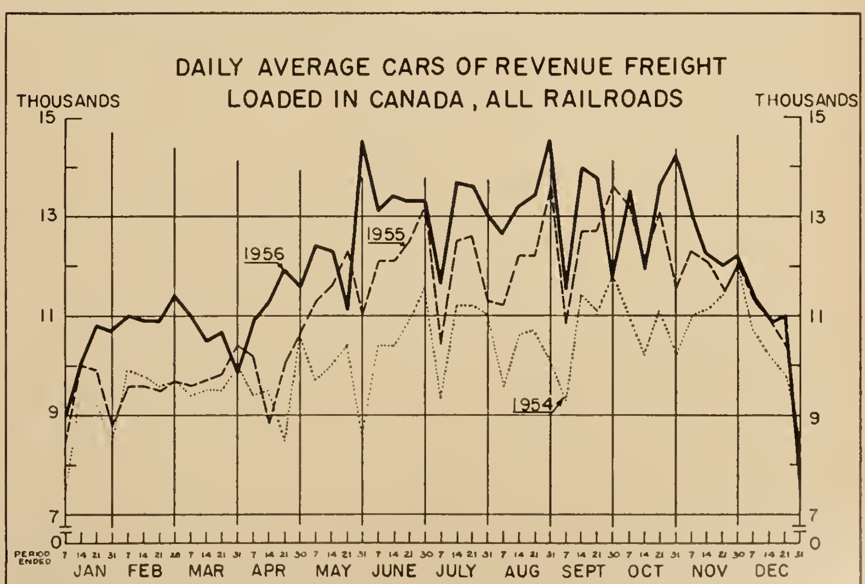
As of June 1956 there was a total of 180,411 railway-owned freight cars on all Canadian railways, of which 7,000 were undergoing repairs. There were also 15,170 privately-owned freight cars.

Canadian National Railways

Canadian National hauled about 12% more freight in 1956 than in the previous year, and record earnings will be reported. Freight traffic, its main source of revenue, is heavily weighted with raw materials which move on low rates. Despite the interim 7% rate increase last July, average revenue per ton-mile continues downward. The further 4% increase to become effective for 1957 on 1 January will still fall short of meeting the full impact of 1956 wage awards.

Equipment. More than $95 million was invested in cars and locomotives during the year. Deliveries of new rolling stock included 324 diesel locomotive units and 4633 freight cars. Two new types of car were introduced for specialized traffic. These are a pulpwood car that increases normal carrying capacity by 70%, and a double-decked automobile transporter that can load eight standard size automobiles compared with the normal four. These, together with an all-purpose box car, are under tests. Orders were also placed for 6110 freight cars and 130 air-dump work cars.

The year saw completion of a five-year plan to dieselize much of CNR motive power. The $220 million spent has resulted in substantial economies. Further development of this plan is contemplated on a territorial basis, commencing at the eastern and western extremities of the system. In Newfoundland 26 diesel units were delivered in November, where complete changeover to diesel motive power is now close to realization. Experiments with motive power were continued. After summer tests in 1956 on a diesel locomotive equipped with hydraulic transmission it is being



observed for winter performance in western Canada.

Operation and Maintenance. For railway track maintenance the company spent some $3 million in continuation of the program for mechanizing track work. Another 140 miles of automatic block signals were added to the 480 miles already installed. The signalling and switching system known as CTC, (centralized traffic control) has raised train speeds and increased traffic volume about 90% without adding physical track. In 1956 the company was able to remove 40 miles of track by applying CTC. There are now more than 700 miles of CTC on Canadian National lines.

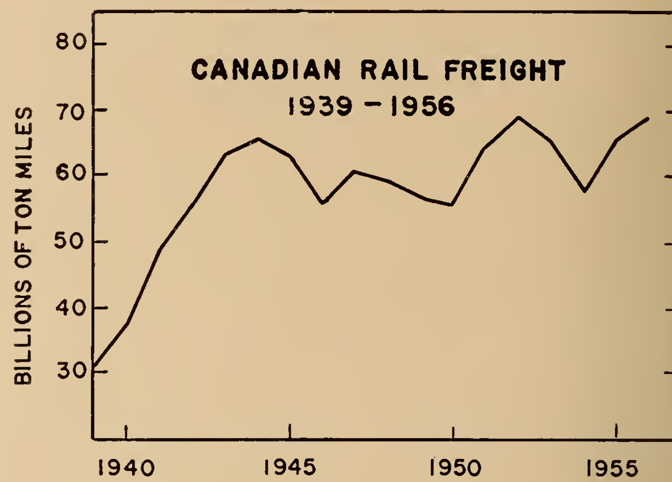
The east-west run of Canadian National's 'Supercontinental' was reduced by 40 minutes and a new 6½-hour mail train was placed on the Montreal-Toronto run. Dinette cars and coffee shop service with popular prices have been well received. Five more dinettes are on order for 1957 delivery.

During the year an entirely new communications service, known as 'Telex' was offered to subscribers. It provides instantaneous two-way written communication between Canada, the United Kingdom, and Europe. It will be extended to other parts of the world in 1957.

Ocean Service. Canadian National Steamships added San Juan, Puerto Rico, to its ports of call during the year, and calls were made in Cuba as warranted. All eight of the vessels in the CNS fleet are now equipped with refrigerated chambers. Fifty-six voyages were made during the year. The motor vessel *Bluenose* commenced operating in August between Yarmouth, N.S., and Bar Harbor, Maine. CNS operates the service on behalf of the Canadian government, and over the first two months of service it carried more than 60,000 passengers and 1,600 vehicles in the daily round trip service.

Construction. Turning to construction, work continued on the company's new Queen Elizabeth Hotel in Montreal, with all but the top three floors closed in at year's end. The hotel will open in 1959. Clearing and grading was commenced at the site of a new automatic hump yard on the outskirts of Montreal.

Elsewhere, a 40-mile diversion of the CNR double-track main line from Montreal to Toronto, between Cornwall and Cardinal, had been built and will be ready for operation in summer 1957. Most of the abandoned section will be flooded a year later, when power from the St. Lawrence is turned on. In Quebec, a 290-mile line from St. Felicien to Beattyville is being constructed through the Chibougamou mining fields, with the track in a usable condition as far as Opemiska at year end.



In New Brunswick, a 22-mile line was cleared and graded through the forest from Bartaboq to serve a new mine site. In Manitoba a route had been surveyed from the Hudson Bay Railway into the Mystery-Moak Lake district to serve International Nickel's new $175 million copper-nickel project, and construction was already under way.

$80 Million Added to Payroll. The cost of wage increases aggregating 11% over the term of a two-year agreement, and a health and welfare plan effective 1 January, 1957, for non-operating employees have to be met following an award made during 1956. This and other awards will add some $80 million to Canadian National's annual expenses. Parallel benefits have been made available to employees not covered by wage agreements.

Canadian Pacific Railway

As was the case with the Canadian National, traffic volume in 1956 for the Canadian Pacific was high and rising, but financial returns were low. The return on net railway investment in 1956 was only some 3.2%, substantially less than earnings in other industries and even below the current return to the investor in many issues of Dominion of Canada Bonds, with their risk-free security.

At mid-1956, the company's rolling stock included 2,000 locomotive units, 80,000 freight cars, 3,000 passenger train cars, and over 6,000 units of work equipment. Investment included an item of $749 million for "rolling stock, steamships and 8 hotels" and another of $199 million for "other properties".

At that time CPR president N. R. Crump told shareholders that during the next 15 years the company would have to meet capital requirements of $1.5 billion, or an average of $100 million yearly. These expenditures would include: for dieselization, $135 million; for renewal and expansion of railway plant, $600 million; for new freight equipment, $480 million; for new passenger equipment $45 million; for new work equipment, $15 million; for hotels, $28 million; for possible construction of a large ship, $22 million; for cargo ship replacement, $28 million; for communication services, $60 million; and for Canadian Pacific airlines $60 million.

Much of the money required, h[e] said, would have to be raised a[s] new capital. Not much more tha[n] $60 million per year would be avai[l]able from depreciation accruals an[d] salvage proceeds. Of the remainin[g] $40 million a year part might co[me] from retained earnings, but much [of] the funds required would have [to] be raised as new capital, and som[e] equity financing would undoubtedly be necessary.

Equipment Modernization. In co[n]tinuation of its modernization and ex[-]pansion program during 1956, Cana[-]dian Pacific placed 115 new dies[el] units into service, bringing to 670 the number of units in operation. Additional high-speed self-propelled diesel operated "Dayliners" were also placed in operation in Nova Scotia on the Dominion Atlantic Railway. They also made their appearance on the Montreal-Boston run, between Montreal and Sutton, between Toronto and Owen Sound, and on Sudbury-Fort William and Moose Jaw-Calgary runs.

A total of 31 of these units were in service at year-end, with a further 11 on order for delivery this year. Some 4,000 freight cars were also added in 1956.

Buildings and Hotels. An extension to the Royal York Hotel, at Toronto, costing some $10 million, was started during the year, to bring its total capacity up to 1,600 rooms, making it the largest hotel in the Commonwealth. Completion is expected for December 1958. A seven-floor open deck 400-car parking building will be added adjacent to the hotel, primarily for hotel patrons. A contract was signed for a new $375,000 office building at Vancouver airport, to serve as a centre for Canadian Pacific airlines $20 million Bristol Britannia expansion program. Completion is scheduled for early this year.

Additions to CPS Fleet. Canadian Pacific's modernization and expansion program was highlighted last year by the entry into service of the 25,000-ton *Empress of Britain*, flagship of the Canadian Pacific Steamships' fleet on her maiden voyage. The company's newest addition to the CPS fleet, *Empress of England*, was launched at Newcastle-on-Tyne in May. (First sailing from Liverpool, April 1957.)

The *Empress of Scotland*, now on North Atlantic cruise service, will reach retirement age in some five years, and purchase of a third new ship, probably of greater tonnage than the *Britain* or *England*, is being considered.

$20 Million Program for Airlines. Canadian Pacific Airlines placed orders for 12 more DC-6B Empress airliners. Four were delivered in 1956, four more are scheduled for delivery in 1957, and the remaining four will be in operation in 1958. CPA last year also undertook a $20 million expansion program to bring a fleet of long range Bristol Britannia turbo-prop aircraft into service on its five-continent airline system. The first five will be delivered in 1957.

Office and Communications Equipment. First deliveries of new yard office and freight office equipment for automatic recording of source data, designed to CPR specifications and first of their kind in use anywhere, were being placed in operation as deliveries were made. The extensive communications network which links this IDB system together was nearing completion at year-end.

The integrated data processing program for streamlining accounting and other railway paper work, begun in 1955, was going forward. Rapid conversion from traditional procedures took place in nearly all departments. The installation at Montreal headquarters of a large electronic computer, equipped with memory core, was also progressing, and operation on an expanding scale was effected early in 1957.

An international teleprinter exchange service from Canada to over 30 countries was completed in 1956 as a joint project with Canadian National; this should be most helpful to Canada's world trade.

PGE Reaches Vancouver

An important event in the annals of Canadian railroading took place on 11 June, 1956, when the Pacific Great Eastern completed its 25-mile extension from Squamish, B.C., the previous southern terminal of the line, into North Vancouver. This extension overcomes the need to ship by ferry to Squamish to connect with the Squamish-Prince George line. The extension was undertaken in 1954 and now provides a system equipped with radio communication between Vancouver and all trains. Currently, a further 330-mile extension north of Prince George is under construction with termini at Fort St. John and Dawson Lake.

TRACK MAINTENANCE

The metal hands of this multiple tie tamper are designed to tamp rock ballast firmly into place around and below the wooden ties. The railways spent large sums of money during 1956 on construction and maintenance machinery. *(Photo: Canadian National Railways.)*

HIGHWAY FREIGHT

COMPILATIONS of statistics relating to the movement of freight carried over Canadian highways on a national basis, commenced in the mid-forties, has to date fallen far short of being a complete coverage. Continued cooperation of provincial authorities and trucking associations is bringing gradual improvement, but much still remains to be done. Since little capital is required to enter the trucking business, many marginal operators are associated with the industry. The large turnover and numerous changes in operators each year creates many problems in the collection of records.

For example, mergers, business failures, the necessary discarding of unsatisfactory reports, inadequate descriptions of business operations, and often lack of maintaining records of tons hauled, have made it impossible to compare reports with those of prior years without adjustments.

In 1954, the most recent year for which a complete annual report was issued, 2411 freight carriers owned or rented revenue equipment consisting of 8455 trucks, 6343 road tractors, 8034 semi-trailers, and 895 full trailers. Operating revenue totalled $181.5 million, and average employment during the year was 20,284 persons.

Tons of freight carried totalled almost 27 million tons. Ton miles were not reported, thus a realistic comparison with rail freight traffic is not possible. From a comparison of tonnages hauled by highway and rail, however, it would appear the highway freight movement amounted to about one sixth of the rail freight moved.

Sample Surveys Being Conducted

Over the past two years, the Dominion Bureau of Statistics, with the cooperation of provincial authorities, has undertaken sampling surveys on highway transport with a view to obtaining more complete and accurate data. To date, results of these surveys for the provinces of Manitoba and Ontario have been published, including the volume of freight carried on both highways and streets. Sample surveys are now being carried out in all other provinces and annual reports will follow until traffic statistics can be produced annually for all Canada.

As a measure of the limited coverage of highway transport operations up to and including 1954, Ontario freight-carrying motor vehicles of all types reported that year added up to 11,365. Freight carried for the year was shown as 10½ million tons. In the sample survey for Ontario in 1956 replies to questionnaires indicated a total of 251,679 trucks registered in Ontario, which carried 142 million tons of goods. Total ton miles amounted to 9.81 billion.

Sixteen Per Cent of Freight Haul by Truck?

In 1954, highway freight carried in all provinces was recorded as some 2.4 times the total for Manitoba and Ontario. Assuming the same ratio maintained in 1956, when the sample surveys were conducted, a similar sample survey for all provinces would have shown some 400 million tons. This total multiplied by the weighted average distance each ton was hauled in Manitoba and Ontario of 30 miles, would indicate some 12 billion ton-miles of highway freight haul for all provinces in 1956. Comparing this with the 74 billion ton-miles of rail freight for the same period would suggest railways may carry about six times as much freight traffic as is handled by motor vehicles of all types in cities and on highways. Expressed in another way about 16% of the entire freight movement in all Canada is possibly handled by motor vehicles.

Industry's Prospects are Excellent

John Magee, executive secretary for the Canadian Trucking Associations of Canada, told the Canadian Manufacturers' Association convention at Toronto in June 1956 that Canada had 69,500 "for hire" trucks engaged in the intercity and rural freight movement, out of a total of 869,000 trucks of all kinds. By 1980, he predicted, this "for hire" fleet would be expanded to more than 156,000 units.

Decentralization was likely to continue, he pointed out. Small centres and light industries form the most important markets for highway freight service. The demand for trucking services would increase proportionately with the growth of these new markets. Automation would increase the need for an even and fully controlled flow of parts and materials, creating a demand for quality transport service.

But some of the industry's problems were the result of factors responsible for its very growth, said the speaker. Wages in the trucking industry would show a tendency to increase faster than the national average. A considerable overall increase in productivity per worker was essential if the industry were to continue to price itself within the market. If the trucking industry's wage bill increases by 30%, the ton-miles carried per employee must increase by 45%, he warned, to reserve its competitive position vis-a-vis other forms of transport.

In many parts of the country the state of the highways had put a severe limitation on the application of technological progress to vehicle construction, said Mr. Magee. Loss of time due to traffic bottlenecks had in many instances been more serious than the savings of time obtained through safe speeds on the open road. Growing importance of international freight movement by trucks made further careful planning of customs clearance facilities and inland sufferance warehouses imperative.

There was little interest among truck operators in immediate use of two-way radio, but there was a rapidly decreasing supply of frequencies. Unless the industry soon reserved frequencies, there would be none left when needed, he warned.

The average outlay per truck had increased by an estimated 50% to 75% over the past ten years. Other capital outlays had increased more than proportionately. In order to maintain the industry's competitive position, the speaker predicted the capital invested per worker would have to increase by 50% over the next decade.

The Automotive Transport Association of Ontario took a searching look at itself at its convention last November. Though delegates foresaw continued growth, they also saw many problems ahead. There was a lack of reciprocal licensing deals which would allow trucks to cross border freely. Average gross revenue per truck in the "for hire" category was only $12,000 per year. Canada lagged behind in the development of trans-continental roads. However, cargo loss and claims damage was better than U.S. coverage and lower tha ail figures. Proper training and licensing was the best way to reduce driving hazards.

Regulation of Motor Vehicles in Inter-Provincial Operation

Regulation of vehicles operating across provincial borders is a controversial subject. After the Imperial Privy Council ruled that such regulation was within federal, not provincial, jurisdiction, Parliament passed legislation giving effect to the judgment but turning regulatory powers back to the provinces on a trial basis.

A conference of provincial representatives at Toronto in September 1956 to discuss the situation failed to arrive at any decision on how to effect uniform regulation.

There is a growing belief within the industry that federal control of interprovincial carriers will soon replace provincial regulatory authority, unless there is immediate action on the part of the provinces towards unification of motor carrier regulations. The need for uniformity is greater now than at any other time in the history of Canadian motor transport.

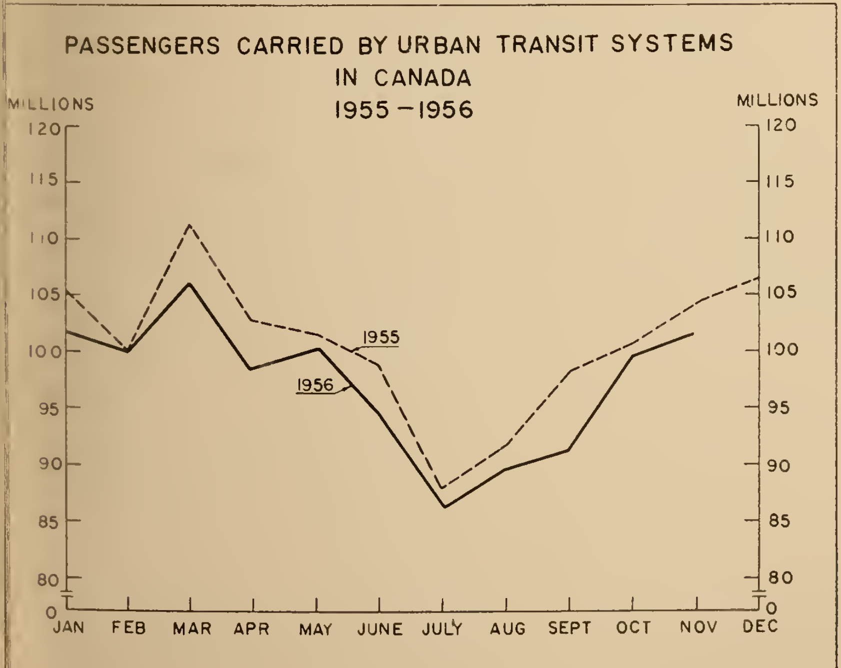
URBAN TRANSIT

EVERY YEAR since 1945 Canada's urban electric railways and their urban motor bus and trolley coach lines have carried fewer passengers than in the previous year. The cumulative drop over the last decade adds up to about a 20% decrease.

In an effort to arrest this creeping paralysis and to keep solvent, the various transit systems have raised fares more than 20%. But with operating expenses mounting yearly for a cumulative rise of more than 40% over the same period, the fat net operating revenues enjoyed during the war years have now practically disappeared.

Statistics for the first 11 months of 1956 indicate the downward trend in passengers had continued for all provinces with the exception of British Columbia. Gross revenue was up some 10% for all Canada, up 19% in Quebec cities, up 14% in Ontario cities, up 10% in British Columbia, and down in cities of all other provinces. Similar trends in transit traffic have been experienced in most cities in the United States.

At the end of 1954, the last full year for which records have been published, 21 transit properties across Canada owned 2,128 electric cars, 56 electric locomotives, 1,144 trolley coaches, 2,348 motor buses, 224 trucks, and 368 express, freight, and miscellaneous vehicles. Total employment for the industry stood at 20,318 persons. By the end of 1956 the number of electric cars was sharply lower while the number of motor buses had been correspondingly increased.



Trend From Trams to Buses

The shift from electric railway to bus operations is illustrated by the fact that over the past 30 years some 43 electric railway systems have ceased operating as such. The convenience of operating over a 'right-of-way' maintained by the municipality or province, combined with the greater manoeuvrability inherent in a free-wheeling vehicle, have encouraged this transformation in transit operations. In 1946, 19% of passengers carried were moved on motor buses and trolley coaches. By 1954 this percentage had risen to more than 55% and the trend was continued in 1955 and 1956 with nearly 75% carried by trolley and motor coaches during the past year.

Solution for Congestion

Addressing the 51st annual meeting of the Canadian Transit Association in May, 1956, C.T.A. president S. E. Preston described Transit's predicament in part as follows: "A solution of the problem of how to provide adequate facilities for the speedy, safe, and economical movement of people in Canada's booming urban areas must soon be found if our cities are to remain desirable places to live and work and do business. Within the next quarter century many of our larger cities will double in size and some may increase threefold. This means transit service will become even more vital than it is today . . ."

"Traffic congestion created by the convenience of the automobile, is the core of the problem. The fact that what has been done to correct the situation is not nearly enough, is generally acknowledged. In the past five years large investments in modernization have failed to pay off, simply because the new vehicles have not been allowed to accomplish the intended purpose through increased scheduled speed. Transit riders have become motorists, and the squeeze on the streets creates a financial squeeze for transit operations . . ."

Outstanding developments during 1956 included a change-over from streetcars to buses in the west end of the city of Montreal last September, and a cessation of operations by the Montreal and Southern Counties' Railway last October.

Interurban and Rural Bus Lines

At the end of 1954, last year for which complete figures are available, there were 298 passenger carriers in Canada (intercity and rural). These carriers owned and operated some 3,000 buses and 78 trucks of all classes, down from 3,245 the previous year. Employment totalled some 2,700 persons. Property account stood at $25 million; transportation revenue at $48.3 million; and net operating revenue at $1.38 million.

These carriers transported 96,250,000 revenue passengers and 28,000 tons of freight, and operated 108 million vehicle miles during 1954. Gasoline consumption for the year was 15 million gallons and diesel fuel used totalled 3 million gallons. Passengers and freight carried in 1955, as well as the number of vehicles and vehicle miles, was lower than for the previous year. These statistics exclude the buses and passenger revenues, etc., which are part of the urban electric railways.

Intercity and rural bus operators in Canada carried fewer passengers during the first eight months of 1956 than in the same period of 1955, but took in more money than in the 1955 period. Only in Saskatchewan and on interprovincial lines were slight increases in traffic shown. Bus miles operated decreased also but not to the same extent. This was in continuation of the trends experienced in 1955 when 203 carriers showed a 7% drop from 1954 in passengers carried, a slight decrease in miles operated, but a moderate increase in revenue. The decreases in vehicles and passengers was principally due to the growth in the number of automobiles in use.

WATER TRANSPORT

THE CANADIAN water transportation industry included 2,246 vessels of Canadian registry at the end of 1955, according to latest available statistics. This total included 1,738 Canadian owned and operated vessels and 508 chartered vessels, but excluded 89 Canadian ships that did not operate. Several ocean-going vessels in the foreign shipping service of Canadian Pacific Steamship Co., being under British registry, were also excluded. These vessels represented a gross investment of $287 million before depreciation, and the employment in the industry amounted to 21,400 persons.

During 1955, vessels of Canadian registry carried 25.6 million short tons of cargo, or a third of the total loaded and unloaded at Canadian ports in foreign shipping. They also handled 94% of all freight carried in coastwise shipping and all freight on inland lakes and rivers. Operating revenue for that year for freight and other services at $263.3 million was 17.8% over 1954.

Principal cargoes unloaded in 1955, the latest year for which complete figures are available, in order of importance and in millions of tons, were: coal, 13.7; iron ore, 4.7; petroleum and products, 3.9; bauxite, 2.9; crude oil, 2.4; and general cargo, 2.0. Principal cargoes loaded were: grains, 19.1; iron ore, 13.7; gypsum, 3.1; lumber, 2.4; newsprint, 2.2; and pulpwood, 1.8. Following previous trends, the largest part of Canada's waterborne commerce was with United States and the United Kingdom, which combined accounted for three quarters of the total tonnage.

Total cargo loaded and unloaded at all ports for the first nine months of 1956 showed an increase of some 22 per cent over 1955, while coastwise cargo unloaded for the same period increased some 15 per cent. Coastwise service includes vessels of Canadian or British registry only, which arrive at or depart from one Canadian port from or to another, respectively.

Grain, Alumina Raised Pacific Tonnage

Pacific ports had a good year in 1956. More grain passed through than ever before, overtaking loading facilities. Grain shipments are now all in bulk. There was also a sharp increase in tonnage of alumina handled from Jamaica, as Kitimat production built up. Movement of coal to Japan showed an increase over 1955. On the other hand, lumber shipments to foreign countries declined sharply. This was mainly due to the release early last year by Britain of her strategic stockpile of lumber. Much of the B.C. lumber was absorbed by the Canadian housing program.

Grain and Ore Made Up For Decreases

Atlantic ports also enjoyed a record year. Though little lumber was shipped overseas, and the movement of bauxite into Port Alfred dropped due to the longshoremen's strike, grain, coal and iron ore more than made up for the losses. Grain shipments were up sharply from 1955. Iron ore shipments, about 80% of which comes up the St. Lawrence, established a new record. The volume of coal from north central states to Ontario and Quebec ports substantially exceeded the 1955 imports.

Canada's export tonnage always exceeds her import tonnage, due to the fact that the former is mainly made up of heavy bulk shipments of grains, ores, forest products and the like, while the latter is predominantly package goods.

Ocean Rates Rising

Ocean shipping rates are trendin[g] upward. Rates for ocean carriage o[f] all dry cargo move up or down wit[h] the trend of ocean coal rates. I[n] November 1956 it cost some $10 to move a ton of coal across th[e] Atlantic; in January 1957 the rat[e] was around $14. Tanker rates als[o] were trending sharply upward a[t] year-end, mainly due to events a[t] Suez and in the Middle East. Th[e] overseas rate structures on packag[e] goods are set up by the 'Easter[n] Conference' and 'Western Confe[r]ence', both of which have offices i[n] Canada. Changes usually call for 6[0] days' notice.

Tramp business was very acti[ve] last year, exceeding even the lev[el] attained during the Korean war; [a] healthy position from the owne[r's] point of view, though hard on t[he] shipper. Rates charged by tra[mp] vessels are set by their owners [by] the law of supply and demand di[c]tates.

Highlights of 1956 Shipping Season

The 1956 navigation season on t[he] St. Lawrence river and through t[he]

An unusual application of water transport inaugurated in 1956 was the bulk transport of kraft pulp, in "noodle" form, in the specially-constructed tanker S.S. *Duncan Bay* from the Campbell River mill of Crown Zellerbach Canada Limited to the converting plant in California. *(Photo: Jack Cash.)*

TRANSPORT BY WATER AND RAIL

A new record was set in 1956 for iron ore shipments, and a major part in this was played by the Sept Iles, Quebec, terminal of the largest producer, the Iron Ore Company of Canada. The mineral is brought by rail to the terminal, below, and transferred to ore-carriers.

Great Lakes was one of the longest and busiest on record both for freight and passenger service. Ocean navigation opened on 27 March on the river, and on 2 April on the Great Lakes. The Lachine Canal closed on 10 December and the last ocean vessel cleared Montreal on 17 December.

Several hundred vessels docked at Montreal during the year for the first time, and the list included 35 ships from 11 companies on their maiden voyages. Several European shipping lines and a large number of European ships made their initial appearance on Great Lakes runs. Alcoa inaugurated a fortnightly service in November between Canada and Venezuela.

Passenger liners on maiden voyages included the C.P.S. *Empress of Britain*, in April; Cunard's 22,000-ton *Carinthia* and Home Line's 26,000-ton *Homeric* (at Quebec) in June, and Cunard's *Ascania* in November. Freight vessels on maiden voyages to or from Montreal included *Sunoak, Sunmoss,* and *Sunpolyina* for Saguenay Terminals' bauxite runs; *Prinz Willem V,* of Oranje Lines; Furness Withy's *Vanguard* and *Venture;* Montreal Shipping Co.'s *Montclair* and *Capo Faro;* Robert Reford's *Lisa Maersk*; and Swedish American Line's *Voxholm.*

Launchings

Launchings took place in Britain of Cunard's 22,000-ton passenger liner *Sylvania*; and for Canadian Pacific's *Empress of England,* both of which are due on Atlantic runs to Montreal in 1957; the *Sunvictor* which will enter Saguenay Termi-

nal's service in 1957; and in Canada the lakers *Sarniadoc,* and *Metis; Calgaradoc* for Canada Steamship Lines; the *Baffin* for government hydrographic service; and a new icebreaker, the *Montcalm,* which will replace the *Lady Grey.* A 21,000 'laker' of 780,000-bushel capacity, being built at Port Willer for St. Lawrence Transportation Co. will be ready for the 1958 navigation season.

Improvements to Seaway Ports

Though improvements at National Harbours' Board ocean ports in the maritime provinces and in British Columbia were not extensive during 1956, anticipation of the Seaway opening in the spring of 1959 had initiated plans for developing many St. Lawrence and Canadian Great Lakes ports. The N.H.B. expects to spend some $50 million on eight major federal harbours over the next eight years.

Chief beneficiary will be the port of Montreal, where an $11 million program is already well under way. The port of Toronto's Port Authority is keeping well ahead with its traffic handling facilities. At Lakehead, Sarnia, Windsor, Hamilton, Brockville, Cornwall, Trois Rivières, and Quebec, development programs for improvements of harbours and cargo handling facilities of various dimensions and at various costs are planned.

In this respect, development of seaway ports is being paced by the huge sums appropriated for American Great Lakes ports, notably Chicago, Milwaukee, Detroit, Toledo, Cleveland, and Rochester. The United States government is also committed to an expenditure of some $150 million over the next ten years for channel improvements in the five Great Lakes.

Bigger Lake Traffic Means Lower Rates

Few national projects have so captured the imagination of the Canadian people as the St. Lawrence seaway and power project. Several study groups, both in Canada and the United States, are conducting continuous studies of the traffic and economic aspects. Apart from the 2.2 million horsepower to be developed, of which Canada gets one half, the prospects for benefits to navigation and trade are colossal. Tonnage to be carried annually is variously forecast at from 30 to 36 million tons.

Rates on the Great Lakes are generally patterned on the rail rates between the same points. They are influenced by special 'commodity rates' allowed by the railroads over certain periods of the year. Thus they are little affected by changes in ocean rates.

Ungava iron ore production was the leading factor in finally bringing the project to reality in 1954. Economists and engineers foresee inbound traffic due to increase sharply due to this ore movement, resulting in more empty outbound cargo space and thus a trend towards lower shipping rates for Canada's farm and forest products and mineral resources.

Shipping men predict that 'lakers', rather than ocean vessels, will derive the lion's share of the increased traffic. This is due to the extension of a calm protected waterway, wide and deep enough to float these economical, large capacity inland vessels, from its present limits at Prescott right down to the gulf.

Should U.K. Cabotage Treaty Be Repealed ?

But there are many doubts and misgivings among the shipping interests, most prominent among them being the divergent views about legislation respecting coastal shipping. About 8% of this movement is customarily handled by non-Canadian ships, mostly of British registry. Submissions to Canada's Royal Commission on Coastal Shipping, set up in 1954, broadly speaking have criticized Canada's cabotage treaty with the United Kingdom, which permits British flag vessels to carry cargo between Canadian ports and asked its repeal, or argued strongly against any change in legislation.

Owners of Canadian vessels plying the Great Lakes, Canada's shipbuilders, the Dominion Marine Association and some industries are for protection of Canadian vessels by repealing the legislation. The Shipping Federation, the British shipbuilding industry, and grain growers and other groups which want to hold rates down, argued for no change.

They point to the need for Britain to earn dollars to pay for the primary products we sell her. Some urged a wait-and-see policy until it is shown Canadian shipping cannot meet the competition. The railways suggested a compromise by forcing owners of British ships to pay their crews Canadian wages. It appears likely a decision will be deferred as long as possible on this 'hot-potato' issue.

American Subsidies a Threat

Of deep concern to Canadian shipowners was the U.S. Maritime Administration's announcement a year ago that American Great Lakes ship operators would be made eligible for government subsidies by declaring the ocean route between lake ports and Western Europe 'essential' to U.S. trade and economy. Under the new subsidy program U.S. vessels may pick up and discharge at any Canadian lake ports. The program will probably be extended to traffic from lake ports to the Mediterranean, the West Indies, and the Caribbean.

This would create stiff competition for Canadian vessels plying the same route. The Canadian Shipowners' Association contends this means "the seaway will become a beautiful highway for everybody but Canadians, though Canada puts up the money for it".

Tolls Must Be Applied

Seaway tolls present another problem. The Dominion Marine Association, and the Lake Carriers' Association (its American counterpart) have urged that seaway canals should be toll free, saying they had already been tried in Canada and had been abolished. A prompt and firm 'no' was given them by Canadian government officials. It had been a condition of the 1954 agreement between the United States, they pointed out, that tolls should be assessed on shipping sufficient to amortize the cost of building the navigation facilities over a term of fifty years.

Could Seaway be Kept Open In Winter ?

Many ideas have been advanced for keeping the Seaway open in winter by utilizing warmer lake-bottom water, and by diverting its flow through the gulf, but estimated costs outweighed advantages. Interest has arisen, however, in recent proposals to keep seaway channels open by 'bubbler systems', as now used at many Canadian power plants to keep intakes open and to reduce upstream ice pressure on dams, thus permitting more slender designs.

Sweden has been using this idea for years for keeping a ¾-mile ferry channel open, now plans to utilize the principle in maintaining winter navigation on a 60-mile channel connecting the port of Vasteras with the Baltic Sea. For the Seaway, its use would be confined to parts of the 400-mile stretch between Lake Erie and Quebec City, at canal locks and on improved channels, since lake surfaces only freeze over along the shore line and in shallow bays.

Flexible perforated polyethylene pipe of 1½-inch diameter would be used. Total cost of installation is not expected to exceed $2 million. The pipe would be weighted down, and anchored in stretches where the current was swift.

PIPELINE TRANSPORT

At the end of World War II, transportation of oil and natural gas by pipeline in Canada was still in its infancy. Edmonton, Calgary, Lethbridge and surrounding areas received natural gas from the Viking-Kinsella, Bow Island and Turner Valley fields, while in Ontario, Union Gas Co. of Chatham had a pipeline system in Southwestern Ontario. Turner Valley crude was delivered by pipeline to refineries in Calgary, and twin pipelines built during the war brought foreign crude from Portland, Maine, to the Montreal market. Elsewhere movement of crude was entirely by railway tank cars, lake tankers and tank trucks.

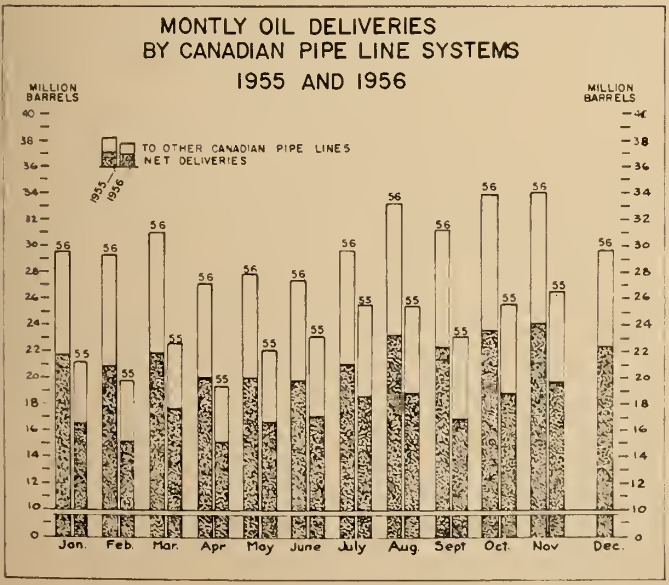
The Boom in Oil Pipelines

Discoveries in the late 'forties' in Alberta made outside markets for Alberta's Leduc and Redwater oil fields an economic necessity, and the 20 inch Interprovincial oil pipeline was built in 1949 from Edmonton to Superior, Wisconsin to fill lake tankers. Later it was extended south of Lake Superior, across the Straits of Mackinac and northern Michigan, right into Sarnia, Ont. By 1952 the 24 inch Transmountain oil pipeline was laid from Edmonton to Vancouver and the B.C.-Washington boundary via the Yellowhead Pass and Kamloops. In 1956 these two main pipelines transported some 97 million and 47 million barrels of oil respectively.

Seven Year Delay For Gas Pipelines

Natural gas pipelines for exporting British Columbia and Alberta gas to distant markets had to wait many years for clarification of policies on the part of the Alberta and Canadian governments, and on U.S. Federal Power Commission approvals. As far back as 1947 many pipeline companies had sought incorporation and competed for the right to serve rich untapped markets in the Pacific Northwest states and in Canada's central provinces.

Finally in October 1955 FPC approval was given for Westcoast Transmission to export gas to the Pacific states. The Trans Canada pipeline system, however, did not get government approval until 1954, when amalgamation between two rival pipeline companies was forced by the Federal government. It could not even then prove its ability to finance the project. Not until June 1956, after long and heated debates in the Canadian House of Commons, did it win promise of government assistance in building its line through the thin market area in Northern Ontario, and approval and loans for building as far as Winnipeg.



1956 Pipeline Building

While pipeline mileage continued to grow during the first half of the fifties, pipeline construction in 1956 topped all previous years by a wide margin. This was of great significance, pointing as it did to a continuing program of this type of hydrocarbon transportation.

Natural gas led the parade of the record pipeline construction season in 1956, with an enormous outbreak of activity from British Columbia to Central Saskatchewan. Westcoast Transmission's 650 mile 30 inch natural gas pipeline, started late in 1955, was 70 per cent completed at year-end and will be in operation by September 1957, connected up at the International Boundary to the Pacific Northwest system, which already is servicing Vancouver with New Mexico gas on a temporary basis. The Saskatchewan Power Corporation laid a record mileage of new trunk lines for its rapidly expanding system. In between, Alberta's domestic markets accounted for even more mileage than Saskatchewan. Finally the long-delayed 34-inch export gas pipeline eastward from Alberta fields made a start on its route to Winnipeg and had 230 miles laid by freezeup, out of its 575 mile distance to Winnipeg.

Though crude oil pipelines assumed a secondary position for construction of new projects and looping of old lines, the economic significance of the year's accomplishments was far greater than the reduced mileage of 1955 would have indicated. New markets were opened up for oil from both Saskatchewan and Alberta by major pipelines, and geographical allocation of fields to markets was readjusted in both provinces.

Products pipelines in eastern Canada expanded their traffic volume much faster than expectations, and plans to loop one products line in

Ontario were completed. Interprovincial announced firm plans to extend 150 miles from the present terminus at Sarnia to Port Credit outside Toronto in 1957, demonstrating Toronto's rising importance as a refining centre.

Total natural gas pipeline mileage for trunk and gathering lines built during 1956 added up to almost 2,200 miles, bringing total gas-line mileage for Canada to close to 5700 miles. City and town distribution system construction across Canada from Vancouver to Toronto added 5 million feet or over nine hundred miles. The total for these distribution lines amounted to over 6700 miles at the end of the year. Total oil pipeline mileage laid in 1956 added up to some 770 miles exclusive of looping, bringing the total oil pipeline mileage in Canada to some 5770 miles. Thus construction of oil, gas, products and gas distribution lines during 1956 totalled some 2970 miles, as shown in detail in Table I.

$118 Million for Purchase of Main Line Pipe

Up to year-end, orders placed for pipe in large sizes for the two major pipeline systems had amounted to some $118 million. Westcoast bought their 30 inch mainline pipe from the South Durham Steel and Iron Works in Britain at a cost of some $32 million. Trans Canada purchased 575 miles of 34 inch pipe for the Alberta-Winnipeg section from U.S. Steel Corporation at a cost of $32 million, and placed a $9 million order with the same company for 24 inch and 12 inch pipe for the Toronto-Ottawa-Montreal section.

In June, Trans Canada announced a contract with the South Durham Steel and Iron Works for supply of 30 inch pipe for the 636 mile northern Ontario section of the line to be built by the Crown Pipeline Corporation from Winnipeg to Kapuskasing. With a pipe mill under construction to produce pipe in large sizes in Canada, a contract for 30 inch pipe from Kapuskasing to Toronto was placed last fall at a price of some $45 million.

Most of the 120,000 tons of pipe needed for the Alberta Gas Trunk Line Company's gathering system, as well as that needed for distribution systems, are of sizes that can be rolled in Canada. Pipe rolling mills have been built at Vancouver, Edmonton, Regina and Sault St. Marie, as well as the big mill of Welland Tube Co., at Welland Ontario, which will commence rolling pipe early in 1957 in sizes up to 34 in. diameter.

Table I. Pipeline Mileage Built In 1956

Company	Miles	Size	From	To	Completed
Gas					
Westcoast	460	30"	Taylor, B.C.	U.S. Border	70% Completed
Westcoast	46	20"	Huntington	Vancouver	Completed
Sask. P.C.	120	12"	Success Field	Moose Jaw	Completed

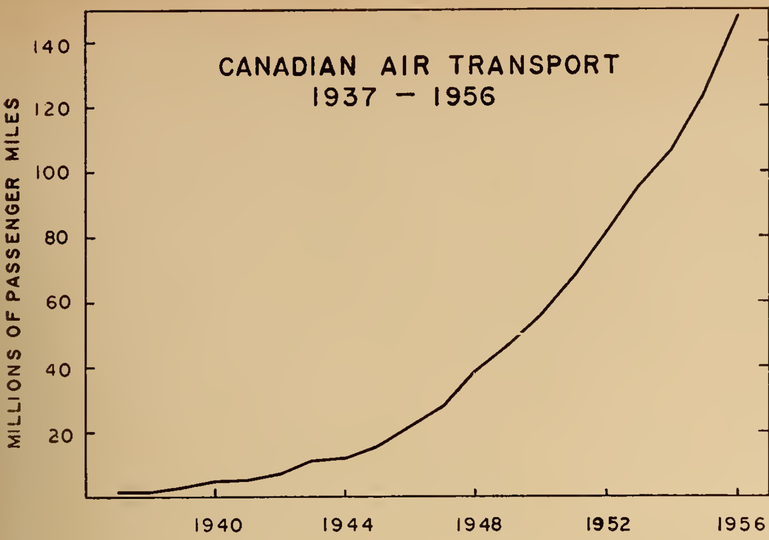
1956 Total Oil Lines	776				

Big Mileage Assured Over Next Two Years

Trans Canada's western section will be completed through Winnipeg to Port Arthur during the current year, as well as the leg between Toronto and Montreal with a branch to Ottawa. The entire gap between Port Arthur and Toronto is scheduled for completion by the late fall of 1958. Construction of the Alberta gathering system will be carried out in three stages over the next three years. Distribution lines including those for the sprawling Inland Natural Gas system throughout interior B.C. and Union Gas Co.'s system in Ontario will also be built. Thus further new records are probably in store for 1957 and 1958.

A products pipeline costing $60 million from Alberta to Lakehead, to be integrated with the Trans Canada system, was proposed during the year by Canadian Hydrocarbons Ltd. Though the exact route was not established, it will include a gathering grid in Alberta with an 8 inch line to Regina and 6 inches eastward.

It will move large quantities of liquid hydrocarbons from the 'wet gas' fields of Alberta which are removed from the gas before it enters the Trans Canada pipeline. Being a common carrier it would also move refined gasoline from Edmonton refineries to Winnipeg. Propane and butane will be carried in liquid state under pressure and sold as heating fuels to distributors along the route. With initial capacity of 10-12 thousand barrels daily, it will have storage facilities along the route. Completion is called for by the end of 1958.



CIVIL AVIATION

The best yardstick with which to measure the growth in Canada's commercial air transport is to compare it with rail transport. Over the past decade, while rail passenger travel decreased 55 per cent, air passenger travel increased by 880 per cent. Air freight during the same period has increased more than threefold.

Though full statistics for 1956 are not yet available, current rates of growth can be measured from the records of Trans Canada Airlines, Canada's 'chosen instrument'. T.C.A.'s passenger traffic for 1956 was 23 per cent higher than in 1955, while air express and air freight recorded gains of 20 and 19 per cent respectively over the previous year. Due to the 'all up' carriage of mail introduced in 1948, air mail ton miles have also grown in an impressive fashion; 1956 witnessed a 12 per cent increase in mail flown compared with the previous year.

Trans Canada Airlines

The traffic increases were made possible by continuance of TCA's program of fleet expansion and modernization. During the year six new aircraft were added to its fleet, which now includes 18 Viscounts, 18 other turboprop aircraft, 9 Superconstellations, 21 North Stars, and 24 DC-3's. The company has almost 8,000 employees distributed over its 2,500 miles of air routes.

At present on order are two Viscounts, as well as four Douglas DC-8 jet aircraft for 1960 delivery, with an option on two more. These DC-8's are powered with Rolls Royce Conway turbojet engines and will carry 120 passengers and three tons of cargo at 550 miles an hour. They will cut present flying time almost in half.

A third of T.C.A.'s service last year was tourist class. Family fares, extended in 1955 to North Atlantic service, were continued. The company also introduced overseas excursion fares and an extra-cities plan for European travellers. Additionally, reduced immigrant fares were started in November. Jointly with other airlines, T.C.A. also cooperated in the carriage of refugees from Hungary and flew large quantities of relief supplies.

Canadian Pacific Airlines

Canadian Pacific Airlines, whose domestic service in Canada is limited to routes of lower traffic density, is developing its services rapidly on transpolar routes to Europe, to the South Pacific, to Mexico and South America, and to Japan. Service was extended last year from Lima, Peru to Buenos Aires, with two flights weekly.

Flights over the North Pole between Vancouver and Amsterdam were increased with a second weekly flight, and a third for the summer traffic peak. In addition, services to Mexico from Toronto were increased from one to three flights weekly, while flights from Vancouver to Honolulu were boosted from two to five flights weekly for the winter tourist season.

During the past year CPA placed orders for 12 more DC6B Empress Airliners. Four of these were delivered in 1956, four will be delivered this year and the remaining four will be in operation by mid-1958. The company also undertook a $20 million expansion program in 1956, which includes a new office building at Vancouver Airport, and a fleet of five long range Bristol Britannia turbo-prop aircraft, the first of which will be delivered in 1957.

To provide a speedy and economical means of international communications to help in developing Canada's world trade, CPA completed a joint project in 1956 with the Canadian National for installation of an international teleprinter exchange service to over 30 foreign countries.

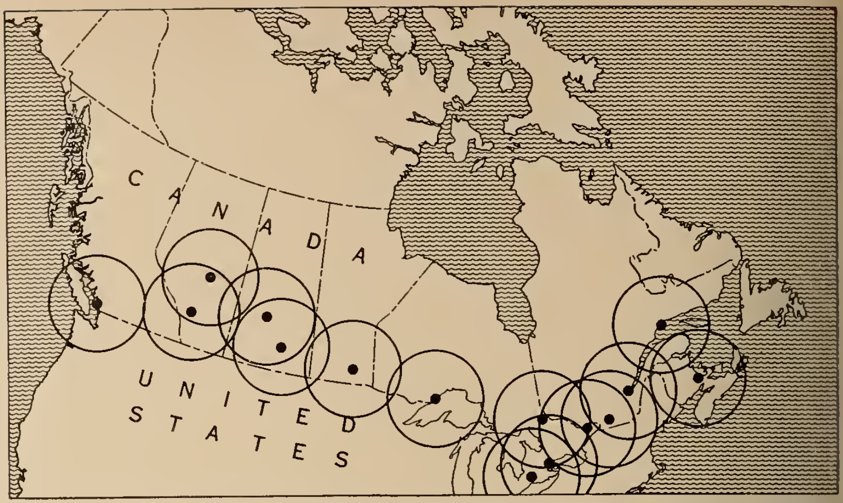
Other Air Carriers

In addition to Trans Canada Airlines, five other scheduled air carriers are operating in Canadian domestic service. These are Canadian Pacific Airlines, Central Northern Airways, Maritime Central Airways, Queen Charlotte Airlines, and Quebecair. These five carriers owned 80 aircraft at the end of 1955 compared with 63 operated on domestic service by T.C.A. at that time. They handled 116 million passenger miles

Steelwork for Montreal's Dorval Airport building. (*Photo: Dominion Bridge Co.*)

in 1955 compared with 668 million for T.C.A., and carried 3 million ton miles of freight compared to T.C.A.'s 13 million ton miles. These scheduled air carriers employed about 2,000 persons.

Beyond these are a group of Class B, C and D non-scheduled air carriers which between them owned or leased 578 aircraft in 1955. Revenue passenger miles for these 'non-scheds' in 1955 amounted to some 9.4 million compared with 826 million for all scheduled domestic air carriers, and 613,000 ton miles of freight haul. The non-scheduled carriers employed some 2150 persons.



Part of the Department of Transport's program of airport development and air traffic control is the installation of radar control, at fifteen of the main airports across the continent, as shown on the map. Network will be almost continuous.

Northern Operations

Northern operations include special airlifts, aerial surveys for industry and for governments, aerial spraying for forest areas, air exploration and geological surveys for the mining and petroleum industries, and other charter flying such as service for the DEW and Mid-Canada radar lines. Looking at civil aviation in these fields, there is little doubt that the future was never brighter.

The wealth of experience gained in the operation of multi-engined aircraft under severe Arctic conditions has been of tremendous value to our civil carriers and to the nation. Air surveying in Canada is experiencing a phenomenal growth and this country now leads the world in the development of airborne geological survey equipment and techniques.

In the helicopter field, the demand in northern areas for this type of service increases each year, and in 1956 more than 60 civil aircraft were registered in this service. Rotary-wing aircraft are playing an increasingly important role in the development of our natural resources. Their use in mainline operating however, is difficult to predict at present.

Ground Facilities and Services

Airports are inadequate in many places and are barely keeping pace with the rapid developments aloft. New runways will have to be built, and at some airports present runways need to be increased in size. At some of the larger airports existing runways will need strengthening to bear the weight of the new and heavier aircraft types. Elsewhere new airports will have to be built in their entirety.

The problem of congestion at airports, while not yet as serious as in the United States, is becoming increasingly acute. Measures must be taken for creation of satellite fields for segregation of military and lighter aircraft in the growing volume of civil aviation operations. New and larger terminal facilities are required at most of Canada's airports, with adequate accommodation for passengers, cargo, and mail, as well as for ground transportation.

There has been rapid development over the past decade in technical aids to navigation over land, sea and in the vicinity of airports. This trend is likely to continue, including provision for better meteorological service, replacement of existing medium-frequency radio ranges, and automatic approach aids. Airborne radar will be further developed for storm surveillance and flight control.

Current additions to airports include a new administration building at Dorval commenced late in 1955, with structural steel now erected, a new terminal building at Ottawa airport costing $2½ million, started in June 1956; new terminal facilities at Torbay Airport in Newfoundland, to be completed in 1957; and a terminal building at Quebec airport costing $750,000 announced August, 1956.

Department of Transport has a sum of $38 million in its 1957/58 estimates, some $17½ million higher than appropriated in 1956. New terminal buildings are proposed at Gander, Dartmouth, Winnipeg, Edmonton, Aklavik, and Yellowknife.

It was announced in April 1956 that Long Range Surveillance radar for control of aircraft on fifteen major Canadian airports would be in operation within two years.

A 40-foot antenna of the type to be installed for the Dept. of Transport was designed to give a scanning range of 200 miles with tracking up to 70,000 feet. ***(Photo: Raytheon Manufacturing Company.)***

CONSTRUCTION

At the close of 1956, having experienced a year in which one in every five dollars spent in end goods and services was a construction dollar, the industry through the Canadian Construction Association, issued a statement of policy.

Its recommendations covered such things as development of increased trade training and immigration programs, conservation of resources, the development of a Dominion-provincial highways board.

Among the conditions accounting for the well being of the construction industry in 1956 were improved economic conditions, increased production of cement, steel, etc., and a larger volume of winter construction.

A point on the C.N.R.'s Beattyville-Chibougamau-St. Felicien branch line in Quebec.

Piledriving for Stelco's new reversing cold mill, November 1956.

THE CONSTRUCTION INDUSTRY is by far the largest in volume of production of all industries in Canada, with an estimated value of work performed totalling about $6 billion in 1956, or 18 per cent of the gross national product.

Some of the main achievements in 1956 were: 136,000 houses and apartment units completed; the St. Lawrence seaway close to the halfway mark in construction, with work well advanced on related hydro-electrical power developments; large power projects such as the Sir Adam Beck and Bersimis hydro projects in operation; the gas pipelines from Alberta to the Pacific Coast and Eastern Canada progressing. Other projects in the news were: the DEW-line and Mid-Canada line of radar installations; pulp and paper mills; oil refineries and petrochemical projects and a number of large scale mining projects; a record roadbuilding program. The huge Camp Gagetown in New Brunswick neared completion, and large projects like the Queen Elizabeth hotel in Montreal, the Imperial Oil building in Toronto and new post offices in Winnipeg and Vancouver were under construction.

The Statistics

The statistical problems relating to the compilation of an up to date report present many difficulties. For this reason a full report is always about a year late in publication.

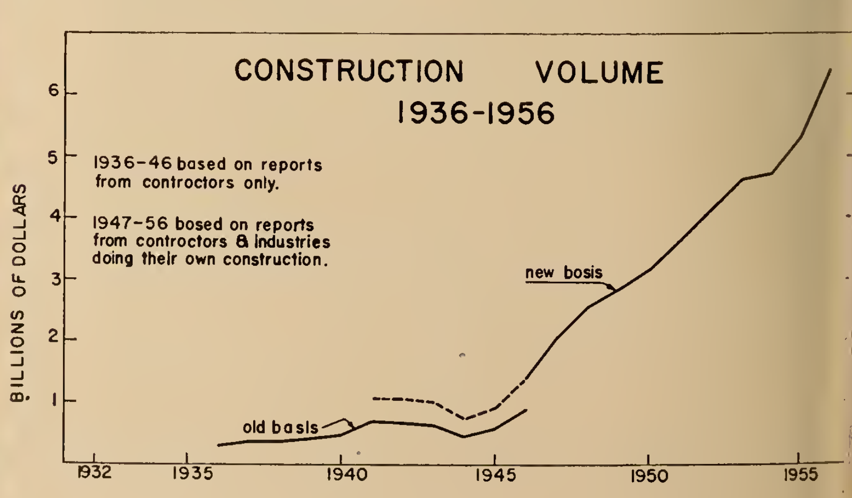
Customarily, however, the full report for any year includes a forecast of intentions for the ensuing year, based mainly on data collected at the same time and from the same sources as that used in the Department of Trade and Commerce Survey of Private and Public Investment in Canada for the year following. Estimates of intended construction in the past have been found to be from 3 to 8 per cent lower than the final estimates after the year was over. In 1955, the estimate of the intended construction program was some 5 per cent lower than the actual total volume put in place during the year. The breakdowns by categories and provinces are of course subject to greater error than the total for Canada.

The value of intended construction for 1956 had been forecast at $6.27 billion, or 19 per cent above the 1955 level, with most of the increase occurring in industrial building and in engineering construction, particularly in gas and oil facilities and in electric power construction, with increases over 1955 of $149 million and $131 million respectively.

Residential building was expected to remain about the same as in 1955. But due in part to the steel strike in the United States last summer, as well as to the tight money situation which developed, and to the sharp drop in residential construction during the last few months of the year, the actual volume may turn out to be nearer to $5.75 billion for 1956, an increase of only about 9 or 10 per cent over 1955.

This is borne out by the report on "Contract Awards" for 1956, published in the Maclean Building Guide, which is based on reports covering about 60 per cent of actual construction done. Awards for residential construction in 1956 were 11½ per cent below those in 1955, though business and industrial category awards were up 9 per cent and 18 per cent respectively, while engineering construction awards showed an increase of 30 per cent over the previous year. Total awards in 1956 showed a 7.6 per cent increase over the total for 1955.

The gain over 1955 in physica



volume was not as great as seemed highly probable even as late as midsummer 1956, and in terms of constant dollars was probably about half cancelled out by the rise in the cost of construction index of about 3.4 per cent during the period.

For the same reasons, the expected average employment in the industry of 648,545 workers as indicated from the survey of "intentions" for 1956, or 100,000 over the average employment in 1955, will probably be an over-estimate. The actual average number of workers in the industry last year will probably be found to be close to 600,000.

Pattern of the Industry, 1955

In the year 1955, the last for which a complete report has been published, the industry employed an average of 550,200 workers, purchased materials valued at $2.46 billion and performed a volume of work valued at $5,285 million. The number of employees working for different groups was divided as follows: contractors, 366,743; utilities, 72,245; governments, 63,862; and others, 47,380.

By regions, British Columbia, employed 54,000 and performed work valued at $572.6 million; the Prairie Provinces employed 109,360 and performed work valued at $1,141 million; Ontario employed 187,870 and performed work valued at $1,841.7 million; Quebec employed 148,670 and performed work valued at $1,343 million; and the four Maritime Provinces employed 50,325 and performed work valued at $387.3 million.

Broken down by categories, values of construction performed in 1955 in millions of dollars for both new construction and repairs, were as follows: residential, $1,734; industrial, $409; commercial, $529.7; institutional, $461.3; other building, 239.8; marine, $77.2; highway and airport, $508; waterworks and sewage, $182.3; dams and irrigation, 29.4; electric power, $328.4; railway and communications, $310.6; gas and oil facilities, $309.6; other engineering construction, $166.3.

Construction Costs

Basic construction costs for residential and non-residential types of construction were on the average 3 per cent higher in 1956 than in the preceding year. This rise compares to a per cent rise from 1954 to 1955. These are C.M.H.C. indices, supplied Canadian Construction Association.

The MacMillan and Bloedel building, Pender at Bute Streets, Vancouver. (Right)

The Nickel District Collegiate, Sudbury, Ontario.

Extensions to Saint John General Hospital, Saint John, N.B.

Residential building materials prices averaged 3.3 per cent higher compared to the year before; for non-residential materials the increase was 3.6 per cent. Wage rates rose by 2.9 per cent.

Since the base year of 1949, wage rates of construction workers have advanced considerably more than the other main component of basic construction costs, building materials prices. Basic construction costs in 1956 for residental and non-residential types of construction were 36 and 35 per cent respectively over the levels of 1949. Hourly earnings in these seven years have increased by 50 per cent, while prices of the two major classes of building materials averaged a 30 per cent climb.

Credit

There was basis for the opinion that the credit curbs instituted during the year as an anti-inflationary measure seriously affected the industry, especially housing. The restrictions seemed, to some, to be directed mainly against construction. But the higher financing costs on the part of both owner and contractor could have the effect of increasing costs without reducing the number of projects. The industry through C.C.A. asked the government in a brief submitted in February 1957 to consider these effects, as well as the better timing of credit curbs to the seasonal aspect of construction.

There was discussion of methods o cutting costs on new homes to com pensate for the increased interest o mortgages, which was provided t help to make more investment fund available for this purpose.

Efforts were being made to obtai exemption of building materials fro federal tax. Full exemption was re ommended for such things, now onl partially or conditionally exempte as reinforcing or structural stee plumbing, heating, and ventilatin materials; lumber; soil and sewer pipe; and also exemption was requested for a number of electrical materials, nails, septic tanks, air conditioning equipment, some builder's hardware items and construction equipment and tools. The C.C.A. was supported by the Canadian Manufacturers Association and the Canadian Tax Foundation in these requests. It was said such exemptions would remove an appreciable factor in construction costs.

Among other recommendations made toward the financial stability of the industry were requests for certain income tax adjustments, and close supervision of special tariff arrangements concerning temporary importation of construction equipment. Foreign project insurance was recommended. Still outstanding is a decision on C.C.A. recommendations that the use of guarantee or surety bonds be adopted instead of security deposits on federal government projects.

Accounting For The Volume

Manufacturing industries, according to preliminary report of the Department of Trade and Commerce, made capital expenditures of well over one billion dollars in 1956. This included construction at close to $500 million, and machinery and equipment at around $800 million.

Expansion characterized most of the industries, as a later section of this *Journal* will show, taking many forms, and with many projects only partially completed at the end of the year. Some of the larger projects are complex, comprising several phases and costing up to $200 million, and intended to provide power facilities and shops, mills, plants, dock extensions, townsites, etc.

"Warehouse, plant and office" was familiar description of a new project. But published plans contained such various specifications as: smelter wharf and townsite; coal washing plant; power plant; $15 million iron ore development; paperboard mill and office building; cement plants; automotive equipment plant; steel pipe plants; hardwood pulp mills; for the chemical industry, chlorine and caustic soda plant, a pentachlorophenol plant, an ethanolamine plant, polyethylene plant, acrylic fibre producing plant, catalytic reformer; mills in the uranium areas; iron treatment plant; mine buildings; $7 million extension to an already large electrical plant; underground

Federal Building in Lunenberg, N.S., housing postal, fisheries, customs and unemployment offices. Curling Club at Bridgewater, N.S.

reservoir and pumping station.

Geographically the expansion was general, moving steadily if not equally in volume, to the east, south and west, but with an increasing pace to the northern development sections.

Many of the large contracts resulted, of course, from the St. Lawrence seaway. The pipelines also represented a large factor in the 1956 volume.

Other components of the capital investment in construction were expenditures by governments on buildings on other structures; by the public utility systems on water works and power projects; by transportation agencies on civil aviation, railway and water transport facilities; by communication companies; by wholesale and retail trade and financial and commercial services on buildings.

Defence Construction awarded contracts to the average value of $10 million a month in 1956—the major projects being accommodation for the Army and communications for the R.C.A.F., the Mid-Canada Line.

Housing was a major item, as always, despite adverse financial conditions. The number of houses completed in 1956, 136,000 dwelling units, is a new record in numbers. The actual size and value of these units increased in value also. The number of starts among housing units of modest size fell off sharply in the second half of the year.

The adverse conditions mentioned above are as follows: the untapped sections of the housing market which could affect the volume are mainly in the lower income groups of potential home owners — but a reduction in prices of homes must overcome such factors as rising wage rates, more expensive installations, inflated land costs and often the expense of servicing the land hitherto carried out by the local municipality, higher interest rates and general financing costs, more stringent standards of construction and planning controls.

The C.C.A. has made strong recommendations that the industry and government study the question of the provision of houses to those with annual incomes of $5000 or less.

Institutional Construction

Schools were built in every province to a total estimated cost of $202 million to accommodate the increasing number of students in all levels of education. Enrolment, generally, is higher than ever and promising to be greater still due to postwar birthrates and immigration. On the lists for 1956 were elementary schools, high schools, university additions, convents, kindergartens, school administration buildings, normal schools, vocational schools, many of them large projects.

Hospital construction cost about $130 million in 1956. This phase of construction was also a coast to coast activity. Boards of health and private hospital boards carried out earlier plans or launched programs for needed medical facilities, orphanages, homes for the aged, nurses' residences, etc. Some structures cost up to $15 million.

THE SEAWAY

At the end of the 1956 construction season, with a couple of months more than half the alloted time elapsed, work on the St. Lawrence Seaway and Power Project was 'on schedule', and almost half completed. This was the opinion expressed by officials of the four 'Authorities', one for power and one for navigation in each of the nations concerned.

Some elements were well ahead of schedule. Others were slightly behind, but for these there was still time to catch up. The Long Sault dam, moreover, was being built on a very tight schedule, and continuation of the good progress to date was a 'must' if the first generators can be 'on line' by September 1958. Progress on two of the locks had been slow, but here delays could be overcome by longer or double shifts, or by winter placing of concrete.

Employment Peak in 1957

At the peak of the 1956 construction season in late summer a total of close to 16,000 men were employed 'on site' by all four Authorities. During the winter the force dwindled to around half that figure as dredges closed down and as the placing of concrete on most of the structures on the American side stopped for the winter. Peak employment in the summer of 1957 will exceed that for 1956.

Close co-ordination between all four authorities and the contractors concerned has been imperative. Exact timing for water handling or for changing the course of the river from one channel to another must be carefully followed, due to the interdependence of the various operations and the effect a delay by one may have on others.

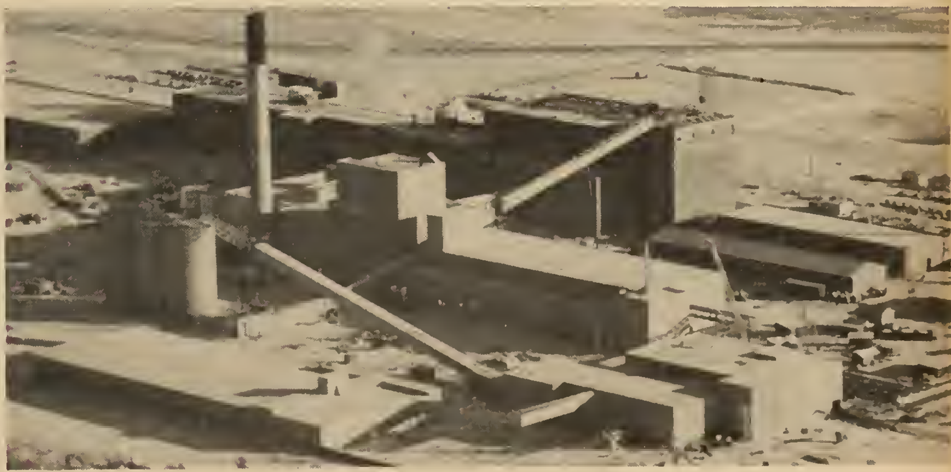
Costs Up

Original estimates for the cost of the project, in round figures, had been set at some $200 million for Canadian navigation channels, five locks and bridge alterations; $105 million for the American navigation channels and two locks. Power facilities were estimated at some $650 million, to be shared equally between the New York Power Authority and the Ontario Hydro. Meantime some additional dredging and two more bridges had been authorized. It was too early to assess what the overall cost would be, but the final bill will likely be considerably higher.

American Channel and Locks

Dredging and excavation of the Long Sault channel across the islands at the upstream end opposite Massena was 95 per cent completed and excavation and dredging along the overland mainland canal was almost half done. Excavation for the two American locks and approaches was two thirds completed. Some 45 per cent of the concrete was placed in the Eisenhower lock, bringing lock walls to two thirds and half height on south and north walls respectively. At the Grasse River lock about a third of the concrete was placed, bringing both lock walls to half height, bringing it to 40 per cent of completion. Placing of concrete on these locks was shut down 1st December.

Three illustrations of industrial expansion, top to bottom: small motors plant for Canadian Westinghouse Limited, at Stratford, Ontario; pulp mill at Hinton, Alta., for North Western Pulp and Power Limited; Dominion Rubber building and warehouse in the Grandview industrial area of Vancouver.



Canadian Navigation Channels

Progress on navigation channels and five locks on the Canadian side by the Canadian Seaway Authority in 1956 was marked by completion of several contracts and a change in emphasis from excavation to the building of structures. All contracts had been awarded excepting for dredging of approach channels to the Iroquois lock and for two dredging contracts for the Welland Canal.

Thirty million yards or 46 per cent of the channel excavation had been done by early November; 250,000 yards of concrete or 15 per cent of the total, had been placed in the lock structures and bridge piers. Only in the summer had placing of concrete been commenced in the first three locks, while on two it was barely started.

Excavation will be substantially completed by the end of 1957, while the next two years will be devoted to finishing the locks, installing gates and equipment, and erecting bridges. About a third of the south lock wall at the St. Lambert lock under Victoria bridge was completed, as well as a substantial portion of the downstream entrance wall. The Côte St. Catherine lock, delayed last winter by high water, was now back on schedule. Concrete for the north wall was almost all poured and a start had been made on the south wall.

The new Children's Memorial Hospital in Montreal, as at January, 1956.

The Lord Simcoe Hotel in Toronto, photographed in November, 1956.

At the upper and lower Beauharnois locks, started early last summer, three contractors were actively excavating the tough sandstone rock at a combined rate of 10,000 yards daily. Excavation for the highway tunnel under the lower lock had been completed and placing concrete for the tunnel started.

For the Iroquois lock, first one to be started, early completion was a necessary factor in the co-ordinated development of the river by Seaway and Power entities. A large and deep excavation across Iroquois Point had to be done first. Concrete placing will continue during the winter.

Three contracts had been awarded for excavation in the dry between locks 1, 2, 3, and 4 of the Welland Ship Canal, to be done during the winter seasons of 1955, 1956 and 1957 while navigation is halted, another for dredging the bottom in the Port Colborne area.

Bridges

There had been little visible sign at year end of bridge construction. However, various steel mills were producing the steel, and fabricating firms were preparing the steel work and completing their plans for erecting the bridges. The south end of Jacques Cartier bridge has to be raised and a new span inserted over the ship channel to provide 120 feet clearance for ships. Lift spans have to be provided on the Victoria rail-highway bridge, lift spans at the C.P.R. Caughnawaga railway bridge, and new high level approaches to the Honore Mercier highway bridge are to be provided. All contracts for these were awarded.

Agreement had been reached for replacing the Roosevelt rail-highway bridge across Cornwall Island, with a high-level highway bridge, with Canada building the piers and United States building the superstructure. Contracts for both had been awarded. A fourth bridge for highway traffic between Montreal and the south shore across Nun's Island was also proposed, and designs and methods of financing and carrying out the work were still under consideration.

Additional Work on Channels

A controversy between the two governments lasting several months had finally been resolved, concerning the dredging of a channel on the north side of Cornwall Island, required for restoring the natural balance of flow under the Boundary Waters Treaty. The Americans had feared this meant early provision of a duplicate channel and locks on the Canadian side. This dredging would be carried out with each Seaway Authority sharing the cost of some $34 million less $12 million from the two power authorities. Canada maintains it is merely a preliminary to possible future duplication.

Above, the Hudson Bay Oil and Gas Co. Ltd. building in Calgary, at this stage in August, 1956.

ROADS AND BRIDGES

A Year-end summary released by the Canadian Good Roads Association stated that "The year 1956 was the biggest road construction year in Canadian history." A substantial mileage of new modern roads was added to the nation's highway system. A year of peak activity was forecast for 1957.

The most recently published full Dominion Bureau of Statistics report on highways was for the year 1954. This had shown expenditures during that year on highway, bridge and ferry construction of $429 million. Compared with this, all provinces budgeted a total of some $722 million for highway development during the fiscal year of 1956, an all time high. According to the Canadian Good Roads Association, they would actually have spent more than $700 million at the end of that period, 31 March, 1957.

The report on highways for the year 1954 showed a grand total of 524,055 miles of roads in Canada at the end of that year, 192,616 of which were surfaced roads. According to an unofficial Good Roads Association estimate, mileage of all roads today totals some 538,000 miles, 210,000 of which are totally surfaced roads. Probably a little more than half of the two-year growth, or some 8800 miles of all classes of highway were thus added during the year 1956, some 7000 miles of which were surfaced.

Annual "Roads Roundup"

Each year in the months of October or November a "Roads Roundup" is a feature at the Canadian Good Roads Association's annual convention. On this occasion, Provincial Highway Ministers give forecasts of their expected accomplishments to the end of the current year.

British Columbia. At the October, 1956 "Roads Roundup", British Columbia reported a 1956 budget of $80 million, with 149 miles of highway built to date, 62 of which were on the Trans-Canada Highway, bringing the province's total of good highway to 2,498 miles. B.C.'s share of Trans-Canada mileage was 585 miles, reduced by 100 miles from the originally planned project due to a change in location from the "Big Bend" to the Rogers Pass route.

Twenty-one bridges were built at a cost of $3.8 million. Under construction were four major toll bridges, the Agassiz-Rosedale, the Oak Street bridge, and the Second Narrows bridge at Vancouver, and one over the Kootenay river, at Nelson, to be opened in 1957. A four-lane highway tunnel was being built under the Fraser River for completion in 1959.

Alberta appropriated $62 million for 1956 road construction, $7½ million of which was for the Trans-Canada Highway. Greater emphasis was placed on paving, with 267 miles of base course and 308 miles of paving planned; 324 miles of subgrade and grade would be built during the full year and more than 257 miles would be gravel-surfaced, as well as 22 bridges. The Trans-Canada was complete from Calgary to the Saskatchewan border with another 67 miles under construction west of Calgary.

Saskatchewan appropriated $19.7 million and total 1956 expenditure including the Trans-Canada will exceed $26 million. This total excluded expenditures on local roads by grants, etc. Wet weather in June and July had retarded surfacing and equipment was in short supply. Only five miles of surfacing remained at that time on the Trans-Canada, and there was a completely paved route across the province.

Manitoba did not report the province's appropriation for the year, but highway budgets at all levels had been increased over the previous season. The Cabinet had approved a resurfacing program equal to nearly half the total annual vote. The early part of the season had seen most road building equipment and personnel engaged on a system of diking in the Greater Winnipeg area.

The Midtown Bridge in downtown Winnipeg is a four-lane structure with a centre girder span of 170½ feet.

The Agassiz-Rosedale bridge in Vancouver, has a total length including approaches of 6127 ft., with a centre span of 1859 ft.

Ontario's total highway expenditure in 1956 was expected to amount to some $226 million, calling for 800 miles of new paving, 350 miles of resurfacing, 780 miles of grading, and 156 structures. Every effort was being made to complete key sections of the trans-provincial controlled-access Highway 401, 504 miles long. The Queen Elizabeth Way was resurfaced from Burlington to Niagara. The new Burlington Skyway will open early in 1958, while the Allumette bridge near Pembroke was completed. A five-year program for completion of Ontario's 1465 mile share of the Trans-Canada was begun, at an annual outlay of $15 million.

Quebec, with a 1956 roads budget of $100 million, reported that the main highway on the Gaspé Peninsula was near completion and the

Lake St. John and Saguenay highways were completed. The Quebec Murray Bay section of the Quebec Sept-Iles highway was also completed but the balance would take two or more years to complete. By year's-end Quebec's road network of 45,000 miles would have 31,000 miles of improved road, 9000 of it paved with concrete or asphalt. Thus 72% of the network was in good condition.

New Brunswick had allocated some $7 million from capital account for roads and bridges in 1956. An additional $14½ million had been earmarked for roads and bridges, including maintenance and ferries. New paving was under way for 52 miles of highway and 44 miles of recap on existing paved roads. By year's end some 324 miles of surface treatment was expected to be finished, plus some 114 miles of seal coating. About 234 miles of grading and gravelling projects had also been scheduled for 1956.

An extensive bridge-building program included new large bridges at Fredericton, Hartland, Rexton, Andover, Coles Island, Eel River, and Edmundston. Design was completed for two bridges at Oromocto for access to the Gagetown Army Camp.

Nova Scotia expected to spend $13 million on maintenance and $12 million for capital construction, including the Trans-Canada Highway where 30 miles of grading and 18 miles of paving were under way, as well as preparing for another 80 miles of paving. Some 140 miles of paving on other highways was under contract and another 50 miles of paving by the Roads Department.

Prince Edward Island built 10½ miles of subgrade, 7 miles of concrete pavement, and 17½ miles of asphalt pavement for the Trans-Canada Highway, which would complete 90% of the Province's TCH mileage.

Newfoundland's roadbuilding program for 1956 was about the same as for the previous year, with work limited to improvement of drainage and addition of ballast, so that a greater mileage could be reconditioned for traffic during the 1957 Spring breakup. No paving had been scheduled for 1956. The Trans-Canada was open for traffic from Port au Basques to 35 miles east of Gander Airport. Between there and Clarenville a rail-car ferry was operating daily. Contracts for the 16 miles of this gap were let for 1957 construction. It is then proposed to operate a car ferry on the two-mile stretch of water at Clode Sound, making travel possible for the full 600 miles to St. John's.

Report on Trans-Canada Highway

Almost two-thirds of the full length of the Trans-Canada Highway was paved by the end of 1956, according to Federal Public Works Minister Robert Winters; 2735 miles out of the total of 4480 miles were surfaced, with 1536 miles completed to standards of construction agreed upon by Federal and Provincial Governments.

Provinces were preparing realistic schedules to achieve a maximum of reconstruction and new highway by the end of 1960 he stated. There still remained a 164-mile gap on the north shore of Lake Superior, which was not even graded; 100 miles of it was under contract, with the Federal Government paying 90% of the cost versus 50% in the more populated areas.

Vehicle Miles up 6 per cent

According to C. W. Gilchrist, managing director of the Canadian Good Roads Association, Canadians drove their motor vehicles more than ever before during 1956. Preliminary calculations show they drove 37 billion miles during the year, or 6% more than in 1955.

Motor vehicle registrations in 1955 totalled some 3,949,000 an 8.3% in-

Part of Stelco's new pumphouse, under construction at Hamilton, showing one of three pumps, each having capacity of 20,000 Imp. gal. per minute.

Below, an illustration of a new technique. This was the first plastically designed building in Canada, designed by Professors J. W. Brooks and D. T. Wright of Queen's University and recently completed.

crease over the previous year. Passenger car registrations were 9.2% higher and commercial vehicles 6.4% higher than for 1954. There were thus ten motor vehicles registered for every 40 Canadians. This represented an increase of 164% over a ten-year period from 1945.

New passenger car sales at 387,000 units were up almost 25% over the previous year. In addition, foreign tourist vehicles entered Canada in greater numbers during 1956 than ever before, with 8.34 million passenger cars and 387 commercial vehicles crossing the international boundary. Consumption of taxable gasoline, used almost entirely for automotive purposes, rose 10% over 1954.

Preliminary figures by the automobile industry for 1956 indicate a domestic retail sales volume of 405,000 passenger cars and 91,000 commercial vehicles, while the industry expects 1957 volume to reach 425,000 passenger cars and 100,000 commercial vehicles for domestic use.

This poses a most perplexing problem for Canada's road planners, and nowhere is this more evident than in the streets of the large cities. The present balance between miles of modern roads and streets and the requirements of some 4.4 million motor vehicles is tipped so heavily in favour of the vehicle that governments at all levels are finding themselves hard pressed even to maintain the present situation. Continued prosperity may increase vehicle registrations to double the present number over the next 25 years.

TECHNIQUES AND TRENDS

The inroads of new techniques into construction must become more apparent with expansion, as designers adapt new, or conventional, materials to new purposes and locations.

One major construction method more apparent in 1956 than formerly was curtain walling. This is described as cladding of a building in a sheath of glass and panels. It represents a controversial concern of builders, offering for the architect a flexibility of design in a variety of colours and materials. There remains to be settled, it's said, the matter of economy in view of speed of erection, cost of materials, the effect of the design on air conditioning costs. Meanwhile Canadian builders have produced some fine examples of this new style, while many of the major projects also continue to use masonry.

The Canadian Standards Association continued to encourage standardization of building materials. It called attention to the growing interest in dimensional or "modular" co-ordination. It is predicted co-ordinating the dimensions of building elements can effect tremendous savings, without inflicting standardization of design. This would call for co-operation from all quarters supplying building materials. C.S.A. has a committee studying the problem.

The powerhouse of the St. Lawrence seaway project under construction in December 1956. Both American and Canadian sections are shown, with the former in the foreground.

Wintertime construction gained ground in 1956 — reducing the number of employees displaced in the recent season. The major effort of this kind was the Ontario Hydro's work on the St. Lawrence Seaway power-house project. Research is being carried on in techniques and costs, to advance this phase of building, an important one in this country.

A departure in construction was the plan undertaken by Professors D. T. Wright and J. W. Brooks of Queen's University to design, fabricate and construct an office building in Kingston according to their theory of plastic design.

Trends

Some building trends were noted; these were largely influenced by cost, efficiency and use.

It was found that industries tended toward decentralization to take advantage of favourable land costs in suburban and small city locations. Leasehold arrangements of major proportions were carried out or announced in 1956.

Shopping centres, and apartment developments were continuing and typical factors. House builders were using new methods of production, new materials, public relations and merchandising, to attract new buyers. It became practical in 1956 to move towns, house by house, as the Ontario Hydro demonstrated at Iroquois and Morrisburg, Ontario.

IRON AND STEEL

THE PRIMARY iron and steel industry set a new record in 1956 with ingot production of 5,179,347 net tons, 16.6% higher than the 4,441,743 net tons produced in 1955. Last year's ingot production was 62% higher than in 1954, and more than double the production a decade ago. The industry operated at 99.76 of its rated ingot capacity. In the final quarter of the year it reached its best pace at 100.2% of capacity.

In recent years Canadian ingot capacity has expanded more rapidly than the steel industry of any other major nation. Ingot capacity for all Canada is now rated at 5,504,000 net tons yearly, a 6% increase over the capacity at the end of 1955. Of this total 754,000 tons or some 12% represents electric furnace capacity. Canada is thus capable of producing some 72% of the nation's primary steel requirements.

Sixteen blast furnaces in Canada are now rated at a combined capacity of 3,900,000 net tons of pig iron. Production for 1956 at 3,368,359 net tons was almost 5% higher than the 3,213,764 tons produced the previous year.

Pattern of the Industry in 1954

The annual statistical report for the industry for 1954, the last complete one available, covered operations of 49 firms and included reports from 63 plants or departments with 5 blast furnaces, 4 ferro-alloy plants, 39 steel furnace divisions and 15 rolling or drawing mills. These firms had a total employment of 28,861 persons, 17.4% lower than for the previous year, 70% of whom were employed in Ontario. Materials used were valued at $145 million.

Charges to iron blast furnaces included 2.96 million tons of imported ore, 0.79 million tons of Canadian ore, 1.97 million tons of coke, and 0.78 million tons of limestone. Imports of pig totalled 20,000 tons, and exports 202,000 tons. At year-end producers' stocks of pig stood at 128,000 tons.

Output of pig iron at 2,211,029 net tons in 1954 was 26% lower than in 1953. Production of basic iron was 1,740,710 tons or 78.7% of the total. Foundry iron amounted to 167,797 tons and malleable iron to 302,520 tons. Producers' sales of pig iron totalled 455,552 tons. Actual production at 2.2 million net tons showed an operating rate of 57%.

Steel Ingots and Castings

Thirty-nine steel plants in operation in 1954 had 128 furnaces including 42 basic open-hearth and 82 electric furnaces, two converters, two oxygen converters, and two Bessemer converters. These furnaces used 1,767,300 tons of pig iron, 1,629,866 tons of scrap, 203,120 tons of iron ore, 182,970 tons of limestone, 136,000 tons of dolomite, 81,440 tons of lime, 74,000 tons of sand, 9,900 ton of magnesite, and 41,530 tons of ferro-alloys. 1954 steel production at 3.2 million tons was 22.4% below 1953, with most of the decline occurring in ingots. Factory sales totalled 86.066 tons valued at $35.4 million.

Rolled and Drawn Steel

Of twelve mills operating in 1954 for hot-rolling of steel products and three mills making only cold-drawn and cold rolled shapes, nine were in Ontario, two in Nova Scotia, two in Quebec, one in Manitoba, and one in British Columbia. Rolling mill sales for 1954 at $301,926,000 were down 12.6% below 1953. Main items sold were 445,519 tons of hot rolled bars, 201,524 tons of plate, 283,297 tons of rails and fastenings, 150,917 tons of blooms and billets, 180,144 tons of structurals, 274,870 tons of wire rods, 28,829 tons of cold reduced bars, and 900,484 tons of other rolled products.

Ferro-Alloys

Ferro-alloys were produced in 1954 by ten establishments, five of which received ferro-silicon as a by-product from abrasive producers. Output amounted to 116,141 tons, a decline of some 24½% from 1953 production.

Consumption by Industries in 1954

The total tonnage of iron, iron castings, and products made in iron and steel rolling and drawing mills in 1954 and shipped to various industries, amounting to some 3.79 million tons, was divided as follows in millions of tons: construction 0.372; merchant trade products 0.348; wholesalers and warehouses 0.330; railway operation, 0.307; containers, 0.272; pressing, forming and stamping, 0.161; machinery and tools 0.152; automotive industries, 0.140 mining and lumbering, 0.137; railway rolling stock, 0.121; farm implements 0.074; national defence, 0.037 shipbuilding, 0.015; miscellaneous

In this general view of the Dominion Foundries and Steel Company's plant at Hamilton, Ont., may be seen the oxygen steel-making plant (prominent light building, right centre). Coal handling plant and coke ovens are immediately behind the stack, and the blast furnace is at the top left.

0.013; producers interchange and exports, 1.32.

Imports and Exports

Imports of primary forms of iron and steel in 1954 included 1,095,-858 tons of carbon steel, 78% of it from United States; 33,566 tons of alloy steel, 94% of it from United States and 8,151 tons of stainless steel, 75% of it from the United States.

Exports the same year totalled 260,868 tons, 78% of it in the form of pig iron, 11% in the form of plates, sheets and strips, 5% in the form of iron and steel castings, 4% in the form of ingots, blooms, billets and bars.

Industry Leaders in 1956

"Stelco", or the Steel Company of Canada, Canada's leading steel producer, produced 2,367,134 tons of ingot in 1956, up 15% from the previous year, and increased sales to $272.9 million, up 20% from 1955. The company has invested $185 million in expansion since 1945. At the end of 1955 it authorized an expansion program for its Hamilton works costing $70 million, including a new blooming mill, scheduled for completion by the end of 1958. Last year it joined with Page Hersey Tubes Ltd. in forming a new company, Welland Tubes Ltd., to build a $10 million pipe mill for initial 1957 production of steel pipe in sizes up to 34 inches diameter.

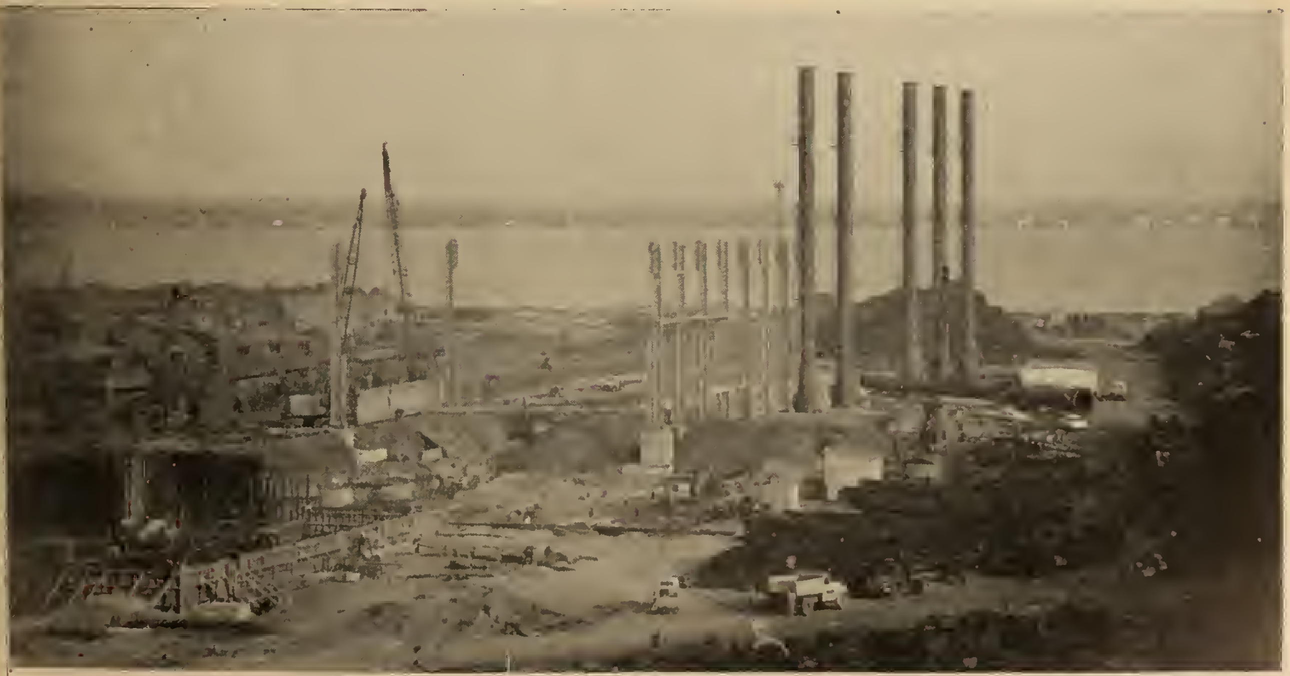
Steel ingots are heated in soaking pits before further processing. *(Dosco photo.)*

Below is a general view of construction work at the No. 2 blooming mill site of The Steel Company of Canada Limited plant at Hamilton. In the far right background may be seen the piers of the Burlington Skyway.



Sault Ste. Marie increased its ingot production to 1,104,750 tons of ingot in 1956, 11½% more than in the previous year. Shipments of iron ore and steel were also up at 1,476,613 tons; new records in both cases. The company is undertaking a $67 million program this year to expand ingot capacity by half a million tons, with the objective of a 25% sales increase by 1959. Capacity production is anticipated during the first half of 1957.

In 1956 the company spent $8 million in expansion, double the amount spent in 1955, to bring capacity up to the present 1,280,000 tons. The new Mannesmann tube mill at the 'Soo', with which it is affiliated, will provide Algoma with a further outlet for some 225,000 tons of plate for seamless pipe.

Dominion Steel and Coal Corporation, Ltd., (Dosco) apparently increased ingot production in 1956 to some 653,000 tons, up 25% from 1955. The company's ingot capacity from three blast furnaces at the end of 1956 was 720,000 tons. A subsidiary, Canadian Tube and Steel Products Ltd., at Montreal, produces a further 100,000 tons. After completion next July of Dosco's new 225,000 ton open hearth furnace, capacity will be increased to 950,000 tons.

Dominion Foundries and Steel Co., Ltd., at Hamilton had eleven furnaces in operation last year, five of them electric and two of them oxygen vessels, with a combined capacity of 785,000 tons. Last year the company spent $26.6 million to install a third oxygen steel furnace and a second blast furnace. Production has been doubled in recent years. Plans for 1957 include a new hot-roughing mill.

Atlas Steels Ltd., of Welland, Ont., produces ferro-alloys and specialty and stainless steels. Its six electric furnaces have a combined capacity of 169,600 tons. A $12 million five-year expansion program at present under way will add 17,000 tons per month to capacity. Recently it has started continuous casting and has added a hot planetary mill, both well in advance of U.S. practice. It has also been first to introduce the oxygen-steel converter to Canadian practice.

The runner hub assembly of one of the turbines for the Niagara pumped storage scheme. Six such units will pump off-load water into a reservoir; by reversal of the units power can be generated. (*Photo: English Electric Company of Canada.*)

Industry Measures to Meet Foreign Competition

Canada's steel industry, with ingot capacity only some 2% of world capacity, is extremely sensitive to world influences and to competitive conditions. It must compete cost-wise with producers in the United States whose output is 25 times larger than our own. Technical advances have allowed us to narrow the gap between our mill prices and theirs. But our steel prices must also be competitive with those of the mills in Western Europe with a combined ingot capacity 16 times as large as Canada's and with wage scales only about a third of those paid to Canadian workers.

The Canadian iron and steel industry is following its own line of steel development. Evolution is proceeding in three phases,—first, through attempts to boost production from existing equipment; second through introduction of new low-cost methods to compete with established companies; and third, through new processes suitable to Canada for processing ore to steel for export.

Canada will soon become the free world's third biggest producer of iron. Production has already passed that of Britain and of Germany and will soon exceed that of France and Sweden. Today's 15 blast furnaces produce some 3½ million tons of pig iron. By 1980, industry leaders see Canada needing almost double this production, which would mean addition of seven big new blast furnaces. However, by using beneficiated ores (iron pellets or sinter) the number needed might be reduced to two new furnaces, at a saving of an investment of some $90 million to $100 million.

SECONDARY STEEL

To ROUND OUT the record of Canadian steel production, statistics of three other secondary industries not included elsewhere in this issue should be added. Complete records of production of these industries are not available for 1955 and 1956, but their relative importance can be measured from DBS reports for 195[illegible] the most recent year for which complete reports are available.

Sheet Metal Products

Factory shipments of sheet metal products in 1956 were valued

$278.6 million, 8 per cent higher than in 1955 and 19 per cent higher than in 1954.

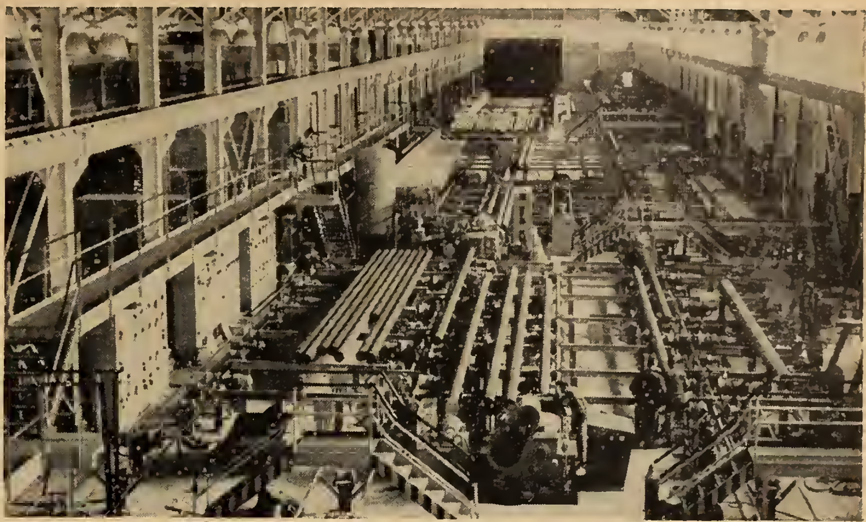
There were 343 establishments in 1954 engaged in the manufacture of articles from steel sheets, tinplate, and galvanized plate, whose main products were tin cans, galvanized sheets, bottle caps, building material, kitchenware, culverts, barrels and drums, and eavestrough. These plants together employed some 18,000 persons: 10,554 of whom were in Ontario; 4140 in Quebec; 961 in British Columbia; 875 in Manitoba; 384 in Alberta; 228 in Saskatchewan and 107 in the Maritimes.

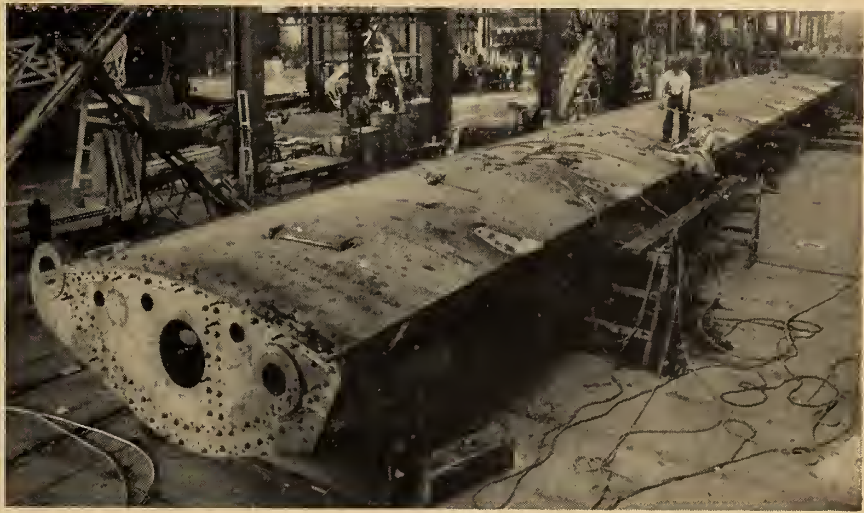
Materials purchased were valued at $118.8 million. Value added by manufacture amounted to $112.2 million, and gross selling value totalled $232.7 million. Values of the main items produced were as follows; cans, $77.8 million; steel and aluminum windows, $15 million; bottle caps $10.5 million; culvert pipe $10.8 million; roofing and siding, $6.8 million; hotel kitchen equipment, $4.4 million; motor vehicle bodies, $3.8 million; barrels and drums $2.3 million; metal lath $3.4 million; and other products $9.5 million.

Miscellaneous Iron and Steel Production

Shipments of miscellaneous iron and steel products in 1955 were valued at $119.5 million, 5 per cent lower than for the previous year.

There were 320 establishments in the miscellaneous iron and steel industry, in 1954, which between them employed 12,150 persons; 6573 of whom were in Ontario, 3635 in Quebec, 898 in the maritimes, 595 in Manitoba, 420 in Alberta and British Columbia. Materials purchased were valued at $46.3 million, and included 11,853 tons of pig iron, 140,000 tons of steel in various forms and





Development of the Canadian oil and gas industries has led to increased demand for steel pipe. Top picture shows the finishing bay of the Alberta Phoenix Tube & Pipe Limited plant at Edmonton, established in 1956.

9300 tons of scrap. Value added by manufacture amounted to $75.9 million, and gross selling value to $126.1 million. Products included ornamental and structural ironwork, steel forgings, safes and vaults, railway track equipment, mining machinery, fireplace furnishings, and steel wool.

Gross selling value of the principal products were as follows: forgings $16.6 million; sanitary ware $14 million; iron and steel architectural work $15.2 million; aluminum architectural work $1.1 million; railway track equipment, $2.7 million; safes and vaults $2 million; and machinery $1.95 million.

Bridge Building and Structural Steel Production

Value of factory shipments of bridge building and structural steel in 1956 amounted to $199.5 million, 27 per cent higher than the value of shipments in 1954.

There were 43 establishments in 1954 in this industry, which includes all those chiefly occupied in fabricating or erecting steel for bridges, buildings, etc. Total employment amounted to 10,881 persons, most of whom are included with employment shown in the construction industry. Twelve of the plants were in Quebec, 21 in Ontario, four in British Columbia, three in Alberta, two in Manitoba and one in Nova Scotia.

Value of the principal products was as follows: 276,590 tons of structural steel for buildings, valued at $82 million; 66,067 tons of structural steel for bridges, towers, etc., $24.2 million; plate and tank work, $12.9 million; mechanical work such as cranes, trolleys, and machinery, $9.5 million; and sales of plain materials, $13.74 million.

Apart from the millions of tons of iron and steel shipped last year to warehouses, the mercantile trade and various industries in the form of castings, ingots, plate rails, bars, blooms, billets and slabs, a partial list of some of the structural steel end-products supplied or currently being fabricated for the construction industry are of special interest.

Some 22,000 tons of structural steel for eight large bridges at Vancouver, Winnipeg, Montreal, Lachine and Toronto.

Some 25,000 tons of structural steel for two hotels at Toronto and Montreal, a post office at Vancouver and two office buildings at Montreal.

Some 26,000 tons for 48 headgates, 32 control gates and a gantry crane for the St. Lawrence seaway development as well as several submersible lock gates and drum gates.

About 15,000 tons for Ontario uranium developments; 2,000 tons for an Alberta pulp mill; 2,000 tons for 40 microwave towers in Western Canada; and gates for a large irrigation dam in South America.

IRON CASTINGS

Canada's iron foundry industry established new records in 1956, with over a million tons of castings, pipe, and fittings being produced during the year. Some 700,000 tons of this was in the form of grey iron general castings. *Per capita* consumption of Canadian castings has risen during the past decade from 61 to 89 pounds.

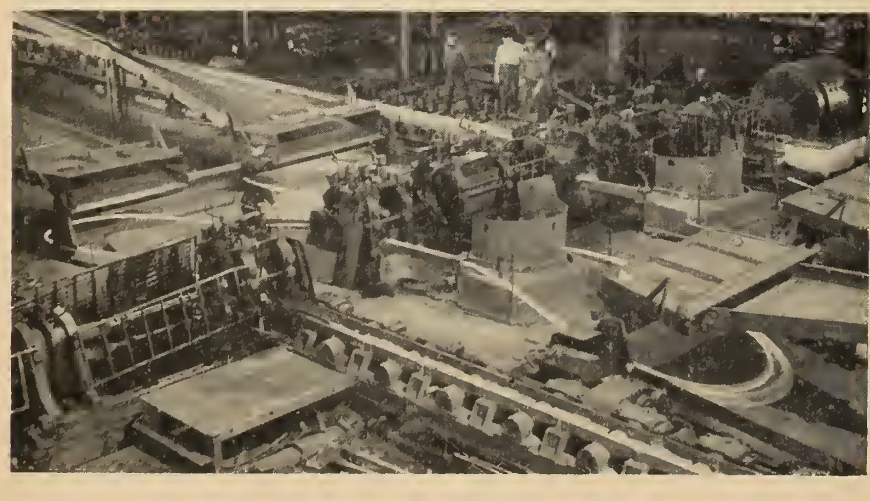
Total tonnage made in 1956 included 72,081 tons of cast iron castings, cast iron pipe and fittings, soil and water pipe, and 30,200 tons of steel pipe tubing and fittings. Tonnage shipped for use in Canada or for export during the year, excluding quantities used to make other products such as stoves, machinery, etc., totalled 1,182,000 tons, compared with 992,660 tons in 1955; an increase of 19 per cent. Consumption of pig iron at 356,700 tons and of scrap at 796,600 tons was higher than in 1955 by some 8 per cent.

The industry covers operations of iron and steel works occupied chiefly in making commercial iron castings or iron and steel pipe and tubing. Some machinery, boilers, engines, stoves and furnaces, etc. were made as secondary or minor products. Some makers of agricultural implements and stove manufacturers who have their own foundries are included elsewhere with the Farm Implements and with Heating and Cooking Apparatus industries, respectively.

In 1954, the last year for which complete industry statistics are available, based on 202 establishments reporting, 75 per cent of them in Ontario and Quebec, the industry employed 13,784 persons, purchased materials valued at $61 66 million, added a value of $76.67 million by manufacture, and shipped products valued at $139.9 million during the year. This value of shipments was 11 per cent lower than in 1953. Employment in the industry totalled over 23,000 in 1929, dropping to 9,635 in 1939 and recovered to 18,340 in 1949, since which year it had dropped steadily to 13,748 in 1954.

A special study of all reports submitted to D.B.S. has indicated a total of some 400 operating foundries distributed across Canada in 1954, which together used 267,000 tons of pig iron, 529,000 tons of scrap, and 147 tons of cupola coke. Their production totalled 713,000 tons of iron castings.

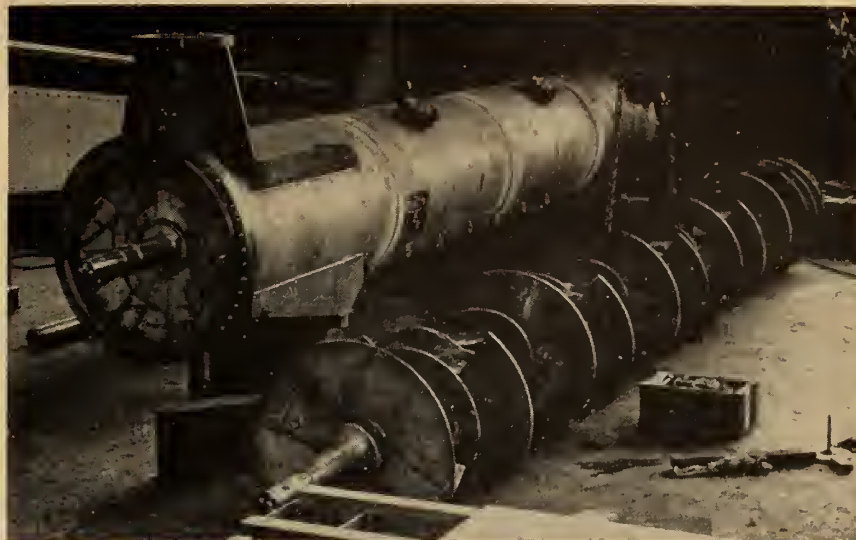
Consumption of the principal materials used by the industry in 1954 were valued, in millions of dollars, as follows: skelp, 23; pig iron, 8.8; scrap iron and steel of all kinds, 8.8; hot or cold rolled steel, 2.42; coke,



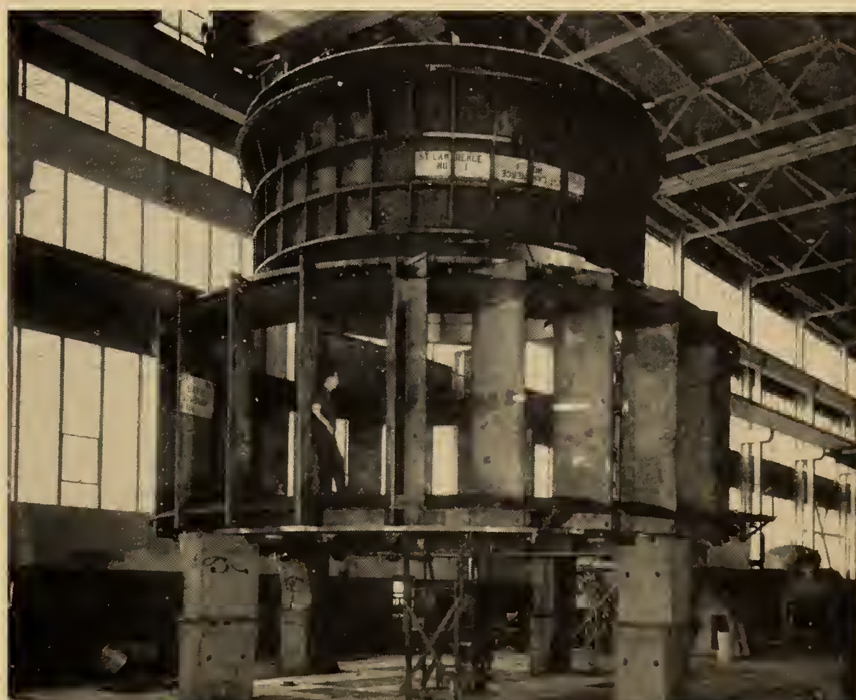
STEEL PROCESSING

Further steel processing operation is the passing of steel billets through a series of reducing rolls to make smaller-sized rod and bar. *(Photo: Dominion Steel and Coal Corporation.)*

New to Canada in 1956 was this screw-type digester for the pulp and paper industry. *(Photo: Dominion Bridge.)*



The manufacture of heavy equipment for the hydro-electric power industry is a major activity on the Canadian industrial scene. The picture below shows a discharge ring being lowered through the speed ring for a matching and blending operation. *(Photo: English Electric Company of Canada.)*



2.0; iron and steel pipe, 1.7; brass and bronze, 1.6; other iron and steel, 1.26; zinc 0.86; ferro-alloys, 0.86; aluminum, 0.21; nickel 0.26; sand, 0.28; firebrick, 0.24; lumber, 0.20; core oil, 0.16; paints, 0.19; containers, 0.36; and other materials, 8.51.

The industry continues to make progress towards better technology. The CO_2 process of mould making and core-making is finding useful applications. A new modification of standard core-oil formulas which decreases baking time is proving valuable particularly for cost reduction in heavy work.

Canada's first hot-blast unit on a foundry cupola, aimed at decreasing costs and at better metal quality was put into operation in Toronto in 1956. Improved foundry practice and metallurgical techniques have contributed to enhanced quality and range of metal properties available in iron castings.

BOILER AND PLATE

THE BOILER and plate work industry includes the operation of establishments that make as their chief products such articles as heating and power boilers, heating radiators, tanks and miscellaneous products from steel plate such as bins, hoppers, smokestacks, etc.

Shipments of boilers, radiators and other products of the industry during 1956, according to preliminary reports of the Dominion Bureau of Statistics, amounted to a value of some $124.6 million, 42 per cent higher than in 1954.

In 1954, the latest year for which full statistics have been published, there were 89 such establishments in Canada, which employed 8,127 persons, purchased materials valued at $35.9 million, added a value of $50.44 million by manufacture and produced goods valued at $87.6 million. This compared with production valued at $96.6 million the previous year and production valued at $90.4 million in 1952.

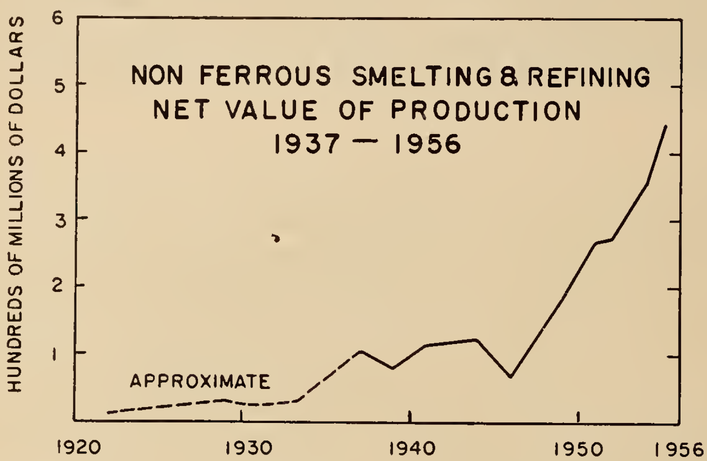
Forty-eight firms in Ontario account for nearly three quarters of the total employment in the industry, while 17 firms in Quebec account for a fifth of employment. British Columbia with 11 firms comes next, with the three prairie provinces employing 340 persons between them.

A list of the principal materials used in manufacture in 1954 included some 137,000 tons of steel, 20,000 tons of pig iron, 16,000 tons of scrap, 41 tons of aluminum, 15 tons of copper, 4½ tons of nickel, 25 tons of lead, 5 tons of babbitt, 8,000 tons of coke, 9,000 tons of sand, 9,000 barrels of oil.

During 1954 some 19,000 heating boilers of various sizes and some 330 power boilers were shipped, combined value of which was $16.35 million. Total production of heating radiators totalling 14.7 million square feet were produced, having a value of $9.2 million. Capital and repair expenditures for the industry in the same year totalled $4.7 million.

NON-FERROUS METALS

The smelting and refining industry includes only those firms engaged primarily in smelting of non-ferrous ores or concentrates and in the refining of metals recovered therefrom. The smelting of imported ores is included, but secondary smelters, which treat scrap metals only, are not. The list of metals covered includes copper, nickel, lead, zinc, aluminum, magnesium, titanium, molybdenite, tungsten, cobalt, antimony, bismuth, cadmium, selenium, tellurium and precious metals. Refining of crude oil is not included.



Full statistics for 1956 are not available for smelting and refining of metals but the value of shipments by the industry in that year reached a total of some $1,239,000,000, up 2¼ per cent from the previous year.

In 1955, the last year for which a complete report was published, 24 establishments employing 28,600 persons showed a combined gross value of products shipped during that year, including containers, of $1,211,716,-481. They spent $118,189,000 in wages, purchased supplies valued at $60,874,000, purchased fuel and power valued at $56,949,000, and added a net value of production amounting to $444 million.

The gross value of products shipped in 1955 was more than double the value in 1949 and up almost fourfold from production shipped two decades ago. Capital and repair expenditures for five years ending in December 1955 totalled $481 million. Smelting capacities for the principal metals at the end of 1955 in tons per year stood as follows: smelting of copper ore and concentrates 5,455,000; copper refining, 350,000; lead smelting 711,000; electrolytic zinc, 273,000.

In 1955, production was: 289,000 tons of refined copper, 174,928 tons of nickel, 148,811 tons of refined lead, 256,542 tons of refined zinc, 960 tons of cadmium, 133 tons of bismuth, 612,543 tons of aluminum, 246 tons of tin and antimony, 971 tons of refined tungsten and molybdenite, 786 tons of cobalt, 117,042 tons of titanium dioxide slag, 213 tons of selenium, and 4½ tons of tellurium. Production of new gold and silver were valued at $156.8 million and $24.7 million, respectively.

ALUMINUM

Canada's production of aluminum ingots during 1956 reached a record total of 614,721 tons, compared with 612,543 tons the previous year, and more than three times the annual production ten years ago.

Although there is no bauxite mined in Canada, the aluminum smelting industry is exceeded in size only by that of the United States. The principal factor favouring establishment of the industry in Canada is abundant and low-cost hydro power at points where necessary raw materials can be cheaply and conveniently assembled.

The principal imported raw materials used in the industry are bauxite from British Guiana, alumina from Jamaica, coal and coke from the United States, fluorspar from Newfoundland, and cryolite from Greenland and the United States. The Aluminum Company of Canada, Limited, operates its alumina plant at Arvida and its reduction plants at Arvida, Isle Maligne, Shawinigan Falls, and Beauharnois. The Company's new plant at Kitimat, B.C., which began production in 1954, is being expanded. Electric power for this plant is generated at Kemano, while alumina for the smelter is brought by ship from Jamaica.

For the year 1955, the last year for which full statistics are currently available, producers' shipments of aluminum ingots amounted to 612,-543 tons. Canadian comsumption amounted to 91,522 tons, and exports totalled 506,879 tons, while 99 tons were imported. Exports in primary forms were valued at $197.66 million and in semi-fabricated form at $9.15 million. Exports of aluminum scrap were valued at $4.2 million, aluminum foil at $951,000, aluminum manufactures at $770,000 and kitchen utensils at $34,600.

Imports the same year were 199,-800 tons of alumina valued at $3.74 million; 2.89 million tons of bauxite valued at $20.8 million; 3400 tons of cryolite valued at $752,600; and aluminum metal in various forms valued at $20 million. The price of aluminum ingot at the end of 1955 was 21 cents per pound. The U.S. import tariff on aluminum metal and alloys was 2 cents per pound. The U.S. price in December 1955 was quoted at 24.4 cents per pound.

Current Expansion Program

The Kitimat plant commenced operations in the summer of 1954 at a rated capacity of 90,000 tons per year. In October of that year a further expansion of 60,000 tons was authorized, while under the 1955 program new capacity would come in over a period extending late into 1959, bringing the Company's total Canadian capacity to 900,000 tons of ingot per year commencing in 1960.

During 1956, 90,000 tons of new capacity was brought into operation at Kitimat. More than 3000 persons were employed at year's end on townsite and smelter construction. Two new hydro-electric generators, each of 150,000 horsepower capacity, were added during the year at the Kemano power plant. The present generating capacity of 828,000 horsepower can support an ingot capacity of 225,000 tons yearly.

Currently the Company is adding a new power development in the Saguenay district, which will add some 700,000 h.p. to the firm power output of the Saguenay system as a whole. First production will commence in the summer of 1959. Concurrently ingot capacity at Arvida and Isle Maligne is being increased by 150,000 tons. If plans both in the west and the east proceed, total ingot capacity will slightly exceed one-million tons in 1960.

By the summer of 1957 the Jamaica alumina plant will have a capacity of 550,000 tons, and a second plant now under construction will add a further 250,000 ton capacity.

The Canadian-British Aluminium Company Ltd., is building a $130-million plant for production of primary aluminum near Baie Comeau, Que. The project, which ultimately will produce 320 million pounds of ingot yearly, will be developed in four stages, the first stage scheduled for production in 1958 and the entire project by 1965. Power is being developed on the Manicouagan river jointly by the Company and North Shore Paper Co. Ltd.

The Aluminum Products Industry

This industry comprises the operation of factories occupied chiefly in the fabrication, casting or rolling of aluminum to make bars, sheets, wire, cable, foil, cooking utensils, etc. It does not include primary aluminum smelting or castings, cable, utensils, and so on, made as secondary or minor products, or brass or iron foundries.

The value of shipments for 1955 totalled some $79.8 million, practically the same as for 1954. Employment in 1956 averaged 6834 persons compared with 7000 in 1954. The value of shipments in 1956 totalled $84.73 million; 6 per cent higher than for 1955.

In 1954, the last year a full report was issued, there were 99 factories, 25 in Quebec, 61 in Ontario, one in Manitoba, 5 in Alberta, and 7 in British Columbia. Materials purchased were valued at $46 million and factory shipments were valued at $80.5 million.

Value of the various categories of production in 1954 in millions of dollars was as follows: cooking utensils, $7.5, while other industries made aluminum ware worth $0.45 million, bringing the total to $7.95 million. Output of extruded shapes, $7.09; utensils $7.5; castings, $5.2; castings (other), $1.02; die castings $0.63; other products such as ingots bars, rods, foil, forgings, tubing and cable $59.0.

Below, the smelter at Kitimat, B.C., of the Aluminum Company of Canada Limited.

MACHINES AND EQUIPMENT

The machinery industry covers operations of iron and steel works occupied chiefly in making industrial, household, office and business machinery and machine tools. (Farm implements and electrical machinery are covered elsewhere.) Some concerns in other groups made machinery as secondary or minor products, so production figures do not represent the total output of the commodities listed.

Products made in this industry include household and office machinery, conveying, transmission and elevating machinery, machinery for the pulp and paper, mining and metallurgical, road making, logging, lumbering, woodworking, and grain handling industries, and machinery for service stations, firefighting and refrigeration, as well as hydraulic turbines, pumps, elevators, air compressors, furnace blowers, power shovels, steam and diesel engines.

As defined above, this industry included 399 firms in 1954, the most recent year for which full statistics are available. These establishments employed 32,851 persons in 1954, 20,000 of whom were in Ontario, 10,000 in Quebec, 1500 in British Columbia, with the balance divided between five other provinces. Materials purchased were valued at $131 million and gross production totalled $342.3 million, practically the same as production for the previous year.

According to preliminary DBS reports, production in this industry during 1956 was estimated at some $366 million.

A broader classification covering the entire machinery production in Canada, as assembled from all industries, including as well as the categories listed above: motors, generators, electric washers, refrigerators, dryers, oil burners, knitting machines, typewriters, welding machinery, accounting and calculating machinery, is also recorded in the statistical report for 1954. During that year the value of this total production for the entire group totalled $503.8 million. For this broader group no preliminary estimate of 1956 production was available before this publication.

Manufacture of heavy machinery and equipment under way in 1956 included two 100-ton extrusion presses for aluminum alloy; calandria for the NRU reactor for Atomic Energy of Canada Ltd.; waste heat boilers for the City of Montreal; a rotary kiln 12 ft. diam. and 450 ft. long; a rotary ball mill 13 ft. x 16 ft.; hydraulic actuating cylinders; a Churchill roll grinder 63 inches by 408 inches; as well as many hydraulic turbines of various capacities up to 150,000 horsepower.

To these should be added landing gear of ultra-high-tensile steel for the CF-100 and other assemblies for aircraft industry; compressor parts, vessels for oil refineries; a large high temperature stress-relieving furnace 18 ft. x 18 ft. x 82 ft.; and a new radial drill with 10 ft. arm and a 29 in. dia. column.

FARM IMPLEMENTS

Although total farm cash income for the first three quarters of 1956 showed an increase of some 11 per cent over the previous year, the value of shipments of farm implements and equipment over the same period indicated a lower volume of sales than for 1955. No estimate of 1956 sales was available for this survey.

Canadian sales of farm implements and equipment during 1955 amounted to $155.1 million, an increase of 5.7 per cent over 1954, but only some 62 per cent of the peak sales volume of $250.2 million experienced in 1952. Sales of repair parts in 1955 increased 4 per cent to $28.45 million.

Half of all types of farm implements and equipment were sold in the three prairie provinces. Dollar values as quoted are wholesale prices, and information submitted to the Dominion Bureau of Statistics indicates an average retail markup of 22.3 per cent for implements and equipment and 33.3 per cent for repair parts.

Sales volumes for major groups in millions of dollars were as follows: tractors and engines $58.7; harvesting machinery, $27.7; haying machinery, $21.7; ploughs, $8.22; water systems and pumps, $7.8; tilling, cultivating, and weeding machinery, $7.0; planting, seeding and fertilizing machinery, $5.35; machinery for preparing crops, $4.8; dairy machinery and equipment, $3.9; barn equipment, $2.6.

Purchases in the prairie provinces by groups amounted to the following percentages of the total for all Canada: tractors and engines, 46%; harvesting machinery, 78.6%; haying machinery, 44.5%; ploughs, 65.8%.

HARDWARE, TOOLS AND CUTLERY

The hardware, tools and cutlery industry enjoyed a year of record production in 1956, with production valued at some $191 million according to preliminary estimates, compared with production valued at $132.5 million in 1955, an increase of 44 per cent.

For a full description of the industry we must look back at the year 1954, the last year for which full statistics are available. That year there were 379 establishments in Canada with employment of 13,264 persons, 971 of them in Ontario, 2900 of them in Quebec and most of the remainder in British Columbia. These firms purchased materials valued at $40.1 million, added a value of $77.3 million by manufacture, and produced goods with a gross selling value of $118.5 million.

Output included bolts, nuts, rivets, hardware, razors, saws, screw machine products, metal stampings, twist drills, milling cutters, machine knives, axes, hatchets, spades, forks, shovels, carpenters' tools, etc. Razors and cutlery produced were valued at $5 million; hardware at $26 million; hand implements at $3.4 million; tools and dies at $4.4 million; hand tools and small tools at $20.2 million; and bolts, rivets, dies, saws and miscellaneous products, $59 million.

The quantities of some of the principal materials used in manufacture during 1954 were as follows: steel bars and rods, 30,000 tons; sheets, 12,000 tons; wire, 14,000 tons; strip, 7,000 tons; plates, 2,260 tons; structural shapes 1,300 tons; bronze and brass 2,000 tons; aluminum 1,900 tons; zinc, 800 tons; copper 170 tons; lumber 2,277 M fbm.*

The industry's capital and repair expenditures during 1954 amounted to $10.17 million, approximately the same amount as during the previous year.

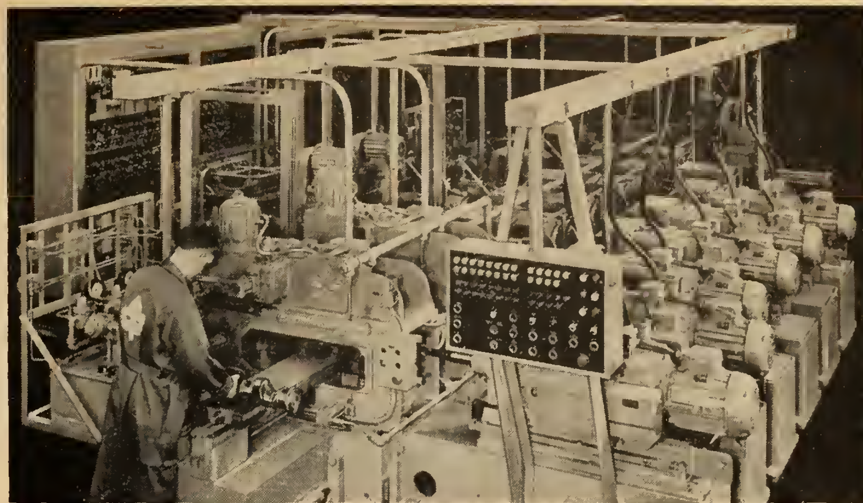
---

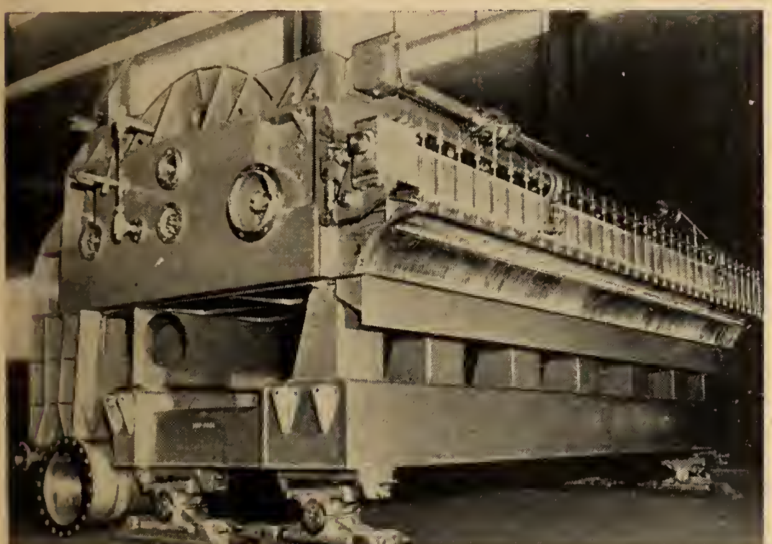
*Foot board measure.

RAILWAY EQUIPMENT

THE RAILWAY rolling stock industry includes all establishments chiefly occupied in making railway cars and locomotives or parts for same such as wheels, brakes, tires, bolsters, springs, etc. The principal repair shops of the CNR and CPR are also included.

Shipments of railroad and rolling stock equipment in 1956, according to preliminary reports from the Dominion Bureau of Statistics, were valued at some $356 million. This included 439 diesel locomotives and 8633 railway cars for the Canadian National and Canadian Pacific Railways.





Above is an example of the machine tools made by the industry in 1956. This is an 11-station transfer machine for the British automobile industry; the machine does 36 operations on automotive crankshafts. *(Photo: Gordon Rice, Standard Modern Tool Company Limited.)*

The pulp and paper industry is a large user of heavy machinery. At left is the pressure head box for the new No. 9 newsprint machine of Powell River Company. *(Photo: Dominion Engineering Works Limited.)*

The Banbury mixer, below, was installed in 1956 at the Phillips Electrical Company plant at Brockville, Ont. The machine mixes 500-lb. batches of rubber compound and extrudes it in strips which are used for various electrical applications.

Production in 1954, the last year for which a full report is published, showed a value of $283.4 million, 16.2 per cent lower than for 1953. Output included 8527 railway cars valued at $88.4 million and 244 diesel locomotives valued at $41.1 million.

Thirty-six firms were in operation in this group in 1954; sixteen in Ontario, eight in Quebec, four in Manitoba, three in Alberta, three in Nova Scotia, and one each in New Brunswick and British Columbia. Employees numbered 29,214. Employment had more than doubled since 1933, while gross selling value of production had more than doubled since 1946. Half the employment was in the province of Quebec, mainly due to the CNR and CPR shops in Montreal.

Materials used in manufacturing or repairs cost $162.2 million. The main items purchased in 1954 included

iron and steel valued at $29 million, car and locomotive parts valued at some $54 million, brass and bronze valued at $4.4 million, lumber valued at $3.2 million. Capital and repair expenditures for the year amounted to some $18 million, compared with an average of $20 million annually over the previous four years.

Imports of cars, locomotives and parts for same during 1954 amounted to some $44 million and exports to some $8.5 million.

ELECTRICAL EQUIPMENT

Electrical manufacturing has joined the ranks of Canada's billion dollar industries with a record production of $1,100 million in 1956, five per cent higher than for the previous year. Employment in the 475 establishments operated by the industry also has risen to a new high of 80,000. Year-end inventory held amounted to $126 million for finished products; $149.7 million for goods in process and $111.5 for raw materials; a total of $387.1 million, compared with $343.5 million at the end of 1955.

The industry is now capable of producing almost all of Canada's electrical requirements. Imports of electrical apparatus and supplies have been steadily rising, from $82 million in 1948 to an estimated $450 million in 1956. This growth, added to the steadily growing production of supplies and apparatus in Canada resulted in a market of $1.5 billion in 1955 and a market estimated at $1,550 million in 1956.

Industry Statistics for 1954

In 1954, the latest year for which a full report was published, the industry employed some 75,000 persons, purchased some $397 millions worth of materials, added a value of $463 million by manufacture and sold products at a gross value of some $864 million. Selling value by subgroups, in millions of dollars, was approximately as follows: miscellaneous products 268; radios and parts, 228; heavy electrical machinery, 202; refrigerators and appliances, 130; and batteries 35. Opening inventories for that year amounted to $229 million, and closing inventories to $208.5 million.

Value of factory shipments during 1954 was divided between seven provinces as follows: from Ontario, $636.6 million; from Quebec and Nova Scotia, $207.8 million; from Manitoba and Saskatchewan, $9.4 million; from British Columbia, $9.1 million; and from Alberta, $1 million.

Imports during the year of some of the principal commodities used in manufacture, in order of value and expressed in millions of dollars were: radio and wireless apparatus 58; electric apparatus and parts, 23; refrigerators, 17.7; rheostats and starting and controlling devices, 15.7; electric motors, 12; radio receiving sets, 11; switches, switchboards and circuit breakers, 10.7; telephone apparatus, 10.5; heating and cooking apparatus, 9.5; radio tubes, 8.8; electric irons and parts, 8.4; and air conditioning apparatus, 8.2.

Exports of selected commodities during the year, in order of value and expressed in millions of dollars, were: radio and wireless apparatus, 6.8; electrical apparatus (n.o.p.); 3.7; dynamos and generators and parts, 2.4; spark plugs, 2; telephone and telegraph apparatus, 1.8; radio receiving sets, 1.5; meters and parts, 1.4.

1954 value of production was down from the previous year for refrigerators, ranges, washing machines, sharply down for radio receiving sets, but slightly higher for batteries.

Values of some of the principal materials used by the industry in 1954, expressed in millions of dollars, were approximately as follows: copper and products 56.7; radio and T.V. parts, 45; iron and steel and their products, 31; radio and T.V. tubes 23; radio and T.V. cabinets, 14; lead and products, 12; alloy steel, 8; brass and products, 7; containers, 7; glass bulbs, 3; cotton and linen, 2.8; paint, 2.5; insulators, 1.8; rubber and products, 1.5; lumber, 1.6; and steel tanks, $1.2 million.

Rate of Profits Won't Support Expansion

Although the industry faces almost unlimited opportunities due to the nation's rapid development of hydro-electric power, this imposes a responsibility upon it to risk large investments in expansion, modernization, and the development of manpower. The industry's current net earnings, however, will not support these necessary expenditures.

Keen competition among domestic producers and rising labour and material costs, together with competition from prices for imports, have kept returns on capital unreasonably low. The 2.9 cents net profit on the electrical sales dollar in 1955 was discouraging compared with the average profit of 5.9 cents for all manufacturing industry. Though profit in 1956 will be somewhat higher, it will still be below the level necessary for a 'growth' industry.

Some Segments Show Spectacular Growth

Performance for the entire industry, however, cannot be taken as a reliable measure of performance for each part or for any particular category. Nor does the performance of one manufacturer in any production line measure reliably the performance of all producers of the same type of goods.

Member companies of the Radio-Electronics-T.V. Manufacturers' Association, for example, increased the value of factory shipments of manufactured goods from $20 million in 1939 to $505 million in 1955. While the gross national product only doubled, the electronics industry increased sevenfold in ten years. During 1956 the telephone companies spent $320 million on plant compared with $279 million in 1955 and $249 million in 1954.

All Major Industries Need Apparatus

During 1956 the apparatus segment of the industry had a record volume of orders from Canadian utilities and industries. The steel industry is carrying out a record expansion program to increase capacity. The pulp and paper industry is adding new mills and expanding existing mills. Uranium mining is opening up new areas of expansion. Oil and gas pipelines are placing large orders for apparatus. The installation of an additional 1,350,000 horsepower by Canada's power companies last year called for vast orders of new apparatus for generation transmission and distribution of electrical energy, and for the industrial equipment to put it to work.

1957 Emphasis is on Consumer Spending

Looking ahead, the apparatus segment foresees another record volume of orders in 1957 from Canadian utilities due to the sharply expanding use of electrical energy. But where the dominant force in 1956 came from business capital spending, the emphasis in 1957 is expected to shift to consumer spending.

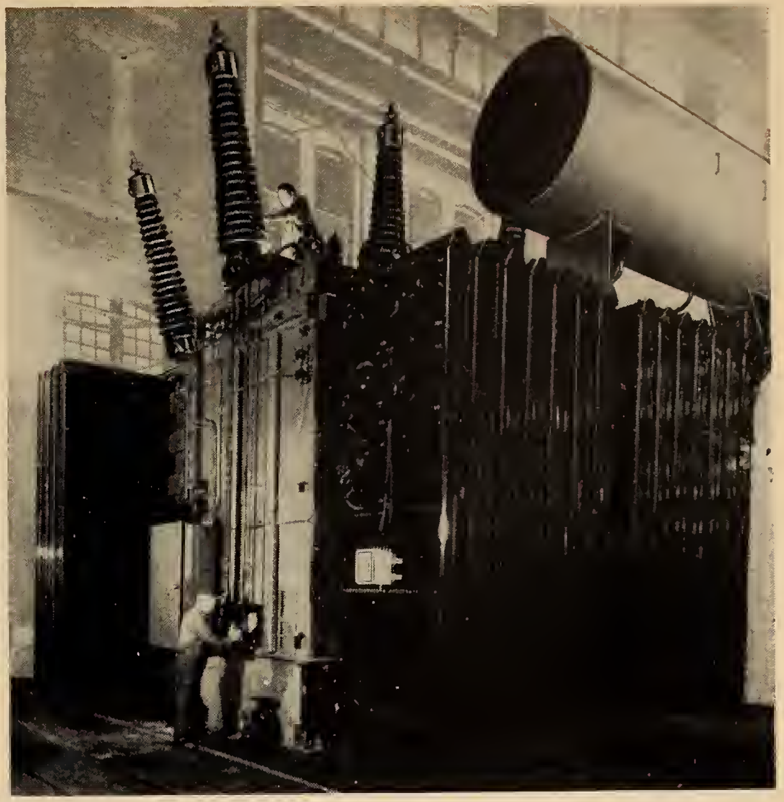
Though increases for staples such as ranges and refrigerators may not be spectacular, newer, low-saturation appliances such as laundry equipment, dishwashers, electronic ranges, air conditioners and dehumidifiers, will show substantial gains. The increasing application of electronic apparatus will be a major factor in the growth of the industry, placing it among the fastest growing manufacturing industries in Canada.

More Home Appliances and Better Wiring

The average consumption of electricity per residential customer rose from 1,423 kilowatt hours in 1939 to 3,750 kilowatt hours in 1956. Some 94 per cent of the four million occupied dwellings receive electrical service. Three million more will be added over the next 25 years, and *per capita* domestic consumption per year will continue its steady rise.

A long range program has been launched to convince the public of the need for better wiring in homes, business establishments and industrial plants. Initiated by electrical manufacturers, it will be developed in co-operation with provincial electric service leagues and with utilities, dealers, distributors, contractors and inspectors.

To emphasize the immediacy of the program, industry spokesmen are pointing out that most Canadian homes lack sufficient electrical outlets to operate more than a small portion of the more than 70 household electrical appliances now available to the consumer.



Heavy electrical equipment for the power industry is exemplified by this 300-ton autotransformer built for Hydro-Quebec's Bersimis development.

Rapid Growth in Electronics

The electronics business has had spectacular growth in post-war years, growing to a half-billion dollar industry. Sales of T.V. and radio receivers, radar and other electronic equipment for defence purposes, closed circuit T.V., electronic computers and other devices added up to more than $500,000,000 in 1956. To this must be added considerable volume sales of the phonograph and records industry based on electronics. The growth of electronics is only beginning. Hundreds of operations now done mechanically and electrically will be operated electronically in the future.

Among the engineering facilities for the improvement of electrical equipment is a new environmental laboratory, of which the vibration test area is shown below. The laboratory is equipped with a stratosphere chamber and with equipment to subject electronic and mechanical components to impact, vibration, and sustained acceleration tests. *(Photos: Canadian Westinghouse.)*

Television production, though sales were down some 13 per cent in 1956, has grown faster in Canada than any other country in the world, becoming as dominant in the home as radio was five years ago. The trend towards high-fidelity play, greater convenience and lower cost, and purchase of the small 45 records and 'long-plays' is expected to continue many years.

In rolling of steel, aluminum, tin, and paper, electronics measures the precise thickness of material and automatically adjusts the rollers to keep the required thickness to very minute tolerances, in some instances to an accuracy of 1/10,000th inch.

Equipment for fighter aircraft, radar lines in the north, and various communications systems for all services is designed and built in Canada's electronic plants. Canada can justly claim a leading position among nations of the world in making use of electronic weapons and devices.

In Quebec province one of the longest industrial microwave communications systems was placed in operation between Montreal and Bersimis. Other systems, shorter but similar, are being installed in three western provinces.

Many New Uses on Horizon

Closed-circuit T.V. is beginning to come into industrial use in Canada. Its use will mushroom as automation of industries goes on. Electronic stoves, refrigerators and air conditioners are products of the very near future. Modern appliances, electronically operated, will require less space, will have no moving parts, and will be more convenient and much less expensive to operate.

Control, measurement and manipulation of radioactive material for nuclear generators rely solely on complicated electronic equipment. Successful atomic power development lies in the discovery, not yet made, of suitable 'direct' means of converting radioactivity into electricity without making steam to drive turbines.

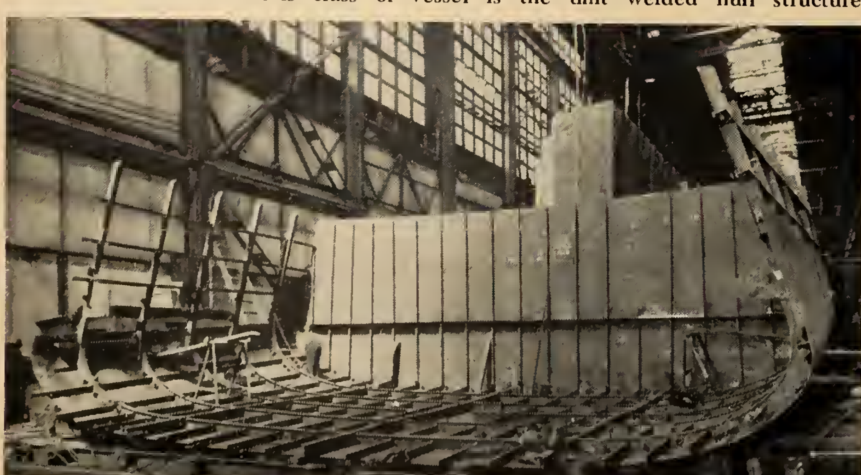
Electronics has now demonstrated the possibility of converting solar energy directly into the form of electricity which can be stored for cloudy periods. It is already done by R.C.A. on a pilot scale.

SHIPBUILDING

The canadian shipbuilding industry was only moderately active during 1956. Satisfactory progress was made on the Navy's current shipbuilding program, the most ambitious ever undertaken in Canada. Without the naval program however, the year would have been difficult and uncertain for many of the shipyards. This building program, commenced in 1949, is now well advanced and will be completed in 1958, with no assurance of its being extended.

Only some 27 ocean going vessels are left on Canadian registry. Nearly all Canadian-owned deep sea vessels have been transferred to British registry because, under the Canadian flag, the wages their owners are obliged to pay make it impossible to compete with British and foreign ships with wage scales half as high. Nor do Canadian operators feel they can build ocean going ships in Canada unless the Canadian government gives some assistance to offset the high level of shipyard wages.

The hull of HMCS *St. Laurent* during construction at Canadian Vickers Limited, Halifax. A feature of this class of vessel is the unit welded hull structure.



Production in 1954

In 1954, the last year for which complete statistics are available, Canada had 76 shipyard establishments, with total employment of 19,356 persons. They purchased materials valued at $56.2 million, added a value by manufacture of $98.6 million and showed production totalling a gross selling value of $156.6 million. This compared with 75,847 employees and production valued at $376.5 million in 1943, the most active year in the industry's history.

The industry, as recorded in Bureau of Statistics reports, includes all establishments occupied in making commercial or naval vessels, plus yards doing ship repair work or outfitting ships for delivery. Naval dockyards on Canada's east and west coasts are not included though considerable repairs and overhauling are done there.

Completions in 1956

Completions for the Navy in 1956 included three Canadian-designed destroyer-escorts, one minesweeper, and an ocean-going tug. Three barges, a lighthouse tender, and a survey vessel were built for federal government departments other than Defence. Thirty-eight ships were also completed for domestic commercial owners; of these, four 'canallers' and one ocean-going tug were the only ones over 1000 gross tons. The remaining 33 were barges, scows, tugs, and dredges, ranging from 25 to 1056 registered tons, the largest being for use on the Pacific coast.

Outlook Moderately Improved

Toward the end of 1956 there were signs that the industry was beginning to cash in on the world shortage of deep sea ships. Shipyards that are members of the Canadian Shipbuilding and Ship Repairing Association estimated there were about 14,300 persons employed in their yards compared with some 12,800 at the beginning of the year. Officials of the Canadian Maritime Commission estimated Canadian shipyards had orders on hand for some $48 million worth of commercial shipping, well ahead of the backlog at the end of 1955.

This improvement was primarily due to the Suez crisis which had

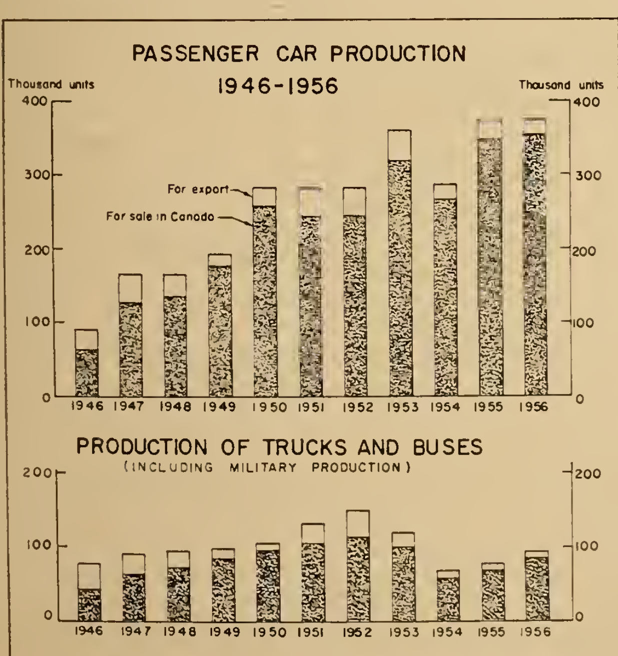
A general view of the yards of Davie Shipbuilding Limited, at Lauzon, Que. Vessels of 28,000 tons have been built in these yards. Fabricating of industrial equipment is also carried out in new shops.

stimulated demand on shipbuilders around the globe, particularly for large tankers and bulk carriers. Completion of the seaway is also expected to bring orders for some big vessels. Unfortunately the scarcity of steel is preventing Canadian yards from promising early deliveries.

What the future holds in orders for ships for the coastal trade depends on the findings of Canada's Royal Commission on Coasting Trade, and on the government's decision on its recommendations. If, after deepening the St. Lawrence, Canada permits shipowners to build ships in the United Kingdom for Canadian coasting trade, it will be disastrous for the Canadian shipyards. Many Great Lakes operators, uncertain of the future, are delaying orders until this question is settled.

MOTOR VEHICLES

The canadian automotive industry made its biggest contribution to the Canadian economy in 1956, with peak employment at 37,225 and shipments of about 475,000 automobiles and trucks with a retail value of $1.4 billion. This sales volume raised total registrations in Canada over the four million mark, including 3,200,000 passenger cars and 1,000,000 commercial vehicles. The 375,000 passenger cars and 99,255 commercial vehicles produced compare with 375,000 and 78,569 trucks produced in 1955. Percentage shares of production were: General Motors, 39.7; Ford of Canada, 29.7; Chrysler, 24.7; Studebaker, 2.2; and American Motors, 1.5.



Most of the industry's gain in 1956 over the previous year can be attributed to the strong comeback of the market for trucks. Factory shipments of Canadian vehicles built for export likewise showed a gratifying increase from 35,000 in 1955 to an estimated 38,000 in 1956. Sales of some 425,000 passenger vehicles and 100,000 trucks appear possible for 1957 and could be achieved without straining the industry's capacity.

In 1955, latest year on which full figures have been published by the Bureau of Statistics, fifteen establishments employing 33,429 persons purchased materials valued at $631 million, added a value of $269.6 million by manufacture, and produced vehicles and parts with a gross selling value of $907.4 million; 68,629 of the trucks and 9,383 of the passenger cars produced that year were exported.

During 1955, 9,600 vehicles were exported to South Africa, 3600 to Australia, 2400 to New Zealand, with all other countries receiving the remaining 3000 in lots of 377 or under. Shipment of cars in 1955 was divided between 224,357 4-door sedans, 70,835, 2-door sedans, 30,600 hard-top convertibles, 17,000 station wagons, 13,345 chassis without bodies, 9700 5- or 6-passenger coupés, 2600 soft top and 15,300 other models. Shipments of trucks included 39,784 of gross weight 5000 pounds and under; 11,624 of weight 5000/10,000 pounds, 4088 of weight 10,000/14,000 pounds, 9395 of weight 14000/16000 pounds, 9239 of weight 16000/19500 pounds, 3391 of weight 19500/26000 pounds, and 491 of weight over 26000 pounds. Buses included 333 transit type and 224 chassis.

Imports during 1955 included 4681 freight automobiles, 19,989 passenger automobiles valued at under $1200 each, 8981 passenger autos valued at over $1200 each, 292 motor buses, and 9539 of all other types of passenger vehicles.

In 1955, motor vehicle registrations for all Canada totalled 3,948,787, of which 2,935,412 were passenger automobiles, 938,115 commercial vehicles, 39,007 tractors and 36,253 motor cycles. During the year withdrawals from use were estimated at 150,883 passenger vehicles and 20,730 commercial vehicles.

AIRCRAFT

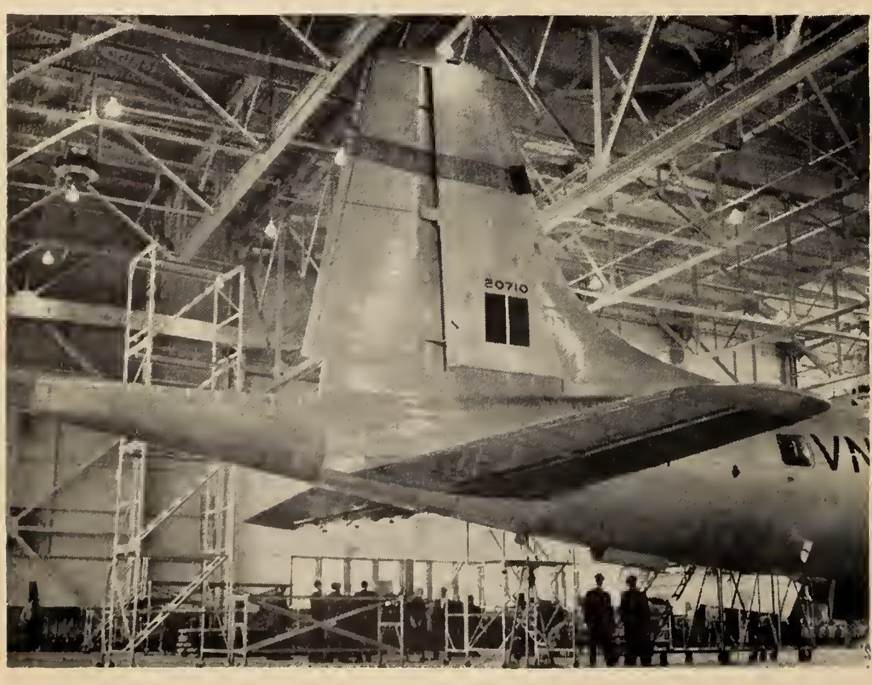
For Canada's aviation manufacturing industry, 1956 was a year of solid accomplishment and one of achievement in production, design and engineering. Ranking third among Canada's manufacturing industries in the number of employees and ninth in the value of sales, the aircraft and parts industry in 1956 maintained employment at close to the 1954 total of 35,000, though total value of production rose to some $360 million.

In 1954, the most recent year for which full statistics are available, forty-three parts plants and four assembly plants produced aircraft and parts valued at $343 million. During that year the industry purchased $158.9 million worth of materials and added $181.4 million value by manufacture. Production was 15 per cent lower than in 1953.

Production in 1956 was only exceeded by the peacetime record year of 1953, when 38 establishments employing 33,356 persons showed production valued at $398.7 millions, and by the wartime record year of 1944 when 45 establishments employing 79,572 persons showed a production valued at $427 million.

Today, Canada's four assembly plants are Canadair Limited, at Montreal, Avro Aircraft Ltd., and de Havilland Aircraft of Canada Ltd., Toronto, and Canadian Car and Foundry Co. (controlled by Avro Aircraft) at Ft. William. Among the 43 parts plants, outstanding are: Orenda Engines Ltd.; Canadian Steel Improvement Ltd.; Bristol Aeroplane Co. of Canada (1956) Ltd.; Bristol Aero Engines Ltd.; Bristol Aircraft Western, Ltd.; Canadian Pratt and Whitney Ltd.; Fleet Manufacturing Ltd.; and Rolls Royce of Canada, Ltd.

The largest aircraft so far built in Canada is the RCAF maritime patrol *Argus*, derived from the Bristol *Britannia*. The tail stands some 37 feet above the hangar floor at the Montreal plant of Canadair Limited. (*National Defence Photo.*)



Major Accomplishments in 1956

The year 1956 saw the birth of a new Canadian-designed and produced jet engine, Orenda's "Iroquois," It saw near-completion of Canadair's submarine-reconnaissance CL-28, an adaptation of the Bristol 'Britannia', the largest aircraft ever built in Canada. A start was made on quantity production at de Havilland of the Grumman CS2F-1, and commencement of production of the Wright R1820 by Canadian Pratt and Whitney, Ltd.

Avro Aircraft is working on a 'mock-up' and tooling for the CF-105, with the first unit to be produced by mid-1957. Work on the delta-wing supersonic CF-100 is continuing. The company is also working on 'Project Y' V.T.O. aircraft designed and developed on a U.S. airforce contract.

De Havilland Aircraft has started production of the Grumman CS-2F-1 for the Canadian Navy, and has orders for 60, with spares for 100 units. The same company is developing a twin engine transport known as the DCH4 which will be named the 'Caribou'. This will be launched with piston driven Pratt and Whitney engines but later may be powered with turbo-prop engines. It will have a 5000 pound payload and a take-off and landing run of 5000 feet.

Canadair, Ltd., beside the 75 'Sabres' it is building for the Canadian government for West Germany, has export orders from Colombia for 6, and from South Africa for 34. While production of Sabres and T-33 jet trainers is down to a few per month, the company has an order for 25 of the CL-28 reconnaissance aircraft. The CL-44, being developed from it, will replace the R.C.A.F.'s present North Star transport fleet, and may also conceivably be adapted to commercial use.

The company is also designing and building a nuclear research reactor for Atomic Energy of Canada, Ltd. A sizeable order from Republic Aircraft for tooling for the F-105 has been received; as well as subcontract work from de Havilland and Avro, and the building of airframes for Velvet-Glove air-to-air missiles. Design for a small jet trainer has been completed and is under consideration by Ottawa.

The Canadian Car and Foundry Co. Limited aircraft division is fabricating the complex wing assemblies of the Grumman CS2F-1 for de Havilland, as well as wing-and-tail-assemblies for the 'Otter'. Bristol Aircraft (Western) Ltd., formerly MacDonald Brothers Aircraft of Winnipeg, is preparing to build an anti-submarine version of the Bristol 191 twin-rotor helicopter for the Canadian Navy.

Canadian Pratt and Whitney, Ltd., is undertaking a $5 million expansion program. Fleet Aircraft is doing sub-contract work on wheel-ski assemblies for 'Beavers' and 'Otters' and on wing extensions for the CF-100 Mark 5.

Orenda Engines, Ltd. successfully completed the first 50 hour flight test on the new 20,000-plus h.p. PS-13 'Iroquois' jet engine. The engine will be flight-tested on a modified B-47 and will power the new Avro CF-105 interceptor. Production of 'Orenda' engines is still proceeding at a reduced rate.

The latest version of the Canadian-designed CF-100 interceptor is the Mark V *Canuck*. During 1956 progress was made with the supersonic Avro CF-105 delta interceptor, which will eventually replace the CF-100. *(National Defence Photo.)*

ASBESTOS

Shipments of asbestos from Canadian mines during 1956 amounted to 1,017,848 tons, compared with 1,062,000 tons the previous year. Exports at 964,000 tons were also lower than the 1,001,800 tons in the previous year. Productive capacity for the industry reached a new high level, however, as the result of the expansion during the past few years.

The moderate drop in production was due primarily to competition from fibre of Russian origin shipped to European countries under barter or other trade agreements. A moderate decline in construction activity and automobile production in the United States which takes some 60 per cent of Canadian asbestos sales volume also contributed to the decline. Shipments to Britain were also affected by credit restrictions. On the other hand, shipments to Japan recovered to almost their prewar level.

Winding pipe-covering sections made of corrugated and flat asbestos papers. *(Photo: Canadian Johns-Manville Limited.)*

In 1956 there was a fall in demand for spinning grades, but in the relatively more important market for medium grades there was a definite increase in demand, reflecting world wide expansion in the asbestos cement products industry. Short fibres continued to move well, though not quite at the high level of 1955.

The largest producing area continues to be in the Eastern Townships area of Quebec in the vicinities of Thetford, Black Lake East, Broughton, and Danville. Ontario's production comes from Munro Tp., while British Columbia production comes from the Cassiar district. Canada leads all nations in volume of production, with some 60 per cent of world output. Soviet Russia and the Union of South Africa come next in that order.

Asbestos Products Industry

Asbestos has a variety of industrial uses. The longer-fibred spinning material is formed into textiles, and into packing, insulating, and heat-resisting frictional materials. Other fibres are used in the asbestos cement industry for production of pipe, shingle, tile, millboard, siding, roofing, etc., and for the production of asbestos paper. The short fibred material is used in protective coatings, plastics, in lubricating greases and in some specialized applications as an industrial filler. 1955 price quotations per ton were crude no. 1, $960/1500; crude no. 2, $595/900; spinning fibres, $321/514; shingle fibres, $150/200; paper stock, $109/137; waste, $77; and shorts, $35/70.

Production in 1955

In the most recent full statistical report of the industry published for the year 1955, it was stated that 30 mining establishments employed a total of 6729 persons, purchased supplies and containers valued at $11.18 million, and had an output valued at $83.8 million. During the year 17.7 million tons of rock were mined and 12.4 million tons were milled.

Selling values at shipping points for the various grades, exclusive of value of containers, were as follows, in millions of dollars: group 4 (shingle), $36.6; group 7 (refuse), $17.4; group 3 (spinning), $16.0; group 5 (paper), $12.8; group 6 (stucco), $12.25; crude no. 1, no. 2, and other, $0.61; group 8 (sand), $0.46.

Exports during the year included products valued as follows, in millions of dollars: milled fibres, $63.4; waste, refuse and shorts, $30.9; asbestos, $0.48; brake lining facings $0.37; and packing, $0.04; a total value of $97.7.

Imports for the year were valued at $4.05 million, nearly three quarters of which were classified as 'asbestos in any other form than crude, and all manufacturers'.

CEMENT AND CONCRETE

PRODUCTION OF Portland cement in Canada during 1956 amounted to 29.56 million barrels, an increase of 16 per cent over the 1955 production of 25.18 million barrels, while stocks at plants and warehouses at year-end amounted to 1.63 million barrels. During the year 3.2 million barrels were imported.

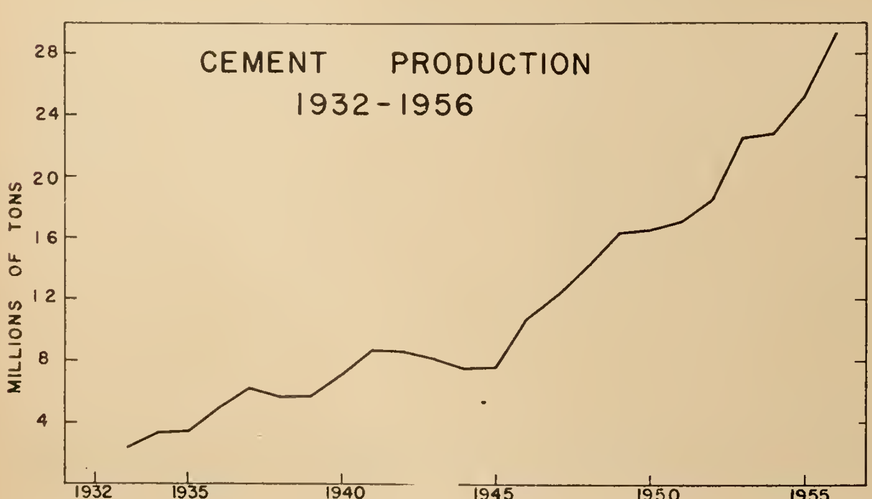
During the year 102.5 million concrete bricks were produced, compared with 130 million the previous year, while 102.5 million were shipped. Production of concrete blocks other than chimney blocks amounted to 109.7 million, with 118.4 million shipped. Production of concrete chimney blocks amounted to 879,000 with 862,000 shipped. Production of cement pipe for drains sewers, culverts and water totalled 551,900 tons , with 553,700 tons shipped. Production and shipments of ready-mix concrete totalled some 4,987,000 cubic yards.

Production of concrete brick for the year was 21 per cent lower than in 1955. Production of all types of concrete blocks was slightly lower than in 1955. Production of concrete pipe was 30 per cent higher than in 1955, while yardage of ready mix concrete also exceeded 1955 production by some 30 per cent.

These figures represent production by the principal manufacturers, which normally account for 85 per cent of the total Canadian output of concrete products and which have not been expanded.

Pattern of the Cement Industry

The cement manufacturing industry in 1955 (last year for which a full report has been published) consisted of 12 plants with combined employment of 2800 persons. These plants purchased materials, containers, and process supplies valued at $11.5 million, while value of production f.o.b. works amounted to 144.3 million. There were 29 kilns in all, with a total capacity of 70,900 barrels per 24 hours.



Imports and exports of cement both increased in 1955. The apparent consumption as computed from shipments, plus imports, less exports amounted to 27.16 million barrels as compared with 24.6 million barrels in the preceding year.

Producers' shipments by provinces, in millions of barrels, for 1955 were as follows: Quebec, 9.5; Ontario 7.66; Alberta, 2.8; Manitoba, 1.94; British Columbia, 1.9; Newfoundland 1.47; and New Brunswick, 0.47. Raw materials consumed during the year included 6 million tons of limestone, 219,500 tons of gypsum, 798,700 tons of clay, 91,400 tons of sand, 71,600 tons of shale, 23,740 tons of iron oxides, and varying amounts of other additives. 501,600 tons of Canadian coal and 325,350 tons of foreign coal were used, as well as 491 million kilowatt-hours of electricity.

During 1955 the St. Lawrence Cement Company brought a new plant into production at the beginning of the year while Canada Cement Company expanded its plant at Fort Whyte in Manitoba. Inland Cement brought a new plant into production at Edmonton early in 1956. Construction of a fourteenth mill will be commenced in 1957 at Vancouver costing one-million dollars.

In 1953 Canada held tenth place among nations of the world in production of hydraulic cement.

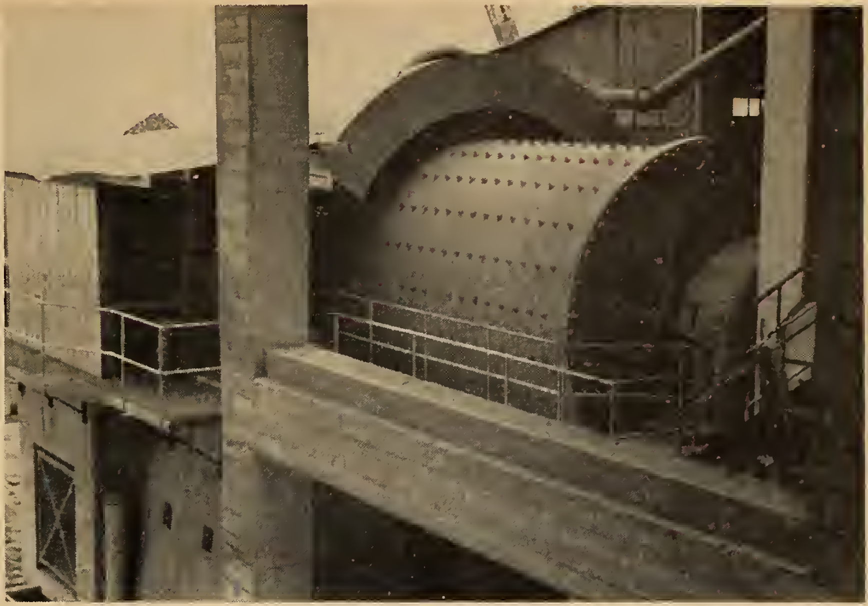
Pattern of the Concrete Products Industry

In 1954, the most recent year for which full statistics were published, 555 operating plants had a total employment of 7539 persons: 3574 in Ontario, 2094 in Quebec, 685 in Alberta, 534 in British Columbia, 181 in Manitoba, 118 in Saskatchewan and 173 in the Maritimes. Production that year included (in terms of millions of dollars in value): ready mix concrete, 42.7; concrete pipe 11.6; gravel blocks, 20.7; cinder blocks, 3.7; other light-weight aggregate blocks, 2.9; artificial stone, 3.1 concrete bricks 4.2.

Value of materials used totalled $46.8 million; value added by manufacture amounted to $53.34 million. Gross selling value was $102.1 million.

In 1955 employment increased to 8,400, and value of shipments rose to $122.4 million, up 20 per cent over 1954.

CLAY AND PRODUCTS



CLAY PRODUCTS made from Canadian clays during 1956 reached a record value of some $38 million, up nearly 9% above the value of production in 1955, of $34.27 million. Most of the gain was due to the increased production of building brick, though increases were also shown for sewer pipe and in fireclay blocks and shapes. With the addition of production from imported clays of some $17 million, total 1956 production from domestic and imported clays for the year would show total value of some $57 million compared with $48.3 million in 1954.

The industry is divided into two sections for statistical purposes: (1) production from domestic clays, including building brick, structural tile, roofing tile, drain tile, stoneware, sewer pipe, pottery and refractories, and (2) production from imported clays, including manufacture of electrical porcelains, sanitary ware, sewer pipe, table ware, artware, floor and wall tile, and fireclay blocks and shapes. The manufacture of sand-lime bricks and blocks is treated as a separate industry.

The industrial clays of Canada may be classed as common clays, stone-clays, fireclays and china clays. Common clays are produced in all provinces. Stoneware clays are found in Saskatchewan, Manitoba and Nova Scotia. Fireclays are found in Saskatchewan and British Columbia, and to a lesser extent in Nova Scotia. China clay is not produced in Canada but ball clay is produced in Saskatchewan. Bentonite is found in Manitoba and

A reinforced concrete structure houses B.C. Cement Company's new 1,500-h.p. finish mill at Bamberton, B.C. (top).

The largest type of cement kiln used in Canada is the 450-ft. long 12-ft. diameter unit in the Woodstock, Ont., plant of Canada Cement Company Ltd.

Below, the brick plant at Estevan, Sask. A $1.2 million plant at Regina for vitrified clay products is planned by Western Clay Products Limited. (*Photo: Sask. Govt.*)

Alberta. Large quantities of fireclay and china clay are imported.

A total of 161 plants operated in the domestic and imported clay products industries in 1954, the most recent year for which full statistics are available. These plants employed 5973 workers. Combined production was valued at $48.34 million compared with $44.6 million in 1953.

Production in 1954 from Domestic Clays

There were 125 plants in the domestic clay industry in 1954, which employed 3929 persons and produced goods having a gross value of $32 to $36 million. Ontario employed 1887, Quebec employed 867, Alberta employed 382, British Columbia, 244, Nova Scotia 40, with other provinces employing the balance. Materials used were valued at $770,000.

Production of fireclay and firebrick was valued at $231,000; structural tile was valued at $70,000. Production of drain tile, sewer pipe and flue linings was valued at $6.2 million; and pottery at $534,000. Production of bentonite in 1952 was valued at $388,000, while production of fullers' earth amounted to some 16,000 tons in 1953. Exports of clay and clay products in 1954 were valued at $2.2 million.

Production in 1954 from Imported Clays

In 1954 the imported clay products industry had 36 establishments employing 2044 persons, which had a total production valued at just under $16 million. Ontario employed 1126 of these, Quebec employed 733, while Alberta and British Columbia together employed 185. Materials used were valued at $4.1 million.

Products of the imported clay products industry were valued as follows: firebrick and stove linings, $1.29 million; high temperature cements, $291,000; electric porcelains, $4.76 million; pottery, artware, $275,000; sanitary ware, table ware, stoneware; $6.25 million; and all other products, including sewer pipe, floor tile, walltile, flue lining, etc., $3.1 million.

The Sand-Lime Brick Industry

Four plants in Canada operated in this industry during 1954; three in Ontario and one in Quebec. These plants employed 146 persons. Materials used were valued at $515,000. Factory shipments including some building blocks, haydite tile, etc., were valued at $1.93 million. Factory shipments of sand-lime bricks amounted to 38,600 M valued at $1.11 million. Output of sand-lime building blocks were valued at $164,500.

LUMBER

Production of lumber in 1956 in Canada amounted to 7.64 billion board feet, compared with 7.8 billion board feet in 1955, a drop of 2 per cent from production in 1955. In spite of this, the industry enjoyed a good year. The export market was disappointing, however, with exports to the United Kingdom falling 38½ per cent, exports to the United States falling 7 per cent and exports to other countries falling 20 per cent. More than half of the year's production was exported.

Ontario, Quebec and New Brunswick produced somewhat more than in 1955, while Nova Scotia produced somewhat less. Production in the prairie provinces and British Columbia fell slightly. Manufacture of hardwood made a sharp comeback and demand for most grades was steady throughout the year. No general resistance to prices was evident, though resentment was seen growing in the United States market at the increasing exchange premium. Higher ocean freight rates were a dominant factor in price levels in the U.S. and in Europe.

In the domestic market, increasing industrial expansion and the record activity in the construction industry largely made up for the drop in exports. During the second half of the year, however, a sharp drop in housing starts developed in Canada due to the tight money situation.

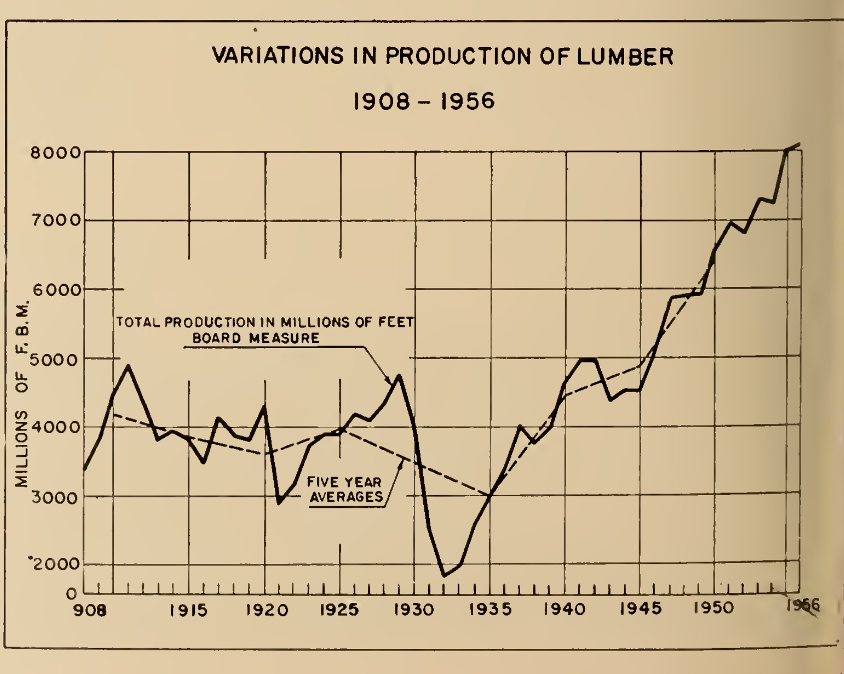
Industry Statistics

To obtain a perspective of Canada's lumber industry as a whole, it is necessary briefly to review operations for 1954, the most recent year for which full statistics are available. In that year, production of sawn lumber amounted to 7.24 billion feet, exceeding the seven billion mark for the second year on record, but down 0.9 per cent from the peak of 7.3 billion feet reached in 1953.

The industry includes not only production of sawn lumber of all dimensions but also that of shingles, box shooks, staves and heading, other saw products, and the barking of pulpwood in plants other than pulpmills. Operations in the woods are not included.

Of the 7696 active sawmills reporting in 1954, 1910 were located in British Columbia, 1721 in Quebec, 1112 in Ontario, 750 in Alberta, 667 in Nova Scotia, 550 in Newfoundland, 388 in New Brunswick, 377 in Saskatchewan, 136 in Manitoba, 68 in the Yukon and N.W.T.

For the year, 1028 small mills were



excluded as well as a few hundred small plants in other groups. Output of these mills accounted for less than one per cent of total production.

The mills range in size from the gigantic mills of the Pacific Coast, cutting up to half a million fbm per shift, to the little mills cutting one to two thousand board feet daily. Larger mills are concentrated around Vancouver, New Westminster, and the lower B.C. mainland, as well as along the Ottawa valley, Georgian Bay, Rainy River and on the coast of New Brunswick.

Employment in 1954 for the industry totalled 57,000 persons of whom 44,500 were production workers; 29,300 were employed in British Columbia mills, 9500 in Quebec, 7500 in Ontario, 2800 in Nova Scotia, 2800 in Alberta, 2500 in New Brunswick and 900 in each of the provinces of Saskatchewan and Newfoundland.

Gross value of all sawmill products produced in 1954 amounted to $572.2 million. Cost of materials and supplies used totalled $301 million, while value added by manufacture amounted to $263.6 million. Exports of lumber during the year totalled some 4 billion feet valued at $326 million, while imports the same year totalled 172 million board feet valued at $19 million.

Production in 1954 was divided between 6.8 billion feet of soft woods and 427 million feet of hardwoods. Of the softwood production 35% was spruce; 29% Douglas fir; 12% hemlock, 6½% cedar and 6% white pine, 4½% jackpine, and 3% balsam fir, with the remaining 3% tamarack, red pine, yellow pine, and cypress.

Of the hardwood production 39% was yellow birch, 25% maple, 12% poplar, 6% basswood, 5% white birch, 4½% each of elm and aspen, with the remaining 4½% beech, oak, ash, alder and cherry.

Principal sawn products in 1954 were divided as follows: lumber 7.2 billion feet valued at $483 million; shingles 2.7 billion feet valued at $24 million; ties 4.7 billion feet valued at $8.1 million; shooks 31 million feet valued at $2.7 million; flatted mine timbers 887,000 valued at $1.8 million; laths 141 million feet valued at $1.5 million; hardwood squares 11.8 million feet valued at $1.4 million; and pickets, staves and heading 33 million feet valued at $1.9 million.

Outlook for the Future

Industry leaders at the Canadian Lumberman's Association Convention early in 1957 pointed to growing signs of resistance to buying both in export and domestic markets, with substitutes out-selling lumber because of price, due to costs of production going up everywhere. Predictions of a 20 per cent drop in housing for 1957, with one dollar being spent on lumber and lumber products out of every six spent on materials for new houses, gave cause for concern. Nevertheless they foresaw production and demand approximately the same in 1957 as for 1956.

Looking further into the future, observers saw the United States market becoming of critical importance to Canadian lumber exporters when the Anglo-European common market, with its 200 million people, becomes a reality. Though the United States can meet its own lumber needs, Canadian exports can still compete and increase if technological improvement and conservation practices limit production costs.

LEATHER

THE ONLY PORTION of the leather products industry of direct interest to the construction and heavy industries is the leather belting industry. Firms classified in this industry are those whose chief item of manufacture is transmission belting of leather. The industry is confined to Quebec and Ontario. Production consists of leather belting, welting, straps, washers and miscellaneous items.

Production in 1954

In 1954, the most recent year for which full statistics are available there were 12 establishments: 6 in Quebec, and 6 in Ontario. Total value of shipments was $1.29 million, 26 per cent lower than in 1953. Of this total production in Quebec was valued at $619,300 and production in Ontario was valued at $667,300. These 12 plants employed 45 persons. Value of materials and supplies used amounted to $513,000, of which 279,300 lb. of belting leather was valued at $382,400. Of the total gross value of shipments amounting to some $1,286,600, production of leather belting was the principal item and was valued at $810,150.

Though statistics for the leather belting industry by ~~itself are not avail~~able for 1955 and 1956, shipments of all leather products in 1955 and 1956 were valued at $225 million and $238 million, 10% and 16% higher respectively, than in 1954.

RUBBER

CANADA'S SUPPLY of synthetic rubber is entirely produced at Sarnia, Ontario by the Polymer Corporation of Canada Ltd., while the nation's supply of natural rubber is all imported. Polymer Corporation, with a total employment of some 1,600 persons, produced some 116 million pounds of synthetic in various forms during 1955, while production in the first 10 months of 1956 was some 17 per cent higher than in the same period of the previous year.

Synthetic production is predominently in the form of Buna-S, followed by Butyl and small quantities of all other types. In addition to a $4 million expansion program now under way, the company will spend a further $7 million on capital projects this year.

The Rubber Products Industry

Canada's rubber products industry in 1955, the last year for which full statistics are available, comprised 82 establishments of which 32 were in Quebec, 42 in Ontario, four in British Columbia, three in Manitoba, and one in Alberta. Ontario accounted for 81% of factory shipments and 70% of the employment, while Quebec accounted for 19% of shipments and 30% of employment.

In 1955, consumption of all types of rubber added up to 223 million pounds: 66% was used in the manufacture of tires and tire repair materials; 2½% in wire and cable; 9.3% in footwear; and 22½% in other products. Production of tires and tubes consumed 45% of natural and 40% synthetic. Wire and cable covering was almost entirely made from synthetic, while footwear was made from 44% of each type.

Canadian industry used more synthetic than natural rubber in 1956, for the first time since the end of World War II. Consumption of synthetic jumped to a record 108.4 million pounds, representing nearly 45% of all rubber used. This compares with 90 million pounds and 40½% of the total in 1955. In 1943, first year for which statistics are available, consumption of synthetic was 8.25 million pounds, jumping the following year to over 55 million pounds.

Consumption of natural rubber in 1956 fell to 96.4 million pounds or 39.8% of all rubber used; from 99.3 million pounds the previous year, 44½% of the total. Top for any year in use of natural rubber was in 1941 with 119.2 million pounds. Consumption of reclaimed rubber in 1956 rose to a record 37.3 million pounds compared with 33.7 million the year before. Stocks of rubber at the end of the year 1956 amounted to 4713 long tons of natural, 6755 tons of synthetic, and 1,589 tons of reclaimed.

CHEMICAL INDUSTRY

THE CHEMICAL industry has expanded steadily since the war years, and the value of production of chemicals and allied materials was estimated, in 1956, to have reached some $1,150-million as compared with (in round figures) $1,050-million in 1955 and $660-million in 1950.

Official statistics for 1956 will only be available after this report is printed, but it is reasonable to accept a figure of about a ten per cent increase in value of total output for 1956 against 1955, or about seven per cent increase in physical volume, allowing for increased selling prices in the later year, which is in line with the average rate of increase in recent years.

The strength of the consumer market and construction activity are reflected in the most apparent increases in the chemical field among primary plastics, pharmaceutical products, and explosives.

Capital outlay for expansion of the industry was announced at the beginning of 1956 to the extent of some $165-million, but some of this proposed work was not completed in the year and will be carried over into 1957, for which no great reduction in the rate of capital expenditure is anticipated. The final figure for 1956 is expected to be at least double that for new investment in 1955 and not much below the 1952 record of $141-million.

Petrochemicals

Probably the outstanding feature of the present general expansion of the chemical industry is associated with petroleum and is noted in the growth of the petrochemical industry. Though not simple to define, this may be said to include the production of chemicals (including plastics) from petroleum or raw materials derived from petroleum (i.e., by-products of oil refineries).

The value of petrochemical production in Canada more than trebled from 1949 to 1955, when it reached about $127-million, and this figure is expected to double again in the next five years.

Sulphur is a particular by-product of the petroleum industry that is becoming increasingly important, and the combined capacity of sulphur plants existing or projected during 1956 will be more than half of current Canadian needs for elemental sulphur, with further capacity in view as sulphur has to be removed from the ever-increasing natural gas supplies.

First item in a new industrial development at Shawinigan East was a sulphuric acid plant, shown below, with a capacity of 25,000 tons per year. *(Shawinigan Chemicals Limited.)*

Other Chemicals

The development of natural resources, particularly the mining and pulp and paper industries, maintains the need for heavy chemicals used in those fields. The extent of the operations is also leading to the construction of chemical plants in areas remote from the existing centres of production, though most of the expansion of the chemical industry continues to be in the industrialized areas of Ontario and Quebec.

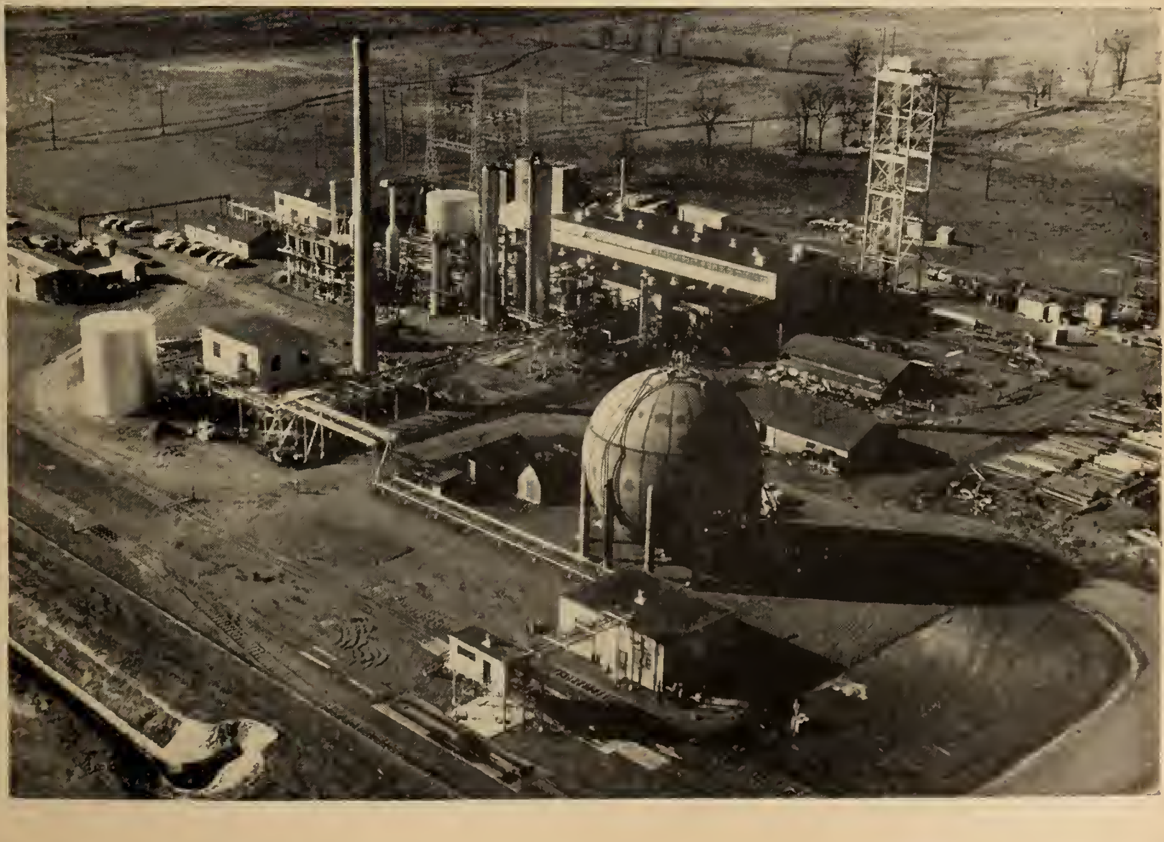
Imports and Exports

Though exports of chemicals in 1956 rose somewhat over 1955, imports from foreign sources increased considerably. Of the total $260.5-million of imports in 1955, over 85 per cent came from the United States and under 9 per cent from the United Kingdom; exports in 1955 showed a sharp increase to $210-million (from $161-million in 1954), of which over 53 per cent went to the United States (more than the pre-war ratio) and less than 10 per cent to the United Kingdom (about half the pre-war proportion of such exports).

Scope of the Industry

For statistical purposes, the chemical industry is considered as a "chemical and allied products" group,

Above, is part of the synthetic rubber plant at Sarnia, Ont., of the government-owned Polymer Corporation Limited, the only indigenous producer of synthetic rubber. Below, a view of the $9,000,000 ammonia plant of Canadian Industries Limited, at Millhaven, Ont., which was brought nearly to completion in 1956.

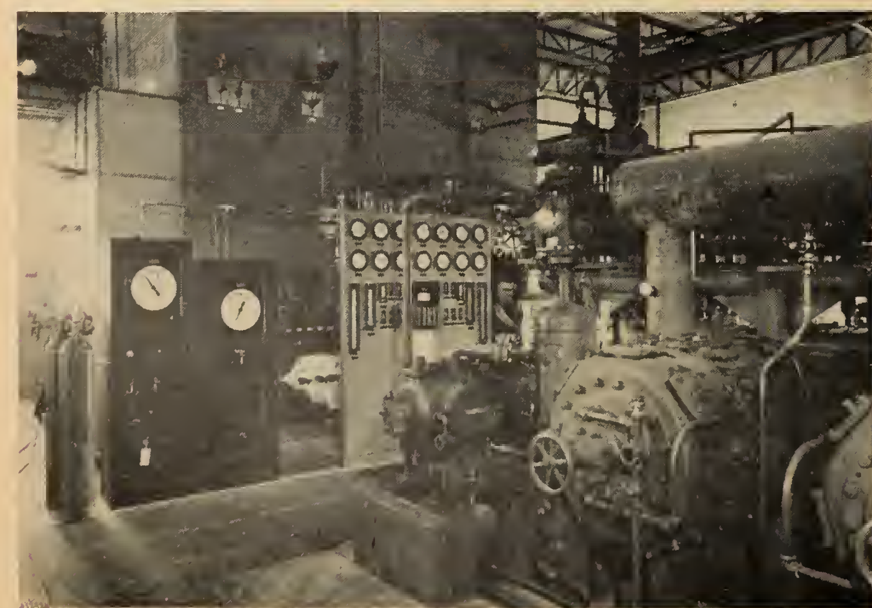


which includes the following main divisions: coal tar distillation; heavy chemicals; compressed gases; fertilizers; medicinals and pharmaceuticals; paints and varnishes; soaps and washing compounds; toilet preparations; inks; vegetable oils; adhesives; polishes and dressings; primary plastics; and a miscellaneous category of such items as explosives, hardwood distillation, insecticides, matches, dry colours, and so on.

In 1955, there were 1112 establishments under this grouping, employing nearly 51,500 persons. The gross selling value of the products of these establishments was nearly $1050-million, for an at-plant cost of materials of almost $482-million and a total cost of fuel and electricity at plant of some $33.3-million. The leading categories, in terms of gross value (in millions of dollars, to the nearest unit) were: the 'miscellaneous' group mentioned above, 218; heavy chemicals, 175; paints and varnishes, 120; medicinals and pharmaceuticals, 105; soaps and washing compounds, 100; fertilizers, 93; and primary plastics, 75.

Extensive construction and development programs call for increasing supplies of explosives. Above is the acid building of a commercial explosives plant near North Bay, Ont., under construction in 1956. *(Photo: Du Pont of Canada.)*

Canadian production of acetylene in 1956 was some 183 million cu. ft. and of oxygen 1,278 m. cu. ft. New plant sites included Moncton, N.B., Sudbury, Ont., Kitimat, B.C., and (an oxygen plant, below) Montreal. *(Photo: Canadian Liquid Air.)*



Expansion in 1956

It is not possible here to record all the details of new plants and extended facilities that were completed, started or projected during 1956, but a few specific examples will serve to indicate how the industry expended its large capital investments.

In Ontario, construction included a new ammonia plant at Millhaven, caustic soda and chlorine extension at Cornwall, sulphuric acid plant at Copper Cliff, hydrogen peroxide plant at Hamilton, and laboratories for paint and plastics research in the Toronto area. At Maitland, Ont., a new plant for acrylic fibre was under construction and bulk storage and filling facilities for hydrogen peroxide were installed. At Kingston, nylon yarn facilities were expanded and new plant started which will produce nylon resin. A new explosives plant at North Bay was nearly completed.

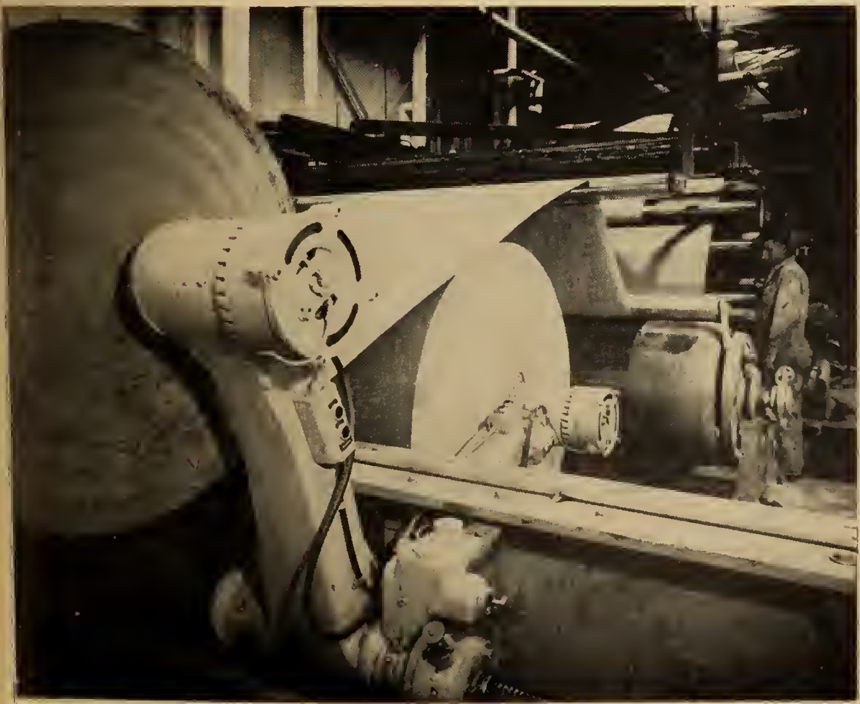
In Quebec, construction included an explosives plant at Sept-Iles; expanded cellulose film facilities at Shawinigan Falls; sulphuric acid, caustic soda, and chlorine at Shawinigan East; vinyl chloride and resins at Shawinigan Falls; phenol, acetone, and hexylene glycol facilities at Montreal East; oxygen and acetylene at Sept-Iles.

In addition to this expansion in existing centres, a new caustic soda and chlorine plant was nearing completion in British Columbia, and the Blind River mining area of Ontario, previously without such industry, will be served by about a quarter of Canada's sulphuric acid capacity.

A government survey in 1956 showed the extent of research in the Canadian chemical industry. This industry spent about $8 million on research during 1955, and planned expenditure proposed at the beginning of 1956 was to be increased by about one-third. Research spending by the chemical and allied groups in 1955 was the third largest.

The giant stackers at the La Tuque mill of Canadian International Paper Company, where a $20-million expansion program was completed during 1956.

PULP AND PAPER



PRODUCTION IN 1956 AND NOTES OF THE MAJOR DEVELOPMENTS IN THE INDUSTRY

The largest corrugator in Canada, installed in the new paper box and converting plant of Crown Zellerbach Canada Limited, at Richmond, near Vancouver, B.C. *(Photo: Jack Cash.)*

THE GREAT forests of Canada have long been one of the country's major assets. On them is based the pulp and paper industry, which is not only one of the largest in terms of manpower and value (it is one of the "billion dollar" industries), but is second in the world only to the United States, regarding the industry as a whole, and considerably the greatest producer of newsprint in the world.

Preliminary figures for 1956 have been published by the industry (final D.B.S. figures are not available until later); these figures show that the gross value of output in 1956 was some $1,400,000,000. This was about $100-million above the 1955 figure of $1.3-billion. Not only was this a record total, but another notable feature was the attainment, for the first time, of a figure for value of exports for the industry in excess of one-billion dollars; this easily kept the industry in its leading foreign-trade position with some 22 per cent of all Canadian exports.

An aerial view of the site of a $38-million pulp mill being constructed near Duncan, B.C., for British Columbia Forest Products Limited. Deep-sea wharf, ferry slip, and scow dock are in centre, rear. Town of Crofton is in the right background.

The individual items that reached new maximum levels of production included pulp, newsprint, paperboard, fine paper, and wrapping paper. The physical output of all products from Canadian mills was about eleven million tons, higher by nearly six per cent than the previous maximum in 1955. The main comparative statistics for production during 1956 and 1955 are shown in Table I.

Pulp

Canadian production of wood pulp in 1956 was 5.7 per cent greater than in 1955. The total figure of some 10.5 million tons compares with the total production in the United States of over 22 million tons, which represented an increase of about 6 per cent over the previous year. Al-

Table I. Principal Statistics for the Pulp and Paper Industry°

	Production 1956	Production 1955	Exports 1956	Exports 1955
Gross value of output	$1.4 billion	$1.3 billion	$1,040 million	$991 million
	tons	tons	tons	tons
Total wood pulp	10,543,016	9,967,641	2,388,484	2,368,420
Dissolving and spec. chem.	411,747	419,899	344,551	358,146
Bleached sulphite paper grades	674,765	637,408	443,530	463,056
Unbleached sulphite	1,834,325	1,738,413	379,893	368,525
Bleached sulphate	812,534	770,155	670,281	652,044
Unbleached Sulphate	801,269	670,229	225,385	214,273
Other chemical	234,022	201,972	45,628	40,917
Groundwood	5,679,983	5,429,162	268,491	259,344
Newsprint	6,468,815	6,190,647	5,971,692	5,805,113
Containerboard	474,227	391,032	56,555	22,608
Boxboard	412,176	397,204	25,274	30,755
Total paperboard	886,403	788,236	81,829	53,363
Fine paper	248,005	215,306	16,712	13,506
Coated paper	29,167	26,198	1,006	1,097
Other printing paper	91,135	79,537	60,684	51,089
Special papers	122,171	113,292	6,437	5,787
Wrapping paper	280,591	257,870	14,309	14,985
Bldg. papers and boards	281,000	262,564	22,500	25,000

There are some slight duplications in the foregoing figures. Some paperboard and wrapping paper is used by the mills for packaging. Coated paper covers a tonnage that undergoes a further processing after it leaves the paper machine and thus is also included under other grades. Total wood pulp production includes screenings, but excludes defibrated and exploded pulp. In addition to wood pulp, the industry uses annually in the manufacture of paper some 570,000 tons of stock including waste paper, straw, rags, cotton linters, flax, leather, jute, and other fibres.

°Provided by the Canadian Pulp and Paper Association. Preliminary 1956 figures.

though consumption rose almost universally, so did the output of the main producers, so that Canadian exports of wood pulp only rose by less than one per cent; there was, however, a substantial increase in domestic consumption of all paper grades of pulp, due to larger production of paper and paperboard by Canadian mills.

Newsprint

The demand for newsprint in 1955 and 1956, particularly from the United States, was such that Canadian mills were regularly operating around two or three per cent above rated capacity. By the end of 1956 increased production rates through plant improvements and the installation of new capacity had overcome the shortage. At the same time, Canadian consumers received 7.4 per cent of output compared with 6.9 per cent of the (smaller) output in 1955. It is anticipated that increased capacity of the industry will allow

Nearly complete in 1956 was the $35-million Hinton, Alta., project of North Western Pulp and Power Corporation (top). A whole townsite and a $5-million natural gas pipeline to bring fuel from the oilfields have been built. Centre, the dark buildings to the rear are new grinder and paper machine rooms added to the Kenora, Ont., mill of The Ontario-Minnesota Pulp and Paper Company, as part of a $20-million construction project. Below, the Elk Falls Company division of Crown Zellerbach Canada Limited at Campbell River, where a $15-million kraft pulp mill was completed in 1956.

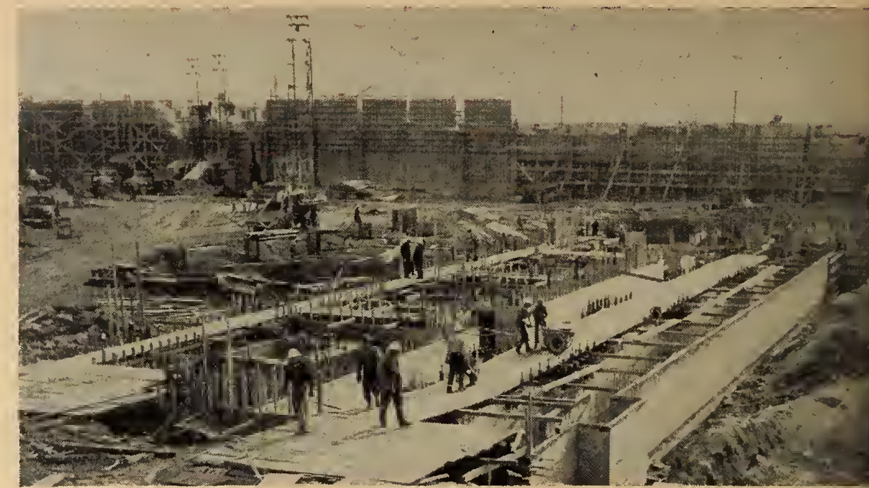
Canadian newsprint mills to operate somewhat below 100 per cent capacity for the immediate future.

Paperboard and Other Papers

Nearly a quarter of the value of the industry's products in 1956, amounting physically to some two-million tons, came from mills making paperboard and papers other than newsprint. Output of nearly all grades was larger than in the previous year, and total exports of paperboard were about 50 per cent greater than in 1955. In Canada, some 1.8 times as much paperboard as newsprint is used, and two-thirds of the paper consumed in Canada is in the industrial categories such as paperboard, wrapping, tissue, and other industrial papers.

Expansion of the Industry

In his report to the 44th annual meeting of the Canadian Pulp and Paper Association, in January 1957, the Association president, R. M. Fowler, compared the position of the industry with that of the whole Canadian economy. Since World War II the value of the pulp and paper industry had risen three-and-a-half times to its 1956 value of $1.4 billion; in the same period, the gross national product of Canada had risen only two-and-a-half times (though this rate of expansion was itself enormous).

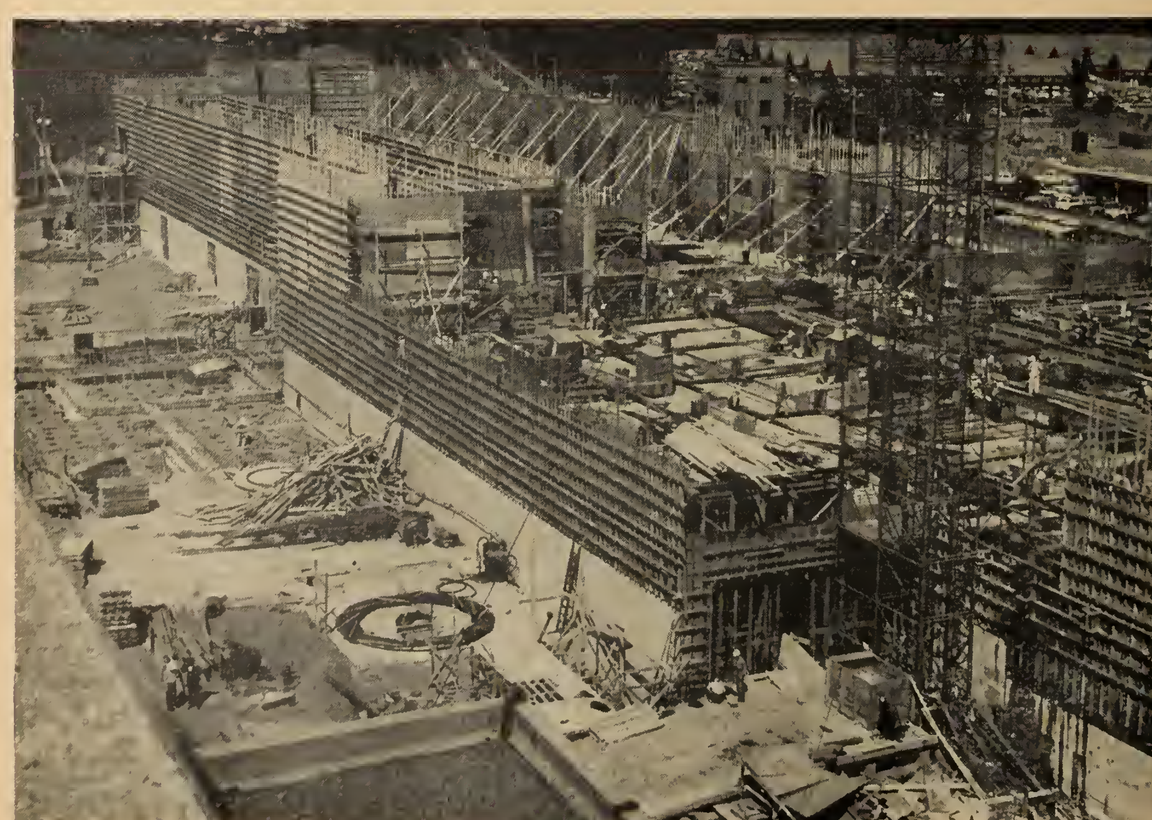


The replacement and modernization of equipment is a continuing process throughout the industry and is of considerable concern to the engineering profession, as are the many entirely new developments that are in hand or projected. It is not possible here to give details of even those projects that were valued at over a million dollars, but a summary will show the magnitude of the operations involved in the expansion of the industry and some of the more important developments are illustrated.

Surveys of the industry* in 1956 showed that in March there were in hand or planned 84 projects for construction and modernization, valued at over $713 million. By June these figures had risen to 101 projects valued at nearly $853 million (less than March by $42 million of the March projects completed and $131 million deferred, but with $312.5 million of new work added).

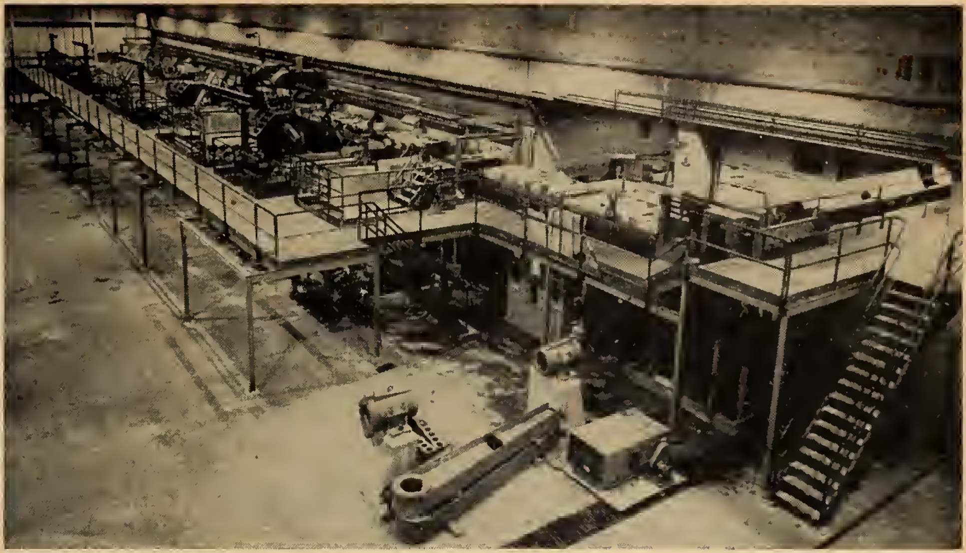
The June survey showed that the industry was developing in areas

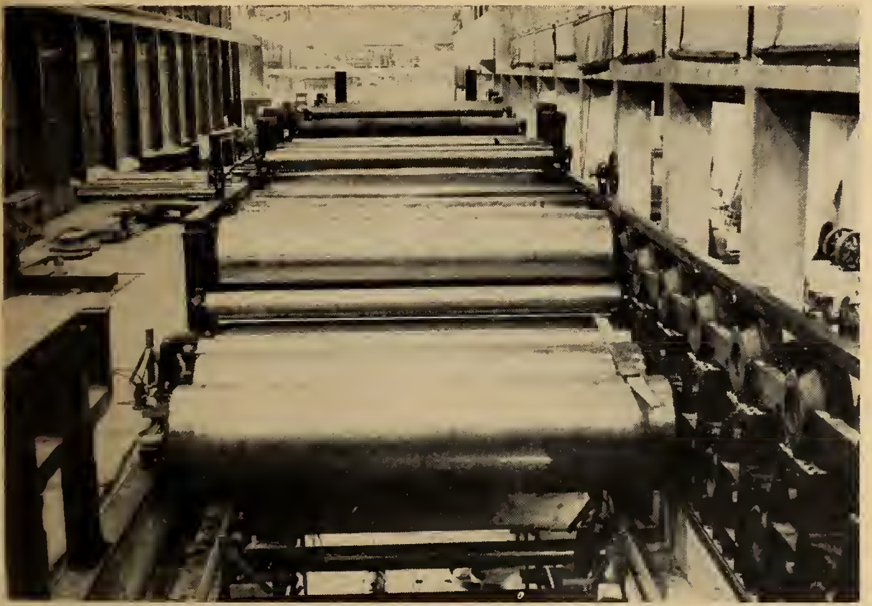
*"Survey of Pulp and Paper Mills in Canada"—*Pulp and Paper Magazine of Canada.*



FROM START

At left (p. 640) is a view of construction during 1956 of Powell River Company's ninth paper machine building (background) and groundwood and screen rooms. In the centre of this page are the dryer section rolls being installed for the No. 9 paper machine.





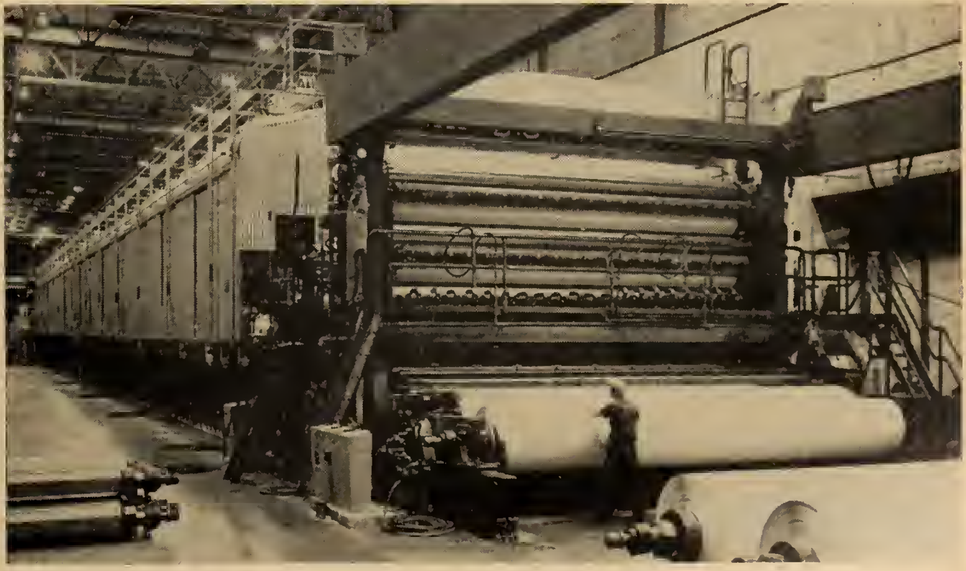
other than the traditional provinces of Quebec, Ontario, and British Columbia, particularly in the prairie provinces. The number of projects listed was divided by provinces as follows: Quebec 33, Ontario 27, British Columbia 17, Newfoundland 8, New Brunswick 4, Nova Scotia 3, Saskatchewan 3, Manitoba 2; Alberta 2; one site was undecided and one company with Canadian headquarters had a project in the U.S.A.

By December, 1956, the carryover of unfinished projects had risen to nearly $945 million. This figure shows the confidence of the industry in the long-term prospects, though there was some slowing of the announced rate of expansion during the year. For example, the cost of new projects announced during the second quarter, already mentioned, was some

TO FINISH

At right is the completed No. 9 paper machine, from the dry end. At the top of this page is an overall view of the new groundwood mill.

At left (p. 640) is a scene of construction at the Port Alberni, B.C., mill of MacMillan and Bloedel Limited, part of a $63-million expansion program. *(Photo: Dominion Construction Company.)*



$312.5 million, whereas the value of such projects announced from July to December was considerably less at $120.2 million.

It would appear that, on the whole, the various fields within the industry are being regarded by those responsible for the progress of the pulp and paper industry in Canada with an eye to keeping abreast of demands for products, or even a little behind the immediate demand, rather than to provide capacities that could become excessive by an uneconomical margin within the reasonably near future.

Power Developments

The establishment of a producing centre of the pulp and paper industry in any particular area depends on the availability of sufficient quantities of power. For this reason, the industry frequently sites its plants within reach of the large hydro-electric developments and several companies have their own extensive interests in power production.

One of the outstanding developments under way during 1956 was the Hinton, Alta., project of North Western Pulp and Power Company. This is not only a major undertaking, and the largest of its kind so far in Alberta, but is claimed to be the first mill in the world to use natural gas as fuel for all operations. To supply this fuel a $5-million pipeline has been built from the Alexandria oil-fields near Wabamun.

In the more conventional field of hydro-electric power production, a few examples will indicate the relation between the two industries.

Part of the Ontario Paper Company operations during 1956 was the start of construction on the McCormick dam project No. 2, on the Manicouagan River. This will eventually add 150,000 h.p. to the existing 100,000 h.p. capacity of the generating station. The project is in an area, also being further developed by Hydro-Quebec, that will supply aluminum developments at Baie Comeau and requirements of the Gaspe Peninsula.

Work was also started on the Murdock-Wilson power development on the Shipshaw River, which will bring in a new powerhouse to supply mills of Price Brothers and Company who operate nine power plants.

The expansion program of the Powell River Company (illustrated in this report) involved the provision of additional facilities from B.C. Electric Company, including a 107-mile transmission line that crosses Jervi Inlet; this aerial crossing, at 10,10 ft., is the fourth longest in the world

NATIONAL DEFENCE

A FULL REPORT on the National Defence Program for the fiscal year 1956-57 will not be published until May 1957. Thus it is only possible to quote the Department's intentions for the year as outlined in the Annual Estimates approved a year ago by Parliament, and to add thereto comments from the three armed services, from Defence Research and from Defence Construction (1951) Ltd. as to what extent these intentions were carried out.

In the main, production of equipment for the services, with exception of imported equipment and construction of barracks, air fields, and other facilities, is included in production figures contained elsewhere in this special review issue from various industries, such as those concerned with steel production and processing electrical manufacturing, shipbuilding, aircraft production, motor vehicle production, and construction.

In practice, each service prepares its estimates, gets them approved by Parliament and does much of its own engineering and design. Purchases of supplies and equipment are made through Defence Production, while contracts for construction and for engineering supervision thereof are awarded by Defence Construction (1951) Ltd.

Defence Estimates for 1956-57

National Defence Estimates for the fiscal year 1956-57 totalled $1,775 million, the same as for the previous year, of which only $1,750 million had been actually spent as of March 31, 1956. This total of $1,775 million was divided as follows, in round figures: military personnel costs, $480 million; operations and maintenance, $570 million; procurement of equipment, $533 million; construction, $146 million; NATO and Infrastructure budgets, $18 million; mid - Canada Line, $100 million. Deductions for charges to special accounts amounting to $72 million reduced the total to the amount of the official Estimates.

The total was earmarked for the various services and for other purposes as follows: navy, $325 million; army, $477 million; air, $872 million, defence research, $79 million; mutual aid, Infrastructure and NATO budgets, $143 million; and administration and pensions, etc., $68 million. Deductions due to credits for mutual charges to special accounts of $189 million reduced the total to the amount of the official estimates.

Military and Civilian Personnel

Strength of the regular forces at the end of 1955 including cadets and apprentices stood as follows: navy, 19,223; army, 47,162; air force, 50,330; a total of 116,715. Total strength of reserve forces stood at 56,490. Added thereto were civilian employees in the three services and the Defence Research Board, and for inspection and administration, numbering 54,500, and at National Defence Headquarters a further 4330 civilian employees. Officer candidates in training at Canadian service colleges, at universities, and under other plans as of the same date totalled 6,947. Militia personnel attending training courses at summer camps totalled 20,568 (all ranks).

Military personnel costs totalling $480 million in 1956-57 estimates were divided as follows: navy, $80 million; army, $198 million; and air force $202 million. Principal items under this heading are pay and allowances, travelling and removal expenses, clothing and food.

Operations and Maintenance

Estimates for 156-57 totalling $570 million for operations and maintenance included major classes of expenditures for the three services totalling $478.7 million, divided as follows: navy, $95 million; army, $127.2 million; and air force $256.5 million. By categories they included: civilian employment $148.3 million; communications, printing and advertising $11.6 million; barracks and stores, $51 million; gas and oil, $41.8 million; equipment, repairs and spare parts, $155.3 million; property and building maintenance including rentals and utilities $155.3 million; and miscellaneous $62.4 million.

Equipment Estimates

Excluding the Mid-Canada Line, total provision for equipment in the 1956-57 estimates was set at $138.7 million for the navy; $78.8 million for the army; and $256.9 million for the air force. Equipment purchases were forecast as follows: aircraft and engines, $229.7 million; ammunition $70.2 million; ships, $60 million; electronics, $44.8 million; armament $29 million; vehicles, $23.5 million; tanks and A.F.V.'s, $0.6 million; miscellaneous technical equipment, $15.2 million; special training equipment, $8.9 million; and other items, $50.6 million.

Continuing production at reduced rates was provided for CF-100 and F-86 aircraft. Production of Wasp aero engines for mutual aid would be completed in 1956. Deliveries for the CL-28 long range maritime reconnaissance aircraft were to be commenced and pre-production models and production tooling costs for the CF-105 were provided for.

Production of the ammunition program was reduced and revised to maintain production at reduced rates over a longer period of time. Production of the new type small-arms ammunition for the army was to be started. The RCAF estimate provid ed for procurement of test-vehicles for air-to-air missiles.

No new major ship construction programs were planned for 1956-57. Estimates for construction of HMCS *Bonaventure* were the same as for the previous year, and those for anti-sub escorts, minesweepers and modernization of frigates were less than for the previous year.

The estimate for electronics equipment, excluding that to be procured for the mid-Canada line, was $2 million below that for 1955-56. Provision was made for improvement and standardization in the power supplies and navigational equipment aboard naval vessels and in electrical and electronic equipment of naval aircraft. Procurement of new types of wireless equipment for the army was provided for.

For the army, there was increased provision of production of the FN-CI rifle, and for procurement of special military pattern vehicles of ¾-ton, 2½-ton and 5-ton capacities. Final payments on existing contracts for tanks and armoured vehicles were also included. Substantial production of two new types of navigational aids developed by the RCAF for installation in aircraft were provided for.

Defence Research

The appropriation for defence research during 1956-57 of $79 million was 50 per cent higher than for the previous year. This reflected both the challenging nature of the rapid evolution of military equipment needed by the fighting services and the growing ability of Canadian scientific and engineering team to provide vital assistance to the armed forces.

The 1956-57 estimates included provision of $23.1 million for operation of the Board's 11 research laboratories across Canada, as well as for grants and contracts with Canadian universities. The balance of the appropriation covered development programs of the three services. The principal increase of some $23 million was directly related to anticipated expenditures in connection with the CF-105 project and the guided missile program.

Also included therein was provision for research on geophysics and meteorology, oceanography, etc., in the far north; electronics and telecommunications, military medicine; environmental protection; materials; aeronautics; civil defence; evaluation of weapons systems; guided missiles.

Construction

Provision in the estimates for construction was divided as follows: for the navy, $11.2 million; for the army, $72.7 million; and for air, $56.9 million. A breakdown by types of construction showed: station development barracks, hangars, supply depots, workshops, etc., $93.9 million; married quarters and schools, $26.6 million; airdrome development, $6.5 million; minor construction projects, $9.2 million; and purchase of property $4.6 million.

Purchase of Equipment (Air Force)

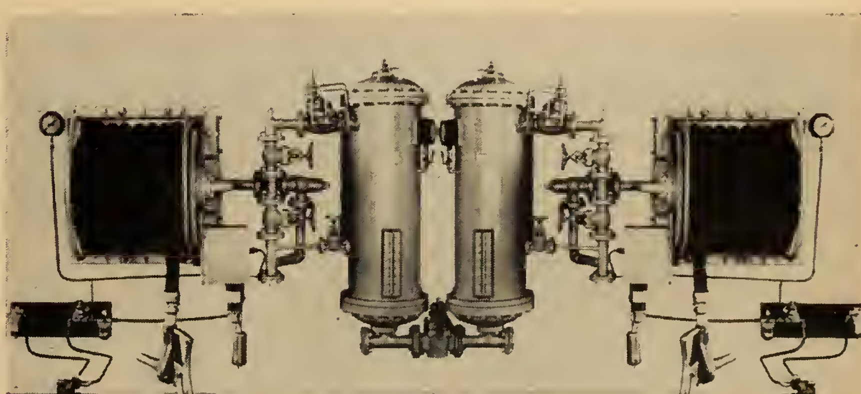
Though 1956-57 estimates for air force equipment remained at $872 million, the same as for the previous year, the current trend was indicated by the drop in appropriations for new aircraft and engines to $197 million from $293 million in 1955-56. Among the major items in the 1956 production were included the following:

(1) Mock-up and tooling for the supersonic delta-wing CF-105.

(2) Continuation of production of the CF-100 Mark V on a limited basis, with one squadron equipped for service in Germany during the year and two more to follow in 1957.

(3) Successful completion and flight test of the new 'Iroquois' engine by Orenda Engines Ltd., with production of 'Orenda' engines continuing at a low rate.

The aviation fuelling system for HMCS *Bonaventure* has 28 fuelling points on flight and hangar decks; each point can filter 150 g.p.m. of fuel (a hangar deck unit is shown below). A duplicate system can blend gasoline and kerosene in the range of ratios 1:1 to 1:5 at 300 g.p.m. Lower picture shows a reduction gear casing cast in aluminum alloy; light alloys are widely used in Naval vessels.



The illustrations on pp. 643-648 are from National Defence photographs.

(4) Preparation at Bristol Aircraft (Western) Ltd., for producing a large number of anti-submarine helicopters for the navy.

(5) Conversion of 50 CF-100 Mark 3's to two-place CF-100 trainers and conversion of a number of B-25's to light bombers, both for the RCAF.

(6) Commencement of the new overhaul repair project on C45's and other aircraft.

(7) Completion of the first CL-28 maritime reconnaissance aircraft, first of an order for 25. An order for the military transport version, the CL-44, is expected for 1957 production.

(8) Production of Wasp R-1340 and Wright R-1820 engines for the navy's CS2F-1 program.

(9) Commencement of production on an order for 60 Grumman CS2F-1 aircraft with spares for another hundred for the navy.

(10) Production of DHC-3 'Otters' and DHC-1 'Chipmunk' basic trainers.

(11) Completion of an RCAF order for 'Nene-10' engines for T-33 trainers, and overhaul of J-33 jet engines for new 'Banshees' for the navy.

Purchase of Equipment (Navy)

The largest number of war vessels ever completed in a peace-time year were commissioned in 1956. HMCS *Assiniboine*, the first entirely Canadian-built destroyer escort, was commissioned for service in August. Two more destroyer escorts, HMCS *Saguenay* and HMCS *Ottawa* were also completed. HMCS *Gaspe* and HMCS *Cowichan*, the first two of fourteen 390-ton MCB class minesweepers, were launched in November, while another, HMCS *Fundy* was under construction.

HMCS *Bonaventure* a new light fleet aircraft carrier, carried out her first, sea trials at Belfast towards the end of the year. HMCS *Bluethroat*, a new mine layer and loop layer, entered the service during the year. Launching of the 840-ton ocean-going naval tug, the *Saint John*, took place in May. This is one of three such vessels under construction for the navy. Other completions during year included three PCS vessels, HMCS *Cormorant*, *Blue Heron*, and *Mallard*, one YMT-10 clearance diving vessel and one YSF ammunition lighter.

The first of the navy's jet-fighter squadrons VF 870 was equipped in 1956 with McDonnell F2H-3 Banshee aircraft purchased late in 1955 from the US Navy. Addition of these fighters made necessary the establishment of new jet overhaul facilities at Dartmouth. The navy also took delivery last year of the first of its new anti-submarine aircraft the CS2F-1 tracker, one of an order for 100 such aircraft, a Canadianized version of the Grumman S2F-1 Sentinel.

During the year the search was continued for new techniques for meeting electrical power requirements with equipment of improved performance, compactness and durability. Trials were carried out on ship-prewetting systems for keeping ships wet in order to wash away radioactive particles. Applications of glass-reinforced plastic were tested for small boat construction.

The Army's new field telephone set TA-43/PT was designed for efficient operation under rigorous conditions. It weighs 9½ lb. and range of operation is 14 miles under wet conditions, 22 miles in dry conditions.

Another new Army means of communication is the field radio set AN/PRC-510, a portable, continuously tunable FM unit with a working range of about five miles in the 58.0-54.9 Mc. frequency range. The set is immersion-proof and is designed to withstand dropping by parachute.

Purchase of Equipment (Army)

There was no new armament procurement nor any new production program set up in 1956-57 estimates with significant impact on the 1956 program, with exception of $2 million to be spent on new types of wireless equipment and increased provision for production of the FN-C1 rifle. Completion of the 1955/56 contracts for 2½-ton and 5-ton vehicles was provided for at a lower rate than in 1955. Provision in estimates for tanks and armoured fighting vehicles was for final payments on existing contracts for which deliveries had been completed the previous year.

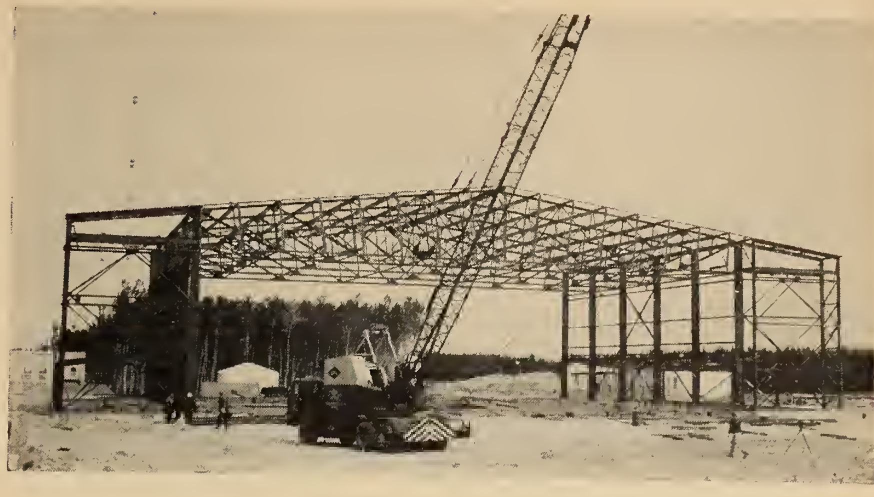
Expenditures in 1956 included (approximately): $45,000 on a 3.2-in rocket launcher, and $1.4 million on 3.2 rockets; $1.65 million on the FN (C1) rifle; $495,000 on a new field radio set (AN/PRC-510); and $400,000 on the new TA-43/PT field telephone set.

DEFENCE CONSTRUCTION

The government agency responsible for the construction aspects of the defence programme is Defence Construction (1951) Limited, known as D.C.L. When requested by National Defence to erect a building and supplied with necessary funds, it is the responsibility of D.C.L. to call tenders, award contracts, supervise construction work, make payments, and turn over the completed building to the service involved. When required D.C.L. engages engineers and architects on a consultant basis for the design of buildings and facilities and for various engineering services. In the six years of its existence D.C.L. has processed $950 million worth of defence construction contracts. In this period expenditures were averaging $140 million a year.

In addition to the defence construction program which is the prime responsibility of D.C.L., this agency has a part in two non-defence projects. In connection with the construction aspects of the Colombo Plan, D.C.L. has been assisting the International Economics and Technical Co-operation Division of the Department of Trade and Commerce and the Canadian Commercial Corporation. D.C.L. is also advising and assisting the Northern Ontario Pipe Line Crown Company on the construction aspects of the Northern Section of the Trans-Canada pipe lines.

1956 was a busy year for D.C.L. Payments made for work performed under D.C.L. contract exceeded $160 million, compared with $104 million in 1955 and $97 million in 1954. More han half of the total was spent on RCAF projects, with the Army construction projects second, the Navy program third and the Defence Research Board program fourth in dollar volume. The two outstanding projects, as in the previous year, were he Mid-Canada Line and the Gagetown camp. It can be expected that vith these two very large projects in heir completion stage the total volume



t top, a permanent hangar being built t Cranberry Portage, northern Manioba, on the Mid-Canada Line, of which n operations building and antenna ower are shown, centre; the tower is me 350-ft. high. The bottom picture hows the CL-28 *Argus*, in production Canada for the RCAF Maritime Command. (See also "Aircraft", p. 628).

of construction work in 1957 will be reduced approximately to the level of 1954 and 1955.

Projects for RCAF

A large proportion of RCAF expenditures on construction in 1956 was for work contributing to the common air defence system of Canada and the United States. The jointly operated system for warning of the approach of enemy aircraft and for the control of interceptor aircraft consists of four main elements. The first chain of radar installations, known as the Pine Tree Line, runs through the populated part of Canada, was jointly built and is jointly operated by Canada and the United States. The second element of the defence system is the Mid - Canada radar warning line, built and operated by Canada. The northernmost Distant Early Warning Line (DEW Line), built and operated by the United States, is the third element. The fourth element added to the system by the United States is formed by radar stations covering the seaward approaches on both flanks of the continent.

D.C.L. has been taking a part in all of these projects except the DEW Line. The work carried out in 1956 was in connection with the Mid-Canada Line (the largest RCAF project currently under construction), and three additional stations for the Pine Tree Line. The last of these projects was administered by D.C.L. on behalf of the United States government.

Other RCAF projects under construction in 1956 included continuing work on RCAF bases in Canada and in France where two Canadian Fighter Wings and the Air Division Headquarters are stationed. These units together with two other Fighter Wings stationed in Germany constitute the Canadian contribution to the NATO air forces in Europe.

Projects for the Army

The most important Army project under construction in 1956 was Camp Gagetown in New Brunswick where last year $20.5 million worth of work was put in place.

At present Camp Gagetown presents a very different picture from what it was at the beginning of the project three years ago. In an area which was completely wooded, there is now quite a large built-up area complete with all services such as roads, water, sewer, light and power. At the end of last summer's work there had been completed 17½ miles of paved streets as well as the paved vehicle compounds and two large parade squares with an area of approximately ten acres each.

In all, 102 buildings have been built or are under construction, 24 of these are now in use by the Army and most of the remaining buildings are over 90% complete. The buildings are all centrally heated from one of the most up-to-date hot water plants and distribution systems on the continent. The main lines of the distribution system run in underground tunnels of which there are about 5 miles. In addition to the heat distribution these tunnels also carry such services as water, light, and communication lines. The work of landscaping or ground improvement is scheduled for this coming summer and the cost of this is estimated at three-quarters of a million dollars.

Camp Gagetown is the largest establishment planned under the Home Station development program. Most of the remaining large Army projects now under construction are also part of the program. The second largest camp of this type is being built at Petawawa, Ontario. In 1956 construction work continued in all three areas. The largest expenditures, as in previous years, were for work in the Halifax area.

The largest Defence Research Board project under construction in 1956 was the Suffield Experimental Station in Alberta. This 100-square mile establishment, the largest of the Defence Research Board stations is engaged in experimental and trials' activities related to the defensive aspects of biological, chemical, and radiological warfare. The main building, the largest modern laboratory in Western Canada, was completed in 1955. In 1956 work continued on smaller buildings, roads, and other facilities.

The very high level of construction activity in 1956 has placed a strain on the available supply of skilled labour and certain key materials especially structural steel. D.C.L. in an effort to avoid long delays in steel deliveries, has reverted to a practice used in 1952 and 1953 when steel was in short supply. As soon as plans are sufficiently advanced to allow ordering of structural and reinforcing steel, tenders are called for these materials separately and well in advance of the tender call for the erection of the building, so that steel may be available on the job when required. In addition to avoiding some delays this practice reduces the contractors' costs of financing the job.

The problems of winter unemployment, the hardships and wastes created by it have been receiving more attention and publicity in the past two years than ever before. For D.C.L. to have permitted winter shutdowns on construction sites would have meant delays in completion of urgently required defence facilities. Therefore it has always been the policy of D.C.L. to insist that work be continued throughout the winter months whenever practicable.

This requirement is embodied in a clause in all D.C.L. contracts. The degree of success achieved is indicated by the fact that 45% of all construction work carried out is being put in place each year in the six months between November and April. This policy, apart from securing the earliest possible completion of a project, is also contributing towards development and general acceptance of methods making winter construction work possible.

STATISTICAL REPORTS of government services at all three levels, federal, provincial, and municipal, are not compiled as such by the Dominion Bureau of Statistics. Complete annual government reports are not published until about a year or more after the end of each fiscal year. For an up-to-date review of the work undertaken in 1956 it is thus only possible to piece together information gathered from several sources.* From these sources a somewhat indefinite picture of government construction, excluding defence, may be developed.

Apart from the many and diverse services performed by federal, provincial, and municipal governments such as regulation, supervision, research, police and fire protection, rentals, finance, justice, public health and welfare, wild life protection, veterans affairs, national defence, postal services, and many others, which cannot be valued in dollars, the end product is in the form of buildings, highways, canals, airports and public works. The dollar volume of production of these, value of materials used and the number of employed are included in the DBS reports of the construction industry; or under defence construction, railways, transit, civil aviation, and other industries reviewed elsewhere in this issue.

Government Construction About 15% Of Total

In the fall of 1955, the annual survey of proposed capital investment conducted by the Department of Trade and Commerce for 1956 disclosed intentions by governments at all levels for buildings and public works amounting to $1,155 million, or roughly 16 per cent of the total 1956 construction volume for Canada. Of this, $330 million was proposed by the Federal government, $510 million by the ten provinces and $315 by municipalities, including cities.

Building construction alone, totalling $317 million, was divided as follows: federal, $210 million; provincial, $60 million; and municipal, $47 million. Government office buildings totalling $100 million and institutional buildings at $65 million, most of them proposed by federal and provincial agencies, were main items.

Public Works at $838 million were divided thus: federal, $120 million; provincial, $450 million; and municipal, $268 million. Of the total, largest outlay proposed was for highways, bridges, tunnels, and subways at $26 million by the federal government, $428 million by the ten provinces, and $119 million by municipalities.

Division of Work by Regions

For a breakdown of these government intentions as between regions we must examine the figures on 'Contract Awards' for 1956 as published in the MacLean *Builder's Guide.* These award figures are generally found to cover between 60 and 90 per cent of actual construction accomplished, depending on the type of contract, category of work and the region where it is done. For Maritime and Western provinces coverage is generally less complete than for central Canada.

Contract awards for government building construction in 1956 showed 39% of the total value was for Ontario; 30% for Quebec; 17% for the prairie provinces; 8% for British Columbia and 6% for the Maritimes. Awards for public works showed 35% for Ontario, 27% for Quebec, 15% for the Prairie provinces, 16% for British Columbia, and 7% for the Maritimes.

Forecast of Institutional Building

In its annual review issue, at the end of 1955, the *Daily Commercial News* reviewed the work under way or proposed for 1956 on government buildings, schools, hospitals, and water and sewage projects. Not all of the schools and hospitals were necessarily government projects, some of them being financed by religious orders, by universities, colleges, school boards or private individuals or groups.

Government buildings were summarized as follows: five in Quebec valued at $26 million; six in Ontario costing $16 million; six in the prairie provinces costing $26 million; and two in British Columbia costing $11 million; a total of $79 million.

Hospitals were listed at nine projects in the Maritimes costing $6 million; twenty-four in Quebec costing $82 million; fifty-nine in Ontario at a cost of $70 million; eleven in the prairie provinces costing $8.4 million; and six in British Columbia costing $19 million; a total of $185 million.

Proposed construction of schools included ten projects in the maritimes at a cost of $3½ million; forty-four in Quebec costing $40.7 million; ninety-three in Ontario costing $90 million; fifteen on the prairies costing $5 million; and two in British Columbia costing $2 million; a total of $141 million.

Water and sewage projects, which are predominantly municipal responsibilities, were forecast at a cost of $113 million for Ontario alone for 1956. For all Canada no comparable financial estimates are available, but recent figures showed the number of municipal sewage treatment plants to be about 520, of which 309 were primary treatment. Sewered municipalities in Canada totalled 845 and serviced about 55 per cent of the Canadian population. When this percentage is compared with nearly 1600 municipal waterworks systems, serving some 65% of the population, it is obvious that many more sewers and treatment works are required for Canada's growing communities.

Preliminary Estimates of Work Done

Preliminary Department of Trade and Commerce estimates of actual work accomplished in 1956 showed a value of some $200 million for schools, compared with $189 million for the previous year. Expenditures in 1956 for hospitals were estimated at some $132 million for construction and $19 million for equipment, as compared with $146.6 million the previous year. In both categories the volume is expected to be higher for 1957. The outlay for government public buildings on the other hand, is expected to be less in 1957, with a larger number of smaller buildings projected. Various governments are expected to spend some $770 million during 1957 on highways and structures.

Provincial Public Works

Typical of the work carried out by the public works departments in the ten Canadian provinces is that of the Ontario Department of Public Works, which has a large construction program under way and planned to meet the requirements of the several departments of the government in carrying out their programs of public services to citizens of the province.

This program consists of new buildings for educational purposes, mental health, administrative offices, provincial police buildings, reformatory institutions, court houses, registry of-

* Department of Trade and Commerce, annual survey of capital investment; Federal Department of Public Works, annual reports; MacLean's *Builder's Guide;* and *Daily Commercial News.*

fices, divisional buildings for the Department of Highways and service buildings for the Department of Lands and Forests.

The Department also builds storage dams in the northern part of the Province and assists various municipalities in connection with drainage problems.

Largest Construction Volume

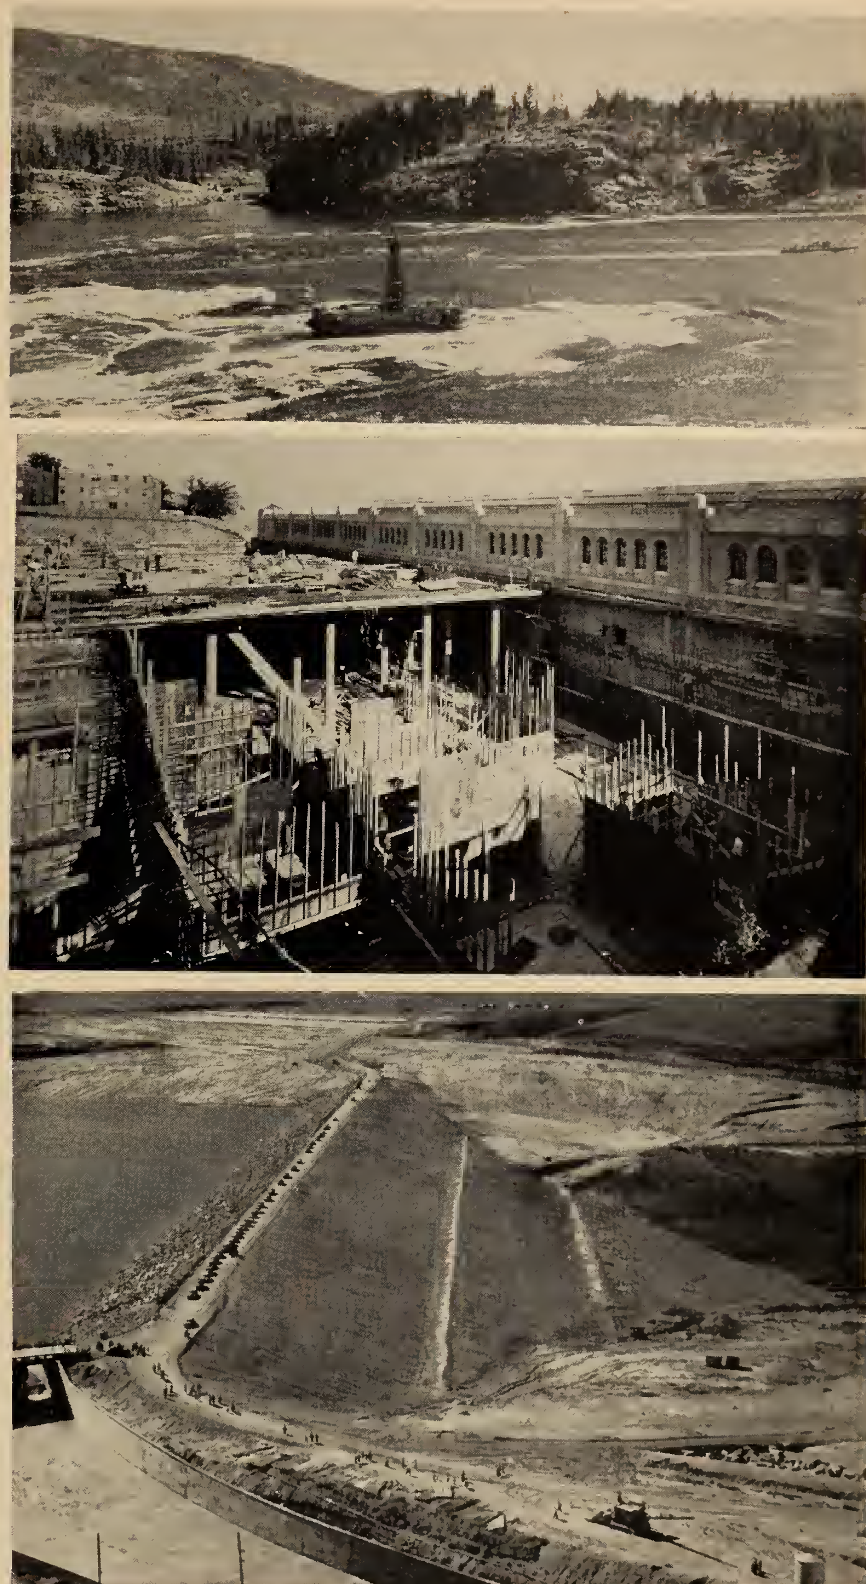
During 1956 the largest volume of construction in the history of the Department was carried out and this effort will be at least equalled or surpassed during 1957. One of the largest sections of construction work was to provide bed accommodation with other ancillary facilities for the Ontario mental hospitals.

During 1956 additions to mental hospitals at Hamilton, Kingston, and Toronto were completed. In addition, major construction work was under way in eight other Ontario cities. It is planned to supplement this large program with construction of a complete new hospital unit in south-western Ontario, as well as other additions to the existing mental hospitals.

For buildings to be used for educational purposes, teachers' colleges, echnical institutes or other educational facilities were under construcion in eight Ontario cities adjoinng universities, colleges or experiiental stations.

Plans were being worked out at ear's end to provide administrative nits for provincial police across the rovince, with a new general headuarters building in Toronto and disict headquarters buildings in stratgically located centres of which iree have been started and others re in the planning stage. A comlete new reformatory institution was earing completion at Millbrook and group of new buildings was being arted at the Burwash Industrial arm.

With the province's large highway rogram under way, typical plans or highway administrative buildings id been prepared, and nine such uildings were nearing completion or ere well under way across the provce. The many individual buildings ider construction for the Department of Lands and Forests form the isis for protection of the forest inistry and wild life including a large out rearing station at Sault St. arie. To keep pace with the conuous expansion and to provide for e services by other departments, e head office of the Department



Work started in 1956 on the latest of many attempts to reduce the navigational hazard of Ripple Rock, in the Seymour Narrows between Vancouver Island and the B.C. mainland. The Department of Public Works is carrying out a major tunnelling operation which will culminate in blasting the rock with 750 tons of explosive. The top picture shows a 1945 attempt at drilling from a scow anchored over the rock. This attempt was abandoned as uneconomical. Centre, an extension to the R. C. Harris water purification plant for the Municipality of Metropolitan Toronto. of Public Works in Toronto has been enlarged by two new office buildings and a start will be made in 1957 on further increasing office accommodation there.

During 1956 expenditures for public works for capital account amounted to $25 million and during 1957 capital payments will approximate $31 milliion.

With slight differences in emphasis on the needs of the various departments and services, the foregoing pattern of provincial public works in Ontario is being repeated in other provinces with total capital expenditures in each roughly proportionate to population. Ontario's share of contract awards last year for public works, at $25 million, represented about 39 per cent of the total government intentions for building construction. Proportionately, Quebec's share might be expected to be about $17 million, the three prairie provinces' share would total about $10 million, British Columbia's share and the Maritime provinces' share $4.8 million and $3.8 million, respectively; making up the total of 'intentions' for Canada of $60.5 million.

British Columbia and the Maritime provinces probably had relatively more *per capita* expenditure for the benefit of the fishing and forestry industries and smaller proportions for agricultural facilities. In the prairie provinces there would be increased emphasis on facilities to serve the farming industry. Outlays for buildings such as hospitals, schools and other institutional buildings, as well as sewage and water supply facilities, would probably be comparable with Ontario on a direct *per capita* basis.

PRAIRIE FARM REHABILITATION

The prairie farm Rehabilitation Administration was set up in 1935 under the Prairie Farm Rehabilitation Act, during the severe drought of the 'thirties'. In 1937 the act was amended to increase its scope and authority, and land utilization became one of the major activities of the rehabilitation program.

The administration is a branch of the Federal Department of Agriculture, with its head office at Regina, Saskatchewan. In the summer of 1956 there were some 1050 employees; 129 of them non-graduate technicians, 177 year-round unclassified staff, and 371 seasonal employees. The engineering services are staffed with highly qualified specialists in the fields of soil mechanics and foundations, hydrology and structures, engineering geology, air photo interpretation, soil and topographical surveys, drainage, and construction.

The land utilization policy is based on a complete soil survey of the prairie provinces covering an area of 50 million acres. It provides a means of taking sub-marginal land out of cultivation and regrassing these areas for grazing purposes as 'community pastures'. Some 1,750,000 acres have so far been taken out of cultivation, and 200,000 acres have been regrassed. Sixty-one operating units at present graze 110,000 cattle yearly. Measures are also provided for control and prevention of soil drifting and erosion, for encouraging improved tillage and cropping practices, and for tree-planting.

Water Conservation

The administration's water conservation program consists of two main divisions: (1) individual and comunity projects, and (2) large water-storage and irrigation projects. The former is concerned with individual stock-watering 'dug-outs' and small dams with storage of one acre-foot of water or thereabouts, and with community projects ranging in storage capacity from a few acre-feet up to thousands of acre feet. Some 55,000 such projects have been constructed to date, most of them small individual projects.

There are some three million acres within the so-called 'drought area' of western Canada for which there are water supplies available in the rivers and so situated that they can be economically irrigated. Alberta has 783,000 acres at present under irrigation while Saskatchewan has 200,000 acres.

Surveys have been made by the PFRA for a large number of extensive projects and many of these have been or are being constructed. Notable among them is the St. Mary project for watering 510,000 acres in the Lethbridge-Medicine Hat area, now partly completed. The St. Mary Dam, built in 1950/51, is a 186 ft. high earth fill structure. Half the land in the project is now 'under the ditch'. The Federal Government has spent some $14.9 million on the storage facilities and main canals, while the province of Alberta has spent a like amount to date on the distribution system which is now about half completed. This is the typical pattern for cooperation between the Federal and respective provincial governments.

Another undertaking is the Bow River project west of Medicine Hat, taken over from the Canada Land and Irrigation Company in 1951. The project has a potential 240,000 irrigable acres of which 57,000 were then served by the ditch. The PFRA is currently undertaking an orderly rehabilitaiton of the works.

Another is the Saskatchewan River reclamation project, for reclaiming an area from annual flooding in the delta of the Saskatchewan river near the Pas, Manitoba, by means of dyking and drainage, and involving reclamation of a million acres in Saskatchewan and Manitoba. Canada's share of its Pasquia section, comprising 35,000 acres in Manitoba, is nearing completion and will soon be ready for settlement. Jointly with the Manitoba government, reclamation of the eastern slopes of Riding and Duck mountains is also being carried out, as well as flood protection along the Assiniboine river.

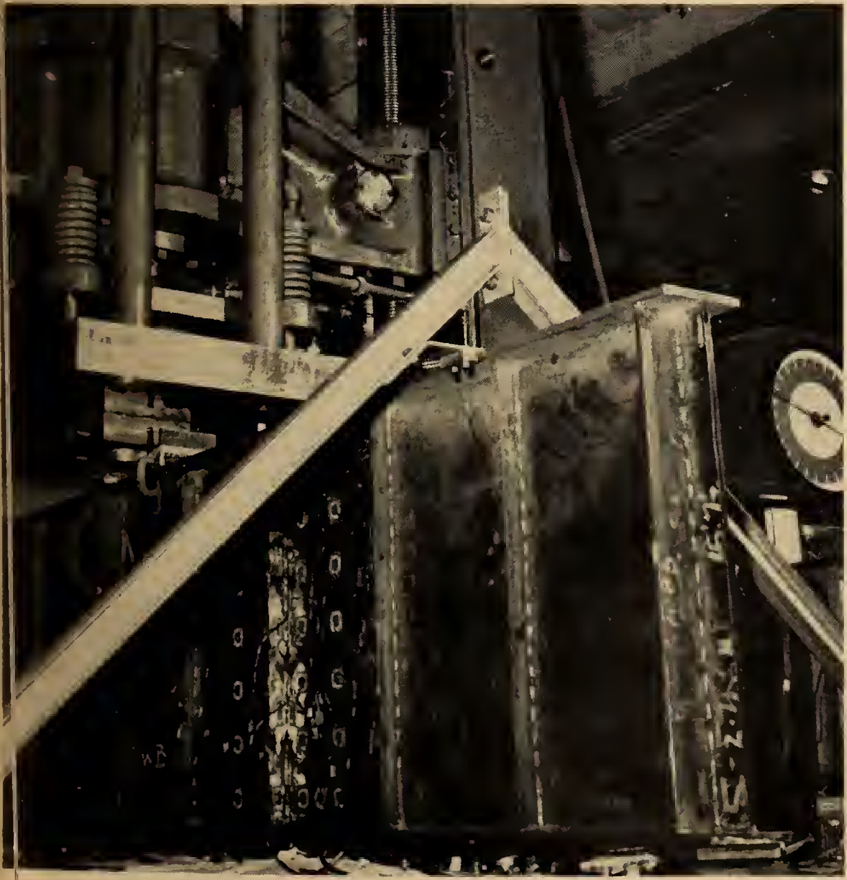
Smaller Irrigation Projects

Numerous smaller irrigation projects have been constructed in central British Columbia in cooperation with the Department of Veterans Affairs under the Veterans Land Act. One of these, recently completed in the Lilloet area under special agreement with the province, has resulted in protection of land under cultivation and in the reclamation of some 14,000 acres of additional land. In all, some 30,000 acres of high-class land were salvaged by the project.

Other major projects still under survey include the Red Deer River project in Central Alberta and the South Saskatchewan project in Central Saskatchewan. The former would irrigate some 500,000 acres, while the latter would supply water to a further 500,000 acres in Saskatchewan.

Expenditures to date by the Canadian Government through the PFRA proper are estimated at about $50 million; including special appropriations, the expenditure to date is approximately $120 million. An appropriation of $12 million is set up in the annual estimates for work to be undertaken by the Federal government in 1957/58. Figures for employment and value of work done on irrigation and drainage projects are included with the construction industry.

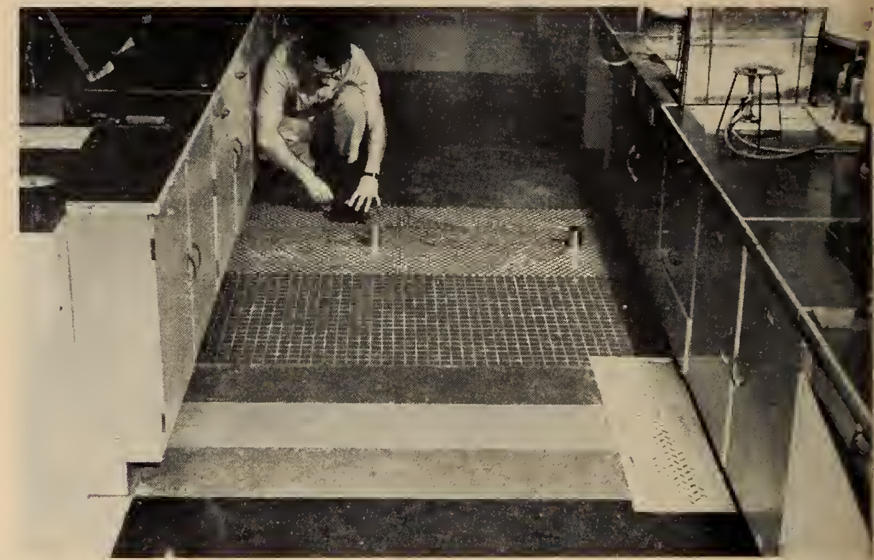
A REVIEW OF ENGINEERING RESEARCH IN CANADA



Above is one of a series of tests on conventional and trussed roof constructions carried out as part of the work of the Division of Building Research, National Research Council. At left is a test being made during an investigation into stresses in a thin-webbed steel plate girder (courtesy McGill University Engineering Library).

THE TERM engineering research is not easy to define. Professor Mordell, of McGill University, has defined it as "research done by engineers". He argues that, broadly speaking, the engineer's training embraces the same range of disciplines as that of a more fundamental scientist, and that, in his research, he resorts to the same logic and attack that the scientist employs.

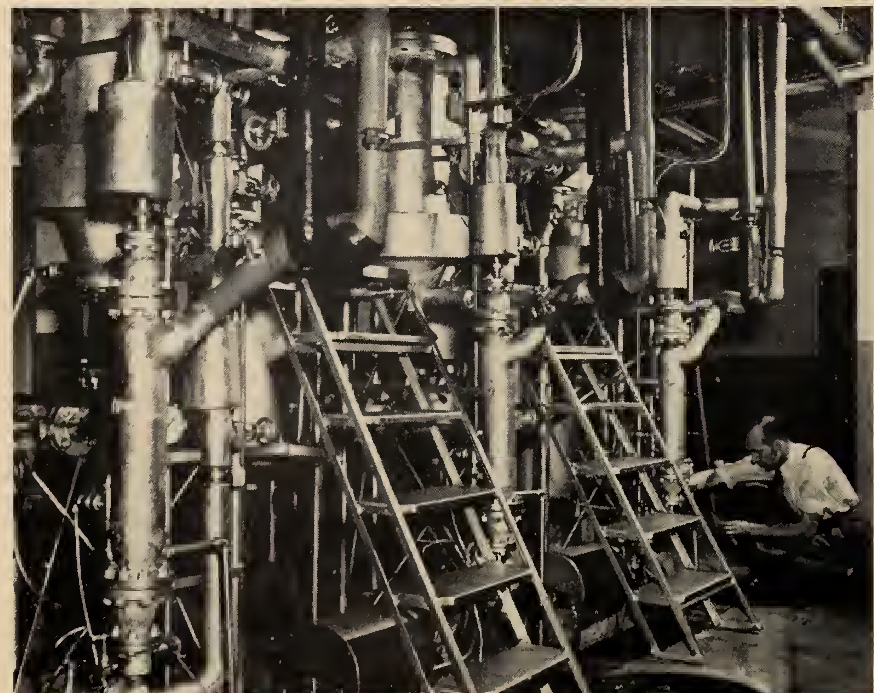
Nevertheless, the engineer's training frequently does not penetrate as deeply into the fundamental sciences and, in general, he leans to applied research rather than fundamental research. He is usually concerned with a method of applying natural laws rather than a philosophical exploration of the laws themselves. This tendency is particularly evident in industrial laboratories.



An investigation of the properties of different types of conductive flooring, for laying where electrostatic charges must be avoided; for example, where explosive gases are used. (Division of Building Research, National Research Council.)

Until recent years, Canada has been pre-occupied with the development of her primary resources and primary industries. Research in mining and agriculture developed rather early and it is only now, as an increasing tendency to process our own raw materials has developed, that research in the secondary industries is becoming more active. Several factors have affected this trend. One of the most important is the structure of Canadian industry which, to a large extent, is composed of subsidiaries of parent firms in other countries, and these subsidiaries have relied almost exclusively on the parent firms for their designs and their development. In some of the larger, independent industries in Canada, such as the pulp and paper industry, research has developed more rapidly. Most Canadian industry is now displaying an increased interest in research and a trend toward greater self-sufficiency in design. This trend appears to be essential if the industry is to obtain a fair share of foreign markets and even to maintain its own domestic market against competition from modern designs from outside the country. Another factor is that the universities were not in a position to engage extensively in engineering research. The professors rarely had time or equipment to pursue their own research and their teaching load usually precluded any possibility of their directing research of students pursuing post-graduate studies.

A battery of 2-cu. ft. experimental digesters in the chemical pulping division of the Pulp and Paper Research Institute of Canada.



Post-graduate training is desirable, and even essential in many fields of research, but there had been little or no incentive for engineers to pursue post-graduate training. Graduates with post-graduate training had no greater guarantee of employment than those without and, indeed, this condition still prevails. Post-graduate training has offered little, if any, financial attraction. The engineering position differs in this respect from the more fundamental sciences.

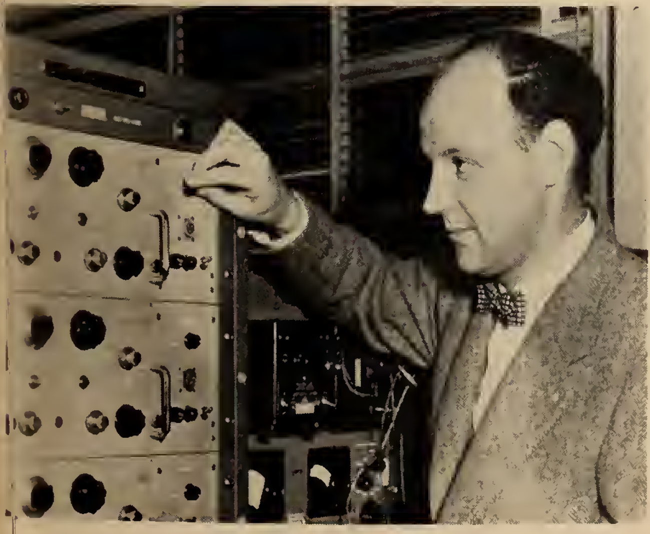
However, the situation is changing. There is an increasing demand for engineers with post-graduate training, both in industry and in the expanding system of research laboratories in the country. They need men with vision, creative ability, originality, and a sound understanding of science, who can introduce new concepts into design. They need men who can expand the frontiers beyond present-day textbook design; they need men who can make new textbooks possible.

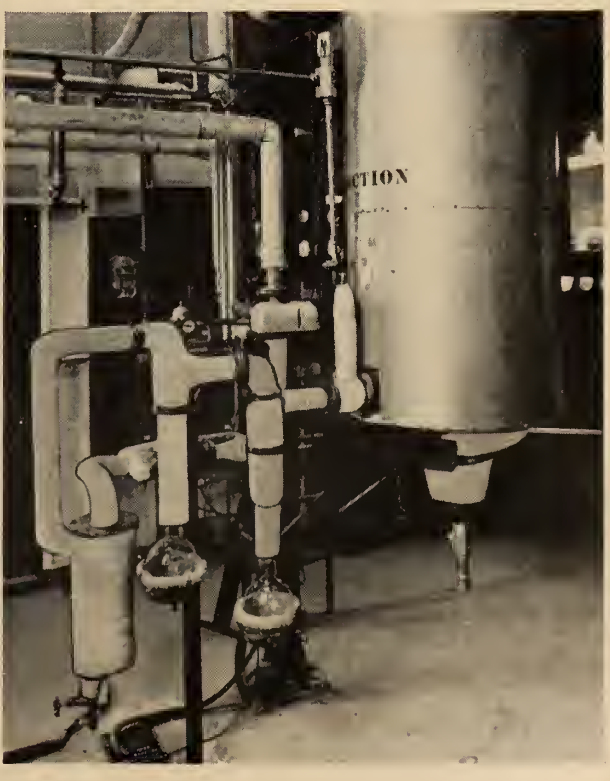
Prior to World War I, there was practically no engineering research in Canada, although there was an occasional notable exception such as the work of Alexander Graham Bell on aeronautics at Baddeck, Nova Scotia. The National Research Council which began its activities in 191 had contributed importantly to scientific research, but its efforts until recently have been devoted mainly to the more fundamental sciences. Its early efforts were confined to the ıward of grants in aid of research ınd scholarships to students pursuing post-graduate work. The grants enıbled university professors to undertake their own research by providing noney for the purchase of equipment ınd to engage students or others to ıssist them. At that time the total National Research Council expendiure on grants and scholarships ımounted to about $100,000 annuılly. More recently, there has been ı marked increase in assistance to ıniversities for research, not only rom the National Research Council ıut from several other sources. The National Research Council alone is ıow contributing directly or indiectly approximately three million lollars annually for this purpose. Support has been increased by a factor of six since the end of World War II.)ther organizations, such as the Deence Research Board and Atomic Energy of Canada, are making imıortant contributions and industries re assisting.

However, the percentage of this upport which has been expended on ngineering research has been disppointingly low, and even now, debite increased emphasis on this hase of research, does not exceed 0 per cent, but an encouraging aspect is that the effort is growing more rapidly than that for all other scientific research.

Occasionally Canada is compared unfavourably with other nations with respect to the effort which she devotes to research. It is true that some other countries are more active, but Canada's position is by no means low on the scale. Unfortunately, it is difficult to assess the true effort in Canada or in other countries. Government expenditures on research are fairly well known, but it is difficult to separate military expenditures from non - military expenditures, and, where governments award research and development contracts, it is not always possible to determine how much of the effort is devoted to conventional engineering design of a new device and how much to investigational work which might properly be called research or development. But, if the problem is difficult in the case of governments, it is much more so in the case of industry. In Canada, the total expenditure by government on research in the fiscal year 1956-57 amounted to approximately 105 mil-

bove, a method of measuring pulpwood boom strain with SR-4 auges on a test bar; right, a small pilot-plant reactor for the omized suspension technique, a new method developed for ringing liquids and solids into thermal reaction; both are amples of the work of the Pulp and Paper Research Institute f Canada. Below, the Radio Physics Laboratory, a Defence esearch Board establishment, in 1956, announced a communiations technique for long-distance transmission of radio signals y reflection from ionized trails of meteors.





lion dollars. An additional 30 million dollars was expended on defence development contracts and this total figure corresponds to a *per capita* expenditure of approximately $9.00. Of the above total, non-military expenditure accounts for approximately 80 million dollars corresponding to a *per capita* expenditure of $5.40. In the United States, the total *per capita* expenditure on research is about $13.70, whereas that in Great Britain is about $11.00 *per capita,* at $2.80 to the pound.

Considering the fact that the figure for Canada does not include money paid to parent firms outside of the country for research and development, it does not compare unfavourably with that in the other two great industrial nations mentioned. Nevertheless, the comparison is based on the total expenditure on research. If it were restricted to industrial research, it is probable that the Canadian position would be somewhat less favourable, but unfortunately no reliable data are available.

All research laboratories, whether government, industrial, or university, are confronted with the problem of recruiting staff and no discussion of research would be complete without some consideration of this very vital factor. The proportion of Canadian population obtaining a degree in science or engineering is about 220 per million. As far as can be determined, only three countries in the world exceed this figure, namely the United Kingdom, Soviet Russia, and the United States. The ratio in the United Kingdom is not significantly greater —certainly less than 10 per cent greater, although in the United States and Russia the ratio is something over twice that of Canada. Here again, the Canadian picture is not too unfavourable.

The fact remains, however, that there has been a very heavy demand for engineers which the universities have not been able to fill. Those who visit university campuses for the purpose of recruiting staff will appreciate the keen competition for graduates. Unquestionably, Canada can absorb the entire university output of engineers and it appears that there will be an increasing demand for some years to come. The universities are endeavouring to meet this challenge. New universities are emerging and existing institutions are enlarging their training activities. Some universities which have not heretofore given training in engineering are now developing degree-granting courses. It is important, also, to insure that an adequate supply of high school students will be available to the universities to make this expansion of facilities worthwhile. Certainly the high schools are expanding at a rapid rate, and it appears likely that the present popularity of the engineering profession will attract many high school students.

Salaries are, of course, always an important factor. Engineering salaries are, in general, comparable with those of other professions in Canada. Engineers in private practice have approximately the same income as members of other professions in private practice, although a greater percentage of engineers are engaged on salary as compared with other professions. The annual income of a salaried engineer is generally lower than that of an engineer in private practice, but this condition is compensated somewhat by a reduction in risk and by the usual fringe benefits of retirement pension, and sick benefits which are associated with a salaried status.

We are in direct competition with organizations in the United States for the services of engineers, and there is definitely a migration of Canadian engineers to lucrative research posts in the United States. However, the Canadian salary structure for research men is approaching that of the United States, particularly for junior engineers, and it is likely that the two will become more nearly comparable. Even so, it is interesting to note that the loss of engineers to the United States is more than balanced by incoming European engineers who are well qualified in training and experience.

In conclusion, the rapid expansion of research in Canada and the promise of a greatly increased interest in engineering research is encouraging. Expenditure on research by industry is still relatively low, but there is a tendency for Canadian industry to become more self-reliant and to undertake a greater and greater percentage of their own design and development. It is to be expected, however, that a significant percentage of research will continue to be undertaken by parent firms and it is probable that government research organizations will continue to perform a higher percentage of the total applied research than in most other industrial nations, although government research organizations are encouraging industry to undertake their own research because it is believed that this is much more effective than research undertaken by a separate body, whether it be government or university. Research is attracting an increasing number of engineers. Industry, universities and government are co-operating to provide increased training facilities and to encourage increased enrollment.

ACKNOWLEDGMENTS

The Engineering Journal wishes to acknowledge the assistance and support received from the many contributors to this issue. It is not possible to refer to them in detail, but they include many federal, provincial, and municipal government departments; the armed services; universities; National Research Council; Canadian Construction Association; Canadian Pulp and Paper Association; Pulp and Paper Research Institute of Canada; *Pulp and Paper Magazine of Canada;* The graphical presentations are taken from the Dominion Bureau of Statistics. Much of the material has been prepared, and other assistance given, by H. G. Cochrane, M.E.I.C.

TRANSACTIONS

As announced in the annual report of the Publication Committee, circulated with the April issue of *The Engineering Journal*, Council has approved the publication of *Transactions* of the Institute. This will contain only technical material and, in the first instance, will be sent to all *Journal* subscribers. The first issue is to appear shortly.

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE ELECTIONS AND TRANSFERS

The Journal in the House of Commons

Recently in the House of Commons there was a discussion about the proposal to increase the grants to the universities. This finally got around to consideration of the shortages of engineers and scientists and to quoting the *Engineering Journal.*

It is interesting to see that the subject which has been discussed by the profession and by employers has at last reached the floor of the House. Also it is interesting to see the personal knowledge the Prime Minister has of the subject, as illustrated by the reference to his friends and associates and their sons in the City of Quebec.

The following is quoted from Hansard of January 29, 1957.

"**Mr. Green:** Will the Prime Minister bring us up to date concerning the situation with regard to engineers and scientists? We all realize that this vote provides for payments without any conditions direct to universities but we hear most alarming reports from time to time about the great shortage of scientists and engineers. For example, there was a report published last week by the Engineering Institute of Canada with reference to the alarming current and prospective shortage of Canadian engineers and scientists. This paragraph appeared in the press report.

More words have been spoken and printed about this situation than about most anything else. Many voices have proclaimed the urgency, but after years of talk no one has done anything of consequence that will improve the situation quickly.

"And again:

There is some promise now that government and industry will help, but the needs appear to be away beyond any sums that are being mentioned as available shortly.

"We all know how important scientists and engineers are to Canada at present and in the years immediately ahead. Can the Prime Minister tell us what is the opinion of the government with regard to all this talk of an acute shortage, and if there is such a shortage whether any steps are being taken to meet it?

"**Mr. St. Laurent (Quebec East):** I cannot give any precise figures to the hon. gentleman. At the present time there are indications of intentions to provide structures of various kinds to a total amount that would be beyond the capabilities of the available scientific or engineering or skilled or unskilled manpower, and greater than the materials available. There is a certainty that not everything that Canadians and Canadian corporations would like to do or have expressed intentions of trying to do during 1957 can be accomplished.

"**Mr. Green:** Because of the shortage of trained men?

"**Mr. St. Laurent (Quebec East):** Because the total is greater than the population of this country, with its savings and even the savings that come from abroad, with its manpower and its materials, can realize in the one year. During last year I understand the amount of capital investment was of the order of about $7.75 billion. Estimates that have been gathered for what I believe are called intentions for the present year would indicate an increase of as much as 12½ per cent over what was realized in 1956. Of course that would not necessarily be 12½ per cent in actual volume because there is an expectation that prices over the year in the construction trades —the capital investment trades — are apt to be as much as 5 per cent higher than in 1956. That would still leave an actual physical increase of 7½ per cent over what was realized in 1956, and my information from the data available to our experts, and their best estimates, is that this is more than the economy can produce.

"Now, with respect to the so-called shortage of engineers, I know there is a greater demand for engineers than there was when either the hon. gentleman or I were at university. Just as one illustration of what I have in mind let me mention this. The hon. gentleman knows the reputation of the Taschereau family in the province of Quebec; it was always producing either clergymen or lawyers or judges. That family has supplied a number of very distinguished clergymen to Canada. The first cardinal was a Taschereau. They have supplied a number of very distinguished judges, and a still larger number of brilliant members of the bar in the province of Quebec. A Taschereau was my partner when I was at the bar. He has only one son, and the son, instead of following in his father's footsteps as has been done for generations by male members of that family, is studying to be an engineer.

"This is because there is now a realization among the young people that there is a greater demand for engineers, and consequently there are more young people adopting the vocation than formerly. I feel therefore, that there will be a greater number of engineers in the future. There will be a greater demand upon the universities to train engineers, and I know that right here in Ottawa there has been a very substantially filled subscription list in response to an invitation to Quebec and Ontario industrialists to contribute to the establishment of an engineering faculty at the University of Ottawa. They are doing this because they feel their businesses will require that kind of equipment. It is just as essential to their businesses to have trained staff as it is to have the machines which they install in their plants. It is, I think, a very encouraging sign that our industrialists should be realizing, as I said, a moment ago, that the greatest of our natural resources are our human resources, and that these human resources have to be developed and cultivated if we want to make full use of the other material resources with which our land is blessed."

Victory For The Self-Employed

Many members of the Institute will have been made happy by the recent announcement of the Federal Government that self-employed workers will be permitted to make income deductions for tax purposes for monies which they have paid in to recognized pension plans.

As conditions were, a person who was employed by a company which had a recognized pension scheme could deduct his contributions from his income for tax purposes, but a person who was working for himself, such as a doctor, a lawyer, dentist, a consulting engineer, or a business man, was denied this privilege.

Upon being informed by the general secretary of the Canadian Medical Association that the Association, along with l'Association des Medicins de Langue Francaise du Canada, was petitioning the Federal Government to have this situation overcome, the Council of the Institute approved of a proposal to join the others in petitioning the Minister of Finance.

This new regulation of the Finance Department will mean considerable to a great many consulting engineers in Canada and to many members of the Institute who, though not actually in engineering at the moment, are heads of their own businesses of one kind or another.

The Institute is indeed proud to have been associated with the sister societies in so worthy an effort.

Field Secretary for Western Canada

The four western provinces are a long way from Montreal. It is not easy to take care of the Institute's responsibilities in that part of Canada from so great a distance or by occasional tours of the president and the general secretary. Consequently for some time consideration has been given to opening a district office there.

It is possible now to announce that a field secretary for Western Canada has been appointed. He is Commodore (E) A.C.M. Davy, R.C.N. (retired) M.E.I.C. He will make his headquarters in Vancouver but will visit branches and members throughout the four western provinces. His services began on May 1.

A. C. M. Davy, M.E.I.C.

His address is: 1370 Minto Crescent, Vancouver 9, B.C.

Commodore Davy is well known across Canada and in his travels will meet many of his earlier associates. The Institute is confident that with such a competent person available full time, much useful work can be accomplished in the West. Branches are urged to use Commodore Davy's advice and services, whenever they may require them.

Commodore Davy retired last June from an active naval career after thirty-nine years' service.

Originally from Montreal, Commodore Davy attended naval college at Halifax and then went on to England for training at the Royal Navy Engineering College at Devonport, England in 1923.

He has held numerous appointments at sea and at naval stations across the dominion, at Halifax, Esquimalt, Vancouver and Kingston. Through the years he has also served as director of naval engineering with the Department of National Defence, Ottawa in the early thirties, and, during World War II, held the responsibilities of wartime director of shipbuilding for the R.C.N.

In 1946, then a captain, he was among those honoured with the award of the O.B.E.

Commodore Davy was appointed deputy chief of naval technical services and engineer in chief at naval headquarters, Ottawa, in 1949.

Distinguished Visitor to Canada

Many Canadians had the opportunity recently of hearing Sir Claude Gibb during his Canadian tour.

In London, Ont., he was entertained by the president of the Institute, V. A. McKillop. In the picture below: Mr. McKillop, Sir Claude Gibb, and D. J. Matthews, chairman of the London Branch. This important tour will be reported in June.

Spectacular Nuclear Congress

If size is a measure of importance, the 1957 Nuclear Congress was important. Doubtless there are many other and more significant standards by which to judge a meeting, but thinking in terms of size leads to figures which can be grasped more readily than other characteristics.

The 1957 Congress produced these figures. The technical program was made up of 282 papers, panels and addresses, with 450 people listed as authors or speakers. The total registration was 7000. In the exhibition there were 125 exhibits.

The Congress was a getting together of four separate groups who for several years have been interested in the studies and practices in the nuclear field. Firstly, there was the Second Nuclear Engineering and Science Conference, then the Fifth Atomic Engineering in Industry Conference, then the Fifth Hot Laboratories Equipment Conference and lastly the Third International Atomic Exhibition.

The Congress, which was held in Philadelphia, extended over five days — March 11 to 15. Most of the meetings were held at the gigantic Convention Hall, but some of those arranged by the National Industrial Conference Board were held at the Benjamin Franklin Hotel. The exhibition naturally enough was in the Exhibition Hall section of the Convention Hall. It was a tremendous show but that it required less than half of the floor space of this one section of the convention centre.

The Congress was sponsored by 26 engineering and scientific bodies including The Engineering Institute of Canada. To show the extent of the interest in the subject and the support for the Congress the names of these organizations follow:

American Chemical Society
American Geological Institute
American Institute of Chemical Engineers
American Institute of Electrical Engineers
American Institute of Industrial Engineers
American Institute of Mining, Metallurgical & Petroleum Engineers
American Institute of Physics
American Nuclear Society
American Rocket Society
American Society of Civil Engineers
American Society for Engineering Education
The American Society of Heating and Air Conditioning Engineers
The American Society of Mechanical Engineers
American Society for Metals
American Society for Testing Materials
American Water Works Association
Engineering Institute of Canada
Federation of Sewage & Industrial Wastes Associations
Health Physics Society
Institute of the Aeronautical Sciences
Institute of Radio Engineers
National Industrial Conference Board
Society of Automotive Engineers
The Society of Naval Architects & Marine Engineers
The American Public Health Assn.
Hot Laboratories Committee.

Nuclear Congress, 1957. This photo shows a portion of the head table of the all-congress banquet, March 13. The Institute's official delegate was Dr. R. E. Heartz, shown third from the right end. Reading from right to left, here are the other delegates: Karl Z. Morgan, president, Health Physics Society; Emil C. Jensen, president, Federation of Sewage and Industrial Wastes Associations, Dr. Heartz; R. A. Schatzel, president, American Society of Testing Materials; William F. Ryan, president, American Society of Mechanical Engineers, Elmer R. Queer, vice-president, American Society of Heating and Air Conditioning Engineers; Marion W. Boyer, member, Nuclear Congress Policy Board; Rev. John Robbins Hart; Lewis R. Gaty, chairman, Philadelphia Committee, 1957 Congress; W. Kenneth Davis, director, Division of Reactor Development, A.E.C.

The Engineering Institute of Canada is proud to be in such good company. It is the hope of the Institute that by such association in so important a study, much valuable information and many important contacts may be made available to Canadians.

The Institute was represented officially by the immediate Past-President, R. E. Heartz, president of Shawinigan Engineering Company. In view of the president's inability to be present, it was a fortunate circumstance that made it possible for Dr. Heartz to represent him, for Dr. Heartz is himself deeply concerned in nuclear matters and his company is active in the field of design.

It will be difficult in an account of this kind to list all the papers and speakers, but members will be interested to know that the complete set of papers will be in the Institute library. Those who are interested may borrow a copy of the 75-page program from which to select the papers they would like to see. The library will be ready at any time to send on loan those which may be selected. If a member desires to purchase copies the library will supply them as long as they last. In any event photo copies can be made by the library.

It is planned that some of the papers will be published in *The Engineering Journal*. The entire group will be submitted to the Publications Committee for selection of those of most interest to Canadian readers.

1958 Nuclear Congress

The 1958 Nuclear Congress will be held in Chicago from March 17 to 21.

The Engineering Institute of Canada will again be one of the sponsoring organizations. Members of the Institute may obtain through the Institute all the information including registration forms, programs, etc., that will be required. The planning of the congress will be reported from time to time in *The Engineering Journal*.

Any member of the Institute wishing to contribute a paper to this congress should communicate with Headquarters as soon as possible indicating the nature of the subject in which he is interested and the manner in which he proposes to handle it. Preliminary abstracts of proposed papers must be turned over to the Planning Committee by July 15th, 1957. The theme of the congress will be "Industrializing the Atom".

"Daylight Through the Mountain"

This is the title of the book which the Institute is publishing shortly telling in considerable detail the story of the lives of Walter and Francis Shanly, two pioneer Canadian engineers.

As has been stated earlier the book will be unique in the annals of Canadian engineers. It will become a permanent part of the history of the profession as well as the history of Canada. Canadian engineers now reading of the great projects of these early pioneers will be just that much prouder of their profession.

By way of interesting members of the Institute in the publication, the *Journal* will publish from time to time short extracts from it. The following material has been supplied to us by the author of the publication, Dr. Frank N. Walker. The story of the Hoosac Tunnel is indeed one of the highlights of early engineering in North America. The fact that several other engineers and contractors failed to complete the work adds just that much more glory to the Canadians who did it "with colours flying". Herewith is Dr. Walker's reference:

The Hoosac Tunnel Project

The "Western Railroad", now the *Boston & Albany*, was built through the *Green Mountains* in the early 1840's. Its grades and curvature were such that many people thought that it could never carry freight in such quantities as the anticipated prosperity of Boston would demand; so attention was turned to the *Mohawk Trail*, further north. There the water-shed between the Hudson and Connecticut Rivers was only five miles across, but it took the form of the Hoosac Mountain which rises to over 1,000 feet above the surrounding country. In 1847, a scheme was put forward to tunnel through this obstruction and charters were obtained to allow such work. This began in 1851 and proceeded with a series of disasters, financial failures and organized opposition until 1868.

In that year the Legislature of Massachusetts decided to offer an over-all contract for the completion of the wôrk and voted $5,000,000 to see the thing through. Francis Shanly, who was in Nova Scotia investigating the possibilities of the prospective Intercolonial Railway, received an invitation to tender on the Tunnel in June, 1868. This he did in conjunction with his brother Walter; but they did not get any encouragement until October when a long expensive grind of meetings and discussions began at which the opponents of the venture were given a very free voice.

In the letter which follows, Walter Shanly writes to his brother on Christmas day from Montreal where he had just arrived that morning after finally signing the contract.

Montreal, Xmas day, 1868.

My dear Frank;

I arrived here this morning, just a fortnight away. I telegraphed you from Boston yesterday to say that the "Broad Seal" of Massachusetts was affixed at 3 p.m. Enclosed you have a complete copy. Only the most dire mismanagement and blundering can prevent our making more out of this thing, at its worst, than we can reasonably hope to make in any other way within the next five years. The letting has caused a widespread commotion. Men turned round to look at me and point me out in the streets, of Boston, the last few days, as one on whom great good fortune had fallen. Heaps of letters already from the poor and needy: I have not time now for discussing details, but we must have an early meeting to lay down the plan of campaign. I shall probably have a call early next week to meet Wentworth, or someone else on the work, to go into the question of properties and take over such things as we require.

I wrote you a day or two ago to say that A. T. Galt had been making overtures to be let in. Subsequently he sought me out again and put the thing in definite shape. He could put in of himself $125,000 U.S. currency, and undertake all the rest of the financing; a good offer. Of course, he wants to see the Contract before closing; and I, on my side, said, I would have to consult you before entertaining any proposition. He is to be here Tuesday. Try and be here too. Prompt action is absolutely necessary. From and after Monday next we will be under $25 a day expenses pumping Central Shaft, which the Commonwealth have kept going ever since the bodies were taken out. That part of the work must be let and I think Alex. S. Brown, of Belleville, is the man to do it. I will write him today to ask if he is still prepared to make me an offer. He told me (in Halifax) that he would do so, saying that he felt sure we would have the work. Wentworth told me that the Council might better have closed with us two months ago, as they had all made up their minds from the first day we were before them that we were to do the work! If there is any of the Old Fire left in us, we must wake it up in this Hoosac business.

I believe we can let DAYLIGHT THROUGH THE MOUNTAIN in *four* years, and that, if we do, we can easily get a bonus of $100,000 from the State. There is one strong point in our favor, *everyone thinks it is a great Contract;* and that is CAPITAL in itself . . . Telegraph me on receipt, as to whether you can be here Tuesday.

As ever yours,
W. Shanly.

Hungarian Students in Toronto

Ninety refugee Hungarian students, are the guests of the Ontario Government and the mining industry of Ontario, at Chorley Park, Toronto.

For the most part from the University of Sopron, they arrived in Canada in January.

Having undertaken an intensive training in English under the sponsorship of the Ontario Department of Education, these students hope to have attained sufficient facility in English to be accepted into various engineering courses at the University of Toronto in September.

Professor H. R. Rice of the Faculty of Applied Science and Engineering, who is chairman of a committee planning their integration into the university, wrote to the *Journal* in March. At that time the students were being introduced to English texts and periodicals, and supplies of technical magazines were being solicited from various sources. The Institute was only too pleased to send an adequate number of subscriptions, and to commend all concerned for the hospitality offered to these very deserving students. The Institute president and general secretary had the opportunity of speaking to some of the young men during a recent visit to the University.

They would be going into summer jobs about the middle of June. Prof. Rice reported, and the Chorley Park establishment would be closed. The students would not be together again until they enter the university in the fall.

Life Members Meet

Once again the Life Members in the Montreal area held a social evening in the auditorium at Headquarters. The date was Friday, March 22.

Following the pattern created last year the meeting took the form of a series of films. At 5.30 a buffet supper was served and by 6.30 the films were in process.

Three films were shown, the first one being on automation, the second one a recruiting film loaned to the Institute by the Institution of Electrical Engineers, called "Inquiring Minds", and the third one a newly acquired film donated to the Institute's library by the Hydro-Electric Power Commission of Quebec. It was called "Beneath the Broad St. Lawrence". The whole performance was over precisely at 8.00 o'clock.

There are 708 Life Members in Canada. The thought has been expressed that similar "parties" might be held by Life Members in other parts of Canada. Already arrangements are under way for one in Toronto, but the Life Members Committee would be interested in hearing from other centers which may be interested in similar gatherings. Such letters should be sent to J. A. Freeland, M.E.I.C., secretary, Life Members Committee, c/o The Engineering Institute of Canada, 2050 Mansfield Street, Montreal 2.

Elections and Transfers

At the meeting of council held at Montreal, April 13, 1957, a number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected:

Members: L. J. Alfreds, London, Eng., H. W. Alting-Mees, Peterborough; R. P. Armstrong, Montreal, R. N. Bartlett, Montreal, L. R. Bechamp, Montreal, G. M. Binnie, London, Eng., J. A. T. Bousfield, Montreal, C. T. Carson, Walkerville, A. G. Carter, Hamilton, A. Compare, Montreal, F. V. Drowley, Clarkson, M. Dufour, Montreal, K. M. Ed, Montreal, C. K. Fraser, Peterborough, R. E. Frischknecht, Montreal, F. D. Hall, Vancouver, K. T. Harris, Arvida, D. J. Hilton, England, G. S. Jardine, Cornwall, F. R. Jeffery, Lachute, J. C. Kingston, Montreal, B. T. P. Lewis, London, J. E. M. MacAllister, Montreal, I. A. MacLean, Calgary, I. C. MacNabb, Calgary, A. H. McCallum, Montreal, N. M. McCallum, Lethbridge, A. McDougall, Baie Comeau, J. J. Magill, Walkerville, P. M. Meis, Calgary, R. H. Meier, Ottawa, J. P. Pickard, Cornwall, G. W. Redwood, Shawinigan Falls, K. E. Rolison, Toronto, M. D. Saunders, Montreal, G. A. Stone, Bird, Man., R. E. Walker, Montreal, J. S. Whitton, Vancouver, G. G. Wotton, Granby.

Juniors: R. W. Beneteau, Windsor, W. R. Bishop, Edmonton, T. O. Maginess, Hamilton, J. C. Nicholson, Arvida, H. R. Paterson, Montreal, A. J. Rensaa, Edmonton, C. P. von der Weid, Montreal.

Junior to Member: J. A. Brown, Fort William, R. H. Currie, Vancouver, J. C. Davidson, Sherbrooke, P. Donato, Sarnia, J. C. Holden, Montreal, J. H. Jackson, Morrisburg, E. B. Lindsay, Montreal, W. A. McDill, Ottawa, R. L. Pellatt, Brantford, H. G. Rindress, Montreal, S. L. Sachs, Montreal, R. G. Smith, St. Vincent, B.W.I., R. G. Smylie, Vancouver, J. M. Takacs, Windsor, M. G. Tallon, Toronto, D. Wermenlinger, Quebec.

Student to Junior: K. C. Booth, Montreal, J. M. Katrusiak, Montreal.

Students Admitted:

Nova Scotia Technical College: G. L. Basso, R. R. Butterworth, J. F. Cahill, A. S. Cohen, G. F. D'Eon, L. E. Deveau, J. D. Devlin, R. J. Edwards, W. J. Ernst, J. S. Gaunce, B. L. Giffin, T. S. Goodyear, R. J. Goosney, G. C. Himmelman, G. H. Jenkins, J. R. D. Kaulbach, A. E. King, D. H. Kirby, G. W. Kyte, B. A. Leger, R. D. MacDonald, E. V. MacInnis, H. B. McCabe, R. N. Pereira, H. J. Porter, R. G. Slaunwhite, V. G. Stewart, J. G. Tourneur, C. E. Weaver, W. G. Wells, D. H. Whitman.

University of Alberta: R. N. Briggs, G. C. Byrtus, J. M. Chittick, G. A. Clark, H. C. Dickout, R. Dubas, G. W. Ellis, A. B. Fox, J. N. Fry, S. E. Lawrence, A. E. Munz, J. Shymoniak, D. J. Taylor, G. E. Vincent, A. V. Widholm, D. Williams.

Queen's University: L. R. Baker, J. A. Bennett, T. Bonnema, S. R. Buchanan, C. W. Dingham, G. R. Duff, B. E. C. Joyce, P. G. Mallory, J. S. Marling, D. G. McNaughton, I. W. Schaub, D. N. Stevens, R. N. Zwicker.

University of New Brunswick: R. J. Gallant, G. T. Hayes, J. S. Luffman, C. T. Page, J. D. Paton, G. L. Peer, F. R. Wood.

University of Toronto: F. J. Forbes, A. H. M. Jones, D. J. O'Connor, N. M. Seagram.

St. Mary's University: B. V. C. McKoy, B. G. W. Peter, B. E. Wayland.

McGill University: P. P. Attobrah.

Royal Military College: R. G. Ross.

Mount Allison University: G. W. Felszegi.

Graduates: R. E. Dowling, B.Sc. (Elec.) Alberta, 1956; E. G. Bazeley, B.A.Sc. (Mech.) British Columbia, 1956; K. Vincent, B.A.Sc. (Elec.) Toronto, 1956; A. L. E. Schluter, Student, C.P.E.Q.; James Wilson, A.R.T.C. (Hons.) Royal Coll. of Science and Technology, 1956.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members: P. H. Bouthillier, E. E. Cocklin, M. W. Dewis, H. L. Farney, R. A. Fisk, G. Ford, J. A. Green, G. R. Haun, R. M. Helmer, H. A. Hornfelt, D. G. Pearson, R. R. Steiner, B. G. J. Thoms, R. P. Thurston, A. F. Tottrup, R. Walker.

Junior to Member: W. Buryniuk, A. P. Foster, J. P. Walsh.

Student to Junior: J. Sveinunggaard.

SASKATCHEWAN

Members: J. S. Anderson, A. C. Armstrong, F. L. Blackhall, G. W. D. Kermode, J. J. McCartan, D. F. Matheson, K. T. Matheson, G. E. Merritt, D. C. Nellis.

Juniors: D. B. Dundee, C. Steffensen.

Students: W. W. Boucher, R. E. Isted, J. G. McHattie, R. E. Stauch, K. B. Woodhouse.

Junior to Member: D. A. Bailey, G. H. Dash, R. Jones, J. P. Kot.

MANITOBA

Members: S. C. Irving.

Junior to Member: W. L. Garvin, W. R. McQuade.

NEW BRUNSWICK

Member: J. W. Wilson.

Junior to Member: H. N. Dixon, E. R. Quinn.

NOVA SCOTIA

Member: W. M. McDonah.

The Seventy-first Annual General and Professional Meeting of The Engineering Institute of Canada

June 12, 13, 14, 1957
Banff Springs Hotel, Banff, Alberta

The meeting will be a good one, and members are encouraged to come. In the Preliminary Program, mailed to all members about the end of April, information was given about accommodations, registration, transportation, and special events. These are some further program notes.

Annual Meeting Notes

REGISTRATION

Advance registration is the most satisfactory. Registration forms must be sent to reach Institute Headquarters in Montreal by Saturday, May 25, and thereafter to the Banff Springs Hotel. The form in the middle of the Preliminary Program booklet should be used for this purpose. Members may also register during the meeting. Registration opens at 3.00 p.m., Tuesday, June 11, and continues on Wednesday at 9.00 a.m.

LADIES' PROGRAM

Mrs. H. M. Hunter, chairman of the Ladies' Committee, has written a message to the ladies, offering gracious hospitality. Her message, printed in the Preliminary Program, indicates how much there is to enjoy about a visit to Banff for the annual meeting.

There will be a special meeting on Wednesday morning June 12 to consider the setting up of a national association of engineers' wives.

COUNCIL MEETING

An annual meeting of Council will be held at 9.30, Tuesday morning, June 11.

CONFERENCES

Students' and branch officers' conferences will start at 9.00 and 9.30 Tuesday morning.

ANNUAL GENERAL MEETING

Members are invited to attend the annual general meeting at 10.00 a.m. Wednesday, June 12.

SOCIAL EVENTS

The President's Dinner will be Tuesday evening, June 11, for outgoing, incoming and continuing Institute officers and special guests (with ladies).

There will be a get-together reception for all visitors on Tuesday evening commencing at 8.30 p.m.

There will be dancing every night at 10.00.

Dinner on Wednesday will be preceded by a reception at Muriel's Room at 6.30. The speaker at dinner will be V. A. McKillop, president of the Institute.

Refreshments at 6.30 p.m., Thursday, at Muriel's Room precede two dinner meetings. For the "Petroleum Dinner", the speaker will be C. O. Nickle, M.P., Calgary. The Association of Consulting Engineers of Canada will have their annual dinner at the same time.

Special entertainment, "The Pipe Line Musical Review" at 9.00, is another Thursday evening feature attraction.

The annual banquet at 7.30 Friday evening will have as speaker Mr. Justice S. Freedman, Court of Queen's Bench, Manitoba. The new president, C. M. Anson will be introduced, and new

Annual Meeting Notes

members of Council. The annual dance follows, at 10 o'clock.

All places at the annual banquet will be reserved. Members who desire to be seated with friends or in special parties must provide full particulars with advance registration. Otherwise places will be allocated by Headquarters staff and in the order in which they are received.

LUNCHEONS

Luncheon on Wednesday and Thursday will be informal, with no speakers, except for a short welcoming address on Wednesday.

The Friday luncheon will be the occasion for presentation of Institute medals and awards.

GOLF TOURNAMENT

The Banff Springs course will offer a challenge to all golfers. It is one of the world's best. The golf tournament is set for 2.00 p.m., Thursday.

SCENIC BUS TOUR

A tour by bus from Banff is scheduled for Thursday, June 13. Starting at the hotel at 1.45 p.m., there will be a drive through Banff, and on to Lake Minnewanka, passing the Cascade Plant of Calgary Power Ltd. Coming back through Banff, the trip will take the route up to Mount Norquay, where tea will be served.

CAMBIE MEMORIAL

At a time to be announced later, there will be the unveiling and dedication of the Institute's plaque to honour the late Henry John Cambie, M.E.I.C., a distinguished pioneer engineer of Western Canada.

TRIP TO JUMPING POUND

On Saturday, June 15, there will be a trip to Jumping Pound if a sufficient number of members express interest. Jumping Pound is within reasonably easy range of Banff, about ten miles off the Banff-Calgary highway. This Shell Oil Company gas and distillate field, set up to process approximately 100 million cubic feet per day of raw gas would provide an interesting field trip.

TRANSPORTATION

Railway, air, and automobile transportation is covered in detail in the Preliminary Program. Of particular interest is the possibility of a special train to take passengers westward after the meeting to Vancouver. The advance registration will determine the practicability of this feature.

Alberta Committee

W. A. Smith, chairman; D. C. Jones, S. J. Hampton, vice-chairmen; J. J. S. Harris, A. J. Branch, members; J. A. Webb, secretary treasurer; J. S. Neil, entertainment; F. L. Perry, meeting arrangements; D. C. Hutchinson, Muriel's Room; P. A. Brett, publicity; T. D. Stanley, plant visits; J. J. Hanna, reception, J. McGill, transportation; Mrs. H. M. Hunter, ladies.

Technical Program

The technical program starts on Wednesday, June 12, at 2.00 p.m. A selection of 35 technical papers will cover the currently interesting and important engineering fields. For example there are eight papers on the oil and gas and petrochemical industries; five on mechanical and thermal power projects; one on mining; eleven papers on civil engineering subjects, including two on wintertime construction; five papers dealing with electrical engineering developments; three on chemical engineering; and two aeronautical papers. This program is rounded out by a management panel discussion. The complete list was printed in last month's *Journal*, and in the advance program already received by members.

THIRTY-FIVE YEARS AGO

Comment on the Journal of May, 1922

The world does move. In the May, 1922, *Journal*, A. S. Runciman, A.M.E.I.C., writes, "It is actually possible to set up in homes in Ontario and Quebec a simple receiving set which bring in the concerts from Pittsburgh and New York, not every night, but often during the winter." This quotation is lifted from Mr. Runciman's paper on "High Frequency Telephone as Applied to High Tension Power Lines", an excellent treatise on the fundamentals of radio communication, but rather belying its title, since it mentions the Shawinigan Water and Power Company's system only incidentally, saying ". . . If the weather looks bad at any of the stations, the battery switches are closed and the system is ready for instant use."

The second paper in this *Journal* was a review of current sewage disposal methods read before the Calgary Branch by Dr. C. J. Mackenzie, HON. M.E.I.C., There was nothing startling in it, but it gave a good overall view of the state of the art in 1922. A section is devoted to a description of the "Miles acid process". It is a safe bet that not ten of our readers will ever have heard of it. Of course, such relatively modern steps in the process as elutriation, the separate digestion of sludge and lagooning are not mentioned.

Dr. R. W. Boyle, then Dean of the Faculty of Science at the University of Alberta held forth on "Rainmaking" in this 1922 *Journal*. There was no question then of the efficiency of any method of inducing rain; none tried up to that date had shown any promise, so the author remarks, "It is the earnest wish that some way to induce rain to fall when and where it is wanted, might be reported here, but it is impossible to do so and nobody is known who can." If Dr. Boyle were writing today, he would not be so positive. Rainmaking is now big business, though still regarded as a sort of quack profession by some.

The Institute Committee on Policy was reported as studying "the objects of the Institute, its relation to cognate bodies and its organization under the headings of membership, Council and general, in addition to special matters." The Committee had reached no conclusions it was willing to make public.

The editor of 1922 published a strong appeal to employers in this *Journal*, asking that they should do everything they could to employ engineering students during the summer holidays. Council even passed a resolution to this effect. It appears that jobs were pretty scarce then.

Personals

Personals in this issue of May, 1922 were more than ordinarily interesting. They noted that J. G. Sullivan, president of the Institute, and Col. J. S. Dennis, M.E.I.C., had been asked by the Government of British Columbia to investigate and report on the Pacific Great Eastern Railway, the former on its engineering features and the latter on its economic prospects. This is the railway which for years ended at Squamish north of Vancouver and is now being extended into the city, much to the disgust of residents of the city's residential suburbs on the north shore of Burrard Inlet.

It was also announced that expresident R. A. Ross had been appointed a member of the Royal Commission set up by Ontario to investigate the affairs of its Hydro-Electric Power Commission.

Robert Angus, consulting engineer, of London, Ont., had just been admitted to membership. The fact that he was eighty-one years of age occasioned some *Journal* comment.

Seven members were looking for jobs and there were some vacancies advertised, including sales representatives in the Orient for an agent of a Canadian agricultural machinery manufacturer, with "preliminary expenses (to be borne) by managers in . . . assigned territory," whatever that may mean; a chief traffic officer for the Board of Transport at $6,500 a year and several foresters at $1,680 to $2,000 annually, with a possible $20 per month additional for housing.

The Branches

World War I was still not far from anybody's thoughts. The Victoria Branch had listened to an account of a military survey in Syria, and L. B. Tillson, A.M.E.I.C., had spoken to the Border Cities Branch about "The Work of the Field Artillery". The *Journal* made an odd error in this account. The calibre of the long range gun used by the Germans for the bombardment of Paris was given as "8'-2"! The latter branch was sponsoring the formation of a field company of the Royal Canadian Engineers. The Saint John Branch heard a lecture on underground engineering in France.

The Winnipeg Branch was continuing its interest in the corrosion of underground pipes, especially of those in its own area. The Peterborough Branch was interested in radio and had been listening to broadcasts from Pittsburgh, Schenectady and Newark, but found it "out of the question" to hear a broadcast from Toronto. Before the Ottawa Branch, Dr. J. G. Rutherford, chairman of the Board of Railway Commissioners, characterized the "American invasion of the Northwest" as "sheer exploitation. Land had been deliberately worked out and a yield of thirty-five and forty bushels per acre had been reduced to an average of ten." His concluding remarks might be pondered with profit by all of us, particularly by organized labour, commuters and shippers: "The railways (are) necessary to the country and to the farmer, but they (have) to earn a dividend for the stockholders. The position simply (is) that the people using them (have) to pay for them. It (is) not fair to make others do it."

In 1920 the Saint John Branch and the federal Department of Public Works started a series of tests of the durability of concrete in sea water. No conclusive results had been arrived at in 1922, but certain facts were evident. ". . . During the summer season . . . disintegration (is) not apparent, but with the advent of winter it is rapid and very apparent . . . Blocks of . . . wet consistency . . . disintegrate most rapidly." In 1921, blocks were made of concrete with various admixtures — kerosene, crude oil, pine tar, alum, gypsum, barium chloride, copper acetate, raw sugar, infusorial earth, ochre and sodium silicate. One wonders why some of these additives were chosen and the common ones, like calcium chloride and hydrated lime, omitted. Some of these 1921 blocks were in bad shape in 1922. R DeL.F.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

Annual Meeting

The thirty-eighth annual meeting of the 6,200 member-strong Corporation of Professional Engineers of Quebec was held on Saturday, March 23, 1957 at the Sheraton-Mount Royal Hotel, Montreal, under the chairmanship of Leo Roy, 1956-57 president of the organization.

Dr. O. M. Solandt, assistant vice-president, research and development division with the Canadian National Railways, was guest speaker at the dinner, which was followed by the annual dance.

The *Journal* will print a full account of the convention in the June issue.

SASKATCHEWAN

A.P.E.S. Regina Meet

The twenty-seventh Annual Meeting of the Saskatchewan Association convened at the Hotel Saskatchewan in Regina on February 15, 1957 with E. J. Durnin, president acting as chairman. Approximately 125 members were in attendance.

R. Bing-Wo, secretary-treasurer, presented the report of council. It was reported that eight ordinary meetings and one meeting with the board of examiners was held for the transaction of Association business. The secretary reported that one matter agreed upon with the board of examiners was a set of rules of procedure in dealing with applicants having unaccredited academic qualifications. Eleven such cases had been referred to the board for recommendation. The secretary also referred to other council business on engineers and the Trade Union Act to be more fully reported upon by the chairman of the committee concerning temporary licensing, engineers and civil defence, and illegal advertising.

Membership at the end of 1956 totalled 526 profesional engineers.

Dominion Council Report

The report of Dominion Council was presented by Prof. W. R. Staples, Saskatchewan councillor. He reported that uniform registration was again discussed, with British Columbia on one hand, still requiring four years' experience following graduation, and Quebec, requiring none.

Legislation and enforcement was also dealt with. A committee was formed to draft an "Ideal Code of Ethics". Dominion Council had decided to support the Canadian Committee on counselling in Engineering and Science. A motion was passed to make representation to the Dominion Goverment to have professional fees deductible for income tax purposes. A committee was formed to investigate the possibility of setting up a plan of pensions for self-employed engineers. Dominion Council endorsed the National Conference on Engineering Man-Power Shortage. Licensing and reciprocal privileges with U S. engineering bodies was discussed with L. R. Durkee of Seattle, vice-president of the National Society of Professional Engineers in the United States.

The report of the committee investigating engineers and the Trade Union Act was presented by the chairman Prof. W. R. Staples. Briefly summarizing the events up to the previous annual meeting Prof. Staples then reported fully on subsequent developments. A meeting was held on September 7, 1956 with a committee of the Cabinet at which the engineers' case was again presented. One member of the cabinet committee opposed changing the Trade Union Act in any way and proposed that the Association apply to the Labour Relations Board for discertification of professional engineers. The Association Committee felt that this would not be a satisfactory solution. The Union then met with the Cabinet committee on November 28 and presented a counterbrief which the Association felt was very weak. J. T. Douglas arranged a meeting of the Association Committee and the Union Committee for December 18 for further discussion. However the Union had not been in favour of a meeting with the Association committee, but rather with the government engineers presently in the Union. After that meeting, the Association prepared and submitted a further brief in rebuttal to the Union brief. On January 23, 1957, J. T. Douglas officially notified the Association that Cabinet were reticent to amend the Labour Act and suggested a submission to the Labour Relations Board for decertification. Prof. Staples reported that this course of action was now in progress.

Plan for Unity

The committee formed to consider the Plan for Unity reported to the membership in printed form, sent out to all members. This report was prepared under the chairmanship of E. J. Durnin. It discussed in summary form the history of the Plan, basic functions of the proposed national organization, branch activities, membership, fees, affiliated technical societies, a national council, the executive committee, and the present status of the proposal for confederation.

J. McD. Patton commented to the meeting that he was impressed with the large volume of business being handled by Council and various committees, and the efficient, effective action and decisions made. Mr. Patton moved that a vote of thanks be tendered to the president, council, all committee chairmen and members, and the registrar, for their work on behalf of the Association. The meeting concurred with the motion and so indicated by hearty applause.

The election of officers in the Association is as follows: W. G. McKay, Saskatoon, president; J. C. Traynor, Regina, vice-president; K. W. Allcock and M. B. Pierce, of Regina, and B. B. Torchinsky, Saskatoon, councillors; J. Bortolloto, R. V. Tomkins, and D. K. Parkington, chairman, comprise the nominating committee.

ONTARIO

Professional Recognition

Air conditioning, like many other modern conveniences, is now in a stage of advanced development; no matter what the outside temperature may be, the "climate" of offices and homes can be adjusted for maximum comfort and for working conditions which will stimulate maximum efficiency. And just as a healthful temperature, humidity, and circulation of air are conditions for a wholesome climate in a room, professional recognition is one of the conditions under which an invigorating "climate" can be achieved in the relationship between professional engineers and management.

Besides showing management that he

wants professional recognition, the engineer must prove that he merits such recognition, and must work with management to achieve it. The first step in this direction is to be professional, on the job and off the job, all the time; assume responsibilities with the confidence and assertion of a professional; maintain professional standards not only at work but also in the community as a whole.

Double Responsibility

On the job the engineer has a double responsibility, first as an individual and secondly as a team member. The employee-engineer should integrate himself with the firm for which he works. He should be a worthy representative of that organization in business circles and in the management team he should be prepared to serve effectively in any capacity, even though his services may include activities not directly concerned with engineering.

In all professions emphasis is placed upon personal appearance and performance. Imagine a doctor without a gracious bedside manner, or a barrister without a commanding courtroom presence! Without an outward appearance of confidence and a bearing which suggests enthusiasm the professional man is relegated to back rooms and dingy offices. Tackle your job professionally! Discuss it, do it, and report it, professionally.

Continued Study Essential

The man who succeeds is the man who studies; who is continually expanding his interests and keeping in touch with the latest developments both in his profession and in the world about him. It has been estimated that eleven cents of every dollar to be spent three years from now will be for products not yet known to most people. New materials, new techniques and new developments will bring new challenges, new concepts, and new opportunities. So, take advantage of opportunities to learn more about your job, your company, and your profession. Enroll in and support training courses. Take an active part in and contribute to, as well as benefit from, discussions. Prepare yourself to meet the demands which will be made upon you and your profession in the future.

But don't disregard non-engineering subjects. Get to know the other side of the subject and the other fellow's viewpoint. As knowledge broadens, so does the sense of responsibility. When you know what program your firm is planning, see to it that you are part of the program. Make your employer's program your program, and adopt his ambitions as your own.

Responsibility Essential

To share the common task of making your firm succeed in every line of effort, you must be willing to accept administrative or other responsibilities, even though it means that you must turn over your engineering duties to those who are coming along behind you. Don't accept your responsibilities lightly. Remember that management depends on you, and that it may be in reliance upon your findings or your analysis of a situation that huge outlays of time, money and materials may be planned.

As you earn your place in your profession you will find that your importance to your community grows apace. You will be in demand for public services, and the community will look to you for leadership and guidance. How can better leadership be provided than by a man who subscribes to the code of ethics of a professional engineer?

As your stature in the community grows it will enhance your standing in your profession. Thus your social status and your professional standing help each other towards developing you to the full extent of your capacity and your ambition.

You are a professional engineer. Be proud of it and make your status known. Display your certificate of qualification in a prominent place in your office. Declare your membership in technical groups and in your Association. Be proud of your association with fellow professionals. Use the designation "P.Eng." after your name, in signing documents and communications, on letterheads, on business cards, and on the door of your office.

Above all, remember that the broad view is important to full understanding, and that with understanding comes professional stature. As you attain professional stature you are doing your part to create the ideal "climate" in your relationship with management.

Engineers in the News

H. E. McCann, of Phillips Electrical Co. Ltd., Brockville, Ont., has been named assistant to the president of the company, T. A. Lindsay.

Mr. McCann has been with the company since 1944 and has been methods engineer. After obtaining his degree in mechanical engineering from McGill in 1934, he attended M.I.T. and secured a further degree in engineering and business administration. Prior to joining Phillips, he was with Canadian Car & Foundry's Amherst plant and also with stevenson & Kellogg, Toronto management consultants.

I. N. Lobb, has recently obtained his release from the R.C.A.F. and is now employed as an application engineer with the Arthur S. Leitch Co. Ltd., 33 Torbarrie Road, Downsview, Ont., manufacturers and distributors of pumping and heating equipment and engineering specialties.

David R. Smith, city engineer of Woodstock, Ont. since 1953, has retired from that position. Prior to moving to Woodstock, Mr. Smith followed his professsion in New Brunswick and Nova Scotia. From 1937 to 1947 he was director of works and city engineer of St. John, N.B. Prior to becoming city engineer in Woodstock, he was town and public utilities engineer at Bridgewater N.S.

S. E. Geiszczykiewicz, has been granted leave of absence by H. G. Acres & Co. Ltd., of Niagara Falls, Ont., in order to accept an appointment with the United Nations Technical Assistance Administration. In this connection he is proceeding to Karachi, Pakistan, where he will act in an advisory capacity to the Government of Pakistan on Electric Power Development.

Eric H. Holloway, is Industrial Sales Representative of McColl-Frontenac Oil Co. Ltd., Hamilton, Ont. He was previously with Empire Brass Mfg Co. Ltd., of the same city.

G. Otty Machum, has joined Jan H. Reimers, consulting metallurgical engineer, in Toronto. He was formerly employed by the International Nickel Co. of Canada Ltd., at Copper Cliff, Ont.

John Sutherland, is associated with the Warnock Heisey Co. Ltd. as consultant and branch manager of the Ottawa office.

George R. Trewin, has resigned from his position with the Ontario Department of Health and has joined the drainage division of the Metropolitan Toronto Works Department.

Graham P. Kemp, has been engaged as a design mechanical engineer by Dilworth Ewbank, consulting engineers, 4210 Dundas Street W., Toronto 18, Ont. His prior employment was with Wm. Kennedy and Sons Ltd., Owen Sound, Ont.

K. Sumi has returned to the fire research section of the division of building Research, N.R.C., Ottawa, after two years in Great Britain where he completed studies towards his doctorate. His main interest has been the problems of flame suppression and his work was carried out at Imperial College of Science and Technology, University of London. Prior to his return to Canada he had the opportunity of visiting fire research organizations in France, the Netherlands and Germany.

M. L. Vogel who for the past three years has been a lecturer in the heat engines section of the mechanical engineering department of the University of Toronto, has joined the engineering division of the Chrysler Corporation at Detroit, Mich. As a laboratory supervisor at Chrysler, he will organize a new heat transfer laboratory to service research and engineering groups.

Prior to coming to Toronto, Mr. Vogel taught at the University of Wisconsin, directed a research group at A. O. Smith, Milwaukee, and served as industrial engineering consultant for the Government of Israel in Haifa. Mr. Vogel entered Massachusetts Institute of Technology on discharge from the U.S. Army and received his bachelor degree in mechanical engineering in 1947 and his master's degree the following year.

Stephen Kryzevicius, has recently accepted employment with Lazarides, Lount & Partners, Toronto consultants. Previous to this change he was with the Abitibi Power and Paper Co. Ltd., Toronto.

W. A. Carter, has resigned as manager for Area Mines Ltd., and has been appointed general manager for North American Rare Metals Ltd., with offices at 100 Adelaide Street W., Toronto.

Joseph E. Mah, formerly with Toronto Testing Laboratories, has joined the Royal Canadian Mint in Ottawa.

L. W. Swain, has joined E.M.C.O. Ltd., (Empire Brass Co.) London, Ont., as development engineer in charge of engineering. He was previously associated with Babcock-Wilcox & Goldie-McCulloch Ltd., in Galt.

Clarence D. Murdock, has been appointed general manager of Radio Condenser Company Ltd., 6 Bermondsey Road, Toronto 16, according to an announcement of R. E. Cramer, Camden, N.J., president of the company.

Mr. Murdock has been associated with the Radio Condenser Co. Ltd., for the past six years in the capacity of assistant manager. He graduated in electrical engineering from the University of Manitoba in 1932.

C. Alen Geddes has been appointed chief engineer of Bawden Industries Ltd., Toronto.

Mr. Geddes graduated in mechanical engineering after his discharge from service with the R.C.A.F. during World War II. Before joining Bawden Industries, which produces special machinery, he was on the engineering staff of Canadian Westinghouse Co. Ltd., in Hamilton.

F. Tuke has been appointed sales manager of the Auth Electric Co. Inc., of Long Island City, N.Y.

A graduate in electrical engineering of the University of Toronto, Mr. Tuke has had a number of years' experience in the manufacture and sales of signalling equipment in Canada and the United States.

John M. Beattie has moved to South Norwalk, Conn., where he accepted the position of senior design engineer with Remington Rand Univac. Mr. Beattie was formerly with the Canadian Westinghouse Co. Ltd. at Hamilton, Ont.

R. Muirhead has returned to resume his regular work on the engineering staff of Phillips Electrical Co. Ltd., Brockville, Ont., following a period of training in England.

W. C. Ewing has moved to Fort Frances, Ont., from Edmonton, and has been appointed Town Engineer of Fort Frances.

E. Saurazas of Toronto is senior electrical engineer with Catalytic Construction Co. of Canada Ltd., 900 Yonge Street, Toronto. Prior to accepting this post, Mr. Saurazas was with Arthur G. McKee Co. of Canada Ltd. as electrical design engineer.

M. B. Hastings, and **G. F. Dean**, of Toronto have been honoured by the Illuminating Engineering Society.

Mr. Hastings has been elected to the grade of Member Emeritus of the Society of which he is the only Canadian and one of only 37 in with the United States and Canada.

Mr. Dean was elected earlier to the grade of Fellow, of which four others hold similar membership in Canada.

W. Gordon Wilson of the National Sewer Pipe Co. Ltd., Toronto, has been named production manager of the company. In this capacity he is responsible for production at the company's vitrified clay pipe plants at Clarkson, Hamilton and Swansea, and the plain end pipe coupling plant. Also under his supervision is the concrete pipe plant at National Concrete Products Ltd., Mimico.

BRITISH COLUMBIA

Certificate No. 3000

Presentation of registration certificate No. 3,000 to Wilfred Pegusch, highlighted the Association of Professional Engineers of B.C.'s annual dinner for the graduating class of engineers from U.B.C.

Col. W. G. Swan, O.B.E., D.S.O. made the special presentation. Col. Swan, who was the first elected president of the Association (1921) is also head of Swan, Wooster & Partners, consulting engineers, where Mr. Pegusch practices.

U.B.C. Professor Emeritus J. M. Turnbull, holder of registration certificate No. 5 was also present and added his congratulations to Mr. Pegusch.

Inter-Club Competition

Another feature of the evening was the first annual inter-club competition between members of Beaver (engineers) Toastmasters Clubs from Vancouver, Victoria and Britannia Beach. The Association trophy was awarded to **H. D. Currey**, of Vancouver, who won out over **A. R. D. Robertson**, of Victoria by the narrowest of margins. **G. C. Lipsey**, representing the newly-formed Britannia Beach Club, brought greetings and a message from his club that they would be very much in the running for the trophy next year.

Four professional engineers were presented with Life Membership medallions at the meeting by President W. O. Richmond. They were **A. G. Graham**, Vancouver, **D. A. Spalding**, Haney, **E. F. Cooke**, Sechelt, and **T. E. Price**, Vancouver.

Engineers in the News

W. E. Atamanchuk, of the Richmond Exploration Company has moved from Caracas to Maracaibo, Venezuela.

R. Battistella has been promoted from chief electrical engineer to chief design engineer at the City of Edmonton power plant.

S. D. Cavers is now associate professor of chemical engineering at the University of British Columbia. He was formerly with the B.C. Research Council as a research engineer. He was associate professor of chemical engineering at the University of Saskatchewan in 1952.

Lawrence D. Smillie has moved from the North West Territories some time ago and now holds a position as mill superintendent of the Iron Benefication plant at Texada Mines Limited, Gillies Bay, B.C.

E. J. Huckson of New Zealand has joined the field staff of Dominion Construction Limited at Port Alberni, working on the MacMillan and Bloedel Pulp plant extension project.

David Liberson has taken up engineering duties with the B.C. Electric Company Ltd.

K. R. Main, recently arrived from Great Britain, has taken up a civil engineering appointment with Lafarge Cement of North America Limited.

H. R. Shawk has been acting as consultant to the National Government of China.

J. Dan McGuire has joined the staff of Conveyair Limited, North Vancouver.

ALBERTA

Annual Meeting

The thirty-seventh Annual General Convention of the Association of Professional Engineers of Alberta was held at the Palliser Hotel, Calgary on March 29 and 30. Special speakers were the Right Honourable C. D. Howe, minister of Trade and Commerce, and Dr. N. H. Grace, director of research for the Research Council of Alberta at Edmonton. Dr. Grace addressed the luncheon meeting.

A full report of the two-day affair will be carried in the June issue of the *Journal*.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Air Vice-Marshal E. W. Stedman, C.B.E., M.E.I.C., retired director general of research with the R.C.A.F., died on March 27, 1957, at Ottawa.

Born at Malling, Kent on July 21, 1888, he received his primary education at Maidstone, Kent. This was followed by four years at a combined workshop and technical school, where he won the Whitworth Medal and a free studentship providing entrance to the Royal College of Science, London.

Three years later he secured a first class associateship in mechanics, the Bayliss prize for the highest standing in the qualifying examination for Associate members of the Institution of civil Engineers, and a Whitworth scholarship.

Another year of study in civil and mechanical engineering followed, at the City Guilds College, London, and during that period the future Air Vice-Marshal was associated with the artillery as a member of the University of London Officers Training Corps.

He began his graduate career as a draughtsman in a Southampton firm. In 1913 he received the appointment of scientific assistant in aeronautics at the National Physical Laboratory, Teddington.

Commissioned a lieutenant on the outbreak of World War I, he joined the Royal Naval Volunteer Reserve, attached to the Royal Naval Air Service. Later, when the Royal Air Force came into being in 1918, he became a major. The following month brought a promotion to the rank of lieutenant-colonel and in addition, the O.B.E.

On demobilization from the R.A.F. in 1919 he was appointed chief to the technical staff in the aircraft firm of Handley Page, Limited, London.

In May 1919 he went to Newfoundland to take charge of the entry by that firm for the £10,000 prize put up by the Daily Mail for the first transatlantic flight by a heavier than air aircraft. Alcock and Brown succeeded in taking off first, however, and won the prize and much distinction. Shortly after the creation of the Air Board, Air Vice-Marshal Stedman came to Canada to take charge of the technical directorate responsible for stores, supplies and contracts. In 1921 he joined the Canadian Air Force and on its formation in April 1924 became a member of the R.C.A.F., rising steadily in the service as chief aeronautical engineer.

Among his most notable exploits was a flight across the Atlantic as representative of the R.C.A.F. in August 1930 in H.M. Airship R-100. The journey commenced at St. Hubert Airport, Montreal and was concluded fifty-seven hours later at Cardington, Eng. On his retirement from the R.C.A.F. in 1945 he represented the Canadian Government at the Bikini atomic test in 1946.

He became professor of mechanical engineering at Carleton College, Ottawa, in 1946, remaining there until 1955.

He was, during the last few years engaged in the preparation of a history of aviation in Canada, under the auspices of the Canadian Government. He was also a member of a government appointed committee establishing the present plan of officer training for all three services.

A/V/M E. W. Stedman, C.B.E., M.E.I.C.

Air Vice-Marshall Stedman was a Member of the Institution of Civil Engineers, the Institute of Metals and the Canadian Advisory Committee of the Institution of Civil Engineers. He was a Governor of the Royal Aeronautical Society and of the Institute of Aeronautical Sciences. He was an Honorary Fellow of the Canadian Aeronautical Institute. He held the chairmanship of the Associate Committee of Aeronautical Research of the National Research Council, in 1935.

A winner of the Julian C. Smith award of the Engineering Institute, he also held the Daniel Guggenheim Medal.

In 1947 the United States honoured him with the award, Commander of the Legion of Merit.

Air Vice-Marshal Stedman joined the Engineering Institute as a Member in 1921. He was in 1934 elected chairman of the Ottawa Branch of the E.I.C., and the following year sat on the Council of the Institute. He attained Life Membership in January, 1957.

Matthew Balls, M.E.I.C., retired assistant vice-president of the Shawinigan Water and Power Company, and manager of the company's hydraulic resources department died at Sweetsburg, Que., on February 12, 1957.

Mr. Balls was born at Ryton-on-Tyne, Eng., on October 8, 1887 and had his education in that country. Moving to Canada in 1906 he was employed with the Spokane, Portland and Seattle Railway as a chainman and rodman on location survey.

He was later employed with railways in Alaska, B.C., Idaho and Washington.

Appointed assistant engineer with the Dominion Government Hydrometric survey in 1915 Mr. Balls was the following year named hydraulic engineer with the Dominion Department of the Interior, and spent the next ten years in irrigation and water power surveys in B.C. and the Yukon.

Mr. Balls joined the staff of Shawinigan Water and Power Company in 1926. He was named manager of the water resources department in 1941. He became assistant vice-president in 1948. On his retirement in 1954 he also held the post of manager of the hydraulic resources department.

He was for several years a member of the National Research Council's subcommittee on ice and snow research.

He became a director of the St. Maurice Power Corporation in 1945 and its secretary in 1950.

Mr. Ball joined the Institute in 1910 as an Associate Member, transferred to Member in 1940 and attained Life Membership in 1954.

Thomas Leo Hughson, M.E.I.C., civil engineer with the Department of Veteran's Affairs at Ottawa, died in that city on February 18, 1957.

Born at Niagara Falls, Ont., on January 26, 1891, he had his education there and graduated at Queen's University in 1916. In 1917 he enlisted with the R.C.E. and served overseas until 1919. Returning to Canada at that time he became associated with the Hydro-Electric Power Commission, Ontario power development, in the construction department and worked with several construction companies in the United States and took part in the erection of the Detroit-Windsor tunnel. Also at about that time he became vice-president of Robertson Construction and Engineering Company Limited at Niagara Falls. In 1930 he travelled to Russia as a representative for the Albert McKee Company of Cleveland, Ohio. On his return to Canada in 1932 he had experience on the Trans-Canada highway and was again associated with the A. B. Robertson Construction and Engineering Company at Niagara Falls.

Moving to Ottawa in 1946 to take over the position of district superintendent of buildings with the Department of Veteran's Affairs he remained there until the time of his death. In 1947 he was promoted to regional engineer.

Mr. Hughson joined the Institute in 1919 as an Associate Member and was transferred to Member in 1940.

Personals

News of the Personal Activities of Members of the Institute.

Dr. R. E. Heartz, M.E.I.C., past-president of the Institute and president of the Shawinigan Engineering Company Limited has been elected to the board of directors of the Shawinigan Water and Power Company.

Dr. Heartz is a member of the board of governors of Sir George Williams College in Montreal; the board of regents of Mount Allison University at Sackville, N.B., where he received an honourary doctorate of laws in 1952; and the board of governors of the Royal Edward Laurentian Hospital, Montreal.

Dr. Heartz is a past-chairman of the Montreal Branch of the Institute, has also served as a councillor and in 1949 was elected vice-president of the Institute for the Province of Quebec.

Dr. R. S. Jane, M.E.I.C., president of Shawinigan Chemicals Limited, has been elected to the board of directors of the Shawinigan Water and Power Company.

Dr. Jane is also a director and vice-president of Canadian Resins and Chemicals Limited, a director of B. A. Shawinigan Limited, Montreal and of Shawinigan Resins Corporation, Springfield, Mass.

Bruce B. Shier, M.E.I.C., has been appointed marketing manager of Automatic Electric Sales (Canada) Limited.

Mr. Shier is a graduate in electrical engineering from McGill University, class of 1923. After several years' experience in the inspection engineering and field surveys of communication equipment, he joined the staff of Automatic Electric in 1935 as sales engineer. Since 1947 he has been in charge of the sales promotion of all products handled by the company.

B. B. Shier, M.E.I.C.

C. K. McLeod, M.E.I.C., of Montreal, recently elected to the board of directors of the Permutit Company of Canada has now been elected vice-chairman of the board.

He was earlier this year elected president of Walter Kidde and Company of Canada Limited.

Mr. McLeod is also a past vice-president of the Institute.

Dr. R. L. Hearn, M.E.I.C., has been elected to the board of directors of Humphreys and Glasgow (Canada) Limited, Toronto, a recently established subsidiary of Humphreys and Glasgow Limited, London, Eng.

Until recently chairman of the Hydro-Electric Power Commission of Ontario, Dr. Hearn is still active as a consultant to the organization.

On many occasions openly acclaimed for his contribution to Ontario's publicly owned hydro enterprise and the Canadian engineering field, he was given lasting recognition in 1951 when Canada's largest fuel-electric power plant, the Richard L. Hearn Generating Station was named in his honour.

In the period of more than forty years since first joining the commission, Dr. Hearn has played a major part in the growth of the organization, with its unprecedented power expansion program, embracing major hydro-electric projects and Canada's largest steam generating installations.

J. G. Hall, M.E.I.C.

H. W. L. Doane, M.E.I.C.

John G. Hall, M.E.I.C., who retired from the Combustion Engineering Corporation, Toronto, as district manager in 1956, has been appointed executive vice-president with the Bituminous Coal Institute of Canada. Affiliated with the Canadian Commercial Coal Dock Operators Association, an extensive program of research and marketing projects, similar to one conducted by engineers of the Bituminous Coal Institute in the United States is being planned under Mr. Hall's direction.

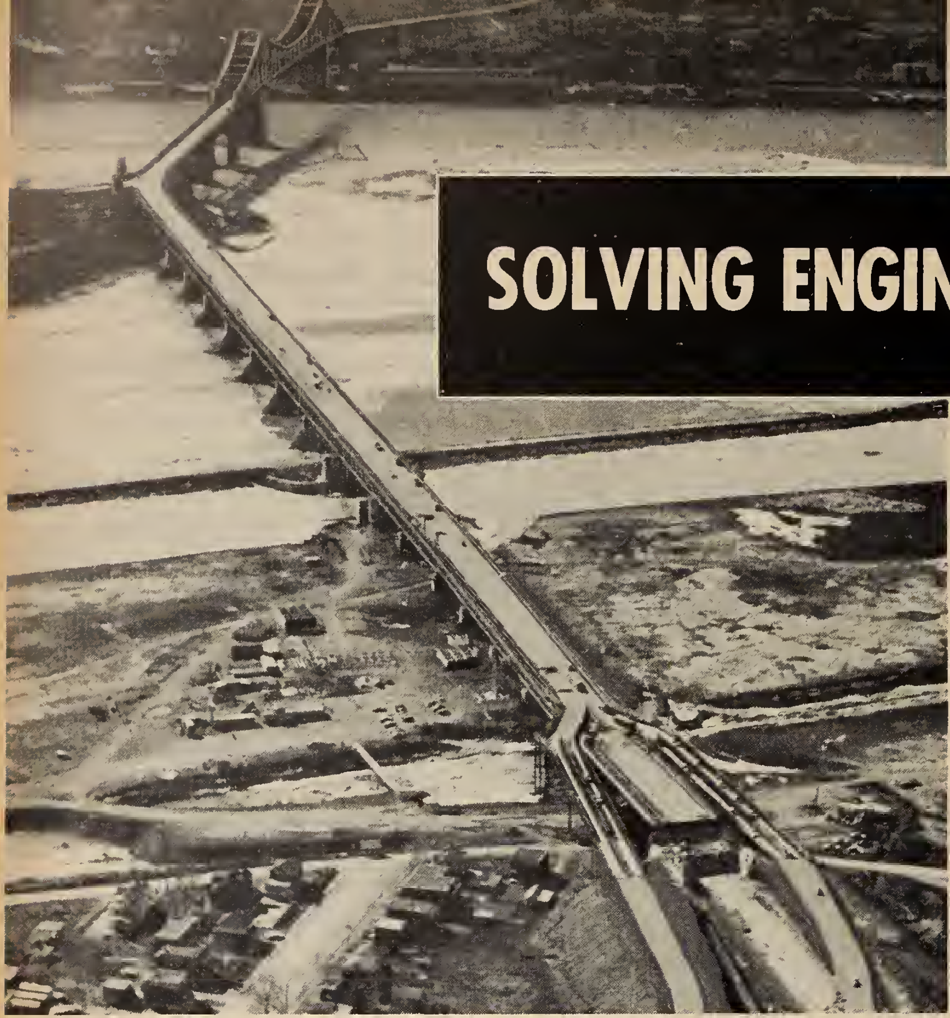
Under the plan Mr. Hall will also be available for consultation with architects and consulting engineers planning major industrial projects.

He is a member of the American Society of Mechanical Engineers and is an Associate Member of the Institute of Power Engineers.

Mr. Hall is a past chairman of the Toronto Branch of the E.I.C. He served on the council of the Institute in 1940-42.

H. W. L. Doane, M.E.I.C., of Halifax, vice-president of the Institute, manager and director of Standard Paving (Maritime) Limited, has been awarded an honourary Doctor of Engineering degree at the annual convocation of the Nova Scotia Technical College on May 8, 1957.

Mr. Doane was educated in the Halifax public schools, Dalhousie University, and the Nova Scotia Technical College, receiving his B.Sc. in civil engineering from the latter institution in May 1913.



SOLVING ENGINEERING PROBLE

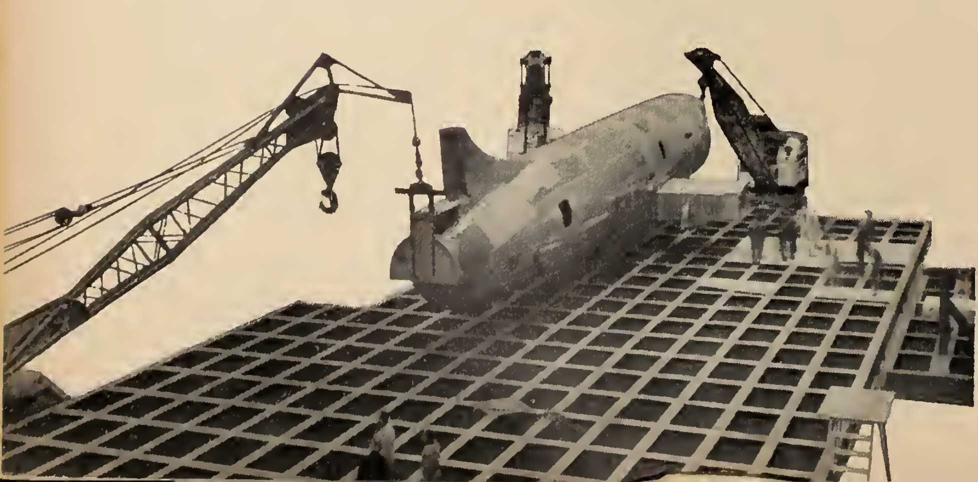
UNIQUE SEAWAY PROJECT

One of the early operations in raising the Jacques Cartier Bridge, Montreal. At this stage traffic has been diverted to permit the raising of the South approach and uninterrupted traffic will be maintained over the bridge during the construction period. Seven other major seaway contracts have also been awarded to Dominion Bridge.

Expansion brings diversified engineering problems—as these recent examples.

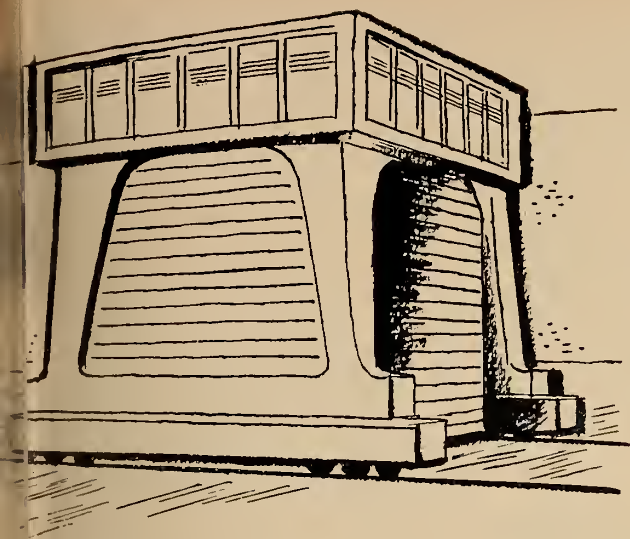
In every province and in every major industry, Dominion Bridge gineers are making important contributions to Canada's phenomer growth.

To help Canada's expansion Dominion Bridge last year announced own four year expansion programme. Now in full swing—this will ha the effect of increasing the Company's overall capacity by 40 per cent a will assure even better service to our customers from coast to coast.



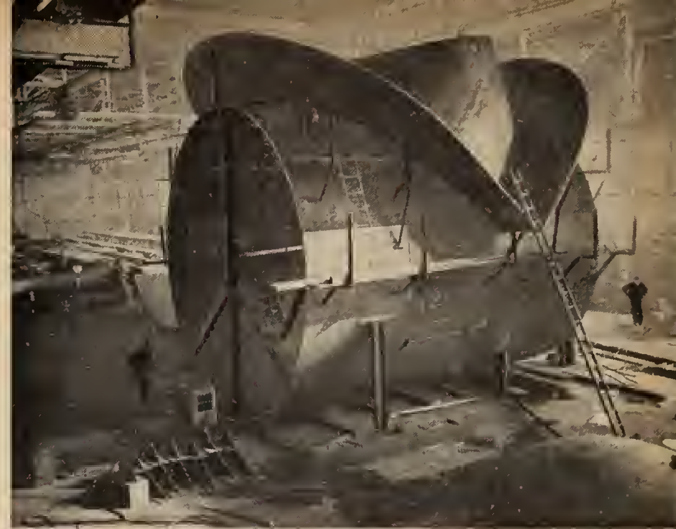
TEST BED FOR CANADA'S LARGEST AIRCRAFT:

To avoid distortion during fitting and ing of this massive steel grid, for Can Ltd., special field welding procedures devised by Dominion Bridge engineer



MDERN TREND IN CRANES:

Th 300-ton gantry crane, the largest ever built in Canada, wa designed and fabricated by Dominion Bridge for the Cadian half of the St. Lawrence Power Project. Completely nosed, it illustrates a modern trend in design.

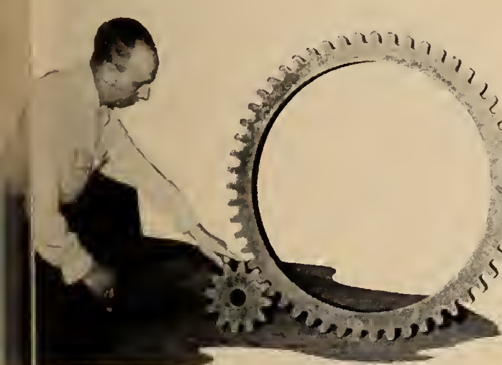


22′ diam. T SECTION FOR POWER PROJECT:

One of many large platework components recently built by Dominion Bridge for the Ladore Falls Power Development, B.C. Other items included Y sections, penstocks and scroll cases.

MODERN TREND IN BOILERS:

Newly developed Dominion Bridge water tube package unit boiler. Units such as this are shop assembled and shipped complete to the site ready for connecting to steam, oil and water lines.



FLME CUT GEARS:

Ou steel warehouse division frequently ssts other manufacturers in solving the own engineering problems. This pa of gears, 2½″ in thickness, was recntly supplied in less than a day for a r h order.

"SEEL FOR URANIUM":

Thusands of tons of structural steelwork ha been fabricated and erected by Dminion Bridge for Canada's huge uraium developments. One example is Algm Uranium's Nordic Mill, near Blid River.

DO INION BRIDGE COMPANY, LTD.

DOMINION BRIDGE

• PERSONALS

Following graduation Mr. Doane practised as a consulting engineer, until his enlistment in the Canadian Artillery during World War I. He returned to Halifax with the rank of major in 1919 following extensive service overseas.

In 1919 Mr. Doane was appointed assistant city engineer for Halifax, which position he occupied until 1928 when he became manager of Argyle Motor Services. Three years later he undertook the management of Standard Paving Maritime Ltd., of which he is now manager and director.

During 1944-47 he was manager of the Halifax Utilities Commission.

Mr. Doane is a former chairman of the Halifax Branch of the Institute. He served the council of the Institute in the 1925, 1945 and 1951 terms of office.

K. O. Elderkin, M.E.I.C., has been elected a director of Bowater Corporation of North America Limited.

Mr. Elderkin is president of Bowaters Research and Development Incorporated, of Calhoun, Tennessee. This company has recently been formed to co-ordinate development and production for all units of the Bowater organization in North America.

Mr. Elderkin is one of the leading paper experts in North America. Until his appointment to head the research and development company he was vice-president and general manager of Bowaters Southern Paper Corporation at Calhoun.

He is a graduate of McGill University. Mr. Elderkin is president of the Technical Association of the Pulp and Paper Industry.

Fernand Dugal, M.E.I.C., who was a few months ago named chief engineer, shops and transportation with Quebec Hydro, has joined Sorel Industries Limited as works manager.

Mr. Dugal, a graduate of McGill University, class of 1939 in mechanical engineering, began his career with the Canadian Car and Foundry Company, Montreal, served with the R.A.F. as a technical officer during world War II, at Dorval, Que., and in 1944 joined Cartier Industries, Montreal as a consulting engineer and works manager. The following year plant engineer with the Montreal Locomotive Tank Arsenal he transferred to the American Locomotive Company at Schenectady, N.Y. as a plant engineer in 1946. He became associated with Hydro-Quebec in 1949 when he was engaged as an assistant chief engineer of shops and transportation.

J. W. Ross, M.E.I.C., has been promoted to the position of assistant manager, development, of the Linde Air Products Company, division of Union Carbide Canada Limited.

Prior to his new assignment as assistant manager of engineering he was also a short time ago appointed operations manager of the electric products department of the firm. Mr. Ross will be located at the Linde General offices at Toronto and will be engaged in the development of new products and processes and their application to industry.

Mr. Ross graduated from the University of Toronto in 1941 with a B.A.Sc. degree in mechanical engineering and has been associated with the firm for twelve years.

Gerald G. Fisch, M.E.I.C., has been named a vice-president of Bruce Payne and Associates, Inc., management consultants. Mr. Fisch who joined the company in 1955 and became an assignment director in 1956, was formerly with Canada Packers, Ltd., and also served as vice-president and general manager of a leading consulting firm in Canada.

A graduate of McGill University, Mr. Fisch has degrees in management and engineering from the Massachusetts Institute of Technology gained in 1950.

In his new position Mr. Fisch will maintain headquarters in the firm's New York office and will also be concerned with company activities in several American and Canadian cities.

• PERSONALS

Harry G. Stead, M.E.I.C., has for a number of months held an appointment as manager with the Winnipeg firm of Betts-Eastman at their Simcoe, Ont. processing plant. Betts-Eastman specialize in the field of hydraulics.

Mr. Stead was, prior to joining the company president and chief engineer and latterly general manager with E. Leonard and Sons Limited, London, Ont. He joined the organization in 1923.

Mr. Stead is also a past-chairman of the London Branch of the Institute.

John E. Bright, M.E.I.C., formerly district engineer with the Department of Public Works, Canada, at Halifax, has assumed the position of chief of the maintenance and operations division.

Mr. Bright joined the Department of Public Works as an engineer in the London, Ont., district office in 1946, on his return to Canada after several years overseas with the Royal Canadian Engineers. Transferred to headquarters in Ottawa in 1953 he was employed first in the bridge design section and then in the structures division of the development engineering branch. The following year he was moved to the Harbours and Rivers Engineering Branch and worked in the Atlantic section until his appointment as district engineer in 1955.

He is a 1938 graduate of Queen's University, Kingston, with a bachelor of science degree in mechanical engineering.

Charles K. Hurst, M.E.I.C., has been appointed chief of the Marine Excavation Division, Department of Public Works, Canada, following service with the Department of Northern Affairs and National Resources as hydraulics engineer, hydraulics division, Water Resources Branch.

Mr. Hurst is a 1937 graduate of the University of Alberta in civil engineering. He obtained an M.Sc. degree in hydraulic engineering at the University of Iowa in 1940. The following year employed with the City of Edmonton as a hydraulics engineer he also became associated with the Department of Transport, Canal Services, as a junior hydrometric engineer before joining the Royal Canadian Navy.

Returning to the Canal Services of the Department of Transport in 1945 following overseas service he has since then worked with the general engineering branch of the department, with the Peterborough office of Canal Services, as assistant superintending engineer. In 1952 he was appointed engineer adviser to General A. G. L. McNaughton, chairman of the Canadian Section of the International Joint Commission. In March, 1955 he became chief of the International Waterways Section, Water Resources Branch of the Department of Northern Affairs and National Resources.

• PERSONALS

James A. Brown, M.E.I.C., who has for the past seven years been manager of the Toronto Branch of the Dominion Welding Engineering Company Limited has been transferred to the Montreal head office as assistant general manager. Following graduation from Queen's University in mechanical engineering, in 1944, Mr. Brown joined the R.C.N.V.R. He transferred later from marine engineering to the Fleet Air Arm, attended the Royal Naval Engineering College in England and served with the Royal Navy.

Returning to Canada at the end of the war he joined the Spruce Falls Power and Paper Company at Kapuskasing as a design engineer and was later appointed special expeditor at head office in Toronto.

He also held positions with the Ford Motor Company and the International Nickel Company.

J. G. Lefebvre, M.E.I.C., formerly technical staff officer, grade two, holding the rank of major with the Canadian Joint Staff, London, Eng., recently obtained release from the Canadian Army in order to accept the position of general manager of the firm of Aero Mechanic Limited at Quebec, Que.

Now a member of the reserve army, he has affected to the 8 Militia Group Headquarters.

While on active military service Mr. Lefebvre was with the Defence Research Board as head of the design section at the Canadian Armament Research and Development Establishment. Later he was posted to the Armament Design Establishment, which is a branch of the United Kingdom Ministry of Supply.

He is a 1948 graduate in mechanical engineering from McGill University.

Vassyl Nakonechny, M.E.I.C., formerly an estimator in the industrial drawing office with Canadian Vickers Limited, Montreal, has accepted an appointment in Washington, D.C. Mr. Nakonechny is employed as a naval architect with the David Taylor Model Basin.

He is originally from Belgium where he studied at the University of Louvain.

W. Rothwell, M.E.I.C. production manager with TCF of Canada Limited, has been elected chairman of the Cornwall Branch of the Institute for the 1957-58 season.

Mr. Rothwell, who came to this country from England in 1947 has since that time held appointments with Montreal Cottons Ltd., at Valleyfield, Que., and with TCF of Canada Ltd., in 1952 on the building of a new plant in Cornwall for the manufacture of transparent cellulose film. He was named to his present position in 1955.

A graduate of London University, class of 1938, he served as part-time lecturer in mechanical engineering at the

• PERSONALS

Bradford Technical College and the Carlisle Technical College until 1942, as well as being associated with Vantona Textiles Ltd., Manchester, and the Bradford Dyers Association Ltd., as chief engineer of the Bowling Dyeworks, Bradford, Yorks.

In 1942 volunteering for military service he was until the war's end a member of the Royal Electrical and Mechanical Engineers. Released from military duties in 1945 he returned to the Bradford Dyers Association and received the appointment of chief engineer of the subsidiary Egyptian company called Beida Dyers S.A.E., at Alexandria where he was responsible for all engineering activity including the building of an additional new plant.

In 1947 he returned to England and was appointed works engineer with Ferguson Brothers at Carlisle. It was shortly after this that he came to Canada.

W. Rothwell, M.E.I.C.

W. H. Ackhurst, M.E.I.C.

W. H. Ackhurst, M.E.I.C., manager of sales, motor and control department with the Canadian General Electric Company Limited at Peterborough, Ont., has been elected chairman of the Peterborough Branch of the Institute.

A graduate in electrical engineering from the Nova Scotia Technical College, class of 1939, Mr. Ackhurst has been associated with the company for some time.

He joined the firm prior to enlisting in the R.C.E.M.E. during World War II and returned to the organization in 1946.

J. C. Savage, M.E.I.C., has for a number of months held the position of assistant to the general superintendent, the Aluminum Company of Canada Limited, chemical division, at Arvida, Que.

Mr. Savage recently spent a year in Europe at the Centre d'Etudes Industrielles, the international school of business administration founded by the company at Geneva.

He is a McGill University graduate, class of 1948, and was formerly assistant superintendent of the Bayer Ore plants at Arvida.

significant advance in rail POWER for industry and switching

DIESEL HYDRAULIC LOCOMOTIVES OFFER

smooth power - operating economy - easy maintenance

Diesel Hydraulic locomotives use exactly the same principle of power transference to the driving wheels, as does the automatic transmission of a motor car. Since there is no rigid connection between engine and wheels, possible damage to the transmission or engine due to coupling, is eliminated.

Specialized Facilities and Personnel are not required to service and maintain Diesel Hydraulic Drive Locomotives. Due to the absence of electrical rotating equipment, it is not necessary to maintain stocks of spare renewal parts such as, brushes, relay contacts etc.

Diesel Hydraulic Locomotives are built in the following sizes:

12 — 15 tons	20 — 25 tons
30 — 35 tons	40 tons
44 tons	50 — 65 tons

CLC also build:

Diesel Mechanical
Steam and Steam Fireless and
Diesel Electric Locomotives

15 ton, 0-4-0 Diesel Hydraulic switching locomotive—typical of the class of locomotive used for switching all over the world.

40 ton, 0-4-0, 300 h.p. Diesel Hydraulic locomotive for medium duty switching service

40 ton, 0-6-0, 300 h.p. Diesel Hydraulic switching locomotive.

• PERSONALS

R. W. J. Moore, JR.E.I.C., a 1954 graduate of the University of Toronto in civil engineering has been named city engineer at Woodstock, Ont.

He has, since his graduation held the post of assistant city engineer of that community.

James Q. Calkin, JR.E.I.C., who has been in Great Britain for the past two and a half years has returned to Canada. He is with Avro Aircraft Limited, Malton, Ont., as a design engineer in the initial projects office.

Originally employed with Avro Aircraft Limited as an engineer in training, following his graduation from the University of New Brunswick in 1953, he was in 1954 awarded a Cranfield scholarship for two years post-graduate study at the College of Aeronautics, Cranfield, Eng. Specializing in aircraft design he was awarded the diploma of the College of Aeronautics (D.C. Ae.) on completion of the course last year.

He then accepted a position with A. V. Roe and Company, Manchester, Eng., as a design technician in the project development department and remained there until early this year.

Mr. Calkin graduated from the University of New Brunswick in 1953.

B. C. Halley, JR.E.I.C., who graduated from the University of London, class of 1948, with a B.Sc. degree in civil engineering now resides at Kingston, Jamaica. He is at work as an assistant civil engineering superintendent on the construction of an aluminum plant for Alcan.

D. G. Couroubakilis, JR.E.I.C., a 1953 graduate of the University of British Columbia has been appointed structures engineer with the Sudan government, ministry of irrigation and hydro-electric power, known as the Managil Scheme at Wad-Medani.

Mr. Couroubakilis went to the Sudan shortly after his graduation and worked as an irrigation engineer on the White Nile Pumping Scheme and the Zuleit Pumping Scheme, located at Kesti.

R. E. Moore, M.E.I.C., formerly of the Department of Mines and Technical Surveys at Ottawa has left Canada and will be resident in the Netherlands for a period of one year, where he will be located at the International Training Centre for Aerial Survey at Delft.

Mr. Moore was a 1949 graduate of the Nova Scotia Technical College and holds a B. Eng. degree in civil engineering.

Pierre La Rochelle, JR.E.I.C., a Laval University graduate in civil engineering, class of 1954, is in London, England, studying under an Athlone Fellowship.

Mr. La Rochelle carried out two years' research on frost action in soils, following his graduation. Through the Fellowship he is now specializing in soil mechanics under Professor Skempton, at the Imperial College of Science and Technology, at London.

J. I. B. Williamson, JR.E.I.C., for a number of years an officer with the Royal Canadian Engineers, is now employed with Canadian Fairbanks-Morse Company Limited, engine and pump and electrical division at head office, Montreal.

On graduation from the Royal Military College in civil engineering in 1952, commissioned as a lieutenant, he served in Korea as a troop and reconnaissance officer. He was engaged in planning and executing road building, in maintenance projects, tunnelling and field defence works, and mine welfare.

In 1954, awarded a B. Eng. degree in civil engineering at McGill University, he later embarked on a long

• PERSONALS

survey course in England and followed instruction on the techniques and organization of survey and mapping.

He was appointed to the Army survey establishment at Ottawa and was during the summer of 1955 given command of a field mapping operation in the Arctic.

John K. Abel, JR.E.I.C., who has for some time held the position of chief engineer in the Automotive Manufacturing Division of Thompson Products Limited, St. Catharines, Ont., has been promoted to manager of the replacement division of the firm.

Mr. Abel began his professional career with the Canadian Comstock Company Limited. He is a 1947 graduate of McGill University in mechanical engineering.

J. J. Hamilton, JR.E.I.C., a 1955 graduate of the University of Manitoba, who obtained an M.Sc. degree in soil mechanics and hydraulics at the University of Manitoba the following year, is working with the National Research Council, Ottawa.

Employed with the division of building research, soil mechanics section, his work is in conjunction with the cooperative research project being carried out with the St. Lawrence Seaway authority on special soil mechanics problems.

W. A. Neale, JR.E.I.C., has been appointed manager of the Toronto Branch of Dominion Welding Engineering Company Limited.

Following graduation from the University of Toronto in mechanical engineering in 1946 Mr. Neale served with the R.C.E.M.E. and until recently was chief engineer and general manager of E. B. Magee in Port Colborne, Ont.

J. B. Bowron, JR.E.I.C., has been appointed gas turbine sales engineer in Western Canada by the English Electric Company of Canada Limited with headquarters at Calgary.

A University of Alberta graduate in electrical engineering, class of 1950, Mr. Bowron has recently returned from England, where he was with the English Electric Company Limited in their gas turbine department at Whetstone. His experience in England included the erection, testing and sales of gas turbines.

Richard A. Sara, JR.E.I.C., of the Taylor Instrument Company, has been transferred from Toronto to their Los Angeles office. He continues to work as a sales engineer.

Mr. Sara is a graduate of the University of Manitoba in mechanical engineering, class of 1949.

W. A. Godfrey, JR.E.I.C., a 1954 graduate of the University of Manitoba, in electrical engineering is employed with the Bell Telephone Company of

• PERSONALS

Canada, Montreal as an engineer engaged in work on the Trans-Canada microwave relay system.

Mr. Godfrey returned to Canada a few months ago after spending two years in England under an Athlone Fellowship. While in England he was engaged in post-graduate work in radar development with a large electrical manufacturing firm in Rugby.

E. J. Lockwood, JR.E.I.C., has accepted an appointment as district engineer with the Trans Mountain Oil Pipe Line Company whose offices are located at Kamloops, B.C., and is responsible for engineering work carried out in the area.

Previously with the British Columbia Forest Products Limited, Hammond Sawmill division, he was for more than five years employed as plant engineer.

Mr. Lockwood is a 1950 graduate of the University of British Columbia, with a bachelor of applied science degree in mechanical engineering.

Captain J. J. Eatock, JR.E.I.C., has moved from Edmonton, Alta., to the office of the chief eingineer at Army headquarters, Ottawa. Captain Eatock previously held the appointment of officer commanding, the N.W.T. and Yukon Detachment of the R.C.E.

He was previously stationed in Eastern Canada with the Fifty-eighth Independent field squadron of the R.C.E. at Montreal in 1952. Captain Eatock is a University of Alberta graduate, class of 1949, in chemical engineering.

G. T. Fenwick, JR.E.I.C., has for several months held the appointment of chief engineer with the London, Ont, firm of Unifin Tube Company Lmiited.

A University of Saskatchewan graduate in mechanical engineering class of 1952, he was previously employed with the Canadian Westinghouse Company Limited, Hamilton, Ont.

O. Schavo, JR.E.I.C., formerly of Montreal has gone to London, Ont., where he is employed with the Minnesota Mining and Manufacturing Company as a mechanical engineer.

He was previously employed with Northern Electric Company Limited.

Mr. Schavo is a 1954 graduate of the University of Toronto.

G. R. Walker, JR.E.I.C., has joined the staff of the Ontario Hydro-Electric Commission, research division at Toronto.

He is a University of New Brunswick graduate class of 1954 and was last year engaged as a field engineer with the Foundation Company of Canada Limited at Chalk River, Ont.

W. G. McGaughey, JR.E.I.C., has been transferred from Montreal to Toronto with the Foundation Engineering Corporation Limited.

He is a Queen's University graduate in electrical engineering, class of 1952 and began his engineering career with the Canadian General Electric Company at Toronto.

R. W. Lockie, JR.E.I.C., has accepted an appointment with the B.C. Power Commission, mechanical engineering department, power development division in Victoria, BC.

Formerly with the English Electric Company of Canada Limited, at Toronto, he was employed in the hydraulic department of the firm.

Mr. Lockie is a graduate of the University of British Columbia, class of 1950.

T. L. Salmon, JR.E.I.C., of the British American Oil Refinery has been transferred from Toronto to the Regina, Sask, office.

Mr. Salmon has been with the company for some time.

He graduated in mechanical engineering from the University of Saskatchewan in 1949.

NEWS OF THE BRANCHES

Activities of the Forty-Seven Branches of the Institute and abstracts of the papers presented at their meetings

BELLEVILLE

E. T. HILBIG, JR.E.I.C.,
Secretary-Treasurer

General Meeting

D. C. Warren of the Canada Metal Co., Toronto, delivered a most interesting talk on the most modern method of producing precision castings as for bearings. In his talk he mentioned that the process of casting cylindrical shapes centrifugally had been developed by the Schwietzke Company of Dusseldorf, Germany and that his company had actually obtained this technique from the German Company.

The older method of sand casting has very decided limitations especially when it comes to texture of the finished product. It was for this reason that advantages of the newer method were readily realized.

With the use of slides, Mr. Warren pointed out the significant components of a typical centrifugal casting machine. Essentially it consists of an electric furnace thermostatically controlled, in which the molten alloy is contained. A predetermined quantity of this alloy is measured by a balanced hopper. From the latter the hot metal is poured down a spigot which directs it to the internal periphery of a rotating water-cooled drum. As soon as the molten metal contacts this drum the latter moves longitudinally away. The result is a cylindrical shape of cast metal having an extremely homogeneous grain texture because of controlled chilling.

Numerous castings produced by the above process were on display and were inspected with interest by all present.

CALGARY

J. A. WEBB, M.E.I.C.,
Secretary-treasurer

R. G. PRICE, M.E.I.C.,
Branch News Editor

'Slide Rule Soirée'

The annual Calgary Branch ball, known as the Slide Rule Soiree was held on February 14, 1957, at the Palliser Hotel. A capacity crowd of more than three hundred were in attendance.

A floor show put on by engineers and their wives was enthusiastically received and was repeated for patients in Calgary's Colonel Belcher Hospital.

Introduction to P.D.

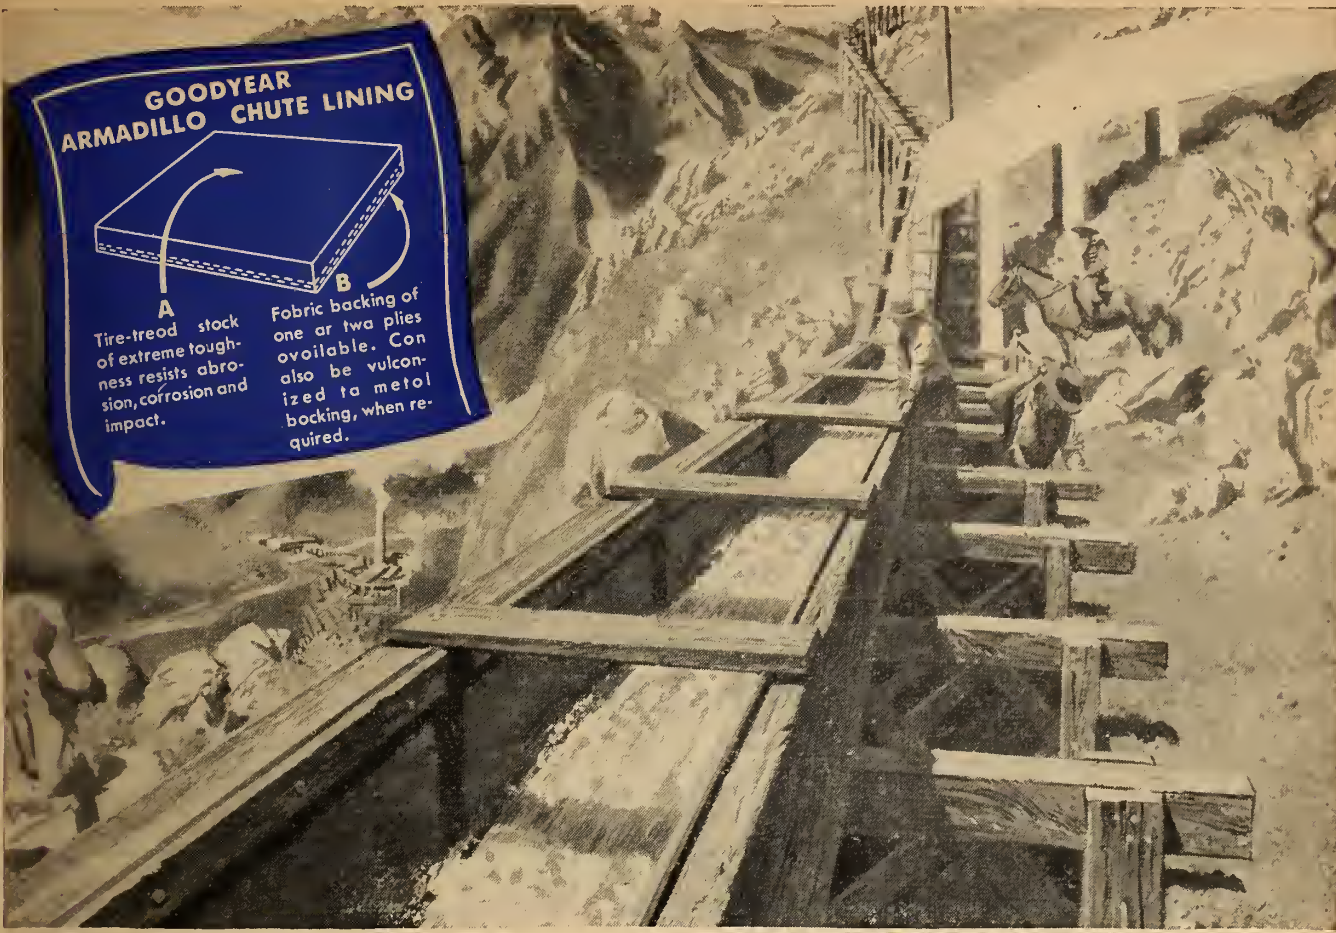
A capacity crowd also turned out for and enjoyed the first of two professional development meetings on March 5, at Penley's Academy. Addresses were presented by N. Emms Read of Calgary on "The Art of Public Speaking", and Dr. Dwight Palmer of Los Angeles, internationally prominent management consultant, whose subject was, "How to Motivate the Young Professional". The meetings were held in conjunction with the Alberta Society of Petroleum Geologists and the Canadian Institute of Mining and Metallurgy. Programs dealt with the subjects of Finance, Human Relationships, Management and Self-Expression.

Over the past six years great progress has been made by the E.I.C. in the field of professional developments across the country with as many as twenty-six branches actively engaged in these types of programs in a given season. After giving serious consideration to adding this type of personal development opportunity to their regular program of activities, program chairman F. L. Perry secured the services of four speakers, building a program broaching the field of professional developments and built around the speaker, rather than the subject.

N. Emms Read — N. Emms Read, manager of the International Correspondence Schools, at Calgary, is highly regarded in the field of public speaking and associated subjects. He has had twenty-five years' experience in training professional people in public speaking throughout Alberta. Mr. Read was one of the founders of the "Radio Round Table of the Air" and one of the best known speakers in Alberta. Many prominent Albertans owe their interest in "the Art of Public Speaking" to training received under the guidance of Mr. Read.

Dr. Dwight Palmer — Second speaker of the evening was Dr. Dwight Palmer of Los Angeles, manager and owner since 1945 of Dwight Palmer and Associates

Taken at the Slide Rule Soiree, annual ball of the Calgary Branch held in February, members and wives participating in the floor show are shown below. Fifty couples were unable to get seats for the popular event which drew a capacity crowd of more than 300.



Rubber armour can outlast steel 12 to 1

Goodyear Armadillo Chute Lining wins fight with 10,000,000 cubic feet of "Chuting Slurry"

As consulting engineer for a hard rock mining company, you're working on a new system for disposing of 10,000,000 cubic feet of concentrator tailings on a tough ten year project.

Conditions suggest gravity flow to stocking area in concrete conduit, metal pipe, or wooden or metal launders. You've ruled them out because none could withstand biting acids and abrasive slurry.

What kind of Armour could meet your long-term requirements? You recall a discussion you had with the Goodyear Representative who presented facts and figures to prove that Goodyear Armadillo Chute Lining has outlasted steel 12 to 1. You decide to give him a call. Soon, both of you are going over plans for a wooden chute that's protected by a hide of this tough, abrasion and corrosion resisant "rubber armour".

That was two years ago; since then your pet project has continued carrying an unending river of tailings from your back doorstep to the disposal area and it's still as good as new. Tire tread toughness of Armadillo Lining is so effective you're looking forward to trouble free operation for years to come.

Armadillo Chute Lining is your most effective deterent to abrasion wherever it occurs. The Goodyear Representative can recommend the Armadillo Lining best suited to reduce replacement costs. Call your nearest Goodyear Office . . . at Moncton, Saint John, Quebec City, Montreal, Toronto, London, Windsor, Winnipeg, Regina, Saskatoon, Calgary, Edmonton, Vancouver or Head Office, New Toronto.

INDUSTRIAL RUBBER PRODUCTS ENGINEERED FOR THE JOB

GOODYEAR

THE GREATEST NAME IN RUBBER

consultants in management, industrial relations and organization. Dr. Palmer studied at Pomona College, where he majored in economics; at the University of Chicago graduate school of business, specializing in industrial management, labor law and labor economics; and in 1935 was awarded a Ph.D. degree in economics at Stanford University. During the next three years he also attended the London School of Economics and was engaged in post-doctorate research training at Geneva with the Inter Labour Office and League.

Professor E. D. MacPhee — On March 14, Prof. E. D. MacPhee, dean of the faculty of commerce, University of British Columbia addressed the group on "Professional Management". No greater authority on this subject existing in this continent, he is the ex-chairman, president or managing director of operating companies in textiles, leather goods, aircraft and chemicals and speaks on the subject as a highly successful business man, rather than as a university professor.

T. W. Meredith — Second speaker on this bill of fare was T. W. Meredith, manager of Osler, Hammond and Nanton who presented a talk entitled "The Investment Industry".

The Journal hopes to carry a full report of these meetings in an early issue.

CAPE BRETON

W. A. DODSON, M.E.I.C.,
Secretary

F.O. JOHN RICHARD, JR.E.I.C.,
Publicity Chairman

Tour R.C.A.F. Station

Through the kind invitation of the commanding officer, Squadron Leader L. J. Lomas, and the collaboration of the construction engineering officer, F.O. John Richard, the Cape Breton Branch had the pleasure of holding a well attended meeting at the Officers' Mess on March 14, 1957.

The group was welcomed by Squadron Leader C. A. Brunger, chief technical services officer, and guided through a limited tour of the station facilities. The trip wound up at the newly completed recreation hall and then adjourned to the Mess where an excellent buffet supper had been prepared for the "Gourmets".

W. A. McDonald, chairman of the Branch, expressed the thanks of the members for a most enjoyable and entertaining evening. He also congratulated the commanding officer and staff on the well organized reception and tour and the obviously efficient construction and operation of all facilities at the Station.

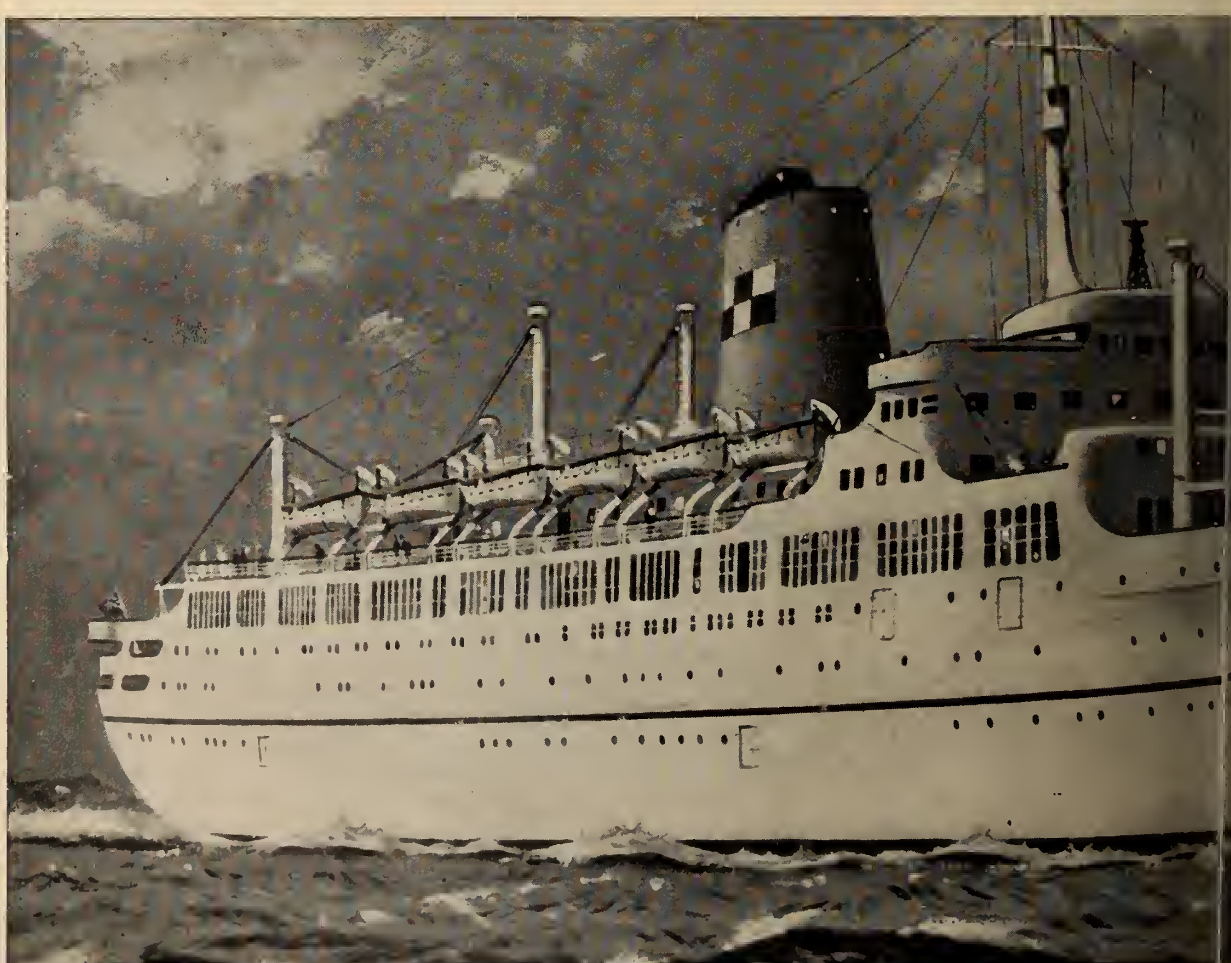
C. M. Anson Reports on UPADI

The monthly dinner-meeting of the Cape Breton Branch was held on February 20, 1957, under the chairmanship of Charles Campbell, treasurer.

For the occasion, C. M. Anson, vice-president and general manager of the Dominion Iron and Steel Company, Ltd., presented an informal report on the Pan-American Engineering Convention held in Mexico City. After refreshments and dinner, a deserving presentation to Mr. Anson was made by Mr. Laing, of Eastern Light and Power. Mr. Laing outlined the well-filled career of an engineer who can still find time and energy to identify himself with community life and spirit, even while carrying the burden of responsibilities and duties as the chief of steel operations at DOSCO.

Mr. Anson expressed his great pride in receiving the honour of the presidency of the Institute for 1957-58, from the finest group of authorities in the field, "his fellow engineers".

As representative of the E.I.C. at the UPADI convention, Mr. Anson was impressed by the feeling of co-operation and understanding, that prevailed throughout the meetings, where the chief



aim of everyone was, no doubt, the promotion of the engineering profession. In this respect, the Convention brought together engineers from all over the Americas, and through the dissemination of engineering information and understanding, endeavoured to advance the engineer's standing in the community and produce uniform engineering standards. After a look at the Congress, Mr. Anson led everyone around Mexico City and the magnificent countryside through the medium of fine color slides, all of which was to the credit of the man behind the lenses.

FREDERICTON

O. I. LOGUE, M.E.I.C.,
Secretary,

G. R. W. BLISS, JR.E.I.C.,
Chairman, Public Relations Committee

Association Council Guests

The March meeting of the Fredericton Branch was held on March 22 with chairman, Ira M. Beattie presiding. Special guests at the dinner were the council of the Association of Professional Engineers. This was the last general meeting of the branch before the annual meeting in April.

I. Beattie opened the meeting by welcoming the members and guests and introducing those at the head table. He then called on Prof. E. E. Wheatley, professor of mechanical engineering at the University of New Brunswick, to introduce the main speaker of the evening, R. D. Neill, mechanical design engineer, with the N. B. Electric Power Commission. Prof. Wheatley pointed out that Mr. Neill was a 1954 graduate from U.N.B., the second graduating class in mechanical engineering from that institution. Mr. Neill has been employed by the Commission since graduation.

Mr. Neill's paper was entitled "The Selection of the Most Economical Steam Conditions for Central Station Generating Units". He said that the statement has been made that the electric utility industry is one of the most cost conscious industries in America today. This attitude, he stated, has been fostered by the continual struggle to produce electrical energy at ever decreasing costs while the prices of all the factors which go into its production are continually going upward.

Mr. Neill said that although his paper dealt solely with thermal power plants, the methods of analysis outlined can be applied to any industry or situation where more than one system of obtaining a desired result is available.

The Chairman then called on J. L. Feeney, chief engineer of the Power Commission, who congratulated Mr. Neill on his presentation of the subject. He suggested that other speakers from the Branch ranks present papers at forthcoming sessions.

HAMILTON

W. A. H. FILER, JR.E.I.C.,
Secretary-Treasurer

J. R. CURRIE, M.E.I.C.,
Branch News Editor

President's Visit

This meeting, also considered as Ladies' Night, with the showing of the film "Leonardo da Vinci", held on February 21, 1957, marked the annual visit of the president and general-secretary to Hamilton. The Branch was most happy to welcome Mr. and Mrs. V. A. McKillop and Dr. Austin Wright. Over three hundred members and guests attended the affair.

Introduced by chairman D. B. Annan, Mr. McKillop spoke briefly concerning the responsibilities of engineers and the challenge presented the engineering profession in the future development of Canada as revealed by the Gordon Report. Mr. McKillop outlined the active interest taken by the Engineering Institute of Canada in the development and education of the young engineer.

The film was presented by Dr. Wright who gave a brief history of this outstanding work. The rights for showing the film in Canada have been obtained by the E.I.C., and many favourable comments have been accorded it by critics throughout the world.

Refreshments were served by members of the Ladies' Auxiliary.

Before the evening meeting, N. A. Eager held a cocktail party at which President McKillop met a number of the industrial leaders of the Hamilton area.

Papers Night

The annual students' and juniors' papers night was held on March 21, at McMaster University. Papers were presented for competition by G. R. Mason, V. O'Doherty, B. C. Compton, and J. C. Sinclair.

The winning paper was presented by J. C. Sinclair, for his work on the development of the transistorized remote broadcast amplifier. The newly developed broadcast amplifier was shown to the audience to illustrate the saving in space through the replacement of the older vacuum tubes with transistors. V. O'Doherty, who spoke on Low Voltage Switchgear Protection, and G. R. Mason, who presented the paper "Future Power in Canada", were also winners.

Judges were R. H. Stevenson, A. E. Archibald, and J. C. Buchanan. Prizes were presented by L. C. Sentance, past-president, and D. B. Annan, chairman.

LONDON

G. W. CHORLEY, M.E.I.C.,
Secretary-Treasurer

GEORGE HAYMAN, JR.E.I.C.,
Branch News Editor

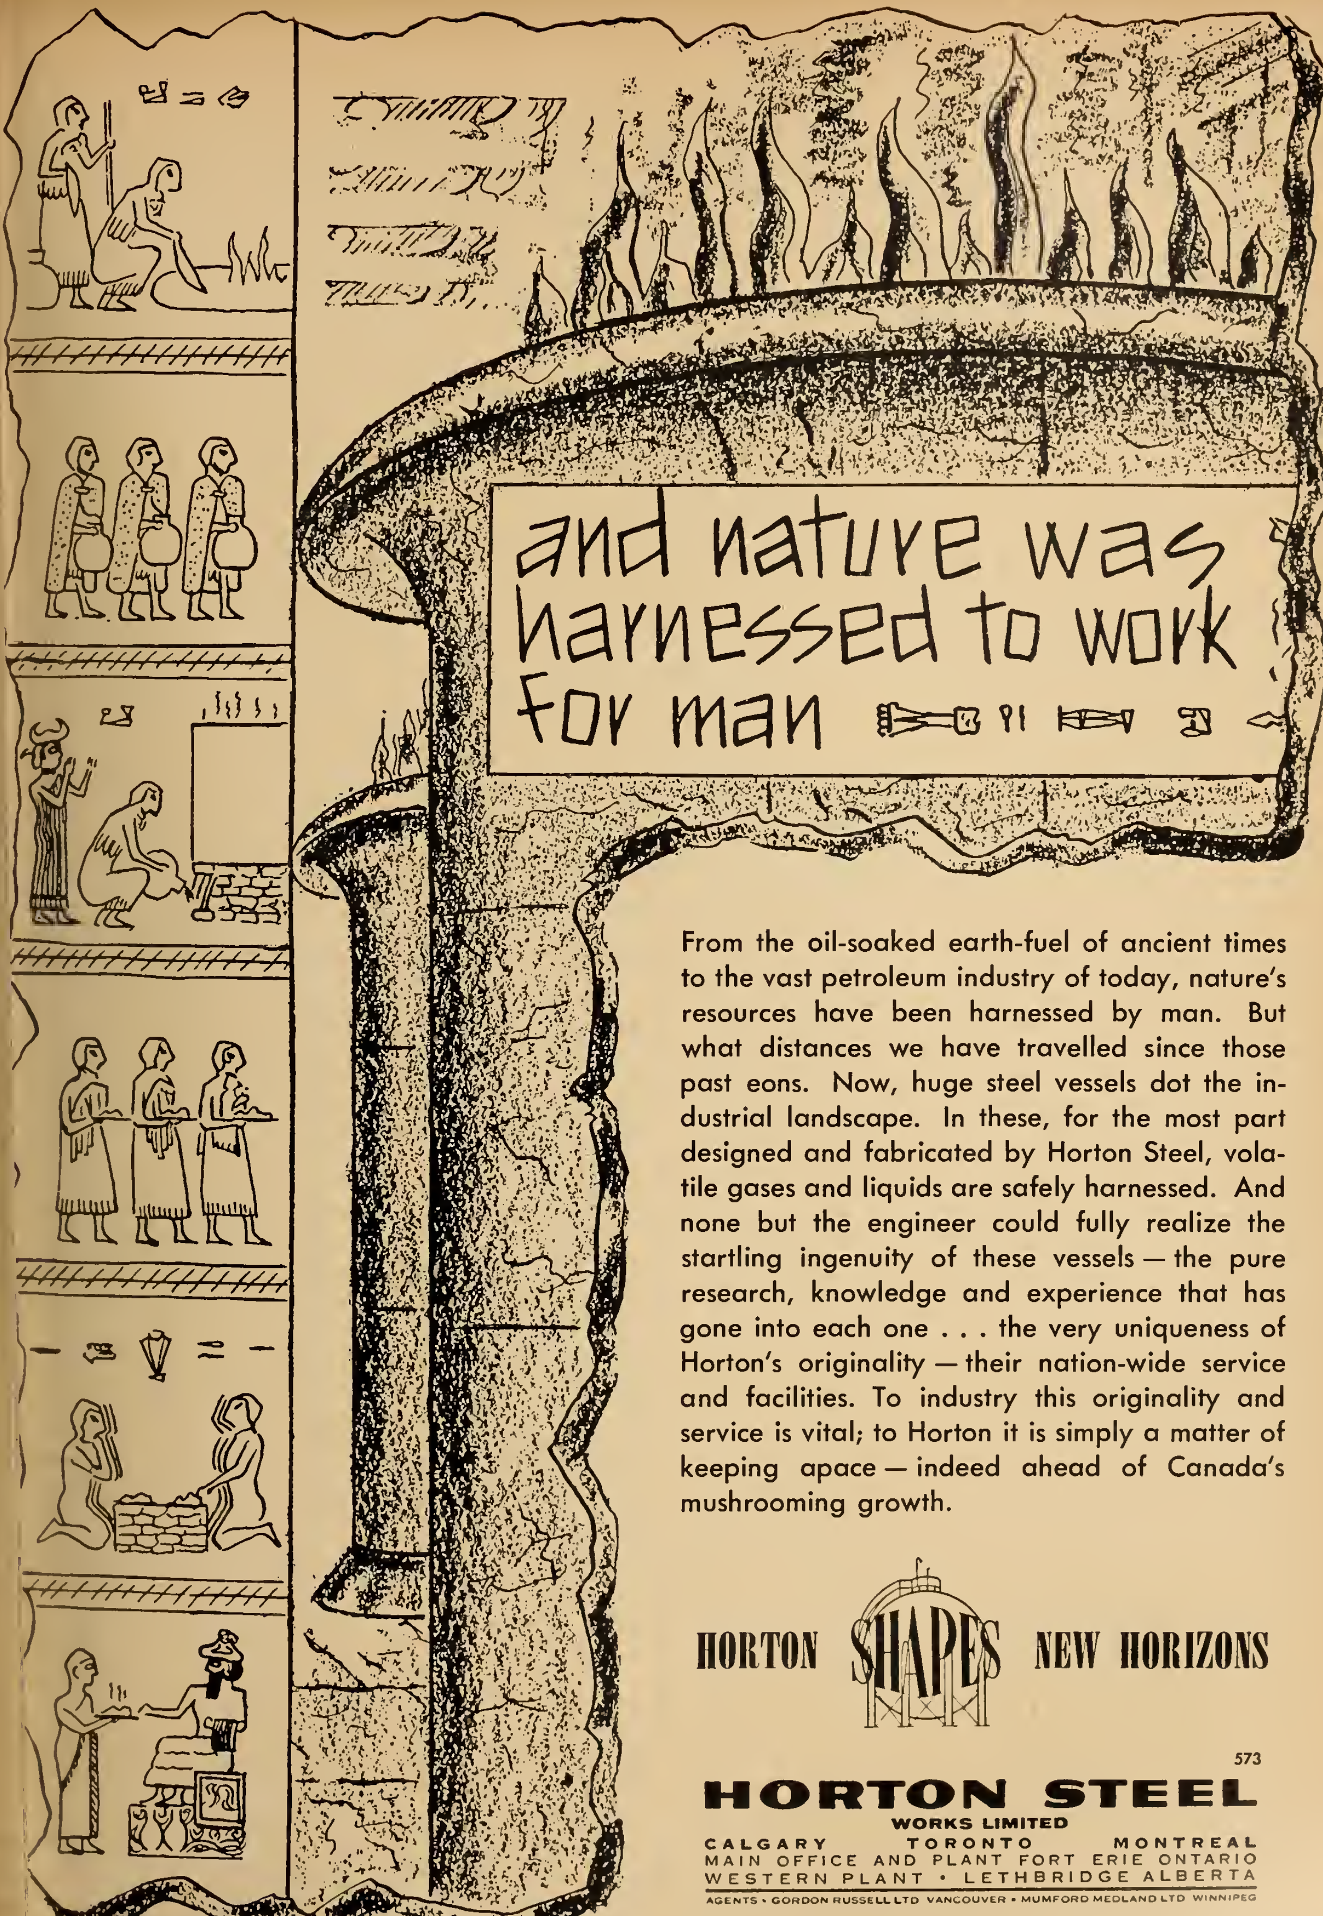
President's Visit

The February meeting of the London Branch took place in the form of the annual dance. This dance also marked the official visit of President V. A. McKillop to his own branch.

During the afternoon, prior to the dance, the local executive met with Mr. McKillop and Mr. Wright to discuss problems regarding the Institute locally and nationally.

About seventy members and their ladies attended the dance in the evening. It was generally regarded as one of the most successful ever held. A buffet supper was served at 10.30 p.m., followed by entertainment supplied by Dave Broadfoot, one of the stars of Toronto's Spring Thaw, which was playing in London at the time. Don Douns' orchester provided music for dancing.

Several local firms donated prizes which were awarded during the evening



and nature was harnessed to work for man

for special dances. Another highlight of the evening was provided by five of the local branch members who held a jam session with banjo, ukelele, piano, traps and gut bucket. This entertainment was presented at one o'clock and was warmly received. It is hoped that this may be repeated in years to come.

General Meeting

The March meeting of the London Branch was held on March 19 at Wolseley Barracks. Guest speakers were former city engineer Roy Garrett, alderman Terry Ferris, city engineer Eric Skelton and chief sewer engineer Frank Ball. These men took part in a panel discussion on the recent sewer survey in London.

Mr. Garrett outlined the past history of London and its sewer installations up to the present time. Mr. Ferris discussed the political problems leading up to city council hiring an outside consulting firm to survey London's sewer needs. Mr. Ball outlined the consulting firm's recommendations and Mr. Skelton described the action that has taken place and that which will follow, on these recommendations. Considerable expense is to be born by the London tax-payer as a result of these suggestions.

The branch members felt that this meeting helped clear minds of the confusion surrounding this issue. It has received a tremendous amount of publicity in the local press. This meeting served to consolidate the thinking on this subject as the newspaper had seemingly failed to do prior to the discussion.

MONTREAL

JEAN RIEL, S.E.I.C.,
Students' Representative

Students' Night

Le 11 février dernier avait lieu le "Students' Night" annuel, aux quartiers généraux de l'E.I.C. Ce "Students' Night" est un concours oratoire entre deux étudiants de l'Université McGill et deux étudiants de l'Ecole Polytechnique. Ces étudiants présentent des sujets techniques se rapportant au génie. Ils sont jugés d'après la valeur du sujet choisi et leur habileté à le présenter.

Cette année monsieur Jules O'Shea de l'Ecole Polytechnique remporta le premier prix en présentant son sujet: "A Grammatical Word Computer", c'est-à-dire une description d'un compteur électronique pour calculer le nombre de mots écrits sur un dactylographe. Il est intéressant de noter que monsieur O'Shea est l'inventeur de ce compteur électronique.

Monsieur Claude Villeneuve de McGill, qui fut choisi second, exposa la formation d'un "Retaining Wall" employé sur un champ de construction en vue de l'agrandissement d'une usine.

Le troisième prix fut décerné à monsieur Georges Starke de l'Ecole Polytechnique. Son sujet s'intitulait: "A Thermal Model of Heated Flat Slabs used as Floors in Basementless Houses". C'est un travail qui a été élaboré au Conseil National des Recherches à Ottawa, durant l'été dernier.

Enfin moniseur John Gillman de McGill présenta "An Electrical Estimating". Ceci était un exposé concernant l'évaluation d'un projet en électricité.

L'invité d'honneur était monsieur Léo Roy, président de la Corporation des Ingénieurs de la Province de Québec et président du comité exécutif de l'E.I.C. (division de Montréal.) Il présenta les prix et les certificats de l'E.I.C. au gagnant et aux trois autres étudiants.

Les trois juges étaient monsieur G. L. MacLean, président sortant de charge de la section junior de l'E.I.C., monsieur H. S. Racey de Racey, MacCallum and Associated Limited, et monsieur R. Langlois, professeur de l'Ecole Polytechnique.

Deux courts métrages furent présentés pendant que les juges délibéraient.

La soirée fut très intéressante et un nombre imposant de membres furent présents.

Students' Night

The annual "Students' Night" was held last February 11, 1957, at E.I.C. headquarters. This so called "Students' Night" is an evening during which two students from McGill University and two students from l'Ecole Polytechnique present technical subjects concerning engineering. They are judged according to the value of their chosen subject and their ability to present it.

This year, Jules O'Shea from l'Ecole Polytechnique won the first prize in presenting the paper, "A Grammatical Word Computer". This was a description of an electronic computer used to add the number of words written on a typewriter. It is interesting to note that Mr. O'Shea invented this electronic computer.

Claude Villeneuve from McGill, who took second place, explained the formation of a "retaining wall" which was used during construction of a building.

Third prize went to Georges Starke of L'Ecole Polytechnique. His subject was: "A Thermal Model of Heated Flat Slabs used as Floors in Basementless Houses". This was work done at the National Research Council in Ottawa last summer.

John Gillman from McGill presented "An Electrical Estimating". This concerned the evaluation of an electrical project.

L. Roy, president of the Corporation of Engineers of Quebec and chairman of the executive committee of the Montreal Branch, was guest of honour. He presented the prizes and the certificates to the winner and the other students.

The three judges were G. L. MacLean, ex-chairman of the Junior Section of the E.I.C.; H. S. Racey, of Racy MacCallum

and Associates Ltd.; and R. Langlois, Professor, from l'Ecole Polytechnique.

While judging was in progress, two short films were shown. The evening was most enjoyable and was attended by many members.

NIPISSING AND UPPER OTTAWA

G. R. KARTZMARK, JR.E.I.C.,
Secretary-treasurer

J. W. MILLAR, E.I.C.,
Branch News Editor

President's Visit

On March 8, 1957, the Nipissing and Upper Ottawa Branch was honoured by a visit from the president of the national organization, V. A. McKillop and Mrs. McKillop. During the afternoon the executive committee met with Mr. McKillop and discussed Institute affairs. Later a tour by H. R. D. Graham, regional manager, was made of the Ontario Hydro's new regional offices in North Bay.

While Branch members were occupied with the foregoing activities, wives entertained Mrs. McKillop at tea at the home of Mrs. Macnabb, wife of Branch chairman, T. C. Macnabb.

In the evening an informal dinner and dance was held. Mr. T. C. Macnabb, chairman, presided and President McKillop was introduced by J. S. Cooper, branch councillor. Mr. McKillop is general manager of the Public Utilities Commission of London, Ont. and president of the Canadian section of the American Waterworks Association, as wel as president of the E.I.C.

In addressing the gathering, the president pointed out the important role that the engineers had played in the development of Canada. He said Canada was a nation of only 16,000,000 people and yet held fourth place in world trade. Part of this happy state was due to abundance of power. He called for engineers to become united to gain better recognition and mentioned that the membership in the Institute had doubled since the war and there were now 47 branches across Canada. He strongly supported confederation of organizations of engineers and expressed the belief that in the end the effort would be well worth while. Mr. McKillop said he was much interested in engineering education. Canada has been suffering from a shortage of engineers and scientists for many years and this problem was studied at an engineering education conference in May, 1956. Mr. McKillop urged that branches make their programs attractive in order to bring people together. This problem had been greatly increased as over one million Canadians had moved into suburban areas since the war.

Chairman, Publicity

Visit to Quaker Oats Plant

Great interest in the local industry and E.I.C. activities was reflected in the splendid turnout of members and guests for the visit to the Quaker Oats Company of Canada Limited plant in Peterborough on February 27, 1957.

About 80 persons enjoyed the tour under the guidance of Albert J. Bonney, M.E.I.C., plant engineer, and other members of the company's staff.

Visitors saw the operations of flour and feed mills, manufacturing processes

for shredded wheat, muffets and other cereals of the well-known Quaker brand. The tour gave a good picture how the modern flour mill meets market's demands of special cereals, flour mixes and special feeds. Some of them have over ten ingredients and the machinery is capable of mixing as low as a few pounds of a certain ingredient per ton of total mixture in a continuous process with great accuracy.

It is also interesting to note that the Quaker plant in Peterborough was founded in the beginning of the century to supply the British market with rolled oats and flour. Today, the biggest products in dollars are ready-to-eat cereals for the Canadian market.

As the majority of visitors are in their daily work engaged with the electrical industry, the company's hydro-electric plant and substation were also inspected. The power plant lies on nearby Otonabee river and has three 1800 KVA generators.

After the tour, a light lunch was served in the company's cafeteria where M. E. Clarke, plant superintendent, welcomed the engineers and their guests. Mr. Clarke gave a brief summary of the company's operations and answered questions.

A brief business meeting was conducted by W. H. Ackhurst, Branch chairman. R. A. Blount thanked the company officials for the interesting tour.

In the first half of 1957 the Peterborough Branch will have several more field trips. An inspection tour of Peterborough's new million dollar Memorial Community Centre will be made and some of the latest hydro-electric power developments in Ontario will be visited.

SAULT STE. MARIE

L. F. MASON-TULBY, M.E.I.C.,
Secretary-treasurer

President's Visit

The Sault Ste. Marie Branch of the Institute was honoured with the visit of President V. A. McKillop at its annual meeting, held March 5, 1957.

Arriving in the early part of the day he attended a luncheon meeting of the Branch executive in which confederation was the main issue of discussion. During this time, Branch members' wives, Mrs. K. H. Snell, Mrs. Mason-Tulby and Mrs. K. Kansikas entertained Mrs. McKillop at lunch.

After an early evening appearance on T.V. President McKillop joined Branch members for refreshments and dinner at the Country Club. Guests at the affair included Professor R. C. Brown of the Michigan Institute of Mining and Technology and Mrs. Brown and Ralph Tinkney, of the Toronto Branch of the E.I.C. Mr. Tinkney was in the city on an engineering inspection assignment.

Addresses Branch — Addressing the Branch at dinner, Mr. McKillop stressed the fact that confederation of the two major professional engineers' groups in Canada is an aim of the membership of the Institute. He also emphasized that the time had come to eliminate personalities and protect the futures of the Institute and the Association of Professional Engineers. Mr. McKillop said that the opportunity now exists to think of unity as a means to minimize our differences and look for accomplishment of aims towards building a better, and stronger association and furthering engineering education.

He also commented on the shortage of engineers in relation to the construction and expansion of industry.

Uneasy Balance — Insofar as education was concerned Mr. McKillop felt that there had never been a time when so many people were concerned about education. With three jobs available for every newly graduated engineer, this is an uneasy balance. Although it was encouraging to know that the number of freshmen in universities has increased by

18 per cent he pointed out that this does not mean that there are eighteen per cent more graduates. With industrial requirements for engineering graduates increasing by 11 per cent annually, this is not enough. It was, he felt, just an example of the responsibility which exists for the future in the expansion of technological improvements and multiplying the ability to produce. He pointed to power developments in the St. Lawrence Seaway and in British Columbia as signs of the Canadian national production growth and said that the Institute anticipates the continuance of this growth.

International Standing High — Mr. McKillop rates the international relationships of the Institute highly and pointed out that Canada and its engineering advances enjoy the same reputation in the estimation of international and commonwealth groups.

President McKillop was thanked for his talk by Frank MacKay, chief engineer of the Great Lakes Power Company. The dinner was followed by dancing.

Before leaving the following morning, March 6, President McKillop was taken on a tour of parts of the Algoma Steel Corporation plant at Sault Ste. Marie under the direction of K. H. Snell and K. Kansikas.

Head table guests attending a dinner in honour of President V. A. McKillop during his visit to the Sault Ste. Marie Branch are shown below. Left to right are Miss E. Cassell, L. F. Mason-Tulby, Mrs. McKillop, K. H. Snell, Alderman Frank Ianni and Mrs. L. F. Mason-Tulby.

SASKATCHEWAN

R. BING-WO, M.E.I.C.,
Secretary-Treasurer

Annual Meeting

The thirty-ninth annual meeting was held at the Hotel Saskatchewan, Regina, on Friday, February 15, 1957 with E. J. Durnin, Branch chairman presiding. Approximately 125 members were in attendance.

Before commencing the formal business of the meeting, the chairman introduced guests representing the Western professional engineering associations. They were W. A. Merchant, registrar of the B.C. association, A. E. McDonald, executive-secretary, Alberta, and J. Hoogstraten and L. Bateman, of Manitoba.

The report of the Committee on Professional Development was presented by Dr. J. D. Mollard, chairman. E. F. Dur-

In the beginning...

an EXPLOSION

and access to Sub-Arctic ore!

Behind the craggy barriers of the Quebec-Labrador frontier prodigious ore wealth lay beyond the reach of man. But engineers armed with C-I-L Explosives as a mighty tool, breached the barrier rock and muskeg and blasted a way for man to claim the ore.

C-I-L Explosives have blasted away many other obstacles to Canada's growth and development. With them, Canadians have sculptured an industrial economy, cleft roads through rock-bound land, wrested minerals from the Precambrian Shield, driven steel through mountain barriers, coralled the force of surging rivers.

Unsurpassed in meeting the most exacting requirements, C-I-L Explosives and accessories have been job-proven under the most severe Canadian climatic conditions. They are available from coast to coast through strategically located plants, sales offices, magazines and dealers.

C-I-L Sales and Technical Service representatives have gained incomparable experience in blasting under Canadian conditions; because of this, they can provide technical service unsurpassed in meeting the needs of those engaged in blasting operations everywhere in Canada.

Always in the front line of industrial expansion, Canada's powdermen have learnt their trade with C-I-L Explosives and skillfully use them as precision tools.

C-I-L Explosives

"Everything for Blasting Everywhere in Canada"

rant had acted as co-chairman. Dr. Mollard reported that 48 persons registered for the course, with an average attendance of 32. Nine lectures were held between September and December. The subjects covered a wide range of subjects, including finance, advertising, industrial relations, the arts, international affairs. The course was concluded by a banquet and dance at which more than 170 were present. The committee recommended that a sub-committee on Professional Development be set up to operate under the general direction of the Papers and Meetings Committee and that the Professional Development Committee ascertain the wishes of the membership by distributing a questionnaire. A suggested questionnaire was filed with the report.

Reports were received from Saskatoon, Prince Albert and Moose Jaw sections of the Branch. Lee G. Morrison, president of the Engineering Society at the University of Saskatchewan reported on activities of the engineering students.

Prof. J. B. Mantle presented the report of the Student Guidance Committee and said that thirteen high school principals had been informed of engineers in their area who would be suitable to give guidance advice to students on engineering as a career.

Atomic Power Talk

Ian N. MacKay addressed the Toronto Branch on "Progress in Atomic Power", on February 28 at the University of Toronto in an informative talk on the various aspects of power generation, using reactor type boilers in Canada, the United States and in Great Britain.

Presently associated with the Civilian Atomic Power Department of the Canadian General Electric Co. Ltd., as manager of engineering, Mr. MacKay was with the Atomic Energy Commission at Chalk River from its early stages, leaving to join C.G.E. in Peterborough in 1955.

Any nuclear reactor for steam generation is essentially a container holding a number of uranium rods, or some form of uranium rods, surrounded by a moderator. The rods are allowed to get hot, and the heat is removed by some transfer medium which in turn yields up its heat to a more conventional medium such as water. The whole assembly must be kept from corroding, both in the usual ways employed in any boiler installation, and by fission products.

Canadian Installation — The Canadian installation consists of a steel tank made up of plates 5 inches thick. The container is 11½ feet in diameter, and 37 feet high, weighing 150-160 tons. The head alone weighs some 60-70 tons. It contains 109 tubes of a zirconium alloy which in turn hold the fuel rods of sintered uranium dioxide. The fuel is actually in the form of pellets about ½ inch in diameter and ¾ inch high stacked in the tubes. There are two cylindrical shields which protect the reactor vessel from the gamma radiation of the core. The moderator is heavy water, presently obtained from the United States.

The Canadian reactor is the most compact of all those presently built or building, and shows great promise of producing nuclear power more economically than is being done just now. The reactor is called N.P.D. or Nuclear Power Demonstrator, and is intended for demonstrating only, rather than for

This blast furnace bustle pipe is one of a number of components built by MLW for the Dominion Foundries and Steel Company's recently completed No. 2 blast furnace at Hamilton, Ontario.

Dofasco's No. 2 blast furnace during construction.

MLW builds Heavy Equipment for Canada's Industrial Expansion

In addition to serving Canada's railways as a foremost builder of diesel locomotives, MLW builds a wide range of products for Canadian industry. Blast furnace components are an example of the Company's diversity of production.

A completely equipped plant, and years of manufacturing experience, are available in the manufacture of industrial equipment and machinery.

MLW

power generation on a continuous basis, although it can develop 20,000 kw. It is hoped that the construction of the plant will demonstrate the practicability of nuclear power generation to the public, as well as to various groups interested in power generation, and of course supply cost data.

American Reactor — The American reactor, (PWR) being built presently for the Duquesne Power Corp. is slightly smaller than the Canadian reactor. It uses enriched uranium and light water. The control is different to the Canadian method, and is done by lowering moderator rods into the reactor. Although apparently simple in operation, the rods sometimes stick which is obviously dangerous. Sticking rods did in fact contribute to the accident in the Chalk River reactor, so that the NPD reactor is arranged on an "inherent" shut down basis, involving the movement of heavy water, a fluid, through large orifices, rather than a solid rod into a tube.

Calder Hill Station — The British nuclear power station at Calder Hill is notable for its great size. The reactor itself is some 37 feet in diameter and 70 feet high, using a graphite moderator, the whole weighing some 1700 tons. Heat transfer is affected by using carbon dioxide gas. There are four heat exchangers with some eight acres of transfer surface. The great size of the Calder Hill equipment is not from choice, but from economic necessity. There is not the power available in Britain to manufacture heavy water. Faced with a dwindling coal supply, and increasing power requirements, the British had to get power from nuclear fission, and get it quickly. Right now the British have something to show customers on the continent of Europe, who may wish to purchase equipment.

Customers in South America are not too anxious to buy reactors using enriched uranium, they are interested in equipment which can operate on materials available at home should a world crisis develop, cutting them off from the United States.

In the ensuing discussion, Mr. MacKay brought out the fact that the cost of power from nuclear fission is about 50 mils per kwh in the U.S., 10-15 mils in Britain, and about 20 mils in Canada. The figure for Britain should be used with caution, as the method of write-off for plant is entirely different to that in Canada and the U.S. The NPD will use about 21 tons of fuel per year, which can be supplied very easily by Canadian mines. Cataclysmic failures of the plant are not expected.

Altogether, the generation of power using a nuclear reactor as a steam generator is not only feasible, but practical and cheap. These established facts are in contrast to an excerpt from the Journal of Applied Physics, vol. 10, Sept. 1939, shown by Mr. MacKay. The writer of the article could not envisage practical applications for fission for a very long time to come.

Inspection Trip

The new Vancouver Post office will have many devices for efficient operation that are classed as the "first in the world". Some of these were described to members of the Vancouver branch of the Institute on February 16 when they were conducted through the building by representatives of the engineers and architects; McCarter, Nairn and Partners,

and of the contractors, Smith Bros. and Wilson Ltd.

J. H. Swerdfeger, M.E.I.C., gave a brief talk on the $13,000,000 building and then assigned the visitors to guides who first took their parties to the top floor and penthouse structure. This section houses the offices and is designed for seven additional floors when required. Dropping floor to floor the elaborate conveyer systems were described. For the Vancouver area alone mail is first split into about 30 zones.

Construction is just starting on the conveyer tunnel from the post office basement to the C.P.R. station. Trucks will handle mail to and from other transportation terminals.

When completed in October, 1957 Vancouver will have the most modern mail sorting system that is economical to design and have built at this time.

Shown standing in this wood stave pipe are some of the members of the Vancouver Branch during a field trip to the Pacific Coast Pipe Company, Limited, which was reported in the April issue of the *Journal*.

Architects' conception of completed plant

TO keep ahead of the rapid load growth, occasioned by rural electrification and industrial expansion, the Saskatchewan Power Corporation has constantly anticipated the needs of its customers.

Latest step in a long-range expansion program is the new South Saskatchewan River Generating Station. The completed plant will consist of four 66,000 KW generators. The initial two units will each be served by a 600,000 lbs. per hour Foster Wheeler steam generator, operating at 870 psig at 910°F and arranged for pulverized coal, oil, and gas firing.

The use of combination radiant and convection surfaces, in conjunction with FW condenser type control for superheating, permits constant final steam temperatures over a wide operating range, stabilizing steam conditions for maximum turbine efficiency.

The units are conservatively rated, with low heat absorption rates per unit area and low furnace exit gas temperatures. Each steam generator is equipped with two ball mill pulverizers and eight burners to further contribute to high fuel economy per pound of steam.

The proved dependability and long-range economy of Foster Wheeler steam generators are backed by more than 50 years of experience in pioneering power plant equipment. For further information consult Foster Wheeler Limited, St. Catharines, Ontario.

ASCE Spring Convention, Buffalo

Civil engineers from the United States and Canada, and other parts of the world will meet in Buffalo, N.Y., in large numbers for the Spring Convention of the American Society of Civil Engineers, June 3 - 7, 1957.

Focal point of the convention will be the St. Lawrence seaway and power projects. The program features many papers and discussions concerning the design, construction and administration of the seaway. Supplementing this information there will be an extensive one-day tour of the St. Lawrence sites.

ASCE Divisions will sponsor tours and inspection trips in the Buffalo area: the New York State Thruway (the highway division); Bethlehem Steel's Lackawanna plant (structural division); the Canadian Sir Adam Beck hydroelectric station, the Huntley steam electric generating station, the remedial work at Niagara (the power division).

These three divisions, as well as the other ASCE divisions (construction, hydraulics, waterways and harbors, sanitary, soils mechanics and foundations, and the committee on conditions of practice) have also provided technical papers.

Some of the St. Lawrence seaway and power project phases to be dealt with in papers will be: hydraulic model research; design features associated with regulation of water in the project area; water intake design; earthwork features in the International Rapids Section; the canals and channels and locks; special highway problems; electrical engineering features.

An afternoon session for Wednesday, June 5 will be conducted by the Engineering Institute of Canada, and features papers by D. A. Chamberlain, Jr., by T. Broendum-Neilson and Per Hall, and by E. John Racey. Canadian personalities will participate in other phases of the program also as speakers or chairmen. They are: M. V. Jones, Metropolitan Planning Board, Toronto; J. M. Muir, Dominion Council of Professional Engineers; Otto Holden and J. B. Bryce, of H.E.P.C. of Ontario; W. D. Baines, National Research Council; R. H. Clark, Department of Northern Affairs and National Resources, and others.

Headquarters of the Convention will be the Hotel Statler in Buffalo.

C.I.M. Convention

The Canadian Institute of Mining and Metallurgy met for its fifty-ninth annual general meeting at the Chateau Laurier, Ottawa, on April 22, 23 and 24, 1957.

The program commenced with a business meeting of the Geological Association of Canada, chaired by H. C. Gunning; followed by meetings of the John T. Ryan Trophies Committee, the Sixth Commonwealth Mining and Metallurgical Congress committee, and annual business conferences of the coal, geology, industrial minerals, metallurgy and metal mining divisions.

Greetings were extended by His Worship the Mayor of Ottawa, during the luncheon, April 22. The guest speaker, the Honourable George Prudham, minister of Mines and Technical Surveys of Canada, in his address on "Government in Industry in a Free Economy", said that with particular reference to the mineral industry the relationship between private enterprise and government in a free economy should be that of a practical partnership with the common aim of producing the greatest possible economic benefits for the greatest possible number of people. The state must supply some of the conditions, both practical and intangible, indispensable to industrial advance. The state can be valuable in fostering and providing that ingredient known as confidence; however it is the personal drive, initiative, and enterprise of individuals which forms the dynamic progress in a free economy.

Keeping pace with today's rapid development, the Department had realized the need for radically new departures in order to speed up geological survey work.

This had been accomplished. A very extensive program is also under way in 1957, with the main object of evaluating the mineral possibilities of the Canadian north.

Mr. Prudham urged Canadians to foster and maintain the individual enthusiasm of adventure and enterprise in order to rise to the challenge of this country and its resources. He added that it is to be hoped that social measures and social security, prominent in the public eye today, will never become an end in themselves.

The inaugural general session and a symposium on the St. Lawrence seaway and power projects comprised the afternoon's program.

Further technical sessions were held the following day, April 23. Presentation of the Institute honours and awards was made following the annual dinner. President-elect, Dr. Horace J. Fraser, president of Falconbridge Nickel Mines, Limited, of Falconbridge, Ont., was introduced. Guest speaker for the event was Dr. W. A. Mackintosh, C.M.G., vice-chancellor and principal of Queen's University, Kingston, who spoke on "Challenges of Growth." Dr. Mackintosh warned that Canada, difficult to develop, over the past three hundred and fifty years, will for obvious reasons continue to present problems. Greater than the need for industrial resources or capital, he said, was the need for educated persons of integrity; and in all fields of endeavor. No luxury, this is an essential of national life.

On the pressing subject of university expansion in Canada, Dr. Mackintosh stated that the question is not whether or not universities expand and multiply, but whether they do so in a way which will produce first class results? Variety in outlook, reasonable autonomy and specialization among them, will be necessary, as well as a greater number of technical institutes; an enlarged and improved corps of teachers, scholars, and scientists, and, of course, added facilities, and a selection of students, due to growing numbers. The range and stature of a select group of the graduates must be increased, as well as the number of classes graduating.

Turning to the international scene, Dr. Mackintosh felt that Canada has now shown readiness to exercise her own judgment in matters previously conceded to other nations. Regarding the investment of foreign capital in this country, it should be remembered that without external investment, the whole rate of progress and development would be sharply reduced.

The induction of the incoming president, Dr. Horace, J. Fraser, the reading of the presidential address and that of Charles Gavsie, guest speaker and vice-president of the St. Lawrence Seaway Authority, highlighted the last day's activities.

The president's reception and the annual dance rounded out the three-day affair.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

AIR CONDITIONING REFRIGERATING DATA BOOK; APPLICATIONS VOLUME. 6th ED.

This useful handbook has had a number of revisions, in various chapters, notably those pertaining to food refrigeration. Specific problems and data are given, as usual, in this applications edition. Sections are: frozen foods; refrigeration in food industries; refrigerated warehouse practice, refrigerated food distribution; low temperature applications, industrial applications of refrigeration; comfort air conditioning; and industrial air conditioning. American Society of Refrigerating Engineers, New York, The Society, 1956. Irreg. pging, $10.50.

AMERICAN HIGHWAYS TODAY

This collection of twenty-eight articles and speeches on the history, problems and future of American highways is a valuable addition to the literature on current road administration and construction. Pro and con arguments regarding compulsory auto insurance, tax and toll schemes to finance highways, the trucking industry and road upkeep, and American legislation on traffic are presented. The final section explains the U.S. 1956 Federal-Aid Highway and Highway Revenue Acts. This is the first number of volume 29 of the Wilson Company Reference Shelf series, and a full bibliography is included. P. Tyler, ed. New York, Wilson, 1957. 204p., $2.00 (U.S.).

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

LIBRARY HOURS
Monday to Friday
9 a.m. — 5 p.m.
Saturday 9 am. - 12 noon.

ANALYSIS FOR PRODUCTION MANAGEMENT

Growing out of a course given at M.I.T. by the authors, this book tends to concentrate on the economic problems of production management, presenting the methods developed for their analysis.

The book is divided into four sections, the first of which provides an historical introducton and general background material. The second covers programming, including linear programming, whilst the remaining two deal with statistical and economic analysis. Throughout the book, the theory and generalizations are illustrated by concrete examples, and problems are presented at the end of each chapter. Ten cases are presented at the end of the book, giving as accurate a picture of the production operation as possible, and leaving the reader, or student and instructor to decide how the problem would best be solved by the use of the formal methods of analysis expounded in the text.

This should prove a very useful text. E. H. Bowan and R. B. Fetter. Homewood, Ill., Irwin, 1957 503p., $6.50 (U.S.).

BOILER HOUSE PRACTICE, 2nd ED. REV.

This basic text, newly revised, gives information on the most recent developments in boiler house practice. The entire range of subjects covered by the syllabuses of the Boiler House Practice courses of the City and Guilds of London Institute is treated in the book under the following headings: theory and practice of combustion; heat transmission; boilers and boiler operation, control and feeding; coal and coke; oil fired boilers; refractory, insulating materials and lagging; cleaning and maintenance; measurements and tests.

This present book supersedes the author's *Steam Generation* which was published in 1946, and was recommended as a text by the City and Guilds. J. N. Williams. London, Allen and Unwin, 1956. 624p. 60/–.

*BUILDING COST MANUAL

This manual provides tabulated data contributed by more than 150 architects, engineers, builders, and manufacturers all over the U.S. Parts 1 and 11 give brief introductory information on cost data and their use, regional variations and cubing instructions. In Part III 150 classified building types are illustrated photographically, each accompanied by a tabulation of structural elements and materials, mechanical equipment and base costs. Photographic depictions of many older types are included with code numbers showing the nearest modern equivalent in each case for determining present replacement costs. American Institute of Architects, Chicago Chapter and Chicago Real Estate Board. New York, Wiley, 1957. 367p. $15.00.

COMPANY INVESTIGATIONS OF AUTOMATI[C] DATA PROCESSING

The increasing number of firms investigating the possibilities of using automatic equipment for data processing wi[ll] find this report both interesting and use[ful].

The author discusses the approache[s] of different companies in investigatin[g] their data-processing needs to determin[e] what equipment, if any, should be pu[r]chased. The report falls into three se[c]tions, the first of which describes brie[f]ly the various types of automatic equi[p]ment available and its uses.

The second part is devoted to actu[al] case histories, including a detailed repo[rt] of the experiences of one company fro[m] the time when it was first decided to i[n]vestigate the possibilities of the actu[al] installation of a computer.

The final section discusses various a[s]pects of the problem including organizi[ng] for the project, selecting an applic[a]tion for the computer, cost and savin[g] estimates, selecting equipment, and rel[a]tive merits of punched-card and aut[o]

matic installations. P. B. Laubach. Boston, Harvard School of Business Administration, 1957. 259p., $3.00. (U.S.).

DETERMINATION OF MOISTURE IN SOLIDS

A survey of the known methods of determining the moisture content of solids, this book includes brief descriptions of the forty techniques surveyed, together with references to further material on each. Apparatus commercially available in England for use with each method is also listed. There are indexes to the authors of the references listed, and to the manufacturers of apparatus. P. J. Geary. Chislehurst, Kent, British Scientific Instrument Research Assoc., 1956. 51p., 9/6.

DIGITAL CALCULATING MACHINES

Written primarily for engineers and scientists, this book discusses the various types of digital calculating machines available, and their use in solving problems.

The machines are divided into four groups. The first has a limited storage capacity, and includes all the usual desk-type calculators. The second, represented by punch-card systems, has a large storage capacity for numbers but not for instructions. Group three has a limited storage capacity for numbers, but the machines will perform a variety of operations. The machines in this group are usually special-purpose machines. The last group of machines has an extended storage capacity for both numbers and instructions, and includes the large general-purpose computing machines or "electronic brains."

Examples of problem-solving with calculating machines are given throughout the book, and a final chapter deals with programming for large computers. References for further reading are included. G. A. Montgomerie. Glasgow, Blackie, 1956. 262p., 30/-.

*ELEMENTS OF GASDYNAMICS

Stressing fundamental theory, this book deals with waves in supersonic flow; flow in ducts and wind tunnels; small-perturbation theory; transonic flow; and other topics of interest to engineers who work on problems involving the aerodynamics of compressible fluids. The book has been written as a text for senior and graduate courses and as an introduction to the more specialized studies for practicing engineers. H. W. Liepmann and A. Roshko. New York, Wiley, 1957. 439p. $11.00.

*ENGINEERING STRUCTURAL FAILURES

The author has surveyed the causes and results of failure for over a century of engineering in various types of structures including earthworks, dams, sea walls, wharves, buildings, bridges, and tunnels. Vibration problems in foundations, earthquake effects, and cracking in welded steel structures are also considered. The last chapter deals with the lessons of failure and various modern methods of testing materials, such as the strain gage, scale models, the de Havilland moving-coil vibrator, and X-rays. Among the famous cases of failure discussed are the Knickerbocker Theatre in Washington, the Quebec and Tacoma Narrows bridges, and the Sydney water-pressure tunnel. Rolt Hammond. New York, Philosophical Library, 1956. 224p., $12.00 (U.S.).

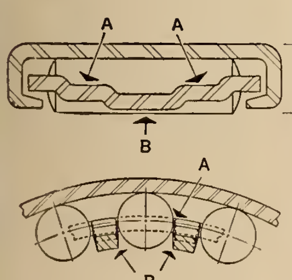
THE FINAL FORMING AND SHAPING OF WROUGHT NON-FERROUS METALS

Included in this volume are the eight papers presented at a Symposium held in April 1956, together with the discussion on them.

As indicated by the title, the papers are all concerned with the final forming and shaping of non-ferrous metals and include machining properties, deep drawing and spinning, cold roll-forming stretch-forming, bending, the hot forming of magnesium alloys, and rubber pressing.

The paper on machining properties is by Dr. D. F. Galloway, who, members will recall, gave a special address at the 1956 annual meeting of the Engineering Institute of Canada. This volume is the twentieth in the series of Monographs and Reports issued by the Institute of Metals. London, Institute if Metals, 1956. 128p., 21/-.

Features of the new
TORRINGTON DRAWN CUP ROLLER BEARING



- rollers end-guided at pitch line (A)
- shaft-riding retainer (B) designed to permit lubricant circulation
- high capacity in small cross section (C)
- long pregreased life
- efficient at high speeds
- mounted by press fit
- simple housing design
- low unit cost

INTRODUCING

a new low-cost precision roller bearing...

THE TORRINGTON DRAWN CUP ROLLER BEARING

For the first time, the advantages of drawn cup outer race construction are available in a precision roller bearing.

This compact, lightweight bearing consists of spherical end needle rollers, a one-piece hardened steel retainer and case-hardened thin-section outer race. Designed to run on a hardened shaft or with an inner race, this new series takes a press fit in a simple housing without snap-rings or shoulders.

Highly efficient roller guidance and lubrication are outstanding features. The shaft-riding retainer contacts the roller ends at the pitch line where guidance can be obtained with the least effort. The design provides ample storage for lubricant and promotes its circulation.

These features make the new bearing particularly suited to applications requiring compactness with precision, high-speed endurance or long pregreased life.

For information on sizes now available and for application assistance, call on our Engineering Department or write for the new bulletin, "Torrington Drawn Cup Roller Bearings." *The Torrington Company Limited*, 925 Millwood Road, Toronto 17, Ont., Canada.

*A HISTORY OF TECHNOLOGY, VOLUME 2. THE MEDITERRANEAN CIVILIZATIONS AND THE MIDDLE AGES

This is the second volume of a series of five which will cover the development of technology from the Old Stone Age to the later 19th century. The first volume, already published, was from early times to the fall of ancient empires c.500 B.C. The present one covers the Mediterranean civilizations and the Middle Ages. Only the technology of Europe is dealt with, and the concern is mainly with the development of processes, techniques and devices rather than with social and economic implications. The range of subjects includes all those activities which provide for material needs: mining, quarrying, metallurgy, agriculture, leather, textiles, ceramics, glass, building construction, transportation, metal work, machinery, power, hydraulic engineering and sanitation. Six hundred ninety-five illustrations including maps and diagrams and an additional 44 plates are provided. Literature sources are found at the end of each chapter, and personal and place name indexes are appended. Charles Singer and others, eds. Torinto, Oxford, 1956. 802p., $25.50.

HOW TO INSTALL AND SERVICE INTERCOMMUNICATION SYSTEMS

Enough information is given in this book to enable the qualified reader to install and maintain an electronic intercommunication system.

The book is based on the author's experience, and covers basic amplifiers, a-c and a-c/d-c systems, wireless systems, paging systems, one and two way systems, and requirement for particular applications. An appendix lists American manufacturers of intercommunication systems. Jack Darr. New York, Rider, 1957. 151p., $3.00 (U.S.)

*INTERNATIONAL ASSOCIATION FOR BRIDGE AND STRUCTURAL ENGINEERING. PUBLICATIONS, VOLUME 16

Twenty-eight papers, 16 in English, 6 in French, and 6 in German, with titles and summaries given in three languages. Some examples of the topics covered in the papers are: analysis of thin-walled continuous shells; scale model investigation of shell roofs; a method for calculating circular cylindrical shells; the plastic design of aluminum structures; vibrations in steel and reinforced concrete bridges; impact accompanied by fatigue; and assembly of prefabricated reinforced concrete components for hangers. Zurich, Verlag Leemann, 1956. 550p., price not given.

AN INTRODUCTION TO JUNCTION TRANSISTOR THEORY

This study is intended to bridge the gap between solid state physics and the circuit properties of a junction transistor for the electronic engineer. It develops the basic theory of transistor action from the discussion of crystalline structure and electron movement in crystals to the setting up of a representative small-signal equivalent circuit. This circuit is suitable for use in the design of small-signal amplifiers covering the entire useful range of the transistor. For the circuit designer, formulas are given for its transformation to a form usable in a practical transistor. R. D. Middlebrook. New York, Wiley, 1957. 296p., $8.50.

*INTRODUCTION TO OPERATIONS RESEARCH

A general survey of this rapidly growing field is presented with particular reference to industry covering such subjects as inventory, waiting time, allocation, and replacement models. The setup of scientifically valid conditions for model testing, including the defining of properties and conditions of observation, and the checking of test results, is the subject of a later chapter. The concluding parts deal with the control and carrying out of the solution in actual practice, and with administration problems. Case histories illustrate each method and models and chapter bibliographies provide for further reading. C. W. Churchman and others. New York, Wiley, 1957. 645p., $12.00.

L-C OSCILLATORS

General information on L-C oscillators in this publication includes oscillator elements, energy conversion, frequency range, stability, power considerations, oscillator efficiency, harmonic generation, series and parallel resonance, and critical damping. The section entitled circuit analysis treats the factors affecting the feedback loop and the circuit requirements for an amplifier to reach a condition of oscillation. Following sections cover low, medium and high frequency oscillators. This is volume 13 of Rider's Electric Technology Series. A. Schure, ed. New York, Rider, 1957. 66p., $1.25 (U.S.).

LOW POWER TELECASTING

Because of recent interest in local community telecasting this book has been written to give basic information on such

matters as: lower power antennas; signal propagation and prediction of coverage; low power transmitters; the Vidicon pickup tube and camera lens; Vidicon camera chain for live pickup and film; and station installations. Actual economy stations, planning procedures, space, conduit, and power requirements are described. H. E. Ennes. Indianopolis, Sams, 1957. 106p., $2.95. (U.S.).

MANUAL ON INDUSTRIAL WATER. 1956 ED.

This standard manual is intended as a general reference book for those concerned with the many uses of water in industry. It is intended as a guide for all types of personnel, although the water specialist will find only general information in this publication. Subjects covered are: uses of industrial water; difficulties caused by water in industry; composition of industrial water and water-formed deposits; treatment, sampling, and analysis of industrial water; sampling, identification and analysis of water-formed deposits. The appendix lists all ASTM standards relating to industrial water for sampling, analysis, reporting of results, methods of testing; and includes a glossary and bibliography of ASTM publications on industrial water. Philadelphia, American Society for Testing Materials, 1956. 502p., $6.00 (U.S.).

MATERIALS AND PROCESSES IN MANUFACTURING

Written for undergraduate engineers who do not intend to enter the fields of either metallurgy or machine tool design, this volume describes the materials and processes used in manufacturing.

The section on materials shows how and why any particular material is used for a specific application, and includes chapters on metals and alloys, heat treatment, alloy steels and irons, non-ferrous alloys and plastics.

The processes described in detail are casting and forming, machining, welding, brazing and soldering. A final section considers actual manufacturing and covers such topics as layout, jigs and fixtures, surface treatments, mass-production tools and techniques and the planning of manufacturing operations.

A useful bibliography concludes this work which may be used equally well for an undergraduate text or a refresher for the practicing engineer. E. P. Degarme. Toronto, Brett-Macmillan, 1957. 755p., $8.75.

*THE MECHANISM OF PHASE TRANSFORMATION IN METALS

Included in this publication are eighteen papers delivered at a symposium held in November 1955. The papers are in two groups, one dealing with nucleation and growth processes, the other consisting if papers on martensitic transformation. Each group contains a general review paper followed by papers describing original research on specific problems; precipitation in lead-tin alloys; superlattice formation in the alloy CdM-33; the allotropic transformation of cobalt; the bainite reaction in high-carbon steels; and so on. A subject index is provided. London, Institute of Metals, 1956. 346p., 50/-.

METHODS OF BOOK DESIGN

Book design is defined as the planning which determines the physical qualities of the book, and in this volume the reader wll find information on every aspect of the subject, starting with the preparation of typescript. The author discusses format, composing machines, choice of type and the varieties of type, text design, preliminary pages, printing processes, colour, illustrations, the binding, and the jacket.

The author received his training at the Oxford University Press, and is now production manager of a large publishing house. The book is admirably illustrated and produced, and is highly recommended to authors and publishers as well as to those readers who are interested in the production of their books. Hugh Williamson. Toronto, Oxford University Press, 1956. 430p., $9.00.

MODULAR CO-ORDINATION IN BUILDING

This is a report of the first phase of a project undertaken by a team of ex-

perts from eleven countries to develop a method of co-ordinating the dimensions of building materials.

The first phase of the project involved the discussion of theories of modular construction, and of the methods to be used in carrying out the second phase, the actual erection of buildings.

The first part of the report, design, discusses the reference grids and the size of the module. The second covers the size of the various building components while the third describes the use of grid lines and the location of components relative to the grid line.

This is, in effect, the latest textbook on modular co-ordination and as such will prove extremely valuable. Organisation for European Economic Co-operation. Toronto, Ryerson, 1956. 168p., $1.50.

*OXYGEN IN IRON AND STEEL MAKING

A review of previously published information, together with the results of some unreported trials made by British iron and steel making companies. About half of the contents is devoted to the treatment of molten metal — the desiliconization of iron; oxygen in the Bessemer process; oxygen injection in the open hearth process; the use of oxygen in the electric arc furnace for the production of stainless steels, and the effect of oxygen treatment on metallurgical properties. The remainder of the book is concerned with flame-enrichment and with blast enrichment as applied to the blast furnace, the cupola, and the gas producer. J. A. Charles, W. J. B. Chater and J. L. Harrison. Toronto, Butterworth, 1956. 309p., $6.50.

*PATENT NOTES FOR ENGINEERS, 7th ED.

This is a discussion of the practical problems that arise from the moment of conception of a patentable invention to the acquiring of patent rights. Illustrated by numerous cases and examples, the discussion covers invention as defined in patent law; the need for good records and adequate disclosures; the preparation and prosecution of applications; and the ownership and use of patents. C. D. Tuska. Toronto, McGraw-Hill, 1956. 192p., $4.80.

THE PHYSICS OF FLOW THROUGH POROUS MEDIA

Based on a bibliography compiled by the author some years ago, this volume summarizes available information on the physical principles of hydromechanics in porous media, information which has not previously been collected in one text.

As over two thousand references were collected, some selection had to be made, and emphasis was therefore placed on the general aspects of the subject rather than on particular cases, and theoretical aspects have been stressed more than experimental ones. Also, only one solution has been presented for some of the basic differential equations, even though many may have been available.

The topics covered include the properties of porous media and fluids, Darcy's Law, the physical aspects of permeability, general flow equations and multiple phase flow. Throughout the book, the emphasis is on the flow of homogeneous, single phase fluids, as most applications are concerned with these. There is a twenty-four page bibliography, keyed to the different chapters.

The author is now a geophysicist at the Dominion Observatory. A. E. Sheidegger. Toronto, University, Press, 1957. 236p., $13.50.

STATISTICAL QUALITY CONTROL

This publication of the European productivity agency of the Organization for European economic co-operation includes the attempts of the agency to introduce statistical quality control to nations other than the United States, where it is practiced extensively. Contents includes an account of the work done in various European countries in connection with this project; an introduction to modern techniques in the field written by an American expert, P. C. Clifford; accounts of two conferences held in Paris in July

COMPLETE LINES OF WALWORTH VALVES *for* POWER PLANT SERVICE

Featuring Walworth Pressure-Seal Valves

Here are cast steel valves built for high-pressure, high-temperature service. The unique bonnet-to-body design utilizes internal line pressure for a tight, leakproof connection. The higher the pressure the tighter the bonnet joint! Bulky, heavy bonnet flanges, bonnet studs, and nuts are completely eliminated providing a modern valve design of truly streamlined proportions. Maintenance is simplified as Walworth Pressure-Seal Valves are easily assembled, disassembled, and insulated.

Walworth Pressure-Seal Valves are available in Series 600, 900, 1500, 2500, and in a wide range of sizes and types. Complete information is available from your nearby Walworth Distributor—or—write Walworth for for a free copy of Circular 16.

and including these valves for "'round-the-plant" use!

WALWORTH SMALL CAST STEEL Y-GLOBE VALVES. Simplified design eliminates many of the problems encountered in high-temperature, high-pressure service. No bonnet joint. Improved back-seat design means longer life for packing rings.

WALWORTH LUBRICATED PLUG VALUES. Easy turning—quick operating. Lubricant can be renewed while the valve is in service. Lubricant completely surrounds the plug ports for a tight seal against leaks. Remember, always use Walworth Lubricant in Walworth Lubricated Plug Valves.

WALWORTH BRONZE VALVES. Standardized lines of bronze valves provide an unsurpassed system of interchangeability of parts, drastically reducing inventory problems. Walseal Valves with brazing ends also available in a variety of types.

WALWORTH IRON BODY GATE VALVES. Straight-flow port design reduces fluid turbulence to a practical minimum. Seat rings of end-seated type are screwed into the body. Brass liner on glands assures greater resistance to corrosion and scoring. Available with threaded or flanged ends.

WALWORTH CAST STEEL GATE VALVES. Bolted bonnet, wedge gate, OS&Y. Bonnets and bodies are engineered to withstand pressure and minimize distortion. Heavy steel walls provide extra strength and longer life. Deep stuffing boxes in all sizes (2" to 24") insure tightness and maximum packing life. Also available in globe and angle types.

WALWORTH also offers Plastic Valves, Fittings, and Pipe of polyvinyl chloride, moulded to Walworth's specifications by General American Transportation Company of B. F. Goodrich Chemical Company Geon!

WALWORTH COMPANY OF CANADA, LIMITED

DISTRIBUTORS IN PRINCIPAL CENTERS THROUGHOUT THE WORLD

1955 in which the present state of development of control techniques in Europe was reviewed and a number of the recommendations made. Paris, O. E. E. C., Toronto, Ryerson, 1956. 89p., 75c.

SURVEY OF MINES, 1957

This thirty-first annual survey of the Canadian mining industry gives detailed information on the companies active in Canada including current earnings, finances, ore position and production, directors, dividend performance, subsidiary connections and inter-company holdings.

There are twenty-eight pages of maps of the principal mineral areas, price ranges of stocks over the last eight years, and mineral production tables.

This survey is a must for all those with money to invest in Canada's expanding mining industry, and for those connected with it in any way. Toronto, Financial Post. 1956, 392p., maps, $3.00.

TUNNELBAU

Modern methods of tunnel construction are described for both the practicing engineer and the student. The major part of the book is devoted to the simpler types of tunnels and tunnel construction, with separate sections on subaqueous work, subway construction, and tunnel breaks and repairs. There is a brief chapter on the history of tunneling operations. Carl Aussendorf. Berlin, Verlag Technik, 1955. 312p., illus., DM 33.00.

YEAR BOOK OF THE HEATING AND VENTILATING INDUSTRY, 1956

The articles included in this 1956 edition cover oil firing, panel heating, and the electric surface heating of fuel oil lines and storage tanks. Other sections give: an index to heating and ventilating literature, list of British standards, legal and labor agreements covering the British heating and ventilating industry The classified buyers list and manufacturers directory comprise about one half the volume. London, Technitrade Journals, 1956. 398p., 10/6.

TECHNICAL BULLETINS AND PAMPHLETS RECEIVE[D]

Bridges

The evaluation of highway bridges. D. T. Wright.

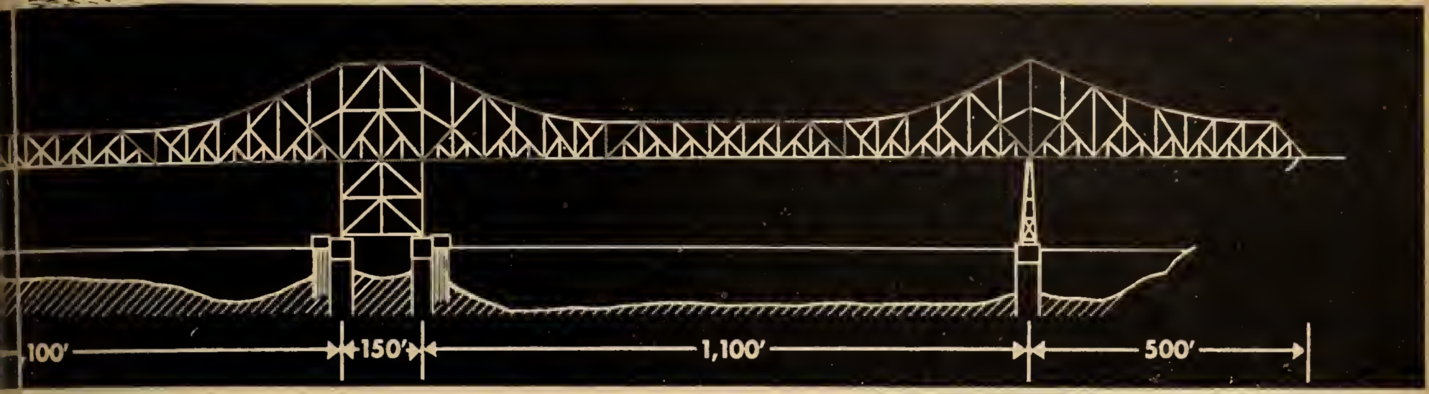
Proposed specifications for the ratin[g] of existing bridges. D. T. Wright. (Kingston, Queen's University, Reports No: Q6-1 and Q6-2.).

Concrete

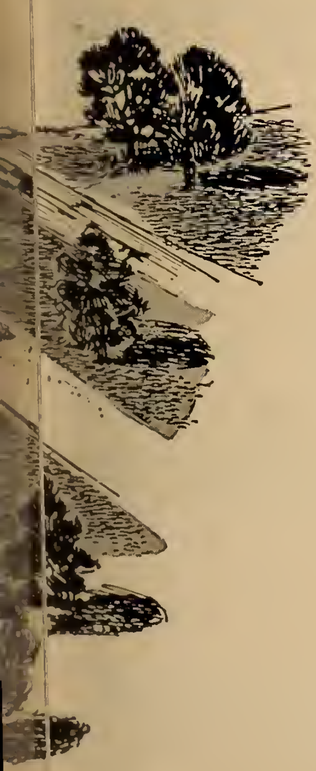
Calculation of stress from strain i[n] concrete. K. Jones. (U.S. Dept. of th[e] Interior, Bureau of Reclaim. Tech. Mem[o] 653.).

Tests on the old dental hospital, Jo[-] hannesburg. General report. A. J. Ockl[e]

NEARLY 500 of the more than 1,000 gusset plates and 142 of the 664 truss members in the new bridge were made from USS "T-1" Steel. The weldability and very high strength of this remarkable alloy steel saved weight, time and money.



WILL SAVE $800,000 IN FIRST MAJOR BRIDGE APPLICATION



Next year the State of California will open a new toll bridge paralleling an existing structure across the Carquinez Straits. This will be the final step in a mammoth project underway to relocate some twelve and a half miles of very busy highway connecting the San Francisco Bay Area with the Sacramento Valley.

The new $20-million bridge will be unusual. While, in appearance, it is a near carbon copy of the present structure across the busy straits, it will employ some 2,900 tons of USS "T-1" Steel in its most highly stressed truss members. Of 664 members in the trusses, some 142 will be of welded construction and made of "T-1" Steel.

The weldability and 90,000 psi minimum yield strength of USS "T-1" Steel will dramatically simplify design and fabrication of critical members. Take one example, a lower chord member: In the new structure, it will be made from just five welded plates of "T-1" Steel and require 340 feet of 5⁄16" automatic fillet welds. But, had it been put together by stitch riveting, the method used in the original span, this same chord member would have required *eight* vertical plates, *four* angles, and *two* cover plates . . . plus *1,000* rivets and *3,600 punched and reamed holes!*

Besides ease of fabrication gained through welding, "T-1" Steel's tremendous strength permits big weight savings. For example: one of the top chord members of the new bridge will weigh 400 lbs. per ft. and have a section area of 117.19 sq. in. A structural carbon steel (ASTM A-7) member for the same location would weigh 996 lbs. per ft. and would require a section of 293 sq. in. Lighter, smaller members mean reduced moment of inertia and important reductions of secondary stresses.

According to design computations by the State of California, USS "T-1" Steel will save approximately $800,000 in building the new Carquinez Straits Bridge—the first major bridge application of this remarkable constructional alloy steel.

ENGINEERING CAREERS

The Opportunity for Professional Engineers in Education

THE THESIS that all mankind can be divided into two groups as "those who do" and "those who teach" has sometimes been frivolously proposed. The implication being that those who do the one are either unwilling or unable to do the other! Admittedly this has been the prevailing condition in the majority of both business and educational institutes in the past. Schools of business administration, utilizing the case-study method, and schools of field engineering, using practical problems, are indicative of the current and altered philosophy of education. A proven ability "to do" has been established by many of the country's educational institutes as mandatory for appointment to the teaching staff. Beyond this, and perhaps more important, a peculiar combination of circumstances both forces and permits the instructional staff to work each year in their chosen field within the world of business.

It is particularly recognized in connection with applied science (engineering), that technological advance is best made when there is a contemporary development of theory and practice. Combine with this the authority that accomplishment bestows upon a teacher, and the professional engineer engaged in education can be considered as occupying a somewhat unique and favoured position.

The Canadian School Structure

The subjects usually taught in schools above the elementary level may be conveniently divided as

(a) Non-professional subjects (e.g. trigonometry)

(b) Professional subjects (e.g. surveying.

Differentiation is made on the basis that application of knowledge of the first type of subject by itself would not normally be of economic value, while proficiency in the latter has a realizable value.

With some training pedagogy an engineer may be thoroughly qualified as an instructor in the non-professional subjects, and may frequently find rewarding employment in such a field. His own professional training however adds little distinction to such an encumbency. Of primary interest then is the engineer's occupation as a teacher of professional subjects. In Canada the technical education facilities are found within four types of schools; each having a special purpose and therefore offering different opportunities to the engineer-teacher.

High schools serve as continuation schools to the elementary education system. Collegiate high schools present chiefly non-professional courses, and are preparatory for admission to the universities. To all the subjects taught in these schools the engineer may contribute an emphasis of practical application which is invaluable in capturing student interest. Vocational and technical schools operate at the same level but are concerned with elementary trades training. Teachers having practical trades experience augmented by professional training should be of value in raising the standard of material presented by such institutions.

Technical colleges and trades schools are the advanced level counterparts of the collegiate and vocational schools. The technical colleges may serve as finishing schools qualifying men for junior and intermediate grade professional work. Frequently they are but the first phase of a full professional training. Trades schools give completion training of the highest order in the skilled trades. Both of these types of schools are of increasing necessity and popularity in a country having a dispersed but growing population. Consequently these schools offer the widest opportunity for engineers seeking to enter the teaching profession.

The Royal Military College is one of the Canadian Services colleges operated by the federal government, which offers an integrated military and academic program of the highest calibre. Because of the diverse needs of the three defence services a very broad engineering training is given, and the graduates of R.M.C. are generally required to take the final year of the engineering course at a university to obtain full professional status. At this college the academic instructional staff are either civil servants or military personnel.

The Present Opportunity

Virtually all of the universities in Canada are engaged either in the expansion of their engineering faculties or in the establishment of these. Besides the demand for instructors to accommodate increased enrolments there is the more difficult-to-satisfy need for men with specialized training capable of teaching the many new subjects which are yearly added to the curriculum. Typical of such subjects are business administration, soil mechanics, nuclear power, and aeronautical engineering.

Every mature engineer realizes a sense of gratitude to some senior engineer who has made an invaluable contribution to his own professional development. It has been said that "It takes an engineer to make an engineer"; perhaps this is the most pertinent in the academic phase of an engineer's training.

This article was prepared by D. A. Selby, Assistant Professor, Civil Engineering Department, McGill University.

By way of illustration of the entrance and progress of an engineer within education, three case histories involving men currently teaching in one of the larger universities can be cited.

Case 1. "A" had a background of considerable experience with an engineering firm before entering college. He graduated with a Bach. Eng. degree in 1949. Thereafter he remained at the university to do graduate studies to obtain his Masters degree. "A" was then appointed a lecturer and in 1954 was promoted to Assistant Professor. Currently he is lecturing in intermediate level professional subjects and in advanced non-professional subjects.

Case 2. "B" also graduated in 1949 but joined the staff of a large corporation and obtained considerable experience in several engineering departments. By 1956 he had attained the lower level of management category but resigned to accept the appointment of Assistant Professor.

Case 3. Engineer "C" had graduated in 1939 and had been employed until 1946 in design engineering work for a large company. "C" returned to university then to do graduate work for the degree of M.Eng. There followed appointment to the staff as a lecturer (1947), then promotions to Assistant Professor (1951), and Professor (1957).

Quite obviously the advancement of these men was comparable with that occasioned within industry during the same period. The cause for this advancement being identical in both spheres is an expanding economy and an advancing technology.

Opportunities for Professional Activity Contingent with Teaching Duties

Traditionally and naturally the university should be the centre of research and hence the origination point of scientific progress. Regrettably some measure of this leadership has been lost to industry due to the latter's potent and proper proprietary interests. Nevertheless the atmosphere of an institute of learning is conducive to advanced thinking and scientific investigation. Thus the engineer in the teaching profession has frequently the means, within himself, and the opportunity, within the university, to conduct research of the purest scientific purpose. Frequently this research is advantageously sponsored by one or more interested commercial bodies.

Only in private consulting practice does the engineer assume his full professional capacity. It is only reasonable then that at some time, every engineer will yearn within himself for the role and deserved title of consulting engineer. However the realization of this is more difficult. To require the necessary ability, confidence and reputation required for an independent practice which will provide remuneration equal to the current salaries in industry, normally requires many years of intensive work. The significance in this respect of a working engineer's appointment to a professional post is immeasurable. There is immediately created an enhanced professional standing based on confidence, and an expectation that the subject engineer will keep himself fully informed of contemporary theories and developments.

Compensation

The direct remuneration received from the colleges and the universities does not compare with what the same engineer could receive from competitive industry. Even overlooking salaries offered by industry to engineers with seven to fifteen years' experience, a comparison of the salaries cited in the accompanying tabulation with amounts currently being offered to the members of the graduating classes this year ($4,800-$6,000 per annum) makes this plainly apparent.

Significant Salary Figures from Ten Canadian Universities ($ per annum)

	Lecturer	Assistant Prof.	Assoc. Prof.	Professor
Average	5,000	5,840	7,320	8,590
Low	3,500	4,500	5,120	5,700
High	7,000	8,500	11,500	12,000 and up

However there are some compensating considerations. The first of these is the opportunity for obtaining supplementary income from a consulting practice. Then there are some so called "fringe" benefits such as some social distinction within the community (of uncertain significance at times) and the extended summer vacation.

Intrinsically however there are three powerful factors which attract men to, and hold them in, the teaching profession.

The first of these is a real sense of freedom of activity not commonly enjoyed by the servants of industry. The academic freedom essential for the advancement of learning is but one aspect of this. At the same time it would be grossly incorrect to assume that the engineer-teacher has a large amount of leisure time. To the contrary, he is usually extremely busy but the majority of his activity is subject to his own election and organization.

The second of these factors is the large measure of job satisfaction associated with teaching. This arises from several causes including the full utilization of one's own training, and the constant need and facility to keep current with technical development.

Akin to, and part of, this job satisfaction is the genuine thrill of teaching that is experienced by a teacher. Perhaps this is but the realization that by education one makes a contribution to society that has the capacity of expanding itself geometrically. From another aspect it may be that satisfaction of a natural urge for reproduction—in this case—of one's professional personality.

To summarize it all—a sincere teacher must be a dedicated man—and there is a manifest satisfaction in being a dedicated man.

President—V. A. McKillop
Treasurer—R. A. Emerson
General Secretary—L. Austin Wright

Message from the President

NEVER BEFORE in the history of the world has there been a period requiring such momentous decisions as those which must be made today.

Hitherto slumbering peoples in vast numbers, living in crowded areas, are awakening to demand their rights to better living. Those peoples who have already achieved a relatively prosperous way of life have ambitions to attain a better.

Jealousies between nations and ideologies have never been so pronounced, nor fraught with the possibilities for such evil consequences.

Yet all these difficulties, these ambitions, these jealousies are susceptible to solution and, with God's help, that solution will be found.

As engineers living in a world so dependent on science and its application, we have an ever increasing responsibility to play our part in building the foundations, and on them the structure by means of which we are to reach that solution and make it secure. Too many people are depending on the engineer to lead the way, to permit of failure.

That I have been accorded the privilege of being selected by my fellow engineers to preside over the affairs of the Institute for the ensuing year makes me proud and humble. I am indeed grateful for the privilege, and with the example before me of those who have preceded me in in this high office, and with your understanding and help, I will endeavour to justify your selection of me for the honour which I prize so highly.

C. M. Anson, M.E.I.C.
President

Some Engineering Problems in Connection with The Industrial Application of Nuclear Energy

Sir Claude D. Gibb, K.B.E., F.R.S.

Chairman and Managing Director, C. A. Parsons and Co., Ltd.

The forty-third Thomas Hawksley Lecture delivered to the Institution of Mechanical Engineers, February 1957, and subsequently to meetings of E.I.C. The paper is reproduced here by arrangement with the Institution.

AN INVITATION to deliver a Thomas Hawksley Lecture is an honour which, onerous though it be, is not lightly refused. When that invitation permits the setting down of some of the engineering problems uppermost in the minds of many scientists and engineers in the past few years, it is accepted with considerable appreciation.

These notes were prepared at a time when the Middle East territories were sorely troubled and the major nations of the world sharply divided. But the outcome of those international problems do not affect the basic fact that Great Britain has faced, and is today facing, the urgent need to develop the industrial application of nuclear energy almost as a matter of national salvation.

Power, and more power, in the service of man in industry and in his home, is the only way by which we can improve living standards in Britain or elsewhere in the world. Outstandingly the most easily applied and transported form of power is that provided by electricity. These are facts demonstrable beyond dispute.

Those nations of the world — and those families within a nation — who have the highest consumption of electricity per head, also have the highest living standards. Those nations who have the greatest rate of increase in electricity usage, also have the highest rate of increase in living standards. Hence it can be stated with certainty and conviction, that in Britain and elsewhere in the world, the greatest single factor in increasing national industrial productivity is an ever-increasing use of electricity per man in industry. For Britain, dependent as she is for existence as a major nation upon the quality and competitive price of its exports, this increase in electricity usage is of paramount importance.

In the past fifty years in Britain, the consumption of coal per unit of electricity produced has fallen from about 4 lb. to under 1 lb. But in that same period the consumption of electricity per head of population has increased by almost thirty times and shows no signs of ceasing to increase. Our consumption of coal for electricity production has doubled, trebled, and quadrupled. But our total annual production of coal has fallen by some 25 per cent and today is in short supply to the extent that we have changed from an exporting to an importing coal country. The reasons for this are fairly obvious and were and are inevitable. By a huge sum of capital investment there may be some increase of coal production but not by any means sufficient to meet the ever-growing need for more fuel to produce more electricity.

Ten per cent of all our industrial production is now based on oil. Transport, aviation, farming, the fighting Services all depend upon oil. World oil demand by 1965 is expected to be 70 per cent higher than it was in 1955. In those ten years American production is expected to increase 30 per cent, other Western Hemisphere production 70 per cent, and Middle East production by over 150 per cent. Will Britain have the dollars to purchase American oil in any increasing quantity? The answer is an emphatic 'No'.

Oil will be essential for so many industries and services that the ever-continuing threat to our oil supplies from the Middle East will demand the husbanding of such oil as we can obtain for those uses where there can be no alternative.

Until the Calder Hall Atomic Power Station demonstrated to the contrary, the large-scale production of electricity — other than from hydro power — was considered to require either coal, oil, or natural gas as the primary fuel. Coal we know will not be available in sufficient quantities to provide all the electricity we must have. Gas we have not. Dare we rely upon oil as a complementary or substitute fuel? Only as a matter of expediency and then only because there was no alternative should we, as a nation, become dependent upon oil to the extent that further wars become inevitable in preservation of it.

An alternative fuel to coal and oil in the production of electricity is today available. It is on the engineer, much more than on the scientist, that the future of Britain and the world depends. The scientist will devise new methods for the more efficient utilization of nuclear fuels and the engineer will apply them. And it will be primarily the mechanical engineer who faces the great challenge to the nation and the world today.

In a series of outstandingly valuable papers read before the British Nuclear Energy Conference some three months ago, the researches, investigations, and considerations which preceded the final designs of the Calder Hall Nuclear Power Plant were outlined by those engineers and scientists who were so intimately concerned in that great project. Some of the considerations leading to the final design decisions were economic, and some of expediency dictated by availability of supplies and materials. Had there been more time available to conduct further researches—time to study other alternative types of reactor; consider other moderators, other coolants—would the final decision have been different? I believe not. Intuition amounting to genius played a major part in those final decisions which now have been proved to have given Britain a commanding lead in the development of nuclear energy in the service of man.

So much has been spoken, written, and published on the subject of nuclear energy, that it is now well known that a nuclear reactor is merely another source of heat capable of being harnessed to produce steam which, by means of a more or less orthodox turbo-generator, develops power in the form of electricity. The key to the industrial development of nuclear energy is the reactor and the means adopted to transfer the heat released during nuclear fission into the steam required to drive a steam turbine. It is not at present believed to be possible to generate power economically by nuclear fission except through the medium of the steam cycle and, since this lecture is to be concerned with engineering problems, it is not proposed to theorize on hypothetical reactors of the future.

Reactors available today may employ as fuel either natural or enriched uranium. The moderator, necessary in thermal reactors to slow down the neutrons and make them more effective may be graphite, heavy water. or ordinary light water. Beryllium need not be considered at this stage since it is not available in quantity and is too costly for large-scale use. Light water demands some degree of enrichment for its fuel and the engineering problems are very great if it is to be used as a moderator for industrial large-scale power generation.

The essentials of any system for electricity generation are well established and may be stated as:

(1) reliability of the highest possible order with its consequential high availability of supply;

(2) minimum cost per unit of electricity delivered for sale, this covers capital and fuel and maintenance costs per unit;

(3) minimum of nuisance from smoke, dust, effluent, or other factor likely to cause opposition to the siting of the power station in a location most favourable for minimum transmission costs.

If the power station employs steam turbines then large quantities of condenser cooling water are required but this condition must be met regardless of the fuel used.

The need for reliability is obvious since if there are doubts regarding the plant availability when power is required, then standby plant must be provided at increased capital cost which must be charged against the unreliable plant. This factor leads to a philosophy of design which must determine and dominate all stages of research, development, and construction in nuclear as in orthodox power stations.

Safety is inherent in reliability and also will play an important part in deciding on the siting of a nuclear power station, since if there is any possibility of danger arising during its construction or operation there will be opposition to any site near a load or population centre thus increasing transmission costs. Hence the selection of Dounreay, in the far north of Scotland, for the siting of Britain's first large-scale fast-breeder reactor until it is known for certain that its many engineeing problems have been solved with resulting absolute safety. The fast-breeder reactor may be considered to be the ideal reactor offering the greatest fuel economy at present envisaged and, after many years of development, may well play a major part in future industrial nuclear power. It is not, however, at present available for use in Britain's urgent need.

In recent years, Britain has become less than self-sufficient in fuel resources. Enough cheap coal is no longer available; the economic supply of petroleum fuels is uncertain. Britain has, therefore, to develop the commercial production of electric power from nuclear fuels sooner and perhaps less economically, than may be obtained elsewhere. Few people are better qualified to discuss the engineering problems connected with such a project than the present author.

Enriched uranium is not available at present and, while the international situation remains unsettled, will not be available in quantity for industrial purposes. In any case, enriched uranium is what Sir Christopher Hinton has rightly called it, namely, 'potted electricity' since the major cost item in its production is that of the electrical power used to drive the compressors in the diffusion plant. Since electricity costs are higher in Britain than in the United States of America and Russia because of higher coal and oil costs, it is obvious that British produced enriched uranium would not be competitive in world markets as a fuel. Thus, because enriched uranium has not been, and is not now, available, the British nuclear power programme had perforce to be based upon natural uranium as the fuel. Perhaps we were fortunate in this respect since the field of research and design was narrowed and diversity of effort thereby avoided.

Similarly with considerations of using heavy water as a moderator. Thinking only in terms of neutron economy — and this is very necessary with natural uranium as the fuel — heavy water is an excellent moderator, superior to, but costing some one hundred times as much as, graphite which was available readily whereas heavy water was not. A major cost item in the preparation of heavy water again is the considerable amount of electricity used in its production and thus Britain could not produce it competitively.

The factors of availability, cost, and expediency, almost forced the decision to proceed with the Calder Hall project on the basis of natural uranium with graphite as the moderator. When the cooling medium came to be settled, here again expediency provided the same answer as the engineering and economic considerations and dictated carbon dioxide gas as the coolant. This almost makes it appear as though the designers had an easy task in making these decisions. Let me assure you that this was not so. The brilliant deductions leading to the final selections were outlined in a factual but quite excellent series of papers read before the British Nuclear Energy Conference in November 1956.

What is important to Britain as a nation, to its electricity supply industry and to British industry generally, is that those decisions taken by Hinton, Owen, Moore, and their colleagues, have produced in the Calder Hall nuclear power station a model which is the envy of the world. British industry, trained and given experience by the United Kingdom Atomic Energy Authority, and in collaboration with them and the Central Electricity Authority and the South of Scotland Electricity Board, has produced advanced designs based upon and developed from Calder Hall, which have now commenced or are about to begin construction. The designs are 'optimized' for electricity production and comply with the criteria outlined earlier. Figs. 1 and 2 are typical of the completed appearance of such a nuclear station, which because it makes a complete break with tradition in the fuel used and in the absence of smoke, dust, grit, or other nuisance, has enabled an equally complete change to be made in architectural design and appearance. It will be noted that the heat exchangers or boilers are enclosed, which was not the case at Calder Hall seen in Fig. 3. It was considered that the additional cost involved at least balanced the simplification of maintenance and the avoidance of frost problems on drains and small-bore pipes, and of course it improved architectural appearance.

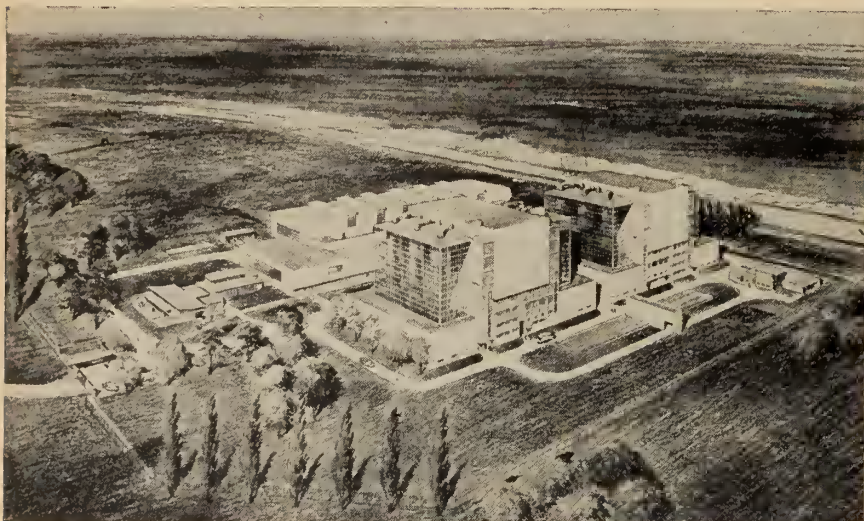

Fig. 1. Artist's impression of nuclear power station.

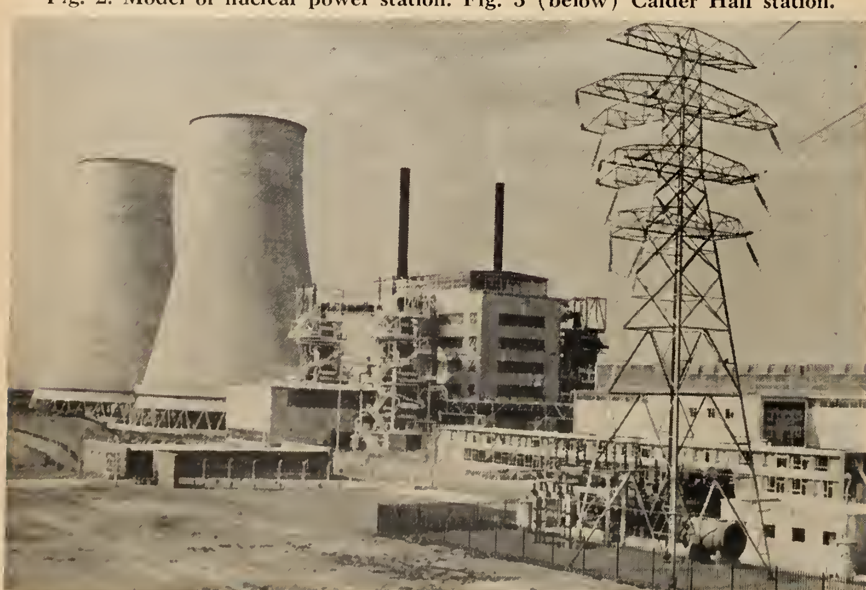
Fig. 2. Model of nuclear power station. Fig. 3 (below) Calder Hall station.



It will be evident to all engineers that, just as the boiler size and the amount of fuel consumed per day in an orthodox coal-fired or oil-fired power station determines the electrical output, so also does the reactor, its dimensions and fuel burn-up rate, determine the output in a nuclear station. Hence the nuclear physicist and the turbo-generator designer must work hand in hand at every stage of design and development. But in between reactor and turbines are the equally interdependent circulators, ducts, boilers, and auxiliaries. Of at least equal importance to all these plant items is the concrete shielding surrounding and encasing the reactors, which calls for great experience in design and construction to ensure safety for the operators against radiation effects. There are few, if any, engineering projects which demand such close co-operation between such a wide range of scientists and engineers, each a specialist in his own field.

THE REACTOR

Nuclear calculations for a natural-uranium, graphite-moderated, gas-cooled reactor are extremely complex and are greatly simplified and speeded up by the use of a special form of analogue computer for determining the power reactivity relationship of the core. Fig. 4 shows such a computer.

Nuclear physicists will state the minimum size of core and the amount of uranium to obtain criticality, and from this information and considerations of fuel rating the output expressed in megawatts from varying core dimensions may be determined. Fig. 5 shows a typical relationship. It will be appreciated that an increase in the core size above the critical pays a handsome dividend due to reduced leakage and the possibility of flattening by the introduction of an absorber thereby increasing the mean rating of the fuel.

The maximum rating of the fuel in the centre channel of the core which very largely sets the seal on the reactor economy is determined by the maximum temperature permissible in the fuel rod and the can. These must be determined by the thermodynamicist and the metallurgist working in the closest collaboration.

These factors largely determine the mass flow of the gas and its inlet and outlet temperatures.

The heat exchanger or boiler designer must now decide how much steam, and at what pressures and temperatures it can be supplied to the turbines, whose designers then provide a figure for electrical output. The designers of the duct work and gas circulators then determine the pressure drop in reactor, ducts, and boilers and, with a known mass flow, can design their portions of the plant.

But, during this preliminary study, the designers of the shield around and above the reactor have been calculating the amount of protective concrete and other materials required to limit radiation hazards, and their requirements certainly will affect the civil engineering and duct work layouts thus calling for design modifications. Many trial and error calculations are necessary before even semi-finality is obtained.

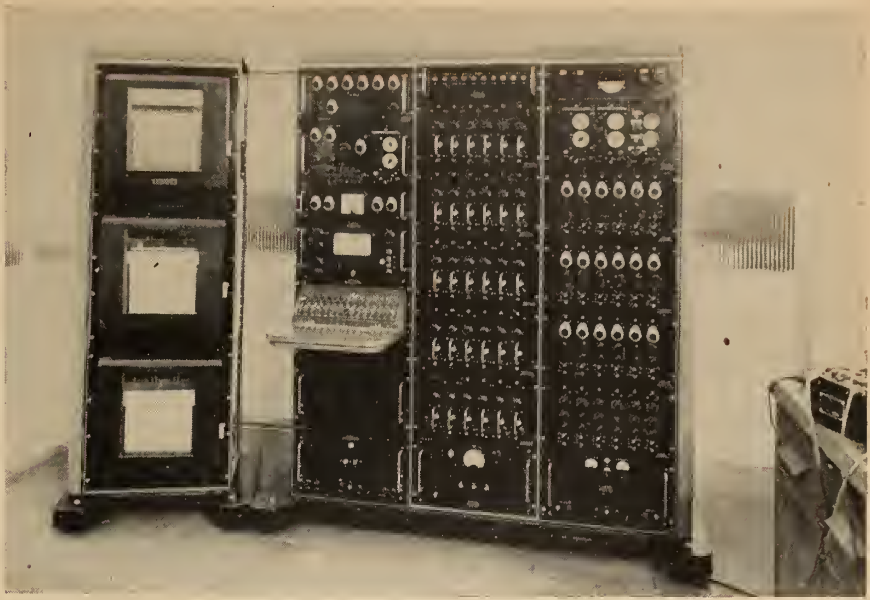


Fig. 4. Analogue computer.

No mention has yet been made of the reactor pressure-vessel designers whose experience, views, and potentialities are vital to final design decisions. Once the pressure-vessel designer has been given a preliminary estimate of the reactor-core dimensions, he can consider whether to use a cylindrical vessel as at Calder Hall, or a spherical vessel which so obviously is to be preferred if considered purely as a vessel to contain gas pressure. But he must consult the designers of the fuel element charging and discharging gear, because that mechanism requires certain space above the reactor core and also almost riddles the crown of the pressure vessel with holes or tubes to provide access to the fuel channels. The pressure-vessel designer must also know the dimensions of, and how many, ducts carrying the gas have to be brought into the reactor shell. He must also consider how to transmit the very considerable weight of graphite and uranium through the vessel to the foundations without complicating and increasing locally the stresses resulting from the gas pressure. That harassed designer also has to consider the changes in temperature between inlet and outlet gases and the stress pattern induced in consequence, and then face the crowning problem of the irradiation effects upon the shell materials available to him.

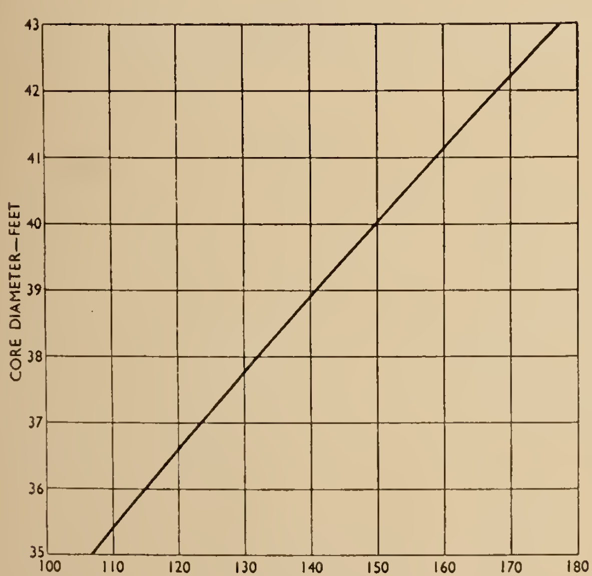

Fig. 5. Core diameter and net electrical output.

The higher the gas pressure the vessel designer can allow, then the greater the heat transfer from uranium through the can to the gas; the smaller the mass flow required for a given heat quantity removed and the lower the power needed for gas circulation which thus increases the net electrical output from a given quantity of uranium. This auxiliary power used for gas circulation is particularly important in nuclear station design, since it may take some 10 per cent of the total potential useful power output of the reactor. It is the possibility of raising the net power output by reducing auxiliary power (and also raising the temperature of the cooling medium outlet with its improved steam-cycle conditions and efficiency) that has turned the attentions of so many designers to the liquid-metal-cooled graphite-moderated reactor.

But, for the generation of electricity for normal industrial use, it is essential that the changing of fuel elements should be done without affecting the electrical demand on the station. Changing fuel elements in a gas-cooled reactor is relatively difficult and calls for ingenious, costly, and massive charge and discharge machines which now are available. The problems to be solved in changing fuel elements with liquid-metal cooling whilst the reactor is on load are much greater and, when allied to the determining of faulty fuel elements, will call for exceptional ingenuity. This is one of the engineering problems awaiting an elegant solution and, when solved, will simplify reactor-vessel design and lead to a marked improvement in fuel efficiency provided that the canning material allowing higher temperature does not nullify its advantages by absorbing too many neutrons or costing so much more than aluminium or magnesium oxide as to increase the cost of a unit of electricity produced.

The designer of industrial nuclear stations must never lose sight of his prime object which is to produce electricity at the lowest cost possible consistent with safety and reliability. There are so many solutions to nuclear power problems that appear to offer advantages in one or other direction, but always either at the expense of safety or of generating cost so that they provide pitfalls to be avoided.

Fig. 6 is a typical curve of capital cost per kw. of output plotted against net electrical output for a particular design of gas-cooled reactor, and shows how the capital cost falls with output. In practice the curve would be in a series of steps corresponding (amongst other factors) to steps in the reactor-vessel wall thickness. But the reactor vessel for outputs of all possible designs using natural uranium, necessitates at least final welding on the construction site and this limits the thickness of the pressure vessel to that which can safely be site welded, and this in turn limits upper gas temperatures because of metallurgical considerations.

The Calder Hall reactor-vessels were of 2-inch thick special mild-steel plate but subsequent research and experimental weldings have shown that site welding of 3-inch plate is now possible and, with further experience, still thicker plates will be used in future with corresponding increases in pressure and efficiency. To change from the vertical right cylinder vessels as at Calder Hall to spherical vessels enabling higher gas pressures to be adopted, necessitated finding solutions to many problems, not the least being the sealing of inlet and outlet gas paths from the walls to the core, doing this without adding appreciable temperature stresses to the already pressure stressed walls.

A fundamental philosophy of design in nuclear reactors should be never to put anything inside the vessel which has to move yet which cannot be removed and replaced once the reactor has been to full

power and those parts have become strongly radio-active. Charge and discharge mechanisms and control rods should all be capable of withdrawal and replacement if necessary. The full long-time effect of radiation is not as yet sufficiently known to face the possibility of failure inside the reactor of any moving parts which could not be removed.

STATION AT BRADWELL, ESSEX

The major particulars of the nuclear station at Bradwell, Essex, for the Central Electricity Authority are:

Guaranteed net output 300 Mw.

Reactor vessels. Two reactors each contained in a sphere of 66 feet in diameter in 3-inch thick special steel.

Heat exchangers. Six heat exchangers or boilers per reactor with dimensions substantially similar to those at Calder Hall but with double the unit heat output.

Gas pressure. Carbon dioxide circulated at 10 atmospheres pressure.

Steam conditions. Dual presssure cycle with steam at 730 lb. per sq. in. gauge, 700 deg. F. and 180 lb. per sq. in. gauge, 700 deg. F.

Cycle efficiency. Net cycle efficiency taking into account all station auxiliaries will exceed 28 per cent.

Turbines. Six main turbo-alternators which together supply power direct to the national grid, to the station auxiliaries, and to the variable-speed reactor gas circulators. The total installed capacity of all machines is 390 Mw., which includes a margin for subsequent improvements in reactor performance. One of the auxiliary turbo-generators serves as a standby for the other two. The main turbines have two cylinders with twin exhausts and are arranged across the station.

Fuel charging. Reactor designed for continuous recharging of fuel while remaining at full output.

Goliath or gantry crane. The compact arrangement of reactor buildings seen in Figs. 1 and 2 has made possible the employment of a new tool for rapid erection of the station. This is a Goliath crane of height 140 feet, span 167 feet, lifting capacity 200 long tons.

Fig. 7 shows a layout of the nuclear station which is on the estuary of the River Blackwater, in Essex. The soil is mainly typical 'London' clay and provides some difficult civil engineering problems.

Fig. 8 shows a section through the core of the reactors for the Bradwell station. The machining of the graphite blocks calls for a high degree of accuracy, to ensure the correct alignment of fuel-rod channels and to prevent neutron streaming at joints yet still allowing for some measure of Wigner growth. The geometry of core design demands great patience and critical analysis.

FUEL ELEMENTS

A number of severe thermodynamic and mechanical problems are involved in the design of the fuel elements. The use of natural uranium as the fuel limits the canning material at present to magnesium or possibly aluminium. Magnesium is superior on two accounts — lower neutron capture and better compatibility with uranium — and has therefore been selected for Calder Hall and for the British stations now building, in spite of the well-known limitations in the physical properties of this metal. With magnesium the maximum surface temperature of the fuel can is limited to approximately 450 deg. C. (842 deg. F.) and the aim in design is therefore to obtain the optimum between the conflicting demands of high outlet gas temperature, high heat rating in the fuel, and an economic pumping power.

The choice of a suitable heat-transfer surface is further complicated by nuclear considerations. The amount of metal in the can, the channel diameter and the disposition of the fuel are restricted within certain limits by the nuclear design. The 'optimization' of all these parameters is a formidable problem which is always present as new surfaces and canning materials are developed and as further experience is obtained on core design with respect to fuel-rod geometry.

The mechanical problems are concerned with the support of the elements in the channel, and the forces imposed on the fuel and canning material by the method of support. Consideration must also be given to the handling of the element during charge/discharge operations at power, and the strength of the element must be sufficient to resist damage under these conditions.

Natural uranium changes its crystalline structure at about 650 deg. C. (1,202 deg. F.). Though this in itself is not significant the considerable change in volume accompanying it can lead, especially if repeated several times, to the complete loss of the mechanical strength of the fuel bar, and, what is more important, to the destruction of the container surrounding it, thus allowing fission products to escape. Consequently, for the time being, the temperature at which this α-β transition occurs dictates the temperature limit of the reactor.

For nuclear reasons, the shape of the uranium should be such that the ratio of surface to volume is small but this is in direct contrast to the requirements for maximum heat removal. Practical reasons of support preclude the use of spherical fuel elements and, with one cylinder per channel, the fuel-rod optimization requires a diameter slightly over 1 inch. Uranium is such a bad heat conductor that with the reactor on load there is a temperature drop of about 100 deg. C. from centre to periphery of the fuel rod. A further, though smaller, temperature drop occurs at the boundary between uranium surface and can surrounding it. The temperature drop in can wall and fins is small but that between can surface and cooling gas is appreciable and so is that between cooling gas and working fluid. All those temperature drops, which constitute ther-

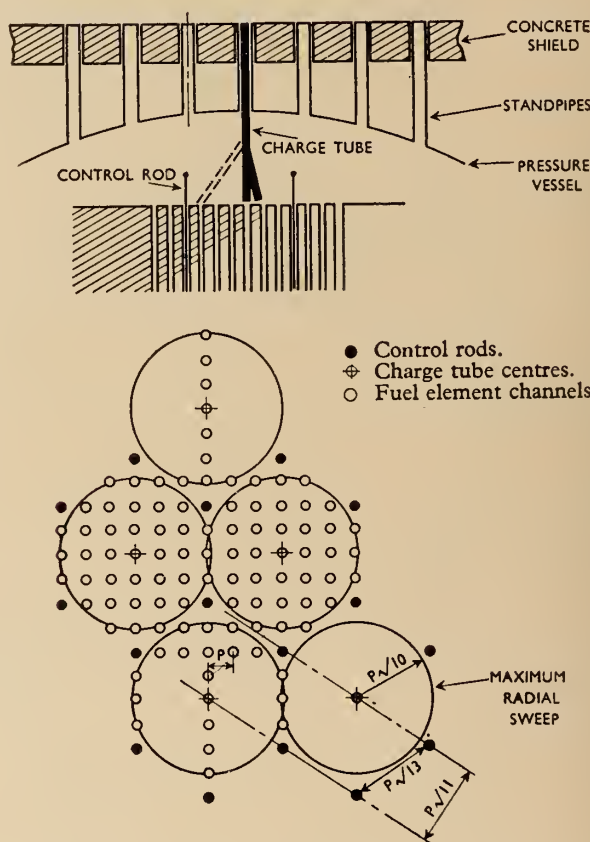

Fig. 9. Control rod and charging system.

modynamically irreversible losses, are a challenge to the applied physicist.

To reduce the temperature drop, we should work at high Reynolds numbers; apply large secondary areas, and create surface configurations which produce high heat transfer with relatively low pressure drops.

High Reynolds numbers necessitate, in order to keep pumping power within acceptable limits, high gas pressures or short channels. The gas pressure is limited by the pressure shell which is large and hot. Shortening of the channels leads to an increased diameter to height ratio of the core and thus reduced neutron economy, as well as uneconomic design of the pressure vessel.

Applying large secondary areas leads to increased neutron capture which, particularly with natural uranium, soon exceeds acceptable limits but also its thermodynamic effectiveness falls if the can fins become either too long or too close.

Hence it is to surface configuration that special attention must be given. The thermal conductivity in gases being low, the aim must be to scour the hot fuel element surface continuously by cooling gas, which is as nearly as possible at bulk gas temperature. This is best achieved if the gas which has been heated by contact with the fuel element is periodically transferred to, and replaced from, the main gas stream. It is important that this process be accomplished with the formation of few free vortices, which tend to increase the pressure drop without correspondingly increasing heat transfer. A considerable advance has been achieved by such a development.

The uranium in a power reactor will be at temperatures in the range 200 to about 600 deg. C. (392 to 1,112 deg. F.), depending upon the position of the element in the core. At the higher temperatures, the uranium is relatively weak and there is also evidence that creep may be accelerated by irradiation in the low-temperature portion of the reactor. Therefore the uranium must be arranged so that the forces imposed by its own weight are relatively small or, alternatively, supported continuously along its length to resist distortion.

Under irradiation, volume changes occur in the uranium, and the canning material must be sufficiently ductile to absorb these changes without splitting and thus exposing the uranium to the gas. The sealing of the ends of the can, the restraint applied by the extended surface and the metallurgical properties of the canning material are each important factors.

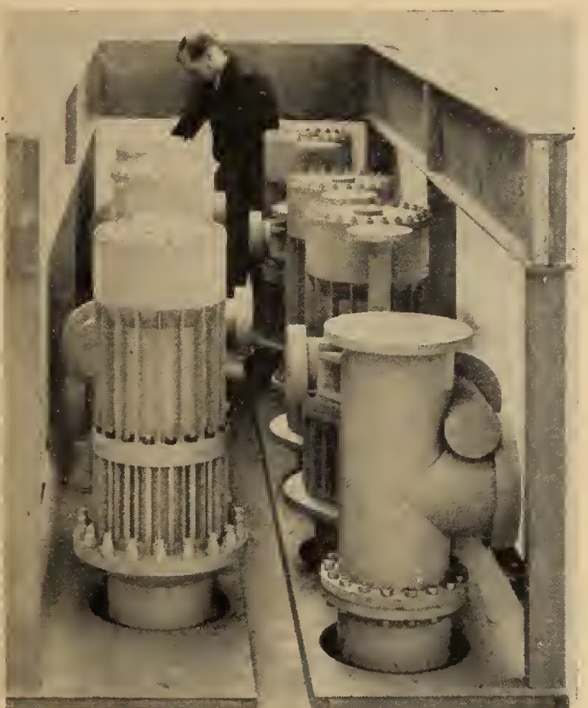

Fig. 10. Model of a portion of a pile cap.

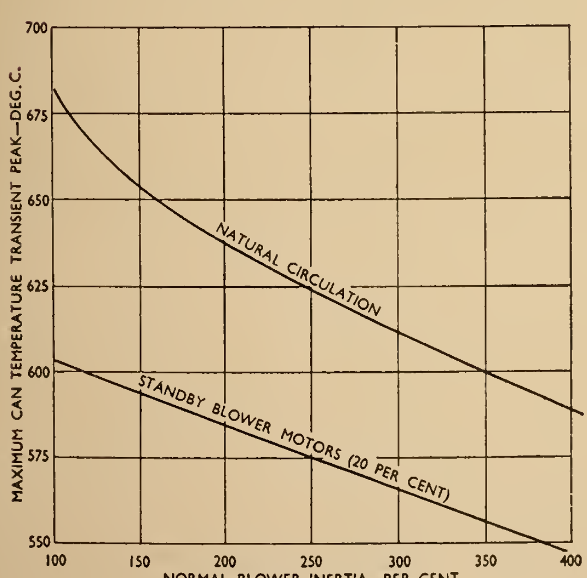
Fig. 11. Blowers fail. Control rods fail to trip.



Refuelling

For several reasons, including the containment of maximum size of core in a given pressure vessel, load of duct work, better natural circulation in the event of circulator failure, stress and differential movements in the core and pressure vessel, a core with vertical channels is preferable for power reactors. Refuelling has therefore to be carried out completely either from above or below or by passing new fuel in at the top and spent fuel out of the bottom. The last method has many attractions but requires twice the equipment and cannot be justified economically. Systems for refuelling from below have been devised, but they involve the insertion of relatively complex mechanisms into the pressure vessel and operating rams into the core. Thus it is possible that their reliability may be less than the simple mechanisms which are gravity assisted when charging from above.

It is at least highly desirable that refuelling on load be carried out without interference to the control system. This implies the use of separate standpipes for refuelling and control rods. The necessity to achieve a minimum ratio between fuel channels and control rods in the core determines a minimum pitch of the control-rod standpipes. The problem is to be able to insert charging standpipes between the control standpipes without weakening the pressure vessel, while maintaining adequate strength and the shielding properties of the reactor-roof biological shield, and achieve satisfactory coverage of fuel channels below the charging standpipes and avoid interference between the control rods and charging mechanism which has to be inserted into the vessel. A typical arrangement which meets these requirements is shown in Fig. 9. Fig. 10 shows the full-size model which was prepared to test accessibility and the ability to locate the essential reinforcing steel in the biological concrete shield.

SAFETY

It is now generally accepted that the gas-cooled graphite-moderated reactor does not present any hazard to the general public. Equally important, although not generally appreciated, is the fact that by careful design, it can be arranged that the reactor will not suffer serious damage due to the failure of its control or main cooling systems. The prime consideration in this respect is the prevention of excessive fuel temperatures. If at any time the ratio of the heat output to coolant flow exceeds the design value, overheating of the fuel will occur. An increase in this ratio can be due either to an increase in heat output or a decrease in coolant flow. It is essential that under either condition the rise in fuel temperature shall be a minimum.

The most likely cause of increase in reactor power is withdrawal of the control rods. It is very simple to arrange the maximum rate of withdrawal so that maloperation at start-up cannot produce dangerous power surges and the possible rate of rise of power at operating levels made such that, should automatic tripping devices fail, there would be time to make manual correction on receipt of warning given by a number of independent devices.

Reduction of coolant flow due to a failure of the main circulators would cause a more rapid rise in fuel temperature than that due to control-rod withdrawal and particular attention must be paid to maintenance of an adequate flow of coolant at all times.

Elaborate systems of protection are provided to ensure immediate reactor shut-down following such incidents as failure of main circulators, excessive gas pressure, excessive fuel temperature, and excessive power level, but when considering the inherent safety of the reactor, the reliability of the protection systems cannot be assumed.

The most serious case to be considered is, therefore, coincident failure of the main circulators and the trip circuits. Under this condition the transient temperature rise of the fuel elements depends upon three main factors:

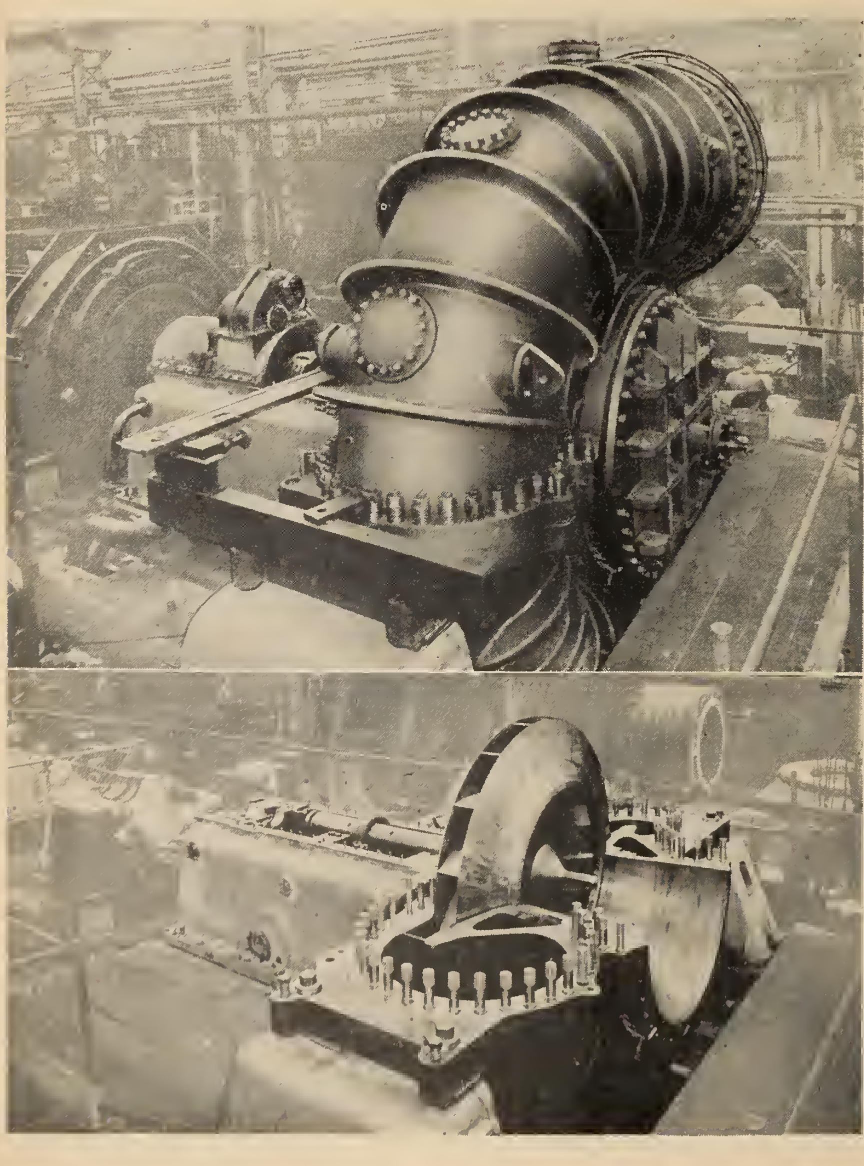
(1) the negative uranium temperature coefficient of reactivity;

(2) the run down time of the main circulators;

(3) the capacity of standby coolant plant and the natural circulation inherent in the coolant circuit design.

As soon as the flow of coolant falls, the fuel temperature rises, and because of the negative temperature coefficient of the fuel, the power

Fig. 12. Centrifugal gas blower.



starts to fall. If the rate of change of flow is small enough, the power falls almost in step with it and there is only a slight rise in fuel temperature. However, the collapse of power cannot follow rapid reductions in flow and the rise in temperature can be excessive.

The rate of fall of flow on failure of the main circulator drives can be reduced by increase in the inertia of the main circulators. The effect of this on maximum fuel temperature is shown in Fig. 11. By careful design of the coolant circuit, it is possible to achieve a sufficient flow of coolant by natural circulation to remove the heat and keep the fuel element temperature only slightly above the normal operating level when ultimately the circulators come to rest. The provision of auxiliary circulator drives which automatically take over and maintain forced circulation further limit both the maximum and final fuel temperatures. This is also shown in Fig. 11.

During the transient following circulator failure, the increase in coolant temperature causes increase in coolant pressure which, if great enough, would cause the safety valves to lift. With a suitable rundown time of the main circulators, this blow-off can be prevented.

The fracture of a main duct or other portion of the pressure circuit with consequent loss of coolant is a possibility which must be considered in the mechanical design of these components and, particularly with the expansion joints, long time life tests with pressure and temperature cycling are necessary researches to make preparatory to finalizing design. Should, however, failure occur, with auxiliary drives to the circulators maintaining them at 20 per cent normal speed, the fuel temperature can be maintained only slightly above the design value with the coolant at atmospheric pressure. With natural circulation, while the temperature rise is considerable, it is still appreciably below the melting point of the fuel cans.

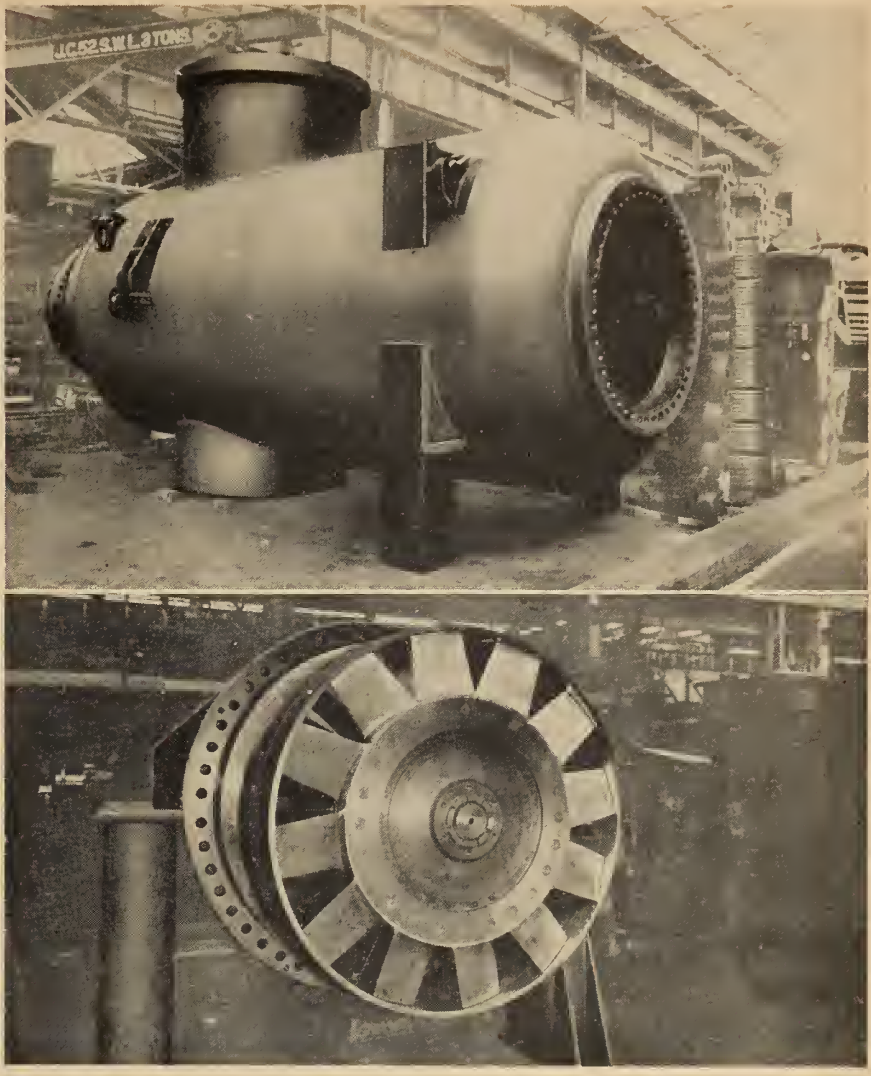


Fig. 13. Axial gas blower.

THE REACTOR VESSEL

In the construction on site of large vessels made from thick plates brittle-fracture is a definite hazard since the danger of this increases with the size of the vessel, the thickness of the plates and the depth of the welds which, besides increasing the stress due to welding, increases the difficulty of locating defects. Once the vessel has been constructed and stress relieved the danger of brittle fracture is diminished but not eliminated, since, although the plant operates at a temperature well above the transition temperature of all steels, it is subjected to a pressure test while cold before being charged, it is almost certain to be allowed to cool sometimes during its life and it is known that irradiation raises the transition temperature of the steel.

The danger of brittle fracture in pressure vessels can be reduced by using a low-carbon, high-manganese, aluminium-killed steel with a low transition temperature, that is, a high notched bar toughness at low temperature. But such steels have poor creep properties at high temperatures. Silicon-killed carbon steel has been used extensively in high-temperature plant and has good stress/-temperature properties but would be likely to fracture on site in cold weather.

One solution is to use a silicon-killed, high-manganese, low-carbon steel and thus obtain the high-temperature properties associated with boiler quality steel suitable for high-temperature service combined with a fairly low transition temperature. Another solution is to obtain, by the addition of alloying elements, a steel with satisfactory stress/temperature properties and a sufficiently low transition temperature. A steel that appears to fulfil those requirements has been developed and is under long-term high - temperature high - stress testing.

An obvious solution to this difficult problem is to build a double-shell vessel in which a thin inner shell that takes the temperature is made from a suitable steel while a thick outer shell that takes the pressure is kept cool and can therefore be made from an aluminium-killed steel. Like many first solutions in engineering problems, the difficulties increase as detail design develops. The double-skinned reactor vessel becomes less promising when endeavouring to accommodate gas ducts, control rods, and charge-discharge standpipes.

Were it possible to increase gas temperatures to the point that austenitic nickel-chromium steel became economic for the pressure vessel, the problem might be simplified, since this steel combines a high resistance to brittle fracture with good mechanical properties at high temperature.

Allowance in design must be made for the corrosion by hot carbon dioxide on the pressure vessels, ducts, circulators, and heat exchangers. Experiments have determined the wastage rates for the different steels used and adequate margins allowed.

The Cooling Gas

Helium and hydrogen are alternatives to carbon dioxide for the coolant. The use of helium would simplify the metallurgical problems but this gas is expensive and in short supply. The use of hydrogen would, however, intensify the metallurgical problems because uranium reacts with hydrogen to form a hydride of lower density, and hydrogen diffuses readily through many metals at high temperatures so that it would be difficult to find a canning material which, while suitable in other ways, would prevent hydrogen reaching the uranium and producing a volume expansion that would burst the can.

Blowers

The blowers to circulate the gas can be of the centrifugal or axial type. Mechanical problems, rather than aerodynamic problems, tend to predominate and the design of blower for a particular project will be influenced mainly by the form of station layout, the requirement for gas-tight enclosure and any limitations of speed imposed by the type of drive.

On the Calder Hall plant a centrifugal design was selected and the machine is shown in Fig. 12. In general the optimum speed for a centrifugal blower is much lower than that of the axial, and in this case the design was suitable for the Ward Leonard drive. The large diameter of the impeller, however, introduced a severe problem in obtaining a satisfactory pressure casing and a heavily ribbed structure is required to resist distortion at the sides. The horizontal joint also introduced gas sealing problems because of its size and shape. With regard to station layout, the centrifugal blower, unless mounted vertically, must impose a 90-deg. change of gas flow in the horizontal plane and this is not always desirable when considering duct expansions and general aesthetics.

If the blower drive is suitable for a rotational speed of, say, the order of 3,000 r.p.m., then the duty for a gas-cooled reactor can be met by a single-stage axial design. The diameter of the pressure casing can be reduced compared to the centrifugal design, and this enables the impeller to be inserted or withdrawn horizontally to provide a better form of joint in the vertical plane which avoids non-circular shapes. Such an axial blower is shown in Fig. 13. The casing lends itself to fabrication and is designed on normal pressure vessel principles using dished ends. Large flat surfaces are avoided and the resultant increased rigidity of the vessel ensures that flanged joints are not distorted by pressure to produce gas leaks.

To attain a high efficiency with a single stage of axial-flow blading it is necessary to provide an efficient diffuser at exit and to keep the axial velocity of the gas as low as possible. The blower shown in Fig. 13 is arranged with the diffuser coaxial with the shaft to obtain the highest possible efficiency.

The single impeller can be conveniently accommodated on an overhung shaft and only one gas seal is required. A seal suitable for the gas pressures and speeds of these special blowers has been developed from hydrogen-cooled alternator practice. The seal requires oil and the system must be designed to prevent contamination of the gas in the circuits. Present development work is aimed at a gas viscosity plate type of seal which will avoid the use of oil, but much work remains to be done in this direction.

A further possible line of development is the use of gas bearings to enable the complete enclosure of blower and motor in a gas-tight casing. Apart from the problems present in the design of suitable gas bearings, there are others such as the cooling of the motor and the possible contamination with active matter which would complicate maintenance. Although an enclosed design would have advantages from considerations of gas leakage and layout, it is a matter for conjecture whether these advantages would outweigh additional complications. If a suitable gas viscosity seal can be developed then this may prove to be an attractive solution to the problem.

Blower Drive

It is essential that the driving units of the blowers should be reliable and have a high availability in service. Outages for maintenance or faults mean the loss of a complete circuit and an appreciable reduction in output.

The main problem associated with the blower drive is the provision of a variable-speed range. During operation as a base load station the output must be varied between about 70 and 100 per cent full load, and for the highest efficiency the reactor gas outlet temperature should be maintained while the mass flow of gas is reduced by change of blower speed. Apart from retaining good steam conditions by this method, there is an appreciable saving of blower power. At 80 per cent load, for example, the blowing power is reduced to about one half of the normal requirement, and on a large station this may mean a saving of 10 or 15 Mw.

Speed variation between about 70 and 100 per cent of normal speed is therefore required on this account, and it is also desirable to have a small overspeed margin to cater for unknowns in the design which might otherwise prevent the guaranteed station output being obtained at design temperatures. In providing such a speed range, it is usually possible to specify a wider range of, say, 5/1 without materially increasing the cost of the equipment. The facility of being able to run the blowers at low speeds or at any desired intermediate value up to full load increases greatly the flexibility of operation, and can help to avoid undue thermal cycling of fuel element temperatures.

The speed variation may be provided in several ways, for example, by variable-frequency or variable-voltage supplies to electric motors, by hydraulic couplings or by direct steam-turbine drive. As stressed previously, reliability is the outstanding consideration and a squirrel-cage induction motor, used in conjunction with a variable-frequency supply or alternatively a hydraulic coupling, is to be preferred for the blower drive. The variable-frequency drive is superior in having good efficiencies down to quite low speeds, and the power savings at part loads can be shown to justify the extra capital cost of auxiliary turbo-alternators to provide the supply. These auxiliary turbo-alternators reduce the output required from the main machines and therefore ease the turbine exhaust problems on the larger machines.

Gas Ducts

Gas cooling of the reactor requires a number of ducts of large total flow area to transfer the heat output to the boilers even though gas pressures of about 10 atmospheres are used. The main problem in providing the flow area necessary to give an economic pumping power is to limit the duct diameter to a dimension which will allow the thermal expansion of the pressure vessel, boilers, and ducts themselves to be accommodated. The diameter should also be such that severe problems are not introduced into the design and manufacture of gas valves required for isolation and possibly control.

The choice of the number and diameter of the ducts is obviously a problem which is closely related to the problems of the boiler design, and a compromise must be found for both of these plant items, although the number of ducts per reactor and the number of boilers need not necessarily be equal. In general, however, the provision of a number of small ducts for each boiler circuit is not economically desirable and necessitates the control of a large number of valves. One duct per boiler is usually a better solution, and the use of restrained bellows units to accommodate the expansion avoids high thrusts on the pressure vessels and boilers.

If the ducting can be arranged so that it lies in one plane, then the bellows units are required to rotate in only that plane and a flexible torque rod mounted inside the unit can replace the external hinge pins normally used (Fig. 14). This type of unit avoids the problems associated with high bearing loads on the hinge pins and also the necessity for ensuring adequate lubrication to reduce friction.

STEAM CYCLES AND GENERATING PLANT

The gas temperature at outlet from the reactor is restricted to a maximum of about 750 deg. F. with magnesium fuel cans, and steam conditions are therefore representative of practice fifteen to twenty years ago. Overall cycle efficiencies with a normal condensing steam cycle would be about 26 per cent, allowing for a reasonable temperature difference between gas and steam in the boilers, but this efficiency has been raised to over 28 per cent by the application of the dual pressure cycle. Consideration has been given to other applications in order to improve upon this efficiency and these include triple pressure cycles, single pressure with reheat, and single pressure with separate superheating from external sources. In general, the dual pressure cycle offers a reasonable compromise between gain in efficiency and complexity and cost, and also offers the advantage that it can facilitate the control of reactor gas temperatures.

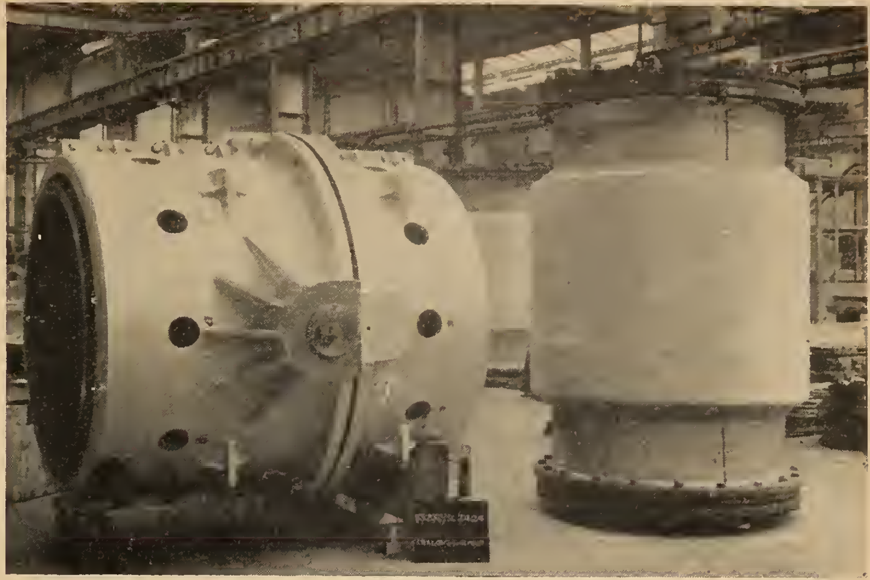

Fig. 14. Single hinged type of bellows unit.

In this cycle a quantity of steam is generated at a low pressure, say about 200 lb. per sq. in., and the remainder at a much higher pressure, say, 700 lb. per sq. in. This results in a turbine with two sections with two injection points, the first section being injected with steam from the high-pressure range expanding down to a mixing chamber. At this point steam is injected from the low-pressure range and mixes with the steam from the high-pressure section and finally expands through the second section to a condenser. The choice of high-pressure and low-pressure operating pressures for optimum efficiency is dependent upon the degree of feed heating and the ratio of high-pressure steam quantity to low-pressure steam quantity. The steam pressures at the optimum efficiency produce a high wetness at the turbine exhaust, and because of low temperature there is a large volume flow of steam for a given output in comparison to modern machines. The design of the exhaust is therefore the limitation on unit output, and with two exhausts an output of 50-60 Mw. is achieved at a speed of 3,000 r.p.m. compared to 120 Mw. for a plant operating at 1,500 lb. per sq. in. and 1,050 deg. F. The steam wetness and volume flow show little reduction in moving from the optimum efficiency and there is no incentive to lose station output for only a small improvement in these parameters. Consideration has to be given to the use of Stellited blades, water extraction belts and a reduction of blade peripheral velocities in order to obtain a satisfactory design of turbine. The use of three or four exhausts will be necessary to attain unit outputs of 100 Mw.—moderate by present-day standards.

To obtain maximum cycle efficiency it is desirable to raise both the high-pressure and low-pressure steam to the same temperature in the superheater section of the boiler. Large temperature differences are created between the low-pressure steam and the steam in the turbine at the low-pressure injection point, and care has to be taken to avoid problems of differential expansion.

The introduction of two injection points into the turbine presents a problem of control. Also associated with this is the problem of control of the reactor-gas inlet temperature. In a nuclear reactor it is advisable to keep thermal stresses in the fuel elements to a minimum and it is to this end that the temperature of the gas at inlet and outlet are kept substantially constant. The inlet gas temperature is controlled by the low-pressure steam pressure in the boiler and, to achieve this, a pressure-control valve is installed in the low-pressure governing system. The high-pressure steam pressure has little effect on the inlet gas temperature and therefore does not require pressure control for normal operation. However, it is not advisable for the high-pressure to be allowed to float up or down unchecked as load demands fluctuate, and a definite limit has to be set on this range. Control of the lower limit is achieved by the introduction of a high-pressure unloading device set at a predetermined level which unloads the turbine should the pressure in the line fall below the control setting. The higher limit is controlled by the use of a valve which operates if the pressure in the line increases to above a predetermined setting, allowing the steam to flow into a dump condenser.

Speed governing of the turbine is also essential if the turbine is to have normal frequency regulation. This has to be incorporated in the governing system and it is essential that it does not interfere with the reactor-gas inlet temperature control. This necessitates the introduction of two separate governing systems, one for the high-pressure steam which is used for speed control and the other for low-pressure steam which is used for pressure control.

LIFTING FACILITIES

The method of construction of a nuclear power station can strongly influence the overall design and must be considered in the initial planning.

There are two fundamental methods of constructing the large pressure vessel and boilers on the site, and the method adopted is largely dictated by the time available for construction.

If a speedy erection programme is required, and this is generally the case on a large capital contract, then, undoubtedly the best method of construction is to fabricate the large sections of the pressure vessel and complete boiler shells in construction areas away from the reactor buildings. This method of construction gives the minimum of mutual interference and allows the various trades to perform very exacting operations in less confined spaces. In the case of the pressure vessel, this method allows the further use of automatic welding and, in particular, eases the very real difficulties which are encountered in the fabrication of the vessel cap and the charge and standpipe assembly tubes. The boiler shells can also be automatically welded and hydraulically pressure tested in a horizontal position.

The other method is to weld the plates of the pressure vessel and boilers *in situ*. It can be shown, however, that on a large nuclear power station, the construction time will be lengthened.

An economic study of the two methods shows that quite apart from the workmanship aspect of the construction, the saving in time of the former, far outweighs the cost of a crane capable of lifting some 200 tons.

Advantages of Crane

Of the four practical ways of lifting the pressure vessel parts and boiler shells into position, a Goliath crane has many advantages. It is estimated that a saving of at least four months can be achieved, due to the high availability of the crane and complete freedom within the erection programme, when compared with its nearest competitor. Furthermore, the Goliath tracks can be extended away from the reactor to cover a marshalling yard which reduces the congestion around the reactor buildings during the civil engineering construction, and, as the Goliath would be designed to span the completed reactor building, a single construction area can serve more than one reactor.

Mention should be made of the nearest competitor to the travelling Goliath, which is the tower-mounted guyed derrick. Undoubtedly its initial cost is lower than the Goliath but it has the following disadvantages on a large nuclear power station. Due to the limited operating radius of the jib, it is necessary to frequently relocate the tower and the very long guy ropes. A large and specialized labour force is necessary during most of the construction period to carry out the lifting and frequent relocation of the derrick and tower. The necessary guys can also affect the layout of the principal buildings and generally prevent the engineer from siting the main buildings close together, and in their ideal engineering position.

These disadvantages, together with a longer construction time, when compared with the travelling Goliath would indicate that the extra capital cost of the Goliath is well justified.

Other types of crane tend to eliminate themselves on capital cost and appear to possess no additional operational advantages.

SUMMARY

From every point of view, economic, metallurgical, and mechanical, it is essential that the pressure vessels, reactors, ducts, boilers, and circulators should be maintained at as near constant pressure and temperature as possible. In that way, safety and reliability are maintained at the highest level and this in turn leads to the lowest cost per unit of electricity sent out. The whole philosophy of design must be directed to this end. It is a well-established fact that the extent of maintenance on turbo-generators bears a direct relationship to the number of times the units are started and stopped. It is stress and temperature cycling which leads to increased maintenance costs.

The reactor vessels particularly should avoid stress cycling since the irradiation effects on the crown of the shell are thus made of little consequence and no danger.

The boilers will receive oxygen-free condensate feed if the turbo-generators are continuously on load and on the gas side will have relatively pure carbon dioxide. Hence the amount of maintenance required by the boilers should be negligible.

CONCLUSION

It has been possible to mention a few only of the many problems associated with the development of industrial nuclear power and those only briefly. It is hoped that they will have been of interest and have shown how closely interrelated are the many components of a nuclear power station.

ACKNOWLEDGMENT

Many colleagues in the team of designers with whom I am proud to work have contributed to these notes, and my acknowledgment and thanks are gladly given to them.

Will Ultimate Strength Design of Reinforced Concrete Beams Simplify Stress Calculations?

E. M. Rensaa, M.E.I.C.

Rensaa & Minsos, Edmonton

THE FUNDAMENTAL principles of design of reinforced concrete structural members have lately come in for an increased review and criticism. It is especially the correctness of stress calculation and safety factors which are being questioned. This applies particularly to the concrete part of the combination section for which actual stresses may differ considerably from those calculated by the triangular stress distribution theory. At present, structural members are designed on the basis of assumed dead and live load conditions and on allowable stresses for concrete and reinforcing. Some engineers think that ultimate stresses and load carrying capacity of the member should rather form the basis for design. Allowable loading would then be reduced to a certain proportion of the maximum capacity of the member. In this article an attempt will be made to discuss some of the considerations that have a bearing on which of the two methods should be preferred. This discussion will be limited to horizontal members in bending.

One of the first to use reinforcing in a concrete beam was an Englishman, W. B. Wilkinson, who in 1854 patented such a combination. This was followed by other inventors of which the best known is the Frenchman, Monier. The first designs were based on trials and guesses as no method of calculating stresses in such reinforced members was known. It was as late as 1886 that the German engineer, Koenen, developed a fairly accurate method of calculating the stresses in reinforced concrete beams. The design theory of reinforced concrete is thus only 70 years old which is rather surprising when considering the tremendous amount of such construction that has been done. A great deal of testing and theoretical investigation was carried out during the two decades following the development of stress analysis and it may be said that the principal facts of reinforced concrete had been learned shortly after the turn of the century.

There is currently much discussion about the advisability of abandoning the use of working stresses and adopting ultimate strength as the basis for design of reinforced concrete members. Opinion on this is divided, and the author here presents a valuable discussion on the controversial subject.

Assumed Stress Distribution

Our present method of calculating stresses in a reinforced concrete member is based on Hooke's law that strain is proportional to stress and on Bernaulli's hypothesis that a plane section remains plane after bending. It was known quite early from tests that none of these assumptions are strictly correct for high concrete stresses. An originally plane section is certainly not plane after it is partly cracked. The value of the modulus of elasticity would not only depend on the concrete strength but would also vary with the stress. This will often make concrete stresses, calculated by use of the triangular stress distribution theory, quite erroneous for ultimate load conditions and especially if concrete forms the weaker part of the section. The calculated stresses will be much higher than those obtained from direct compression tests of the same kind of concrete. The early investigators understood quite well that the reason for this apparently higher beam strength was not that concrete in a beam became so much stronger but that the stress distribution was more favourable than indicated by the straight line theory. Both European and American engineers, early in this century, proposed other kinds of stress distribution than the triangular type for calculation of ultimate concrete stresses. The reasons for adopting the straight line triangular stress diagram was not ignorance of true conditions as some now might believe but rather that it did not seem possible to find a simple method which would be universally applicable for all steel percentages, concrete strengths and load conditions. The problem of developing such a satisfactory simple method is, in the author's opinion, still unsolved.

It was found early that the triangular stress distribution would be accurate enough for the purpose of obtaining the strength of a beam where the steel strength was the deciding factor. For a beam with such a high steel percentage that the concrete would fail first, it was quite obvious that concrete stresses calculated from triangular stress distribution was rather fictitious. However, by raising the allowable concrete stress to such an extent that the concrete section in bending only retained a proper safety factor, no economy was really lost. It is, therefore, incorrect to contend that the stresses allowed at present are not based on ultimate concrete strengths. When for concrete beams we allow a working stress of 45 per cent of the axial crushing strength at 28 days and only about half of this stress for axially loaded columns, it is not because we think that actual safety factors for beams could safely be that much lower. The allowable stresses are therefore based on tests of ultimate strength and not on a theory which only has a limited field of approximate correctness. Outside such a limit, we must find another theory which will conform to applicable test results. Theory is necessary as a means of enabling us to design members which in form and function are not materially different from those which have been tested and investigated previously. Any theory, which is to be usable must, however, be in accordance with the laws of nature.

Condition Governing Ultimate Strength

There are two principal conditions which govern the ultimate carrying capacity of a reinforced concrete member in bending. The first is the ability of the concrete section to resist compression and the second condition is the tensile strength of the reinforcing steel. It might appear that the best and most economical method would be to utilize both materials to their full capacity and then apply a certain safety factor applicable to both in order to obtain the allowable loading. Such a procedure may seem proper to theorists but generally it is not very feasible in practice. Members designed that way would not necessarily be the most economical even in the case of slabs and rectangular beams. In the case of T-beams, such a "balanced" combination is seldom economical. Furthermore, a balanced design might give very slender members which, when deflecting, could cause unsightly cracks in partition walls they might support. Simplicity of forming, desirable uniformity and architectural requirements, must also be considered. For all these reasons, full utilization of balanced design is rather the exception than the rule. Even if it was possible to build a structure in which for each member the critical section was of a balanced design, (the same safety factor for concrete as for reinforcing) it certainly would be impracticable to balance stresses along each individual member. In most cases when we want to obtain economy in a reinforced concrete beam, we maintain a uniform concrete section and decrease the amount of steel reinforcing to what is required by static conditions. We might thus get a condition where a certain part of member is over-reinforced, changing into parts having balanced reinforcing and then into under-reinforcing. To each of these conditions there would be a different concrete stress diagram and a different position of the neutral axis. Proper design of reinforced concrete members is, for the above reasons, just as much a matter of practical experience as of knowledge of theory. What is indispensable in any case, however, is a thorough understanding of the functions and limitations of reinforced concrete. In that respect, the ordinary American textbooks on reinforced concrete fall far short of giving sufficient fundamental information.

The modulus of elasticity of concrete is a very variable figure. It not only varies with the strength of concrete but also with the stress. Since the strength generally increases with age it also varies with this.

Critical Strain and Ultimate Load Capacity

Even more variable than the modulus of elasticity is the strain at which a concrete specimen carries its maximum load. This strain, which is not necessarily the maximum one, may vary considerably even for the same concrete strength. This critical strain varies also with the speed of loading which makes comparisons of results found by different investigators difficult. For axial compression test this strain is most often somewhere between 0.15 to 0.25 per cent of the length, but greater variations from 0.1 to 0.3 per cent are sometimes found. After the maximum load has been reached breakage will follow so quickly that it is difficult to measure the strains corresponding to decreased stresses. Even so, some investigators claim to have established such stress-strain relations considerably beyond the point of maximum load. It may be questionable how much reliance can be placed on the internal coherence of concrete which has passed the maximum stress stage. It is most likely that diminishing load capacity is caused by internal splitting and disintegration of the concrete test specimen and measurements beyond the maximum load capacity stage are thus probably worthless.

It is hardly possible to measure concrete stresses in a beam directly with sufficient accuracy. Several attempts have been made to carry out direct measurement of stresses in beams. (1) How reliable such measurements are may be questionable. Strains may however be measured without too much difficulty. It is, therefore, necessary to calculate the stresses from the measured strains on basis of what has been oberved for similar concrete under direct load. For beams it will be found that the maximum strain may be much higher, 0.3 to 0.7 per cent, than obtained for maximum load in direct compression specimens. If we assume that such high strain could only happen with a falling stress and that the maximum stress would occur for the same strain as in direct test specimens, we would obtain a concrete stress diagram somewhat as shown on Fig. 1. We do not know for sure, however, that with lateral support from less strained neighbouring concrete, the strain for maximum loads may not be higher in beams than in a test specimen where every part has about equal stress. One condition which points in that direction is the fact that an over-reinforced beam loaded by a concentrated load at the centre of span will sustain a greater bending moment than a similar beam with two loads placed at the third points exerting the same calculated bending moment. An extra bending moment capacity of up to 16 per cent has been found by tests. (2) While some of this extra load capacity may be explained by distribution of the single concentrated load to both sides down to the centre of beam, and by the possibility that the transverse pressure from the load might increase the compressive strength of

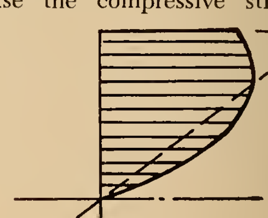

Fig. 1.

the most highly stressed concrete, this would hardly account for all of the extra strength. The fact that a sharply diminishing stress concentration may allow a higher unit stress was a good reason for permitting higher compressive stresses for negative bending moments at beam supports such as is contained in some building codes. It is clear, however, that since we cannot measure the stress variation in the compression zone directly with much accuracy, the actual distribution is to a considerable extent a matter of opinion. A great many assumptions have been and are being made in that respect varying from the second degree parabola to parabolas of 5th degrees or higher or even to rectangular stress distribution. (3) The probable truth is that there is no specific form for ultimate stress distribution in the compression part of a reinforced concrete beam. Both older and newer tests (4) have shown that the relation between concrete strength in beams and axially loaded prisms is not constant but varies to some extent with the concrete strength. The ratio may vary between 1.2 to more than 2 and generally decreases for higher concrete strengths. This would indicate that for high concrete strength we certainly may be far off if we assume the stress distribution to resemble a rectangle.

The question may then be asked if reinforced concrete, which shows such an uncertain and variable stress distribution, is not a rather unsafe material. That would also be the case if we tried to utilize what we think is the concrete strength right up to the limit. In practice, we generally limit the amount of reinforcing to such an extent that the strength of the beam depends on the tensile strength of the steel. Since steel is the most uniform and reliable construction material we have, this procedure makes the reinforced concrete beam about as reliable in bending as a steel beam. All we have to do is to use a higher safety factor for concrete to take care of its greater variability. Some concrete experts think that it is now possible to mix concrete which has such uniform strength that we could use almost as low a safety factor as for steel. Apart from the fact previously stated that full utilization of balanced design is most often impracticable, we must also consider the cost and availability of full scientific control. The majority of our jobs are so small that the cost of complete scientific control would, in most cases, be prohibitive.

In addition to the apparent impossibility of making strength of concrete as uniform as the strength of steel, we also have to contend with the effects of shrinkage, plastic flow and long time duration of load on strength and deflection. It is known that a concrete column under constant load will only carry 70 per cent to 80 per cent of its short time load capacity. Little is known about the carrying capacity of concrete in a beam under long time loading, but we may assume that about a similar decrease as for columns will occur. This reduction will eliminate from practical use the complete stress range beyond the maximum load and 20 per cent to 30 per cent before this load has been reached. The fact that loading above 70 per cent to 80 per cent of maximum capacity will eventually cause a failure would seem to prove definitely that this upper so-called plastic condition in reality constitutes a gradual internal disintegration of the concrete. We cannot, therefore, generally base the assumption of ultimate strength and safety factors on short time tests. So let us not be too optimistic about what savings we may make by adopting the plastic theory of stress distribution.

How Concrete Stresses Vary

Let us now consider how the concrete stress may vary along a beam uniformly loaded up to full capacity. The beam is under-reinforced so that its strength is determined by the tensile strength of the steel. Stress diagrams are indicated at four points along the beam. At section A, near the support we have a rather peculiar stress situation corresponding to that of a beam very high compared to its length. The neutral axis is quite low and the compression part of the stress diagram is not triangular. There is generally no tension crack this near the support and the concrete below the neutral axis will therefore carry some tension. (Fig. 2)

At section B farther out on the beam, we may still not have any tension crack. The stress diagram on the compression side is nearly triangular and the neutral axis has moved upwards possibly above the centre line of the beam. If the concrete on the tension side is stressed nearly up to the tensile limit, there may be some plastic deformation and the tensile stress diagram may be somewhat curved.

Section C shows the stress diagram for working loads after a crack has formed on the tension side. The neutral axis has moved farther upwards and there is only a negligible part left of the tensile part of the stress diagram. The compressive stress diagram is still not far from a triangular shape. The diagram may become more curved due to plastic deformation if the loading is heavy and of long duration.

Section D shows what happens after the steel has been stressed beyond its yield point. A large crack will form and the neutral axis and resultant concrete compression will move upwards giving the beam some extra bearing power. If the load is further increased the reinforcing will stretch even more, the compression zone diminishes until failure occurs by crushing of the concrete. Under-reinforced concrete beams will have an extra carrying capacity of 5% or more above the load which stresses the steel to its yield point before the beam fails by crushing of the concrete. The failure of such an under-reinforced beam is, therefore, relatively slow and there is a warning period during which the danger of impending failure may be observed and remedial measures taken.

It is clear that for an under-reinforced beam, it would make no dif-

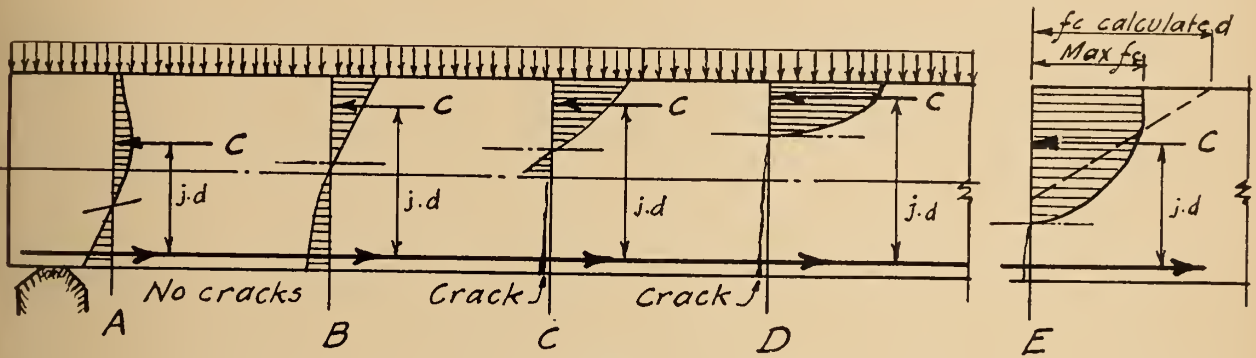

Fig. 2.

ference what shape we assume for the final concrete stress diagram near failure, since we know quite accurately the magnitude of the internal lever arm of the stress couple at the time the steel reaches the elastic limit. The strength of the beam depends principally on this limit and it would hardly be sensible to allow for the relatively small increase in carrying capacity after the steel has been stressed beyond that point.

Section E indicates how the concrete stress diagram might have looked for an over-reinforced beam near failure. There is considerable difference of opinion about the exact shape of this diagram. Most likely the shape is quite variable depending on concrete strength, etc. Since the ratio of beam strength to cylinder strength decreases as the concrete strength increases, the diagram will be less curved for high strength concrete. Duration of loading will also undoubtedly have a great effect on the curvature.

While for an under-reinforced concrete beam, the resultant compression will move upwards towards ultimate loading, the opposite is the case with over-reinforced beams. For such we get a decrease in the lever arm of the internal stress couple and a lowering of the neutral axis. Such a beam if overloaded will fail suddenly without any previous warning. Since the compressive strength of concrete is much more variable than the tensile strength of steel, a beam whose strength depends on the concrete will have a much greater variation of actual load carrying capacity than an under-reinforced beam. When some concrete experts advocate the plastic theory because our present method of design is wasteful, how far into this field of uncertainty do they want us to move? If it is found that we can safely increase the allowable concrete stresses, we might do so, but that does not necessitate the use of new method of design. It would, of course, be possible to save concrete if we allowed only a safety factor corresponding to 0.45 f'_c for the curved stress figure. That would be the same in reality as the raising of allowable concrete stress on the basis of a triangular stress distribution or, in other words, a lowering of the safety factor for the beam. If the same safety factor as at present were to be used, we would have to lower the allowable concrete stresses in compression to a figure closer to what is used for direct stresses. It should be understood that we cannot change the actual stresses in a beam by a different method of calculation. For a given beam design it makes no difference as far as strength is concerned how we arrived at the section either by calculations or by guesses. From a practical point of view our aim should be, with the least effort, to work out a safe, economical and practical design. The calculation of stresses for their own sake is quite unimportant. In practice such work need only be done to an extent where we can be sure of not having any "weak link in the chain".

It has been stated by proponents of basing reinforced concrete design on the plastic theory that by this means it will in most cases be possible to avoid the use of compression reinforcement. Such statements are again based on the wrong conception that we can modify actual stresses by a convenient method of calculation. It is uneconomical in most cases to use compression reinforcing in beams. The use of such reinforcing is only justified under conditions where it is required for short lengths, such as at supports, or where span lengths make saving of dead weight important, or where uniformity or limited height are important factors. We know that the distribution of stresses between concrete and compression steel is about the same as in a column. For that reason building codes allow us to assume the steel to be twice as effective as indicated by the usual calculation with triangular stress distribution and the specified "n"-ratio. We would not have gone very wrong in that respect if for ordinary beams we would allow the same stress for the compression reinforcing as for the tension reinforcing.

It seems to be impracticable to base our design of reinforced concrete beams on the actual stress distribution in the concrete since the distribution is so uncertain and variable. That more or less compels us to use a stress distribution which in some cases is fictitious. We would not gain much if we changed over to another assumed stress distribution which might be just as fictitious for other cases unless such a change made the end results more safe, economical and consistent.

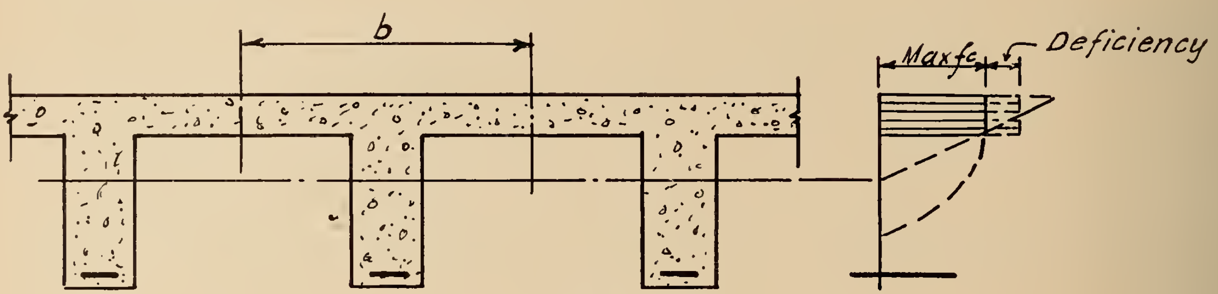

Fig. 3.

Over-reinforced T-Beams

Regarding safety and consistency, it must be admitted that the triangular stress distribution in conjunction with the allowable concrete stresses for working loads in beams does not always give satisfactory results. One such case deserves special attention and that is the over-reinforced or "balanced reinforced" T-beam. It happens occasionally that the stems of such beams are spaced so closely together that the complete flange width is utilized in compression. If the calculated concrete stress in such a beam is as high as that for a rectangular beam, we may then have a condition where the safety factor is much lower than for the rectangular beam. Looking at Fig. 3 the reason for this is rather obvious. In the over-reinforced rectangular beam, the concrete below the calculated position of the neutral axis comes to the rescue when a plastic deformation towards ultimate load conditions occurs. Below the thin slab flange there is no such concrete which will help to carry compression excepting in the relatively narrow beam stem. Our fictitious triangular stress distribution, therefore, does not give us

(Continued on page 840)

Electrical Energy from the Wind

E. W. Golding

Electrical Research Association, England.

The history of the use of wind power is traced briefly to provide a background to the present renewal of interest in the subject. The characteristics of the wind as a source of power are discussed together with its possibilities for the generation of electrical energy. A short review of the different types of windmill is given leading to a description of the main features of some recent designs. Wind-power research and development work in Great Britain is described with an account of the progress made during the last six years. The economy of wind power on three scales of utilization is dealt with and suggestions are made for making the most effective use of energy available. The author of the paper has played an important part in this work in Britain, and in other countries on behalf of their governments and of the United Nations; his book "The Generation of Electricity by Wind Power" treats the subject fully and authoritatively.

As CIVILIZED man, under the continual urge to improve his standard of living, realized the limitations imposed upon him by the paucity of his power resources as represented by human and animal power, he turned to the natural sources of energy, in the forms of falling water and the wind.

Water mills were apparently developed first and are referred to in Greek and Roman literature. In spite of casual references to very early windmills in Persia, the Middle East and China, no authentic accounts of their use much before the beginning of the Christian era can be found although in "The Pneumatics of Hero of Alexandria" a simple form of the horizontal-axis type of windmill is described. This would place its date about 200 B.C. Ancient remains of Persian mills — of the vertical-axis type and dating from about the 5th century A.D.—have been found, but the sail type of windmill, with a horizontal axis, seems to have appeared in western Europe only in the 12th century and the earliest reference to an English windmill is for 1191.

After that date they became increasingly common and, through the efforts of inventors such as Andrew Meikle, Edmund Lee, Stephen Hooper, Sir William Cubitt and John Smeaton — who presented to the Royal Society in 1759 a paper "On the construction and effects of windmill sails" — they reached a high state of development.

At one time some 10,000 windmills were running in Great Britain. They were widely scattered over the country but were commonest in the eastern counties, where they were used for corn grinding and water pumping. Their rotor diameter was often 60-80 ft. and their power output was 30-40 h.p. in a good wind.

While water-mills had to be located close to the water driving them, windmills were built, with a little more freedom in the choice of site, near to their work — hence their frequency of occurrence in the eastern counties of England, which are, in fact, much less windy than the western district.

With the introduction of the steam engine the windmills met competition which had previously been lacking, and their gradual decline in the 19th century was hastened towards its close by the re-organization of the flour-milling industry on the basis of large milling plants, dealing with vast quantities of imported grain. The fickleness of the wind was always a disadvantage and the specialized workmanship needed to maintain the old-fashioned windmills became less easy to find as the mechanization of industry advanced with the steam engine and, later, with electrification.

As the benefits of electricity became more widely recognized there was a demand for it in remote parts of this and other countries which had then little prospect of receiving a mains supply. Especially in windy districts such as those near our western coasts, on the Canadian prairies

LIST OF PRINCIPAL SYMBOLS

V_{am}=Annual mean wind speed.
V_p=Wind speed for full power capacity, or "rated wind speed."
V_c=Wind speed for "cut-in."
V_f=Wind speed at which an aerogenerator is "furled."
P_c=Rated power capacity.
T_s=Specific output in kilowatt-hours per annum per kilowatt.
C_p=Power coefficient, or (power produced by the rotor)/(power in the wind)
C_{op}=Overall power coefficient, or (electrical power output)/(power in the wind)
μ_0=Tip-speed ratio, or (peripheral speed of the blade tips)/(speed of the wind)

Paper presented to and reproduced by permission of The Institution of Electrical Engineers.

and in the United States, the demand for electric light was met, in part, by the installation of many thousands of small wind-driven d.c. generators of up to some 3kw. capacity, operating with a battery for storage to cater for calm spells.

There, in general, the matter rested, but there were some instances of more ambitious developments. In Denmark, following the work of Prof. P. La Cour at the Danish State Testing Station at Askov between the years 1891 and 1908, wind-driven generators of up to 30kw. capacity were built. They were applied to various farm purposes and were used as supplementary generating units at the village power stations. These machines, with sail-type rotors, proved useful especially during the two World Wars when oil fuel was difficult to obtain. During the Second World War 88 wind-driven generating plants, some of which were of a new propeller-driven type of up to 70 kw. capacity, generated more than 18,000Mwh. for local supply networks in 7½ years.[1]

In Germany also, during the Hitler era, very large designs, some of which are best designated as "fanciful," were put forward. Their sizes ranged up to 20,000kw. or more.

An experimental 100kw. aero-generator was built by the Russians at Balaclava in 1931. This ran connected to the a.c. network and was intended as a pilot plant for much larger units to be developed by the Central Wind Power Institute established at Moscow soon after the First World War. Since then many smaller machines have been installed in Russia to supply power for agricultural communities.

A 1,250kw. aero-generator for use connected to the a.c. network in Central Vermont, United States, was built during the Second World War, and this ran satisfactorily in commercial operation for a short period before the breaking of a propeller blade caused its abandonment.[2] Other design studies for wind-driven machines of 1,500, 6,500 and 7,500kw. were made in the United States during the Second World War.[3,4]

The recent resurgence of interest in wind power generation is due to a number of causes. Among these are the costs of fuels and their high rate of exhaustion in some countries, the need for alternative sources of energy in countries where the end of the exploitation of economic water-power sources is in sight, the desire for independence of imported fuels and the urge to make fuller use of some of the under-developed areas of the world where a mains supply of electricity would be out of the question in the early stages of development.

One can recognize, therefore, three scales in the possible use of wind power: (a) small scale, by 0.5 to 10kw. sets, for isolated single premises, (b) medium scale, by 10 to 100kw. plants, for communities which cannot otherwise be supplied economically, and (c) large scale, by generators, having a unit capacity of up to 1,500kw. or more, used as fuel savers through the energy fed by them into a main network.

WIND-POWER CHARACTERISTICS

The characteristics of the wind as a source of power, and of annual energy, are considered below with particular reference to the bearing which they have on the operating range of wind speeds to be chosen in design of wind-driven machines.

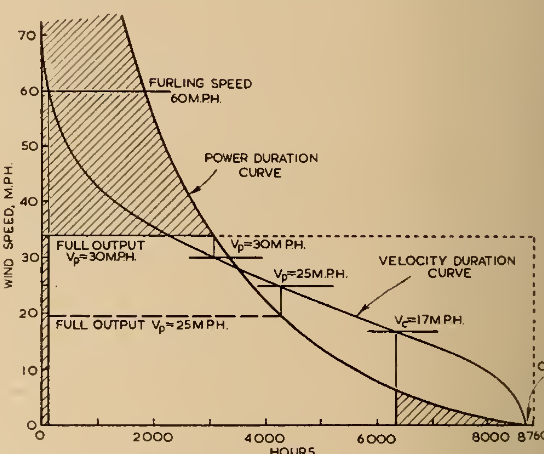

Fig. 1. Velocity- and power-duration curves for a wind-power site.

The Extraction of Power by a Windmill

The power in a wind stream of cross-section A and moving with velocity V is $\frac{1}{2}(\rho AV)V^2$, or $\frac{1}{2}\rho AV^3$, where ρ is the density of the air. Expressing the power in kilowatts, A in square feet, and V in miles per hour, and using for ρ the standard value of 1,201g/m^3, (at a barometric pressure of 1000 millibars and 290°K) the formula for the power becomes.

$$P = \frac{5}{10^6} AV^3$$

Thus, when the wind speed is 30 m.p.h., for example a windmill rotor of 50 ft. diameter is met by a column of air the power in which is 265kw. But the rotor cannot extract all this power. Betz, of Gottingen, has shown[5] that the fraction which can be extracted, called the power coefficient, C_p, has a maximum value of 16/27 (or 59.3%). Mechanical losses, and those in the generator and control gear, further reduce the power output from the wind-driven machine so that the "overall power coefficient," C_{op}, may not greatly exceed 40%. Since the wind is a free source of energy the low power coefficient is not directly important; a reduction of the power output to 40% can be corrected by increasing the rotor diameter in the ratio $\sqrt{(2:5)}$: 1. Indirectly, therefore, the effect is to enhance the cost of the windmill because of the larger rotor which is needed. This, together with the initial disadvantage of the low density of the air, constitutes one of the two main difficulties in using wind power economically. The other is the inconstant nature of the wind.

The counterbalancing advantages of wind power are that it is an inexhaustible source of energy which is abundantly available in many parts of the world, and that its utilization, up to the maximum degree which may be feasible, is not likely to be detrimental to the region concerned through the occupation of valuable land or otherwise.

Although, even in very windy places, one cannot rely upon wind at any given time, the variations in the annual average wind speed at a site do not generally exceed ± 10% of the long-term mean. Wind is therefore a dependable source of energy but an unreliable source of power.

At sites with an annual average wind speed approaching 30 m.p.h. there are sometimes calm periods of several days' duration, while almost windless places have their occasional hurricanes.

The annual average wind speed is the best guide to the energy which may be obtained, and this varies over the world from about 2 m.p.h. to

50 m.p.h. At most of the places where the economic use of wind power may prove feasible the wind régime, as expressed by the velocity-duration curve (see Fig. 1), takes the same general form with small percentages of calms and of hourly wind speeds above 60 m.p.h. When the wind is gusty its instantaneous speed may change 50 to 100% within 0.5 sec. Gust speeds do not seem to be related in a direct way to the annual wind speed, so that although gusts of 125 m.p.h. were recorded (in January 1953) at the E.R.A. testing site on Costa Hill, Orkney, where the annual speed is 25 m.p.h., gusts of over 90 m.p.h. have been measured, for example, at observation stations in India, Australia and South Africa — regions which are normally much less windy than Orkney. The inference is, therefore, that wind-power plants must be designed to withstand high wind pressures no matter where they are to be installed.

It is of interest to examine wind records to determine whether any regular pattern can be recognized in wind behaviour. Taking monthly mean wind speeds first, these may vary from the yearly mean sometimes by as much as 30 or 40%, but very seldom does one find a station which has a reasonably high annual wind speed and yet has some months which are consistently calm. In Great Britain and many other parts of the northern hemisphere, January is the windiest month and July and August the least windy.

There is a rather more pronounced pattern in the diurnal variations of wind speed. Thus, at coastal meteorological stations situated on the continental land masses — as, for example, in India or South Africa — throughout the year there are higher wind speeds during the period from noon to early evening, with lower winds during the night. These effects are caused by temperature differences between the land and sea; as the ground warms up there are rising air currents which draw in air from the cooler sea. Land and sea breezes — the former during the night and the latter during the day — may extend to about 10 miles inland in temperate climates, but even 60 miles or more in some tropical regions.

At the sites selected for wind-power studies in Great Britain it is impossible to distinguish any regularity in the diurnal variations; high winds appear as likely to occur during the night as in the daytime. The probable explanation is that diurnal variations are so often masked by storms.

The conclusion to be drawn is that, while in some parts of the world some reliance can be placed on the occurrence of wind each afternoon, in others, such as Great Britain, the wind must be accepted as truly random.

It has been suggested, particularly by Thomas,[6] that some firm power may be obtained through the effect of diversity when wind-driven generators, on widely separated sites, are connected to an extensive network. It is true that the output from a number of interconnected machines is steadier than from a single one, but examination of the wind records from E.R.A. wind-power sites during the past six years shows that a spell of calm weather often covers a large area, so that all the machines would sometimes be out of operation at the same time.

Wind direction is another factor which may have importance in choosing a wind-power site. There is often misconception about the expression "prevailing wind." The direction of this is that direction from which the wind blows for the greatest percentage of the year, but (taking the eight principal directions) this may be only some 15 or 16% as compared with the 12½% which would be the average duration for each direction if the wind were uniformly distributed. There are a few regions, as, for example, the Rhône valley and around Aqaba Bay at the southern end of the Wadi Araba, where the prevailing direction is very marked. At Eilat, on Aqaba Bay, the wind is from the north or north-east for 78% of the year. For such sites there is the possibility of using a non-orienting — and, perhaps, cheaper — windmill without incurring much loss of energy throughout the year.

Annual Energy Output

The annual output of energy from a wind-driven generator of given capacity depends mainly on (*a*) the wind régime at the site, and (*b*) the operating range of wind speeds chosen in designing the machine.

The velocity-duration curve for a site, drawn from an analysis of the measured hourly wind speeds there, gives the number of hours in the year during which the speed equals or exceeds any particular value. Fig. 1 shows the velocity-duration curve for the E.R.A. wind-measuring station at Mynydd Anelog, in Caernarvonshire (annual average wind speed, V_{am}, is 26 m.p.h.). The power-duration curve shown is obtained by cubing the ordinates of the velocity-duration curve.

It would be uneconomical to design an aero-generator to operate over the whole range of wind speeds. The machine is designed to cut-in at low wind speed, V_c, at which its output is merely sufficient to supply its own power losses. At the rated wind speed, V_p, which is chosen to be some 5-10 m.p.h. higher than V_{am} for the site, the plant produces its full rated power, while for high wind speeds, up to the furling point, V_f, when it may be shut down to avoid damage, the output is controlled to the full rated value, P_c. The control is by some form of governor, which, in effect, spills the excess power. Referring to Fig. 1, the unshaded area lying under the full-output line and the power-duration curve over the operating range is proportional to the annual output of energy. The specific output, T_s, expressed in kilowatt-hours per annum per kilowatt, is the equivalent number of hours at full output. It is obtained by dividing this area by that of the surrounding rectangle (shown broken). Specific output is a function of the shape of the power-duration curve and of the operating range of wind speeds used. It is thus reasonable to speak of the specific output of a site as *x*kwh/year/kw. for a rated wind speed of *y*m.p.h.

There is, of course, the implication that the overall power coefficient, C_{op}, is constant over the operating range from cut-in to rated wind speed. This is not quite true — since

TABLE I

Operating range			
Cut-in speed, V_c	Rated wind speed, V_p	Furling speed, V_f	Specific output, T_s (V_{am}=26 m.p.h.)
m.p.h.	m.p.h.	m.p.h.	kwh/year/kw
24	45	60	2 000
21.5	40	60	2 600
18.5	35	60	3 400
17	30	60	4 400
13	25	60	5 500

the output is obviously zero at V_c — but the power co-efficient/wind-speed curve is flat-topped so that C_{op} does not fall appreciably until the power output is down to about $P_c/3$. The effect of this upon estimates of annual energy output made from wind measurements is therefore usually negligible; this is particularly true at a very windy site when some two-thirds of the annual energy may be given by winds of rated speed or above.

It is probable that the characteristics of the output-controlling mechanism (usually blade-pitch changing) will have a greater effect upon the energy obtained. Power fluctuations in a gusty wind are considerable in magnitude and unpredictably variable in rate. Even with full knowledge of the performance of the controls to be used, the output from a gusty wind may be calculated only with difficulty; without such knowledge precise estimates are impossible. The energy output under gusty conditions will depend on the rate of response of the controls in relation to the fluctuations of wind power, so that the power output of the machine for a given mean wind speed is not quite constant — it will vary with a "gustiness-factor," an agreed definition of which has yet to be found.

The effects mentioned above may, however, be considered rather as of secondary importance. To return to the more important question of choice of the operating range, consider a change in this range as indicated on Fig. 1, where the effect of a reduction of V_p from 30 m.p.h. to 25 m.p.h. can be observed. This effect is a great reduction of the annual output of energy from a machine with a given rotor diameter But this is accompanied by an increase in T_s, as represented by the ratio of area under the power curve to the area of the surrounding rectangle. Table I shows how T_s varies with the operating range of wind speeds chosen in the design of the machine.

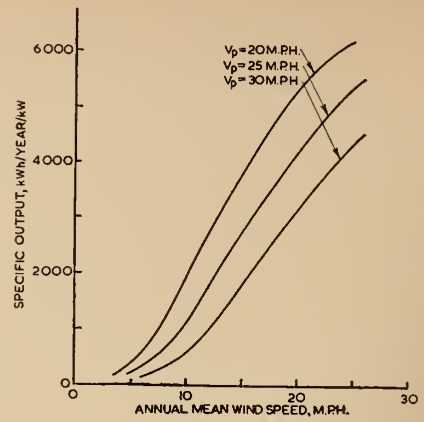

Fig. 2. Relationships between specific outputs and annual mean wind speeds.

The lower the rated wind speed the higher the specific output but the larger the rotor for a given power capacity. Obviously, from the power formula in Table I.

$$\text{Rotor diameter} \propto \sqrt{\left(\frac{P_c}{\rho V_p^3}\right)}$$

Relationship Between Mean Wind Speed and Specific Output

As the work of analysing the wind records from selected measuring sites in Great Britain progressed, it became clear that the velocity-duration curves were all of similar shape, especially over the range which might be employed for wind power. A very important fact thus emerged, namely that V_{am} for a site could be accepted, for estimation purposes, as a sufficiently accurate — though indirect — measure of the specific output. The curves shown in Fig. 2 were drawn, and almost all the wind régimes so far studied — including those for places abroad — conform to them. There may be a few exceptions for stations characterized by unusual percentage durations of very high winds or of calms.

The importance of this for wind survey work is easy to understand; a simple counter instrument measuring run-of-wind, in miles, from which the mean wind speed is easily calculated, can be used for most of the measuring stations, instead of a more complicated and expensive wind-recording equipment giving hourly wind speeds which must subsequently be classified from analysis of the records.

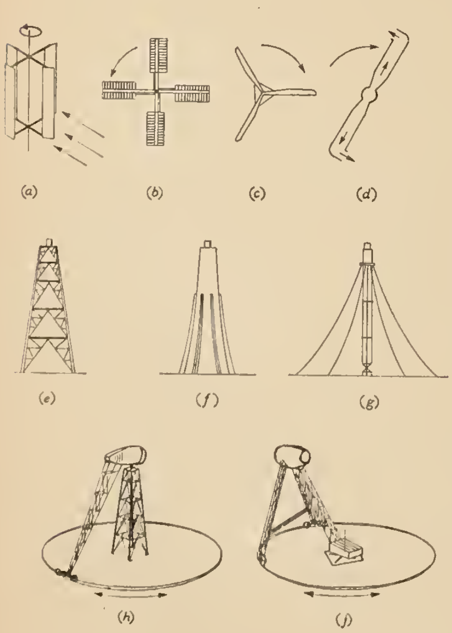

Fig. 3. Features of windmill construction.
V_p = 30 m.p.h.
(a) 50 ft high and 20 ft. diameter for 10 kw.
(b) 60 ft. diameter for 35 kw.
(c) 100 ft. diameter for 500 kw.
(d) 80 ft. diameter for 100 kw.
(e)—(j) Tower height = ½ (dia. of blade circle) + 30 ft.

WIND-DRIVEN MACHINES

To obtain power from the wind one must place in its path a machine which, by retarding it, can extract some of the kinetic energy contained in the passing air. A sailing ship receives its driving power as a simple product of its linear motion, with the wind, and the wind pressure on the sails, but a stationary machine can capture the power only by rotation about an axis which may be vertical or horizontal. Its structure must withstand the full force of the wind because there is no relief, as in the sailing ship, through relative motion.

Types of Windmill

Since the first machine driven by the wind was made, many centuries ago, literally thousands of individual designs must have been invented. Their number is still growing; some modern inventors are "re-inventing" types which were familiar to the ancient Persians. But all can be placed in one of two main classes, namely:

a) *The solid type*, with the effective surfaces of the rotor moving in the direction of the wind.

(*b*) *The propellor* (*or wind-wheel*) *type*, with the rotor rotating in a plane perpendicular to the wind.

The solid type — machines so called because they interpose continuously, in the path of the wind, active rotor surfaces [see Fig. 3 (*a*)] which almost fill the cross-sectional area of the column of air acted on — as distinct from the propellor type, in which only a fraction of the swept area is occupied by rotor surface. Another name for this type is the "panemone."[8] A cup anemometer is a simple example.

Usually, although not necessarily so, they have a vertical axis and the rotor has paddles, or moving vanes, the shape, number and arrangement of which is very variable. They can receive wind from any direction without the need for orientation, but, while the paddles on one side, moving with the wind, are urged forward by it, those on the other side, returning against the wind, are subjected to a back pressure unless this is removed by some form of screening or by turning them edgewise as they meet the wind. The paddle surfaces, moving in a circular path, are not all subjected at the same time to the full wind pressure, and there is a screening effect of one on another. It can be shown also that the maximum theoretical power coefficient of a panemone is 0.33 (as compared with 0.593 for a propellor type of rotor). The actual power coefficient is thus low.

Further, since the active surfaces must always run at a speed lower than that of the wind, the rotational speed—which falls with increasing rotor diameter — is low so that expensive gearing is needed if a high-speed electrical generator is to be driven.

The panemone is not, therefore, a promising type for electrical purposes of any appreciable scale, although crudely-constructed machines of this type, having a wooden framework and rush mats for the moving vanes, still serve a useful purpose in pumping water or brine in parts of China and other eastern countries. It has to be borne in mind that efficiency (or power coefficient) is not the main criterion when the input power is free; low initial cost for a machine which operates satisfactorily is the prime requirement, and this can sometimes be met, in small-scale work, by one of the panemone type.

Propellor type. — While the active rotor surfaces in the type of machine just described are struck perpendicularly by the relative wind velocity (wind velocity minus the velocity of active surface) those in the propellor type make only a small angle (the angle of attack) with the direction of the relative wind and they rotate at much higher speed [Figs. 3(*b*) and 3(*c*)]. The rotational speed increases as the number of blades is reduced. Two or three blades are used for the high-speed machines generating electricity. The optimum power coefficient is obtained at a value of the "tip-speed ratio"

$$\mu o = \frac{\text{peripheral speed of blade tip}}{\text{wind speed}}$$

which varies from about 1 in the slow-running multi-bladed rotor used for water pumping to 2.5 for the old-fashioned 4-bladed windmills, and 6 or more for high-speed aero-generators.

When a wind rotor drives an a.c. generator connected to a constant-frequency network, it must run at constant speed, hence the tip-speed ratio must vary with the wind speed. Optimum power coefficient can then only be maintained (approximately) by variation of the blade pitch, but the cost of control gear needed to vary the pitch with a continually-varying wind speed is probably not justifiable. It may be better to accept the small reduction of power, from this cause, over the operating range of wind speed, and to use pitch-changing — if at all — to control the power output for wind speeds above the rated value V_p. The Danish experimental aero-generator of 45kw. capacity installed in 1953 by the South East Zealand Electricity Supply Company,[1] follows this principle; its blade pitch is set to match the most frequent site wind speed.

The maximum power coefficient obtainable, in practice, with a high-speed rotor of the propellor type is probably a little over 0.5, which would give an overall power coefficient, C_{op}, of approximately 0.4.

Features of Recent Designs

In Table II the main features of several designs for a large or medium scale aero-generators of the propellor type are compared.

It will be observed that the design capacities range from 45 to 7,500kw. (with twin rotors) for rotor diame-

Table II

Item	Design	Rotor diameter	Rated wind speed Vp	Generator	Form of rotor	Control of speed or output	Optimum tip speed ratio	Rotational speed of rotor	Height of hub above ground	Method of weather-cocking
		ft	m.p.h.	kw				r.p.m.	ft.	
(i)	Russian (Balaclava)	98	24.6	100 (Induction generator)	3 blades	Variable pitch by flaps	4.75	30	76	Tail vane and electric drive
(ii)	P. H. Thomas (United States Federal Power Commission)	200	34	7500 (d.c. converted to a.c.)	Twin, 3-bladed	Speed control through generator field	9	Variable maximum 42.75	475	Electric drive
(iii)	United States War Production Board	200	30	1500 (Induction generator)	2 blades	Blade pitch control; electro-mechanical system	12	50	150	—
(iv)	Smith-Putnam	175	30	1250 (Synchronous generator)	2 blades (Rectangular form)	Hydraulic pitch control through fly-ball governor	6	29	110	Yaw vane. Servo-mechanism. Hydraulic yaw motor
(v)	Folland (Ministry of Fuel and Power)	225	35	3760 (Induction generator)	2 blades, 2 stage taper, 11½° twist, fixed coning	Blade pitch control by aileron. Start/stop by pilot wind-mill	9.74	42.5	135 (tripod)	Fantail coupled to bogey wheels through centrifugal clutch on fluid flywheel.
(vi)	John Brown	50	35	100 (Induction generator)	3 blades, tapered, untwisted. Free to cone and drag	Hydraulic control of blade pitch	6.5	130	78	Automatic electric control
(vii)	Enfield Cables	80	30	100 (Synchronous generator)	2 hollow blades	Automatic pitch control by hydraulic system. Variable coning	—	Variable maximum 95.4	100	Self-orienting but assisted by wind-sensitive power control system
(viii)	S.E.A.S. (Danish)	43	23	45 (Induction generator)	3 blades	Blade-tip rotation, spring controlled	5.4	56	66	Yawing vane and electric motor drive

ters of 43 to 225 ft. and rated wind speeds of 24.6 to 35 m.p.h. There is agreement on the number of blades as 2 or 3, and variation of blade pitch is used in most designs. The S.E.A.S. machine has braced blades with fixed pitch except that the outermost portion of the blade can rotate through 45°, under spring control, so acting as an air brake. Thomas's design[4] with twin rotors also has fixed-pitch braced blades, and the rotors, running at variable speed, drive a d.c. generator feeding its output into a convertor.

The generators are most commonly of the induction type, which is robust and is stable in automatic operation, although Putnam[2] used a synchronous generator for the Grandpa's Knob aero-generator, and this type is used also in the Enfield machine.

Another possibility which has been suggested, although so far as the author is aware it has not yet been incorporated in an aero-generator, is an a.c. commutator generator running at variable speed yet supplying constant frequency.

Smaller blades may be made of solid or laminated wood, but for the larger blades stainless steel and aluminum alloy are the most probable alternatives. For the highest efficiency the blades should have a twist and should taper, but the inner portions, near the hub, contribute little to the total power, and the higher cost of such blades, as compared with that for rectangular plan-form blades, may not be worth incurring. To relieve the stresses at the roots of the blades under fluctuating wind conditions they may be flexibly mounted so that they can "cone" or "drag."

Starting and stopping may be done through a small pilot wind-mill which initiates adjustment of the blade pitch according to the predetermined limits of operating wind speeds.

Except in very small fast-running machines, the high rotational speed needed for the generator is attained through gearing. There is usually a gear-box aloft in the nacelle which houses the generator, but some medium-sized machines — such as the Danish Lykkegaard windmills—have a vertical driving shaft running down inside the tower with bevel gears at top and bottom. Alternatives to gearing, which is expensive and may prove a limiting factor in the construction of very large machines, have been proposed. Some large German designs show two contra-rotating propellers, one carrying the rotor of an alternator and the other its stator, but such a scheme would appear to introduce difficulties in operating with an economically short air-gap.

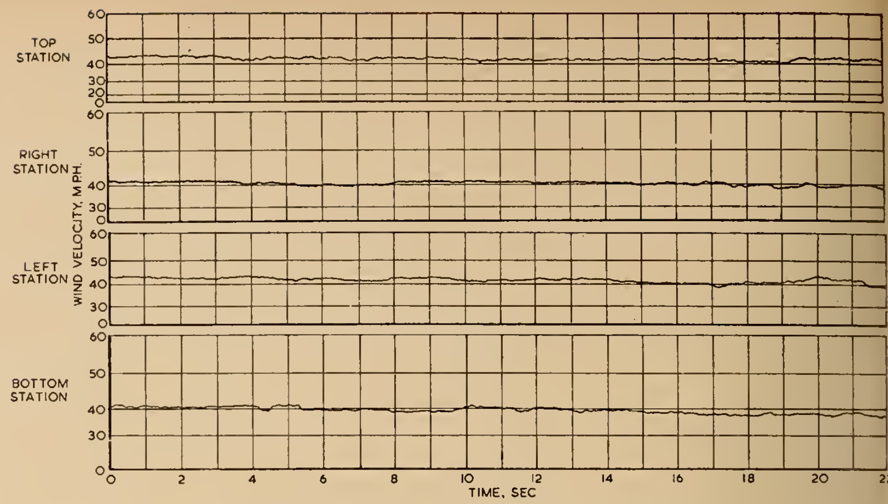

Fig. 4. High-speed records of wind-speed distribution.

The Andreau principle of pneumatic power transmission [see Fig. 3 *(d)*] is interesting. Air is thrown out centrifugally from the blade tips, and the depression created drives an air turbine at the base of the supporting tubular structure. Power losses must be incurred in the double conversion of energy from aerodynamic to mechanical form, at the top and bottom, but there are advantages in having the machinery at ground level and in the lack of any specific relationships needed between the speed of the rotor, the generator and the wind. Rapid changes in torque due to gusts may be damped out.

The form of the supporting structure for windmills is open to considerable variation according to the ideas of the designer. A few possibilities are shown in Figs. 3*(e)*, *(f)*, *(g)*, *(h)* and *(j)*. The tripod design of diagram *(h)* has advantages in allowing the head of the aero-generator to be assembled at ground level and then raised, using two limbs of the tripod as shear legs. It also allows the slip rings to be housed in the central building instead of aloft.

RESEARCH AND DEVELOPMENT

For the successful exploitation of wind power it is necessary to:

(a) Find windy sites;
(b) Make an aero-generator to operate satisfactorily;
(c) Test the performance of the machine;
(d) Study the methods of loading to ensure that the available wind energy is fully utilized.

The E.R.A. wind power research programmes have been based upon these four requirements. First, as part of its rural electrification work, and with financial support from the Ministry of Agriculture and Fisheries, research on the small-scale use of wind power for isolated premises was started. This had the twofold object of finding, through performance tests on existing small windmills generating direct current, the most satisfactory one for use in the windy — and often remote — districts of Great Britain, and of determining the best methods of loading to utilize the available wind energy in the fullest possible degree.

Then, as interest in the possibilities of large-scale a.c. generation grew, research on this subject began in 1948 under a newly-established committee on wind-power generation. The initial assumptions[9] were, first, that a number of sites could be found which were windy enough for a specific output of 4000 kwh/year/-kw. to be obtained from an aero-generator with a rated wind speed of about 30 m.p.h., and secondly, that suitable large machines, to be operated automatically when feeding their output direct into main networks, could be built, in quantity, for about £50 per kilowatt.

These two assumptions, if proved to be justified, would make a *prima facie* case for large-scale wind power by leading to an energy cost of 0.25d. per kilowatt-hour — as compared with rather more than 0.4d. per kilowatt-hour for the fuel component of generating cost at coal-fired steam power stations.

The progress made during the first six years is summarized below.

Wind Surveys and Wind Structure

Meteorological Office data on wind regimes for observation stations in Great Britain were studied, and analyses were made to relate them to wind-power possibilities.[10] Following this preliminary work, wind surveys were started in the especially windy western coastal districts. The first were in Orkney, Wales and Cornwall, followed by others in Shetland, the Hebrides and West of Scotland and, later, in Northern Ireland, the Republic of Ireland, the Isle of Man and the Channel Islands. In all, more than 100 measuring sites have been used.

These sites have been chosen mainly on the summits of well-exposed smoothly-shaped hills without precipitous faces and with no trees or other obstructions to disturb the wind flow over them.

With the valuable aid of local observers, wind measurements have been made by counter-type cup anemometers, mounted on 10 ft. poles and giving the run-of-wind, in miles, at most sites. On others, 30 ft. poles, carrying electrically contacting cup anemometers and used with specially-built recorders,[11] have been installed. These give hourly winds speeds from which velocity-duration curves are plotted. Comparisons are made with the long-term records from local Meteorological Office stations.

At a few sites 70 ft. masts, carrying anemometers and wind-direction indicators at different heights, have been used with photographic and impulse recorders to determine the vertical wind gradients over the hill summits.

Located in districts with mean annual wind speeds ranging from 12.5 to 17.5 m.p.h., the chosen sites have been found to have mean wind speeds of up to 29 m.p.h. Out of 65 hill sites, of altitudes from 150 ft. to 2,795 ft., 39 have annual mean wind speeds exceeding 20 m.p.h., with estimated specific outputs (for V_p = 30 m.p.h.) from 3,000 to 4,750 kwh/year/kw (see Fig. 2).

In the areas surveyed, only representative hills have been selected; doubtless there are many others equally windy.

Experimental studies of the vertical wind gradient have shown that over a hill summit the mean wind speed increases with height less rapidly than over level ground. Mean hourly wind speeds for the highest and lowest points on the circle to be swept by a large rotor are not likely to differ by more than 10%.

Fig. 5. 120 ft. rotatable mast used for wind measurements on Costa Hill, Orkney.

Gust anemometers[11,12] have been developed for use with quick-response recorders to measure gusts with a 0.1-sec. response. A balsa-wood windmill - type anemometer, used with an electronic counter, has also been built to measure mean wind speeds over periods of a few seconds.

Measurements with these instruments have indicated that:

(*a*) In a gusty wind of mean speed 40 m.p.h. the short-period mean speed may vary between 20 and 84 m.p.h. and the rate of change of wind speed in a gust may exceed 120 m.p.h./sec. (e.g. 52 m.p.h. to 85 m.p.h. in ¼ sec.).

(*b*) The energy contributed by a gusty wind (as calculated by cubing short-period mean speeds) is not likely to exceed that calculated from hourly mean speeds by more than 2 or 3 per cent.

(*c*) The vertical component of the wind velocity, affecting an aero-generator located on a hill summit, will usually be small.

(*d*) There are periods, of perhaps 10 sec., when the distribution of wind speed over the circle swept by a rotor of, say, 60 ft. diameter will be uniform to within ± 2 m.p.h. This is supported by the gust anemometer records shown in Fig. 4. They were obtained from instruments mounted at 110 ft., 80 ft. (at the two ends of the cross-arm) and 50 ft. on the rotatable measuring mast at Costa Hill, Orkney (see Fig. 5).

(*e*) At the summit of a roughly conical hill the direction of the wind does not influence the preceding statements significantly.

In an endeavour to obtain information to guide the selection of wind-power sites, laboratory work has been done using scale models of hills in an electrolytic tank. The distribution of current in the conducting solution above the model is taken as analogous to wind flow over the hill, but the analogy is by no means perfect and the useful information to be so gained may be rather limited.

Aero-Generator Prototypes and Pilot Plants

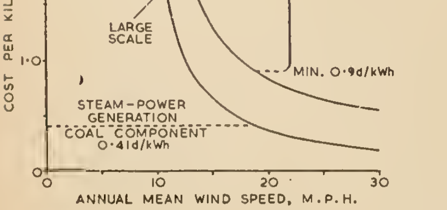
The construction and operation, with an a.c. network, of wind-power plants of significant size lay outside the normal scope of E.R.A researches. This important part of the work was undertaken by the North of Scotland Hydro-Electric Board and the British Electricity Authority; both placed orders for 100kw. wind-driven generators. These are of different types, the main features of which are given in items (vi) and (vii) (respectively) in Table II.

The first experimental machine was erected during 1951-52 on Costa Hill, Orkney, and has since been subjected to a number of trials. There are many difficulties, some of an unexpected nature, to be overcome in the development of a machine of this kind and in its operation on a very exposed site where the weather conditions are often severe. It is not surprising, therefore, that modifications have had to be made as a result of the trials. These modifications have been connected particularly with the methods of blade mounting and pitch control. For technical reasons, also, the blade-circle diameter has been reduced from 60 to 50 ft., while the rated wind speed has been increased from 30 to 35 m.p.h. which is more economical under the wind régime at Costa Hill. Since its erection the structure has withstood several very severe gales without damage. The machine has generated its full rated output during test and has been subjected to loads of up to 150kw. for short periods. It has run in wind speeds up to 70 m.p.h. Following the experience gained, its manufacturers are now undertaking the design of a 250kw. aero-generator.

The 100kw. Andreau-type aero-generator being made for the British Electricity Authority has been built and subjected to some preliminary trials at St. Albans prior to its installation on its final site.

In Denmark, during the same period of development, two machines, the first of 13kw. and the second of 45kw. capacity [Item (viii) of Table II] have been built and tested.[1] These have run satisfactorily for more than 12 months connected to a.c. networks. Their specific outputs have been just under 2,000kwh/year/kw, at sites with annual mean wind speeds of 11 m.p.h. — performances estimated from wind measurements.

Fig. 6. Curves of energy costs for medium- and large-scale utilization.



For use on farms and at isolated premises, two wind-driven machines of 8-10kw. capacity have been developed. The first, with a rotor diameter of 8 metres, is of the Andreau type, and the second, which is now on the market, is a German machine of more conventional design. It has a rotor diameter of 10 metres and produces 8kw. in a wind of about 25 m.p.h. Tests[13] have been made with this machine driving an induction generator connected to an a.c. network.

TABLE III

Machine	Capacity	Diameter of blade circle	Tower height	Total weight
	kw.	ft.	ft.	tons
Conventional type (*a*)	10	20	45	1.1*
	100	50	80	20
Conventional type (*b*)	8	33	33	1.4
Andreau type	10	28	61	2.8
	100	80	100	40.5

* Without the tower.

Design Studies and Performance Tests

During the past six years a vast amount of information on wind power has been obtained through correspondence and the exchange of visits with engineers abroad, particularly in Denmark, France, the Netherlands and Germany. International co-operation has been organized through a wind-power committee of O.E.E.C.[14] and through the Arid Zone Advisory Committee of UNESCO. More than fifty countries appear to be seriously interested in wind power and several have instituted wind surveys to provide data for the designers of wind-power plant and to serve as a guide to the possibilities of utilizing this form of power.

Many, and very varied, designs have thus come to light and the need for design and utilization studies has become obvious.

The Ministry of Fuel and Power started to give financial support to wind power development in 1949-50 and put in hand a comprehensive design and costing study to determine the best lines of constructional development to be followed, and also the probable costs of large wind-driven machines.

A suggested design emerged from this study [see Item (v), Table II] and, based on January, 1951, prices and on the wind régime at Costa Hill, Orkney, a generating cost of rather under 0.2d. per kilowatt-hour was estimated.

The Ministry have also supported E.R.A. work on the testing of the two 100kw. pilot plants already referred to. At Costa Hill, Orkney, a rotatable 120 ft. mast (Fig. 5) carrying gust anemometers and other wind-measuring instruments has been installed, together with electrical instruments to obtain both short- and long-period measurements of output from the aero-generator, corresponding to different wind conditions. A 70 ft. measuring mast and similar testing equipment have also been provided for tests on the B.E.A. 100kw. machine.

In addition, a windmill testing station has been established at Cranfield, Bedfordshire, close to the College of Aeronautics. Here a number of small windmills of different types up to 10 kw. capacity are being tested in the same wind régime, and a series of investigations will be made to test the effects of artificially-created, irregular conditions of operation. The object is to provide information for aero-generator designers and to test the possibilities of a very simple and cheap construction.

Also at the Cranfield station, in conjunction with tests on small windmills in normal operation at remote premises, studies are being made of the methods of loading best suited to the fullest utilization of the annual energy becoming available. This work is particularly of interest to the Ministry of Agriculture and Fisheries, which support it financially.

The Economy of Wind-power Utilization

The cost of energy production by wind power is governed by the annual charges for interest, depreciation and maintenance of the plant, on one hand, and by the annual energy output on the other. The economy can be judged only by comparison of this cost with that for alternative means of energy production.

Where electrical energy is cheap, large wind-driven machines must be located at sites with high mean wind-speeds if they are to be competitive, but where generating costs are high, smaller machines and lower wind-speeds may prove economically practicable. Thus the question of economy is relative rather than absolute. It is closely connected, also, with the cost of providing storage to cover calm spells. Storage of energy by a battery, or by any other means involving the provision of equipment which serves no other purpose, is expensive, and, even when used in only a limited degree, may double or treble the cost of the energy supplied to the load.

Under most circumstances, however, it is important that every kilowatt-hour of energy generated by the wind-power plant shall be utilized. This calls for its acceptance at the random times of its occurrence, and if storage is essential it should be by means of loads having inherent storage so that no great additional costs are involved in affording it.

The economic possibilities under the three scales of use already mentioned are discussed here.

Small-Scale Utilization

Small wind-driven generators, of perhaps 1 or 2kw. capacity, are usually d.c. machines of low voltage— often not more than 32 volts — and are provided with battery storage to cover calm spells of a few days' duration. Because of the low voltage, they must be located close to the premises to be supplied so that there is not free choice of site to obtain optimum wind conditions. The specific output, even in windy districts may not therefore exceed 1,250kwh/year/kw.

A representative cost, with battery, is £200 per kilowatt, while annual capital charges, enhanced by the short life of the battery, may be 15%. This leads to an energy cost of the order of 6d. per kilowatt-hour, assuming that the machine is operated to make full effective use of the energy generated; probably, in practice, a figure of about 9d. per kilowatt-hour would be more realistic. This cost is high, but, for lighting purposes in a remote district, may not be considered excessive.

A study is being made of the possibilities of using such small machines, without a battery, for the sole purpose of water heating. Matching of the generator and load characteristics is then important, but the advantage may be that the need for a battery is eliminated.

Medium-Scale Utilization

The scope for wind-driven generators in the capacity range 10-100kw. is very varied. They may be used on farms or at other large premises remote from public electricity supplies, to act as fuel savers in supplementing Diesel generation on islands or in isolated districts where small local networks exist, or to act as autonomous, or semi-autonomous, generating plants to supply communities which are being established in many of the under-developed areas of the world.[15,16]

In such places the alternatives of bringing in an electricity supply from outside the area or of generating by Diesel engines may, because of the distances and transport costs involved, be so high as to be almost prohibitive, yet frequently, especially on islands, wind is abundant, so that a sound case can be made for its exploitation. In assessing the economic possibilities it may, in fact, be a question of deciding how low the mean wind-speed can be before the large wind-rotor which it calls for involves installation costs — and therefore annual capital charges — which are too high to compete with the admittedly expensive alternative.

There are, as yet, no firm cost data on which to base estimates of the costs of medium-scale plant in general, but evidence from Germany and Denmark on costs for the lower end of the capacity range indicates £120 per kilowatt (without battery storage) as a reasonable figure. Taking 12% annual charges and a specific output of 2,500kwh/year/-kw., the generating cost, for random energy, would be 1.4d. per kilowatt-hour.

Approximate weights and dimensions for wind-driven generators at the upper and lower limits of this range of capacity are given in Table III.

Fig. 7. The combination of wind power with other power sources.

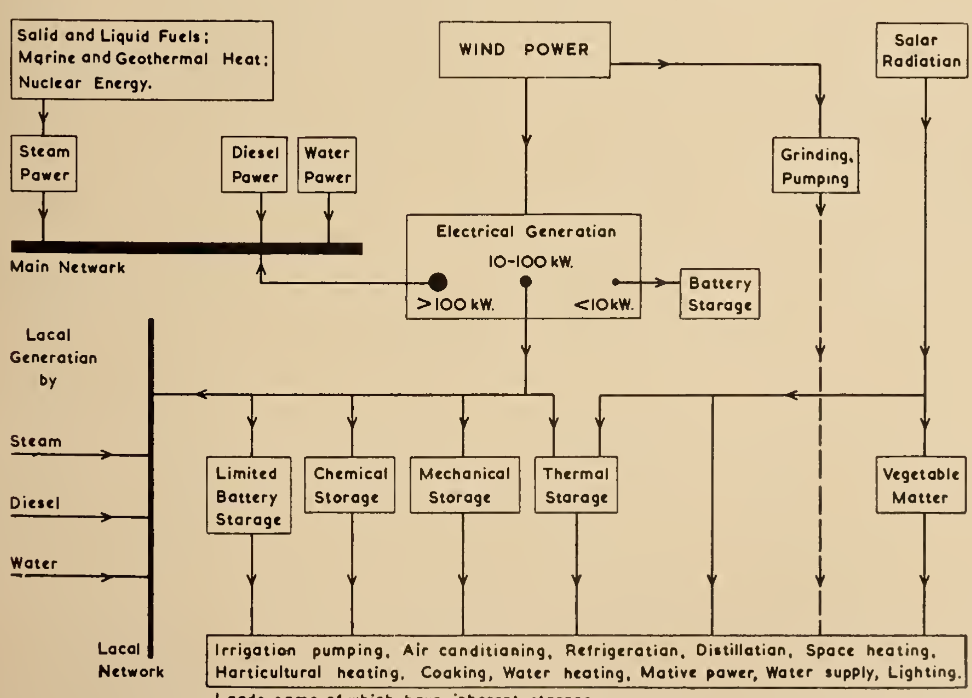


Fig. 8. 100 kW wind-driven generators.
(a) Generator installed on Costa Hill, Orkney (above).
(b) Andreau-type generator at St. Albans, Herts.

The economic possibilities of using such medium-scale plant as a fuel saver, associated with Diesel generation, are illustrated by a curve in Fig. 6 which gives the variation in the costs of wind-generated energy, on this scale, for sites with different annual mean wind speeds. The fuel component for Diesel generation may vary over the range 0.9d./kwh. (where fuel prices are normal) to about 3.7d./kwh. (at places where heavy transport charges cause the fuel cost to be high). From this curve it appears that the economically usable mean wind speed may be anything from about 10 m.p.h. upwards according to the generating conditions.

The costs for random wind-generated energy in this scale seem reasonably low, but if battery storage is provided to cater for even one-fifth of the annual energy to be supplied through it, the total capital charges will be approximately doubled as will also the total cost per kilowatt-hour of energy. Regarded in another way, the energy supplied through the battery will cost at least six times that for the energy which is supplied direct. The uses to which the output of medium-size machines might be put, with or without storage, are shown in Fig. 7. It might be fed direct into a local network which is supplied from another main energy source, and, in addition or as an alternative, it might be used with one of several forms of storage. Only limited battery storage to supply lighting and other small essential loads would be envisaged. The other loads would usually provide their own storage in chemical (electrolytic), mechanical (water pumping) or thermal form or would be such as could be supplied at random times without calling for storage. There may be scope for the hydrogen-oxygen fuel cell as a means of storing wind-generated energy if a practical and economic form of cell results from present researches on the subject.

In some places where communities are established in under-developed areas having ample sunshine, solar radiation would be combined with wind power, particularly for heating and cooking.[17, 18]. Another possibility is the use of waste vegetable matter as fuel, for example, in the small steam engine, the development of which has been sponsored by the National Research Development Corporation. Water pumping without the intervention of electricity generation is another obvious and commonly employed means of using wind power.

Varied utilization for the loads suggested would doubtless demand some planning to distribute the available energy automatically between them according to a predetermined schedule. Thus, for example, when the batteries for supplying the lighting load were fully charged, the generator output could be used for water pumping. This duty, in turn, could be succeeded by a heating load employing thermal storage. Relays, time switches or other physically-sensitive elements could be used for such control, which would appear to be a fairly straightforward matter from the electrical point of view; the planning of the controls to suit the users' requirements would be more difficult.

Large-Scale Utilization [19-22]

Wind-driven a.c. generators used in connection with main networks have the function of fuel savers. Up to the limit of the minimum power demand on the system — a limit high enough to provide ample scope for wind-power development — the output can be fed direct into the network to be used without any question of storage. Clearly the cost per kilowatt-hour of the energy so generated must not exceed the fuel component of generating cost by steam. At present this is about 0.41d. per kilowatt-hour in Great Britain, and from the curve in Fig. 6, a mean annual wind-speed of 18 m.p.h. or more at the site would thus be required for economy of wind-power utilization. This curve is based on a construction cost of £55 per kilowatt for the wind-power plant (which is thought to be reasonable for the largest size of aero-generator built in quantity) and on annual charges of 8½%.

In such estimations it is assumed that the network is sufficiently extensive for the output from large aero-generators, of unit capacity perhaps between 2,000 and 3,000 kw. and built in groups, to be picked up without very high transmission costs between the sites and the network.

It is perhaps worth noting that wind power might be combined very satisfactorily with hydro-electric power. The annual energy output from 500kw. of wind-power plant located at a site where the specific output is 4,000kwh/year/kw. would be equivalent to the potential energy of some 200 million cubic feet of water at 400 ft. head. If adequate water storage were available, some firm power value might be allotted to the wind power through the additional hydro-electric generating capacity which might then be installed justifiably.

Conclusions

To those investigating the possibilities of wind-power utilization it proves a fascinating subject which, admittedly, engenders enthusiasm not unmixed with optimism. Within reason, however, these are not harmful qualities and there are times, in the pursuit of such an elusive quarry as the wind, when they may be useful. There is much to be done before wind power will be able to take its full share in the world's annual production of energy, but the author and his associates in this work do not see insuperable difficulties in the way. In their view, also, the contribution which wind power could make to power production, while certainly limited, is much greater than has been suggested recently by some writers who discuss it as merely an interesting possibility.

Acknowledgments

In conclusion, the author would like to thank the Director of the Electrical Research Association for permission to present this paper and to express his gratitude to his colleagues who have played so large a part in the research work which has been described.

A Plan for Ontario Highways

A limited edition of a report by the Ontario Department of Highways, described as an engineering analysis of needs on King's Highways and secondary roads, is an exceptionally well-presented publication as well as an indication of the active concern of that province with its highway system (a concern that might well be emulated in other parts of the country).

The report summarizes the results of intensive engineering studies carried out over the two years 1955/56 and is intended as a basis for future planning and expansion that is considered necessary. Presented in five chapters and an appendix, the report shows the inadequacy of the system in relation to population and economic growth, discusses the problems of financing highway work, and goes on to outline a functional classification plan of the highway system into three major classes: freeway highways, and feeder highways. On the basis of the proposed system, plus additional routes for which the province is responsible, a factual engineering appraisal of the needs was prepared. This indicates deficiencies that should be remedied immediately.

As an example, the analysis revealed that 44 per cent of the 8600 miles of King's Highways should have immediate improvement. Of the 1284 bridge structures on these highways, 30 per cent were deficient in width or load-carrying capacity. Of the secondary roads, 60 per cent of the 2400 miles were intolerable because of insufficient width or poor surface condition.

The report is well illustrated with maps, pictures, graphs and tables, and other presentation of data.

Trends in Professional Compensation

Dr. Edward B. Peck

Rutgers University

Presented at the Engineers Joint Council General Assembly, January, 1957.

THERE IS A great deal of interest in engineers' and scientists' pay. The American Chemical Society published a salary survey in 1955 and the Engineers Joint Council presents this survey in January 1957. There have been a lot of publications on the subject that emphasize "telescoping salaries". This means that engineers' salaries do not grow with experience as much as they used to. A similar "telescoping" is observed in merit differentials. This exemplifies what has happened to all middle class salaries. Most of the upper middle class has been squeezed by the social and economic levelling in our economy. Productivity and wages have been rising rapidly, while top salaries have, until quite recently remained static. This has produced the squeeze or telescoping that has reduced experience and merit incentives.

The full paper presents an analysis of engineers' salaries from 1939 to 1956 in relation to the important economic factors: productivity, wages and consumers' costs. It proposes a framework of salary administration that takes account of the factors, experience, merit and the economic trends.

The paper concludes that engineers' salaries have not kept up with national productivity and wages. Probably most upper middle class wages have reacted in much the same way. There are, however, no sound data comparable to that of Engineers Joint Council, except that of the American Chemical Society.

This condition is largely attributed to the attitudes on salaries that prevailed up to about 1952. Salary and wages increases were related to cost of living and cents per hour rather than a percentage increase. Since 1952 the percentage principle seems to prevail.

This is a condensation of a paper presented at the Engineers Joint Council Third General Assembly, in January 1957. The Engineers Joint Council published the results of their salary survey at this meeting.

Another factor in holding down older engineers' salaries was the failure to separate general raises from merit and promotional raises.

It is proposed that salary administration recognize and take account of three independent factors. The first is the secular trend or general increase that is granted to all without regard to individual experience or merit. The next factor is experience, which must be taken account of throughout the whole career. The percentile curves (described below) suggest this trend. Finally, there should be re-established a merit differential that has real incentive value.

A pattern for pricing different degrees of experience and merit is proposed. It is reduced to formulae that start a salary policy, and provide flexibility for changes due to the secular trend.

The graphical treatment of the subject is dealt with in the following sections.

Engineers' salaries, 1956

The 1956 Salary Survey of the Engineers Joint Council, for engineers employed in industry (rather than in government or education) is summarized graphically in Figure 1. The coordinates are salary in current dollars per year and experience is measured in years from first or bachelor's degree (YFD). The curves show the percentile salaries as they vary with experience (YFD). The top line represents the minimum salary of the top 10% of engineers as it varies with experience. The lower lines have the same significance for the other percentiles.

These percentile curves mark out merit levels. Any engineer can spot his 1956 salary on this graph and know what percentile his salary falls in, and he can relate this position to an evaluation of his performance and potential. (Of course there are a lot of correction factors to be applied; for example, all industries do not pay equally well.)

The horizontal lines at $8,300 and $7,600 represent craftsmens' pay. It is considered appropriate to compare engineers' salaries with craftsmens' wages because they are alternate careers for young men capable of becoming engineers. These are the rates in this area for the building trades. They are $4.00 and $3.65 an hour for one year at full time and without overtime. Certain highly skilled crafts in industry are paid

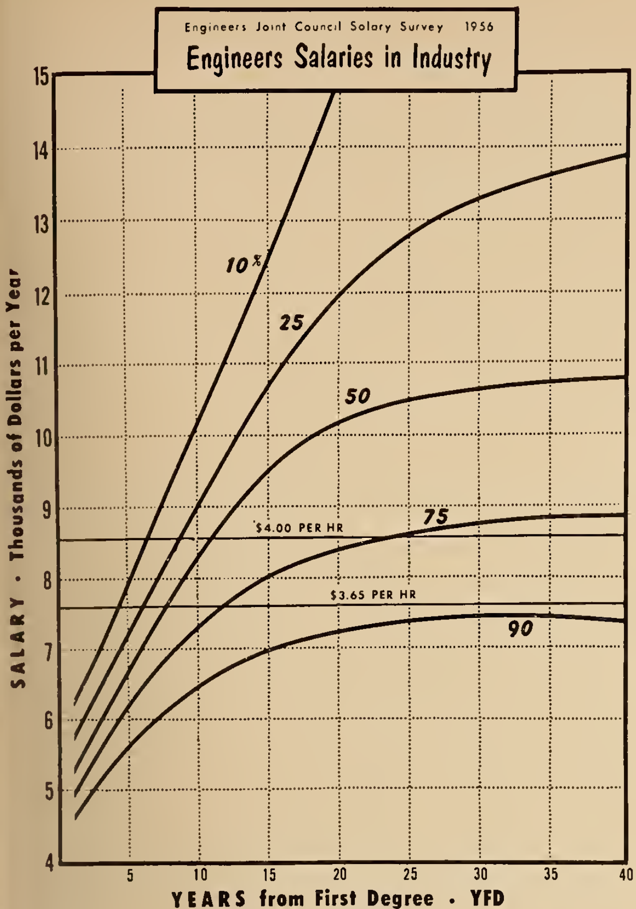

Fig. 1

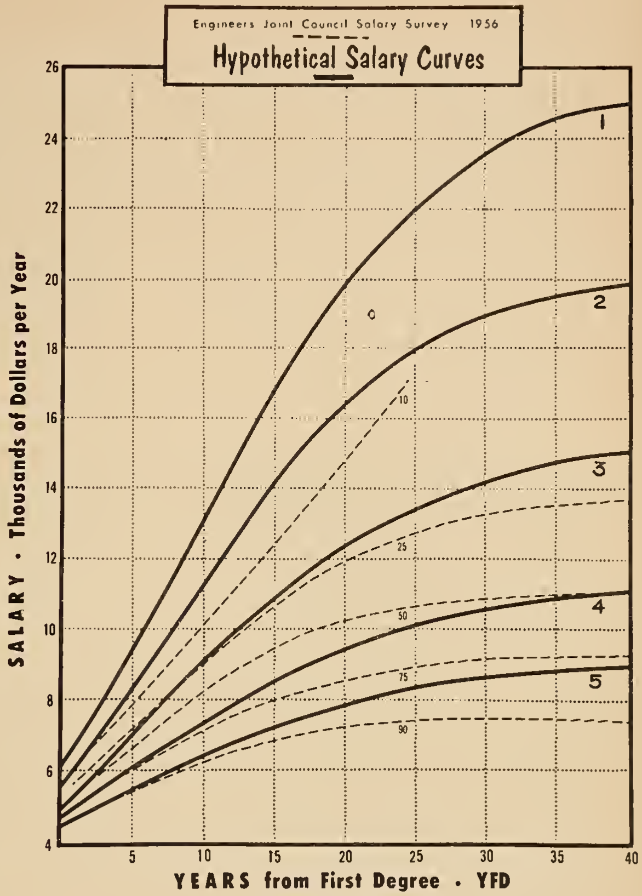

Fig. 2

this much or more, but the statistics are obscured in average hourly rates of industry.

The median salary curve for engineers intersects the craftsmens' wages at 7.5 and 10 years' experience. This means that the average engineer is 30 years old before he catches up in pay with the carpenter and electrician, and it takes two and a half more years to catch up with the plumbers and bricklayers. When the pay represented here is integrated over a career of 43 years (age 22 to 65), the median salary of engineers exceeds the carpenters by about $80,000 and the plumbers by less than $50,000. This is not an attractive return on the investment for an engineering education.

Comparison should be made with management salaries, but the data are limited. It is likely that some elements in industry have done this. Two developments suggest this. First, chief engineers have moved up to be vice-presidents where before they reported to one. Secondly, some companies have adopted parallel levels or advancement that recognize professional competence on a par with executive competence.

A Pattern for Merit and Promotional Salary Administration

A variety of plans have been developed for using a salary survey as a guide in salary administration. The following analysis is based on a plan that has been moderately successful for ten years.

The survey (Figure 1) shows salaries at a particular time; and it shows relationships for merit and experience at that time. When a general salary adjustment occurs, as with wages, and without regard to merit or experience, the survey and salary chart are obsolete. A new one must be made. It is therefore desirable to have a formula for making each succeeding chart.

Salary curves run for a whole career of 40 odd years, and salaries increase with experience for the whole period. It is presumed that the main purpose of merit and promotional raises is to provide incentive for improved and sustained productivity. These incentives should be provided for the whole career.

The curves are guides for distributing merit and promotional raises over a career. They are much clearer than some of the traditional guides. Furthermore, when the curves are expressed as mathematical equations, they can be translated into clear statements of policy.

The next problem is to develop a rational and equitable system for all levels of merit. The analysis of earlier surveys together with an analysis of annual merit and promotional increases as a function of experience, showed that several equations could be used. The one selected says that at any merit level, the annual rate of salary increase is proportional to the salary, multiplied by the amount of money left for salary increases for the rest of the career. This is how the potential idea got into salary administration. These salary curves suggest that each curve is aimed at a goal which is a potential for the employee. This potential had been, perhaps, an unconscious factor in salary administration. This analysis made it a conscious factor in merit rating and professional development. It does not mean that an employee is tagged with a potential early in his career and has to live with it. Periodic merit ratings and performance reviews change these potentials.

The mathematics of this statement is as follows:

$$ds/dt = k\,S\,(A - S)$$

where "S" is the salary, "t" is the experience, in YFD in years, "k" is a constant computed for each curve from the end conditions. "A" is the potential salary or asympote of each curve. The value "A" in relation to the final salary at 40 YFD determines the distribution of raises between the first and second half of the career. Experience shows that when "A" is 3% above the final salary at 40 YFD, theree is good distribution.

The equation is integrated to:

$$\log \frac{A - S}{S} = \log \frac{A - So}{So} - kt$$

And this is the equation of the curves. (This equation is also used to express a variety of other forms of growth).

A set of curves has been calculated as presented in Fig. 2, running from the starting salaries in the survey to $25,000, $20,000, $15,000, $11,000, and $9,000 respectively at 40 YFD. In practice the curves might run from starting salaries to the maximum salaries of job classifications. This relates the curves to the job evaluation system. It also allows for a definition of potential terms of job specifications.

The slopes of these curves which show the annual salary increase along these curves are shown in Fig. 3. It is interesting to note that these slopes of the curves rise to maxima fairly early in the career. In this sense they conform to the productivity curves for outstanding intellectual people as shown in Lehman's book "Age and Creativity".

Henry J. Cambie — Explorer Surveyor Engineer

Canada stands today on the threshold of greatness. When the path to that threshold was still through the wilderness, during the turbulent years which followed Confederation, the political leaders realized the part transportation would play in welding together this new nation, spanning a continent. Their names are history, for they were the dreamers, the planners, the money-raisers. But there were others — who put substance in the deams, translated the plans to reality, got value for the money.

One of these was Henry John Cambie, explorer, surveyor, engineer. His colleagues of a later generation have chosen him for recognition by dedicating a testimonial tablet to his achievement at the Annual Meeting of the Engineering Institute of Canada in June, 1957.

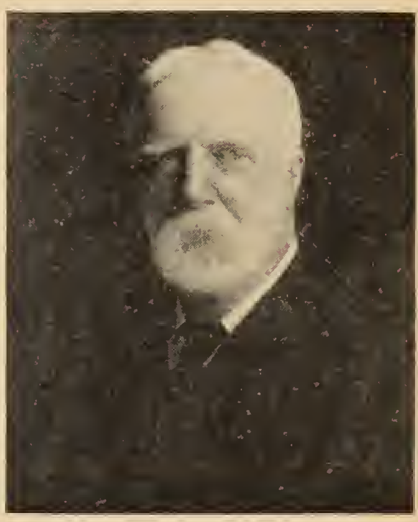
The achievement was the part which Cambie played in locating, surveying and supervising the construction of the Canadian Pacific Railway through the Fraser River canyons. This was the climax, but not the end, of a long and distinguished career which lasted sixty-eight years. From the day of his arrival in Canada, Cambie had prepared for this achievement as inevitably as the waters of the Fraser found their way to the sea.

Henry J. Cambie was born on October 25, 1836 at Castletown, the family estate in County Tipperary, Ireland. He came to Canada with his parents and brother at the age of sixteen. Soon after his arrival, he joined the office of the Toronto and Guelph Railway. From 1853 to 1859 he worked for Gzowski and Co., contractors who were building the western part of the Grand Trunk Railway. He then worked on surveys for the Upper Canada Government and qualified as a Land Surveyor in 1861. He conducted surveys and explorations for the Intercolonial Railway in Quebec, Nova Scotia and New Brunswick from 1863 to 1866. His next job was to survey and supervise the construction of the Windsor and Annapolis Railway in Nova Scotia until 1868.

It was during this period that he courted, won and married Miss Helen Elizabeth Fay. The wedding ceremony took place in Bridgetown, Nova Scotia in 1870. Born in 1848, his bride was educated in Halifax and Boston. She died in 1900.

Canada was still young when British Columbia entered Confederation in 1871. In the negotiations which preceded its entry into Confederation, the new province had stipulated that a transcontinental railway should be built. There were many political considerations. Among them was the question whether the railway should be privately or publicly owned. Sir John A. Macdonald, the proponent of the privately-owned railway, lost the election because of a money scandal involving the contributions to party funds by the syndicate originally formed to build the line. When, three years after British Columbia entered Confederation, there was still no evidence of a start being made on the railway, the premier of the new province protested bitterly. It was then that the Ottawa government proposed immediate construction of a railway — from Esquimalt to Nanaimo on Vancouver Island.

Cambie was sent to British Columbia in 1874 to take charge of this work. But the new province would not be sidetracked and refused to accept the substitute. The project fell through. Sandford Fleming, the chief engineer of the proposed transcontinental railway decided to take a leave of absence. Marcus Smith, in charge of surveys in British Columbia



HENRY J. CAMBIE, M.E.I.C.

returned to Ottawa to replace Fleming. Cambie replaced Smith and took charge of surveys and explorations in British Columbia.

The same year, Cambie visited Burrard Inlet to examine its possibilities as an ocean terminal harbour for the proposed transcontinental railway. One of his recollections of the visit was of being called a "damned fool" for thinking of Burrard Inlet in that connection. There was more opposition to come a few years later.

From 1876 to 1878, explorations and surveys were made continuously under Cambie's direction through all the passes in the Cascade Mountains, from the Pacific coast toward the Yellow Head Pass. The route from Burrard Inlet, via the Fraser and Thompson Rivers, was selected as the most favourable. As already mentioned this choice was not without opposition, as recalled in Mr. Cambie's reminiscences:

"In 1877 while I was in charge of a survey of the line from Yellow Head Pass to Burrard Inlet, the chief engineer, Sir Sandfold Fleming, applied to the Admiralty for reports on the various terminal ports in British Columbia, which it was possible to reach with a railway line, and more particularly on Burrard Inlet. These reports were to be by some of the naval officers who had charted the Coast, many years before, and were then, most of them, on the retired list with the rank of admiral. The naval officer (admiral) then in command at Esquimalt was also asked to report on these harbours. He consulted with people on Vancouver Island who were personally interested in, and partisans of other routes, and by their advice, he made a trip to Yale and the Fraser canyons, and reported that he had inspected the line and could state from personal knowledge, that it was impracticable for a railway. Also that he had been advised to the same effect by prominent engineers and that it was therefore useless to report on Burrard Inlet as a terminal harbour for that line, so he passed it over without a report."

In 1879 the Minister of Railways and the chief engineer decided to postpone construction for another year. Cambie was charged to make as comprehensive a survey as possible of the Peace River country. One of the purposes of this survey was to establish once and for all if the route selected was the right one.

Even as late as 1880, when construction began on the western end of the line, the route to be followed by the railway from Winnipeg to the coast was still in doubt. Sir Sandford Fleming's report of 1880 still showed the route across the prairies angling north-westward from Winnipeg, to pass through Battleford, then considdered the capital of the territories between Manitoba and British Columbia. Yet by December, 1882, the railway had reached the spot which became Moose Jaw and was soon to reach Calgary. The route through the Fraser River canyons, notwithstanding the opposition from many quarters, was chosen.

When talking to the reporter from *McLean's Magazine* in the early 1920's of his experiences as a railway builder, Cambie said: Please make it very clear that, though I explored and surveyed and planned the whole course of the C.P.R. through a large section of the Province of British Columbia, the only part that was built under my direct supervision was that which runs through the canyons of the Fraser."

CONSTRUCTION THROUGH THE FRASER RIVER CANYONS

The route was chosen. The railway would go through the Yellow Head Pass, via the Thompson and Fraser Rivers to Port Moody at Burrard Inlet. Tenders were immediately called for the construction of 128 miles of line to extend from Emory's Bar to Savona's Ferry at the outlet of Kamloops Lake. The job was divided into four contracts, awarded to separate bidders. An enterprising young contractor, Andrew Onderdonk, bought out these contracts. The job was on.

Cambie, who had explored and surveyed the route through the Fraser River canyons and recommended its choice, was appointed engineer in charge of construction for contract No. 60, from Emory's Bar to Boston Bar, which covered the most difficult 29 miles through the canyons.

When Cambie and his engineers had laid out about two miles of line, using four-degree curves and one per cent grades, he received a telegram from the chief engineer to "Locate the cheapest possible line with workable curves and grades". Work stopped. Cambie and his engineers re-examined the terrain in light of the new instructions. While the grades were not increased, the maximum curvature was increased to eight degrees to reduce the number of tunnels as much as possible while maintaining the curvature within the limits considered necessary for a transcontinental railway. Grasshopper trestles, later replaced by retaining walls, were used extensively to reduce excavations and fills.

Labour difficulties were the contractor's headache but they could not help affecting the work of Cambie's engineers who laid out and supervised the work. According to Cambie, "Employment agents in San Francisco sent up men who had never done a day's work before and we often saw broken-down bar-keepers, or men of that class, in cuttings, with fashionable but shabby clothes and perhaps patent leather shoes." Early in 1882, Onderdonk had two shiploads of Chinese coolies sent in, one thousand to each ship. They looked healthy enough when they reached the work site but many soon developed scurvy and the mortality rate was high.

The work was dangerous. The terrain was itself hazardous to work in and the danger was increased by dynamiting and the difficulty of finding safe cover when blasts were set off. There was clumsiness and carelessness.

As work continued the quality of the labour force improved. Cambie was later surprised "at the great number of them who were well-informed men who had drifted through most parts of the world, many of them highly educated. They were good workmen too". The contractor paid good wages, $2.00 and up per day. He provided good sleeping quarters and meals.

Construction through the canyons was completed in 1884. Cambie, who had then been in the service of the federal government in B.C. for ten years, joined the staff of the C.P.R. to take charge of construction from Savona eastward to Shuswap Lake.

As in the Fraser canyons, where one engineer lost his life in 1881, laying out the line was difficult. Cambie recalled that "Quite a stretch of it was laid out by a very small proportion of our engineering staff, consisting of two sailors, who strung ropes from rock to rock or from tree to tree, and a few engineers, who, steadying themselves with these ropes, went along in their bare feet to lay out the work, with a precipice and then Kamloops Lake of unknown depth immediately below them." The tracks from the West met those from the East on November 7, 1885, at Craigellachie, 350 miles from Vancouver.

The occasion was marked by a morning ceremony attended by Sir Donald A. Smith (later Lord Strathcona), Sir William van Horne, Sir Sandford Fleming with Marcus Smith representing the federal government, M. J. Haney representing the contractor, and Cambie and Rogers representing the railway engineers. The photograph of the ceremony, usually titled "Driving the Last Spike" has probably been reproduced more times than any other Canadian picture. It is in many books of Canadian history. The practice, then prevalent in the United States, of using a gold spike for the ceremony was not followed. In his poem "Toward the Last Spike" E. J. Spratt described how Donald Smith missed his first swing with the sledge-hammer, bent the spike and had to call for another which he drove home successfully.

The biggest part of the job was done. From 1886 to 1903, Cambie was Pacific Division engineer for the C.P.R. Early in 1886, the company decided to extend the line from Port Moody, the Pacific terminus by statute, along the shores of Burrard Inlet to Coal Harbour. He supervised the building of this extension as well as the construction of the first wharves and terminals. He also superintended the replacement of wooden bridges with steel and masonry and of most of the grasshopper trestles with fills and retaining walls. The branch lines built to New Westminster in 1887 and to Nicola in 1906 were also his work. In 1903, he became consulting engineer for the company and continued in that capacity until his retirement in 1920. He had been at work for almost sixty-eight years.

"I've been working on the railroad
All the livelong day.
I've been working on the railroad
To pass the time away."

Whether or not he ever sang this ditty, Cambie had done more than pass the time away.

PERSONAL GLIMPSES

Though there may be no place in a factual report for personal glimpses and reminiscences, a biographical sketch confined solely to relevant fact might as well describe a machine. Cambie was a man. According to one of his surviving colleagues, T. E. Price, Life M.E.I.C. of Vancouver, Cambie was a "great and good engineer and MAN!"

He took an active part in community, church and professional affairs. A memorial tablet, erected by the congregation of Christ Church in Vancouver gives evidence of the work he did for the church. He became a member of the Canadian Society of Civil Engineers, later to become the Engineering Institute of Canada, in the second year of its existence, 1888. He served on its council for five separate years. Two of his papers were published in the *Transactions.*

His paper on "The Fraser River Bridge" appeared in the *Transactions* of 1891. The following excerpts from that paper may startle his colleagues of the 20th century, who may think that rush jobs were unknown before the turn of the century.

"The work was started rather hurriedly, only four days being taken to prepare a plan and specification, and contractors having only three days in which to tender, nevertheless the work has not been materially altered since its commencement."

"The chief difficulty lay in designing piers of moderate cost which would be safe in winter when there is thirty-five feet of water, a current of two and one-half miles an hour and at times ice which shoves with great force, and in summer when there is fifty-nine feet of water, a current of five miles an hour and driftwood coming in tangled masses, sometimes nearly an acre in area, as well as trees of great size."

His second paper on "An Unrecorded Property of Clay" appeared in the *Transactions* of 1902. This dealt with the loss of cohesive properties in thoroughly dried clay subsequently wetted again. The author recorded that it became "almost a liquid mud". Clay which had not been so dried would not absorb any more water and would lose "only some of its outside particles in the washing". The experiment used to demonstrate this property was a model of simplicity:

"When a block of this dry indurated clay was placed in a soup plate and water dropped upon it, the clay absorbed 50% of its own weight without any change of form or other visible effect, but when it had absorbed about 60% of water, its structure completely collapsed, and it became as fluid as water."

The results of the experiment were used as evidence in a lawsuit in which the C.P.R. was involved, dealing with the incidence of landslides in clay soils.

Some of Cambie's experiences, particularly during his work as an explorer and surveyor, are worth recounting briefly. They give some indication of his character and of his sense of humour. In the early days of the West, encounters with Indians were part of the surveyor's life. Some of the encounters were amusing, others were frightening.

About ten years before his surveys through the country of the Chilcotin Indians, a party headed by a Mr. Waddington had deeply offended the Indians. When they returned to their camp the following spring, the Indians one night waited until the camp was asleep and, dropping the tents on the sleeping men, stabbed sixteen men to death while they were tangled in the canvas. Only one survey party, armed and accompanied by a magistrate, had been through that part of the country since the massacre, and had seen little of these Indians. Cambie's experience with them is recounted in his "Reminiscences" which appeared in the October, 1920, issue of *The Engineering Journal*, in part as follows:

"Before making an actual survey, I went for a four or five days ride into the Pass, accompanied by Mr. M. Eberts, my assistant, and a couple of packers, a Frenchman and a Mexican. We took with us some blankets, clothes and tobacco as presents for the Indians if we should meet any. On our second day out from the main party, we found a band of thirty or forty Indians camped on a sandbar between a lake and a swamp and putting up (smoking) fish for the next winter. We offered them presents which they scorned, ordered us to turn back, and one man got up on a stump, gesticulated wildly and made a most impassioned speech. So we packed up our presents and proceeded on our way for another couple of days ride.

"On our return, about three days after, we passed over a mountain spur about two miles away from the Indian camp, and could see them on the sandbar, men, women and children at their various occupations. When we reached there, however, every soul had disappeared, even the horses and dogs—and though often there afterwards, I never discovered where they had gone.

"Our pack horses were running loose and I called to the packers to lead them by the halters, which they did, as the Indians were evidently very hostile and might stampede them. So we passed on quietly and had gone, say a couple of miles further, and were in a narrow defile between two hills and riding in single file, when I heard a noise behind and on looking back saw a dozen or more Indians coming full gallop on horseback, with very scant clothing but each one armed with a Hudson Bay Company's musket, having a barrel over three feet long and a knife or some other weapon in a belt—when they came close they opened out into two columns, one passing at each side of us, and when the last man came even with me they stopped dead, throwing their horses on their haunches. No one spoke—we kept on our way, a fast walk, and soon left them behind. I confess that, knowing these men to be of the same families who had murdered Waddington's party ten years before, it gave a cold chill down my spine, but I kept outwardly calm, knowing that any sign of weakness would be very bad.

"When we had travelled another mile or two, our friends repeated the operation, and when they pulled up next to me, one of the Indians opened a conversation in "chinook" and said they would accept the presents offered them five or six days before. This I absolutely refused to consent to, and stuck to it, notwithstanding sundry threats, but on the advice of a priest who came to visit them a few days later, consented to hand them over."

"Chinook" was the universal language of the day, consisting of approximately 200 assorted French, English, Spanish and Indian words. Cambie reported that he had had people speaking five different languages in survey parties of twenty or twenty-five and that the only way to communicate was by using Chinook.

He also recalled an excursion into the occult when he was asked by a group of Indians for a demonstration of Hell. This is how he reported it: "A number of the men came to my camp one Sunday, shortly after, and told me they had come from Mr. Jennings' camp, thirty miles away, to ask me if I believed in Hell, as it had been described to them by the priest and illustrated by Mr. Jennings. On being pressed for an accurate description it appeared Mr. Jennings had burnt something in a soup plate, which I afterwards found to be brandy, and as it was in a brilliant sun they could not see the flame, though its burning power was good. I backed up Jennings' description, and gave them a similar exhibition to their very great satisfaction."

Other reminiscences were reported in the articles published in *McLean's Magazine* in the winter of 1923-1924 under the title "Blazing Trails in B.C." written by Noel Robinson. Perhaps one of these should be recounted here, not because it was spectacular or amusing, but rather to indicate how Cambie felt when he thought he had been abandoned by his party, with winter fast approaching. The incident occurred during his survey of the Peace River, the Skeena Valley and the Pine River.

This is part of the story, as Cambie told it to the reporter:

"I arrived at Hudson's Hope as intended, but found that the spurs of the mountains reached out forty miles farther to the eastward, so attempted to go straight south by way of Moberly Lake. There I found a hunter named Armstrong with a good outfit of all that a hunter needs, and, as we had got into a country with a good deal of fallen timber, I induced him to come with me for some days and help to cut a trail to get the horses through. After three days' travel, in the course of which we had made, perhaps ten miles, we got into a cul de sac.

"So I got Armstrong to remain with me while I sent my two men forward on foot to find Pine River and the main body of my pack train. We were getting very nervous, as it was the end of September and winter was approaching rapidly; so after remaining two days and the men not returning I left Armstrong to watch my animals and climbed up some steep hills in front of me. When I reached the top of a ridge which blocked my way it turned out to be only fifty feet wide and dropped into a valley which was far below. I knew this must be Pine River, and as the men had been so long away, I feared that they had waited for me as long as they had thought judicious and had then deserted me. I determined to find out and started down the hill. When I got some distance down I thought I heard a bell such as packers put on their horses. But I was excited and out of breath and could hear nothing clearly but the beating of my heart. The same thing occurred several times before I reached the bottom and I began to wonder what was the matter with me. Finally as I got to the bottom of the hill, I felt confident again that I heard a bell. Suddenly I stopped in astonishment. There was the whole pack train of about forty horses in front of me! I gave one great war-whoop that would have wakened the dead.

"A few minutes before I had made up my mind that if the men had passed I would go back to Hudson's Hope, kill one of the animals, as I was almost out of food, make a raft and drift down to Dunvegan and make my way to Fort Garry by the Spring. But the risks of such a proceeding so late in the year, with a scarcity of food, would have been very great."

Other stories and anecdotes may be found in the original articles and in his "Reminiscences".

RECOGNITION AND HONOURS

After his retirement from the C.P.R. in 1920, his services were retained by the company in an advisory capacity. A station on the company's main line was renamed Cambie during his lifetime and a street in Vancouver was also named after him. The Vancouver Pioneers Association presented to him the Hudson's Bay Company medal, an award made to the pioneer most worthy of the honour. Perhaps the greatest tribute paid to Cambie was the respect and affection he received during the last years of his life. For it had been such that there was no need to let tempers cool or to allow time for injuries and hurts to heal before honouring him.

When he died on April 23, 1928. at the age of 91, he had earned and kept the respect and affection of those who knew him. Those who remember him still are proud to have known him, for he was "a great and good engineer and MAN!".

E.I.C. TABLET DEDICATED

This is the inscription appearing on the Engineering Institute plaque honouring Henry J. Cambie:

In recognition of the outstanding engineering achievements of Henry John Cambie, M.E.I.C., 1836-1928, whose surveys and explorations determined the location of the Canadian Pacific Railway through British Columbia and who supervised its construction through the Fraser River canyons, 1880-1884. Erected and dedicated by The Engineering Institute of Canada, June 1957.

Amplifying the Baccalaureate Education

A panel discussion held as Session 4 of the joint Conference of the American Society of Mechanical Engineers and the Engineering Institute of Canada, University of Western Ontario, October 1956

H G. Conn

Dean of Engineering, Queen's University, Moderator of the Session

You may all recall from your early school days that you had a burning desire to learn about things not taught in your engineering classes. Many of you longed for time to just sit and think. I have had students who claim they could become interested in almost any subject including Religion, Theology, Art, etc., if they were not so busy. Many of them deplored the fact that they did not have time to go to a few concerts, to read a really good book or to study an interesting biography.

All this hustle and bustle is caused by the pressure imposed on the student by our engineering educational system. As such, it is considered to be beyond the control of any one particular person and is accepted as inevitable. There are sufficient murmurings to indicate that there is something amiss.

When the student graduates he shakes off the shackles and finds that he can now do as he wishes. Never again will he open a book. He will go to work, do well at the job for which he has been so well prepared, quit at 5.00 p.m. and enjoy life. It may take a full year for this new graduate to realize that this type of life is very boring and soul-destroying. He wakes up some morning and realizes that he knows little more than he did a year ago except maybe where the first-aid room is and a little about the day-to-day operation of the plant.

It is at this phase of his development that the graduate engineer becomes conscious of the need to "Amplify his Baccalaureate Education".

I think that three distinct channels present themselves as offering opportunities for positive action in the solution to his problem.

(*a*) Further study of technical matters.

(*b*) The study of non-technical subjects associated with his work, e.g., economics, marketing, sales, personnel work, corporation finance, etc.

(*c*) The study of things not associated with his life as an engineer but designed to round him out, make him a more useful citizen and a better parent—in other words, pursue those fields of which he had fond dreams as a student but which were denied him due to the inevitable time element.

I hope that the Panel will cover some or all of these channels of endeavour.

Cornelius Wandmacher

Head, Dept. of Civil Engineering, University of Cincinnati

Perhaps the most distinctive characteristic of a professional man is his continuing interest in education as a medium of personal growth. But interest alone on the part of an individual is not automatic. Even when it exists, it is not in itself sufficient.

What then must we do to insure the necessary stimulus for amplifying the baccalaureate education? The following steps seem essential:

(1) To instill in the undergraduate a spirit of initiative and self-reliance.

(2) To provide for co-operative educational efforts between industry, education, and the profession in the community where the young graduate begins his career.

(3) To aid the young man to identify and define his educational objectives after graduation.

(4) To foster the concept of engineering as a dynamic profession.

Initiative and Self-Reliance

To be well prepared to "amplify" his baccalaureate education an individual must have had a suitable basic education. Therefore, it is essential for us to consider first what kind of an educational background will serve best in establishing the foundation and framework for later amplification.

Clearly the need is for an educational program which will stress the development of favourable attitudes as much as the immediate attention to subject matter details. The need is for a program which will instill in the student the spirit of initiative and of self-reliance in the educational process. It should be one which will help him see in professional accomplishment the "wholeness" of knowledge, experience, and continuing education.

It is appropriate to stop at this point and consider how this sentiment has been expressed over the years in various reports on engineering education.

As early as 1929 the Carnegie Foundation report pointed out that the most serious deficiency in engineering education was not so much in any subject matter omitted from the college program but rather in the custom of allowing the orderly process of education to stop, where it so often does, at graduation.

Experience in this survey led to the following conclusion concerning the marks of retarded professional development in young graduate engineers:

"Many are victims of a deficient education, not in the sense that college failed to teach them all that they would ever need to know, but rather failed to inculcate in them a taste and a capacity for continued learning under self-direction."

This was one of the first awakenings to the need for continued education on a broad basis beyond the bachelor's degree. Naturally there has been considerable progress in intervening years.

The Impact of Teaching Method

Unfortunately, discussions concerning engineering education more often than not center around the question of subject matter content of the curricula. Only infrequently is full attention given to the primary question of objectives. Even less frequently is due attention given to the most effective means of achieving these goals through appropriate teaching methods.

In 1950-52 the American Society for Engineering Education devoted its principal attention to this matter as a national project. The resultant ASEE Monograph on the Improvement of Engineering Teaching identified the following as one of the major challenges of teaching:

"How to instill in the student the desire to continue to learn after graduation and how to provide a cultural foundation which will encourage him to contribute to his local community as a mature, thinking, human individual."

Laying the Groundwork

In short, this report indicated that a primary task in undergraduate teaching is to lay the groundwork for amplifying the baccalaureate education. It is, therefore, not so much the question of *what* we teach, but more so the matter of *how* we teach, which in the long run will measure our success or failure in these formative years.

Again in the conclusions of the most recent report (1955) of the ASEE Committee on Evaluation of Engineering Education we find a reference to the need for amplifying the baccalaureate education. This statement broadened the base of educational responsibility over that in previous reports. It said:

"The entire educational process is more inclusive in scope than an undergraduate curriculum, for it also includes training in high school and post-baccalaureate study in a university or in industry, along with continual self study and with experience in engineering practice before full professional status can be achieved."

This is the first of such reports to point directly to the responsibility of the employer for education in the post-baccalaureate period.

At this time when faculties are faced with the problem of sharply modifying engineering curricula, they find themselves under pressure from many sides to include one or another subject in the undergraduate course of study.

Amplification — A Co-operative Effort

For this reason it is all the more important to re-emphasize that much desirable work in the way of subject matter fields must be deferred until after graduation. At the same time it is well to point out that the necessary "amplification" of the baccalaureate program is a joint responsibility of industry, the University, and the professional societies of the community in which the young graduate finds his first full-time job.

While each one of the triumvirate —industry, education, and the profession — may be carrying forward a substantial part of a professional development program, the results of a concerted effort integrating the work of all three will be of far greater significance than the results of three separate efforts. This fact has been well borne out by the recent community experiences in Cincinnati and Detroit with the "First Five Years" program of the Engineers' Council for Professional Development.

Professional societies through the medium of meetings and seminars make many important contributions in the task of amplifying the young engineer's educational background.

Identifying Objectives

A question frequently asked is: "What makes the day after graduation different from the day before commencement?"

The most striking difference, of course, is the need for identifying new objectives. While in college the striving for completion of a curriculum and the goal of a degree have given the young man a definite objective, the objective of a group. After graduation the objective must be more individual and more personalized.

Discussing the need for well-identified objectives, James B. Conant brought the matter clearly in focus when he said:

"They represent goals toward which men and women move by concerted action. They never can be reached in practice — almost by definition since they are ideals — but we can recognize whether we are moving toward them or retreating.

"Objectives are not merely goals; they are motivating forces for action; they furnish an incentive, a purpose, and help to chart a course."

Need for Sponsors

It is at this point that the young man must seek a new counsellor to aid him in identifying new objectives for his post-college development program. Personal associations through a "sponsor" plan as developed by many industries and by a number of professional societies can be of invaluable service to this end. With proper guidance in this period the young man may "find himself" more fully than ever before.

In his well-known paper The Second Mile" William Wickenden sounded an optimistic note on the manner of dealing with this problem and put his finger on several key points when he said:

"Much has happened in recent years to strengthen the belief that possibilities in the mile of voluntary advancement are more hopeful than any lengthened mile of compulsory discipline.

"What has been particularly noteworthy is that so many postgraduate students are pursuing interests and needs which they have discovered for themselves in their early professional experience rather than a further discipline, however ideal, which others had imposed upon them."

Engineering — A Dynamic Profession

Contrary to the notion in the minds of many young graduates, engineering science is far from the established, well-ordered, definitive state in which they might wish it to be. Today's answer and tomorrow's answer to the same problem may be quite different. Formulas, empiricisms, even laws and principles have a way of taking on new aspects with every passing day.

In his paper "Objectives of Professional Education" presented at an interprofessional conference, Harry S. Rogers, representing engineering, said:

"In scientific-technological thought conclusions are accepted tentatively. We speak of principles and laws as truth with full realization of the fact that they are conditioned by the present state of knowledge.

"We utilize principles we know to be inaccurate because they are currently the most useful tools available for the solution of practical problems. Knowledge is considered progressive and the current state approves and accepts, or corrects and amends the earlier."

The Hazard of Stagnation

One of the major factors frequently overlooked in the present critical shortage of engineering manpower is the number of engineering graduates who have been effectively lost to the profession. They have become lost because they have become inadequate in the light of recent scientific developments. They have become inadequate because they failed to amplify their baccalaureate education. They have failed to understand that unless we are constantly forging ahead we are in fact falling behind.

In summary we may conclude that for optimum professional growth there must be four supporting elements:

(*a*) An inculcated sense of individual initiative.

(*b*) Opportunity for group activities.

(*c*) Means of identifying personal objectives.

(*d*) The concept of a dynamic profession.

With such supporting elements the continuing education program of any professional group will become self-perpetuating.

Left to right: F. E. Verdin, Management Consultant, Cleveland, Ohio; C. Wandmacher, University of Cincinnati; H. G. Conn, Queen's University, Kingston (Moderator); R. E. Jamieson, McGill University, Montreal; Dr. B. B. Hillary, Research Co-ordinator, Dow Chemical of Canada, Limited, Sarnia.

B. B. Hillary

Research Co-ordinator, Dow Chemical of Canada, Limited

As one of the industrial representatives on the panel I will attempt to give some information as to what industry is doing to amplify the baccalaureate education and at the same time try not to infringe too far on the subject matter of the other panels.

The continuing education of the graduate can take the form of post graduate courses, evening courses, correspondence courses, or special courses such as executive development, all offered by universities. Along with this there are formal courses administered by industries themselves as well as various forms of in-plant training. I shall use as a case example one large American industry with a program that embraces most of these phases of education.

The case example selected is the educational program of the Dow Chemical Company, Midland, Michigan (this happens to be the parent company of Dow Chemical of Canada, Ltd.).

It provides an excellent example of a well balanced program and in some aspects it is unique, but the same conditions could apply to other companies in similar types of locations. Much of the program was made necessary because of the remote and rural situation of Midland, a town with a population of 20,000. In order to develop tradesmen and operators from such a limited labour pool special training courses were necessary. In the case of those wishing technical and liberal arts education it was not practical for them to go eighty miles to the nearest university for night classes. Midland's industries are predominantly chemical, with Dow Chemical having approximately 12,000 employees and Dow Corning 1,400 employees. As is characteristic of the chemical industry a large percentage of the employees are technical; scientists and engineers. All branches of engineering are represented with chemical and mechanical leading.

The Dow Educational Program comprises two main types of education: the Midland Public School adult education program, a co-operative effort of schools, universities and the company; and the in-plant training program for technical and non-technical employees.

To administer this program the company has a large and active educational department. This department is not set up for the sake of teaching, it is a service department. It will not duplicate anything a school or university can do. Its role in the adult education program is one of assistance and co-operation. It will find out what the employee wants and assist the Adult Education Advisory Council in making the arrangement with schools or colleges and, when necessary, give financial support.

Briefly, the Midland Public School adult education program is administered by a full time director who works closely with the extension agencies of the University of Michigan at Ann Arbor, Michigan State University at East Lansing, Central Michigan College at Bay City, the Midland Adult Education Advisory Council, and the Dow Education Department.

The program has no rigid organizational structure. Courses are added and dropped as dictated by student interest, availability of instructors, space and teaching materials. Courses cover a wide range of subjects from handicrafts to advanced chemical subjects. Cost of the program is borne by the students, who pay fees and materials cost, if any; the Midland School system; and Dow.

The program of courses is divided into four levels — graduate college, undergraduate college, post high school and high school, and correspondence at all levels.

Graduate college level courses are given by the University of Michigan and Michigan State University in technical areas pertaining to chemistry, physics, mathematics, engineering education, and business administration. Some courses are taught by Dow employees, experts in their own right and certified by the administering school. Credit is available for successful completion of such courses ultimately leading to advanced degrees from one of the two universities. In the case of some courses credit can be transferred to other institutions.

Arrangements have been made whereby if a student has taken the pre-requisite evening courses he can obtain a degree from the University of Michigan or Michigan State University by spending a minimum of eight weeks in residence at a summer course. He is expected to utilize his vacation period as part of this time and he receives full pay during his leave of absence. In the case of a student seeking a Ph.D. degree he is allowed one year's leave of absence with income and welfare benefits.

Undergraduate courses are given by the Universities and Central Michigan College. Here a much wider variety of courses, including liberal arts as well as technical courses, is available. Instructors usually come from the administering institutions. Successful completion of some courses gives the individual full college credit.

Post high school and high school subjects are the most popular in the program. Nearly 50 different courses are taught in this category.

Correspondence courses are an integral and important part of the adult education program both at the high school and college levels. In the case of high school courses the Midland High School provides teachers and classrooms and the correspondence school texts, lessons and examinations.

It should be emphasized that students on the adult education program spend fully as much effort and time for a given course as does a student normally enrolled in the administering institution. By law the number of class hours is the same.

In the past year approximately seventy-five different courses were taught in the adult education program and there were 2,039 courses completed. Or, 94 per cent of those starting courses at the beginning of the term completed them. This speaks highly of the ambition of the people and the quality of the courses.

Thus by means of this comprehensive Midland adult education program the engineer can broaden his education not only in technical fields but in vocational training and management development; communications fields, such as public speaking, foreign languages, psychology and personnel; crafts, music, literature and fine arts.

The other main part of the Dow Educational Program, in-plant education, covers maintenance training, powerhouse training, production training, supervisory development, and college graduate training. The approach is to develop special skills required by people to do their job. Here again the Education Department acts as a service department in that it helps line supervisors discharge their training duties, this in keeping with the basic policy of Dow management that training is the responsibility of line supervision.

Through the training available within the company, the graduate engineer can expand his knowledge of human relations and economics, so necessary for supervisory development. By means of the special assignment program, several six to eight week training assignments in various departments, where accomplishment is measurable and each project has a definite beginning and end, the graduate feels he is making a worthwhile contribution while he is becoming oriented within the organization.

Other than the brief mention of a few of the concepts of the Dow inplant educational program no details can be given as time does not allow and the subject matter gets beyond the scope of this particular panel.

Attitude of Canadian Industry

It was considered it would be interesting to have a picture of the practices and attitudes of Canadian industry in respect to the continuing education of the engineer. In order to get this a random selection was made of some thirty industries employing engineers. These represented a cross-section of automotive, chemical, electrical, metal, petroleum, pulp and paper manufacturers. The purpose of the conference was outlined and they were asked if they cared to report on their program for the continuing education of the engineer and what they thought should be done. Had they been presented with a check list of specific questions we would have had more detailed replies in a form that could be compared. However, it was not considered appropriate to ask companies for too much detail of their organization. The response was very gratifying and much interesting information was given. I will review it briefly.

As would be expected there was a definite correlation between the size of the company and the amount of educational activity it carried on. The number of companies in Canada employing large numbers of graduate engineers is limited, thus we do not have as many elaborate programs as we find in American companies. No two companies have the same type of program but some are similar in parts. Each is patterned to meet its own type of manufacture, location, and management philosophy.

Most of the reporting companies have no formal organized plan for the continuing education of the graduate. A few have well developed programs and some are close to having a plan in operation or are contemplating it.

In the field of graduate studies a few companies reported they encourage employees who are interested in continuing their education. In some cases financial assistance is given. This included payment of tuition in full or part and where leave of absence was necessary and salary was not paid employee welfare benefits were maintained.

Evening and correspondence courses were recognized by numerous companies as a means by which the individual could improve himself. Where the initiative came from the individual some provided financial assistance ranging from 50 per cent to 100 per cent of the fees. Here, strong emphasis is placed on cultural courses or courses improving the overall knowledge of the employee in addition to purely technical courses.

Most companies send personnel to executive development courses. In some cases this was confined to senior men and in others it included junior executive talent. Types of courses and institutions selected covered a wide range. Some companies are now stressing management development courses that emphasize cultural as well as business training.

Most companies had some form of in-company training program. These range from special training courses run by consultants, to company-operated courses taken by all new graduates as part of their indoctrination into the company. Others have a system of job rotation for the first 12 to 18 months. Some multi-plant companies have found that transfers from plant to plant provide an excellent means of adding to a man's education. Some keep elaborate records of performance on the job, courses taken and other means of employee improvement to determine future promotion. These records are also used to determine what courses are required by the individual for his future advancement.

Most companies support active participation in technical organizations and attendance at meetings to broaden the individual's background. Likewise civic and community committee activities are encouraged.

Some companies hire an engineering graduate because he has the specific educational background for a particular job. Such people are ready to start to work with little or no additional training and as long as they are in design or operational work they are adequately equipped technically to carry out all assignments. If any of these people are of potential management calibre they do need further education along the lines of human relations and management training and are given the opportunity to acquire this.

Several companies state that they consider the undergraduate technical training of the engineer adequate but feel that more emphasis should be put on liberal arts education. They would like to see him get more of a grounding in the humanities and economics in his undergraduate years. Though it is true that during his first few years of employment he draws exclusively on his technical training, he should have some background of ethics or a framework of philosophy upon which to reorganize and develop the economic, political and social relationships which he must have to carry out his job effectively as a supervisor or manager.

From the foregoing it can be seen that the industries sampled expressed widely varying viewpoints on the subject of the continuing education of the engineer. While no definite conclusions can be drawn one thing stands out prominently. Many industries expect to draw, to a large extent, their future management personnel from engineers. They recognize these men must get additional liberal arts and business education to supplement their predominantly technical training. They are concerned with, when, where and how these men can get the necessary education and for this they look logically to the educational institutions.

R. E. Jamieson

Dean of the Faculty of Engineering, McGill University

The needs of the graduate engineer for post-baccalaureate study have been emphasized in much of the previous discussion during this present conference and are, I believe, well recognized by the individual. For the individual it becomes largely a question of the availability of formal courses and of his opportunity to participate. Generally there is no problem when one lives within easy distance of an engineering school. Most schools provide courses in the evening, usually in an extension department. These courses include some which are at the post-graduate level and which in many cases can be used to form part of the training for a master's or higher degree. Others are purely of the extension type and are not acceptable toward degree work.

The people who undertake these courses fall into three broad groups. There are those who are primarily interested in further training, whether in their own field or in new work, and who are not seeking recognition for their work in the form of a certificate or diploma. Then there are those who, while interested in the further training, are also eager for academic recognition in the form of a post-graduate degree. And between these two goups are those whose circumstances permit them to take formal courses in their own fields and at the post-graduate level, but who cannot meet the residence or thesis requirements of the school concerned. I think I can perhaps discuss the problem best by referring to the conditions as I know them at my own school, McGill University, as I believe that our conditions are fairly typical for Canada.

For the first group mentioned, namely, those who are not greatly concerned about receiving academic recognition, there is no problem for the man who can attend at the university during the evenings. He may select any courses he desires, and there are no prerequisite academic qualifications which he must meet. A very large and varied group of courses is available to him.

For the people who wish to do something toward a post-graduate degree by way of evening study, the requirements for admission to such study must first be met. That is, these students must submit academic credentials and secure acceptance by the Faculty of Graduate Studies and Research. All schools have some form of residence requirement, which means, in effect, that the candidate must live within the atmosphere of the university for a period if he is to qualify for that university's degree. In addition, Canadian schools demand a thesis based on independent and original work by the candidate, and in the case of engineering students, this usually involves some experimental work in the laboratories. These requirements cannot be met by evening work alone and therefore constitute a stumbling-block. I might add that the thesis and experimental work are requirements in Canada both at the master's level and at the doctorate level.

McGill has recently made some special arrangements for people of the second group who are able to take the formal course work in the evenings but whose circumstances do not permit the meeting of the residence requirement or thesis. We have recognized that men who complete successfully a group of formal courses which would normally satisfy this segment of the requirements for the master's degree, should have something to show for it. It should be noted that such men are fully qualified for post-graduate study in the field of their choice. Our Senate has authorized the award to such people of a certificate of performance covering their work. We feel that while this certificate is perhaps in danger of being confused with the actual diploma of the master's degree, it is only right that these men should have something of an official nature to show their degree of attainment. For example, we have instituted such a certificate for award after completion of a group of post-graduate courses in aeronautical subjects.

In the nature of things, educational institutions are the most natural agency for giving the formal course work at the post-baccalaureate level, and we are very happy to do it. Our policy at McGill is to put on any course for which there appears to be a real demand, and our only stipulation is that the number of registrants shall be at least sufficient to make the course self-supporting. At the present time we have evening courses at the graduate level in the general fields of electronics and of aeronautics. The former includes some thirteen separate courses and the latter some nine courses. The requirements toward the master's degree would include a selection from one or other of these groups. Situated as we are in a large and highly industrial community, it is natural that we find no difficulty in attracting sufficient registrants to justify the programme.

In addition to formal courses of instruction, the facilities provided by engineering societies through professional meetings, papers, and discussions, are important agencies in post-baccalaureate training. Since local branches of the societies are much more numerous and widely dispersed than are our engineering schools, the numbers who can use their facilities are consequently much greater. And because formal courses are probably the most efficient means of effective training, it might be possible for local branches to expand their educational efforts along that line. This would at least serve the group who do not especially desire academic recognition.

However, neither universities nor local branches can be of much help to the man who is not living close enough to the centre to be able to participate. I am afraid that I have no ideas to offer as to what may be done for such a person in furthering his post-baccalaureate training by formal courses. So far as I can see he will be thrown on his own resources. Perhaps some suggestions along this line may be forthcoming from the discussions at this conference.

Florent E. Verdin

Management Consultant,
Cleveland, Ohio

It has been my privilege to look at our subject from a number of different viewpoints. While in industry's personnel field, I encountered the problem of how to broaden employees with engineering education and experience, so that they might accept the responsibilities associated with supervisory and administrative positions. Along with that problem comes that of appraising the potential of technical employees, and charting a possible course for their development — including education and training in areas not necessarily touched upon in their undergraduate days.

The opportunity has come to me to see this problem through the eyes of the educational institution, through participation in the original planning of two courses, of the management development character, in two U.S. universities. One was the University of Michigan, and the other Case Institute of Technology.

And, a touch of the "firing line" has come to me through participation as a speaker or moderator in university courses of this nature and in various activities of organizations such as the American Management Association.

As a result of these experiences, plus consultations with clients on this matter, it is my conclusion that industry and educational institutions must get ever closer together in their joint approach to building better managers. This is not to imply that much good has not already been done, nor that industry and education are blind to each other's points of view.

However, this problem of amplifying the education of the engineering Bachelor of Science can be likened to that of a purchasing agent in determining what to buy. He first determines the needs, measures stock on hand, and goes out to acquire the difference. The key to the whole matter is in determining the need.

If we can determine the need for additional education and training and agree upon what the objectives are we can provide the means to achieve such goals.

There are three parties to this endeavour: the man himself, his employer in industry, and the educational institution from which he may seek help or to which he may be sent by his employer for further training.

The Individual

Unfortunately, today's competition for the young engineering graduates has created an illusion in the minds of many young engineers. The fantastic starting salaries and employment conditions have developed a picture of a land of milk and honey. I do not say that these young men are in the slighest way to blame for the condition, but it places a handicap upon their future growth. Partly as a result, too many lack the ambition to extend themselves to the full extent of their abilities. Too many refuse to accept the compromise between pure science and economic practicability. Too many become disgruntled upon finding, after the honeymoon, that the economic road for strictly technical personnel has many rough spots.

Then these individuals have the problem of adjustment. Their background of education has emphasized the "engineering approach". This implies the use of a specific set of mental and physical tools to each specific problem and tends to exclude any other approach. In fact, it tends to create a line of exclusive thinking on their part which sets them apart from other trades and professions upon which they look with amused forebearance, to say the least.

This sort of thinking leads the engineer to "stick to his last", to specialize, to ignore other facets of a going business and even to create social strata bound by the lines of the engineering degree. Thus he works to his own disadvantage because the one thing he needs is breadth of viewpoint, experience, knowledge and human relations.

Company Management

As to industry itself, we can draw a long list of possible criticisms. Let's take three important ones.

First, with respect to the shortage of technical and scientific employees, some of it is created by industry itself. Too many technically trained people are assigned to non-technical work. Much of the duty assigned, particularly to young engineers, can be performed by technicians and clerical, stenographic, accounting or secretarial personnel. We must recognize, of course, that part of on-the-job training for the young engineer requires his participating in many of these non-technical tasks to learn the business. However, it is my opinion that not enough technical work is assigned to these young engineers and that not over a tenth of the engineering graduates in industry are loaded anywhere near their mental capacity during their first five years in industry.

This indictment may fall not upon top management but upon engineers who are managing squads, sections or departments of engineers, such as some of you at this meeting. Many managing engineers are slow to trust important assignments to the youngsters until they've had several years of so called "apprenticeship" just because that's the way it was in the "good old days".

Second, let's look at industry's approach to management development courses, a field where much fine progress is being made. A great many companies — like their executives at the 19th hole — talk a great game. They are keeping up with the Joneses; they are sending executives to Harvard; they are up on the A.M.A. reports; they have intra-company programs; they're offering fancy salaries to young engineering graduates through a high-pressure recruiting operation.

But, I suggest, why do they do these things and how much good comes out of them? Perhaps a lot!

However, the mistake of doing these things *only* because they are popular business techniques, propounded by high-priests of business management can be pretty costly. Much more effective are the specific procedures upon which I have cast aspersions, if they are the result of long range planning to meet certain predetermined needs.

Third, many companies have handled the matter of salary progress in a manner which appears to be unwise, among these technical groups. It is the employer of technical and scientific personnel who has bid up the starting rate for young graduates to levels which are somewhat startling. These levels in many instances are equal to — and, I fear, in some instances above — the present salaries of similar personnel with five, or even more, years of service. Can any employer permit such conditions to exist and expect the morale and performance of the group to be up to par?

The Colleges

And now, to suggest a few questions for the educators.

First, are they preparing these young people to expect that their first few years in industry will be the equivalent of post-graduate training? It is then when they learn the *application* of the principles learned in college. It is then when they see the light of considerations such as cost, marketability and a host of other economic questions. It is then when they "unlearn" the application of "pure" scientific approaches to every problem. It is then when they realize that many economic answers are indefinite and decisions must be based on factors which are not exclusively engineering economics.

Second, are our colleges giving due significance to the need for breadth of knowledge among technically trained students? To assume places in the field of industry which their native talents warrant, engineers must have a broader appreciation, understanding and knowledge of the humanities, arts and social sciences, which were neglected in my day. Several of our institutions are making noteworthy progress in this direction.

Third, do our educators know enough about the educational requirements of industry? Some educators are so steeped in the "pure" sciences that they fail to recognize the practical problems of applying those sciences. Some engineering educators encourage students to isolate themselves from sales, social sciences, public relations, finance, personnel and other aspects of business which the growing engineer must comprehend if he achieves his full intellectual potential. Some educators think "more of the same at a higher level" when planning courses of executive development for use of industry, rather than ascertaining the needs of the prospective advanced management students and meeting those needs. Some educators have never looked at the inside of industry.

Moving Forward

And now if I have not alienated all of you — as individuals, managers or educators — by listing certain shortcomings and criticisms, let us look at a few recommendations through which I believe we can move forward to improved development of the talents of our technical and scientific personnel.

(1) Industry can take definite steps to reduce the shortage of engineers by eliminating much of the waste of engineering talent.

(2) Industry can correct the distortions in the compensation of engineers which has resulted from the rapid lifting of the starting levels without sufficient commensurate modification at other levels.

(3) Industry can adjust on-the-job training in the early years to give greater emphasis to the business relationships which engineers must learn, thus stimulating their efforts in the non-technical areas of learning.

(4) Industry must spot-light its needs for advanced education by: (*a*) Long range determination of managerial needs. (*b*) Inventory and appraisal of potential candidates for greater responsibilities. (*c*) Planning specific courses of action to meet the needs indicated by the inventory and appraisal. (*d*) Conferring with educators to apprise them of those needs which can be met by educational institutions.

(5) Educators must strive to give engineering students a better concept of the areas of knowledge which will be encountered in business and community life. To the extent time permits they should include courses of basic understandings of these areas in their curricula.

(6) Educators also must pattern their post-graduate activities to meet the needs of individuals in industry as well as the purely academic needs as they see them.

(7) Colleges and universities should take a close critical look at what is now being done in the field of management training. They should ask themselves: (*a*) Are the courses practical? (*b*) Do they provide growth in personal stature as well as intellectual improvement? (*c*) Are the leaders adequate to the job? (*d*) Is the whole undertaking tuned to the needs or particular characteristics of the area served? (*e*) Are they aiming at attracting youthful executives or attempting to retread old-timers?

(8) Industry and education must co-operate more fully and effectively. Seminars initiated by either group to explore each other's and mutual problems can make a forceful contribution toward better education.

These are certainly not all of the constructive steps which can be taken. They are steps which have come within my own experience and observation and which are effective.

The fact that every member of this group should have an interest in any better methods or techniques of "Amplifying the Baccalaureate Education" was well stated by Lawrence Appley, president of the American Management Association.

"International, national and local affairs have such a profound bearing upon the management job today that we must keep ourselves constantly aware of the world in which we live and alert to significant new developments."

Summary

H. G. Conn

As a result of the discussion here, I think it is agreed that the baccalaureate degree needs amplification. It was pointed out that this is merely another phase in the education of the engineer and is a very important phase. As stated before (Session 3) the onus of producing a good curriculum for this phase of study has now shifted from the teacher to the student and this may explain why many do nothing in the way of self-improvement after graduation. Mr. Verdin pointed out that many facilities exist for furthering one's education after graduation and each facility had its advantages and disadvantages, its strong and weak points. However, the assessment of these facilities is again up to the student. We can all help when help is asked for and can give the normal common-sense advice which it is the responsibility of all senior engineers to pass on as diplomatically as possible to their juniors.

DISCUSSION

of Technical Papers and Other Articles

LATERAL RIGIDITY OF STEEL BUILDING FRAMES

J. L. de Stein, M.E.I.C. and J. O. McCutcheon, M.E.I.C.

The Engineering Journal, 1956, October, 1343.

D. T. Wright,* JR.E.I.C.

The main implication of the authors' paper, that more or less typical single-storey building frames have inadequate lateral rigidity (which may lead to deformations of several inches under design loads), deserves some further comment. The authors have done a most useful service in applying the results of researches on structural connections to the often-neglected problem of structural rigidity. From the results of their computations it would appear necessary to increase the lateral rigidity of frames to guard against excessive lateral deformation. Although the validity of the computations is unquestioned, their practical significance should be examined in the light of what other knowledge can be brought to bear on the subject.

Such large deformations, as calculated by the authors, are practically unheard of in actual structures. It does not seem reasonable to attribute this only to the infrequent occurrence of wind loads of a magnitude approaching design levels. Deformations of 5 to 10 inches would be most apparent if they *ever* occurred. Instead it would seem that the actual rigidity of building frames must be larger than provided by the raw skeleton. Recent work[1] at the Building Research Station in England has been directed at this problem as it affects multi-storey frames (where lateral deformations would be very great if only the steel frame were effective). More applicable, here, are the results of tests performed by J. H. Percy[2] to determine the actual rigidity of a single storey pitched roof frame (which had been designed by plastic theory). He found that when one bay only was loaded (in a long building) deformations were only one-third as great as those calculated, and that even in a very long building loaded uniformly along its entire length deformations would never be as great as those calculated. These results are due, of course, to the effect of the wall and roof cladding, secondary members, bracing, etc. The building tested had only very light cladding, and with 32-ft. columns, with slightly over half the wall devoted to continuous glazing, could hardly be considered as very rigid.

One must conclude then that even with very light cladding, stiffness is greatly increased, and that a locally loaded area is able to share its load. Since wind gusts are very local in nature,[3] it is most improbable that a long building could be loaded over more than a small fraction of its length. Accordingly deformations would be significantly smaller than computed. For short buildings, where the entire wall might be loaded, the effect of the end walls provides similar restraints.

This then, seems to be another of those cases in structural engineering where calculations based on the customary assumptions (here, that only the bare frame contributes to rigidity) do not reveal what actually happens to real structures. Relatively little is known about the actual deformations of structures in service. It would be unreasonable, however, to become excited about large calculated deformations before real deformations of the same order had been experienced.

In their conclusions, the authors suggest that because of the large flexibility indicated in single-storey frames of conventional design "it is apparent that a plastic analysis has little practical application for these single-storey frames", inasmuch as plastic designs invariably lead to much lighter sections than are ordinarily used. In fact, plastic design has been used more for single-storey frames than for any other building type. It should be emphasized that plastic theory is concerned only with strength. The significance of plastic theory is that it is a rational method; whereas elastic theory predicts stresses which do not agree with experimental deviations,[4] plastic theory predicts load capacities which agree very well with test results. In designing on plastic theory, it is possible then to produce structures with known factors of safety against collapse. Deformations (under working loads) must be considered independently. The work by Mr. Percy,[2] which was described above, indicates that in real buildings deformations are much less than would be computed by usual methods. Further research on this problem being carried out by Mr. Percy at Cambridge University is expected to lead to means of estimating the actual deformation of buildings designed by plastic methods. In the meantime, over 100 single storey frames designed on plastic theory have been constructed in England.

THE ECONOMIC POSITION OF CANADIAN SCIENTISTS AND ENGINEERS

John F. Haberer, and F. L. McKim

The Engineering Journal, 1956, October, 1366.

(This subject, as it concerns the United States, is dealt with on p. 820)

Dan N. Hendricks, Jr.[1]

I would like to make a comment on the article "The Economic Position of Canadian Scientists and Engineers" by Haberer and McKim in your October, 1956, issue. I think that it might be useful to draw attention to an erroneous assumption made by the authors even though this assumption played only a very minor part in their article. This concerns the plots of salary *v.* years since graduation (or age) for Canada, the United Kingdom and the United States. In discussing these curves, the authors noted that the slopes of these curves represented slightly different rates of advancement. To make such a statement requires the assumption that these curves are actually salary *growth* curves. Actually, they are simply plots of salaries of a group of people relative one to the other at one point in time (we call these salary *structure* curves). If the salary administration policies are in equilibrium, i.e., not changing from year to year, then the salary structure curve can be used to predict salary growth (if inflation is ignored or accounted for).

Now it happens that we have had an opportunity to conduct some statistical studies on the actual growth rates of particular groups of engineers. Even when these growth rates are corrected for the changing salaries paid new engineers, we have discovered that the average growth rate is substantially greater than that predicted by the slope of the salary structure curve.

For many years, we also made the assumption that the authors have made in this article. We have since learned that this assumption is so much in error that it leads to many conclusions which are very seriously in error. Anyone who is concerned with trends in engineers' salaries simply must resist the temptation to use a salary structure curve as if it was a salary growth curve. Otherwise, I do not believe he will ever come to an accurate understanding of the true circumstances.

[1]President, Seattle Professional Engineering Employees Association

[2]Chief, Personnel Services, National Research Council, Ottawa

[2]F. L. W. McKim

The points raised by Mr. Hendricks in connection with the comparison made in the paper of the slopes of what he calls the "salary *structure* curves" are interesting and well taken.

The slope of these "*salary structure* curves" are in practice, I agree, never equal to the actual average rates of advancement for any particular group of graduates. Accordingly, the wording in the paper in the third paragraph of the section headed "Salary Treatment by Type of Employment" was poor. Here we compared the slopes of the "salary *structure* curves" in Canada, the United States, and the United Kingdom and erroneously designated these slopes as "rates of advancement". As I see it, the slope of the "salary *structure* curve" is actually the *increase in average salary per additional years experience,* at one point in time. On the other hand, would it not perhaps be true that in general where the slope of the "salary *structure* curve" is steeper, there the actual rate of advancement for any group of graduates would be higher than for a corresponding group of graduates in an organization or country where the slope was smaller.

I was interested in the use of the term "salary *structure* curve" for the "plots of average salaries by year of graduation at one point in time. I would have thought that this wording might better be reserved for charts or graphs which would show the *number of persons at various salary levels within a group,* the salaries of which are being examined. A suitable term might be "salary experience curve".

I very much appreciated Mr. Hendricks' offer to send us copies of past material his Association has published in the field of salary studies. We do have a continuing interest in this field and would appreciate receiving such material as well as results of future studies.

REFLECTED RIPPLES IN THE RIDEAU CANAL

(Abstracts)

The Engineering Journal, 1956, January, 36.

D. C. Fisher[3]

The following is my explanation of the "Ripple Angles": It is evident the boat has not followed a true course through the canal. From the wake, I judge it is a twin screw.

If the boat is not at exactly dead centre of the canal, the change in direction of the water caused by passage of the boat, together with the fact that the rudder may be a degree or so to starboard or to port, causes this flow or current to strike one side of the canal before the other.

The first current to strike changes direction and angles back, and will therefore travel farther towards the opposite side before the two meet again. This process is repeated until such forces are overcome by the natural current.

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

PAPERS OF THE INSTITUTION OF ELECTRICAL ENGINEERS

Convention on Ferrites

A convention on ferrites was held, 29 Oct. - 2 Nov. 1956, in London, together with an extensive exhibition to illustrate the subject. Some fifty-eight papers or presentations were made at the technical sessions, which included the following subjects: chemical and physical properties and preparation; magnetic spectra; molecular interaction; D.C. and L.F. properties; radio and television applications; new materials; square-loop materials; square-loop applications; microwave theory and measurements; microwave measurements and properties; microwave apparatus; and carrier frequency applications. The complete proceedings of the convention, including discussion, is to be published in a supplement to Part B of the *Proceedings* of the Institution of Electrical Engineers.

The BBC sound broadcasting service on very-high frequencies. E. W. Hayes and H. Page. (No. 3220).

The paper describes the developments leading to the inauguration of the BBC very-high-frequency service of sound broadcasting, which works in the band 87.5-100 Mc/s. The need for a very-high-frequency service is explained, and the considerations leading to the choice of frequency modulation rather than amplitude modulation, and of the national planning standards, are summarized.

In July 1954 the Postmaster-General authorized the first stage of the development plan, comprising nine stations. Later it was agreed that another station should be included in this stage, which is now virtually complete. In July 1956 the BBC was given authority to build a further six stations, which will be in service early in 1958. These sixteen stations will cover 95% of the population of Gt. Britain and Northern Ireland with three programmes. At a later date the BBC plans to build additional stations to extend the population coverage to about 98%. At the majority of the stations three programmes are radiated from a common aerial; special precautions are taken to minimize the generation of intermodulation terms.

The experience gained during the first year's service is described, with special reference to the performance of commercial receivers. The present stage of development of very-high-frequency sound-broadcasting services abroad is briefly summarized.

Frequency modulated V.H.F. transmitter technique (with particular reference to the British Broadcasting Corporation United Kingdom broadcasting network). A. C. Beck, F. T. Norbury, and J. L. Storr-Best. (No. 3235).

Equipment and performance requirements for frequency modulated broadcasting transmission are given, with particular reference to the British Broadcasting Corporation's recently introduced network of V.H.F. transmitters.

The general planning and design of the complete transmitting equipment used at the new high power V.H.F. sites is surveyed, including problems of unattended operation, automatic phasing of paralleled amplifiers and three-programme common antenna working, to indicate the progress made in this new field of broadcasting.

The design features of a current 10 kw. FM., transmitter operating in Band II (87.5-100 mc/s.) are described with special mention of the method of generating the frequency modulated carrier, its automatic centre frequency control and means for automatic phasing of the high power amplifiers operated in parallel. Details are given of a newly introduced system of transmitter control designed to increase the service reliability, thus reducing the demands on the time of visiting maintenance personnel.

Reference is made to the B.B.C.'s requirement of combining three independent F.M. carriers of 10 kw. spaced 2.2 Mc/s. in frequency to feed one half of a wideband horizontally polarized antenna, the other half being fed with an identical set of transmitters kept in phase within a few degrees. The necessary filter circuits, giving sensibly zero coupling between transmitters and negligible cross-talk, are described. Overall performance figures are quoted.

Cathodic protection. L. B. Hobgen, K. A. Spencer and P. W. Heselgrave. (No. 3285).

The paper deals with the theory and practice of the method of corrosion mitigation known as cathodic protection. The nature of electro-chemical corrosion and the fundamentals of cathodic protection are briefly discussed. Then follows a survey of the two practical methods of achieving cathodic protection — sacrificial anodes and power impressed currents. Since the method of measuring potentials is not that of normal electrical practice, this subject is considered in some detail together with the method of measuring soil resistivity. The possibility of adversely affecting other buried services is noted, and current practice in carrying out potential tests with the owners of such services, and of bonding to eliminate adverse effects is considered. Finally the application of cathodic protection and the general economics affecting its use are discussed.

DEFENDING BRITAIN BY ROBOT

Society of British Aircraft Constructors, *News Letter A. 1913*

Recent Government announcements have indicated that the role of the defensive manned fighter will soon be partially taken over by guided weapons and bombers will be superseded by medium or long-range rockets (intercontinental ballistic missiles).

Defence against manned bombers flying at 50,000 - 60,000 ft. at more than 600 m.p.h. carrying nuclear bombs must be made as near 100% effective as possible.

Work on guided weapons in Great Britain to counter this threat was initiated after the last war, but their development was influenced by the Staff assessment that there was little chance of major conflict before 1957.

The British guided weapon programme is co-ordinated by the Ministry of Supply. The English Electric — Marconi Wireless Telegraph — Napier group is working on a ground-launched anti-aircraft missile, Bristol and Ferranti on a ramjet-powered ground-to-air device, Armstrong Whitworth and General Electric are collaborating on a ship-to-air missile for the Navy, and de Havilland Propellers are evolving an air-to-air weapon.* In addition, Fairey has already produced the *Fireflash* for use by the R.A.F. as a training weapon, and a large number of other companies is engaged on power-plant, radar and guidance systems.

These weapons are "geared" to the radar-chain which encircles the British Isles. The American radar system is different, and it is, therefore, unlikely that a large-scale adoption of U.S. guided weapons is imminent, as has been suggested in some quarters. The cost of adapting either the defensive radar system or each American weapon purchased would be prohibitive and it is logical to suppose that British guided weapons may be operational fairly soon.

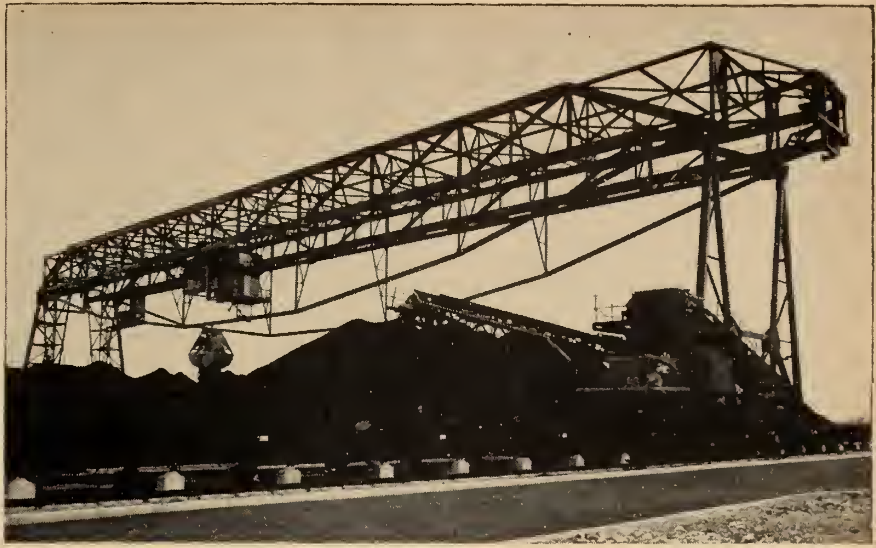
It is possible that one or two American interim weapons — such as *Nike Hercules* or *Talos* — not dependent on a radar chain for guidance, may be suitable as a stop-gap measure. (Once released, these "beam-riders" fly along a thin radar beam emitted by the ground station on to the target.) But it is unthinkable that effort and expenditure on guided weapons in Britain should be abandoned.

What of the long-range rocket or ICBM? The industry is developing these, but their effective operational use (in any country), is still some years distant. The main problem is their accurate guidance.

What defence measures can be expected to counter these missiles, equipped with nuclear warheads? There is no known answer at present. Assuming the ICBM descended at 10,000 - 15,000 m.p.h. or 3-5 miles a second, there would be little or no time for defensive action.

The best answer may lie in a stock of long range rockets kept constantly ready. The evolution of the ICBM is therefore of paramount importance. The greater part of the British aircraft industry — more than 400 companies — is engaged on guided weapon work of one sort of another. This work includes the sinister ICBM.

*It has been announced by the company that this weapon, the *Firestreak*, which incorporates infra-red homing, has been ordered by the Royal Air Force and will be fitted to the English Electric P. 1. and the Gloster Javelin aircraft.



LARGE TRAVELLING COAL TRANSPORTER

The largest travelling transporter in Britain is in service at the Central Electricity Authority's new power station at Tilbury. The transporter, designed and built by Mitchell Engineering Ltd., London, can spread and reclaim coal from the store at 800 tons an hour. Normal storage capacity is about 165,000 tons. The transporter bridge travels on tracks, 275 ft. apart, at 32.5 ft./min. A man-operated carriage, with a 9-ton grab, has a cross speed of 700 ft./min. and hoisting speed of 150 ft./min. The transporter bridge is of bow-string construction, supported by one fixed leg and a hinged leg at the other end to deal with track irregularities and to provide for expansion; each leg is mounted on four two-wheel bogies for travelling. Two bogies on each leg are motor-driven, and alignment gear is provided to ensure equal travel at either end of the bridge. Main current supply is through a specially-designed cable reeling drum with three flexible multi-core cables connected in parallel. The travelling carriage is made of rolled steel sections, braced and riveted to form a frame to accommodate the mechanical units. The grab is of the four-rope type and the hoisting winch is mounted on the travelling carriage. *(U.K. Information Service, Engineering Notes No. 52 (Ed., E. Mayson)).*

LARGEST MECHANICAL ORE-DRESSING INSTALLATION

Bureau de Presse Suédo-International, Stockholm, February 1957

A giant ore-preparation plant for the Kiruna mines, in the Swedish Arctic, under construction since 1954, has recently been put into service. When completed, at a cost of some $10-million, the plant will be the largest of its kind in the world, with eight pairs of magnetic separators each having a capacity of 500 tons an hour.

The plant will be officially inaugurated on 1st October 1957, when the iron ore workings in this district are transferred to the nationalized organization LKAB.

Open-cast mining at Kiruna has

been carried out since the end of the nineteenth century, but will finish in 1960 when conversion to underground mining will be complete. The new plant, 11 stories (170 ft.) high and some 380 ft. long by 95 ft., is one of the main facilities built for the new development. Output from these high-grade iron ore deposits (the largest in Europe and perhaps in the world) is to be raised from 10 million tons in 1956 to between 15 million and 20 million tons a year by improved extraction methods and without increasing the labour force.

The new plant has a capacity of 4600 tons an hour, corresponding to an annual capacity of 13 million tons. Each of the eight pairs of separators, mentioned above, is fed by six underground crushing stations in which blocks of ore weighing up to 10 or 12 tons are reduced to about four-inch pieces. The crushers will eventually be doubled.

Hoppers containing 20 tons are raised from the crushing stations at a speed of 36 ft./sec. to the dressing plant, where they are discharged into a system of screens and conveyors leading to the magnetic separator installations. Five different grades are produced, from 68% iron, 0.03% (max.) phosphorus, to 60% iron and over 0.8% phosphorus.

The graded ore is passed to one of twelve 8000-ton underground storage chambers connected to two railway tunnels which lead to the main Kiruna railway. Ore is discharged by gravity into 35- to 42-ton trucks; one load is completed in 30 seconds. Ore-trains go to Lulea, over 180 miles away on the Gulf of Bothnia, or to the Atlantic port of Narvik, at which a large installation was completed in 1956 to hold 3,500,000 tons of graded ore which can be loaded into ore-carriers at 4000 tons an hour.

The construction of the Kiruna plant presented several special problems, particularly because of the severe climatic conditions. Winter temperatures frequently fall to the range -20 deg. F. to -40 deg. F., but the building is well insulated and is heated throughout by the unusual means of using the heat generated by the electrical equipment that operates the separators. The main concrete structure was poured in two stages, using a sliding form no less than 720 feet long; over this is a layer of plasticized glass fibre about four inches thick, in turn covered by corrugated aluminum sheet (about 0.04 in.).

THE WORLD'S LARGEST LADLE CRANE

Seen here is the partly assembled bridge of what is described as the world's largest ladle crane. One of three being made by Morgan Engineering Company, Alliance, Ohio, for the steel industry, the capacity of the crane is 500 tons. Without the ladle, the crane weighs 1,841,000 lb. Drive is by eleven electric motors with a total output of 1658 h.p.; nearly 1.7 miles of steel wire rope or cable is used for reeving. The ladle to be used will be over 17 ft. high, 17 ft. top diameter, and will hold 375 tons of hot metal. Self-equalizing four-wheel trucks, each weighing 20,000 lb., are used; bridge wheels can be changed quickly. The main trolley frame (47.5 by 30.3 by 11.9 ft.) was designed to be shipped in about eight sections, re-assembled on the bridge by bolting with high-tensile bolts, and welded in the field. A five-deck cage housing the electrical equipment and crane operator is over 46 ft. deep from the top of the crane runway rails and the 31,300 cu. ft. volume enclosed is about three times that of a normal five-room house. Welded construction is widely used.

EUROPE'S LARGEST SUSPENSION BRIDGE

French Economic and Technical Bulletin, No. 11, 1956

The 77 miles of the river Seine from Rouen to the English Channel present an obstacle to traffic as there are only ferry crossings in this reach. Studies over a long period indicated that a suspension bridge was the best solution for overcoming the inherent difficulties of providing a suitable crossing, and construction is now under way on a bridge at Tancarville, near Le Havre. This will cost over $11.5 million and is due to be completed in spring, 1959.

Three suspended spans will support a continuous metallic roadbed, 3152 feet long between two anchorage blocks. Total length, with the left-bank approach, will be 4593 feet; clearance over the river will be 160 feet. The bridge will require some 2,000,000 cu. ft. of concrete, including over 700,000 for the two anchorage blocks and nearly 900,000 for the superstructure and tower foundations.

Fifteen thousand tons of steel will be used, including 3210 tons for the supporting cables and vertical sling cables. The two supporting cables, suspended from four 426-ft. high reinforced-concrete towers, will each be 0.6 mile long and made of 56 elementary cables (for a total of nearly 15,000 miles of solid steel wire strands). Maximum stress for each cable will be 8500 tons.

The prestressed concrete anchorage block on the left bank will consist of two parallel walls in the longitudinal axis of the bridge. Average height of the block will be 147 ft., length at top 130 ft., and length at base 153 ft. The forward section of each wall rests on a caisson 72 by 26 ft., filled with concrete. In the rear, the wall will rest on a caisson, 33 by 16 ft., also filled with concrete and fill.

The two walls will be 52 ft. apart and connected by struts, arranged in some cases to contain ballast. Difficulty was caused by the fact that there is no bedrock on the left bank.

On the right bank, the anchorage block will consist of two structures to carry the supporting cables, two reinforced concrete chambers, and two concrete-lined galleries dug out of the rock base and forming the actual anchorage.

INDUSTRIAL APPLICATIONS OF MICROCALORIMETERS

Prof. H. Prat, Dept. of Biology, University of Montreal

The Calvet micro-calorimeter is described with details of construction of the apparatus, the accessory devices, and its numerous applications in pure and industrial research, in the book: "Micro - calorimétrie; applications physico-chimiques et biologiques" by E. Calvet and H. Prat. (Masson, editor, Paris. 1956.)

In its most common form the apparatus consists of four calorimetric groups, each one containing 192 thermo-couples radiating in 12 super-stars of 16 around a cell of 18 mm. diameter. These thermo-electric piles are connected in two opposing pairs with two high sensitivity galvanometers. The whole is placed in a set of five successive enclosures made in either aluminum or copper. The penultimate is provided with a temperature stabilizing device (heating or refrigeration by thermostatic control) and the space between it and the external enclosure is filled with a thermal insulant (asbestos or polyethylene foam).

This apparatus does not operate as an adiabatic calorimeter (without loss or gain of heat) nor as an isothermic one (with total compensation), although it is totally insulated and its variations in temperature are very small (of the order of one thousandth of a degree). Its principle is as follows: the thermal capacity of the investigated material is relatively small compared with that of the enclosures; thus the heat produced is rapidly absorbed by the mass of the apparatus, permitting very little variations in the temperature of the cell. Under these conditions A. Tian has demonstrated that the electromotive force produced by the thermo-electric pile is proportional to the thermal output; that is to say, the calories produced per unit time. In practice the deviations of the galvanometer may be calibrated in calories per hour. On a chart a continuous curve is obtained (a *thermogram*) giving thermal output as the ordinate and time as the abcissa. Mounting the piles in opposition assures the stability of the zero and permits differential or additional combinations if desired. Finally the thermo-couples are connected in such a way that it is possible to use some of them to generate a Peltier effect (cooling of junctions), thus to obtain a partial compensation of the heat, when the deviation is too great.

These improved apparatuses have been available for only about eight years and, up to now, only a few have been built. In France six of them are in operation. In Canada three are currently being used at the University of Montreal and one at the University of Ottawa. Six more are in process of construction at Montreal, Marseilles and Lyons. In spite of their small number the twelve apparatuses in operation have already produced considerable results in various fields; for example, in laboratories working in industrial chemistry, agronomy, microbiology, entomology, pharmacodynamy; for fundamental research as well as for applications, apparatus of this type are expected to become as useful as spectrophotometers or precision balances. To give an idea of their sensitivity, the thermogram of a single small fruit fly *(Drosophila)* weighing one milligram can be clearly recorded. Outputs of heat representing one ten-thousandth of a small calorie can be recorded and measured.

In addition, in order to extend the possibilities of the apparatus, E. Calvet has now constructed micro-calorimeters capable of operating at high temperatures, others at sub-zero temperature, and yet others with cells of 35 mm. diameter capable of holding larger animals. This pioneer work is extremely promising, both from results already obtained and by the variety of its possibilities.

LABOUR IN CANADA

The forty-fifth annual report on labour organization in Canada has been published by the Department of Labour. It contains the results of the 1956 survey of union membership carried out by the Department. The report includes a statistical analysis of union membership and, secondly, a directory of labour organizations giving officers, publications, and location of Canadian branches.

STEEL EXTRUSIONS THAT SAVE MACHINING TIME

The picture above shows an unusual steel extrusion made during a research and development project of Allegheny Ludlum Steel Corporation. The particular extrusion die was designed with a ratio of cross-sectional area to perimeter of 1 to 10, thus imposing high stresses in the complex die. However, twelve-foot lengths of type 410 stainless steel were extruded at production speeds and at production temperatures. The company is already producing steel extrusions of an airframe section for the aircraft industry; previously made of bar stock, the SAE carbon steel extrusions are said to save 75 per cent in machining time. Conditions for extrusion from a 25 sq. in. billet to an 0.4 sq. in. T-section are severe: 150,000 p.s.i. at about 2250 deg. F. produces 25-ft. lengths of 0.140 in. thickness at speeds up to 45 m.p.h.

SANDS OF THE SEA

F. A. Hauck, *Yale Scientific Magazine,* v. 31, no. 4

Deposits of minerals which are becoming increasingly important in the atomic and electronic applications of industry are found in the sand dunes of Florida. In the last few years successful recovery methods have been devised based chiefly on the specific gravity, magnetic, and electrostatic properties of the minerals which are monazite, rutile, ilmenite, zircon, and garnet. During geological time, particles of the deposits have found their way from the mountains by wind, rivers and streams, ocean tides and currents, storms, and perhaps by subterranean streams to their resting places on the beaches. There are both shore line beaches and others at some distance inland indicating partial elevation of the coast line subsequent to the decomposition of the rocks. Where water from waves and tides wash the shoreline these minerals, which are much heavier than silica sand, are separated from the lighter sand and accumulate in rich deposits, sometimes as high as 90 per cent concentrates. The incoming wave carries the minerals with the silica sand to its crest. At the crest of the wave the water momentarily stops, at which instant the heavy minerals fall while the lighter silica sands are carried back with the receding wave. This goes on hour after hour and when the wind is in one direction for days quite a depost is formed of heavy minerals, sometimes several inches thick. In this way alternating layers of mineral and of silica sand comprise rich deposits on the shore of the ocean in the area.

A peculiarity of the Florida deposits is the uniformity of the ratios of the minerals — ilmenite 45-55% of concentrates, rutile 10-20%, zircon 10-20%, garnet 10-15% and monazite 1.5%. A wet separating plant consisting of a dredge, screening equipment, and rougher is set up at the source upon a man-made lake. This recovers a primary concentration of mixed heavy minerals (60 to 80 percent in the product) which is transported to a central separation plant and the minerals are further high-graded by wet tabling and then dried. An electrostatic separation follows and is a method of recovering finely-ground mixtures, taking advantage of variations in their electrical properties to make them react differently when passed through a field of static electricity. Magnetic separation after the electrostatic operation pulls out from the concentrate all iron-bearing mineral such as the ilmenite.

The ilmenite contains 53 to 58 per cent titanium. Minerals rich in titanium are few, and only ilmenite and rutile have commercial importance. The metal is becoming increasingly important in military aircraft for air frame construction and in jet engines for compressor components. It has excellent corrosion resistance and will prove useful in the chemical industry and in marine environments. Zircon is a common widely distributed accessory mineral. It has a high melting point and is resistant to corrosion by acids and alkalis. Zirconium does not absorb neutrons easily and is therefore a splendid material for use in structural supports for nuclear reactors. Zirconium refractories can withstand temperatures up to 4500 deg. F. Hafnium is also found in zircon and its high neutron-absorption factor makes it a useful material for nuclear energy equipment. Zirconium is suitable for use in surgery. Body fluids will not corrode it and human tissue grows to it without decay or deterioration. It may replace tantalum in dental and surgical work.

Ultimate Strength Design of Reinforced Concrete Beams

(Continued from p. 808)

sufficient security. Most European codes have taken care of this condition by lowering the allowable concrete stress if the calculated position of the neutral axis falls a certain distance below the bottom of slab. One code takes care of this condition in perhaps a more logical manner. The total resistance of the concrete section is the sum of resistance of the projecting part of the flange with allowable concrete stress as for direct loading plus the resistance of the beam stem to top of slab with allowable stress as for a rectangular beam. Our reinforced concrete building code should certainly be corrected to take care of this condition.

Conclusion

It seems to be clear that it would be necessary for a designer to have a very clear understanding of the fundamental facts of reinforced concrete if he should base his design work on ultimate strength of reinforced concrete beams. There may perhaps be some doubt if all of those who now design by means of tables and formulas have this knowledge. The above discussion would indicate that no change of design method is needed for normally reinforced beams. The question might then be asked if a more realistic stress calculation (which would hardly change the end result) of the over reinforced or double reinforced beam is of sufficient importance to warrant the abandonment of our present method.

There is still a considerable difference in opinion about what the basis for design by the plastic or ultimate load theory should be. (5) It has been stated that up to 1951 there were 23 different proposals of which 10 were markedly different. (6) Perhaps some day a method will be worked out which will be both accurate, consistent and simple to apply. Until such time, we probably will do well to use our present method with such improvements as are found to be desirable.

The author is quite aware that there is a great difference of opinion about the present method versus plastic or ultimate load methods of design of reinforced concrete beams. This matter certainly deserves thorough consideration and it would be desirable that other engineers do their share in helping to clarify this contentious question.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Progress during the month of March was highlighted by diversion of the river through the completed stage 1 of Long Sault dam at the end of March, after removal of the final plug in the cut through Long Sault Island.

Full scale concrete placement operations were resumed on the American half of the power-house, while at Iroquois dam, with stage 1 completed, the upstream dike was nearing completion. Five channel improvements by the two power authorities showed 63 per cent of completion at month's end.

On the Canadian side, the Cornwall canal diversion was completed and ready for navigation; on the railroad diversion most of the signal system had been installed and five railway stations were being built. The final house moving program for Long Sault (New Town No. 2) was completed while preparations were started for the major house moving program at Morrisburg.

Employment during March averaged 2750 persons on the American side and 3650 on the Canadian side.

Progress by Ontario Hydro

During April the work force was increased. There was a total of 4,150 persons employed on the various sections of the project at month end. Dry, favourable weather in April aided construction greatly and permitted first dike building in 1957 to commence. The dike work was started at the power-house area, also at the closure structure and at the north end of the dike line near Mouinette.

By the end of April all the concrete had been placed for ten draught tubes and was proceeding on the eleventh. The deck for the erection bay had been completed over the north end ice sluices. A total of 555,000 cubic yards of concrete had been put into the Canadian half of the power-house structure. Seven speed rings had been erected for the generating station. The turbine cases had been put in position over six of these rings and the meticulous work of aligning the speed rings was in progress.

Relocation of the 40-mile C.N.R. main line between Cardinal and Cornwall was virtually finished and ready for freight trains. The line is controlled by a double track block signal system and this is fully installed in the new sector and tied in with the existing main line. Telegraph and dispatchers' lines are in operation and the automatic crossing protection is functioning. Construction of the five new stations is well advanced and these depots are expected to be ready for passenger service in June.

In April, the channel improvement work at Iroquois Point continued at a favourable rate even with interruptions for trucks hauling away material caused by the canal bridge being in operation with resumption of the navigation season. The excavation to month end amounted to 1,350,000 cubic yards.

Channel enlargement work at Point Three Points had been intermittent. A start had been made in excavation there and roads to the disposal areas had been prepared. At the Galop contract wet conditions slowed down activities. A total of over 11,000,000 cubic yards of earth and rock had been removed from the new channel. Dredging had been resumed in the Chimney Island channel section and over 30,000 cubic yards had been taken out from the river bottom.

Services were held on April 21 in the Presbyterian church, the first new church in Iroquois to be opened. During the month ground was broken for the construction of the United Church, the separate school and the new town hall. Tenders have been called for building the new Anglican church which will complete all the major contracts for Iroquois. Iroquois' new shopping centre was occupied by the merchants who opened their new stores for business during the month.

House moving operations were centred in Morrisburg with 22 houses moved during the month, for a total of 45 homes moved to date, in that community. Work commenced on the plumbing rough-in for Morrisburg shopping centre and construction of 36 rental housing units was begun. Erection of the elevated water storage tank was completed in April. Concrete work for the new railway station was finished and the freight shed erected.

At the new towns of Ingleside and Long Sault, work was concentrated on grading roads, ditches and building of sidewalks and culverts. Construction was begun during the month in Ingleside on two churches and the separate school. At Long Sault, building of the elementary school and the separate school was started.

Ontario Hydro announced the award on March 15 of a contract for the construction of grade separation, C.N.R. relocation and Highway No. 31. The successful bidder was the St. Lawrence Construction Company Limited of Quebec, the amount of the tender being $641,289. The work is to be completed by June, 1958.

Progress by NYPSA

Weather conditions in April were favourable and overall construction continued on schedule. Concrete placement for all features passed the one million cubic yard mark and excavation had exceeded 37.5 million cubic yards. Employment averaged 3,900 for the month.

On the American half of the Barnhart Island power-house concrete placement operations continued at a rapid pace, as approximately 53,000 cubic yards were placed during the month, bringing the total to date to 523,000 cubic yards. Erection of the 150-ton travelling crane was completed and erection of the 300-ton gantry continued. Installation of turbine bedded parts was continued, with stay ring set for unit 20.

Concrete was placed in the various switchyard structures concurrently with excavation of the tunnel between the power plant and the switchyard. Contractors for the power dam and switchyard electrical work arrived at the job site.

With completion of diversion at Long Sault dam, rock, gravel, and earth materials were being placed on the upstream side of cofferdam E and on the downstream side of cofferdam DD to seal off leakage. Excavation for the north abutment was proceeding.

At Iroquois dam, concrete placing operations were stepped up as approximately 15,000 cubic yards were poured in the sections of the spillway and west bulkhead block.

At Massena intake, construction of the upstream cofferdam cells was progressing. Placement of fill in the downstream rockfill cofferdam was completed and the entire flow of the canal was diverted through the stage 1 structure on April 23. Excavation work under the five channel improvement contracts was progressing at an accelerated rate and was approximately 65 percent completed.

Continued good progress was being made by the reservoir clearing contractors with 4,600 of the required 11,000 acres cleared to date. Clearing of the right of way for the Barnhart-Plattsburg transmission line was completed with only the chemical treatment remaining under the contract. Materials were being unloaded and structures were being staked out for the transmission line.

A contract was awarded for construction of bridges on state highway route 345 and Franklin Road in Waddington, New York.

Progress by SLSDC

SLSDC officials reported at the end of March that the American share of the seaway locks and navigation channels was 30 per cent completed, based on contractor's earnings and government costs.

About a million cubic yards of earth were moved during the winter from the Long Sault navigation channel, bringing the mainland portion to 55 per cent of completion at the end of April, while across Long Sault Island it had been completed. No work was done on the American dikes during the winter.

Work was resumed early in April on the two American locks. By the end of April half the concrete had been placed in the Eisenhower lock and guide wall, while the lock structure itself was built to half the height throughout its length. Placing of concrete in the Grass River lock was about 45 per cent completed. Two contracts have yet to be awarded for the channel excavation below this lock.

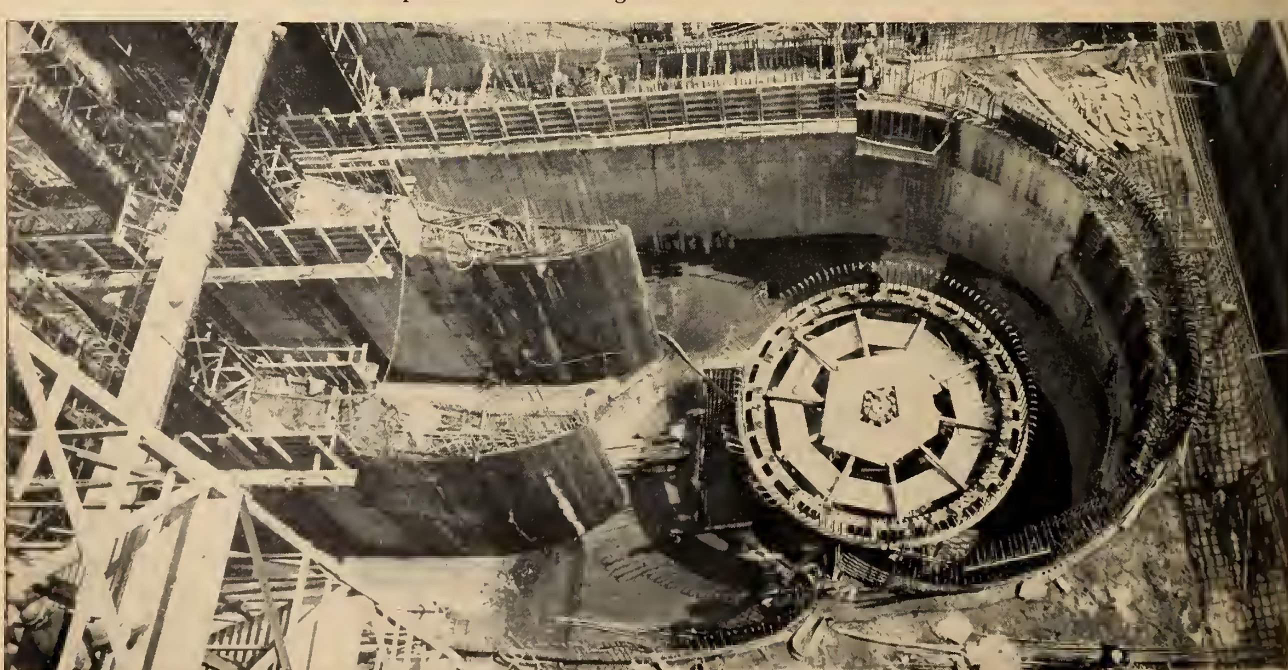
Dredging in the Thousand Island section, started last fall but closed down for the winter, was resumed in April. Two U.S. dredging companies were reported ready to commence in April on a $22 million contract for dredging 600,000 tons of clay and rock from the Amherstburg channel in the Detroit river, deepening it to 27 feet.

International Bridges

Contracts were awarded in March for the first section of the substructure for the Ogdensburg-Prescott Bridge, comprising four piers and cable anchorages for the 2150-ft. suspension bridge with five further contracts to follow for superstructure and approaches. The main span will be 1150 feet in length with side spans 500 ft. each.

There are also twelve 250-ft. deck-truss spans and seventeen 128-ft.

St. Lawrence power dam — looking down on scroll cases of units 31 and 32.



deck girder spans. The bridge is being built for the New York State Department of Public Works. Operating the structure will be the Ogdensburg Bridge Authority. New York will advance $15 million, to be repaid by revenue bonds after the bridge is opened.

U.S. Seaway Channel Costs Almost Doubled

SLSDC Administrator Lewis G. Castle testified before the House of Representatives Appropriations Subcommittee in April that United States Seaway expenditures were now estimated at $133 million, compared with the original estimate of $68 million. Price rises since 1952 account for $19 million of the increase; added construction items account for $37 million and design changes for $12 million. SLSDC was asking Congress to authorize an additional loan of $35 million from the treasury, to be amortized through toll charges over 50 years.

The additional funds were needed he said, to meet unexpected expenditures. Costs of $24 million for dredging the north and south channels of Cornwall Island were to have been paid by NYSPA and Ontario Hydro. The power agencies had objected and 1½ years were spent in discussions. A compromise called for SLSDC and SLSA to pay $6 million each toward the work. Bids on the dredging, however, were substantially above the estimate of $24 million.

Progress by SLSA

By the end of April, with dredging operations being resumed after the April 15 opening of navigation on the Lakes, and with resumption of channel excavation on overland sections, activity was general on the 1957 season's program. Placing of concrete was recommended in mid-April on the St. Lambert lock, where cleaning out of the excavation had been the only work done during the winter months. Preparations were under way at the Cote Ste. Catherine lock for pouring concrete again early in May.

At the Iroquois lock, with entrance wall and upper gate section done, lower gate section half completed and half the chamber walls poured to full height, the contractor had caught up with the schedule. Excavation was 95 per cent completed and 225,000 yards of concrete placed. One derrick was installed and permanent upstream stoplogs were in place.

On the Upper Beauharnois lock with more than a third of the earth and rock excavation done, placing of concrete for piers on the New York Central bridge would soon be under way. On the lower lock, with excavation for highway tunnel and for the lock completed, concrete was all placed for the highway underpass and about half the pavement poured on the road approaches.

At the Jacques Cartier bridge, with traffic passing in both directions over temporary Bailey bridge spans since December, the Dominion Bridge Company was jacking up four bridge spans at the south end and had raised them vertical distances of some 15 feet to connect with a temporary bridge abutment which had been built at the south shore end by the National Harbours Board.

No work had yet been started on the Victoria bridge, although at the Caughnawaga (CPR) railway bridge railway forces were doing some filling. At the Honoré Mercier bridge the temporary diversion approach fills had been built and were in service, while two contracts had been awarded for raising and widening the bridge piers and another contract for raising the superstructure.

Subsidies a Threat to Canadian Trade

Hearings concluded at Chicago early in April on applications for subsidies to U.S. ships from American ports to the Caribbean and South America disclose the basic difference between U.S. and Canadian shipping policies, which have already led to Canadian insistence on a separate Cornwall canal in the future. Applicants asked the U.S. Maritime Board to declare the U.S.-Caribbean routes essential—the initial requirements for payment of subsidies.

No Early Decision on Tolls

SLSDC Administrator Lewis Castle and SLSA President Lionel Chevrier announced early in March, following a conference in Washington, that "it would be months and maybe not until next year" before it is decided how much ships will have to pay in tolls to pass through the Seaway. However in spite of costs exceeding original estimates, tolls would not be higher than originally considered, but would be met by spreading out the repayment period.

Discussing the Welland Canal, Mr. Chevrier said tolls would be charged for ships using it when the present $25 million improvement work is completed. Presumably the charge for passing through it would be included in one over-all seaway toll. The two seaway officials also indicated they were near a decision on the maximum size for ships using the seaway.

Seaway News

$57 Million for Port of Montreal

Transport Minister George Marler announced on May 1 a $57 million program of capital works for port facilities at Montreal. Some of the work had already been completed and contracts amounting to $17.6 million had been awarded, he said. Tenders would be called shortly for other works.

The expected pattern of grain movement along the seaway is chiefly responsible for the outlay, which is exclusive of the cost of the Nun's Island Bridge. Largest single item is $27 million for improvements to the port's elevator system, increasing storage capacity by 44 per cent and increasing loading and unloading capacity by 80 per cent.

Additional wharf facilities will cost $17 million. Transit sheds will cost $5 million. $7½ million has been earmarked for dredging, part of it to enable 35,000-ton tankers to use the refinery wharves at the east end of Montreal.

Gavsie Succeeds Chevrier as SLSA President

It was announced on April 25 that Charles Gavsie, C.B.E., Q.C., formerly vice-president of the Canadian Seaway Authority, would succeed the Hon. Lionel Chevrier as acting president. Mr. Chevrier becomes President of the Council as one of the Ministers in the Liberal Cabinet at Ottawa. He will be responsible to the Canadian Cabinet for the St. Lawrence seaway.

Mr. Gavsie is an honours graduate of Dalhousie University, Halifax. Following a post graduate course at Harvard, where he received his master of laws degree, he practiced law in Montreal until he went to Ottawa in 1941. He served as general counsel of the Department of Munitions and Supply and later of the Department of Reconstruction and Supply. In 1948 he transferred to the Department of National Revenue as assistant deputy minister and was appointed deputy in August 1951.

Water Power Resources of Canada

The Water Resources Branch, Department of Northern Affairs and National Resources, Canada, in its annual review Bulletin 2570, records water-power resources of Canada as totalling 32 million horse-power under conditions of low stream flow and over 57 million horse-power at average flow. The latter figure represents a feasible turbine installation of about 74 million horse-power. The total turbine installation at the end of 1956 is given as 18,356,148 hp. indicating that less than 25 per cent of available resources has been developed.

During 1956 hydro-electric construction was accelerating and new capacity to the extent of 845,000 hp. was brought into operation with good progress made on other new developments; additional projects also were being investigated or planned. Of hydraulic plants, 87 per cent serve as central electric stations and, in 1956, production reached a new high level. The pulp and paper and the mineral industries are the more important consumers of hydraulic power. The installed capacity of water-power plants in Canada now equals 1,149 hp. per thousand of population.

Table II — Industrial Distribution of Developed Water Power At End of the Year 1956

Province or Territory	Turbine Installation — H.P. Central Electric Stations	Pulp and Paper Mills	Other Industries	Total
1	2	3	4	5
British Columbia	1,163,340	141,270	1,210,350	2,514,960
Alberta	282,950		2,060	285,010
Saskatchewan	109,800		35	109,835
Manitoba	795,000		1,900	796,900
Ontario	5,139,417	223,507	80,842	5,443,766
Quebec	8,084,153	350,344	55,460	8,489,957
New Brunswick	134,700	23,872	5,558	164,130
Nova Scotia	164,705	10,337	4,676	179,718
Prince Edward Is.	369		1,513	1,882
Newfoundland	140,450	182,300	14,000	336,750
Yukon & N.W.T.	13,540		19,700	33,240
Canada	16,028,424	931,630	1,396,094	18,356,148
Percentage	87.3	5.1	7.6	100.0

Table I — Available and Developed Water Power in Canada At End of the Year 1956

Province or Territory	Available 24-hour power at 80% efficiency — H.P. At Ordinary Min. Flow	At Ordinary 6-Months Flow	Installed Turbine Capacity H.P.
1	2	3	4
British Columbia	10,200,000	17,300,000	2,514,960
Alberta	508,000	1,258,000	285,010
Saskatchewan	550,000	1,120,000	109,835
Manitoba	3,333,000	5,562,000	796,900
Ontario	5,407,000	7,261,000	5,443,766
Quebec	10,896,000	20,445,000	8,489,957
New Brunswick	123,000	334,000	164,130
Nova Scotia	25,500	156,000	179,718
Prince Edward Is.	500	3,000	1,882
Newfoundland	958,500	2,754,000	336,750
Yukon & N.W.T.	382,500	814,000	33,240
Canada	32,384,000	57,007,000	18,356,148

Table I lists the total water power resources of Canada and the present total capacity of all water power plants.

The figures in Columns 2 and 3 do not include the power potential of major river diversions that have been investigated but not developed. For example, in British Columbia the potential of the Chilko River itself has been included, but not the potential of the Chilko-Homathko River diversions quoted in other publications as 1,000,000 hp. A number of other major diversion possibilities exist, particularly in British Columbia, where topographical conditions favour such rearrangements of flow. The addition of these potentials may be necessary to reconcile these figures with those from other sources.

Many unrecorded power sites exist on streams throughout the country, particularly in the less explored northerly districts, but these cannot be included until more detailed survey work has been completed. Thus the listed figures of available power represent only the *minimum water-power possibilities of Canada.*

Because excess capacity is usually installed at developed sites, the figures of Column 4 are not directly comparable with those of Column 3; that is, in computing the relationship between the figures of presently developed power and those of total resources, Column 3 should be increased by 30 per cent. On this basis, the figures of power available at Ordinary-Six-Months Flow which total 57,007,000 hp. may be said to be conservative as *these presently recorded water-power resources of Canada* will permit an economic turbine installation of about 74,000,000 hp.

Remaining reserves of not-too-distant power are sufficient to meet the prospective needs of a considerable part of the more closely settled areas for some years at the very least; also, improvements in the technique of long-distance transmission, including the use of higher voltage, are bringing additional sites within the orbit of existing systems. In more remote districts, water power will facilitate the utilization of mineral and other resources and promote the establishment of new communities; from the viewpoint of moving Canada's frontiers northward, the availability of considerable amounts of potential power in the more northern and at present rather inaccessible regions of the country is a definite advantage.

Progress In Development During 1956

In 1956, the appreciable amount of 845,000 hp. of new hydro-electric generating capacity was brought into operation in Canada. Construction also was active on a number of other projects comprising about 3,500,000 hp. to come into operation in the years 1957 and 1958, while an additional 4,500,000 hp. was under preliminary construction or under planning for later years. A detailed review of new and prospective developments was given in the Branch's free bulletin No. 2551 "Hydro-Electric Progress in Canada, 1956" which was issued in January 1957, and is still available upon request.

Utilization of Developed Power

For the purpose of showing the general manner in which developed water power in Canada is utilized, Table II lists the hydraulic installation of each province under three industrial divisions.

In table II, Column 2 includes only hydro-electric stations which develop power for sale. Column 3 includes only water power developed directly by pulp-and-paper companies for their exclusive use. Column 4 covers water-power installations made by other industries and used solely for their own purposes. Column 5 totals all hydraulic turbines and water wheels installed in Canada.

Canadian Pipeline Projects

Westcoast Transmission

Canadian Husky Oil Co. of Calgary has announced an agreement with Westcoast Transmission and El Paso Natural Gas Co., allotting its 32½ per cent interest in the Savanna Creek gas field to Westcoast. With the 27½ per cent interest in the field recently acquired from Phillips Petroleum Co., Westcoast will thus control half the output from the field. El Paso has offered to advance $2 million to Husky towards Husky's development costs for the field, to be repaid from half the proceeds of gas sales to Westcoast. El Paso has also invested $3 million in Canadian Husky common shares.

Inland Natural Gas Co.

Because of an unusually mild winter in the interior of British Columbia, additional financing for a $15 million issue was moved ahead. Three spreads were already working on the main line, with three more working on distribution systems. Most of the pipe had been delivered, with the balance expected by the end of May.

Alberta Gas Trunk Line

Construction of the Alberta Trunk Lines gathering main was under way at the crossing of the Red Deer River early in April, with pipe laying scheduled to start as soon as the frost was out.

A 4000 ft. suspension bridge will span the South Saskatchewan river. When the Provost-Bindloss sections are completed, gas from these fields will be available to feed Trans Canada's first customers at Winnipeg.

In 1958 the Company's main pipeline is scheduled to be carried 64 miles west to its three-way junction point, while a 149 mile, 24-inch line will be run from Pincher Creek, Cessford and Sunnybrook. Expenditures on construction will amount to $11 million in 1957 and $29 million in 1958.

Alberta Gas Trunk awarded contracts late in April for the first part of its gathering system to Fulton Banister, Ltd. The contractor will start by mid-May on the first section which includes 17 miles of 34-inch main from the Western Terminus of Trans Canada at Burstall to a point near Cavendish, Alberta. From Cavendish he will build 84½ miles of 18-inch line north to Provost. The contract, worth $10,963,000, is due for completion in September. The line will initially draw gas from the Provost and Bindloss fields.

Trans Canada Pipelines

By early April most pipeline work had come to a temporary halt due to road bans. Stringing had been completed on sections 3 and 4 during the winter. Dunn Brothers (Canada) Ltd. had strung 35 miles of 34 inch pipe on section 5 between Miniota and McGregor and were moving to section 6. A second loop was pulled at the Assiniboine crossing late in March.

The first shipment of 30-inch pipe from Britain for the line east of Winnipeg reached Halifax on March 18, and was forwarded by rail to Lorette, Man. More than 70 shiploads will be required to complete the 200,000-ton, $32 million order. Further 30

Operators make inside and outside welds on pipe at the Price-Poole double joint yard, Crandall, Man.

inch pipe will be obtained from Welland Tubes Ltd.

Pipe deliveries on the 34-inch pipe were completed by the end of April, including the pipe for sections 4 and 5. Delivery of the 30-inch pipe for section 7 east of Winnipeg will commence in May or June.

Marine Pipelaying and Dredging Co. had completed welding of the 34-inch pipe at the Red River crossing by late April, but crossing will not be laid until the river flow is down to normal summer levels. Majestic had started rock drilling on section 7 but pipelaying was not expected to commence before June. Pipelaying on the balance of the 34-inch line had been suspended until the road bans were lifted but stockpiling and double jointing was continuing on sections 5 and 6.

Northern Ontario Pipeline Crown Corporation

Contracts for clearing right of way along the northern Ontario section of Trans Canada from the Manitoba-Ontario border to Port Arthur were awarded on April 2. These contracts covering a distance of 315 miles, involve an expenditure of $807,225. The two remaining clearing contracts were awarded in mid-April to Harris Construction Co.

Tenders closed on April 26 for grading and pipelaying on this 315 miles between the Manitoba border and Port Arthur, divided into four sections. Trans Canada engineers will supervise construction. Engineering and design was handled by Trans Canada for the Crown Corporation.

Interprovincial Gas Purchased

Consumers Gas Co. of Toronto has acquired the physical properties of Interprovincial Utilities Co. which supplies manufactured gas to the Ottawa-Hull area. The purchase price is about $2.7 million. Plans involve a long-term purchase contract of natural gas from Trans Canada, and Trans Canada will push construction of the 40 mile line extension from Morrisburg to Ottawa. Meantime Interprovincial will continue to supply the Ottawa-Hull area with manufactured gas.

Quebec Natural Gas Takes Over

The Quebec Natural Gas Corporation offering of $12½ million in Canadian bonds and $7.45 million in U.S. bonds was made during the week of April 20. The Canadian offering also included $20 million of 5¾ per cent debentures and 800,000 shares of common stock. Shortly thereafter operation of the system was taken over from Hydro Quebec by Quebec Natural Gas Corporation.

FPC Hearings to Reopen

The Federal Power Commission set May 14 as the date for hearings on applications to serve the midwest United States with natural gas. FPC ordered the consolidation of proceedings for hearings to commence on 20 applications by nine pipeline companies, all relating directly or indirectly to natural gas services in the midwest states.

Hearings are in connection with the proposal by Midwestern Gas Transmission Co. to build a pipeline system from Portland, Tennessee, to the U.S.-Canada border where it would receive 204 MM c.f.d. from Trans Canada. Another 204 MM c.f.d. would be purchased from Tennessee Gas Transmission at Portland.

Three other companies are proposing to build competitive projects which are mutually exclusive in part with facilities proposed by Midwestern. Applications from five other companies have an independent relationship to the other proposals.

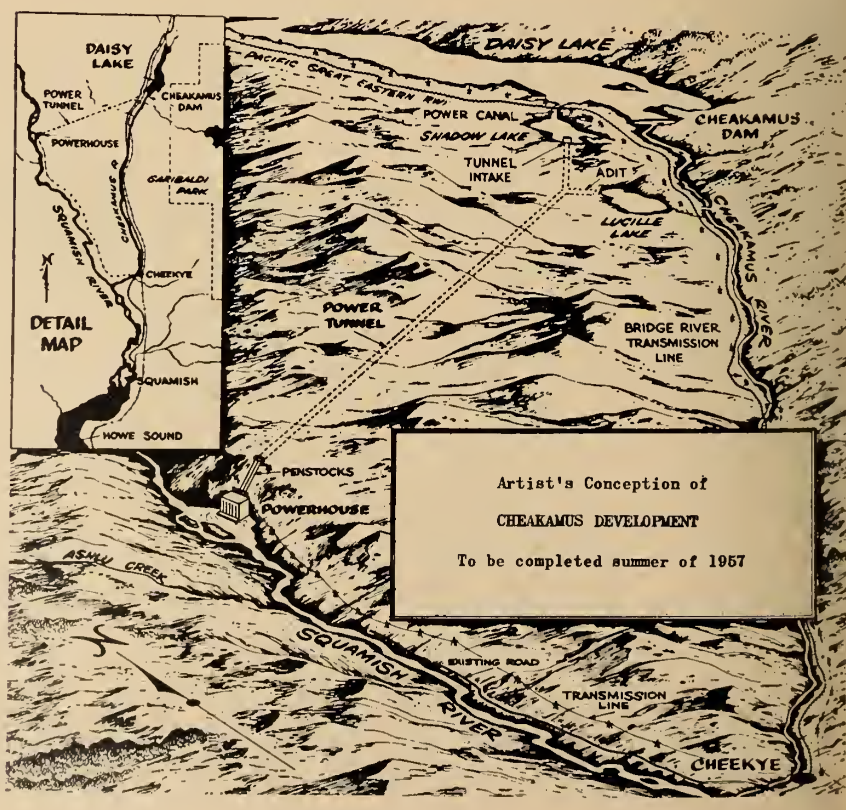
The FPC has announced it would not accept any further applications proposing service in whole or in part to these competitive areas.

Seven Mile Power Tunnel in B.C.

British Columbia Electric Co. Ltd., has completed a nearly seven mile tunnel through Cloudburst mountain.

The diagram illustrates the scheme: a diversion dam on the Cheakamus River, 90 feet high and nearly half a mile in length, will create a 1000-acre head pond, designated as Daisy Lake. A 3000-ft. canal will carry the water to Shadow Lake, 1240 ft. above sea level, from where it enters the tunnel.

Two surface penstocks connect the tunnel with a power house on the Squamish River, which will accommodate two 95,000-hp. turbines driving two 70,000-kw. generators. The first is scheduled for operation in July, the second in December, 1957.



New Port for British Columbia

Premier Bennett of British Columbia disclosed a plan at the end of April for developing a multi-million dollar deep-sea port at Squamish, once the terminus of the Pacific Great Eastern. Two thousand acres of lowland now under sea water would be reclaimed at a cost of some $20 million for commercial and residential development, and for railway yards, factories, warehouses, etc. The shallow harbour would be dredged and three large piers developed for ocean-going vessels.

The Pacific Great Eastern, owned by the B.C. Government, will control the development. Preliminary work will be started this summer. A start on land reclamation will be made by diking along the Squamish river. The present town with it's 1800 inhabitants will be moved a mile north of its present site to higher ground. Federal Fisheries Minister Sinclair, recalling Ottawa's 1949 offer of half-a-million dollars to develop a lumber wharf there, indicated federal assistance was still available.

If the plan were carried out to its full fruition, Squamish's population might grow to 25,000 within the 25 year period visualized for its development, the Premier said. The investment would be to some extent self liquidating through the sale of industrial sites. Three major firms are anxious to establish plants in the area and many more would follow once the scheme got under way.

Squamish is still the site of the P.G.E. main marshalling yards. The railway drains off lumber, cattle, minerals and farm products from the central and northern interior of the province. Much of these could be processed around Squamish, since hydro power is abundant. The town is also the jumping-off point for the Garibaldi Park recreational area.

Baffinland Aerial Survey

Canadian planes have been mapping the Antarctic for the British Government. Two Canadian Cansos have carried out 40,000 square miles of aerial photography in the rugged Grahamland Peninsula in the Antarctic. The two aircraft are part of a fleet of Kenting Aviation, flying arm of The Photographic Survey Corporation, Toronto.

Now the PSC has undertaken a commercial mapping expedition for the Canadian Government in Baffinland to obtain lattice photographic coverage of some 40,000 square miles.

This operation will continue the Government's Shoran-controlled survey of the north, which was begun in 1947 by the Canadian Goedetic Survey.

A B-17 Flying Fortress is being used for the survey, with support from a Canso amphibian for bringing out the crews and equipment after the ice break-up, a DC-4 for airlifting the personnel and material to Foxe Inlet on Melville Peninsula in May, and a DC-3 Dakota to relay them to eight Shoran sites, all to be occupied simultaneously.

Base of the expedition is an airstrip at Foxe Inlet, some 2,000 miles north of Toronto. At Foxe the photographs, taken on day to day flights at heights up to 28,000 feet and spaced at intervals of approximately 20 miles, will be processed and then inspected by a government official. Film processing will be done at Foxe and the film will be forwarded to Toronto.

The airlift began in May, and photography started about the first of June. Preparations started last summer when 100,000 gallons of fuel were shipped to Foxe. A reconnaissance flight was made last August by a Canso, and another earlier this year.

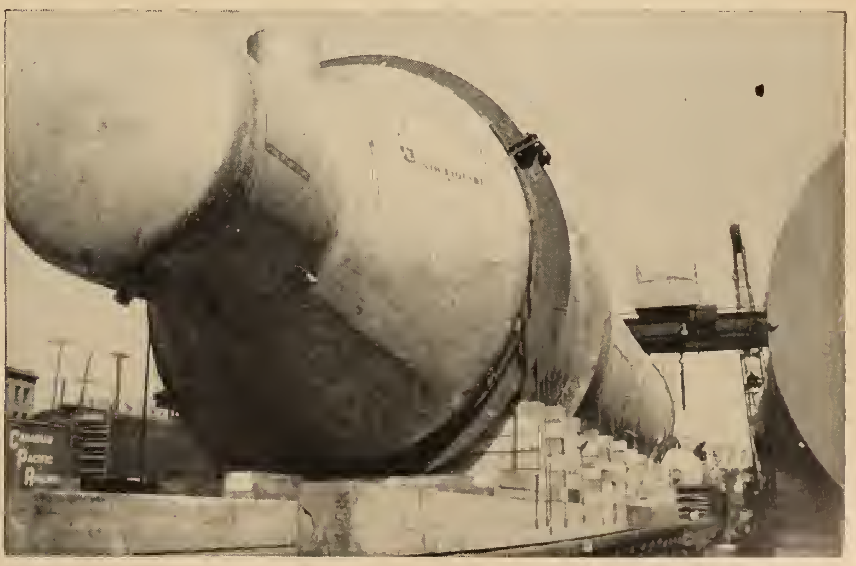
Firm Ships Chemical Equipment to U.S.

Fractionating units built in Canada for the low temperature separation of gases, part of a 300-ton-per-day tonnage oxygen plant were recently completed and shipped to a large chemical company in the United States by L'Air Liquide, Montreal (engineering and construction affiliate of Canadian Liquid Air).

Consisting of four vessels of unusually large size: a high pressure column, 24 ft. long by 8½ ft. dia., low pressure column, 48 ft. long by 9 ft. dia., vaporizer, 34 ft. long by 6 ft. dia., and exchanger, 19 ft. long by 3½ ft. dia., the whole assembly required two railroad flat cars and a gondola car to transport it.

All-welded of stainless steel, these fractionating units are the heart of a huge air separation plant designed by L'Air Liquide to produce 300 tons of oxygen and 140 tons of pure nitrogen per day. To accomplish this, the plant will have to process 1,875,140 cubic feet of atmospheric air every hour. Separation of the gases from the atmosphere by this process is carried out at temperatures in the vicinity of 300 degrees (F) below zero,

Fractionating column being shipped to U.S.A.



when the air becomes liquid and flows like water. This liquefaction process is also widely used for the separation of hydro-carbon gases in the petroleum industry.

The oxygen and nitrogen from this plant are to be used in the synthesis of a number of chemical products.

What Goes On

Great Lakes Power

A $5 million issue of Great Lakes Power Corporation 5¾% debentures has been sold at par. Proceeds will be applied to the company's development program.

The company sells power to the city of Sault Ste. Marie, and to mining and smelting, pulp and paper, and manufacturing industries in the area. A seventh hydro-electric station for the company's system is now under construction, and will bring the installed capacity to 201,000 hp. This total is expected to be 226,000 hp. by 1959. (Financial Post, May 4).

Saint John Hospital

Contracts in the value of $2.5 million were awarded recently, to put into effect the last stage of the expansion of the Saint John General Hospital, Saint John, N.B.

Completion of the $5 million scheme is scheduled for May, 1959, having been set in motion in 1952. With a power house, a nurses' residence, an expanded kitchen, dietary and laundry facilities already constructed, the next stage will supply a section to house the cobalt bomb (this unit to be in operation possibly by the end of 1957). (Financial Post, May 4).

McIntyre-Ventures

McIntyre-Porcupine Mines will acquire an interest in Ventures Ltd., according to a recent announcement of a proposed plan, the effect of which would be a change of policy for both companies. There would be more rapid development of Ventures projects in Canada and elsewhere, McIntyre providing $20 million in exchange for an initial 16 per cent interest in Ventures with options on additional shares, up to 30 per cent (Financial Post May 4).

Britain Will Buy Uranium

That Britain will buy $115 million worth of uranium from Canada during the next five years was disclosed after the March Bermuda talks between Prime Ministers St. Laurent and Macmillan.

A contract was approved at the meeting whereby the United Kingdom atomic energy authority will purchase uranium from Canada's governmental agency, Eldorado Mining and Refining Limited, which in turn has entered into purchase contracts with Canadian mining companies. This uranium, the communique said, "will greatly assist in carrying out the expanded nuclear power program of the United Kingdom". (Montreal Star, March 27).

Ontario Hydro

Ontario Hydro will start construction this spring on a single-unit, remote controlled, 43,500-kw. generating station at Silver Falls on the Kaministikwia River, about 25 miles northwest of Port Arthur. It is scheduled for service late in 1959, and it, with other developments under way, will add 206,900 kw. to the generating capacity in the Commission's north-western division by that time.

Ontario Hydro also announced recently that a fourth 200,000-kw. unit will be added to the Richard L. Hearn Station in Toronto. This will raise the total installed capacity to 1,200,000 kw.

There are now four 100,000-kw. units at this station. In addition, three 200,000-kw. units are scheduled for service in 1958, 1959, and 1960 respectively. The fourth such unit is also tentatively scheduled for 1960. This installation will mark the completion of the Richard L. Hearn generating station.

Cunard to Serve Detroit

Deputy Chairman Sir John Brocklebank of Cunard Steamship Lines Ltd. announced at Detroit late in March that his company would inaugurate cargo service into Detroit this spring in anticipation of the 1959 opening of the seaway. Two 1500 ton vessels would commence the service, with the first one due to arrive at Detroit May 7. The operation would be experimental to learn how the trade works.

McMaster Nuclear Reactor

Ottawa has issued a permit for the construction of a nuclear reactor at McMaster University. The McMaster plans, directed by Dr. H. G. Thode, principal, Hamilton College, met the requirements of the Atomic Energy Control Board, and with the approval of the atomic scientists, health and engineering authorities, construction may proceed.

The contract for the design and construction of the research reactor has already been let to AMF Atomics (Canada) Limited. Detailed plans for the reactor building itself were to be ready in May, and breaking of ground was scheduled for June. Full power operation of the reactor in the fall of 1958 is expected.

Urban Renewal in Montreal

An area comprising 19.7 acres in downtown Montreal is due for acquisition, clearance and redevelopment. The Federal Department of Public Works announced in March that the Federal Government had entered into agreements with the Province of Quebec and the City of Montreal to accomplish the project.

Acquisition and clearance of the area, bounded by St. Dominique, Ontario and Sanguinet Streets, and the rear lot lines of properties fronting on St. Catherine Street, will be undertaken by the City of Montreal with financial assistance under the National Housing Act. The maximum federal contribution will be $2,467,-587, about one-half of the estimated cost of acquisition and clearance less the price at which the land will be made available for a Federal-Provincial subsidized rental housing project. The Provincial Government has indicated that it will contribute $1 million.

The rental housing project, to be constructed under the National Housing act will consist of approximately 800 units. Capital costs of the project and rental subsidies will be borne 75 per cent by the Federal Government and 25 per cent by the City, acting as the agent of the Province of Quebec.

Rentals will be based on the income and size of tenant families, all former residents of the area being eligible for re-housing. Units not rented to these families will be offered to families with incomes of between $150 and $350 per month.

Central Mortgage and Housing Corporation will collaborate in the design and construction of this project, the first redevelopment and public housing project in Quebec under the National Housing Act.

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE ELECTIONS AND TRANSFERS

No More Union In Saskatchewan

For many years the engineers in the civil service of Saskatchewan have been required to belong to a trade union. Naturally in a heterogeneous union of that kind they were a very ineffective minority.

For years they have been trying to extricate themselves from this unhappy situation and recently it has been announced that they have been successful. A Labor Relations Board order handed down recently, granted an application submitted by Bernard C. Laws, M.E.I.C., P.Eng. and Ronald E. Pelkey, M.E.I.C., P.Eng., both of the highway department, for exclusion from the collective bargaining agreement.

This development should have real significance to engineers in many parts of the country and in the United States as well. Here is a case of a group of engineers about forty in number who have been forced for years to be members of a union. They have not liked the experience and have successfully fought their way out of it.

Congratulations to the engineers in the Civil Service of Saskatchewan and to the Association of Professional Engineers who have worked with them. They have certainly been courageous and tenacious and it is nice to know that at last they have received their reward.

Change In Plans

Many members will have read in the daily press the announcement made by the Atomic Energy of Canada Limited a short time ago relative to the suspension of work on the nuclear power reactor which was to be built at Des Joachims, Ontario.

It will be a disappointment for many to know that the completion of this project is now going to be set back a substantial period of time. Canadians are taking a real pride in the advanced position in which Canada has placed herself in the nuclear field and they may well be discouraged at this latest news.

It was the good fortune of the general secretary to be informed of this move by the Atomic Energy of Canada just prior to the public announcement. At the interview in the Company's office in Ottawa the story was revealed in detail with the result that it is now realized that great praise is due to the A.E.C. for the courage they had in making this decision.

As is so frequently the case in new developments the engineers discovered as they proceeded with the design that there were other ways of accomplishing the desired results. New methods, new ideas, were found which were much more promising than those being used so that finally the company decided that in the best interests of everyone the work should be suspended temporarily.

As a matter of fact, almost every reactor being built today will be out of date in a matter of a very few years. Canada was in the fortunate position that she was not desperate for power and therefore could afford to set the whole project back a bit in order to develop safer and more economic methods.

Instead of being disappointed Canadians should be happy to know that this work is in the hands of people who have the courage to take this sort of action. The work will go on and eventually there is every prospect that the Canadian reactor will be as good or better than any other in the world when it finally comes to completion.

Herewith is the official release which puts into newspaper language the thoughts that in the previous paragraphs we have tried to express.

Atomic Energy of Canada Limited, the Hydro-Electric Power Commission of Ontario, and the Canadian General Electric Company Limited, partners in the Nuclear Power Demonstration project which is underway at Des Joachims, Ontario, announced today that construction work at the site had been suspended temporarily because of major design changes in the reactor which are now under study. The present design of the NPD reactor is based on an outline specification which was established as the result of a nuclear power feasibility study carried out by representatives of certain of the utilities, including Ontario Hydro, and the staff of Atomic Energy of Canada Limited.

Cover Picture

The cover picture is a view of the fabrication of a microwave parabolic reflector designed to transmit ultra high frequency radio waves over long distances.

Photo courtesy Dominion Bridge Company, Limited.

Important technological advances have occurred over the period since the detailed design of the NPD reactor began. These are of such significance that it seemed most desirable that an attempt should be made to incorporate them in the design of the NPD reactor even at the expense of some delay in bringing the reactor into operation. These changes in design do not affect the basic concept of the design — that is, the use of heavy water as a moderator and natural uranium as a fuel — nor do they affect the power rating of the NPD reactor, which has been established at 20,000 kilowatts electric. The work at Des Joachims has only reached the stage of preparation for the foundations. Therefore the decision to consider a change in design will not involve the abandonment of any construction which has taken place at the site.

British Engineer Speaks To Branches

It was the Institute's good fortune to have Sir Claude Gibb, K.B.E, F.R.S., chairman and managing director of C. A. Parsons and Co. Ltd., Britain, speak to nine of the Branches on the subject of Some Engineering Problems in Connection with the Development of Nuclear Energy. There are few people as well qualified to speak on this subject as is Sir Claude. He heads up one of the three great groups in Great Britain who have combined their forces in order to put that country ahead of the rest of the world in the development of this type of vital energy. Not only is he the executive head of these leading companies but he is himself one of the best nuclear engineers in the country. He is chairman of the Nuclear Power Plant Co. Ltd., and of A. Reyrolle and Co. Ltd., Britain; and president of C. A. Parsons of Canada Limited.

Sir Claude spoke at the following branches and the approximate numbers in attendance are indicated in brackets after each branch.

March	28	Toronto	600 to 700
March	29	Huronia Branch	250
April	1	London	135
April	3	Chalk River	400
April	4	Ottawa	200
April	5	Montreal	200 to 300
April	8	Winnipeg	600
April	9	Regina	200
April	10	Edmonton	165

After this tour, Sir Claude returned to Toronto on the 11th and then flew from Toronto back to London on the 12th.

This was a highly intensified tour and at the same time it was a triumphant one.

Headquarters have received reports from every center where he spoke and without exception the branch officials and members claimed that this was as fine a lecture as had ever been delivered before the Institute.

Sir Claude not only is an expert in this field but he is one of the finest speakers in the profession. He has a way of dealing with a technical subject that does not seem to make it technical at all. This, capped with his fine sense of humour, makes it

Prior to giving his lecture in Montreal, Sir Claude Gibb was entertained at luncheon by the Council of the Institute and at dinner by the executive of the Montreal Branch. Shown at the luncheon, head table, are: R. E. Heartz, Sir Claude, R. L. Dunsmore, J. B. Challies, J. B. Stirling, I. R. Tait.

Below: groups in Toronto and Montreal greet visiting lecturer. Left to right: Sir Claude, Toronto Branch chairman E. R. Davis, and President V. A. McKillop; Leo Roy, Montreal Branch chairman, Sir Claude, and Past President Heartz.

D. J. Matthews, London Branch chairman, with Sir Claude Gibb.

a pleasure to listen to every word, although to this writer and to many others in the audiences most of the words were not too well understood.

The Institute is greatly indebted to Sir Claude and to the Institution of Mechanical Engineers through whom arrangements were made for Sir Claude to come to this country to deliver the lecture for which he had been awarded the Hopkinson prize by that Institution.

The Institute in Pakistan

Recently through the Canadian High Commissioner's office an invitation was extended by the Institute of Engineers (Pakistan) for The Engineering of Canada to be represented at their fourth annual convention which took place in Karachi from March 29 to April 2.

It was the Institute's good fortune to have a member in Pakistan at that time who could attend as the representative. He was E. L. Miller, M.E.I.C., project manager for the H. G. Acres & Company Limited, who are consulting engineers on the Warsak Colony power project.

Mr. Miller has reported that the conference was interesting and successful. The principal official speaker was the Prime Minister, H. S. Suhrawardy.

The technical program included papers on a great variety of subjects including Need for Consulting Engineering Profession in Pakistan.

On the Sunday which came right in the middle of the program there were plant tours to a prestressed concrete pipe factory and several other points where the guests were met by prominent officials and were addressed by the minister for labour and works.

One innovation which has never been tried in Canada as far as the Institute is concerned is to have the conference set for a Friday, Saturday, Sunday and Monday. If the Institute could get its members to attend on these days it would be a lot simpler to get hotel accommodation than it is today.

The Institute of Engineers ("Pakistan") is built on the same basis as The Engineering Institute of Canada; that is, it caters to all branches of the profession. As would be expected in these early years of the country's history, the work underway is largely of a civil nature. It was not so long ago that the same condition was true of Canada but within recent years the industrial development has made papers available in a greater variety of subjects.

It is interesting to observe that the people of Pakistan have considered it important that they should have a national engineering society almost from the time of the birth of their country. Pakistan was established in 1947 and the Institute was established in 1952. This is but further proof, if such proof were necessary, that a profession cannot operate without a national society to represent it.

"The Future of the Western Alliance"

Once again the Institute was well represented at the annual meeting of the American Academy of Political and Social Science held in Philadelphia on April 5 and 6. This was the 61st such meeting.

The Institute's two representatives were S. Logan Kerr, M.E.I.C., consulting engineer, of Philadelphia, and W. S. Pardoe, M.E.I.C. These two gentlemen have attended these conferences on behalf of the Institute for several years.

Herewith is a report as submitted by Mr. Kerr, which is written in a very interesting style to the members of the Institute.

L.A.W.

Your two delegates to the annual meeting of the American Academy of Political and Social Science between them attended all six sessions.

The theme of this meeting was "The Future of the Western Alliance". A wide range of delegates were in attendance and a copy of the attendance record is also enclosed as a matter of information as to the scope of the meeting.

The opinions expressed by the various speakers were just as varied as the background of the speakers themselves. Several of the addresses were of very substantial interest, particularly those by Mr. de la Grandville of the French Embassy to Washington; Mr. Arthur Dean, formerly special U.S. Ambassador to Korea; Major General Biddle; His Excellency, Heinz Krekeler, Ambassador of Germany to the United States. All of these took a very objective view toward the situation in Europe and felt that NATO was acting as a war deterrent, the Western Alliance would also survive in spite of Suez, and that the effectiveness of NATO and the Western Alliance was giving the Soviets considerable worry.

The general feeling of these speakers was that the troubles in the Middle East were instigated largely by the Soviets and were part of the broad program of giving the Western Alliance and its individual members as hard a time as possible short of war.

Many of the other speakers seemed to think that much of the efforts to contain Communism or to act as a deterrent against its expansion were rather hopeless. A certain percentage of the speakers at this meeting and at previous meetings belonged to the "left of center thinking" and due allowances should be made.

The procedure was like several previous meetings attended by your two delegates, namely that the speakers were selected to promote discussion, the length of the program, left only a few minutes for discussion and this was used up by individuals from the floor making speeches prior to proposing their questions and thus the answers were limited as was the amount of discussion.

One significant history making event should be recorded, namely the 100 per cent of the members of the Engineering Institute of Canada, resident in the Philadelphia area, were present at the free luncheon on Saturday. These comprised the two official delegates and honorary member William L. Batt.

The delegates are again indebted to the Institute for the privilege of being the official representatives at this meeting.

The President

Continues his Travels

Visiting Toronto in February, President McKillop met with the officers, and attended a branch meeting. At dinner preceding the branch meeting (above) he and Mrs. McKillop and their daughter were seated at head table, with Branch Chairman E. R. Davis and Field Secretary L. F. Grant.

The two groups above right were photographed at the Toronto meeting. In the first there is Prof. J. Roy Cockburn loooking hale and hearty and thoroughly belying his 77 years, talking with branch secretary D. S. Moyer. In the second group Mr. and Mrs. George Cunningham (centre) with Mr. and Mrs. H. C. Graham.

The president visited the Montreal Branch. Left to right: R. F. Shaw, the president, Leo Roy, Branch Chairman, and Leo Nadeau, secretary-treasurer of the Corporation of Professional Engineers. He presented Institute student prizes to students at Ecole Polytechnique (at right): prize for 1956 to Pierre Fortier, and for 1957 to Gilles Gascon.

The Eastern Townships Branch marked the president's visit with a dinner and dance. Here are the head table guests. Seated: Mrs. Mawhood, Mrs. Masse, Mrs. Dunsmore, Mrs. McKillop, Mrs. Lemieux, Mrs. Wright, Mrs. Dick. Standing: Gaston Masse, George Dick, L. Austin Wright, President McKillop, Mayor Armand Nadeau, Branch Chairman Jacques Lemieux, R. L. Dunsmore, and R. D. Mawhood.

At the Mayor's office, Mr. McKillop received the key to the city, and signed the golden book. Standing, left to right: Mr. Masse, Mr. Lemieux, Mayor Nadeau, Dr. Wright, Mr. Dick, and Mr. Mawhood.

Council meeting in Toronto. Shown, left to right: P. E. Buss, Thorold, B. G. Ballard, Ottawa, L. J. R. Sanders, Galt, M. W. Huggins, Toronto, L. C. Sentance, Hamilton, T. M. Medland, Toronto, R. E. Hayes and R. F. Legget, Ottawa; in the foreground, D. D. Whitson, Toronto. Below: R. A. Emerson, treasurer, George Dick, John Fox, president of A.P.E.O., M. A. Montgomery, Kitchener, and President McKillop.

Daylight Through The Mountain

The book, "Daylight through the Mountain" by Dr. Frank N. Walker, will be published shortly by the Engineering Institute.

This is the second extract, included in the *Journal* to interest engineers in the forthcoming book, which tells the remarkable story of Walter and Francis Shanly, two pioneer Canadian engineers.

Ed.

The Shanly brothers were always at their best when under pressure. The "Erie Railway" was increasing the speed by which it approached Lake Erie, but the owners of the Ogdensburg Railway were determined that their road should connect the Atlantic Ocean with the navigation of the Great Lakes first. The president, T. P. Chandler, of Boston, took Walter Shanly aside and told him that he was depending upon him and his brother Francis to push the work through on schedule. On May 5, 1850, Walter as Resident Engineer wrote to Francis:

"I am offering $1.25 for horses and carts, but my credit must be very low as not a single one will work for me. Quartz' are the only additional horses on the work. It is the first time I ever failed to get all I required to engage with me. I have despatched a messenger to Lower Canada to enlist Frenchmen, and will pay the duties on all the horses and carts he may bring with him. You must take care and not employ on our own work any of those ruffians who broke their engagements with me. I have strong faith in getting up a good gang of French Carters who will render us independent of those Irish Ruffians. I am equally in a fix for a foreman and after losing a week waiting for John Agent have been compelled to fall back on a damned Irishman. I shall require 3 or 4 more and will I suppose be driven to employing all the same sort. Angus McDonald is sulky and doing all he can to oppose my proceedings. He is determined not to put a night gang in the Thomas Cut and as the Cars all belong to C., W. & Co., I don't know what to do. The fellow is making a d--d fool of himself because he does his employers no good and he has applied to Mr. Chandler for a situation as a Freight Clerk. I will be obliged, very unwillingly, to cut off his head. I shall give him written orders to send down the Wheels, but if Abbott has given him a hint about the night work, he won't do it. The fact of the Cars being theirs gives them a certain hold on us and McDonald knows it, but the result of the opposition on the part of C., W. & Co. will be a total extinction of their contract.

"If that fool Worral was here, I could frighten him into giving orders, but McDonald sulks and I can get no good of him. I see no hopes of getting the track through here except by running through the Cut on a Grade of 80 feet to the mile. This I am resolved to do, sooner than not lay track before July. You must drive all you possibly can and where they fail to obey orders, *put on men*. See Section 10 be completed forthwith in every point. Raise the embankment by a grade of 26 feet in the mile to the level of the Piling. It will not do to let small things wait until the large are finished. Everything must go on at once.

"Chandler left on Saturday and gave me full power to do as I think best, only to push the work. I promised him I would and I will. He was very confidential with me towards the close of his visit, but I didn't ask for the $1,600. He would have ponied up right off. Could you save time at Freeman's by embanking from the West end also, taking material from the back of the Depot Ground? If this could be done, we might put a force into the East end of the Ridge and waste some excavation. Think over it and do whatever you can to let the engine go right on when I get her that far. Put a night gang in Hamblin and don't let John Roy sleep until he has got to the length of his tether with the embankment from the East.

"Touching the Culvert, I see no use in giving C., W. & Co. any more to do. So let Willard employ a gang to get out the covering and pier stone. Take off the Arch and Skeyback, but no more. Lay the Arch stones aside. They may be of use. Make a drawing of the Culvert as it is before pulling down.

"I will send by next mail Releases drawn up by Russell for Russell Worthen and Old Henderson. You can't survey until you get these, but do it as soon after as possible. Go out to Morley and see what Bridge lumber Barrett has sawn, also what 18 feet logs he has. I must come down upon him at once.

Yours as ever,
W. Shanly."

Elections and Transfers

At a meeting of Council held in Montreal, on May 10, 1957, a number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected:

Members: H. N. Black, Toronto, F. B. Bunting, Vancouver, R. F. Cole, Windsor, F. W. Cranston, Toronto, H. R. Davies, Toronto, O. Dorval, Ste. Foye, Que., W. Downs, Trinidad, D. A. Elliott, Calgary, M. E. Erfle, Calgary, G. H. Gallimore, Brockville, B. W. Gilbert, Montreal, J. I. Halporn, Montreal, H. D. Hamilton, Aurora, Ont., W. R. Hoffman, Port Hope, J. F. Howard, Peterborough, C. S. Kitchen, Hamilton, C. Lemesch, Montreal, J. T. Martin, Niagara Falls, V. Petrov, Montreal, H. D. Savage, Vancouver, D. Sawyer, Windsor, B. J. Seaman, Calgary, M. S. Thompson, Cornwall, G. A. Vissac, Montreal, W. White, Victoria, R. A. Yates, London, Ont.

Juniors: R. J. Bishop, Brownsburg, B. D. Blann, Hamilton, D. C. Burman, Toronto, L. A. Deschamps, Montreal, J. F. Fulton, Kingston, W. M. E. Kaye, Toronto, W. D. McDougall, St. John's, Nfld., R. R. Nicolet, Montreal, T. E. Pelton, Vancouver.

Junior to Member: D. E. Burnham, Cornwall, F. C. Creed, Ottawa, K. R. Fulton, Hamilton, J. Haworth, Cornwall, O. G. Hubley, Kentville, G. W. Joly, Montreal, A. E. Jones, Vancouver, E. Nenniger, Montreal, K. Piekarski, Toronto, T. M. Wardle, Victoria.

Student to Junior: H. Nahaiowski, Calgary.

Students Admitted:

University of New Brunswick: M. R. Cossitt, H. J. Fullarton, J. R. MacPhae, J. A. Parker.

Queen's University: W. R. Hough, N. L. Jeppesen, D. J. Wilson.

University of Alberta: N. M. Sokolowski.

Laval University: J. H. W. M. Chamberland.

Nova Scotia Technical College: R. J. Churchill.

Student A.P.E.O.: E. B. Logothetis, A. B. Frazer, P. J. Hoes, A. T. J. Wickins.

Graduates: A. R. Canzi, B.A.Sc. (Elec.), University of Toronto 1956.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Prefessional Engineers, the following elections and transfers have become effective:

ALBERTA

Members: M. A. Domecki, W. W. Laughlin.

Juniors: D. A. Hanenberg.

SASKATCHEWAN

Members: R. P. Couturier, E. F. Evoy, R. E. Melvin, G. F. Watts.

Juniors: J. Maandag.

Students: G. F. Blair, D. E. Cherry, J. D. Kilburn, H. Pelech.

Junior to Member: S. K. McMillan.

Student to Junior: J. A. Haynes, J. B. Street.

NOVA SCOTIA

Members: L. L. Centa, K. L. Farquharson.

Junior to Member: M. S. Boyd, A. B. Drew, R. J. Flinn, H. E. Reid.

NEW BRUNSWICK

Members: J. E. Callaghan, A. Sibson.

Junior to Member: T. Turgeon.

Student to Member: H. M. Keirstead.

E.I.C. Annual Meeting, 1958

Quebec City, Chateau Frontenac, May 21, 22, 23.

A Library Is For People

Shirley Courtis

Chief Librarian, Engineering Institute of Canada

Contrary to a belief held by certain people, a library is run for the benefit of its patrons, and not for that of the librarians! This applies particularly to the library of the Engineering Institute of Canada which is one of the best technical libraries in Canada. Its services are available to all members wherever they live, Vancouver or St. John, Labrador or London, the Yukon or Jamaica.

An engineer's studying days are not over the day he receives his degree, and many of the problems he has to tackle can be solved only through the resources of a technical library. The collection in the Institute library contains many thousands of books on all branches of engineering from a seventeenth century text on surveying to the latest on guided missiles and nuclear power plants. Five hundred different periodicals are received from all over the world, and in addition there are encyclopedias, dictionaries and all the reference books found in a general library, as well as five filing cabinets of pamphlets.

You may wonder how a member living out of Montreal can make use of the library facilities. The answer is, in many ways. Nearly all the books and magazines in the collection will be mailed on loan and the Institute pays the postage.

If you want a particular book or magazine article, a written request will send it on its way if it is in the library, and if it is not, it will be borrowed from another library, or a substitute sent. Librarians are also good at tracking down that book that you remember is about so big, and green, and something to do with . . . well, try and remember what it is to do with! The same applies to that magazine article that Joe told you he saw a year or so ago, in *The Engineering Journal*, or maybe it was in *Civil Engineering*, or maybe . . . anyway it would be just the thing.

If you are starting a new job, and would like to do some background reading, request a couple of general books on the subject. When you are coming to grips with a problem, write and explain the situation, and if there is a book or magazine article which will help, it will be sent to you. More complicated problems mean that a bibliography has to be compiled, listing all the books and articles available. It is important to give as many details about the problem as possible — it is very difficult to read between the lines, especially at a distance of a thousand miles or so!

Once you start research on a subject, try and compile a bibliography for yourself as you go along. Nearly all books and magazine articles contain lists of references, and some of them may provide just the information needed. Note down all the details given in the reference, as the omission of a volume number or part of the title may make the reference quite incomprehensible.

Students writing theses often request bibliographies on their topics, but the library cannot undertake to compile these, although books on the subject will be recommended. A very large staff would be needed to compile bibliographies for all the students writing theses each year!

Library Services

What else does the library do for you?

It provides a photostating service, at a very cheap rate. Through it you can subscribe to periodical publications of many other engineering societies at a reduced rate, and you can buy any technical book or pamphlet, at the ordinary retail price. New books are reviewed each month in *The Engineering Journal* and by reading these you can keep informed of the latest in your field.

If you are lucky enough to be within direct reach of either the Institute or another technical library, you can of course select your own material.

The first thing to do is to find your way around the library. Ask the librarian to show you how to use the card catalogue if it is a type with which you are not familiar, and how the numbers in the catalogue connect up with the way the books are arranged on the shelves. Find out where the periodicals are kept, and how to use the periodical indices. There are two of these which are important in a technical library, the Engineering Index and the Industrial Arts Index. Between them, they index by subject all the articles appearing in over twelve hundred technical periodicals — Did you realize there were that many — and more?

Take note of where the reference books and handbooks are kept. These will answer many questions from when was the first World Series, and who won it, to what is the length of the longest bridge in the world, and they are a good starting point when approaching a new subject. The latest information on any topic often appears in pamphlets — find out how the library keeps these, and do not be deterred by the term "vertical file". Usually it only means filing cabinet.

Professional Help

Familiarize yourself with the library regulations, and get to know the librarians — they can really be helpful. When you have a problem ask the librarian, maybe someone else was working on the same thing last week, or last year. She may remember, or have a note of it.

An engineer is a professional worker, and so is a fully-qualified librarian. She too has spent at least five years at university, because nobody can enter the one year course leading to the degree of Bachelor of Library Science without having at least a B.A. or a B.Sc. Although a librarian may have no previous knowledge of the subjects covered in her library, in this case engineering, this is not an unsurmountable difficulty. It is not actually knowing the answer which is important to a librarian, it is knowing *where* to find the answer that counts. As a result of her library school training, the librarian has this knowledge at her finger-tips.

If you are starting to work on a particular topic, begin by looking at the handbooks and textbooks, take note of the references they give, consult those, and then check the periodical indices and pamphlets for the latest articles.

Whether you are asking for information by mail, over the telephone, or across the desk, be as specific and informative as you can, a lot of your valuable time may be saved in the long run. Always ask for help if you need it, that is what librarians are for, and remember, the library is for people, and never let anyone tell you anything else.

There's Life in The Old Dog

In the minds of many Canadians the daily newspaper, *The Times*, represents a serious matter-of-fact uncolorful daily publication. To one who has the opportunity to read *The Times* every day, the publication soon becomes almost a daily necessity. Throughout its long career it has been one of the outstanding publications in the world.

Just by way of proving that you can teach an old dog new tricks, the *Times* has come out recently with a publication called *Technology*. At the time of writing there have been just two issues. On its own masthead it describes itself as "The Monthly Review of Training and Education for Industry", and the publications so far issued certainly live up to that description.

Technology is filled with up-to-date news and observations on the very newest developments in the field of engineering and science. The articles are contributed by outstanding people in their field and are amplified by special short articles, letters to the editor and so on, which are both informative and entertaining.

It is a pleasure to welcome into the field of technical publication this new member. The Institute library has it so that members will have available to them in the reading room this very up-to-date and readable technical publication.

Science Bursary

A new educational grant, to be called the Elsie Gregory Magill Bursary after the first woman aeronautical engineer in Canada, has been established by the Toronto Business and Professional Women's Club.

The bursary will be a grant of $500 per year for five years for a girl secondary student who is interested in science. The recipient will study for four years at the University of Toronto and for one year at the Ontario College of Education. She will teach for a few years in Toronto secondary schools after graduation.

Miss MacGill, a member of the Engineering Institute, practises as a consulting engineer in Toronto.

Clement Matthew Anson

PRESIDENT

THE ENGINEERING INSTITUTE OF CANADA

1957

To fill the office of president this year the Engineering Institute of Canada has chosen a man reared in the steel industry, whose family has for two generations played an active role in its development.

Clement Matthew Anson, born at Rotherham, England, in 1901 is today vice-president and general manager of the Dominion Iron and Steel Limited; James Pender and Company Limited; and the Dominion Shipping Company Limited; all of which are subsidiary companies of the Dominion Steel and Coal Corporation Limited.

Mr. Anson's grandfather had built blast furnaces in India and the United States, as well as at home in England. His father, a steelmaker, and an open-hearth man, took part in the original development and production of raw steel for stainless steel products. He was one of the organizers of the Steelworkers Union of England, and eventually became a manager of a steelworks in Australia.

A child at the time his family left England, Clement Anson was within a few years absorbed in the family tradition. Familiar with the laboratory of the steel plant at fifteen, he assumed the duties of superintendent of a new steelmaking plant three years later.

In order to enroll in engineering at McGill University he left Australia at the age of twenty. He graduated with a bachelor of science in metallurgy in 1925.

From an initial position as a laborer with the blast furnace department of the Dominion Iron and Steel Limited, Sydney, N.S., at the time of his graduation, Mr. Anson has worked his way up in this primary Canadian industry. After a turn in the open hearth he served as a coke oven specialist, and in two years' time was assistant blast furnace superintendent. Successive appointments have been those of assistant superintendent of heavy mills, assistant general superintendent, and assistant general manager. In 1940 these promotions culminated in his appointment as general manager of Dominion Iron and Steel Limited, and subsequently his responsibilities were enlarged to include Seabord, Dominion Limestone, Pender, and Dominion Shipping. He took office as vice-president and general manager of Dominion Iron and Steel Limited in 1952.

In his capacity as general manager Mr. Anson's responsibilities cover not only the basic steel making and steel fabricating operations of the huge Sydney plant, but also include limestone quarrying at Agauthuna or Port-au-Port, Nfld; the manufacture of wire and nails at James Pender and Company, (Limited) Saint John, N.B.; the vast power generating and distributing network carried on by the Seabord Power Corporation Limited, Cape Breton, and the shipping operations of Dominion Shipping Limited.

A member of the Canadian Institute of Mining and Metallurgy, the British Iron and Steel Institute and the American Iron and Steel Institute, some of his other professional activities include membership in the board of governors of the Research Council of Nova Scotia and of the Nova Scotia Centre for Geological Sciences. For six years he was a member of the Board of Governors of the Nova Scotia Technical College.

His active participation in the affairs of the Institute dates to 1931, when he became an Associate Member. Mr. Anson transferred to Member in 1941, and later carried out the duties of vice-president of the maritime zone for the term 1946-47.

In 1950 he became the first engineer in the steel industry to enjoy the honour of receiving the two coveted awards of the Engineering Institute, the Julian C. Smith Medal, presented to him in 1950, and the Leonard Medal in 1954.

He is actively associated with many Sydney community enterprises. He is president of the Protestant Home for Aged People.

Mr. Anson is married to the former Dorothy Elizabeth O'Neil; they have two children, a son and a daughter.

Newly Elected Officers of the Institute

At the Annual Meeting, three vice-presidents and thirty-three councillors will take office, and will serve with others whose terms of office continue. The complete list of Council appears in this issue.

E. A. Leja, M.E.I.C., managing director of Lundrigan's Concrete Limited at Corner Brook, Newfoundland, has been elected councillor of the Institute, representing the Newfoundland Branch of the Institute for a two-year period.

A native of Latvia, Mr. Leja graduated from the University of Latvia at Riga in 1930 with a degree in chemical engineering. He immediately undertook the work of assistant superintendent of the finishing department with a glass manufacturing concern in Latvia. Appointed a lecturer at the Institute of Commerce in Riga, in 1932, he was within the next few years named a professor and lectured on the subject of the technological processes in the manufacturing of merchandise. In 1936 he left the University and assumed the duties of engineer in charge of extension with an asbestos-cement works at Riga. In 1937 he was made superintendent of the plant. From 1938, through the war years, he held various positions in Latvia as technical manager and managing director, one of which was a United Building Material and Portland Cement Works at Riga. Moving to West Germany in 1944 he again held similar positions until 1950.

E. A. Leja, M.E.I.C.

Upon his arrival in Canada in 1950 he took over the responsibility of chief engineer in charge of the construction of a cement plant and the gypsum and wallboard plant at Corner Brook for the Province of Newfoundland.

Managing director of the North Star Cement Ltd., and the Atlantic Gypsum Limited in 1951, he severed his connections with the latter concern in 1955 to take over the post he now holds with Lundrigan's Concrete Limited.

W. Watson, M.E.I.C.

W. S. Veale, M.E.I.C.

W. S. Veale, M.E.I.C., who has been elected councillor representing the Prince Edward Island Branch, is a native of that province. He attended Acadia University and graduated from the Nova Scotia Technical College in 1950 with a B.Eng. degree in civil engineering.

With the Canadian Army during the last three years of the war he served with the Intelligence Corps in Australia, the Phillipines, and Japan.

Mr. Veale is employed with the Federal Department of Public Works, harbours and rivers engineering branch, at Charlottetown, P.E.I.

He joined the Institute in 1950 as a Student Member and was transferred to Member in 1951.

William Watson, M.E.I.C., of the Canadian General Electric Company, St. John's, Newfoundland has been elected to represent the Institute as councillor for a two-year period.

Educated at Bishop Field College, Mount Allison Academy and Mt. Allison University he moved on to McGill University for the completion of his engineering studies and graduated in 1924 with the degree of B.Sc. in electrical engineering.

For the first two years of his career Mr. Watson served the Sir W. G. Armstrong Whitworth Company Limited as an assistant electrical engineer on the construction of a hydro-electric power station at Deer Lake, Newfoundland, now operated by the Bowater Power Company. He then joined the General Electric Company at Schenectady, N.Y., and embarked on the Test Course. Returning to Newfoundland in 1927 he opened an engineering sales and service office for the International General Electric Company in St. John's and continued as manager until Newfoundland confederated with Canada in 1949. At

W. A. Devereaux, M.E.I.C.

S. B. Cassidy, M.E.I.C.

that time he transferred to the Canadian General Electric Company Limited to organize and manage a new branch office and warehouse in the tenth province.

Mr. Watson was chairman of the Newfoundland Branch of the Institute for the term 1954-55. His membership dates from 1951. He is also an executive member of the Association of Professional Engineers of Newfoundland.

W. A. Devereaux, M.E.I.C., newly-elected councillor of the Institute, representing the Halifax Branch was chairman of the Branch in 1955 and has also held office on the executive.

Mr. Devereaux, who was born at Georgetown, Ontario, enrolled in the mechanical engineering course at the University of Toronto in the early thirties. Graduating in 1937 with a B.A.Sc. he went to Cleveland, Ohio, to attend the Bailey Meter Company Limited cadet engineering course. He returned to Canada a year later and spent a twelve month period at the head office of the company in Montreal before being transferred to Winnipeg. Carrying out service and sales engineering work in Western Canada he became in 1941 their first resident engineer in Vancouver. However, the following year he was recalled to Montreal in connection with defence project work for the Navy and Air Force on the East Coast and in Newfoundland.

In 1945 he opened the Halifax branch office of Bailey Meter Company Limited and was appointed its first manager, a position which he has held since then. This office handles all sales and service engineering for the company in the Atlantic provinces.

Mr. Devereaux is also affiliated with the Association of Professional Engineers of Nova Scotia, and was a member of council for two years. He served on the Association's examining board and the committee on professional relations.

He is a member of the American Society of Mechanical Engineers and the American Water Works Association, Maritime Branch.

He was the first chairman of the Halifax Branch E.I.C., committee on professional development in 1952.

Mr. Devereaux joined the Institute as a Member in 1946.

Stanley B. Cassidy, M.E.I.C., communications and electrical contractor of Fredericton, N.B., has been elected councillor to represent the Fredericton Branch of the Institute for a two-year term.

A native of New Brunswick, born at Sussex, he had his education in the province and graduated from the University of New Brunswick in electrical engineering in 1933 with a B.Sc. degree. Six years later he was awarded an M.Sc. degree in communications from the same university.

From 1933 to 1939 he was engaged in geophysical work with the New Brunswick Gas and Oil Field and was then appointed chief engineer with Radio Station C.F.N.B. He held this appointment until 1946 at which time he began the communications and electrical contracting work in which he is still engaged.

Apart from his engineering work Mr. Cassidy owns a restaurant, a hardware and a service station.

He joined the Institute in 1936 as a Junior Member and transferred to Member in 1943.

A. G. Watt, M.E.I.C., vice-president and general manager of the structural steel and warehouse divisions of the Consolidated Steel Corporation Limited, Saint John, N.B., will serve the council of the Institute representing the Saint John Branch for a second term.

A native of Scotland Mr. Watt came to Canada in 1927 and joined Canadian Vickers Limited in Montreal as a structural draughtsman. In 1929 he went to Saint John, N.B. and was chief draughtsman with the Saint John Drydock and Shipbuilding Company Limited for eleven years, and personnel manager for an additional two years.

He joined Foundation Maritime Limited in 1942 at Pictou, N.S. as a personnel manager. He was industrial relations and personnel director of Ferguson Industries of Pictou from 1943 to 1945 and then returned to Saint John Drydock and Shipbuilding Company Limited as chief draughtsman of the structural steel division, becoming chief engineer in 1950. He joined the Consolidated Steel Corporation in 1954.

Mr. Watt is an active member of the Saint John Branch and was its chairman in 1953. He joined the Institute in 1946.

Arthur G. Baxter, M.E.I.C., of Amherst, N.S., chief engineer with the Enterprise Foundry Company Limited at Sackville, N.B., in charge of the heating engineering department of the firm, has been elected to serve the council of the Institute for a two year term.

Born at Amherst, and educated there, Mr. Baxter qualified for an engineering certificate in 1916.

Beginning his career as a draughtsman and rodman at Wabana Mines, Wabana, Nfld., for the Nova Scotia Steel and Coal Company in 1916, he joined the Canadian National Railways at Quebec City in 1919 and remained there for two years. During the twenties he became shop engineer with the company.

In 1929 he joined the Anglo Canadian Pulp and Paper Company at Quebec City and held this position until 1931. At the end of the depression years he became engaged as an engineer salesman in the firm with which he is still associated.

Mr. Baxter joined the Institute in 1948.

Albert Deschamps, M.E.I.C., president of Deschamps and Belanger Limited, Montreal consulting engineers has been elected vice-president of the Institute

A. G. Watt, M.E.I.C.

representing the province of Quebec, or zone 'C' of the Institute.

Born in the United States, at Brockton, Mass., Mr. Deschamps studied engineering in Montreal and graduated from McGill University in architecture in 1916. Superintendent of construction with Atlas Construction Company at Montreal from 1914 to 1918, and later general superintendent with Bate McMahon Company in Ottawa, he has since 1922 engaged in contracting and engineering consulting work. Associated with an extensive program carried out for the Department of Munitions and Supply in Europe during World War II, in connection with the building of airfields and installations, he was in 1946 awarded the O.B.E.

He was named representative of industry on the National Advisory Council of Man-Power in 1951. The following year he was appointed to supervise Canadian interests in defence construction in Europe by the Department of Defence Construction.

Mr. Deschamps is a past-president of the Canadian Construction Association.

He joined the Institute in 1945 and previously served as treasurer of the E.I.C., in 1950.

R. B. Winsor, M.E.I.C., general manager of the Canadian Industries Limited, textile fibres division, at Montreal, will hold office as a councillor of the Institute representing the Montreal Branch for a three-year term.

Born in Newfoundland, Mr. Winsor had his early education there and later attended Mount Allison University and McGill University. He was graduated from McGill with a B.Sc. degree in civil engineering in 1927, and that year went to work as construction engineer with W. I. Bishop Limited, on pulp and paper mills in Quebec. The following year he returned to Newfoundland to work for Newfoundland International Paper Company, at Corner Brook, as a design engineer.

In 1930, again resident in Quebec, he joined Canadian Industries Limited, beginning his lengthy career with the company. Project engineer at that time, he was two years later promoted to assistant works manager at Shawinigan Falls, and later works manager, also at that location.

With the onset of World War II, named construction manager of Defence Industries Limited, Montreal, he was, through the early forties, successively works manager, and manager of D.I.L. small arms ammunition division at Montreal. Named construction manager in the D.I.L. atomic energy project at the close of hostilities he was in 1946 appointed general manager of Canadian Titanium Pigments Limited. The following year he was named production manager with the Canadian Industries Limited chemicals division. In 1949 he became assistant general manager of the division, and three years later chief engineer. His present position dates from 1954.

Mr. Winsor is vice-president and director of the Canadian Fabrics Foundation and director of the Silk and Rayon Institute of Canada.

He joined the Institute as a Member in 1952.

L. P. Dancose, M.E.I.C., engineer and superintendent of the Canada and Gulf Terminal Railway Company, at Mont Joli, Que., has been elected a councillor of the Institute to represent the Lower St. Lawrence district.

Born at St. Evariste, Frontenac County, Que., Mr. Dancose received his education at Laval University and at the Ecole Polytechnique. On graduation employed with the Canadian National Railway, Levis division, for the first five years, he was then promoted to assistant division engineer at Quebec, serving the Laurentian division. Early in 1948 he joined the Canada and Gulf Terminal Railway Company as an engineer and superintendent, and, at the end of that year was promoted to superintendent.

R. B. Winsor, M.E.I.C.

Active in the Lower St. Lawrence Branch since its inauguration in 1952 he was appointed its first councillor, and has held this office consecutively since that time.

Mr. Dancose joined the Institute as a Student in 1942. He became a Junior Member in 1946 and in 1951 transferred to Member.

G. J. Cote, M.E.I.C., dean of engineering at the University of Sherbrooke, has again been elected to the council of the Institute to represent the Eastern Townships Branch of the Institute. He previously held office in 1953-54, 1955-56.

Mr. Cote was born at Sherbrooke, obtained his education at the St. Jean Baptiste Academy, St. Louis College, and the Ecole Polytechnique. He was awarded a B.A.Sc. in civil engineering in 1936.

Before his graduation engaged in survey work he immediately afterwards joined the firm of Crepeau and Cote and was a junior partner until 1940, supervising bridge construction and municipal projects. With the outbreak of World War II, Mr. Cote joined the Royal Canadian Engineers in 1940 and served overseas.

Beginning on a post-war career, he was on his return appointed senior associate member of the firm of Crepeau and Cote, which was later to be renamed Cote, Lemieux, Carignan and Bourque.

He joined the Institute in 1946.

He is member of the Corporation of Professional Engineers of the Province of Quebec.

Archibald B. Sinclair, M.E.I.C., superintendent of the hydro-electric department of Price Brothers and Company at Kenogami, Que., has been elected councillor representing the Saguenay Branch of the Institute for a two-year term.

Born at Truro, N.S., and educated in Western Canada, he received a B.Sc. degree in electrical engineering from the University of Manitoba in 1927. In his

A. Deschamps, M.E.I.C.

G. J. Cote, M.E.I.C.

first graduate year associated with the Canadian Westinghouse Company at Hamilton, Ont., as a student, he was in 1928 appointed assistant to the general superintendent with Price Brothers and Company Limited. Three years later he became chief operator with the Kenogami Substation of Price Brothers and Company Limited, and held that position for some time.

With the Canadian Army directorate of artillery at Ottawa, during World War II, he was engaged in the design and production of radar equipment for the allied service.

Retiring from the army with the rank of major in 1946 he returned to the firm of Price Brothers at Kenogami and accepted the position of general superintendent of the hydro-electric department of the firm.

Mr. Sinclair joined the Institute in 1927 as a Student Member, transferred to Junior in 1928 and to Associate Member in 1935. He became a Member in 1940.

A. B. Sinclair, M.E.I.C.

E. D. Gray-Donald, M.E.I.C.

E. D. Gray-Donald, M.E.I.C., past-chairman of the Montreal Branch of the Institute, has been elected a councillor of the Institute to represent that branch for a three-year term. Mr. Gray-Donald was previously chosen for this office in 1953, and earlier in 1942 and 1948 served the Quebec Branch. He was chairman of the Quebec Branch in 1944-45.

He is the vice-president of personnel and public relations with the Shawinigan Water and Power Company, Montreal; also vice-president and director of the Quebec Power Company, Quebec City, and a director of the Montreal City and District Savings Bank.

Born in Amoy, China, he followed his early studies at Victoria, B.C., and in Edinburgh. He returned to Canada in 1921 after spending two years in Palestine on general engineering work, and enrolled at McGill University where he obtained a B.Sc. in electrical engineering in 1926. He carried on post-graduate studies at Laval University, and obtained the degree of M.Sc. in 1934.

He joined the Shawinigan Water and Power Company in 1926 and followed the company apprenticeship course, being transferred to the Quebec Power Company in 1927. Filling various positions through the next few years he was appointed general superintendent in 1937 of the Quebec Power Company and the Quebec Railway, Light and Power Company. In 1942 he was appointed chief engineer for both companies, and was named vice-president and chief engineer of the Shawinigan Water and Power Company in 1950. His present position was announced in 1954.

Mr. Gray-Donald is a member of the Institution of Electrical Engineers; the American Institute of Electrical Engineers; the Society of Automotive Engineers; the Corporation of Professional Engineers of Quebec and the Canadian Electrical Association. He was appointed to the executive committee of the Canadian Transit Association in 1941, and was elected president 1946-48. He was vice-president of the Canadian Electrical Association in 1947-49, and president in 1949-50.

From 1940 to 1950 he was actively engaged in the work of the Reserve Army, and at retirement held the rank of lieutenant-colonel in the Royal Canadian Electrical and Mechanical Engineers.

Mr. Gray-Donald joined the Institute as a Student Member in 1922, transferred to Junior in 1926 and to Associate Member in 1934. He became a Member in 1939.

J. H. Budden, M.E.I.C., assistant superintendent of switching systems engineering with the Northern Electric Company Limited has been elected a councillor to represent the Montreal Branch of the Institute for a three-year term.

Born in Surrey, England, Mr. Budden attended Wellington College, England, and completed his studies in Canada at McGill University, graduating with a B.Eng. degree in electrical engineering in 1937. Later he attended a General Electric Company post-graduate test course at Witton Works, Birmingham.

On active service with the Royal Canadian Corps of Signals in Canada, England and Italy in World War II, he spent the greater part of the time with the Fifth Canadian Armoured Division.

Early in 1945 joining the Northern Electric Company Limited as a telephone equipment engineer he became, three years later, an engineering supervisor and was promoted to his present post in 1952.

Mr. Budden joined the Institute as a Student Member in 1936 and transferred to Member in 1946.

Very active in the work of the Institute, he served on the Montreal Branch membership committee in 1951 and also held the office of committee chairman at that time. A member of the executive committee in 1952 and chairman of the admissions committee in 1953, he worked on the Nominating Committee from 1954 to 1956.

Mr. Budden has been a member of the Corporation of Professional Engineers since 1946.

Walter G. Seline, M.E.I.C., of Trois Rivieres, Que., manager of the Quebec manufacturing division of the Packard Electric Company Limited, will carry out the duties of councillor for the St. Maurice Valley Branch.

Born in Finland and educated in Winnipeg, Mr. Seline graduated from the University of Manitoba in electrical engineering in 1945. On staff at the University the following year, he joined the Shawinigan Water and Power Company at Shawinigan Falls, Que., in 1947. From 1948 until his appointment to his present post in 1956, he was design engineer in Shawinigan's electrical repair department at Trois Rivieres.

Active in the affairs of the Engineering Institute he has served as chairman of

J. H. Budden, M.E.I.C.

the junior section of the Institute in St. Maurice Valley and as a member of the Branch executive.

Mr. Seline is a member of the Corporation of Professional Engineers of the Province of Quebec, and the American Institute of Electrical Engineers.

He is secretary-treasurer and vice-chairman of the section of the American Institute of Electrical Engineers, and a member of the Committee on Unity for the Corporation of Professional Engineers of Quebec.

Mr. Seline joined the Institute in 1944. A Student Member at that time, he became a Junior in 1947 and was transferred to Member in 1951.

W. J. Ripley, M.E.I.C., of Sudbury, Ont., has been chosen a vice-president of the Institute representing the province of Ontario. Now economic consultant for Pineland Timber Company Limited, Sudbury, and vice-president of the firm for Ontario, he was for twenty-eight years associated with the International Nickel Company of Canada Limited at Copper Cliff, Ont.

Mr. Ripley attended Mount Allison University for the first part of his engineering training and graduated from McGill University in 1914 with a degree in civil engineering. He was born in Nappan, N.S.

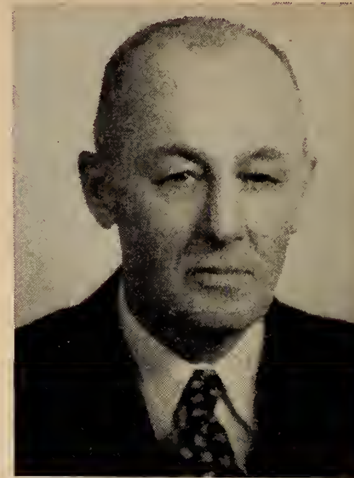
He gained his early professional experience with the Canadian National Railways as a transitman. Later he worked for the Koppers Company at Sydney, N.S. and with the Dominion Coal Company at Glace Bay, N.S. during the twenties.

He first became associated with the International Nickel Company in 1928 at Copper Cliff, Ont., first as a designing draughtsman, later as a master mechanic of reduction plants, in charge of all mechanical maintenance and has done considerable construction for reduction plants. He retired in 1956.

Mr. Ripley is a past chairman of the Sudbury Branch and was a committee member of the Sault Ste. Marie Branch.

He joined the Institute in Cape Breton in 1923 as an Associate Member and was transferred to Member in 1926.

G. E. Humphries, M.E.I.C.



W. J. Ripley, M.E.I.C.

George E. Humphries, M.B.E., M.E.I.C. vice-president and general manager of M. M. Dillon and Company Limited, and director of Allied Consultants of Canada Limited has been elected councillor to represent the London Branch of the Institute for a two-year term of office.

Born in England, he was educated at Wolverhampton and Staffordshire Technical College. He received a national certificate in mechanical engineering from the Institution of Mechanical Engineers in 1927. The following year he came to Canada and worked with the Hamilton Bridge Company and in 1929 became engaged in structural design for the Hydro-Electric Power Commission of Ontario. Later he worked for a time with McClintic Marshall Construction in Pittsburgh. With the Department of Lands and Forests in the early thirties he was for several years afterwards employed in the mining industry. From 1935 to 1940 he was associated with the Canadian Comstock Company Limited at Toronto, working on the design and construction of the metallurgical and power plants in mines in Ontario.

Overseas with the Royal Canadian Engineers in World War II he has since that time engaged in private practice in the firm with which he is now associated.

He previously served the Institute as chairman of the London Branch in 1951.

He joined the Institute in 1930 as a Junior Member and was transferred to Member in 1943.

F. A. Orange, M.E.I.C., of Sudbury, Ont., has been elected to the council of the Institute representing the Sudbury Branch. This follows previous E.I.C. service including that of branch chairman in 1954-55. He was also a charter member of the Branch on its formation in 1950.

A mechanical design engineer with the International Nickel Company, Mr. Orange was born in the United States, but has been a resident of the Ontario city most of his life. He had his early education in Sudbury and later attended Queen's University, graduating with a B.Sc. degree in mechanical engineering in 1927.

His initial experience gained with the Carborundum Company at Niagara Falls, N.Y., he began his career with the International Nickel Company in 1931. He has been connected with the mechanical and construction department since that time. During World War II and until 1947, he served with the Royal Canadian Engineers. During the latter part of this term he was posted to the directorate of engineer research and development at National Defence Headquarters in Ottawa.

He is a member of the Association of Professional Engineers of Ontario.

Mr. Orange joined the Institute in

W. G. Seline, M.E.I.C.

F. A. Orange, M.E.I.C.

1927 as a Student Member, became an Associate Member in 1934, and a Member in 1940.

Peter S. Dewar, M.E.I.C., chief maintenance engineer with the Ford Motor Company at Windsor, Ont., has been elected councillor to represent the Border Cities Branch of the Institute.

Mr. Dewar was born at Windsor, Ont. He attended the University of Toronto and graduated with a B.A.Sc. degree in 1943. Employed as a student with the Ford Motor Company during the summer months he later joined the company as a designing engineer in foundry design, on graduation. He was promoted to assistant engineer of foundry design in 1949, and of mechanical design, mechanical engineering division, the following year.

Mr. Dewar joined the Institute in 1944 as a Junior member and transferred to Member in 1951. He served as secretary-treasurer of the Border Cities Branch in 1953.

Ralph Choate Wilson, M.E.I.C., publisher of the *Evening Guide* at Port Hope, Ont., will represent the Port Hope Branch of the Institute as Councillor for a two-year term.

Mr. Wilson is a native of the city in which he now lives and is a graduate of the University of Toronto in mechanical engineering, class of 1927.

He is associated with the firm of George Wilson and Son, Port Hope, Ont.

He joined the Institute as a Member in 1952.

John Stanley Waddington, M.E.I.C., chief engineer of Phillips Electrical Company Limited, has been elected a councillor representing the Brockville Branch of the Institute.

Mr. Waddington was born in Winnipeg. He received his B.Sc. degree in electrical engineering from the University of Manitoba in 1934, and the following year joined the Canadian Marconi Company in Montreal.

He entered the Phillips Electrical Works Limited in 1936 and was associated with the company's manufacturing department in Brockville and Montreal until 1938 when he was appointed technical secretary to the president in Brockville. In 1944 he entered the engineering department and three years later was named chief engineer.

He is a member of the American Institute of Electrical Engineers; the Canadian Standards Association and a member of several technical committees of C.S.A. and C.E.M.A. He is chairman of the Canadian Electrical Manufacturers Association Wire and Cable Division technical committee, and a former member of the Committee on the Canadian Electrical Code Part I.

He joined the Institute in 1947 with the status of Member. He was chairman of the Brockville Branch in 1954.

W. B. Pennock, M.E.I.C., president of the firm of Pennock Canadian-British Limited, consulting engineers, Ottawa, has been elected to represent the Ottawa branch of the Institute as a councillor.

Mr. Pennock is a native of Ottawa and a graduate of McGill University. He was awarded a B.Sc. degree in 1915. He went overseas with the Canadian Engineers, Canadian Expeditionary Force, immediately on graduation. At war's end, returning to Canada, he was for two years District Vocational Officer in the Department of Soldier's Civil Re-establishment.

In 1920 he accepted a position with the Gray-Dart Motor Car Company as an agent and field representative. Four years later he was named department manager with the Canadian Fairbanks Morse Company at Windsor, Ont., and in 1925 set up a manufacturing agency and engineering contractor practice in Windsor, London and Hamilton. After ten years he joined the Department of National Defence, Ottawa, as chief mechanical engineer. He later returned to his business as sales engineer, acting for a number of manufacturers.

The second world war entailing further military service Mr. Pennock was, during the years 1940-45, second in command of the engineering training centre, and later C.R.E., 8th Canadian Division, in Western Canada, which appointment carried the rank of lieutenant colonel.

On demobilization he became re-established as sales engineer in operating his own business, and continued under this arrangement until 1949 when Pennock Engineering Company was established as a consulting engineering firm, associated with Canadian-British Engineering Consultants, in Toronto, Halifax and Vancouver.

The firm Pennock Canadian-British Limited was formed in January 1957.

J. S. Waddington, M.E.I.C.

Mr. Pennock served as chairman of the Ottawa Branch of the Institute in 1956. His association with the Institute dates from 1919 when he was a Student Member. He became an Associate Member in 1936 and transferred to Member in 1940.

K. F. Tupper, M.E.I.C., has been chosen to represent the Toronto Branch of the Institute for a three year term as councillor. He is the president of Ewbank and Partners (Canada) Limited, at Toronto, a firm engaged in the engineering design of thermal power stations.

Mr. Tupper was born in the United States and had his early education in Western Canada. He graduated from the University of Toronto in 1929 with a B.A.Sc. degree in mechanical engineering. Later he obtained an M.Sc. degree in aeronautical engineering in 1938. On receiving his bachelor's degree in 1929 he joined the staff of the Riverside Iron Works Limited, Calgary, as a draughtsman, and later that year accepted a position with the National Research Council, Ottawa, where he was engaged

K. F. Tupper, M.E.I.C.

W. B. Pennock, M.E.I.C.

in the design and operation of aeronautical research equipment. In 1943 he was appointed Member of the Canadian team to report on aircraft gas turbine developments in Britain. Merging from this work, a company called Turbo Research Limited was formed, which was a forerunner of the Aircraft Gas Turbine Division of A. V. Roe Canada Limited at Malton. It subsequently became Orenda Engines Limited. In 1946 when this project passed from Turbo Research to A. V. Roe, Mr. Tupper returned to the National Research Council and joined the atomic energy project of Chalk River. In 1947 he was appointed director, with the engineering division of the project.

Mr. Tupper became the fifth dean of the faculty of applied science and engineering at the University of Toronto in 1949. However, he retired from this post in 1954 to join the firm in which he is now president.

In 1947 Mr. Tupper was awarded the O.B.E. in recognition of his wartime services.

He has been a Member of the Institute since 1949.

C. H. R. Campling, M.E.I.C.

S. Sillitoe, M.E.I.C.

Sydney Sillitoe, M.E.I.C., who previously served on the council of the Institute, representing the Belleville Branch from 1953 to 1956, has been re-elected for his third term.

A Westerner, from Edmonton, he had his engineering training at the University of Alberta and was graduated with a B.Sc. degree in 1931. For an additional two years he studied communication and structural design and in 1933 received an M.Sc. degree. He later undertook post-graduate research work at McGill University.

Now production superintendent of the Northern Electric Company Limited communications equipment division, Belleville, Ont., he became associated with the company in 1934 in Montreal as a junior engineer. Ten years later named technical engineer in charge of production engineering he was promoted to broadcast equipment design engineer in 1946. The following year he became an equipment engineer at the Belleville plant and in 1950 received the appointment of assistant superintendent of general assembly.

During World War II he was assigned to the Department of Munitions and Supply on a technical mission to England in 1941.

Mr. Sillitoe is a member of the Association of Professional Engineers of Ontario and an associate member of the Institute of Radio Engineers.

He is a charter member of the Montreal section of I.R.E., having served as its secretary in 1937-38 and its chairman in 1938-39. He has been associated with the work of the Canadian Radio Technical Planning Board, and of the Radio Manufacturers Association of Canada. He has also served on the rehabilitation advisory committee of the school of electronics at Ryerson Institute.

When the Belleville Branch of the Institute was formed in 1950 Mr. Sillitoe was elected secretary and was in 1952 the first elected councillor.

He joined the Institute in 1930 as a Student, was transferred to Junior Member in 1936 and became a Member in 1943.

R. R. Prescott, M.E.I.C.

C. H. R. Campling, M.E.I.C., associate professor, department of electrical engineering at Queen's University, Kingston, Ont., has been elected to represent the Kingston Branch of the Institute as councillor for a two-year period.

A native of Melville, Sask., Mr. Campling attended Melville Public School and Queen's University where he received a B.Sc. degree in electrical engineering in 1944.

During 1944 and 1945 Mr. Campling served with the Royal Canadian Signals and at war's end was named an instructor in the department of mathematics at Queen's University. Appointed research engineer in 1948 in the servo-mechanisms laboratory of the Massachusetts Institute of Technology he also at that time received the S.M. degree.

During the following year he was engaged in research work in the field of magnetic amplifiers with the National Research Council. It was in 1950 that he became assistant professor at the Royal Military College. He was responsible for the installation of the electrical power laboratory and the organization and teaching of courses on the power aspects of electrical engineering. He has held his present position since 1955.

Professor Campling is an associate member of the American Institute of Electrical Engineers and a member of the Institute of Radio Engineers, and the Association of Professional Engineers of Ontario.

Active in the affairs of the Institute he served on the executive of the Kingston Branch in 1952 and 1953, as vice-chairman in 1953-54, and as chairman the following electoral term. He is also the E.I.C. representative on the committee on Education and Accreditation of the Engineers' Council for Professional Development.

He became a Student member of the Institute in 1943.

R. R. Prescott, M.E.I.C., electrical superintendent of the Canadian International Paper Company's Kipawa mill at Temiskaming, Que., has been elected a councillor of the Institute, representing the Nipissing and Upper Ottawa Branch of the Institute.

Born at Walton, N.S., he attended Acadia University and obtained a certificate in applied science, later graduating from the Nova Scotia Technical College with a B.Sc. degree in electrical engineering in 1932.

Toward the end of the depression years he obtained a post as chief operator at the St. Anthony Gold Mines, power plant, at Savant Lake, Ont., in 1936, and after two years was promoted to chief electrician.

He joined the Canadian International Paper Company at Dalhousie, N.B. as an electrical engineer in 1940. Seven years later he was transferred to the C.I.P. Gatineau Quebec mill as an assistant electrical superintendent, and in 1951 was moved to the Kipawa mill at Temiskaming where he held the same position. His promotion to electrical superintendent dates to 1954.

Mr. Prescott joined the Institute as a member in 1948. He was a charter member of the Nipissing and Upper Ottawa Branch of the E.I.C. on its formation in 1952. He has served the Branch executive since that time and was the 1956 choice as chairman of the group.

E. T. Charnock, M.E.I.C., superintendent of technical services of the Great Lakes Paper Company, Fort William, Ont., will be a member of the Council representing the Lakehead Branch of the Institute.

Associated with that company since 1942, he was at first employed in the capacity of sulphite engineer and was later named assistant sulphite superintendent. Three years ago he assumed the position he now holds.

Mr. Charnock is a native of Fort William and a 1938 graduate of the University of Toronto with a B.A.Sc. degree in chemical engineering. He worked at that time with the J. R. Walkings Company as a chemist at Winnipeg.

He was elected chairman of the Lakehead Branch in 1955. Mr. Charnock's association with the Institute dates to 1944 when he joined as a Junior Member. He transferred to Member in 1948.

S. C. Montgomery, M.E.I.C., has been elected to represent the Western Provinces as vice-president for two years. He is a maintenance engineer with the Consolidated Mining and Smelting Company at Trail, B.C., smelting and refining division.

Mr. Montgomery was born in Winnipeg, Man., and attended public and high schools there. Commencing his university studies at the University of Manitoba he transferred a year later to McGill University graduating with a B.Sc. in mechanical engineering in 1915.

Enlisting in the Canadian Field Artillery in 1915 he joined the First Brigade, Canadian Field Artillery, First Division in France. He later transferred to the Fifth Brigade, Second Division, and served until 1919. He was awarded the Military Cross and also received mention in despatches. After a refresher course at the Royal Technical College, Glasgow, he returned to Canada late in 1919.

Re-established in this country he began the next phase of his engineering career as a designing draughtsman with the Whalen Pulp and Paper Company in British Columbia, worked in the logging industry on Vancouver Island and in 1925 became assistant superintendent of construction and maintenance.

In 1929 he joined the Consolidated Mining and Smelting Company at Trail,

E. T. Charnock, M.E.I.C.

S. C. Montgomery, M.E.I.C.

again as a designing draughtsman and was shortly transferred to the duties of assistant construction engineer on the construction and maintenance of the Tadanac plants in 1929. During the depression years he held a variety of posts and in 1936 was named assistant construction engineer of the Tadanac plants. His present position of maintenance engineer, smelting and refining department dates to 1948.

Mr. Montgomery joined the Institute as a Student in 1911, became a Junior Member in 1920, transferred to Associate in 1929 and to Member in 1940. He is a charter member of the Kootenay Branch and was its first chairman and councillor.

J. L. Phelps, M.E.I.C., president of the Yukon Hydro Company Limited and a member of the firm of Phelps and Scott Engineering, consulting engineers, will represent the Yukon Branch of the Institute as councillor for a two-year term.

A native of the Yukon Mr. Phelps was born at Whitehorse and had his early education there, later attending Upper Canada College and the University of British Columbia. He graduated with a B.A.Sc. degree in 1940. Since then he has held positions as superintendent and secretary-treasurer of the Yukon Electrical Company from 1940 to 1950 and secretary-treasurer and managing director of the Yukon Hydro Company Limited in 1950-51. He became a partner in Phelps and Scott Engineering in 1949.

Mr. Phelps joined the Institute in 1951 as a Member. Secretary-treasurer of the Yukon Branch in 1953-54 he was in 1954-55 elected to fill the duties of chairman of the Branch.

He was also a member of the Yukon Council from 1952 to 1957.

W. D. Hurst, M.E.I.C., city engineer and commissioner of buildings, at Winnipeg, will represent the Winnipeg Branch on the council of the Institute for a two-year term.

A native of Manitoba, Mr. Hurst is a graduate from the University of Manitoba, class of 1930, in civil engineering. He received a C.E. degree in 1931, following graduate studies at the Virginia Polytechnic Institute while on a teaching fellowship.

Associated with the City of Winnipeg Engineering Department in 1930, he rejoined it in 1931 and began his career as a resident engineer on reservoir construction. Ultimately he became an investigating engineer, engineer in the water works branch and assistant city engineer. His present appointment dates from 1944.

He has been chairman of commissioners of the Greater Winnipeg Water District since 1949. Chairman of the Rivers and Streams Protection Authority since 1951 he has also been chairman of the Winnipeg Building Commiittee since 1944.

Mr. Hurst served as secretary-engineer on the Board of Engineers for the Greater Winnipeg Sanitary District from 1935-39, and was appointed commissioner of the Winnipeg-St. Boniface Harbour Commission in 1946.

In World War II he was captain and officer commanding the Engineers First Workshop and Park Company with the Tenth Reserve District Engineers of the R.C.E.

Mr. Hurst served the Association of Professional Engineers of Manitoba as its president in 1950 and 1951. A member of the American Water Works Association, he was chairman of the Minnesota section in 1947-48; and also chairman of the Canadian Section in 1952-53; he was a director from 1952 to 1955. He was elected a director of the American Public Works Association for the term 1956-58. He is also a member of the Canadian Institute of Sewage and Sanitation.

Mr. Hurst is a registered professional engineer in the province of Manitoba and in the state of Minnesota, and is registered as an architect in the province of Manitoba.

His professional service was recognized by the award of the George Warren Fuller Award of the American Water Works Association in 1946.

As to Institute affairs, Mr. Hurst was chairman of the Winnipeg Branch in 1938 and was again elected in 1951. Mr. Hurst joined the Institute as a Student Member in 1927. He transferred to Associate Member in 1935 and became a Member in 1940.

M. L. Wade, M.E.I.C., has been elected Councillor of the Institute, representing the Central British Columbia Branch for a two-year term of office following previous service from 1950.

He is a consulting engineer at Kamloops, practising in the electrical and hydraulic field and serving the interior of British Columbia and parts of Western Alberta.

Born in the United States, he came to Canada at an early age and had his education in this country. A 1912 graduate from McGill University in electrical engineering, he joined the staff of the Canadian Westinghouse Company and worked at Montreal, Hamilton and Winnipeg. For an additional two years located at Regina, Sask., he then moved west to British Columbia where he was employed with the Canadian General Electric Company at Vancouver as a service engineer.

During the next few years Mr. Wade worked with the East Kootenay Power Company as superintendent of generating stations, and was promoted to general superintendent the following year. In 1930 he was engaged by the West Kootenay Power and Light Company to carry out damsite investigation and superintend surveys in connection with the Adams River Canyon. This led to the establishment of Mr. Wade's present consulting practice.

He is a member of the Association of Professional Engineers of British Columbia and of the American Waterworks Association, Canadian Section.

M. L. Wade, M.E.I.C.

W. L. Sharpe, M.E.I.C.

Mr. Wade was active in the inauguration of the Central British Columbia Branch of the Institute in 1949, and was its first chairman. He joined the Institute as a Junior in 1914, transferring to Associate Member in 1917, and to Member in 1936.

W. L. Sharpe, M.E.I.C., city engineer for the City of Weyburn, Sask., has been elected to council for a two-year term, representing the Saskatchewan Branch of the Institute.

A native of Yorkton, Sask., he received his early education there, and then entered the College of Engineering at the University of Saskatchewan in 1931 where he studied for three years. During the Second World War, he served for five years as an officer in the Royal Canadian Artillery, second division, and on discharge returned to the University of Saskatchewan where he graduated in civil engineering in 1947. Mr. Sharpe then spent one year with the Saskatchewan Department of Highways as a resident engineer and in March 1948 accepted his present position in Weyburn.

W. D. Hurst, M.E.I.C.

R. N. McManus, M.E.I.C.

He is a member of the Association of Professional Engineers of Saskatchewan, serving as councillor for two consecutive terms in 1953-55.

Mr. Sharpe joined the Institute as a Junior member in 1948 and transferred to Member in 1950.

R. N. McManus, M.E.I.C., who has been elected to serve as councillor for the Edmonton Branch, is an associate professor of civil engineering at the University of Alberta. Also occupied with Institute affairs in another sphere, he is a member of the papers committee, for the annual meeting in June.

Professor McManus is a westerner by birth. Born at Lomond, Alta., he was a 1942 graduate of the University of Alberta in civil engineering. He was a member of the teaching staff of the department of civil engineering, from the time of his graduation until 1956. He obtained an M.Sc. degree in civil engineering in 1946 from the University of Alberta in the field of structures. In 1952 he obtained a Ph.D. degree in engineering from the University of Illinois in structural engineering.

His professional engineering experience has been related to his consulting practice conducted for nine years while a member of the university faculty. From 1952 to 1956 a principal in the consulting firm of Structural Engineering Services Limited, he was the resident principal at Edmonton. In this position he shared major professional responsibility for the design of such structures as Nisutlin Bay Bridge, North-West Highway System, Groat Bridge in Edmonton Chin Reservoir Crossing near Lethbridge, Sheep River Bridge near Okatoks major overhead crossings of the Peace and Fraser Rivers of the West Coast Transmission Gas Lines and many millions of dollars worth of specialty designs such as pre-stressed concrete bridges and buildings.

At present on leave of absence from the University until the beginning of th

1956 fall term, he is devoting full time to his consulting practice.

Mr. McManus is a member of the board of examiners of the Alberta Association of Professional Engineers, alternate representative on the Edmonton architectural panel and a member of the special committee on architect-engineer relationships. He also holds non-resident license in the Association of Professional Engineers of British Columbia. He was the chairman of the Edmonton Branch E.I.C. in 1956.

Mr. McManus joined the Institute as a Student Member in 1941, became a Junior in 1943 and transferred to Member in 1946.

Commander **P. F. Fairfull,** M.E.I.C., superintendent of the Graving Dock at Esquimalt, B.C., has been elected to represent the Vancouver Island Branch on the council of the Institute for a two-year term.

A native of Great Britain, Commander Fairfull began his engineering career as an apprentice with William Simons and Company Limited, engineers and shipbuilders at Renfrew, Scotland.

Established in this country in 1925, he accepted a position in Toronto with Chapman and Oxley, architects and engineers. In 1933 he went to work for the Toronto Star as development engineer but with the onset of the war, once more was connected with shipbuilding. He served as chief engineer for the Crown operated Toronto Shipbuilding Company which firm he joined in 1941. In the Naval Service two years later, he was appointed overseer of ship construction on the Great Lakes and later Principal Naval Overseer on the West Coast. He then became manager of the constructive department, H.M.C. Dockyard, Esquimalt, B.C., and still retains the rank of Constructor Commander, R.C.N., (R).

In 1948 the Department of Public Works of Canada named him superintendent of the Graving Dock at Esquimalt, B.C.

Commander Fairfull has been helpful to the Institute on many occasions since his election as a Member in 1949. He is the immediate past-chairman of the Vancouver Island Branch, and a former secretary-treasurer also.

Cdr. P. F. Fairfull, M.E.I.C.

W. O. Richmond, M.E.I.C., head of the department of mechanical engineering of the University of British Columbia has been elected a councillor to represent the Vancouver Branch of the Institute for a two-year term.

Professor Richmond was born in Rouleau, Sask., and obtained a B.A.Sc. degree in mechanical engineering from the University of British Columbia in 1929. In 1933 he was awarded an M.Sc. degree in mechanical engineering from the University of Pittsburgh.

W. O. Richmond, M.E.I.C.

On attaining his bachelor's degree he joined the Westinghouse Electric and Manufacturing Company in East Pittsburgh as a research engineer in the mechanics division. He remained there until 1934. During the next two years he was research assistant in the testing materials laboratory of the Massachusetts Institute of Technology and the following year became instructor in mechanics and materials at the Case School of applied science in Cleveland, Ohio.

He joined the mechanical engineering staff of the University of British Columbia in 1937 as an assistant professor of mechanical engineering, was named associate professor in 1943, and four years later received the appointment of professor of mechanical engineering. He has held the responsibilities of head of the mechanical engineering department since 1950.

He is a member of the American Society of Mechanical Engineers. His affiliation with the Association of Professional Engineers of British Columbia has resulted in his election as president for 1957.

He was the choice in 1954 of the Vancouver Branch of the Engineering Institute for chairman, after several years of work in Institute activities. He joined the Institute as a Member in 1950.

W. K. Gwyer, M.B.E., M.E.I.C., assistant manager of the engineering division of Consolidated Mining and Smelting Company of Canada Limited in Trail, B.C. has been elected councillor for two years to represent the Kootenay Branch of the Institute.

Mr. Gwyer was born at Vancouver and had his early education in Penticton, B.C. He followed his engineering studies at the University of British Columbia and received a B.A.Sc. degree in civil engineering in 1936.

He assumed the duties of construction engineer in 1938 on coastal defense installations with E. J. Ryan Contracting Company and Northern Construction Company Limited.

Mr. Gwyer served with the Royal Canadian Air Force from 1940 until the end of World War II. He commenced his service as a pilot officer in navigation in Canada and England. He was, in 1943, named a Member of the British Empire. On his discharge he held the rank of squadron leader.

In the first five post-war years Mr. Gwyer was associated with the firm of Stevenson and Kellogg Limited and was engaged in plant layout, time, method and organization studies, job evaluation, as well as standard cost and budgetary control installations.

He joined the staff of the Consolidated Mining and Smelting Company Limited in Trail, B.C. as an assistant to the construction superintendent in 1949. Three years later he was named assistant manager of the company's engineering division.

In 1954 Mr. Gwyer was elected chairman of the Kootenay Branch of the Institute. He has been a Member since 1950.

He is a member of the Association of Professional Engineers of British Columbia.

W. K. Gwyer, M.E.I.C.

THIRTY-FIVE YEARS AGO

Comment on the Journal of June, 1922

The most important item in the contents of the *Journal* of June, 1922. was undoubtedly the report of the Institute's Committee on Policy, which occupied nearly eight pages of solid text and was accompanied by four additional pages of appendices, tables and charts. Space does not permit us to quote at any great length from it, but we may at least set down here what the committee favoured, in its own words:

Broadening of the Institute's objectives . . .; More effective co-operation with sister societies . . .; Gradual verification of the status of the Institute as the one national . . . professional organization; . . . Internal economy changes (that) will strengthen the branches . . .

Making Council more . . . representative . . .; Mileage to Councillors . . .; More . . . general distribution of the . . . office of vice-president . . .

Recognition . . . of the . . . importance of . . . engineering educational facilities . . .; Action to link . . . the Institute . . . with . . . students in engineering . . .

Action to secure . . . recognition for the engineering profession comparable to that extended to . . . law and medicine . . .

Analysis of the . . . code of ethics, so that it may be more of a positive influence . . .; Action toward securing just and adequate remuneration for engineers . . .

We leave it to readers to form their own judgments as to how far these suggestions have been implemented over the past thirty-five years. Our own feeling is that most of them have been pretty well taken care of, so far as it is in the Institute's power. Some of them depended almost entirely on the attitude of the individual member, e.g., the Institute's national standing and the influence of the code of ethics, so the Institute as an organization could do little more than encourage and support its members, which it did.

Technical Papers

Of the three papers in this *Journal*, "The Self-corrosion of Buried Lead Pipe", by W. N. Smith, M.E.I.C., and Professor J. W. Shipley, both of Winnipeg, was the most important; the second half of this paper was to appear in July, 1922, and both parts were by way of being an extension of a similar paper dealing with cast iron pipe and published in the *Journal* for October, 1921. The conclusion of the authors is that not all corrosion of buried pipe can be charged to electrolysis.

The two other papers were on 220 kv transmission, by J. F. Peters, and a description of the Bell Island iron mines in Newfoundland, by S. C. Mifflin, A.M.E.I.C. It might be noted that the first 220 kv transmission system was just going into service in California.

Branch Affairs

If one has the patience to plow through the reports of the branches, he will sometimes find there bits of information which may tickle his funny bone. Some branch treasurers were congratulating themselves on winding up their fiscal years with money in the bank, though the credit balance might be as low as 87 cents. We wonder if operating a branch within its budget is as much of a task now as it seems to have been in 1922.

Col. H. C. Boyden of the Portland Cement Association, Chicago, was touring the branches, expounding the theories of concrete design, mixing and placing of Duff Abrams. By June, 1922, he had visited Montreal, Peterborough, Halifax, Quebec and Saint John. The Canada Cement building in Montreal had just been completed and was cited as an example of what could be accomplished by rigid control. The compressive strength of the concrete in this building varied less than four per cent from the desired value.

The Hamilton Branch had inspected the Burlington Canal bridge and was present at its official opening, when it was christened "by breaking a bottle, said to contain liquor, over the main trunnion. The cheering died down suddenly 'when the ancient odour failed to materialize." This bridge was of the Strauss bascule type, of 160-foot span and with a 22-foot roadway, one street railway track and two 9-foot sidewalks.

The sixteen branches reporting in this *Journal* had all had prosperous years, with membership up in some cases by over a hundred per cent and with balanced budgets. Their reports all breathed a spirit of optimism, though all agreed that in general business was bad and jobs few and far between.

Engineering Legislation

The Engineer's Act was before the Ontario legislature again. The general atmosphere seemed to be favourable to its passage, but some M.P.P.'s did not like its Clause 34, which set the penalties for contravention of the Act. A revised version was being prepared by the legislative committee, the Institute's Ontario advisory committee and the executive of the Toronto Branch.

Readers who use the Canadian Pacific Railway Company's Windsor Station in Montreal will be quite familiar with the company's memorial to those of its employees who fell in World War I. This was unveiled by Lord Byng on April 22, 1922. Of all the numerous similar memorials we have seen, this is our favourite. Its conception seems to us better than execution is equally good. This is just our personal opinion; doubtless a professional art critic could point out to us wherein we are all wrong.

Salary demands in 1922 were modest. One advertiser in this *Journal*, a civil engineer with two years' experience in the pulp and paper industry, asked for $165 to $180 a month, while a mechanical engineer with seven years' experience as a plant engineer, wanted $275 a month, about five-eighths of a green graduate's salary today.

1922 Graduates

We see the names of a good many friends and acquaintances in the graduation lists of Queen's and McGill, published in this *Journal*, and in the considerable number of personals and lists of applicants for admission or for transfer. There are too many to mention, and they would probably mean little to the reader, but some he would recognize as those of well known business leaders of today and of members active in Institute affairs.

R.Del.F.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

Thirty-Eighth Annual Meeting

The 38th Annual Meeting of the Corporation held March 23 at the Mount-Royal Hotel, Montreal was the most successful one in the history of the Corporation. The business meeting in the afternoon was attended by 300 members; 600 members and their guests were present at the dinner and many more turned out for the dance.

Slowly But Surely

In opening the business meeting, the chairman, President L. Roy made the following observations: "Your Council, Gentlemen, made every possible effort during the year to achieve whatever you asked of it; matters arising from the last general meeting, from the referendums held during the year or from visits we made to different sections. I submit respectfully that your Council accomplished much work. Elaboration of these remarks is contained in the annual report which, undoubtedly, you have read. We leave it up to you to judge for yourselves.

Before proceeding to the discussion of the annual report, please permit me to voice a few remarks:

The sole objective of the Corporation is the common good of all and is not designed for the exclusive advantage of a group or of an individual at the expense of others. This spirit of one for all and all for one motivated your Council and the decisions it reached this year.

We believe it might be opportune to emphasize anew that the application of any law cannot be extended further than the limit set by the legislator. The law governing professional engineers is no exception. Thus the reason why your Council advocates making haste slowly because it would be unfortunate if any premature decision were to cause more harm than good to the profession.

There are some among our membership who maintain that the Council acts too slowly and that it lacks both initiative and firmness. What should never be lost from mind is that such claims come most frequently from a minority group and that their accusations are ill-founded, for the most part, or their sponsors have an axe to grind. I would venture that if these complaints where submitted to the members by means of referendums, they would receive a hostile reception in the majority of cases.

The Council cannot and should not reach decisions which could endanger the fundamental basis of the Corporation and, in so doing, could weaken its status in the eyes of its members and of the public. The Council has a duty to perform. It also shoulders a responsibility—the responsibility of protecting its members and the public, not of protecting one group of its members at the expense of others or one group of its members to the detriment of the public!

Plan For Unity

Guillaume Piette, who acted as chairman of the Committee on Confederation in 1956 submitted the report of his committee. So active was the latter that it was able, in only a year's time, to analyze thoroughly the many aspects of the Plan for Unity and arrive at a list of recommendations.

The committee's report was submitted to Council in February, and received the latter's approval. It has recently been transmitted to Dominion Council for consideration at its next annual meeting in June.

Employee Engineers

The report of the Committee on the Advancement of the Employee Engineer was received with great interest. Exemplifying this were the following comments from one of the members present: "My impression is that this committee has just been formed in the last year and, glancing over their report, as we say sometimes, it is pregnant with possibilities. In other words, this report certainly covers a very vast field. I think they are to be congratulated on the scope of their work."

Recommendation was made in the report "that the Corporation undertake a complete and thorough study on the feasibility and format of an individual obligatory contract between engineer and clients (i.e. employers)." W. J. Riley, chairman of the Montreal sub-committee explained that this came as a result of a petition which was submitted to the sub-committee by a group of Montreal Corporation members. He added that this matter had not yet been investigated, but that it will be, provided of course that Council approves of it.

It was moved, seconded and approved that study be also made on the possibility of sponsoring an employment contract between groups of engineers and their employers.

Remuneration

R. K. Eadie, chairman of the committee on remuneration explained that the task of finding means of promoting better salary conditions for engineers is a long and arduous one. He went on to say that the technique which has been in use in Ontario for some years now and which is presently being implemented in this Province "will have quite a few unsuspected developments which will greatly influence our position in the salary field."

Concluding Remarks

G. L. Wiggs, who, in his capacity of past-president sat on the outgoing Council, was invited to say a few words. Mr. Wiggs said in part: "I say that the title "engineer" is one which should be guarded very zealously by every member of the Corporation not merely by the consulting engineers." And he added: "There should be more efforts made to prevent the abuse of the title and possibly illegal practice — but the abuse of the title certainly."

R. A. Phillips, vice-president, 1956 Council and outgoing member of Council was also requested to address the meeting. Commenting upon factors which are going to be important in the future of the Corporation, Mr. Phillips said: "The first one that comes to my mind is the importance of the Corporation and its members not losing sight of the basic objectives and responsibilities that we have and our first and foremost responsibility is to serve the best interests of the public in the best way we know how. Another factor that has come to my mind is that we must not confuse our thinking by categorizing or segregating ourselves into groups but rather, if we are going to grow and progress as we want to, we must strive constantly to bring ourselves together as professional engineers of Quebec. That brings to mind another point, and it is the last point I would like to make; and that is the question of professionalism. If we are going to strive to achieve a unity of professional engineers of Quebec, we must keep in mind professionalism . . . the first requirement being to place the interests of society ahead of one's own."

Mr. Roy concluded the meeting by

saying: "Sol lucit omnibus. Assuredly, God will be in His Heaven and all will be right with the world if we keep faith in our profession and maintain its spirit by observing our Code of Ethics at all times."

New Council

Immediately after the business meeting, the new Council met and elected its officers for the current year. They are: C. A. Peachey, president; Guillaume Piette, vice-president; L. Nadeau, honorary secretary-treasurer. Other members of Council are: L. Roy, past-president; Robert Painchaud, Yvon De Guise, W. J. Riley, and A. G. Ballachey.

Dr. O. M. Solandt

Guest speaker at the annual dinner was Dr. O. M. Solandt, vice-president of research and development with Canadian National Railways who delivered a major speach on "Some new Responsibilities for Professional Engineers".

Dr. Solandt emphasized the need for more and especially for better-trained engineers, engineers who will maintain the highest ethical and technical standards and assume social leadership as it is becoming increasingly incumbent upon them to provide such leadership in this era of great technological development.

The Dumont Family

The Dumont family of engineers, a father, seven sons and a daughter married to an engineer, were honoured at the annual dinner. Joseph Dumont, 78, who lives in Amos, was given a certificate of honour in recognition of his contribution to the profession and to the development of the north-western region of the province.

Mr. Dumont's sons are: Georges, Wilfrid, Lomer, Rodolphe, Eudore, Paul and Robert. Georgette, Joseph Dumont's eldest daughter, is married to Benoit Marcotte. Another daughter, Marthe, is a student.

Exhibition of Film Slides

Twenty-Five Corporation members participated in the Exhibition of Film Slides held at the time of the annual meeting. More than 400 slides were carefully screened by a group of Montreal art critics before the winners of the exhibition were picked. They are: — Maurice Desjardins, first prize; Gilles Gagnon, second prize; Claude Lacombe, third prize.

ONTARIO

Engineers in the News

Thomas J. Nolan, of Atlas Steels Ltd., Welland, Ont., has been given the post of chief engineer of the company.

A graduate in electrical engineering of the University of Toronto, Mr. Nolan joined Atlas Steels in 1943 after several years with Ontario Hydro and the Chemical Construction Corporation. With the exception of 1956, when with H. G. Acres and Co. Ltd., he has been a member of the Atlas engineering department since 1943, being appointed electrical engineer in 1948 and assistant chief engineer in 1956.

C. T. Muirhead of Canadian Vickers Ltd., has been appointed technical manager of engineering sales with headquarters in Montreal.

Mr. Muirhead has been with Canadian Vickers for a number of years and for the last four years has been manager of the Toronto office.

A. W. F. McQueen, president of H. G. Acres and Co. Ltd., of Niagara Falls, Ont., has announced several staff appointments in that firm. **R. A. H. Hayes** has been named chief engineer of the technical division; **J. H. Ings**, chief engineer of special projects; **J. Hvilivitzky**, chief engineer special projects; **W. P. London**, chief engineer, thermal division; **C. N. Simpson**, chief engineer, hydraulic division; and **H. P. Schweder**, chief engineer, petrochemical division.

Gerald L. Sandler, of Chrysler Corporation of Canada Ltd., Windsor, Ont., has been named to fill the newly created post of organization analyst of the company. His duties will include the responsibility of conducting special studies into the organization of corporation activities.

Mr. Sandler graduated in engineering from Toronto and subsequently obtained his master's degree in business administration from the University of Michigan. He is also a graduate of the Chrysler Sales Analysis Institute and joined Chrysler in 1955.

MANITOBA

Hoogstraten to N.S.T.C.

Professor Jack Hoogstraten, of the University of Manitoba, retiring president of the Association, has accepted an appointment as president of the Nova Scota Technical College. Mr. Hoogstraten served as president of the Association from 1955 to 1957 during which time membership grew from 544 to 835. Well-equipped offices and a permanent secretary were also secured. In the fall of 1956 the Association began publication of its own newspaper. A great deal of the credit for its initiation goes to Mr. Hoogstraten.

As to the future of the Association Mr. Hoogstraten feels that the greatest problem to be faced by the Association is the shortage of technically trained personnel and that it is a responsibility of the Association to participate in steps to alleviate this situation. A recent development is the proposal to train "engineering technicians". These men, rather than taking the full four years engineering course, would receive intensive training in a narrow range or phase of a particular engineering field for a much shorter period. Mr. Hoogstraten supports this proposal and feels that the engineering associations will have to take the lead in establishing curriculums and controls since only professional engineers will know the training required.

BRITISH COLUMBIA

Engineers in the News

Professor F. W. Vernon of the mechanical engineering department, U. B. C., was recently honoured by former students at a banquet held to mark his retirement. Professor Vernon was presented with a hi-fidelity set at a dinner held in the Hotel Georgia, Vancouver. The professor came to U.B.C. in 1926.

R. C. Robson has accepted a position with Crown Zellerbach Canada Limited as plant engineer, Canadian Western Lumber Company, Fraser Mills. Mr. Robson was formerly with H. A. Simons Limited.

J. Pomeroy, has been promoted to regional maintenance engineer for No. 2 Region, B.C. Department of Highways. His operations will center around Kamloops, B.C.

E. Cecil Roper, has been elected Director of Howe Sound Company. He became executive vice-president of the company in 1956.

A. N. Lucie-Smith, has been appointed to an engineering position with the petroleum natural gas branch of the Department of Mines, Province of British Columbia.

T. F. Hadwin, has been appointed district manager of the Bridge River Area, with the B.C. Electric Company Limited, at Shalath, B.C. He was formerly superintendent of substations with the company.

ALBERTA

Thirty-Seventh Annual Meeting

The thirty-seventh Annual Meeting of the Association of Professional Engineers of Alberta, held at the Palliser Hotel, Calgary, on March 30, 1957, was called to order by president J. G. Dale. Present were four hundred professional engineers and E.I.T.'s.

Visitors representing the E.S.S. and Mining and Geological Society of the University of Alberta, the B.C. Association, the Ontario Association and the Saskatchewan Association were introduced and welcomed to the meeting.

J. J. Hanna, representative on the Dominion Council, P. M. Sauder, from the E.I.C., and J. G. Dale, engineering faculty Council Representative read their reports. J. F. McDougall gave the report as registrar, and made some interesting comparisons of membership records during the ten years in which he has acted as registrar of the Association. He stated that ten years ago the total registered membership was 410 as compared with 2055 today. Twenty-four members attended the Annual Meeting ten years ago. Mr. McDougall also reported on the Student Loan Fund, and on Scholarships and Medals.

Public Relations

In a report from the Public Relations Committee, J. N. Ford, chairman, discussed setting up of branches of the Association throughout the province; liaison with the university students; and the revision, by a sub-committee of the Information Booklet with the object of selling the Association. The sub-committee pointed out the need for an Association objective; such an objective to provide a basis for selling the Association. As a result, several of the recommendations of the Council have been approved. The purpose of the Association of Professional Engineers of Alberta is to serve and safeguard the public by ensuring that only those who have the proper qualifications shall practice engineering; insisting that the members achieve self-discipline through following the Code of Ethics; being concerned with the standards of education; educating employees and the public as to the goals, ideals, practises, and ethics of the professional engineer. The Association will also present membership certificates during a suitable ceremony; will be the ways and means of producing closer liaison with the technical engineering societies; supply the Professional Recognition Bulletin; and employ Public Relations counsel. It was recommended that consideration be given to the employment of such counsel.

Counselling and Education

Submitting the report of the Counselling and Education Committee, J. G. Dale, in response to a question as to what success career nights and the Provincial Guidance Branch have had, replied that their effect is threefold. Students who should further their education are encouraged; direction in the correct fields of endeavour is given; and those who may not be prepared or qualified for engineering are discouraged. Professor L. E. Gads explained the organization of guidance programs.

It was also reported that work is proceeding on a draft of a counselling pamphlet designed for use in Alberta by the University, the provincial director of Guidance, and the Association office. A comparison was made of the entrance requirements for, and the courses taught in the first year of engineering at the Universities in Canada. The committee also recommended that the Association participate in a television Guidance or Counselling program being sponsored by the Edmonton South Side Kiwanis Club. Speakers on professional engineering have been provided for the Provincial Guidance Branch and the Edmonton School Boards. The Calgary section of the Committee has started work on a study of the place of technical schools in Alberta.

Forum Discussion A forum discussion was also held on the question "Should the Engineering Profession Act provide for separate designations for Geologists and Geophysicists?" It was decided by a four-man panel that more study should be given this matter by the Act and By-Laws Committee.

Legal Aspects G. M. Blackstock, QC., former chairman of the board of Public Utility Commissioners, discussed "The Legal Responsibilities of A Professional Engineer".

Election of Officers

Elected president by acclamation was Dr. J. C. Sproule; vice-president, Dr. G. W. Govier; and four councillors for a term of three years; Dr. R. N. McManus, W. D. Stothert, C. W. Coote, R. D. Halk. Serving as councillor for a term of two years is B. A. Monkman.

The new president and councillors were then introduced to the meeting.

Right Honourable C. D. Howe

The Right Honourable C. D. Howe was introduced to the dinner audience as an outstanding engineer, who in 1935 left a flourishing consulting practice to enter the rough and tumble of the political arena. In his speech, Mr. Howe suggested by argument and personal example that despite the alleged shortage of engineers in the profession, the political field offered fertile soil for the engineer. Among the restrictive qualifications that Mr. Howe thought to mention, however, were middle age and private means. Mr. Howe entertained his audience by a sprightly account of the part that he and the government had played in developing Canada's resources by encouraging with government aid the inauguration of industries and public services that private enterprise could not alone have initiated.

The success of Mr. Howe's address may be measured by the fact that even the most hard-headed of his opponents left the meeting feeling that, after all, the government's part in financing the Trans Canada Pipe Line might have its merits.

A.R.C. Director is Speaker

Dr. N. H. Grace, director of the Alberta Research Council, in his address to the luncheon audience outlined the part played by his organization in developing Alberta's natural resources.

Since its inception in 1919 the Research Council has been primarily interested in the province's fuel reserves and their effective utilization. Dr. Grace outlined the researches presently conducted on coal, natural gas, petroleum and oil products. Naturally, the geology of the province is of vital importance to the proper development of fuel resources, and therefore the Research Council maintains an active geology group.

The Council, it was explained, has for many years offered the services of its group of industrial engineers, who collaborate with the National Research Council technical information service to assist provincial industries.

Provincial soil surveys and irrigation programs have been assisted by the work of the Research Council; and a recent development has been the formation, under the direction of Dean R. M. Hardy, of a highway research group. Another recent project, which was started last year, is an investigation of cloud systems (made in conjunction with several provincial and federal groups) in the hope of overcoming the problems of hail damage.

President's Address

Delivering the president's address Mr. Dale said that his talk was chosen with a view to its usefulness to the young engineer. Whether he remains within his own field or finds himself in one other than the one in which he specialized, Mr. Dale said that as he continues in his field or even advances in it he will likely find that he is dealing in two things that may greatly affect his situation and which were not included in his early training. These are business, and people. Such things as accounting, marketing and business organization and the inexact sciences of human relations, personnel problems and labour relations may well baffle the engineer as he seeks advancement.

Advancement and Administration The further an engineer advances in his company the closer he comes to or the more he becomes involved in administration and its attendant problems. In his rise to an administrative post, one of the things to be learned is the necessity of delegation. He will probably receive a great deal more delegated work and authority than he will give. On his ability to execute this may depend his promotion into administration. Mr. Dale said that there is a strong comparison between an engineering report on a problem with its resulting conclusion and completed staff work, and described the terms "staff" and "line" as they apply to engineers.

Stressing the importance of "completed staff work" he remarked that its benefits are twofold. The chief is protected from half-baked ideas, voluminous memorada and immature oral presentments. The staff man who has a real idea to sell is enabled more readily to find a market.

Concluding his remarks Mr. Dale stated that he had presented two thoughts, one of which was that an engineer may not practice in his field of study and that he will learn his specialty after graduation, and that secondly, a chance of promotion may be better in business administration and may be enhanced through further study of the methods of doing business and of handling people.

OBITUARIES

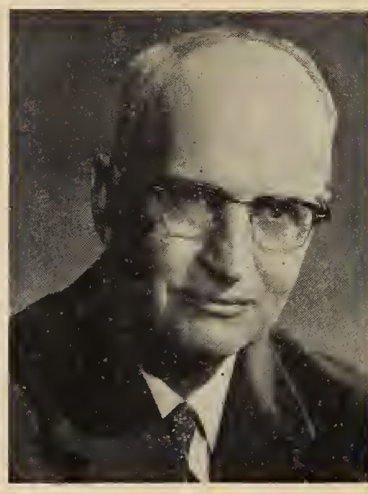
The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

John Dibblee, M.E.I.C., assistant general manager of personnel with the Hydro-Electric Power Commission of Ontario, who recently observed his fortieth anniversary of service, died on April 4, 1957, while on vacation at Montego Bay, Jamaica, B.W.I.

Born at Woodstock, N.B., on May 7, 1894, Mr. Dibblee had his general education there and then proceeded to the University of Toronto where in 1915 he was awarded a bachelors' degree in applied science.

In his first year as a graduate he gained valuable experience as a job foreman at Georgetown for the Lambton-Guelph Railway and as a demonstrator in hydraulics, in the faculty of applied science and engineering, at the University of Toronto. Early the following year he joined the firm of Smith, Kerry and Chase as a resident engineer for a twelve month period. Beginning his association with the Hydro-Electric Commission in 1917, he was with the station design section. He also served with the R.A.F. during World War I and on his return to the Commission became a district operating engineer, on the Eastern Ontario System. In 1926 he was named general superintendent of the Niagara Falls district of the company. Five years later in 1931 he became assistant chief operating engineer and in 1937 he was named assistant chief engineer. Promoted to the post of chief engineer in 1945, he was called in to take over the responsibility of manager of personnel in 1947. In 1955 he became assistant general manager of personnel.

As manager of personnel, Mr. Dibblee pioneered a significant advance in Canadian labour-management relations. At the commencement of the construction of the $340 million Sir Adam Beck Niagara Generating Station No. 2, Mr. Dibblee foresaw that the Commission would be involved, for the first time, in bargaining with the international unions. He played a part in the establishment, by eighteen A.F. of L. craft unions, of an Allied Council and negotiated with this council on behalf of the Hydro, a single agreement covering the entire project. This was the beginning of a new experience in labour-management relations for the contractors and their supervisors, and for the men and their union representatives.



J. Dibblee, M.E.I.C.

During the entire five-year project, on which 5,000 men worked at the peak, not a single hour was lost through work stoppage.

The relationship between the Commission and the Council of eighteen A.F. of L. Unions has been described as being without parallel in Canadian history, the essence of it being a whole-hearted trust and confidence founded on forthright honesty and understanding, that has to be lived to be understood. The main credit for this was given to Mr. Dibblee, whose constant concern was for men in Canadian industry to understand the ideological nature of events in the world today, and to begin to live in industry an adequate answer.

Mr. Dibblee attributed any effectiveness he may have had in labour relations to his training in Moral Re-Armament, and said, "We have an entirely new relationship of inestimable value, in which both sides try their utmost to cure their own shortcomings."

The Allied Council principle was later extended on a province-wide basis to construction forces on other projects including Hydro's St. Lawrence Power Project.

Mr. Dibblee's role in labour relations began in 1936, when the Employees' Association was formed. He took an active part as management's representative in the initial organization of this group, and before negotiations the following year, acted as a member of the Working committee. In later years he became associated with the Labour Relations Committee and in 1947 assumed responsibility for representing the Commission in negotiations with the bargaining unit, the Employees' Association.

Mr. Dibblee was a member of the Association of Professional Engineers of Ontario and was also active in the American Institute of Electrical Engineers.

Mr. Dibblee joined the Engineering Institute as a Member in 1939.

Joachim Antonisen, M.E.I.C., retired engineer of Port Arthur, at one time city engineer at Port Arthur, Ont., died in that city on April 16, 1957.

J. Antonisen, M.E.I.C.

Mr. Antonisen was born at Christiania, Norway on February 24, 1869. He attended schools at Bergen and at Christiania and spent three years in the United Stats in railway work before embarking on a four-year engineering course at the University of Dresden, Saxony, from which he graduated in 1898. He was an assistant engineer with the Saxon Government Railways for the first two years of his graduate career. He then transferred to another department and received an appointment as assistant engineer on roadbuilding and river improvement. Four years later, in 1904, he emigrated to Canada. Beginning his career in the new world with the Canadian Pacific Railway at Winnipeg he was the following year named city engineer at Port Arthur and later, in 1911, was made manager of all public utilities. He also took on an appointment as City engineer for the municipality of Moose Jaw, Sask, for a short time and carried out several private engineering enterprises in connection with railroad yard construction and elevator construction work. He held the appointment of City engineer at Port Arthur until the time of his retirement from public life in 1935.

Mr. Antonisen has always maintained an interest in the affairs of the Lakehead Branch of the Institute and was in 1935 chairman of that Branch. Since then it had been his custom to tender a vote of thanks each year to the visiting president of the Institute. Mr. Antonisen will be well remembered by all those who had occasion to be so addressed by him during the past seventeen or eighteen years.

Mr. Antonisen joined the Institute as an Associate Member in 1907 and transferred to Member in 1921. He attained

Life membership in the Institute in 1937.

James Patton Gordon, M.E.I.C., retired official of the City Engineers' Department, at Hamilton, Ont., died on January 31, 1956 in that city.

Born at Toronto on January 3, 1883, he was a graduate of the class of 1904 at the School of Practical Science of the University of Toronto.

Engaged in engineering projects while yet a student Mr. Gordon had had experience in the fields of land surveying and draughtsmanship, the latter with the Canadian Pacific Railway before graduation. Later he worked with an Ontario Land Surveyor on township subdivision, was locating engineer on the transmission line of the Toronto and Niagara Power Company in 1905, and a draughtsman on a railway survey the following year. For the Toronto firm of Chipman and Power, consulting engineers, at Toronto he was engaged as an assistant in charge of construction of Waterworks and Sewers in 1907 and remained in this work for a number of years at various points across the prairie provinces.

He was with the City engineer's department of the City of Hamilton for thirty years.

Mr. Gordon joined the Institute as a Student member in 1907; became an Associate member in 1913 and a Member in 1940. He attained Life Membership in 1949.

Harold Forsyth Finnemore, M.E.I.C., retired chief electrical engineer with the Canadian National Railways, Montreal, died on April 8, 1956, in Montreal.

Mr. Finnemore was born at Chicago on March 18, 1893 and gained his engineering qualifications at Queen's University where he was awarded a B.Sc. degree. He enlisted with the Royal Canadian Engineers in 1914 and served overseas in World War I. On demobilization he joined the Canadian Government Railways at Moncton, N.B., as a draughtsman in the electrical engineering department. Five years later he became assistant electrical engineer in the Canadian National Railways mechanical department at Montreal, and in 1938, electrical engineer. He was appointed assistant chief electrical engineer in 1943 and chief electrical engineer in 1945. He retired in 1956.

Mr. Finnemore was latterly engaged in the development of electric motive power and installations, and the introduction of air-conditioning on the Canadian National passenger equipment.

Mr.Finnemore served the Institute for several years as a member of the Library and House Committee and was a member of the Council from 1948 to 1950.

Mr. Finnemore was also chairman of the planning and building committee of the Protestant School Board of Greater Montreal.

He joined the Institute as an Associate Member in 1921 and was transferred to Member in 1940. He gained Life Membership in 1956.

Beverley A. Evans, M.E.I.C., supervising engineer in charge of design services with Du Pont Company of Canada (1956) Limited, engineering department, at Montreal, died in that city on May 16, 1957.

A native of Kingsey, Que., where he was born on January 14, 1903, Mr. Evans was a graduate of the University of Saskatchewan, graduating with a B.Sc. in civil engineering in 1930 and an M.Sc. in 1936.

He had been design engineer for Saskatoon on that city's Broadway bridge, assistant secretary-treasurer of the town of Asquith, Sask., chief designer and resident engineer for the federal public works department on the Bordern Bridge in Saskatchewan and was responsible for the design and construction of the Kingston, Ont., nylon plant of Du Pont of Canada.

During the war he was assistant project engineer for Defence Industries Limited on the design of the de Salaberry, Que., smokeless powder plant and undertook secret war work for the National Research Council.

H. F. Finnemore, M.E.I.C.

Mr. Evans joined the Institute as an Associate Member in 1937 and was transferred to Member in 1940.

Lewis J. Barron, M.E.I.C., district manager of the Foundation Maritime Limited, construction department at Halifax, N.S., died suddenly on March 15, 1957 in that city.

Born at St. John's, Newfoundland on January 7, 1914 he had his early education there and later studied engineering at the Nova Scotia Technical College. A 1941 graduate in civil engineering, his first graduate appointment was with the Pictou Foundry and Machine Company Ltd., shipbuilding division, as plant engineer. This followed experience gained while a student and prior to that time, with various concerns, including the Newfoundland Government, the Anglo-Newfoundland Development Company Limited, the Department of Natural Resources, Newfoundland and the Department of Mines, Province of Nova Scotia.

In 1943 he accepted the position of maintenance and safety engineer, Foundation Maritime Limited, shipbuilding division at Pictou, later transferring to the engineering construction department in Montreal. With the Foundation Companies a total of fifteen years he was associated with many spectacular projects across Canada, in particular at Churchill, Man., where he spent more than two years. Among other projects supervised by Mr. Barron from the Montreal office were the construction of water intakes for paper mills at Hawkesbury, Ont., and Cap de la Madeleine, Que. For three years he held the post of supervisor at Montreal of the Canadian Johns-Manville Company Limited Construction program at Asbestos, Que.

Mr. Barron joined the Institute as a Member in 1943.

John Frederick Mellish, M.E.I.C., retired district engineer of the Harbours and Rivers Engineering Branch of the Department of Public Works, at Winnipeg, Man., died at his new home in Penticton, B.C., on February 22, 1956.

Mr. Mellish was born at Galt, Ont., on June 24, 1892. He attended the Galt Public School and Collegiate Institute, the University of British Columbia and the University of Washington, Seattle, where he was graduated with a B.Sc. in civil engineering in 1918. He worked with the former Department of the Interior as a resident engineer in the national parks of British Columbia at that time and the following year transferred to Alberta to accept a similar position, which he held until 1925. Briefly associated with the Sydney Junkins Construction Company as a field engineer at Vancouver, for a twelve-month term, he later transferred to the Department of Public Works of Canada at Ottawa, as a junior engineer, early in 1928. Promoted to assistant engineer and senior assistant engineer transferred to Winnipeg in 1936 and 1944, he was to become acting district engineer for the Department at Winnipeg in 1947. On his retirement Mr. Mellish was district engineer of the Harbours and Rivers Engineering branch.

Mr. Mellish was a member of the Association of Professional Engineers of Manitoba and of the American Wood Preservers Association.

He became a Member of the Institute in 1948.

Sec.-Treas., W. J. M. Owen, 634 Eckhardt Ave., W., Penticton, B.C.

CORNER BROOK

Chairman, Milton G. Green; *Vice-Chair.,* E. J. Leja; *Treasurer,* W. S. Read; *Secretary,* Eric R. Scanes, c/o Bowater's Nfld. Pulp and Paper Mills Ltd., Corner Brook, Nfld.

CORNWALL

Chairman, W. Rothwell; *Executive,* D. Burnham, V. Harrison, G. Biard, J. Moriarty, J. Pescod, L. Snelgrove.
Sec.-Treas., D. W. C. McEwan, c/o Courtaulds (Canada) Ltd., Cornwall, Ont.

EASTERN TOWNSHIPS

Chairman, Jacques Lemieux; *Vice-Chair.,* R. D. Mawhood; *Executive,* J. C. Davidson, M. Grondin, G. B. Moffat, J. Freeman, J. Bourassa, C. D. McKinney; *Treasurer,* A. S. Mitchell.
Secretary, J. P. Champagne, 762 Argyle St., Sherbrooke, Que.

EDMONTON

Chairman, S. J. Hampton; *Vice-Chair.,* T. H. Newton; *Executive,* R. H. Cronkhite, D. H. Sands, G. Ross, S. R. Sinclair, H. Hole, R. H. Gardener, R. H. Nicolson, J. Longworth.
Sec.-Treas., G. Hodge, 10615-146th St., Edmonton, Alta.

FREDERICTON

Chairman, R. P. Lynch; *Vice-Chair.,* O. I. Logue; *Executive,* J. J. Gorman, W. L. Barrett, L. W. Smith, F. J. Abbass, R S. Shephard, L. W. Bailey; *Treasurer,* R. D. Neal.
Secretary, A. M. Stevens, Box 62, Marysville, N.B.

HALIFAX

Chairman, R. D. T. Wickwire; *Vice-Chair.,* J. D. Kline; *Executive,* L. J. Barron, G. H. Dunphy, P. M. Lane, A. H. MacKinnon, W. J. Phillips, G. F. Vail, B. N. Cain, J. E. Clarke, L. D. Hopkins, J. W. Powers.
Sec-Treas., J. E. Reardon, P.O. Box 33, Halifax.

HAMILTON

Chairman, D. B. Annan; *Vice-Chair.,* R. C. Mitchell; *Executive,* R. H. Stevenson, H. E. Seeley, H. E. Archibald, E. R. Bushfield.
Sec.-Treas., W. A. H. Filer, 23 Maple Ave., Hamilton, Ont.

HURONIA

Chairman, R. MacKay; *Vice-Chair.,* L. G. McNeice; *Executive,* S. R. Walkinshaw, J. Richardson, C. Campbell, D. M. Harris, J. L. Armstrong, B. C. Lamble, J. E. Sears.
Sec.-Treas., L. Morgante, 36 Borland St. W., Orillia, Ont.

KINGSTON

Chairman, C. W. Jones; *Vice-Chair.,* E. C. Reid; *Executive,* J. W. Dolphin, W. B. Rice, S. D. Lash.
Sec.-Treas., D. I. Ourom, 991 Princess St., Kingston, Ont.

KITCHENER

Chairman, J. F. Runge; *Executive,* B. Nichols, R. Senyshen, R. Blezard, C. Leicht.
Sec.-Treas., A. H. Austin, c/o Armco Drainage & Metal Products of Canada Ltd., Box 300, Guelph, Ont.

KOOTENAY

Chairman, W. G. Small; *Vice-Chair.,* J. T. Higgins; *Executive,* R. F. Bailey, D. J. Turland, D. Danyluk, W. V. Nicholson, E. Rohatynski; *Treasurer,* J. I. McClelland.
Secretary, J. L. P. Limbert, 649 Forrest Drive, Trail, B.C.

LAKEHEAD

Chairman, D. B. McKillop; *Vice-Chair.,* V. B. Cook; *Executive,* W. E. Mercer, C. M. Cotton, E. D. Manchul, R. C. Hodge, W. D. MacKinnon, W. H. Bulger, E. H. Jones, J. H. Hargrave.
Sec.-Treas., J. E. Rymes, 624 South Selkirk Ave., Fort William, Ont.

LETHBRIDGE

Chairman, A. J. Branch; *Vice-Chair.,* J. R. Milne; *Executive,* P. A. Harding, A. A. Kenwood, W. B. Thomson.
Sec.-Treas., R. D. Hall, Utility Engineer, City Hall, Lethbridge, Alta.

LONDON

Chairman, D. J. Matthews; *Vice-Chair.,* R. W. McMeakin; *Executive,* H. Osborne, R. Fuller, G. Hayman, S. Lauchland, H. Martin, R. Smith, W. Sinkins.
Sec.-Treas., G. W. Chorley, c/o M. M. Dillon & Co. Ltd., P.O. Box 1026, London, Ont.

LOWER ST. LAWRENCE

Chairman, Jean R. Menard; *Vice-Chair.,* M. Lanouette; *Executive,* T. Bernier, R. Joncas, A. Leroux, G. Santerre.
Sec.-Treas., Claude St. Hilaire, 10 Rue St. Jean, Rimouski, Que.

MONCTON

Chairman, R. M. Wickwire; *Vice-Chair.,* G. E. Franklin; *Executive,* J. L. W. Harris, L. McIsaac, R. M. MacIntosh, G. A. Peck, W. M. Steeves, C. L. Trenholm.
Sec.-Treas., V. C. Blackett, 97 MacBeath Ave., Moncton, N.B.

MONTREAL

Chairman, J. E. Leo Roy; *Vice-Chair.,* R. F. Shaw; *Executive,* C. A. Colpitts, J. O. McCutcheon, H. Audet, R. A. Phillips, L. M. Nadeau, L. Nenniger.
Sec.-Treas., G. M. Boissonneault, Shawinigan Water and Power Co., P.O. Box 6072, Room 809, Montreal, Que.

OFFICERS OF THE BRANCHES

NEWFOUNDLAND

Chairman, G. E. Knight; *Vice-Chair.*, C. W. Henry; *Executive*, R. P. Hunt, A. H. McKinnon, D. S. Templeton, G. N. Cater, R. W. Myers, R. F. Martin.
Acting Sec., C. W. Henry, c/o Newfoundland Light & Power Company Limited, St. John's, Nfld.

NIAGARA PENINSULA

Chairman, P. L. Climo; *Vice-Chair.*, E. C. Little; *Executive*, R. D. MacKimmie, D. A. Barnum, H. C. L. Joe, H. J. Saaltink, C. A. O. Dell, C. A. McDonald, G. W. T. Richardson.
Sec.-Treas., P. Saldat, c/o H. G. Acres & Co. Ltd., 1259 Dorchester Road, Niagara Falls, Ont.

NIPISSING AND UPPER OTTAWA

Chairman, T. C. Macnabb, Jr.; *Vice-Chair.*, T. Chantler; *Executive*, E. A. Watson, F. R. Marshall, J. Crothers, D. T. Nagle, A. Booy, P. Rebin.
Sec.-Treas., R. A. Booy, Box 1, Temiskaming, Ont.

NORTH EASTERN ONTARIO

Chairman, A. A. Kidd; *Vice-Chair.*, J. S. Whyte; *Executive*, C. McIntyre, J. Blakeman, J. N. Greggain, J. Shipman, M. McLean, W. Swann, G. Flett.
Sec.-Treas., J. S. Busby, c/o C.N.R., Cochrane, Ont.

NORTHERN NEW BRUNSWICK

Chairman, A. R. Bonnell; *Vice-Chair.*, L. L. Marshall; *Executive*, C. K. Steeves, P. G. Robinson, D. C. MacCallum, R. A. Cameron, A. L. Bond.
Sec.-Treas., V. G. MacWilliam, P.O. Box 100, Atholville, N.B.

NORTH NOVA SCOTIA

Chairman, D. J. MacNeil; *Vice-Chair.*, W. I. Fisher; *Exec.*, C. McGibbon, M. Wolfe, Rev. W. Fogerty, J. K. Godfrey.
Sec.-Treas., D. G. Dunbar, Pictou County Power Board, New Glasgow, N.S.

OTTAWA

Chairman, Col. W. A. Capelle; *Vice-Chair.*, H. Chaput; *Executive*, T. M. Patterson, R. C. Silver, A. H. Graves, G. C. McRostie, J. P. Stirling, S. G. Frost; *Treasurer*, H. C. Brown.
Secretary, W. V. Morris, 2078 Knightsbridge Road, Ottawa.

PETERBOROUGH

Chairman, W. H. Ackhurst; *Executive*, I. N. MacKay, E. Oliver, F. R. Pope, R. A. Blount, L. E. Marian.
Sec.-Treas., D. B. Chase, Canadian General Electric Company, Waddell House, Monaghan Rd., Peterborough, Ont.

PORT HOPE

Hon. Chair., J. G. G. Kerry; *Chairman*, A. F. Alexander; *Vice-Chair.*, T. F. Kennedy; *Executive*, R. Waterfall, D. A. Runciman, J. L. Sylvester.
Sec.-Treas., J. A. Pollock, 8 Shortt St., R.R. 3, Port Hope, Ont.

PRINCE EDWARD ISLAND

Chairman, N. F. Stewart; *Vice-Chair.*, C. W. Currie; *Exec.*, R. D. Donnelly, J. D. MacDonald, L. A. Coles, G. Milligan.
Sec.-Treas., C. F. Buckingham, 46 Green St., Charlottetown.

QUEBEC

Life. Hon. Chair., A. R. Decary; *Chairman*, Ben O. Baker; *Vice-Chair.*, Roger Desjardins; *Executive*, L. Boulet, C. E. Demers, J. B. Delage, H. T. Kane, A. Longpre.
Sec.-Treas., Marc Bergeron, Concrete Repairs and Waterproofing Co., 128 Blvd. Ste. Anne, Quebec, Que.

SAGUENAY

Chairman, C. C. Louttit; *Vice-Chair.*, E. N. Coulthart; *Executive*, F. A. Brown, D. W. Stairs, E. E. Paine, W. W. Robertson, P. R. Thomas.
Sec.-Treas., D. L. Aker, c/o Electrical Maintenance Dept., Aluminum Company of Canada, Ltd., Arvida, Que.

SAINT JOHN

Chairman, J. J. Donahue; *Vice-Chair.*, H. W. M. Townshend; *Exec.*, K. V. Cox, G. C. Mouland, H. N. Day, J. B. Eldridge.
Sec.-Treas., D. I. Higgins, 30 Elizabeth Court, Saint John, N.B.

ST. MAURICE VALLEY

Chairman, J. U. Moreau; *Vice-Chair.*, C. J. Hebert; *Executive*, M. Wood, E. E. Copping, J. Pearson, H. L. Nicoll, B. Pangborn, J. W. Gathercole, C. M. Williams, C. Kinley, J. Edwards; *Treasurer*, J. J. Daoust.
Secretary, J. H. A. Lavalle, c/o Bell Telephone Company of Canada, 1635 Royale Street, Three Rivers, Que.

SARNIA

Chairman, G. W. Ames; *Vice-Chair.*, T. H. Dobbin; *Executive*, P. Maguire, R. Routledge, J. Newton, K. Radcliffe; *Treasurer*, D. Livingstone.
Sec.-Treas., J. H. Douglas, 213 London Road, Sarnia, Ont.

SASKATCHEWAN

Chairman, W. G. McKay; *Vice-Chair.*, J. C. Traynor; *Executive*, K. W. Allcock, M. B. Pierce, B. B. Torchinsky, J. B. Mantle, W. F. Hayes, K. R. Pattison, J. A. Wedgwood.
Sec.-Treas., R. Bing-Wo, 2043 Cameron St., Regina, Sask.

SAULT STE. MARIE

Chairman, K. H. Snell; *Vice-Chair.*, R. H. Tooley; *Executive*, K. Kansikas, K. I. Fletcher, N. A. Paolini, W. Sproule.
Sec.-Treas., L. F. Mason-Tulby, P.O. Box 624, Sault Ste. Marie, Ont.

SUDBURY

Chairman, J. W. Smith; *Vice-Chair.*, W. B. Ibbotson; *Executive*, F. J. DeStefano, H. Stavang, E. A. Fletcher, J. F. McCallum.
Acting Sec.-Treas., H. M. Whittles, 10 Wembley Drive, Sudbury.

TORONTO

Chairman, E. R. Davis; *Vice-Chair.*, H. Self; *Executive*, J. H. Ingham, A. C. Davidson, T. Dembie, R. C. Norgrove, J. E. Wright, P. S. Croft, A. M. Toye, L. F. Bresolin, B. L. Farrand, C. MacInnis.
Sec.-Treas., D. S. Moyer, c/o Canadian Radio Mfg. Corp., 11-19 Brentcliffe Road, Leaside, Ont.

VANCOUVER

Chairman, P. N. Bland; *Vice-Chair.*, W. G. Heslop; *Executive*, C. H. White, J. F. Muir, W. J. Johnson, J. H. Swerdfeger, J. J. Kaller, E. S. Hare; *Treasurer*, R. H. Carswell.
Secretary, A. D. Cronk, 658 West 13th Ave., Vancouver, B.C.

VANCOUVER ISLAND

Chairman, G. Griffiths; *Vice-Chair.*, H. Graham; *Executive*, H. T. Miard, L. C. Johnson, W. G. McIntosh, A. F. Paget.
Sec.-Treas, J. A. Cowlin, 3340 Richmond Rd., Victoria, B.C.

WINNIPEG

Chairman, N. S. Bubbis; *Vice-Chair.*, L. A. Bateman; *Executive*, J. Hoigstraten, R. N. Sharpe, J. B. Striowski, W. L. Wardrop, L. E. Poyser, R. T. Harland, J. P. C. McMath, P. Shane, W. D. Hurst, A. Baracos, T. E. Storey, W. R. McQuade.
Sec.-Treas., C. S. Landon, P.O. Box 541, Winnipeg 2, Man.

YUKON

Chairman, Capt. S. Thomson; *Executive*, C. E. White; *Treasurer*, J. D. Scott.
Secretary, Capt. E. I. Crouse, H.Q., NWHME, Camp Takhini, Whitehorse, Y.T.

ONTARIO DIVISION

Chairman, G. R. Henderson; *Vice-Chair.*, M. A. Montgomery; *Board of Management*, P. E. Buss, H. G. Conn, H. R. Sills; *Treasurer*, G. R. Turner.
Secretary, G. H. Rogers, c/o Engineering Institute of Canada, 236 Avenue Road, Toronto.

Personals

News of the Personal Activities of Members of the Institute.

Dr. O. M. Solandt, HON. M.E.I.C., assistant vice-president, research and development, with the Canadian National Railway has been appointed vice-president of the division.

Dr. Solandt, who is a native of Winnipeg, followed a career in physiology, worked on the teaching staff of the department of physiology at Cambridge, and became a Fellow of Trinity Hall. During World War II engaged in research on the relation of physiology to warfare, in Great Britain, he was in 1944 named superintendent of the Army Operational Research Group.

In the immediate post-war years he served with a military mission at Hiroshima and Nagasaki on the evaluation of the effects of the first atomic bombs.

Later in 1946 Dr. Solandt returned to Canada to join the Department of National Defence in Ottawa to take on the job of forming a permanent defence research organization for Canada. Dr. Solandt was the first chairman of the Defence Research Board in 1947 and a scientific member of the chiefs of staff committee and defence council.

Air Commodore C. A. Cook, O.B.E., M.E.I.C., has been appointed an air vice marshal and air officer commanding the Air Material Command of the R.C.A.F.

Air Vice Marshal Cook held the appointment of chief logistics officer at headquarters since 1952.

A graduate of the University of Saskatchewan, class of 1933, he was commissioned in the Royal Canadian Air Force in 1939. Overseas during the Battle of Britain in 1940 he served as an engineering officer with No. 112 Army Cooperation Squadron. On his return to this country he became staff officer at various stations and headquarters, and later took over a position in the Directorate of Postings and Careers, at Air Force Headquarters in Ottawa. In 1948 he was posted to the Canadian Joint Staff, Washington, D.C., returning to the Air Material Command headquarters as senior logistics planning officer.

For distinguished wartime service Air Vice Marshal Cook was appointed an officer of the Most Excellent Order of the British Empire in 1946.

A/V/M C. A. Cook, O.B.E., M.E.I.C.

G. Penney, M.E.I.C., who has had extensive experience in the pulp and paper industry with the Bowater and international paper organizations has been appointed vice-president of Sandwell International Limited.

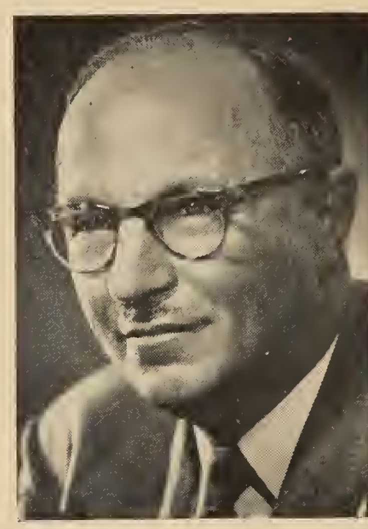
Mr. Penney who is a Queen's University graduate, class of 1925, was mill superintendent at Bowaters Pulp and Paper Mills, Newfoundland from 1938 to 1945. At that time he received the appointment of mill manager.

Sandwell International, formed in 1955, to provide management services has been awarded a management contract by the Pakistan Industrial Development Corporation, in connection with a pulp and paper mill in East Pakistan.

S. W. Fraser-Underhill, M.E.I.C., has been elected to the board of directors of the firm of Ewbank and Partners (Canada) Limited, engineering consultants, and has been named general manager of the firm. Since its establishment in 1954 Mr. Fraser-Underhill has taken a prominent part in bringing the company to its present state of activity.

E. E. Orlando, M.E.I.C., of the Canadian Westinghouse Company Limited has been appointed a vice-president of the firm.

Mr. Orlando, who has spent thirty years with Westinghouse is in charge of the district apparatus division of the firm which includes heavy apparatus sales, application engineering, and service facilities across Canada. This was one of three new operating divisions formed by the company at the time of his appointment to the post early in 1953. Prior to that time he was eastern regional manager of the Company.



O. W. Titus, M.E.I.C.

Dr. Otto Holden, M.E.I.C., chief engineer of the Hydro-Electric Power Commission of Ontario addressed the Commonwealth Section of the Royal Society of Arts, London, England on May 9, 1957.

Internationally known in engineering circles, Dr. Holden devoted much of his address to a discussion of the St. Lawrence Seaway and Power Project, with special emphasis on the power development being built jointly by the Ontario Hydro and the Power Authority of the State of New York.

Before returning to Canada later in the month Dr. Holden conferred with eminent British engineers and inspected some of the principal power developments in the British Isles.

O. W. Titus, M.E.I.C., who has since 1952 held the appointment of vice-president and general manager of the Canada Wire and Cable Company has been elected to the post of president of the organization.

Mr. Titus who started his engineering career with a B.A. Sc. degree gained at the University of Toronto in 1917 joined his present firm in 1929, being at the same time associated with the Underground Cable Company of Canada. As chief electrical engineer and chief engineer he was representative for Canada Wire and Cable Company on such standardization bodies as the Canadian Engineering Standards Association. Instrumental in some of the most difficult cable installations in Canada, Mr. Titus was responsible for the design and installation of a 120,000 volt underground cable system including cable and accessories supplied to the Montreal Light, Heat and Power Commission in 1940.

In 1948 vice-president of the English Electric Company of Canada Limited, he became at that time also general manager of the Canada Wire and Cable Company Limited.

Mr. Titus has served as a member of the Canadian National Committee International Conference on Large Power Systems and the National Executive of the Canadian Manufacturers' Association.

G. R. Davis, M.E.I.C., general manager of the Kingston Public Utilities Commission has been elected president of the Association of Municipal Electrical Utilities.

Mr. Davis who has beeen engaged in engineering in Kingston for several years formerly served with the Ottawa Hydro-Electric Commission in a variety of posts including that of general manager and chief engineer.

A. E. Berry, M.E.I.C., director of sanitary engineering for the Ontario Department of Health, Toronto, has been elected an honourary member of the American Water Works Association.

Mr. Berry has been with the Department of Health since 1926 and has been a member of the American Water Works Association since 1920. He represented the Canadian section on the Association's Board of Directors from 1937 to 1940 and was the Association's president in 1952. He received the George Warren Fuller Award in 1938 and the John M. Goodell Prize in 1950.

A. E. Berry, M.E.I.C.

Mr. Berry served on the council of the Institute in 1941-42, representing Toronto Branch.

S. Logan Kerr, M.E.I.C., of S. Logan Kerr and Company, consulting engineer of Fluortown, Pa., has been elected an honourary member of the American Water Works Association.

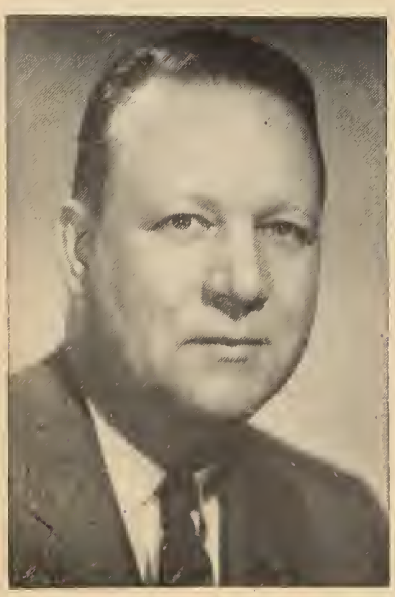
S. L. Kerr, M.E.I.C.

A member of the Association since 1935, Mr. Kerr is internationally known in the public water supply field and allied professions as an expert on water hammer effect. He has served on several of the Association's committees on this subject and is now chairman of the Association's special task committee to study allowances for water hammer.

R. G. Barbour, M.E.I.C., who has been appointed president of T. Pringle & Son Limited, Montreal. The firm has been engaged in consulting engineeering in the industrial field since 1892 and has served many prominent Canadian industries on plant design for aircraft, textiles, pharmaceuticals, asbestos and many other heavy industries.

R. G. Barbour, M.E.I.C.

Mr. Barbour was born and educated in St. John, N.B., and is a graduate of the University of New Brunswick, 1924. He was also awarded an M.Sc. degree in 1927. Following a two-year engineering course with Canadian General Electric, he spent four years with Aluminum Co. of Canada at Arvida on plant construction. From 1930 he was on design work with McDougall & Friedman, consulting engineers, until 1937 when he joined T. Pringle & Son Limited as mechanical engineer. He was appointed general manager in 1952 and vice-president and managing director in 1954.



F. H. Fargey, M.E.I.C.

F. H. Fargey, M.E.I.C., of Brown Boveri (Canada) Limited, formerly Ontario Branch manager for the organization has been named to the post of vice-president and sales manager.

Mr. Fargey is a graduate of the University of Manitoba in electrical engineering. He joined Brown Boveri in 1950 and for the past four years has made his headquarters in Toronto.

S. D. Ford, M.E.I.C., was among those three recently named to vice-presidency in the firm of Sandwell and Company Limited, consulting engineers of Vancouver.

Mr. Ford joined the Sandwell organization in 1949. He was appointed chief engineer of the firm in 1955.

A 1939 graduate of the University of British Columbia he gained experience with the Boeing Aircraft Company of Canada in Vancouver where he was in charge of the design section. In 1945 he transferred his services to the Powell River Company as assistant to the project engineer.

Edgar Lion, M.E.I.C., has been appointed chief engineer of Sir Robert McAlpine and Sons (Canada) Limited. He was formerly chief project engineer with

• PERSONALS

Montrose Builders, Inc., and prior to that engineer and chief estimator with Louis Donolo, Inc.

Mr. Lion is a graduate in civil engineering of McGill University, class of 1945.

C. S. Leclair, M.E.I.C., has been appointed chief engineer of Peacock Brothers Limited, in their new project and development department.

Mr. Leclair has held senior engineering positions in England and Japan, and prior to joining Peacock Brothers Limited directed his own consulting business in Toronto, under the firm name of Leclair Engineering Company.

During the course of his career, his original contributions to the engineering field have brought him over one-hundred and fifty patents.

W. L. Wardrop, M.E.I.C., who established engineering consulting offices in Winnipeg in 1955 under the name of W. L. Wardrop and Associates, is president of the newly incorporated company, known as W. L. Wardrop and Associates (Management) Limited. He is also a director of the firm which specializes in municipal, structural and industrial engineering.

Mr. Wardrop graduated from the University of Manitoba in electrical engineering in 1939 and received a degree in civil engineering in 1947. He joined the engineering department of the City of Winnipeg in 1937 and received the appointment of engineer of waterworks and sewage in 1949 after several years military service with the Royal Canadian Corps of Signals.

Col. W. A. Capelle, M.E.I.C.

J. E. Butler, M.E.I.C.

R. W. McKnight, M.E.I.C., has been elected vice-president of the newly incorporated firm of W. L. Wardrop and Associates (management) Limited, engineering consultants. He is also a director of the company.

He is a 1950 graduate of the University of Manitoba in civil engineering, and has had several years' experience with the Foundation Company of Canada Limited, on heavy construction at Fort Churchill, Man., on the atomic energy project, at Chalk River, Ont., and other work. More recently he has been employed with Defence Construction Limited at Winnipeg as an assistant engineer on administrative work for army and navy projects. In 1953 he joined Moody and Moore, architects, as a designer on defence construction projects.

A. V. Armstrong, M.E.I.C., former senior Canadian executive for Amalgamated Electric Corporation has been appointed manager of the magnet wire division of the Canada Wire and Cable Company Limited new modern plant now under construction at Simcoe, Ont. This plant will be the major unit.

Mr. Armstrong who started his engineering career with the English Electric Company of Canada Limited, and who is a 1923 graduate of McGill University also served the Canadian Cutler-Hammer Limited and Northern Electric Company at Toronto before joining Amalgamated Electric Corporation Limited in 1938. He was appointed president and director of the firm in 1952.

Colonel W. A. Capelle, M.E.I.C., director of works at Army headquarters, Q.M.G. Branch, Ottawa, has been elected chairman of the Ottawa Branch of the Institute.

Colonel Capelle is a graduate of the University of Manitoba, class of 1932. He joined the R.C.E. at that time and has since folowed the career which has combined engineering and a military life. At the outbreak of World War II, then commanding the 7th Army Troops Company in Winnipeg, he assumed command of the First Corps Field Park Company in Winnipeg and took the Company overseas.

E. Lion, M.E.I.C.

C. S. Leclair, M.E.I.C.

Command and regimental appointments followed and in 1944 he became staff officer of the Royal Engineers at First Canadian Army Headquarters.

For his service in World War II Colonel Capelle was awarded the Croix de Guerre avec Palme in 1946.

Since the war he has held the appointments of assistant director and then director, Directorate of Works and Accomodation, in the branch of the Quartermaster General at Army Headquarters. In 1950 he was appointed command engineer of the Central Command.

His promotion to the rank of colonel and his appointment as director of works was announced in 1952.

J. E. Butler, M.E.I.C., has been appointed manager of Sales and Fiberglas Canada Limited, at their new branch office at London, Ont., serving Southwestern Ontario.

Mr. Butler, who graduated from the University of Manitoba with a B.Sc. in civil engineering in 1950 was employed by the A. P. Greene Firebrick Company

of Weston, Ont., at the outset of his career. He has been with Fiberglas Canada Limited since 1951 in the capacity of sales engineer.

D. L. Mackinnon, M.E.I.C., has been appointed project manager of the Northern Manitoba mining and development at Thompson Lake, for the Foundation Company of Canada Limited, general contractors for the INCO development in that area.

Mr. Mackinnon who has been associated with the Foundation Company for a number of years. He was awarded an M. Sc. degree in civil engineering from the University of New Brunswick in 1944 following an initial degree obtained at U.B.C. in 1939. He gained early experience with the Foundation Company in 1940, served with the R.C.A.F. as a pilot and returned to the company in 1946 as manager of the building department of the Foundation Company of Ontario Limited, with headquarters in Toronto.

In 1948 he accepted an appointment as managing director of the Bayside Construction Company Limited, at Campbellton, N.B. and held that post for some time. Mr. Mackinnon was again with Foundation Company of Canada Limited at Montreal in 1954.

N. S. Bubbis, M.E.I.C.

J. Stuart Johnston, M.E.I.C., formerly manager of the western district of Linde Air Products Company, division of Union Carbide Canada Limited at Vancouver has received the appointment of sales manager, industrial gas products, with the organization. He will make his headquarters at the Linde General Offices in Toronto.

Mr. Johnston has been associated with the Linde Air Products Company since his graduation from McGill University in 1939. He has held positions as service engineer at Montreal and Toronto, process service manager at Montreal, and district manager at Winnipeg prior to his most recent appointments.

W. L. Garvin, M.E.I.C., is now associated with the Winnipeg office of the consulting engineering firm of Haddin, Davis and Brown Limited, of Calgary, Edmonton, Regina and Winnipeg.

Mr. Garvin obtained a B.Sc. degree in mechanical engineering from the University of Manitoba in 1950. Following graduation he was employed by General Motors Diesel Limited, and the Hydro-Electric Power Commission of Ontario at Toronto as a mechanical design engineer. For the past four years he has been with Defence Construction Limited and latterly served as area engineer responsible for the supervision of construction of new mechanical installations.

N. S. Bubbis, M.E.I.C., general manager of the Greater Winnipeg Water and Sanitary Districts has been elected chairman of the Winnipeg Branch of the Institute.

Mr. Bubbis was born in the United States, received his general education in

Winnipeg as well as his engineering qualifications. He is a 1934 graduate from the University of Manitoba in civil engineering.

At first working with the City of Winnipeg as a pipe plant inspector, he transferred to the draughting and designing branch, where he was later promoted to engineer in charge.

In 1944 he was appointed engineer of water works and sewerage. That position he held until in 1949 he was named to his present work.

He is a member of the executive of the Canadian section of the American Water Works Association; is past-president of the Canadian Institute on Sewage and Sanitation, of the Western Canada Water and Sewage Conference and of the Minnesota Section of the American Water Works Association.

A. A. Laughlin, M.E.I.C., has joined the Winnipeg office of the firm of Haddin, Davis and Brown Limited, consulting engineers. He will have charge of structural engineering design.

Mr. Laughlin is a University of Manitoba graduate, class of 1936. During

P. N. Brown, M.E.I.C.

World War II serving as a technical representative of the British Air Ministry in the Eastern United States. For the past ten years he has been with the Bridge design office of the Highways Branch, Department of Public Works of the Province of Manitoba. Last year he resigned as chief bridge and structural engineer.

P. N. Brown, M.E.I.C., has been elected chairman of the Border Cities Branch for the year 1957.

Born at Brantford, Ont., Mr. Brown received his early education in Windsor and Walkerville, Ont., schools.

During World War II Mr. Brown served with the R.C.A.F. in the South East Asia Command and on his discharge held the rank of flying officer. In 1950 he graduated from the University of Toronto with a B.A.Sc. degree.

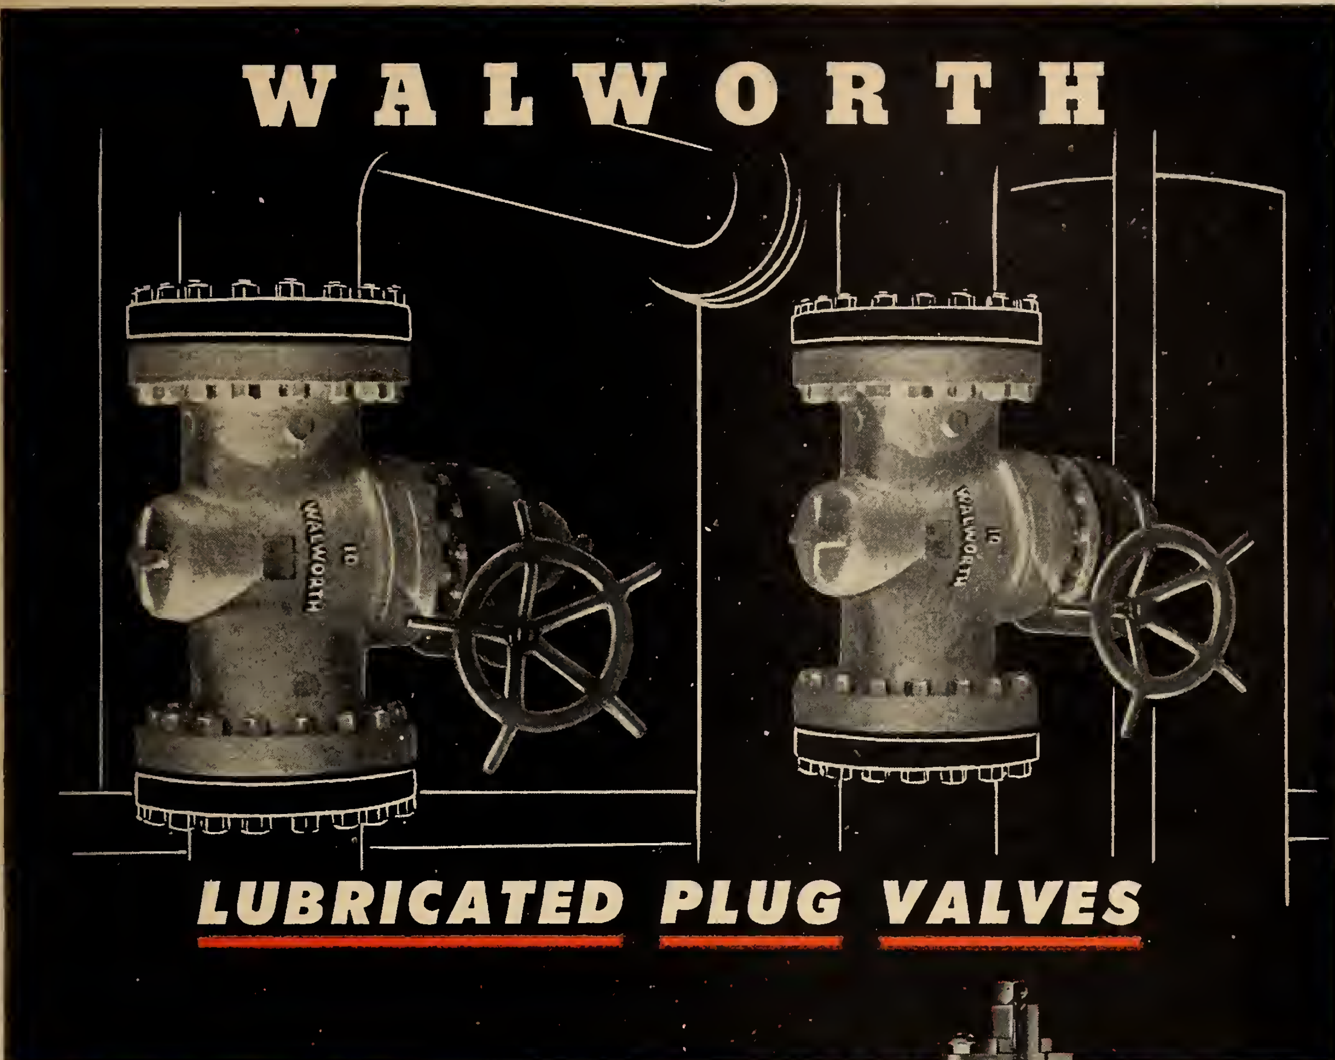
Prior to his military service and during summer vacations Mr. Brown worked with the Canadian Bridge Company Limited as a structural detailer. On graduation he joined the company as an estimating engineer and is presently assistant contracting engineer.

He has already had active participation in Institute activities, serving in various executive capacities includng those of secretary and treasurer.

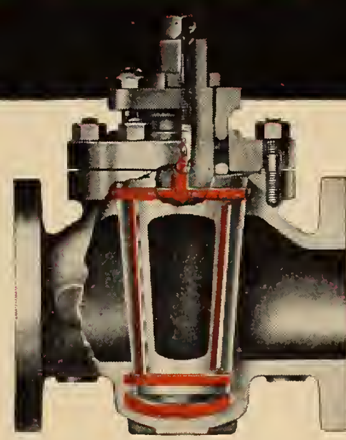
R. J. Wood, JR.E.I.C., of Honeywell Controls Limited has been appointed sales supervisor for the power industry following service with the company since 1951.

He is a 1949 graduate of the Nova Scotia Technical College in mechanical engineering and gained his initial experience with the Canadian Celanese Limited.

R. L. Walker, JR.E.I.C., a civil engineer from the University of British Columbia, class of 1950, has joined the firm of Hunting Technical and Exploration Services Limited, of Toronto. His first assignment will be in Ceylon where he will act in a liaison and co-ordinating capacity in connection with studies of



Better because . . . They are *pressure sealed* with an insoluble lubricant readily renewed while the valve is in service. Lubricant completely surrounds the plug ports assuring a tight seal against leaks. It also insures ease of operation by reducing friction between the body and the plug while at the same time protecting the finished surfaces against corrosion and wear.



Lubricant system of a Walworth No. 1700F Regular Gland, Wrench Operated, Steel-iron, *Lubricated Plug* Valve. Other Walworth *Lubricated Plug* Valves include Single Gland, and Ball Bearing types. Sizes to 30-inches — pressures to 5,000 psi, and for vacuum service.

Walworth Lubricated Plug Valves are the most satisfactory valves available for the handling of gritty suspensions, and many other destructive, erosive, and corrosive industrial and chemical solutions.

They are ideal for general refinery and pipeline service.

DISTRIBUTORS IN PRINCIPAL CENTERS THROUGHOUT THE WORLD the island's water resources under the present Canadian Colombo Plan integrated survey.

Experienced in specialized water resources in Malaya and in Canada Mr. Walker went to his last position as executive assistant to the Fraser River Board in Victoria, B.C. in 1953. In Malaya for three years previous to this time, he was with the Drainage and Irrigation Department of Malaya, engaged in designing and supervising construction of drainage and irrigation projects. While in Johore West he was responsible for the maintenance and operation of a mechanical plant. He was responsible for the collection and collation of hydrometric and meterological data, as well as supervision of a design office and various projects.

R. L. Walker, JR.E.I.C.

O. N. Smith, JR.E.I.C., of Honeywell Controls Limited has been named to the post of sales supervisor of the Montreal Branch, industrial division.

Mr. Smith graduated from McGill University in 1954 in mechanical engineering. With the firm since that time he has been active in sales work in connection with the oil and chemical industries.

K. R. Piekarski, JR.E.I.C., is the president of the newly formed Japan Industrial Equipment Company of Canada Limited, which will specialize in the design, service and sales of heavy industrial machinery and will design custom equipment in Canada for manufacture in Japan.

Mr. Piekarski entered the University of London to study mechanical engineering, in 1945, after having his previous studies at the University of Warsaw broken by five years of capitivity during World War II. On receiving his qualifications at London University he became assistant to the professor of metallurgy. He has also held appointments as design and development engineer for a British firm dealing with precious metals. In 1951 he became head of the metallurgy department of the Ryerson Institute of Technology. Recently he has been engineering manager for MN Automation

K. R. Piekarski, JR.E.I.C.

• PERSONALS

Limited, Canada's only firm of automation consultants.

A. S. La Mothe, JR.E.I.C., has been named engineering manager with the firm of Industrial Maintenance Limited, at Montreal.

Formerly associated with McColl-Frontenac Oil Company Limited, at Montreal, he held the position of construction maintenance engineer, marketing.

He is a MGill University graduate, class of 1950.

T. A. Buckle, JR.E.I.C., of the University of Saskatchewan, class of 1955, is with the Hydro-Electric Power Commission of Ontario at Toronto, where he is at work in the system planning department of the organization.

John W. Gouge, JR.E.I.C., has assumed responsibility as chemical economist, with the Stanford Research Institute, assigned to the Portland office of the organization.

Mr. Gouge is a University of British Columbia graduate, class of 1950 and formerly held the post of market research analyst with the Consolidated Mining and Smelting Company of Canada Limited at Montreal.

C. V. Flanagan, JR.E.I.C., a 1951 graduate of the University of Toronto with a B.A. Sc. degree is employed with the Chrysler Engineering division in Detroit as a development engineer in the fluid dynamics section.

Mr. Flanagan was previously associated with the Dunlop Rubber Company in Toronto as a development engineer.

W. J. Hardy, JR.E.I.C., of the University of British Columbia, class of 1952 is working as an assistant mechanical superintendent in Vancouver where he is with the Canadian White Pine division of MacMillan and Bloedel Limited.

Mr. Hardy gained his initial experi-

A. S. La Mothe, JR.E.I.C.

ence in engineering with the Powell River Pulp and Paper Company Limited at Powell River, B.C., as a mechanical engineer.

E. H. Gilliatt, JR.E.I.C., of the Nova Scotia Technical College, class of 1952, has received the appointment of regional

E. H. Gilliatt, JR.E.I.C.

transportation engineer with the Canadian National Raliways at Moncton, N.B.

Mr. Gilliatt began his career with the C.N.R. as a trainee engineer, research and development department at Montreal. Since then he has been promoted to assistant engineer and assistant transportation engineer, the latter appointment at Montreal in 1955. He returned to Moncton last year and was appointed acting regional transportation engineer a short time later.

G. Gow, JR.E.I.C., has left the Electric Reduction Company Limited, where he has been employed at various centres in Quebec and has accepted a post with the Mersey Paper Company Limited at Liverpool, N.S.

Mr. Gow is a Queen's University graduate in electrical engineering, class of 1950.

H. Roach, JR.E.I.C., of the Harbours and Rivers Branch of the Department of Public Works of Canada has been transferred from Charlottetown to St. John, N.B. In his new location Mr. Roach will serve the French-speaking districts of New Brunswick.

He is a graduate of the Nova Scotia Technical College, class of 1953.

G. Sobering, JR.E.I.C., has been appointed assistant plant manager, car division of the Canadian Car Company Limited at Montreal.

Mr. Sobering who is a graduate of McGill University, was formerly with the

• PERSONALS

Canadian Pratt and Whitney Aircraft Company at Longueil and prior to that was with Ford Motor Company of Canada at Windsor, Ont. He served overseas as a bomber pilot in the R.C.A.F. and is now a member of 438 (F), City of Montreal, auxiliary squadron.

D. J. L. Kennedy, JR.E.I.C., has accepted a post with the University of Toronto, in the capacity of lecturer in the department of civil engineering.

Mr. Kennedy graduated from that University with a degree in civil engineeering in 1951 and has since then been associated with the Foundation Company of Canada at Montreal and with Geocon Limited, Toronto.

W. H. Potts, JR.E.I.C., has accepted a position with the firm of Guildwood Development Limited, Scarborough, Ont.

Mr. Potts, formerly associated with the Electric Reduction Company of Canada Limited at Buckingham, Que., and with Shepherd and Powell, consulting engineers of Toronto, is a graduate of Queen's University, class of 1948.

H. D. Stevenson, JR.E.I.C., of the firm of Robertson-Irwin Limited, has recently been transferred from Hamilton to Vancouver where he continues to be active in the sales and engineering field.

Mr. Stevenson is a University of Manitoba graduate of the class of 1953.

John Westaway, JR.E.I.C., a Queen's University graduate class of 1952 has transferred his professional services from the Canadian Westinghouse Company Limited, Hamilton, Ont. to the Potash Company of America at Saskatoon, Sask.

Wm. A. H. McCorquodale, JR.E.I.C., has accepted an appointment as an electrical engineer with the firm of Sargent, Webster, Crenshaw and Folley, architects and engineers at Syracuse, N.Y. With the Ford Motor Company in Windosr, Ont., for several years, he has also at an earlier date worked with Northern Electric in Montreal. He is a University of British Columbia graduate, class of 1949.

J. S. Howard, JR.E.I.C., who graduated from the University of London, England, in 1956, and who has since then been employed with Dominion Textile Company Limited, Montreal, has transferred his services to the firm of Babcock-Wilcox and Goldie McCulloch, at Galt, Ont.

R. J. Fulton, S.E.I.C., has terminated his employment with the Department of Highways, Province of Ontario and has accepted a position with the Aluminum Company of Canadaat Arvida, Que.

He graduated in civil engineering, class of 1956, at Queen's University.

NEWS OF THE BRANCHES

Activities of the Forty-Seven Branches of the Institute and abstracts of the papers presented at their meetings

BROCKVILLE

F. E. TREWARTHA, M.E.I.C.,
Secretary-Treasurer

Annual Report

The Brockville Branch held eight meetings and one tour during 1956. Two of these meetings were joint meetings with other technical groups, one with the Canadian Institute of Chemistry and the other with the local branches of the C.I.C. and the National Association of Corrosion Engineers. Dinner meetings were particularly successful and a total of four were included in the eight meetings held. The total membership of the branch increased from 58 to 69 during the year. With the continued growth of industry in the area it is expected that the branch will continue to grow at a steady rate.

Membership chairman, H. Gilchrist, took on the job of chairman of a professional development committee. It plans to commence a course in January 1957. It is expected that this first venture in running a P.D. course will be successful as twenty-five members have expressed their intention of participating.

Colonel Grant, field-secretary, visited Smith Falls on February 29, 1957 in order to increase the interest in Branch activities in the outlying areas of the Branch. Members of the executive joined in a dinner meeting with members from Merrickville, Elgin, Kempville and Smith Falls.

The 1956 program began with the showing of the film "Leonardo da Vinci" and moved on to the E.I.C.-C.I.C. dinner at which "Current Progress on the St. Lawrence" was clarified by Mr. W. Hogg. In February and March the "Pelee Island Submarine Cable," discussed by Mr. J. S. Waddinton, and the E.I.C.-C.I.C. dinner dance at which Mr. A. S. Proctor of Du Pont delivered an address on "Orlon Acrylic Fibre", comprised the Branch activities. This was followed by an address on the "Cement Industry in Canada" by Mr. Tremaine, and a tour of the St. Lawrence Seaway in May.

Resuming activities late in September members heard a talk on "Corrosion" during the joint meeting held with the C.I.C. and the N.A.C.E. In October, "Geese on James Bay" was presented by Dr. Stearrett. Closing the year's activities Clarence Marshall spoke on "Nation Wide Toll Dialling" in November.

PROFESSIONAL DEVELOPMENT IN CALGARY

Shown below are two of the speakers engaged by the Calgary Branch in their recent professional development meetings held March 5 and 14. The lectures covered the subjects of finance, human relationships, management and self-expression. Dr. Palmer, an internationally prominent management consultant of Los Angeles, Calif., spoke on "How to Motivate the Young Engineer", while T. W. Meredith, manager of the Calgary office of Osler, Hammond and Nanton Limited, a nation-wide brokerage firm addressed the group on "The Investment Industry".

Dr. D. Palmer

T. W. Meredith

BELLEVILLE

E. T. HILBIG, JR.E.I.C.,
Secretary-Treasurer

Joint Meeting I.R.E.

On April 8, 1957 a joint meeting with the local branch of the I.R.E. was held. Guest speaker F. A. Smith filled in for R. G. Griffith, chief engineer of the Canadian Overseas Telecommunication Corporation who was unable to attend. Mr. Smith delivered Mr. Griffith's paper on the construction and installation of the trans-Atlantic telephone cables. The paper was supplemented with slides, some of which were taken aboard the S.S. Monarch during the course of laying the cable.

Keen interest was displayed by all present and an active discussion period followed the talk.

Robert Smith thanked the speaker.

CENTRAL BRITISH COLUMBIA

H. D. de BECK, JR.E.I.C.,
Secretary-Treasurer

Annual Report

Branch meeting attendance this year was not as complete as it has been in previous years. This reflects the growing industrial and construction activity in the British Columbia interior. Most of the engineering professions are overworked due to the shortage of qualified persons. So much time is being devoted to the interests of others that our own are suffering from lack of attention. Each of us must continue to urge our membership now totalling 86, to devote some

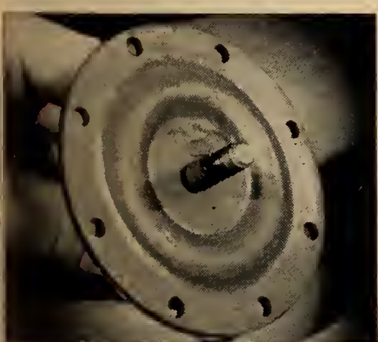
▸▸ USING

DU PONT ELASTOMERS
neoprene · Hypalon® in industry

Neoprene lining protects scrubber from acid fume and abrasive grit

Exposed to 66° Be. sulfuric acid —HYPALON diaphragm gives 2 years' perfect service on acid pump

In November, 1954, a Hypalon diaphragm was installed in a proportioning pump in the plant of Fields Point Mfg. Corp. at Providence, R. I. Since that time it has been on continuous service handling 66° Be. sulfuric acid.



Before the use of Hypalon, diaphragms were oxidized and embrittled by the strong acid and had to be replaced every few months.

The diaphragm flexes about 26 times a minute through a ¼-in. stroke and is fabric-reinforced for 125 psi. service. The sulfuric goes from the pump to a stoneware tower where it dries chlorine gas from electrolytic cells.

Hypalon is a new Du Pont synthetic rubber which is noteworthy for its resistance to oxidation—by chemicals, heat, ozone or sunlight and weather. It is being used in the chemical industry for tank lining, acid hose, colored protective coatings, gaskets, valve inserts and pump parts.

For additional information about Hypalon, just mail the coupon.

Neoprene lining is still good after a year. The best of several other kinds of linings only last a fraction of this time.

Corrosion of this scrubber once was the No. 1 production problem at the Bessemer City, N. C., plant of Lithium Corporation of America.

The scrubber cleans combustion gases from a long rotary kiln where lithium ore is given an "acid roast." Contaminants in the gas are sulfur trioxide and abrasive dust picked up from the acidified ore. Gases from the kiln pass first through a brick-and-lead-lined precooler; they enter the scrubber at 140° F. and spiral upward through water sprays to be exhausted through a fan and ductwork to a stack.

The original scrubber tank and fan were of plastic-coated mild steel, but abrasives in the gas scoured off the protective film. The fan was recoated and a temporary plastic-lined stainless steel scrubber installed. All failed, as did the stainless steel ductwork, and had to be replaced several times in the first few months of operation.

Finally, sheets of neoprene were applied to scrubber, ductwork and fan — and after a full year of round-the-clock operation, the neoprene-lined equipment was still in good condition. Equipment repairs no longer shut down production, and inexpensive mild steel can now be used instead of stainless.

Abrasion-and-acid-resistant tank linings are only one of many applications for neoprene in the chemical industry. It's used also for its resistance to oils and to weathering, and in the form of hose, belting, shoe soles, maintenance paint, protective clothing, packing, gaskets, diaphragms — any rubber item in the plant. For more information about neoprene, just clip the coupon.

Scrubber cleans combustion gases from rotary ore-roasting kiln.

time to Branch affairs. However, due to the devoted work done by the executive and by the active membership of the Branch we should consider it a successful year.

Our contacts with the B.C.E.S. have been maintained. The visit of the registrar of the Association of Professional Engineers of B.C. was most welcome. Invitations were made to members of C.I.M.M., from time to time, to attend our meetings.

Meetings during the year 1956 were handled by a joint executive B.C.E.S. and E.I.C. This arrangement has been satisfactory. If at all possible a similar arrangement should continue at least until confederation or some other circumstances bring about a change. Two very topical subjects were brought up for discussions at meetings during the year were the Kelowna Bridge, and Natural Gas Development.

Important Film Shown

The firm "Leonardo da Vinci" was secured from headquarters. This was first shown at a meeting held in Penticton on April 20 when colleagues were invited from the Pacific Northwest Snow Conference. The film was later shown to members at a meeting in Kamloops.

Engineers' Wives

The Engineers' Wives Association, active in Penticton for several years, continues to function. General discussions and talks comprise the programs. An interesting illustrated talk was given by Mrs. Gay, an exchange teacher, recently returned from Great Britain.

The Association acted as co-hosts to the ladies attending the municipal Engineers' Association convention in Penticton, a buffet lunch, drives, and a tea being very much enjoyed. Chairman and secretary of the organization for 1956 were Mrs. W. J. Owen, and Mrs. G. Brockhouse.

HAMILTON

W. A. H. FILER, JR.E.I.C.,
Secretary-Treasurer

J. R. CURRIE, M.E.I.C.,
Branch News Editor

Joint Meeting

The April meeting of the Hamilton Branch was held at Westinghouse Auditorium on April 4, 1957, as a joint meeting with the Hamilton and Toronto Branches of the American Institute of Electrical Engineers. These annual joint meetings were inaugurated in 1919, and have afforded engineers in this area an opportunity of hearing outstanding speakers discuss subjects of current interest.

Guest at the meeting was Dr. W. E. Shoupp, technical director, Commercial Atomic Power Activities of Westinghouse Electric Corporation, who spoke on "Atomic Power Developments". Dr. Shoupp discussed at length the types of reactors and their basic components, and the relationship of the reactor to the steam power and turbine generator systems.

Main plants at Calder Hall, Russia. The main operating atomic power plants to-day are the Calder Hall plants, and the small Russian plants. Dr. Shoupp stated that the large size of atomic power plants would limit their use in the foreseeable future largely to central power stations and military aircraft and ships. Automobiles, trains, and commercial aircraft would continue to use power plants utilizing hydro-carbon fuels. Present indications are the bigger the atomic power plant the better, the ultimate size depending solely upon the development of our knowledge in this new field. At the present time no single type of reactor has shown itself to be the best for all conditions.

WHEN THE LOAD WEIGHS 80 TONS
EXPERIENCE COUNTS!

Transferring this 80 ton motor to a new site at the DOFASCO plant in Hamilton called for specialists. With six KING low-bed semitrailers in operation and noted for fast, efficient service, Aldershot Equipment Rentals Limited were called in on the job. Swiftly and efficiently Aldershot's experienced crew supervised the hoist, placed the 80 ton giant gently on the low bed semitrailer and within minutes were under way.

Experience counted in another way on this same job. Some months before, King engineers were called on to design and build a semitrailer for Aldershot Equipment, capable of tremendous loads, easy loading, extra speed and added safety. To Canada's foremost group of heavy hauling equipment specialists the answer came easily. The result—this 85 ton King-Talbert low bed semitrailer, built to do the many jobs required of Aldershot Equipment Rentals Limited.

Whether your loads are 8, 80 tons—or more, you'll find KING experience will provide you with the answer to more efficient and profitable hauling. Why not discuss your load carrying requirements with KING engineers now. There's no obligation, of course. Phone or write to:

TRUCK ENGINEERING LIMITED

KING *Trailers* A NAME THAT CARRIES WEIGHT

Built in Canada
To Meet
Canadian Conditions

57C-14

The economic life of a reactor would appear to be from 30 to 50 years, and with costs amortized over this period, power costs should not be excessive. The high cost of reactors at present is partly due to over-engineering owing to the emphasis placed upon safety, but as operating knowledge is acquired, the cost is expected to be reduced. Dr. Shoupp stated that no industry in America has a better safety record than the atomic industry.

In response to a question concerning the disposal of atomic waste, Dr. Shoupp felt that the waste problem had been over-emphasized, and in his opinion there were many barren parts of the world which could be used for storage of atomic waste.

Guests of Military Engineers

The Military Engineers' Association of Canada have in the past, co-operated with the local Branch of the Institute in holding one of the meetings and extending an invitation to the members of the E.I.C. Accordingly, on March 25, 1957 members gathered at the R.C.E. Armouries to hear R. F. Shaw, on "Construction of the DEW Line." His talk was accompanied by a colour film covering the construction work from the days of the first landing in the Arctic, which pointed out in great detail the problems of communication and transportation that were faced by the contractors on this job. Mrs. Shaw made a running commentary during the showing of the film. A discussion period followed.

The Institute is indebted to Colonel H. Dickson, O.C., R.C.E., and to Captain W. Landry, chairman of the Halifax Branch of the Military Engineers' Association of Canada, who extended the invitation and mess privileges to the members of the Institute.

Colonel Daryl Calkin, president of the Military Engineers' Association of Canada introduced the speaker.

An invitation had been extended to members of the Engineers' Wives Association, holding an annual meeting that evening, to attend. This was enjoyed by a great many.

KITCHENER

A. H. AUSTIN, JR.E.I.C.,
Secretary-Treasurer

President's Visit

Joined by the Grand Valley Group of Engineers, Branch members held a dinner meeting at the Iroquois Hotel on March 22, 1957, to mark the official visit of President V. A. McKillop. Other guests at the affair included Colonel Grant, field secretary of the E.I.C., and L. J. R. Sanders, Dominion Councillor.

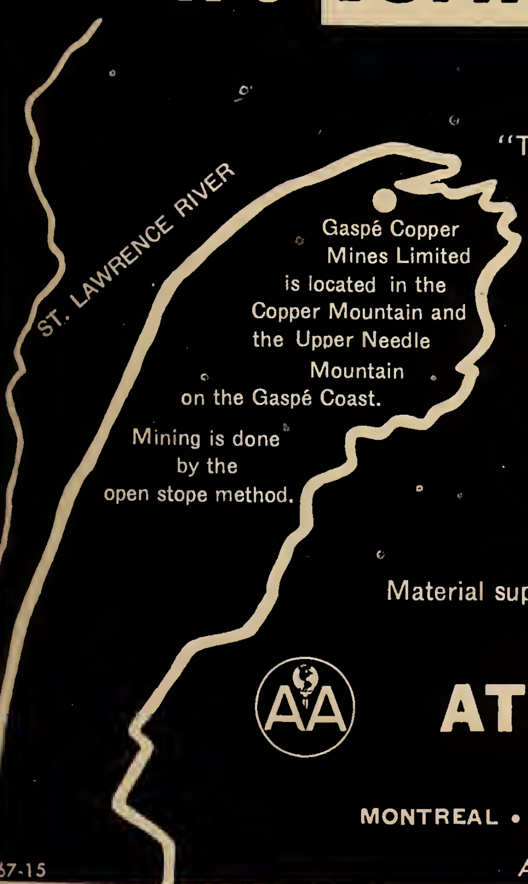
In a short address President McKillop dealt with the work of the Institute throughout Canada.

A technical session followed the dinner, in which Don Hamilton of the Dow-Corning Company delivered a paper dealing at length with "Silicones", accompanied by a film giving examples of the uses of silicones in their various forms. In his talk Mr. Hamilton dealt not only with the manufacturing process but also with the uses of the relatively new substances developed during the last war, now totalling 600 types. Uses in insulation for electrical equipment, paint, greases, fabrics, radar, rubber tires, were amply illustrated.

A discussion period was held at the close of the film.

The president's visit opened with a

General Contractor: Foundation Company of Canada Limited.



noon luncheon with the executive and their wives, followed by an executive meeting in the afternoon. Mrs. L. J. R. Sanders entertained the ladies. For picture see page 908.

KINGSTON

D. I. OUROM, JR.E.I.C.,

Prof. W. B. Rice Speaks

The Kingston Branch of the Institute gathered at Queen's University, Kingston, on March 19, 1957 to hear Professor W. B. Rice, deliver a paper on the subject of metal cutting research. In examining the current theories of metal cutting Prof. Rice gave a description of the experimental investigations which are in progress in the Department of mechanical engineering at Queen's University.

On Tuesday, April 16, 1957, R F. Legget, director of the division of building research with N.R.C., Ottawa, and E. G. Swenson, associate research officer in charge of concrete research addressed the Kingston Branch on the topic of "Concrete Problems in the Kingston Area". Under discussion was the progress made in regards research being carried out on concrete used in the Kingston area.

The concrete used in this area has been found to be subject to unusual cracking tendencies, evident in sidewalks about the town. N.R.C. is carefully pursuing an investigation into this phenomena. Measures showing promise of providing good performance were discussed.

to welcome Dr. J. G. Stewart, B.A., M.A., Ph. D., District Co-ordinator of Testing and Counselling for Trail School District No. 11, as guest speaker.

Dr. Stewart drew upon his immense psychological experience to explain to members the four types of personalities, and examined in turn the outlooks of the idealist, the realist, the naturalist and the pragmatist. The engineer, he felt, was generally in the realist class.

In his own detailed study of 450 students over a period of twenty years as counsellor, Dr. Stewart revealed that over 50 per cent felt that they had been wrongly advised in their choice of a career. He maintained that our economy could only support 7 per cent of the population as professional workers, yet the total number of students today, if successful in their studies, brought this figure to 67 per cent.

President McKillop chats with the Kitchener Branch executive during his March visit. Standing are, l. to r.: L. J. R. Sanders, Dominion counsellor; A. H. Austin, Branch secretary; and Col. Grant, field secretary of the Institute. Seated, John Runge, Branch chairman; Mr. McKillop, Walter Runge, past-chairman, and M. A. Montgomery, vice-president of the Institute.

C. L. Roach, staff engineer of the headquarters engineering department of the Bell Telephone Company, who presented an illustrated talk on "Transitors" and related devices. He also dealt with the fundamental solid state concepts which conveyed an appreciation of how these new devices are operated.

A buffet lunch followed the meeting. *Professional Development Papers Presented.* On March 21, 1957, a meeting at Niagara Falls was highlighted by the presentation of papers by four members of the Professional Development course. F. R. Denham spoke on, "A New Type of Heater," H. J .Wilkinson discussed, "The Concrete Shell." D. P. Fernandes dealt with "Applications of Correlation Analysis, " and D. A. Buchanan presented a paper entitled, "Patents, Trade Marks, and Copywriting."

The Branch prize for the best paper went to F. R. Denham. Mr. Little presided as chairman of the meeting.

NIPISSING AND UPPER OTTAWA

G. R. KARTZMARK, JR.E.I.C., *Secretary-Treasurer*

J. W. MILLAR, M.E.I.C., *Branch News Editor*

Film and Demonstration

The monthly dinner meeting of the Nipissing and Upper Ottawa Branch of the Institute was held Wednesday, April 3, 1957 with presiding chairman T. C. Macnabb. Excellent attendance, particularly from Sturgeon Falls and Temiskaming was noted.

The feature of the evening was a film and demonstration presented by Fred N. Walsh and R. J. Armstrong, representatives of the Plywood Manufacturers Association of British Columbia. The film dealt with the manufacture and uses of plywood, particularly douglas fir plywood. The members were shown the cutting of huge trees in the west coast forests, the preparation of the logs before entering the mill, the log inside the mill being peeled or cut into long sheets of veneer, the processing of the veneer, the gluing and pressing of the sheets of veneer into plywood and finally the finishing and packaging of plywood for shipment.

The film also showed the multitude of uses of plywood, from the forms for pouring concrete in huge construction projects, to a feeder for hogs, or a smart kitchen cabinet. Plywood is of great value in the building trade as it speeds assembly and assures strong and rigid construction.

Mr. Walsh and Mr. Armstrong boiled plywood in water, chopped it, drove nails into it, bent it, hammered it and ably proved that plywood will resist splitting, has greater resistance to bending than ordinary wood and that the glue used to bond the laminations is actually waterproof.

A question period followed the film and demonstration. The number of questions indicated the great interest of the members in plywood and its special properties.

Election of Officers

The monthly meeting and annual election of officers of the Branch was held at White Oaks Inn, Temiskaming, on May 1, 1957.

Following dinner the annual reports of committees were read and the following slate of new officers elected for the ensuing term:

Chairman, J. F. Chantler; vice-chairman, J. S. Cooper; executive committee (two year term) — R. S. MacLennan,

Head table guests shown enjoying the dinner meeting of the Nipissing and Upper Ottawa Branch in March, honouring President McKillop, and reported in the May issue of the *Journal* are shown below. Left to right are: J. S. Cooper, councillor; Mrs. Cooper; J. F. Chantler, vice-chairman; Mrs. McKillop; the president; Mrs. Macnabb; and T. C. Macnabb, chairman.

Blueprinting the Future...
Today, more than ever before, Canada's future is being shaped by the slide rule and the drawing board.
In every construction project, in communications, power development and in public utilities, innumerable items of electrical equipment are required. Ordering these units calls for a high degree of planning and co-ordination.
Purchasing from Northern Electric gives you immediate access to over 100,000 items which are the dependable products of more than 1,000 manufacturers.
With Northern Electric offices and warehouses throughout Canada, electrical supplies and equipment are always available to you at short notice.
Northern Electric
SERVES YOU BEST

North Bay; P. Rebin, Sturgeon Falls; J. Warburton, Temiskaming; and H. Staniforth, of Kiosk. Executive committee members with one year still to run are: — E. A. Watson, North Bay and J. Crothers, Temiskaming. The retiring chairman is T. C. Macnabb.

Brig. Quilliam Guest Speaker

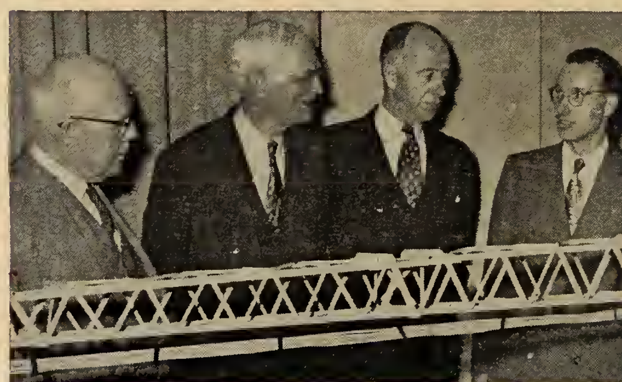
Brigadier C. D. Quilliam, O.B.E., of Kingston who lived for many years in the Middle East, drew on his knowledge of the Arab Nations in his talk to the Branch.

A native of Ireland, he took part in World War I and during the next thirty-two years served in Turkey, India, the Arab countries, Egypt and the Sudan. In World War II he held the post of chief of political intelligence in the Middle East and in the Balkans.

Brigadier Quilliam traced the course of the Arab nations from the time they were part of the Turkish Empire and then broken up and divided after World War I. Considering Israel rightfully theirs, the establishment of a national home for the Jews in Israel has proved not acceptable.

An Arab problem would always exist, he felt, and the creation of a third major

Third year engineering students of St. Francis Xavier University examine a scale model of a ship fender at New Glasgow, N.S.



Members of North Nova Scotia Branch examine cable arm of model fender at New Glasgow, N.S. L. to r.: J. Cavanaugh, general manager, Malagash Salt Co.; D. Dunbar, Branch sec.-treas.; D. J. MacNeil, chairman; R. Morrow, chief engineer, Maritime Steel and Foundries Ltd. **See report p. 914.**

bloc, including the Middle East, Arab Nations, and Africa would be attempted. He said Col. Nasser was a strong man with a mission, but that he would probably not last more than four or five years. The Arab Nations have little in natural resources and poverty is general. In fact the individual has little to lose and is ready to follow the mob.

NORTH NOVA SCOTIA

D. G. DUNBAR, M.E.I.C.,
Secretary-treasurer

Branch Host to Students

On March 8, 1957, the third year engineering students of St. Francis Xavier University were the guests of the Nova Scotia Power Commission on a lecture-tour of the Commission's plants in Stellarton and Trenton, Nova Scotia.

Later, on that date the North Nova Scotia Branch made arrangements to show the students a scale model of the fenders that will be used in the locks along the St. Lawrence Seaway. This model was constructed by the Maritime Steel and Foundries Limited of New Glasgow, and it was through the courtesy of its president, Clyde Cameron, M.E.I.C., that it was made available on this occasion. Maritime Steel and Foundries Limited will build the fenders required in the seaway locks. The model was explained to the students by Robert Morrow, M.E.I.C., chief engineer for the company.

Following the examination of the fender model the students were guests of the North Nova Scotia Branch at a luncheon served in the dining-room of the Norfolk Hotel, New Glasgow.

OTTAWA

W. V. MORRIS, M.E.I.C.,
Secretary

ARTHUR H. GRAVES, S.E.I.C.,
Publicity Committee

Sir Claude Gibb

Sir Claude Gibb's address to the Ottawa Branches of the E.I.C. and the A.I.E.E. at the Chateau Laurier on April 4, 1957 was considered one of the most successful luncheon meetings held this year. Indicative of this was an attendance totalling 160 persons.

Sir Claude was introduced by Lorne Gray.

At the conclusion of his address, which was entitled "Some Engineering Problems in Connection with the Development of Nuclear Energy," a vote of thanks was tendered him by Colonel W. A. Capelle.

A full-scale press conference was held one hour prior to the luncheon meeting with reporters from the three local newspapers present.

Head table guests at the affair were, as follows: Lorne Gray, vice-president of the Atomic Energy of Canada Limited; J. H. Parkin, director of mechanical engineering at N.R.C.; L. N. Moore, chairman of the Ottawa Branch of the A.I.E.E., A. M. Brown, vice-president of C. A. Parsons of Canada Limited; Sir Claude Gibb, guest speaker; Colonel W. B. Pennock, immediate past-chairman of the Ottawa Branch, and Colonel W. A. Capelle, chairman of the Ottawa Branch.

Ottawa Wives—Tenth Annual Meet

On Tuesday, April 30, 1957, the tenth annual meeting of the Engineers' Wives Association of Ottawa was held at Chateau Laurier with 142 of the total membership of 220 in attendance.

Outgoing president, Mrs. S. L. Gertman presided over the affair. An outstanding part of the meeting was that the ten past-presidents attended, the first of whom was Mrs. K. M. Cameron, wife of a past-president of the Institute. Mrs. Cameron founded the association ten

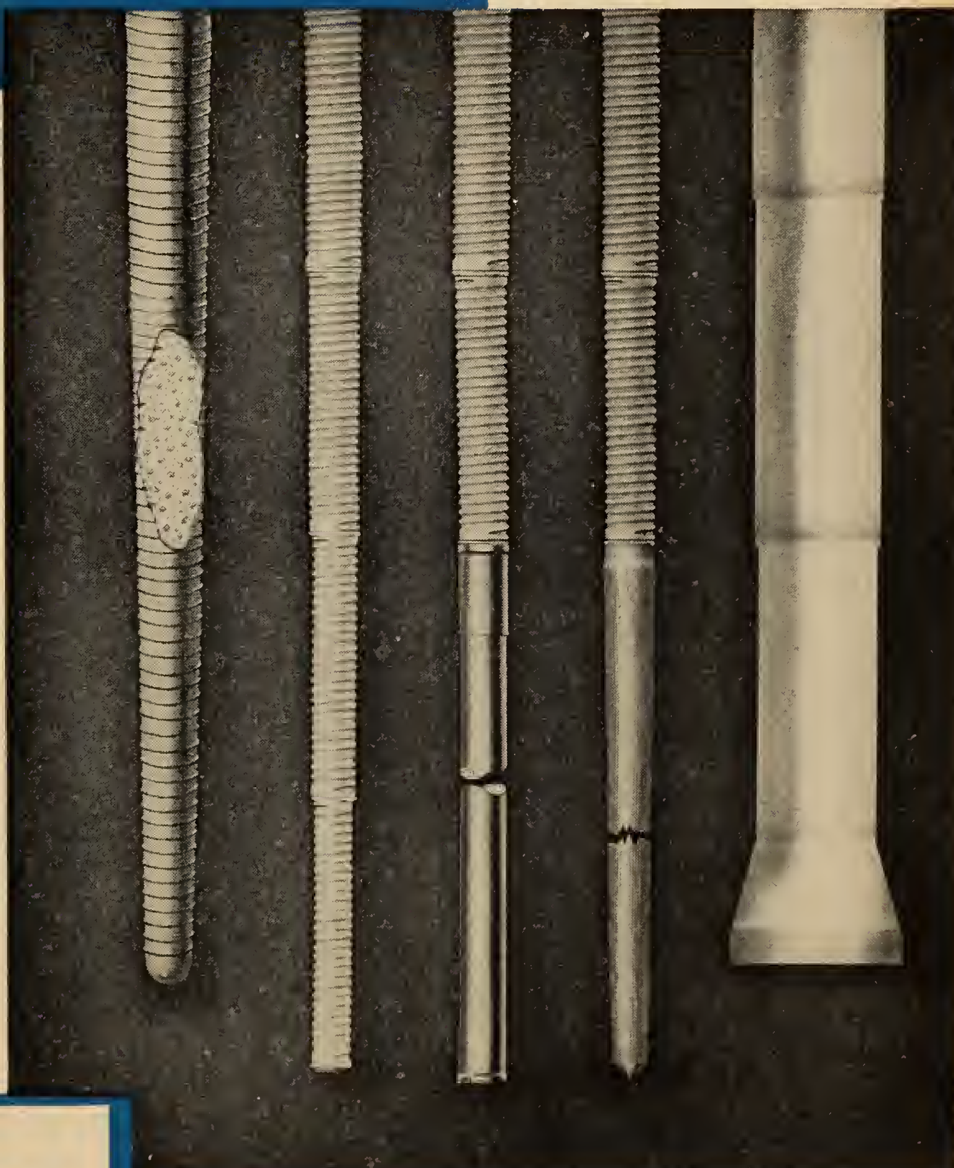
*ADVANTAGES OF RAYMOND CONCRETE PILES . . . Number <u>four</u> of a series

THE 5 TYPES OF RAYMOND PILES SHOWN . . . from left to right

STANDARD • STEP-TAPER
PIPE STEP-TAPER
WOOD COMPOSITE • CAISSON



REGARDLESS of the subsoil conditions here's a Raymond Pile specifically designed to do the job safely and economically. The *Standard Pile* with its heavy taper is ideal as a friction pile. The *Step-Taper Pile* is used where it is desirable for the pile to reach a hard stratum at a considerable depth. The *Pipe Step-Taper Pile* is used where piles of great length are required. *Wood Composite Piles* combine the advantage of the permanence of concrete piles with the low cost of wood piles. *Raymond Gow Caissons* are efficient and economical for supporting heavy concentrated loads under certain soil conditions.

AROUND THE WORLD — FOUNDED 1897

years ago. She also cut the mammoth birthday cake ordered for the occasion.

Mrs. Gertman, in her report listed the high-lights of each of the ten years. This made a most interesting and impressive list of accomplishments, especially the story of the fund which the Association is accumulating to establish a scholarship, now in excess of $5,000. Two luncheons are held each year, in September and in April, to mark the opening and closing of the season. Monthly teas are held for the express purpose of welcoming newcomers to the organization. In December 1956, the annual tea held for the wife of the president of the Engineering Institute was held for Mrs. McKillop, was very well attended. This has always been one of the most popular events of the year's program. The big money-maker, the February fashion show, last year netted over $700. It was convened by Mrs. L. J. Weeks, incoming president.

Total receipts for the year ending March 31, 1957, were more than $3,000.

Primarily Social. Although the group's activities are primarily social, a certain amount of welfare work is also undertaken. Voluntary assistance is given the community by members who assist at the Cancer Clinic, staff the Snack Bar at the Civic Hospital two days in each week, and assist in the Poppy Day Campaign.

Following luncheon Mrs. Lillian Robertson, of the Field Office, of the Engineering Institute, at Toronto, spoke briefly on the proposed national organization of Wives' Associations which will be discussed at the Annual Meeting of the E.I.C. at Banff in June.

Reports on Gana. Mrs. Prudham, wife of George Prudham, Minister of Mines and Technical Surveys, who represented the Canadian Government at the recent ceremonies connected with the formation of the new state of Gana, spoke of the visit they had made and of the ceremonies attended.

Activities for the season were later brought to a close with a bus tour of the St. Lawrence Seaway project.

SASKATCHEWAN

R. BING-WO, M.E.I.C.,
Secretary-Treasurer

W. G. MACKAY, M.E.I.C.,
Chairman, Saskatoon Section

Saskatoon Section Annual Meeting

The annual meeting of the Saskatoon Section of the Saskatchewan Branch of the Engineering Institute was held on February 27, 1957. The report of the annual meeting of the Branch, held in Regina on February 15 was read by Chairman W. G. McKay. W. R. Staples presented the Union Committee report. B. Torchinsky, secretary-treasurer of the Saskatoon Branch, gave the financial and activities report. Newly elected members of the Saskatoon Section are as follows: Chairman: W. G. McKay; secretary-treasurer: R. E. Ludwig, Program Committee, G. Handegord, D. Strayer, C. M. Thompson, and F. Catterall. Publicity will be handled by R. Dupuis. The student representative chosen was R. Hanson.

Student's Paper Night

The Student Papers Night made up the technical portion of the evening. T. MacDonald of the mechanical engineering department, of the University of Saskatchewan, conducted the presentation of these papers. The Student Papers Night was made possible by the grant of $100.00 from E.I.C. headquarters. Funds were made available to the students to assist in the preparation of slides or charts for the presentation of their subjects. The papers, all given by fourth year students were; "Bearing Materials in Boundary Lubrication," by L. E. Torfa-

son, mechanical engineering; "Abandonment of Gas Wells in the Medicine Hat Field," by L. Larson, civil engineering; "On Top of The World", a discussion of Arctic conditions by L. Morrison, geological engineering; and "Cermets" by F. D. Freidrich, mechanical.

Judges were: Prof. C. Forsberg, E. Cole, and D. Carroll. Prizes as follows: First prize, $25.00 was awarded to L. Morrison. The Second prize, of $15.00, went to F. D. Freidrich, while consolation prizes of $5.00 each were presented to L. Torfason, and L. Larson.

A very successful meeting from the viewpoint of students and members alike, thanks were conferred on the latter for their excellent and well-prepared papers by Vern Freibel.

Sir Claude Gibb's Visit

When Sir Claude Gibb arrived in Regina on April 9, he was met at the airport by Mr. R. R. Keith, M.E.I.C., power production superintendent of The Saskatchewan Corporation and lunched at the Hotel Saskatchewan with vice-chairman of the Branch J. C. Traynor, and a few other members of the Branch, notably engineers of The Saskatchewan Power Corporation.

In the afternoon, Sir Claude held press and television interviews, the latter being for delayed release in an evening newscast and again on a week end news review of important local events.

A private dinner was tendered in Sir Claude's honor in the Hotel Saskatchewan that evening by The Saskatchewan Power Corporation. D. Cass-Beggs, general manager of the Corporation was chairman of the dinner. The dinner was an informal affair, and Sir Claude gave a brief talk to those present. Among the invited guests present were Hon. T. C. Douglas, premier of Saskatchewan and E. J. Durnin, president of the Dominion Council of Professional Engineers.

Sir Claude's lecture was held in the auditorium of the Museum of Natural History. Of the 200 members and guests present, the latter included high school science teachers, college students, members of The United Services Institute, and members of the Armed Forces, active and reserve.

Delivered in a forceful and interesting manner the talk was illustrated with well prepared slides. Sir Claude was a very able speaker, having held the intense attention of the audience throughout the lecture. His talk was interspersed with humour, which added spice to a highly technical subject.

Members agreed that this was one of the best papers ever presented to this Branch. A vote of thanks was moved by Mr. H. I. Nicholl.

Branch News Editor

Computers Discussed

The Toronto Area Joint Committee of the Engineering Institute, the Institution of Civil Engineers and the American Society of Civil Engineers had for their speaker on March 7, Dr. R. F. Johnston, Director, systems engineering, of Adalia Limited, Montreal, who spoke on the subject: "Electronic Computers and the Civil Engineer".

Dr. Johnston began by outlining some of the applications of computers generally. Business employs computers to give information on hiring and firing of employees, the giving of bonuses, financial programs, routine payroll and similar operations. In the industrial field the most spectacular application is automation. Machines are even able to reproduce themselves without human intervention.

Three Important Features — The kind of computer that the Civil Engineer will most likely be concerned with has three important features. It must be able to follow long and complicated instructions, have large capacity storage, and operate at high speed. The digital computer has these features, and possesses other desirable characteristics. These are: (1) Allowing instructions to be fed in once. (2) Ability to do the basic operations of arithmetic. (3) Ability to transfer instructions, and (4) control. Such a computer requires a small input and a small memory, and a large computer, in distinction to that used in business, which has a small computer, but a large amount of data coming in and going out.

Rentals — Since computers are expensive to buy the practising engineer should learn about rental possibilities. Doing problems on computers breaks down into four phases: Analysis, programming, set-up and running time, and final analysis of results. Analysis and programming may be done by the customer, and will range in cost from $500.00 to $5,000.00. The machine rental will vary from $25.00 to perhaps $400.00 per hour, and must be done by the staff of the calculator. Analysis and interpretation of the results are done by the customer. At present there are three computers in Canada, one each in Toronto, Ottawa, and Montreal.

Dr. Johnston closed by describing some typical problems which a computer can do. It can for example, do traffic control studies which measure truly the capacity of a given length of highway, or compute and compare the stresses in a framed structure with allowable

What is a "Good" Casting?

"Good" is the measure of performance. A good casting measures up—in performance—to all the requirements of its buyer and its end user.

If, during its life, it must withstand repeated thermal shocks, then it must be heat resistant; if it is going to be subjected to constant friction, then it must be wear resistant; if it comes into contact with salts or acids, then it must be corrosion resistant.

"Very true," you say, "and also very obvious. It is one thing to make fine castings to fit the job but can you make the price fit the castings? That's a requirement, too."

We can. That's where our Special Products Plant comes in. It is run by experienced men, controlled by a first class laboratory and equipped with modern foundry equipment —it's an operation that's geared to meet quality *and* price requirements.

Our electric furnace, for example, allows flexibility, versatility and far greater uniformity of composition in the production of all types of iron.

The result: the best possible assurance against being let down half way through the machining operation. Your shop investment is thus protected.

So when *you* need "good" alloy castings, delivered clean and on time, order them from:

Canada Iron
foundries, limited

FOUNDRY & MACHINE DIVISION

HEAD OFFICE: 921 Sun Life Bldg., Montreal

TORONTO OFFICE: 169 Eastern Ave., Toronto

Literature is available on the following engineering irons and alloy irons produced by our Special Products Plant:

stresses, listing only the stresses which are over the allowable.

Programming time may be longer than the computing time, a point which should be kept in mind.

The modern computer can do iteration, transform, invert, relax, but it cannot "glance" at information. The relaxation method is an example of this latter feature. The machine must relax each part of the algorithm, it cannot examine the solution as far as it has proceeded, and take the largest residual to start the next step as a human being can do. With this thought it is comforting to feel that the machine has not yet quite replaced man.

WINNIPEG

C. S. LANDON, M.E.I.C.,
Secretary-Treasurer

Power Agreement Paper

The electrical section of the Winnipeg Branch met at the Canadian Westinghouse Auditorium on March 7, 1957, to hear a paper by C. G. Mills, load control engineer for the Manitoba Hydro Electric Board, entitled "The Manitoba Utilities Power Agreement".

Mr. Mills traced the growth of electricity supply in Winnipeg and the province of Manitoba from the earliest beginnings, through the events which culminated in the Manitoba Utilities Power Agreement. The basis of this Agreement, with particular reference to the methods of making charges for power, was discussed in some detail.

Executives of the Manitoba Utilities, who were present at the meeting, took advantage of the opportunity to thank Mr. Mills for the part he played in solving the complex problems associated with this Agreement. The Utilities in turn were congratulated upon the spirit of co-operation which made the Agreement possible.

Turbines for Commission

On April 4, 1957 the Electrical Section held a joint meeting with the Institute of Power Engineers at the Canadian Westinghouse Auditorium. The speaker, D. F. Abel, turbine sales specialist, Canadian General Electric Company, presented a paper "Large Gas Turbines for the British Columbia Power Commission". The paper was originally presented by A. O. White of the General Electric Company, Schenectady, New York.

When the B.C. Power Commission plant goes into service it will be the largest gas turbine installation in the world. Mr. Abel discussed the plant layout in general and the turbines themselves in some detail. He also discussed the operational conditions and other factors which led to the choice of this plant.

News of Other Societies

Sixth Commonwealth Congress

It is expected that the Sixth Commonwealth Mining and Metallurgical Congress will be the most important and the most comprehensive event yet sponsored by the Canadian mining industry. An estimated 500 traveling delegates from all parts of the world are expected to arrive at Vancouver, B.C., on September 8, 1957, and to travel across Canada by plane and train on a schedule calling for the final meeting at Halifax, N.S., on October 9.

With the approval of the Commonwealth Council of Mining and Metallurgical Institutions, and on the invitation of the Canadian Institute of Mining and Metallurgy, the Sixth Congress will be held in Canada in September and October.

Many delegates will be representatives of interested government agencies and institutions not affiliated with the Commonwealth Council. The General Committee is also encouraging participation by local residents at centres on the route. Thus several thousands of Canadian technical, industrial and government personnel will have an opportunity to take an active part.

The Congress provides an opportunity for the mining industry to tell its story to an interested and receptive international audience.

Among the main features on the program of the Sixth Congress are: a cross-Canada tour from Vancouver to Halifax by chartered trains; an aerial tour of Northern British Columbia, Yukon, Northwest Territories, Northern Saskatchewan and Manitoba; inspection visits to more than 50 major centres of industrial operations including, metal mines, coal mines, smelters and refineries, petroleum and natural gas wells, oil refineries, chemical and petro-chemical plants, steel plants, and other places of professional, technical and historic interest.

Major meetings of the Congress will be held at Vancouver, Edmonton, Winnipeg, Toronto, Ottawa, Montreal, Quebec and Halifax.

Primary and radius tours will take delegates to mining, metallurgical and related operations at: Kitimat, B.C., Whitehorse, Elsa and Dawson, Y.T., Yellowknife, N.W.T., Beaverlodge, Sask., Lynn Lake and Flin Flon, Man., on the northern aerial tour; Trail and Kimberley, B.C., the Crow's Nest Pass area; Banff, Lake Louise, Calgary and Edmonton, Alberta; Saskatoon, Sask., and Winnipeg, Man., on the western rail tour; Steep Rock, Sault Ste. Marie, Blind River, Sudbury, Falconbridge, Timmins, Kirkland Lake, Noranda, Val d'Or, Toronto, Welland, Niagara Falls, Ottawa, Montreal, Quebec, Thetford Mines, Asbestos, Bathurst, Newcastle, Sydney and Halifax on the central and eastern rail tour. Aerial radius trips will be made to the iron mines of Northern Quebec and to Newfoundland.

Five technical volumes on various aspects of the mineral and metal industries in Canada are being prepared as a feature of the Congress by Technical Divisions of the Canadian Institute of Mining and Metallurgy.

The honorary president of the Sixth Congress is The Right Honourable Louis S. St. Laurent. The president is R. W. Diamond, of Trail, B.C., Authority for planning and direction of the Sixth Congress is in the hands of a General Committee, whose chairman is Robert A. Bryce, president of Macassa Mines, Ltd., Toronto. Co-chairmen of the general committee are H. L. Roscoe, Toronto, and H. R. Banks, Ottawa. The executive secretary is C. H. Mitchell, 507-837 West Hastings St., Vancouver 1, B.C.

Pile Load Investigation

Records of pile loading tests are urgently required by the Joint Committee on Pile Driving of the Institution of Civil Engineers in Great Britain. This Research Committee is gathering data so that a better method of assessing the ultimate bearing capacity of piles can be established. Useful information is invited from any country to assist in this major research program.

In Canada, the Associate Committee on Soil and Snow Mechanics of the National Research Council will assemble all Canadian information, and transmit it to the Institution. To assist in the recording, a questionnaire has been prepared. It contains a detailed explanation of the study. Copies of the questionnaire are available from W. J. Eden, secretary, Associate Committee on Soil and Snow Mechanics, N.R.C., Ottawa.

Canadian engineers and contractors are encouraged to participate in making a useful contribution to this investigation. The Associate Committee will keep in touch and hopes to make results available when they are ready.

Calendar

Mining

The summer meeting of the Institution of Mining Engineers (England) will be held at Newcastle-on-Tyne, on July 24-26, 1957.

Civil Engineering

For the first time, the American Society of Civil Engineers (33 West 39th St., New York 18, N.Y.) will hold a commercial exhibit in connection with its national convention. A civil engineering show will complement the technical program of the annual meeting at the Hotel Statler, New York City, October 14-18, 1957.

Mechanical Engineering

The Institution of Mechanical Engineers (1 Birdcage Walk, Westminster, London SW 1, England) is arranging a Conference on Lubrication and Wear, to take place October 1-3, 1957 in London.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

AMERICAN INSTITUTE OF PHYSICS HANDBOOK

This handbook is the first American publication of its kind to be exclusively devoted to physics. The increasing amount of specialization within this field, the result of modern research and technical development, has added tremendously to the number of areas encompassed by the subject. Much of the information compiled in this publication would otherwise be scattered in various sources, although only the most generally useful data has been included. The eight main sections of the book cover: mathematics; mechanics; heat; sound; electricity and magnetism; optics; atomic and molecular physics, and nuclear physics. Each of these contains numerous sub-sections individually compiled by a specialist. Topics included that are not readily available elsewhere are: geophysical data; rheological data; flow of gases; shock waves; cross sections, fission products, health physics and mesons; properties of paramagnetic salts; high pressure effects; electronic constants in the low temperature heat capacity of metals; low temperature thermal conductivity; and others. The tables are well prepared and some bibliographies are included. This is a useful reference work for anyone using physics in research, application or teaching. D. E. Gray, ed. Toronto, McGraw-Hill, 1957. Irreg. paging, $18.00.

Members may borrow the books mentioned in these notes on application to the librarian. Two books may be borrowed for two weeks.

LIBRARY HOURS
Monday to Friday
9 a.m. — 5 p.m.
Saturday 9 a.m. — 12 noon.

ANTENNAS

Dealing with both the theoretical and practical aspects of antennas, the topics covered in this publication are: fundamental antenna principles; basic antenna types; input impedance and radiation resistance, ground effects; variations of electrical length by loading; gain and directivity; driven and parasitic arrays, various types of long wire antennas; feeding and matching principles, and several variations on the basic dipole design used in current antenna types. A. Schure, ed. New York, Rider, 1957. 79p., $1.50 (U.S.).

AUTOMATION IN BUSINESS AND INDUSTRY

Based on an extension course given by prominent engineers and scientists at the University of California, this book reviews the status of developments and applications in the field of automation at the time, Spring 1955.

The course was organized to show how the various fields of feedback control theory, instrumentation, analog and digital computation, and data processing are becoming integrated as automation is more widely applied.

Special emphasis was placed on those applications of control systems which can perform both complex control functions and data processing, and considerable attention was paid to electronics, computers, and data processing.

References for further reading are given in many chapters. E. M. Grabbe, ed. New York, Wiley, 1957. 611p., $10.00.

AUTOMATION: ITS PURPOSE AND FUTURE

The author reviews here the progress of automation to date in various fields: engineering, chemistry, the petroleum industry, accounting, transport, stores, food, weapons and translation.

He describes the principles of the digital computer, and discusses the speed with which automation is likely to spread in different countries, and expresses his opinions on the effect of automation on men's lives. Magnus Pyke. New York, Philosophical Library, 1957. 191p., $10.00 (U.S.).

BUILDING AN ENGINEERING CAREER, 3D ED.

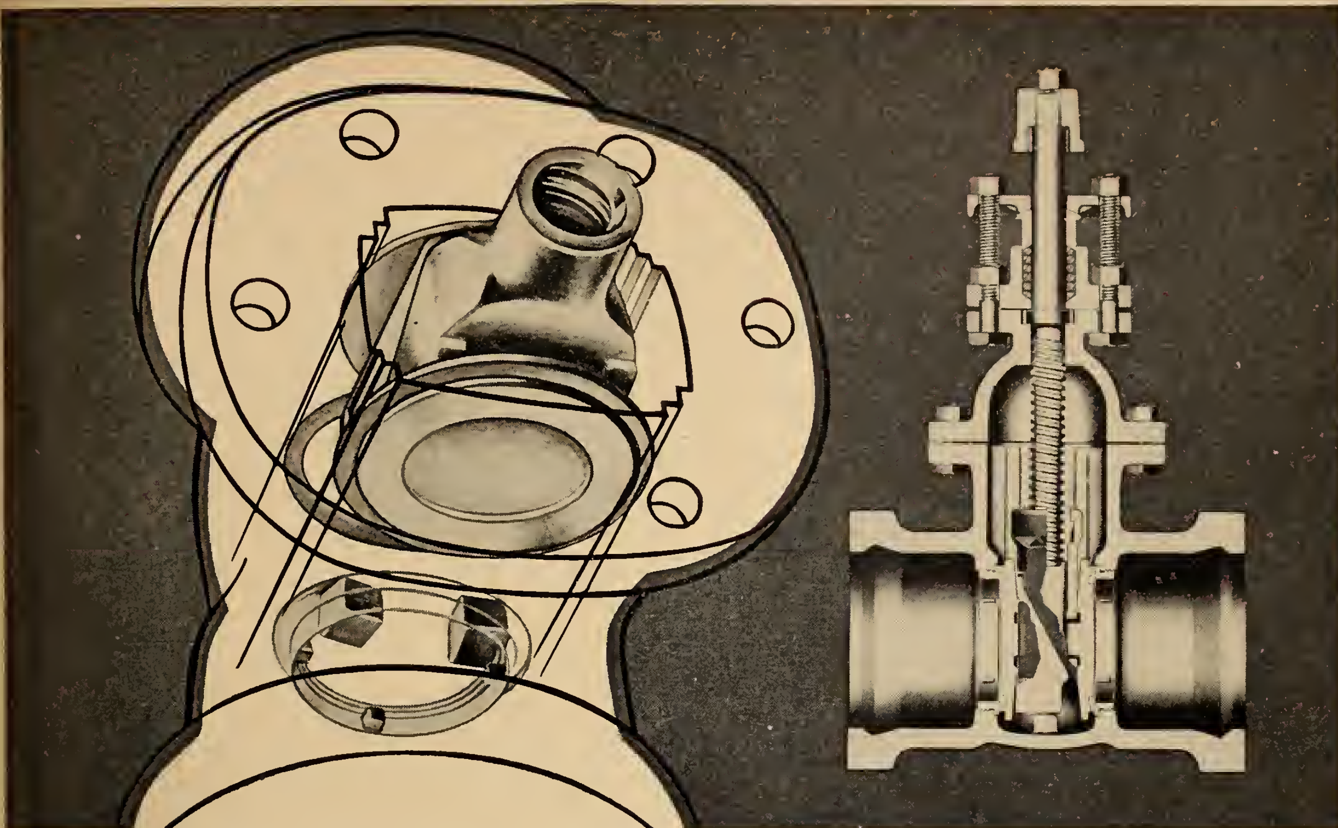
The necessity for orienting the engineering student in the matter of his studies, his future career, and the role of engineering in society has generally been recognized by most instructors. The scope of this book is such that, with mature supervision and direction, it will meet this need.

The three main sections are: education for engineering; historical background of engineering; achievements in engineering. The structure of engineering education is explained, the necessity for learning the basic subjects, and efficient methods of studying technological material. A historical survey of the development of the profession is given, concluding with recent developments and the present importance of engineering in all its fields. Engineering ethics are discussed throughout, and the quantitative and creative nature of the engineer's mode of thinking is explained. Correlated with the latter is a section containing problems. An up-to-date list of visual aids is also included. C. C. Williams and E. A. Farber. Toronto, McGraw-Hill, 1957. 299p., $5.70.

CHEMICAL ENGINEERING REPORTS, 4TH ED.

From the number of enquiries received regarding the best way in which to prepare and write a technical report, we would imagine that this new edition of Professor Kobe's book on preparing a report will be widely welcomed. Although applying specifically to chemical engineering reports, much of his information is equally applicable to other engineering fields, and the book could be profitably read by the majority of engineers.

The author has presented his material in the form of a formal engineering report, and covers searching the available literature, and assembling the findings, emphasizing the importance of



THE OUTLINE drawing shows how the simple, 4-piece disc assembly is held in alignment by the guide ribs. As the disc assembly descends on the stem, the lower spreader strikes a boss in the body. Further closing movement exerts pressure on the spreaders in a wedging action, forcing the parallel discs tightly against the seats.

New Crane disc assembly and guide rib design improve efficiency of AWWA valves

Hub End Valves—No. 480½

Flanged End Valves—No. 2485

Mechanical Joint End Valves—No. 2487½

Two design features—a simple, 4-piece disc assembly and a unique guide rib design—function together to make Crane's new AWWA double-disc gate valves a wise choice for mains and distribution lines.

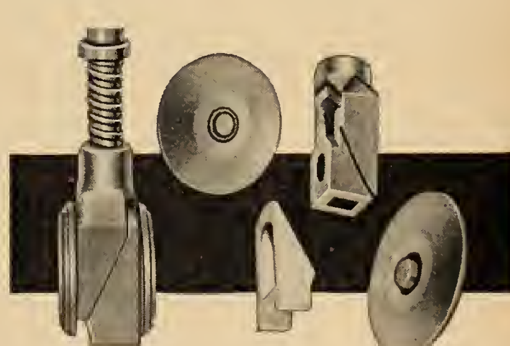
The double-disc assembly, held in close alignment by the new guide rib design, cannot jam or become disengaged in service. The trunnion-mounted discs are free to rotate as they are raised or lowered, preventing concentrated wear on both discs and seats. And, the rotary motion of the discs tends to clean the seating areas.

The new Crane double-disc gate valves meet all AWWA specifications—and more! For example, the 2-piece gland and gland flange with ball type joint is well-known for preventing stem binding even though uneven pull-up may be applied on gland bolts.

These quality AWWA valves are available in sizes from 2″ to 12″. Conforming to AWWA specifications, they are bronze-trimmed and have non-rising stems. For complete specifications, write:

CRANE LIMITED,

General Office, 1170 Beaver Hall Square, Montreal



THIS VIEW of the disc assembly shows simplicity of design that makes it completely dependable in action. Entire assembly is suspended freely in valve body from stem, which engages upper spreader. Discs are suspended from upper spreader by trunnion principle.

1-5672

CRANE VALVES • FITTINGS • PIPING
PLUMBING • HEATING

NATION-WIDE SERVICE THROUGH BRANCHES, WHOLESALERS and PLUMBING AND HEATING CONTRACTORS good style, attractive presentation, and correct citation of sources used. There is also information on the typing and reproducing of a report. As the author points out, many companies have their own style manual, but in the absence of one of these, this report is an excellent guide. K. A. Kobe. New York, Interscience, 1957. 175p., $3.00.

*THE ECONOMICS OF SOVIET STEEL

A four-part study, based almost entirely on Soviet sources, of the development of the Russian iron and steel industry from 1917 to the present. The four parts are concerned, respectively, with the growth of production and investment; the specialization and size of plants and equipment; factors affecting plant location; and productivity. A considerable amount of statistical data is provided in appendixes, and a bibliography is included. M. Gardner Clark. Toronto, Saunders, 1956. 400p., $9.00.

ELECTRICAL ENGINEERING CIRCUITS

This basic text, for use in undergraduate study, presents the a-c circuit, and its underlying concepts in lucid form. Two thirds of the book is devoted to fundamental theory, while the rest introduces more recent material to prepare the student for advanced courses. The newer topics covered are: network theorems; loop and node equations of networks; locus curves and other graphical methods; resonance of high - Q circuits; impedence and admittance functions; poles and zeros in the complex frequency plane; the transform concept; and the Laplace transformation. A knowledge of basic physics and calculus is presumed, but complex algebra is presented in chapter 3.

This book has been used in preliminary form in the classroom by the author, and revised as occasion demanded. Summaries and problems are presented at the end of each chapter, and answers to every fourth question as well as a short bibliography are included. H. H. Skilling. New York, Wiley, 1957. 724p. $8.75.

ENERGY

Newly edited and illustrated, this book, first printed in 1929, and written by the well known English physicist, presents the basic concepts of energy. It may be understood by the layman, and also serves as a basic review for the expert. Perhaps its greatest interest for the latter lies in the form of presentation, which demonstrates how the subject may be interestingly presented and taught, as well as related to daily experience. Oliver Lodge. New York, Rider, 1957. 54p. $1.25 (U.S.).

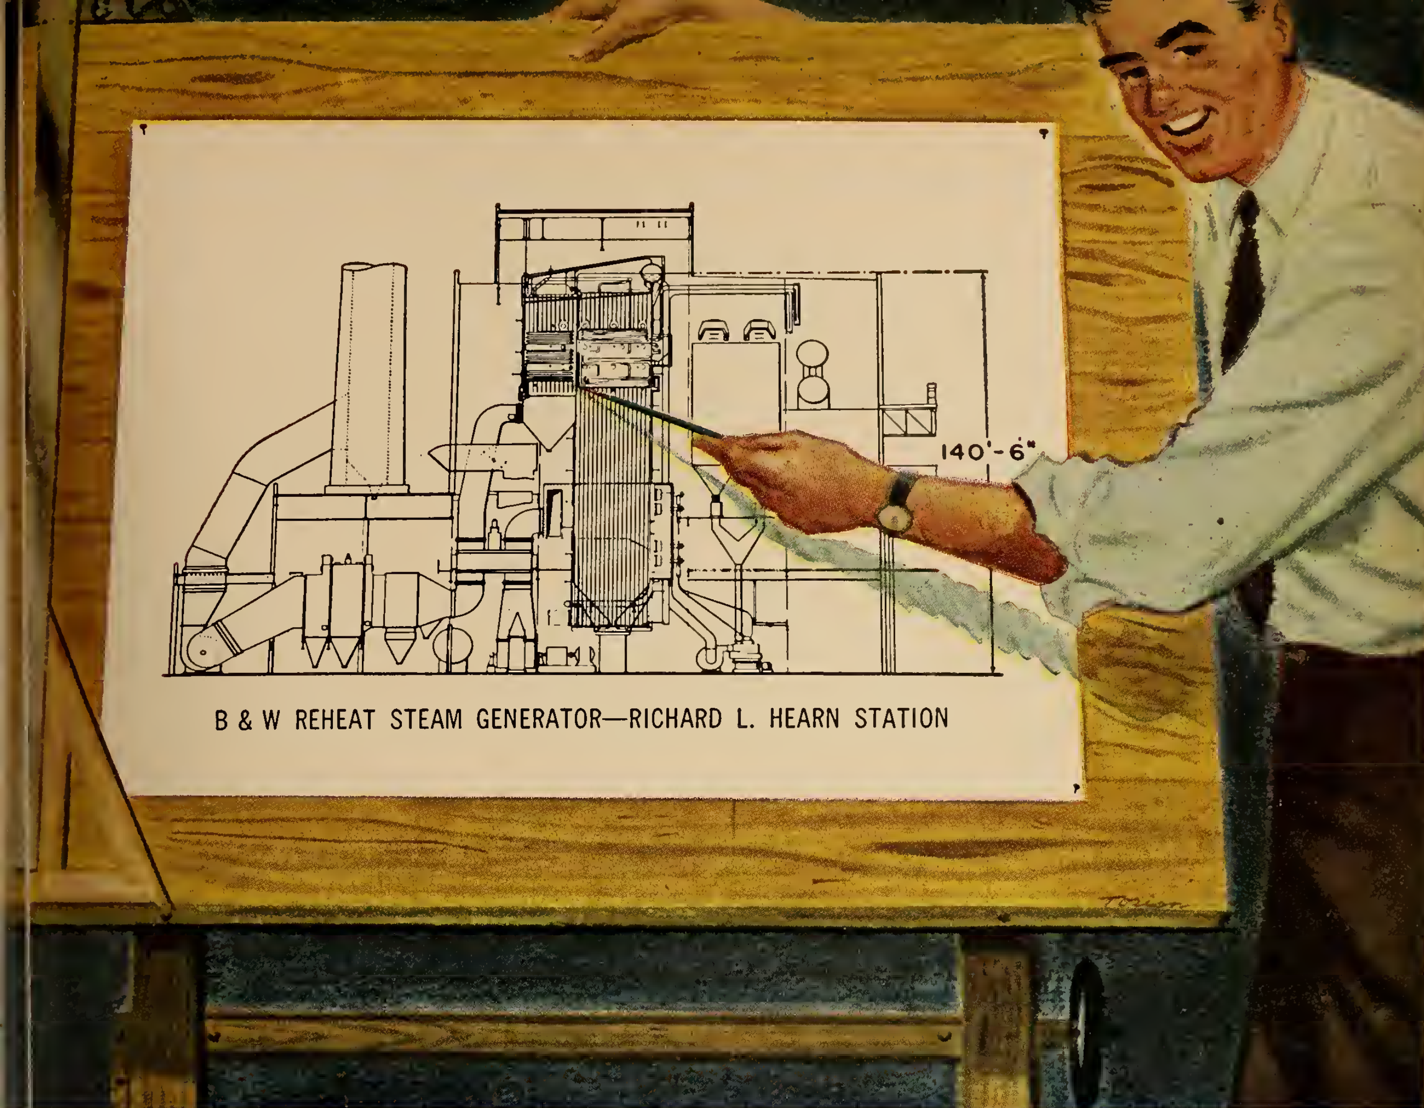
ENGINEERING AND TECHNICAL HANDBOOK

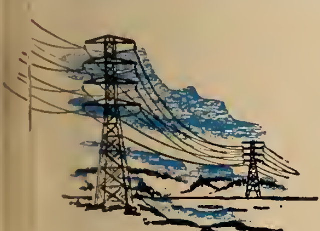
This compact handbook contains information in quick-reference, tabular form on the basic principles and formulas of engineering, technology, and the practical applications of the physical sciences. The five sections cover: basic fundamentals and formulas of general application; properties of materials, containing such information as: physical properties of water at various temperatures, beam diagrams, National Electric Code current carrying capacities, coefficients of friction, kinematic viscosity of various fluids, and numerous other subjects; equivalents and conversions; basic principles of mathematical operations from arithmetic to calculus, and finally, section five, containing twenty mathematical tables generally used in engineering and other technical fields. A. L. Hoag and D. G. NcNeese. Englewood Cliffs, N.J., Prentice-Hall, 1957. 376p., $6.00 (U.S.).

ENGINEERING THERMODYNAMICS

Based on the earlier text entitled Heat Power Engineering, by Barnard and Ellenwood, this book has been completely revised and brought up to date by C. O. Mackey.

The first six chapters include the basic principles of thermodynamics covering historical development; temperature, energy and first law of thermodynamics; processes and energy equations; second





TWO B&W REHEAT STEAM GENERATORS
for
ONTARIO HYDRO'S
RICHARD L. HEARN GENERATING STATION

The existing four boilers in the Richard L. Hearn Station are B & W units, each generating 850,000 lbs of steam per hour. These are, at present, the largest steam generating units in Canada.

To meet growing power demands, a major increase in output, pressure and temperature, including reheat, has been decided on for the extension of this station, and the Commission, through their Consulting Engineers, Stone & Webster Canada Limited, have placed contracts for two new boiler units with B & W. Each will deliver 1,350,000 lbs of steam per hour, at 1900 psig at the superheater outlet, with design pressure of 2200 psig, a superheated steam temperature of 1000° F, and a reheat steam temperature of 1000° F.

Thus, in 1958 Ontario Hydro will have in service a 200,000 kw steam turbo-generator powered by a *Reheat Steam Generator*—the first in Canada.

This will also be Canada's largest steam generating unit, with the steam drum more than 140 feet above the foundation floor. The second of the new B & W units will be similar.

BABCOCK **STEAM FOR PROCESS • STEAM FOR POWER** B&W STEAM

Member: Canadian Boiler Society

BABCOCK-WILCOX AND GOLDIE-McCULLOCH LIMITED, GALT, ONTARIO MONTREAL • TORONTO • CALGARY • VANCOUVER law of thermodynamics, temperature and entropy; general equations; and gases; properties and processes. The following chapters include: one-dimensional flow, properties of mixtures, and reactions of ideal gases; compression of air and other gases; engine cycles-gas; vapors; energy transformation in turbines; refrigeration and air-conditioning. The examples of the practical applications of thermodynamics are given to interest the engineering student by relating principles to practice. Problems and references are given at the end of each chapter. C. O. Mackey, W. N. Barnard and F. O. Ellenwood. New York, Wiley, 1957. 428p., $7.95.

THE FIRST ONE HUNDRED AND FIFTY YEARS

This history of the publishers John Wiley & Sons is more than a review of the titles they have published since 1807, it is also a history of the expansion of science and technology in that time, for Wiley is renowned as a publisher of technical books.

The first three chapters give a brief glimpse of New York as it was in 1807 when Charles Wiley opened his printing shop and bookstore, and the early history of the firm. The remaining chapters discuss, subject by subject, the books which have appeared over the Wiley imprint, showing how they have fitted into the contemporary scene. Nearly all the chapters have been written by Wiley authors, and the company is to be congratulated on the publication of this most interesting book which is also very well produced. New York, Wiley, 1957. 242p., $7.50.

FRICTION AND LUBRICATION

Based on experiments carried out at Cambridge University by the authors and their colleagues, this book gives an account of recent work and views on the mechanism of friction and lubrication.

The first five chapters discuss the various types of friction, and their causes, the part played by oxides and other surface films, and methods of measuring local temperatures caused by friction. Friction in non-metals is covered in chapter six, while the remainder of the book deals with the behaviour of lubricated surfaces.

There is a brief bibliography at the end of each chapter. F. P. Bowden and D. Tabor. Toronto, Ryerson, 1956. 150p., $2.25.

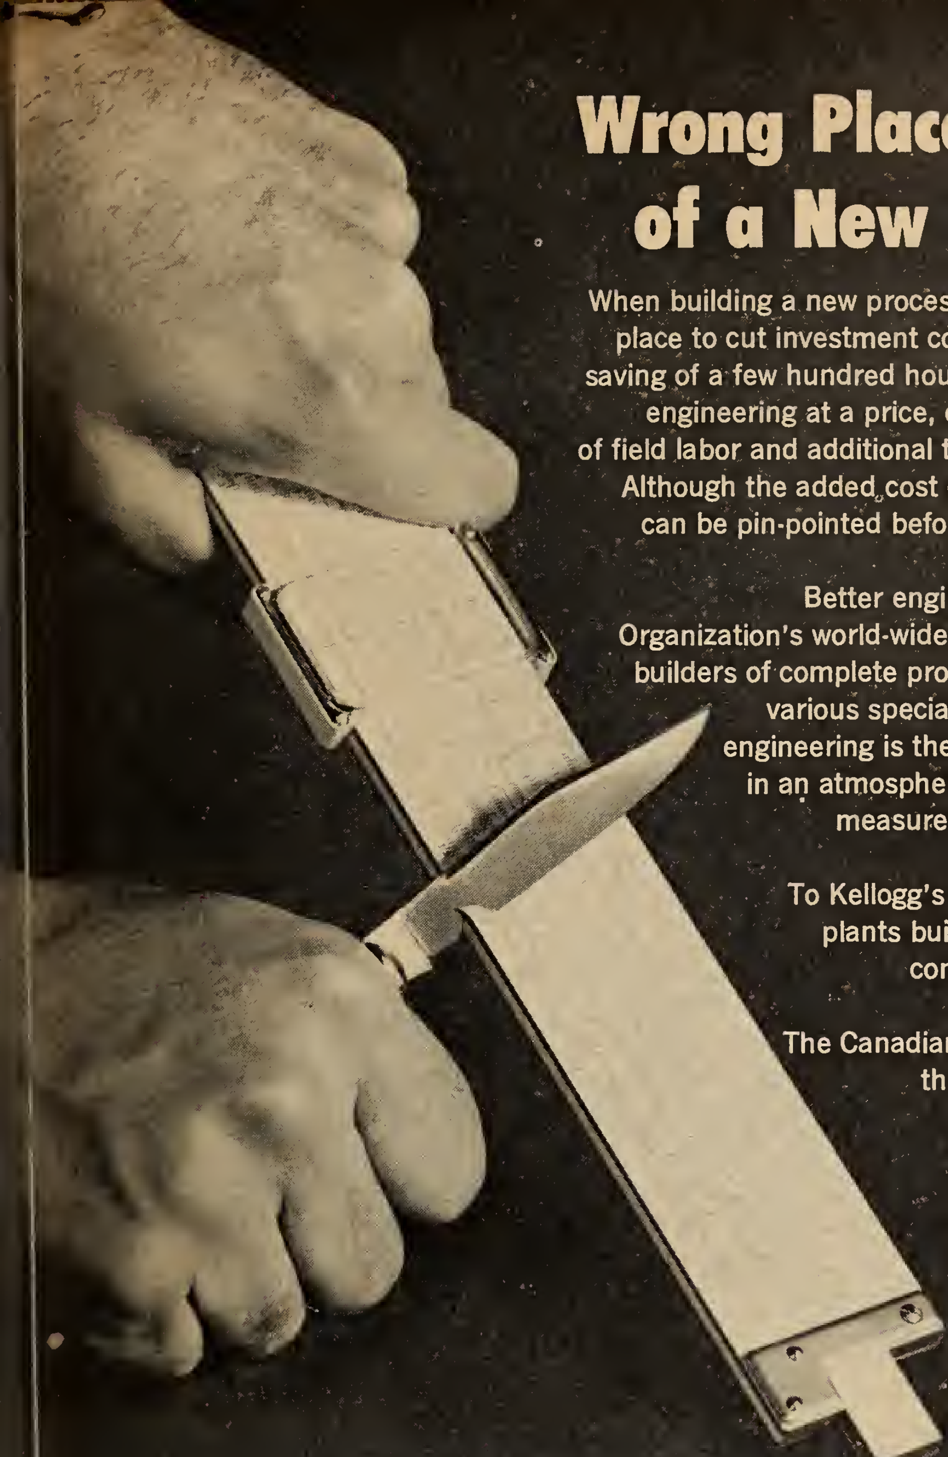
THE FUNDAMENTALS OF ELECTRIC LOG INTERPRETATION, 2D ED.

Electric logs are used to measure two quantities, the first of which is the variation in the borehole of electric currents flowing between shale beds and permeable beds whenever these are in contact. The second quantity is the electrical resistivity of the formations penetrated by the borehole. The book is in two parts, covering the theory and the practice of quantitative log interpretation.

In this second edition various corrections have been made, and the number of graphs greatly increased, a new chapter included on the treatment of abnormal spontaneous potentials, and new sections added on gamma-ray logging, the use of the neutron-gamma log to detect gas zones and determine porosity, and the acoustic velocity log. The section on gamma-gamma density logging has been expanded, and two final sections added on a general method of log interpretation and log quality control. M. R. J. Wyllie. New York, Academic Press, 1957. 176p., $4.50.

GRAPHICS FOR ENGINEERS

A book on engineering drawing which covers the fundamentals, but in which the emphasis is on engineering geometry, multiview representation, basic descriptive geometry, and freehand sketching, with particular attention to perspective pictorials and graphical methods for solving engineering problems. The purpose is to develop the ability to



Wrong Place to Cut Costs of a New Process Plant

When building a new process plant, engineering is the easiest place to cut investment costs. But it's the wrong place! The saving of a few hundred hours of engineering, or trying to buy engineering at a price, can cost thousands of extra hours of field labor and additional thousands of dollars for materials. Although the added cost of inadequate engineering seldom can be pin-pointed beforehand, it is inevitably reflected in the operating record of the plant.

Better engineering is the basis of the Kellogg Organization's world-wide reputation both as engineers and builders of complete process plants and as consultants on various special engineering projects. This better engineering is the result of good engineers working in an atmosphere where sound engineering is the measure of success for both the individual and the organization.

To Kellogg's clients, better engineering means plants built at the lowest capital investment consistent with reasonable operating and maintenance costs.

The Canadian Kellogg Company Ltd. welcomes the opportunity to demonstrate how better engineering can benefit companies contemplating new process plants.

visualize spatial conditions and to use graphical forms of representation as a means of communication. There is a special chapter on graphs, charts, and nomograms. W. J. Luzadder. Englewood Cliffs, N. J., Prentice Hall, 1957. 579p., $8.65.

THE HISTORY OF ELECTRIC WIRING

Any electrical installation can be only as good as its wiring, so that its history is an important part of the history of electrical engineering.

The author, a practising engineeer, has had the co-operation of many firms, organizations and individuals in writing this history which covers the period from 1870 to the present. The first six chapters provide a chronological review, presenting contemporary ideas, the histories of some of the firms in the trade, the effect of legislation, and the exchange of ideas with other countries. One chapter is devoted to Lord Kelvin's contributions to installation practice. The history of the various components is given, including cables, conduits, branch switches, lampholders, plugs and sockets, fuses, and bus-bar trunking and duct systems. One chapter is devoted to the prefabrication of wiring systems, and one to recent developments such as installation in ducts in concrete. John Mellanby. London, Macdonald, 1957. 244p., 32/6.

AN INTRODUCTION TO SEMICONDUCTORS

W. C. Dunlap is eminently qualified to write the first book on semiconductors to completely cover the field. His many years as consultant on semiconductors have enabled him to present his subject simply and without a mass of complex mathematical theory and the space thus saved has been devoted to directly usable information. Therefore having read the book, you are prepared for active work in the field.

Well illustrated with diagrams and graphs, this subject is approached on an almost entirely physical level. The topics covered range from crystals and the solid state theory through statistical mechanics for metals and semiconductors; electron theory of metals and semiconductors; properties of p-n junctions to rectifiers: transistors; photocells, thermistors, hall effect, and other semiconductor applications. It also covers contract and surface properties, experimental measurements, general methods of preparing materials, semiconducting compounds and the properties of the elemental semiconductors.

It is lucidly written, well indexed with extensive references at the end of each chapter. W. C. Dunlap, Jr. New York, Wiley, 1957. 417p., $11.75.

INVENTORS AND INVENTIONS

The story of the development of modern technology is to a large extent that of new inventions. In this publication, the author, who is director of patent operations at R.C.A. Laboratories at Princeton, N.J. examines the psychology and methods of invention. Notable examples of the works of famous inventors are given, whose discoveries have been arrived at through various means ranging from painstaking scientific experiment and discovery to happy accident. The conception of the invention is examined and related to the environment, education and age of the men who have created the things that are now part of our civilization. Finally, the nature of patentable inventions and a non-legalistic explanation of protecting and patenting is given, as well as pointers on marketing inventions. The book is well documented giving relevant graphs and tables concerning the subjects under discussion. References are included at the end of each chapter. C. D. Tuska. Toronto, McGraw-Hill, 1957. 174p., $4.50.

MATHEMATICS AND COMPUTERS

This book, written for the non-specialist, is intended to present the relationship between pure and applied mathematics, and the new role of automatic computers in helping to solve the problems of science, engineering and business. It deals with the field of applied mathematics, with special emphasis placed on the commuting methods and devices used by the mathematician, and the uses and workings of automa-

ART

For attractive distinctive container designs and displays that promote, identify and sell your product, Bathurst Containers maintains Art Departments at Toronto, Hamilton and Montreal. Here we produce designs that assure maximum product identification and presentation at all levels, from warehouse to consumer. To assure the best reproduction of these designs, Bathurst has also developed its own typesetting, engraving and molded platemaking departments.

Whether your requirements are for one-, two-, three-, or four-color containers, call on Bathurst. Remember you can *sell anything—anywhere in Bathurst Containers!*

and the uses and workings of automatic digital computers.

Topics presented are: numerical analysis; digital computer components; logical design of digital computers, analog computers and simulators; computing with random numbers; computer errors; and computers at work. Suggestions for further reading are given at the end of each chapter, and a selected bibliography is included. G. R. Stibitz and J. A. Larrivee. Toronto, McGraw-Hill, 1957. 228p., $6.00.

MODERN CHEMISTRY FOR THE ENGINEER AND SCIENTIST

This collection of nineteen papers by outstanding chemists, each an expert in his respective field, was first presented as an extension course at the University of California to acquaint scientists and engineers, who had been practising for some years, with the newer developments and fields of investigation in modern chemistry. The papers are at quite an advanced level, and deal with subjects that should profoundly affect modern technology in the near future. The subjects covered are: chemical thermodynamics; contact catalysis; photochemistry; chemical kinetics; isotopic tracers; column chromatography; organic reaction mechanisms; rubber elasticity; carbon - fluorine compounds; silicones; petrochemical industry; chemical relations in earth; creep of metals as reaction-rate phenomenon; crystal chemistry and pyrochemistry of clay materials; food technology; biochemistry of insecticides; chemical constitution and physiological action; chemical synthesis in living organisms; and the configuration of polypeptide chains in proteins. References are included with each paper. G. R. Robertson, ed. Toronto, McGraw-Hill, 1957, 442p., $11.40.

*NATIONAL STANDARDS IN A MODERN ECONOMY

Comprised of a series of articles by well-known authorities, this book is an examination and assessment of the standards movement as a whole within the United States. The articles deal with the history of the movement and with applications of standards in specific fields: interchangeable parts manufacture, supply and purchasing, telecommunications, agricultural products, military goods, consumer goods, etc. A review of the international standards movement is included, and a number of articles are devoted to the implications of standardization for management, labor and the consumer. Dickson Reck, ed. Toronto, Musson, 1956. 372p., $6.00.

PIN POINT T.V. TROUBLES IN 10 MINUTES

Intended as a guuide for T.V. servicemen, this publication is concerned with trouble location and correction rather than theory. Check charts and cross references are given for the location of the most probable causes of picture faults. Methods for checking the performance of various receiver parts and components, as well as precautions in making tests and replacements are given. The circuits and designs of the majority of television receivers produced since 1953 are explained and covered in the tables of faults. Chicago, Coyne Electrical School, Indianapolis, Sams, 1957. 299p., $3.95 (U.S.).

PRACTICAL APPLICATIONS OF ENGINEERING SOIL MAPS

During the last nine years, under the sponsorship of Rutgers University and the New Jersey State Highway Department, twenty-one reports on the soil conditions existing in the state have been published. This twenty-second and final report contains information of general interest, as well as a summary of the materials available in New Jersey, particularly those of interest to the highway engineer.

The soil mapping techniques used in the survey are explained, and the symbolic notations employed, and there is a chapter on the practical uses of engineering soil maps and reports.

Anyone considering making a soil survey would be well advised to read this and the first report in the series which dealt with soil environment and methods of research. W. W. Holman and others. New Brunswick, N.J., Rutgers University Press, 1957. 114p., $3.00.

• LIBRARY NOTES

PRINCIPLES OF ENGINEERING GEOLOGY AND GEOTECHNICS

Geotechnics, the application of the earth sciences to the solution of civil engineering problems, forms the subjects of this book written by a foundation engineer and a geologist.

The first eight chapters contain general geotechnical information on engineering properties of rocks and soils, soil mechanics, subsurface water, subsurface exploration, maps and airphotos, and rock as a construction material. Following chapters show the use of this information in the design of buildings, bridges, dams, tunnels, runways, highways and shore structures. There are also chapters on aseismic design, landslides and the legal side of geotechnics.

Of particular interest is the information given relating to frost and permafrost and its effect on construction. There are numerous illustrations throughout this well-presented text, and references are given at the end of each chapter. D. P. Krynine and W. R. Judd. Toronto, McGraw-Hill, 1957. 730p., $12.00

PRINCIPLES OF ENGINEERING HEAT TRANSFER

In this basic text the author describes the principles and concepts of the role of heat transfer in engineering, covering energy transfer, fluid flow, conduction, convection and radiation.

The overall picture of energy transfer is presented first, and the part played by conduction, convection and radiation illustrated. Special attention is paid to the important topic of convection, and the chapters on fluid flow serve as an introduction to this.

A knowledge of physics, mathematics and thermodynamics is assumed, and the book is designed for electrical and industrial as well as mechanical engineering students. W. H. Giedt. Toronto, Van Nostrand, 1957. 372p., $10.00

PROCEEDINGS OF THE SECOND RETMA CONFERENCE ON RELIABLE ELETRICAL CONNECTIONS

This second conference sponsored by the Radio-Electronics-Television Manufacturers Association was held in 1956, and the thirteen papers presented covered soldered, solderless and brazed connections; ultra-sonic joining; equipment and tools; fluxes; surface qualities; soldering to printed wiring boards, etc.

The conference serves to emphasize the importance of reliable electrical connections in the modern world with its reliance on electrical and electronic equipment. New York, Engineering Publishers, 1957. 103p., $5.00 (U.S.).

PROPERTIES OF PETROLEUM RESERVOIR FLUIDS

Although petroleum engineering practice is constantly changing, certain fundamental concepts remain unchanged, and it is the aim of this text to describe those basic concepts connected with reservoir fluids. The properties of ideal fluids are described, as well as empirical correlations necessary in dealing with the complex mixtures generally existing in petroleum reservoirs.

The topics covered include the properties of the hydrocarbons which constitute petroleum, and their behaviour in a gaseous state, the phase behaviour of liquids and the qualitative phase behaviour of hydrocarbon systems, quantitative phase behaviour, reservoir fluid characteristics and the applications of those characteristics.

The principles discussed are illustrated with many worked examples, and many tables and charts needed to solve problems often found in this phase of petroleum engineering are included. The author has also included references for further reading, and problems the working of which will further illustrate the basic concepts presented. E. J. Burcik. New York, Wiley, 1957. 190p., $7.50

THE RADIO AMATEUR'S HANDBOOK, 34th ED.

A standard manual and reference work for radio amateurs and experimenters, this edition includes information on new equipment including v.h.f. high-powered amplifiers, beam antennas, semi-conductors, and new tables on vacuum tubes. Basic theory is included throughout, and the receiver and the transmitter sections give simple as well as more complex unit construction data. Other sections include: high-frequency receivers and transmitters, speech amplifiers and modulators, single side band, transmission lines, and assembling and operating a station. American Radio Relay League. West Hartford, Conn., The League, 1957. 750p., $4.00.

REALITIES OF SPACE TRAVEL

As space travel comes ever closer to being an accomplished fact, astronautical experts are slowly solving the problems that lie in the way of interplanetary flight. The whole field is surveyed in this book, which contains twenty-four papers presented before the British Interplanetary Society. The topics covered include: requirements for leaving the earth's atmosphere and combating gravity; the artificial satellite; limitations of chemical propellents and the introduction and development of the atom rocket; the history and development of rockets; physical and biological aspects of space travel, the dangers of meteors and cosmic rays; probable first targets, the Moon and Mars with an analysis of their physical conditions; establishments and testing stations; and probable future developments. Selected references are included with each paper. L. J. Carter, ed. London, Putnam, 1957. 431p., 35/-.

REPAIRING TELEVISION RECEIVERS

This publication is a manual for those with a basic knowledge of TV theory and test instruments. Repair procedures are emphasized by explaining how to localize defective sections, then the defective stage, and finally the defective component. The first six chapters cover servicing techniques including a key check system for determining trouble. Succeeding chapters explain how to apply these techniques to various servicing situations. A supplementary checklist of causes of trouble is given, indicating circuit components which usually cause particular failures. C. Glickstein. New York, Rider, 1957. 206p., $4.40 (U.S.)

RESONANT CIRCUITS

The theoretical basis of the resonant circuit is treated in this publication, starting with basic theory related to resonance, and continuing with discussions of various arrangements of the resistor, capacitor and inductor in forming circuits. The series, parallel, and series-parallel combinations are discussed and analyzed. Resonant circuits with distributed constants, resonant coupled circuits and circuit applications are included. This is volume 16 of the Rider's Electric Technology Series. A Schure, ed. New York, Rider, 1957. 66p., $1.25 (U.S.)

ROLL-ON, ROLL-OFF SEA TRANSPORTATION

These are the proceedings of a symposium held in November 1956 under the auspices of the Maritime Cargo Transportation Conference. The subject under discussion is the principles and advantages of the "trailership' on which a cargo is loaded and taken off by means of trailer vans or rail cars. The six papers presented cover various aspects of the subject, such as trailership operations, shoreside facilities, and design of trailerships. Washington, Nat'l Academy of Sciences, Nat'l Research Council, 1957. 49p. $1.25 (U.S.).

WATER FOR INDUSTRY

In order to publicize the necessity for continued hydrological investigation and control, this symposium was sponsored by several scientific societies. The control problem under study was that of natural water resources; supply and industrial requirements for the present and future. It is pointed out that without the application of adequate conservation methods, water supply will be a widespread problem, as it is now, in some areas. Subjects covered in the nine papers presented are: the available water supply and water requirements; the treatment and disposal of wastes in the atomic energy industry; water supply and waste disposal requirements for industry; anti-pollution legislation; water in the future. J. B. Graham and M. F. Burrill, eds. Washington, American Association for the Advancement of Science, 1956. 141p., $3.75 (U.S.)

LIBRARY NOTES

°WOOD STRUCTURAL DESIGN DATA, VOLUME 1, 3rd. ED.

This new edition includes significant developments in the field which have occurred since the publication of the second edition in 1939. Among these are the timber connector system of wood construction, structural glued-laminated lumber, simplified methods of column design, and more specific information on the relation of load duration to allowable stresses. Since this is intended as a practical reference aid for wood structural design, the data are presented for the most part in tabular form. There is a subject bibliography at the end. Washington, National Lumber Manufacturers Association, 1957. 362p., Spiral Binding, $4.00 (U.S.).

Z142-1957 Code for the guarding of punch presses at point of operation. $1.25.

Z143-1956 Specification for common names for pest control chemicals. 75 cents.

ENGINEERING CAREERS

Municipal Engineering

MUNICIPAL engineers, in the general sense, are responsible for the development of the communities in which we live and for the operation and expansion of the facilities associated with a modern community.

The operations involved may range from those of a large public works department required to run a city of over a million inhabitants to the single municipal engineer who may administer the public works requirements of a small mining town in a remote area.

The importance of the field in Canada may be judged by the fact that the total expenditure on construction and public works in 1956 by municipal authorities was estimated to be of the order of $300 million, a figure comparable with the corresponding expenditure by the Federal government; the ten provinces spent some $500 million in the same field during the year. Undoubtedly the volume of municipal work will continue to grow considerably—as one example, about 55 per cent of the Canadian population is served by some 845 municipal sewerage systems, whereas there are nearly 1600 municipal waterworks systems serving about 65 per cent of the population. Obviously there is much work to be done to make more adequate provision of these facilities for a growing populace.

Seen during its construction is the new civic auditorium at Calgary. A duplicate auditorium was also built at Edmonton during 1956. Some 1300 tons of steelwork were used in each.

Fields of Engineering

The field of municipal engineering is very wide, and there is a great demand for civil, mechanical, and electrical engineers to keep up with the current rapid growth of the country's communities in general, and of the larger urban centres—the cities—in particular.

A modern urban community demands good roads, lighting, water supply, sewage disposal, hospitals, schools, and other facilities that may be the responsibility of the municipal authorities. These facilities must be planned, installed, maintained, and expanded as the community grows.

Town Planning

Before discussing these municipal engineering operations in greater detail, mention should be made of the important field of town planning, on which the future of the community depends so greatly.

In the words of the director of city planning of a Canadian city that has a population of well over a million people:

"City planning is concerned mainly with providing a decent environment for living. There is no doubt that the art of the engineer has a great contribution to make towards the efficient physical growth and good arrangement of communities in harmony with their social and economic needs. No master plan would be efficient without the engineer's intervention in the fields of circulation systems, such as railroads, rapid transit, bus lines, main highways and local streets and pedestrian ways; of buildings, public and private; of open spaces, such as parks, playgrounds, reservations, waterfronts, and airfields; and of public utilities, including water and sewer mains, sources of supply and places of disposal; gas, electricity, and telephone. The engineer with his sense of scientific knowledge and analysis of facts, is one of the technicians most vitally needed for planning adequately the physical layout of our communities."

Public Works

In the larger cities the municipal engineering operations are usually the concern of a department of public works. Details may vary from city to city, but in general this department is equipped to provide the facilities mentioned above.

A typical department will have a director, or other chief executive, who is often himself an engineer, together with an administrative staff, also with a large proportion of engineers in the senior positions. The main divisions of the department will probably deal with: planning and new developments; construction; and operation and maintenance. New works and the operation and maintenance of existing facilities are usually handled by separate divisions.

Planning — Many civil engineers are required for surveying work and for the preparation of plans, which may be used in the future development of the community. Plans are also required for use in the legal courts in such cases as the expropriation of land by a city and the establishment of property rights. Surveys are carried out for traffic routes, sewers, and so on, and plans and specifications drawn up for such installations as waterworks. To meet the needs of future expansion, long-term planning is carried out by appropriate groups of engineers.

Water and Sewage — The design and construction of water supply and sewage disposal systems calls for engineers with a knowledge of hydraulics for some phases of the operations.

Traffic Routes — Engineers are concerned with the design and construction of roads, bridges, subways, and other routes.

An example of a modern school belonging to a municipality is the 57,000 sq. ft. area regional high school at Liverpool, N.S., of which the entrance to the auditorium is shown here.

Buildings — A public works department may have its own staff of architects to design new buildings such as administrative offices, hospitals, schools, and buildings for public utilities. With this division, a group of mechanical and electrical engineers is required for the design and installation of heating, air conditioning, lighting, and so on.

Electrical — Electrical engineers are responsible for the installation of equipment such as street lighting, traffic signals, and fire alarm signals. A further important field is that of electrical power distribution and such installations as electric motors for water pumping, transformers, and so on.

Local Improvements — When opening a new area of a community, a group of engineers will supervise the provision of new streets and main services for the locality.

Parks — Many large cities and towns have a department responsible for the development and maintenance of parks and other open spaces and recreational facilities. Here, again, engineers are concerned with the surveying of sites, grading of land, drainage, and installation of lighting and other equipment.

Maintenance — The buildings, roads and bridges, and other facilities already mentioned must be maintained in good condition, and to this end a public works department will employ groups of workers under the supervision of engineers experienced in the different fields.

Opportunities for the Engineer

A large public works department will generally accept the newly-graduated engineer for employment (particularly in the fields of civil, electrical, and mechanical engineering, as mentioned above) and, after determining the field to which he is best suited by inclination and training, will place him in the appropriate division to work with a senior engineer in order to get experience on the actual job.

From an engineer in training, advancement is generally in regular steps, according to the salary scale applicable to the particular department, for the first year or so and up to a certain level of experience. Above this the engineer who is suitably qualified may advance to supervisory positions in charge of engineering groups and finally of operations in an administrative district of the city or other area of operations.

As mentioned above, the senior executive positions are also frequently filled by engineers who have advanced in this field.

Consulting Engineers

In many cases the volume of work involved in planned community projects may be beyond the potential of even a large public works department, and in such cases use is made of the services of consulting engineers to carry out certain of the projects. In the case of smaller communities, in which there may be only a single engineer to administer local works, the services of consulting engineers are also widely used.

Salary and Benefits

In the field of municipal engineering, salaries are not always comparable with those that can be obtained in industry, but in general there are other advantages such as shorter working hours and considerable social security. Normal paid vacations apply and pension plans, health and life insurance schemes and similar benefits are available at favourable rates.

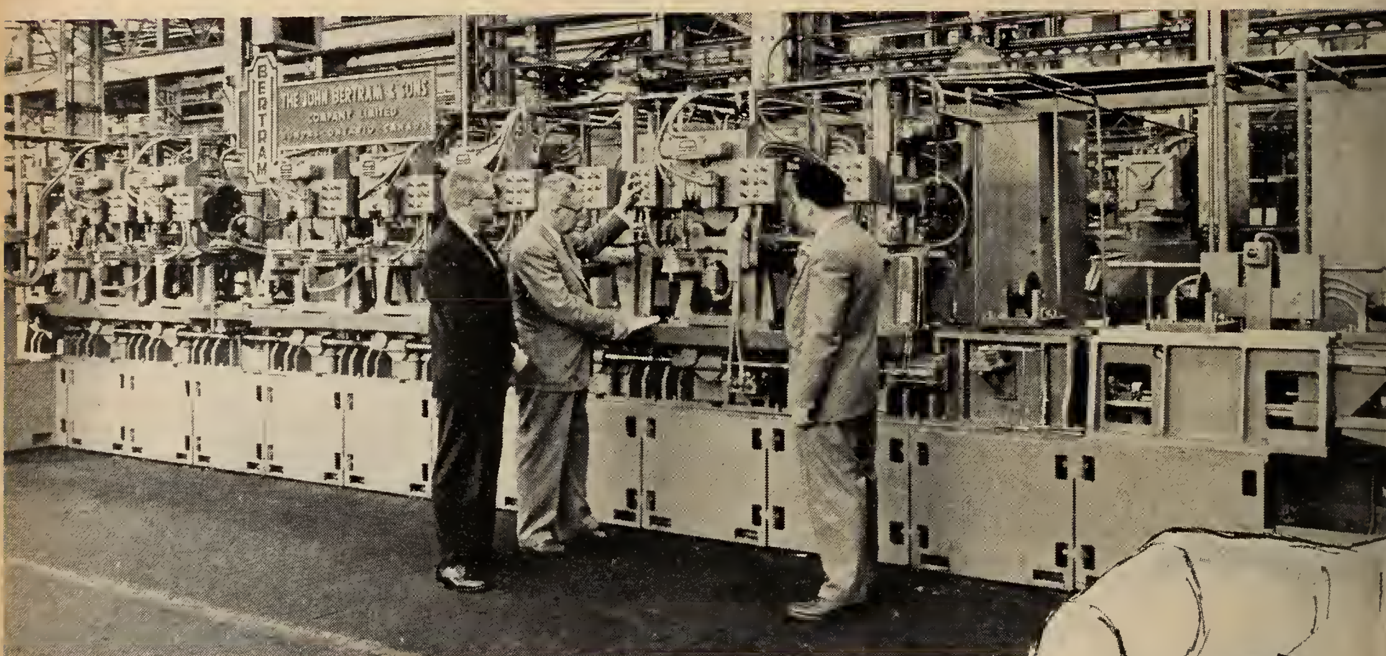
Westinghouse CYPAK at work!



Revolutionary industrial control system speeds and simplifies production at Canadian Acme Screw & Gear

CYPAK controls this intricate, 15-station transfer machine producing differential housings at Canadian Acme Screw & Gear, Toronto. Conceived and built by The John Bertram & Sons Co. Limited, Dundas, Ontario, this machine is one of the largest in Bertram's new line of "building block" designs with interchangeable stations—an important new advance in transfer machine development.

COMPACT CYPAK control panels do the thinking—choose the logical operation—signal the component stations to perform—give maximum continuous operation with least downtime.

Engineering the R.C.A.F. Argus

William K. Ebel, *Vice-president Engineering,*

and

E. B. Schaefer, *Assistant Chief Engineer,*

Canadair Limited, Montreal.

Read at the 71st Annual General and Professional Meeting, The Engineering Institute of Canada, Banff, Alta., June 1957.

To meet the particular requirements of the Royal Canadian Air Force for a maritime patrol aircraft, the Bristol Britannia has been adapted and considerably modified. This paper describes the work done by Canadian engineers to make this adaptation.

THE ARGUS, the largest aircraft which has been built in Canada to date, has rather an interesting design genealogy, and development background.

The Royal Canadian Air Force put forth a requirement for a maritime patrol aircraft that would replace the World War II Lancasters, and supplement the Neptunes which are now operated by the Maritime Command. This decision having been made the next step was to determine which aircraft would meet the requirement, when it would be available for service use, and whether or not the cost would be in line with the budget allowance. At this point the R.C.A.F. requested Canadair to prepare design studies and cost analysis on the basis of two approaches to the problem.

The first of these was to assume design, manufacture and development of an original aircraft that would meet the type specification, and the second was to adapt the Bristol Aeroplane Company's Britannia Mark 100 aircraft to meet the same specification. For a number of reasons the decision was taken to adapt the Britannia type, whereupon the Government of Canada concluded a license agreement with Bristol and appointed Canadair as its agent to procure the necessary engineering information from Bristol, adapt the Britannia basic design to the specific military requirement, tool, manufacture, and develop the maritime patrol aircraft.

The Canadair engineering division staff has been charged with the responsibility of preparing and releasing all drawings and data required to the Air Force specification. In addition complementary test programs on components and assemblies had to be determined, test rigs designed and erected, exacting tests run, results obtained and analyzed for proof of compliance with specification. All of this adds up to a major engineering effort, and this paper is presented on behalf of all those who have contributed to the solution of the engineering problem.

Grateful acknowledgement is made to the Royal Canadian Air Force for permission to present and publish the information contained herein.

The Engineering Problem

In broad terms the problem is one of converting a civil operation type passenger carrying aircraft to a military type capable of transporting a highly trained operational crew with all of the specialized equipment and strike armament on a specified military mission.

The primary role of a maritime reconnaissance aircraft is stated by the R.C.A.F. to be the protection of sea lanes of communication, including the detection and attack of enemy submarines. While security regulations will not permit statement of specific performance characteristics such as speeds, range, endurance etc. several obvious conclusions become apparent from the simple statement of role. In order to protect sea lanes of communication between the coast lines of Canada and those of friendly nations the patrolling aircraft must have long range capabilities. The detection of and attack on enemy submarines obviously require the ability to fly at low altitudes and at slow air speeds for long periods of time. Hence long endurance time in the air is necessary.

The general military requirements just mentioned then sum up to an overall mind picture as to the type of aircraft that will accomplish the objective. It must be large enough to house and power all of the involved detection equipment, carry the attack weapons, provide adequate and comfortable working space for the aircraft operating crew, the tactical crew to direct and carry out detection and attack, provide comfortable rest quarters for off duty personnel and allow for station interchange of crew members in flight. Long range and endurance at low altitudes and slow airspeeds demand large fuel tankage capacities and low fuel consumption engines.

The Britannia Mark 100 is a large aircraft with sufficient body volume to house the personnel and equipment, and wing fuel tankage necessary for the range and endurance. The Britannia power plant is of the turbo-propeller type which operates most efficiently at high speeds and high altitudes, and would therefore not be appropriate for the maritime reconnaissance aircraft flight mission at low altitudes and slow air speeds. The aircraft having been designed as a civil licensed passenger carrying vehicle will require substantial redesign and adaptation to suit the military role.

The next problem to be considered has to do with design and material standards. The R.C.A.F. have established the firm and reasonable policy that aircraft built in Canada shall conform to CAP 479 "Manual of Aircraft Design Requirements for the Royal Canadian Air Force" which manual sets forth detail design and material specifications. In particular, material standards called out are North American standards. Such a policy is obviously logical from a point of view of North American continent procurement and general logistics considerations. The Britannia, designed in the United Kingdom to British Ministry of Supply design requirements and materials standards does not therefore, in all cases, satisfy R.C.A.F. requirements. Thus, an Americanization program is indicated for the adaptation.

A third problem encountered has to do with the aircraft systems. Aircraft systems include such items as electric power supply and distribution, hydraulics, pneumatics, fuel, oil, radio and communication, heating and ventilating, cabin pressurization, de-icing and anti-icing, instrumentation, armament etc. Here again the Britannia aircraft systems have been designed to meet requirements that are at large variance with those for the maritime aircraft with the result that some of these such as the electrical system had to be completely redesigned while others were adapted and changed only where required. As has been mentioned previously, the turbo-propeller power plant of the Britannia was not suitable for the maritime operation, hence an entirely new power plant was designed around a reciprocating turbo-compound engine and fitted to the aircraft.

Fig. 1. Bristol Britannia Aircraft.

The general nature of the problems having been outlined it is now appropriate to discuss some of them in more detail and indicate the solutions and necessary compromises that have been attained.

The Engineering Solution

Airframe.—The airframe is defined as the wing, body, or fuselage, tail surfaces, landing gear, power plant and nacelles. On these items two separate, but still inter-related problems are encountered. These are Amer canization and redesign.

In the case of adaptation of Britan nia structural design all material stan dards and specifications are converte from those of the United Kingdo to those of North America. Whe redesign is called for the conversio process is of course unnecessary. Th broad guides for conversion of sta dards are:—

(1) The use of materials availab in North America.

(2) The use of standard parts an hardware available in North Americ

(3) The use of equipment iten available in North America.

All conversion items are not clear cut as indicated by the rul just given. For example, some pa and equipment designed for Britann could be built in Canada followi United Kingdom standards, and therefore would be wasteful of eng neering time and cost to complete redesign to other standards. Ho ever, in these cases any requir plumbing or wiring fittings necessa for connection to the aircraft pow systems are designed to Americ standards.

In illustration of the areas of m terial standards conversion and design required on the airfran sketches are shown wherein t white backgrounds indicate th areas requiring only conversion material standards and the doul cross hatch backgrounds indic

Fig. 2. Canadair R.C.A.F. Argus.

those areas requiring complete structural redesign. Since there are areas of the airframe which require something less than complete redesign these are indicated by the single cross hatch. The sketches illustrate that the wings and tail surfaces essentially are structurally unchanged in design except for the material standards conversion process. The United Kingdom and American material standards do not, unfortunately, always agree in terms of gauge, weight, metallurgical and physical characteristics so that substitution of materials is a matter of engineering analysis and experience. The prime rules governing choice are:—

(1) Equal or greater strength, within the bounds of weight control.

(2) Equal or greater fatigue resistant characteristics.

(3) Adaptability to Canadair's tooling and manufacturing processes.

The third governing rule was violated in one major respect, namely in the case of structural metal bonding. Metal bonding is the process whereby two or more pieces of metal are structurally fastened together by means of a resin type of adhesive which is set with heat and under pressure. A considerable portion of the Britannia secondary structure is fabricated by use of metal bonding, and conversion of such components to riveting or welding fabrication would entail a large weight penalty. Therefore, it was decided that although Canadair had no experience in the use of metal bonding, the process would be used on the maritime aircraft. As a result the engineering and manufacturing divisions of the Company collaborated in choosing the particular metal bonding process to be used, setting up design and test standards, equipping the shop with the necessary tools and developing the handling techniques required for a satisfactory product.

In contrast to the cases of the wings and tail surfaces it will be noted that the fuselage or body of the aircraft requires a considerable amount of actual redesign of the basic structure, and a complete redesign of interior arrangements and furnishings. In a practical sense the fuselage redesign amounts to about 95 per cent of that required for an original design.

The power plant entails 100 per cent new design forward of the nacelle firewall due to the use of a piston engine and accessories instead

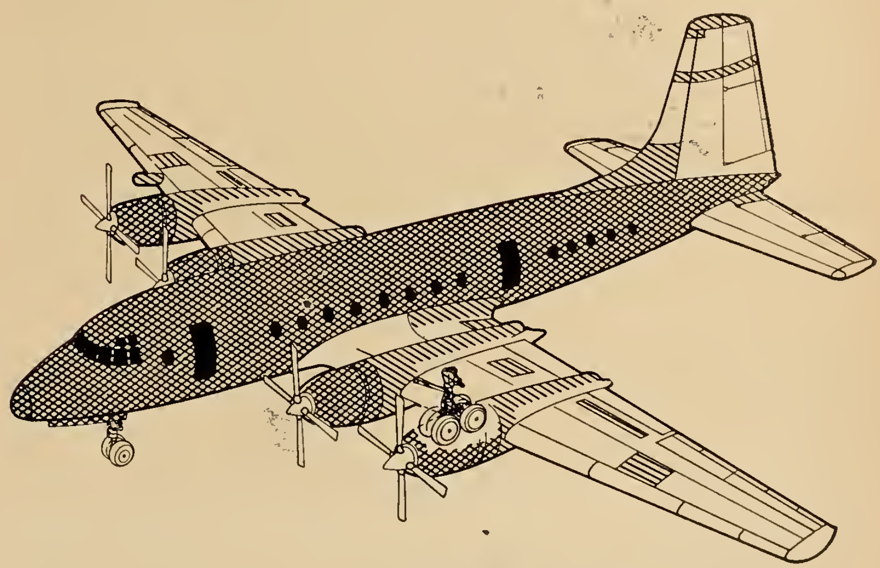

Fig. 3. Redesign Areas Britannia.

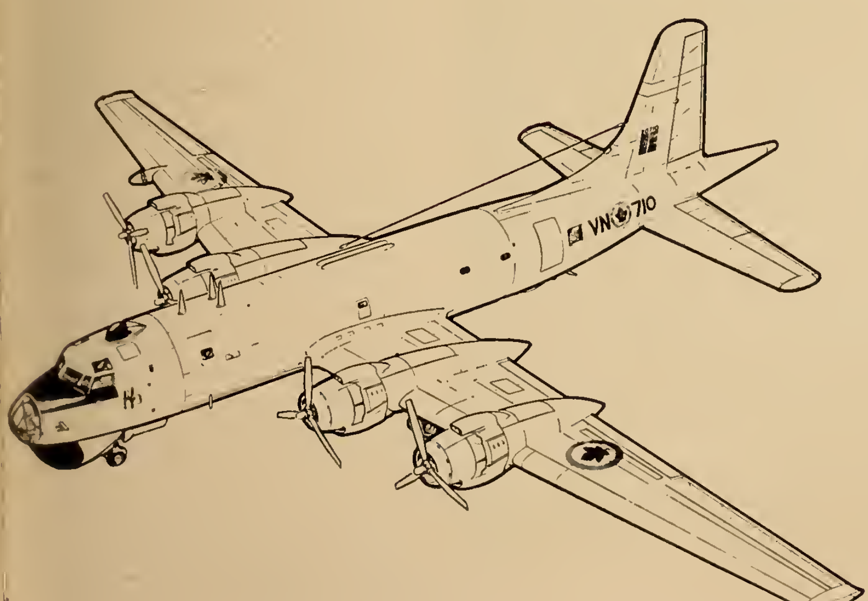
Fig. 4. Argus in Outline Form.



of the turbo-propeller type engine used in the Britannia. The engine nacelle afterbody lines are refaired as compared to Britannia since a gas turbine tail pipe is no longer used.

Aircraft Systems

A discussion of the adaptation of Britannia aircraft systems to the particular requirements of the maritime aircraft, and the complete original design of other systems which are necessary for military operation can become too involved in detail for the general scope of this article but there are three of the systems which are illustrative.

The Britannia hydraulics are designed around a 4,000 p.s.i. pressure supply and is entirely satisfactory in operation. However, practically all aircraft operated by the R.C.A.F. have 3,000 p.s.i. systems and stock supplies of pumps, pressure reducers, accumulators, fittings and lines are available in supply depots. In the interests of uniformity and long term experience, the hydraulic system was redesigned to a 3,000 p.s.i. base. At the same time the capacity of the system was adapted to a somewhat greater demand occasioned by additional hydraulically operated equipment such as bomb bay doors. A pneumatic power system which is not available in Britannia was designed, developed and utilized for sonobuoy ejection. (A sonobuoy is a type of submarine detection device). This latter system is somewhat unique inasmuch as it is the first time these particular stores have been power ejected.

The electrical power supply presents a problem of large magnitude. The Britannia power supply, sufficient for a civil aircraft, is entirely inadequate to meet the military demand. While security forbids detail mention of the various electronic devices installed in the aircraft some appreciation of the power requirements may be deduced from the knowledge that about 4,000 pounds of electronic and communication equipment requiring some 40 antennae are installed. Additionally, other aircraft services such as electrically operated controls, instruments, intercommunication speaker systems, lighting, etc., compound the power demand. A power generating system was therefore designed around a constant frequency 400 cycle a.c., 208/-120 volt three-phase power supply of 160 kva. capacity. Four, 40 kva. alternators each driven by an aircraft engine through a constant speed gear box, with complete fault protection and automatic paralleling and load division, in case of an alternator failure, comprise the main power source. Requirements for d.c. power are obtained by suitable transformation and rectification and an emergency battery powered circuit is incorporated for essential aircraft operating equipment. The 160 kva. power source in comparative terms provides sufficient electrical energy to serve about 60 average 6 room domestic dwellings, and the internal wiring of the aircraft if single stranded would cover a distance of about 60 miles.

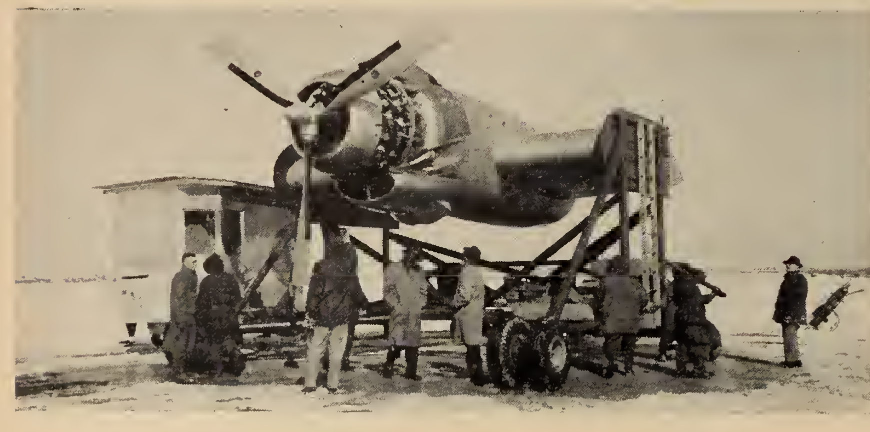


Fig. 5. Power Plant Ground Test Rig.

Fig. 6. Power Plant Ground Test Rig.

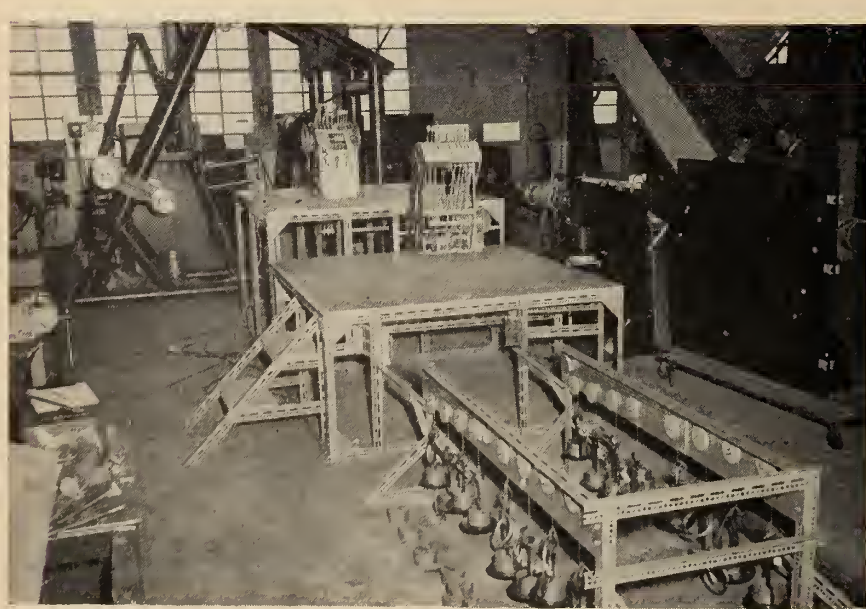

Fig. 7. Control Pedestals Test Rig.

The heating system provides heat for the aircraft cabin, and for the thermal anti-icing of wings and control surfaces. Since operation of the aircraft is required under all climatic conditions of temperature down to lows of -65° F. provision must be made for heat supply of large proportions. The civil Britannia having turbine type engines can tap engine air from the compressors as a heat source while the maritime aircraft having piston engines must have some other heat source provided. This is accomplished by the installation of four internal combustion heaters drawing fuel from the aircraft fuel supply. The four heaters have a capacity of 2,100,000 B.t.u. per hour, which again on a comparative basis would serve about 28 average six-room domestic dwellings.

Finally, on the subject of aircraft systems it can be appreciated that necessary military installations for armament, photography, search and detection gives rise to design and adaptation problems not encountered on a civil airliner.

Testing

The development and proving of airframe and systems for the maritime aircraft require a comprehensive program of model and full scale ground and air testing.

Model tests that have been made include wind tunnel, water tank ditching and metallized models for antennae radiation pattern determination.

Ground test rigs with actual aircraft parts and true simulation of loadings, component runs and cycling of operation are subjected to complete proving tests. Photographs of some of these rigs and test stands are shown.

A rigorous flight testing program worked out in conjunction with the R.C.A.F. specialist groups will be carried out on the first five to seven aircraft, and the program will run for a period of about two years.

Engineering Statistics

As an indication of the scope of the engineering program required to develop the aircraft some general statistics may be of interest.

(1) Approximately 18,000 engineering drawings are required to define some 70,000 detail aircraft parts and associated systems.

(2) Some 8,000 Bristol drawings with proper Americanization processing were utilized. The other 10,000 drawings represent the bulk of the engineering design effort.

(3) The engineering program was started in April 1954 and will be considered completed when the R.C.A.F. retires the last aircraft from active service.

(4) From the start of the engineering program to the first flight of the first aircraft represents an engineering manpower effort equivalent to about 1,000 man years. For a period of about one year manpower peaked at 530 of which 400 were direct charge.

The planning and scheduling of such a large engineering program is a major task in itself. The 18,000 drawings were broken down into about 2,000 packages, each of which could be clearly defined in terms of the problem and desired solution. The required completion date for each package was then established to match the manufacturing planning for the aircraft. Man hour estimates for each item were made and these data in conjunction with the established schedule date determined the assignment of engineering staff.

A continuous review and modification of the basic engineering sched-

ule was essential and inevitable. As the engineering program progressed various changes and modifications were requested by the customer, and some were developed by the contractor. As a result of this natural progression with time, over 400 major specification changes were negotiated and scheduled into the engineering program. This was accomplished without extending the aircraft completion date, but not without some pain, and with the wholehearted cooperation of the Canadair manufacturing division.

The manufacturing, completion and flight of the first aircraft within the originally scheduled dates are an achievement regarded with some pride by all of Canadair Limited.

Annual Meeting Papers

A limited number of copies of the text of the papers presented to the 71st Annual Meeting, at Banff, in June, are available from Institute Headquarters. The Foundation Failure of the Transcona Grain Elevator

A. Baracos, M.E.I.C.

Department of Civil Engineering, University of Manitoba

THE METHODS of soil mechanics development in the past twenty-five years have made possible the determination of the ultimate bearing capacity of soils. The safety factor necessary for sound engineering practice precludes correlation of the ultimate bearing capacity with the analytical determination of the bearing pressures for the impending failure. Thus only on rare occasions when actual failure occurs is a correlation possible. The foundation failure in 1913 of a million-bushel grain elevator at Transcona, a few miles from Winnipeg, Manitoba, provides such an opportunity. It is the purpose of this paper to correlate the data on the foundation failure of the Transcona grain elevator with a recently completed field and laboratory soil mechanics investigation using the latest analytical methods.

At the Building Research Congress held in London, England, in 1951, a notable paper on "The Bearing Capacity of Clays" was presented by Dr. A. W. Skempton[1] The Transcona elevator failure was used by this author as one of his examples and is included in his table of "Field Data on Ultimate Bearing Capacity of Clays". The table, however, was incomplete as presented, with data on actual soil properties missing for two structures, one of them the Transcona elevator.

Another speaker on the same program as Dr. Skempton was R. F. Legget, M.E.I.C., Director of the Division of Building Research of the National Research Council, Ottawa. As he was speaking about "Special Foundation Problems in Canada", Mr. Legget also used the Transcona elevator as an example! In discussion, the desirability of completing the table in Dr. Skempton's paper was stressed. Mr. Legget thereupon promised at the meeting to expedite the study of this foundation failure. This paper prepared cooperatively by the Division of Building Research and the University of Manitoba represents the fulfilment of that promise.

Owing to the necessity of completing other outstanding soil and foundation studies, it was not until late in the summer of 1952 that the work herein described could be started. Only then was it found that some time previously two soil borings had been put down at the site of the elevator under the direction of Professor R. B. Peck, of the University of Illinois. Unfortunately, it was then too late to correlate the proposed Canadian investigation with Dr. Peck's work but it was decided to proceed as planned.

Dr. Peck has now published his results[2], accompanied by an eye-witness account of the failure by Mr. L. Scott White[3]. The investigation now to be described was rather more extensive than the American study, the two being generally complementary, agreement between the various test results being reasonably close, even though carried out quite independently except for a check by the author on a few of the soil samples obtained by Dr. Peck.

Although the foundation failure of the Transcona grain elevator occurred as long ago as 1913, the conditions involved have since frequently been discussed in connection with soil mechanics problems. The author describes a recent investigation made jointly by the Division of Building Research, N.R.C., and the University of Manitoba.

General Description of the Structure

Development of Canada's vast wheat lands in the early part of this century resulted in serious congestion of the Winnipeg railroad yards during peak periods of grain movement. Construction was therefore started in 1911 on the Transcona elevator in conjunction with one of the world's largest railroad yards to facilitate rapid grain movement and to give relief to the Winnipeg railroad yards.

The plan of the elevator is shown in Fig. 1. It consists of a dryer house 18 by 30 by 60 feet high, work-house 70 by 96 by 180 feet high, and the bin house 77 by 195 by 102 feet high, all constructed mainly of reinforced concrete. The foundation failure occurred under the bin house which was designed for storing one million bushels of grain. It consists of 65 circular bins arranged 13 in each of 5 rows running north and south. The 48 interstices between bins are also used for storing grain. A raft foundation, of reinforced concrete 2 feet thick, supports the bins and the conveyor tunnels under the bins. The depth to the bottom of the footings was 12 feet below the ground surface. The design bearing pressure was 6,600 lb. per square foot based on load bearing tests for which the data are no longer available. Dead weight of the bin house was very nearly 20,000 tons.

General Description of Soils

Greater Winnipeg lies in the basin of the glacial Lake Agassiz which existed during the recession of the Wisconsin ice sheet. Generally, in this area, the soils may be conveniently grouped as follows. The top 10 feet or less consist of relatively recent deposits of organic soils, flood-deposited silts and silty clays and outwash from higher ground, and modified lacustrine deposits. Under these are found 40 feet or less of glacial lake deposits forming two distinct layers of approximately equal thickness. The top layer is a brown clay and is distinctly varved with many fractional inch-thick layers of silt spaced between layers of clay ¼ inch or more thick. The bottom layer is a grey-coloured clay, softer than the overlying material and having numerous calcareous silt pockets and containing limestone gravel and stones at the greater depths. Beneath the clays are found glacial deposits of rock flour, silts, sands and gravel. The upper portions were deposited as the glacier receded and are underlain by subglacial drift which has been acted on by the full weight of the ice sheet. The subglacial drift is highly consolidated and supports many of the heavier structures in the Winnipeg area. The total thickness of the drift is about 10 feet but varies considerably from this value. The entire area is underlain by Ordovician limestone.

Description of Failure

The storage of grain in the bin house was begun in September, 1913, with considerable care taken to distribute the grain uniformly. On October 18, when 875,000 bushels of wheat were stored, a vertical settlement of a foot was noted within an hour after movement had been detected. The structure then began to tilt to the west and within 24 hours was resting at an angle of 26° 53′ from the vertical and the west side was 24 feet below its original position. The east side had risen 5 feet above original elevation. Eye witness accounts[3,4] stated that the structure acted monolithically with only a few superficial cracks appearing. Its coming to rest, approximately 24 hours after the movement began, corresponded with the cupola falling off the top of the structure.

It was reported that during the failure, the soil around the structure rose to a height of 5 feet above the ground surface around the entire bin house. Photographs taken after the failure show that the greatest upheaval occurred on the west side and was considerably more than 5 feet.

Calculations based on the dead weight of the bin house, 20,000 tons, and 875,000 bushels of wheat at 60 lb. per bushel, give a unit uniformly distributed pressure of 6,200 lb. per square foot on the clay when failure took place.

The operations to right the structure have been reported in detail by Allaire[5]. The structure has been in successful use since its position was restored.

Above: West side of elevator, showing tilt and soil upheaval. Below: East side following foundation failure; early stages of righting operations are shown under way. (Photos: Foundation Company of Canada Limited.)

Field and Laboratory Investigation

Figure 1 shows the location of seven test holes used to obtain samples for the laboratory tests. Holes 4 and 7 were sufficiently removed from the structure to avoid disturbances caused by the failure and the righting operations.

The remaining holes were located nearer the structure, some 60 feet from the bin house, in an effort to ascertain the effects of failure. It was realized, however, that these holes would show the effects of almost 40 years of continued pumping that has taken place since the bin house was righted. Pumping has been necessary to keep the bottom of the bin house dry. After righting, the bin house was approximately 34 feet below the prairie grade. It was not considered practical to place the test holes any closer to the structure as the entire area nearer the building was disturbed by tunnelling, excavation, etc., during the righting operations. To keep the bins dry, a 12-foot-deep trench had, in addition, been excavated around the bin house on all but the south side, further discouraging test holes any closer to the structure than those indicated.

The holes were bored to refusal at a depth between 40 to 50 feet where the dense and coarse glacial deposits were encountered. A diamond drill adapted for taking thin wall Shelby tubes 2 inches in diameter was used for boring and sampling. Samples approximately 2½ feet long were taken at 5-foot intervals or less where changes in soil were evident.

All samples were examined in the laboratory and notes made on colour, stratification, etc. On each sample, moisture contents, density, degree of saturation, and unconfined compression strengths were determined. On representative samples, grain size, Atterberg limits, undrained quick triaxials under constant load increments, specific gravity, and consolidation tests were performed. The unconfined compression and the undrained triaxial tests were performed on undisturbed samples trimmed to 1.5 inches diameter and approximately 3.0 inches long. Both the field and laboratory testing were conducted during the autumn of 1952 and winter of 1952-1953.

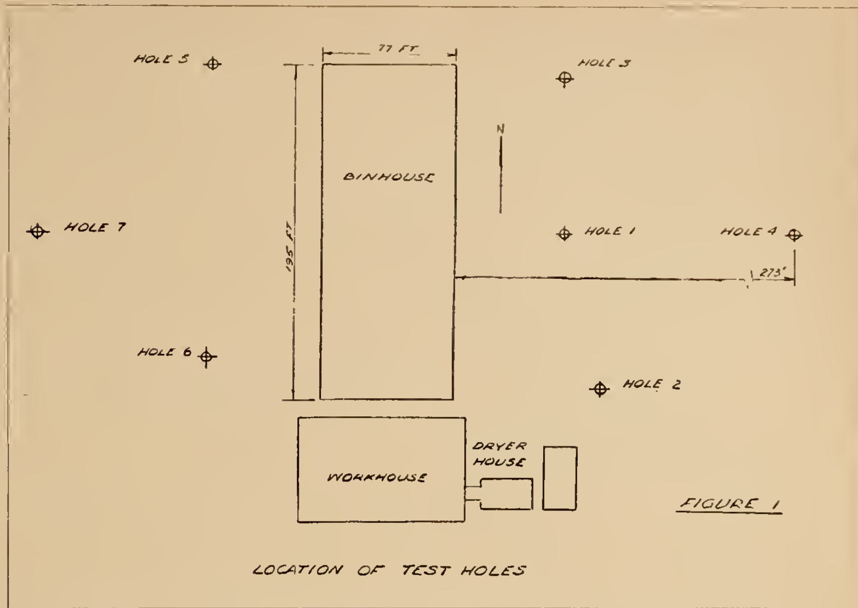

Fig. 1. Plan of the Transcona elevator.

Test Results

Typical results of the tests are shown in the Log of test hole 4, Fig. 3. No tests were performed on the material above 10 feet in holes 1, 2, 3, 5, 6, and 7 where fill placed during the righting of the elevator was encountered. Hole 4 showed the silts and silty clays as they probably were over the entire area prior to the excavation for the foundations.

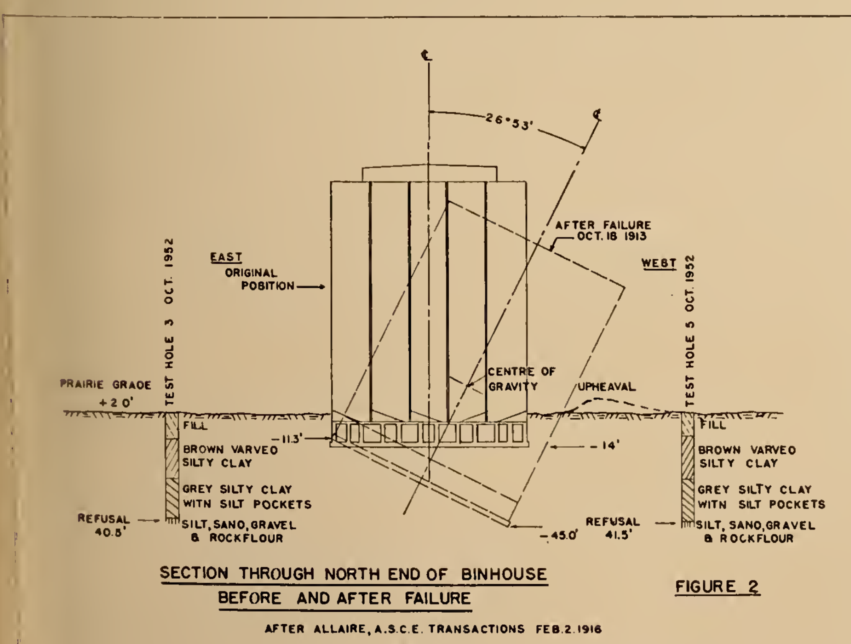
Below the 10-foot level to a depth of 20.5 feet in hole 4, and from 25 to 26 feet in the other holes, a brown highly stratified or varved silty clay was found. The stratification or varves were more or less horizontal and consisted of layers of silt of fractional inch in thickness between closely spaced layers of clay approximately ¼ inch thick. Average test results for this material were as follows:

Unconfined compressive strength (lb./sq.ft.)	2160
Liquid limit	85.3
Plastic limit	29.3
Moisture content (%)	52.4
M.I.T. grain size grouping (%)	
clay 49.4; silt	42.8;
sand 7.4; gravel	0.4
Unit weight of soil (lb./cu. ft.)	107

Under the brown silty clay to a depth of 40 to 45 feet from the surface, a highly plastic grey silty clay was found with numerous tan-coloured calcareous silt pockets and limestone pebbles. This material had about the same moisture content as the overlying brown silty clay and a lower unconfined compressive strength. In holes 1, 3, and 7 the bottom few feet of the grey silty clay were found to be very moist and soft. Holes 1 and 7 showed no distinct boundary between the grey silt and the underlying glacial drift. About 3 feet of a mixture of both materials formed a transition layer. Average test results for the grey silty clay excluding the very moist material encountered in holes 1, 3, and 7 and the transition layer were as follows:

Unconfined compressive strength (lb./sq.ft.)	1641
Liquid limit	75.9
Plastic limit	22.8
Moisture content (%)	49.9
M.I.T. grain size grouping (%)	
clay 38.7; silt	44.5;
sand 13.0; gravel	3.8
Unit weight of soil (lb./cu. ft.)	110

Because of the wide variation in the bottom grey silty clay and the transition layer, no average values are given.



All the samples below the 10-foot depth showed complete or near complete saturation. Twelve undrained triaxial tests on samples from hole 2 confirmed a negligible angle of internal friction for this type of loading. The consolidation test results (for samples from hole 4) indicate a decrease in compressibility with increased depth. Swelling pressures determined by permitting undisturbed samples to swell under a small load and determining the pressure required to return the sample to its original volume, range from 560 to 2050 lb. per square foot and are typical of the Greater Winnipeg clays which contain about 30 per cent of the more active clay minerals (montmorillonite). Preconsolidation pressures are not accurately determined on these clays but indicate that they are somewhat in excess of overburden pressures probably due to desiccation. The void ratio pressure curves are shown in Fig. 5.

The glacial drift was encountered at a depth of 40 to 45 feet. The change from material deposited during the recession of the ice sheet to the subglacial drift appeared to be indicated by a decrease in moisture content approaching or below the plastic limit. Up to 4 feet of the less dense drift were found. Boring refusal was encountered in the subglacial drift corresponding to the depth to which the north end of the bin house settled following the failure. Numerous stones prevented strength and consolidation tests from being performed on the glacial drift. The following data, however, were obtained:

Natural moisture content range (%) 10.0– 13.4
Moist density (lb./cu.ft.) 157. –143
Liquid limit, average 21.0
Plastic limit, average 11.9
M.I.T. grain size grouping (%)
clay (rockflour) 6.0; silt 33.6; sand 32.3; gravel 28.1

The test holes were not extended to the underlying limestone. Eight test holes bored by the owners of the building have shown, however, that the limestone bedrock was at a depth of approximately 50 feet.

Theoretical Bearing Capacity

The relatively rapid loading of the elevator on saturated clay corresponds to the laboratory undrained quick triaxial test for which the unconfined compression test is a special case. For such conditions it is recognized that the angle of internal friction is negligible and thus the cohesion is equal to half the unconfined compressive strength.

In general the ultimate unit bearing capacity of a soil may be expressed by:

$$q_u = N_c c + N_q y d + N_y y \frac{B}{2} \quad \dots\dots (1)$$

where q_u = ultimate unit bearing capacity
c = cohesion
y = unit weight of soil
B = width of footing
d = depth of cover on footing

For long continuous footings, the quantities N_c, N_q, and N_y are pure numbers depending on the angle of internal friction, ϕ. Their values are given in most modern soil mechanics or foundation texts.

For the special case of $\phi = 0$, N_q becomes unity and $N_y = 0$. The equation thus becomes:

$$q_u = N_c c + yd \quad \dots\dots\dots\dots (2)$$

Prandtl, in an early form of equation (2) evaluated Nc as 5.14 and Terzaghi[6] gives 5.7 for general shear failure and 3.8 arbitrarily for local shear failure. The general shear failure applies when the stress-strain curve (from laboratory tests) is of the type shown in Fig. 4a, or is approached when negligible variation exists in both loading and soil conditions.

For rectangular footings the value of Nc has been shown by analytical methods, model studies and a study of actual failures to be a function of $\frac{L}{B}$ and $\frac{d}{B}$, where L = length of footing. Recently, Skempton[1] has given the following formula:

$$N_c = 5(1 + B/5L) \, . \, (1 + d/5B) \quad \dots (3)$$

The theory for equation (1) assumes that the soil fails along a composite curve as shown in Fig. 4B. Although the theory is beyond the scope of this report, it may be noted that when ϕ = o, the composite curve extends to a depth below the bottom of the footing equal to approximately one-half the footing width. As failure commences, there is a rise of soil on both sides of the footing attributed to "edge action". Complete failure is associated with a further large upheaval on the side to which the building tilts.

Stability Analysis

A general examination of the actual failure and test data shows that the failure was consistent with the bearing capacity theory. The undrained quick triaxial test confirmed a negligible angle of internal friction. The composite curve along which the soil failed would have theoretically extended to a depth equal to about one-half the foundation width or 38½ feet below the bottom of the foundation. Since the dense glacial till occurred at approximately the same depth, it did not prevent the full development of this curve.

It may also be noted that the soil upheaval all around the foundations due to "edge effect" at the start of failure actually occurred. Allaire[5], reports an upheaval of 5 feet. Photographs confirm that further large upheaval consistent with theory occurred on the side to which the structure tilted. The actual direction of tilting is not important as even a very minor eccentricity in loading or variation in soil condition could cause a failure to either side.

The nearest test holes to the structure on the side of tilting were 63 feet distant and from the examination and testing of undisturbed samples, the soil appeared to be unaffected by the failure. Although the failure occurred nearly 40 years ago, it is not believed that the loss in strength of the soil resulting from the failure has been regained. Tests on similar Lake Agassiz deposits[7] do not indicate any extensive thixotropic strength regain for this material. Although no remoulded strength tests were performed, it has been generally found that remoulding results in a loss of one-half of the strength of the Winnipeg clays.

It is also reasonable to assume that because of the nature of the laboratory stress-strain curves and the precautions taken to assure uniform loading of the elevator, that the Terzaghi general shear conditions were satisfied. It is questionable, however, whether the assumption of local shear value (N_c = 3.8) would have been applicable had the stress-strain curves been different.

The undrained quick triaxial test confirmed that the angle of internal friction was negligible and that equa-

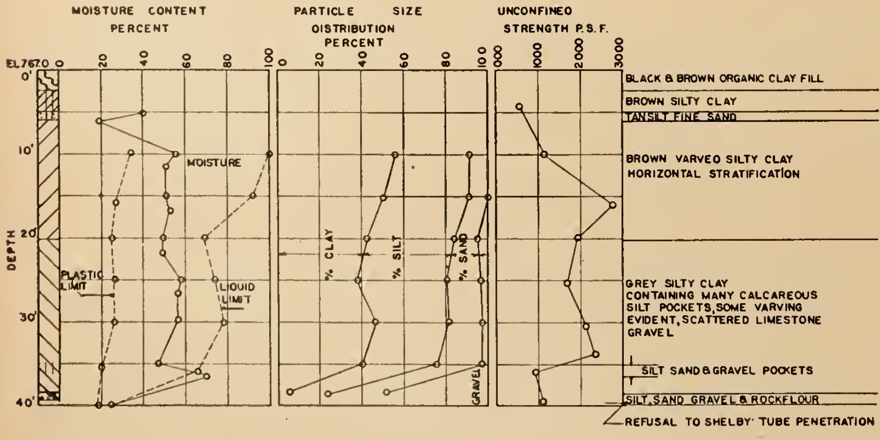


Fig. 3. Typical test hole log. (Test hole 4.)

tion (2) was valid. Substitution in equation (3) with:

$B = 77$, $L = 195$, and $d = 12$ (all in feet) gives $N_c = 5.56$. The ultimate bearing capacity is thus given by:

$$q_u = 5.56c + 12y \qquad (5)$$

It was difficult, however, to ascertain what value of the cohesion should be used in (5). The values for the brown silty clay or the grey silty clay alone would be unjustifiable high and low respectively since the failure plane passed through both materials. Use of the average unconfined compressive strength value of 1850 lb. per square foot for both the brown and grey silty clays from holes 4 and 7 appears the most justifiable. The same value for the remaining test holes 1, 2, 3, 5, and 6, nearer to the building, was 1933 lb. per square foot and probably reflects the effects of consolidation caused by the continuous pumping from under the bin house for a period of almost 40 years. Moisture contents and densities for the grey silty clay when compared for holes 4 and 7 with those of 1, 2, 3, 5, and 6, also indicate the effects of consolidation

	Holes 4, 7	Holes 1, 2, 3, 5, 6
Average moisture content (%)	51.9	48.9
Average moist density (lb./cu.ft.)	107.8	112.2

The average unconfined compressive strength values of 1933 lb. per square foot for holes 1, 2, 3, 5, and 6, and 1850 lb. per square foot for holes 4 and 7, do not include the low values from the 35- to 40-foot depth from holes 1 and 3, and hole 7 respectively. The difference in the values of cohesion, density, and moisture content mentioned, however, are small and could simply reflect statistical accuracy.

Results of substitution in equation (5) are shown in Table I. The unit weight, Y, of the soil covering the footings was taken as 107 lb. per cubic foot and the cohesion as half the unconfined compressive strength.

Discussion

The ultimate theoretical bearing capacity of 6420 lb. per square foot using the most justifiable value of unconfined compressive strength, 1850 lb. per square foot is remarkably close to the actual bearing capacity at failure of 6200 lb. per square foot. The correlation is even better than statistical considerations of the data

Table I

Based on results for:	Average unconfined compressive strength (lb/sq.ft.)	"q_u" ultimate bearing capacity (lb/sq.ft.)
Brown silty clay — all holes	2160	7280
Grey silty clay — all holes	1641	5840
Brown and grey silty clay		
all holes	1933	6660
holes 1, 2, 3, 5, 6	1960	6730
holes 4, 7	1850	6420

Note: actual ultimate bearing capacity = 6200 lb/sq. ft.

Preliminary Estimates of Probable Maximum Precipitation Over Southern Ontario

J. P. Bruce

Department of Planning and Development, Ontario

ENGINEERS CONCERNED with the construction of dams for flood control and other purposes, have long sought a rational method of determining the maximum flood-producing capabilities of rivers. In many cases it is considered necessary to design spillways so that the discharge capacity will accommodate the maximum flood. This is especially true when high dams are constructed upstream from urban centres, and earth-fill construction is used. In these cases overtopping of the dam would likely result in failure and subsequent loss of life and property damage.

It is possible to approach the determination of the maximum flood of a watershed area in several ways. One common method is to apply large safety factors to the greatest flow recorded during the period of record on the stream. Another approach is to try to estimate, by statistical methods, a flow magnitude of sufficiently long return period from the flow records available. A third method is to begin with estimates of the maximum rainfall (or rainfall plus snowmelt) likely to occur over the basin, and by means of infiltration indices and design unit hydrographs convert to maximum flow. This study is concerned with providing the basic data for a determination of the third type, and contains estimates of the physical upper limits to rainfall that could occur over Southern Ontario.

Statistical techniques fail us in this problem, even though we may have up to 100 years of rainfall records at a station within a watershed. It is possible to assess, from the 100-year record, the number of inches of rain that will occur, on the average, once every 100 years (100-year return period storm) at the station. However, as Court[1] has shown, the chance of a 101-year return period storm occurring within any given 100 years is 63 per cent. Thus, there is a 63 per cent chance that a structure, designed for the 100-year return period storm, will have its capacity exceeded during its lifetime, if built to last 100 years. In order to have a 95 per cent confidence that a 100-year structure will not be overtaxed in its lifetime, it should be designed for a 1950-year return period flood. The impossibility of accurately assessing a storm or flood magnitude of such a return period from 10 to 100 years of records by a statistical approach, and the inadequacy of even a 95 per cent confidence in a structure, the failure of which could not be tolerated, makes a study of probable maximum precipitation, based on storm rainfall data and meteorological theory, an essential part of establishing design criteria for flood control structures.

The United States Army's Corps of Engineers has recognized this, and has supported the Hydrometeorological Section of the U.S. Weather Bureau since 1938, to perform such studies. "Standard project storm" studies are also conducted by the Hydrometeorological Section to aid in the design of river structures for which something less than the most stringent criteria may be applied. Several U.S.W.B. publications[2,5], give isohyetals of maximum rainfall across the southern part of Ontario. However, it has been found that these lines were drawn by geographical extrapolation, and that the meteorological conditions peculiar to Southern Ontario were not considered to any great extent in their construction. That is, these estimates were not intended for use in this province.

Method

The Hydrometeorological Section's pioneering maximum precipitation studies[3,4,5] outline techniques applicable to parts of North America to which the "generalized estimates" of the U.S.W.B. do not apply directly. The basis of the method is storm transposition and maximization. The idea of storm transposition is to increase the meteorological experience of the area studied, by considering not only severe storms which have occurred in that area, but also storms which occurred in meteorologically similar adjacent areas. After studying these storms and analysing the rainfall that accompanied them, maximization techniques seek to determine by what percentage the actual storm rainfall could have been increased by physically possible increases in the meteorological factors which affect the rainfall volume.

There are two basic types of upward adjustments applicable to storm rainfall amounts to obtain probable maximum figures. One is an adjustment for higher moisture content of the rain-producing air mass involved and the other is for maximum mechanical efficiency of the storm. The latter type of maximization has been found to be impracticable for three reasons given by Paulhus and Gilman[6].

(1) Little is known of the structure of storms and the factors controlling their efficiency, so the problem of maximization is very difficult to approach.

(2) Major observed storms have undoubtedly produced heavy preci-

pitation because of their high efficiencies rather than high moisture charge. Thus a fairly long record of storms over, or transposable to, the area concerned, should provide one or more of near maximum mechanical efficiency.

(3) "It is generally suspected that the maximum efficiency of a storm is realized when the moisture charge is not a maximum." Thus moisture maximization is likely an over-adjustment for this factor and compensates for absence of adjustment to mechanical efficiency.

The moisture adjustment technique is discussed at length in the U.S.W.B. Hydrometeorological Report No. 23[2]. The basic concept involved is that, assuming a saturated atmosphere with pseudo-adiabatic lapse rate, the moisture content of the air mass is a single valued function of the 1000 mb. dew point. This type of moisture and temperature distribution is closely approached in areas of marked convergent flow and upward motion of the air, as are found near storm centres. This distribution also represents the maximum moisture content of air, of given 1000 mb. dew point, which is undergoing lift to produce precipitation.

The moisture charge of a unit column of air can be determined in terms of precipitable water which is defined as the equivalent linear depth of water in the unit column if all water vapour is condensed. It is given by

$$W_p = \int_0^{P_0} \frac{q}{g\,w}\,dp$$

where q = specific humidity
w = density of water
P_0 = pressure at bottom of air column
g = accel. of gravity.

A graphical solution, assuming a saturated pseudo-adiabatic distribution, in terms of 1000 mb. dew point is available in many publications[7,8,2]. However, precipitable water is really a misnomer as no natural precipitation process removes all the moisture from the air.

The amount of water that can be precipitated from a column of air is known as the effective precipitable water (W_e). W_e is a function of the assumed flow pattern and is indeed a measure of the efficiency of any flow model postulated, when the model is varied at constant dew point. It has been found, however, that the ratio of W_e's at two different dew points is practically independent of the inflow-outflow model, and also that this ratio is very nearly that of the W_p's at the dew points in question (2). From the graphical solution of the equation above a curve giving the effective precipitable water at any 1000 mb. dew point as a percentage of maximum W_e (at dew point 78° F.) has been obtained[2].

Ontario Storm Types

The storms which have produced greatest rainfalls in Southern Ontario in the past, and are most likely to do so in the future, fall into two main categories. These are: (I) "decadent" tropical storms, and (II) thunderstorms formed by squall lines or cold fronts, or within moist, potentially unstable, hot air masses. In the U.S. Hydrometeorological Section report No. 2, on the Ohio Basin above Pittsburgh, it was found that for short durations and small areas, type II storm is most effective in producing heavy rain, but for large areas and longer durations, the type I storm provides greatest rainfall depths, in this area.

The subject of this paper is of particular interest at present to hydraulic engineers, in view of recent unprecedented storms such as Hurricane "Hazel". The paper is reproduced by permission of the Director, Meteorological Branch, Department of Transport.

The thunderstorm type is a midsummer phenomenon and generally follows an unusually hot and dry period. Interception and initial loss of rain to infiltration are likely to be at a maximum. The tropical storm type is dealt with at some length by Mason[9] who studied the twenty-five former hurricanes which passed over or near Ontario between 1900 and 1949. He found that of these, eight were of extraordinary severity and that the common feature of each was that they moved inland as hurricanes into regions of substantial horizontal temperature gradient. If this temperature gradient was strong enough to define a frontal zone, the storms became intense frontal lows. These circumstances produced the most devastating storms of record in Southern Ontario. Outstanding examples are the storms of September, 1878, August, 1915, September, 1932, and October, 1954, but complete listings since 1900 are given in Mason's study. The north-south quasi-stationary front or slowly moving cold front is thus an essential feature of any major storm in Ontario of tropical hurricane origin. Therefore, light to moderate persistent precipitation in the vicinity of such a front is very likely to produce abnormally low initial infiltration rates, for the fall season, prior to the major cyclonic centre's passage. In summary, the run-off to rainfall percentage for the tropical storm type will be much higher than for the summer thunderstorm type due to higher antecedent precipitation and to a general decrease in the initial infiltration loss and interception as the autumn season progresses.

Available Storm Data

The U.S. Corps of Engineers has for some years now supported studies of the rainfall of major storms which have occurred in the United States. The results of this work are found in "Storm Rainfall in the U.S."[10], which gives depth-duration-area (D.D.A.) data for some 500 storms. The D.D.A. data are in tabular form and give the maximum observed rainfall for areas of 10 sq. mi. to 70,000 sq. mi. and durations of 6, 12, 18, 24, etc., hours for each storm studied. Unfortunately, no such studies of Canadian storms have been conducted, except for a very few by the U.S. Weather Bureau. This is a serious difficulty in attempting to estimate probable maximum precipitation. However, a preliminary solution has been arrived at by using the information for pertinent storms reported on in "Storm Rainfall in the U.S." and performing an analysis of the rainfall of the most severe storm on record in Ontario, storm "Hazel" (Oct. 14-15, 1954).

Analysis of Storm "Hazel"

A full description of the meteorological aspects of this storm has been given by Knox[11] and an account of the associated precipitation patterns by Thomas[9]. Suffice it to note here that the period of really intense precipitation north-west of Toronto, from 1800-2400 hours on October 15, occurred as a frontal low (which Knox calls Hazel II) spawned by the hurricane (Hazel I) and passed northward through Southern Ontario at a rate of about 50 m.p.h.

The depth-duration-area analysis

of the rainfall of this storm was accomplished by first constructing isohyetal charts for 48, 36, 24, 12 and 6-hour precipitation. The official records[9] were augmented by the field survey observations taken by Dr. D. V. Anderson of the Ontario Department of Lands and Forests, immediately after the storm in the northern sections of the Humber Watershed and adjacent areas. The figures given by Anderson which were used are shown in Table A.

Reports 1 and 2 corroborate each other to within one inch, as, by matological observers giving 12-hour precipitation amounts and occasionally beginning and ending of rainfall were obtained by the Meteorological Division for the storm period. Synthetic mass curves of rainfall[13] were constructed for each of these 33 locations using the special reports and shaping the curves in accord with the hourly rainfall intensities observed at the nearest continuous recording gauge. Examples of the results of the technique applied to Snelgrove and Bradford for storm "Hazel" were given by Thomas[9]. This procedure was also followed for 4 first-order stations which had reported 6-hour precipitation amounts.

From the mass curves it was found that for the central 5,000 square miles contributing to the depth-duration-area (D.D.A.) values, the intense rainfall for 6, 12, 24, and 36 hours was within two hours of being simultaneous. As two hours is within the possible error of construction of the synthetic mass curves and as the problem in hand was the determination of maximum precipitation, it was decided to plot the maximum rainfall intensities at each station for each duration in the construction of the isohyetal charts.

These charts were then planimetered, and calculations performed as in Table I. The results were plotted on semilogarithmic paper and enveloping curves drawn (Fig. 3).

Table A. Field Survey Observations — Hurricane "Hazel"

	Rainfall (inches)	Remarks
(1) Thompson Lake A	7.6± 0.2	In tub set out 151745E
(2) Thompson Lake B	12± 1	45 gal. drum empty 13th
(3) Nobleton	9± 1	Cement trough empty 14th
(4) Richmond Hill	8± 1	Garbage pail empty 15th a.m.
(5) Cedar Mills	8± 1	Pail empty 15th a.m.

1745E, 3.4 inches of rain had fallen at Malton Airport. This suggests that the total 48-hour rainfall at Thompson Lake (north-east of Bolton) was about 11 inches and this figure was used. Number 3 was taken to be a 36-hour fall and numbers 4 and 5 were taken as 18-hour amounts as the rain in this area ended about midnight on October 15. Report No. 1 led to an acceptance of 7 inches as the maximum 6-hour rainfall amount at Thompson Lake. It is interesting that the U.S.W.B. Technical Paper No. 2[12] noted that unofficial reports, such as Anderson's, usually are about double those of the nearest first-order station. The Malton 48-hour rainfall was 6.03 inches, and that given for Thompson Lake is 11 inches. Malton was the closest first-order station to the centre of heaviest rainfall.

The 48-hour rainfall chart was obtained by plotting official Canadian rainfall amounts for the two "precipitation days" October 14-15 ending at 8 a.m., October 16, Anderson's figures above, and U.S.W.B. figures for stations along the south shores of Lake Erie and Lake Ontario. These two days cover the period of maximum rainfall intensities for all areas contributing to the D.D.A. values. The construction of isohyetal charts for 36, 24, 12, and 6 hours were based on reports from the continuous recording gauges in operation at Guelph, St. Thomas, Kitchener, London, Toronto, Malton, and St. Catharines.

Other Storms

The storms, other than "Hazel", considered here, are reported on in several publications. The only other "decadent tropical storm" of intensity to compare with that of October, 1954, was the September, 1878, storm, which caused widespread flood damage in northern Ohio. The heavy rainfall area of this storm extended into Southern Ontario. Accounts of this storm and depth-duration-area data may be found in references (4) and (10).

Of the thunderstorm occurrences analysed in "Storm Rainfall in the U.S.", four were found to yield limiting depth - duration - area figures when maximized and transposed to the Michigan peninsula area (and by implication to Southern Ontario). These occurred at (i) Beaulieu, Minn. and Ironwood, Mich. July 18-23, 1909, (ii) Cooper, Mich. Aug. 31-September 1, 1914, (iii) Stanton, Neb. June 10-13, 1944, and (iv) Baydon, Iowa, Sept. 17-19, 1926.

Transposition Limits

The question to be answered when considering the transposition of any of these U.S. storms to Ontario is, "could a storm of this type and similar mechanical efficiency occur over Ontario?" To answer requires a study of several corollary problems. (1) Do subsiding currents of dry air aloft, on the east side of the Rocky Mountains, combined with low level flows of moist hot air directly from the Gulf of Mexico, produce widespread and intense potential instability conditions in the mid-western United States not possible over Southern Ontario? (2) Do the Great Lakes exert a significant influence on low level instability of very moist air with trajectories over them, and thus inhibit thunderstorm activity to some extent? (3) Should the location of such storms with respect to the general circulation patterns of the hemisphere impose a limit on the distance over which they may be logically transposed? These are problems which are largely unsolved scientifically and the present state of meteorological knowledge allows answers only on the basis of synoptic experience of weather situations, and climatological data.

From these two points of view, the Sept. 1878 hurricane-spawned storm could very easily have centred over Southern Ontario with little change in intensity. It was very similar to storm "Hazel" and the heaviest reported rainfall was 12.2 inches in 24 hours, 15.0 inches in 66 hours. The only factor affecting its transposition to Ontario is latitudinal. McCormick[14] has found that for areas of 500 to 5,000 sq. mi. and periods of 24 hours and greater, observed rainfall amounts decrease by 2 per cent per degree of latitude north of 30 degrees North in this continent. For smaller areas and shorter periods the factor is very slightly less than this. This reduction of rainfall depths northward from 30° N is attributed to two factors:

(1) The decrease of possible maximum moisture content of the tropical air mass as it is further removed from the Gulf of Mexico or Atlantic source region, and

(2) The decrease in possible maximum vertical velocities, which is associated with the decrease in theoretical and observed maximum horizontal wind speeds in the troposphere, north of 30 degrees North, as discussed by Rossby[15].

The moisture adjustment of this storm will be discussed in the next section. The latitudinal adjustment made was a reduction of 5 per cent (for 2½ degrees) for transposition of the heavy rainfall centre to Southern Ontario.

The transposition of the four thunderstorm occurrences requires more difficult decisions. The Cooper, Mich., storm was one which is of a common type in Ontario, and the warm sector in which the precipitation occurred passed over southern Lake Michigan and was thus subject to whatever stabilizing effect the passage over a section of the Great Lakes might have. Thus this storm has been considered completely transposable to Ontario, and has been adjusted only for moisture content as discussed below ("Moisture Adjustments").

Storm (1), at Beaulieu, Minn. and Ironwood, Mich. occurred during July when the Great Lakes' effect on stabilizing the lower levels of a hot, moist air mass would be at a maximum. However, as there is some doubt as to the significance of this effect on storms giving rainfalls as great as these, and as the consideration here is one of maximization of rainfall, it was decided to consider this storm directly transposable to southern Ontario.

The remaining two storms occurred in the mid-western section of the U.S. wherein the first factor mentioned under "Transposition Limits" (above) has an effect on the maximum precipitation possible in the area. There is a very marked difference in observed precipitation figures and various return period storm intensities calculated therefrom, between the Nebraska-Iowa region on the one hand and the Michigan peninsula-Ontario area on the other. This is illustrated clearly in Yarnell's[16] chart for 24-hour rainfall to be expected once in 100 years. This is reproduced as Fig. 1 with the locations of the Nebraska and Iowa storms marked. While the synoptic weather situations which produced these two thunderstorm series are not unknown in Ontario, it is clear that the rainfall production capabilities of the region in which they occurred is significantly greater than that of southern Ontario. Thus the storms have been considered partially transposable to Ontario. That is, the storm rainfall amounts have been increased to the maximum for the area in which they occurred by a moisture adjustment, and have then been transposed to Ontario by the application of a reduction factor. This factor is an index of the ratios of rainfall production capabilities of the mid-western U.S. and Southern Ontario. It was derived from the ratio of 100-year return period point rainfall of the two regions in question (4.0 in./6.1 in. from Yarnell's chart). As a check on Yarnell's figures, the most recent figures of 100-year return period point rainfall for stations in Iowa were averaged and yielded a figure of 6.5 in. To check the Ontario figure, the Gumbel distribution[22] was applied to the precipitation data for Toronto for the period 1900 to 1955. This gave a 100-year return period rainfall of 3.9 in. Thus the ratio 4.0/6.1 does not appear to be an excessively low index for transposition of these storms to Ontario.

Moisture Adjustments

The adjustments to maximum moisture content for the U.S. storms were facilitated by several references[17,18] and by unpublished U.S. Weather Bureau charts giving monthly figures for maximum 12-hour persisting dew point reduced pseudo-adiabatically to 1,000 millibars (mb.). To assess the maximum moisture content possible in an area for a given period of the year, it is necessary to obtain a maximum dew point below which the dew point did not fall during a 12-hour period, in order to eliminate one-hour readings which are nonrepresentative of the moisture content of the general air mass.

The theory of the moisture adjustment is discussed under "Method", above, the net result being that the ratio of moisture content of the air at the maximum 12-hour dew point, at the time of year the storm occurred, to the moisture content at the observed storm dew point (assuming saturated pseudo-adiabatic lapse rates in both cases) gives the moisture adjustment factor for the storm. By multiplying the observed storm rainfall by this factor the maximum rainfall possible in a storm of the mechanical efficiency of the one which actually happened, can be obtained.

For the four thunderstorms the adjustment factors are given in Tables II and III.

The Sept. 1878, hurricane-type storm latitudinal adjustment has been discussed. The storm dew point was 71° F. and the maximum dew point for Ontario during September is 73° F. The moisture adjustment factor is then 1.10 and is partly compensated by the 5 per cent reduction for latitude, to give a final adjustment factor of 1.05. It will be noted that for the storms of Table II no difference in latitude need be adjusted for, and for the storms of Table III, a latitudinal adjustment is included in the index of transposition.

Moisture Adjustment—Storm "Hazel"

For storm "Hazel" the maximum storm dew point was not readily available and had to be obtained directly from the weather observations taken during the storm.

This was done in the manner recommended by Paulhus and Gilman[12]. A study was made of the dew points reported in surface synoptic observations during the period in which rainfall intensities were greatest, i.e. 150001 E to 152400 E. Hourly reports were then consulted for the stations whose reports were considered to be most representative of the inflow stream of tropical air to the storm in the North-eastern Pennsylvania Central and Western New York States area. The temperature of the dew point below which no dew point observations fell in a continuous 12 hour period (the 12-hour persisting dew point) most common to this area when reduced pseudo-adiabatically to 1,000 millibars (mb.) was 65° F. The upper level radiosonde reports for the area of the storm warm sector, which were also examined, in

Table II

These storms were considered directly transposable to Ontario.

Storm location	Date	Storm dew point	Ontario maximum dew point	Adjustment factor
Beaulieu, Minn. and Ironwood, Mich.	July 18-23, 1909	71°F.	74°F.	1.16
Cooper, Mich.	Aug. 31-Sept. 1, 1914	68°F.	73°F.	1.28

Table III

These storms were considered directly transposable in part by application of factor 4.0/6.1 = 0.66

Storm location	Date	Storm dew point	Storm location maximum dew point	Storm location adjustment factor	Ontario adjustment factor
Stanton, Neb.	June 10-13, 1944	70	76	1.34	.88
Boydon, Ia.	Sept. 17-19, 1926	70	75	1.28	.81

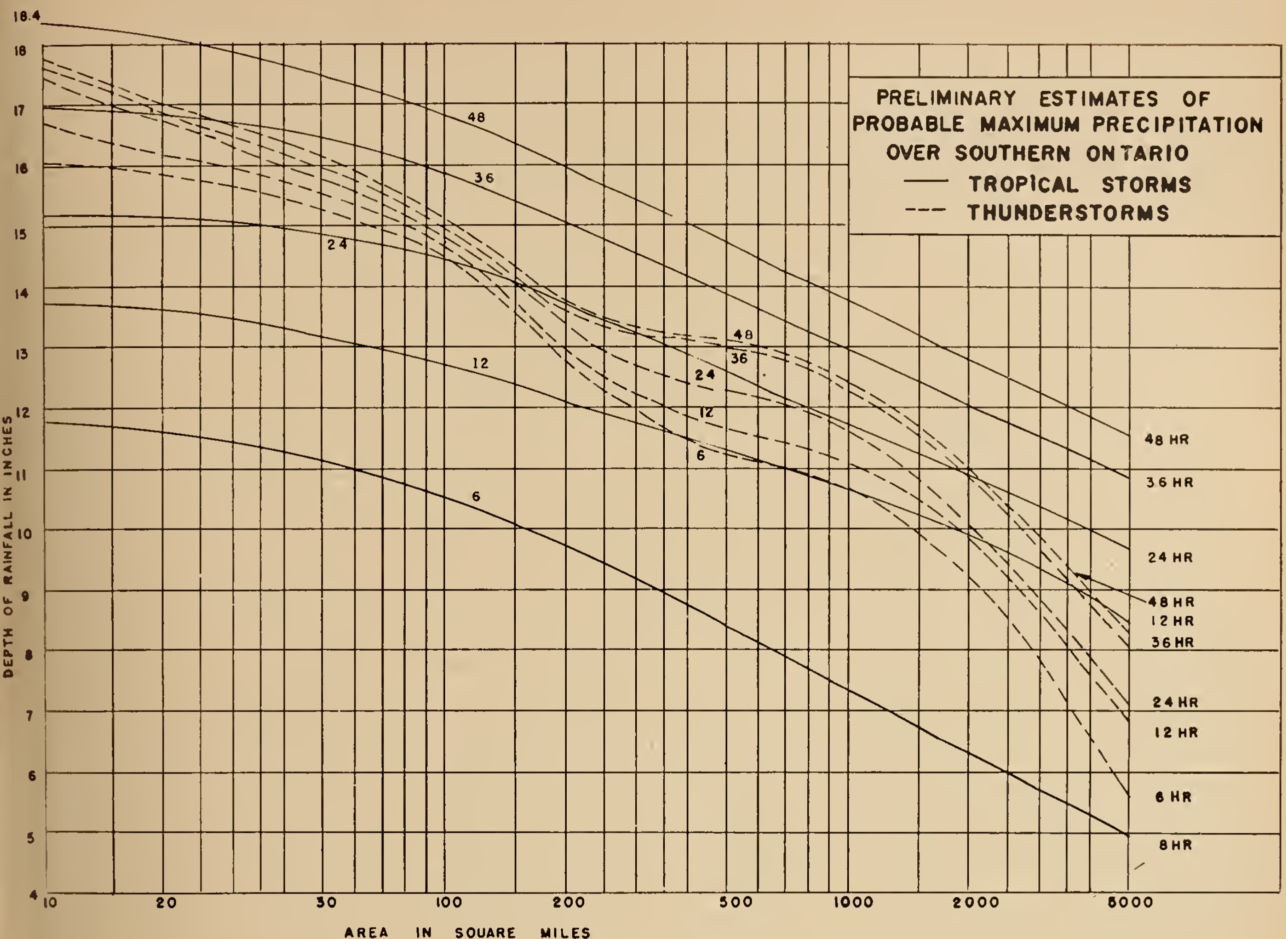

Figure 3.

dicated that a low level wet bulb potential temperature of 18° C. was most representative of the warm air mass at latitudes of Southern Ontario west of the Appalachians (see Buffalo report for 151500Z). A wet bulb potential temperature of 18° C. corresponds to a 1,000 mb. dew point of 64.4° F. at saturation. With this close agreement, 65° F. was accepted as the representative storm dew point.

The U.S. Weather Bureau figures for maximum persisting 12-hour dew point for the hurricane season (Aug.-Oct.), were checked by an analysis of dew points at Malton airport for the period of record available on the Canadian Meteorological Service's punched cards (1952-1955). This analysis confirmed the U.S.W.B. figures.

A frontal cyclone such as storm "Hazel" in its second phase[11] requires a frontal system with temperature contrasts too great to occur in August. One estimate of the available temperature contrast for the production of storm energy over Ontario gives for August only 64 per cent of that which is possible in October. In September, the temperature contrast approaches that possible in October. The maximum persisting dew point for the period Sept.-October was thus taken on the index of the maximum possible moisture content of a storm such as "Hazel". This dew point is 73° F. and the resulting moisture adjustment factor is 1.48.

Correction Factor—Storm "Hazel" Rainfall

A difficulty arose in connection with the analysis of storm "Hazel" which has led to the conclusion that the observed precipitation figures for the storm were somewhat low. The trouble was that estimates of the volume of runoff on the East Branch of the Humber River, closely approached or exceeded the amount of rainfall observed in the area. It seems likely that for a 48-hour rainfall, of which only the last 6 or 8 hours were of extraordinary intensity, the actual runoff percentage must have been somewhat less than 100 per cent. This suggests that either the volume runoff estimates are high or the precipitation figures low. A probable source of error in the rainfall figures is obvious, namely the effect of wind in decreasing the catch of rain gauges. This may be true in the case of the five other "controlling storms", but insufficient data is available to make an allowance for this factor in these cases.

A number of attempts have been made to evaluate quantitatively the effect of winds of various speeds on the catch of rain gauges[19,20,21] although to my knowledge no experimental data of this sort is available for the Met. Service of Canada standard rain gauge. Of the figures available, those most applicable to the present problem were obtained by Bornstein and quoted by Abbe[19], by Hudleston, quoted by Brooks[20] and by various experimenters quoted by Wilson in his discussion of Black's paper[21]. Application of the figures to the hourly precipitation and wind data at Malton yields percentage corrections of 17½, 15 and 20 to be added to the observed rainfall figures. (Note: where necessary the wind speed was reduced from anemometer level to gauge level by an expression of form

$$\frac{U_1}{U_2} = \left(\frac{Z_1}{Z_2}\right)^n$$

where n = 1/7 for neutral stability
U_1 and Z_1 are wind speed and height at level 1 and
U_2 and Z_2 wind speed and height at level 2.

As these three correction factors are in close agreement considering the difficulty of assessing such a measurement error, the average correction factor was taken as 18 per cent.

As available wind reports indicated that the velocities reported at Malton were representative of those which occurred within the heavy rainfall area, and as the light rain was accompanied by light winds and the heavy rain by strong winds, it was considered feasible to apply this constant correction factor to the total storm rainfall figures. Thus the 18 per cent correction factor was applied to the depth-duration-area data for storm "Hazel" before adjusting the figures for maximum moisture content of the rain-producing air mass.

Final Probable Maximum Precipitation Estimates

For each area and duration, the greater of the maximized rainfall figures for storm "Hazel" and for the Sept. 1878, storm, is entered in Table IV. The greatest depth for each area and duration, based on the four thunderstorm occurrences, is shown in Table V.

Enveloping curves of these tabulated values are given in Fig. 3.

Assumptions and Limitations

A recapitulation of the assumptions stated or implied in this derivation of probable maximum precipitation is essential here. These assumptions can be classified into two groups, those which are inherent in this type of hydrometeorological study, and those which were made for this preliminary study. The general assumptions of the storm maximization-transposition technique are: (1) that the probable maximum precipitation can be derived from the optimum combination of moisture charge and convergence of the wind; (2) that a storm (or storms) of record have approached the maximum in mechanical efficiency over or near the area being considered; (3) that the moisture content of the rain-producing warm air is a single valued function of the 1,000 mb. dew point in intense storm areas.

The particular assumptions made in this study are: (1) that frontal lows formed by tropical hurricanes and thunderstorm occurrences will produce maximum rainfall depths over Southern Ontario, (2) that at least one of the six storms considered was of near maximum mechanical efficiency, (3) that the latitudinal variation of precipitation factor of McCormick's is applicable in the Great Lakes area.

Discussions of the validity and limitations of most of these assumptions appear in the text, or in references.

Certain limitations on the applicability of these figures should be kept in mind.

(1) They are *preliminary estimates* and should be considered as such until such time as complete reports, preferably for individual basins, confirm or deny their validity.

(2) They are intended to apply to latitudes near that of Toronto. Areas further south would likely require the use of slightly higher estimates and for regions further north in Southern Ontario slightly lower figures would likely be applicable.

(3) Long term climatic trends which would affect these estimates have not been evaluated as they are much beyond the scope of this report. It is interesting to note, however, that the long-term trend of annual precipitation at Toronto is slightly downward.

(4) It is likely that maximum volume flows for many Ontario streams would result from spring runoff, but it is unlikely that peak flows for a spring freshet would exceed that produced by precipitation of the intensity of the probable maximum rainfall (see (2) below).

Suggestions Regarding Further Studies

The obvious requirement for the future is for complete studies of probable maximum precipitation over individual basins in Southern Ontario. This would involve studies of maximum snow melt, of all other possible controlling storms that have occurred in or near the region, of the effect of local basin topography on maximum rainfall and of the relationship of the basin's shape to the orientation and distribution of rainfall patterns of controlling storms. In addition, the seasonal variation of maximum rainfall should be studied.

However, to permit complete studies of this nature, considerable work must be done on the following: (1) depth-duration-area analyses of major storms of record in Ontario; (2) determinations of maximum snow melt in conjunction with maximum spring rainfall for individual basins in Southern Ontario; (3) augmentation of the present Ontario meteorological observation network to include more precipitation stations, snow measuring locations and temperature-humidity stations. The requirement for additional continuously recording rain gauge installations is especially urgent; (4) effect of winds of various

The Problem of Stream Pollution

A Panel Discussion Organized by the Chemical Section, The Engineering Institute of Canada, November, 1955.

The extent of pollution of Canadian streams, the scientific knowledge of its effects, the trends of legislation, and the efforts of industry and government to deal with the problem were discussed at a panel meeting organized by the Institute. The following version is an abstract of the proceedings that is intended to give an account of the main topics.

Introduction

Lucien Piché

Director of the Department of Chemistry, University of Montreal, Member, Fisheries Research Board of Canada.

With the present rapid development of urban life and with the amazing growth and multiplication of industries, there has grown the awareness that the legendary great volume of our rivers may no longer be adequate to absorb the ever increasing amount of water-borne wastes poured into them.

Pure water is an exceedingly fragile material; it takes only little foreign matter to make it unfit for domestic or industrial use. In order to appreciate this, let us consider that normal sanitary domestic sewage, as foul, dangerous and repulsive as it may be, is still 99.9 per cent water; it is not so remote, in chemical composition at least, from so-called "pure water". Therefore, the issue of pollution of water cannot be lightly dismissed on the grounds that industrial wastes and municipal sewage can adequately be disposed of by dilution and spontaneous purification in our rivers. All sewage can and must be rendered innocuous and all industrial effluents can and must be made acceptable before they find their way into running water and it has become a modern common practice in populated areas to effect a minimum degree of purification before releasing foul waters. It is estimated that 60 per cent of the domestic sewage discharged into sewerage systems in United States is partially or completely treated and a considerable portion of the industrial wastes is also treated to various degrees, either separately or in combination with domestic sewage. Ontario now has 175 municipal sewage treatment plants in operation.

The most common type of pollution of water is caused by the discharge of wastes that contain organic substances either in suspension or in solution. Inorganic wastes are not uncommon, but the organic type of material predominates in domestic sewage and in most industrial wastes, and it includes a large variety of materials and bacteria; all of these, of course, have an objectionable effect on the quality of the water and on its use for domestic or industrial purposes. This organic matter may be present in coarse or fine suspension or in solution and it is composed primarily of carbohydrates, of fats and of proteins. The coarse, and a portion of the finely divided materials settle more or less rapidly to the stream bed, forming sludge deposits that modify its physical and biological character. The finely divided matter remaining in suspension imparts turbidity to the water and it increases the cost of its treatment for domestic or industrial use for it bears directly on the necessity and efficiency of filtration. The oils and fats spread on the surface, forming unsightly sleek, while the remainder may remain in suspension, depending on the velocity of the stream, a continuous or semi-continuous film may prevent normal surface aeration of water over large areas.

Soluble impurities impart taste and odors to the water; in some instances very little quantities of them become highly objectionable; phenols, at concentrations of 1 part in 5 million parts of water are highly undesirable on account of the strong chemical taste that they impart to the water when it is chlorinated before domestic use.

It is, however, in their indirect effects that organic waste materials contribute most to the pollution of water, for the discharge of sewage or of wastes sets into motion a complex chain of chemical, biochemical and biological events, the objective of which is the elimination of the pollution. This is called *autoepuration*, in which bacteria play a very prominent role.

Unpolluted stream water has low bacterial counts. But the numbers of native water bacteria increase greatly and rapidly in response to the addition of food materials to the water, particularly carbohydrates or proteins. These organisms consume the organic substances that they find in water, and combine them with oxygen to produce the energy for their life processes and to multiply in numbers at exponential rates if the food supply is adequate. A number of industrial wastes are ideal forms of food to sustain bacterial growth and while industries do not, as a rule, directly contribute to the bacterial flora of water, their organic wastes are prime factors in the establishment of septic conditions in a river. This responsibility is not generally recognized by industry but it becomes very great, when, as is usually the case, sewage at the same time greatly increases the density of pollutional bacteria, among which there may be present certain pathogenic organisms of intestinal origin such as typhoid or dysentery bacteria.

These microorganisms, as a group, are known as coliform bacteria; their count in waters presumed to be polluted is closely watched because their determination is the best bacteriological index of faecal pollution of water, and is a prime concern from the point of view of public health. For the supply of a modern waterworks, a raw water containing coliform organisms in density greater than 5000 per 100 ml cannot be adequately treated by the ordinary process of coagulation, filtration and chlorination. A water heavily contaminated with any type of native or pollutional bacteria is inadequate for cooling or as process water because of slime formation.

The objectives for river water quality that have been adopted by the Ontario Pollution Control Board have set at 2.500 coliform bacteria per 100 ml of water, the maximum allowable limit; in Quebec, the Ministry of Health does not generally authorize the use of raw water for the feeding of a municipal filtration plant if it frequently contains coliform bacteria in excess of 3000 per 100 ml; in extreme cases, it will authorize the use of water containing up to 5000 microorganisms on the condition of a double chlorination. That is, chlorination of the raw water, filtration and chlorination of the filtered water.

The reaction by which microorganisms break down and utilize organic matter is known as "*biological decomposition*"; oxygen is consumed in large quantities in this decomposition. If oxygen is available in sufficient amount, stable final products such as carbon dioxide, water, nitrates or sulphates will result from biological decomposition and no septic conditions are likely to appear. If the oxygen is not sufficient, it will first be entirely depleted and the stream will become septic; the active natural life of the stream will be destroyed by the toxic nature of the compounds produced by this type of decomposition.

Oxygen, then is the vital element for biological decomposition of an organic waste, including bacteria. Water will dissolve oxygen from the air up to relatively small concentrations to attain saturation. The saturation value depends on the temperature of the water, since more oxygen will dissolve in cold than in warm water, but it is close to 8 or 10 p.p.m. at ordinary summer temperatures and at altitudes neighbouring sea level, that is to say only 60 to 80 pounds of oxygen per million gallons can dissolve in water.

The rate at which oxygen will diffuse into water from the air after it is partially or wholly depleted is a surface phenomenon depending on a number of physical factors, the principal of which is the area of surface exposed and its renewal; reaeration of water therefore largely depends on stream agitation. The more quiet the water, the slower is the rate of diffusion, until in quiescent water, an equilibrium is established, even at low concentration, at which diffusion almost ceases beyond a film of saturated water on the surface.

Industrialization, frequently accompanied with the construction of dams on turbulent segments of rivers usually modifies substantially the pattern of aeration of water in substituting pools of quiet water for falls or rapids. The blanketing of rivers with ice during winter evidently cuts out the possibility of any aeration of water, a factor which becomes a major one in this country. On the other hand, some inorganic materials such as sulphites or ferrous salts are strongly reducing in nature and effluents containing them have an important I.O.D., *immediate oxygen demand*, entering into this pattern of oxygen balance.

In a polluted stream, deoxygenation will decrease the oxygen content of the water, whereas reaeration will tend to increase it. The net result of these two opposing processes on the actual dissolved oxygen level of the stream will, of course, depend on the quantity and nature of the polluting materials in relation to the stream flow and the rate of reaeration.

Concentrations of dissolved oxygen in water are closely watched in the evaluation of the state of pollution of a stream. Oxygen is determined by the Winkler method which is relatively easy to carry out; it is a particularly dependable method and semimicro modifications enabling the determination on 25 cc. of water are becoming popular. It should be carried out at least in its initial phase immediately at the point of sampling since agitation of the water with air will rapidly modify the oxygen content of the sample. Kits for field use are quite simple and easy to use. Concentrations of oxygen are expressed either in p.p.m. or oxygen or frequently as a percent of saturation.

The ability of an effluent to consume oxygen from water is measured and expressed in terms of its biochemical oxygen demand (B.O.D.), that is the amount of oxygen that will spontaneously be used up in a sample of water or of diluted effluent when it is incubated for five days at 20 deg. C. This is an empirical test carried on under standardized laboratory conditions simulating the biochemical oxidation in streams and it is a measure of the amount of oxidizable organic matter present in the sample. Comparing B.O.D.'s of industrial wastes with the average B.O.D. of a domestic effluent leads to an expression of their pollutional effect in terms of a population equivalent. A sulphite mill for instance, producing 300 tons of chemical pulp daily is considered to be equivalent to a population of 250,000 to 400,000, whereas a beet-sugar factory would come to be equivalent to 100,000 people in its pollutional load. In a number of cases, industrial wastes are reported to have a pollutional effect much greater than the local population and as a result of the combined action of both, certain rivers or sections of rivers are subjected to volumes of wastes far beyond their capacity.

However, B.O.D.'s, with oxygen content and coliform counts are the main standbys in stream surveys. But, under certain conditions, more information is required than that available from these main determinations. Determination of oxygen consumed from permanganate or from chromic acid will complement the B.O.D. index in establishing the total amount of oxygen necessary to effect a more complete oxidation of relatively stable organic materials; nitrates, nitrate or ammonium salts may be determined in some cases where nitrogen balance becomes of special interest; pH is frequently a useful index of dilution of acidic or basic materials; colour and hardness are routinely checked in municipal water works.

Methods for all these chemical, biochemical and bacteriological determinations in water or in effluents have been standardized by the American Public Health Association and their code of procedures is the well known "Standard Methods for Water Analysis" which is periodically revised. There are some good texts on Stream Survey or Industrial Waste Treatment Practice, the best known of which are Eldridge's book first published in 1942 and the more recent American Chemical Society monograph edited in 1953. Interpretation of analytical results requires a certain minimum experience since the characteristics of different waters varies so much that it is impossible to lay down absolute standards to which all safe or adequate waters must conform.

Control of Pollution by Pulp and Paper Mills

Douglas Jones, AFFIL.E.I.C.

Executive Secretary, Technical Section, Canadian Pulp and Paper Association.

Under the impact of promising long term influences it is to be expected that the Canadian pulp and paper industry will continue to expand its productive capacity. This expansion can be affected only by the most efficient use of the existing natural resources of the country. For pulp and paper production these are fuel and power, wood fibre and water.

Generally speaking, fuel and power resources are in adequate supply. Surveys indicate that wood is available for present production on a perpetual yield basis and that additional supplies are available for future expansion. With respect to water supply the industry is in a fortunate position as compared with other countries.

Production of one ton of newsprint requires about 1.0 cord of wood; 90 to 100 horsepower days of electrical energy; 600 lbs. of coal; and the use of 35,000 to 45,000 imperial gallons of water.

Water — A Natural Resource

The pulp and paper industry shares with others the right to use our natural resources. To all, water is a natural resource. This concept is perhaps somewhat novel in Canada, though widely accepted in the United States and Europe. It involves the recognition that maximum benefits would accrue to the nation through its most effective use. This in turn requires consideration of its use for power, navigation, fisheries, domestic and industrial water supply; and of the maintenance of the resource so that it may be available as a recreational asset.

For full utilization as a natural resource, its potentials must first be fully assessed. Most rivers and river systems in Canada have been comprehensively surveyed for their power potential. It is doubtful if they have been studied from an overall viewpoint. Such a survey would determine the flow characteristics of the stream, its normal pollution load as measured in terms of solids, oxygen demand, etc., the individual effect of existing dams, industries and communities, and would predict from the hydrologic data and pollution load what the water quality and quantity would be at any point along its course.

The pulp and paper industry accepts this concept of water resource utilization. It recognizes that by the nature of its operations, it is intimately concerned with the problem of maximum water utilization. Its operations are but one of many other potential sources of pollution.

Survey to determine the capacities of rivers for the handling of industrial wastes is a task which must be undertaken by industry and government working together.

In the pulp and paper industry the three major operations each present different problems in control of pollution and the problems are technical as well as economic. These operations are wood preparation, pulp production, and paper manufacture.

Pollution caused by wood preparation has been, or can be eliminated.

Pulp production is either mechanical or chemical. In mechanical pulping, pollution would be caused by residual quantities of very fine and almost microscopic particles, or at the other extreme, by very coarse particles of the groundwood. Control is achieved with specially designed and expensive equipment, which refines the coarse particles to sizes of use for paper, while saveall and recovery equipment — sometimes in conjunction with chemical treatment—make it possible to retain the fines. Suspended matter in effluents can now be controlled to quantitative limits substantially below what they used to be.

The only way to really determine the effect of the recoveries is to test survey each case and thereby establish whether, in fact, the percentage of fibre content at minimum flow is, or is not, harmful.

In chemical pulping, pollution is caused by the chemical content of spent liquors which contain most of the chemicals used to dissolve the wood and thereby isolate the cellulose. They also contain in solution such quantities of the non-cellulose constituents as are removed. Mills using the sulphate or soda digestion processes now concentrate, burn and recover practically all the chemicals in them. Techniques generally used have eliminated harmful pollution wherever stream flow has been adequate, except for controllable amounts.

It is unfortnate, but nevertheless true, that in spite of intensive research on sulphite liquor utilization there is still a problem arising from most, if not all, sulphite pulping operations. The problem is two-fold: first that of developing an adequate and economic process for the concentration and burning of the liquid to recover chemicals and heat, and second, that of developing from the liquor by research other materials or products having a volume market. Some new sulphite mills have been designed to use soluble bases such as magnesium, ammonia or sodium and the problem is less difficult. However the soluble bases may never find general application, for economic reasons, though Canadian mills are experimenting with them.

The problem is being approached from three broad points of view: viz, modification of cooking processes and the obtaining of higher pulp yields; the continued search for a recovery process for calcium base spent liquors; and the development of commercially useful and marketable products from the non-cellulose or lignin content of the spent liquors.

Advances in techniques and equipment have resulted in minimum quantitative use of chemicals, and a yield of 65 pounds of pulp from 100 pounds of wood, for certain grades of paper. Any such gains represent a reduction in quantity of polluting material in spent liquor.

The development of commercially useful products from spent liquors is perhaps the most realistic and practical approach. However, we are dealing with chemical substances of baffling complexities and in very large volumes. To date no one product whose potential market is anywhere nearly equal to the quantities dealt with has been found. Fundamental studies on this challenging problem are in progress.

Paper mill effluents contain minute fibre particles and some mineral fillers. But fibre and filler content can be determined and controlled.

The Canadian pulp and paper industry is one of the major users of our water resources for power and for industrial purposes. In such a position, the industry recognizes its obligations. On the basis of its performance to date in tackling the problems of industrial water usage, and on the basis of its contribution to the economy of Canada and to the communities in which mills are located, the industry can expect that all levels of government will recognize its problems. Such recognition has been accorded in the past. Cooperation and understanding must be maintained between industry and society represented by government. The former must be given time to solve the technical and economic problems involved, and government may expect a cooperative attitude to the work of government bodies.

And coupled with these two requirements, we believe there is a third, which is that some use of rivers for disposal of industrial waste and therefore some "pollution" must be permitted in an industrial nation. It would seem that the minimum degree of pollution from all sources at any given moment is one of the prices to be paid for industrial activity.

The pulp and paper industry which is conscious of the immensity of the problem and has already done much to minimize its pollution load, will continue its efforts and will work cooperatively toward the establishment of reasonable standards after thorough and accurate surveys have been made. However, any general prohibition of the use of streams for mill effluents would destroy the competitive position of Canada's largest industry resulting in damage to Canada's international trade not only in value of export but also in the use of dollars earned on exports and with which we buy much needed imports. It would result in the closing of mills, loss of employment to a labour force of approximately 250 thousand and the ultimate decline of Canada's forest heritage.

Pollution Control in a Petroleum Refinery

H. H. Clare

Engineering Division, Imperial Oil Company, Limited.

Since petroleum products have never been particularly cheap in Canada, loss control programs have always ensured a measure of pollution control. Sooner or later we arrive at a point where the capital cost of loss control equipment shows no economic return for the reduction in losses achieved. It is at this point that we enter the era of pollution control. The responsibility for pollution control is widely recognized as a normal cost of doing business in this age.

Imperial Oil Company's abatement program was formalized in 1943 by the formation of a central refinery loss committee. Detailed reports by each of the nine refineries are made semi-annually to this committee, on losses sustained, and plans formulated to reduce losses and control pollution. This committee constantly studies methods and equipment to improve refinery losses. At each refinery a loss committee meets monthly to study loss reports and recommend improvement measures.

To cooperate fully with government bodies, our company inaugurated efforts for pollution abatement in Ontario and Alberta. Some time ago discussions were held between the four major petroleum refiners to determine if a similar group study could be made in Montreal East. Considerable enthusiasm was shown for a concerted pollution study.

The biggest problem of oil refiners in respect to water pollution is to keep oil out of the streams. To prevent oil leaks from finding their way into streams, all sewers that carry oil and water must pass through a large settling basin before entering a stream.

You would think that it would be a relatively simple matter to separate oil and water since oil is lighter, and then skim the oil off the surface. This is not the case. All types of products, from light gasolines to heavy asphalt are produced in a refinery. When the heavy oils get into the sewers, they mix with the lighter products, the water, and any solid particles present and form very stable emulsions. These emulsions are about the same gravity as water and as a result are very difficult to separate and recover.

The second big problem for refineries, as in chemical plants, is the disposal of used and unwanted chemicals. These chemical wastes may have an adverse effect on the aesthetic qualities of the waters as well as on their physical and chemical properties. Their health significance is considerably secondary to sewage, but they may seriously impair the use of water for domestic, recreational and industrial purposes.

One of the most widely used chemicals in oil refining is caustic soda. In water, this increases the emulsifying tendency of oil and water, which causes higher oil losses. Phenol is another bad actor, when it finds its way into rivers and streams. It has a high B.O.D. and will kill fish and other marine life if too high a concentration is allowed to contaminate a stream. A third nasty chemical is hydrogen sulphide. Fortunately, most of the hydrogen sulphide ends up in the refineries' own furnaces and flares. However, some of it becomes dissolved in water, creating a hazard and pollution problem.

There are methods and equipment used to combat the various forms of potential water pollution. First and most effective of these is a vigorous program of good housekeeping in the plants to prevent unnecessary leaks of oil into the sewers, good designing and cathodic protection of lines.

Diversion of clean process water from oil contaminated water is carried on, to reduce the velocity through the oily water separator.

Imperial builds circular separators for all new construction. There is a 120-foot.-diameter separator at Montreal East. A sour-water deodorizer tower, started up in 1955, was designed to strip 3,000 lbs. per day of hydrogen sulphide from 2100 barrels a day of sour water. Exhaust steam at 15 p.s.i.g. is used to strip out the noxious gas in a conventional gunite lined stripping tower.

Spent caustic soda from treating operations is accumulated in tankage and is no longer allowed in our refinery sewer system. For the trace amounts that do escape, fresh sulphuric acid is added to the sewer to control the pH of the separator effluent as close to 7 as possible.

Phenols are not a major problem at our Montreal East refinery but they were to our Sarnia refinery. A very novel method is used at Sarnia to destroy phenols. Living organisms, such as rod shaped bacteria consume the phenols and convert them into harmless carbon dioxide and water.

A modern waste disposal plant at Montreal East consists of two stages of centrifuging to remove solids from mixtures of slop oil, water, and solids. It was designed to handle 900 barrels per day of sludges. A multi-hearth furnace capable of handling 24 tons per day incinerates the separated oil-soaked solids, leaving only harmless ash behind. A smoke-eye ensures smokeless operation.

In overcoming major disposal problems, Imperial will have improved the quality of effluent beyond reasonable criticism. The cost has been well over $1 million in Sarnia and over $500,000 in Montreal. That is a lot of money, but money willingly spent by our Company to be a good citizen in any community.

The Importance of Stream Pollution Legislation

D. S. Kirkbride, M.E.I.C.

Development Manager, Canadian Industries Limited.

From an industrial point of view we should be particularly concerned about the type of legislation which may have to be implemented in the future to deal with the increasing problems that accompany industrial expansion. Since countries such as the United Kingdom and the United States have reached industrial maturity before us, we can benefit from their experience.

The evolution of legislation has been related directly to population growth, to increased industrialization and to improved standards of living. The pattern has usually begun with the introduction of legislation to protect some specific interest.

With continued population growth and increased industrial activity the need for conservation of water supplies, the problems of interstate and interprovincial streams, the financial burden of limiting pollution, and the high technical effort necessary to devise methods for dealing with pollution problems all accumulate and create major problems of conflicting interests. Legislation directed at specific issues such as public health, navigation, etc., becomes more and more inadequate for resolving these conflicts and a comprehensive approach must be found for dealing with them. Canada is just entering a stage where it must start examining the adequacy of its present legislative machinery.

The United Kingdom in 1951 passed what is called the "Rivers Act". This act deals with the overall problem of pollution, the establishment of standards for effluents, new discharges to rivers and streams, and with tidal waters. The administration of the act has been assigned to a number of River Boards. These boards, authorized in 1948 under the River Boards Act, are responsible for dealing with questions not only of pollution but also of land drainage, fisheries, and the conservation of water in an entire river basin or group of rivers. The River Boards are moving carefully and purposefully to set up their standards and methods of operation and are consulting freely with industry, local authorities and all agencies affected.

In the United States, approximately 40 of the 48 states have regulations dealing with the pollution of streams. Many of these have now been broadened to consider the wider implications of overall pollution matters though some are still far from adequate. In roughly 30 of these, there is provision for cooperation with industry.

In spite of the best efforts of state authorities, the pollution problem reached such magnitude in recent years that the United States federal government intervened in 1948. The Water Pollution Control Act passed at that time called for federal aid in research, technical advice, establishment of standards and similar matters. The passing of this statute had a considerable effect and prompted many of the states, who had become concerned about states' rights, to improve their legislation, and in some instances to join together in interstate compacts for the control of pollution along interstate rivers or streams.

Along with these measures there have been many instances of cooperative effort involving industry and all levels of government where satisfactory improvements in serious pollution conditions have been brought about.

In Canada, legislative responsibility for different aspects of pollution is divided between the federal and provincial governments by virtue of the authority delegated to each under the B.N.A. Act. The federal government exercises control over navigation, commercial fishing, migratory birds and international and coastal waters. The provinces are responsible for public health and other matters.

In the provincial field all the provinces except New Brunswick and Prince Edward Island have legislation. All eight acts specifically prohibit pollution in one form or another or classify pollution as an offence and specify penalties. In all but one there is provision for regulation of waste disposal.

If there is fault to find with this situation, the fault is not with the people responsible for administering these matters, but rather with the fact that conditions are changing and the overall problems are becoming more than the present legislative machinery is designed to cope with.

In recent years, Canada's growth and industrialization have been creating new situations. More comprehensive legislation and understanding of the overall problem are required.

In Canada some provincial authorities are concerning themselves with the overall problem of conserving their water resources. Two provincial administrative bodies exist to deal with overall pollution problems: the Pollution Control Board of Ontario and the Provincial Sanitary Control Commission in Manitoba. Investigation of the problem is under way in Quebec.

In at least two regions there is pressure developing for interprovincial authorities to administer the watershed of interprovincial streams.

Saskatchewan and Manitoba have been urging the formation of an interprovincial river board on the North Saskatchewan river. This action was prompted by the fact that effluents from industries near Edmonton were affecting the drinking water of communities downstream in Saskatchewan. The Alberta authorities and the industries concerned took action on complaints from the offended communities and the situation has been improved.

The International Joint Commission has continued to watch conditions in boundary waters and has made surveys particularly in the river areas such as the St. Mary's, St. Clair, Detroit, and Niagara Rivers, and has prepared standards and recommendations for the control of pollution in them. A report of the Commission's work published in 1951 sets forth general requirements, of a comprehensive nature, for the discharge of all wastes. They specify that wastes shall be in such condition when discharged into any stream that they will not create conditions in the boundary waters which will adversely affect the use of these waters for: domestic water supply, industrial water supply, navigation, fish and wild life, bathing, recreation, agriculture or other riparian activities.

Legislation by itself is not going to solve pollution problems. However, the right kind of legislation can help to create an environment in which intelligent, cooperative action is stimulated. Industry, in its own interest, should encourage suitable legislation. Over and above this, industry must in the construction and planning of new factories make adequate provision for cleaning up and disposing of wastes in ways which are acceptable to all local authorities and which leave the water in the streams below its plants in a form which can be reasonably used by others, for domestic or industrial use or recreation. In addition, industry should be examining all of its present operations to know exactly what wastes it is putting into streams. It should be examining carefully all the measures it might take to reduce these and it should be conducting research on ways of eliminating them.

The Transcona Grain Elevator

(continued from page 977)

can substantiate. Reasonable correlation, however, is gained using the other average cohesion values as shown in Table I. This is in spite of such factors as pumping that may have caused soil changes since the failure.

Difficult to explain is the length of time, 24 hours, which elapsed from the time motion began until the building came to rest. The plastic nature of the soils and the gradual transfer of load from the upper stiffer clays to the softer underlying material may be responsible. The slow failure and the varves in the brown clay do not appear to have invalidated the theoretical formula.

To the engineer, it is most reassuring that the study of the Transcona elevator failure and similar studies reported for the foundation failures on clays in widely separated areas, verify the present theories. The advantages of being able to predict the ultimate bearing capacity from a soil study are obvious. With the information now available and the additional studies being made on settlements, foundations on clay may be designed with reasonable knowledge of the safety factors involved and the future behaviour of the structure.

Acknowledgements

The interest in this investigation of the Canadian Pacific Railway, through Mr. R. A. Emerson, chief engineer, and their permission for the sinking of the test holes on their property is gratefully acknowledged. The test borings were put down by the special soil boring crew under Mr. E. Hargest of the Manitoba Department of Public Works. The author is indebted to the Foundation Company of Canada Limited for the photographs which serve as illustrations. The soil testing was carried out by Mr. M. Bozozuk in the soil mechanics laboratory of the University of Manitoba and to him the author records his thanks as also to Dean A. E. Macdonald, M.E.I.C. and to Mr. R. F. Legget, M.E.I.C., Director of the Division of Building Research, National Research Council, with whose approval this paper is published as a joint contribution from the University of Manitoba and the Division.

Precipitation Over Southern Ontario

(continued from page 984)

speeds on the catch of the M.S.C. standard rain gauge.

Besides these, there is, of course, a great need for much more theoretical research on the factors affecting rainfall production and techniques for their maximization.

Formal Graduate Study

A panel discussion held as Session 5 of the joint Conference of the American Society of Mechanical Engineers and the Engineering Institute of Canada, University of Western Ontario, October 1956

Newman A. Hall,
Professor of Mechanical Engineeiing, Yale University.
Moderator of the Session

It is a pleasure to be here this afternoon and join in a consideration of what has become one of the most pressing problems currently in the field of engineering education. Before introducing our panel, which will discuss this area of graduate training in engineering, I should like to provide a brief introduction.

In graduate studies in almost all fields of endeavour the growth of any area which is developing extensively as a profession has traditionally involved the introduction of graduate work in a purely academic manner at the most advanced levels and then after a long period of development pressures from the profession itself call for the development of advanced training which is of a much more professional nature than the purely academic type of work which is normally associated with the graduate schools. Engineering at the present time is in the midst of this transition where the practising profession is calling for more advanced training than has been traditional in our four-year undergraduate engineering curriculum so that it is becoming necessary for more and more professional training to be given at the graduate level. This advanced professional training is to be distinguished from the type of advanced work of a purely academic nature which represents the research endeavor to expand fundamentally the field of knowledge covered by engineering.

This pressure for expansion of our graduate studies in engineering is a recent development associated primarily with the tremendous technological advances which have come about during the past fifteen or twenty years and which were stimulated so very greatly by the close association of science and engineering during the past war. The circumstances which have existed recently have called upon the introduction into engineering practice many diverse areas of fundamental scientific knowledge which were formerly the province of the physicist and mathematician but which now must be put into practice by the engineer. Many examples of this growth of the area of engineering design and engineering practice could be given. These are all of such a nature that the man who is going to develop new design methods and new procedures in engineering practice will require familiarity with areas which can no longer be covered at an undergraduate level. The industries which depend upon engineers who are so trained are the ones which are providing the motivation for the expansion of our graduate activities.

We thus see a pattern developing where superimposed on top of the research or academic type of graduate study in engineering there is developing a need for training at an advanced level which leads directly to the professional advancement of the engineer. In many cases this advanced training is being given within industry itself and some of these cases will be referred to this afternoon. However, the staff resources of industry are frequently not sufficient to meet this need so that the universities are being called upon to provide all types of training activities within the academic framework which lead to this professional advancement. The growth of graduate studies in engineering, particularly at the Master's level, during the past ten years has been very substantial. Much of this growth can be attributed directly to this increased emphasis on professional advancement. At the same time, however, the growth of more research or academic type of graduate study should not be overlooked and there is much development in this field since the engineer in practice is calling upon the research engineer to provide him with tools in the application of new developments in science which have not been available in the past.

It is our objective this afternoon to give consideration to some of the aspects of these developments and to try to see more clearly the implication of the patterns of graduate training in engineering which are developing. We have four gentlemen with us who are thoroughly familiar with the developments of this problem each of whom will be able to present to you their own analysis of certain phases of the picture with which they are intimately familiar.

D. S. Simmons,
General Manager, Manufacturing, Imperial Oil Limited.

Being a member of the last panel in a symposium much as this gives one the advantage of hearing the viewpoints expressed in the previous presentations and discussions. In view of these discussions there are two additional questions I would like to hear discussed by those present. The first one is directed primarily to the educators and the second primarily to the industrialists.

My first point concerns the business which all of the educators present are occupied with, that is the production of engineers. In this field there seems to be considerable difficulty with semantics. There appears to be general agreement that producing an engineer today requires a considerable "broadening of the base", which I believe means a deeper understanding of the basic engineering sciences. At the same time it appears that the "specialization" will, of necessity, have to be reduced; in fact there is considerable discussion as to the merits of its complete elimination. It seems to me that the usage of these general terms is rather confusing and the business of producing an engineer is really rather simple. I suggest that this process can be divided into two phases. The first phase consists of teaching the prospective engineer the basic sciences necessary for the branch in which he intends to practice. The second phase of his education consists of acquiring the skill to take these basic sciences and apply them to a practical problem and arrive at an economic solution. If we can assume that this is the process involved in the production of engineers, then the question I pose is: Which of these two phases is the harder to teach?

In my twenty years of engineering practice I am quite convinced that most of the engineering failures are in the phase-two area. It has been my personal experience that this phase is the more difficult of the two to teach. If this is called specialization, then I heartily disagree that it should be eliminated and I might even object to it being reduced.

I believe every practising engineer has had contact with persons who are very well informed, even accomplished, in a very broad range of the natural sciences but these same people cannot, in any sense, be classed as engineers. On the other hand, I have known a few men who have Doctor's degrees in natural sciences who have been outstanding engineers. The phase two part of their education is something they were either given as a gift at birth, or something which their special talents permitted them to learn without formal education. It would seem that "specialization" or phase two is the very reason engineering schools were created.

Since we are discussing post-graduate education it would appear essential, from my view, that the course should include both phase one and phase two subjects and not be considered as the time for "specialization".

My second point concerns the discussions on the "shortage" of engineers. It appears that one of the major reasons for this shortage is the large number of engineers doing "non-engineering" work. Various ways of getting these engineers back to "productive" work have been considered. In looking at my own company, and I suspect it is true of a great many other companies, if we took all the engineers out of management positions and put them at engineering work we would have a surplus of engineers. No one to date has seriously suggested we do this as we are quite anxious to keep the business operating. If we consider the number of engineers in industrial management, we are forced to the conclusion that the largest (and most successful) management schools in the country are the engineering schools. Is this not the primary aim of the schools of business and commerce? When we are having discussions regarding the proper content of the curricula for an engineering school we strike, frequently, very wide differences of opinion as to which course will produce the best engineer. In view of the high percentage who become management I feel that many of these differences are insignificant. When the business schools are discussing the best curricula I presume it is just as controversial as our own discussions. I wonder if the business or commerce schools have observed the high percentage of engineers in management and take this into account when debating their curricula? I believe that engineering schools will continue to produce a high percentage of future industrial management and the business of producing management people is an obscure and elusive process. Wherever they go the engineering school can serve industry best by continuing to produce sound and competent engineers. The questions I would like to hear the industrialists present discuss are, first, whether or not they subscribe to these views on the making of management people and, secondly, do they view with alarm the number of engineers who are doing "non-engineering" work?

Warren C. Stoker,
Director of the Hartford Graduate Center,
Rensselaer Polytechnic Institute

The Hartford Graduate Center, a branch of Rensselaer Polytechnic Institute, Troy, New York, was brought into being to provide graduate education in science and engineering in an area lacking such a facility, but having a large number of working engineers.

The single largest industry in the Hartford, Connecticut, region is the Pratt & Whitney Aircraft Division, United Aircraft Corporation, which employs over 5,000 technical personnel. It is one of the leading developers and suppliers of jet engines. The United Aircraft Corporation recognized that its future was very much dependent upon its engineering staff. It felt that graduate education for its engineers was a vital necessity to the future well-being of the corporation.

Since the United Aircraft Corporation was confronted already with a shortage of engineers, the problem was one of making available degree programs at the graduate level on a part time late afternoon-evening schedule so that the engineer pursuing a graduate study program could remain a productive engineer. The UAC recognized also the necessity of an educational facility close to the industrial community so that travel time would not consume an undue amount of the engineer's free time. Rensselaer Polytechnic Institute along with several other schools of engineering in the East, was approached by UAC and asked to submit its proposal for meeting the above objectives.

The proposal made by RPI was selected; and so the Hartford Graduate Center of RPI was conceived in the late spring of 1955. In brief, the Rensselaer proposal called for the establishment of a branch of RPI in the Hartford, Connecticut, area. The branch would offer graduate degree programs in four major fields: namely, aeronautical engineering, mechanical engineering, mechanics, and applied mathematics. The graduate school would operate under the same rules and regulations and with the same standards of admission and course instruction as the graduate school on the main campus. The Hartford Graduate Center would be open to all qualified students (not those of UAC alone). The Graduate Center would have its own campus with a complete educational plant. The staff and faculty would be full time and resident. In other words this would be a true branch, not just an extension activity. Students in attendance at the branch would be in residence.

An existing modern building located in a suburban area convenient to any part of the Hartford area was purchased and converted into an educational plant comprising within its 22,000 square feet of floor space, large classrooms, two seminar rooms, one auditorium, cafeteria, library, and staff and faculty offices. There is parking space for 250 cars. The classrooms were provided with the necessary equipment including sound movie projectors, and desk calculators. The completed structure with all its equipment was given outright to RPI.

To assure that RPI would incur no financial loss in this undertaking, UAC agreed to underwrite the operational budget for a 5-year period

It further established a tuition assistance plan for its employees which permits an employee to obtain an advanced degree at no cost. Under the plan, the employee-student makes a $20 per credit hour deposit at registration. One-half of this amount is returned upon satisfactory completion of the course, the remainder of the deposit is returned upon completion of the degree program.

To ensure that graduate work at the new branch would be a continuance of that at the main campus, a nucleus of six full time professors was transferred from the Troy campus to the Hartford campus. Other full time professors were brought directly into Hartford. In addition to the full time faculty, some adjunct (part-time) professors were obtained from the industries in the Hartford area. These adjuncts, each an expert in his own field, all have advanced degrees, the majority holding a doctor's degree. The majority have had previous teaching experience. They are expected to attend faculty meetings, consult with students, and assist in the preparation of plans of study for students. To assure their willing participation in such activities, the adjunct professors are given a retainer fee, whether they teach or not. They are paid an additional amount for the teaching of a course. This arrangement has worked well. The adjunct professors are familiar with the educational objectives of RPI and contribute to the educational program of the Hartford Graduate Center. They have become well integrated into the faculty. The full time faculty are all now residents of the Hartford area, and devote their full time to the educational programs of the Center. The proportion of teaching adjuncts to full time professors has been such that for each class taught by an adjunct, there have been two taught by the full time faculty. The adjunct professors usually teach the courses of a more specialized nature.

The Hartford Graduate Center has its own library which is intended to provide for the educational needs of the students in the fields of major interest. Under the supervision of a full time librarian, the library currently holds 1,714 books, 210 bound volumes of serials, and 196 serial titles are currently received. In addition, the facilities of the RPI library at Troy are available as are those of public, college, and industrial libraries in the Central Connecticut area.

The Hartford Graduate Center is administered under the dean of faculty and the graduate division by a resident director. The director of the Hartford Graduate Center is also associate director of the graduate division. Non-academic matters are handled by the business manager. The functions of the office of admission, the registrar, and the controller are provided by these officials at the main campus.

There are no departments within the Hartford Graduate Center, nor do the various degree granting departments on the main campus have any administrative function relative to the Hartford Graduate Center. However, the programs in each major field offered at the Center are carefully coordinated with similar programs on the main campus through consultation between the faculties of the two campuses, through attendance at faculty meetings of the Graduate Center by faculty from the main campus and vice-versa, and through the use of a common catalogue and common set of course offerings. The graduate council is composed of representatives of the graduate degree granting departments on the main campus and representatives from the Hartford Graduate Center.

The schedule of classes has been arranged to permit a student to pursue a maximum of two courses per term, with involvement of not more than two evenings per week. The vast majority of the courses are three credit hours. Since a minimum of 30 cr. hr. are required for a Master's degree, a student may earn the Master's degree in a minimum of five semesters or 2 years, if he takes two courses each term. At the present time, the only degree awarded is that of Master of Science in a designated major field, e.g., M.S. in M.E. The classes are scheduled to be 1½ hours each and fall on either Monday and Wednesday or Tuesday and Thursday, there being no classes scheduled on Friday. The first class begins at 3:45 p.m., the second at 5:15, the third at 7:00, and the fourth at 8:30. The UAC permits its employees to leave work, without loss of pay, at 3:15 if they are scheduled for a 3:45 class.

Members of the panel. From left: W. C. Stoker; S. B. Ingram; Dr. M. Katz; D. S. Simmons; and Prof. Newman A. Hall, the moderator.

The first class entered in September 1955. It consisted of 215 students registered for slightly under 1,000 cr. hr. of instruction. Twenty-one different courses were offered. Five adjunct professors taught courses. During the first year the course offerings were expanded to include majors in Metallurgy and Management. Present registration comprises 350 students registered for 1600 cr. hr., in 31 sections involving 26 different courses. It is anticipated two additional majors will become available during the coming year, physics and electrical engineering.

Although the majority of the students were employees of the United Aircraft Corporation during the first term, there were a few students enrolled from other corporations from the outset. The number of corporations in the area participating in the plan has increased, and there are presently employees of 11 different corporations registered at the Hartford Graduate Center.

S. B. Ingram,
Director of Education and Training, Bell Telephone Laboratories, Inc.

It has been suggested by our chairman and by the other members of the panel that I give you a brief account of what we are doing at the Bell Telephone Laboratories through our Communications Development Training Program in continuing the education of our graduate engineers after they leave college and enter the employment of the company. What I say might perhaps be appropriately presented as a part of one of the earlier sessions under the heading of the Training and Orientation of the Graduate Engineer on the Job or of Amplifying the Baccalaureate Education, because what I am describing is an industrial training program not formal graduate study in a university. The excuse for bringing it in here is that although it is an industrial training program, it is unique in its extent and in the fundamental character of the formal course work which we are giving to these college graduate members of our technical staff.

I presented a rather complete paper of this same subject before the American Institute of Electrical Engineers in Chicago about a year ago. Anyone interested in more detail than I can present in the few minutes available here may wish to refer to that paper which appeared in the February 1956 issue of *Electrical Engineering.*

First I should say a few words about the Bell Telephone Laboratories to tell you what kind of an organization we are. We are the research and development unit of the Bell System and are concerned solely with work of a research and development nature in the field of communications and electronics. We are a large and mature organization. Our company goes back in its present corporate form to 1925 but since in its formation we took over the functions and personnel of our predecessor, the engineering department of the Western Electric Company, in effect we can trace our origin back to the turn of the century. We have about 10,000 employees, of whom about 3000 are on the professional technical staff.

The C.D.T. Program

The new college recruits at either the bachelor's or master's level enter the communications development training program, which occupies their entire time for their first year with the company and part of their time for the following two years. In this program our objectives primarily are long range. We are keenly aware that these young graduates are the new blood of our technical organization. As such, it is their ultimate potentialities for development rather than their immediate productivity which really counts most. We are concerned with providing these new technical staff members with engineering training of a fundamental nature which will equip them to attack the complex problems of the future by the most effective analytical methods available. We know that in the dynamic technology of the mid-20th century no training today can equip an engineer to solve the problems of tomorrow. If he is to function most effectively, his education and development will have to be a continuing process and he himself will have to be responsible for keeping his technical capabilities abreast of the technical arts of the future. We are concerned, therefore, with laying an educational foundation on which a sound structure of continuing technical self-development can be built. We believe that the best foundation for such continuing self-development consists of an education in depth and the attainment of technical maturity and not the mastery of numerous specific skills. All of these considerations have led us to the development of a curriculum much more fundamental in content than one might, at first glance, expect to find in an industrial training program.

For the first year, the entire time of the new man is devoted to the program. Classroom work consists of lectures and opportunities for recitation on three days of each week The remaining two days are spent or rotational assignments in the technica departments. In the second and thir years, classroom work is reduced t one day per week, and the studen having completed his rotational assignments enters his technical depart ment and is integrated into one of it regular projects.

The first-year courses are funda mental in nature, and all student pursue the same courses of study, a listed in Table I.

In those instances where a studer has considerable advanced trainin credit is sometimes granted fc courses in which he already is we prepared. Such a student takes a r duced program or, with others lil himself, studies advanced topics ou side of the regular curriculum.

In addition to the orientation cour described below, there are thr groups of courses dealing with tl fundamental disciplines of mathem tics, physics, and communication The mathematics group deals wi

topics of particular importance in the communications field, functions of a complex variable, the LaPlace transform, Fourier analysis, linear vector spaces, and the analytic aspects of linear circuit theory. The physics group contains a course in the physics of waves, inasmuch as wave motion is the basis of all communications phenomena; atomic physics, which is often not included in undergraduate engineering curricula; and the physics of solids, a subject of great importance now that the transistor and related semiconductor devices promise to revolutionize the entire technology of communications during the engineering careers of these young men. The communications group starts with a course in probability and statistics, in which the emphasis is placed on the interpretation and significance of laboratory data. It is followed by courses on logic and switching, largely the mathematics of digital systems; and communication theory, including the concepts of information theory.

The orientation course, called the Bell System, runs throughout the year. It devotes approximately one third of the time to orienting the student in the training program and in the Bell Laboratories, introducing him to the interrelations of the various parts of the Bell System, and giving an introductory treatment of engineering economy and of public utility economics and rate making. The remaining two thirds is devoted to a study of the various transmission and switching systems and of the outside plant which constitute the existing facilities of the company.

The second- and third-year curriculum is more specialized and is largely elective. The program of courses which a student takes is determined by his department and depends upon the needs of the department as well as on the interests and aptitudes of the individual concerned. There are three groups of courses, A, B, and C, shown in Tables II, III, and IV, respectively.

Group A consists of three courses in electronic devices and circuits and a course in technical writing. These are required of all students, because electronics is basic to modern communications, and experiences has shown that almost all engineering graduates can profit by further training in writing and that many need it badly.

Group B, a series of 12 courses on what we consider to constitute the engineering fundamentals of modern communications, leads up to group C, which deals in a rather specific way with various fields of Laboratories work in both the telephone and military areas. Even in the group C courses the attempt is to deal with the principles and the methodology of design and engineering rather than to catalogue the information of the various fields.

During the last several years we have put into the program a group of trainees ranging from about 100 to 150 in number. The total course program taken by each student comprises the equivalent of about 60 semester hours of course work as it would be measured in a university. What we are doing is therefore an educational effort of considerable magnitude.

Administration of the Program

The responsibility for the planning and presentation of the courses is vested in appropriate technical departments of the laboratories in order to keep the curriculum abreast of the most recent advances in the various fields. The research departments contribute heavily to the fundamental disciplines of the first year. The development departments assume responsibility for courses of a more specific engineering nature. In recent years, arrangements have been made with neighboring graduate schools to have certain of the more fundamental courses presented by members of their faculties. This has been done as a part of our program, on our premises, and close coordination with our technical departments has been carefully maintained. We feel that this cooperation between industry and education has added strength to our program, and hope that it has been of benefit also to the institutions and to their faculties. We are desirous of extending it in the future.

Little has been said so far about the rotational work assignments which take place during the first year, although they are a most important part of the program. They are designed to broaden the new member and to increase his potential usefulness to the organization. There are assignments to three departments which have been chosen because they offer technical experience of widely diverse types and because of the relation of their work to that of the man's technical department. In each of these temporary assignments a new member works at a regular and productive job which is a part of the department's regular program. This is in no sense "made work", although prime concern is that the new member learn, rather than that he produce. Care is maintained to see that the grade of work given to the trainee is of professional level. It is intended that in this part of the training program the student encounter in practice the many interrelations of his department with others, and that he learn something of the philosophy of the departments with which he will cooperate in his future work. Moreover, the opportunity to work closely with men in these related departments is of great advantage to a new member. In this way, he becomes acquainted with them, and when he needs advice or assistance in the future, he will know where to go for it.

Graduate Study Plan

Apart from the C.D.T. program which does not lead to an academic degree, the company encourages graduate study on the part of its staff members through a graduate study plan. Under this plan full tuition is refunded to employees who successfully pursue graduate courses in fields broadly related to their work in the company whether as a part of a program leading to an advanced degree or not. Under the plan time may be taken off during regular working hours up to a maximum of 7 hours per week without loss of salary if required for travel or for attendance at daytime courses not available outside of working hours.

In these days of engineering manpower shortage these educational programs are difficult to maintain. They divert a substantial amount of engineering effort from the many pressing and immediate problems which face us. We would not be devoting this effort to them if we did not feel that they were essential in the solution of the greatest problem of all, the building and maintenance of a research and development staff of the highest order of competence. There are doubtless many other ways to approach the problem, we have chosen this one. All of the ways will have one thing in common. They will aid and foster the continuance by the engineer of his education on the graduate level after entering industry.

Dr. Morris Katz,

Occupational Health Division,
Dept. of Health and Welfare, Ottawa.

Canada's rapidly expanding industrial economy in the postwar period and the demands of national defence and other federally-sponsored activities have combined to create a critical shortage of technical and scientific manpower. There is no doubt that this shortage will become more acute before effective remedial measures can be brought into play. A solution of this problem requires the serious attention of industrial leaders, university educationists, engineers and scientists, professional societies and responsible leaders of government. The universities are faced with a lack of class rooms, laboratory and equipment facilities to handle any sudden large increase in student enrollment. It is also of vital importance to increase greatly the teaching staff at existing universities and to provide for teachers and professors from the ranks of graduate and postgraduate students to staff the new buildings and universities which will be needed in the near future.

In some respects the key to the problem of overcoming the shortage of engineers in the future lies in the expansion of financial assistance to both undergraduate and graduate students to ensure that no worthy student is prevented from continuing his university training because of lack of funds alone. In his brief to the recent National Conference of Engineering, Scientific, and Technical Manpower, at St. Andrews, N.B., S. H. Deeks, of Orenda Engines Ltd., indicated that there is an immediate need of 3,700 more university teachers in Canada, or about 60 per cent more than the present staff. Over 20 per cent of the university graduates will be required for the teaching profession. At present there are about 40,000 engineers in Canada, but this force will have to be increased from three to four times within the next twenty-five years if this country is to maintain its competetive position with respect to other progressive industrial nations.

University Enrollment and Immigration of Engineers

To illustrate the role of the engineer in our industrial economy, the number of production workers per engineer in Ontario has decreased from 368 in 1945 to 145 in 1955, whereas in the United States one engineer is required for every 75 production workers. In the postwar period the shortage of engineers has been alleviated to a certain extent by the immigration of engineers into Canada from the United Kingdom and other countries. The extent of this type of immigration within recent years is shown in Table I. On the average, about 280 Canadian engineers have emigrated to the United States annually over the past three years.

Table I
Immigration of Engineers into Canada[2]

	1953	1954	1955 (9 ms. only)
United Kingdom	754	1,003	1,061
United States	168	130	120
Other countries	393	454	532
	1,315	1,687	1,713

The extent of engineering enrollment and corresponding degrees conferred at the undergraduate and graduate levels in universities and colleges of Canada and the United States in 1953 and 1954 is indicated in Table II. It has been predicted by Dr. O. M. Solandt, vice-president, Canadian National Railways, that Canada will require an average of 6,000 engineering graduates each year over the next 25 years, or more than four times as many as are graduated from Canadian universities at the present time.

The post-graduate training of engineers in formal graduate studies is just as vitally important as other training aspects in the continuing education of the engineer. Canada lags far behind the United States in the proportion of graduate to undergraduate engineering enrollments, as shown in the data in Table II. Whereas in the United States the number of engineers enrolled in graduate schools for advanced study in 1953 and 1954 represented 12.6 and 10.7 per cent, respectively, of undergraduate enrollments, the corresponding percentages in Canada were only 3.5 and 3.1. One of the reasons for this disparity is the lack of adequate resources and facilities for advanced study in engineering in faculties of Canadian Universities. About 1,600 graduate students in all branches of science, including engineering, attended Canadian universities in 1955. At the same time, about 800 Canadian students were engaged in graduate studies in the above fields in the United States. A smaller number was registered at post-graduate schools in the United Kingdom and other countries.

In the United States about 50 to 57 per cent of all engineering students engaged in studies towards a master's or other pre-doctoral degree in the years 1952-1954 were taking evening courses. Over the same period evening students working for doctorates in engineering comprised a proportion amounting to approximately 23 to 24 per cent of all doctorate students. No comparable evening courses are available to Canadian students.

Graduate Study in Engineering

Our industrial effort and its dependence on science and technolog for continued growth have reache the stage where the need for grad uate education is well recognized The four or five-year baccalaureat programme is insufficient to provid the necessary scientific foundatio and training for those engineers qual ified to undertake creative work i design and research. Both industr and the teaching profession requir that an increasing proportion of en gineers should have the benefit of more profound knowledge of th basic sciences and mathematics, a well as more understanding of th humanities and social sciences.

The concepts, objectives and r quirements of a graduate study pr gramme have been discussed tho oughly by various American commi tees, such as those of the America Society for Engineering Educatio and the Engineers' Council for Pr fessional Development[5]. It is reco nized that graduate study should re resent a considerable advance i subject matter and attitudes beyon the undergraduate phase. Broa training in new concepts of scientif analysis, synthesis or design is r quired to cope with the increasi rate of development of new indu tries, structures, products or oper tions.

Procedures to Encourage Graduate Study.

At the present, only about one tenth of engineering graduates in Canada eventually acquire graduate degrees. This proportion is about twice as high in the United States. Much more extensive efforts on the part of industry, the universities, and government will be required to remedy this situation, even though it is recognized that graduate study in engineering has become an almost indispensable asset for those who are required to engage in process and plant development, design and research.

It is a well-known fact that a great many Canadian companies are branch plants or associated with United States industries, consequently most of the industrial research and design for such companies are carried on elsewhere. However, there is an increasing tendency for such branch plants and purely Canadian industries to undertake research and design for themselves. Government - sponsored research by Crown companies and other organizations such as the National Research Council, the Defence Research Board, Atomic Energy of Canada, Limited, and Polymer Corporation has been extremely successful, and has attained a high level of recognition all over the world.

Procedures to encourage graduate study involve a three-way effort of cooperation and distribution of responsibility between employers in industry or government, the universities and students. These include the following types of programmes involving financial assistance on the part of industry and government.

(1.) Bursaries and studentships for full-time graduate study.
(2.) Fellowships.
(3.) Assisted part-time or evening courses.
(4.) Grants-in-aid to universities or faculty members.
(5.) Sponsored research programmes.

In the United States, in large metropolitan centres, a considerable number of graduate engineering students attend part-time late afternoon or evening classes for higher degrees while employed professionally. Although such students are usually more mature, they run the risk of being overworked and obviously require a much longer period to complete degree requirements. It is far better to provide sufficient financial assistance to enable qualified students to undertake full-time graduate training.

Specific Plans

Large Industries. Some interesting facts on the procedures and policy of a number of large-scale employers of engineers in Canada for encouraging such staff to undertake advanced degree studies and for sponsoring such programmes financially were obtained from replies to a questionnaire. One large company, employing about 1,000 graduates, has provided assistance for many years to graduates in general through its part-time employment and fellowship programmes, although it does not provide to employees direct financial assistance for postgraduate study. At the present time, about twenty per cent of its graduate employees hold two or more university degrees. This number is considered sufficient to meet its present requirements for advanced technical competance and the present emphasis is upon management training programmes. Enrollment in such administrative courses conducted by universities and professional societies is encouraged and fully supported financially.

Table II. Engineering Enrollment and Degrees Conferred[3]

	Undergraduate		Graduate		
	Enrollment	First Degree	Enrollment	Master's or Pre-Doctoral Degrees	Doctor's Degrees
Year	1953	1952-1953	1953	1952-53	1952-53
Canada	6,662	1,168	232	87	18
United States	171,725	24,164	21,608	3,743	592
Year	1954	1953-1954	1954	1953-54	1953-54
Canada	7,529	1,036	235	90	23
United States	193,692	22,236	20,722	4,177	590

A large smelting company indicatet that, although it had no formal plan covering engineers who wish to return to the university for postgraduate work, various arrangements are made, depending upon the circumstances, after consideration of each case on its merits. Leave of absence is granted to engineers who obtain scholarships or to those returning to the university for advanced degrees. In such cases the individuals continue to be covered for employment welfare benefits and their service is protected for pension purposes. In certain cases, an engineer may be placed on a retainer fee while on unpaid leave of absence to obtain his advanced degree.

Other companies grant leave of absence without remuneration to engineers who wish to undertake formal graduate study but attempt to provide suitable summer employment.

The management of Aluminum Company of Canada, Limited, has for some years operated a post-graduate school, connected with the University of Geneva, at Geneva, Switzerland. The associated company, Aluminum Laboratories Limited, has established a graduate fellowship at McGill University and at the University of Toronto, with preference being given to individuals proceeding to the Ph.D. degree in physical metallurgy or related subjects. These fellowships have a value of close to $3,000 per annum.

The International Nickel Company of Canada, Limited, has announced recently a comprehensive programme of educational grants totalling $2,-500,000, over a five-year period, to assist a large number of institutions of learning in Canada's ten provinces. Of the above sum, approximately $500,000 will be allocated for scholarships, fellowships and special projects, including assistance to teachers of science and mathematics. The Company's present fellowship programme for post-graduate studies will be increased to establish one fellowship in each of Canada's thirteen major universities. These fellowships will have a tenure of three years and provide an annual stipend of $1,500 plus tuition fees, and will include also an additional annual grant of $500 to the institution.

The Imperial Oil Company graduate research fellowships were first introduced in 1946. This plan is open to graduates of any recognized Canadian University for post-graduate study leading to the doctorate, and the fellowships may be held up to three years. Employees that can meet the conditions of the awards are also eligible. Five awards, each of which has a maximum value of $2,000 per annum, are offered for competition every year in the fields of Engineering, Physics and Chemistry.

Government and Affiliated Departments

The National Research Council of Canada

Although the funds expended per capita by Canadian industry on research is much lower than that in the United States, the government per capita spending on research in Canada is probably just as high. It is well known that the National Research Council has had a fundamental influence on the growth of post-graduate research in scientific fields in Canada since its modest beginning in 1917. In addition to the high quality work that is being carried out in various divisions of N.R.C. at its Ottawa and regional laboratories in the fields of applied and pure science in chemistry, physics, biology and various branches of engineering the Council operates an extremely large awards programme consisting of grants and scholarships. Annual grants are made to professors to assist in the promotion of scientific research at the universities. These funds provide for student and other assistants who may be hired by professors, supervising approved research projects, and for the purchase or construction of specialized research equipment not normally available at universities. Scholarships are made available to post-graduate students with the required qualifications for study at Canadian Universities, for Canadians to study abroad, and for foreign students to come to work in Canadian government laboratories. The awards are made on an impartial basis, solely for merit, on recommendations of the Scholarships Committee of the Honorary Advisory Council. The growth of the above programme over the years is shown in Table III.

Within recent years the National Research Council has maintained an overseas post-doctorate fellowship programme which has attracted to Canada considerable numbers of scientists from the United Kingdom for research work at N.R.C. Laboratories and at universities. In addition, the N. R. C. administers consolidated grants for nuclear research and equipment for the Atomic Energy Control Board. The percentage distribution of all N.R.C. scholarships by fields of research, as shown in Table IV, is highest in chemistry and physics. Engineering (including chemical engineering), mathematics, geology and mineralogy account for 21.2 per cent of N.R.C. scholarships awarded for graduate studies as of March, 1956.

Post-doctorate overseas fellowships which are granted to graduates who already have a doctor's degree have a value of $2,500 per annum. Special scholarships for those who are given the opportunity for various reasons to study for advanced degrees outside Canada have a value of $2,000 per annum. Student scholarships for those who are proceeding to take the doctor's degree in Canada are worth $1,200 per annum and bursaries for students in the first year after gaining the bachelor's degree yield $800 per annum.

Table III. National Research Council Awards

Year	Scholarships	Grants-in-Aid	Totals
1919-20	$20,100	$33,316	$53,416
1929-30	49,990	220,442	270,432
1939-40	31,562	337,997	369,559
1949-50	210,670	1,342,106	1,552,776
1955-56	768,249	1,718,720	2,486,969
Totals for period 1917-1956	4,241,675	17,684,148	21,925,823

Table IV. Percentage Distribution of 269 N.R.C. Scholarships by Field of Research, March, 1956

Field of Research	Per cent distribution
Chemistry	25.5
Physics	24.1
Biology and biochemistry	18.6
Engineering (including chemical engineering)	9.3
Mathematics	8.6
Geology and Mineralogy	3.3
Other fields	10.6
	100.0

Civil Service Commission

Employees of federal government departments subject to the rules and regulations of the Civil Service Commission may be eligible for educational leave with pay under specified circumstances as follows.

(1) An employee who is directed to carry out a research project at a university, because of special facilities there, or to do any departmental work at a university, may be permitted to seek academic credit for further studies while at the university.

(2) Educational leave may be granted where it has not been found possible to obtain a qualified person for a specialized position.

(3) Refresher courses or courses of special instruction at a university are open to selected employees of a department, under certain special conditions;

(4) Leave without pay for attendance at university to selected employees, with approval of the Commission, may be granted after at least one year's continuous service, to assist the employee in increasing his efficiency and gaining advancement in the service.

(5) In the case of a university graduate who desires to pursue a planned course of post graduate study, the requirement of one year's continuous service may be waived, if such action is considered by the Commission to be in the public interest.

The Athlone Fellowship Scheme

The background and details of this scheme, which is designed to bring to Great Britain every year thirty-eight Canadian graduates in engineering for post-graduate studies, have been described by Dr. W. Abbott.[9] These Fellowships have a duration of two years and are tenable in industry, in universities, or partly in each of these. The plan has been in full operation since 1951 and the net cost is carried by the British Government. Financial assistance to holders of Fellowships covers the following items: *(a)* the costs of travel from the applicant's home to his place of training, of travel within the United Kingdom as may be approved, and of the return journey; *(b)* a subsistence allowance of £6 10s. 0d. per week, net; *(c)* the cost of tuition at a university; *(d)* an allowance towards textbooks; *(e)* a travel grant of £25 per annum for journeys within the United Kingdom. Industrial employers are asked to pay into a central fund the wages they would normally pay to a trainee of the college apprentice type.

Before the inception of the above scheme, it was well known that although considerable numbers of engineering graduates have come for further training to the United Kingdom from Australia, New Zealand and South Africa, relatively few have come from Canada, mainly because Canadian graduates have available to them the nearby educational resourc

(Continued on page 1087)

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

ROLE OF THE EARTH SATELLITE IN FOUR IMPORTANT IGY EXPERIMENTS

R. W. Porter—*Aeronautical Engineering Review,* May 1957, v. 16 no. 5

Four experiments which can be accomplished using a small earth-circling, instrumented satellite have been selected as having top priority in the current International Geophysical Year satellite program. The satellite will be a highly polished, silvery, spherical body of about 21 lb. and 20 in. diameter. It will contain a radio transmitter operating up to several weeks in the 108-mc. range with a power level somewhere between 10 and 100 milliwatts. This radiation will permit radio tracking. During short periods the power provided by chemical batteries can be increased to permit transmission of data to the ground. If the rocket launching goes as planned the orbit of the satellite will lie entirely above 200 miles altitude but may extend out as far as 1500 miles. At 200 miles it should be barely visible to the naked eye if in the neighbourhood of the observer, within about an hour after sunset or before sunrise. With ordinary binoculars the sphere should be easily visible.

One experiment to be performed is to measure the ultra-violet radiation from the sun at approximately 1216 angstroms. This wavelength is emitted by hydrogen and represents a large part of the total ultraviolet radiation received from the sun. The equipment consists of a tiny ionization chamber filled with nitric oxide gas. This gas begins to ionize at about 1340 angstroms. A lithium fluoride window used in this cell will not transmit wavelengths shorter than 1100 angstroms. Therefore the cell responds only to the narrow band of ultraviolet. Simple electrical circuitry "remembers" the peak value from each orbit around the earth (90 minute trip) and transmits these data together with a short period of continuous observations via radio telemetry whenever the satellite passes over a receiving station.

Most of the energy which is absorbed in the upper atmosphere comes from solar ultraviolet and X-radiation. The absorbed energy appears first as ionization affecting long-distance, point-to-point radio transmission on the surface of the earth, and causing such phenomena as glow of the night sky. Eventually part of the energy penetrates to lower levels in a manner not completely understood and influences weather and climate.

A second experiment is to measure the earth's magnetic field. One part of this field which is constant or changes very slowly is associated with the solid body of the earth itself, and the other which changes rapidly is created by the motion of the electrical charges in the upper levels of the atmosphere at altitudes several times the earth's radius. The instrumentation needs to be extremely precise to determine variations which are relatively small. A proton precession magnetometer will be used. Its operation depends upon the fact that protons have both angular momentum and magnetic moment. If a number of protons are aligned in the same direction by means of a powerful magnet and then released they will precess in the earth's magnetic field at a rate regulated only by the scalar value of that field. This rate will be measured by pickup coils and transmitted directly to the ground by radio telemetry. The data will be useful in analyzing magnetic "storms" which affect communications and aerial transportation, and in testing hypotheses which have been made about streams of charged particles in the upper atmosphere.

The third investigation concerns the nature and origin of the high speed particles known as cosmic rays. Measurements of their characteristics have been difficult because of their interaction with the atmosphere causing creation of secondary particles which obscure the effects it is desired to measure. A Geiger counter will be used to measure the total incidence of cosmic rays at levels well above the atmosphere, without respect to charge, energy or direction. A miniaturized magnetic tape recorder will be included so that data taken during the complete orbit can be played back in a few minutes while the satellite is within range of a receiving station. The practical significance of this cosmic ray information will not be known until later when it can be correlated with data from upper atmosphere "sounding" rocket tests.

The fourth experiment will measure the terrestrial energy balance which is the energy received from and given off by the earth to its environment. The principal energy input of the earth is directional from the sun. Some of the input radiation is diffusely reflected by clouds, the remainder is converted to heat and is ultimately re-radiated in the far infra-red portion of the spectrum. Four bolometers will be used fastened to the exterior of the satellite in a plane normal to its axis of spin. Three will be spherical, one coated black (emissive) at all wavelengths, one white (reflective) in the visible but almost black in the infra-red, and one with a special coating which is nearly black in the visible part of the spectrum but highly reflective in the far infrared. The fourth will have a special shape so that it will respond differently to the diffuse radiation from the earth than to directional radiation from the sun.

The four equilibrium temperatures obtained by the bolometers will be recorded on magnetic tape at approximately 180 points on each orbit and transmitted by radio telemetry when passing over a receiving station. Considering weather as a thermal engine which receives heat input from the sun and exhausts by radiation to space such fundamental data will be useful in predicting large scale movements of air masses.

Other secondary experiments will include pressurized chambers with pressure switches to give an indication of leakage rate in case of puncture by a meteorite, exposed resistance strips to measure surface erosion by micrometeorites and gas molecules, a microphone and counter to record the number of contacts with micrometeorites above a certain minimum energy level, and thermistors to measure skin and internal temperatures. Numerous other experiments which do not depend upon internal instrumentation will be carried out through observations by precision radio equipment and highly accurate photo-telescopes.

NEW POSSIBILITIES FOR PRODUCTION

G. R. Fitzgerald—*SAE Journal,* May 1957, vol. 65 no. 6

New production processes and techniques are being developed through research by the Process Development Section of General Motors. The article discusses some of the developments and may provide some indication as to what the future holds for production.

One of the most interesting fields is the saving of material in the cold extrusion of metal usually giving as well improved physical properties, reduced machining requirements, closer tolerance, and improved finishes. New metal-coating materials and processes show promise of future savings in material. In many cases where high-cost materials are required because of surface characteristics only, new coating processes permit the substitution of low-cost base materials. Resistance to corrosion, wear and heat often can be provided more adequately and more cheaply than through the use of alloys. Many coatings now available such as ceramics, carbides, molybdenum, and others being perfected will find numerous applications in this field. The direct conversion of steel machining chips into parts is another process which has improved to the point where it has great potential for the saving of material. Techniques have been created which make this a relatively simple process and the physical properties of the parts formed closely approach those made from mill-processed steel.

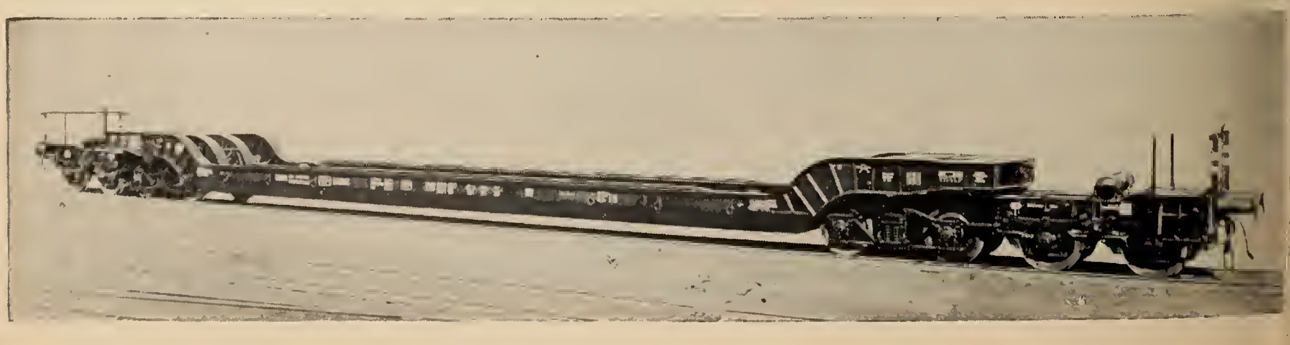
Another recent development is the use of metal adhesives. While they may not completely replace conventional joining processes such as brazing, soldering and welding, they should find wide application. Examples in the automobile industry are in the assembly of aluminum die cast parts and in the application of metal body trim.

The use of modern methods-engineering techniques and procedures greatly improves labour utilization and ensures that even the smallest increments of expended effort are productive. At General Motors the largest single group in the direct labour force is that employed on assembly work. This is an area that has been traditionally manual and i offers great potential for continua improvement through the applicatior of methods engineering and througl the development of mechanical assembly equipment. One GM divisioı has over 100 semi-automatic assembly machines in operation at the present time. The greatest limiting facto to the use of such equipment is economic, the machines being uniqu and therefore expensive, and requiring large run production. Machine in use are assembling such units a spark plugs and engine cylinde heads. Integration of machines an equipment with simple material handling devices provides continuou flow and this is being widely adopte where product uniformity permit The use of electronic computers i the control of production logistic also offers great opportunity for improvement in materials handling.

Developments in the fields of electronics have provided many new inspection tools which are making important contributions to improve quality of products. Use of automatic feedback control with continuou automatic gauging systems have improved the tolerances possible wit modern grinding machines. Gaugin circuits can now be developed whic will do the same for machines usin single point tools, and in addition t policing of size limits, will also indcate tool trends and in many case anticipate cutting tool failure prior t making of a faulty piece. Electroni equipment is being used in the mea

STANDARD GAUGE 16-WHEELED 103-TON WAGON

The loading frame is carried on two 8-wheeled bogies with roller bearing mounted on 940 mm. (3 ft. 1-1/64 in.) dia. wheel Each bogie is composed of a frame carrying two sets of wheels and a 4-wheeled unbraked Diamond bogie. The well-type loading frame is of all-welded St 5 steel construction. Each bogie is fitted with separate draw-and-buffer gear. Two 10 in. air brak systems one for each braked bogie with slack adjuster and brake timing control are provided. In addition, the wagon equipped with two hand-operated screw brakes. The wagon is designed to permit lateral movement of the loading fram facilitate transportation of oversized loads. (Photos: Fried. Krupp/German Industries Fair, Hanover.)



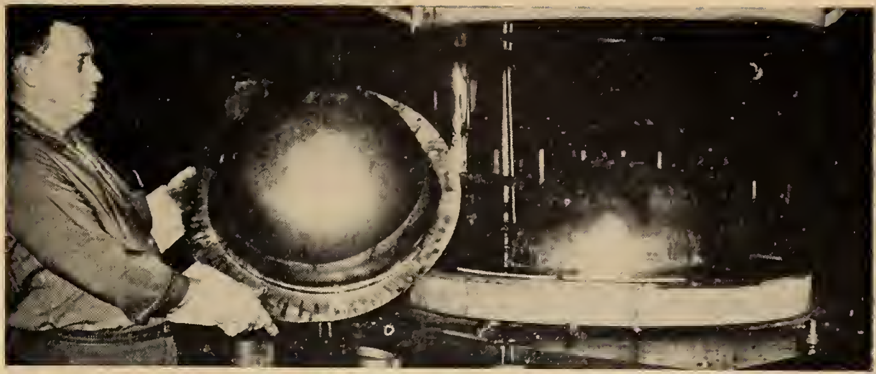
urement of vibration or noise in such items as ball bearings, gear trains and electric motors and in addition to making possible the setting of accurate standards it permits measurement in total and in individual frequency ranges, some of which can not be detected by the human ear. The photocell and phototransistor have relieved the human eye of fatiguing tasks in inspecting ground or polished surfaces for tiny flows. By measuring the change in light reflection between a fault and the desired surface precisely, blemishes barely perceptible to the human eye can be detected with unbelievable rapidity.

Ultrasonics, magnetic and radioactive techniques are now being used to check characteristics which heretofore have been determinable only by destructive means. Ultrasonic instruments which have been commonly applied in the detection of flaws in large steel blocks that are impenetrable by the largest X-ray equipment, are now being successfully used in checking weld quality.

Another electronics application which will be of increasing interest to production engineers is that of static machine controls. One of the most serious problems with modern automatic equipment is the trouble shooting and maintenance of electrical control circuits. Limit switches and relays cannot be expected to last indefinitely nor can the faulty ones always be quickly found and easily replaced. Recently developed static-control systems which eliminate a large percentage of the moving parts of an electrical control system will contribute effectively to improvement in this area. Test comparison of such a system with a normal type resulted in only two operational failures in 9 million cycles for the static or mag-amp circuit while replacement of relays in the standard control was necessary after 3 million cycles.

At present the static control system is more expensive but costs should be reduced as volume increases and as manufacturers gain experience.

Expensive and time-consuming tooling operations caused by design and style changes will receive considerable attention in the future. Development work is going on in "cookie-cutter" type of dies for sheet metal blanking and piercing. Plastic dies for drawing and forming are being considered. Dies made by these techniques are generally one-tenth the cost of conventional types. Although their life is much shorter, improved materials and greater knowledge of their use will prove them to be adequate for many applications.



MANUFACTURING THE IGY EARTH SATELLITE

The spheres for the earth satellite to be launched during the International Geophysical Year are made from 0.091-in. magnesium alloy by deep-drawing from a 32-in. dia. sheet blank, using a graphite lubricant, followed by hot-spinning (at 600°-650°F.) to make an exact hemisphere. The finished hemisphere is machined to a skin thickness of 0.028-in. The outside surface of the shells will have a coating of silicon monoxide, a very thin coating of aluminum (applied by vapour deposition) and a final coating of silicon monoxide. The coatings are to increase heat and light reflectivity. The expected temperature range the satellite will encounter is from about −200°F. to 450°-600°F. (Photos: Acheson Colloids Co.)

ALUMINUM PRODUCTION IN THE CAMEROONS

French Economic and Technical Bulletin, No. 9-10, 1956

Although France's 130,000-ton production of aluminum in 1955 is not enormous compared with the North American production of over two-million tons, it is a sizeable industry and will expand to meet French needs.

The cost of electricity in metropolitan France is too high for expansion of the industry there, but there are three major aluminum production projects being planned in French territory in Africa. Two projects, at Konkoure in Guinea and Kouilou in the Middle Congo, are in the study stage. The third, at Edea in the Cameroons, is under construction and is due to reach full output of 45,000 tons a year at end — 1958.

The Edea project is based on the Edea power plant, opened in 1954 to provide power for the port of Douala, 50 miles away, and now to be sextupled in capacity. This will make it the third largest hydro-electric plant in the French union, producing 1000-million kwh. The original 150 million kwh. will serve Douala, the additional power going to the aluminum plant. The plant will be arranged with a transformer substation feeding four parallel buildings, each some 2000 feet long and containing 52 vats. A special wharf and other facilities are also provided, together with housing and recreation areas for the employees.

Construction on the other two sites mentioned will begin when Edea is in full production. Konkoure, in Guinea, will produce 3000 million kwh., with a potential of 5000 million kwh., and has the added advantage of adjacent bauxite deposits. Kouilou has a potential of about 7000 million kwh.

BRITISH CONFERENCE ON AUTOMATION AND COMPUTATION

Process Control and Automation, vol. 4 no. 5

British industry has recently been interested about the need for a group to concern itself with automation in the widest sense of the word. A preliminary investigation showed that the requirement was for a coordination of the activities of existing organizations rather than the creation of a completely new body which might overlap those already established. Approaches were therefore made to the major Engineering Institutions although it was realized that many other interests would have to be represented. Not only the technological but also the sociological. As a result of the exploratory conference the following statement was issued:—

"Because of the rapid growth of the new industrial techniques popularly known as automation, which also comprise automation, process control and data processing generally, and of the many persons likely to be affected by their application, it became increasingly clear, towards the end of 1956, that there was an urgent need for the establishment of some central organism to afford liaison between all the interested organisations.

"It was realized that a very broadly based structure was desirable and at the invitation of The Institution of Civil Engineers, The Institution of Mechanical Engineers and The Institution of Electrical Engineers, Exploratory Conferences were held on 6th March and 16th April as a result of which the representatives of some twenty organisations with interests in the fields of automation and computation, approved proposals for closer collaboration, and agreed to recommend them to their Councils for adoption. The proposals, if accepted by the bodies concerned will result in the setting up of a British Conference on Automation and Computation which will be organised in three Groups of Societies having the following fields of interest:

Group A—The engineering applications of automation techniques.

Group B—The development and applications of computers, automatic controls and programming techniques.

Group C—The sociological and economic aspects of automation and computation procedures.

"The following bodies would be invited to act as the Convenors and Sponsors of the three Groups:

Group A—Convenor: Institution of Mechanical Engineers, Institution of Civil Engineers. Additional Sponsors: Institution of Chemical Engineers, Institution of Electrical Engineers, Institution of Production Engineers.

Group B—Convenor: Institution of Electrical Engineers. Additional Sponsors: Institute of Cost and Work Accountants, Institute of Physics, Office Management Association, Society of Instrument Technology.

Group C—Convenor: British Institute of Management. Additional Sponsors: Industrial Welfare Society, Institute of Cost and Works Accountants, Institute of Personnel Management, Institution of Production Engineers.

"An essential feature of the proposals is that liaison between the Groups should be established on a permanent basis from the outset, and it is foreseen that the central unit of the Conference which will be established for this purpose will undertake such other duties as, for example, the preparation of periodical digests of published papers falling within the general fields of automation and computation.

"If the proposals are approved by the several Societies the Convenors and Sponsors of each Group will summon further meetings. Any other body would be very welcome to apply for membership. At these conferences detailed arrangements will be settled for liaison within the United Kingdom so that progress in the fields of automation and computation and their applications can be fostered, and so that in the international field, the British contribution to international conferences can be focused.

"There was unanimous agreement that great advantage to the country would ensue from the measures of collaboration, it being fully recognized that, in the framework of automation, the importance of the human side is equal to, if not greater than, that of purely technological aspects."

It is hoped that this organisation will function as a vigorous and forward thinking body. The opportunities presented by automation must not be thwarted by outmoded policies and practices. Dead wood must be rigorously cut out to allow fresh and vigorous industrial growth. This conference can play a great part by assisting in this operation providing it is able to secure the goodwill of all parties concerned. Its widespread character allying the technological and human sides presents a unique opportunity for industrial achievement.

THE SHAPE OF LOCOMOTIVES TO COME

Engineering, 1957, v.183, no. 4755, 27 April.

This might have been the title of the obviously heartfelt plea of the writer of the column "Plain Words", who asks: "Why can't Diesel and electric locomotives be more like steam locomotives? Why can't they have manly lines and robust personalities?"

There is little evidence that the newer forms of railway traction are being given decent outward shapes. They are not allowed to show their functional parts, and components are clothed to the taste of the designer, so that there is no vital and positive idiom of design. Generations of men and boys have had an affection for the steam locomotive; its disappearance will lead to an inestimable loss of good-will towards the railways.

The writer speaks feelingly of current trends in design. "It is more than likely that the new locomotives will develop, in outward form, like the American motor-car — each successive design becoming more and more sensual and cheaply glamorous. The latest products of Detroit show all too plainly how readily an excitable designer could make a pair of locomotive buffers look like a certain vital statistic. This trend might impress an overworked railway officer but it would not affect the boys who are the next generation of passengers and railway officers. Unless, of course, we are misjudging the sophistication of modern youth."

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Progress by NYSPA

Progress during May was highlighted by the completion of the Chimney Island channel improvement work five months ahead of schedule. Despite wet weather conditions which hampered excavation, construction progress on the project as a whole continued on schedule. Concrete placement for all features exceeded 1,100,000 cubic yards and excavation passed 39.5 million cubic yards. Employment averaged 4,860 for the month.

Concrete placement at the Barnhart Island power-house continued on schedule. Approximately 63,000 cubic yards were placed during the month bringing the total to date to 586,000 cubic yards. Concrete also was placed in the various switchyard structures and in the transmission line towers.

At Long Sault dam, approximately 130,000 cubic yards of common material were excavated from within the stage II foundation area, rock excavation was started and the downstream cofferdam was being brought up to grade. At Iroquois dam, 30,000 cubic yards of concrete were placed during the month, bringing the total to date to 138,000 cubic yards.

At Massena intake, work was continued on the upstream and downstream cofferdams. Material was being placed on the downstream cofferdam to reduce the seepage. The area within the cofferdam had been unwatered and preparations were underway for starting the foundation excavation.

Excavation work under two of the five channel improvement contracts was essentially completed. Work was continuing under the remaining three contracts. The channel work was approximately 70 per cent completed. Continued good progress was being made by the reservoir clearing contractors with 5,500 acres or half

The power-house takes shape.

of the clearing work completed.

Chemical treatment of the Barnhart-Plattsburgh transmission line continued. Materials for the line construction were being unloaded and hauled to the structure sites. Erection of structures was started in the Helena-Bombay area.

Work under the three highway relocation contracts was progressing ahead of schedule. The contract was awarded for the construction of Richards Landing dike.

Progress by Ontario Hydro

There were several rainy periods throughout the month of May. This delayed work in some sectors of the project, particularly dike building operations. The work force in May climbed to a total of 4,675 persons.

Erecting of structural steel for the generating station erection bay and administration building was started in May and had advanced well by month end. The steel erection for this building is expected to be completed in July.

Concrete placing at the power-house site progressed favourably throughout the month, bringing the total to 595,000 cubic yards. Concrete operations were completed for No. 12 draught tube and No. 1 ice sluice deck slab, and girder beams have been placed to full height. Progress also was being made with mechanical equipment installation, and speedring No. 7 and the pit liner had been assembled.

On Cornwall dike, work was resumed in all sections. Placing material on the main dike areas in sections No. 1 and 2, north and east of Mille Roches continued, but was hampered somewhat by wet weather. Material also was placed in the sector around the dike closure structure north of the power-house. Nearly half the material had been put into the power-house section of the dike adjoining the U-abutment.

Traffic was again using new No. 2 highway after being re-routed temporarily to the old highway because of the spring thaws. Paving operations had been resumed in the various sections of the new highway with the second lift of asphalt being laid. Work also was started on No. 31 highway overpass at the relocated Canadian National Railway main line north of Morrisburg. Most of the piles had been driven and the footings had been completed for this overpass.

Installation of the transformer and switching control equipment was progressing at the St. Lawrence transformer station. This equipment is being installed now to be ready to receive power from the new generating station in the summer of 1958.

At Cardinal construction of the protective dike around the Canada Starch Company had been finished. Filling the cribs at the upstream end of the dike was the last stage of the work in this sector. Channel improvement progressed well in most areas throughout the month. Three dredges had been working in the Chimney Island contract and at the end of May the total amount of the material removed was 1,050,000 cubic yards.

At Galop Island section, excavation had been concentrated mainly in the dewatered area off the west end of the island. Work also was progressing off the east end of the island in the dewatered section between Dixon and Kellogs Island. About 12,000,000 cubic yards of earth and rock had been removed in this contract.

Removal of material from Iroquois Point was slowed down by wet conditions in the excavation area, but some 1,550,000 cubic yards had been excavated. At nearby Point Three Points, excavation was underway in full scale and favourable headway was being made.

Final house-moving was completed in Iroquois in May, with a total of 150 homes moved into the new townsite. Building of two six-unit multiple dwellings was begun. A highlight of the work at Iroquois was the official opening during the month of the new shopping centre. Temporary locations in the shopping centre had been arranged for United and Anglican Churches. Stores will be used as locale for the churches until the new edifices are ready early next year.

First stage of the house-moving operations in Morrisburg was virtually completed in May with a total of 62 homes having been moved. Work was in progress on the new Morrisburg shopping centre. Construction of the 36 rental housing units continued throughout the month.

At Ingleside and Long Sault townsites work was concentrated on grading, on building sidewalks and culverts, house painting operations and clean-up. Construction of schools and churches in these two towns was continuing.

Ontario Hydro announced early in May the appointment of William L. Fraser as field project engineer on the St. Lawrence Power Project, to succeed William M. Hogg. Mr. Fraser had been serving as project manager on Hydro's Sir Adam Beck No. 2 Development at Niagara. Mr. Hogg leaves to take a senior executive post with Great Lakes Power Company.

Progress by SLSDC

A huge underwater blast in the Detroit River on May 28 signalled the start on the $136 million upper lakes channel dredging and deepening project which will take five years to complete. Authorities have estimated the deeper channels will mean some $10 million in annual transportation savings.

SLSDC will get the additional $35 million in borrowing authority it has asked of Congress. Last week of May the House Public Works Committee approved the full request. But chances are the new total of $140 million will not finish the job, and the corporation will have to come back to Congress again for one more increase next year.

Progress by SLSA

At the end of May, concrete on the lock section of Iroquois lock was nearing completion. Two stiff-leg derricks were erected and work had commenced on installing the sector gates. Stoplogs were all delivered. The only excavation remaining was for the downstream approach wall.

At the Upper Beauharnois lock a start has been made on placing of concrete at the upstream lock entrance, while rock excavation had reached 50 per cent of completion. At the lower lock some 50,000 cubic yards of concrete were in place for the highway underpass and highway approaches, completing this portion, while placing of concrete had been commenced for both sides of the lock chamber, with 25,000 cubic yards placed to date.

Placing of concrete has also been resumed on the Cote Ste. Catherine lock, with about 130,000 yards or 37 per cent of the concrete placed to date, all of it on the lock chamber. The lock was completed to full height for about half its length, though little work had yet been done on the approach walls. Sixty per cent of the common excavation and 85 per cent of the rock excavation had been completed.

On the St. Lambert lock the downstream entrance wall was about 65 per cent completed and the lock chamber about half poured. 60,000 yards of concrete had been placed during the month of May, bringing the total to date of 190,000 cubic yards placed or close to half of the total. Installation of machinery had not yet been started but work had been commenced on the contract for excavating the regulating channel on the land side of the lock.

On the various dredging and channel excavation contracts, work was again under way, with all of them pretty well up to schedule and some of them far ahead of schedule. Dredging of the Lancaster Bar had been completed, as well as the excavation on the Welland canal between Locks 2 and 3.

Work continues on the St. Lawrence Seaway Authority's head office building at Cornwall, but with little likelihood of its being ready for occupation until late this year.

Progress on Bridges

At the end of May, with the four most southerly spans of the Jacques Cartier bridge raised some 20 feet and traffic diverted over Bailey bridges on to a temporary approach, work was about to start on raising the spans on either side of the seaway channel. A derrick had been erected on falsework just south of the channel for placing the steel towers on which the new through span will be erected alongside the existing deck span.

The superstructure will be jacked up on successive piers in six-inch lifts. Raising of the supporting piers will follow in four-foot lifts. Traffic will be re-routed from Bailey bridges to the original spans in August. By November the spans will be raised to their final position and the new span over the seaway channel will replace the old deck-span.

With the temporary rock-fill approach at the south shore end of the Mercier bridge ready for traffic, seventeen of the original bridge piers at the south end were blasted out on May 8 and traffic re-routed over the rock-fill. Work is now proceeding on building the pier foundations for the new locations of the permanent approaches, with one pier already completed to full height.

Prime Minister St. Laurent announced on May 28 the confirmation of Charles Gavsie as President of the St. Lawrence Seaway Authority, effective June 1. Also announced was the appointment of Jean-Claude Lessard, M.E.I.C., Canadian head of the Standard Railway Equipment Company, as vice-president, effective July 1.

Seaway News

Schedule Tight but Practical

Construction schedules on two phases of the seaway project were described as 'tight but entirely practical', following a meeting of the St. Lawrence Joint Board of Engineers and representatives of the four authorities concerned with its construction, at New York City on May 7.

The schedules call for raising the water level in the Long Sault pool above the international power-house, and for re-routing of ships requiring a 14-foot depth from the Canadian canal to the south Cornwall channel on the U.S. side in July 1958. By 1959 the seaway is expected to be navigable by ships with draughts up to 25 feet.

Announcement on Tolls

Acting SLSA President Charles Gavsie and SLSDC Administrator Lewis G. Castle announced on May 15 that toll committees of the two seaway authorities had been exploring various bases for assessing tolls. In developing a formula the Committees' objectives had been: procedural simplicity which would minimize cost of collection and expedite dispatching, and recovery of the cost of the seaway and its operation on a basis that would provide economical rates and encourage traffic.

Following studies of toll structures of other international waterways and of pertinent maritime rules and practices, they announced, the committees had under consideration a composite basis of toll assessment as being most suitable. Such a toll structure would encompass an assessment per ton of cargo or its equivalent, together with an assessment on the vessels' registered tonnage.

The committees were continuing their studies of traffic factors and other elements involved in the development of a tariff of toll rates, and would continue to obtain the views of prospective users of the seaway, they stated.

Gains in Port Traffic Predicted for Montreal

Dr. Pierre Camu, professor of geography at Laval University, estimates the seaway will increase shipping traffic at the Port of Montreal by between 19 and 17 per cent. He was the principal speaker at two recent luncheon meetings sponsored by the Montreal Board of Trade.

The most probable gains in shipping through the port of Montreal, he predicted, would be made in the carrying of grain and general cargo. Of the estimated 36½ million tons potential on the St. Lawrence canals, Montreal would likely gain between a minimum of 3 million tons and a maximum of 9 million tons.

Iroquois dam. Looking downstream from the Canadian mainland on Iroquois Point, Stage II construction in the foreground.

Grain, he stated, was the largest single commodity handled at Montreal, amounting to 38 per cent of total tonnage. Petroleum and oil accounted for 14 per cent and coal 9 per cent. Grain also represented 65 per cent of outward foreign tonnage and 61 per cent of inward domestic tonnage.

Atlantic Seaboard ports would lose from 30 to 50 per cent of their grain trade. Chicago and Buffalo would show gains of 13 and 15 per cent respectively and Milwaukee 6 per cent, with lesser gains for Toronto and Duluth-Superior. If grain were not trans-shipped in their local elevators, losses might be felt in lower St. Lawrence ports.

The Hon. Lionel Chevrier, speaking in Montreal on May 13, discussed the general benefits of the Seaway to the Port of Montreal.

Referring to a study made by the Indiana University School of Business and the Chicago Board of Trade on the effect of the seaway on grain marketing, he felt this recent study too important to overlook some of the conclusions arrived at. It was stated in this recent study that by 1966 the Seaway would be carrying from 150 to 200 million bushels of grain exports. Total Canadian exports would approach 200,000,000 bushels, and the combined Canadian - American volume would be in the neighborhood of 350 to 400 million bushels by the mid-'sixties'. "This, of course", he pointed out, "is the result of one study only, but it is extremely significant for the Port of Montreal in the post-seaway era".

In the area between Cote Ste. Catherine and Préville, it might be assumed that the responsible Seaway Authority would see to it that its heavy industrial potential is not overlooked, water-transportation-wise," he said. The navigation channel in the Laprairie Basin was 300 feet wide, two turning basins had been provided and both rail and motor transportation were available. Illustrations of what may happen here could be found in the tremendous industrial development along the Welland Ship canal, or along the Lachine canal where only 14 foot navigation was available.

Referring to the south shore area below Jacques Cartier bridge, the speaker expressed belief that this presently low-lying area possessed great potentialities. "These cannot, however, be fully realized," he warned, "until the ice conditions which prevail in this area have been removed. The ice conditions will be materially improved when the full power potential in the Lachine section has been developed."

Canadian Pipeline Projects

Westcoast Transmission

Construction of the Westcoast Transmission Pipeline was reported to be 85 per cent complete as on June 20, with only 100 miles left to complete. The line is now expected to be operating in August, two months ahead of schedule.

Westcoast officials have been contacting all potential gas producers in southern Alberta during May to increase gas supplies for their programs in California and the U.S. Pacific Northwest. Already Westcoast has control of half the production from the huge Savanna Creek field. Several other promising gas fields are shaping up in the southwest corner of Alberta. Demand and reserves have grown substantially since the last time export proposals from the province were studied, and further approval by a new federal government will have to be sought before additional export is allowed.

British Columbia Electric is already delivering gas to its service areas in the Vancouver area under a temporary arrangement with the Pacific Northwest Pipeline Corporation. During the coming autumn the Company expects to take more than 50 million cubic feet daily of Peace River gas via the Westcoast pipeline. This would be the equivalent of some 817,000 horsepower or almost a third of presently installed electric capacity of the entire province.

President A. E. Grauer told the Investment Dealers Association of Canada at Jasper, Alberta, early in June that his company was "working continuously at the problem of supplying Vancouver Island", and that he was "optimistic about this proving feasible."

Trans Canada Pipelines

Construction on the Alberta trunk line gathering system was ahead of schedule on the first stage by the end of May. Construction is being done in four stages and the whole system will cost $54.2 million. Work between Provost and the Saskatchewan border was under way. The submarine crossing of the Red Deer river was completed. Dutton Williams and Barker Construction Co. have the contract for the overhead crossing of the South Saskatchewan river. Fulton Bannister Ltd. had commenced clearing grading and stringing on the line from Bindloss to the Field Gate. All pipe and equipment for stages 2, 3 and 4 had been purchased on firm orders.

Under the gas transportation contract with Trans Canada, the Trunk Line has accepted a fixed payment of 4 cents per thousand feet during the development period. Based on minimum throughputs it would be three years before the company would be operating on a profit making basis. With larger throughputs than minimums set out in the contract, 'Trunk's' revenue position will improve accordingly.

Spring construction on the western section of the Trans-Canada Pipe-Line's line from the Alberta-Saskatchewan border to Eastern Canada, got under way May 9 at Pense, 15 miles west of Regina. Mannix Ltd., of Calgary, the contractor building section three of the 34-inch diameter pipe line, is now working on all phases of construction.

To speed up trenching while the frost still was in the ground, Mannix used a pilot ditching machine, followed by two more ditchers which cut the ditch to the required six feet. Although frost was not too serious a problem, the pilot ditcher often had rough going due to the heavy mud.

East of Regina, contractors were ready to start construction as soon as the annual spring road bans are lifted sufficiently to allow heavier equipment on the highways. Dutton-Williams Brothers Ltd., building section four, was double-jointing the 40-ft. lengths of pipe on the right-of-way in preparation for operations to follow. Price-Poole Limited, on section five, had completed double-jointing pipe for its section and had almost completed stringing the 80-ft. joints along the right-of-way. Pipe-laying on Sections 4 and 5 started in June. Canadian Bechtel Limited, had started on Section 6 at the end of May and was also completing double-jointing operations. On the

Red River south of Winnipeg, Marine Pipeline and Dredging was completing a dual crossing with the 34-inch diameter pipe. East of Winnipeg, Majestic Contractors Ltd., of Edmonton, was clearing and grading section seven.

Trans Canada called for tenders early in June for the 310 miles of its main 24-in pipeline between Toronto and Montreal.

Crown Pipeline Corporation

From the Ontario border to Port Arthur, Ontario, on the section of the line to be built by the Northern Ontario Pipe Line Crown Corporation, clearing, grading and other preliminary work were well under way. The Crown corporation announced the award of four contracts covering four spreads of varying lengths into which the 310-mile route between the Manitoba border and Port Arthur has been divided, involving a total expenditure of $15,556,429.

Starting at the Manitoba border, Dutton Williams Brothers Ltd. was awarded 58 miles. Spread B, the next section of 94 miles was awarded to Morrison-Shivers, Ltd. Spread C of 80.5 miles was awarded to Majestic Contractors Ltd., while spread D, of 78.5 miles into Port Arthur was awarded to Houston contracting Co. of Port Arthur.

Though almost certain to reach Winnipeg for the 1957/58 heating season, Alberta gas now appears unlikely to be delivered to the Lakehead before winter. The precambrian granite east of the Ontario border requires heavy blasting on ditches, and pipelaying will not start before July on most of the spreads. No pipe is yet delivered west of the provincial boundary. With the best of luck, pipelaying may be completed by late fall. If worst possible conditions occur, apart from any delay on pipe deliveries it may be 1958 before the first stage of the Crown pipeline is all in the ground.

Winnipeg and Central Gas Co. has announced natural gas rates in an application to the Municipal and Public Utility Board for approval of its rate schedule. The application will be heard on May 24. Some 2,500 Winnipeg homes are now heated by manufactured gas. Some 14,000 other premises have installations awaiting delivery of natural gas expected this fall. The company estimates the rates will permit heating moderate sized homes 25 per cent cheaper than with oil.

Most residential customers are expected to select the plan which permits the use of gas for all home purposes through one meter. On this plan the Company sets a price of 99 cents per thousand feet for house heating; $3.75 per 2,500 ft. for water heating; and $1.30 per 500 ft. for cooking. The corresponding rates for manufactured gas are $1.70, $4.85 and $1.45.

Jack hammers and wagon drills, operated by compressed air, preparing right-of-way in Eastern Manitoba.

Union Gas Co. of Canada Ltd. will start in mid-June on its 141 miles 26-in. diameter main pipeline in southwestern Ontario to Hamilton, Oakville and Sheridan. The line, which will cost some $35 million, is the main cog in Union's expansion program. Welland Tubes Ltd. commenced manufacturing the pipe last February.

Canadian Bechtel Ltd. has been awarded the contract and will start with at least two spreads. Initially gas will come from Panhandle Eastern via Windsor. Eventually the flow will be reversed, with Union using gas from Trans Canada Pipelines.

Northwest Nitro-Chemicals Ltd. at Medicine Hat will commence a $150,000 extension to its plant late in June. This will permit production of four new fertilizer formulations and place the company in a stronger position to develop outlets.

Pipeline News

Along the whole length of Canada's Lake Erie shore line the search for off-shore gas is being explored. The new activity has been spurred by Consolidated West Petroleum's remarkable record of successes the last two or three years in drilling opposite Port Alma. The Company has 34 wells capped, capable of producing on average span-flow potential of a million cubic feet daily per well.

Nearly 1½ million acres are involved, plans are to drill some 50 offshore wells this season between the two ends of the lake. There is a big close-at-hand market in Ontario for practically all the gas that can be produced, at delivered prices of close to 35 cents per thousand feet of clean gas. Erie is a shallow lake. Deepest well drilled so far was in 65 feet of water. Gas production comes from shallow horizons (1050-1350 feet). Drilling costs are relatively low.

CGA Sets Test Standards System

Canadian manufacturers of gas appliances will soon be doing business by mandatory Canadian standards instead of optional U.S. standards. Test specifications are now being prepared by the Canadian Standards Association and compliance with the new standards will be required by law in Ontario after September and in British Columbia after January. Other provinces are expected to follow suit later.

The only legal requirements Canadian gas appliance manufacturers have had to meet to date have been minimum safety standards set by provincial authorities, though additional performance tests were voluntarily undertaken by most reputable companies.

Import Bill Offered in Congress

A bill which would practically bar import of Canadian gas was offered in mid-May by congressman John Sager of Pennsylvania. Present U.S. law provides for Federal Power Commission approval of imports 'unless not consistent with the public interest'. The bill would hold it not in the public interest to import or export gas if it will result in economic dislocation, unemployment or injury to competing U.S. fuel industries.

FPC hearings are expected to recess in August. Expert pipeline lawyers predict they will not get down to the basic issues before October, thus hearings are expected to run well into the winter months.

The big issue in the case is whether Midwestern Natural Gas Co. shall be allowed to build a system from which companies around the areas to be served would meet fringe competition. But the question of imported gas, on which the northern half of Northwestern's project would depend, has thus become an issue in Congress.

Coal Dealers to Fight Threat of Natural Gas

The coal industry, in Eastern Canada will wage a fight for preservation of its markets from the threat of natural gas through a new organization, the Bituminous Coal Institute of Canada. An information program will be beamed initially to architects, construction firms and consulting engineers, who will be supplied with information as to competitive costs, recent data on new equipment and handling methods.

Studies will be conducted on a central heating plant idea for groups of buildings. Schools are planned for members and retail coal dealers. A comparative analysis of costs for various fuels has been distributed to those interested in the problem of fuel uses. Heating by soft coal was shown to be 28 per cent cheaper than by oil. Natural gas to compete with coal would have to sell for 42 cents per thousand feet.

In the United States in 1956 a Bituminous Coal Industry survey showed natural gas was 100 per cent more costly than coal in parts of Utah and Colorado, most of Kansas and Missouri and parts of Iowa and Illinois. Gas was 125/200 per cent higher than coal in Wyoming, South Dakota, Nebraska and Iowa. The survey, first of its kind, is regarded as merely the beginning of a general market research program. A survey for Canada, the industry claims, is needed.

Notes on Financing

Public financing by Northern Ontario Natural Gas Co. originally scheduled for mid-May, did not appear on the market until mid-June. $10 million worth of units consisting of one debenture and one common share were offered at $30 per unit. A further $15 million of financing is expected later.

Union Gas Co. of Canada will make a rights offering of common stock to shareholders of record May 23, 1957, at $55.00 a share on the basis of one common share for each four shares held. Further capital required will be provided by debt financing early in 1958.

The Stratford Theatre

The Stratford Theatre, in use since July 1 for the Stratford Shakespearean Festival, is capped by a dome roof of 150-foot span without any supporting columns within the auditorium. It is a circular building, 200 feet in diameter, with a 40-foot foyer extension running 120 feet along the front side. It is aproximately 70 feet in height, and valued at $1.5 million.

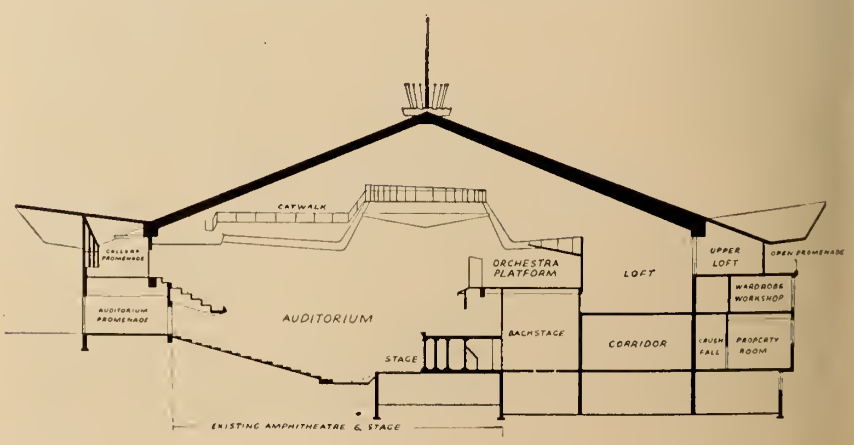
This structure was made possible by a unique engineering design which carries 34 steel beams — each 4 tons — from the perimeter wall to a centre point like spokes to a hub. A massive reinforced concrete ring beam, 4 feet square in section, running around the perimeter takes the thrust of 80,000 pounds pressure from each of these beams. In the centre they converge on a compression ring with a combined pressure of nearly 2.5 million pounds.

To assemble the beams, the steel erectors' crane with its 90 foot beam was inched through an opening in the partially completed structure over an earth ramp. Then a steel tower, equivalent to the elevator shaft for a six storey building, had to be built just to hold the roof beams in position till they could be secured, bolted and welded into a permanent support. The steel tower was then dismantled and the steel erector's crane inched out of the building interior.

Each of the 34 steel beams is actually a roof assembly with trusses and supporting members attached to the beam's 75-foot span. These assemblies were prepared on the ground and erected complete.

The building of the completely round theatre was undertaken by the Foundation Company of Canada, at a profit of one dollar, the work to be done between the closing of the 1956 and the opening of the 1957 seasons.

New Theatre for Stratford Shakespearean Festival



The festival had outgrown its tent theatre.

The distinctive design of the new building, meant to carry on and contribute to the already well known artistic and festival atmosphere of the Stratford productions, had also to provide the practical needs of acoustics for an audience of 2,000 seated around three sides of the stage, and space for a backstage area which is the best in any North American theatre.

The design and choice of materials (reinforced concrete, steel framework, and timber decking) for the 200-ton "petticoat" roof was described by Charles Hershfield, M.E.I.C., of Morrison, Hershfield, Millman and Huggins, consulting structural engineers, in a paper given at the recent annual meeting of the Institute.

Six basic devices are employed for the acoustics. The most important is the curve of the ceiling. The undulating conical pattern of the roof is repeated in the design of the ceiling. The conical facings tend to spread out the sound. A curve upwards some distance in from the perimeter is calculated to reflect and disperse the stage sounds back into the auditorium behind the actor.

There is a 30-foot diameter ceiling centrepiece of composite fibre glass panels in honeycomb design, which forms an acoustic shield to disperse the orchestra tones back into the auditorium like a lighting fixture reflector.

Serrated walls on either side of the stage, and a ring of acoustic treatment on the outer perimeter walls of the auditorium are other important aids. The walls have been specially treated with surface materials which will absorb rather than echo sounds.

The side walls, stretching from the stage back to the perimeter and separating the backstage activity from the audience, are faced with perforated and ordinary plywood in a pattern designed "to make the reverebation time of the auditorium correct at all frequencies".

The theatre structure has been built around and over the existing concrete bowl which served as auditorium seating for the original tent theatre. But the bowl had to be cut back to enlarge the back stage area, and tent columns and supporting bases had to be removed, as well as the reinforced concrete where the bowl was foreshortened. Foundations had to be dug and poured against the existing bowl; scaffolding and forms had to be assembled around and above it.

What Goes On

Industrial Leaseholds

It will take about three years to complete an apartment and office project in Toronto the plans for which were announced recently by Industrial Leaseholds Co. Ltd.

The site comprises an open cut subway strip over half a mile long, the subway retaining a permanent right of way under the development. The site, running parallel and adjacent to Yonge Street, will have eight nineteen-storied apartment blocks and two office blocks each of 14 stories.

The buildings will be set centrally and over the subway cut, which will be covered in and landscaped. They will be on modern type stilts. In size (3,312 rooms in 1,630 apartment units and 492,800 square feet of office space) the project is reported to be the most ambitious of its kind in Toronto.

Also under consideration is a slum clearance redevelopment project in downtown Toronto, known as the Queen-Sumach Redevelopment.

Winnipeg Airport

Close to $10 million will be spent on expansion of the Winipeg airport it was announced in May by the Department of Transport.

First stage would be the completion of plans for the Air Terminal Building, costing some $5 million. Architects were appointed.

The Department planned to construct this year a power-house, an equipment garage, radio and radar facilities at a cost of approximately $500,000. One runway is to be extended to 8700 feet and a new taxi strip constructed, at a cost of over $2 million. A temporary expansion of the terminal building is to be built this summer.

Surveillance Radar

Montreal airport has the first unit of the Department of Transport surveillance radar program, planned to provide radar coverage in the vicinity of major air terminals and airways across Canada. It was officially commissioned in April.

Similar units are being installed at Toronto, Winnipeg and Vancouver airports and eventually long-range radar coverage for airway operations will be installed at fifteen major air centres from coast to coast.

Algoma Steel Corp.

The interests owning stock in Algoma Steel Corp., having purchased them from the estate of the late Sir James Dunn are: Mannesmann International (200,000 shares), A. V. Roe Canada (150,000 shares), McIntyre Porcupine Mines (50,000 shares), and Locana Corp., a private U.K. banking firm (50,000 shares).

Financial Post, May 18

M-H-F Acquires Machinery Firm

Massey-Harris-Ferguson Ltd., has purchased the assets, patents and designs of Mid-Western Industries, Inc., Wichita, Kansas.

Mid-Western operations will become part of the M-H-F industrial division, general manager of which would be Charles J. Davis, president of Mid-Western. Present Mid-Western

---

A concrete chimney, 554 feet high is part of the St. Lawrence Cement Company plant at Clarkson, Ont., officially opened on June 12, 1957. Over a million dollars was spent on special traps within the chimney to reclaim all waste. Their effectiveness is such that less than one per cent of the plume from the stack is waste. The constant plume is almost entirely steam. The photograph was contributed by Ciment Fondu Lafarge (Canada) Ltd.

personnel will be retained in manufacturing and marketing operations.

Financial Times, June 7

Electronic Mill

Canadian Westinghouse Co. Ltd., has received a $3,000,000 order from Algoma Steel Corp. Ltd. to build a huge electronic brain to run a proposed new combination plate and blooming mill.

The project is scheduled to be completed in 1959.

Financial Times, June 7

Nichols Chemicals

Nichols Chemical Company will build a special chemical plant at Valleyfield, Que., which could make Canada independent of foreign sources for a large number of fine chemicals now used in tonnage quantities by the industry itself and by many industries having chemical processes.

Manufacturing such products as metallic and alkali fluoborates and fluorides, nitrates, sulphates and acetates, the plant will serve such industries as electroplating, aluminum, metal finishing, uranium, rubber, automotive and plastics. The sixth major expansion in two years for the company, the new plant is expected to be producing in December.

Financial Post, June 15

Canadian Pacific Airlines

One hundred passengers flown at a time at 400 m.p.h. over the polar route will become a routine matter for the Canadian Pacific Airlines when the mammoth Bristol Britannia airplanes begin their service in the late autumn of this year.

Like any other flying equipment, the planes will undergo rigid inspections and tests before going into service, according to Ian Gray, director of engineering and maintenance, of C.P.A., who recently addressed the Vancouver Branch of the Engineering Institute of Canada.

Overseas Telecommunications

From the new building in Montreal of the Canadian Overseas Telecommunications Corporation a two-way flow of communications links Canada with the world.

This is the headquarters opened in March this year for the publicly owned C.O.T.C. and its domestic affiliate, Canadian Pacific Telegraphs.

VHF Radio Signals In Hydro Plant

Very high frequency radio signals are being used for automatic control of two of Nova Scotia's nine hydroelectric generating plants. R. H. Ferguson and W. H. H. Dean, of Canadian Westinghouse Co., Ltd., Hamilton, Ont., reported recently that utilization of a mobile voice communications band for this purpose was introduced for control of hydro plants at Nictaux and Paradise, because power line carrier was impractical and microwave is often uneconomical when only a small number of channels are required.

In their paper, "Remote Control of Generating Stations over Radio Channel", given at the summer general meeting of the American Institute of Electrical Engineers, they said the VHF in the 152-174 mc band was in existence between the control station at Hell's Gate and the two generating stations in question. "Using this installation, a field survey was made, from which it was concluded that the use of standard designs of high gain antenna would ensure a transmission circuit of the required reliability using standard FM radio transmitter and receivers," they observed. "The novel feature of this installation was the integration of the radio equipment and the supervisory equipment."

The authors pointed out, however, that utilization of a voice communications band for supervisory work may not have very wide application because of licensing restrictions.

The hydro plants supply only a third of the electric energy used in the Province, but their operation at maximum efficiency will play an important part in the over-all generating operation for many years, they said.

Epoxy Resins

The use of Epoxy resins in the electrical industry are many and varied, and range from the many life saving jobs, as they are called, to the toughest of tooling applications.

The Engineering Laboratory at the Peterborough Works of Canadian General Electric Company, in conjunction with engineering and manufacturing components, has produced a number of satisfactory applications for these materials, and is constantly working on new ones.

Among the successful tooling applications that have been developed is a forming die for forming steel fan blades .180 inches thick. This die, made from glass reinforced Epoxy has produced some 2500 parts and is still serviceable. Other types of tooling such as drill jigs, holding fixtures and checking gauges and some types of structural parts, can also be produced by using the Epoxy resins.

The life saving type of application is that with which parts that are in short supply can be duplicated to help production people meet their schedules and shipping dates, or repair broken instruments and other types of cases and porous casings, or rectify miscellaneous errors that occur in the shop.

The general properties of the Epoxy resins are quite well known and any attempt to list any formulations here as a guide would not be feasible, because different hardeners, fillers, curing temperatures, time and additives, all have definite and different effects on the final properties of the cured resin.

The use of these materials in industry of almost any type is virtually unlimited, and the development of new fillers, hardeners, etc. combined with more know how in their use, will broaden the field in which they can be successfully used. However, in many cases it will be necessary for the engineer to design for the use of these materials, instead of trying to make the material fit in with the present design.

There are some difficulties encountered in using the Epoxies. Among the foremost of these are the high cost of suitable production molds and the exotherm generated by the reaction, and the handling problem caused by toxicity of resins and hardeners used.

Annual Meeting At Banff

An Unqualified Success

This resumé of the events at the seventy-first annual general and professional meeting of the Institute is a preamble to the full report which will appear in the next issue of the *Journal*.

Four engineering societies were represented at Banff by this group. Left to right: Mrs. M. G. Lockwood,, M. G. Lockwood, Houston, Tex., president, American Society of Civil Engineers; Mrs. McKillop, V. A. McKillop, retiring president of the E.I.C., Mrs. Coover, T. A. Crowe, Glasgow, Scotland, immediate past president of the Institution of Mechanical Engineers, and M. S. Coover, president of the American Institute of Electrical Engineers.

The seventy-first annual meeting, at the Banff Springs Hotel June 12-14, was an outstanding success in all respects. It created two records—it was the largest meeting of engineers ever held west of Toronto and the largest professional meeting ever held in the Banff Springs Hotel. Total registration was 1058.

From the start things functioned smoothly and this is a clear indication of the liaison and co-operation that existed between the Alberta branches and Headquarters staff — both before and during the meeting.

Early on the Monday morning "Operation Banff" commenced to function. On that day there were conferences of officers, staff, committeemen and all arrangements were finalized.

On the morning of Tuesday the 11th, student delegates met, with Jim Harris of Toronto acting as moderator. At the same time the branch officers and the university engineering faculty members opened their meetings and the annual meeting of Council was convened. All these meetings aroused great interest and provoked excellent discussion and conclusions.

The meetings adjourned at noon for a brief visit with "Muriel" and luncheon. After lunch the meetings resumed their deliberations and the registration desk opened.

At 7.00 p.m.—the President's reception and dinner were held. Among the guests were M. S. Coover of Ames, Iowa, president of the American Institute of Electrical Engineers, and Mrs. Coover, T. A. Crowe of Glasgow, Scotland, immediate past president and official representative of the British Institution of Mechanical Engineers, and M. G. Lockwood, Houston, Texas, president of the American Society of Civil Engineers, and Mrs. Lockwood. Past presidents of E.I.C. in attendance were V. A. McKillop, R. E. Heartz, D. M. Stephens, John Finlayson, T. M. Hogg, L. F. Grant, J. B. Stirling, James A. Vance.

"Muriel" went into operation again during the evening and by nine p.m. every province of Canada and many of the states of the Union were represented at this pleasant and informal gathering.

At 10.00 a.m. on Wednesday June 12, the Annual General Meeting of the Institute was opened by President McKillop. It was well that it had been arranged for this meeting to be held in the ballroom of the hotel as the attendance of members constituted another record in E.I.C. history. The advance printing and distribution of the Annual Report again proved to be a great asset. It facilitated the presentation of reports and provided time for questions and answers without the necessity of running into "overtime". At 12.00 o'clock the meeting adjourned for refreshments and a pleasant, informal luncheon under the chairmanship of annual meeting committee chairman W. A. Smith of Calgary.

At 2.00 p.m. the technical meetings opened. Ten papers were presented on Wednesday with some of the sessions going on simultaneously. This procedure prevailed throughout the meeting and made it possible to have a total of 34 tech-

Representatives of the engineering faculties of seventeen Canadian universities attended the education conference which was part of the annual meeting. Here are some of the delegates (from front row, left): D. L. Mordell, McGill University; President V. A. McKillop; H. G. Conn, Queen's University; J. A. Harle, University of Alberta; J. W. Hodgins, McMaster University; J. F. M. Muir, University of British Columbia; Jacques Laurence, Ecole Polytechnique; L. P. Bonneau, Laval University; A. E. Macdonald, University of Manitoba; M. L. Baker, Nova Scotia Technical College; W. E. Lovell, University of Saskatchewan; I. M. Beattie, University of New Brunswick; E. E. Goldsmith, Carleton College; R. A. H. Galbraith, University of Ottawa.

nical presentations and a management panel discussion before five p.m. on June 14. Many phases of engineering work were covered by the speakers but the emphasis of the meeting was on Canadian oil and gas.

Vice-President R. M. Hardy of Edmonton chaired the dinner on Wednesday evening at which retiring President V. A. McKillop was the speaker. It is hoped that Mr. McKillop's address can be published in an early issue of the *Journal.*

Thursday's technical presentations finished at noon and during the afternoon a golf tournament and a bus tour through the mountains formed the program.

That evening the annual dinner of the Association of Consulting Engineers of Canada and the "E.I.C. Petroleum Dinner" were held simultaneously. At the Institute dinner the speaker was C. O. Nickle of Calgary who gave a clear and concise picture of the past, present and future of oil and gas developments in Canada. J. C. Sproule of Calgary was the chairman.

Following the two dinners there was a presentation of the "Pipeline Musical Revue" — written, produced, sung and acted by the wives and members of our Calgary Branch. This show was one of the entertainment high-lights of the meeting. It was topical, tuneful and clever—and the enthusiasm of the audience equalled that of the performers.

Throughout the Thursday morning the new council held its first meeting and in the afternoon the Consultants held their annual meeting.

On Friday, the fourteenth, technical sessions went on continuously from 9 a.m. until noon and were resumed at 2.00—with final papers of the meeting being presented at 4.00 p.m.

Vice-President R. L. Dunsmore chaired Friday's luncheon at which retiring president Vernon McKillop presented certificates of honorary membership in the Institute to J. O. Martineau, A. G. L. McNaughton, P. M. Sauder, and W. S. Wilson. Prizes and medals of the Institute were awarded as follows:—
Sir John Kennedy Medals to Richard Lankaster Hearn, M.E.I.C., Toronto, and to Irving R. Tait, M.E.I.C., Montreal; the Julian C. Smith Medal, to Edward Victor Buchanan, M.E.I.C., London, Ontario.

David B. Steinman, M.E.I.C., New York, was awarded the Gzowski Medal of the Institute; Douglas Tyndall Wright, Jr.E.I.C., Kingston, Ont., the Duggan Medal and Prize; George Arthur Jewett, Toronto, the Leonard Medal; William Russell Way, M.E.I.C., Montreal, the Ross Medal; and Nicholas E. Hudak, Jr.E.I.C., Toronto, the John Galbraith Prize.

Following the presentation of the awards President McKillop unveiled a stainless steel plaque commemorating Henry J. Cambie, M.E.I.C., a pioneer railroad engineer who spent most of his professional life in the west surveying and building lines for the C.P.R. through the Rocky Mountains

The "Pipeline Musical Review" was a smash hit.

Here and There at Banff

Groups from Winnipeg, Quebec, and British Columbia (below, top to bottom). The delegates shown here are: Winnipeg, Prof. W. F. Riddell, J. P. C. McMath, K. J. Fallis, Brandon, R. E. Chant, W. R. McQuade, Ian Fraser, W. L. Wardrop; Quebec, C. C. Louttit, Arvida, E. B. Schaefer, Montreal, B. O. Baker, Quebec, and G. M. Boissoneault, Montreal; British Columbia, Percy Bland, Vancouver, T. T. Dobie, Trail, T. W. Lazenby, Trail, R. H. Carswell, Vancouver, A. C. M. Davy, Vancouver, and W. G. Small, Trail.

In the groups above, some people taking active parts in the annual meeting. Top, the new president, C. M. Anson (second from left) with three of his officers, Vice Presidents G. M. Dick, Sherbrooke, Que., S. C. Montgomery, Trail, B.C., and H. R. Sills, Peterborough, Ont.

Centre, some of the ladies who graced the proceedings: Mrs. R. C. Jarvis, Mrs. V. A. McKillop, Mrs. H. M. Hunter, chairman of the Ladies' Committee, Mrs. C. M. Anson, Mrs. K. W. Mitchell, and Mrs. B. A. Ellis.

This group of friends of the Institute includes Past-President R. E. Heartz, Mrs. Stirling, Mrs. Dunsmore, Past-President J. B. Stirling, Mrs. Heartz, and Past Vice-president R. L. Dunsmore.

and Fraser Canyon. The plaque will be permanently located in the C.P.R. station at Vancouver.

The Management Panel, held in the afternoon was an outstanding success—Bruce A. C. Hills of Montreal, president of Urwick Currie Limited, was the chairman. His panelists were R. A. Emerson, Montreal, vice-president, operations and maintenance, Canadian Pacific Railway; D. M. Stephens, chairman and general manager, Manitoba Hydro Electric Board; A. L. Bishop, president, Consumers Gas Ltd., Toronto; W. H. Young, manager Chemical-Metallurgical Division, Sherrit Gordon Mines Ltd., Fort Saskatchewan, Alberta.

The Annual Banquet on Friday night was, according to members who have attended many such Institute affairs, one of the most colourful and best arranged events they have attended. The head-table guests were "piped-in" by a lady piper — and they were a true representation of the engineering profession — and its many phases — of Canada, Britain and the United States. Mr. Justice S. Freedman of the Court of Queen's Bench, Manitoba, was the speaker and he based his address on Canadian and world events during the first seventy years of the Institute—1887-1957. His humor, pathos, descriptions, and conclusions held his audience throughout his presentation.

The formal part of the evening concluded with Vernon A. McKillop turning over the presidency of the Institute to Clement M. Anson. This was done before an audience which gave Mr. McKillop and Mr. Anson a standing ovation. Immediately after this dinner the annual E.I.C. ball commenced.

Throughout the meeting the ladies had a program of interesting and entertaining events, arranged for them by a ladies' committee headed by Mrs. H. M. Hunter of Calgary.

On Wednesday morning there was a meeting of the representatives of the E.I.C. Engineers' Wives Associations. In the afternoon they witnessed a demonstration and heard an explanation of the manufacture of petrochemical products for domestic use. The Thursday morning these activities were resumed. A bridge tournament and tea were held Friday afternoon. There were well-timed coffee parties throughout the three days of the meeting and the program was so arranged that the ladies were with the men at all the principal luncheon and dinner functions. As a souvenir of the meeting all the ladies were presented with ceramic lapel pin made from Alberta products.

On the Saturday morning many of the engineers and their wives left for tours of some of the Alberta oil fields and parts of the Trans-Canada Highway.

A special note of thanks is due to the public relations department of the C.P.R. which provided the photographers who made an excellent pictorial record of the meeting; and to those firms and members who supplied photos for the display depicting Canadian engineering work completed or in process during the past year. Industry was again very generous in its support of "Muriel".

A more detailed report of other phases of the meeting will be printed in the next issue of the *Journal* and most of the technical papers presented will be made available to all members through the same medium.

This is the retiring council of the Institute which met at Banff on June 11. Many of these officers will also be in the new council.

Month to Month

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE
ELECTIONS AND TRANSFERS

ASME-E.I.C. International Council

The International Council held its regular semi-annual meeting in Montreal, May 6.

Present to represent ASME were W. F. Ryan, president, A. G. Christie, chairman of the Council, Thompson Chandler, vice-chairman, C. E. Davies, secretary, T. A. Marshall, Jr., assistant to C. E. Davies, O. B. Shier, 2nd deputy secretary of the society.

Representing the Engineering Institute of Canada were V. A. McKillop, president, H. G. Conn, of Kingston, G. N. Martin of Montreal, L. C. Sentance of Hamilton, H. S. Van Patter of Montreal and L. Austin Wright, general secretary.

One of the outstanding pieces of business was the signing of an amended co-operative agreement. This agreement was prepared first in 1943 and at this most recent meeting the various clauses were brought up to date.

Discussions took place on the possible means of further co-operation in both Canada and the United States. Reference was made specifically to the lubrication conference which is taking place in Toronto in October and to the solid fuels conference of ASME taking place in Quebec City also in October.

It was agreed that the third ASME-E.I.C. Education Conference would take place at the University of Michigan, Ann Arbor, on October 16 and 17, 1958. It is planned that the Conference will deal with such subjects as the continuation by colleges of postgraduate education in industry and the training of technicians and the accrediting of engineering curricula, etc. The overall title to the theme might be "The Place of Industry in Engineering Education".

Cover Picture

Two presidents of the Engineering Institute, at the annual meeting in Banff: C. M. Anson (left), who took office for 1957-58, and V. A. McKillop, retiring after a year of distinguished service.

Canadian Pacific Railway Photograph

President of the E.I.C., V. A. McKillop (left), and President W. F. Ryan of ASME, sign co-operative agreement.

Considerable time was spent discussing the possibilities of arriving at a reduced joint fee for membership in both organizations, particularly in relationship to the students. This is quite a complicated problem but it was agreed that settlement would be reached by the time the next conference takes place in the fall of the year.

Consideration was given to the future developments of the mechanical engineering field in Canada. It was emphasized that with Canada's great industrial development the numbers of engineers and their needs would increase substantially. It was hoped that ASME could be of assistance to the E.I.C. in meeting this great expansion.

At the conclusion of the conference a reception and buffet supper were held at the University Club for the ASME members in the Montreal area. Following that, the group adjourned to the auditorium of the Engineering Institute where short addresses by the two presidents were given and a great many questions were asked and answered relative to ASME affairs in Canada.

The next meeting of the International Council will take place in the United States at the annual meeting of ASME.

Aviation Writers Meet Again

The nineteenth annual meeting of the Aviation Writers Association was held late in May in St. Louis, Missouri. Following the well established pattern the meeting was made up of five days packed with events of interest and importance. The program included lectures, speeches, plant visits, special air flights and lots of discussions.

Although the center of the convention was in St. Louis, one day was spent at Kansas City, Missouri, and another day at Wichita. At both these centres there were special objects and events to be seen.

The Canadian delegates flew in a great variety of machines, including Viscounts, helicopters, fighters and troop carriers, jet transports, etc.

There were exhibitions of all types of plain and fancy flying, including a flight in a small rubber plane that was blown up with air but with absolutely no rigid framework.

The conclusion of the meeting was so close to the deadline for material for the July *Journal* that it has been impossible to prepare any for this issue other than this short reference. It is planned to have more details of the machines and other events in later issues.

"Daylight through the Mountain"

Here is a further reference to the biography of the Shanly's which the Institute is publishing. It is both a comment and a quotation. It shows something of the material contained in the book, and it is hoped, will encourage members to read the book itself. The book is now on sale at Headquarters and at the book stores. To members of the Institute it is available through Headquarters only at $5.00. The regular price is $6.00 (Ed.)

The Irish and Construction

It was a 'great day for the Irish' when they started to build railways in Canada. It is true that many played their part with a 'peck and shevell'; but it is also accepted that if you wished to see the foreman you had to ask for Mike. He was there to see that the work was done right or he would have nothing to do with it. This was partly window dressing on Mike's behalf; but it must be recognized that the Irish brought with them considerable talent for construction work. Nor did that ability stop at the foreman .level, for the engineering of both railways and canals in the older parts of the Provinces of Quebec and Ontario was largely designed and executed by natives of Ireland.

We are well aware of the inherent talent of the Irish in the realm of poetry, music, acting and oratory; but in engineering they have not received as frequent notice as they deserve. Such talent is not remarkable when it derives from the environs of old centres of civil law where property was standardized and accurate lines drawn between mine and thine. This was not so in early Ireland for, under the clan system, property was for the use of the clan and lines were not closely drawn within its territorial limits. When these latter changed it was usually by force, followed by long recollections of despair from the evicted.

English invasions of Ireland, over a period of centuries, caused temporary dislocations, without much orderly change, until 1641 when three fourths of the land in that island was confiscated. Little was done at that time to change the appearance of the country until ten years had passed. The matter was brought to a head by Oliver Cromwell's discovery that the Royalists were gaining strength in that quarter. After routing his enemies, Cromwell saw in the great tracts of deserted lands an opportunity to pay off his soldiers. He picked William Petty, a young physician trained at Leyden and Oxford, to survey and plot the Irish land into three and five acre parcels.

Petty must have assembled all the able-bodied surveyors in England as well as some from France, for in thirteen months he had mapped, plotted and recorded one-half of the land in Ireland. The document produced is still known as "The Down Survey". That the work was well done by a group selected for their ability is witnessed by the statement of Sir Thomas Larcom when editing it in 1851. He said that the survey "stands to this day with the accompanying books of distribution, the legal record of the title on which half the land in Ireland is held; and for the purpose to which it was and is applied it remains sufficient".

The surveyors were paid off in Irish land, which many of them accepted, to become citizens of that island. It is this association that may have revealed itself almost two centuries later when such high engineering skill came forth as it recognized in the names Shanly, Killaly and Tully. When the age of canals was about to begin in Ireland, it was soon evident that citizens of that island were not only able to acquire engineering knowledge with understanding but also to add to its total by creative talent. John Killaly was named Chief Engineer of the Irish Board of Works in 1792. Forty years later, his son, Hamilton, came to Canada where he became Minister of Public Works in 1841.

Hamilton Hartley Killaly became the first chairman of the group of engineers and architects who combined to form what is now the Royal Canadian Institute in 1849. It was the first organization of its kind in Canada and Killaly's interest in it sprang from his genuine interest in engineering education. He had for some years before maintained an unofficial school of engineering within the Provincial Board of Works. Happily, the brother of an illustrious uncapped and ungowned graduate from the Killaly School saved the correspondence which passed into his hands during outstanding construction work upon which they were engaged, a century ago.

Shanly Deals with Human Element

In these letters, mostly from Walter Shanly to his brother Francis, there are revealed not only many of the methods of securing their supply cf materials, the methods of fabricating it into durable structures, but chiefly the method of mastering the human element as met with in the persons of both employees and superiors at the various levels. Machinery and materials change, but the nature of man does not at the fundamental level. In this latter regard, the pages of opinions and estimations poured forth by Walter Shanly a century ago are just as true today as when they were written.

During the early days of his engineering responsibility, Walter Shanly used to rehearse his plans on paper by writing to his brother. If we take a glance at his thoughts as Chief Engineer, preparing to build his first railway, the Bytown & Prescott, we find him trying to have Francis return to Canada from a canal enterprise upon which he was engaged in Pennsylvania so that he could divide the burden. Early in February, 1851, he wrote, "My first troubles are about to commence as there will doubtless be an outcry about my employing Yankees . . . I think there is going to be a good opening in Canada and I mean to put the "Bytown" through by daylight. My intention is to make the cheapest possible kind of road, trestle across brooks and valleys and have hardly any masonry. I will put up temporary wooden work at all the crossings leaving room enough to build in the masonry afterwards. If I can only have a *good track* down and a train of cars over the Road in 1852, my fortune is made in Canada and I should not wonder if I had to finish the Western for them yet . . .

"The Montreal and Prescott is pretty sure to be surveyed anyhow and the whole country is astir from here to Toronto. I am, I fear, a victim of treachery. I told you in my last that Tom Keefer showed himself anxious to keep me in the Bytown affair and told me that he would on no account undertake Location, as his health was not good enough. He was here last week and spent the evening with me and coolly informed me that he is to have the Montreal and Prescott. So that his object in forwarding my views at Bytown was simply to get me out of the way . . .

"Dana is a hard-up man and I suppose you will just have to take Peter back and say nothing about it. I wish I had him now instead of hiring horses to take me to Bytown. I would offer to buy him only I think Dana would want cash down.

As ever, W. Shanly."

Great Construction Era

Two weeks later, he wrote giving the first inkling of the great construction era upon which the Government of Canada was about to launch. He had had a letter from their brother Charles, a clerk in the Board of Works. He wrote, "There is still much excitement in the Province on Railway matters . . . Killaly had called upon Charley the night before he wrote. He gave his reason for calling that he wished to learn what my engagements were. The Government, he says, have it in contemplation to enter into the Montreal-Toronto Railroad scheme. In which case, they would have an engineer of their own and that he was resolved to pitch upon me as the man . . . I am the only Canadian Engineer who has any practical knowledge of Railway work and I certainly *ought* to get the place, if such a place is created.

"Anyhow, Canada is going to be good ground, and if I only had the Bytown and Prescott located and the work commenced, I would be easy in my mind . . . I must organise my Corps at an early date. I shall get my instruments from Phelps and Gurley. They say they have improved greatly, and will give me any trial I require and long credit, and after all their levels are good enough for Railway work. I may call upon your man for some stationery. Could you get me a convenient set of pocket drawing instruments when next you go to Philadelphia? I want something very nice and also 3 or 4 good drawing pens, and if you can find it, a first rate protractor with limb; but this latter article, I fancy, can just be got in New York. If I get time next month, I shall probably go to New York and if so to Philadelphia. Will you meet me?"

Walter then answers some of the questions asked by his brother regarding the canal upon which he was then engaged. "As to puddling. If you put in two feet; *good,* it will hold any head of water that you have to provide against. Where your canal is made upon embankment, you must be very careful to have the earth from *bottom to top* laid in layers and carted over, not *dumped* as in railroad embankments. *Complete the section of the canal before you commence puddling* and then dig out the place to be occupied by the puddle. Did I give you a specification for the puddling over the St. Pierre Culvert, Beauharnois Canal? That is the best piece of work of its kind anywhere, only 2 feet thick, 10 feet head of water. I think you took that specification from here. Always use gravel in preference to anything else . . .

"I am getting avaricious, I find myself in possession of the $500 required for the England trip, but fear I can't come that, unless I persuade the President to send me home for iron . . ." F.N.W.

For Senior Engineers

Back in January the chairman of the Niagara Peninsula Branch sent a circular letter to all the senior members within that branch, pointing out that their continued interest in the branch would be much appreciated.

Speaking in the words of Percy L. Climo, who is chairman of the branch, the branch had this to say:

"Do you recall your early experiences as a member of the Institute? Do you remember that, at the monthly meetings, it was a source of great satisfaction to you to associate with better known and more experienced men in the profession? Sometimes, you would get a few words with some of them but even when you did not you had the satisfaction of rubbing shoulders with them. The meetings were that much more important in your mind because such men found them important enough to attend.

"Looking back, it is easy to recognize that those men did something extra for the profession which, perhaps, they did not themselves realize. By their example and their interest they encouraged the younger members to gain some knowledge of the broader aspects of engineering, to look beyond their own immediate jobs.

"This brief letter is intended as an expression of thanks to those of you who attend the meetings of the Branch as often as you can. It is directed, too, to those others who, because of heavy responsibilities or even perhaps because of a feeling of not being needed, have tended to neglect our monthly gatherings. Think back a little and you will realize what your presence means to the junior men. Think back and recall, too, the enjoyment you got out of the meetings.

"This is a personal appeal to you to attend as many meetings this year as possible. They are never oftener than once a month and only about a half dozen in a season and yet the encouragement you will give to the younger men is immeasureable."

The *Journal* is publishing this portion of the branch message in the hope that senior members of every branch will see it and will continue or take up again their interest in branch affairs.

Athlone Fellowships, 1957

Athlone Fellows, 29 Canadian engineers who graduated this year and nine more who have spent some years in industry, will shortly be on their way to Britain. They were chosen this year by the Ministry of Education of Great Britain, whose representative, Dr. H. H. Burness, toured Canada earlier this year.

Athlone fellowships provide two years' training in industry, or two years' post graduate work at a university, or one year of each. Ten of this year's successful applicants will follow the first plan, eight will follow the second, and twenty will have one year in industry and one at university. Their subjects of study will be varied, including aeronautics, nuclear energy, metallurgy and civil, mechanical, electrical and chemical engineering.

This program, inaugurated in 1951, attracts many applications each year and has obvious and highly valued educational benefits for the young engineers selected for this advanced training. Travel, tuition and maintenance allowances are provided by the program.

As always, there are student members of the Institute in the group: M. C. Campbell, of Nova Scotia Technical College; C. Lemyre, Laval University; A. P. Jurkus and P. Fortier, of Ecole Polytechnique, Montreal; R. Fancott, McGill University; K. Vandalen, Queen's University; P. J. Fulford, and D. M. Onysko, University of Manitoba; D. W. Johnson, University of Saskatchewan; and E. V. Jull, a 1956 graduate of Queen's University.

Information about the fellowships is available from the registrars of eleven Canadian universities having engineering faculties. Applications should be made each year before January 15. Information is also available from the United Kingdom Information Offices in Ottawa, Montreal and Toronto.

Correspondence

Engineering Education

To the Editor:

Mr. E. T. W. Bailey's interesting comments in the March issue of *The Engineering Journal* are responsible for this letter, and I agree that the unspecialized graduate might be more acceptable to industry. Personally, I am convinced that a common course in engineering will be adopted before too many years in place of the specialized courses which, in general, are now being given.

An oil company executive commented that his concern preferred a graduate with a sound knowledge of geology rather than one who specialized in oil geology. His company would give the training in that field.

Mr. Bailey's idea of two sessions in one year could be carried out, but the staff problem would be almost insoluble. Queen's University had summer sessions in 1945, 1946, 1947 and 1948 and, since students could not take two successive sessions except in the first two years, the winter students, in summer, and the summer students, in winter, could be used as junior staff assistants. What made this possible was, of course, the fact that these were ex-servicemen and mature.

In regard to producing more graduates, there are two practices in the United States which are almost unknown here. (1) The cooperative colleges in that country go quite a way toward assisting a man to get a degree and, in addition, the comments from industry which work with the plan are most favourable (see "Why Industry Likes the Co-Op" by C. F. Arnold, chief engineer, Cadillac Motor Division, General Motors—*Journal of Engineering Education*, December, 1956.) A free leaflet describing the plan and listing colleges that offer it can be obtained from the U.S. Department of Health, Education and Welfare, Office of Education, Washington 25, D.C. (circular No. 463 entitled Co-operative Education in the U.S.). (2) An engineering degree can be obtained by attending evening classes in our neighbour to the south, whereas, to the best of my knowledge, that is not possible in Canada. The January, 1957, *Journal of Engineering Education* has an article entitled "Evening Engineering Education and its Contributions". On the evidence of the writer, the contributions are considerable.

In line with Mr. Bailey's statement that "the rest of the year valuable physical teaching facilities lie idle" is an article in the *Saturday Evening Post* of June 9, 1956, in which Dr. Litchfield, principal of the University of Pittsburgh, says it is silly for the average student to go to school for about thirty weeks every year and have twenty-two or three weeks off. In professional life an engineer will have only two or three weeks off. An article in *The Engineering Journal* of April, 1956, criticizes the shortness of the college year along with other items.

May 21, 22, 23.

Professional Development

The fifth annual conference of chairmen and delegates of Professional Development Courses was held in London, Ontario, on Saturday, May 4, 1957.

Although all chairmen, committee members and those interested in Professional Development in all the Institute Branches are invited, this conference has come to represent mainly Ontario groups, others having transportation difficulties. This year, however, to the great pleasure of the delegates, Commodore A. C. M. Davy was able to represent the Vancouver P.D. group, which topped all the others with an enrolment of 231.

Nine Ontario branches were represented — Belleville, Border Cities, Brockville, Hamilton, London, Niagara, Port Hope, Sarnia and Toronto—by 47 delegates, who in turn spoke for about 500 members who have taken the courses in the past season in these nine branches.

President of the Institute, V. A. McKillop opened the meeting with an address commenting on the value of Professional Development. It is, he said, a symbol of what the Institute stands for.

E. V. Buchanan was the luncheon speaker, explaining the tie-in of Professional Development as sponsored by the Engineering Institute, with the work of The Engineers' Council for Professional Development (New York). Colonel L. F. Grant acted as chairman of the meeting.

Ten days before the conference, reports from the different groups were circulated, and the topic of the meeting was "Constructive Suggestions for Next Year's Course, Learned from Courses Just Completed".

Fifteen P.D. group chairmen spoke for five minutes each in turn. The interesting result was that no two dealt with the same problems and all made excellent suggestions.

Guests and delegates were invited by the E.I.C. to a luncheon in the Terrace Room of the Hotel London. Discussion resumed after luncheon and the meeting was adjourned at 3.00 p.m. Minutes of the meeting are available from the E.I.C. Toronto field office, 236 Avenue Road, Toronto.

Peterborough was chosen as the site for next year's conference, which will again be set for the first Saturday in May.

Reports from the Groups

Some highlights of the delegates' reports will be of interest.

Vancouver attracted 231 enrolments with a series of lectures on law, given by a judge and several leading barristers. Brockville's experience was that the high quality of the material presented by Queen's University speakers brought enthusias-

---

Luncheon during the Fifth Annual P.D. Conference

Shown standing are guests Edgar Cross, Toronto, E. V. Buchanan, London, E.I.C. member on E.C.P.D. Council; L. F. Grant, field secretary, E.I.C.; President V. A. McKillop; and A. C. M. Davy, the new western field secretary, E.I.C.

Also present were guests D. J. Matthews, London Branch chairman; G. L. Schneider, E.I.C. member on E.C.P.D. training committee; and Mrs. Lilian Robertson, Toronto, assistant to the field secretary.

The delegates were: Belleville, T. E. Flinn, and D. B. Pullan; Border Cities, W. G. Mitchell; Brockville, H. L. Gilchrist; Hamilton, W. H. Hohn, J. A. Walsworth, W. A. H. Filer, K. R. Crean, A. I. Wilkinson, R. A. Gunst, R. F. Hall; London, A. L. Furanna, C. H. Osborne, H. Martin, W. Sinkins.

Niagara, C. A. McDonald, H. Saaltink, Robert Wright, H. C. L. Joe, F. Fernandes; Port Hope, J. A. Pollock; Sarnia, K. J. Radcliffe, M. M. Brown, C. C. Blackmore; Toronto, W. J. Mosley, T. W. A. Morris, Gordon Davidson, John Kirk, W. Breckenridge, J. C. Strang, D. Zavitzianos, Sherman Gauley, W. W. Walker, R. C. Sadler, W. A. Lardner, C. F. Millar, L. C. White.

tic audiences, and accounted for several new memberships.

Speakers for Hamilton emphasized the value of a preplanned program of material not available elsewhere. They described their integrated four-year course. London will have a two-year course, with the second year concentrated on fewer topics.

Niagara Branch plans a high calibre three-year program, with emphasis on participation of members. They will promote enrolment through E.I.C. meetings and through other groups and with the help of management.

The Port Hope secretary gave details of five meetings of last year. Sarnia will have a program in the fall. Toronto speakers expressed appreciation to the Hamilton group for their guidance on the matter of a constitution. They placed much importance on the annual P.D. conference. Border Cities reported particular interest in personnel and management subjects.

Sir Sandford Fleming, Hon. M.E.I.C.

An event which commemorated the achievements of the man who gave the world "Standard Time" was held in Ottawa on May 16, 1957, when a memorial tablet to Sir Sandford Fleming was dedicated.

A prominent engineer, educator and author, Sir Sandford Fleming died in Halifax in 1915, a man famed as a great Canadian scientist, though he was born in Scotland. He had served Canada in many important ways from 1845, when he came to this country, already a surveyor and engineer.

Sir Sandford was a director of the Hudson's Bay Company and of the Canadian Pacific Railway, and he was chancellor of Queen's University for thirty-five years. He was a charter member of the Royal Society of Canada, and its president in 1888. Many other evidences of appreciation were apparent during his lifetime — the honorary degree of LL.D. was awarded to him by St. Andrews University (1884), by Columbia University (1887), University of Toronto (1907) and Queen's University (1908). He was created a C.M.G. in 1877, and a K.C.M.G. in 1897. He was a charter member of the Engineering Institute of Canada and was made an Honorary Member in 1908.

The new tablet, placed on the Dominion Observatory Building serves as a formal acknowledgment of Canada's debt to him. Its inscription reads as follows:

"Sir Sandford Fleming, K.C.M.G., Pioneer in world communication. Engineer in charge of surveys and construction; Northern Railway, 1852-63; Intercolonial Railway, 1863-76; Canadian Pacific Railway, 1871-80. Designer of the first Canadian postage stamp, 1851. Promoter of the system of standard time, proposed 1876 and widely adopted by 1883. Advocate of the Pacific Cable and "All Red Route". One of the founders of the Royal Canadian Institute. Born in Kirkcaldy, Scotland, 7th January, 1827. Died in Halifax, 22nd July, 1915."

Attending the ceremony were Canadians from every walk of life and persons connected with the work and interests he advanced. There were also present three of Sir Sandford's grandchildren, the Viscountess Hardinge, who unveiled the tablet, and Mrs. Jean Holt and Mrs. Joan MacLean; two great-grandsons, John Sandford Fleming, and Joseph R. Fleming; two grand nieces, Mrs. C. A. E. Chapman, and Miss Maude Fleming, and Basil Hall, grand nephew.

Invited to represent various organizations were the Honourable Charles A. Dunning; Donald Gordon, president of the Canadian National Railways; the Honourable George Prudham, Minister of Mines and Technical Surveys; Marc Boyer, Deputy Minister; George McIlraith and J. T. Richard, Members of Parliament; Prof. Fred Landon, chairman, Historic Sites and Monuments Board of Canada; H. J. W. Walker, member of the Board; The Honourable Thane A. Campbell, Chief Justice of Prince Edward Island, and Board member; Lieut. General Maurice Pope; Mrs. W. F. C. Anderson, president, Historical Society of Ottawa. Col. W. A. Capelle, chairman of the Ottawa Branch, represented the Engineering Institute of Canada.

N. R. Crump, president of the Canadian Pacific Railway, outlined Sir Sandford's achievements in the building of the early Canadian railroads. He told of his discovery of the Yellow Head Pass, which is now followed by the Canadian National line. Sir Sandford was the first to demonstrate the practicability of the route through the Kicking Horse, Eagle and Rogers Passes.

Dr. C. S. Beals, Dominion Astronomer, sketched Sir Sandford's career. His advocacy of Standard Time to replace local time was a step toward his dream of an international time system for the world. Dr. Beals explained that the establishing of the observatory at Ottawa stemmed from the building of Canada's early railroads. It was necessary for the work of surveying that there should be some method of absolute time reckoning and the observatory was created to meet the surveying and scientific needs of the time.

Chairman W. Kaye Lamb, Dominion Archivist, and National Librarian, was chairman of the ceremony and of the reception.

The Historical Society of Ottawa completed arrangements for the reception, and the Dominion Observatory and the Department of Public Works assisted in the preparations for the ceremony. The tablet was erected by the National Parks Branch on the authority of the Minister of Northern Affairs and National Resources, and on the recommendation of the Historic Sites and Monuments Board of Canada.

F. M. Becket Memorial Award

An award consisting of a $500 scholarship offered by The Electrochemical Society has been announced. The winner will be chosen for the best project dealing with some aspect of eletrothermics or electrometallurgy.

Although funds for this award contributed by the electro-metallurgical division of the Union Carbide and Carbon Corporation have been set at $500 for the first year of study, it is expected that at least this amount will be authorized by the society in subsequent years.

The award may be won by any student regularly enrolled in any college, university or institute of technology anywhere in the world, in courses leading to the Bachelor of Science degree or its equivalent, who shall have completed two or more years of work toward such a degree in science or engineering at the time of making application. Applications should be submitted by December 31, 1957.

Further information on the contest may be had on writing: G. M. Butler, The Carborundum Company, P.O. Box 337, Niagara Falls, New York.

Engineering and Scientific Manpower

A summary of scientific and engineering manpower in Britain, as disclosed in a recent survey conducted by the Ministry of Labour, shows 51,230 scientists, and 68,470 engineers, or a total of 119,700. The Ministry estimates that the survey missed approximately 5000 scientists and 10,000 engineers in other employment, making a grand total of 134,700. The survey did not include technologists working abroad for British firms or in the Overseas Civil Service. In a total working population of 24 million, scientists and engineers thus comprise 0.6 per cent.

Only a partial breakdown by categories has been reported. In the private and nationalized industries, electrical engineers led with 12,200, followed by chemical engineers (8300), mechanical engineers (6700), and aeronautical engineers and associated scientists (4300).

Of the 13,850 scientists and engineers in government employment, just over one-half are in the defence departments, just over a quarter in the civil departments, and one-sixth in research departments. Of the 6,680 qualified scientists and engineers employed by local authorities, the great majority are civil engineers (80 per cent of the total).

The Ministry of Labour's questionnaire asked for an estimate of needs in the year 1959, and replies from industrial establishments indicated that their technological staffs would be increased by one-third in the three-year period, whereas the increase anticipated in government and education amounted to only 14 per cent. The greatest numerical demands were expected in mechanical, electrical, and civil engineering, and in chemistry and physics. By 1957 it is believed the need will be double what it was in 1956.

The British government appears to be alert not only to the problem it faces in attempting to increase the supply of scientists and engineers, but also to its magnitude. A five-year program of expansion of technical colleges, involving an outlay of 70 million pounds, has been planned. The principal objective is to increase by about one-half the output of students from advanced courses at technical colleges.

It might be noted, with some concern, that the entire program is apparently government-planned, government-sponsored, and government-supported. It is difficult to convey the flavour of these documents in a brief digest, but several passages must warm the heart of any American reader. For example, it is reported that, in Scotland, "The great majority of boys and girls study both mathematics and science for at least three years, and the number taking these subjects up to the level of the Scottish Leaving Certificate has increased steadily. In 1954, mathematics with 7,418 candidates, was second only to English with 8,499, and science with 4,861 occupied fifth place among the 25 subjects of the examination."

One final quotation will indicate the breadth of view with which plans are being made:

"Technical education must not be too narrowly vocational or too confined to one skill or trade. Swift change is the characteristic of our age, so that a main purpose of the technical education of the future must be to teach boys and girls to be adaptable. Versatility has been the aim of a classical education; technical studies should lead to a similar versatility and should, therefore, be firmly grounded on the fundamentals of mathematics and science. It is much easier to adopt new ideas and new techniques when the principles on which they are based are already familiar."

Abstract from the Newsletter of the Engineers' Joint Council, March 1957

Elections and Transfers

A number of applications were presented to council for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected, on June 11, 1957.

Members: K. Bieniecki, Montreal, A. F. Bisschop, S. Africa, N. J. Campbell, Thompson Lake, N. R. Grover, Montreal, I. J. Hammill, Montreal, H. G. Hilton, Hamilton, N. Huq, Montreal, G. F. Jenkins, Toronto, R. P. Jezek, Montreal, D. Krofchak, Toronto, O. Kuch, Montreal, W. J. Malone, Ottawa, T. A. Marshall, Jr., New York, A. G. Overland, Niagara Falls, A. Poblacion, Montreal, J. Robinson, Montreal, F. J. Rolling, Montreal, H. F. Sanderson, Vancouver, R. F. Scott, Toronto, D. Simpson, Toronto, A. F. Smith, Montreal, M. Stein, Montreal, G. H. Tidswell, Galt, G. Wachmann, Montreal, S. N. White, Ottawa, A. Wyatt, England.

Juniors: R. M. McBain, Owen Sound, H. M. F. Warland, Peterborough, G. Y. Williams, Shilo, Man.

Junior to Member: O. Almoslino, Montreal, J. Chisvin, Toronto, W. E. Dowbiggin, Montreal, J. S. Edwards, Montreal, A. M. Heisey, Don Mills, W. Hemerling, Vancouver, R. A. McKay-Keenan, Ottawa, J. M. Royer, Quebec.

Student to Member: P. Corobow, Montreal.

Student to Junior: F. L. Henderson, Moncton.

STUDENTS ADMITTED:

University of Toronto: P. J. Hickson, K. L. Roper, P. D. Scholfield, M. R. Wright.

University of Manitoba: E. M. Lechman, B. C. Semchuk.

Queen's University: L. J. O'Riley.

University of Western Ontario: J. B. Robinson.

St. Francis Xavier University: A. J. Bergeron.

Student A.P.E.O.: Wm. McGilvery.

Graduate: D. A. MacDonald, B.Sc. (Elec.) N.S.T.C., 1957.

Applications through Associations

By virtue of the cooperative agreements vetween the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Member: D. F. Abel.

Junior to Member: J. E. Davis, D. H. Evers.

SASKATCHEWAN

Members: S. Franko, H. M. Gibson, R. F. Gilmour, H. C. Harris, J. M. Murray, W. H. Roe.

Students: O. K. Aschim, J. A. Boulanger, E. W. Cleveland, J. R. Dundas, H. J. Heath, R. J. N. Henderson, J. A. Law.

Junior to Member: G. M. Pearson, H. A. Sabier, R. S. Yoneda.

MANITOBA

Junior to Member: W. G. Maclean.

NOVA SCOTIA

Member: D. J. DeVan.

PRINCE EDWARD ISLAND

Member: E. G. Daly.

Junior to Member: N. F. Stewart.

THIRTY-FIVE YEARS AGO

Comment on the Journal of July, 1922

"Lawyers, the most trusted and distrusted; the men who make contracts and unmake them; who give advice and sell counsel; who make money out of trouble and trouble out of money; who create estates and distribute them; who live by loaning money and often subsist on borrowed capital; who hear and conceal marriage secrets, and drag out faded letters in bitter divorces; who please and persuade when they are lucky, but often go out of court branded and dispraised by the side defeated, and with one side always the loser, — what wonder that the slurs of character fall to the common lot of the lawyer!

"Without the smiles of the merchant's customer, he meets the frowns of business men in trouble. No time is to be lost, no delay for fees. He must win a victory or bear the blame forever. Unlike the builder, who knows that be it ever so perfect, the elaborate house he has finished can never suit the proprietor; unlike the machinist, he controls not his own enginery; carrying the double burden for self and client; invited to win what others have failed in; urged to mend the broken pieces of an ill-made contract; bound to account for unreasonable confessions, blunders and letters; asked to replevin goods already secreted, to attach the effects of a malicious merchant, to unearth fraudulent elections, to reclaim vast estates from costly tax titles, to keep one for years in plenty by restored possession and broken wills, often on doubtful evidence by a lawyer's art and eloquence, — what a happy condition!

"Fated from the start by uncertainty, where clients exact no less than absolute victory, they long to call reasonable what they know is only probable. By logic and argument on the theory of their clients, with the facts only partly stated, and that part deeply shaded, they are often surprised by the other side and called to explain away their defeat in the end by a tirade on the perjury of witnesses and the depravity of human nature. The happy lawyers!

"The men who live so easily, flourish so long on the bounty of a grateful people, make the laws and settle the titles, defend the weak and protect the wealthy, enjoy the rich fruit of the world's praises and abuses, mingled and co-mingled in such rare harmony that none can define where censure ends and approval commences, — who would not be a lawyer?"

We could not resist the temptation to lift this quotation verbatim from the introduction to the leading paper in the *Journal* for July, 1922, "Some Legal Aspects of Engineering Contracts", by Alfred Bicknell, read before the Toronto Branch. The author was obviously a lawyer, though there was nothing to show his profession.

If this be the true feeling of a lawyer for his calling, perhaps some of those who had been demanding that engineering be given professional recognition "comparable to that extended to . . . law and medicine" were only half right in their attitude. If they could have found a doctor as frank as this lawyer, they might have decided that they were wholly wrong and that engineering could have done better than to catch at the coat tails of the accepted professions.

In this *Journal*, too, there was a paper on locating, constructing and starting an industrial plant, read before the Sault Ste. Marie Branch by F. T. Gnaedinger, A.M.E.I.C., and also the second part of the July paper on the corrosion of buried lead pipe.

Engineers' Act Passed

A revised version of Clause 34 of the Ontario Engineers' Act was passed by the provincial legislature, the sections objectionable to the politicians having been deleted. These prohibited practice as an engineer, usurping the functions of an engineer, or acting in such manner as to suggest that the offender was an engineer, all offences which the backers of the bill thought ought to be penalized, but which seem not to have impressed the legislators as serious. The modification took a good deal of its authority out of the Act and were accepted by engineers only as a matter of *force majeure.* The complete text of the Act was also published in this *Journal.*

Technical Committee

The Committee on the Deterioration of Concrete in Alkali Soils, under the chairmanship of Dr. C. J. Mackenzie, now HON. M.E.I.C., met in Calgary, in June, 1922; its proceedings were reported in this *Journal.* Although there were much useful discussion and several trips to inspect concrete structures, the Committee was not ready to make any definite recommendations.

Col. Boyden, the Portland Cement Association's peripatetic lecturer, was still touring the branches, and Professor Duff Abrams himself was also visiting some of them. During June one or the other of them had spoken before the branches in the Border Cities, Ottawa and Calgary.

This Journal reviewed the "first book" of the Canadian Institute of Chemistry, a "record to the . . . progress resulting from the . . . efforts of those men of science who conceived the idea and made possible this much needed organization."

H. L. Seymour, A.M.E.I.C., had a page or so of town planning notes, as usual. One of his bits of information was that every city in the United States of over 300,000 population had adopted town planning as part of its official program by 1922.

Wilson Tayler, A.M.E.I.C., favoured the editor of the *Journal* with a long letter purporting to explain "the location of (the) energy which is hidden or 'latent' in . . . steam." He wrote as one with authority, but I must confess that in the short time I devoted to his letter, I got precisely nowhere. Mr. Wilson promised a more extended exposé of his ideas in the *Journal* for August, 1922, but there was none. If submitted, perhaps the paper foundered in the Publications Committee, which has always had a hard time to distinguish between novel ideas of value which ought to be promoted, and those which may be called "crack pot" and have no place in the *Journal,* like a paper offered us not so many years ago on the organization of the cosmos, based on the uncompromising statement that the earth is flat.

R. DeL.F

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

DOMINION COUNCIL

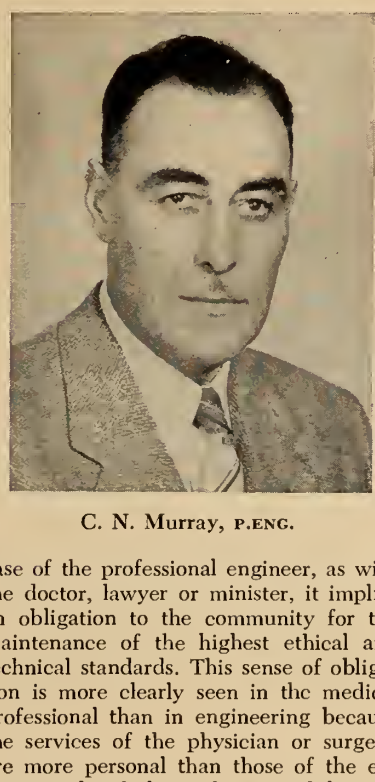
N.S. Man President

C. N. Murray, P.Eng., of Sydney, N.S. was elected president of the Dominion Council of Professional Engineers at its three-day annual meeting at Halifax, succeeding E. J. Durnin of Regina. The 30,000-member Council represents the engineering associations of the ten Canadian Provinces and the Yukon.

General superintendent of the Dominion Steel and Coal Corporation, at Sydney, Mr. Murray served as president of the Association of Professional Engineers of Nova Scotia in 1956.

Mr. Murray joined the Dominion Steel and Coal Corporation as an instrument clerk shortly after his graduation in mechanical engineering from the Nova Scotia Technical College. In 1943 he was appointed superintendent of blast furnaces and was subsequently named assistant to the general superintendent.

Also serving the Engineering Institute Mr. Murray is a past-councillor of the Institute and a past-chairman of the Cape Breton Branch of the Institute.



C. N. Murray, P.ENG.

QUEBEC

Address by Dr. O. M. Solandt

In his address to the Annual Meeting of the Corporation of Professional Engineers of Quebec on March 23, 1957, speaking on, "Some New Responsibilities for the Professional Engineer", Mr. Solandt said that undoubtedly one of the most pressing tasks that confront the engineering profession today is the training of more engineers to meet the growing needs of Canada's rapidly expanding industrial economy. An essential and difficult part of this task is to ensure that the high standards of engineering education and of professional conduct we have achieved in Canada are not only maintained, but even improved during this growth. We are rapidly becoming a highly industrialized nation, and more and more engineers will be engaged on projects that take them to the very frontier of existing scientific knowledge. The distinction between the scientist and the engineer, is fast disappearing. But, important as is the task of producing more and better engineers, it is of much less fundamental importance than some other tasks that confront the engineering profession.

Fostering a Spirit of Engineering. The first of these is the fostering of the essential spirit of engineering as a true profession. The word professional is much misused nowadays, but in the case of the professional engineer, as with the doctor, lawyer or minister, it implies an obligation to the community for the maintenance of the highest ethical and technical standards. This sense of obligation is more clearly seen in the medical professional than in engineering because the services of the physician or surgeon are more personal than those of the engineer. This feeling of responsibility for the use of a body of knowledge by a group of specially trained individuals has been expanded into the whole concept of a profession with its high standards of honesty and integrity and of self-discipline and discipline by the group.

It seems that this basic concept of professionalism might be extended to include almost everyone in a modern community. Professional organizations have always quite rightly sought to foster the interests of their members along with the interests of the community. Unfortunately, in a few cases they have become devoted entirely to the promotion of the selfish interests of their members.

But if we look at the world today, the greatest cause for apprehension is not a decline in the sense of responsibility of educated and other privileged people. It is the way in which man's mastery of his environment is outrunning his social organization. Scientists are now making discoveries and engineers are applying them, both for war and for peace, at a rate which far exceeds the capacity of our society to adapt to them. This has led to the state of continuous industrial revolution that is referred to as automation, and in the field of war it has led to a state that has been called a "balance of terror" due to the perfection of the hydrogen bomb.

Ultimate Effects Agreed Upon. Everyone is agreed that the ultimate effects of automation can be beneficial to every part of the community. It will increase productivity and real wages and give more people interesting and challenging jobs. Until recently, our western civilization has been able to absorb and adjust to new machines as fast as they appeared. However, new means of eliminating men in productive and clerical jobs, have appeared so rapidly that we must take care to see that too rapid automation does not produce transitory disruptions of our social organizations.

Unfortunately, there is something radically new about thermonuclear bombs. Their destructive power is far greater than that of any previous weapons. In a future war there is a real chance that civilization and even the race might be wiped out. The stakes are now so high that man cannot risk another war, and the possibility of war still exists.

Rapid Evolution of Social Organization Important. We can only avoid destruction by the rapid evolution of the social organization of the world to keep pace with the realities of the hydrogen bomb. Our ultimate objective must be some sort of world state in which we have the same acceptance of the rule of law and of its enforcement as we now have in our own communities.

This ideal will only be attained when ordinary men all over the world fully comprehend the threat of the bomb and also understand the promise of abundance that is held out to mankind by the discoveries of science. More than any other group in the community, engineers must accept responsibility for the interpretation of scientific discoveries to the man-in-the-street.

But there is another related aspect of this problem that looms even larger. Science and engineering are among the most attractive and exciting careers open to young men and women today. We are making careers in these fields even more attractive by increasing monetary rewards and social prestige. Even in the past twenty-five years a high proportions of the able people in Canada and in the world have gone into science and engineering. Prior to that era, many of the most competent young people took courses in the classics or history and became leaders of church and state.

Leaders of Vision and Understanding a Requisite. The greatest need in the world today is for leaders with vision and with understanding, both of man's past efforts to eliminate the need for war and of the broad significance and possibilities of modern scientific development. It is another of the duties of the engineering profession, and possibly the most important one, to share in the task of finding, training, and supporting these leaders. An increasing number of community, national and world leaders will come from the ranks of scientists and engineers.

But we must not let our enthusiasm for science and engineering lead us to feel that we can solve these problems alone. We must also encourage the pursuit of the classics, history, art, literature and the social sciences, so that Canada can offer the world leaders with diverse background and experience.

The only thing that can cut short our dreams for the future of Canada and of the world is World War III. This possibility must always be in our minds, and we must never fail to do anything we can, no matter how small, to lessen the likelihood of war.

ONTARIO

Engineers in the News

J. Lorne Gray, vice-president of Atomic Energy of Canada Ltd., was guest speaker at the thirtieth Annual Meeting of the Canadian Standards Association in Ottawa on May 31. Mr. Gray spoke on "Recent Developments in Industrial Uses of Atomic Energy."

D. C. Alexander, has moved from Baltimore, Md., to Pasadena, Cal., and has accepted a position as development engineer with the Advanced Electronic Data Laboratory Division of the Consolidated Electrodynamic Corporation. While in Baltimore, he was employed as an assistant project engineer by Bendix Radio.

Frank A. Ross, has resigned from the staff of Amalgamated Electric Corporation Ltd., and has joined Canadian Allis-Chalmers Ltd., in St. Thomas, Ont.

has moved from Toronto to Ottawa, Ont., and is employed as a structural engineer in the building construction branch of the Department of Public Works of Canada.

William E. Field, who has been engaged in mining engineering in Boulder, Montana, has accepted the position of mine manager of National Explorations Ltd., at Uranium City, Sask.

Bruce D. Newman, of Toronto, has been promoted to the position of secretary of Barber-Greene Canada Ltd., Toronto. He is also chief engineer and assistant to the president of the company.

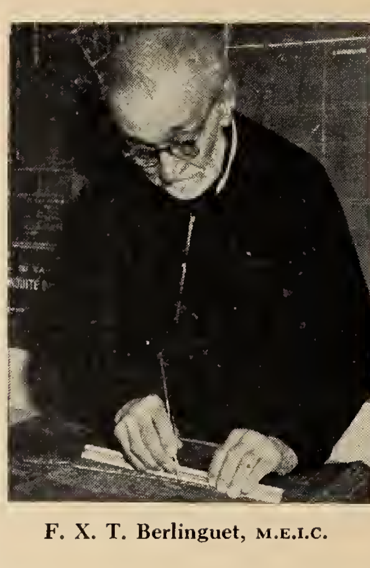
Mr. Newman is an engineering graduate of McGill University and joined Barber-Greene Canada Ltd. in 1952.

William R. Hood, has moved from Montreal to Corunna, Ont. where he is employed by the Ethyl Corporation of Canada Ltd., as an electrical and instrument engineer. Mr. Hood is a University of Toronto graduate in engineering and was with the engineering department of Bell Telephone Company of Canada at Montreal.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Francois Xavier Thomas Berlinguet, M.E.I.C., of Trois Rivieres, Que., oldest member of the Institute, who celebrated his one-hundreth and first birthday in 1956, died at Trois Rivières on May 15, 1957.



F. X. T. Berlinguet, M.E.I.C.

Born at Quebec, Que., on March 15, 1855, educated at Laval University, he studied civil engineering and land surveying and was graduated in 1876. He began his career as a contractor's draughtsman with the Intercolonial Railway. He was employed by the Federal Government on harbour work in Quebec and Trois Rivieres, becoming chief engineer of public works for the district. In the early days of his career he worked on the Quebec Harbour Survey in 1877; became an assistant engineer on the Lake St. John Railway in 1881; and the following year worked on the Trois Rivieres Harbour Survey, and the St. Lawrence River survey in 1883. Between 1884 and 1890 he was resident engineer for the St. Maurice River and Trois Rivieres Harbour.

After forty-six years of service with the department of Public Works he retired to private practice at Trois Rivières. He celebrated his seventieth year of professional practice and his ninety-first birthday in 1946, carrying on business as usual.

On the occasion of his one-hundredth birthday, in 1955, the Institute was represented at the ensuing festivities held by his family at Trois Rivieres by vice-president of the Institute, J. O. Martineau, of Quebec City. Mr. Berlinguet was able to participate in all parts of the program.

A Life Member of the Institute since 1931, Mr. Berlinguet joined as an Associate Member upon its foundation as the Canadian Society of Civil Engineers, in 1887, and was transferred to Member in 1890.

Andrew Edward Chalmers, M.E.I.C., city engineer at Peterborough since 1946, died on May 23, 1957, in that city.

Born at Cobourg, Ont., on December 18, 1899, Mr. Chalmers had his education at Queen's University and attained a B.Sc. degree in civil engineering in 1923. In his student years he worked during the summer months with the Toronto and York Roads Commission and the Department of Highways of Ontario. On graduation he accepted a position as resident engineer for the Smith Falls filter plant and in succeeding years to 1932 he was engineer for the districts of Crystal Beach, Bertie, and Welland County, and for the Town of Thorold, Ont.

In 1932 he accepted an appointment as engineer for the County of Peterborough. Joining the R.C.E., Canadian Army in 1940, he became a major in 1942 and returned to the City of Peterborough as assistant engineer in 1945.

Mr. Chalmers was president of the Canadian Institute on Sewage and Sanitation in 1953.

He joined the Institute as a Member in 1954.

Personals

News of the Personal Activities of Members of the Institute

R. W. Diamond, M.E.I.C., has been awarded the "Gold Medal" of The Institution of Mining and Metallurgy (London) for 1956. A year ago Mr. Diamond retired from the position of executive vice-president (Western Region) of The Consolidated Mining and Smelting Company of Canada Limited after thirty-nine years of continuous service with that company.

The Gold Medal was awarded to Mr. Diamond "in recognition of his distinguished services to the mineral industry in Canada".

He is a former president of The Canadian Institute of Mining and Metallurgy (1948-49). Currently he is President of the Sixth Commonwealth Mining and Metallurgical Congress which will be held in Canada this year. Approximately five hundred delegates to this Congress from about forty Commonwealth and other countries around the world will assemble in Vancouver on the 8th September next and from there will travel across Canada for thirty-two days visiting all of the principal mining and metallurgical centers, the oil fields of Alberta and the major cities of Canada. Closing sessions will be in Halifax on the 9th of October, 1957.

Charles E. Garnett, M.E.I.C., for many years president and managing director of Gorman's Limited, Edmonton, has been elected chairman of the Board and remains as director, relinquishing his managerial duties.

Mr. Garnett is also chairman of the Great Northern Gas Utilities Limited and Plains-Western Gas and Electric Limited, both of Edmonton and president of the Edmonton Elevator Service Limited. He is the director of Timber Preservers Limited, New Westminster, Consolidated Finance Company of Vancouver, Olympic Insurance Agents Limited of Vancouver, MacDonald Parking Limited of Edmonton, and a member of the Edmonton Board of the Royal Trust Company.

T. E. Bate, M.E.I.C., has been appointed president and managing director of Gorman's Limited, at Edmonton.

With Gorman's Limited, at Edmonton since 1948 he has held appointments with the firm as sales engineer, assistant manager, and manager of the Edmonton Elevator Service Company division of Gorman's Limited.

At one time Mr. Bate was employed with the Canadian National Railways as an assistant engineer.

Harrison S. Milne, M.E.I.C., was recently appointed by AMF Atomics (Canada) Limited as works manager of their new reactor fuel element manufacturing and development plant at Port Hope, Ont.

Mr. Milne graduated with a B.Sc. degree from the University of Saskatchewan in 1933 and returned in 1937-39 to study mechanical engineering.

In 1940 he joined Defense Industries Limited, engineering department, at Montreal, to work on shell plant layout and in 1941 was moved to small arms ammunition manufacturing at Verdun Works, where he remained until 1945. Transferred to the Chalk River Atomic Energy project he was resident engineer for D.I.L. during the construction of the N.R.X. reactor.

In 1947, when the National Research Council took over operation of the Atomic Energy project, Mr. Milne remained at Chalk River, as superintendent of mechanical and power services and in 1950 transferred to the newly formed Crown Corporation, Atomic Energy of Canada Limited, as superintendent of workshops and design. While at Chalk River he was in charge of fuel element production for the N.R.X. and N.R.U. nuclear reactors.

W. H. M. Laughlin, M.E.I.C.

H. S. Milne, M.E.I.C.

R. M. Robertson, M.E.I.C.

Robert M. Robertson, M.E.I.C., manager of operations for the Dominion Bridge Company Limited, Montreal, has been elected president of the Canadian Institute of Steel Construction Inc., at the organization's twenty-seventh annual general meeting held recently at Montebello, Que.

Mr. Robertson whose present appointment with Dominion Bridge dates to 1953, first joined the company in 1909.

In 1954 he was chosen by the Dominion government to direct Canada's $450,000,000 naval ship-building program.

W. H. M. Laughlin, M.E.I.C., for the past eleven years a member of the Toronto consulting engineering firm of Proctor, Redfern and Laughlin, now Proctor and Redfern, has announced the formation of the consulting firm of Laughlin, Wyllie and Ufnal. Both Mr. Laughlin's colleagues were formerly associated with him professionally over the last eleven years.

Carrying out the same fields of operation as previously the firm will be engaged in the planning, design and supervision of industrial plants, buildings, bridges and other diversified civil engineering work.

Mr. Laughlin's engineering career began with the Dominion Bridge Company Limited in 1928, a short time after his graduation from the University of Toronto in 1927. Holder of a B.A.Sc. degree at that time he later qualified for an M.A.Sc. degree and was awarded a C.E. at that university in 1938.

A structural designer and engineer with the firm for a number of years he was later appointed chief engineer for the Ontario division of the company.

In 1951 Mr. Laughlin was elected president of the Association of Professional Engineers of Ontario.

Always active in the Institute Mr. Laughlin has served in the capacities of chairman and councillor of the Toronto Branch.

Ernest Gohier, M.E.I.C., chief engineer of the Department of Roads of the province of Quebec, at Quebec City, for many years has retired from that post to become chairman of the Montreal-Laurentian Autoroute Board.

Mr. Gohier has been in private practice since 1914, shortly after his graduation from McGill University.

Over the years he has served as consulting engineer for the Montreal Metropolitan Commission, the Harbours of Quebec, Three Rivers and Chicoutimi and for several municipalities throughout the province of Quebec.

Dean R. M. Hardy, M.E.I.C., of the faculty of engineering, University of Alberta, received an honourary doctorate of science at the University of Manitoba convocation exercises held recently.

L. W. Pillar, M.E.I.C.

Dean of the faculty of engineering since 1948 he has been associated with the University of Alberta for many years in the civil and municipal engineering departments. He also had experience in the general engineering department of the Aluminum Company of Canada Limited, at Montreal.

In 1955 he was named a director of the Foundation of Canada Engineering Limited.

Dean Hardy was in 1949 elected president of the Association of Professional Engineers of Alberta.

Leslie W. Pillar, M.E.I.C., has joined De Leuw, Cather and Company of Canada Limited, consulting engineers of Toronto and Ottawa in the capacity of chief engineer.

Prior to joining De Leuw, Cather, Mr. Pillar was for three years director of planning and works for the City of Ottawa where he was responsible for a program of major highways, bridging and drainage schemes.

He brings to his new sphere of activity over twenty-five years' experience in civil and highway engineering schemes in England, Europe, the East, Africa and Canada. During World War II he served six years in the Royal Engineers.

Born in Essex, England, and educated at Christ's College and King's College, London, Mr. Pillar holds a diploma in civil engineering. He is a member of the Association of Professional Engineers of Ontario, and the American Society of Civil Engineers.

T. F. Hadwin, M.E.I.C., has been appointed district manager of the Bridge River area for the B.C. Electric Company Limited.

This area, with a present installed capacity of one 42,000 kva unit and four 50,000 kva units is being increased by the addition of one 22,000 kva unit and four 62,500 kva units to a total of 514,000 kva of hydro electric capacity.

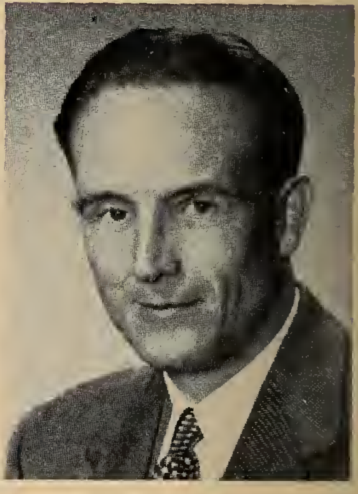
Mr. Hadwin is a graduate of the University of British Columbia with post-graduate training at the University of Pittsburgh. He has been active on the executive of the Vancouver Branch and on the Papers Committee for the 1957 annual meeting at Banff.

He was formerly superintendent of substations for the B.C. Electric Company Limited.

W. A. MacDonald, M.E.I.C., of Sydney, N.S., manager of the Seaboard Power Corporation Limited has been elected chairman of the Cape Breton Branch of the Institute.

Beginning his career with Northern Electric Company in 1929 at Montreal, he later went to the Provincial Highways Department of Nova Scotia. In 1934 he joined Dominion Steel and Coal Corporation at Sydney as an assistant to the

W. A. MacDonald, M.E.I.C.



T. F. Hadwin, M.E.I.C.

chief electrical engineer, carrying out field and construction work. He was appointed field engineer in 1942 and was associated with engineering and construction on the more recent units added to Seaboard's expanding facilities. The company supplies electrical energy for industrial and domestic purposes in Cape Breton.

Long interested in the activities of the Institute Mr. MacDonald represented the Cape Breton Branch of the E.I.C. as a councillor in 1948-49.

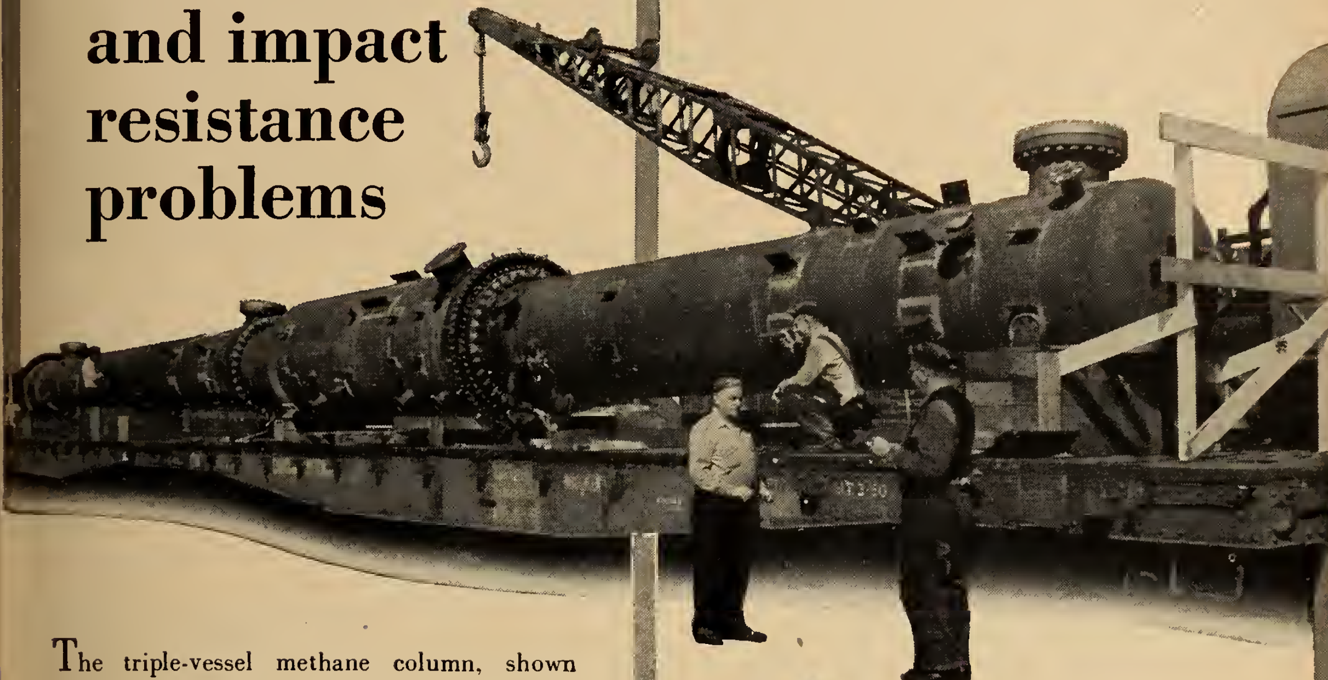
C. S. Landon, M.E.I.C., registrar of the Association of Professional Engineers was recently awarded an honourary doctorate of law at the University of Manitoba convocation exercises this spring.

Mr. Landon has been secretary and registrar of the Association for a number of years.

William L. Fraser, M.E.I.C., of the Hydro-Electric Power Commission of Ontario, has been named field project engineer for the Commission's St. Lawrence Power Project.

Formerly project manager for Ontario Hydro's Sir Adam Beck-Niagara No. 2

Solving corrosion and impact resistance problems



The triple-vessel methane column, shown above, was designed for an unusual combination of pressure and temperature conditions. It operates at a maximum working pressure of 300 psi with temperatures from plus 300°F to minus 238°F.

This vessel, of extra low carbon type 304 stainless steel, was especially designed and fabricated to resist corrosion at high temperatures and to provide impact resistance of welds and base material at low temperatures. Vessels for this type of service demand careful design, exacting control of fabricating processes and unexcelled welding skill.

The enlarged photograph, right, shows the finished appearance of the ground and polished weld contours which resulted in complete freedom from notches.

development, Mr. Fraser has also held the posts of project manager for Ontario Hydro's Chenaux development on the Ottawa River. Prior to that, during World War II, he was on the staff of the Department of National Defence, Naval Service and was district engineer on works and buildings along the Atlantic coast.

Mr. Fraser served with the Royal Canadian Engineers in World War I, and as a graduate of McGill University, shortly afterwards joined the staff of C. D. Howe and Company, consulting engineers at Port Arthur. Over the years he has maintained a number of important engineering posts, including that of resident engineer on highway construction for the Nova Scotia Department of Highways. He was a designing engineer for the Shawinigan Water and Power Company on hydro-electric power developments, and was resident engineer for the Nova Scotia Power Commission during the building of the Cowie Falls Development. He has also served as assistant chief engineer for the Nova Scotia Department of Highways and Public Works.

E. H. Peck, M.E.I.C.

William M. Hogg, M.E.I.C., formerly field project engineer of the Hydro-Electric Power Commission of Ontario, St. Lawrence Power development, has accepted an executive engineering position with the Great Lake Power Corporation Limited at Sault Ste. Marie, Ont. He will take charge of a new department of the Great Lake Power Corporation to be known as planning and development.

Mr. Hogg who has had extensive experience with Ontario Hydro has for ten years held the post of design engineer in the head office generation department. Appointed senior resident engineer at the Des Joachims development on the Ottawa River in 1949 he held the appointment of assistant field project engineer for the Sir Adam Beck Niagara No. 2 development, two years earlier. His appointment as field project engineer dates to 1954.

Mr. Hogg is a 1939 graduate of the University of Toronto.

John J. Miller, M.E.I.C., has been appointed general manager for Alumina, of the Ormet Corporation, situated at Burnside, Louisiana.

Mr. Miller who is a 1939 graduate of the University of Toronto was formerly assistant chief engineer of the Aluminum Company of Canada.

Adrian R. Leger, M.E.I.C., has been appointed general superintendent of operations with the Anglo-Newfoundland Development Company Limited at Grand Falls, Nfld.

Mr. Leger is a 1946 graduate of Laval University in chemical engineering, and was formerly control superintendent with the organization.

Esmond H. Peck, M.E.I.C., has received the appointment of manager of the Shawinigan Water and Power Company economic research department, at Montreal.

Associated with the firm since his 1936 graduation from McGill University Mr. Peck held an appointment in the firm's water resources and statistical depart-

. . . at C. S. F.

teamwork persists through every phase

Rigid inspection and strict adherence to quality control through every phase of manufacture is positive customer assurance that the finished product is right.

Good castings start at the design level. You'll save time and money by calling in C.S.F. Sales Engineers in the initial stage of product development.

CANADIAN STEEL FOUNDRIES (1956) LIMITED

5227 NOTRE DAME E., MONTREAL 4.

Member: A. V. Roe Canada Limited and The Hawker Siddeley Group ment, for a number of years and was more recently assistant manager of the economics and statistics department of the company.

P. A. O'Connor, M.E.I.C., formerly Director of Works for the Canadian Army, holding the rank of lieutenant-colonel, has retired to civil life and has incorporated a company. President of the firm of P. A. O'Connor Company Limited, consultants and representatives, he is concerned with problems which arise out of contracts held by consulting engineers and architects and contractors with the government departments in Ottawa.

The firm deals with the interpretation of plans and specifications, discussions with owners, to arrive at design intent, submissions for certificates to the Inter-Service Equivalents Board and various other matters which arise out of engineering and construction contracts.

J. Maurice Macé, M.E.I.C., has been appointed Quebec regional manager of the sales division of Northern Electric Company Limited.

Mr. Macé is a graduate of McGill University in electrical engineering, and has been with Northern Electric since 1938 when he joined the power apparatus sales department in Montreal.

J. M. Macé, M.E.I.C.

For a period during World War he was a sales engineer for mari power and degaussing equipment. Afi a year in the rural electrification depa ment, he was appointed manager Quebec house in 1947.

In 1949 Mr. Macé was appointed ma ager of the rural electrification a power company sales, in 1951 manag of wire and cable sales, eastern distri he became in 1955 assistant district sa manager. (Eastern.)

Major Malcolm Turner, M.E.I.C., l been promoted to the rank of acti lieutenant-colonel. The appointment w be effective August 15, 1957. He was the same time named commander of Works Company, Royal Canadian En neers, at Vancouver, and area engin officer of the British Columbia area.

Major Turner now holds the respo sibility of second-in-command, first fi engineer regiment, at Camp Chilliwa B.C.

He is a graduate of the Royal Milit College, Kingston, 1939, and also graduate of Queen's University, class 1947 in civil engineering. Major Turn spent a year in the United Kingdom the R.C.E. Staff College in Camber in 1954.

Joseph A. D'Angelo, M.E.I.C., has b named budget manager of the eng division of the Chrysler Corporation, I troit, Michigan.

He was formerly associated with Ford Motor Company of Canada budget supervisor of the machine sl and stamping plant in the Wind manufacturing division.

He is a University of Manitoba gr uate in electrical engineering, class 1946 and also holds a bachelor of co merce degree from that university.

D. D. Dick, M.E.I.C., has resigned fr the staff of the North Western Pulp Power Limited, Hinton, Alta., to t up a position in Montreal. In his n capacity he will serve as chief civil en neer with the Power Corporation of C ada Limited.

Earlier in his career Mr. Dick gained experience with the B.C. International Engineering Company, and H. A. Simons Company, both of Vancouver, and with the firm of McMillan and Bloedel, Harmac pulp division, Nanaimo, B.C.

T. G. Anglin, M.E.I.C., consulting engineer of T. G. Anglin Engineering Company Limited, Montreal has moved from the Dominion Square Building where he has practised for the past ten years, to his company's own office building at 4294 St. Catherine Street West, Montreal.

L. H. Harper, JR.E.I.C., a 1951 graduate of Queen's University in civil engineering is engaged as a project engineer with Defence Construction (1951) Limited, at the R.C.A.F. Station, Rockcliffe, Ont.

With Gore and Storrie Limited from 1951 to 1955, he later joined Algoma Uranium Mines at Elliott Lake, Ont. as an assistant construction engineer. In 1956 he became employed by Defence Construction Limited, Camp Borden, Ont. as an assistant project engineer, and was later transferred to the R.C.A.F. Station, Uplands, Ont., in the same capacity. His present duties involve additional work at Shirley Bay and Connaught Ranges.

C. J. Konzuk, JR.E.I.C., has lately been promoted to manager of the operations division with Canadian Aviation Electronics at their main plant in Montreal.

Mr. Konzuk who is a graduate of McGill University, in electrical engineering and was a wartime radar officer in Canada and overseas. He has been with C.A.E. since 1951. He has progressively filled the posts of manager of the repair and overhaul and the electronics maintenance and manufacturing departments.

C. J. Konzuk, JR.E.I.C.

W. A. Doby, JR.E.I.C., University of Manitoba, class of 1951, and later sales engineer with the Canadian Westinghouse Company Limited, is presently employed with the Los Angeles, Calif., consulting engineering firm of Ralph M. Parsons Company. He is an electrical design engineer in the architect-engineering division of the organization which is prominent in the oil manufacturing design and rocket and missile launching devices and control.

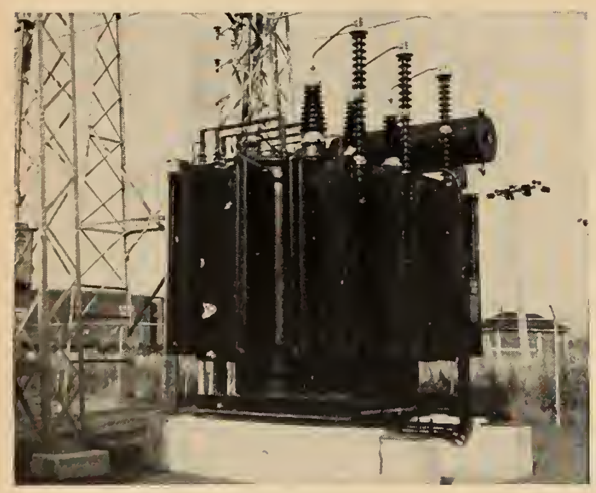
L. L. Anderson, JR.E.I.C., of the Department of Mines and Technical Surveys, at Ottawa, has been promoted to the post of chief of the legal surveys section, legal surveys and aeronautical charts division of the Department.

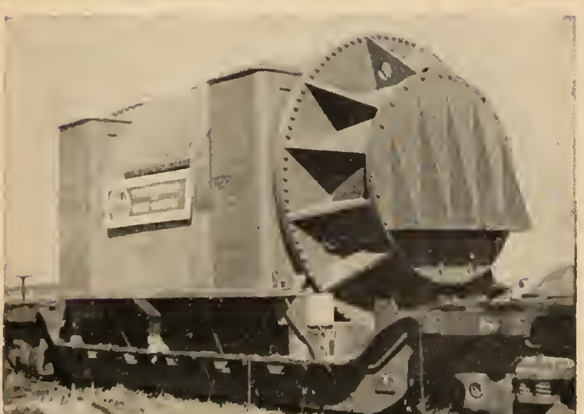
Mr. Anderson was first employed as a surveyor and engineer in the government department. He is a B.A.Sc. graduate in civil engineering of the University of Toronto, class of 1950.

W. D. Parsons, JR.E.I.C., has been recently appointed assistant plant engineer with the Cerro de Pasco Corporation in Peru. The Cerro de Pasco Corporation is one of the world's largest producers of copper, lead and zinc located in La Oroya, high in the central Peruvian Andes.

Mr. Parsons joined the Corporation in

If power is your responsibility



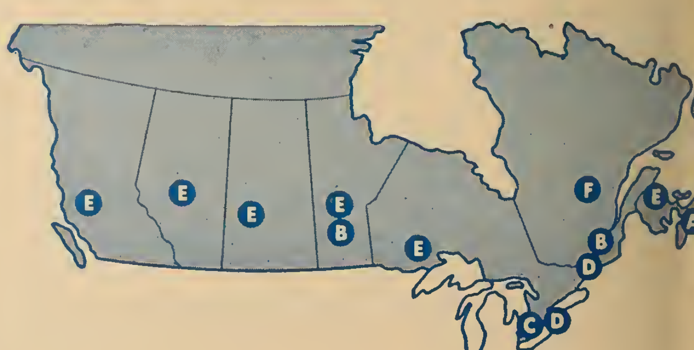


A DISTRIBUTION TRANSFORMERS

The "BB-99" Distribution Transformer was designed by Brown Boveri to meet the standards of the Canadian utility. BB-99 installations like this one in Halifax, N.S. have been service-proved from coast-to-coast.

B POWER TRANSFORMERS

Industries and utilities across Canada are being dependably served by Brown Boveri transformers like this 10,000 KVA 66,000/4160 volt type ONS unit, supplied to Quebec Power Co. Limited.



C SYNCHRONOUS CONDENSERS

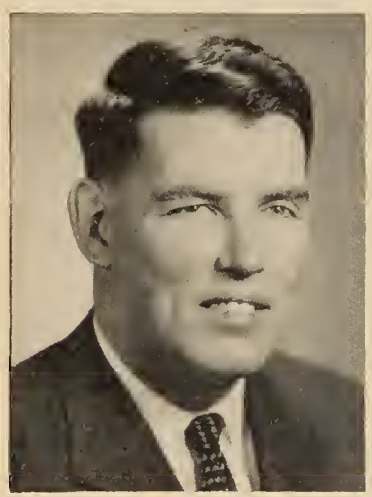
This 48,000 KVA 13,800 volt, 900 rpm hydrogen-cooled equipment in transit to Hydro Electric Power Commission of Ontario is typical of the many types of heavy duty rotating machinery built by Brown Boveri.

December 1955 as mechanical engineer and staff engineer. He was previously employed as mechanical superintendent in the Colombian operation of South American Gold and Platinum Company.

Mr. Parsons is a 1952 graduate from McGill University.

P. J. Tansey, JR.E.I.C., has been appointed manager of the asphalt department, eastern division, Shell Oil Company of Canada Limited. He will be responsible for asphalt sales within the eastern division marketing area, with offices in the Shell Tower Building, Montreal.

A McGill University graduate, class of 1948 Mr. Tansey has spent a number of years with the Shell Oil Company of Canada Limited, serving as a sales engineer at Ottawa and Montreal. In 1955 he was the St. Lawrence Seaway representative for the Shell company.



P. J. Tansey, JR.E.I.C.

J. R. Marchand, JR.E.I.C., formerly a flying officer with the R.C.A.F., 408 (P) Sqn., at Rockcliffe, Ont., has returned to civilian life and has accepted a position with the Manitoba Telephone System at Winnipeg.

A 1954 graduate of the University of Manitoba in electrical engineering Mr. Marchand has previously been employed with the R.C.A.F. as Shoran Telecommunications Officer for 408 (photo) squadron and was involved in the Shoran Survey of northern Quebec, the Yukon, and the Arctic Islands. Shoran, a contraction of the words, "short range navigation", is an electronic method of measuring distances, utilizing a network of ground radar stations operating in conjunction with airborne radar equipment.

W. R. Badun, JR.E.I.C., who was this year awarded a master's degree in business administration at the University of Western Ontario, has accepted an appointment with Super Motor and Electric Limited at Kitchener. He will serve the company in an executive capacity.

Mr. Badun graduated from the University of Alberta in 1952 in electrical engineering and then worked for two years with H. H. Angus and Associates, as field supervisor of electrical and mechanical construction.

At a later date he worked with the Aluminum Company of Canada as assistant electrical supervisor on plant maintenance and construction.

George S. Bowes, JR.E.I.C., University of Toronto, 1949, who formerly held a position with the Brantford Roofing Company Limited at Thorold, Ont., has been appointed a technical director of the No-Co-Rode Company Limited, a subsidiary of Dominion Tar and Chemical Company Limited, at Cornwall, Ont.

L. R. Broderick, S.E.I.C., a University of Toronto graduate, class of 1957, in civil engineering holds an appointment as assistant project engineer with the Greater Vancouver Water District.

EDMONTON

G. HODGE, M.E.I.C.,
Secretary-treasurer

S. R. SINCLAIR, M.E.I.C.,
Branch News Reporter

Active Season

The past season, dating from the last annual meeting in April 1956, has been an extremely active one for the Edmonton Branch. A total of twelve meetings have been held, covering the field of engineering activity very thoroughly. In May a talk on "Reservoir Engineering" was delivered by Prof. J. W. Gregg of the University of Alberta and an annual meeting picnic held in June. Getting underway again in September, "Trends in cable Insulations", and a Dew Line Film by W. J. Pardy of Northern Electric Company, followed by "What's Ahead in Lighting", by J. W. Bateman of the Canadian General Electric Company were enjoyed. The Annual Engineers banquet and dance marked the visit of President McKillop in November. In January "High Temperature Reaction Systems", by Dr. D. Quon, of the Research Council of Alberta, and "Edmonton's New Sewage Treatment Plant", by Commissioner D. B. Menzies was heard. The February meeting took the form of the annual smoker. In March, "Light Weight Aggregates" by L. S. Thorssen of Consolidated Concrete Industries Limited and "Air Conditioning", by G. Greenwood of Cumming Galbraith Limited were heard. Closing the program Sir Claude Gibb of Great Britain delivered an address on "Nuclear Generation", followed by the Annual Meeting and tour of the Northwest Industries.

In addition, arrangements had been made for a tour of the Hinton pulp and paper plant. Unfortunately, the opening of the plant has been delayed and the proposed tour was postponed until October 1957.

While attendance at the social functions was good, representation at the technical and general meetings was far below expectation. Out of a membership of 727, attendance averaged 63 persons per meeting.

Attendance at the branch meetings has indicated that the membership will turn out in large numbers for "project" type talks such as that presented by Commissioner D. B. Menzies on Edmonton's sewerage treatment facilities. Attendance at the more specialized talks indicates that the idea of technical divisions presently under consideration at headquarters is probably the best answer to maintain the interest of engineers in the Institute.

The annual ball at the Macdonald Hotel was again a great success, 328 attending. The visit of president V. A. McKillop was very pleasant and marked the first time such an event has been filmed and presented on TV in Edmonton.

Annual Meeting

On April 17, 1957, the members of the Edmonton Branch were the guests of Northwest Industries Limited. There were approximately 125 members present.

After a delicious dinner, prepared and served in the plant cafeteria, B. W. Pitfield, vice-president and general manager of Northwest Industries Limited, welcomed the members and gave a brief talk on the role of his company in the aviation industry.

Northwest Industries has approximately 900 employees, and is the largest Canadian-owned aircraft repair company. The company is equipped to work on all types of commercial aircraft, although the major part of its work is for the R.C.A.F.

Mr. Pitfield's talk was followed by an interesting tour of the plant, during which the members saw various types of aircraft, both civil and military, under repair. For those members who were not familiar with the operations at this plant, the tour brought out the important contribution which Northwest Industries Limited is making to both civil and military aviation in Western Canada.

The Branch annual meeting was held in the plant cafeteria following the tour.

Arrangements for the evening were made by R. H. Gardener, planning and control manager of Northwest Industries Limited.

LONDON

Wives' Association

Steps toward organization of an Engineers' Wives Association in London, Ont., took place on May 23, 1957, with the formation of an informal executive.

Mrs. D. J. Matthews, wife of the chairman, invited the following ladies to luncheon: Mrs. V. A. McKillop, wife of the president of the Institute, Mrs. L. Stuart Lauchland, Mrs. D. M. Jenkins, Mrs. C. H. Osborne, Mrs. H. R. Hayman, Mrs. H. E. Martin, and Mrs. R. W. McMeekin, to hear Mrs. Lilian Robertson of the Field Office, Toronto, speak on the activities of the Wives' Associations and on the proposed discussion in Banff regarding a national organization.

The group was most interested, especially in the idea that a purely social group be formed, which would probably hold two social gatherings a year, with very small membership fee; and particularly welcome newcomers among engineers' wives who move to London.

Mrs. McKillop offered her home for a coffee party or afternoon tea in the fall, which would be the first general meeting to which the wives of all E.I.C. members would be invited. In the meantime the others who were at luncheon will form an informal committee to divide the branch list into telephone sections, and meet early in June to discuss further plans.

NEWFOUNDLAND

C. W. HENRY, M.E.I.C.,
Secretary

SUCCESSFUL YEAR

The Newfoundland Branch has had a successful year to date.

The first meeting of the year was held October 19, 1956. This was a business meeting and a number of topics of interest to the Branch were discussed. Chief among these was the possibility of sponsoring the introduction of C.S.A. Standards to Newfoundland on a provincial basis. It was decided that the Branch Secretary should write C.S.A. to see if practical help might be obtained.

A. M. Fraser, M.P. Speaker

A. M. Fraser M.P. addressed the next meeting on November 12, 1956. Mr Fraser was professor of economics and political science at Memorial University for 25 years before his election to Parliament. He described the background and

Edmonton's new 10-story Federal Building typifies the city's growing stature as one of the world's leading oil capitals. Scheduled to open in January, 1958, the massive building will house every federal department except the Post Office and the Unemployment Insurance Commission. Reliable Jenkins valves have been installed by the contractors to direct and control the flow of heat for the $6,000,000 building. For unsurpassed efficiency, long life, and trouble-free maintenance, *it pays to deal with specialists.* When specifications call for valves, call Jenkins.

Making Quality Valves is Our Business — Our Only Business.

personalities involved in the Middle East situation in a most interesting way. His talk was followed by a question and discussion period. Those attending felt that Mr. Fraser had given a very lucid account of causes and possible affects of present troubles in the Middle East.

It had been intended to hold the December meeting at Bell Island and to include a tour of the iron ore mine as part of this program. Unfortunately this trip had to be put off until later, due to last minute difficulties. A program of films was arranged instead and a film on Atomic Energy was given.

Deputy Minister of Mines is Guest

At the January meeting, Fred Gover, Deputy Minister of Mines for Newfoundland, discussed "Exploration by Concession". He explained the Provincial Government's policy of arranging for mineral exploration by private companies in areas in which they had been granted an exclusive right to search for, and develop mineral deposits covered by their concession agreements within the time stipulated in the agreement. Mr. Gover then discussed the factors which determine the feasibility of developing a mineral discovery and concluded by describing the results of the concession system in Newfoundland.

Railway Problems Outlined

At the February meeting, E. J. Cooke, manager of the C.N.R. Newfoundland district, outlined some of the basic problems with which his company has had to contend since taking over rail and coastal steamship services in Newfoundland in 1949. Mr. Cooke said that in many ways the Newfoundland operations were unique in Canada and required special techniques in railroading, however, the extension and modernization of facilities and equipment should result in an adequate and satisfactory transportation service. Mr. Cooke then described some recently completed improvements and some which are planned for the future.

Students' Night

The 5th annual "Students' Night" program was featured at the March meeting held March 11th, 1957. The Students' Night program is the culmination of the public speaking seminar conducted by Dean Carew with the engineering students at Memorial University. During the course of this seminar the engineering students are given practical training in the techniques of public speaking and at the end of this series, the three best speakers are chosen to compete for a prize of $50.00 offered by the Newfoundland Branch of the Institute.

Chairman V. A. Ainsworth, M.E.I.C., was in the chair and the following speakers were introduced by Dean S. S. Carew, M.E.I.C., E. Dunne, who spoke on The Quebec Bridge, A. Knight, who chose Flash Bulbs, and D. Noble whose subject was Guided Missiles.

The winner will be announced and the prize presented at the annual meeting of the Branch in May.

Programs planned for the balance of the year were, on April 8, "Power and Passage", a film prepared for Canadian General Electric Company about the St. Lawrence Seaway; the Annual Dance on April 25 and the Annual Dinner Meeting, May 13.

The objective of the meeting was to discuss aspects of the engineering profession with student engineers and inform them about the work done for the profession by the Engineering Institute of Canada and the Association of Professional Engineers of Ontario.

The evening started with a film followed by a panel discussion on the subject "The Engineering Profession". Panel members agreed that the primary responsibility of an engineer is to provide the public and his employer with high quality technical service. The engineering organizations are very valuable help to the individual engineer in promoting the exchange of technical information, issuing a code of ethics, etc.

In the panel discussion Albert J. Bonney, counsellor for Peterborough area, P. W. Doddridge, J. F. Howard, R. H. Stuart, participated, as well as students J. G. Pearsall and B. Ahearn, moderator.

As guest speakers T. C. Keefer, field secretary of A.P.E.O. and D. D. Whitson, counsellor of the E.I.C., Toronto area, represented the two main engineering organizations.

Mr. Keefer explained the role of A.P.E.O. as the legalizing body of professional engineers in Ontario.

Mr. Whitson stressed the importance of E.I.C. as the nationwide Canadian engineering organization with the aims of promoting exchange of technical information through meetings, technical papers and the Engineering Journal.

W. H. Ackhurst, chairman of the meeting also demonstrated the technique of opening the oysters to the student engineers.

New Community Centre Discussed

Design features of the new Peterborough Memorial Community Centre were discussed at a Branch meeting held at the Centre April 10.

The million-dollar Centre is the biggest community building project of the past decade in Peterborough and was officially opened by Governor-General

Massey in November, 1956.

Three Speakers. The speakers on the symposium were James S. Craig, architect, Peterborough, G. R. Williams, structural engineer from Wallace Carruthers & Assn., Toronto, and C. E. Beynon, mechanical engineer from McGregor & Beynon, Toronto. These men were the main designers of the Memorial Centre.

Mr. Craig explained the extreme flexibility in use of the main auditorium. When mainly used as a hockey arena, the ice can be covered with an extra floor in a very short time to convert the auditorium into a concert-hall.

The main ice floor is of unique design, different from and superior to others, because the concrete slab does not rest directly on the ground but has an air space between. This type of design prevents frost heaving of the ground underneath and permits quicker defrosting.

The structural design uses basically only four trusses to carry the weight of the whole building and leave the main floor free of obstructing columns.

An inspection tour, conducted by the speakers, was made through the building.

In connection with the new Memorial Centre, it is interesting to note the importance of E.I.C. members in the Peterborough community planning. Alderman Ross Dobbin, past-president of E.I.C. was chairman of the building committee for the Memorial Centre. H. R. Sills, vice-president, is a past-chairman of the City Planning Board and A. L. Malby, is at present chairman of the Board.

Wives' Association

The Wives' Association of the Peterborough Branch was formed at a meeting held on May 8, when Mrs. H. R. Sills invited the wives of fifteen E.I.C. senior members and executives to a coffee party at her home. This group decided to hold the first general meeting on May 29 at the Kawartha Golf and Country Club, starting at 8 p.m., followed by supper, and to invite Mrs. Lilian Robertson of the Field Office in Toronto, to describe the various engineers' wives' groups now organized, and the plan for a national organization.

The group telephoned all the E.I.C. wives in the branch and invited them to attend. They were very pleased to have 65 at the meeting, and all wished to become members of the new association immediately.

It was decided to hold four general meetings a year. Four social groups, such as a book exchange, crafts, bowling and bridge would be included.

Mrs. Sills was chairman of the meeting and Mrs. B. G. Ahern acted as secretary. The following will meet during the summer to draw up a slate of officers and complete arrangements for the official opening meeting in September: Mrs. H. R. Sills, Mrs. B. G. Ahern, Mrs. P. F. Peele, Mrs. B. L. Barnes, Mrs. P. W. Doddridge, Mrs. J. G. Pearsall, Mrs. A. Bonney, Mrs. W. H Ackhurst, Mrs. I. N. MacKay, Mrs. D. B. Chase, Mrs. R. Bergey, Mrs. M. Uloth and Mrs. F. R. Pope.

Niagara Falls Tour

Members of the Peterborough Branch visited Niagara Falls last Saturday for a tour through the remedial works area and power plants. Guided by Ontario Hydro's public relation man, the engineers first toured the control dam above the falls. The dam, which nears its completion has 13 control gates and is the main part of the remedial works for preservation of the Falls.

Second stop was made at the new pumping-storage plant in Queenston. This pumping-generating station, which is under construction, will pump with its six 55000 h.p. pump-motor units extra water, available during the night, into a 750 acres reservoir. The water will be used to generate electricity in the same turbine-generator sets during peak load periods in daytime.

This pumping station is one of the first of its kind in North America featuring turbines of unit design.

Finally Sir Adam Beck Generating Station No. 2 containing sixteen 8050(kva. generators were inspected. H. R·

Operations Research

About 60 members heard a well delivered talk on "The Engineer and Operations Research", on March 14, given by Dr. Peter J. Sandiford, director of operations research, Price Waterhouse Company. Developing his talk on informal lines, he held the interest of the audience for nearly two hours.

Dr. Sandiford was introduced by Morgan H. Pryce, who was in charge of meeting arrangements. Before joining Price Waterhouse, Dr. Sandiford was chairman of the operations research group of the Ontario-Hydro. He is vice-president of the Canadian Association of Physicists, and a past president of the Operations Research Society of Toronto.

He began by inviting the audience to choose some specific topic in operations research on which he might speak. As few had experience in this realm, the audience was considerably puzzled. Such an approach emphasized forcefully the nebulous nature of the subject, in fact, no one has produced a good definition so far. The application of OR, as it is called in industry, speaks for itself.

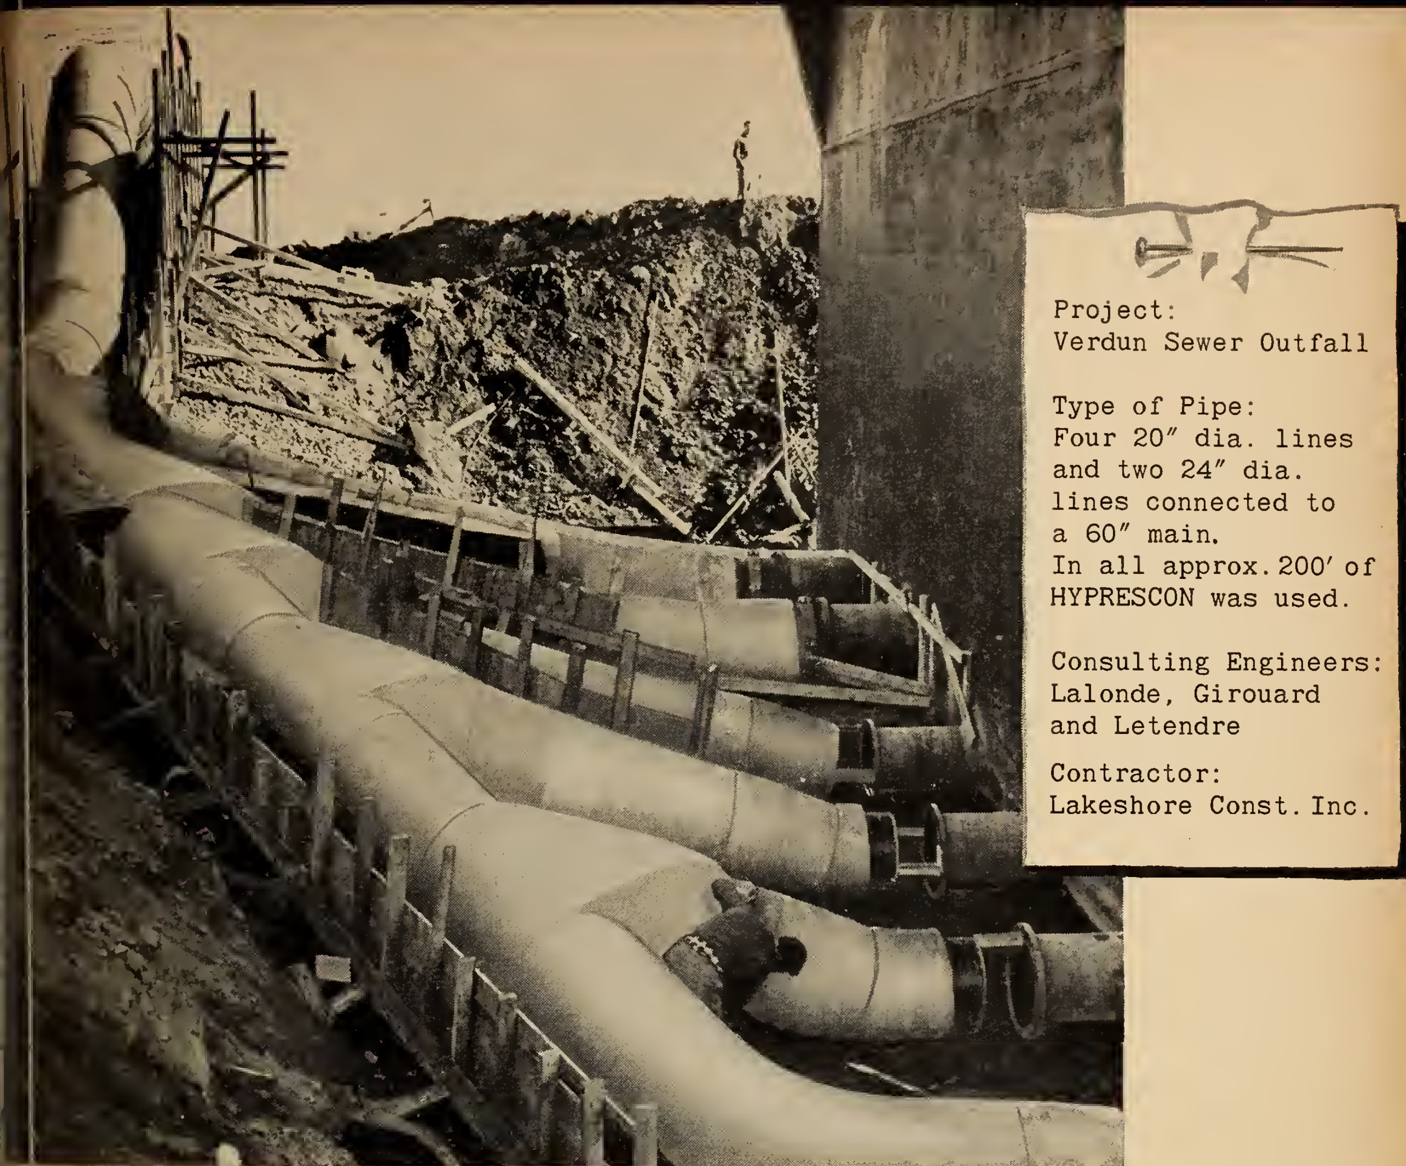
Three Main Groupings — The application may be broken down into three main groups: personnel, technique and organization.

The Personnel are scientists "Take a savvy boy and give him a job to do". who are interested in business, able to read mathematics, and who are clear thinkers. An OR team may consist of two engineers and one mathematician. The successful teams usually contain engineers (of the honest variety) and consequently OR is a good field for them.

The techniques involved are principally mathematical. Algebra, mathematical statistics, calculus, the calculus of variations, and probability theory are the most commonly used. Linear programming, another technique very dear to the heart of an OR man, involves the use of queue theory, the monte carlo method, statistical theory, and the theory of games. The fields where these techniques burgeon are: inventory control, production scheduling, capital equipment replacement budgeting, and lastly, forecast and planning. The first two applications are receiving the most atten tion at the present time.

Organizational Chart — Dr. Sandiforc then proceeded to demolish the audi ence's inhibitions with some fun anc games on an organizational chart, o from machine operator to president i six crazy stages and back again. Th clashes between problems and person alities at various stages and levels bring in the OR men on the run. In this char at the upper level, grand strategy mus be employed. How capital should be allo cated, and whether a new field of en deavor should be entered by the firr are a couple of sample problems at th level. Strategy of the following kind de velops between the high level and th next lower: What should the replace ment policy be? How should a natur resource be developed? What is the be inventory policy? How should the en trances and exits be placed on that ne super highway?

Tactics Level — At the tactics lev questions like these arise: How shoul the product be shipped to produce minimum freight bill? How should pr duction be scheduled to minimize lo in the product? How should gasoline b blended for the most profit? What a the re-order points and the amounts l in an inventory control program? Ho long should delinquent accounts be pu



HYPRESCON PROVES ITS VERSATILITY —at Verdun Sewage Outfall Project

... And Another Tough Problem is Solved

Over a short distance HYPRESCON funnels sewage from six pumping outlets into one 60″ main. Five Y's and one elbow were prefabricated by Pressure Pipe Company of Canada Limited to make this unusual connection.

To prevent sewage from backing up into the pumps, a siphon (see upper left of illustration) had to be constructed—and here too, HYPRESCON proved its exceptional flexibility.

HYPRESCON, noted for its qualities of strength, sustained high flow co-efficient and long life has become first choice of engineers right across Canada; its field records of easy installation and bottle-tightness are unbeatable.

If you do not already have full technical data on HYPRESCON, write to:

PP

sued? How should aircraft be stacked over an airport?

Where do these three divisions fit into the operations of a business? Where does one stop and the other start? It is hard to say. Tactics might be looked on as a combination of industrial engineering and mathematics. Grand strategy could be a combination of economics and mathematics, and strategy lie somewhere in between. Take your choice — now it can be seen why it is so hard to pin down OR with a definition.

The process of education in OR is to read for one's self. Dr. Sandiford said that he could only stimulate interest and direit attention to books.

OR as a Career — If anyone is seduced by the siren call to drop everything else and take up OR, he must remember that it is nearly impossible to leave again. The transmigrator stops being a technical specialist and becomes a business generalist. The transition is fast, and may be very shocking to the man who makes the change.

In the question period which followed, Dr. Sandiford made many important points, among them the fact that stating the problem correctly at the beginning is the first step in solving it, and just as important, is the payoff worth the cost of doing the problem? Fees for such service run at current consulting rates.

Several examples of the application or mis-application of linear programming were also given.

Sir Claude Gibb

Between five and five hundred and fifty members and guests heard Sir Claude Gibb, the chairman and managing director of C. A. Parsons Limited, talk on nuclear power generation developments in Britain. Sir Claude was introduced by A. W. Manby, general manager of the Ontario Hydro Electric Power Commission. Mr. Manby told of Sir Claude's many scientific and commercial interests, and the honours which have been bestowed on him for his services to Britain.

Sir Claude himself stated that he would deliver the paper which he had given before the Institution of Mechanical Engineers in Great Britain on the subject of "Engineering Problems in the Development of Nuclear Power". This paper was given at the request of the Institution and is known as the Thomas Hawkesley Lecture, and is one of the events in the Institution's year.

Nuclear Power For Survival. Due to Middle Eastern events and division among the great powers, Britain must develop nuclear energy sources in order to survive. Electrical power is the easiest to use, and the nation with the highest consumption of electricity per head has the highest standard of living. The greatest factor in increased production is the increase in the use of electric power. Even though the consumption of coal per kw. generated was reduced, and the production of coal increased, Britain must consider other sources of energy. Oil for power generation was ruled out for obvious reasons, and gas was not obtainable. If oil became a vital part of the power picture, Britain might have to fight for it. A more peaceable way must be sought if Britain was to maintain her position in the brotherhood of nations.

Contingent on Scientist, Engineer. The future then, depends on the scientist and the engineer, with the scientist developing and the engineer applying the knowledge found. Calder Hall was an intuitive guess bordering on genius. After considering all the possibilities and their economic significance as far as Britain was concerned, it was finally settled that the uranium-graphite moderator-carbon dioxide transfer medium was the best, and most reliable. Sir Claude claimed that Calder Hall, the first operating nuclear power plant is a "model

which is the envy of the world". The overriding requirement of safety governs the philosophy of design. The reliability of the operation and high availablity of supply come next. Siting of the plant depends on the attitude of the population. With these factors in mind, detail development of the plant can be considered. Many possibilities were considered in the Calder Hall design, but it was really nothing more or less than the old and tried method of trial design repeated many times.

Sir Claude described many of the intimate details which were worked out as the design progressed and the urgent problems which had to be solved.

In the question period which followed Sir Claude brought out a number of interesting points. The cost of power based on a 5 per cent write-off and a 20-year life with uranium at today's cost, in a 400 mw. plant is about 7 mills per kwh. Ordinary commercial contracts are now possible.

To avoid corrosion from carbon dioxide, the gas must be dry. So far no corrosion has been experienced at the operating temperature range.

The nuclear power plant is a base load plant running as close to 100 per cent capacity as possible. No shut-down or start-up should be made in the operation if this can be avoided. Brittle irradiated steel should remain at constant pressure and temperature. Problems of stress in the structure are minimized under constants operating conditions. The present requirement of the Board of Trade that a thorough inspection of every pressure vessel be made each 14 months should be raised to 5 or 6 years at least.

A pinhole in a rod sheath to be visible to the eye must run for at least 72 hours. A burst slug can be found quickly and on full load.

Two important cardinal rules should be followed: Don't put anything into the reactor which may become radioactive if it has to be removed at a later date. Don't use an auxiliary fuel for superheater firing, as two different kinds of operator will be needed.

The thanks of the meeting were tendered by V. A. McKillop who suggested that nuclear power be studied by all serious-minded engineers.

Wives' Association

A group of twenty-seven wives of executive members, past and present, met at the home of Mrs. K. F. Tupper on March 28 to discuss the formation of an Engineering Institute wives group in Toronto. The meeting was unanimously in favour of this. It was decided to send out invitations to the wives of all members and juniors to attend a coffee party on May 15, from 1.30 to 3 p.m., at the North Toronto Memorial Gardens, when they would be invited to join a group.

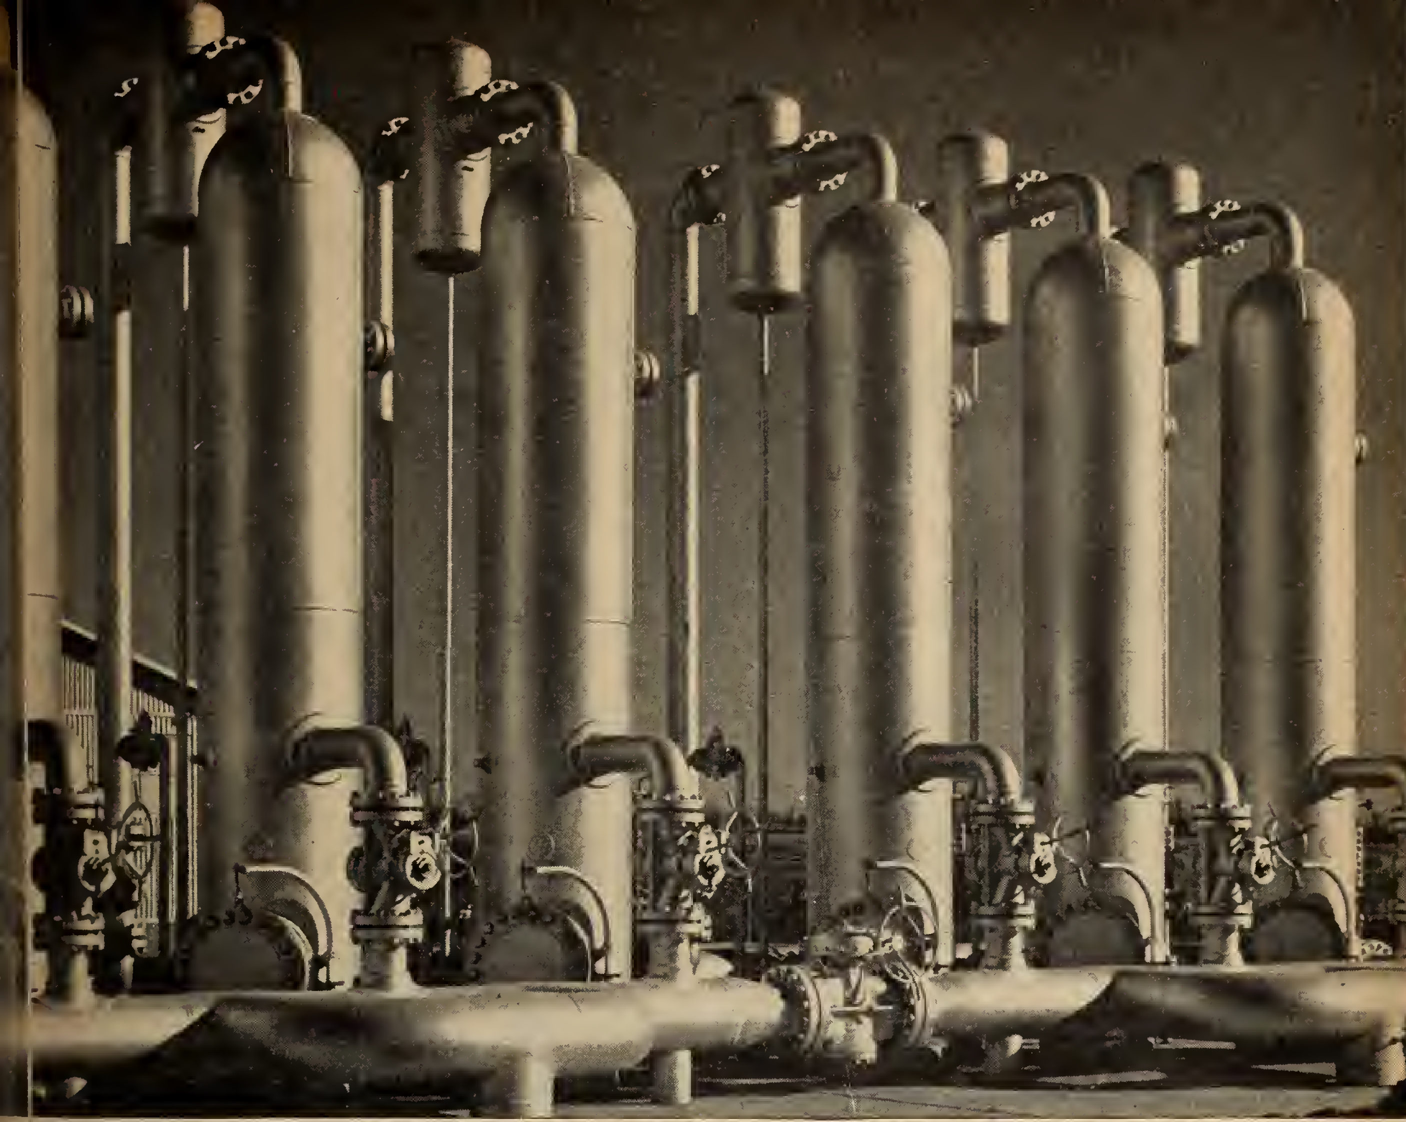
Despite rainy weather, more than 220 ladies attended the party, and 137 registered as being interested in joining. It is, therefore, felt that the E.I.C. Toronto Wives' Association is now established

Mrs. D. D. Whitson, Mrs. K. F. Tupper and Mr. E. R. Davis received the guests and forty hostesses passed coffee and cake and introduced the guests to one another. The large room looked most attractive with bouquets of spring flowers and two large coffee tables set up at either end.

Mrs. Whitson welcomed the wives attending, and asked Mrs. Lilian Robertson of the Toronto office to describe what the Ottawa and Hamilton groups are doing, and the proposed national organization which will be discussed at the E.I.C. annual meeting in Banff.

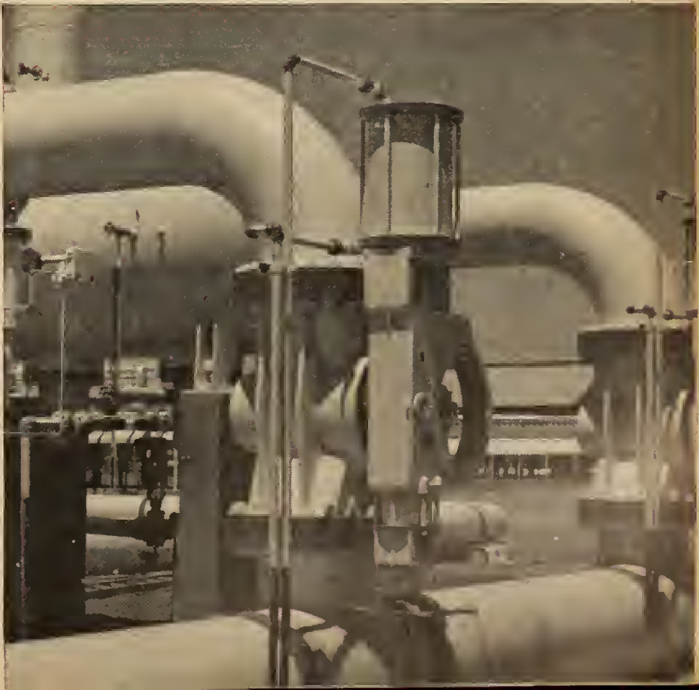
During the afternoon Mrs. H. L. Hillgartner, Mrs. L. C. Sentance, and Mrs. G. L. Schneider arrived from Hamilton with the good wishes of their group, and a telegram of congratulations came from the Ottawa Wives Association.

There were expressions on all sides



40th YEAR

of lubricated plug valve leadership



of pleasure that such a group is now formed in Toronto. It is expected that the next meeting in October will be even more successful.

Names of those comprising the committee in charge of the event are: Mesdames D. D. Whitson, K. F. Tupper, E. R. Davis, C. D. Carruthers, Peter Dalton, W. H. Paterson, C. E. Potter, and D. S. Moyer.

W. M. Armstrong Talks on Steel

"Planning a Steel Industry for British Columbia" was the subject of an address before the Vancouver Branch of the Engineering Institute of Canada on February 28. The subject is of particular interest to British Columbia at this time and the speaker, Mr. W. M. Armstrong, was well qualified to speak with authority on the subject. Mr. Armstrong is well known in Vancouver and British Columbia being prominent in the consulting and teaching fields. Hs is an Associate Professor of metallurgy at the University of British Columbia and conducts a consulting practice. He was supervisor of the metallurgical laboratory of the Steel Company of Canada and in 1946 joined the B.C. Research Council.

Value to Province

Mr. Armstrong first indicated the value of a steel industry to the Province by giving the comparative values of ore in the ground at $18.00 a ton to rolled steel at $125.00 a ton. The differences was value added by wages and services within the province. The price of steel at a given location is affected materially by the cost of transportation from the mill and in the case of British Columbia this allows a margin of about $22.00 a ton over production in Eastern Canada. For the same reason of high freight costs, the British Columbia market is limited to the two western provinces. The export market cannot be relied on so that the total market is very limited and may not exceed 200,000 tons a year.

Low Costs Essential

Even this low market will permit a local steel industry providing ore is obtainable at an economic cost and the site of the plant is selected for minimum cost of power, coal and shipment to market. As ore must be mined in large daily tonnages to keep the cost down Mr. Armstrong considered that ore export must accompany local usage. He stated that known ore reserves were ample to sustain a steel industry but that total ore reserves would not be known until there was an incentive for the prospector and the miner to investigate the many outcroppings ignored to date.

As a blast furnace was impractical for the low steel tonnage that could be marketed, low cost power or natural gas would be factors determining the site of the industry. Raw material in the form of tailings is available at Kimberley, natural gas could be obtainable in many locations, low cost power was found near Vancouver and probably low cost large blocks of power will be available on Vancouver Island so that a careful economic analysis was necessary to determine the most favorable site.

Summarizing, a steel industry is economically feasible now and it may not be long before it is a reality.

Students' Night Awards

University of B.C. student, W. Calderwood, was awarded first prize; L. Hunt second prize and J. Mawdsley third prize at a presentation of engineering papers at the Branch Annual Students' Night.

• BRANCH NEWS

Host to members of the University of British Columbia Student Section, the function was held March 7, at the Faculty Club. Following dinner the students took over the meeting with C. Day, acting as chairman.

Under the direction of the University Toastmaster Club, the students had arranged an excellent program. Toastmaster J. West called on an introducer and thanker for each of the following student speakers. L. Hunt who spoke on "The Theory of the Atom as Developed by Lucretius", W. Calderwood on "The Development of Transistors" and J. Mawdsley who chose "A Very High Frequency Transmitter for Airport Traffic Control".

Three Vancouver Branch members, T. V. Berry, F. Cazalet and J. T. Turner, undertook the responsibility of judging the speakers. Mr. Berry complimented the speakers on their presentation and awarded prizes following an instructive criticism of each paper.

The Vancouver Branch vice-chairman, P. Bland, closed the meeting with a few words of appreciation to the student section for their handling of the meeting and for the way in which they had demonstrated the value of the student Institute activities.

Taken at the Annual Students' Night of the Vancouver Branch earlier this year, l. to r. are shown, C. Day, chairman of the U.B.C. student section, and prize-winners, H. Hunt, J. Maudsley, and B. Caldherwood.

At right are l. to r.: C. Day, H. C. Gunning, dean of applied science, U.B.C.; P. N. Bland, Branch vice-chairman; and W. O. Richmond, president of the A.P.E.B.C.

Canadian Aeronautical Meeting

Group Captain H. R. Foottit of Ottawa, director of aircraft engineering, A.F.H.Q. was elected president of the Canadian Aeronautical Institute at the annual meeting of that Institute held on May 27 and 28, in Ottawa.

S. L. Britton, of Orenda Engines Limited, Toronto, was elected vice-president, and nine councillors also took office during the meeting.

The McCurdy Award for technical achievement was presented to E. K. Brownridge. The F. W. (Casey) Baldwin Award, a newly established medal for the best paper published in the Institute's *Journal*, was presented to H. T. Stevenson and Dr. P. Mandl of the N.A.E., for a paper entitled, "A Repeating Parachute". The Hon. J. A. D. McCurdy personally presented the first award, and Mrs. F. W. Baldwin presented the Baldwin awards.

Fourteen technical papers were presented during the two-day meeting to an audience of Canadian and American aeronautical engineers.

C. A. Bloom of Canadair Limited detailed the elaborate tests used to ensure that the *Argus*, largest aircraft ever built in Canada, would be safe and reliable. Two R.C.A.F. officers, S/L O. B. Philp and F/L K. D. J. Owen, described the cooperation needed between test pilots and flight test engineers. J. A. Fortune of Orenda Engines Ltd., Toronto, reviewed the use of non-metallic material in jet engines. K. B. Young, International Nickel Company of Canada, Ltd., told of the search for new metals for high temperatures.

R. V. Campbell and S. C. M. Ambler of British American Oil Company Ltd., discussed lubricants for modern aircraft engines. E. J. Richards, of the University of Southampton, England, gave information on noise research in the United Kingdom, as related to jet aircraft. Canadian research on this problem was recounted by Dr. K. K. Neely of Defence Research Medical Laboratories.

Icing problems occupied an entire session of the meeting; with papers on Some Aspects of Helicopter Icing by J. R. Stallabrass, of N.R.C.; on Aircraft Gas Turbine Ice Prevention, by D. Quan of Orenda Engines Ltd., and C. K. Rush, of N.R.C.; and Ice Crystals, a New Icing Hazard, by O. R. Ballard, Ministry of Supply, and B. Quan, of N.R.C.

In a session on Aviation Medicine and Human Engineering, there were three papers: Introduction of Human Engineering, R. E. F. Lewis, Avro Aircraft Limited; Safety First and Always; by J. A. Gillies, R. J. Burden, and K. E. Marsden, of Canadian Pacific Air Lines Limited; Specific Aeromedical Problems in High Performance Aircraft, S/L R. A. Stubbs, of the R.C.A.F., Institute of Aviation Medicine.

The meeting included a session on aerodynamics, which took the form of an unprepared and informal general discussion. Presiding was R. J. Templin of N.R.C., and leading the discussion were Dr. G. W. Johnson, DeHavilland Aircraft of Canada Limited, H. C. Eatock, Orenda Engines Limited, and S. J. Pope, Canadair Limited.

E. T. Jones, director general of technical development (air) of the Ministry of Supply, was the principal speaker at the annual dinner, May 27. Mr. Jones is the president of the Royal Aeronautical Society.

Canadian Good Roads Convention

Saskatchewan will be host this year to the 38th convention of the Canadian Goods Roads Association. Hon. J. T. Douglas, general chairman of the Convention Committee and Minister of Highways and Transportation of Saskatchewan, in a letter to members and friends of C.G.R.A., promises a warm western welcome. The place is Saskatoon, the dates September 25 to 27.

C.G.R.A.'s convention, the national "Parliament of Roads", is the most widely representative meeting of road interests held in Canada during the year.

The Bessborough Hotel has been chosen as convention headquarters. To ensure sufficient accommodation there and in other good hotels and motels, a housing committee has been set up.

Representatives of provincial, federal and municipal governments and of industry from all parts of Canada will confer on road and street problems and discuss developments in the highway transportation industry. The meeting will be opened by Honourable W. J. Patterson, Lieutenant Governor of Saskatchewan. Premier T. C. Douglas will be the speaker at the annual banquet, September 27.

C.G.R.A.'s president, Hon. P. A. Gaglardi, Minister of Highways of British Columbia, will preside over the convention and deliver the annual review on significant matters in the national highway picture. Arthur C. Nagle, assistant to the executive director of the International Road Federation, Washington, D.C., will present an address for that organization.

Luncheon speaker will be Bertram D. Tallamy, Federal Highway Administrator in the United States.

The technical sessions of the convention will bring together some of the most distinguished highway technologists in Canada.

A regular feature of C.G.R.A. conventions, "Forum 57", will occupy one and a half days, with speakers and discussions on soils and materials; economics, finance and administration; planning and design; safety education; traffic education; traffic engineering; and construction and maintenance.

C.G.R.A. delegates will hear from Dr. Gordon D. Campbell, engineer observer on the AASHO road durability test. The "Roads Round-Up" will again report road building activities across Canada.

The C.G.R.A. office is at 270 Maclaren St., Ottawa.

Welding Council

As was earlier announced in the *Journal*, membership for Canada in the International Institute of Welding is now held by the Canadian Welding Bureau, the Canadian Welding Society and the Department of Mines and Technical Surveys. In order to expedite and direct the activities of the I.I.W. in Canada, these participating members have joined together to form a Canadian Council. The first meeting was held December 1956.

This new Council will now direct and conduct the affairs of the Institute and its Commissions in Canada.

The purpose of this first meeting was to adopt rules and regulations governing the activities of the Council, to elect officers, to draw up a budget and to appoint delegates to represent the Canadian Council at the 1957 Congress of I.I.W.

Appointed chairman and executive secretary, respectively, were R. A. Dunn and W. R. Stickney. These appointments are effective from January 1957 to September 1957. Delegates to the Canadian Council are W. P. Campbell and H. J. Nichols, of the Department of Mines and Technical Surveys; R. M. Gooderham and W. R. Stickney of Canadian Welding Bureau; and R. A. Dunn and E. A. Gill, of the Canadian Welding Society.

● OTHER SOCIETIES

H. Thomasson of Canadian Westinghouse, R. A. Dunn, and R. M. Gooderham were appointed to represent the Canadian Council at the 1957 Congress in Germany.

It is the work of the Council to serve the interest of its three sponsor bodies, and Canadian science and industry in the activities of the International Institute of Welding, and to officially act jointly on their behalf in such activities. The Canadian Council will strive to select official chairmen, alternates and experts to serve on I.I.W. Commissions. Each member country is entitled to representation on these Commissions by one delegate who may be assisted by experts. The Commissions meet on occasions of assemblies of the Institute. The chairman will be responsible for organizing the work of the parallel Canadian commissions. Through these parallel Canadian commissions the Council will strive to publish for its sponsor bodies and for Canadian industry the vast wealth of knowledge available through the international body.

At the present time actual delegates appointed to I.I.W. commissions and also serving as chairman of Canadian commissions are as follows: Guy Savard, Canadian Liquid Air, the Commission on Gas Welding; R. F. Scott, Horton Steel Works, the Commission on Electric Arc Welding; W. A. Amos, Upton, Bradeen and James, the Commission on Resistance Welding; W. P. Campbell, Department of Mines and Technical Surveys, the Commission on Control of Welding; G. dal Molin, Northern Electric, the Commission on the Creation of a Dictionary; H. J. Nichols, Department of Mines and Technical Surveys, the Commission on Weldability; George Hamer, Horton Steel Works Ltd., the Commission for Stress Relieving in Welds; A. Clarke, Ontario Paper Company, the Commission for the Study of Brittle Fractures.

Calendar

Aeronautical Engineering

The Institute of the Aeronautical Sciences (2 East 64th St., New York 21) announces the National Naval Aviation meeting for August 5 to 10, at San Diego, Calif. The I.A.S. is co-sponsor of the sixth International Aeronautical Conference, (with the Royal Aeronautical Society) at London and Folkstone, England, September 1 to 16, 1957.

Pan-American Meeting

The Seventh Pan-American Highway Congress will take place in the City of Panama from August 1 to August 10, 1957.

This meeting has been called by the Inter-American Economical and Social Council. The Organizing Committee is at: "Palacio Legislativo, Calle 22 B, Apartado 3543, Panama, R. de P.

Symposium on Gas Dynamics

The second symposium of the series initiated by the American Rocket Society and Northwestern University will be held August 26-28, 1957 at the Technological Institute of Northwestern University, Evanston, Ill.

Theme of the meeting will be "Transport Properties in Gases at High Temperatures and Pressures".

It is hoped that the symposium will be of interest to scientists and engineers concerned with research and development entailing the transfer of mass, energy and momentum.

Inquiries may be addressed to: Dr. Ali Bulent Cambel, Gas Dynamics Laboratory, Northwestern University, Evanston, Ill., U.S.A.

Chemical Engineering

The American Institute of Chemical Engineers will hold two meetings during the closing months of 1957. The first will be held at the Lord Baltimore Hotel, Baltimore, Maryland, September 15-18. The second takes place in Chicago, from December 8 to 11, at the Conrad Hilton Hotel.

Construction Engineering

The Canadian Construction Association western regional meeting will be held this year from September 12 to 15 at Jasper Park Lodge, Alta.

Canadian Construction Association headquarters are at: Construction House, 151 O'Connor St., Ottawa.

Industrial Chemistry

The thirtieth International Congress on Industrial Chemistry will be held at Athens, Greece, September 17 to 24, 1957.

Held in one of the centres of European culture it is expected to attract chemists, scientists and technicians from all parts of the world.

As in former sessions, meetings will be accompanied by visits to various factories. A complete program for sightseers has already been arranged to allow excursions during and after the Congress.

Further information may be had on writing: Trentieme Congres de Chimie Industrielle, Comite D'Organisation, 10 rue Kaningos, Athenes, Grèce.

Material Handling Meeting

A wide range of subjects will be discussed by 23 Canadian and American specialists at the conference sessions of the Canadian material handling show and conference September 30 to October 4, 1957 in Montreal.

Sponsored by the Montreal Chapter of the American Material Handling Society, four panel discussions will be held the first day, followed by group discussion and the Canadian Material Handling Clinic on the consecutive days.

Further information may be had on enquiry from: M. H. Engeland, c/o Sherwin Williams Company Limited, 287 Centre Street, Montreal, Que.

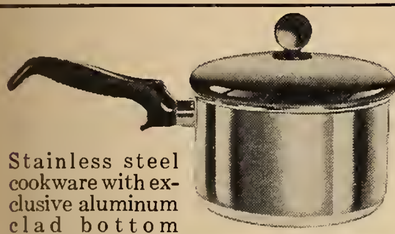
Correction

In the May issue of The Engineering Journal, (Page 631) this picture of the 450-ft. cement kiln of Canada Cement Company Limited at Woodstock, Ont., was inadvertently reproduced in the wrong position. This is the correct view of the unit.

ATLAS STEEL NEWS

TOOL STEELS • HIGH SPEED STEELS • MINING DRILL STEELS • SPECIAL PURPOSE STEELS • STAINLESS STEELS

WHAT'S NEW IN STAINLESS products for the home



Stainless steel cookware with exclusive aluminum clad bottom (patented)—latest product from Sunshine Waterloo Co. Ltd.—features a design-award-winning nine-piece set including covered saucepans, skillets and boilers which are available in three sizes. For lifetime beauty and service these utensils are made of type 302 Atlas Stainless Steel.

True beauty with utility is evident in cutlery made of Stainless Steel.

Illustrated, a knife, fork and spoon in Oneidacraft "FLIGHT" pattern which features elegant design with lifelong wear. Easy-to-clean, always sparkling, a pleasure and pride to have on your table—that's cutlery made from Stainless Steel.

CHALLENGE!

From Norway comes something new and exciting—stainless steel decorator bowls and plates in many beautiful "baked-on" enamel colours. Here is a challenge to the Canadian designer—a challenge that he can easily meet with Atlas stainless steel.

ATLAS STEELS LIMITED

WELLAND, ONTARIO

BRANCHES: TORONTO, MONTREAL, HAMILTON, WINDSOR, WINNIPEG, VANCOUVER

REPRESENTATIVES: LONDON, ST. CATHARINES AND SUDBURY. AGENTS THROUGHOUT THE WORLD.

Designers And Consumers Join the Swing to Stainless

Right across Canada—indeed, right across the world—more and more designers and consumers are turning to stainless steels for beauty and durability that defies time. In the kitchen . . . on the dining table . . . for the family car . . . for any place where lasting quality must stand the test—Atlas Stainless Steels are proving the wisest, most practical choice for better modern living. As Canada's *only* basic producer of stainless steel to any specification, Atlas Steels Limited is proud to be the leader in Canada's newest trend.

Why G.E. Chose Atlas Stainless Steel Tubing For This Refrigerator De-Frost Valve

General Electric chose Atlas Stainless welded tubing, type 304, for this most intricate valve body because it provided a closer diameter tolerance than could be obtained with seamless tube. This is only ONE instance where Atlas Stainless Steel Pipe and Tubing has filled a vital need. For the whole story on these precision made Atlas products write us for this illustrated brochure.

UPTREND IN USE OF STAINLESS FOR AUTOMOBILES

Stainless steel is making itself felt more and more in the automobile industry. For example, wheel covers for all the "big three" cars—Chevrolet, Plymouth and Ford—are now made for a lifetime of beauty with gleaming, rust-proof stainless steel. Plans for the future include many additions to the long list of parts and accessories now made from stainless.

Shown below is one of General Motors' cars of the future the "Impala" . . . which features shaded pale blue stainless steel roof, and a long blue fibreglass body embellished with tasteful silver blue stainless steel. As illustrated by this application, the natural beauty of stainless can be enhanced by a coat of transparent color glaze.

The "Impala" contains many spectacular new features which may be incorporated in future stock model G.M. cars.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

AIRCRAFT HYDRAULICS, V.1 HYDRAULIC SYSTEMS

Although the design and manufacture of hydraulic equipment for aircraft is such an important part of the industry, very few textbooks have so far been made available. The Royal Aeronautical Society is trying to remedy this by issuing a series of texts for students which will also prove of interest to practicing engineers.

This first volume is concerned with the general problems of hydraulic systems, and includes chapters on fluids; hydraulic theory as applied to aeroplane systems; hydraulic systems and circuits; the installation, operation and testing of systems.

Later volumes in this most useful series will discuss component design of aircraft hydraulics and landing gear design. (Ed. by H. G. Conway. Toronto, British Book Service, 1957. 146p., $6.00.)

*ANNUAL REPORT ON THE PROGRESS OF RUBBER TECHNOLOGY, VOLUME 20

This selective review of the developments and literature of 1956 has separate papers on a wide variety of rubber goods for industrial and other uses. There is a general historical and statistical review of the year, also papers on planting, production, properties, compounding ingredients, testing, and the chemistry and physics of rubber and latex. (Ed. by T. J. Drakely. London, Institution of the Rubber Industry, 1957. 141p. 25/-.)

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

LIBRARY HOURS
Monday to Friday
9 a.m. — 5 p.m.

AUTOMATIC CODING

The eight papers given at a symposium on automatic coding held in January 1957 by the Franklin Institute are reproduced in this volume, outlining new techniques and new applications of automatic coding for digital computers used in industry and science. The authors of the papers are all experts on automatic coding, and they present the latest information and experience available in this expanding field. (Philadelphia, Franklin Institute, 1957. 118p., $3.00. Institute monograph no. 3.)

BASIC REINFORCED CONCRETE DESIGN: ELASTIC AND CREEP, 2ND ED.

A textbook for a basic course in reinforced concrete design, the new material in this edition includes chapters on creep, shrinkage, ultimate strength and prestressed concrete. The book covers the fundamentals of beam bending, shear, columns and practical continuity, introducing each new topic at an elementary level, and showing how problems may be solved by methods already familiar to students. Solution by formulas or charts are introduced later. The author includes full page calculation sheets showing design methods.

The 1956 American Concrete Institute Building Code has been followed and is explained in the text. There are problems and bibliographies included in each chapter. (By G. E. Large. New York, Ronald, 1957. 527p., $7.00.)

BETON-KALENDER 1957: TASCHENBUCH FUR BETON UND STAHLBETONBAU

The forty-sixth edition of this well-known handbook needs no introduction to those connected in any way with concrete construction. All types of cement and concrete are dealt with, and all aspects of concrete construction. Each chapter is written by a specialist, and much of the information is given in tabular form. Reference is made throughout the book to the German standards for steel and other construction materials.

This is an invaluable reference book, incorporating as it does all the latest German information. (Ed. by George Ehlers. Berlin, Ernst, 1957. 2vols, 18DM.)

CARGO SHIP LOADING

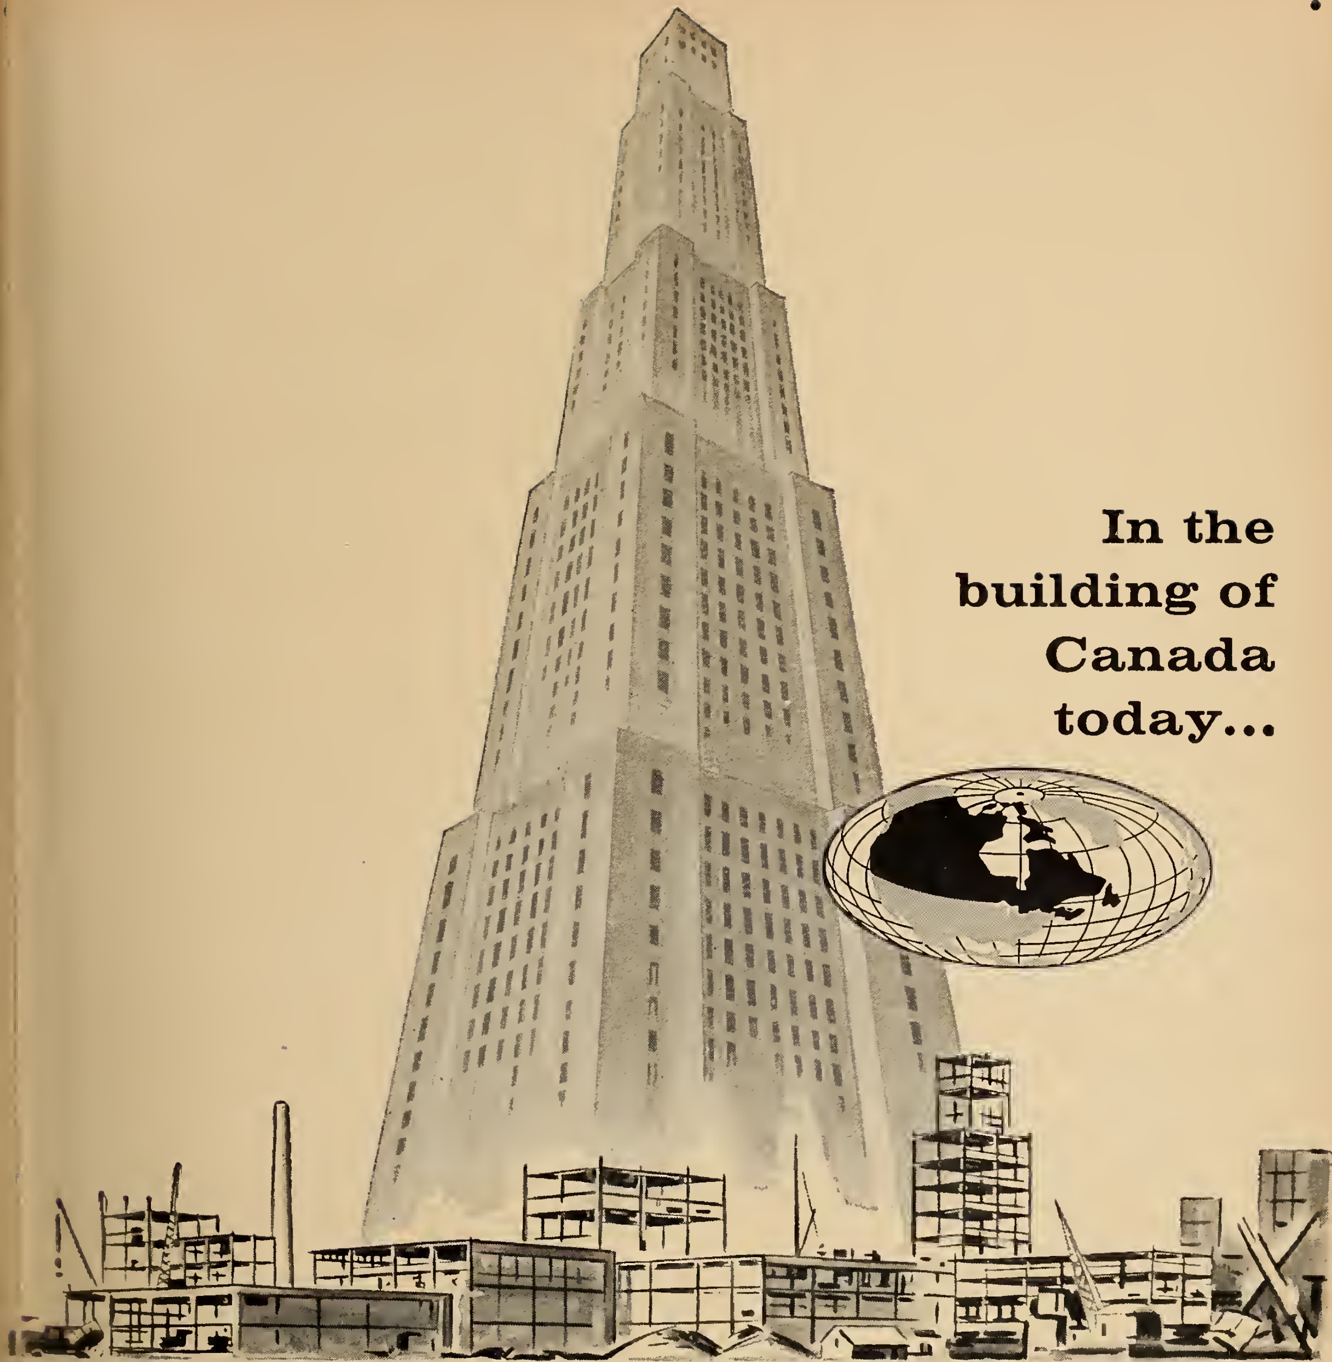
An analysis of general cargo loading in selected ports in the United States, this report presents data on overall loading rates, on various loading processes, costs, and estimated break-bulk loading capabilities. Much of the material is presented tabular form, and the conclusion reached is that most loading systems are operating well below their capacity. It would be interesting to see the results if a similar survey were made in Canada. (Maritime cargo transportation conference. Washington National Research Council, 1957. 91p., $2.00. Publication no. 474.)

COMBUSTION AND HEAT TRANSFER IN AN OPEN-HEARTH FURNACE

This is the report of a large scale trial initiated with the object of checking a mathematical theory of heat transfer in the open-hearth furnace. The team which carried out the test was composed of specialists from British industry, the Iron and Steel Research Association, and the University of Sheffield.

The report covers such topics as design and control of a trial furnace, combustion measurement and control, temperature measurements, heat losses through the brickwork, and general heat balance.

The trials demonstrated that the theory was essentially sound in predicting the influence of flame characteristics on heat transfer, and on working rates. The authors indicate that there is still much research to be done in relating theory and practice in the open hearth



furnace. (London, Iron and Steel Institute, 1956. 82p., 37/6. Special report no. 59.)

°ELASTIC BEHAVIOUR OF STRUCTURAL MEMBERS: THE FRAME CONSTANT METHOD

The method of stuctural analysis presented in this book is based upon "The various deflections of the free end of a member considered as fully restrained cantilever beam with all the direct loads applied and the influences of all the members in this system considered as loads." The author provides detailed analyses of a variety of structural members, discussing elastic behaviour, moment equations, the unit beam, the general behaviour of the continuous girders of from two to six spans. Charts and tables are included as necessary. The present volume considers only those structural members with constant moment of inertia. (By Odd Albert. Belmar, N.J., Opla Company, 1956. Various paging, $6.00.)

°ELASTIC WAVES IN LAYERED MEDIA

The outgrowth of a plan to make a uniform presentation of investigations on earthquake seismology, underwater sound, and model seismology, the scope of this book was enlarged to include a selection of related problems. Many of the methods used in seismological problems were originally developed in studies on electromagnetic waves and in general the methods used in the work covered by this book are close to those used in electromagnetic waves, water waves and shock waves. Extensive bibliographies are included. (By W. M. Ewing, W. S. Jardetzky and F. Press. Toronto, McGraw-Hill, 1957. 380 p., $10.00.)

ELECTRICITY AND MAGNETISM

This textbook commences with two introductory chapters on electrostatics and magnetism, followed by a study of current electricity, including electrolysis, electromagnetism, electrodynamics and capacitance.

The often abstract concepts of electricity are fully explained, and are followed by chapters which cover electrostatics and magnetism in more detail. An introduction to the physics of the atom is included, as is an explanation of the m-k-s system of units. Many of the questions included in the chapters have been taken from the examinations set by University of London. (By J. Newton. New York, Philosophical Library, 1956. 613p. $10.00.)

°ENGINEERING ECONOMY, 2ND ED.

The theory and practice of the determination and evaluation of economic factors are here set forth for engineers and engineering students. This edition, in addition to general revision, has a new chapter on income taxes in engineering economy studies. Other subjects treated in the book include: depreciation; first, fixed, variable, incremental, differential, marginal, and sunk costs; break-even and minimum cost points; evaluation of replacements; and economy and utilization of personnel. (By H. G. Thuesen. Englewood Cliffs, N.J., Prentice-Hall, 1957. 581p., $6.95.)

°ENGINEERING ENROLLMENT IN THE UNITED STATES

Presents basic statistics on the subject in both tabular and graphic forms. The period covered varies but generally includes the last 25 to 35 years. In addition to general coverage there are chapters on all major fields of engineering, and one chapter on engineering training in Russia. Considers the effects of proliferation of curricula in engineering specialities, large-scale enrollment in graduate study, and attrition of engineering students. Concludes that the current shortage of engineering talent is critical with respect to engineers with a high degree of mathematical and scientific orientation and those with unusual analytic and design creativity. (Ed. by N. N. Barish. New York, New York University Press, 1957. 226p. $7.50.)

FORGEMASTERS' MEETING 1954

In 1954 a joint meeting was held in London by the Iron and Steel Institute, the National Forgemasters' Association and la Chambre de la Grosse Forge Française at which papers were presented by authors from both sides of the Channel. The topics covered included the production and ultrasonic inspection of heavy upset forgings; thermal stability testing of rotor forgings; continuous grainflow process; heating and soaking of ingots for forging, etc. References are given in most papers, and the discussion following the papers is also reproduced, adding to the value of this interesting volume. (London, Iron and Steel Institute, 1957. 92p., 37/6. Special report no. 60.)

°FROST UND TAUSCHÄDEN AN VERKEHRSWEGEN UND DEREN BEKÄMPFUNG

A specialized treatment of frost and thaw damage to highways and railways. The book cites the basic factors; discusses the primary and secondary influences of weather, structural conditions, surfaces, loads, etc.; gives a résumé of current knowledge; and devotes a considerable section to remedial or preventive measures, both for existing roads and for new construction. (By L. Schaible. Berlin, Ernst, 1957. 176p., DM22.)

THE GENERAL THEORY OF ELECTRICAL MACHINES

Based on a graduate course given at Imperial College, London, this volume, as its title implies, presents a general theory applicable to all types of electric machines, rather than concentrating on one particular type. The author was a designer and consulting engineer with British Thomson-Houston for twenty years, and his experience is incorporated in this book, as is much information obtained from published papers which are listed in the bibliography.

The author discusses the basis of the general theory, methods of analysis, D.C. and A.C. machines, synchronous and induction machines, methods for generator and system analysis and the generalized rotating machine.

Much of the material presented is necessarily at an advanced level, but many of the ideas are simple, and can be used in teaching undergraduate courses. The volume is one of a series of advanced engineering textbooks written by the staff of the British Thomson-Houston. (By Bernard Adkins. Toronto, British Book Service, 1957. 236p., $7.75.)

°A GUIDE TO THE LITERATURE OF CHEMISTRY, 2ND. ED.

This important reference book, first published thirty years ago, has now been thoroughly revised to keep pace with the rapid growth of chemical literature. The authors describe and classify the important books, journals, indexes, and other types of literature; discuss such sources of data as patents, trade publications, theses, and unpublished material, and outline helpful principles for searching the literature. Lists of symbols, information on libraries, and other useful data is given in extensive appendixes. (By E. J. Crane, A. M. Patterson, and E. B. Marr. New York, Wiley, 1957. 397p. $9.50.)

HIGH SPEED DIESEL ENGINES, 6TH ED.

A well known and reliable text fo[r] over twenty years, this new edition ha[s] been largely rewritten, and new chap[-] ters added on supercharging, small ve[-] hicle engines, air-cooled and speci[al] purpose engines, and the starting of en[-] gines.

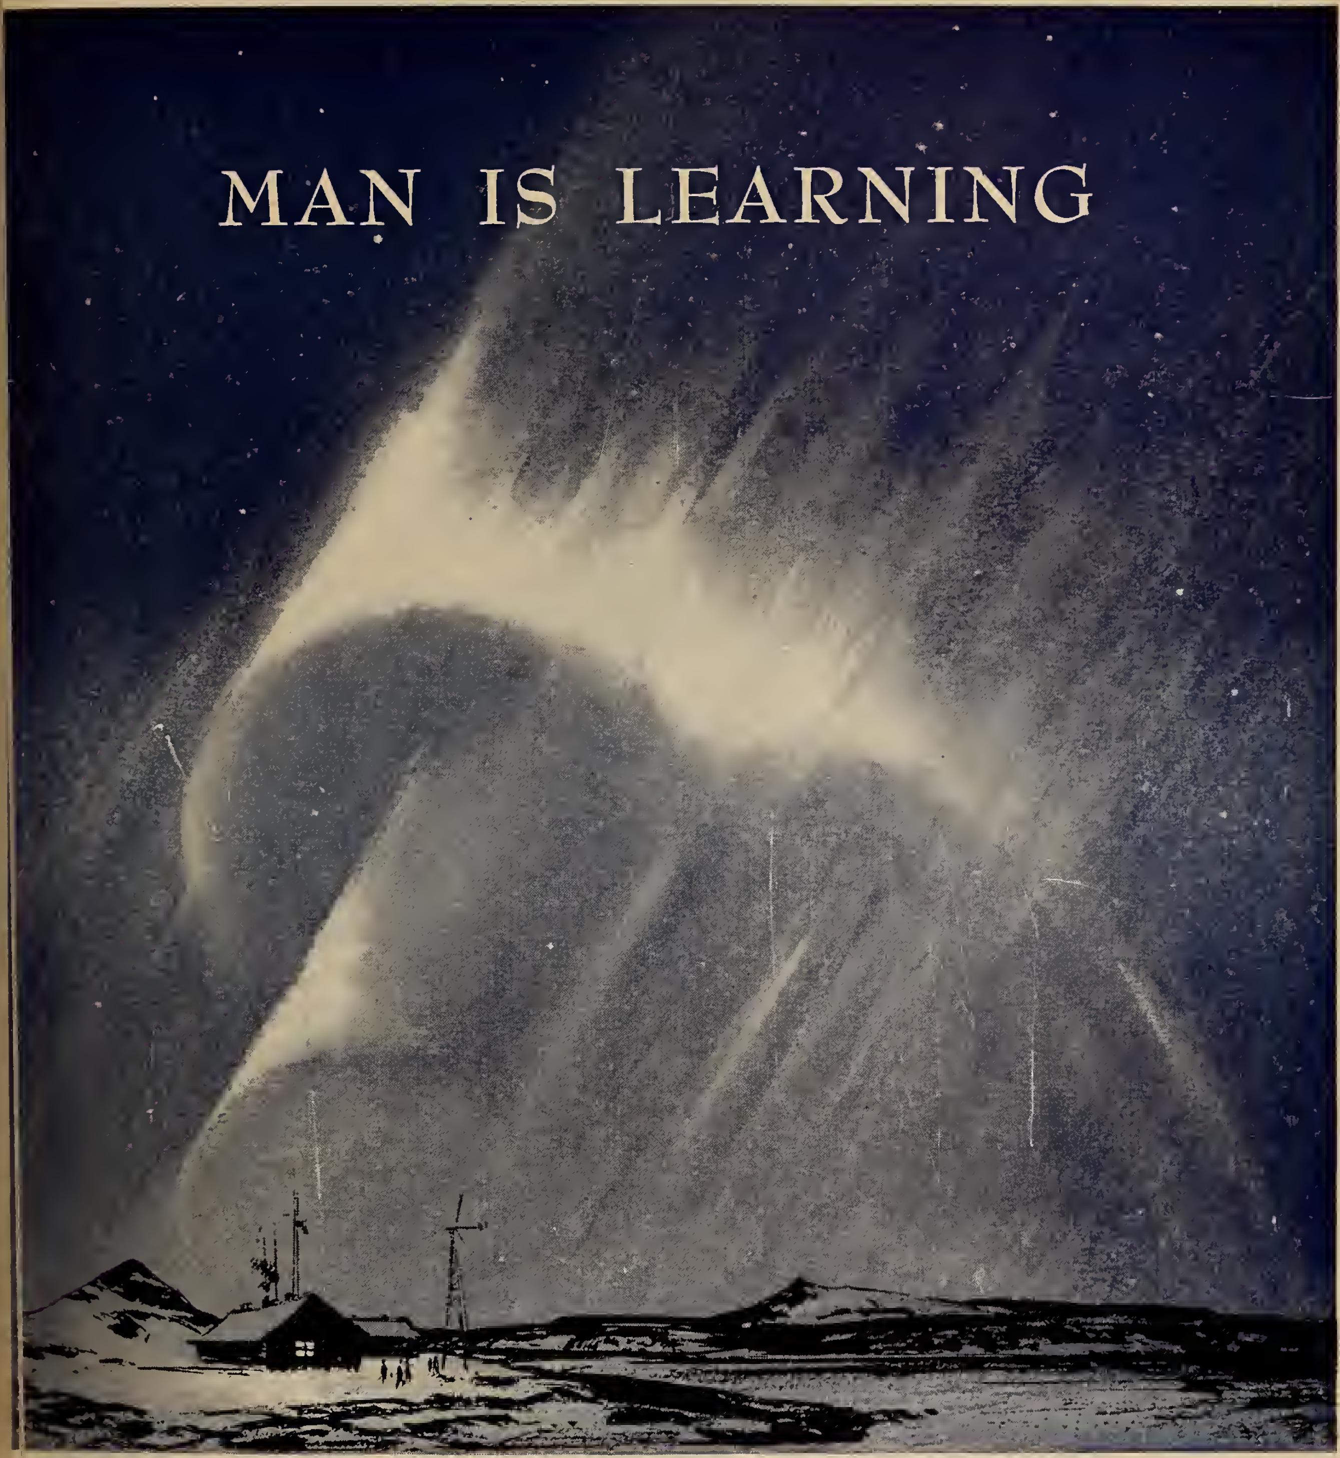
The material is presented at a fairl[y] elementary level, and covers the gen[-] eral principles and the construction [of] small and medium sized engines, wi[th] special reference to traction, stationa[ry] and marine types. (By A. W. Judg[e]. Toronto, British Book Service, 195[7]. 578p., $11.10.)

°HILFSTAFELN ZUR BERECHNUNG WANDARTIGER STAHLBETONTRÄGER

Tables and graphs for the design [of] deep panel-type reinforced - concre[te] girders as used in silos and bunkers. T[he] accompanying text provides the theore[t-] ical basis, analysis of loads, the fo[rm] and reinforcement of panel-type girde[rs] and three examples of calculations. ([By] O. Theimer. Berlin-Wilmersdorf, Ern[st], 1956. 38p., DM 7.20.)

A HISTORY OF MECHANICS

This history of one of the most i[m-] portant branches of the history of scien[ce]



MAN's unceasing quest for more knowledge of space and his world will continue with new vigour during the International Geophysical Year. Of the 43 countries uniting to make simultaneous observations, Canada's contribution will be significant for its studies of the ionosphere and of changes in the earth's magnetic field. Canadian Applied Research Limited is honoured to work with the Canadian scientists. Such new and unique instruments as the Auroral Recorder, the Stationary Magnetometer and a recording camera were engineered and produced for the project by Canada's leading instrumentation firm.

CANADIAN APPLIED RESEARCH LTD

(formerly PSC Applied Research Limited)

1500 O'CONNOR DRIVE, TORONTO

MEMBER • A. V. ROE CANADA LIMITED & THE HAWKER SIDDELEY GROUP is the first to appear for more than sixty years, and the author not only re-evaluates early history in the light of modern knowledge and ideas, but introduces recent developments. The text is translated from the edition published in Switzerland in 1950.

Part 1 deals with the forerunners and pioneers of the field of mechanics, covering the important men, schools of thought, fields of activities, and developments from the Greeks and Arabs to the time of Kepler in the 17th century. The formulation of the classical mechanics during the 17th century is discussed in part 2, with parts 3 and 4 covering the organization and development that took place during the 18th and 19th centuries. Part 5 takes up the 20th century concepts: the relative theory; quantum mechanics; wave mechanics; and the various developments of statistical mechanics. (By René Dugas. New York, Central Book, 1956. 671p., $15.00.)

*HYDRAULICS OF MULTIPLE MAINS

A book that will serve somewhat as a manual or handbook for engineers employed in enlarging or modernizing an inadequate water supply system. There are sections on classification and design of mains, basic equations for fundamental hydraulics, relative rates of flow for feeder mains, and pipe lines in series and in parallel. The concluding chapters give material on additional pipe lines, the life of the system and typical problems. The appendix contains nomographic charts. (By O. G. Goldman. Connecticut, Columbia Graphs, 1957. 145p., $6.50.)

*MECHANICAL ENGINEERING LABORATORY INSTRUMENTATION AND ITS APPLICATION

The author makes a distinction between part 1 which is devoted to the subject of instrumentation and part 3 which deals with the applications of instrumentation to typical engineering problems. Part 2, Determination of selected physical and chemical properties of fuels and lubricants, introduces the engineer to some of the tests developed by ASTM and ASME for obtaining qualitative evaluation of many complex physical properties which cannot be measured directly. Although intended for the first courses in mechanical engineering, it is designed to give necessary background for all laboratory courses in this field. (By J. S. Doolittle. New York, McGraw-Hill, 1957. 396p., $6.50.)

*MOTION ECONOMY AND WORK MEASUREMENT

This revision of the book previously published under the title "Time study and motion economy" has been expanded to include the application of motion study to office work, micromation study, use of film in motion study, motion time standards, work sampling (ratio delay), fatigue measurement, and recent material in connection with automatic machines. Emphasis is on application and theory for application. Charts, graphs and tables are extensively used to illustrate the text material. (By R. L. Morrow. New York, Ronald Press, 1957. 468p. $7.50.)

*NUCLEAR REACTORS FOR RESEARCH

In this third volume in the Geneva Series on the Peaceful uses of atomic energy, part 1 contains the following sections: the kinds of institutions that may wish to build and install a research reactor, and their fields of research; technological factors affecting choice; performance data, safety considerations and the uses of research reactors in physics, chemistry, engineering and biology. Part II describes research reactor projects of all types now in operation at specific locations in Europe and America, including Russia. The book provides a list of the papers relevant to research reactors presented at the 1955 Geneva Conference, a subject index, and a name index. (Ed. by C. K. Beck, Toronto, Van Nostrand, 1957. 267p. $8.50.)

*PHYSICAL BASIS FOR ELECTRICAL ENGINEERING

This textbook is concerned with the broad physical basis of electrical engineering phenomena; theory and concept are stressed rather than experimental or

SKF

• LIBRARY NOTES

analytical methods. Both the macroscopic and microscopic viewpoint are presented. The chapters contain material on electrostatic and static magnetic fields in vacuum, extranuclear atomic structure, nuclear structure, structure and behaviour of metals, semiconductors and semiconductor devices, vacuum tubes, insulators and capacitors, magnetic properties of matter and inductance. Problems are given at the end of each chapter, and charts and diagrams are included throughout. (By T. L. Martin, Jr. Englewood Cliffs, Prentice-Hall, 1957. 410p. $10.00.)

*PLASTIC DESIGN OF PORTAL FRAMES

This volume deals with the practical application of the plastic theory of design developed at Cambridge University in England. Intended for practicing engineers and advanced students, the book gives a concise exposition of basic principles and show the application of the method to the design of the single-storey, pitched roof portal frame. Practical design examples are worked out. (By J. Heyman. Toronto, Macmillan, 1957. 104p., $2.00.)

PRACTICAL GEOMETRY AND ENGINEERING GRAPHICS, 6TH ED.

The first section of this textbook covers plane geometry and engineering graphics, paying particular attention to the applications of graphical methods of computation. The second part is concerned with solid, or descriptive, geometry. There are numerous illustrations and worked examples.

This is the sixth edition of a work first published in 1929, and is intended for those students who already have a knowledge of elementary plane geometry, graph plotting and the use of vectors. (By W. Abbott. London, Blackie, 1956. 366p., 22/6.)

PRODUCTION ENGINEERING: JIG AND TOOL DESIGN, 6TH ED.

This popular work has now reached its sixth edition in sixteen years, and the two chapters added cover transfer machining, which is a stage between the usual operation on a single machine and complete automation, and recent achievements in deep-hole trepanning.

The author brings many years experience to the writing of this book, which is highly recommended by the Institution of Production Engineers, and will be welcomed by experienced jig and tool designers, as well as by students. (By E. J. H. Jones. Toronto, British Book Service, 1956. 355p., $5.10.)

*PROJECT ENGINEERING OF PROCESS PLANTS

Written to record information and techniques in plant design and to discuss ideas developed by process engineers, this book is for the project engineer and for any engineer who designs process plants or equipment. The four sections are: major steps in plant design; business and legal procedures; detail of engineering design and equipment selection; and construction of the plant. Chemical engineering plants and equipment are emphasized but some of the material will be applicable to other fields. (By H. F. Rase and M. H. Barrow. New York, Wiley, 1957. 692p. $14.25.)

*THE PROSPECTS OF NUCLEAR POWER AND TECHNOLOGY

A non-technical report on the present status of nuclear fission, and an appraisal of the future of our society in a nuclear age. Part 1 gives a comprehensive picture of actual and future atomic energy plants here and abroad, the legal and economic factors involved, and the social consequences. Part II covers the technology of nuclear industries and the problems which have arisen. The processing, extraction and disposal of fission products, and future prospects are discussed in this part. (By G. Wendt. Toronto, Van Nostrand, 1957. 348p. $6.00.)

RUBBER IN ENGINEERING

The five papers presented at a recent conference on rubber in engineering

have been reprinted by the Natural Rubber Development Board. The first paper dealt with the correct use of rubber, and set the tenor of the symposium. The remaining papers covered load deflection relations and surface strain distributions for flat rubber pads; the use of rubber in heavy engineering; dynamic fatigue life of rubber components; and rubber in agriculture. The value of these excellent papers is increased by the illustrations and discussion included. (London, Natural Rubber Development Board, 1957. 160p., free.)

THE SPECIFICATION AND MANAGEMENT OF MATERIALS IN INDUSTRY

A long-neglected subject in the field of productivity control, materials application engineering is discussed at length in this book. As a means of achieving better quality and lower costs as well as improved managerial co-ordination and control, the author describes the utilization of the principles of standardization, purchasing and inspection work and the conduct of a departmental office and laboratory. The point of view used is that of a manufacturer engaged on quantity production in general precision light engineering work. Materials used by such a firm must be both specified exactly for the particular job in hand, or difficulties will occur at various working states, and examined to see that they accord with specifications, in line with modern statistical methods.

Topics covered include the organization and running of a materials department, technical purchasing, specifications, and the conduct of a materials engineering laboratory. (C. H. Starr, London, Thames and Hudson, Toronto, Longmans, Green, 1957. 194p., 21/-.)

*STATISTICAL METHODS IN QUALITY CONTROL

The first twelve chapters are mainly on statistical methods with illustrations from the field of quality control. The subjects covered include: statistical data, elementary principles of probability, binomial and multinomial distributions. normal distribution, and analysis of variance. Chapters 13 through 29 are concerned mainly with process control including specification limits and tolerances, use of control charts for variables, and for non-normal distributions, selected techniques for analysis of defectives and the Poisson distribution. Chapter 29, dealing with the economics of control charts contains some original methodology. Chapters 30 through 40 deal mainly with product control containing such subjects as hypergeometric distribution, single, double and sequential sampling and analysis of the pattern of variability. (By D. J. Cowden. Englewood Cliffs, N.J., Prentice-Hall, 1957. 727p., $12.00.)

SURVEYING, 2D ED.

This second edition of a textbook first published in 1942 has been brought up to date, and new material added, and the chapter on aerial surveying and photogrammetry completely re-written.

The book covers the fundamentals of surveying, and places particular emphasis on the principles of the subject, and on the use of surveying instruments. Field exercises and problems are given in each chapter.

The author is well known for his other texts on surveying written in collaboration with G. L. Hosmer. (C. B. Breed, New York, Wiley, 1957. 495p., $5.50.)

*SYSTEM ENGINEERING

In organizing the various aspects involved in the systems approach to the problem of designing equipment, this book logically combines the new set of tools, new classification of parts, and the team of workers necessary to this approach. At the same time it provides for the engineer, as a member of the system-design team, a background for his job and describes system - design methods. A selective bibliography and illustrative problems with solutions are included. (By H. H. Goode and R. E. Machol. Toronto, McGraw - Hill, 1957. 551p., $10.00.)

THERMODYNAMICS

This edition of a standard college text has been extensively rewritten, reoriented, renamed and to some extent reorganized because of the increase in knowledge surrounding the concept of entropy.

This is not intended to be a complete coverage of the subject, as the reader is told repeatedly, but it does provide an outline of the information most useful to engineers, and an introduction to more advanced study. (By V. M. Faires. Toronto, Brett - Macmillan, 1957. 543p., $7.50.)

TUBE SELECTION GUIDE 1956-57

This guide is intended to aid in the selection of tubes for various purposes. Tables include: all types of tubes manufactured by Philips, or other companies; most important properties of each type; types preferable for new apparatus; tubes to be used exclusively in existing apparatus; tubes which may be used for replacement of obsolete types; descriptions of type number systems and data of tube bases and holders. A translation key enables French, German and Spanish users to understand the guide. (T. J. Krocs, comp. Eindhoven, Philips Technical Library, 1956. Irreg. paging., $1.50.)

TUBES FOR COMPUTERS

Electronic computers at the present time are serving many purposes in business and industry, and are being put to ever increasing use. The application of the electron tube in computers, although resembling ordinary amplifying circuits in operation and set-up is rather unconventional. The tubes described in this publication are especially designed for computer use. Topics covered are: computer circuits; requirements imposed on tubes in multivibrator and gate circuits; vacuum tubes in high speed and low speed computers. (Eindhoven, Philips Technical Library, 1956. 51p., $1.50.)

U.H.F. TUBES FOR COMMUNICATION AND MEASURING EQUIPMENT

The subject of this publication, the U.H.F. Tube, has become of increasing importance because of the greater use of high frequency apparatus in mobile transmitting and receiving units, as well as other modern applications. These tubes, using decimeter and centimeter ranges, are necessitated by these smaller units, as well as by the overcrowding of longer wave ranges. The use of centimetric waves requires changes in the design of conventional tubes capable of even the decimetric wave range, and the new tube types differ fundamentally in design and construction.

Included in this book is the range for U.H.F. and S.H.F. waves, as well as some applications of tubes for measurement of the noise factor at high frequencies. (Eindhoven, Philips Technical Library, 1956. 60p., $1.50.)

THE UNFIRED PRESSURE VESSEL CODE SIMPLIFIED

This simplified analysis of the new 1956 A.S.M.E. Unfired Pressure Vessel Code makes it easy to use and can save valuable time and material.

The 1957 edition contains simplified charts for internal and external pressure, shell thickness, flanged and dished head thickness, flat head thickness, flat cover plate thickness, and openings and reinforcements. Lengthy problems can be solved quickly and easily with the use of these charts. Also included in the book is a section on welding procedure which is a guide to solving welding procedure problems.

Written in an easy to understand manner, this compact book brings you, in condensed form, all the useful information gained in 20 years of approving A.S.M.E. Code design. (By Robert Chuse. Leonia, N.J., The Author, P.O. Box 91, 1956. 30p., $6.50.)

WAVE PROPAGATION

This volume, number eleven in the Electronic Technology series, deals with the various factors involved in the make-up and transmission of electromagnetic waves. Specific attention is given to wave motion, frequency-wavelength relationships, radiation, field intensity, wave fronts and polarization. Analyses are given of the natures of sky waves, ground waves, wave reflection, refraction and diffraction. A general discussion on the effect of atmosphere on radio transmission includes details on the ionosphere, stratosphere and troposphere. One chapter covers scatter propagation. (A. Schure, ed. New York, Rider, 1957. 56p., $1.25.)

• ASME-E.I.C. CONFERENCE

(continued from page 998)

es of the United States. One of the principal objectives of the Athlone Fellowship Scheme is to correct the above tendency by encouraging Canadian engineering graduates to study in Great Britain and thereby become more familiar with British industrial practices and resources. Indirectly it is hoped that the Scheme will foster an eventual improvement in the balance of trade between Britain and Canada. Fellows may choose to spend their period of postgraduate training in industry or may elect to continue their studies in a university with a view to securing a higher degree.

Relative Merits of Various Procedures

Of the various procedures which have been put into practice to encourage postgraduate study for brilliant students or employed professional graduates of merit, the scholarship or fellowship plan is undoubtedly one of the best. In this respect the experience of the National Research Council is of outstanding value to industrial employers who realize that more advanced formal training is a necessity for those engineers working on research, design and development problems. Both Canadian industrial and government organizations that must undertake research work recognize the need of providing a financial subsidy for the maintenance of highly qualified employees who would be better equipped to undertake their tasks after a period of postgraduate study.

The trend in favour of the fellowship plan is increasing steadily in industry and is well established on the government level. Canada's scientific achievements and progress in technological development could not have been realized without the N.R.C. system of encouragement and financial assistance through scholarships, research associateships and grants-in-aid. The N.R.C. is also administering a number of scholarships sponsored by outside industrial and other organizations, such as those of the Shell Oil Co., Nuffield Dominion travelling fellowships, the Merck & Co. postdoctoral fellowships and others. Major industrial employers could follow, with ultimate benefits to their organizations, the examples set by the International Nickel Co., the Imperial Oil Co. and some other industries in making provision for the continued university education of outstanding engineers to ensure professional advancement in those cases where in-service training does not provide sufficient background in the basic sciences and specialized subjects. A completely altruistic approach to the fellowship plan by industry which would make fellowships available to qualified graduates of any Canadian university is, of course, the ideal one.

Schemes which provide for leave with half pay or full pay are also meritorious and have a practical advantage in that they assure the employer that the engineer, after completion of his course of study, will return to his job. Merely granting leave, without salary or other benefits, is not a practical approach as it places the burden of financial support for the engineer and his family entirely on his shoulders. If savings prove inadequate the results can be unfortunate.

Part-time or evening courses of study are available to engineers, while fully employed, in the United States at large metropolitan centres where the universities have sufficient resources to make adequate teaching staff available to students. It is doubtful if such a plan for formal graduate study can be implemented in Canada for some time to come. There are obvious disadvantages for both the university and the student in such a course, as mentioned earlier.

The current shortage of engineers and scientific personnel leads many young graduates, who are well-qualified for postgraduate schools, to seek employment immediately after receiving the bachelor's degree. Starting salaries are now more attractive than formerly, and this provides the incentive for some. Others desire employment for financial or personal reasons or feel that they need the experience and maturing influence of industry before undertaking more advanced studies. After a period of transition, if some want to continue their education as a matter of principle or responsibility, the required assistance should be available for application.

The wide-spread practice in industry of making the top positions commanding high salaries available only to those who have supervisory, sales or administrative experience has had the result of effectively removing skilled engineers from research, design or development fields. If industry needs engineers and scientists it must provide more attractive careers than high starting salaries to remedy the situation. It should be possible for competent professional employees to attain positions equivalent to those of top management by virtue of productive and creative work, of value to the industrial enterprise, in their own fields of endeavour. This applies with equal force to those engaged in teaching at universities or in the employ of government departments.

Much has been written recently about the emphasis on the production of trained engineering and scientific manpower in Russia in relation to that in the United States and other Western Nations. In 1955, about 120,000 engineers and scientists were graduated in Russia as against approximately 70,000 in the United States. The disparity is accentuated by the fact that about 35 per cent of the graduate engineers in the United States take up other activities after graduation and do not practice engineering. In the interests of self-preservation, national economy and the continued development of our country, this problem of engineering education is one which commands the urgent attention of industry, the universities and all levels of government.

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Canadian Car Company — E. J. Cosford has been elected to the position of chairman of the board of the Canadian Car Company Limited, in succession to Sir Roy Dobson. Other appointments announced are A. C. MacDonald, vice-president and general manager, railway car division; E. G. Burgess, vice-president, planning and development, and assistant to the president; L. M. Hart, vice-president, truck and trailer sales; L. G. Main, co-ordinator of merchandising.

Canada Wire Appointment — L. G. Lumbers has been made general manager of Canada Wire and Cable Company Limited. Mr. Lumbers is a director of the company, and a vice-president and director of Telecables & Wires Ltd.

Directors Appointed — J. Gordon Mock and Charles L. Dudley have been made directors of Jenkins Bros. Limited. Mr. Mock, treasurer of the company, has also been appointed secretary; Mr. Dudley is also director, secretary, and treasurer of Jenkins Bros., New Jersey.

Dominion Structural Steel — D. D. Currie has been made sales manager, crane division, of the Dominion Structural Steel Ltd.

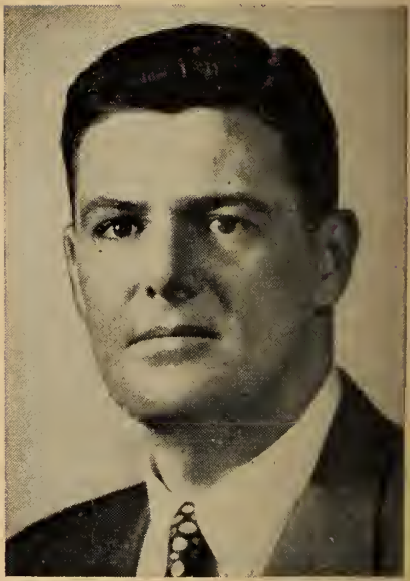
New Westinghouse Appointments — It has been announced that the two new vice-presidents of Canadian Westinghouse Company Limited are Edward E. Orlando, M.E.I.C., general manager of the district apparatus division, and John A. Campanaro, project development group general manager. Edward W. Hill has been made manager of the new utility department, district apparatus division.

Bridge & Tank Directors — The election of R. A. Robertson and Dr. Richard L. Hearn, M.E.I.C., as directors of Bridge & Tank Company of Canada, has been announced.

C.G.E. Appointments — The following appointments have been announced by Canadian General Electric Company Limited: Charles A. Morrison, vice-president, reports to board chairman Harold M. Turner and will be concerned with marketing problems; Walter G. Ward becomes general manager, wholesale department.

J. Gordon Mock

Charles L. Dudley



D. D. Currie

United Steel Vice-President — The appointment of W.T.E. Smith as vice-president of United Steel Corporation Limited, Toronto, has been announced.

British Thomson-Houston — It has been announced that H. G. McHaffie has been appointed managing director of The British Thomson-Houston Co. (Canada) Ltd.

Alexander Fleck — It has been announced that L. W. Fleck has been elected chairman of the board of The Alexander Fleck Limited, and that H. D. Hyman has been elected president and general manager. K. F. Fleck remains vice-president and secretary - treasurer. All the above, with E. D. Berry, Jr., form the board of directors.

Powerlite Appointments — Recent appointments at Powerlite Devices Ltd., Toronto, are as follows: Gordon E. Wallace, general sales manager; Ian Y. Morrison, Ontario sales manager; N. K. Newell, sales engineer.

Shallenberger, a Westinghouse engineer- invented induction meter. This Westinghouse "old faithful" is the grandaddy of all modern meters.

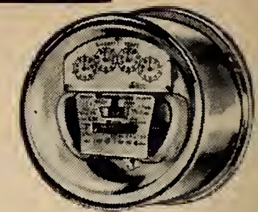
1911

The Westinghouse 60-amp, 2,000-V, polyphase integrating wattmeter. In its day, the finest instrument of its kind.

1922

Westinghouse Type CD 25-amp meter introduced many design advances ... opened the way to more compact construction, neater appearance.

1934



Westinghouse Type S meter gave the industry its first all-weather socket and made *outdoor* metering possible.

From Shallenberger's cast-iron marvel to the "Lifetime" meters of today...

WESTINGHOUSE WATTHOUR METERS

are backed by the kind of pioneering that gives you better performance and longer life!

TODAY Westinghouse "Lifetime" Watthour Meters carry on the tradition of Westinghouse leadership in the development of finer meters. Their precise accuracy and long service have never been surpassed.

ALL COMPONENTS of Westinghouse Meters are made with "watchmaker" craftsmanship to exact mechanical and electrical tolerances. Light-load and full-load adjustments have a calibration range of 20 per cent. Full compensation for class 1 and 2 temperature errors is provided. Electromagnets are permanently adjusted for power factor. And the high insulation level of Westinghouse Meters to withstand extreme voltage surges is backed up by built-in lighting protective devices.

Making finer meters is a tradition at Westinghouse! It began when Shallenberger, a brilliant Westinghouse inventor, introduced the world's first practical means of measuring power used. It makes today's Westinghouse "Lifetime" Watthour Meters the finest you can buy. They're built with precision accuracy. Their performance is guaranteed with a 30-year warranty!

Get detailed performance data and a feature-by-feature outline of Westinghouse "Lifetime" Watthour Meters in Bulletin DBH-42-101. Write for your copy *today!* Canadian Westinghouse Company Limited, Hamilton, Canada.

Design and Operating Features of

The Canada-India Reactor

F. J. Bleackley, M.E.I.C.

C.I.R. Project Manager, The Shawinigan Engineering Company Limited

A paper read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June, 1957.

The Canada-India Reactor—known as C.I.R.—is an experimental nuclear reactor now being constructed near Bombay as a joint Canada-India project under the Colombo Plan.

The reactor is designed to provide facilities for research work on peaceful applications of atomic energy. It will be used for the development of fuels and materials for use in nuclear power reactors and for the production of radioactive isotopes for industrial, medical and scientific applications.

Plutonium may be recovered as a 'by-product' from the spent fuel elements and will be used later as a fuel in a more advanced reactor for power production. A limited amount of uranium 233 will also be produced, by irradiating thorium metal in regions of the pile where neutrons might otherwise be 'lost' in the reflector and shielding outside the areas of high flux. Uranium 233 is used as an enriching agent with natural uranium for fuel in other reactors.

The C.I.R. is a high flux (max. 6.5 x 10^{13}neutrons/sq. cm./sec.) slow neutron, heavy-water moderated and fresh-water cooled reactor using natural uranium as fuel and is designed to be operated at a maximum power level of 40 megawatts (thermal).

This paper describes, in general terms, the design and construction of the project; from the point of view of the civil, mechanical and electrical engineers engaged upon the task of interpreting the ideas of nuclear specialists in terms of conventional engineering materials and techniques suitable for employment in a relatively undeveloped tropical country.

THE DESIGN of the "pile" or reactor proper is based on Atomic Energy of Canada Limited's NRX reactor which has been in operation at Chalk River for the past ten years. The design of the rest of the Project, however, including the buildings, enclosures, cooling systems, air-conditioning and exhaust air plants, electrical equipment and auxiliaries generally, has been developed to suit the special requirements of the site and to permit the entire plant to be erected and maintained by the particular type of skilled labour available in India.

Building — The design of the building housing the reactor was dictated by the condition that in no circumstances should radio-active gaseous products be liberated into the atmosphere in the event of malfunctioning of the reactor. The C.I.R. is located adjacent to an area containing about 3 million people and in the extremely unlikely event that the reactor should be out of control, even temporarily, there must be no possibility of gaseous fission products escaping.

The pile and the storage block, i.e., the units containing the fissionable material, are, therefore, housed in a pressure-tight steel shell to which access can be gained only through ventilated airlocks.

The large diameter of the cylindrical vessel required (120 ft. 0 in.), dictated the adoption of the hemispherical dome as the only reasonable method of forming a true pressure vessel.

Reactor

Whilst it is, of course, beyond the scope of this paper to deal with nuclear considerations *per se*, the nuclear considerations which govern the design of experimental reactors generally must be kept in mind as they form the background against which all the "conventional" engineering problems must be viewed.

An experimental reactor is primarily a source of neutrons. The heat generated during the chain reaction producing the neutrons and the reaction occurring when neutrons are captured, is a necessary evil to be disposed of as unobtrusively and as efficiently as possible and is of interest only as a measure of the power level at which the reactor is operating. In a so-called power reactor, on the other hand, the pile is a source of heat and neutrons are of interest only in so far as they effect the heat-producing capacity of the pile and the amount of shielding required. The reaction is the same in both cases, it is merely the designers' points of view which are different.

The principal nuclear considerations governing the design of C.I.R., and all experimental reactors of this type, are as follows:

(*a*) Neutrons must be conserved and not wasted (i.e. not "captured").

(*b*) When certain materials enter an area of neutron flux radioactive isotopes are produced having varying intensities of radioactivity and varying "decay periods".

(*c*) Heat is produced in all reactions involving neutrons.

(*d*) Neutrons, gamma rays and other radiations associated with nuclear reactions are extremely harmful to organic tissue and every precaution must be taken to shield personnel and sensitive materials from them.

(*e*) Nuclear reactions progress rapidly and silently so that the instruments used to detect faults, measure quantities and indicate the state of a given process, and the equipment provided to act upon the signals given by those instruments must all respond with equal rapidity and must be automatic and reliable to a degree not required of equivalent apparatus used in other branches of engineering.

In the C.I.R. the nuclear reaction

takes place inside a cylindrical aluminum tank called the calandria. This tank is 8 ft. 9 in. diameter and approximately 10 ft. 6 in. high. It consists of a thin shell attached to end tube-sheets each about three inches thick. Into the tube sheets are expanded light vertical tubes through which the fuel rods, shut-off rods and experimental (loop) rods are inserted.

The calandria contains the heavy-water which acts as a 'moderator', slowing down the fast neutrons emitted by the U235 until they have only the so-called 'thermal energy' necessary to maintain the chain reaction. The fast neutrons are slowed down from speeds of 10,000 miles per second to one mile per second.

The power-level at which the reactor is operating at any time is controlled by varying the level of the heavy-water in the calandria. Shutting down the reactor is accomplished by "dumping" part of the heavy-water into prepared tanks below the pile and at the same time inserting into the pile what are called 'shut-off rods containing boron (which absorbs neutrons).

On C.I.R. provision has been made for 186 fuel rods with six additional positions into which either fuel rods or 'loop' experiments may be placed.

A fuel 'rod' consists of a long aluminum tube having a central portion, approximately the same length as the calandria, containing a cylindrical core of uranium 1.36 in diameter. The uranium is protected from the cooling water by a thin cladding of aluminum which is drawn down over the uranium core. An outer sheath of aluminum, separated from the core by a space 0.070 in. wide, forms an annular passage for the cooling water. The central "working" portion of the rod is attached to top and bottom sections which serves to conduct cooling water to and from the uranium section and provide shielding to the ends of the uranium core. The total length of the fuel rod is approximately 30 ft. 0 in. and the rod is handled in this length by a suspension device at its upper end.

Fuel rods are suspended in the pile from seatings formed at their upper ends which bear on bevelled shoulders in holes in a master plate at the top of the pile. The inlet ends of the rods seat against prepared sealing faces in a header assembly above the master plate. The bottom of the rods seal against similar faces on another header assembly below the pile and water is circulated through the fuel rods from the upper header to the lower header.

Having in mind a picture of the central core of the reactor in which the principal reaction takes place, attention can again be focused on considerations *(a)* to *(e)* above in so far as they affect the design of C.I.R.

(a) Neutrons which would otherwise escape from the sides of the calandria are returned to the core by a reflector. The reflector consists of two concentric hollow cylinders of graphite having an inner ring 9 in. thick, separated from the wall of the calandria by an annular clearance of 1½ in., and an outer ring 24½ in. thick separated in turn from the inner ring by an annular gap of 2½ in. Both rings of graphite are approximately 11 ft. 4 in. high.

In the 2½ in. annular gap provision is made for the suspension of up to 92 thorium rods to be irradiated by neutrons which have penetrated the inner, thinner, ring of graphite.

(b) The materials in the pile core must not absorb neutrons to any great extent and whilst aluminum and carbon do not have high 'capture cross sections' the impurities normally associated with these materials do have high cross-sections and besides absorbing neutrons they become highly radioactive in the process. For this reason special reactor grades of aluminum and graphite are used but their compositions are regarded as industrial secrets by the manufacturers.

Similarly, the cooling water and the heavy-water circulated through the pile must not contain impurities which will capture neutrons and thus become radioactive. The water in the cooling system is therefore treated before being charged into the system and continuously thereafter whilst the pile is operating.

The space above the heavy water in the calandria varies during operation and is kept filled with an atmosphere of helium which is not affected by radiation and does not combine with heavy water. Air is not permitted to come into contact with heavy water as it would be carried into the pile and be irradiated. Air would also downgrade the heavy-water by the contaminating action of the nitrogen compounds formed during the irradiation so that a helium atmosphere must be provided over the heavy water at all times.

(c) Of the 40 megawatts tota heat output of the pile approxim ately 38 megawatts are produced i the fuel elements themselves. Th maximum temperature of the urani um at the centre of a rod is ap proximately 977 degrees F., and th maximum temperature of the inne sheath is 239 deg. F. The coolin water enters the upper header at maximum temperature of 125 deg F. and leaves the lower header a approximately 175 deg. F.

The minimum temperature of th fresh water coolant, which circulate in a closed circuit through heat ex changers, is set by the temperatu of the sea-water used on the secon ary side of the system. The se reaches a temperature of 90 deg F. in the hot season and the min mum temperature to which the prin ary cooling circuit can be cooled u der these conditions is assumed to b 117 deg. F.

Primary cooling water is circulate at a maximum rate of 25 Imp. ga lons per minute per rod, making possible total of 5000 I.g.p.m. for th whole pile under full load condition The maximum pressure at the upp header is approximately 220 lb./ s inch. The pressure drop through th rod corresponding to a flow of 25 ga lons per minute is 135 lb./ sq. inc

The pressure at the lower head is 37 lb. per sq. inch, the balanc being the pressure-drop across an o ifice placed between the bottom the fuel-rod and the lower head for the purpose of calibrating an measuring the flow of water duri operation.

The reaction within the calandr produces heat in the heavy wat and so further heat exchangers a provided to dissipate a total of 20 kw. of heat from the heavy wate

Heat is also generated when ne trons and other radiations are sto ped by the shielding materials pr vided for the protection of personn as outlined below under *(d)*.

As the calandria tube-sheets a 3 in. thick it is not considered nece sary or practicable to install refle ors above and below the calandria, neutrons would have to pass throu the 3 in. aluminum plate twice a most of them would be captured the process.

To absorb neutrons and oth radiations escaping through the en of the calandria, devices called the mal shields are provided above a below the pile cord.

Immediately below the calandria is a shallow aluminum vessel consisting of a short shell and two heavy tube-sheets drilled for and provided with tubes through which the lower ends of the fuel rods pass. The vessel is called a removable thermal shield and rests in the centre of a fixed steel vessel of similar construction but of doughnut shape.

The inner aluminum section and the outer steel section of the shield are filled with water and the assembly forms a sandwich in which the water slows down the fast neutrons and the metal captures the resulting thermal neutrons and other escaping radiations.

Below the first section of the lower thermal shield are two more fixed shields of sandwich construction made from heavy steel plates. The object of using aluminum for one section is that if it should ever be required to remove it to gain access to the steel shield below, the high purity metal would not contain radioactive impurities having so long a decay period that handling the shield would be out of the question.

Above the calandria is a similar steel 'doughnut' fitted with a removable aluminum centre section and above this are steel 'doughnuts' having removable steel centre sections. All three of these water-cooled shields are fitted with tubes through which the fuel rods and other facilities can be inserted.

Two separate water cooling systems are used on the thermal shields, one for the steel shields and one for the aluminum shields. This is done to provide cooling-water having the correct anti-corrosion characteristics appropriate to the metals in the systems. Each system is further divided to the fixed and removable sections.

From the two aluminum shields a total of approximately 100 kw. of heat is removed and from the steel shields approximately 130 kw. This heat also is dissipated in heat exchangers using sea water at 90 deg. F. on the secondary side, thus the minimum temperature of the cooling water entering the aluminum shields is approximately 100 deg. F.

Water cooled shields are not provided at the sides of the pile to stop radiations which escape from the reflector graphite. Instead, two concentric rings of cast-iron, each 6 in. thick are provided, separated from each other by an annular gap of 2 in. and from the outer ring of graphite by an annular gap of 2 in. The cast-iron shields, the graphite and the J-rods are cooled by a stream of air which emerges from a circular duct below the cast-ion shields and passes upwards, through the annular spaces between the cast-iron rings and between the outer ring and the concrete construction, and then passes down between the concentric rings of graphite, over the J-rods and into a second duct concentric with the inlet duct and thence out to the exhaust air fans and the stack.

Openings are provided in the cast-iron thermal shields to accommodate the thermal columns, to be described later, but the annular air passages are maintained to facilitate the flow of cooling air over the cast iron and graphite surfaces.

(*d*) Whilst the water-cooled and cast-iron thermal shields effectively contain most of the neutrons within the pile, gamma rays and other radiations associated with the neutron capture in the thermal shields, are radiated from the sides of the shields. Further protection must be provided therefore to reduce the intensity and strength of the escaping radiations below what is called the biological tolerance.

The additional shielding is called biological shielding; it is made of concrete which contains sufficient hydrogen to slow down any fast neutrons and sufficient heavy material to capture slow neutrons and absorb secondary radiations.

The biological shield around the side of the pile consists of a wall of concrete 8 ft. thick, poured in position at the time of construction. Above the thermal shields, four steel trays are provided, each 12 in. deep, filled with reinforced concrete and fitted with vertical tubes through which the fuel and other rods can be inserted. These shields are supported on cast-iron webs embedded in the structural concrete and may be removed to gain access to the pile core.

To prevent neutrons from streaming out of the pile along the sides of fuel rods and other openings in the shielding, all holes are stepped and the rods, plugs and other inserts are similarly stepped so that there are, at all times, no direct paths along which neutrons may escape.

Below the lower thermal shields it is not considered necessary, or practicable, to provide biological shielding as the area is not accessible whilst the pile is in operation.

To guard against the effects of pos-

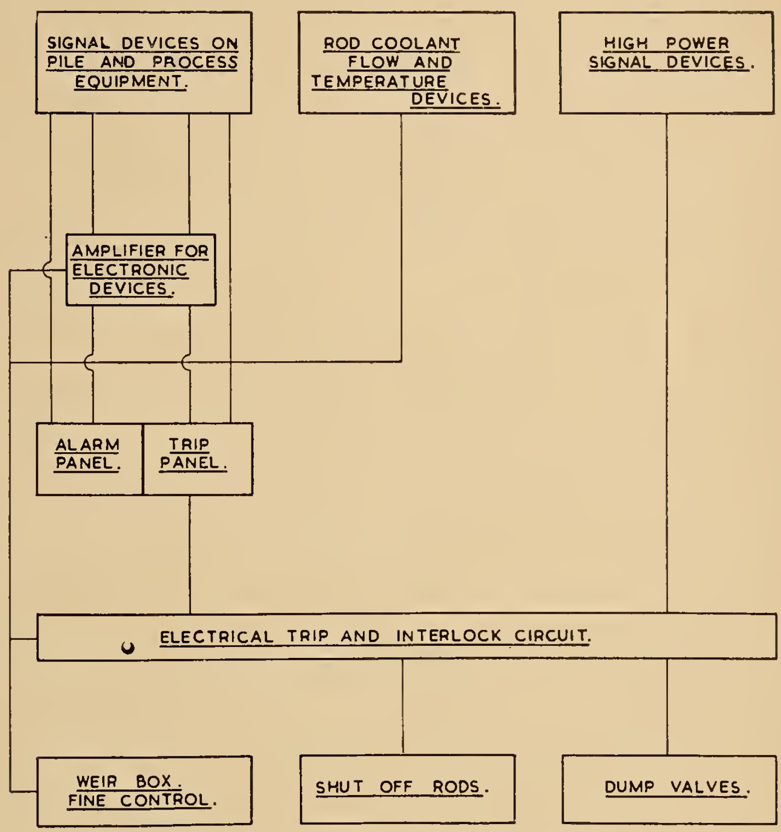

Fig. 1—Schematic arrangement of automatic safety control system.

sible radiations escaping from the tops of the shut-off rods and from fuel rods being removed from the pile, a final shield is provided in the form of a hollow floor at the top of the pile. The floor consists of a steel and water sandwich, similar in construction to the steel shields except that the water is not circulated because very little heat is generated.

The floor is circular and contains a concentric revolving centre section which, in turn, has a further revolving section within it but eccentric to the axis of the main turntable. The small inner turntable contains a hole over which the rod handling flask can be centred. By revolving the two turntables through predetermined angles the hole may be located over any rod position in the reactor.

(e) When the reactor is operating at full power a great deal of heat is generated in the components, as has been described, and adequate cooling capacity must be available at all times. If the reactor should be allowed to start with inadequate cooling available, or if it should be allowed to exceed the rated power with only normal cooling capacity present, then serious damage could result.

To prevent the reactor from starting if an unsafe condition exists and to shut it down if an unsafe condition develops during operation, the reactor and its auxiliaries are provided with an automatic safety control system. The system is shown diagrammatically in Fig. 1.

The two principal devices in the automatic safety control systems are:

(i) Shut-off rods

(ii) Dump valves.

The shut-off rods are considered the primary protective devices and are designed to "trip" or shut the reactor down quickly. The dump valves permit the heavy-water in the calandria to fall rapidly from the maximum level of 307 cm. to the 150 cm. level, giving supplementary shut down at a moderate rate.

The automatic safety control system is a very involved one, designed to fulfil the requirements that the reactor be started-up, operated and shut-down safely. Information from various signal devices is fed into an electrical trip and inter-lock circuit which interprets the information and actuates the principal control devices.

The automatic safety control system is also designed so that operational mistakes will not contribute to disastrous consequences.

To protect the reactor from the effects of faulty instruments and defective circuits, signals are divided into two types, trip signals and alarm signals. Generally, three signal devices are provided to indicate a particular type of fault or condition; a signal by one device alone will actuate an alarm signal which may be a visual or an aural device, but a signal from two out of the three instruments will actuate a trip and an alarm signal.

Trips are further subdivided into two types — conditional trips and absolute trips:

Certain trip signals are 'conditioned' by low-power measuring devices as follows:

(i) The trip signals result in a shut-off rod release and heavy-water dump if the power is above one per cent of full power, e.g., when the pile is shut down and some of the shut-off rods are raised.

The principal reason for operating at less than 1 per cent power is to keep the reactor from "poisoning out" while troubles are being corrected.

Absolute trips result in the release of all the shut-off rods and the dumping of heavy-water in both the low and high power stages. Absolute trips prevent shut-off rods from being raised or the heavy-water dump valves being closed if the equipment is not in good working condition. Absolute trips also prevent shut-off rods from being raised when the pile is at low power stage with heavy-water in the calandria if the shut-off rod mechanisms are in any way faulty and cannot be re-lowered.

All signals actuated by high-power devices give rise to absolute trips, even if the signal results from faulty equipment (conditioned, of course, by the 2 out of 3 coincidence system) as it would be hazardous to operate or even to start the pile with high power devices unserviceable.

All the safety control devices are designed to "fail-safe" so that, as far as possible, failure of the equipment will not prevent the control device from operating. For example, the calandria dump - valves are held closed by compressed air and are opened on the release of the compressed air by powerful springs, so that in the event of an air failure the valves would automatically open and the pile would shut down. The shut-off rods are similarly designed so that they are raised mechanically, but lowered automatically by the action of gravity aided by springs which accelerate the rods into the pile with high velocity.

In setting up the reactor safety control circuits, the following items were among the most important considerations.

(a) The maximum power level at which the reactor may be operated is governed principally by the ability of the cooling system to remove the heat produced. If the power level should suddenly rise above this maximum, then the pile must be shut down. As the power may rise almost instantaneously, measurement of thermal output to the cooling system is inadequate for safety control due to the time lag in temperature measurements. Therefore, ionization chambers which produce an instantaneous electrical signal directly proportional to neutron flux (power level) are used for safety control. One group of ionization chambers located in the thermal column is used with appropriate electronic amplifiers for automatic reactor control. Trip signals for overpower and excessive rate of rise of power are obtained from these amplifiers. In addition, a second group of ion chambers placed in a different position in the reactor are used for back-up protection on high power. These chambers are connected directly to sensitive relays with no intervening amplifiers so as to reduce the possibility of "no trip" due to instrument failure.

Ion chambers are very sensitive to neutron flux changes but they do not provide a sufficiently accurate measurement of the thermal power of the pile. For fine control of the reactor during normal steady-state operation, the ion chamber signal is automatically compensated by measurements of the temperature rise of the cooling water, thus giving a more accurate indication of the power output.

(b) Failure of the main electrical power supply, which would cause circulating pumps, air - conditioning plant, compressors, etc., to stop, must also give rise to an absolute trip and this is accomplished by relays actuated by the power-circuit itself.

(c) In certain circumstances a fuel rod may become distorted, causing the inner protective sheath to split. This would result in radioactive fission products being released into the cooling system and portions of the sys-

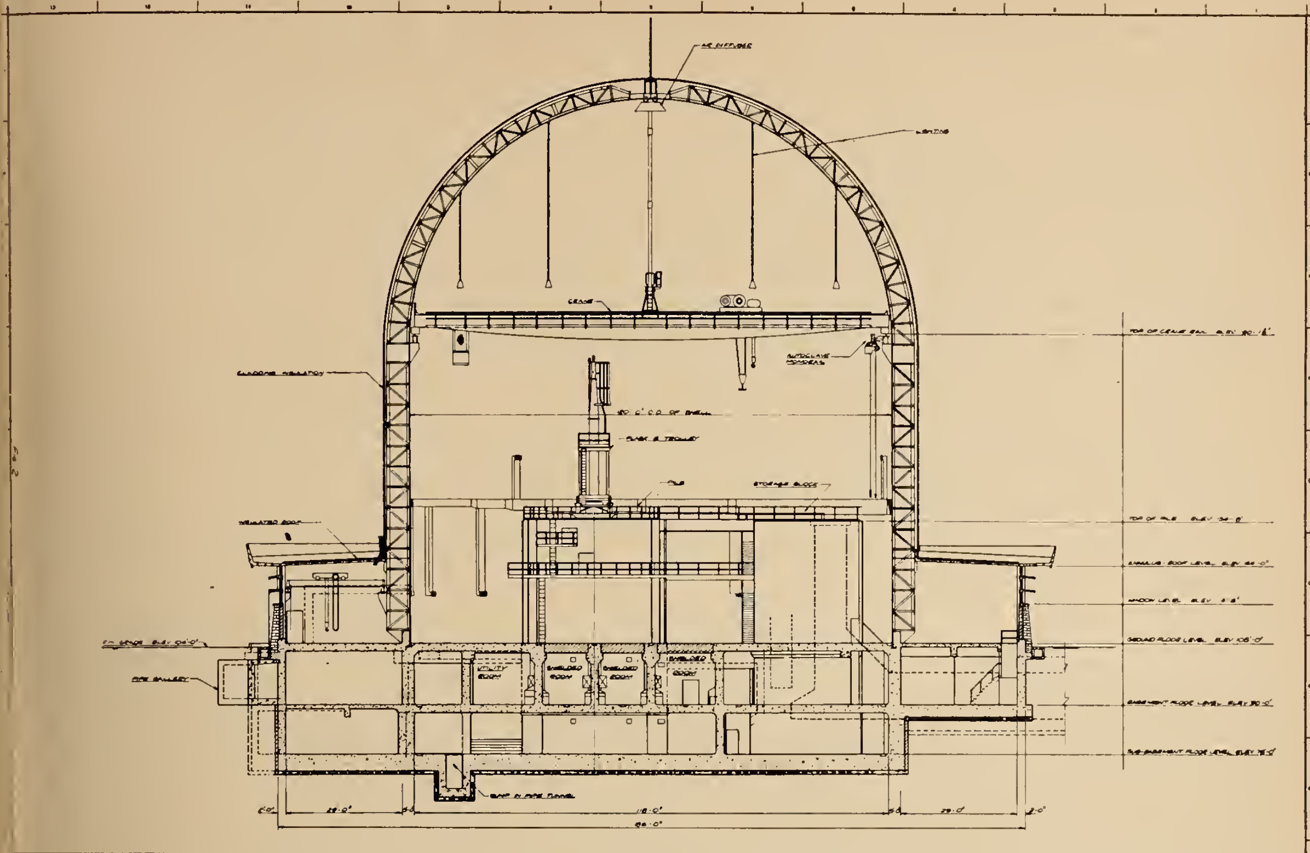

Fig. 2—Cross section of reactor hall and annulus.

em would become contaminated.

When this occurs, a radiation de-ector trips the pile, stops the main umps and transfers the cooling to n emergency system which carries ie contaminated water into a large ump tank.

A device called a gaseous fission-roducts monitor is provided to sam-le the cooling water as it emerges om the bottom of each fuel rod. he gaseous fission products will es-ipe to the cooling water before an tual rupture of the sheath occurs. hese radioactive gases are detected v this monitor in the following way: A sample of water is passed rough a 'stripper' unit, where air bubbled through it to strip out the iseous fission products for passing a beta counting head.

If the beta activity in the gas pass-a certain predetermined level, an irm is sounded and the split rod identified on an annunciator pan- in the control room. With the uipment provided it will be pos-ble to set the alarms so that a rning may be given before the ac-ity reaches a dangerous level, thus rmitting removal of the damaged l and preventing contamination of t cooling system.

(*d*) Failure of important auxiliary equipment which might lead to dangerous conditions on the pile or to health hazards to personnel will also trip the pile.

In addition to failure of the main cooling pumps, as outlined above, failure or malfunctioning of the heavy - water pumps, sea - water pumps, or the air supply and exhaust fans will also trip the pile. High or low pressure, beyond the normal range of the cooling water at the bottom of a fuel rod will also actuate the trip and alarm circuit as an indication of a fault affecting the flow of water through that rod.

Instruments connected to all parts of the process and mechanical equipment will, on a fault being detected, transmit signals capable of actuating trips or alarms or both, depending upon the nature of the fault and the importance of the equipment in question.

Pile Construction

To ensure that the pile could be erected in its final location at the site without recourse to heavy machinery and other equipment for final adjustment, it is designed for pre-assembly at the plant of the manufacturer in Canada. Dummy fuel rods are provided to test the dimensional accuracy of each and every hole in the assembly.

The pile proper is carried on a heavy steel frame consisting of a machined assembly of welded plates and shapes supported on four heavy steel columns. On the supporting frame, the main floor plate of the reactor is fitted; this is a steel plate 6½ in. thick, 18 ft. 0 in. diameter. The floor plate supports the lower thermal shields which, in turn, support the calandria and the graphite reflector.

The main floor plate also supports the cast-iron side thermal shields and the peripheral ducts through which cooling air is supplied to and removed from the pile.

The upper thermal shields are supported by the shielding concrete surrounding the pile and by a steel structure provided to facilitate assembly; these support also the cast-iron webs into which the four removable biological shields are fitted and on which the 4 in. thick top master plate rests.

The top master plate is provided with the holes having bevelled shoulders on which the fuel and other rods are suspended in the pile. The master plate positions the rods at the correct spacing in the pile as determined by the characteristics of the reactor.

The upper cooling water header is supported by saddles on the master plate and is free to move radially as the four supply nozzles to the feed pipes are connected through expansion joints.

A cylindrical steel shell supporting the revolving floor above the pile, forms the upper header room which contains the upper ends of the fuel rods, the driving mechanism for the shut-off rods and, of course, the upper header itself.

The upper header room is connected to the shielded rooms by vertical chases in the shielding concrete. At the base of the pile the space beneath the main floor plate is called the lower header room and it also is connected to the shielded room by chases in the concrete.

The chases permit the pipes of loop experiments to be brought, from the ends of the assemblies in the piles, to the equipment set up in the shielded rooms.

The materials used in the steel shields, the top master plate, main floor plate and revolving floor are standard low carbon steels selected for weldability. To avoid cracking and to secure sound welds, low hydrogen electrodes are used and the completed weldments are stress-relieved, before being machined, to prevent distortion.

The cast-iron side shields are of ordinary gray cast-iron, also stress-relieved before being machined to prevent distortion.

Wherever possible, standard materials are used and the manufacturing tolerances are kept as open as possible in order to keep the work within the range of good industrial practice.

In the past, attempts have been made to build reactors with a high order of precision, but experience with the NRX reactor has proved that the advantages of close tolerances are, in many cases, more apparent than real — even when they are attained in practice which is not quite as often as might be expected.

A feature of the upper thermal shields is the provision for removing tubes from the calandria without removing the upper shields. By mounting a heavy drill on top of the pile and drilling downwards, using a special technique developed by A.E.C.L. at Chalk River, it is possible to remove and replace damaged calandria tubes without dismantling the reactor.

In the removable steel shields the tubes have extra thick walls to permit them to be bored out, to allow a calandria tube to pass through, without seriously weakening the shield. The tubes in the aluminum shield above the pile and the tubes in the removable biological shields are made large enough to pass the calandria tubes without drilling.

Experimental Facilities

Another important design consideration is the provision of experimental facilities in the pile which will permit the maximum possible use to be made of the high flux available.

The experimental facilities include the following:

(*a*) Thermal columns.
(*b*) Horizontal holes.
(*c*) Vertical holes.
(*d*) Self - serve holes.
(*e*) Central experimental hole.

(*a*) The thermal columns are used to obtain thermal neutron beams of high purity and large cross-sections; they are projections of the graphite reflector which extend horizontally through the shielding on the east and west axes of the reactor.

Each column consists of a stationary and a removable section of graphite. The stationary section is 5 ft. 0 in. square and extends from the reflector graphite to a point immediately outside the cast-iron thermal shields. The removable section extends to the outside of the shielding concrete and is separated from the fixed sections by a slot left to complete the cooling-air annulus between the two sections of the side thermal shields.

The removable section of the column is divided into three assemblies of graphite blocks, mounted on shallow-four-wheel trucks so that they may be removed from the reactor. The three movable assemblies are each 2 ft. 6 in. thick and 6 ft. 8 in., 6 ft. 3 in., and 5 ft. 10 in. square respectively.

The four sides of the thermal columns are enclosed by a cast-iron frame, 12 in. thick at the inner end of the movable section and diminishing by steps to 3 in. at the outer end. A clearance of 3/16 in. is provided between the movable sections and the cast-iron frames to allow passage of air. The cast-iron frames serve to support the weight of the removable sections and to protect the surrounding concrete from the damaging effects of radiations.

The graphite blocks in the removable sections are each 6 in. x 6 in. x 30 in. and certain pieces may be removed to vary the intensity of the neutron beam desired. A central block may be removed forming a hole extending all the way to the calandria shell and other blocks may be removed to form openings of various sizes.

The outer face of each thermal column is covered with a large vertical sliding door of lead and steel having a thin layer of cadmium on the inside surface. A small door, sliding in grooves in the main door, is also provided.

In the east thermal column are located the ion chambers for power measurement and steady-state operating control of the pile.

(*b*) The horizontal holes extend from the outer face of the biological shielding concrete to the calandria shell. Each hole has a cast-iron inner door, which operates like a large plug-cock, located on the inner face of the biological shield. The gate is operated by a worm-drive shaft which extends to the reactor face. The outer end of each hole is provided with a lead gate operated by a hand-screw located on a cast-iron housing at the reactor face. Through these gates and doors equipment can be inserted into the pile without exposing personnel to excessive radiation.

The horizontal holes include the following:

(1) Twenty - nine experimental holes 4 in. diameter.

(2) Five experimental holes 12 in diameter.

(3) Fourteen experimental holes 8 in. diameter; four of which contain the ion chambers actuating the low and high power trips for pile control whilst the remaining twelve are available for future instrumentation or experimental purposes.

(4) Four horizontal holes 2⅝ in diameter carrying temperature and pressure measuring instruments located in the J-rod annulus.

The experimental holes provide means of irradiating a few large samples or of obtaining neutron beams external to the reactor. The 'holes' consist of stepped holes extending through the reactor structure to the face of the calandria. They are lined with aluminum tubing in the graphite reflector and with steel tubing in the cast-iron thermshields and in the biological shields.

When not in use for experimental purposes, the holes and plugs are cooled by a stream of air drawn into the J-rod annulus through the annular space around the plugs. When samples are being irradiated, however, additional cooling may be required and special arrangements are made to suit each particular experiment.

When the horizontal holes are not actually containing instruments or experiments, they are filled with temporary wooden plugs fitted with end sections of lead and cadmium; soft wood is used for this purpose as it forms satisfactory shielding and is relatively inexpensive.

(*c*) Six vertical holes are provided in the calandria, each having a diameter of 4 in. into which either standard fuel rods or loop experiments may be placed. In a loop experiment, test equipment is located in one of the shielded rooms and the material under test is circulated from the shielded room, through the pile and back to the shielded room. When these holes are used to contain normal fuel rods, special sleeves are provided in the upper thermal shields to reduce the size of the holes so as to prevent streaming of neutrons past the fuel rods.

(*d*) Six self-serve or sample units are provided, each fitted with a five-receptable plug, thus permitting a total of 30 samples to be irradiated at the same time.

The self-serve holes provide a principal means of producing radioactive isotopes. They are designed for the irradiation of small samples in the region of the graphite reflector and close to the calandria shell. The samples must be capable of enclosure in a 2¼ in. diameter aluminum sphere as they are allowed to roll to the carrying plug for insertion and to roll out to sample flasks for removal from the pile.

The units are provided with electrical and mechanical interlocks to prevent the insertion of more than one sample in one position and to avoid exposure of personnel to irradiated samples. They are so designed that the special shielded sample flasks must be in position at the discharge holes to receive samples before the carrying plug can be unlocked and the sample released.

(*e*) The central experimental hole in the pile, called the central thimble, is 5½ in. diameter and is available for use where high neutron density and a high proportion of fast neutrons are required, and where a relatively large sample or experimental assembly must be accommodated.

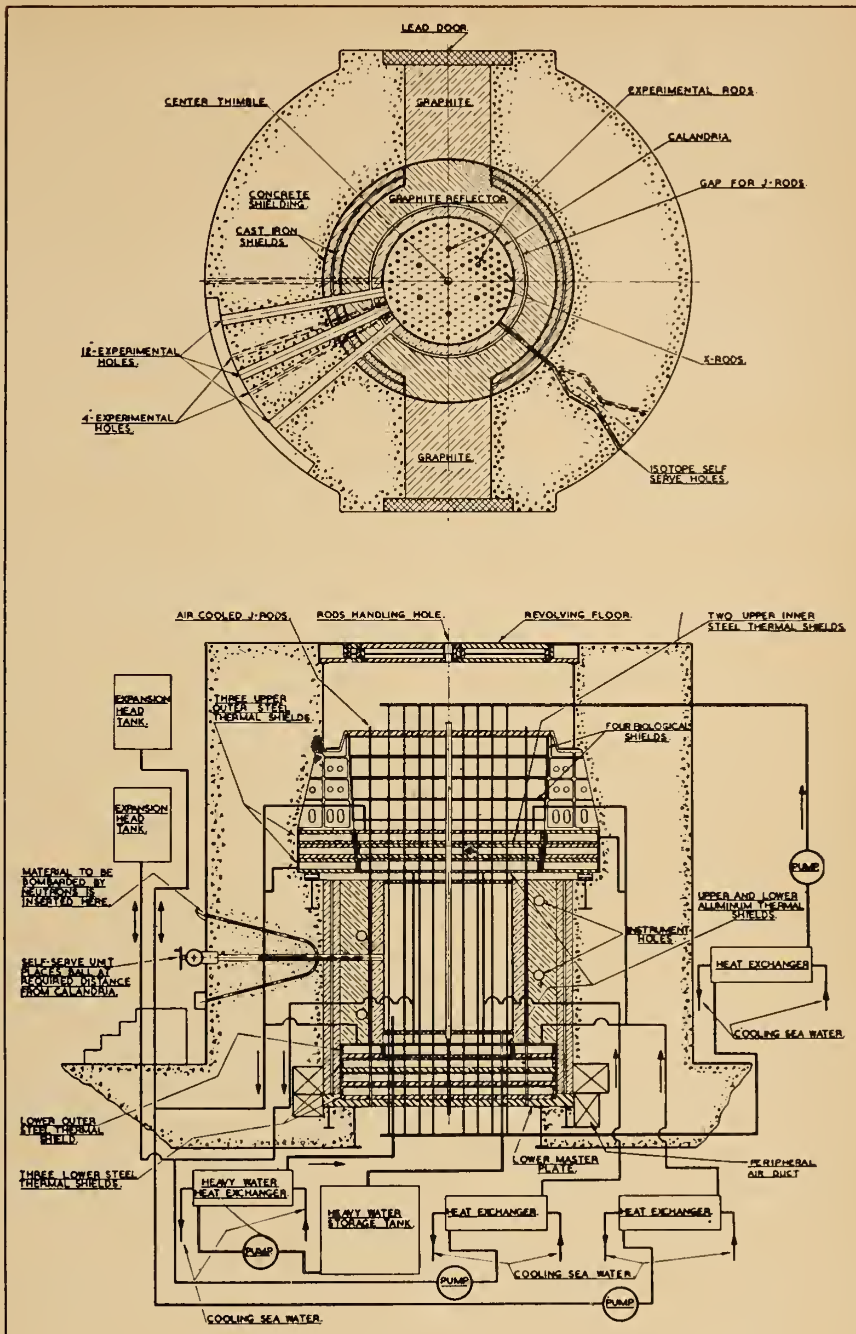

Fig. 3—Schematic diagram of reactor core and ancillary equipment.

This tube, when not in use, is also provided with a stepped plug (of steel) and the facility is cooled by air drawn from the process air system at the rate of approximately 90 cubic feet per minute.

Loop experiments of large size are also placed in this central thimble and connected to shielded rooms as described above.

The pile is also provided with a number of smaller holes and facilities for special experimental purposes, but the bulk of the work to be done with this reactor will be carried out on the facilities described above.

Rod Handling and Storage Equipment

As has been described, fuel rods are charged into the pile and discharged through a hole in the revolving floor. Whilst it is possible to lower a new fuel element into the pile by any convenient means, it is quite impossible to handle a spent or partly spent element in this way because the uranium section is so highly radioactive that exposure to personnel would result in death or serious injury.

All rods are, therefore, moved into and out of the pile by means of a vertical flask. A flask consists of a steel tube surrounded with sufficient lead to effectively stop any radiations from a fuel rod — even in its most dangerous condition.

The flask is mounted on an electrically driven carriage, and a portion of it is capable of being raised or lowered so that it can be positioned close to the pile floor to receive or discharge a rod. It can also be traversed across a bridge, shown in Fig. 2, to the storage block where rods can be discharged to or removed from storage.

The flask is designed to handle the central thimble plug and also a special adaptor for enclosing ruptured fuel rods and removing them from the pile. It is provided with manual hoists for raising and lowering the rods and with other facilities and flexible connections to permit them to be cooled after they have been removed from the pile.

Electrical and mechanical interlocks and other safeguards are provided to prevent fuel rods being removed when the flask is not in close contact with the floor and when personnel are in the upper header room.

The procedure when removing a rod is as follows: The pile is shut down to permit an operator to enter the upper header room for the purpose of disconnecting the normal cooling water supply and connecting a flexible hose from the flask above. At the same time, a flexible hose is connected to the lower end of the rod so that cooling interruption is kept to a minimum. The operator then leaves the upper header room to a point where a key must be inserted in the interlock system before the fuel rod can be raised. The rod is raised into the flask and the temporary hose from the lower header room is disconnected; a hose from the storage block is then connected to maintain the circulation of cooling water whilst the flask carriage is moving to the storage block.

New fuel rods are stored in racks in the area adjacent to the storage block and are transported to the storage block by the monorail for loading into the flask.

Spent fuel rods are stored under water in a tank in the storage block. There they are left for several months to permit radioactivity to decay to the point where they may be further treated.

After a short period of storage in the full length condition, the rods are placed into an automatic sawing machine built into the storage block. This machine cuts off the portions above and below the uranium centre section and then strips the outer sheath from the remaining section of the rod. The uranium section, with its thin aluminum cladding, is then transferred to the wet storage tank until such time as it is desired to remove it for further processing.

The upper and lower sections of the rods are removed, and after cleaning and decontaminating they are re-used on other fuel rods,

The storage block contains also the following additional facilities:

(i) Horizontal holes for storing plugs and experimental assemblies from the horizontal holes in the pile.

(ii) Vertical holes for storing central thimble plug and ruptured rod flask.

(iii) X-ray equipment for radiographing irradiated fuel elements,

(iv) Facilities for loading and unloading samples in special 'tray rods'. These are used to irradiate small samples in fuel rod positions for the production of radio isotopes.

(v) Trench system connected to outside water-filled cutting bay for cutting and dismantling loop experiments.

Layout of Reactor Hall Rotunda

The general arrangement of the reactor building is shown in Fig. 2. The central rotunda contains the steel pressure shell, housing the pile and the storage block. The lower, annular, single storey building at the base of the rotunda contains all the auxiliaries and services not actually required at the pile itself.

The rotunda stands upon a reinforced concrete substructure, consisting of a basement and a sub-basement founded upon rock; the annular building stands upon a similar substructure, but has for the most part only a single basement.

The rotunda consists of a heavy steel framework supporting, on the inside, the plating of the steel pressure shell and covered on the outside with insulating material and the outer cladding of the architectural treatment. The cylindrical shell plate is ⅞ in. thick and the dome plate is ½ in. thick, these thicknesses being necessitated by practical considerations rather than by pressure requirements.

The design pressure for the shell is 5 lb./ sq. in. above atmospheric and under this pressure the shell will be stressed to only about 4.5 kips per sq. in.

The shell is constructed of low-carbon steel to A.S.T.M. Standard Specification A285 Firebox Quality Grade C. The welding electrodes used are low hydrogen electrodes to AWS Classification E7016. The field welding is subject to 100 per cent gamma ray inspection.

The ribs are designed for assembly with bolts of high tensile steel. In addition to the dead load of the structure, they support the 30-ton revolving crane inside the rotunda and the roof of the annulus building outside.

As there is a general uncertainty regarding the magnitude of the pressures which might develop within the reactor shell, in the event of a temporary uncontrolled power rise, the structure is designed for a nominal pressure of 5 p.s.i. above atmospheric, but the working stresses are selected so that a pressure rise of 30 p.s.i. will be required to produce serious deformations in the shell and substructures. In the case of the substructures, this is made possible by back-filling with concrete between the walls of the basement and the rock excavation.

Figure 3 shows the layout of the equipment on the main floor of the rotunda; the principal items here are the pile block and the storage block. The floor at this level is provided with covered channels connected to a peripheral channel at the base of the shell, for the accommodation of temporary wiring and other services to instruments and experiments which may be set up around the pile block and round the periphery of the building.

In the experimental area around the pile, provision is made for experiments involving equipment and lead shielding equivalent to a superimposed loading of 6,000 lb. per sq ft. Elsewhere, this floor is designed for a loading of 3,000 lb. per sq. ft

In the main floor also are removable slabs which form the roofs of the shielded rooms in the basement below. Eight of these shielded rooms are provided, where loop experiments can be set up in which fluid may be circulated through the pile and through experimental equipment in the rooms, in such a manner that highly radioactive materials may be handled without danger to staff.

The rotunda can be entered only at this floor level, through the personnel and the vehicle entrances. Both entrances are fitted with airlocks approximately 25 ft. long inside; tional king-post, the problem of centring the crane is solved by attaching a heavy roller elevator-bucket type chain to the crane rail girder. The chain is arranged so that the rollers form horizontal rack teeth on a circular path parallel to the crane rail. Sprockets with horizontal shafts, geared to the drive wheels at each end of the crane, engage the rack pacity of 1,000 lb. This monorail will be used to handle new fuel elements which are either under construction or being tested prior to insertion in the pile.

In the basement are situated, in addition to the shielded rooms, a utility room for the use of maintenance and other personnel; a monitoring room containing flow monitoring

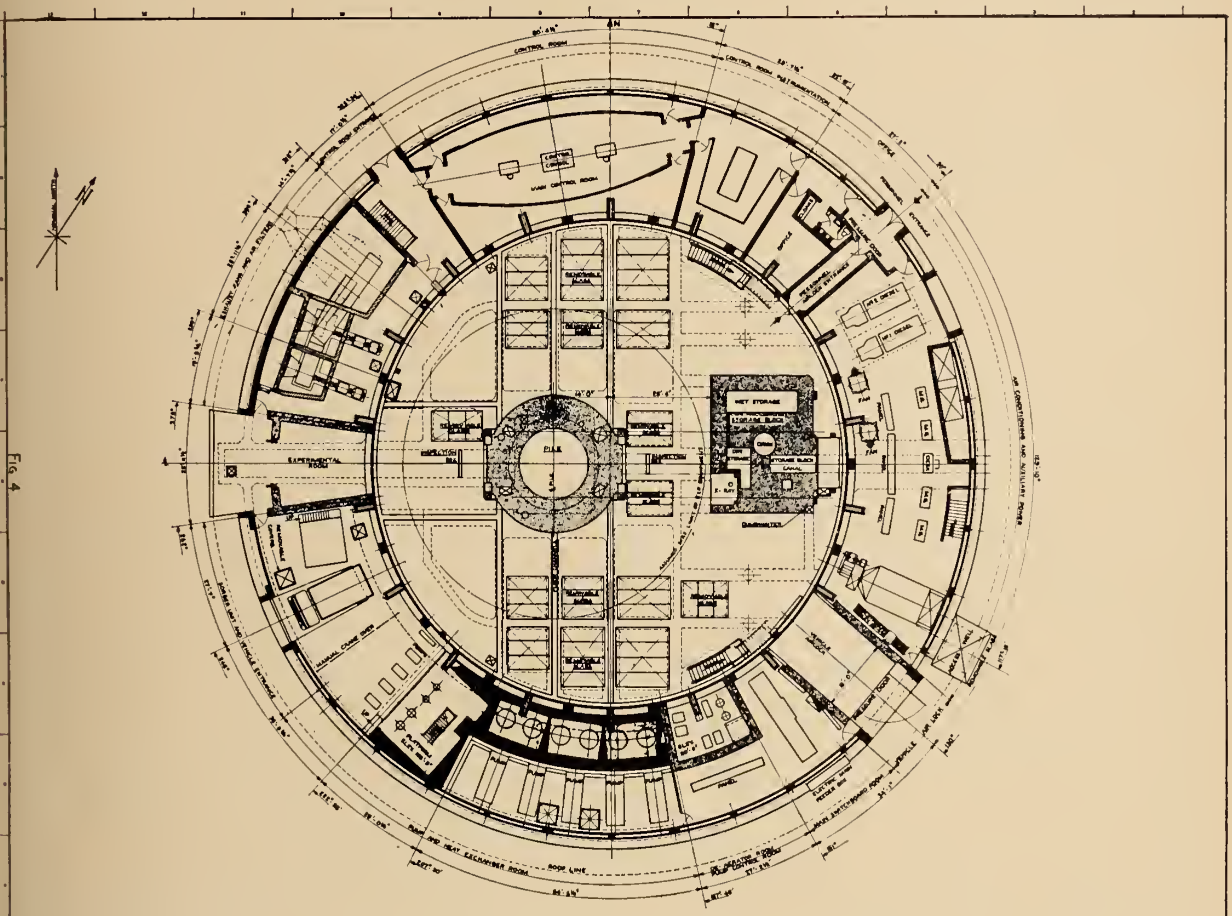

Fig. 4—Ground floor plan of reactor hall and annulus.

to permit all forms of normal traffic to enter and leave the reactor hall without violating the principle of maintaining a pressure-tight shell at all times. The two doors in each entrance are interlocked to prevent more than one being opened at the same time and the power supply to all the doors in the entrance will, in an emergency, be controlled from the main control room in the annulus building.

The reactor hall is serviced by a revolving crane having a 30-ton capacity main hoist and a 5-ton capacity auxiliary hoist. As the hemispherical dome of the rotunda is too high to permit the use of a conventeeth and ensure equal angular motion of the end trucks about the centre-line of the crane.

The crane is fitted with normal hoisting, lowering and holding brakes and all the movements, both vertical and horizontal, are at standard speeds; except that the 5-ton auxiliary hoist is provided with a secondary drive to permit hoisting and lowering at a speed of 1 foot per minute, when necessary, to handle fuel elements, experimental equipment, and so on.

In one sector of the building, a light monorail is attached to the crane rail beam to accommodate an electric monorail hoist, having a caequipment from the fuel rods and a room containing the heavy - water heat exchangers which must of necessity be placed close to the pile in order that the pipe-runs may be limited to conserve the amount of heavy-water required.

The sub-basement contains ventilating and air-conditioning ducts, power and instrumentation cables and service piping generally and will not be used for experimental or similar purposes.

The main floor of the annulus building is at the same level as the main floor of the rotunda and contains the control room, the vehicle and personnel entrance airlocks; air-conditioning plant; the main fresh water cooling pumps, the power supply distribution board and battery room; the motor control centre; the helium purification plant, together with part of the water treating plant and an experimental room in line with the west thermal column.

The area containing the main-pumps and heat exchangers is serviced by a 10-ton crane having electrical hoisting machinery and manual traversing movements.

In the basement of the annulus building, the heat exchangers are situated below the main pump room and the centrifugal compressors of the air - conditioning plant are located below the air-conditioning unit. The heavy-water tanks, heavy-water pumps, and the helium gasholder are located below the helium purification unit. In the room beneath the control room all the leads and wiring connected to the process and other instruments are collected on trays and lead up to the panel boards and console in the control room and to the trip and alarm panel in the room adjacent to the control room.

The basement also contains the ion exchange columns and deaerators of the water treating plant, together with the compressed air plant, main exhaust fans, air filters and the access chambers leading to the filter compartments.

Adjacent to a pipe tunnel on the west side of the rotunda basement is a small sub-basement under the annulus, containing the heavy-water salvage tank and catch tanks for the shield cooling systems.

The pipe tunnel is the primary means of access, through which the piping of the cooling circuits is led to the reactor. This tunnel is designed to be completely sealed off after all the pipes are in place in order to maintain the basement in a pressure-tight condition.

Details of Cooling System

As mentioned above, sea-water is used for cooling the reactor. Fresh water is circulated through the pile and the water - cooled shields in closed circuits and transfers heat to sea-water in heat exchangers located in the annulus. The heavy-water circulates in another closed circuit and is cooled directly by sea-water in heat exchangers located in a shielded room in the basement adjacent to the pile.

The primary cooling system has six heat exchangers arranged so that any number can be operated together in parallel. Under maximum normal operating conditions there are five units operating and one on standby.

The pumping plant for the primary cooling system consists of five horizontal centrifugal pumps each having a capacity of 1200 I.g.p.m. against a total head of 560 feet. These pumps have cast-iron bodies and bronze impellers.

The steel and aluminum shield cooling systems each consists of two heat exchangers, one operating and one on standby.

On the heavy-water system there are three heat exchangers arranged so that any number can be operated together in parallel; the system is designed so that two units only are required for the maximum operating conditions with one unit on standby.

The pumping plant for the heavy-water system consists of two circulating pumps each having a capacity of 250 I.g.p.m. against a total head of 162 feet; and two supply pumps each having a capacity of 50 I.g.p.m. against a total head of 76 feet. The pumps are horizontal centrifugal type made of stainless steel. The supply pumps are used for transferring heavy-water between any one of three storage tanks and the calandria or from one tank to another. Full standby capacity is provided as only one supply pump and one circulating pump are required for normal operation.

One of the storage tanks is in the circulating system and remains empty whilst the reactor is running at full power. The tank forms part of the line and the heavy-water merely flows through it. When the pile trips, the dump valves open and the heavy-water is literally "dumped" into this tank which then holds the requisite amount to shut down the pile.

During start - up, control valves on the discharge lines from the calandria to the tank are closed and the circulating pumps transfer heavy-water to the calandria at the rate of 250 g.p.m. for the purpose of rapidly bringing the pile up to the required power level. When this level is reached, the control valves are automatically opened so that the pumps then circulate the heavy - water through the cooling system, regulating the power output by the level in the calandria.

For what are termed "critical height" experiments, control of the level of heavy-water in the calandria is maintained by the overflow of heavy-water through a wire box which can be raised or lowered accurately to any height depending upon the power level at which the reactor is required to operate.

All valves, pipes, pumps and tanks in the heavy-water system are of stainless steel, to ensure absolute freedom from corrosion and consequent contamination of the system by irradiated corrosion products.

All heat exchangers are of the shell and tube type and are mounted vertically with floating heads at the lower end of the tube bundles. All the heat exchangers are arranged so that the tube bundles can be removed without dismantling the shells and in each set of identical exchangers the tube bundles are interchangeable.

In all cases, the sea water passes through the tubes, which are ¾ in. diameter and straight to facilitate cleaning. The sea water is chlorinated at the intake to inhibit the formation of marine growths. Experiments carried out near the site indicated that chlorine injected continuously in sufficient quantities to provide a residual chlorine content of 3 p.p.m. one half hour after injection would prevent serious fouling by marine growths under the most adverse monsoon conditions.

One of the problems in the design of the heat exchangers was the selection of suitable materials. The sea water carries a heavy silt load which has an erosive action if the water velocities are too high; on the other hand, if the velocities are too low the exchangers will silt up and fouling of the tubes will proceed at an accelerated rate.

On the fresh water coolers 70:30 copper nickel alloy is used for all the tubes and tube sheets and the sea water velocities are restricted to a range of 3 to 6 feet per second. For heads, channels and other fabricated parts in contact with sea water, silicon-bronze is used.

In the heat exchangers on the primary cooling and on the steel and aluminum shield cooling systems using fresh water, the shells are of copper - bearing corrosion - resisting low carbon steel.

The heavy-water coolers presented a more difficult problem as it was felt advisable to avoid copper and copper alloys in the heavy-water system. These heat exchangers are fitted with duplex tubes, having 70:30 copper nickel on the sea water side and type 304 stainless steel on the heavy-water side. The stainless steel outer walls of the tubes terminate in type 304 stainless steel tube-sheets and the copper alloy inner walls are secured in tube-sheets of 70:30 copper nickel. The double tube-sheets at each end of the exchangers are separated by air gaps and spacer rings of "Inconel" are provided and drilled to permit leak detecting probes to be inserted between the tube-sheets.

In the special heavy-water coolers, the heavy-water is exposed only they are insulated by means of Neoprene gaskets and the bolts securing the dissimilar metals are provided with insulating sleeves and washers.

The upper and lower headers and the supply pipes embedded in the pile concrete are of stainless steel. Stainless steel has been selected for the headers because mild steel will rust on the outside in the moist conditions created by leakage of water from the rod connections and contamination of the rusty headers times, a storage reservoir is provided of sufficient capacity to supply cooling water to the pile in an emergency for approximately four weeks with the pile operating under shutdown conditions.

Delay System

Although the cooling water is continuously treated during pile operation to remove impurities, certain isotopes having very short half lives are produced. To prevent a danger-

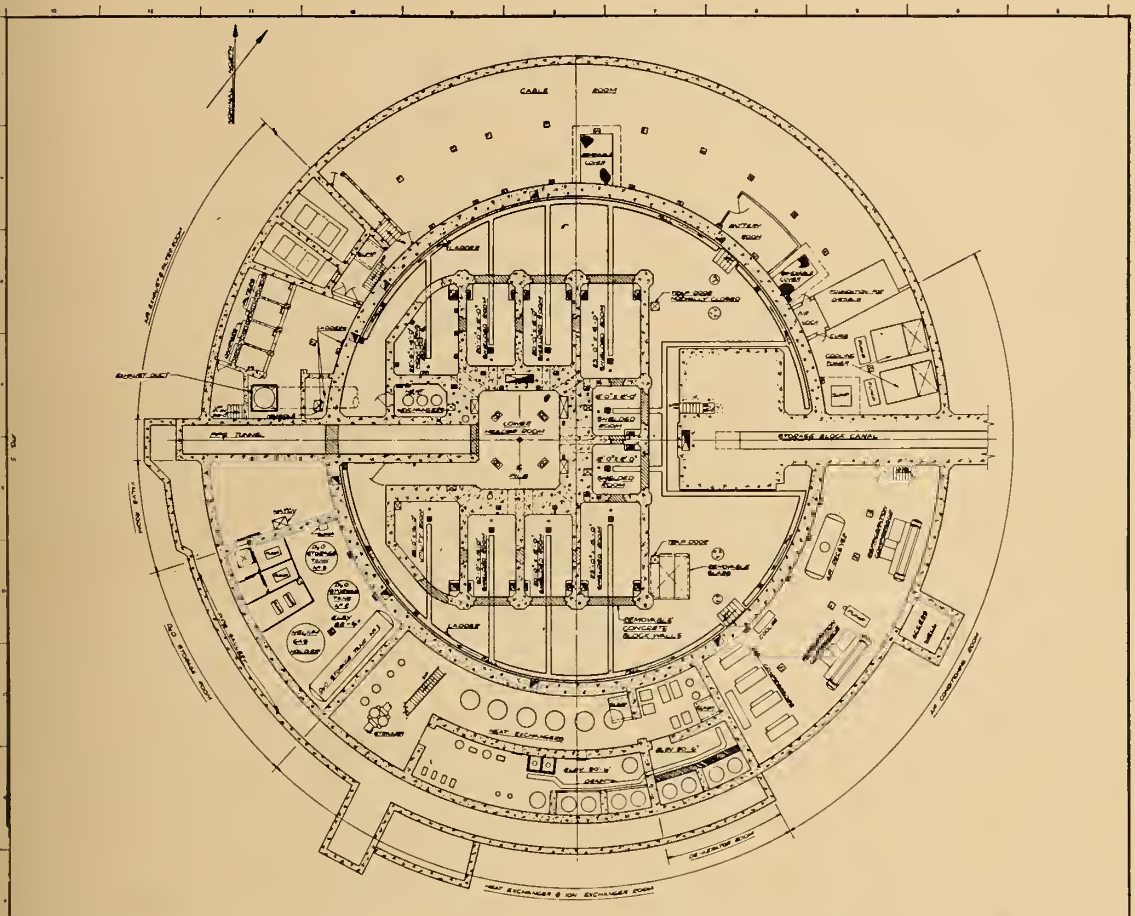

Fig. 5—Basement plan of reactor hall and annulus.

to stainless steel and the sea water to 70:30 copper nickel or to silicone bronze. No dissimilar metals are connected together in the presence of a common electrolyte so that galvanic corrosion will not be a hazard.

On the fresh-water coolers the sea-water is exposed only to 70:30 copper nickel alloy and silicon bronze and the fresh-water is exposed to the copper alloy tubes and tube sheets and to the corrosion-resisting steel in the shells. Where dissimilar metals are connected together in the presence of a common electrolyte, would make maintenance difficult. The embedded pipes are of stainless steel because they are totally inaccessible for maintenance after the pile concrete has been poured.

Type 347 stainless steel is used for the headers to permit them to be given a thermal stress-relief treatment during manufacture. Type 304 stainless steel is used for the embedded supply pipes.

Fresh water for the closed circuit main cooling system is supplied from the city water mains; but, as the city supply is not dependable at all ous build-up of activity in the cooling water, a delay system is provided to permit the cooling water to remain outside the pile for a pre-determined length of time.

This delay system consists of a 5 ft. diameter pipe 800 ft. long, in the form of a large 'U' (to save ground space). The pipe has a capacity of one hundred thousand gallons, thus providing a delay of 20 minutes with a flow of 5000 g.p.m.

The delay pipe is located at the foot of a nearby hill, directly under the storage reservoir. The entire system of delay tank and connecting pipes slopes upwards away from the pile to provide positive drainage when required and positive venting at all times. The system is vented through an open standpipe which also maintains a constant head on the low pressure side of the cooling system.

Twenty-inch diameter mild steel pipes connect the delay pipe to the pile; the delay pipe itself is constructed of low alloy corrosion-resisting steel (U.S.S. Corten).

Normal flow of cooling water is from the pumps to the fuel rods, through the delay tank, through the heat exchangers and back to the pump suctions, thus providing a total delay of a little over half an hour.

Water Treatment Plant

Water for the primary cooling system is initially charged into the system by feeding city water through a vacuum deaerator and a demineralizer bed until the system and the storage reservoir have been completely filled. During operation, approximately 100 gallons per minute is fed through the vacuum deaerator and demineralizer bed to maintain the purity of the water at the required level. Control is provided to maintain the pH between the value of 6 and 7.

Water for the steel shield cooling system is charged into the system through a deaerator and demineralizer of the primary cooling circuit. The system is controlled to maintain the pH at a value between 9.5 and 10.5 and sodium sulphite is injected to remove dissolved oxygen. No demineralizer is provided on this system.

The aluminum shield cooling system is initially charged through the demineralizer of the primary cooling circuit, the deaerator being bypassed for this purpose. Control is provided to maintain the pH at a value between 6 and 7, and approximately 5 g.p.m. is fed through a mixed-bed demineralizer to ensure the removal of copper from the system.

Cooling water for the tanks of the wet storage area is initially charged through its own vacuum deaerator and demineralizer, and during operation this water is normally circulated at the rate of 100 g.p.m. through a filter, but provision is made to bypass approximately 20 g.p.m. through the vacuum deaerator and demineralizer in order to maintain the purity at the required level. No pH control will be included in this system. This equipment will be used to clean up contaminated water from both the storage block and the contaminated dump tank in the event of a rod rupturing.

On the heavy-water system, a demineralizer only is provided and no provision is made for pH control.

Emergency Cooling

Under normal conditions the pile is cooled by a re-circulating system as described above, but under emergency conditions cooling of the fuel rods will be by gravity flow in a one-pass system.

Failure of the main pumping system or a ruptured fuel rod will cause the pile to trip and also automatically bring the emergency cooling system into operation. For this purpose a storage reservoir of 850,000 gallons is provided on the side of a nearby hill. An additional storage of 150,000 gallons is maintained for fire protection.

An emergency dump tank of one million gallons capacity is located at an elevation below that of the lower header of the pile and remains empty during normal operation of the main cooling system.

This dump tank is provided with compartments so that if the emergency system is dealing with a ruptured rod the contaminated water will be isolated from the rest of the tank which must be kept clean to receive water from the pile during emergency cooling due to pump failure alone.

The main 850,000 gallon storage reservoir rides on the high-pressure side of the system through a check valve, normally kept closed by the 240 p.s.i. pump pressure. Should the pump pressure fall below approximately 50 p.s.i., the check valve will open and a second, automatically operated, valve above the emergency dump tank will also open, permitting water from the reservoir to flow by gravity through the pile and into the dump tank.

If a rod splits, the fission products monitoring system will trip the pile and shut down the main pumps. Tripping the pile and pumps in this way will result in a loss of pressure and the emergency cooling system will come into operation as described above. The contaminated water from the ruptured rod will flow into one of two 75,000 gallon compartments in the dump tank until the ruptured rod has been isolated.

During the few seconds required for the pumps to stop, a certain amount of contaminated water will flow in the twenty inch line from the pile to the delay tank but it will not reach the delay tank. When the emergency cooling system is operating the delay line is by-passed and the "slug" of contaminated water will flow directly into the contaminated compartment of the dump tank. The line will be flushed with clean water flowing through the pile from the storage reservoir.

Emergency cooling water discharges over a loop at a higher elevation than the top of the calandria to prevent accidental un-watering of the entire system.

When a ruptured rod has been isolated and the lines cleared of contaminated water, a sufficient number of pumps will be started to provide cooling for the pile to operate, under shut-down conditions, on the re-circulating system in order to conserve the supply of emergency cooling water.

The contaminated water in the smaller compartments of the dump tank will be pumped through the clean-up treating plant at the rate of 50 g.p.m. and thence to the 850,000 gallon clean water compartment of the tank from where it will be returned to the reservoir by the 300 g.p.m. pumps provided for that purpose.

The maximum flow obtainable from the emergency supply is 1400 g.p.m., so that ample cooling will be provided, since only 30 per cent of the normal flow is required one second after shut - down. As the heat load falls off still further, with increasing time of shut-down, the flow will be regulated and reduced still more to provide sufficient cooling water for four weeks operation under shut-down conditions.

As a pile trip will automatically cause part of the heavy-water to be dumped into its own tank, it is not necessary to provide emergency cooling for the heavy-water. Similarly, the steel and aluminum shields will generate almost no heat under shutdown conditions so that it is not necessary to provide emergency cooling for the water-cooled shields.

Sea-Water System

The sea-water carries an unusually heavy silt load, which increases considerably during the monsoon season when surface material is carried down from the surrounding hills by the heavy rains.

The sea bed slopes very gently downwards, away from the shore line, and is covered with a layer of mud approximately 15 ft. thick. The water off the site is so shallow that it is necessary to go out approximately 3500 feet from shore to secure sufficient depth of water for pumping.

As the sea area off shore from the site is a turning ground for oil tankers arriving at a nearby oil dock, the choice of site for the sea-water intake was somewhat restricted.

The pumping station consists of a caisson having three compartments; two compartments being screening chambers and the third containing the pump suctions. Water enters a screening compartment through a coarse screen and a gate in the wall of the caisson and flows through a second gate and a second finer screen into the pumping chamber. From there it is pumped into the main pipeline. When one screening chamber requires cleaning its gates will be closed and water will be passed through the other one into the pumping chamber.

For the pile cooling requirements four vertical centrifugal pumps are provided, each having a capacity of 2700 g.p.m. against a total head of 120 feet. Only three pumps are normally required, the fourth being standby. A fifth pump will be installed later to supply additional cooling water for loop experiments and this will be identical with the main pumps and will, of course, discharge into the same header and pipeline. The sea water pumps have nickel cast-iron bodies; Monel impellers.

To prevent fouling of the system, by silt settling out of the sea water during shut-down periods, by-pass lines are provided to permit the sea water lines to be flushed before the heat-exchangers are brought into operation.

Chlorination of the sea water is carried out at the intake as outlined above in the description of the cooling system.

The pipeline to the shore is a welded steel pipe, lined inside with concrete. The pipe is carried on a pier of reinforced concrete constructed on the rock of the sea bed.

For the disposal of return sea water, a pipe is carried from the reactor to the sea wall where the return flow discharges into an open channel.

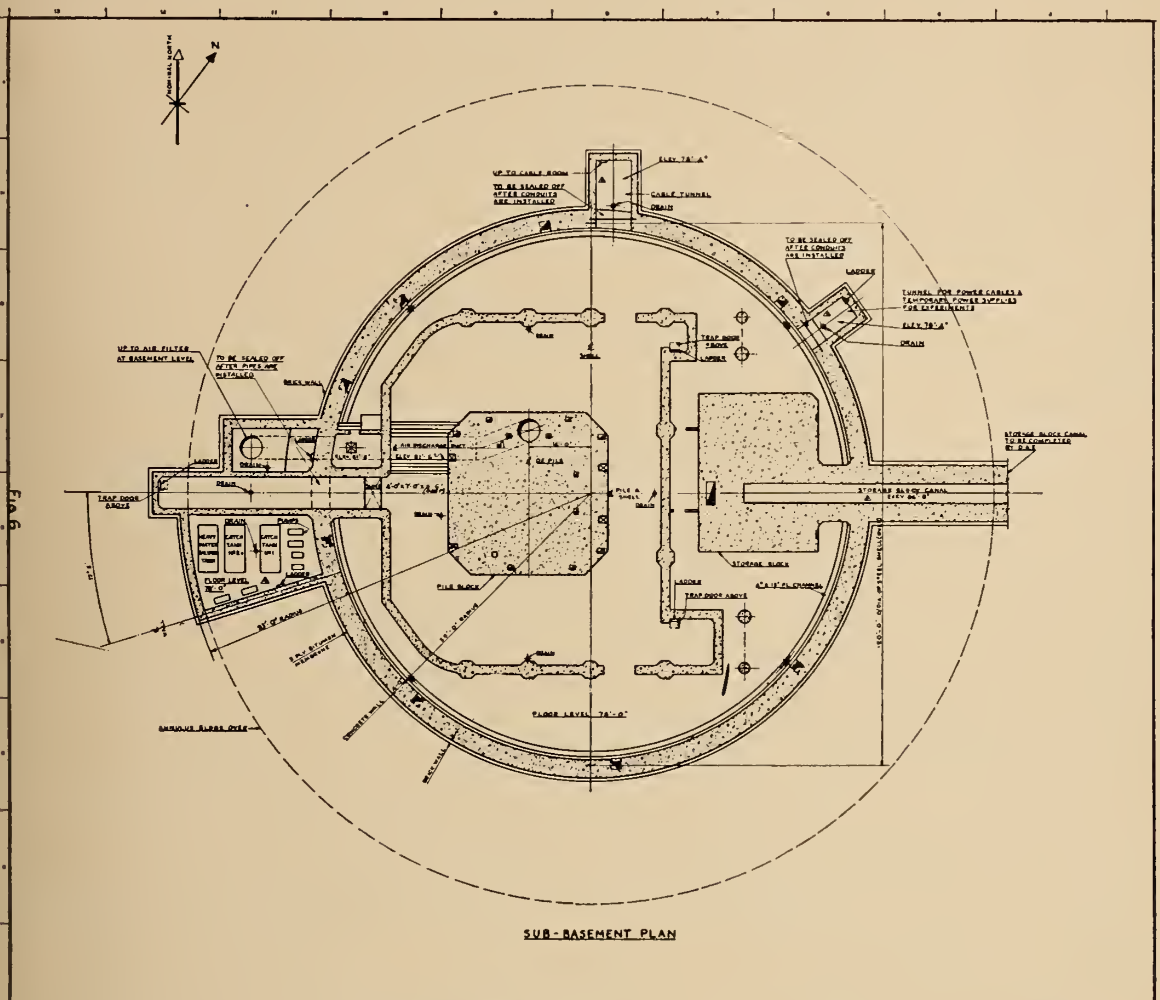

Fig. 6—Sub-basement plan of reactor hall and annulus.

Electric Power Supply

Power for the operation of the plant is supplied from the grid system feeding the Bombay area. Two single circuit, 22 kv. widely separated lines transmit the required power a distance of approximately two miles to the main substation of the Atomic Energy Establishment. From this station power is distributed at 11 kv. to the various load centres including those of the C.I.R. project.

The reactor load centre comprises the necessary switching and two transformers, each rated 2500 kva. and capable of carrying the full load requirements of the reactor. Power is supplied at 440 volts by underground cables to two separate sections of the distribution board. The load of the reactor building is divided equally on these two bus sections and provision is made for instantaneous transfer of either section to the sound feeder circuit in the event of failure of one of the two circuits. This arrangement reduces the short circuit duty on all switching equipment and also the hazard of complete shutdown.

Power for the sea water pumps is transmitted via overhead cable along the pipeline pier at 11 kv. and separate transformers are provided at the intake caisson to reduce the voltage to 440.

Push button stations for the control of the various motors are located at three principal stations in the plant:

(*a*) The pump control panel for the cooling system, located near the main switchboard in the annulus building.

(*b*) Control panel for all fans, pumps and compressors of the air-conditioning and exhaust system, located in the air-conditioning plant room in the annulus.

(*c*) Heavy-water pump controls located in the main control room.

Push-button starters for air-compressors, sump-pumps, motor-operated doors and other special equipment are mounted adjacent to the equipment as they are always started under the supervision of an operator.

A message system is provided to transmit written instructions from the main control room to the two motor control centres in the annulus building.

The sea-water pumps are controlled from the annulus pump room, but provision is also made for stopping and starting them at the intake caisson during maintenance work or in emergencies.

Standby power of 440 kw. is furnished by a diesel set consisting of two 220 kw. Diesel generators.

The Diesel plant will carry only the loads essential for operation when the pile is shut down. Failure of normal power will automatically trip the pile.

On failure of the regular power supply, the starters of the two Diesels will operate simultaneously and the machines should start within 15 seconds. In the event of one machine failing to start, however, protection is provided for the standby system; the standby power load is divided into two sections and all the more vital lighting and equipment are included in a 200 kw. preferred load. The first Diesel to start will pick up this preferred load so that should either machine fail to start, power will be available for the important equipment. Two identical machines are provided, to simplify the work of maintenance and for which simpler equipment for synchronizing is required.

Direct current for the instruments is supplied by motor generator sets with storage batteries 'riding on the line' to supply current in the event of a power failure.

Control Room

The main control room is located in the annulus building and contains all the instruments and control devices necessary for the proper and efficient operation of the reactor. On a large graphic panel are shown simplified flow diagrams for the heavy-water, helium, primary cooling and shield cooling systems, on which miniature instruments are mounted to show the relation of each to the process.

Adjacent to the control room is an instrument room containing the trip and alarm panels and other panels for which constant attention by the operator is not required, and an office and cloakroom for the convenience of shift operators.

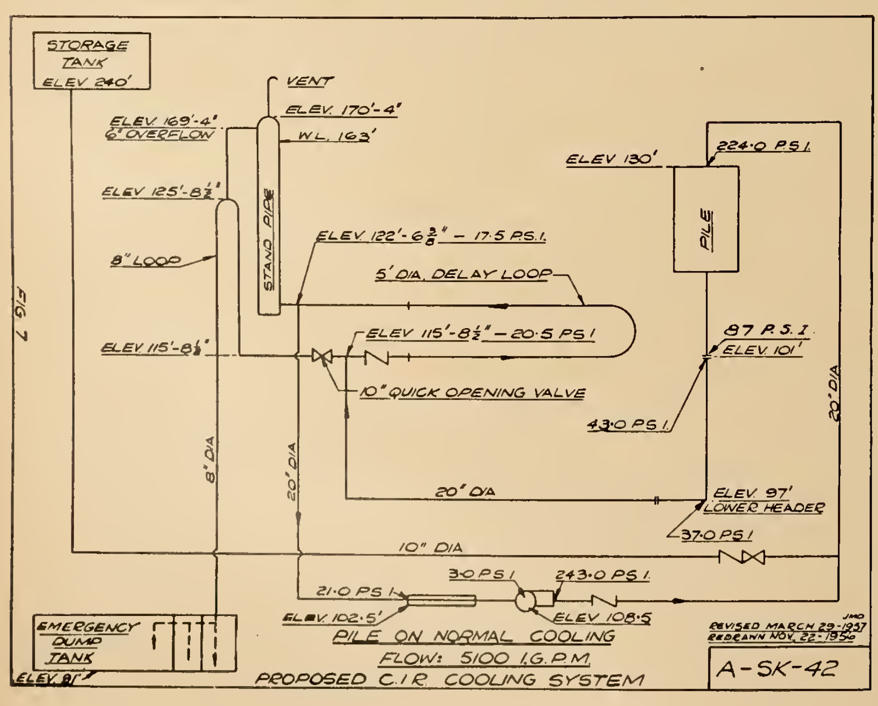
The control room is not accessible directly from the reactor hall as there is nothing to be gained by being able to look into the pile building from the control room and, in fact, windows or any means of access between the two rooms would constitute a definite weakness and would defeat the object of the pressure shell.

If an incident should occur which would justify the adoption of the pressure shell, one room above all others which must be entirely free from contamination is the control room. Similarly, if an incident should occur it will be of immense value to have as many instruments and as much control equipment as possible outside the contaminated area.

On C.I.R. therefore, as many instruments and controls as possible are placed outside the pressure shell. Where local controls are necessary they have been duplicated at appropriate points. Instruments which cannot be conveniently located in other areas, such as the pressure and temperature measuring instrument for the lower header assembly, are automatically scanned locally and the readings recorded in the control room.

The centralization of controls in a few locations as possible is made necessary by two factors which have influenced much of the design of this project. These are, first, the isolation of the reactor in a gas-tight pressure shell to guard against the effects of accidents and, second, the lack of suitably trained personnel and

Fig. 7—Flow diagram of normal primary cooling system.



the function of the project as a training ground for Indian scientists and technicians. With centralized controls for all the important equipment, a comparatively smaller number of highly trained men will be required to keep the equipment under control at all times.

Air-Conditioning Plant

The design of the air-conditioning and ventilating plant for the C.I.R. involved many factors not encountered in the design of other such plants. In addition to providing sufficient quantities of cooled and dehumidified air to meet comfort requirements in the building, the system is required to provide positive and extremely reliable ventilation to both the occupied areas and the pile itself.

Sufficient air must be drawn through the pile to remove the heat equivalent of about 200 kw. in the regions of the thermal shields and J-rod annulus. Air pressures within the pile itself must be held below those in the experimental areas surrounding it so that all air leakage will be inwards. All contaminated areas must be liberally ventilated to prevent dangerous build-up and escape of radioactive air.

All contaminated air must be efficiently filtered and discharged from the reactor building in a manner which will not create a health problem and will not increase the background radiation in other experimental areas of the Establishment.

Both fatigue of operating personnel and damage to experimental equipment must be prevented, in so far as they can be prevented by close control of temperature and humidity, irrespective of the outdoor climate.

All the above objectives must be accomplished with adequate and reliable safeguards and alarms against faulty or abnormal operation of the equipment.

For the reactor hall, pile and basement, the air-conditioning and ventilating system is equivalent to a one-pass or series system. Only one source of conditioned air is provided to the reactor hall. Once inside the building the conditioned air is made to flow in the direction of increasing exposure to contamination, until the main exhaust filters are reached. Just as much fresh conditioned outdoor air is supplied to the reactor hall as must be drawn through the pile and

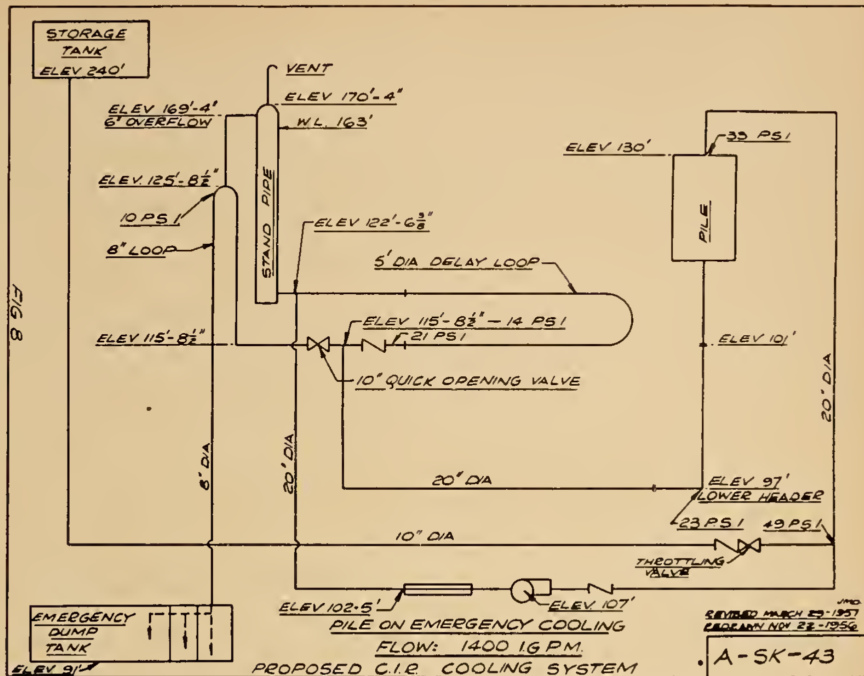


Fig. 8—Flow diagram of emergency cooling system.

exhausted from the contaminated areas. No re-circulated air is used in the reactor hall conditioning plant.

The reactor rotunda, basement and sub-basement areas are maintained continuously at a positive pressure of 0.5 in. w.g. with respect to the outside temperature; this provides improved control of the air motion and facilitates balancing the various ventilating systems within the building, especially those connected to contaminated areas and it also prevents the infiltration of untreated air.

Air is filtered and conditioned in the central conditioner, located in the annulus, at a rate of 24,000 cubic feet per minute. Of this, 22,000 c.f.m. are discharged through a duct and a (normally open) automatic pressure damper into the reactor hall and 2,000 c.f.m. are diverted to serve the fresh air requirements of certain rooms in the annulus building.

Approximately one-third of the air supplied to the reactor hall is drawn through secondary filters and into the pile through one of two intake ducts. A further one-third of the air is drawn through the basement shielded rooms and thence through filters and a booster fan into the second intake duct to the pile. The remaining one-third is made up of air used in ventilating the header rooms and storage block and of air finding its way by leakage into the pile structure.

The ventilation provided is as follows:

Reactor Hall	—22,000 c.f.m.
Shielded rooms	—Not less than 10 changes per hour
Lower header room	—22 changes per hour
Upper header room	—28 changes per hour
Storage block openings	—min., velocity of air 100 f.p.m.

Air (withdrawn from the pile header rooms and storage block), originally conditioned but now contaminated, is drawn through an exhaust duct and a second (normally open) automatic pressure damper to the filter compartment.

The filter compartment is located in the annulus diametrically opposite the conditioner location. It contains four parallel banks of absolute filters, with each filter element supported in a specially constructed pressure-type frame designed to eliminate air leakage past the filtering media.

Air leaving the filters is discharged to the stack through either one of two identically rated electric motor-driven blowers, each capable of handling the total exhaust air requirements. A mechanical shut-off damper is provided on the upstream side and a water-seal is provided on the discharge side of each blower to facilitate maintenance of the fans and motors.

In the annulus building the main concern is with air conditioning and ventilating for the comfort of the occupants. A few of the annulus rooms are regularly occupied and in the tropical Indian climate some measure of cooling is desirable. The control room has its own air-conditioning plant which, like the reactor hall conditioner, is capable of providing independent control of both dry bulb temperature and humidity. Unlike the reactor hall system, however, the control room conditioning system is designed to take full advantage of the economies associated with the utilization of re-circulated air.

In the remaining areas where cooling is required, that is, the exhaust fan motor room, electrical equipment room, switchboard room and air-conditioning equipment room, ceiling suspended unit coolers are used.

A central refrigerating plant has been provided to serve the total cooling and dehumidifying requirements of the reactor hall and conditioned annulus rooms. It consists of two, identically rated self-contained, water chilling machines, operating in parallel and delivering water at a temperature of 46 deg. F. to the conditioners and unit-type coolers strategically located throughout the conditioned areas. The rated capacity of each machine is 130 tons of refrigeration.

Conditions at the site are such that for the five year period 1951 to 1955 inclusive, the daily maximum temperature recorded at Santa Cruz Airport near Bombay reached a value above 80 deg. F. on 1,785 days; that is an average of 357 days each year. An analysis of the meteorological data has shown that it would be most unwise to have designed for a wet bulb temperature of less than 84 deg. F. with a simultaneous dry bulb of 92.5 deg. F.

The humidity in the area is such that under certain conditions it is necessary to heat the air before delivering it to the conditioned zone, for if air were to be delivered to the occupied zone at the temperature required to lower the humidity to the design figure of 50 per cent, the dry bulb temperature would be considerably below the figure of 75 deg. F. adopted as standard for the occupied zone. This would result in a serious health problem.

Amongst the most important areas serviced by the ventilating plant are the upper and lower header rooms and the storage block, and the ventilation of these three sources of contamination must be adequate under all conditions.

The upper and lower header rooms and the storage block are connected to a common exhaust system which joins with the main exhaust duct from the pile in a plenum chamber located above the main exhaust duct and adjacent to the sub-basement wall. Normally, the suction head for this exhaust system is provided by the two main exhaust fans in the annulus.

In the event of failure of the main power supply, the quantity of air handled by the main exhaust fans will be reduced by lowering the fan speeds to avoid excessive loading on the standby power plant. Reduction of the main fan speed, however, inevitably leads to a reduction in the suction head on the upper and lower header rooms and storage block ventilating ducts with a consequent reduction in the ventilation of these areas. A small booster fan is therefore, located in the sub-basement plenum and under normal operating conditions it is by-passed, but on interruption of the main power supply, it will start up and run on standby power. By this means the storage block and the upper and lower headers are adequately and continuously ventilated irrespective of the condition of the main power supply.

All the annulus areas which are not air - conditioned are positively ventilated with filtered outdoor air. Contaminated exhaust air from such areas as the heavy-water storage and salvage rooms, ion exchange and deaerator rooms, etc., is drawn through the absolute filters already described and discharged to the stack by the main exhaust blowers.

Canada's NRU Reactor

F. W. Gilbert

Manager, Operations, Atomic Energy of Canada Limited

AS EARLY as 1949 it became apparent that the NRX reactor at Chalk River could not fulfil all the requirements for experimental atomic energy work in Canada. Although the neutron flux was one of the highest in the world, still higher fluxes were needed for many experiments. These experiments were both for basic research in nuclear physics and for engineering development studies for power producing reactors. As a result it was decided to proceed with conceptual designs of a reactor having approximately five times the NRX neutron flux.

In 1957, as a result of the effort and ingenuity of many people and organizations, the NRU will begin operation. Its design and construction has involved every phase and type of engineering. The total cost of the reactor without heavy water is about $52,000,000. With 70 tons of heavy water at $56,000 per ton, the cost is nearly $56,000,000.

The reactor as built has a nominal heat output of 200 Mw*. It is hoped that this figure will be exceeded. It is moderated and cooled with heavy water (99.75% D_2O). The fuel is natural uranium. The maximum flux is 2.5×10^{14} neutrons/cm^2/sec.

The choice of fuels and moderators is somewhat controversial. Canadian experience has shown that the combination of natural uranium with heavy water as a moderator, results in a reactor small enough to give high flux at a given power, but large enough to permit the insertion of experiments of appreciable size. As it is a natural uranium reactor, NRU is a good plutonium producer. Some revenue will be realized in the first few years of operation by the sale of irradiated uranium containing plutonium, to the U.S. Atomic Energy Commission.

The building of a reactor of this size involves a number of problems. To appreciate some of these problems, certain parameters more or less unique to nuclear reactors should be described:

This paper describes the design and operation of the new research reactor of Atomic Energy of Canada Limited, at Chalk River, Ont. Known as the NRU reactor, this will probably be the most powerful neutron-flux producer of its type in the world when in full operation during 1957.

(*a*) There is a very concentrated heat output. In a vessel less than 12 ft. in diameter and 12 ft. high are generated 200 Mw. of heat, i.e. 6.8×10^8 B.t.u. per hour. Each fuel element contains only 120 pounds of uranium. Some generate 1.5 Mw. of heat each. The cooling system and heat-transfer rates have to be adequate to cope with this problem. The upper limit of power output is the heat that can be removed, not the heat that can be generated. In a nuclear reactor there is no practical limit to the latter.

(*b*) Everyone is now aware that personnel must be protected from the intense radiations generated in a nuclear reactor. Not so many realize that this same radio-activity, particularly in the form of gamma and neutron radiation, generates heat on being absorbed in reactor materials. In the NRU reactor approximately 1 Mw. of heat is formed in the structure by radiation. Any piece of metal, for example, that is in an intense radiation field must be cooled. In the NRX, air cooling is adequate for most components, but in the NRU water cooling is required.

(*c*) Practically any material in a neutron field becomes radio-active—the higher the flux†, the greater the activity. Maintenance under radioactive conditions is very costly. Hence it is economical to establish very high standards of construction to avoid future maintenance expense.

(*d*) All materials absorb neutrons but they do so to varying degrees. The spread in relative absorption is as much as a factor of 10^9. Neutron economy is directly related to the cost of construction and operation of a reactor. Any steps taken to reduce the absorption of neutrons will generally reduce costs. Hence considerable care is taken in the selection of materials of construction. It is to improve the neutron economy that heavy water is used as a coolant in NRU, but light water in NRX.

With these parameters in mind the resulting design of NRU can be more clearly understood. Figure 1 shows diagramatically the NRU reactor. The various components are:

1. The reactor vessel and reflector. 2. The upper header. 3. The lower header. 4. Upper shielding sections. 5. Side thermal shields. 6. Biological shield. 7. Thermal column. 8. Heat exchangers. 9. Circulating pumps. 10. Research facilities.

Not shown in this sketch are the following main components:

11. Auxiliary cooling circuits. 12. Heavy water purification system. 13.

*The unit megawatt (Mw.) is equivalent to one million watts. It is used here to measure heat output.

† No. of neutrons/sq cm./sec.

Helium purification system. 14. Reactor ventilation. 15. Control system. 16. Services. 17. Fuel handling and storage equipment. 18. Fuel rod design. 19. The building.

It is proposed to discuss each of these components or groups of components separately, relating them to the whole reactor.

Reactor Vessel and Reflector

The reactor vessel is a cylinder 11 ft. 6 in. in diameter and 11 ft. 9¾ in. high, inside dimensions. It is made up of three separate components, the shell, an upper and a lower header. These headers are bolted to the shell and closed with metal-to-metal seals. The reactor vessel is normally filled with heavy water, which flows in by way of the lower header and out of the top header to heat exchangers. Its purpose is to moderate the neutrons and also to remove the heat generated by fission. In the heavy water are suspended the fuel rods, the control-shut-off rods, and the experimental rods.

Aluminum is chosen for the reactor vessel as it absorbs relatively few neutrons, thus improving the reactor performance and also providing the maximum number of neutrons at the experimental holes. If stainless steel had been used there would have been a considerable attenuation of the neutron flux in passing through the vessel walls.

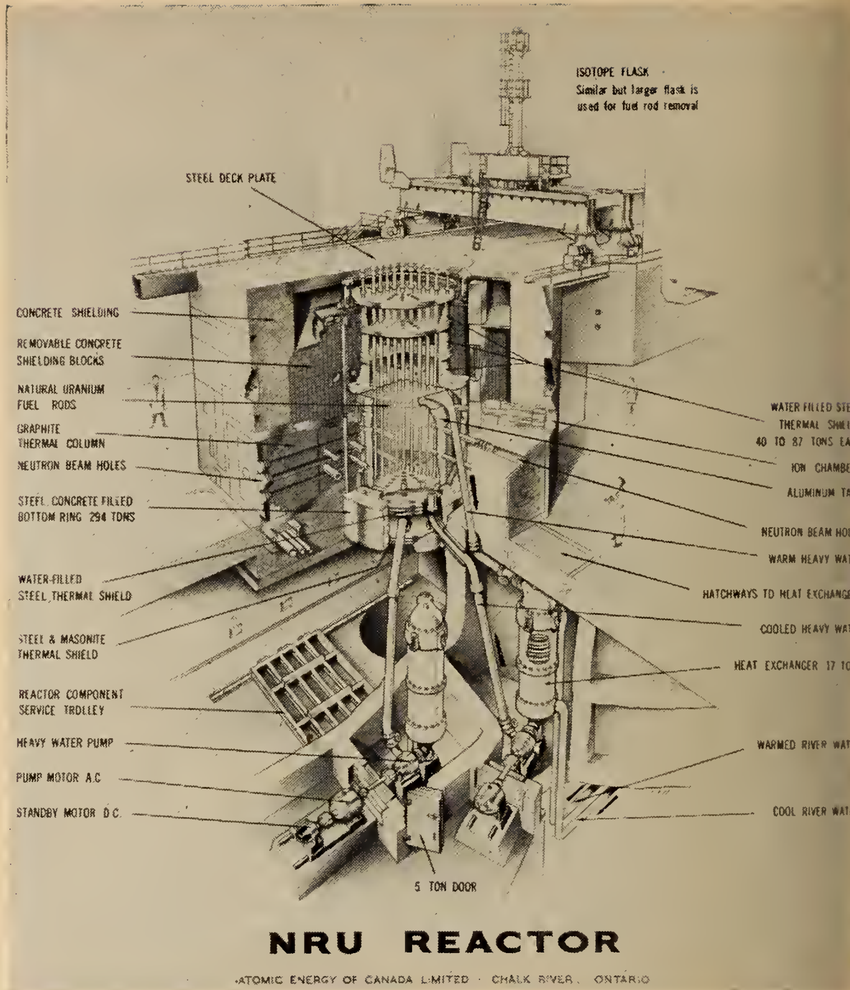

Fig. 1 (above) and Figure 2.

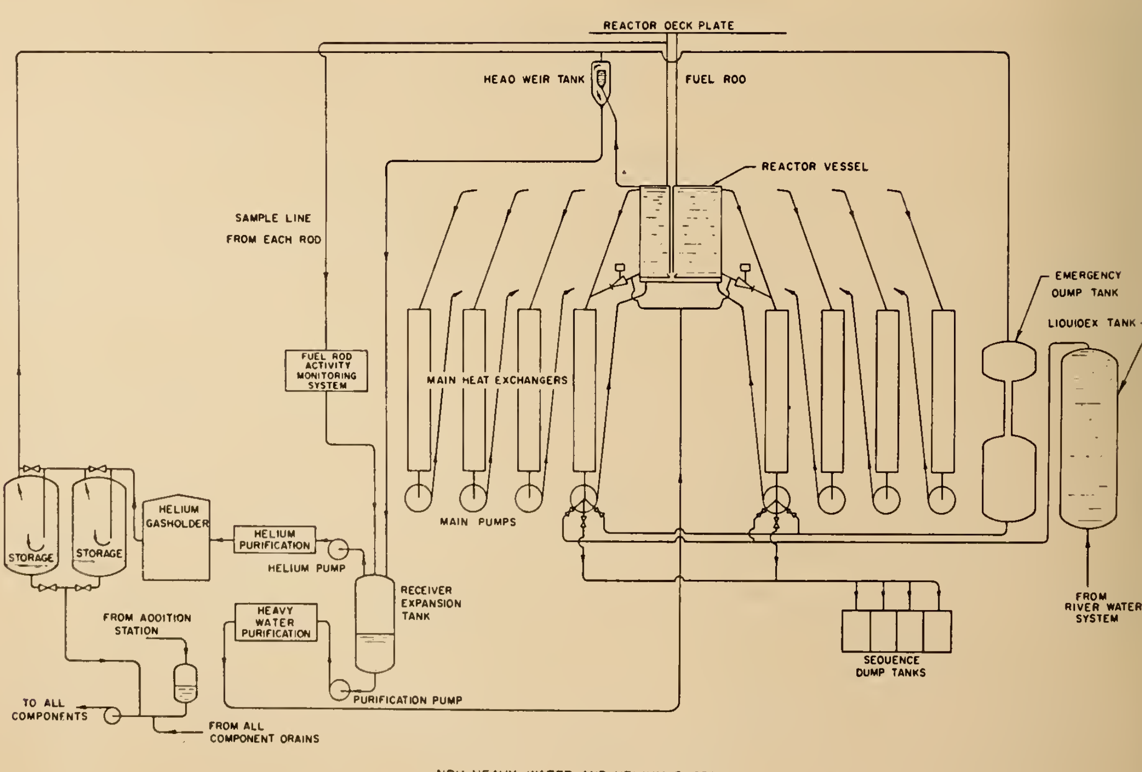


Outside the reactor wall there is a 6 in. annulus filled with CO_2 and then a neutron reflector. The reflector is an annular tank, 12 in. thick and 11 ft. 6 in. high made of aluminum and filled with ordinary water. The water is circulated through one of the auxiliary cooling systems. (Fig. 3.)

The Upper Header

The upper header is made of two tube sheets of stainless steel. Into it are rolled 227 tubes that extend to the top deck of the reactor. The tubes are seal-welded to the lower tube sheet, are supported above by springs, and are rolled into both sheets of the header. A system is provided to detect leaks into the intervening space.

To prevent distortion and failure of the top header by heat generated by the intense radiation, heat baffles are provided, consisting of blocks of steel fastened to the lower side in a mosaic pattern. They are cooled with heavy water from the vessel.

The upper header is connected by eight volutes to the heat exchangers.

The Lower Header

The lower header is connected to each of the eight circulating pumps and distributes heavy water to the fuel rods. Inserted into the upper face are bushings into which the lower end of the fuel assemblies are inserted. Most of the heavy water flows up through these assemblies, and leakage ports in the inserts provide a small flow into the moderator. A heat baffle is also provided for the lower header.

The normal flow of heavy water is into the lower header, through the reactor, and out through the volutes in the upper header. The flow-diagram is shown in Fig. 2.

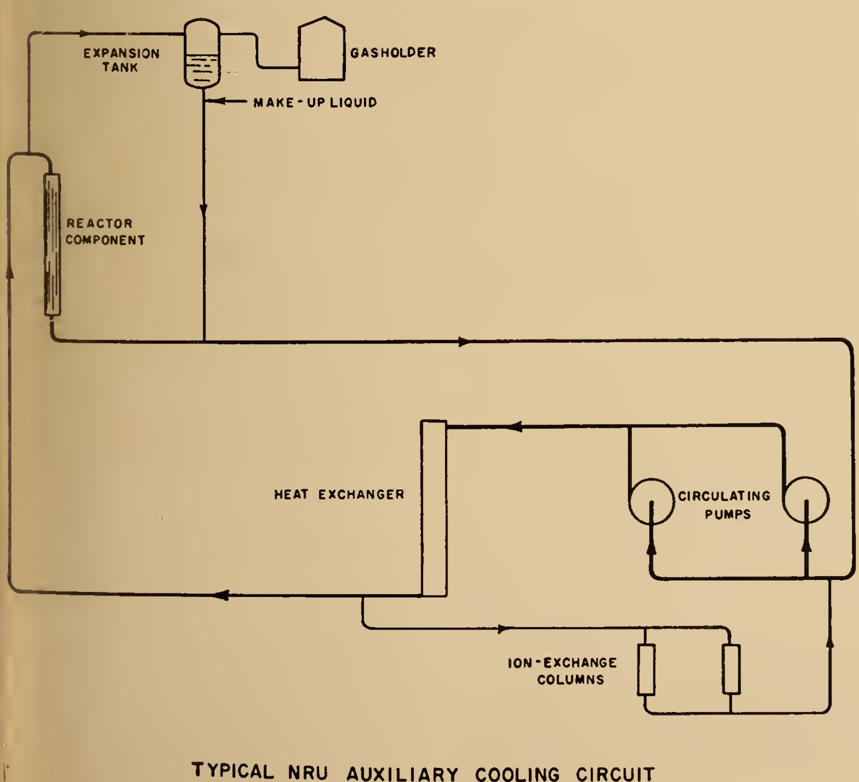
The Upper Shielding Sections

Three carbon steel shields, known as "boiler sections", supply the main shielding for the top of the reactor. The fabrication consists of two tube sheets into which are welded 406 vertical tubes, the whole being surrounded by a steel shell. Water is circulated through each section. The boiler sections provides 23 in. of steel plus 9 ft. 7½ in. of water shielding.

The lowest boiler section is also one of the main structural members. It is supported by three columns which are bolted to the base ring. With the base ring it supports the other boiler sections as well as the deck plate, the top header, the fuel rods, and all equipment associated with them.

As an added complication, the reactor was designed for a possible change-over to a pressurized vessel. If this is done there will be an upward thrust of 500 tons on the lowest boiler section.

Figure 3.



Side Thermal Shields

Outside the reflector of the reactor vessel there is a steel thermal shield, fabricated in sections of cast steel 12 in. thick. The sections slightly resemble barrel staves. Each is cooled by a flow of water across the inner face. The sections are fitted step-wise together, close enough to prevent radiation leakage but loose enough to provide for thermal expansion.

The Biological Shield

This surrounds the thermal shields. It is 9 ft. 6 in. thick and is made of high density concrete. Ilmenite ore and magnetite sand are used as aggregate. The resulting concrete has a weight of about 220 lb. per cubic foot.

Thermal Column

A major research facility provided is the thermal column. The purpose of a thermal column is to provide a large volume in which thermal or slow neutrons are present but very few high energy neutrons and little gamma radiation. To accomplish this the column is filled with closely-packed, high-density graphite blocks, forming a column which is approximately 8 ft. square at the inner end, expanding to 10 ft. 5 in. square as a maximum. It is 12 ft. long. The inner end is separated from the reactor by two thin walls of aluminum and a number of bismuth rods. These bismuth rods provide some shielding to reduce the gamma flux in the column. The column is surrounded by a series of castings which range from 12 in. to 15 in. thick. The castings are covered on the inside with a cadmium plating 0.040 to 0.060 in., plus ¼ in. boral plates. Boral plates are made of a mixture of boron carbide in an aluminum matrix, and the whole clad with 0.20 in. of aluminum on both faces.

The purpose of the boron and cadmium is to reduce the gamma radiation which would come from the steel surfaces if they were irradiated with neutrons. The bismuth rods and the steel castings around the thermal columns are water cooled. The graphite itself is air cooled.

Near the inner face of the column is a shutter made of lead about 2½ in. thick, with a surface of boral. On the outer end of the column is a lead shield, approximately 18 in.

thick, which has a boral inner liner.

Heat Exchangers

The design of the heat exchangers is a little unusual due to the high cost of heavy water. Some of the design parameters are:

(*a*) Heat to be removed: 200 Mw.
(*b*) Heavy water flow: 22,000 i.g.p.m.
(*c*) Pressure drop: 9 p.s.i.
(*d*) Temperature drop 48 deg. F.
(*e*) Heat transfer rate: 350 B.t.u./hr./ft.^{2}/F°.

The heavy water flow is inside from normal cooling systems for four reasons:

(*a*) When the reactor is once started, cooling must be provided unless the full charge of fuel elements is removed. The heat generated after the reactor is shut down one hour amounts to about 1% of full power.

(*b*) In the winter the cooling water from the river is near 33° F., so that there is danger of freezing the heavy water, which has a freezing point of 38.8° F.

(*c*) Heavy water is expensive ($28.00/lb.)

(*d*) During operation the heavy

(3) Four pumps are equipped with motors that can be run at half speed to permit reduced flow if desired.

(4) The above four pumps are also equipped with d.c. motors connected through over-riding clutches. In case of complete hydro power failure these motors will provide sufficient circulation for cooling with the reactor shut down.

The pumps themselves are centrifugal. Each is capable of delivering 2800 i.g.p.m. of heavy water against a head of 188 ft. Double mechanical shaft seals are used.

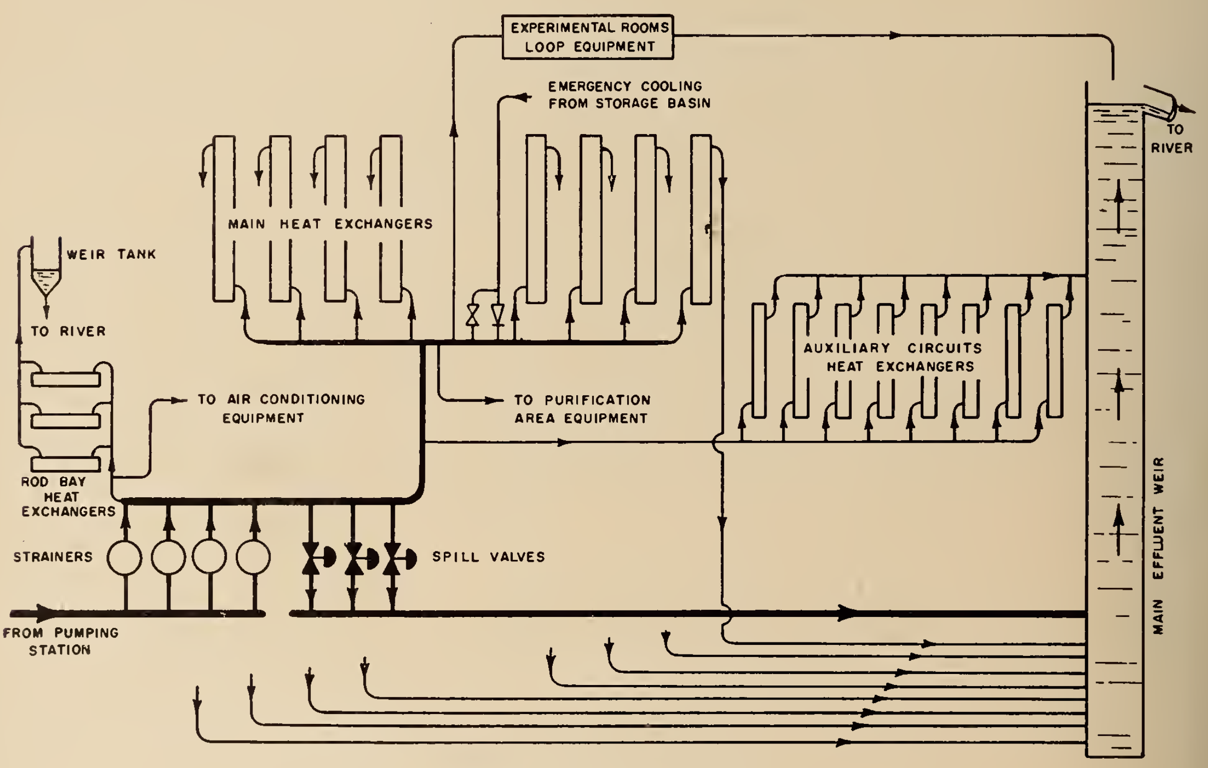


Fig. 4. NRU river water system.

the tubes with light water in the shell.

Number of coolers 8
Number of tubes per cooler 2869
Diameter of tubes ⅜ in. O.D.
Effective length 186 in.
Material Type 304 Stainless steel

Each end has a double tube sheet with a means of detecting leakage into the space between.

Heavy Water Circulating Pumps

There are eight heavy water circulating pumps. When any are operating, heavy water is circulated into the bottom of the reactor vessel, out of the top and through the heat exchangers. The maximum rate is about 22,000 g.p.m. (see Fig. 2).

The reactor cooling system departs

water emits gamma radiation due to the decay of N_{16} formed by neutron irradiation of O_{16}. At the same time some deuterium atoms give off neutrons under gamma radiation. As a result heavy shielding is required around the pumps and heat exchangers in the reactor system.

A number of precautions are taken to ensure that heavy water circulation is not interrupted.

(1) Power is brought into the plant from two sources — des Joachims and Bryson power stations.

(2) Half the pumps are powered from each station with switching gear so that if either source fails the whole load is taken by the other in three seconds. Flywheels maintain the motor speed during this period.

The following motors are used:

(i) Four two-speed motors: 250 62.5 h.p.; 1800/900 r.p.m.; 2300v 3-phase; 60 cycle.

(ii) Four single-speed motors: 25 h.p.; 1800 r.p.m.; 2300v; 3-phase 60 cycle.

(iii) Four auxiliary motors: 20 h.p 690 r.p.m.; 115v; d.c.

Research Facilities

The reactor and the thermal co umn are equipped with approximate ly 24 beam ports. These are tub or holes through the biological shiek to allow the passage of beams neutrons as required. (When not use the holes are plugged.) Also is possible to place materials or equi ment in these holes for irradiatio

A flux as high as 1.6×10^{14} neutrons/cm^2/sec. is available.

Materials can also be irradiated in the "J-rod" annulus. This is the space between the reactor wall and the water reflector. Materials to be irradiated in this space are inserted in rod form.

Provision is made for four pneumatically-operated tray rods — two in the J-rod annulus and two inside the reactor vessel. These tray rods are for the irradiation of small samples. There are forty positions in each.

Three rod positions are designed to allow tubes to run completely through the reactor. These tubes can then be connected to their own external cooling systems independent of the normal heavy water circulating system. Such a system is known as a "loop" and is used for testing fuel material and sheathing under temperatures, pressures, and neutron fluxes expected in power reactors.

Auxiliary Cooling Circuits

Nine auxiliary cooling circuits provide cooling for reactor components. Each of these circuits (see Fig. 3) is a closed loop so that close control may be maintained both on radioactivity and corrosion. The equipment is generally constructed of mild steel except in a few instances where heavy water cooling may be used or the piping is inaccessible. Stainless steel is used in these instances.

The systems cooled are: 1. Reflector. 2. Heavy water J-rod. 3. Grouped J-rods. 4. Bismuth rods. 5. Thermal shields. 6. Experimental hole gates. 7. Experimental hole plugs. 8. Interspace concrete. 9. Fuel rod monitors.

Each of these circuits requires high reliability. In the case of the rods, reliability must be equal to that of the main cooling system.

Heavy Purification System

It is necessary to maintain high purity in the heavy water used for moderator and coolant. A conductivity of 5 x 10-7 mho is the objective. At this purity the net rate of decomposition under irradiation to D_2 and O_2 is very low. Activation of impurities is low and corrosion is predictable.

To maintain high purity water only aluminum-stainless steel systems are used, and part of the heavy water is circulated through a degassing system, a filter, and a mixed bedion exchange resin.

Monitors are installed in the heavy water system to detect failures of fuel sheaths. A small stream from each rod cooling channel is analysed for both fission product gases and "delayed" neutrons. The presence of either indicates a failure in a rod sheath.

Helium Purification System

A gas is necessary to fill the voids in the system. Argon becomes very radio-active under irradiation and would increase the shielding requirements; nitrogen combines to form nitric acid; CO_2, SO_2, etc., form acids with the heavy water to cause corrosion or to load the resins. Helium is found to be the perfect gas for the purpose as it is completely inert.

Helium of high purity is desirable so as to reduce the radiation from activated argon or other radioactive gases, to help maintain the heavy water purity, and to reduce corrosion in the vapour phase of the system.

Impurities in the helium are removed by sorption on coconut charcoal at liquid nitrogen temperatures. Any heavy hydrogen in the system due to the decomposition of D_2O is recombined with oxygen using a catalyst. It is removed prior to the purification.

Reactor Ventilation

Air that is subject to neutron

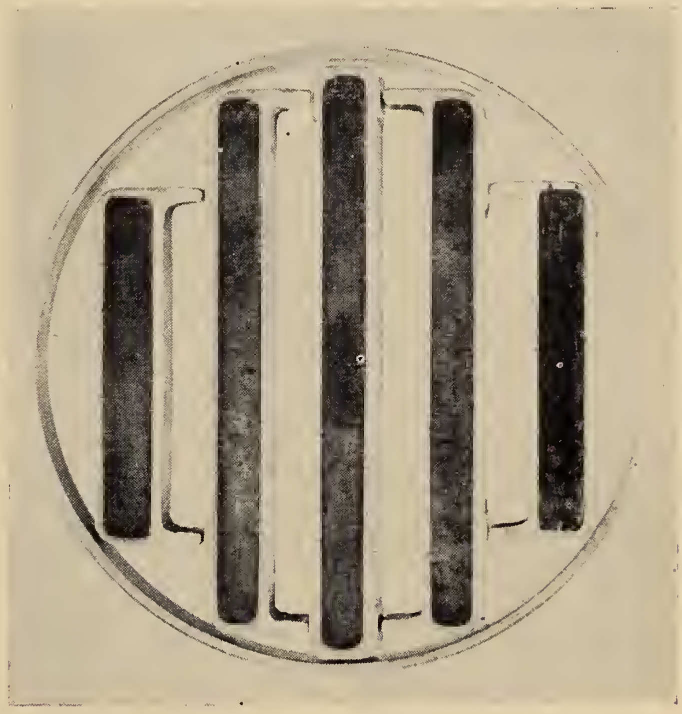

Fig. 5 (above) and Fig. 6.

bombardment becomes radio-active, chiefly due to the formation of argon 41 with a half life of 1.8 hours. Airborne dust can also become active, depending on the material. For this reason it is essential that there be no flow of air or gas from neutron fields out into operating areas. To prevent such a flow the interior of the biological shield is kept at a pressure slightly below atmospheric. This system is coupled with the air cooling that is provided in the thermal column.

About 10,000 c.f.m. of air is pumped from the combined system. This air is passed through "absolute" filters to remove dust and then is blown out of a stack which is on a hill half a mile from the reactor building. The top of the stack is 383 ft. above the main floor of the reactor building. Except under very severe atmospheric inversion conditions this provides sufficient dispersion so as not to interfere with sensitive experiments in any of the laboratories.

Further ventilation is provided in the building for removing any radioactivity which might be released from the surface of fuel rods after removal, from pump glands, from other leakage, or during maintenance work. The same disposal principle applies. Dust is removed on filters, gases are dispersed.

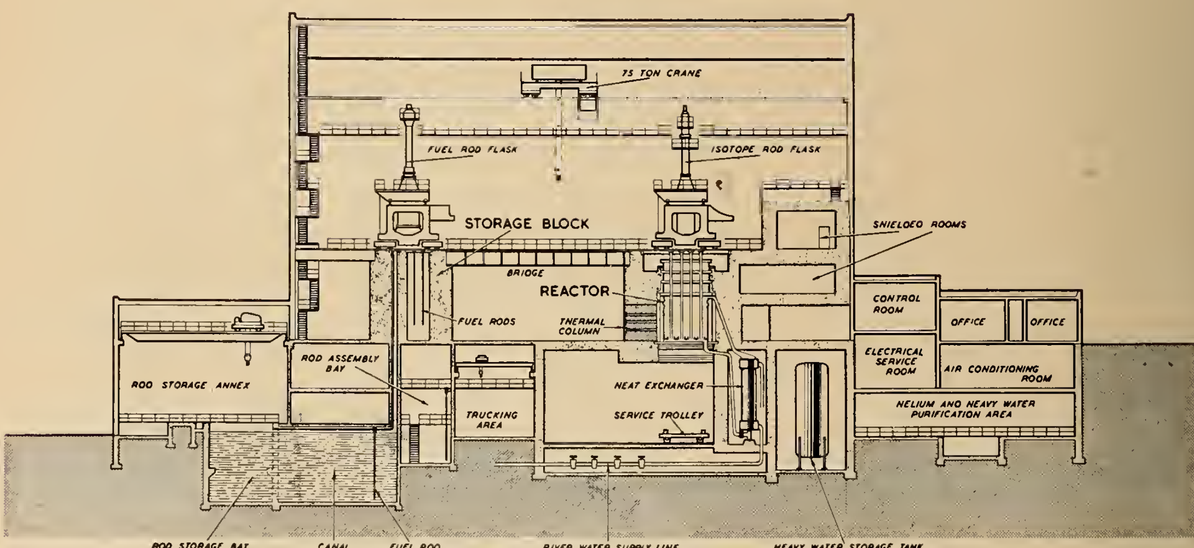

Fig. 7. East-West cross-section of NRU building.

Control System and Safety System

A reactor control system is of necessity complex. Four requirements must be met:

(*a*) It must be fast enough.

(*b*) It must be reliable.

(*c*) It must have a minimum of false signals.

(*d*) Each component in the reactor system must be checked according to its contribution to the hazard.

The main control of the NRU reactor is by the use of 16 neutron-absorbing rods. These rods serve the double purpose of control and shut-off. Under normal control, the rods are automatically operated to bring the reactor to a pre-set power and to maintain this power. Any failure in the system will cause all rods to drop in, hence shutting the reactor down. The reactor cannot be started until all hazardous conditions are removed. Such hazards as:

1. overpower;
2. too rapid an increase in power;
3. high temperature in the heavy water;
4. failure of cooling systems;
5. failure of electric power;
6. failure of fuel sheathing;

will cause the reactor to shut down. To provide reliability all instruments are "fail safe"; i.e., an instrument failure will be interpreted as a hazardous condition. This provides for safety of operation but does result in a number of false shutdowns.

To overcome false shutdowns many circuits have three instruments so coupled that it requires the identical signal from two to shut the reactor down. The arrangement not only reduces the incidence of false trips but also permits instruments to be inspected and removed for servicing while the reactor operates.

It should be noted that failure of any component in the reactor system could result in major damage; therefore it is necessary to have continuous instrumental inspection on over 250 systems. These include the overall reactor, each fuel element, all auxiliary circuits and most experimental units.

The large number of instruments requires a close balance between safety, costs, and continuity of operation. To provide the service considered necessary, there are 4,000 process instruments and 1,200 electronic devices.

Heavy water is not normally used to control the reactor, but if necessary the reaction can be stopped by dumping the heavy water from the reactor vessel and cooling can be maintained. (See Fig. 2.)

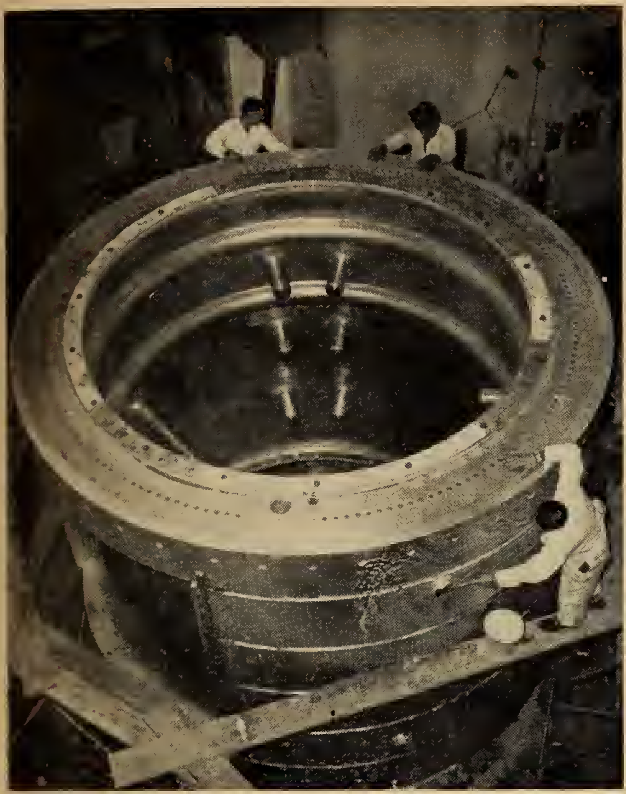
Services

Very elaborate services are required for an operation such as the NRU. The main systems are water, steam, air, vacuum, gas, electrical and mechanical.

Water — The main water supply is the process (or river) water which cools the heat exchangers in the reactor system. (Fig. 4). No treatment is given except to pass it through a 1/16 in. mesh strainer and to dose it periodically with chlorine for algae control. The flow rate is about 22,000 i.g.p.m.

In addition, service water is supplied for general use other than reactor cooling. It is chlorinated and contains corrosion inhibitors.

Clarified water is supplied to the



fuel rod storage bays. It may be treated for corrosion and algae control.

Chilled service water is circulated to various air conditioning systems. The air conditioning units are required in some areas to improve electronic instrument reliability.

Distilled water is supplied for the rod handling equipment other than the main storage basins. It is also used for make-up in the auxiliary services.

Steam — is supplied for heating the building, for hot water, and as one of the services in laboratories. It can be used to drive a fan in the reactor ventilating system and a process water supply pump.

Compressed air — is supplied and distributed throughout the building at various pressures for instruments, laboratory service, cooling of reactor samples and to supply air masks when required. Both normal and oil-free air are available.

A service vacuum — is distributed to experimental and maintenance areas. The main receiver is held at 26 in. of mercury below atmospheric.

Propane gas — is also distributed to experimental and maintenance areas.

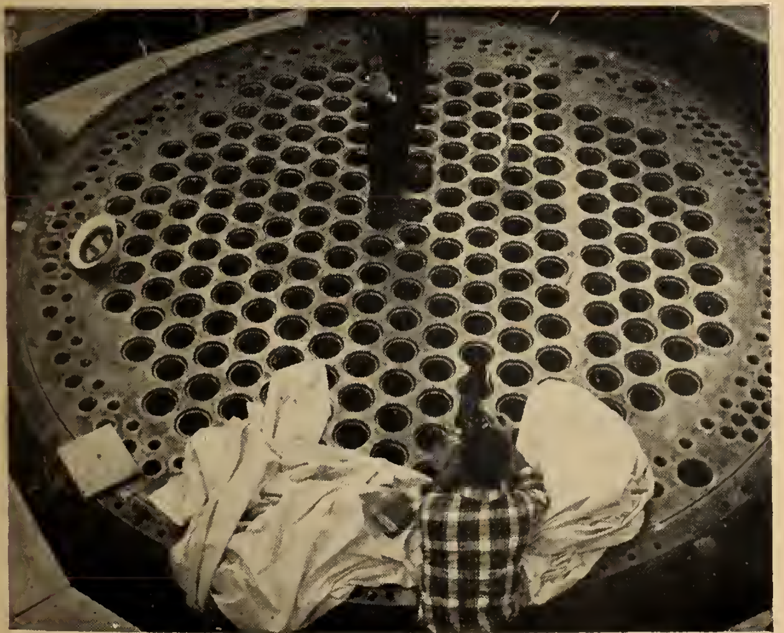
Power — is supplied to the plant at 120 kv. from two feeder lines — one each from Bryson and des Joachims. Part of the load is taken from each feeder. In case of failure of one, the whole load is placed on the other within three seconds.

In addition to the variety of voltages, there are four main power systems:

Class I — 125v. d.c. supplied by rectifiers and having two batteries riding on the line. Each battery consists of 60 two-volt cells.

Class II — 600v. a.c. supplied by d.c. motor generators. The d.c. motors use Class I power.

Class III — 600v. a.c. coming from the Hydro supply but backed



Top left: View of reactor vessel side walls complete with reflector tank. Expansion corrugations, re-entrant cans, and part of one through-tube can be seen. *Top right*: Installing permanent tubes. These are rolled into the top tube sheet and seal welded. These tubes extend through the boiler sections and are supported by springs in a plate resting on the uppermost boiler section. *Left*: View of the middle boiler section. The split in the lattice is where the experimental through-tubes pass between the rods.

up with diesel-generated power. The diesels start automatically if the Hydro power fails completely. The rectifiers for the Class I and II power are supplied by the Class III system.

Class IV power supplies a.c. power to the remainder of the system. The majority of the load is carried by the Class IV system.

The total power demand for the reactor can be 5,550 kva. An added 2,000 kva. may be required to operate experimental loops.

Cranes — Because maintenance involves the movement of heavy shielding and equipment there are 15 cranes in the building. The largest of these are a 75-ton crane in the main room and one 50-ton in the fuel rod annex. There are also seven monorails with numerous hoists.

Communications — In addition to the normal telephones, a private automatic exchange is installed. A public address system permits persons to be called and instructed in all parts of the building. Normally instructions for operational changes are given in writing. A pneumatic carrier system is installed to take messages from the control room to key points in the building.

Fuel Handling and Storage

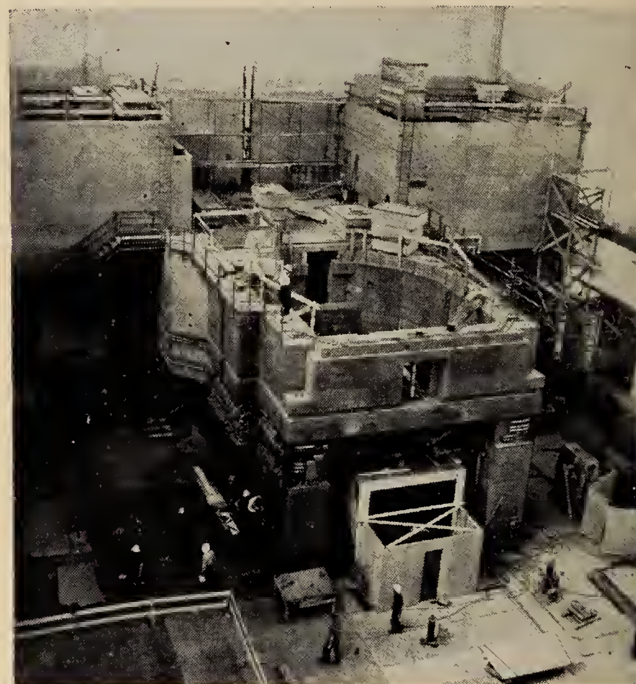
Uranium fuel clad in aluminum and in an outer tube (see Fig. 5) will be delivered to the assembly room in the NRU buildings. Here it will be assembled with the complete top section and flow tested. When installed, the top section fills the tube from the deck plate to the top header. When needed the rods are taken to the top of the storage block in the main reactor hall and inserted in drying tubes, in which the last traces of water are removed. A rod may then be picked up by the main flask, taken to the reactor and exchanged for an irradiated rod in the reactor.

The irradiated rod is transferred by way of the storage block to the storage bay. The top end, including the orifice section, is cut off and stored until most of the activity has decayed. The bottom or fuel end is held in storage for about 6 months before shipment.

After the radio-activity of the top section has decayed sufficiently it is taken apart. The components are decontaminated and inspected for reuse. If suitable they are sent to the rod assembly area.

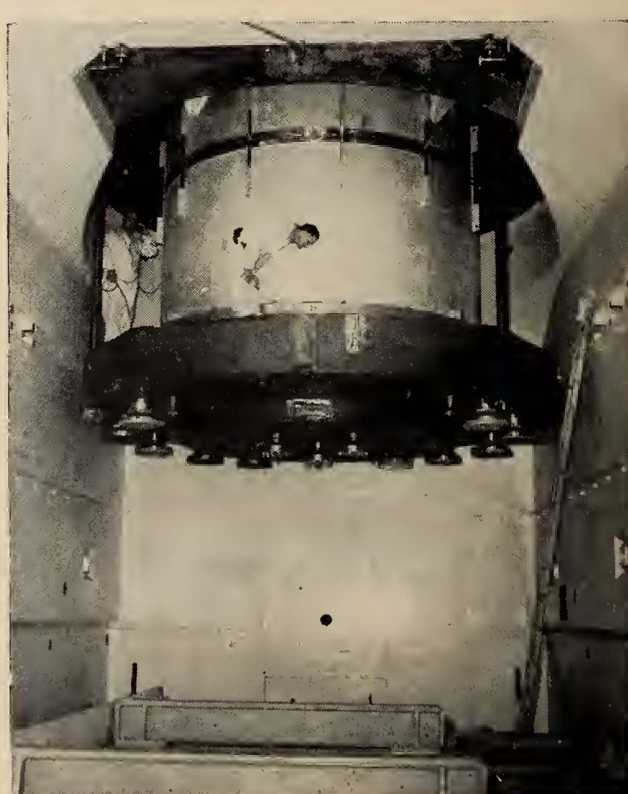
In addition to the uranium fuel rods, provision is made for other rods that go into the reactor or the annulus between the reactor vessel and the reflector. These are the control-shut-off rods, thorium rods, bismuth rods, and other special irradiations. Equipment is provided to assemble, test, install, remove, and store all these.

The transfer flask for irradiated fuel rods has a complex task. It must have the mechanical devices for mak ing the removal remotely and mus provide adequate cooling at all times the transfer from heavy to light wate must be done with a minimum loss o heavy water; and the whole operatio must be shielded to prevent hazard from both gamma and neutron irrad



Above: **Reactor hall during early stages of construction.**

Below: **Lifting a test reactor vessel into place. Bottom header and upper bottom shield are included.**



ation. The resulting flask weighs 240 tons. A second flask weighing nearly as much handles other type rods. Both of these are mounted on the rails above the reactor. (Only one shows in Fig. 1.)

Provision is made in the storage block for storing a complete charge of reactor rods in cooled, distilled water. Rods stored in this position may be returned to the reactor.

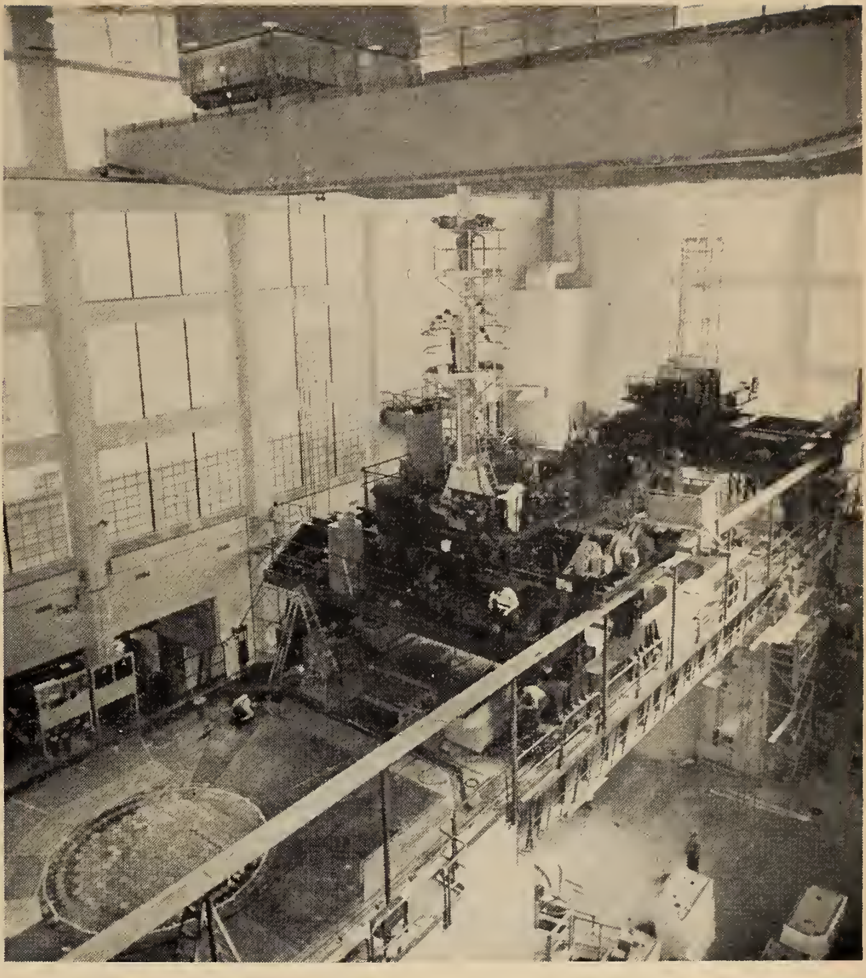
Fuel Rod Design

The heat output of an NRU fuel rod can be as high as 1.52 megawatts or an average of 152 kv. per linear foot. The vertical flux, however, is distributed according to a sine function. Therefore, the peak heat output is 238 kv. per linear foot. To provide sufficient surface for cooling, the rod is constructed of five flat plates. The plates are clad in aluminum and enclosed in a tube. A cross section is shown in Fig. 5. At a reactor power of 200 Mw., the maximum heat transfer rate is about 500,000 B.t.u./ft.²/hr.

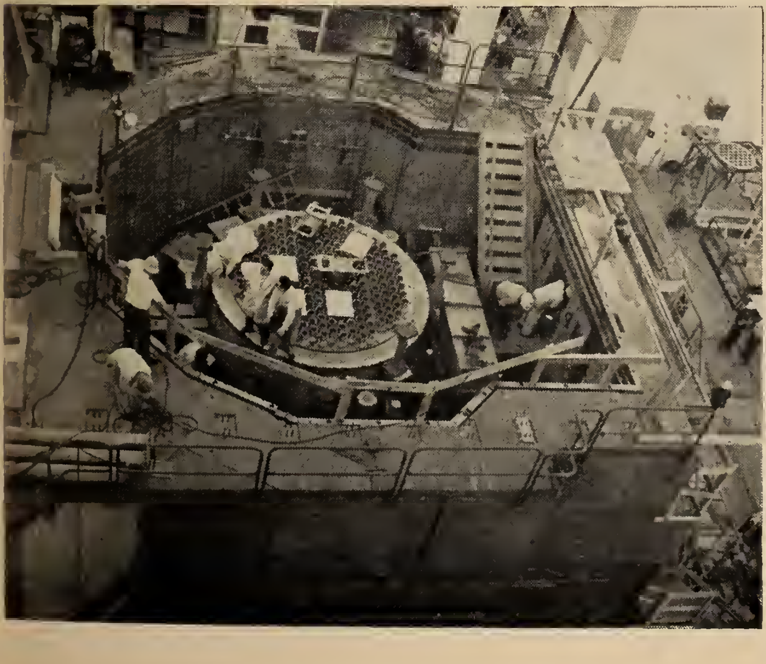
The Building

The building is constructed of brick walls on a steel framework. (Fig. 6). The main hall, which is 175 ft. long, 100 ft. wide, and 87½ ft. high, houses the upper part of the reactor and the storage block. (See Fig. 7.) Two side wings provide space for physics laboratories; one end wing houses the control room, change rooms, and offices; the other end wing houses the rod storage.

There are three basement levels containing service equipment, heat exchangers, building ventilation equipment, heavy water and helium purification equipment, as well as service and research laboratories. The total volume of the building is 4,100,000 cu. ft.



***Above*: An interior view of the NRU installation taken in April, 1957.**



***Below*: A view into the top of the reactor showing boiler sections and tubes leading to the upper tube sheet.**

Interior surfaces are generally painted to permit easy decontamination if such should be necessary.

The first reactor to operate in Canada, the ZEEP, became critical in 1945; the second, the NRX, in 1947. Both of these reactors have operated at capacity since. It is expected that they will continue to do so. NRU will supplement and extend the range of nuclear studies both theoretically and practically.

Original design studies were done by members of the staff of Atomic Energy of Canada Ltd. (at that time a division of the National Research Council of Canada).

Engineering has been done by the C. D. Howe Co.; Foundation Company of Canada are the prime contractors. Comstock of Canada subcontracted the electrical and instrument work. Hundreds of other firms contributed.

The Latest Prospects for Economic Nuclear Power

W. K. Davis and L. H. Roddis

Director, and Deputy Director, Division of Reactor Development, U.S. Atomic Energy Commission

Presented at the 5th Atomic Energy in Industry Conference of the National Industrial Conference Board, Philadelphia, March, 1957

WE HAVE been asked to look into the future of nuclear electric power in the United States. We are in a position much like that of the weatherman preparing a forecast for your daily paper. He looks at various signs and portents. He has trained himself to understand them as best he can. Some of the portents point one way; some point another but his audience isn't interested in his reasoning. They want his single best judgment, as you presumably want ours.

We trust this parallel with weather forecasting won't apply too literally. We are reminded of a test conducted by a friend who made trial weather forecasts for the Boston area for a year by use of random numbers. He then calculated the correlation with the actual weather, both of his forecasts and those made by the local weatherman, and — you guessed it — the random numbers achieved slightly better results. We refer to this experience merely to let you know how keenly aware we are of the perils of forecasting and of the widely different forecasts which different people may arrive at after looking at the same portents. But we have been asked for our forecasts of the nuclear climate ahead and here they are.

We have made estimates both as to the costs and the amount of nuclear power. Let us consider these in turn.

Costs of Nuclear Power

The cost levels expected to be achieved by large nuclear power plants going into service at various times during the next twenty-five years are shown in the descending shaded area drawn on Chart A (attached). There are numerous complexities involved in talking about power costs, whether nuclear or conventional. It is not our wish to go into many of these here. However, it is necessary to arrive at some sort of a working definition of what we mean when we refer to nuclear power costs over a period of time, especially in relation to their competitiveness with costs from conventionally fuelled plants.

An essential point to remember is that a company which may be considering whether its new plant should be nuclear-fuelled or fossil-fuelled is interested in the cost performance of the plant over its useful life, not just at the start. Thus, the decision might be to build a nuclear plant even though it is not likely to be competitive at first because it seems inevitable that nuclear fuel costs will decrease over the next thirty years or more while conventional fuel costs seem likely to increase — slowly, we hope. Even if comparison over the life of the plant favours conventional fuels on the basis of best present-day cost estimates, a nuclear plant might be selected as a hedge against the possibility of unusually large future increases in conventional fuel costs.

We have attempted to illustrate some of these considerations on Chart A. In addition to estimates of power costs from large nuclear and conventional plants, shown in the shaded bands, there is an illustration regarding the factors underlying the decision to build a hypothetical nuclear Plant X.

A given utility may be interested in authorizing design and construction of the plant at time A shown on the chart. This plant will not actually come into operation until time B, three or four years later. As shown, intitial costs of operation at time B will be high due to the special problems involved in start-up of nuclear reactors. It is expected that costs will stabilize at a lower level after two or three years of operation, i.e. at time C as shown on the chart. Presumably this cost was predicted with a fair degree of assurance before the project was authorized (time A).

We have attempted to predict such stabilized costs as a function of the times when the various plants come into initial operation. This is indicated by point "X" on the chart. Such points are the ones to which we have reference in the cost estimates presented here and in the descending shaded band on the chart.

Following achievement of stabilized costs at time C, there is likely to ensue a long term slow decline in costs for Plant X, as shown by the Plant X line on the chart, due to a lower nuclear fuel cost. As indicated earlier, anticipation of such lower costs might prove influential in the decision to build the plant.

Let us now consider the stabilized costs expected to be achieved by large nuclear plants in general. In thinking of the genealogy of nuclear power we consider the plants which will go into service during the years 1957 through 1959 to belong to an experimental period during which there can be no hope of achieving costs competitive with modern conventionally fuelled plants in the

United States. Costs achieved by these early plants may range from about 20 to as much as 50 mills per kilowatt-hour.

The years 1960 to 1964 will bring what we consider to be the first generation of true industrial nuclear power plants. These plants will build on the technology and experience accumulated in the design, construction and operation of the earlier experimental plants, and may be expected to achieve lower costs.

As can be seen on Chart A, however, we do not expect plants in the first generation to produce power at costs competitive in the United States with the most advanced conventionally fuelled plants. Our estimate is that first generation nuclear plants, after their initial shakedown period, will achieve costs in the range of 10 to 13 mills per kilowatt-hour. We are assuming 1957 price levels, of course. Our estimate compares to present costs of electricity from modern coal-fired plants which are as low as 4½ mills in especially low cost fuel zones and range up to 9 mills in other areas. As of 1964 the costs from new coal-fired plants may have changed slightly but should still be in this approximate range.

Table 1. Nuclear Power Plants Expected to be in Operation by End of 1959

Name	Location	EKW (Thousands)
Federal Government-owned		
Pressurized Water Reactor (PWR)[2]	Shippingport, Pa.	100.0[1]

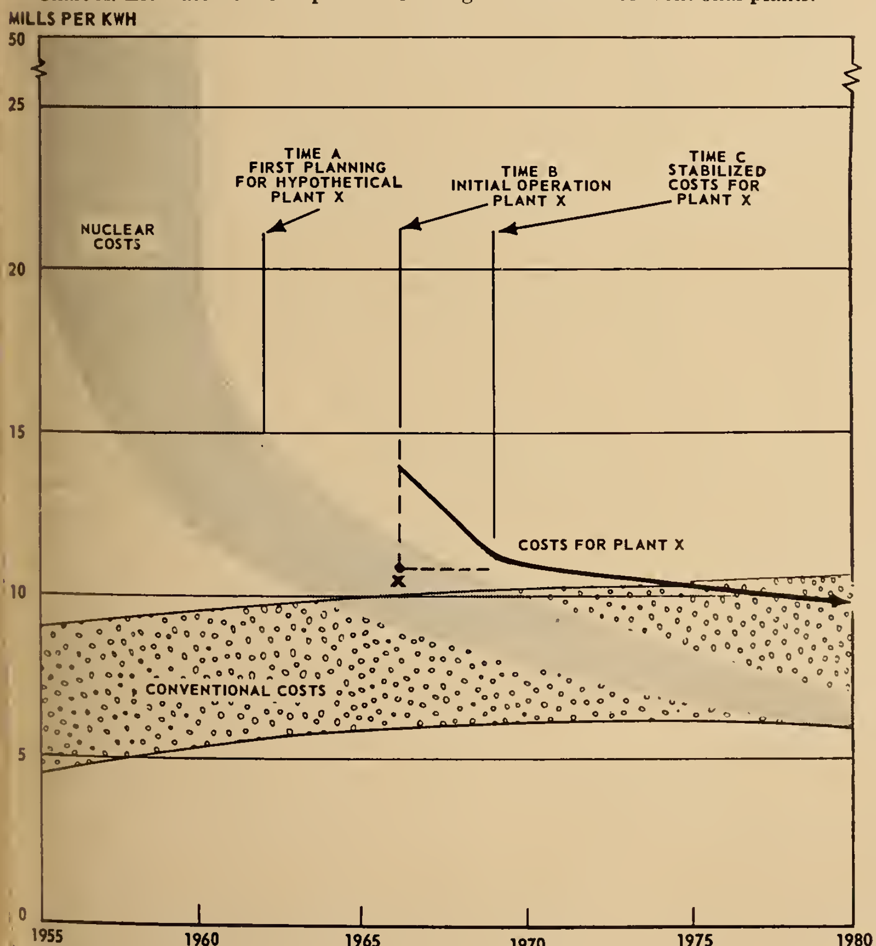
Argonne Low Power Reactor (ALPR)	NRTS, Idaho	0.2
Privately Owned		
General Electric Co. & Pacific Gas and Electric Company	Livermore, Calif.	3.0
Total electrical kilowatts (thousands)		133.7

[1]Represents approximate expected capacity of second core. First core is expected to produce 60,000 EKW.
[2]Electric generating portion of plant privately owned.

The estimated discrepancy as of 1964 between power costs from nuclear plants and modern conventional plants is accounted for both by first capital costs and by operating costs, including primarily fuel cycle costs.

Capital costs for first generation nuclear plants are expected to range from $300 to $400 per kilowatt of capacity compared to costs for coal-fired plants which vary from about $115 to $180 per kilowatt, depending on location. Factors keeping nuclear plant costs high in this first generation include high costs for obtaining safety at a time when little factual information is available and the use of expensive materials because of lack of experience with cheaper substitutes.

Chart A. Estimated costs of power from large nuclear and conventional plants.



High fuel cycle costs may be expected for the first generation plants because of high fabricating costs and relatively short-lived fuel elements. A recognition of the importance of lowering fuel cycle costs is implicit in the terms of the third invitation under the Power Demonstration Reactor Program, which provide that assistance may be offered for research and development on fuel cycle problems as well as on the reactor plant itself.

Costs achieved from first generation nuclear plants may be low enough to be attractive in some countries abroad. The experience gained in supplying the foreign market will be a great help to American manufacturers in achieving further domestic cost reductions.

We consider a second generation of nuclear plants to be those which will go into service between 1965 and 1967. Capital costs for these plants may be expected to approach a competitive level with increases in plant size, more knowledgeable approaches to safety needs. and less costly materials. Fuel fabrication and fuel life problems may still require further solutions. Nevertheless, plants going into service toward the end of this generation, after their initial shakedown, should achieve costs in the range of from 9 to 11 mills. Considering the further cost reductions to be expected during the lifetime of the plants, they should be competitive with modern conventional plants in at least some parts of the United States.

Following the second generation, as Chart A indicates, we estimate that further cost reductions will take place, reaching a range of 6 to 7 mills by 1980. This would make nuclear power competitive with conventionally fuelled plants in all parts of the United States except a few locations with very low fuel costs.

Amount of Nuclear Power

By the end of 1959, we expect ten experimental plants to be producing nuclear power. Only one of these, however, the Shippingport pressurized water reactor, is a large scale plant, and our estimate of total nuclear generating capacity as of the end of 1959 is the order of only 130,000 kilowatts. These first nuclear plants with their expected outputs are listed in Table I, attached.

Intentions regarding certain of the installations for the years 1960 to 1964, which we consider to be the first generation of nuclear power plants, have already been announced. Other announcements are expected. We think some will undoubtedly come in response to the Commission's third invitation under the Power Demonstration Reactor Program which, among other requirements, specifies that proposals must be for plants able to produce power by June 30, 1962. Some additional plants may be built entirely with non-AEC financing, some entirely with AEC financing.

The first generation plants announced as of the end of February are listed in Table II. Adding to these the PWR and other experimental plants of 1957-59 vintage, and allowing also for an estimate of other plants as yet unannounced which may be undertaken for installation before the end of 1964, we have estimated a total installed nuclear capacity at that time of about 2.5 million kilowatts.

Toward the end of this first generation it is felt that a turning point may occur when a fairly large number of power producers and equipment manufacturers will become confident that plants can be planned and designed which will be economic when built and successfully operated over a long period of time during which coal and oil prices would be increasing slowly. This turning point may be partially psycholog-

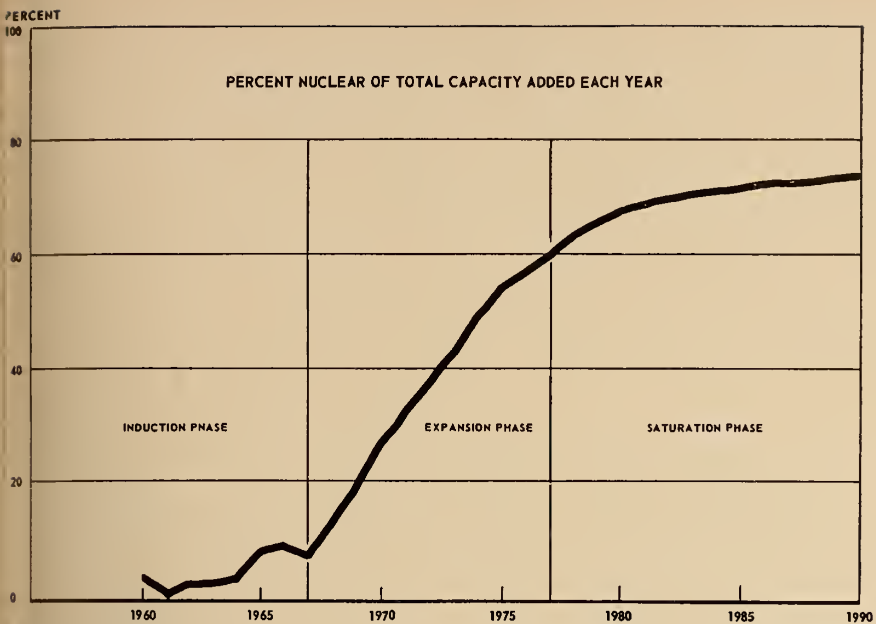
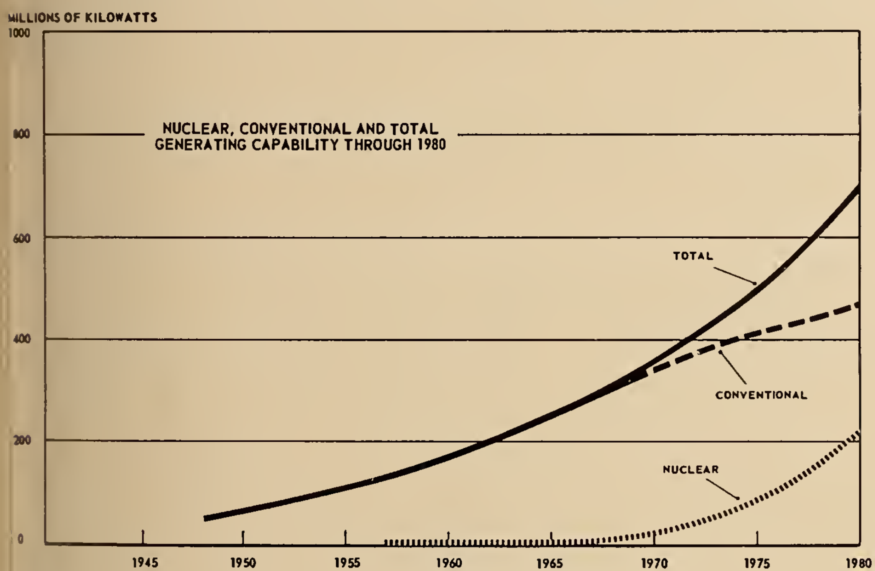
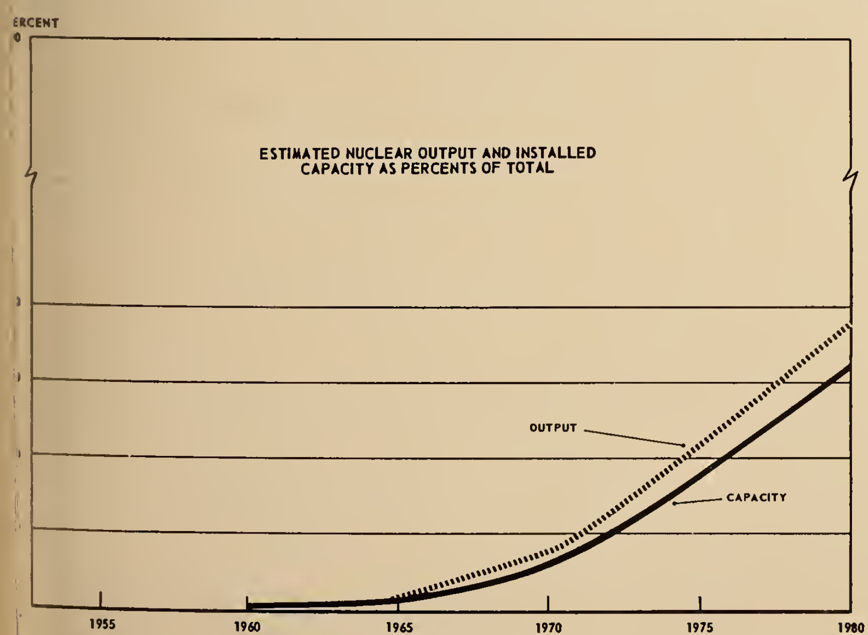
[1]Repeated in testimony at 1956 Section 202 Hearings before Joint Committee o Atomic Energy.







ical in nature, although based to a considerable extent on scientific and engineering judgment.

Because of the lead time required between first planning and final completion of a nuclear power plant, several years will elapse before this turning point takes effect. After this period of time, however, we expect that the percent of total installations which is nuclear-fuelled will begin to increase. We conceive the curve of nuclear installations as percents of total to appear as represented in Chart B. It will be seen that an expansion phase is expected beginning in 1967 when added nuclear capacity is estimated as 8 per cent of total additions. Thereafter, this percentage should begin to increase sharply until in 1980 two-thirds of all capacity added will be nuclear. Thereafter the rate of increase may be expected to decline as a near-saturation point is reached. The non-nuclear portion may be expected ultimately to hold steady at about 25 per cent of capacity added each year, in the form of hydro plants, very small plants or plants located where fossil fuel costs are very low.

On the basis of these key expectations it has been fairly simple, with some further assumptions, to arrive at estimates of installed nuclear capacity for various dates in the future. The derivation of these results is shown in Table III.

The estimates shown in column 1 of the table for total capability are based on forecasts made in September 1956 by *Electrical World* Magazine. Those forecasts carried through 1970 and we have extrapolated them through 1980. It should be noted that this *Electrical World* forecast is at a higher level than those which have been made before and which formed partial bases for previous AEC forecasts about nuclear power.

As will be seen on Table III, we arrive at estimates of nuclear capacity which may be summarized as:

Estimated Nuclear and Total Utility Generating Capability (1955-1980, in millions of electrical kilowatts)

Year	Total Capability	Nuclear Capability	Nuclear as % of Total
1955	116.3	....	......
1960	175.3	0.8	0.5
1965	251.7	4.0	1.6
1970	360.3	22.6	6.3
1975	500.0	88.9	17.8
1980	700.0	227.2	32.5

These results are seen in Chart C.

Charts B, C, D (top to bottom).

Our forecasts of *energy* output from nuclear plants involve slightly higher percentages of totals than do the above capacity estimates. This is shown in Chart D. The reason for the difference is that nuclear plants may be expected to operate at higher average load factors than the average of conventional plants. The estimates for output at specified years are as follows:

Estimated Nuclear Output Related to Total Utility Output
(1955-80, in billions of kilowatt hours)

Year	Total Utility Output	Nuclear Output	% of Total	Average Load Factor
1955	546.3	....	....	....
1960	811.9	2.4	0.3	60%
1965	1175.8	22.8	1.9	80%
1970	1700.1	133.9	7.8	80%
1975	2400.0	526.3	21.9	75%
1980	3400.0	1285.9	37.8	70%

Our estimates of long-range future nuclear capacity and output are somewhat higher than those we made two years ago and substantially higher than those made by some of our fellow forecasters. Table IV compares some of these estimates.

To a large extent, these higher estimates are explained by higher expectations regarding total utility installations, both nuclear and non-nuclear. In the percentage of total capacity added each year our estimates are more nearly comparable to those made by others, as shown in Table V.

Table V. Forecasts of Nuclear Additions Each Year as per cent of Total Additions 1965-1980

	1965	1970	1975	1980
Current Estimate	8	26	53	67

Conclusion

This is a period of some discouragement with respect to the cost of building and operating power reactors. After the excessive optimism of two or three years ago, we are at grips with the hard realities of developing and building real nuclear power plants. This does not turn out to be an easy task. There are many difficulties and the way ahead is not wholly clear.

However, just as it was unfortunate to have had this over optimism two or three years ago about 4 and 5 mill nuclear power, it would be equally unfortunate to let the present frustrating but not unexpected engineering difficulties lead us to undue pessimism about the future of nuclear power in the United States.

Some years from now, we believe that nuclear plants will have higher capacities than the present conservative designs permit and that they will be built more simply and more cheaply. We believe also that we will find ways of making fuel elements of long life cheaply and with adequate reliability. Some of this, perhaps the major part, will be accomplished simply by dogged engineering development work. The rest will come from the new ideas and inventiveness which have ever characterized the advance of technology in the United States.

These advances will take time, money, facilities, and, most importantly, they will require the best engineers and scientists working in the most effective manner. We acknowledge that in the light of present day knowledge the estimates we have presented may appear optimistic. They depend upon vigorous and successful prosecution of the present development program. They assume a fertile climate for the growth of a nuclear power industry in the United States. The history of similar developments in the past fully justifies our optimism.

We must be realistic about the task that lies ahead and the problems which must be solved. Let us be optimists — but realistic optimists. We believe that the task can be and will be accomplished.

Proceedings of the 1957 Nuclear Congress

(Special Rate to E.I.C. Members)

The Proceedings of the 1957 Nuclear Congress, held in Philadelphia, Pa., in March, is to be available on 15 August in three volumes. The regular publisher's price is $45, but the American Society of Mechanical Engineers (the managers of the Congress), in view of the publication date of this issue of the *Engineering Journal*, have extended to members of the Engineering Institute of Canada (a sponsor of the Congress) the opportunity of obtaining these Proceedings at the pre-publication price of $35, if they apply through the Engineering Institute before 30 August, 1957.

There are two volumes covering Advances in Nuclear Engineering, and one volume on Hot Laboratory Operation and Maintenance. These are concerned with the following subjects:

Advances in Nuclear Engineering

Volume I (62 contributions) — Manufacture, production, recovery, and economics of nuclear fuels; spent fuel processing; plant containment concepts and design; plant components; waste disposal; protection and safety measures; radiation processing.

Volume II (73 contributions) — Reactor design; reactor core design; operation and maintenance of reactors; metallurgy; heat transfer and heat evolution; educational uses of reactors; standardization planning in the nuclear field.

Hot Laboratory Operation and Maintenance

Volume III (61 papers) — Equipment for hot chemical, physical, mechanical, and metallurgical operations; hot cell installations; hot laboratory facilities; operation and administration; specialized hot operations.

A resume of the international outlook for atomic power and the highlights of the 1956 meeting of the American Nuclear Society are also given.

(A list of the papers given at the Congress appears on pages 1139-1140 of this issue.)

Remote Handling Facilities at Chalk River, Ontario

A. S. Bain

Atomic Energy of Canada Limited, Chalk River, Ont.

A REMOTE CONTROL handling cell was built by Atomic Energy of Canada Limited at Chalk River, Ontario to complement a program of (a) fundamental research on the effect of radiation on the properties of materials, and (b) the development of fuel elements for future reactors. The cell was installed when the metallurgy building was constructed in 1954. Active operations commenced in October 1955.

Description of Cell

A general layout of the cell and surrounding rooms is shown in Figure 1. Figure 2 is a photograph showing the front face of the cell and, on the right, a horizontal flask being fitted against the loading port on the end of the cell. Figures 3 and 4 show the construction details more fully.

The room in which the cell is ocated is 21 ft. wide, 36 ft. long and 24 ft. high. The floor of the room is six inches of concrete covered with asbestos tile. The pressure in the oom is maintained slightly lower than hat in the corridor; i.e. there is always a flow of air into the room. The xhaust air from the room is not filtered, but passes directly into the main ventilation ducts of the metallurgy building.

The inside dimensions of the cell re 10 ft. long, 6 ft. deep and 12 ft. igh. The front and side walls are menite concrete two feet thick. The oncrete was poured into a welded ame of ⅜ in. mild steel plate, nd the steel left in place after the our. The back wall is an eight inch ick steel plate in which there is a ft. high by 6 ft. wide opening. The of of the cell is reinforced ilmenite oncrete, one foot thick. The ilmenite oncrete, of density approximately 3.3 gm./cc. was made by adding ilmenite, $FeO.TiO_2$, and magnetite, Fe_3O_4, to a concrete mix, and it has the chemical composition shown in Table I.

The floor of the cell is one foot of ordinary concrete poured on bedrock This is covered with a ½ in. thick mild steel plate which is welded to the inner walls of the cell. In a rear corner there is a 15 in. diameter by 12 in. deep sump.

There are two 8 ft. high by 4 ft. wide by 8 in. thick steel doors covering the opening in the back wall. These doors, each of which weighs 5¼ tons, slide together manually and meet in the centre in a tongue and groove joint.

The construction, operation, and approximate cost of an intermediate level remote control handling cell are reported in this paper. Shielding experiments using Co^{60} sources are described.

The four windows are made of dense, 3.3 gm./cc., non - browning glass. The two front windows are both made in a stepped construction of three sheets, each 8 in. thick. (See Figures 3 and 4.) The largest, or inside, sheets are 35 in. x 40 in. The window on each end is 24 in. x 34 in. x 18 in. thick, constructed of two sheets 9 in. thick. All the windows are mounted dry, (without oil seals or moisture traps). All windows are covered, inside and outside the cell, with a ¼ in. thick sheet of lucite.

Table I. Chemical Composition of Ilmenite Concrete

	wt. %
Fe	39.5
Ti	14.7
O	35
Si	3.5
Al	2
Ca	3
Mg	1.5
H + C	<1

Spaced at intervals around the walls are thirty horizontal holes of 4 inch diameter, and two holes of 9 in. diameter (See Figures 3 and 4). The holes were formed by welding lengths of 4 in. or 9 in. pipe in the steel frame before the concrete was poured. Normally the holes are kept plugged with 24 in. long cylinders made from two inches of lead plus twenty-two inches of aluminum. The cylindrical plugs can be removed to extend operating mechanisms through the cell wall. Some of the cylinders have spiral grooves milled in them to bring electrical leads or flexible tubing through the wall.

Illumination is provided by sodium vapour lamps. There are eight 140-watt bulbs and six 45-watt bulbs. In addition, six incandescent lamps are connected to an emergency power supply.

There are three exhaust ducts in the cell, one on the ceiling and two half way down the wall in the rear corners. The system is exhausted by a 1000 c.f.m. fan. The exhaust air passes through an absolute filter immediately after leaving the cell and then enters the main ventilation ducts of the building. In addition, there is a complete stand-by system which operates on emergency power, and is wired to start automatically whenever the other fan is shut off. This emergency system, which is exhausted by a 250 c.f.m. fan, branches off the regular cell ventilation system through a separate filter and exhausts to the atmosphere.

The services for the cell are contained in a panel which runs along the front and two side walls. Services available are 110 volt and 220 volt normal power, 110 volt emergency power, 110 volt direct current power, high pressure air, water, steam, and propane gas. There are no service outlets inside the cell.

---

ad at the 1957 Nuclear Congress, Philaphia, Pa., (see pp. 1128, 1139)

The cell is equipped with one pair of Argonne model 8 master-slave manipulators. The through tubes are mounted at a 28 in. centre-to-centre distance on a three inch thick steel plate which can slide across the front of the cell.

At one end of the cell a through-the-wall stereomicroscope-camera is installed. It is possible to view specimens at magnifications of from 1x to 90x, or to take stereo-photographs on a 5 in. x 7 in. film plate. Specimens are mounted on a staging which is directly below the objective lenses of the microscope. The staging is used for focusing and locating the specimens. There are five separate motions, all of which are controlled by the operator as he looks through the microscope.

A half-ton pneumatic hoist is installed inside the cell on a two-way moving trolley.

The inside surface of the cell is coated with a heavy layer of paste wax, then lined with polythene sheet.

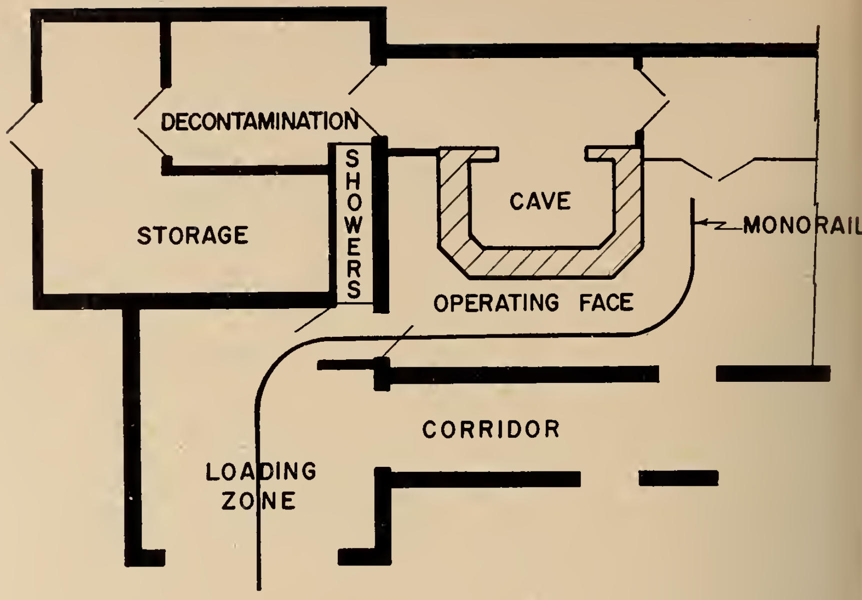

Figure 1.

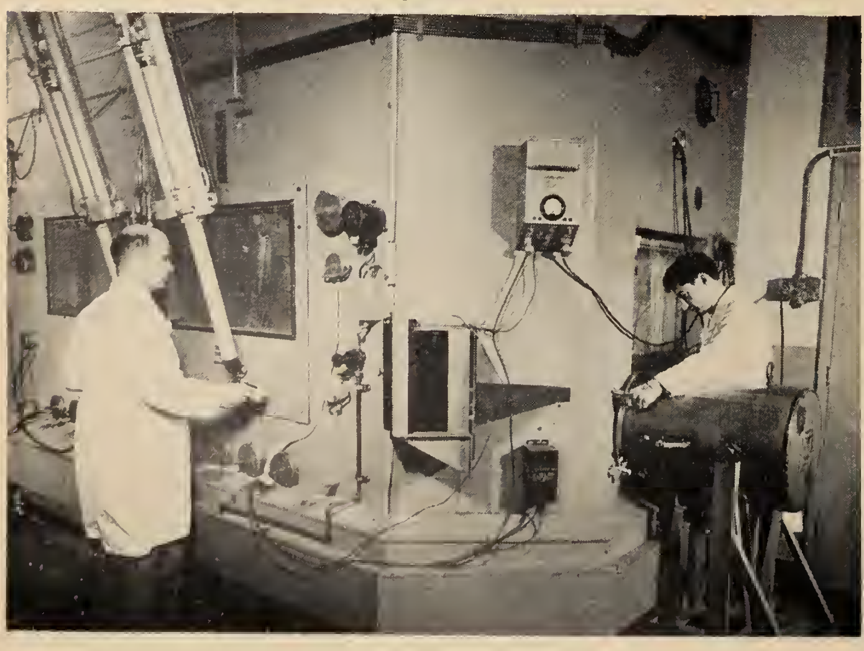
Procurement and Transportation of Samples

Specimens which are examined in the cave have been irradiated in the NRX reactor. This reactor and its radiation facilities are described by Hurst & Ward.[2] Connected to NRX is a system of trenches in which fuel rods are handled, desheathed, or sectioned under ten feet of water. In these trenches, specimens for examination are removed from their in-pile components and put into the drawer of a lead-filled flask. The flasks are lifted out of the water, allowed to drain, then brought by truck to the metallurgy building. A hoist and monorail are used to transport the flask from the unloading platform to the unloading port at the end of the cell. The drawer, which has six inches of lead shielding on each end, is pushed from the flask, through the wall of the cell and on to a shelf inside the cell. The specimen is then removed from the drawer with the manipulators. Two different flasks, both of which will fit against the unloading port, are available: one has six inches of lead shielding and will hold a 2.5 in. square specimen 11.5 in. long; the other has eight inches of lead shielding and will hold a 14.5 in. long specimen of similar cross-section. Another flask with eight inches of shielding is being constructed to permit the transport of samples up to 2.5 in. square and 32 in. long. Specimens which will not fit in any of these flasks must be put in suitable flasks which are then manually wheeled inside the cell.

Figure 2.



Storage of Specimens

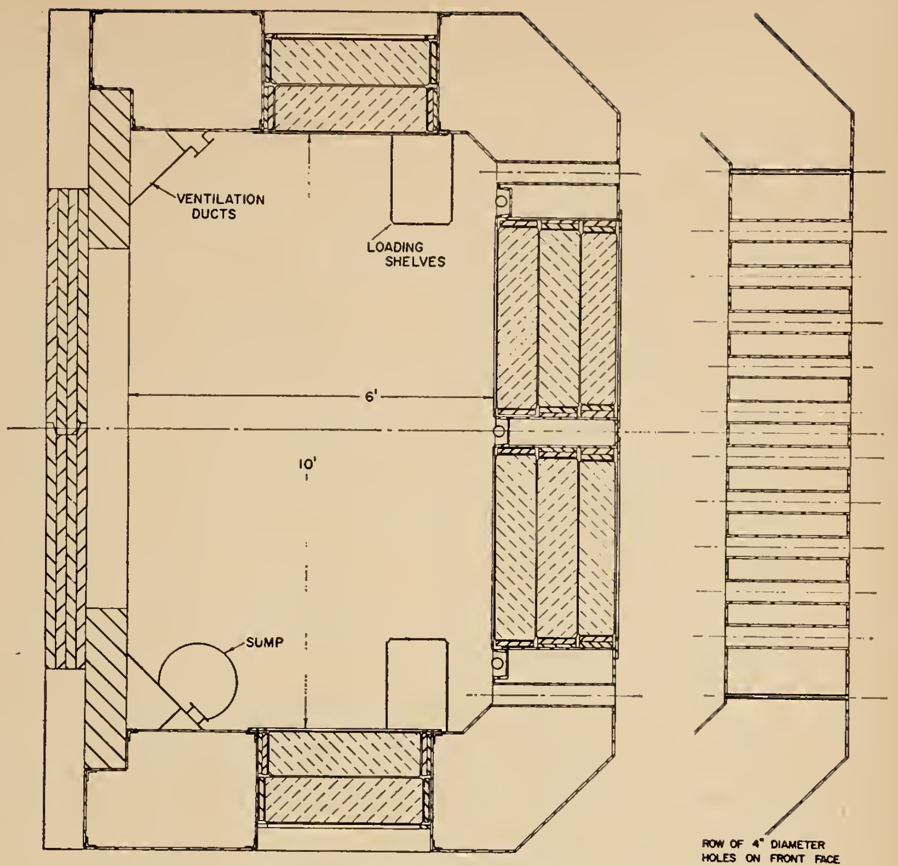
There are six storage wells, each ten feet deep, in a separate room near the cell. Each well is lined with a stainless steel insert which has two compartments designed to accommodate the drawer and flask liner from the six inch shielding flask The flask is wheeled to the storage room where it is lifted off the trolley and swung into a vertical position The flask is lowered until a boss on the end mates with a similar shaped hole in the top plate of the storage well insert. The drawer and flask liner are then lowered into the storage well. Figure 5 shows one well with two drawer and liner assemblies The largest specimen which may b stored in the wells is 2.5 in. squar and 11.5 in. long.

There is a 3 ft. wide by 4 f deep by 10 ft. long storage troug in the same room. This trough i above floor level and is surrounde by twelve inches of ordinary con crete shielding.

Operation of Cell

There are four people assigne directly to the cell program. Th professional man looks after scheduling all work, writing necessary reports, checking design of all equipment to be used inside the cell, and generally supervising operations in the cell. The three technicians do most of the work with the manipulators as well as developing and printing all the photographs taken with the stereo-camera. The cell is normally operated one shift per day, five days a week. If any new apparatus is being used, a dummy run is made, if possible. Persons requesting work done in the cell assist in making observations and recording data, but all work with the manipulators is done by personnel assigned to the cell program.

Equipment for a job is installed in the cell, then after the job is completed, the equipment is removed, washed and stored in an adjoining room, (See Figure 1). An operator, when entering the cell to change equipment wears cotton overalls covered by a plastic suit which has moulded feet and double sleeves. He wears a fresh-air type respirator and a clear plastic hood. Finally, he puts on two pairs of rubber gloves which are taped to the sleeves of the plastic suit, and steel-toed rubber boots. When leaving the cell he showers with the plastic suit on, then steps into an undressing chamber where his clothes are removed. He then showers in a second stall, after which he dons fresh clothes. Since all personnel are allowed only 5 roentgens per year total body radiation, it is necessary to bring in men from the labour crew to assist when the cell is being decontaminated. During the past year the cell has been shut down for decontamination approximately two weeks in every three months.



CELL PLAN 4'-4½ ABOVE CELL FLOOR

Figure 3.

The cell and associated equipment have been relatively free from break down. Since active work started, the cell has had three one-day shutdowns to replace broken tong cables in the manipulators.

Equipment

The following equipment is available for use inside the cell: micrometers and verniers, hardness tester, bend strength tester, impact tester, portable tensile tester, stud welder, lathe, micro drill press, density measurement apparatus and profilometer. A cut-off wheel, desheathing saw, tensile tester, and micro-profilometer are on order and will be available for use soon.

With the aforementioned equipment and method of handling specimens it has been possible to remove a test section fom the reactor and examine it in the cell, then assemble and reinsert it in the reactor during a three-day reactor shut-down.

Cost of Cell Facilities

Since the cell and storage facilities were built along with the Metallurgy Building it is difficult to determine their construction costs. The costs of equipment purchased and the internal charges levied by A.E.C.L. for services, such as machinist and millwright work etc. have been recorded, however, and are shown in Table II. Also given in Table II is an estimate for the construction cost of the bare cell and its services, the storage wells and trough, and the equipment storage, decontamination and shower facilities. Costs shown in Table II are direct costs and do not

Table II. Approximate Construction and Equipment Costs for the Cell

A. Construction Costs (*Including basic equipment*)	$	
Concrete and steel shell plus storage room*	50,000	
Shielding windows, steel doors, manipulators and sliding shield, monorail and hoists.	50,000	
Lighting and ventilation	6,000	
Radiation monitoring system	3,000	
	$ 109,000	$ 109,000
B. Extra Equipment Costs	$	
Extra set of manipulators	8,000	
Lead filled flasks and storage drawers	14,000	
Special equipment, stereomicroscope, physical testing apparatus, lathe etc.	31,000	
Work done by A.E.C.L. services for construction and installations of equipment	10,000	
Total	$ 63,000	$ 63,000
		$ 172,000

* This $50,000 estimate includes the bare concrete and steel shell, the storage wells and trough, and the shower, decontamination, and equipment storage facilities.

include overhead or salaries of personnel assigned to the cell program.

Shielding of Cell

Experiments using calibrated Co^{60} sources * were carried out to determine the shielding properties of the concrete and the windows.

The sources were cobalt pellets contained in aluminum capsules which were ¾ in. diameter by 1⅜ in. long. The counter was a Tracer Lab Radiation Survey meter model SU1D, and was calibrated just prior to the experiments by the Radiation Hazards Branch of A.E.C.L., using a standard Co^{60} source.

The source strengths were as given in Table III

A. Radiation through Components of Cell — The radiation transmitted through the concrete walls, the front and end windows, and the steel doors, when the source was in contact with the inner surface and the meter in contact with the outer surface are given in Figures 6 and 7.

B. Build-up Factor of Ilmenite Concrete and 3.3 Density Glass — The build-up factor is defined as the ratio of the actual gamma flux to that which would be calculated using the simple exponential expression $I = I_o \exp.(-\mu t)$ where μ is the linear absorption coefficient, and t is the thickness of the shielding material. The measured and calculated values of gamma flux differ because the calculated linear absorption coefficients are based on narrow beam geometry and thin sections of absorbing material so that any photon which is deflected once is deflected out of the beam, whereas, in actual practice, using finite shielding slabs, a photon which is deflected once is not necessarily stopped from passin; through the shielding. The main pro cesses for the build-up of radiatio due to scattering and secondary emis sions are Compton scattering, photo electric effect and pair productior Theoretical methods of determinin the build-up factors have been de veloped,[3] and tables for variou shielding materials are available.[4,5,6,7] However, no experimental data ar available for ilmenite concrete an 3.3 density glass. Calculations usin the data plotted in Figures 6 and .

* Sources were supplied by Industrial Operations Division, A.E.C.L.

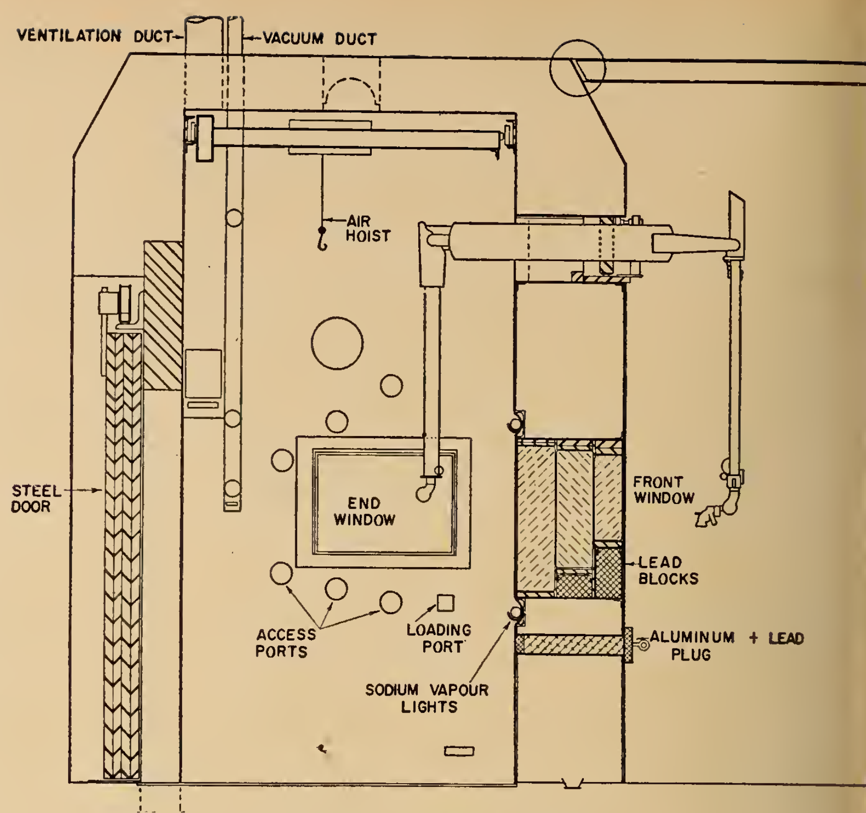


Figure 4 (above). Figure 5 (below, left).

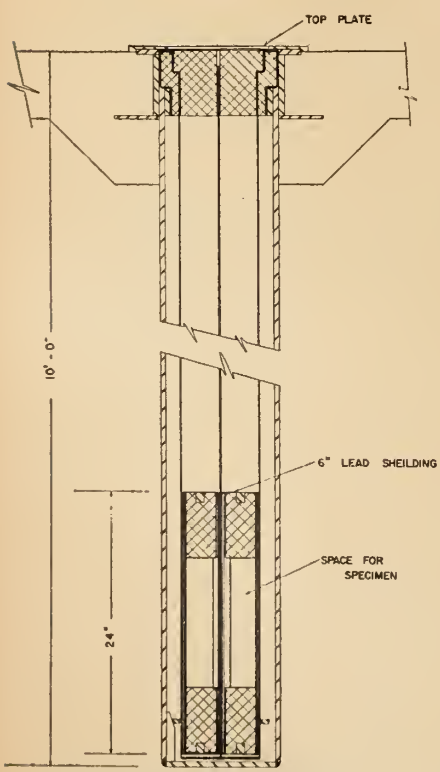


STORAGE WELL ASSEMBLY WITH TWO DRAWERS IN PLACE

Table III. Co^{60} Sources, Used in Shielding Experiments.

Source Strength	Accuracy	Radiation at 1 Metre
14 curies	± 10%	Not measured
50 "	± 10	"
100 "	± 5	"
235 "	± 5	315 R/hr.
1015 "	± 5	1352 R/hr.
1080 "	± 5	1450 R/hr.

Table IV. Build-up Factors for Ilmenite Concrete and 3.3 Density Glass Using Co^{60} Radiation

Shielding	Build-up Factor
23⅝ in. of 3.3 density glass	7.0 — 9.0
18⅛ in. of 3.3 density glass	3.5 — 5
23¼ in. of ilmenite concrete	5.0 — 7

Table V. Strength of Various Gamma Energy Sources to Give 0.6 mr/hr. Fiel Through the 3.3 Density Glass Windows on the Front Face of the Cell

Gamma Energy	Source Strength
Co^{60}	10 curies
1 Mev.	70 "
0.9 Mev.	136 "
0.8 Mev.	415 "
0.7 Mev.	1110 "

gave the build-up factors listed in Table IV.

Calculations were made using the formula reported by Rockwell.[6]

$$\frac{B.\ DK4\pi\ x^2}{S_0 \exp.(-\mu t)} \quad (A)$$

where

B = build-up factor (dimensionless)

D = dose rate (R/hr.)

S_0 = point source of gamma rays (photons/sec)

K = conversion factor from gamma ray flux to dose rate

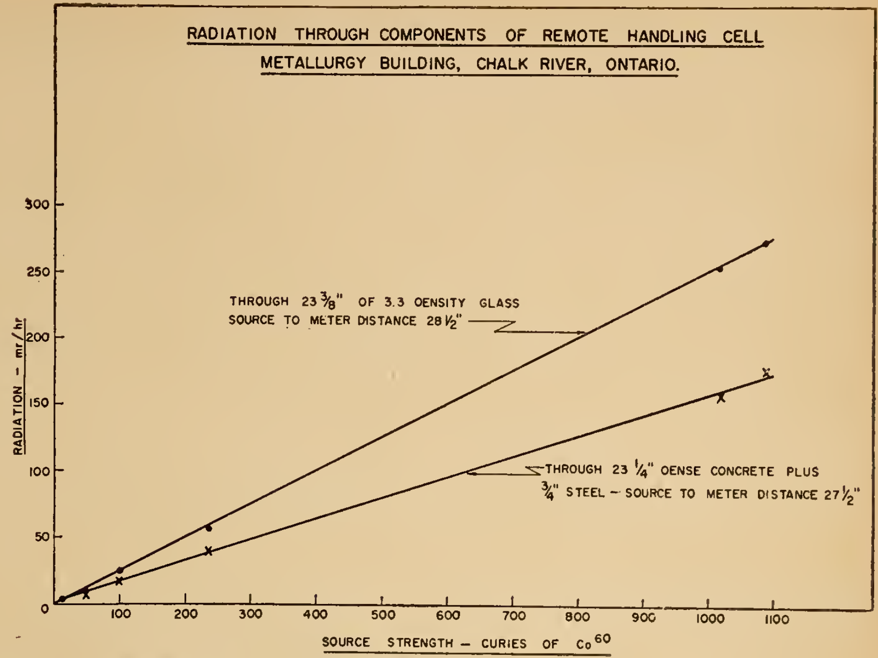
μ = linear absorption coefficient (reciprocal length)

t = thickness of shield (length)

x = distance from source to detector (length)

The following are assumptions:

(1) Radiation emanated from a point source.



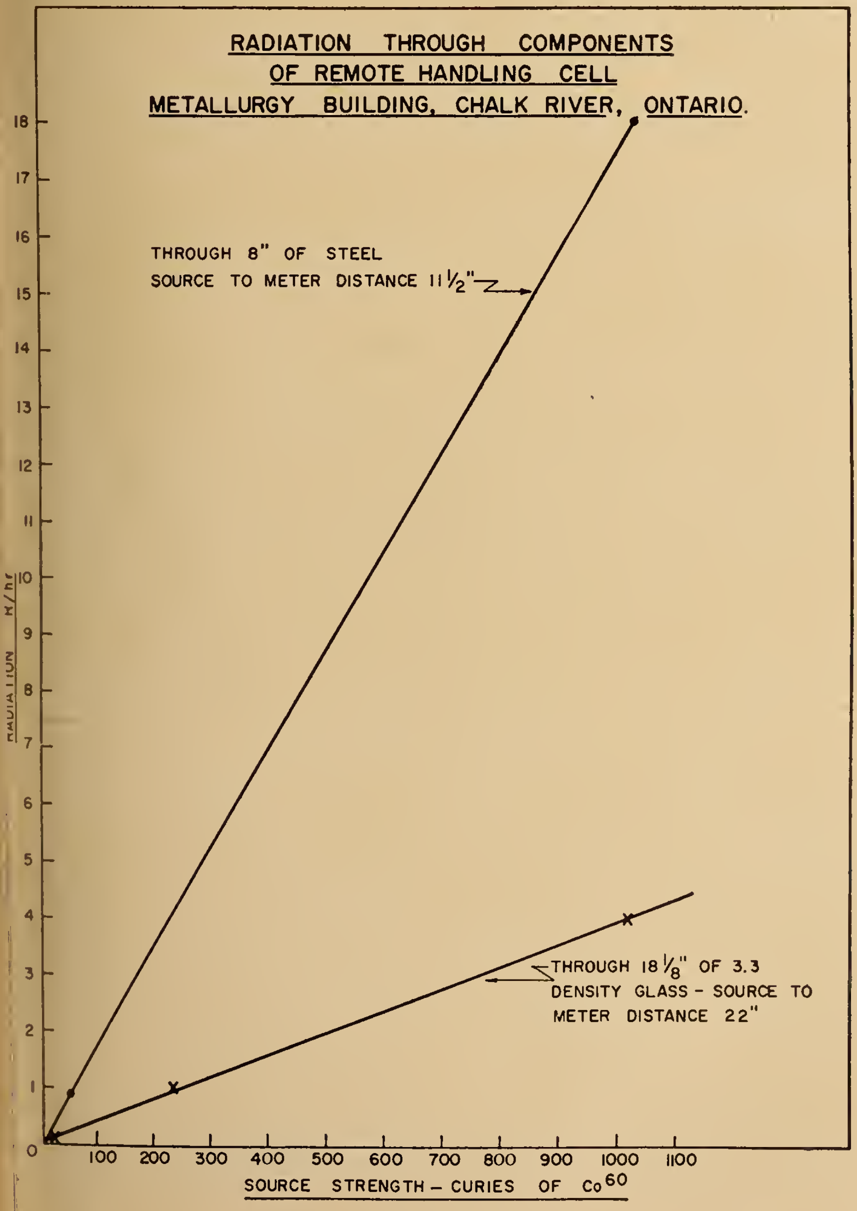


Figure 6 (above). Figure 7 (below).

(2) Co^{60} emitted two gamma rays of 1.25 Mev. each, instead of one of 1.17 Mev. and one of 1.33 Mev.

(3) The linear absorption coefficient of ilmenite concrete is 0.47 per inch[2] and 3.3 density glass is 0.48 per inch for 1.25 Mev. radiation.[8]

C. Allowable activity in cell — Since the allowable total body irradiation at Chalk River is 100 milli-roentgens per week, averaged over one year, the maximum field outside the cell should not be higher than 3 mr/hr., based on a 33 hour work week. This latter figure, however, would not allow any time for working inside the cell, where the residual activity is approximately 100 to 300 mr/hr. Therefore, a safety factor of five is used, bringing the maximum permissible field outside the cell to 0.6 mr/hr. From the slope of the curve in Figure 6 the source strength which produces 0.6 mr./hr. radiation outside the front windows is 2.3 curies of Co^{60}. This is a pessimistic figure, since it is calculated with the source and meter in contact with the inner and outer surface of the windows respectively. In normal operation, the source to operator distance would not be less than four feet, or twice the window thickness. Therefore the source strength to give 0.6 mr/hr. field on the outside of the cell would be approximately 10 curies of Co^{60}. The source strength to give 0.6 mr/hr. for other gamma energy radiation can be calculated from equation (A),

(Continued on page 1138)

The International Outlook for Atomic Power

Paul F. Foster

Assistant General Manager for International Activities, U.S. Atomic Energy Commission.

Delivered at the All Congress Banquet of the Nuclear Congress, Philadelphia, Pa., 13 March, 1957

I HAVE CHOSEN AS MY topic for tonight, "The International Outlook for Atomic Power", which could take hours, but about which I hope it may be possible for me to say something worthy of your time and consideration in less than half an hour.

A realistic appraisal during your first Nuclear Congress, a year ago in Cleveland, would not have been nearly so encouraging as one that can be made now. There have been great developments during the past year in the field of atomic energy and also there have been international political events that have influenced the thinking of governmental and industrial leaders throughout the free world. You will recall that the closing of the Suez Canal last October emphasized the fact that today petroleum for Europe is as much a political weapon as it is a commodity in international trade. A clearer realization of this grim fact undoubtedly has accelerated atomic power programs in both England and Europe.

An increased confidence in the prospects for atomic power has been engendered in this country during the past year by the announcement of plans or commitments for a number of large-scale atomic power projects in the United States; by contracts that have been placed with United States firms for the construction of three small atomic power plants for Latin America; by serious negotiations that American manufacturers have in progress for the construction of large atomic power plants in Italy and Japan and for smaller plants in Belgium, Taiwan, the Dominican Republic, and the Philippines; and by Congressional approval for the construction of an atomic powered merchant ship.

The outlook for atomic power was brightened just a week ago yesterday by the announcement in the House of Lords of a bold program to triple Britain's planned production of atomic energy for industry by 1965, notwithstanding the fact that this program, admittedly, would put a very heavy burden on her capital resources at a time when they are to be seriously strained by other requirements.

The new British program as outlined by Lord Mills, Minister of Power, calls for the construction in the next nine years of sixteen atomic power stations in England, Scotland, and Wales and one in Northern Ireland, in addition to the three stations now under construction as part of the program authorized in 1955. Lord Mills stated that the new program would provide at least 5,000 megawatts of atomic power by the end of 1965, but he added that, ". . . if technological development continues to be favourable and the necessary physical and financial resources can be found, a figure of 6,000 megawatts can be achieved by that date." The cost of building the new atomic power plants is estimated at about 2 billion and 77 million dollars. The initial fuel charges for new reactors will cost an estimated additional 496 million dollars thus bringing total initial capital costs up to about 2 billion 573 million dollars at current prices.

The press accounts of the British announcement included the very significant statement that the costs of the atomic power plants would be more than double that of conventional power stations. This, I might add, is indeed a very large premium to pay for atomic power, but a full year's operation of Britain's twenty atomic power stations would save 18 million tons of coal. As you know, coal is Britain's principal natural resource and it is in diminishing supply and its price trend is upward.

From a study of London newspapers carrying the story of Lord Mills' announcement and the discussions that ensued in the House of Lords, I gleaned some informative data that may be of interest to this audience.

1. British estimates of costs for their new atomic power program are based on an average figure of $346 per kilowatt of installed electric power and on the assumption that a capacity of 6,000 megawatts will be reached. If, however, a capacity of only 5,000 megawatts is reached the cost per kilowatt would be $415. These estimates do not include the costs of the initial fuel charges for the reactors.

2. Costs of the new atomic power stations now being built at Berkeley and Bradwell are estimated at $386 per kilowatt of installed electric power, without initial fuel charges; the Berkeley station will have a capacity of 275,000 kilowatts and Bradwell a capacity of 300,000 kilowatts.

3. The cost of a 150,000 kilowatt atomic power plant to be built in Northern Ireland is estimated at 70 million dollars, or about $467 per kilowatt of installed electric power; this estimate apparently includes the cost of the initial fuel charges.

These new estimates of British

costs for atomic power stations appear to be materially higher than the estimates of costs for the Yankee pressurized water type reactor and the Dresden boiling water type reactor both of which use slightly enriched uranium as fuel instead of natural uranium as in the gas-cooled Calder Hall type reactor.

In connection with the announcement, the London *Times* of March 6 quoted Sir Edwin Plowden, Chairman of the United Kingdom Atomic Energy Authority, as having stated in a press conference on the day before that within the period covered by the program it would be possible to proceed to reactors of the Calder Hall type using slightly enriched fuel and that the effect would be to reduce the capital cost of nuclear power stations, but to add slightly to fuel costs.

I should like to comment on this authoritative British statement about the advantages of slightly enriched uranium over natural uranium as a reactor fuel. The principal advantage relates to the physical characteristics and the savings in construction costs made possible by the use of smaller reactors for a given installed capacity. An improved 150,000 kilowatt Calder Hall type reactor is estimated to require some 250 tons of natural uranium, whereas the 134,000 kilowatt Yankee pressurized water reactor in Massachusetts will use only about 25 tons of uranium enriched to 2.7% and the 180,000 kilowatt Dresden boiling water reactor in Illinois will use only some 60 tons of uranium enriched to 1.5%.

While I am drawing comparisons between the initial capital costs of reactors of different designs, I should add that operating costs after start-up are often a more important factor. There have been many conflicting statements in the press, on the radio, and on television in recent months about the operating costs of gas-cooled natural uranium reactors of the improved Calder Hall type compared to the operating costs of pressurized water and boiling water reactors using slightly enriched uranium as fuel. The methods of calculating cost of power in this country are not the same as those used in many other countries, particularly those with nationalized power. I shall not attempt tonight to go into the details of this complex issue, but I do want to call attention to the need for each country to place such comparisons in its own frame of reference with respect to initial capital charges for plant and equipment, costs of fuel, charges for taxes, depreciation, amortization, interest rates on domestic and foreign loans and credit allowed for plutonium produced in the reactor. All these are factors that significantly effect the calculations of cost of power at the bus bars.

Let us now take a look across the English Channel at the prospects for atomic power on the Continent. Although the need for a new source of energy is generally as pressing in Europe as it is in Great Britain, the progress toward atomic power has been slower in France, Germany, Italy, Belgium, Luxembourg and the Netherlands. However, these six nations are joined by strong economic ties in the Coal and Steel Community, and they are now nearing final, formal agreement for the pooling of their efforts in the atomic energy field. As you know, this joint enterprise, known as Euratom, has reached the point where a treaty has been signed by the Foreign Ministers of the six nations involved. The Heads of State expect to sign the treaty in Rome on March 25 and to submit it promptly to their respective Parliaments for ratification during the early summer.

The author reviews the current nuclear energy developments that are under way in various parts of the world, particularly in relation to the high degree of co-operation that will be necessary between Britain, the Euratom countries and the United States. Competition will also be keen.

You have heard the message read to you by Mr. Iddles from Mr. Etzel, vice-president of the Coal and Steel Community and a member of the Committee known as the "Three Wise Men" who visited this country last month. It will not be necessary for me to explain the task assigned to the Committee nor to elaborate on Euratom's need for atomic power on a large scale and on an urgent time schedule. *(Note — the Euratom group is made up of Belgium, France, Germany, Italy, Luxembourg and the Netherlands.)*

During the visit of the "Three Wise Men" in Washington last month a joint communique was issued by them, our State Department and Atomic Energy Commission in which it was stated:

"Examination of the Committee's program indicates that its objective is feasible."

In view of our Government's public statement, I am particularly desirous that nothing I say here tonight be interpreted as casting doubt on the feasibility of the Euratom program. But I do wish to point out that the communique's one sentence dealing with the question of feasibility did not mention some obvious assumptions. Among these, I might identify the following:

(1) The member nations of Euratom must be ready, willing and able to finance the program, which might cost on the order of 6 billion dollars by 1967.

(2) American and British industries must be willing and able to cooperate with industries and the governments of the Euratom nations.

(3) Euratom will establish promptly its Atomic Energy Commission — with adequate planning, coordinating, and administrative authority to carry out an agreed program.

I do not think we need to worry at this time about Euratom's ability to finance the atomic power program. The Euratom nations are now paying dearly for imported fuels and they will have to spend in the hundreds of millions of dollars annually for new conventional power plants if they do not build atomic ones. Therefore, Euratom's financial problem probably will be more concerned in the near future with the re-allocation of expenditures than in the raising of new revenues.

It goes without saying that American and British industry will cooperate with industry in friendly foreign countries. There has been no hint from any source that either American or British industry would be expected to declare a moratorium on profits. Regardless of any profit incentive, industry will benefit by the two-way flow of technical information and from the opportunities to expand its lists of licensee affiliates and customers.

I am sure you will be interested in some of the problems that Euratom must solve in carrying out its atomic power programs.

The Euratom program admittedly is an ambitious one. Its size and cost can be judged by comparison with the new British atomic power program. Whereas the British have set a goal of 5,000 to 6,000 megawatts of atomic power by the end of 1965, the Euratom goal is 15,000 megawatts by the end of 1967.

It is logical to assume that Euratom will adopt a policy of rapidly building up the technical know-how and the manufacturing capacities of its members so that their imports will be held to a minimum. To acquire the necessary technical know-how and to save time in actually getting into the business of manufacturing power reactors, it will be necessary to develop licensing arrangements with American and British reactor builders. I believe that such licensing arrangements can and will be worked out and that they will be mutually advantageous.

I do not think that Euratom will find it either desirable or possible to standardize initially on only one type of reactor. Speaking only for myself and *not* for the Atomic Energy Commission, I would expect Euratom to place orders for several reactor types with the idea that these would be imported in their entirety, erected and operated as soon as possible as prototypes for the training of Euratom engineers. Incidentally, the most serious handicap for Euratom to overcome is the shortage of engineering talent with experience in the many special aspects of the building and operation of reactors.

There are possibilities for standardization in the reactor components, fuel cycles and steam conditions of the reactors installed in the early years of the Euratom program. The advantages derived would be important in time savings, but, to be effective, a standardization program would have to be defined and adopted by European industry.

It is reasonable to assume that industry will want assurances from Euratom with respect to third party product liability. I understand that a precedent for limiting liability has been established in respect to international airplane travel. Also, some uncertainties about patent rights need to be cleared up.

Earlier I expressed my personal belief that Euratom initially might select several prototype reactors, but I did not mean to imply that Euratom's purchases of reactors would be limited to only those prototypes. On the contrary, I believe that if Euratom is to approximate its schedule for installations in 1963 and 1964, it will be necessary to buy as many reactors as can be manufactured short of an expensive crash program in this country.

Since Euratom will have only limited supra-national authority, its atomic power program will be achieved by six separate national programs which, however, will be coordinated by its Atomic Energy Commission. Euratom's biggest leverage will come from its ownership and effective control of all nuclear fuels used by the six member nations and by joint training and research efforts and possibly by joint ownership of such facilities as chemical reprocessing plants. I, for one, am confident that in the broader sense of the word — feasibility — the Euratom program is feasible, but it will require a tremendous, coordinated effort by the six nations to achieve 15,000 megawatts of installed atomic electric power by 1967.

Expansion Program

You will recall that when the Atomic Energy Commission undertook its big expansion program a few years ago, we were fortunate in having all the money we needed and all the authority required to get the job done on schedule. At one time, we were spending over 100 million dollars a month; we had approximately 15,000 architects, engineers, and technicians working directly or indirectly on our program; our construction labor force reached a peak of 74,000; our construction efforts represented about 5 percent of total construction in the United States, and we took approximately half of the entire American output of stainless steel piping. I am confident that we would not have completed our expansion program on schedule had the authority for its planning and execution been divided between different Government agencies. For this reason, I earnestly hope that Euratom will encounter no delays or difficulties in setting up its Atomic Energy Commission and other planning and administrative organizations to effectively coordinate the separate construction programs to be undertaken by the six member nations.

Elsewhere in Europe there is nothing to report as ambitious and spectacular as the Euratom plan. It is true, of course, that Austria, Denmark, Greece, Norway, Portugal, Spain, Sweden, and Switzerland have atomic energy programs in varying stages of development. Up to now, these programs have been devoted largely to research, but government and industry in all of these countries are now actively studying the possibilities for atomic power. Norway is particularly interested in the possibilities of atomic power for merchant ship propulsion. In Sweden, a 95,000 kilowatt reactor is being installed in a suburb of Stockholm to supply heating for a large housing development. Five additional reactors for central district heating are also planned.

Naturally, there is little to say about what is going on in the field of atomic power behind the Iron Curtain. There has been an announcement that Czechoslovakia will begin the construction of a 150,000 kilowatt atomic power plant during the current year and that other plants are planned for completion after 1960. East Germany also has indicated its expectations of starting construction of a 150,000 kilowatt atomic power plant this year. In the Soviet Union, the announced program calling for installation of 2,500 megawatts of atomic power by 1960 appears to be slipping as indicated by recent Russian statements that speak of commencing three of their five large projects in 1958, 1959 and 1960. It is interesting to note that the Soviets are reported to be experimenting with seven different reactor concepts and are not wedded to any single reactor design.

There have been no announcements of plans for large scale atomic power plants in Latin America but such plans are likely to develop within a few years in the Argentine, in Uruguay and other countries where indigenous fuels are lacking and where there are large cities and industries. Two atomic power plants of 10,000 kilowatt capacity are being manufactured in the United States for installation in Brazil and Cuba. Conditional contracts have been given to American firms for the construction of small atomic power plants for installation in Mexico and the Dominican Republic.

Negotiations have been in progress for some time for a 60,000 kilowatt atomic power plant in Manila and recently a contingent order has been placed with an American manufacturer for a 15,000 kilowatt atomic power plant on Taiwan. Two of the largest public utility companies in Japan are in active negotiation with American manufacturers for the installation of atomic power plants of the order of 150,000 kilowatts each. The Japanese Government has sent survey teams to the United States and to England and a few weeks ago announced that new survey teams would be sent to make further studies. Meanwhile, Japan appears to be waiting for the International Atomic Energy Agency to come into existence before proceeding with further negotiations with this country and England for agreements for cooperation in the field of atomic power. However, I am convinced that Japan, like England and the Euratom nations, will find atomic power economically and politically feasible some time before atomic power becomes economically competitive with conventional thermal power in most parts of the United States.

Mr. Etzel also stressed the impor-ance of being assured of an adequate and continuing supply of atomic fuels, both enriched uranium and natural uranium. His concern is understand-ible, for in the minds of foreigners he availability of nuclear materials pparently is the biggest unknown actor in the atomic power problem. However, let me remind you that President Eisenhower, in his Feb-uary 22, 1956, announcement mak-ig available 40,000 kilograms of ur-nium 235 for distribution, half do-nestically and half abroad, said that: ". . . the Atomic Energy Com-nission has informed me that it will ecommend that additional supplies e made available as becomes neces-iry in the future." Also, the joint ommunique issued last month in Washington by the State Depart-ent, the Atomic Energy Commis-on and the Three Wise Men stated at: ". . . Under present circum-ances, the availability of nuclear els is not considered to be a limit-g factor."

Obviously, this Government can-ot make at this time a firm commit-ent to Euratom as to the availabil-of specific amounts of atomic els. First, the Euratom treaty must ratified by the parliaments of the member nations. Next, a treaty an agreement for cooperation be-een Euratom and our Government ust be concluded. But in the mean-ne we can make firm commitments th respect to adequate fuels to individual member nations of ratom under bilateral agreements cooperation to meet their interim eds. We are now negotiating such nmitments and agreements with ance, Germany, and Italy and we e already concluded agreements h Belgium and the Netherlands the field of atomic power. Since can now give adequate assurances h respect to the availability of atomic fuels to the member nations of Euratom through our bilateral agreements, these countries can start construction of atomic power plants without necessarily waiting for the conclusion of a treaty or an agreement between Euratom and our Government. Therefore, I do not believe that the Euratom atomic power program need be delayed because of the absence at this time of a firm commitment directly to Euratom.

Delaying Elements

I should like to discuss very briefly two aspects of atomic power that presently are delaying its progress. I refer to the higher capital costs for atomic power plants than for conventional thermal power plants and to the estimated higher operating costs in most localities around the world. Undoubtedly, these cost differentials will gradually disappear as the result of:

(a) technological improvements in exisiting reactor designs, including particularly the fuel elements and the chemical recycling processes for spent fuel elements; and *(b)* the development of new reactor concepts; and *(c)* the perfecting of methods to burn up the by-product plutonium, and *(d)* possible future increases in the costs of coal and oil.

There are, however, several steps that our Government might take to reduce the present cost differentials between atomic and conventional thermal power plants. The Atomic Energy Commission has announced several measures that have been adopted to encourage private industry to build and operate reactors in this country. We now have under very active study a number of proposals designed to augment our foreign Atoms for Peace Program by accelerating the installation of atomic power plants in friendly foreign countries. Among other things, these proposals would extend to atomic power projects abroad some of the same kind of research and development assistance available to similar projects in the United States. One of the proposals deals with the method of our distribution of atomic fuels outside the United States. The Atomic Energy Act of 1954 provides that only our Government may own atomic fuels in this country. Consequently, the Commission leases atomic fuels for use in reactors within our borders, and, to assist the pioneers in the atomic power field, we have offered to waive the use charges for reactor fuels for the first five years of the active life of reactors built under our Power Demonstration Program.

The same law provides that the Commission may "distribute" atomic fuels abroad only pursuant to agreements for cooperation which provides, among other things, that the cooperating nations must guarantee that any nuclear materials transferred pursuant to such agreements will not be used for atomic weapons, or for research on or development of atomic weapons, or for any other military purpose. There is nothing specific in the law that forbids the Commission to lease atomic fuels to foreign governments under agreements for cooperation.

Costs of Fuel

The difference in method of distribution, that is, whether by sale or by lease, could make a very significant difference in the initial capital requirements for an atomic power plant as well as a difference in the operating costs throughout the useful life of the reactor. For example, a typical atomic power plant of American design costing in the order of 35 million dollars might require about 20 million dollars worth of slightly enriched fuel to charge the reactor and keep the supply pipelines filled between the reactor and the plants where the fuel elements are made and reprocessed. The difference is appreciable between capitalizing the fuel inventory costs and leasing the fuel inventory at 4 per cent per annum, which is the rate charged for the use of atomic fuels in reactors in the United States. A privately-owned utility company in a foreign country might prefer to lease atomic fuel on these terms whereas a foreign government, for political, but non-military, reasons, might prefer to buy and own the atomic fuels.

In the Commission's consideration of this problem, we must look ahead to the difficulties we might encounter at some future time if we should now embark on a course of leasing atomic fuels for large foreign programs. To get an idea of the magnitude of this problem, let us assume that the Atomic Energy Commission would agree to provide half of the atomic fuel required for the Euratom program up to 1967, by which time 15,000 megawatts of electric power is planned for installation. If we further assume that all of the fuel to be supplied by us is slightly enriched uranium suitable for use in American-designed reactors, the value of the inventory in the reactors and in the supply pipelines that we would have out on lease by 1967 might be of the order of one billion dollars. I cannot predict the course of action that the Commission will take, but I am confident that an equitable and effective solution to this complex problem will be found in the near future by our Government.

In conclusion, I wish to say something about what is happening in the field of atomic power in the United States. I assume that most of you in this audience have been participating in the discussions here in Philadelphia during the past three days, and you will have heard many reports from American industrial leaders and from engineers and scientists concerning developments in this country. I shall attempt only to summarize the situation as I see it.

Including the boiling water reactor which formally began operations at the Argonne Laboratory on February 9, there will be five and perhaps six reactors delivering electrical power in the United States before the current calendar year is ended. The largest of these will be the pressurized water reactor at Shippingport with a capacity of 60 to 100,000 electric kilowatts — the world's first atomic power plant devoted entirely to serve civilian needs. The other atomic power plants to be completed this year are the sodium reactor at Santa Susana, California, the boiling water prototype power plant at Vallecitos, California, and the Army package power plant at Fort Belvoir, Virginia, which will be delivering electricity into the Post's power system within a few months. Also, the homogeneous reactor at Oak Ridge may come into operation this year and supply electric power to the great laboratory complex.

According to industry's own published reports, our atomic energy industry in 1956 began construction or received contracts on a total of 59 new atomic reactors, including 29 power reactors and 30 research and test reactors. The research and test reactors will be built for private U.S. buyers, for the Government, and for overseas export. The power reactors are designed for various needs as, for example, naval and merchant ship propulsion, for prototype and demonstration reactors for the Atomic Energy Commission and for land-based power demonstration plants for private purchasers.

By the end of 1962 the Atomic Energy Commission expects that there will have been completed at least 18 civilian atomic power plants including one with a capacity of 180,000 kilowatts which will be similar in design concept to the boiling water reactor now in operation at the Argonne National Laboratory.

Despite the fact that power costs in the United States are far below the cost levels in most other parts of the world, I am confident that atomic power projects to be completed will increase in number and size from year to year during the 1960's. We will have the advantage by then of the development and testing of the ten reactor concepts that the Commission is now supporting. Also our civilian program will continue to benefit from our tremendous naval propulsion program.

With the sound technological base that we have built, with the vast experience that we are acquiring, with our great engineering talent, and with our unsurpassed industrial capacity there are no sound reasons for misgivings as to the standing of our civilian atomic power program a few years hence. Let me remind you that no other nation has offered to make available atomic fuels for power projects as this country has done. No other nation, so far as I know, has received export orders for research approaching in numbers those now being manufactured in the United States for foreign customers. No other country, so far as I know, has actually received firm orders for power reactors of the size now being manufactured in this country for installation in Latin America. And so far as I know, no manufacturers in any country are as close as those in the United States to the signing of firm contracts for large scale atomic power plants for export. I am certain that no other nation matches our experience and know-how in the designing, building and operation of reactors for ships.

I do not say these things boastfully, for I believe that there should be atomic power plant business for both American manufacturers and their competitors overseas. We only want to be in a position to win our fair share of the world's markets on merit.

Remote Handling Facilities (cont. from p. 1133)

using the appropriate values of μ and K which are found in the literature [4, 5, 6, 7, 8]. The value of B for 3.3 density glass has not been determined for other than Co^{60} radiation. Generally speaking, however, the build-up factor increases as the energy of the gamma ray decreases, but for these calculations it has been assumed that the variation is not great over the energy range of interest. Hence B has been kept constant. The results of the calculations are given in Table V.

Fields and Youngquist[9] have stated that an Argonne cell, which has similar shielding walls, is capable of handling 100 curie amounts of 1 Mev. radiation, in reasonable agreement with the above results.

Although the cell is rated at only 70 curies of 1 Mev. gamma radiation, it is possible, by judicious use of personnel, to handle much larger amounts of activity and still have no overexposure. The cell has handled sections of NRX rods which were irradiated to several hundred MWD/tonne, and regularly handles small sections of experimental fuel elements weighing several hundred grams which have been irradiated to several thousand MWD/tonne. The most active source which has been handled was rated at 4,000 curies of Co^{60}

Summary

The remote control handling cell in the metallurgy building at Chalk River, Ontario has been in active operation since October 1955. Although there are some features of the design which could be improved the cell has proved to be a very valuable facility for the examination of radioactive materials.

Papers from the 1957 Nuclear Congress

(Held in Philadelphia, Pa., 11-15 March, 1957)

The proceedings of the Congress included the 2nd Nuclear Engineering and Science Conference; 5th Atomic Energy in Industry Conference; 5th Hot Laboratories and Equipment Conference; and 3rd International Atomic Exposition. E.I.C. was a sponsor.

The papers in this list are available in separate copy form until January 15, 1958. Nuclear Engineering and Science Conference papers are priced at 30¢ each. Please order only by paper number; otherwise the order will be returned. Copies of these papers may be obtained from the ASME Order Department, 29 West 39th Street, New York 18, N.Y.

BASED ON CURRENT LITERATURE AND EVENTS

BATHYTHERMOMETER TELEMETERS OCEAN DATA

J. M. Snodgrass and J. H. Cowley Jr.—*Electronics*, May 1957, vol. 30 no. 5

Ocean temperature as a function of depth provides valuable information for oceanographic studies. Previous methods of measurement by mechanical means provided an accuracy of ±0.5C and ±5 ft. in depth. Resolution of the order of 1 ft. in 1000 in depth and 0.1C in temperature are required today in oceanographic work.

An instrument has been designed and is in use which employs the frequency variation of a thermistor Wien-bridge oscillator to measure temperature and the frequency change of a vibrating wire connected to a flexible diaphragm provides depth information. Both signals are sent over a single conductor to the ship where they are separated by high pass and low pass filters for recording.

The depth measurement device using a Vibraton is a vibrating wire transducer in which a mechanical displacement is converted into a frequency change of a vibrating wire. The wire is connected at one end to a pressure sensing diaphragm. A displacement of the diaphragm changes the tension in the wire thus changing the frequency of vibration. The wire is of non-magnetic material and is placed in a fixed magnetic field at right angles to the axis of the wire. When the wire vibrates at its natural frequency it becomes an a-c generator, generating a voltage that can be amplified by conventional means. If some of the amplified voltage is fed back to the ends of the wire in phase with the generated voltage, vibration is sustained. The amplitude of vibration is controlled and the output frequency is a pure sine wave, regulated by the axial displacement of the wire, and it is nearly a linear function of the pressure applied to the pressure sensing diaphragm. The temperature stability of the amplifier was tested from 5 to 55C and was found to be adequate.

Water temperature is sensed by an oscillator of the Wien bridge type with thermistors in the reactive arms of the bridge. The temperature stability of the oscillator was found to be satisfactory in that when properly adjusted, there was a frequency variation of only one to two cps over an 8-hour period at constant temperature. Speed of response is important since the instrument is lowered and raised through the water at a rate of 2.5 fps. A thermal time constant of one second or less is necessary to resolve all the detail present which has been obtained upon occasion by grinding down the glass surface of the thermistor beads.

Both units are housed in silica-filled epoxy resin capsules. They have been used at sea with good results. The resulting resolution of the overall depth measuring system is of the order of 0.3 inch. Absolute accuracy in depth is better than ±0.25 per cent or ±2.5 ft. in 1000. The temperature sensitivity is approximately 40 cps per degree C. When these parameters are converted to dc and applied to the function plotter with a ten-inch chart width, a depth variation of ±2.5 ft. per 1000 can easily be read. If ten degrees of temperature are applied to ten inches of chart, a temperature variation of 0.05C can be accurately plotted. Reproduction of pressure and temperature plots have been accurately checked and found to take place without significant hysteresis effects.

ULTRASONIC CLEANING OF PRECISION GEAR REDUCERS

Machinery, May 1957 v. 63 n. 9

The production of precision components requires exact manufacturing methods very often including thorough cleaning operations. Small scale assemblies such as instrument speed reducers contain gears, miniature bearings and many other precision parts. In this particular case specifications required that the backlash in each reducer be less than 6 minutes of arc when measured with test loads of 1 inch-ounce. The assemblies needed to be thoroughly cleaned before testing since even the smallest particle of dirt could cause the driving torque to exceed this value.

Previously, the cleaning was performed by spraying with a solvent under pressure but this proved to be a slow and unreliable method. Dirt and other foreign particles inside bearings, in tapped holes and in other inaccessible places often could not be removed. This frequently resulted in excessive rejects, faulty operation or excessive wear. By utilizing ultrasonic cleaning methods these problems have been overcome with less time involved and with improved performance of the product.

The equipment used consists of a generator which supplies electrical energy to a transducer which acts as a container holding a fluid solvent. The transducer converts electrical energy into mechanical vibration which in turn produces cavitation in the cleaning fluid. This cavitation causes a violent scrubbing action which can remove dirt and other foreign matter from places otherwise inaccessible. Performance of the device is closely linked with the magnetostructive material used in the transducer. For durable construction nickel and certain nickel-iron alloys are generally selected. With these metals transducer efficiency can be as high as 90 per cent and the size and shape of the device can be designed to suit the application. For most cases a laminated type of construction gives the best combination of low losses and high capacity. The size is determined by the volume of fluid needed for cleaning and the shape by the operating frequency. The equipment is rated in terms of both frequency and power. Most units on the market range in frequency from 20,000 to 50,000 cycles per second and in power from less than 100 to several hundred watts.

FATIGUE, CREEP AND RELAXATION IN METALS

G. R. Gohn, *Bell Laboratories Record*, v. 35, No. 6, June, 1957

The principal causes of failure of metallic parts are corrosion, wear, fatigue and creep. Corrosion depends primarily on the chemical constituents of the materials and the environment. Wear is a problem which can be modified by machine design and lubrication. Fatigue is the behaviour of a material under repetitive stress and is the decisive factor in the life of many machines. It causes more than 80 per cent of the failures in machine elements. Creep is the behaviour of a material under continuous load. While it is important at room temperature only in special applications, creep becomes more decisive as the operating temperature or load increases. One result of creep, called relaxation, is of interest to the telephone industry.

Repeated stresses in metals cause fatigue. Such stresses exist in springs, diaphragms, rotating shafts, structures that are alternately loaded and unloaded, and in apparatus subjected to shock or thermal changes. Recently the work of physical metallurgists and research statisticians offers what appears to be a plausible explanation of fatigue. Fatigue can usually be associated with the progressive strain-hardening of the material, particularly in areas of high stress concentrations. This process is familiar to anyone who has repeatedly bent or stressed a piece of metal and found that it offered more and more resistance as the bending continued. When repeated stress is applied to a part such as an automobile axle, stress is concentrated in certain areas rather than being evenly distributed. This may lead to overstressing in some areas, starting a small crack. The corresponding reduction in area produces higher stresses and under repeated stressing the crack increases progressively to the point where the cross-section of the part can no longer carry the load. Sudden failure then occurs without advance warning. The failure is usually characterized by a non - ductile, crystalline - appearing fracture in which the failure path ignores crystal boundaries. This type of fracture is the means by which fatigue failures of most metals, except lead, can be identified upon detailed metallographic examination.

While this reasoning can explain many fatigue failures, it has been observed that certain cold-worked materials such as copper, lead alloys and aluminum, soften to a degree during cyclic stressing and that areas of low hardness develop at or near the point of failure. The strain-hardening theory does not adequately explain this phenomenon which may be associated with recrystallization or thermal effects.

The precise fatigue properties of a metal required for engineering design must usually be determined by laboratory tests made on carefully machined specimens. Tests were made on a 5 per cent tin bronze a material commonly used in the manufacture of telephone apparatus springs. At high stresses but at values well below the tensile strength, and usually below the proportional limit failure occured after only a relatively few cycles. However, at lower stresses, a point is reached at which no failure occurs even after an almost infinite number of cycles. Today, for a 40 year life, one billion cycles represents a desirable end point. Changing the spring material to nickel silver or phosphor bronze has resulted in longer life than for brass since they have a higher fatigue strength. Voids and inclusions of non-metallic particles have been reduced through better manufacturing processes and better material specifications thus eliminating many factors that increase localized stresses. This has been supplemented by producing finer grained materials, by elimination of stress-raisers such as tool marks or die stampings in highly stressed areas, by more careful adjustment of springs in the field to avoid nicking and by designing the springs within safe stress limits.

Fatigue failures in open-wire lines have been caused by vibrations set up by winds or road shocks. The damage is done mainly by vibration around 30 c.p.s. This frequency of vibration also can cause fatigue failure in lead cable sheathing. (The frequency is not encountered in th

NEW STRUTTED ROOF CONSTRUCTION

A patented triangular type of roof construction, patterned after the Hess-Grafrath system, has been introduced by a firm in Munich, Germany (Dreieck-Streben-Bau-Auswertung). The system, referred to as DSB, is said to save over half the wood requirements in roof construction. The DSB beam consists of an upper and lower flanged plank, joined by a strutted system attached by a suitable adhesive. The shear strength of the glued joints is at least that of the adjoining grain. The phenolic resin-based glue does not need application of pressure for setting.

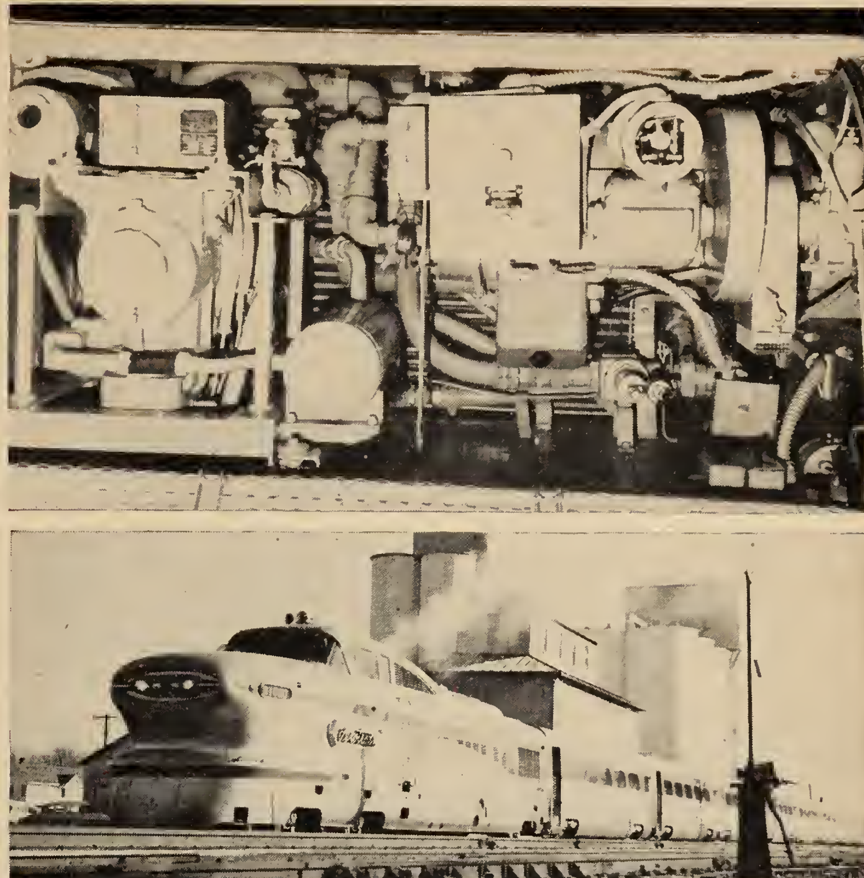
field installations but in transporting reeled cable on railway freight cars with slightly flattened wheels.) Also, the extremely slow cyclic stress changes which occur in aerial cable as a result of daily and seasonal temperature changes can cause failure.

Whereas fatigue occurs because of repeated stresses, creep results from continuously applied unchanging loads. It is defined as the permanent extension of a material under constant load. Except for lead and lead alloys, creep of significant magnitude seldom takes place in metals at room temperatures. Creep occurs as a result of viscous flow in the grain boundaries, of "slip" along crystallographic planes, and of rotation of the grains. Any one set of these mechanisms may predominate but all contribute to the total effect.

Creep problems occurred in the lead cable sleeves used to protect splices in toll cables which were gas pressurized to protect against moisture penetration. Internal pressure produced a constant stress in the sleeve material.

Fatigue and creep properties of a material can be improved by alloying, by cold working or by heat treatment. Of these the most effective is alloying. Fatigue resistant properties are improved by using finer-grained materials, while creep resistance is improved by using coarser-grained materials. Where both fatigue and creep are factors in the service life of apparatus, a compromise must be effected. Where both constant and repeated stresses are superimposed he creep rate will be accelerated by atigue failure and the life of the part is generally shortened.

Relaxation, which is a possible result of creep is the loss of stress in structural member held at constant ength; e.g., loss of tension in the taybolt of a boiler or in a stud holding a cover plate. Loss of stress occurs rapidly for a short time then becomes slower until a stress level s reached at which further change is ery small. Except in the boiler and urbine fields relaxation has played o small a part in deterioration processes that little investigation has been one in this area. During the development of solderless, wrapped ire connections studies of relaxation in copper switchboard wire were arried out at the Bell Telephone aboratories to insure that relaxation henomena would not adversely affect the reliability of the connections.



LIGHTWEIGHT TRAIN VISITS CANADA

Seen in Canada for the first time recently was the lightweight train developed by the Electro-Motive Division of General Motors, in La Grange, Ill., as the result of discussions with American railroad officials. The train (seen above) was developed as an experimental unit of engine and ten 40-passenger coaches. Two trains were built and were intensively tested (including the use of a closed television circuit to follow wheel tracking) before being operated on revenue service by three American railroads for several months. It is claimed that the coaches could be mass-produced for about $1000 a seat, compared with current cost for conventional equipment of over $2000 a seat; the centre of gravity is considerably lower than normal; weight is very much reduced; and operating costs should also be much less than with an ordinary diesel-hauled train. The engine of the "Aerotrain" is powered by a single 1200-h.p. diesel engine and drive is via two electric traction motors operating on the front four-wheel truck; the rear of the engine is supported on a two-wheel idler truck. Each coach has only two two-wheel trucks; suspension is by air bellows (similar to that used on some buses) and is compensated to give a level ride on banked curves. Coupling the coaches automatically connects all services. Each coach also has its individual air-conditioning unit (top picture) located, together with heating units and space for heavy baggage, below the coach floor. Power for these services is supplied from a 440 v., 3-phase, 60-cycle auxiliary generator in the engine. Design maximum speed is 102 m.p.h.

CENTRIFUGAL BOILER COMPRESSION STILL

K. C. D. Hickman, *Industrial and Engineering Chemistry*, v. 49, No. 5, 1957

Methods for desalinification of salt water are being investigated under the sponsorship of the U.S. Department of the Interior. A compression still has been devised which contains a rapidly rotating evaporator-condenser of sheet metal. Under centrifugal force the liquid films on both sides of the rotor are maintained so thin that overall heat transfer coefficients of U = 2500 to 6000 B.t.u./ft., hr., °F. are developed. Many tons of sea water have been distilled from a pair of copper cones 18 in. in diameter, without development of scale and without the heat transfer coefficient changing from an initial U = 3600. A temperature differential as low as 3° F. has been reallized. Experiments have been extended successfully with disks 4 x 5 ft. in dia. and the performance extrapolated to larger sizes. So successful were the tests that a still with 8 ft. rotors has been constructed.

The more significant parameters of

this kind of still have been measured and are recorded in this article. It appears that the relative area of evaporator-condenser surface can be diminished by a factor of 5 to 10 times and the total power requirement of a water-producing installation, given suitable ancillary equipment, can be reduced to less than 5 watt-hours per pound of distillate, or about 42 kwh. per 1000 gallons (U.S.) of fresh water distilled from sea water. This is about 17 times greater than the absolute, "second low" minimum postulated in a previous article, but less than half the power requirements of existing compression stills if they are operated at an acceptable ratio of output to first cost.

ADVANCED CONCEPTS ON THE PROPAGATION OF ELECTROMAGNETIC WAVES

W. T. T. Reikie, M.E.I.C.

The classical approach to the problem of electromagnetic wave propagation has relied heavily on the theory of light. Huygens in the enunciation of his principle concerning the reradiation of a wave front, qualitatively established light as a phenomenon of wave motion. Fresnel in the development of his integrals placed the theory of light on a quantitative basis which in the form of the Cornu spiral became a practical theory.

Fresnel's development of a theory backed by experimental evidence required the acceptance of a principle that has been aptly referred to as the fortuitous law of obliquity and attempt is herewith made to track down the true nature of this law.

Visualize the optical path belonging to a source and receiver consisting of the intervening space zoned into Fresnel zones of increasing order. Also recall the following dominant characteristics of such an optical path, namely the fixed volume of each zone is given by the volume of the initial or polar ellipsoid, and the fixed half wavelength path increment between adjacent zones.

Working upon the basis that a frozen wavefront position cannot be held responsible for the complex signal delivered to the receiver it is of interest to observe that a reradiating wave-front essentially carries its reradiation products along with itself while at the same time obeying the inverse square law which dictates the conservation of wavefront energy. Thus the wavefront from which a sample signal is extracted by the receiver contains in the complex nature of this signal none other than an historical record of the effective reradiation products cumulatively stamped upon itself in travelling through the entire distance from source to receiver.

Postulating that effective reradiation products within any given Fresnel zone originate from those reradiating elements which possess angles of break or obliquities which are not present within higher zones concentrates attention upon a very interesting feature; namely, that reradiating elements satisfying the above conditions are confined to symmetrically disposed mid-path volume elements whose volume for any given zone is proportional to its radial depth. It is now only necessary to consider equal volume elements as supporting equal reradiation product amplitudes regardless of the location of such elements within the effective reradiating zones under discussion in order to ensure the arrival of a wavefront sample at the receiver permitting evaluation in accordance with standard Fresnel integral procedures.

Should we now choose to consider volumes satisfying similar conditions to those described above but selected for angles of break which are not present within the higher Fresnel zones after skipping one or two or more zones initially it will be found that for Fresnel zones sufficiently removed from the polar zone the resulting volumes are twice, thrice, etc., the size of the original volumes for which a zero skip applied. This would appear to indicate that the additional or flanking volumes are basically capable of supporting secondary reradiation products of similar strength to those contained in the original volume. However, detailed construction of individual Cornu spirals for the leading and lagging flanks of such volumes reveals a pair of spirals skewed in opposite directions due to progressive positive and negative increments of field strengths within these flanks as the summation approaches the polar zone (i.e., moving out from the anchored convergence point for such partial spirals of secondary reradiation products).

The above demonstration, that flanking zones support spirals of reradiation skewed relative to the effective spiral of reradiation, coupled with the knowledge that these reradiation products of the wavefront must accumulate in accordance with the conservation of energy, can be tied together in the following manner; namely, all skewed spiral pairs must automatically wash out each other's reradiation products for the optical path to which they belong. Thus the true nature of the law of obliquity appears to be none other than a well-disguised form of the law of the conservation of energy as applied to the interlaced wavefront reradiation products belonging to an optical path.

In introducing the source of effective reradiation products our initial postulation concentrated attention upon symmetrically disposed mid-path volumes as the source of favoured reradiation products and this in turn elucidated the introduction of the concept of skewed spiral cancellation for flanking volumes. If now this latter characteristic of self-effacing skewed spiral pairs be considered as the meat of the matter it is possible to recast our initial concept into the form of a frozen mid-path wavefront which in turn may be translated optically to a frozen wavefront position clear of the mid-path location.

The ability to shift frozen wavefronts to any legitimately desired path location is of great convenience when studying obstructed optical paths requiring a concentration upon conditions at obstructed or shadowed locations within the path.

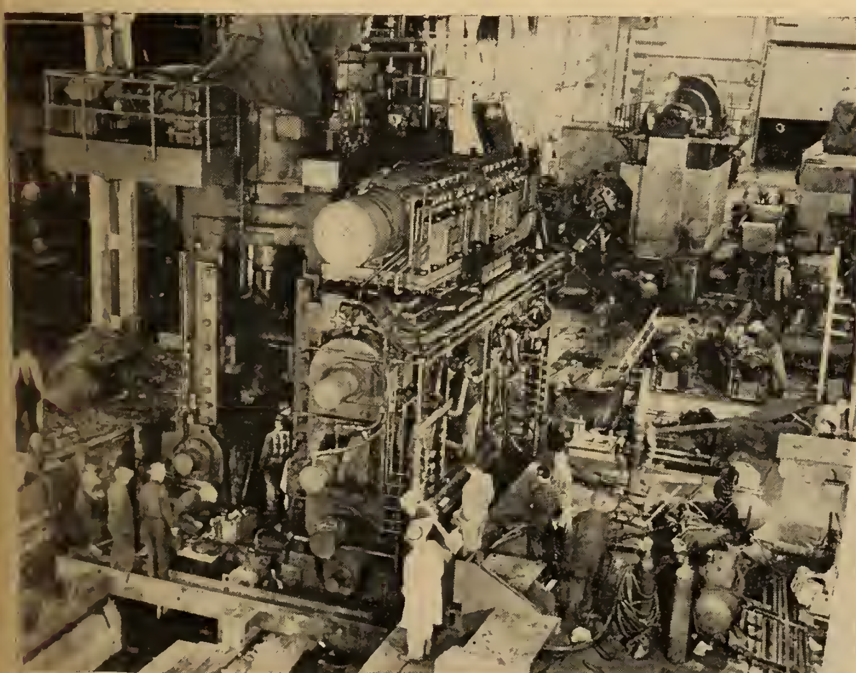
Once the logarithmic decay of resultant wavefront amplitude or strength due to the blotting out of polar Fresnel zones commences it is feasible to consider a knife edge obstruction as effectively blotting out three quarters of the wavefront in addition to the Fresnel zone count fully blanked by such an obstruction. The conversion of a knife edge obstruction to an equivalent iris obstruction has tremendous significance due to the realization that non - disturbed wavefront zones become absolutely necessary for the support of secondary illumination in the presence of knife-edge obstructions. Again, since a knife - edge obstruction ensures none other than the presence of non-disturbed wavefronts above the obstacle it now becomes feasible to reduce all obstacles, including smooth earth as an obstacle, to an equivalent knife-edge obstacle by simply locating the dividing line between non-disturbed and disturbed wavefronts above these obstacles. Such a procedure permits the use of a common language for diffraction problems.

The comprehensive discussion concerning secondary illumination characteristics in terms of light theory as given above requires the introduction of an additional concept in dealing with an optical path for an electromagnetic wavefront originating from a source and being accepted by a receiver possessing one degree of freedom rather than the two degrees of freedom present for a light source and receiver.

Briefly, the complex signal carried within the eye of the Cornu spiral permits evaluation in terms of a simple resultant only in the presence of universally polarized fields exciting a receiver of two degrees of freedom.

Thus an examination of the vector wrapped up within the eye of a Cornu spiral reveals the existence of a series of resultant signal vectors, angularly disposed in this eye, capable of capturing a one-degree freedom receiver excitation so as to delete receiver response in terms of any individual vector in this series. There remains, however, an excitation which in the presence of a tuned receiving circuit or antenna permits the development of a kick-back response. Through the introduction of thermodynamic principles it is possible to calculate that this kick-back response will reduce the simple resultant diffracted signal values.

The requirement for the support of secondary illumination by non-disturbed wavefronts thus is doubly necessary in dealing with propagation of energy at radio frequencies. Scatter theory must therefore be merely considered as an artifice for reintroducing path depth in treating secondary illumination effects due to a failure to realize that frozen wavefronts in themselves required the reference of these depth effects to a single wavefront.



UICK REPLACEMENT OF STEEL-MILL EQUIPMENT

an expansion program at the Hamilton plant of Dominion Foundries & Steel mited an old slabbing mill had to be removed and replaced with a new mill ie largest of its kind in Canada). Careful planning resulted in a down-time of ly 12 calendar days between shut-down of the old mill and running an ingot rough the new one. The new 650-ton, 46-in., 2-Hi slabbing mill was assembled temporary foundations 50 feet from the old mill, which continued to operate. rms for the new permanent foundations were prepared, complete with reinforcing el, ducts, etc., and new piping and electrical equipment installed. The old mill s shut down, dismantled and removed; old foundations blasted out; the new ms placed; and a quick-setting concrete poured. The new mill (above) was ved by a hydraulic jack on two specially lubricated steel rails to its permanent ndations. The work was carried out by the H. K. Ferguson Company.

FUELS: TODAY AND TOMORROW

Mechanical Engineering, June, 1957, v. 79, No. 6

In the United States the domestic market for bituminous coal has shifted radically under the competitive impacts of oil and gas, and as the result of ever-changing technology. Railroads which once consumed 20 per cent of the total coal production now operate with diesels and oil fuel. Residential and commercial use of coal has decreased; new homes tend to use gas, while old ones have switched to oil. The market that remains is subject in the long run to less competition from other fuels, and it is an expanding market.

The electric power industry has become the largest single coal customer. In 1955, 140 million tons were consumed by thermal electric plants, and it is likely that coal will retain its share (two-thirds) of this market, and the share could rise; 107 million tons of metallurgical grade coal were consumed by the coking industry, mostly for domestic steel. General industrial consumption exceeded 106 million tons, and exports amounted to 51 million. Electric power, steel and exports are considered to have excellent growth prospects and are characterized by a relatively stable demand for coal.

Coal prices have shown a long-run rise conforming to an increasing exponential trend averaging 1½ per cent annually since 1910 but this should be viewed in relation to the general inflationary trend. Productivity in underground mines is estimated (1955 data) at 1.1 tons per man-hour; in strip mines it is nearly three times as high. The average for the entire industry is 1.3 tons per man-hour, or over 10 tons per day per man. In mines using continuous mining equipment the output has been at least 4 tons per man-hour. It is expected that productivity will continue to grow through expansion, development, and improvement of continuous mining. About 23 million tons were produced with this equipment in 1955 against a total of 470 million tons. Geologically most continuous mining equipment requires coal seams at least 3½ ft. thick.

The rapid rise in hourly earnings in coal mining over the past ten years should ensure that miners will stick to mining rather than move to other industry. With new methods of shipping coal there has been a shift away from complete dependence on railroads; 79 per cent of all bituminous coal in 1953 was shipped from the mines by rail compared to 84 per cent in 1947. One transportation technique of the future involves a 50 per cent mixture of coal slurry and water in long-distance pipelines. Another prospect is long-distance conveyor belts. Barge traffic will continue to increase and the increasing combination of mine-mouth power generation with either long-distance transmission (as a result of improvements in power transmission techniques), or locational shifts of industry to nearby sites, can also yield savings in coal transportation costs.

The United States energy consumption in 1955 amounted to 40.7 x 10^{15} B.t.u. of which 28.4 per cent was supplied by coal, 41.3 per cent by crude petroleum and products, 26.8 per cent by natural gas, and 3.4 per cent by hydro. This consumption is expected to double by 1980.

The trend is toward the use of materials that require more energy per unit weight or volume for their production and fabrication. For example, aluminum, the consumption of which is rising faster than that of older metals, requires more energy than do many of the materials it is replacing, such as steel, copper, lumber, paper or cement. Synthetic building materials, plastics and fibres use far more energy than the natural materials, to fit them for the market. As a reflection of this upgrading process, the electric power industry, which has been doubling every 10 years, has recently increased its pace so that it is doubling every 8 years.

The fact that energy demand will grow does not mean that all fuels will share equally, though it is inconceivable that the competition from any one fuel will reverse the growth pattern of another. Before 1930 petroleum and gas supplied 31 per cent and coal 66 per cent of the nations' total energy requirements. Now the relation is reversed and oil and gas supply 67 per cent and coal only 29 per cent. But demand for all fuels continues at an increasing rate. Future problems of the petroleum and natural-gas industries will be those of providing supplies, rather than finding markets. Technological development will facilitate location of deposits, permit deeper drilling and reduce cost of transport. Eventually, synthetic liquid fuels and fuel gas manufactured from coal and shale will play significant roles.

In many nations where it is more economical to make large capital expenditures than pay the higher prices for coal and petroleum, development of atomic energy will proceed rapidly. In the United States, industry and government are committed to the expenditure of about $300 million for the construction of six major nuclear-power plants having a total capacity of 800,000 kw. The AEC and the Navy have large financial investment in the development of reactors for use in an 85,000-ton aircraft carrier, a cruiser and some submarines. When the conventional fuels are in too short supply or become too expensive, energy from the fission of uranium or thorium, or even fission of the atom, may supply much of the demand for heat and power.

Development in the harnessing of solar energy is proceeding. Novel applications such as the silicon solar battery and high temperature solar furnaces have been devised and serious research on possible larger scale operations is presently being studied.

SENSITIVE DETECTOR CRAYONS FOR PHOSGENE, HYDROGENE CYANIDE, CYANOGEN CHLORIDE, AND LEWISITE

B. Witten and A. Prostok, *Analytical Chemistry*, v. 29, No. 6

A simple means for detecting and semi - quantitatively estimating the amount of trace quantities of gases in the atmosphere or in an enclosed space is frequently desired. One of the easiest ways of doing this is to use detector crayons, which are made by mixing detector reagents with suitable inert fillers and binders, and forming the resulting mixture into crayons. These can be used to write on many surfaces such as paper, wood, painted surfaces, etc., to give sensitive marks which change colour in contact with the appropriate gas or liquid.

In many cases reagent systems are known which are capable of detecting the desired compound with the requisite sensitivity by a colour change. These systems may often be used as the detector reagents which are incorporated into crayons. Detector papers can also be used for various gases. However, crayons are usually much more stable than the paper in storage because of their much smaller surface area which reduces the tendency of the active ingredients to volatilize and/or oxidize.

One of several ways to manufacture the crayons is to mix the detector reagents with blanc fixe (precipitated barium sulphate) or other fillers, add a suitable amount of wax-in-water emulsion for a binder, form crayons by extrusion, moulding or casting and then dry the mixture. These crayons may suffer from decreased sensitivity, probably because the wax partially protects the active ingredients from the gases.

Another method is to take the above mixture and compress it to make a crayon in a manner similar to making tablets. The simplest method is to dissolve the active ingredients in a suitable solvent, absorb this solution into moulded plain white blackboard chalk crayons and then dry the chalk. By this method, however, it is hard to control the amount of absorption and such soaked crayons often deteriorate more rapidly in storage than other types. In many cases the detector reagents can be mixed with the usual commercial crayon ingredients and formed in the usual fashion.

The sensitivity of the crayon marks to a gas can be expressed as a $C \times T$ value where C is the concentration of the gas and T is the time necessary for the crayon mark to respond to concentration C. If the crayon marks are exposed to similar environments of air turbulence, temperature, humidity, etc., the length of time necessary to cause a colour change is, to a first approximation, inversely proportional to the concentration of the reactive gas. Thus the CT value is approximately constant and is a measure of the sensitivity of the crayon mark. Although their use is primarily qualitative CT values will give a rough estimate of concentration.

Recipes are given for preparation of crayons to determine the gases listed above. An extensive study of the specificity of and interference to these crayons has not been made. They appear to be fairly specific and not too susceptible to interference by other gases. However, high concentrations of chlorine will interfere with most of these tests. No attempt was made to find the optimum composition and proportions of ingredients in these crayons but these described here are sensitive, stable in storage and write well.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

With the labour force on the entire seaway and power project at a new peak of some 17,000 during June, the tempo of construction was accelerating. The international power-house is expected to reach 90 per cent of completion by year-end. At Long Sault dam, work will continue throughout the winter. At Iroquois dam when Stage II is completed late this year and the Galop Island cofferdam breached, the dam will take control of the water level in Lake Ontario.

Progress by Ontario Hydro

Weather was generally favourable for construction work throughout June. The labour force was increased to a total of 4,900 persons.

On the power-house site a total of 635,000 cubic yards of concrete had been placed to the end of June. Concrete placing operations were in progress on No. 11 and No. 12 draught tubes. Operations were also proceeding putting concrete in the No. 3 ice sluice and for the headworks of No. 16 unit.

Structural steel for the power-house erection bay and administration building had been virtually all erected. The framework for the 300 ton gantry crane had been assembled and work had commenced on the erection of the headworks gantry crane.

With setting of 8 speedrings in various stages of completion, the speed ring for No. 9 unit was being installed. The first three headgates had been received and preparation was being made to install them.

Excellent progress was being made on all sections of Cornwall dike, with 65 per cent of the material placed into this permanent structure. Excavation for dike construction had been completed between the power-house and the Cornwall diversion canal closure structure. This had involved the crossing of the old channel of Cornwall canal. The dike will be completed during the current season.

Progress of Ontario Hydro's section of the power-house. Concrete placing can be seen in the foreground; in the background, speed ring and turbine casings; in the extreme background, structural steel for erection bay.

Heavy freight trains had been operating over the relocated Canadian National Railway line between Cardinal and Cornwall during June. Most of the final adjustments on the automatic equipment had been completed in preparation for the operation of fast passenger trains. Work was being concentrated on the new stations and was well advanced.

Paving was virtually completed on the highway diversion between Cornwall and Iroquois. Work was progressing favourably on the Highway No. 31 overpass at the C.N.R. relocated tracks north of Morrisburg.

At the St. Lawrence transformer station, work was being concentrated on the sections that will receive 230-kv. power next year. This sector will tie the power from the new source into the Ontario Hydro system. About 65 per cent of the work on the second stage had been completed.

Excavation had commenced on Canada Island and work was also starting on dredging in the Cardinal area. In other channel improvements contracts, Spencer Island pier had been completed and dredging had started upstream from Galop Island.

At Galop Island, excavation clean-up work was in progress in preparation for flooding the cut. More than half the excavation had been completed at Iroquois Point and a dredge had started to work on the upstream end of the contract. Good progress also was being made in excavating Point Three Points and construction of the perimeter dike.

The first stage of house moving was completed in Morrisburg with seventy - one houses moved. The house moving program will continue on a reduced scale for the remaining seven houses in this phase.

Steel erection for a large block in the shopping centre was completed and bricklaying was underway. Also completed in the Morrisburg area was the final installation of the water intake facilities. Construction of the thirty-six rental housing units was progressing favourably.

At Iroquois, demolition within the old town continued with demolition of the Anglican and the United Churches underway. In the new townsites of Ingleside and Long Sault, general clean-up and painting operations were in progress. In Ingleside the steel erection had been completed for the new separate school and the new shopping centre.

Progress by NYSPA

With work on the project continuing on schedule, concrete placement on all features exceeded 1,220,000 cubic yards at the end of June. Excavation exceeded 41.5 million cubic yards. Employment averaged 5,720 for the month. Five speedrings were installed, while two turbine runners and some generator equipment had been delivered.

Concrete placement on the American half of the power-house continued on schedule. Some 53,000 cubic yards were placed during the month, bringing the total to date to 639,000 cubic yards. Structural steel work for the service building, the river crossing towers and the 115-kv. switchyard was progressing rapidly. Placing of embankment at the forebay training wall continued.

At Long Sault dam, excavation, drilling and grouting in the stage II foundation area had continued at an accelerated pace. Concrete operations were started early in June and 31,000 cubic yards were placed during the month, bringing the total to date to 256,000 cubic yards.

At Iroquois dam, 20,000 cubic yards of concrete were placed during the month, bringing the total to date to 160,000 cubic yards. With 8 piers built on stage II, placing of concrete in the deck had been commenced.

At Massena intake, the required excavation for the stage II structure was completed and concrete placement was started. 17,000 cubic yards were placed during the month, bringing the total to date to 142,000 cubic yards. Construction of the dike adjacent to the intake structure was resumed.

Channel improvement work at Sparrowhawk Point, Toussaints Island, Point Three Points, Leishman's Point and at Ogden Island was progressing on schedule. The channel work was approximately 75 per cent completed. Topsoiling and seeding at Galop south channel spoil areas were resumed. Construction of Richards Landing dike was started. The main dike was 85 per cent completed.

Clearing of the reservoir by the three reservoir contractors continued on schedule with approximately 6,700 acres or 56 per cent of the area cleared to date. The contract was awarded for park and woodland improvement between Barnhart Island power plant and Long Sault dam. Clearing and chemical treatment of the Barnhart-Plattsburgh transmission line right of way were completed.

Work under the three highway relocation contracts were progressing ahead of schedule. All phases of construction operations were in progress. The groundbreaking ceremonies June 14 for Reynolds Metals Company and Chevrolet Motor Division gave evidence of the forthcoming north country development.

Progress by SLSDC

With concrete placement at Eisenhower and Grasse River locks at over 60 per cent completion as of the end of June, final completion is expected by year's end. Some 9 million cubic yards had been removed from the mainland portion of the Long Sault channel out of a total of 13 million cubic yards, representing 70 per cent of completion.

Dredging of the south Cornwall channel was commenced in May on section A and continued on section C. In spite of a late start on this dredging, the required completion to 14 ft. depth by the time the headpond is raised in July 1958 is feasible, at which time navigation through the old 14-ft. canals on the Canadian side will be discontinued.

Progress by SLSA

According to an engineering progress report issued by the St. Lawrence Seaway Authority at the end of June, on the third anniversary of establishment of the Authority, progress was assuming a more rapid pace and work was well advanced. Dry excavation stood at 63 per cent of completion with more than 35 million cubic yards of rock, earth and other materials dug from the stream side to prepare the seaway channel.

A great fleet of dredges had removed from the riverbed no less than 7½ million yards of rock, sand, silt and other overburden for a progress figure of 41 per cent. Placing

The October, 1957, issue of the *Journal* will be a Seaway issue. This will mark the second time a complete technical section will be devoted to this important project, the earlier one being September 1956.

of concrete, which had, of necessity to await excavation, stood at 36 per cent of completion with 725,000 cubic yards placed to date, or 1½ million tons. Some 5,400 men were at work on the 90 general contracts awarded for construction and supply at a value of $230 million.

In the Lachine section, on 47 contracts valued at close to $100 million, 2,724 men were at work and completion had reached 45 per cent. In the Soulanges section on contracts valued at $38 million, 1,242 men were at work and completion had reached 25 per cent. A further 330 men at Lake St. Francis had reached 75 per cent of completion on three dredging contracts valued at $5.76 million.

In the International Rapids section, 628 men were at work on 112 contracts valued at $35 million and had attained 25 per cent of completion. At the Welland ship canal, with 500 men employed, dredging and excavation valued at $21 million were 20 per cent complete.

Nearly $20 million worth of equipquired for operation of the locks and movable spans, such as lock gates of the mitre and sector type; stiffleg derricks, diesel generators, pumps, electrical control desks, lighting and heating fixtures and many other items.

At the St. Lambert lock the downstream entrance wall was 65 per cent complete and the concrete for the lock chamber about 60 per cent completed. Placing of concrete in the upstream entrance wall was just being started. The intake was completed and ready for permanent operation.

Some 30,000 cubic yards of concrete was placed at the Côte St. Catherine lock during June, bringing the concrete to 55 per cent of completion. Earth excavation was half done and rock excavation 85 per cent completed.

On the upper and lower Beauharnois locks, estimated to cost some $29 million, work was proceeding at a rapid pace. With all excavation substantially completed, placing of concrete was proceeding at both locks. The four-lane tunnel to carry highway traffic on highway No. 3 under the lower lock, comprising two tubes of two lanes each, was partially opened to traffic early in June. Fabrication of two movable bridge spans over the Beauharnois canal was also under way.

At the Iroquois lock, which will be the first of the five Canadian locks to be completed, all concrete for the lock structure proper and for the upstream guide and guard walls had been placed by end of June. Still remaining are the guide and guardwalls at downstream end. Completion of the lock is expected for November several months ahead of schedule.

The raising of the Jacques Cartier bridge to provide for 120-foot clearance over the seaway channel was being carried on night and day under the continuing liveload of motor traffic. The whole of the southern half must be raised some 50 feet. On the night of June 9 traffic was halted an hour to place a 'climbing jack' beneath the superstructure at pier 11, where the steel had already been raised some 4½ feet. Plans have been set for the swinging in of a new span over the channel at piers 10 and 11 on November 2.

At the south approach to the Mercier highway bridge, construction of the new concrete piers to carry future road traffic 120 feet above the channel was proceeding rapidly.

On the Welland ship canal, of the six contracts awarded for enlarging the existing channel and providing a governing depth of 27 feet, two contracts had been completed by the end of June and two others were nearing completion.

Seaway News

The Cement Situation Being Watched

With peak demand expected this year for cement on the seaway and power project, officials of Ontario Hydro and Canada's Seaway Authority are attentively watching cement statistics. Canada's productive capacity has been sharply increased over the past year for placing concrete on the seaway project. Because of the reluctance of many customers to place their orders early and stockpile, there may not be enough handling and transportation facilities to fill cement orders for the seaway when it is wanted.

Last year, Canada's total consumption of cement was estimated at over 32 million barrels, which included some 3.3 million barrels imported. This year Canadian construction activities generally are expected to at least equal the 1956 volume. Imports are at about the same level as last year, but exports to date in 1957 are running about a third higher than in 1956. About 3 million barrels are expected to be required for seaway navigation and power structures this year, and almost a third of it will be exported for use in the American section of the power development.

Giant Freighter-Tanker Proposed

A new 27,500-ton tramp freighter for carrying grain and petroleum through the seaway has been proposed by the U.S. Maritime Administration. Grain Fleet, Inc., which already operates three ships in bulk trades, has applied for a construction subsidy and a federal mortgage insurance on the vessel. It will be of novel design, and may be the prototype of a new American flag tramp fleet.

The ship would be the largest planned for seaway traffic. Grain Fleet officials say the ship would be unable to take its full 'lift' through the channels but would be limited to about 16,000 tons of cargo. Experienced tanker men are skeptical about the feasibility of carrying grain and oil on an alternating basis each voyage. But company spokesmen claimed it would be profitable despite the fact that cleaning petroleum tanks for carriage of edible products now costs $20,000 each time.

Tolls

Dr. Pierre Camu of Laval University believes 'very low' tolls should be levied when the seaway opens for navigation in 1959, to attract traffic. "A system might be established", he told the Geographers Association meeting in Quebec City on June 9, "so that during the 1960-65 period annual revenues might be only $5 to $10 millions. This figure could be increased to more than $25 million yearly after 1975 until the end of the 50 or 40 year period needed to recover the cost of the project."

Professor Camu also suggested that tolls be applied regionally. It would be unfair to charge all ships the same toll regardless of whether they were using one or a few sections of the seaway. Also to be worked out, he stated, is who is to collect the tolls. "We hope," he said, "that both countries will agree to set up only one organization. It should be in Montreal, the ideal trans-shipment centre and the entrance and exit of the whole system".

No Pilot Shortage Seen for Seaway

No pilot shortage is anticipated on the St. Lawrence, even with the increased demand from shipping once the seaway becomes a reality, said Louis Hemond, secretary-treasurer of the United Montreal Pilots, in June. No plans were in the making for expanding the organization's membership. Canada has about 50 pilots operating between Montreal and Kingston, he reported, while one hundred were employed for piloting vessels between Father Point and Montreal and an equal number between Quebec and Montreal. American pilots on the Great Lakes, he said, had been complaining Canadian pilots were guiding ships in American waters, and had lodged a warning with Washington authorities on this basis, that sufficient numbers of U.S. pilots would not be available once the seaway is completed, if the practice were permitted to continue.

Bridge Construction at Montreal

Privy Council President The Hon. Lionel Chevrier, in an election speech at Montreal on June 6, stated that Canada's Seaway Authority was building ten bridges to improve road and rail traffic over the seaway channel. Of these, seven are located in the Montreal area, not counting the new and expensive modifications being made to the four metropolitan bridges and their approaches.

"We will be spending some $25 million for bridges in the Montreal area", he revealed. "In addition there will be the future Nuns' Island Bridge, which the Canadian government has decided to build. Plans of this bridge, construction of which is assigned to the National Harbours Board, are in preparation."

Canadian Pipeline Projects

Westcoast Transmission Company

Westcoast Transmission's pipeline will be delivering gas by August 1, two months ahead of its scheduled completion date. The Company has denied the rumor that a large section of the pipeline had been found defective and had to be replaced. During tests of one shipment an unusually large number of breaks were found, but that portion of the pipeline had all been tested again and was ready for operation. Pipe shipped in 1957 has all tested satisfactorily and no further trouble is expected.

Craig and Ralston Construction Co. crews were running tests in June on a 400-mile section of Westcoast's main pipeline between Prince George and the International Border. Tests call for specialized equipment and techniques. The pipe is blown up with water or air pressure to 1170 pounds per square inch — actually more than operating pressures.

The contractors had some 80 men and $800,000 worth of equipment on the work. They also have contracts in the Fraser Valley for 35 miles of 2-inch, 4-inch and 6-inch lines for British Columbia Electric Co. Pipe laying was completed by mid-June in the Langley area and crews had started work on the Albion-Mission distribution systems.

"The demand for natural gas on the West Coast is growing at an almost unbelievable pace" states Paul Kayser, president of El Paso Natural Gas Co., Westcoast Transmission's biggest customer. His company has contracted to provide an additional half million cubic feet daily to its western market where population is growing at three times the national average.

Trans Canada Pipelines

Charles S. Coates, former executive vice-president of Trans Canada, has been elected president, with headquarters in Toronto. Former president N. E. Tanner has been elected chairman of the board, with headquarters at Calgary. Mr. Tanner became president of Trans Canada Pipelines in 1954.

Late in June it was reported that Bannister Construction Co. had started June 12 laying 18 miles of a 10-inch branch line from Trans Canada to serve Brandon. Rapid progress was being made and completion was expected early in July. Canadian Bechtel Ltd., on section 6 between McGregor and Ile des Chenes, was making progress of a mile a day of 34-inch pipe. Canadian Parkhill Pipestringing Ltd. was stringing at the rate of two miles a day and had reached the Ile des Chênes compressor station by the middle of June.

Price-Poole on their 34-inch spread for section 4 resumed work on June 1, and were making progress of 8,000 ft. daily. With 80-ft. double joints they have been able to keep the 'firing line' crew down to 20 weld-

A 357-foot section of 34-inch diameter pipe is ready to be pulled across the Red River south of Winnipeg, in the Trans-Canada Pipe Line's line to Eastern Canada. The 40-foot lengths of pipe have been welded into the long section. Weights will hold the pipe in a ditch below the river bed.

ers, half the number needed on single joints. Marine Pipeline and Dredging Ltd., completed the first section of their 34-inch gas line crossing of the Red River south of St. Norbert on June 15. The second section will be ready for pulling early in July.

Majestic Contractors had commenced rock-drilling on section 7 on their 30-inch spread between Ile des Chênes and the Manitoba border. Pipe deliveries are expected early in July. On this section the pipe has to cross the Greater Winnipeg Water District railway and aqueduct, five road crossings and two railway crossings. Clearing was completed early in June.

Tenders closed on May 28 for three 110-mile sections of the 24-inch Toronto - Montreal pipeline. Awards had not been announced by the end of June, but a start is expected in July.

Union Gas Co. of Canada

Union Gas Company reports sales of 15.2 billion feet of gas for the year ending March 31, 1957, up from 13.5 billion the previous year. Customers at year end totalled 98,672, an increase of more than 5,000 over a year ago. Residential heating customers increased to 45,000.

Construction of the Company's large diameter pipeline from Dawn storage fields is expected to be completed by December. Among the new markets to be served are Hamilton, Guelph, Stratford, Kitchener, Waterloo, St. Mary's and Strathroy. It is hoped gas can be turned on in the new markets by December 1. It is the company's intention to continue this expansion to other towns and villages not now served with natural gas as and when extensions can be justified.

Union Gas awarded contracts in June for a distribution system in Guelph to Majestic Contractors, and distribution systems in Stratford and Strathroy to J. W. Carn.

Consumers Gas Co. of Toronto

Consumers Gas Co. of Toronto sold 10 billion cubic feet in the first seven months of the current fiscal year, up 81 per cent compared with a similar period a year earlier. The relative increase in revenue at 44 per cent did not keep pace in sales volume due to a downward price adjustment made to customers during the period.

In Metropolitan Toronto some 30,000 houses are heated with natural gas compared with 4,000 a year ago. In Ottawa, Interprovincial Utilities Ltd., acquired in May 1957, will be ready to distribute natural gas when it arrives from the west. Interprovincial presently serves 2,300 customers with manufactured gas. Consumers' expansion program from 1957 to 1962 inclusive is expected to cost some $75 million.

Work is under way this year for some 300 miles of distribution lines for Consumers Gas Co. in the Toronto area. Majestic Contractors, F. E. Shaw, Ltd., the Somerville Co. Ltd., and Mid - Canada Contractors are sharing the work.

Trans Canada to Supply Regina

Trans Canada has signed a contract with the Saskatchewan Power Commission for 10 million M.M.cfd. over a 20 year term. The contract is designed as a stopgap until use can be made of reserves in West Saskatchewan and Eastern Alberta.

More Gas Export Deals Shaping Up

A battle is shaping up respecting Alberta's gas reserves and what markets each should serve. Trans Canada and Westcoast are each trying to sign up gas purchase deals to support much larger export programs. Other interests, involving a third gas export proposal, are seeking to sign up long term purchase contracts. Price of gas has been bid up to 12 cents per Mcf at wellhead, up 20 per cent from what Trans Canada originally paid.

Tennessee Gas Transmission's purchase contract from Trans Canada comes up for renewal in November. With competing U.S. pipelines seeking gas from both of them, prices are likely to be revised upwards. Trans Canada's efforts to buy more from producers before any deliveries are made hint Trans Canada officials feel an F.P.C. decision will be in their favour.

All this points to the likelihood of larger exports of Canadian gas to the U.S., probably at higher prices. The Alberta Petroleum and Conservation Board will have to take another close look at its entire reserve position.

Association Meetings Discuss Gas

D. K. Yorath, president of Canadian Western Gas of Clagary, addressing the Canadian Investment Dealers Association meeting on June 14, predicted that acceptance of gas would be more rapid than forecasts. By 1980 gas would supply a quarter of the total energy used in Canada.

Capital expenditure of $2 billion within the next five to seven years on gas development was reasonable, he believed, in view of the $25 billion outlay suggested by the Gordon Commission over a 25 year period. This, he said, was supported by the experience of the British Columbia Electric in Vancouver, and Consumers' Gas in Toronto. The price of gas, he believed, would rise to a point where it may be just competitive with other fuels, and if so it would be selling itself on convenience, efficiency and quality alone.

R. H. Dean, president-elect of IDA will ask incoming executive to consider means whereby the two groups of security dealers, investment dealers and stock brokers, could present a united front, thereby taking their place more forcibly beside such united groups as the Canadian Bankers Association of Canada.

Fred R. Palin, general manager of Union Gas, president of the Canadian Gas Association told the C.G.A. meeting at Jasper on June 25 that the gas industry must ensure that investors retain their confidence in it and that the consumer must be made a satisfied customer. He called for an adequate investor relations program to assure the attraction of required capital and to keep before the investor the importance of the expanding gas industry to the Canadian economy.

Two New Pipe Mills

Mannesmann Tube Company's new $20 million tube mill was officially opened at Sault Ste. Marie, Ontario, on June 17. Production, scheduled at 225,000 tons yearly is expected to attain a speed of one tube every 20 seconds on a site leased from Algoma Steel Corporation. Production will be primarily for the Canadian oil and gas market.

Prairie Pipe Manufacturing Co.'s $3 million Regina pipe mill is now in full operation, with a a rated capacity of 75,000 tons yearly.

Copper Mill in B.C.

Financing has been completed and construction will start immediately on British Columbia's first copper mill, according to a recent announcement by Richard M. Reiner, president of Western Copper Mills Ltd., Vancouver.

The project, which was originally announced over a year ago as a $3½ million investment, will now be in excess of $8 million. It will be completely under-written by Canadian funds.

Originally scheduled to employ 200 workers at full capacity, the plant on completion is expected to employ 350 with a maximum capacity of 18,000 tons annually.

Financing has been arranged by the national financing house of Gardner & Co. Ltd. Toronto, with Western Development & Power Ltd. forming part of the original investment group.

The plant will be located on 15 acres of leased land on the Annacis Island development. It will have 170,000 sq. ft. of floor space with integrated mill and its own casting shop. The administration building will be additional.

Initial production is scheduled for late 1958.

Machinery will be of the latest and most modern type manufactured in the United States and Canada with some specialized items from Europe.

Products will cover a wide range of industrial and domestic applications such as seamless copper, brass and bronze tubing and pipe for condenser and heat exchangers, refrigeration, automotive and marine service and copper tubing for domestic water supply.

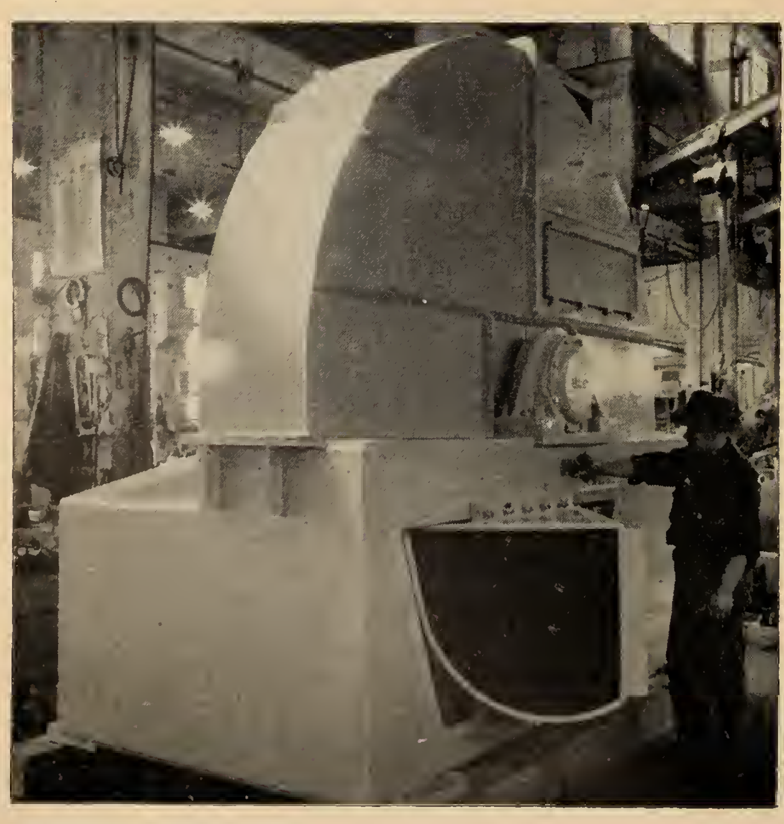
For the electrical industry, a variety of items is scheduled for production, principally buss bars for high as well as low tension switchgear installations, etc.

Other industrial products will be a complete line of brass rods and shapes, and copper rods for the local wire and cable mills.

Using mainly Canadian and U.S. copper, the mill will supply the needs of Western Canadian industry primarily and will also seek markets across Canada and abroad.

Decision to build the mill was prompted by the rapid industrial growth of the western provinces now supplied by eastern Canadian sources; the proximity of Vancouver to raw materials, and the advantages it holds for export.

Dimensions of the huge 112-inch chipper to be installed in the new B.C. Forest Products pulp mill at Crofton, V.I., are well illustrated in this picture, taken just before the machine was shipped. Designed by Hansel Engineering Co. Ltd., Vancouver, the chipper was built by Vivian Diesels and Munitions Ltd. It will consume a whole log up to 25 inches in diameter.



Record Year for Roadbuilding

A recent survey records that all governments plan to spend $861 million in Canada this year on roadbuilding. This is a 20 per cent increase over 1956, when the total budget was $715 million.

The Canadian Good Roads Association made the survey of road and street budgets on which these statements are based.

Provincial highway budgets account for $604 million, for year ending March 31, 1958. This is 70 per cent of the total road budgets of all governments, and is an increase of 24 per cent over provincial expenditures on roads in the previous year.

On the basis of contract reports it is estimated that municipal governments will spend $167 million, an increase of nine per cent.

Federal government plans to spend $71 million, compared with $62 million in 1956.

The Province of Ontario is the largest roadbuilding agency in the country, with a current budget of $236 million. The Province of Alberta will spend the largest amount per capita on its roads and streets.

The same development is evident in the current year as in every year since the war: while paved road mileage has been increasing steadily, the number of automotive vehicles has been increasing. This year's registration figures will be as high as 4.4 million. The concentration on the highways has grown to 21.4 vehicles per mile of surfaced highway, as compared to 11.6 per mile in 1946.

Every government faces this increasing pressure of traffic, and sees in continued economic growth the likelihood of more congestion.

A substantial backlog of road needs exists, states C.G.R.A., and it is conceded generally that long-range programs are indispensable. This same need exists in the field of urban street redevelopment.

Ontario Department of Highways has made a survey forecasting the Province's needs for the next 20 years. C.G.R.A. says that the study illustrates that the development of roads can be made to keep pace with demand and at a substantially lower cost. The planned approach brings about economy and efficiency.

Alberta Power

Calgary Power Limited's Wabamun plant, 42 miles west of Edmonton, combines natural gas, air and water into useful electrical energy by producing high pressure steam which drives a steam turbine and directly coupled electric generator.

The Wabamun plant is an important part in the Company's continuing construction program, required to meet the rapidly growing electric power load in Alberta. Completed in 1956, with an initial rated generating capacity of 66,000 kilowatts, the plant will be extended by means of a second 66,000 kilowatt unit now on order for installation in 1958. A third 120,000-kw. unit is scheduled for 1960.

The plant is presently using natural gas from the Alexandra Field. Eventually it will convert to coal to be supplied by a nearby deposit of 66 million tons.

In the main, the Company's load has been met over the years by the construction of plants on the Bow River and its tributaries, west of Calgary. These plants now serve an extensive high voltage transmission system which is interconnected with the other major electric utility systems in Alberta, and with the East Kootenay Power Co. in British Columbia. Eleven plants already constructed represent one-sixth of the estimated potential hydro power in the province.

Power Requirements Increased

In 1956 the Company's load was over 1,300 million kilowatt hours. This represents a 325 per cent increase over conditions of 1946, as compared to a 225 increase for all of Canada over a ten-year period.

The addition to the Company's load of 200 million k.w.h. per year is explained by the tremendous growth in industry, and the interest of the growing and prosperous population in more electrical appliances and in farm electrification.

The Wabamun development, commissioned in October 1956, is the first thermal power plant built by the Company. The base load has grown to the point where large thermal plants can be operated at near maximum capacity almost continually, thereby decreasing operating costs to a minimum, while taking advantage of the lower capital cost per unit of capacity for a large steam plant. These advantages are combined with the low fuel costs in Alberta and the relative proximity of thermal plants to load centres.

Thermal and Hydro Power

Integration of hydro and thermal plants is under way. Development of remaining hydro-electric plant sites in the province presents some economic problems. However the Calgary Power plan is that generating capacity can be substantially increased at low cost by installing additional generating units in existing hydro plants and by constructing new hydro plants with a generating capacity that is the maximum attainable, to operate in conjunction with base load thermal plants.

A second 23,000-hp. unit is being installed at Cascade, to be completed this year. Second units at Spray and Rundle, totalling 97,000 hp., scheduled for 1959 are under consideration.

By the fall of 1960 the Company's hydro plant capability will be 320,000 kilowatts. When the third unit is installed at Wabamun, the thermal capability, including 25,000 kw. received under contract with the City of Medicine Hat, will be 287,000 kw.

What Goes On

Ore Bridge Shipped

A new ore bridge was scheduled for assembly early in July in the Steel Company of Canada steel mill in Hamilton. The last major part of the 375-foot coal carrying ore bridge—the 20-ton main hoisting unit—was shipped from the Welland plant of United Steel Corporation Limited in June.

The ore bridge is designed to remove coal from lake freighters at a rate of 1200 tons per hour. Its cost is approximately $1.5 million, and it requires more than a year to complete.

The installation of such equipment is an indication of the increased capacity of Canadian steel producers.

Highway Reclassification

The Saskatoon Department of Highways and Transportation has completed a preliminary reclassification of all roads and streets in the province, it was announced recently by Loyde T. Holmes, Deputy Minister of Highways. This was undertaken in conjunction with a comprehensive reorganization of the planning activities of the highways department.

Foreign Investments

Mannesmann Tube Company officially marked the opening of its seamless steel pipe plant at Sault Ste. Marie, Ont., in June.

The financial editor of the *Toronto Daily Star* commented that this development, coupled with the opening of the St. Lawrence Cement's Clarkson plant, results in $50 million in European money going to work in the Canadian economy.

Baffin Island Mining

Ultra Shawkey Mines is doing exploration and drilling on Baffin Island on claims which may prove up a large deposit of concentrating-type magnetite iron ore.

Costs of a mining development on Baffin Island would be up to $150 million, which would require the annual production of 12.5 millions tons of ore.

Other mining groups are known to be interested in Baffin Island which has been reported to contain base metals and coal.

Financial Post, June 15.

THE ANNUAL MEETING

Minutes of the 71st Annual General Meeting

The seventy-first annual meeting of The Engineering Institute of Canada was convened in the Ball Room of the Banff Springs Hotel, Banff, Alberta, on Wednesday, June 12, 1957, at ten o'clock a.m. with President V. A. McKillop in the chair.

The president extended a welcome to all present and commented on the fact that it was just nine years ago that an annual general meeting had been held in Banff. At that time the attendance was about six hundred. This year it was expected to be at least fifty per cent more, a very encouraging sign, marking the growth of the organization.

The minutes of the seventieth annual general meeting as published on pages 1054 and 1055 of the August 1956 *Journal* were taken as read and approved.

Nominating Committee

The membership of the Nominating Committee of the Institute for the year 1957 is as follows:

Chairman C. V. Antenbring, Winnipeg

Branch	*Representative*
Amherst	J. N. Ritchie
Belleville	W. E. Van Steenburgh
Border Cities	C. G. R. Armstrong
Brockville	F. F. Walsh
Calgary	K. W. Mitchell
Cape Breton	M. R. Campbell
Central Br. Columbia	A. F. Joplin
Corner Brook	
Cornwall	D. Ross-Ross
Eastern Townships	R. D. Mawhood
Edmonton	E. K. Cumming
Fredericton	D. J. Brewer
Halifax	J. W. MacDonald
Hamilton	N. A. Eager
Huronia	R. D. Marsh
Kingston	S. H. Rochester
Kitchener	M. A. Montgomery
Kootenay	A. F. Brooks
Lakehead	T. M. Olsson
Lethbridge	E. A. Lawrence
London	I. D. Patterson
Lower St. Lawrence	Marcel Lanouette
Moncton	W. M. Steeves
Montreal	Dean H. Gaudefroy
Newfoundland	H. J. Hermanson
Niagara Peninsula	C. G. Cline
Nipissing and Upper-Ottawa	R. A. Booy
North Nova Scotia	R. S. Morrow
North Eastern Ontario	J. B. Fredericks
Northern New Brunswick	T. H. McSorley
Ottawa	T. Foulkes
Peterborough	B. Ottewell
Port Hope	E. M. Wynn
Prince Edward Island	E. K. MacNutt
Quebec	Jean St.-Jacques
Saguenay	D. W. Stairs
Saint John	T. C. Higginson
St. Maurice Valley	John F. Wickenden
Sarnia	J. E. Harris
Saskatchewan	G. N. Munro
Sault Ste. Marie	R. A. Campbell
Sudbury	A. D. Finlayson
Toronto	J. G. Hall
Vancouver	F. M. Cazalet
Vancouver Island	A. G. Ballantyne
Winnipeg	T. E. Storey
Yukon	H. L. Meuser

Honorary Memberships

The general secretary reported that the following had been elected to honorary membership in the Institute and that certificates would be presented at the luncheon on Friday, June 14:

J. Omer Martineau, B.Sc., Assistant chief Engineer, Department of Roads, Province of Quebec, Quebec, Que.

Andrew George Latta McNaughton, C.H., C.B., C.M.G., D.S.O., D.C.L., LL.D., M.S.C., Chairman, Canadian Section International Joint Commission, and Chairman, Canadian Section, Canada-United States Permanent Joint Board on Defence, Ottawa, Ontario

Penrose Melvin Sauder, S.P.S., Toronto, Manager and Colonization Manager, St. Mary and Milk Rivers Development, Alberta Government, Lethbridge, Alta.

William Stewart Wilson, B.A.Sc., Assistant Dean and Secretary, Faculty of Applied Science, University of Toronto, Toronto.

Awards of Medals and Prizes

The general secretary announced the various awards of the Institute as follows, stating that the formal presentation of these would be made at the luncheon on Friday, June 14.

Sir John Kennedy Medals — "As a recognition of outstanding merit in the profession or of noteworthy contributions to the science of engineering or to the benefit of the Institute", to Richard Lankaster Hearn, M.E.I.C., Consulting Engineer, Hydro Electric Power Commission of Ontario, Toronto, Ont.; and to Irving R. Tait, M.E.I.C., formerly Chief Engineer, Canadian Industries Limited, Montreal, Que.

Julian C. Smith Medal — "For achievement in the development of Canada", to Edward Victor Buchanan, M.E.I.C., formerly General Manager, Public Utilities Commission, London Railway Commission, London, Ont.

Gzowski Medal — "For the best paper of the medal year on a civil engineering subject, "civil" being used in the limited sense to indicate structural, surveying and construction work generally." to — David Bernard Steinman, M.E.I.C., Consulting Engineer, New York, N.Y., for his paper, "The Design of the Mackinac Bridge".

Duggan Medal and Prize — "For papers dealing with the use of metals for structural or mechanical purposes", to Douglas Tyndall Wright, Jr.E.I.C., Queen's University, Kingston, Ont., for his paper, "The Design of Compressed Beams".

Leonard Medal — "For papers on mining subjects", to George Arthur Jewett, M.C.I.M., Scheduling Engineer, Riotinto Management Service Limited, Toronto, Ont., for his paper, "Sampling Design and Grade Estimation of Mineral Deposits".

Ross Medal — "For papers on electrical engineering subjects", to William Russell Way, M.E.I.C., vice-president, Shawinigan Water & Power Company, Montreal, Que., for his paper, "Growth and Development of Large Electric Power Systems".

John Galbraith Prize — "For best paper by a Junior in the Province of Ontario" to Nicholas Edward Hudak, Jr.E.I.C. Supervisor - Application - Engineer Canadian Cutler-Hammer Limited, Toronto, Ont., for his paper — "Trends in Design of Electrical Distribution for Industrial Plants".

ANNUAL MEETING

Seven former presidents of the Institute were at the President's Dinner: left to right: T. H. Hogg, Toronto, L. F. Grant, Kingston, J. N. Finlayson, Vancouver, J. A. Vance, Woodstock, J. B. Stirling, Montreal, D. M. Stephens, Winnipeg, R. E. Heartz, Montreal. The host, V. A. McKillop, retiring president, is at extreme right.

Incoming president C. M. Anson and party receive guests at the annual dance. Seen at Mr. Anson's right, Mrs. Anson and Mrs. McKillop.

Below, at the annual banquet head table: Mrs. McKillop, the banquet speaker Mr. Justice S. Freedman, and President McKillop.

his photograph shows a part of the session of the new council. For want of space lentification is omitted, with the exception of W. A. Smith (left foreground), hairman of the Alberta annual meeting committee.

Below, President McKillop (left) with Dean Hugh Conn, chairman of education conference, 1957.

Report of Council, Report of Financial Committee, Financial Statement and Treasurer's Report

Mr. Dunsmore, vice-president and chairman of the Finance Committee, summarized his report and pointed out that the complete report and financial statements were in the annual report of Council, copies of which had been distributed as a supplement to the April 1957 issue of *The Engineering Journal* and also at this meeting.

Mr. Emerson, the treasurer, presented the treasurer's report and commented on the close cooperation given the treasurer by the general secretary and his staff. His report also was included in the annual report of Council.

On the motion of H. R. Sills, seconded by E. H. Wright, it was resolved that the report of Council, the report of the Finance Committee, the financial statement and the treasurer's report be accepted and approved.

Committee Reports

In referring to the annual reports of the committees, the president expressed his appreciation of the work done by the committees throughout the year. He wished it clearly understood that the work done was greatly appreciated even though the reports of all the committees are passed on a single motion. He reminded the meeting that the work of the Institute was largely the work of the committees.

On the motion of W. A. Capelle, seconded by R. E. Hayes, it was resolved that the reports of the following committees be taken as read and approved: Admissions, Board of Examiners, Life Members Committee, Professional Interests, Legislation, Prairie Water Problems, Papers, Publications, Library Report, Employment Service, Library and House, Report of Field Secretary, Ontario Division, Canadian Chamber of Commerce, Canadian Standards Association.

Branch Reports

On the motion of M. A. Montgomery, seconded by F. W. Orlando, it was resolved that the reports of the branches be taken as read and approved.

Confederation

The president asked Dr. I. R. Tait, chairman of the Institute's Committee on Confederation, to report to the meeting.

Dr. Tait stated that the subject had been discussed in some detail on the day previous at the joint meeting of the Council of the Institute and the Branch Officers Conference. The outcome of that meeting was that the matter had been referred back to his committee for further study and report. However, he was glad to have this further opportunity of reporting to the membership at large.

He stated that the Institute's committee had been practically at a standstill for the past year inasmuch as they were waiting for a report from the committee of the Dominion Council. This report had been received just a few days ago and was the basis of his report to Council.

The Dominion Council's report was an encouraging one but would require considerable study before any formal comments could be made. However, on the whole he and his committee were quite encouraged.

Dr. Tait went on to report that it was now his hope that the two committees would get together and form a joint committee so that a joint report might be prepared within a reasonable period of time.

Dr. Ballard referred to an item on the Dominion Council's report which limited membership in the national body to "membership in provincial and territorial associations and the Corporation of Professional Engineers and that there is no other way that full membership may be obtained." Dr. Ballard's observation was that this would be an impossible position as far as the national body was concerned inasmuch as there were many engineers practising in Canada who are now, or who might wish in the future, to be members of the Institute but who were not registered. Such persons would include many of the engineers in the services of the Federal Government including the armed services.

Dr. Ballard also referred to new Canadians who, at least in the Province of Quebec, are not permitted to register in the province until they have become Canadian citizens which would take a minimum of five years' time.

Dr. Tait said that attention had been called to this proposal and that he realized the difficulties associated with it. He added to the list mentioned by Dr. Ballard, distinguished engineers who reside in other parts of the world and who now belong to the Engineering Institute. He felt it would be unwise to propose that such persons be denied membership in the Canadian national organization.

Mr. Thoms of Edmonton inquired as to the reasons for Confederation. He felt that the purpose of the associations was to regulate the practice of the profession whereas the Engineering Institute's purpose was to disseminate technical knowledge. In his opinion it would be a mistake to try to combine the two.

Mr. Hanna of Calgary was interested to know if faster progress could not be made. In reply Dr. Tait reminded him that it was the wish of the Institute's committee to merge the two committees now to accomplish the purpose Mr. Hanna had in mind.

Federal Election Act

Mr. Sillitoe of Belleville stated that he had been denied the privilege of voting at the advance poll before he left home. He felt the privilege of voting in advance should be made available to more people than enjoyed it today. He recommended that Council approach the Federal Government to have this corrected. Mr. deJong of Vancouver supported Mr. Sillitoe's proposal as did also Colonel Grant of Kingston, Ontario, and Mr. Wardle of Ottawa.

The general secretary reported that for some time he had been in correspondence with the officials at Ottawa on this very matter. Unfortunately he had received no encouragement but he hoped that this meeting would give him instructions to follow the matter further.

Eventually it was agreed that the general secretary should communicate with the leaders of each federal political party urging upon them the desirability of making the privilege of the advance poll available to all persons who for adequate reasons were unable to be at their permanent residence for voting purpose on the date of the election.

The following telegram was sent to Mr. St. Laurent, leader of the Liberal party, Mr. Diefenbaker, leader of the Progressive Conservative party, Mr. Solon Low, leader of the Social Credit party and Mr. M. J. Coldwell, leader of the C.C.F.

The Engineering Institute of Canada at its seventy first annual meeting today passed unanimously the following resolution. "In view of the fact that members of the profession of engineering in Canada are required on many occasions in the ordinary execution of their duties to be absent from their homes on election day, it is unanimously agreed that the Federal Government be requested to so revise the election act that the privilege of voting at the advance poll be extended to engineers and others similarly situ ated. It is the very essence of de mocracy and in the best interests o Canada that no citizen be denied hi fundamental right for any reason. Th very existence of the advance pol proves the truth of these statements For example here at this Banff meet ing, arranged five years ago, there are over a thousand voters all o them disenfranchised for the recen election."

Engineering Students

Professor Lash of Kingston, inquire as to what Council proposed doing tc wards improving the approach to th engineering students on the campuse across the country.

The president replied that the officer of the Institute appreciated the impor ance of the student, and were plai ning several changes that should in prove the Institute's services. He poin ed out that recently the Institute h: appointed a faculty representative c each campus who for all general pu poses would represent the Institute each university. Each of these represen atives had been given one hundred dc lars to be used in furthering the Insi tute's usefulness to the student. Tl president was very optimistic of tl move and believed excellent resu would follow.

The general secretary amplified tl president's remarks by stating that meeting was taking place that very a ternoon between several of the repı sentatives who were at the annual mee ing. Many suggestions for new polici would be discussed at that time.

Mr. Wright stated also that duri the president's visit to several branch an abundance of new ideas had be developed relative to means by whi the Institute could improve its usef ness to students.

Mr. de Jong of Vancouver stress the desirability of the present memb of the Institute taking some share the responsibility for the developme of the students. He felt that the membership by their example could do a great deal to enhance the status of the Institute with the students and that the present situation was a challenge to the entire membership as well as to the Council.

Election of Officers

The general secretary presented the list of the newly elected officers of the Institute as follows:

President

C. M. Anson, Sydney

Vice-Presidents

S. C. Montgomery, Trail
W. J. Ripley, Copper Cliff
Albert Deschamps, Montreal

Councillors

Yukon Branch	John L. Phelps
/ancouver Island Branch	P. F. Fairfull
Vancouver	W. O. Richmond
Central British Columbia	M. L. Wade
Kootenay	W. K. Gwyer
Edmonton	R. N. McManus
Saskatchewan	W. L. Sharpe
Winnipeg	W. D. Hurst
Lakehead	E. T. Charnock
Sudbury	F. A. Orange
Nipissing and Upper Ottawa	R. R. Prescott
London	G. E. Humphries
Port Hope	R. C. Wilson
Belleville	S. Sillitoe
Kingston	C. H. R. Campling
Brockville	J. S. Waddington
Ottawa	W. B. Pennock
	R. E. Hayes
Toronto	K. F. Tupper
Montreal	J. H. Budden
	R. B. Winsor
Saguenay	A. B. Sinclair
Lower St. Lawrence	L. P. Dancose
St. Maurice Valley	W. G. Seline
Eastern Townships	G. J. Cote
Corner Brook	E. Leja
Newfoundland	Wm. Watson
Prince Edward Island	W. S. Veale
Amherst	A. G. Baxter
Halifax	W. A. Devereaux
Fredericton	S. B. Cassidy
Saint John	A. G. Watt
Border Cities	P. S. Dewar

Vote of Thanks to Retiring Officers

Past-President Stirling of Montreal proposed that a vote of thanks be extended to the retiring president and retiring officers of the Institute. As a past-president he had some appreciation of the work that was entailed in the presidency. He knew that Mr. McKillop had worked very hard at his task and had produced excellent results. He emphasized the amount of time required to the presidency and he was glad to join with others in expressing to the retiring president their appreciation of his splendid contribution.

In reply Mr. McKillop stated that while the office did require a certain amount of time and effort he felt indebted to the Institute for the high honour and the privilege of serving which had been given to him. During his year of office he had come to a greater realization of what the Institute means to the profession and to the country at large. He had come to a greater appreciation of the work being done by the engineers both professionally and in community activities. This had led him to a greater appreciation than ever of the profession.

Mr. McKillop also commented on the inspiration he had received from the officers of the Institute who had preceded him. He concluded by saying "Please accept our thanks for your appreciation but in turn accept our thanks for the opportunity".

Finance Committee

Mr. Dunsmore asked the privilege of expressing his appreciation to the members of the Finance Committee with whom he had been associated for so many years. This committee was made up of leading heads of industry who gave freely of their valuable time to aid the Institute in its management. He thought that few organizations had a committee as strong as this one. He wished particularly to commend their work to the meeting. Mr. Dunsmore's remarks were greeted with applause.

Mr. Anson, the president-elect, wished to make a motion expressing appreciation from the members to the Headquarters' staff of the Institute. In this he was supported by Mr. McKillop who said it had been a great pleasure working throughout the year with the Headquarters' staff. This proposal was greeted with applause.

The meeting adjourned at eleven thirty a.m.

Branch Officers' Conference

At 9:30 on Tuesday morning about twenty-five branch officers met in the Oak Room to hold their annual conference. The purpose of this meeting is to permit these representatives of branch management to discuss freely, among themselves, Institute projects and policies which are of closest interest to them, and from the branch point of view.

The branch delegates first nominated and installed their own chairman, in the person of Colonel W. A. Capelle of Ottawa. The choice was a prudent one, and he proceeded to conduct the discussions with efficiency and wisdom throughout the day. Assistant General Secretary E. C. Luke was on hand to provide any information required from Institute headquarters staff.

The agenda was a long one, covering almost all facets of E.I.C. activity and affairs. Among the topics which received special attention from the branch officers were Institute publications, high school student counselling, attendance at meetings, professional development courses, technical sections, regional meetings, participation of non-members in branch programs, and the scale of annual fees.

In accordance with custom, after the lunch break the branch officers were invited to join the council meeting, to hear the reports and discussion on confederation, and one or two other subjects. They resumed their own deliberations later, and concluded their business about 5:30 p.m. Nothing of an urgent nature arose from the day's work, but several important memoranda and resolutions were adopted for the future attention of Council.

Students' Conference

Once again, the E.I.C. Students' Conference was held concurrently with the Annual Meeting of the Institute. Fourteen delegates were present, representing the universities across Canada and Royal Military College. Three observers from the engineering student body of the University of Alberta were also present.

The conference began at 9 a.m. June 11th. Following brief words of welcome and encouragement from President V. A. McKillop, incoming President C. M. Anson and General Secretary L. A. Wright, the delegates tackled the conference agenda with enthusiasm. Under the able chairmanship of J. F. Harris, JR. E.I.C., discussion was lively and participation by the delegates was excellent. Philippe Lemay, S.E.I.C., was appointed secretary for the conference.

The first part of the conference was devoted to student activities in the Institute. How to make these activities more valuable, how to make membership drives more effective, these were some of the topics discussed. Employment conditions and salaries for summer employment were also discussed. Some concern was expressed about the difficulties of first and second year students in finding work providing engineering experience.

A Resolutions Committee of three members was elected to summarize the work of the conference into resolutions to be presented to the Council of the Institute. The committee members elected were: J. N. Fry, S.E.I.C., E. J. Muszinski, S.E.I.C., and N. Seagram, S.E.I.C.

The second part of the conference was devoted to student engineering societies at the various universities. J. F. Riel, S.E.I.C. was elected chairman for this portion of the conference.

Month to Month

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE ELECTIONS AND TRANSFERS

Disenfranchised

The Canada Election Act provides that an advance poll will be available to certain classes of citizens who, because of their occupation, are unable to be at their homes on the date of a national election.

Unfortunately the persons permitted to use the advance poll are very limited in numbers and in classification. Some time ago the general secretary wrote to the government a protest on this situation but a quite unsatisfactory answer was received.

The question was raised at the Annual General Business Meeting in Banff on June 12. Many members complained that they had been unable to vote because they had to leave home for the annual meeting on or before the date of the election. The outcome of the discussion was that the general secretary was instructed to wire the Right Honourable Louis St. Laurent to propose that the privileges of the advance poll be made available to engineers and others similarly situated right across Canada.

Copies of the telegram were sent also to the heads of the other three political parties, including Mr. Diefenbaker. The acknowledgments have been received from all four leaders, but of course no promises can be made at the present time and under the present circumstances.

It was interesting to learn that in the province of Saskatchewan the privilege of the advance poll is already available to all citizens. Is it too much to hope that the federal authorities will be able to learn something from the province of Saskatchewan?

Herewith is the message sent t[o] the then Prime Minister.

"The Engineering Institute of Canad[a] at its seventy first annual meeting toda[y] passed unanimously the following reso[lu]lution. In view of the fact that member[s] of the profession of engineering in Can[n]ada are required on many occasions i[n] the ordinary execution of their duties t[o] be absent from their homes on electio[n] day it is unanimously agreed that th[e] Federal Government be requested to s[o] revise the Election Act that the privileg[e] of voting at the advance poll be extende[d] to engineers and others similarly situa[-]ted. It is the very essence of democrac[y] and in the best interests of Canada tha[t] no citizen be denied his fundament[al] right for any reason and the very exist[-]ance of the advance poll proves th[e] truth of these statements, but it is a[n] injustice to limit its application to so fe[w] citizens. For example here at this Banf[f] meeting arranged five years ago ther[e] are one thousand voters all of them di[s]enfranchised for the recent election."

E.I.C. Education Conference (1957)

Although the minutes of the recent education conference held in Banff are not yet ready for distribution there are some interesting things that can be reported now.

There were thirty-eight delegates representing sixteen universities. The chairman was Dean Hugh Conn of Queen's. Six resolutions were passed for the consideration of the Council of the Institute. These are being studied now for final presentation to the next meeting of Council. Here are the resolutions:

ference held last year justifies th[e] vision of the Council in sponsorin[g] this activity in a field of such wid[e] importance to Canada.

The members of the conference ar[e] particularly appreciative of the o[p]portunity thus provided of meetin[g] with their fellows from other unive[r]sities and colleges and discussin[g] common problems, an accomplisl[h]ment which would otherwis[e] have been difficult or impossible.

Conference Committee

1. *Resolved* that this Conference on Engineering Education (1957) express to the Council of The Engineering Institute of Canada, its deepest appreciation for making this second conference possible. The success of this conference and the con-

2. *Moved* by Dean R. E. Jamieso[n] *seconded* by Professor J. L. deStei[n] and *carried*, that:
"The chairman of this conference a[p]point a standing committee of eng[i]neering educators with power to de[al] directly with The Engineering Inst[itute]

Cover Picture

The cover picture shows a view from the apex of the dome which will form part of the containing structure of the Canada-India nuclear energy research reactor, which is now being built near Bombay. The design and much of the major construction work is due to Canadian engineers. An article on the design and operating features of the reactor starts on page 1099 of this issue.

. session of the Education Conference, 1957, at which sixteen Canadian universities 'ere represented by thirty-eight educators. Their resolutions are published herewith.

ite of Canada on matters of engi-ering education and to represent ie degree granting universities and olleges on matters of engineering lucation that may come before The ngineering Institute of Canada; and at this standing committee remain office until replaced or disband-l at a future conference or other athering representing the degree anting universities and colleges."

Education Committee

Moved by Dean D. L. Mordell, *conded* by Professor L. E. Gads d *carried*, that:

'his conference recommends that e Council of The Engineering Insti-te of Canada consider establishing Committee on Engineering Educa-n to concern itself with matters of gineering education that come be-e The Engineering Institute of nada; and that the standing com-ittee of engineering educators uld welcome an invitation to work h The Engineering Institute of nada Council in setting up such mmittee on Engineering Edu-cion."

Scholarship Program

4. *Moved* by Professor L. A. Madonna, *seconded* by Professor L. P. Bonneau and *carried*, that:

"This conference recommends to The Engineering Institute of Canada Council that they consider establishing a scholarship program to encourage secondary school teachers to improve their professional status through advanced study at a university in order that they may contribute to the number of inspired teachers, so badly needed at the high school level, and that no restrictions be placed on such an award insofar as the field of study is concerned."

During the discussion of this motion, it was the feeling that action as recommended, would help to dispel the generally expressed feeling that engineers are merely trained, are not educated and are interested only in equipment, money, buildings and staff insofar as they may benefit engineering education and not education in its broader sense. The number and size of the scholarship should be left to the discretion of Council.

Postgraduate Registration

5. *Moved* by Dean R. E. Jamieson, *seconded* by Professor J. F. M. Muir, and *carried* that:

"This conference recommends consideration of some plan which would tend to encourage greater numbers of our Canadian-trained graduates to proceed to postgraduate study in Canadian universities."

During the discussion of this motion, it was pointed out that, while substantial numbers of our graduates are at present proceeding to higher degrees, there nevertheless are many others, fully capable and qualified, who elect to develop their careers from the bachelor's level only. It was felt that many of these graduates would profit from post - graduate study, and would thereby enhance their eventual position in the profession, and their value to their country. It was suggested that, while assistance in the form of scholarships, teaching assistantships, and so forth, are quite widely available, there is not much in the way of a centralized Canadian effort to reach the students, and the initiative rests largely with the individual student. The success of the Athlone Fellowships was cited as a case where centralized application, competition, and selection appear to be features which attract many of our outstanding graduates, and the opinion was expressed that this element of centralized competition, coupled with direct personal interviews by the selection committees, has been a beneficial factor. The plan envisaged in the resolution would, in effect, parallel the Athlones in the machinery of applications and selection committees, but would be for Canadian-trained graduates and for post-graduate study in a Canadian university.

Teaching Standards

6. *Moved* by Dean D. L. Mordell, *seconded* by Professor Frank Noakes and *carried*, that:

"It is the wish of this conference that the Council of The Engineering Institute of Canada be informed of the concern which members of the conference have for the maintenance of high teaching standards in the face of increased enrolment. The members are fully cognizant of the natural tendency to meet the greater demand by increasing class size and teaching load and allowing crowding in laboratories, to the detriment of good education. While realizing there are practical problems to be met and solved in providing optimum teaching facilities, the members of the conference will continue to strive for those things that permit close contact with students, so essential to good teaching and the provision of engineers of good quality."

Representation

The universities represented were as follows: University of British Columbia, University of Alberta, University of Saskatchewan, University of Manitoba, University of Toronto, Queen's University, McGill University, Ecole Polytechnique, Laval University, University of New Brunswick, Nova Scotia Technical College, Hamilton College (McMaster), University of Ottawa, Carleton College, University of Sherbrooke, Waterloo College.

The above list includes every university in Canada except one, where engineering is being taught in a degree course.

It is planned to publish more later about the deliberations of the conference and the plans for the future.

The Institute Publishes A Book

Throughout its entire seventy-one years the Institute has been in the publishing business, but never before has it published a full length book. However the thought behind this effort is just the same as that behind all previous publishing efforts — to render a service to the profession.

This publication "Daylight through the Mountain" is a historical biography of two early Canadian engineers who almost a century ago set standards for the profession, and gave it even then a status in the community. They largely, were responsible for lifting Canada from the horse and buggy days and bringing it rapid transportation.

The Shanly brothers, Walter and Francis, left behind them in letters from and to each other the exciting and frequently amusing story of their lives. These letters were found in the archives at Ottawa and other Canadian and American cities, and in the possession of surviving relatives. They were gathered together and put into manuscript form by Dr. Frank Norman Walker and Mrs. Walker of Toronto. It was through these diligent and intelligent searchers and workers that the Institute was given the opportunity to publish the material in book form.

Here is a great segment of the history of the profession of engineering in Canada, never before brought to light or to the attention of today's engineers. The Council of the Institute have authorized this publication because they felt the Institute had a responsibility in preserving the history of its members and their work. Walter Shanly was a vice-president of the Institute at the time of its founding in 1887.

There are other biographies which the Institute proposes to publish later but future ventures will be influenced by the manner in which this one is accepted by the profession. Copies may be obtained in the book stores, but if purchased through Headquarters by members of the Institute the price will be $5.00 instead of the regular price of $6.00.

Don't miss this exciting story of the early days of the profession of engineering in Canada.

Aviation Writers Meet In St. Louis

The nineteenth annual meeting of the Aviation Writers Association presented a number of novelties which were noteworthy even for the Aviation Writers Association which always produces some novelties.

To this writer the outstanding feature was the flight in the French jet liner, *Caravelle*. Judging by the remarks of other delegates they too regarded the experience as exciting and novel. After all there are no jet liners operating regularly and commercially on this continent, so naturally the experience was new to almost all writers.

The plane's interior was a delight to the eye. Trust the French to present a decor that was outstanding. On looking back on the experience one wonders what it was that made the interior so pleasing and acceptable. There were no features that stood out as unusual or noteworthy and yet the "ensemble" was effective. Perhaps its simplicity was the reason.

Of course the real difference between this and the internal combustion job, from the traveller's point of view was the absence of noise. Once the public get used to this sort of travel it will be hard to satisfy them with anything else. Even a jet prop is noisy by comparison.

The plane's take-off was a delightful experience. It was very much like being in a rocket — or so it seemed. The acceleration was unbelievable. Rising on what looked like 35 deg. angle it was no time before 20,000 feet and 500 miles per hour were reached.

At this level the plane was put through its paces, much to the satisfaction and delight of everyone. As one would expect, champagne was served aloft. By the way, the *Caravelle* is made by the Sud Aviation Corporation of France and is powered with Rolls Royce engines.

Air Show

On the same day that the *Caravelle* was demonstrated the group was shown through the plant of the McDonnell Aircraft Corporation which is situated right alongside the Lambert-St. Louis Municipal Airport and which of itself is really something to see. It makes the Can-dian airports look pretty mediocre.

McDonnell's put on an air show that was remarkable in many ways, not least of which was that it was carried out on a commercial airfield operating at full head without interrupting commercial travel. It was a great job of weaving in and out that says much for the facilities and staff of the airport. All the planes in the show were McDonnell products.

The flight show included a cross-country speed dash by an F-101 A *Voodoo,* said to be the fastest fighter in the world; short field take-off, high speed climb, and short field landings; fly-by of F 3H-2 *Demons* equipped with various external stores, and low-level "buddy" refuelling of F3H-2 by another of the same kind.

Here again it was the out-of-the-ordinary plane, that caught the eye and the imagination. The company is working on a "convertiplane" for the army. The machine was flown and gave a first class performance but not too much information was divulged except to say — as one could see — that the plane was a combination machine. Vertical flight was provided by the horizontal propellors as in a helicopter and horizontal flight was provided by an internal combustion engine placed horizontally. It appeared to be very maneuvrable and of course had a much higher horizontal speed than a helicopter. Such a plane should have many uses when the bugs are eliminated.

On to Kansas City

The second day was spent in Kansas City, Mo., seeing something of the facilities of Trans World Airlines. Recently the company has taken over a great area of the Mid-Continental Airport for runway facilities, engine overhaul, test cells and hangars. The engine overhaul deserves a paper for itself and so do the other facilities as well. In fact an effort is being made now to get some papers on these features for the *Journal.*

Westinghouse were hosts for lunch after which the group flew to Olathe, Kansas, the Naval Air Training Station for an exhibition of what the navy boys could do. Unfortunately Mother Nature took a hand in things and put on a demonstration of thunder, lightning and rain that dwarfed man's best efforts.

However, some brave souls of the Goodyear Rubber Company proceeded with their scheduled demonstration. They blew up and flew a tiny all-rubber plane. The pilot handled the machine (if that is the right word for it) as if it were a normal low speed metal craft. Details of this oddity will appear in a later *Journal.*

Eventually it was agreed that the rain had taken over on what seemed a permanent basis so after dinner at the Officers Club, the group boarded the T.W.A. Constellation that had brought them over in the morning and returned to St. Louis.

Wichita Day

Wednesday's opening event was a 7.00 A.M. flight to McConnell Air Force Base at Wichita, Kansas. That is a modest and truthful statement of what occurred but the details provide the colour. The flight was made in four Air Force Lockheed C-130's. Therein lies the colour and several other things. These big monster troop and freight carriers are something to see and hear, and even more to ride in. They sit almost flat on the ground with a ramp at the rear end for loading. The inside diameter must be 14 feet and there are no windows other than a row of port holes at the halfway level.

The power units are turbo props (Allison) of constant speed. This feature produces some very odd effects. A person gets used to the changing sounds of aircraft engines and learns what each means, but here the sound was constant, and flying blind as the passengers were, nobody could tell when we had taken off or when we had landed. On top of this, the plane seemed to have no insulation against sound. It must have been a funny-looking sight for the crew to see the four longitudinal lines of puzzled civilians, strapped to the benches on which they were sitting, half in and half out of their parachute harness, their ears stuffed with protruding rolls of cotton, and not a word being uttered. It was a dizzy noise-drunk group that landed at Wichita, one hour after takeoff.

The hosts here were the Air Force, the Boeing Company, The Cessna Company, and the Beech Aircraft Corporation, and they did a good job although to a Canadian it seemed there was an overdose of self-commendation by some of the manufacturers.

Here also there was an air show—both static and in flight. In fact it was the liveliest show of its kind that this writer has seen in a long time. Both civilian and service craft were flown and a great variety of operations were carried out, including gliding, refuelling, formation flying and a variety of aerobatics — and the weather was perfect.

A Slack Day

Thursday was unusual because the first event (a business session) was not until 9.00 A.M. The program said "sack time, courtesy of the committee". It was well received. Most of the day was given over to Association business, but there was a dinner in the evening courtesy of the Air Transport Association. The speaker was vice-president of the First National City Bank and he spoke on the financing of air transport companies. He referred to the present need of purchasing new and up to date equipment, and from the cost figures which he presented, it appeared as an almost impossible task. Back of it all, this reporter sensed a feeling that the speaker was soliciting the support of the writers in softening up the public for a substantial increase in rates.

After the address the group was treated to a rare and exciting film. It was a colour record of the successful trials of the Ryan "Convertijet". Much has been reported on this craft which takes off and lands vertically but tips over and flies horizontally once it is well off the ground. Here was real proof of its existence and its success. It was of interest to discover by questioning, that the engine was a Rolls Royce Avon, it being explained that this was the only engine available powerful enough to do the job. There is something quite exciting about this machine.

Last Day

Friday started out with a 7.15 a.m. breakfast, followed by a panel discussion on Aviation Safety. The short speeches of the panel members and their replies to questions from the floor left one with the impression that he was lucky if he ever had a flight without an accident. Another point emphasized was as that rules for safety had been drawn up and agreed upon by experts long ago but that the authorities had done nothing to have them adopted. It took the Grand Canyon double disaster to really awaken them to the situation.

Luncheon was a feature, playing up "Le Chateau Village" and its "Dejeuner Francais". The restaurant which is outside the city is most attractive and the meal served was the best of the whole conference but to a resident of Quebec the French atmosphere was not noticeable. Lockheed Aircraft were the hosts.

That afternoon there was the final business meeting and the election of officers, and in the evening the banquet for which A.W.A. was the host to the many kind people who had done so much for the delegates through the strenuous week. Hon. Garrison Norton, Assistant Secretary of Navy for Air was the speaker.

Homeward Bound

Early Saturday morning saw all the out-of-town delegates scrambling for their accommodation on the return airlift. It required seven planes to do the job — and in all directions.

It was a good meeting, and the local committee accomplished miracles in putting the program together. It is hoped that later issues of the *Journal* will present some of the technical information that was divulged. Also there are prospects of getting some very good movies of a technical nature for the Institute film library.

The 1958 meeting will be in Houston, Texas.

Canadian Management Council

B. A. C. Hills M.E.I.C.

Editor's Note: The following article on the Canadian Management Council has been prepared at our request by the president of the Council, who is a member of the Institute.

From its inception the Institute has had an important part in the affairs of the Council, therefore it is a pleasure to publish this article which will bring the members of the Institute up to date on the work of the Council.

The Canadian Management Council (CMC) was formed in 1947 to represent Canada in the International Organization for Scientific Management (Comite International de L'Organisation Scientifique, known as CIOS). Basically CIOS is a committee composed of representatives of 27 countries which for the past thirty years has been organizing management conferences to facilitate the interchange of views on philosophy and practice of management at the international level. Canada's first official participation was through papers presented at the Stockholm Conference of 1947. Two years later, in conjunction with the Engineering Institute of Canada, CMC organized a Western Hemisphere Management Conference in Quebec. In succeeding international congresses at Brussels, Sao Paulo and in Paris (held in June, 1957) CMC has taken an active part in the program.

In addition CMC contributed an important paper at the Pan-American Congress of CIOS held in Santiago in 1956, and has corresponded with a number of other countries on management subjects. It has played host to a number of visitors of other nations, particularly Finland, Australia and Brazil.

But while it is important and gratifying that Canada should be represented in this international exchange of knowledge and ideas relative to the field of management, it was felt by its original sponsors that CMC could play a useful part in acting on behalf of its member societies in certain directions *within* Canada. The member societies are those interested directly or indirectly in management and include:—

- Engineering Institute of Canada
- Society for Advancement of Management
- Institute of Administration
- National Office Management Association
- Canadian Industrial Management Association
- Canadian Industrial Trainers' Association
- Society of Industrial and Cost Accountants of Canada
- Chartered Institute of Secretaries
- Porcupine Institute of Administration
- Montreal Personnel Association
- Toronto Personnel Association.

It will be seen that the society members fall into two groups — one, those associations which have been constituted in order to cover some particular field of management, such as NOMA, SAM, CIMA, IA and PIA, and a second group of associations which cover activities in a functional field such as engineering, cost accounting, personnel and secretarial. But both groups are interested in a common field — that of general management.

Council of Members

CMC is *not* a separate body, competing with any of its society members, but instead it is a *council* of these members, formed by them and supported by them. It is considered that the time has arrived when the society members should use their council in order to centralize some of their activities in the *general management field.* Examples of the kind of work which CMC could undertake of this nature are as follows:—

1. Compiling a register of the educational facilities in the management field available in Canada.
2. Making arrangements with universities throughout Canada so that library and research facilities in management subjects will be available to company members.
3. Assisting society members by building up a roster of qualified speakers on management subjects, drawing on the experience of the various society members.
4. Serving as a permanent means of exchange of information in connection with such matters as workshop seminars, conferences, and educational courses.
5. Holding senior management conferences in various centres when and where required. The outstanding success of the meeting held in Montreal in 1955 shows the great need for Canadian sponsored conferences which will help the development of professional management in Canada.

This could best be achieved through a small permanent secretariat in order to ensure continuity of operation as well as providing full time attention to and direction of those projects which the society members decided should be undertaken in the common interest. It would have the added advantage of providing in one place information relative to the activities of all the societies in the management field.

The idea of one organization to co-ordinate efforts to spread the knowledge of general management and to provide a means of exchange of ideas is, of course, not new. The United States have four such bodies and would like to reduce the number; Australia, South Africa and the United Kingdom each have a single body labelled Institute of Management. But Canada is the only nation which has in CMC a means of combining the efforts of all those interested in the general management field which has not been superimposed upon existing societies and associations. We have, in fact, the perfect means — a council which consists of the existing societies, which is run by the existing societies, and which depends upon them for its own existence. What is now required is to activate this body so that it makes its maximum contribution in increasing our knowledge of management and in making available that knowledge to as many Canadians as possible. CMC is the tool which all member societies can use in their desire to increase and make available this knowledge.

The first step is active participation by the presidents or permanent officers of the member societies in the *direction* of CMC. It has been proposed that they should become Directors of CMC so that they can the more directly combine in determining on behalf of their various associations the projects which CMC can most usefully undertake in addition to representing Canada on CIOS. It is hoped that the response will be such that we shall indeed see a virile council of the representatives of such important professional bodies as E.I.C. as well as of those directly interested in management.

The Canadian Conference on Education

Out of the conviction of many people that wider public understanding of Canada's educational needs and problems would be a major step toward their solution have grown plans for the Canadian Conference on Education, to be held in Ottawa on February 17-20, 1958.

Attempting to focus attention on the objectives and needs of education in Canada in the next decade, the conference will seek ways and means to meet them. Examining the educational needs of our society and of the Canadian economy, it will also give attention to the needs of the individual. In particular, it will study such matters as organization and curricula, quantity and quality of teaching personnel, financing of education, encouragement of youth to proceed to further education and training beyond high school. It will discuss the role of the home, and agriculture, business and industry and organized labour in education. Other key topics to be included in the discussion are physical well being, mental health and the social development of children and youth as well as education for leisure.

With advance study groups exploring the various areas of discussion, the Conference plans call for opening plenary sessions at which outstanding speakers will highlight Canada's main educational problems and those likely to confront us in the next decade. The middle portion of the Conference will consist of workshops. The concluding general sessions will receive and discuss reports and make recommendations.

Chairing the over-all conference committee is Lt.-Col. K. R. Swinton, general manager of Thomas A. Edison of Canada Limited, who represents the Canadian Chamber of Commerce. Under this there is a steering committee of twelve persons as responsible for the planning, preparation and operation of the Conference. Max Swerdlow, director of education for the Canadian Labour Congress has been appointed chairman. George G. Croskery, secretary-treasurer of the Canadian Teachers' Federation will direct the Conference.

Nineteen national organizations make up the list of sponsors. Among them are the Canadian Association for Adult Education; the Canadian Mental Health Association; L'Association Canadienne des Educateurs de Langue Francaise, the National Council of Women, the Industrial Foundation on Education as well as the Engineering Institute of Canada.

Further information may be obtained from:

George G. Croskery, Director,
Canadian Conference on
Education, 444 Maclaren Street,
Ottawa, Canada.

Correction

It was stated that the gentleman shown with Sir Claude Gibb on Page 851 of the June issue was D. J. Matthews of the London Branch—whereas it is Col. W. A. Capelle, of Ottawa.

Furthermore, the accuracy of the lower caption on Page 850 was affected by the switch of the two pictures concerned. To describe the pictures as shown, the caption should have read: "Groups in Montreal and Toronto greet visiting lecturer. Left to right: Leo Roy, Montreal Branch chairman, Sir Claude, and Past President Heartz; Sir Claude, Toronto Branch chairman E. R. Davis, and President V. A. McKillop."

The editors regret that these errors should have been made in reporting so important an event as the most successful lecture series of Sir Claude Gibb.

THIRTY-FIVE YEARS AGO

Comment on the Journal of August, 1922

The editor of the *Journal* gave practically the whole of his issue for August, 1922, to reports of the proceedings of the British Columbia professional meeting, held in Vancouver on June 16 and 17, 1922, and to the publication of three papers presented there. One hundred and thirty members and some of their wives registered, mostly, of course, from British Columbia, but with a fair smattering from the other provinces. . . "The native ability and energy of our Pacific Coast engineers provided a gathering to be remembered with pleasure by all who attended;" thus the editor.

There were the usual social functions and visits, including an inspection of the Ballantyne pier, then under construction, where "the latest methods were pointed out, the product being of a very superior order." Some of the members were taken by the city to see the Seymour creek works of its water supply.

Institute affairs came in for their share of discussion. The meeting resolved unanimously to endorse the recommendations of the Committee on Policy, which were published here in abstract last June. By a similar unanimous resolution, the meeting suggested that the Institute should "strive for coordinated legislation throughout the Dominion" to govern the practice of engineering. It is doubtful if our various provincial acts are even yet coordinated to the extent envisaged by this resolution, though a start in that direction has been made by the establishment of the Dominion Council.

James Ewing, M.E.I.C., of Montreal, contributed a short, but comprehensive paper on "The Engineer and the Town Plan" to the proceedings; this evoked considerable discussion. There was little or nothing in Mr. Ewing's paper that had not been said a dozen times before, but it did bring together the basic ideas of town planning into small space. "The great trouble is that the need for town planning is never imperative, and seldom even apparent (until) its cost becomes prohibitive." . . . What was a little playful calf has become a ferocious bull that it requires some resolution to tackle."

Irrigation Studies

E. A. Cleveland, M.E.I.C., provided a paper describing irrigation in British Columbia. Most of the "foreigners" in his audience were somewhat surprised to learn that irrigation was necessary anywhere in the province. One whose acquaintance with British Columbia weather was limited to that of Vancouver might well be excused for such ignorance. However, areas around Quesnel, Kamloops, Summerland, Vernon, Grand Forks and Invermere have average annual precipitations below 20 inches and even Victoria has only about 28 inches, as against about 59 inches in Vancouver. And what precipitation there is in these low areas occurs largely in the non-growing season.

In 1922 there were 22 irrigation districts operating in the province, ranging from that at Vernon, with about 14,000 acres under water, down to those of much smaller area. The ten large ones accounted for about 35,000 acres or about 54 square miles.

The early private land and water companies had been expropriated and turned over to irrigation districts owned and operated by the water users themselves, or this change was in process. The oldest company was the one that had operated on Coldsteam creek near Vernon, which sold its first orchard only in 1893, though there was a "water record" on the creek dating back to 1868. "If . . . in the future . . . errors may be avoided which in the past made the way difficult, and additional attention given to new projects, there appears to be no doubt but that the industry will afford . . . ample justification for the confidence of those who pioneered it and for the pledge of public credit which has come to the rescue."

Eastern visitors must also have been interested in a description of coast logging methods by T. W. Fairhurst, A.M.E.I.C. They were then and still are very different from those prevalent in our eastern forests, naturally so because of the difference in the size of logs in the two areas.

Tribute to the Engineer

The editor reprints in this issue a tribute to the engineer by Dr Frank Crane, which originally appeared in the *American City*. It wasn't the quality of the tribute that caught my eye; it was the author's name. Frank Crane was the pastor of a church which I used to attend occasionally in my college days. He had a flair for "inspirational writing" and discovered that there was more money to be made as columnist than as clergyman, though I doubt if the term "columnist" had been invented in his time. Most of his writing wa on the Pollyanna side, which canno be said of today's moulders of publi opinion; it was immensely populai I can testify that he was an excel lent preacher.

The history of the Ontario Engi neers' Act was presented among th editorials of this *Journal* by Willi Chipman, M.E.I.C. After outlining th various steps in the "*mutilation*" o the original bill by the legislativ committee, he concludes, "The bi as passed has been reduced to a regis tration bill only." One gathers tha Ontario engineers were not too happ about the affair and that they wer hoping for early amendments whic would restore the bill to somethin like its original form, though th Ottawa Branch thought the Act " tremendous step towards the goal

There was little room for branc news in this *Journal*. Only eigl branches reported at all and mo of their reports were only of one (two paragraphs. The local newspap had given the Peterborough Branc a pat on the back for its interest i civic affairs. Several of the wester branches had entertained the secr tary of the Institute on his way bac to Montreal from Vancouver.

"Reforming the Calendar" was tl subject of a long letter to the edito The writer advocated a 28-day mon with 13 months in the year. The e tra day was to be at the beginni of the year, to be called "Ne Year's Day" and to have no dat In leap years, another extra day w to be inserted between the ne month — Sol — and the first July; this would be called "Sol (or "July O". Calendar reform is st a live topic, but its progress towa realization is slow, in spite of i manifest advantages. One scheme h been endorsed by several natio but seems not to appeal to the larg ones, notably to the United Stat

R.DEL

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

C. A. Peachey, P.Eng. of the Northern Electric Company Limited, has been elected president of th eCorporation of Professional Engineers of Quebec.

Mr. Peachey graduated from the University of Toronto in 1927 in mathematics and physics, in that same year joining Northern Electric Company Ltd., as an engineer in the field of vacuum tube development.

He became a supervisor in the engineering group in 1930 and was later put in charge of shop methods. In 1954 he was appointed general manager of the communciations equipment division, including both the Montreal and Belleville plants of the company. He has been active over the years in both engineering and management affairs.

Mr. Peachey is a member of the selection committee of the Defence Research Board, a past president of the Canadian Management Council and was Canadian representative on the International Committee of Scientific Management at their International Management Congress in Belgium in 1951. He is also a past chairman of the Institute of Administration and, in 1951, was metropolitan chairman of the Canadian Red Cross Society campaign for Montreal.

Mr. Peachey has been connected with the Corporation of Professional Engineers of Quebec for many years; he has served on various committees and has been a councillor for the past two years. He has long been active with the Engineering Institute of Canada, having served for six years as a councillor and on numerous committees.

Special Meeting

Three hundred and seventy-five members of the Corporation of Professional Engineers of Quebec filled the Auditorium of the Physical Sciences Building of McGill University to capacity on Saturday, June 1. The Special Meeting had been called to discuss, approve or disapprove the implementation by Council of the conclusions presented in 1956 by the Committee on Directing Principles, particularly with respect to the practice of the engineering profession by limited liability companies.

C. A. Peachey, P.ENG.

The meeting was under the chairmanship of President C. A. Peachey, P.Eng. Dr. T. A. Monti, P.Eng. who acted as chairman of the committee on Directing Principles in 1955 spoke briefly on the report under discussion. He was followed by Mr. D. C. MacCallum P.Eng. who spoke in favour of the corporate practice of the profession and by Mr. Gilles Sarault, P.Eng. who addressed the meeting in favour of the individual practice of the profession. Other briefs were presented by Messrs. Hector Cimon, P.Eng., Georges Demers, P.Eng., Roger Desjardins, P.Eng., H. L. Hurdle, P.Eng., E. S. Kelsey, P.Eng., Maurice Royer, P.Eng., Paul Tourigny, P.Eng., and G. Lorne Wiggs, P.Eng.

The members present approved two motions: (1) that the opinion of the membership at large be obtained on this question and that the General Secretary be instructed to send out ballots together with a résumé of the arguments pro and con, made at the meeting, and (2) that the report under discussion be approved with the exception of section 10 dealing with the practice of engineering by limited companies.

A lot has been said for and against the practice of the profession of engineering by corporations and individuals, and it appears that a lot more is to be said before the question is resolved.

Staff Nomination

In view of the continuous development of the Corporation, the addition of an officer to the C.P.E.Q. staff had long been felt as a need.

In January, members were invited to suggest candidates for the new position of Public Relations Officer; some 150 applications were received.

The President and the Council of the Corporation take pleasure in introducing Mr. Robert Préfontaine, M.A. whose duties will be to better acquaint engineers with the Corporation, and the public with engineers. Under the direction of Mr. Pierre Bournival, P.Eng. General Secretary, he will work with the other senior officers of the Corporation: Mr. Jean Barcelo, P.Eng., Registrar and Mr. B. R. Lachapelle, P.Eng., Specialized Services Officer.

Born in Manitoba, Mr. Norbert Préfontaine holds B.A. and M.A. degrees and has completed the required credits for his Ph.D. He has had extensive experience in radio and has worked with the Canadian National Railways in Montreal as District Superintendent of the Department of Colonization and Agriculture.

Correction

A list of officers comprising the Council for the current year appeared in the June issue of the *Journal*. Unfortunately the name of Councillor O. S. Gislason was omitted from that list.

ONTARIO

Technician Registration

The first official certification of engineering technicians in Canada was carried out June 5 when Premier M. Frost presented certificates to six men.

The ceremony, held in the Council Chambers of the Parliament Buildings at Queen's Park, was attended by officials of the A.P.E.O. Included were John H. Fox, P.Eng., Toronto, Association president; Dr. George B. Langford, P.Eng., of the University of Toronto, and Blake H. Goodings, P.Eng., Association field representative.

The 16,000-member Association was the first engineering body in Canada to establish a plan to certify technicians in five grades. Announcement of the program was made earlier this year in the April issue of the *Journal*.

Premier Frost said he felt great satisfaction in knowing that the idea for certification of technicians originally came from his office. D. J. Collins of the Premier's staff, after receiving a report from the Department of Highways, recommended that some study be given to the establishment of an association to accord recognition to the many technicians in the province. On this suggestion a voluntary program was initiated by the A.P.E.O.

The APEO's certification program was based upon the fact that certification would encourage technicians to progress through the five grades to top efficiency, and would also serve industry as a method of defining the upgrading of technical employees, employment needs and salary structures.

It is estimated that there are some 50,000 technicians in Ontario.

Engineers in the News

Fred H. D. Haiblen, of Jedwin of Canada Ltd., 170 Bloor Street West, Toronto, states that the company has recently been awarded the Canadian and United States agency of Wilhelm Breitenbauch Maschinen fabrik Unna, Westfalen, Germany, manufacturers of wire working machinery. For several years Jedwin of Canada Ltd., has represented in Canada and the States the firm of Mueller & Schwamborn Maschinenfabrik, of Bruehl, Germany. This concern manufacturers steel wire rope and electric cable machinery.

Ian R. Dutton is associate editor of "Electronics Engineering", a technical publication of Maclean-Hunter organization in Toronto.

Mr. Dutton graduated in electrical engineering from the University of Toronto in 1951 and was latterly with J. A. Wilson Lighting & Display Ltd., Toronto.

John R. Platts, of The British Thomson-Houston Co. (Canada) Ltd., is sales manager of the company for Quebec and the Maritimes and is located at 758 Victoria Square, Montreal.

Harold A. Whincup, formerly with Ontario Hydro, Toronto Region, has accepted the post of construction and maintenance engineer with the North York Hydro Electric Commission. His office is at 5145 Yonge St., Willowdale, Ontario.

T. Petterson has been appointed director of the engineering staff of W. R. Watkins Co. Ltd., Toronto, wholesale distributors and representatives of industrial and aircraft products.

A graduate from the University of Toronto, Mr. Petterson was for four years production engineer of Dowty Equipment Ltd. Recently he was a technical representative with Rogers Majestic Electronics Ltd.

Gerald G. Fisch, of Bruce Payne & Associates, Inc., management consultants in Westport, Conn., has been named vice-president of the company.

Mr. Fisch who joined the company in 1955 and became its assignment director in 1956, was formerly with Canada Packers Ltd. He graduated in engineering from McGill University and later obtained degree in both management and engineering from the Massachusetts Institute of Technology. In his new position he will maintain headquarters in the firm's New York office and will coordinate activities in the area offices in Boston, Chicago, Atlanta, Montreal and Westport, Conn.

N. E. Wilson is chief engineer of the Approval Division of the Canadian Gas Association, 6 Hadyen St., Toronto.

Mr. Wilson graduated in mechanical engineering from the University of British Columbia in 1950. Prior to joining to Canadian Gas Association's staff he was with the fire prevention division of the Underwriters Laboratories of Canada.

Frederick R. Duncan, is associated with Frederick P. Varcoe, C.M.G., Q.C., in carrying on his practice of law as Varcoe, Duncan & Associates. He is located at 7 King Street West, Toronto. The firm also has offices at 77 Metcalfe St., Ottawa.

Mr. Duncan graduated in electrical engineering from McGill University in 1940 and followed this by a course in law at Osgoode Hall, Toronto. He has been following his practice as a barrister-at-law in Toronto.

BRITISH COLUMBIA

Engineers in the News

C. E. Oliver, has been elected mayor of Penticton at a recent mayoralty election in the Okanagan city. Mr. Oliver is general manager of the Oliver Chemical Company Limited, Penticton. He has been engaged in civil and community activities for many years and was reeve of Penticton district for ofur consecutive terms from 1932 to 1936.

Walter J. Hardy, has been appointed assistant mechanical superintendent, Canadian White Pine division of MacMillan & Bloedel Limited.

G. T. Hughes, formerly with Ripley and Associates, Vancouver, has taken an appointment as associate professor, department of civil engineering, at the Royal Military College, Kingston, Ontario.

F. Lee has been appointed distribution design engineer. Vancouver Island, with the B.C. Electric Company.

O. W. H. Roberts has joined A. B. Sanderson & Company Limited as contract engineer. Mr. Roberts was formerly with the Department of Highways Province of British Columbia, as divisional engineer in the Peace River district. He was regional maintenance engineer at Prince George when he resigned from the department.

William A. Dale has been appointed resident manager of the chemical cellulose mill at Port Alice, B.C. for Alaska Pine & Cellulose.

Joseph W. Fraser received the appointment as assistant resident manage at Port Alice, B.C. Mr. Fraser is a gradu ate of the University of British Colum bia.

J. S. Slater has been appointed gen eral manager, Pembina Pipe Line Lim ited, Calgary, Alberta.

Allan Gall has registered with th Oregon Board of Engineering Examiner to practise in that State.

Graham F. Somerville has been awarc ed the Association of Professional Er gineer's Gold Medal for heading th graduating class in applied science at th University of British Columbia.

V. Raudsepp has received the appoin ment of Deputy Comptroller of Wat Rights, Department of Lands and Fo ests, Parliament Buildings, Victoria.

L. E. Wight has been named ar manager of the southern interior regi of the B.C. Power Commission and S. Burnell will be area manager of tl central interior.

The Commission also announces C. **Wale** will be district manager at Wil ams Lake, B.C. and **Larry Harper**, no distribution supervisor for the Caribc will move to the district manager's po tion at Nakusp. **Basil Gale** has been a pointed district manager for the Colu bia Valley.

H. B. R. Graves, has been appoint production manager, with the B.C. Co crete Limited.

Robert W. Lasby, has been appoint mine geologist for Chibougamau Jacu Mines Limited, Chibougamau, Queb He was formerly at Copper Mounta B.C.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Charles McGill McKergow, M.E.I.C., emeritus professor of mechanical engineering at McGill University, died at Montreal on June 5, 1957.

Professor McKergow who was born in Montreal was a graduate of McGill University. He gained his engineering qualifications in 1903. He received a master's degree in engineering in 1904 following which he taught engineering at the University of Virginia.

Returning to Canada in 1906 he accepted an appointment with the department of mechanical engineering at McGill University and was named associate professor in 1912. He was awarded the chairmanship of the department in 1921. He remained there until his retirement as professor of mechanical engineering in 1947.

Professor McKergow joined the Engineering Institute as a Student Member in 1903, became an Associate Member in 1911 and transferred to Member in 1921. He attained Life Membership in 1943.

Nicol MacNicol, M.E.I.C., village engineer, Forest Hill, Ont., died suddenly at Toronto, Ont., on June 2, 1957.

Mr. MacNicol who was born at Barrie, Ont., was educated in Toronto at Parkdale Collegiate Institute and graduated in civil engineering from the University of Toronto in 1919. He began his professional career in Windsor, then joined a firm of consulting engineers in Detroit, Michigan. He also gained experience with the Toronto firm of James, Proctor and Redfern Ltd., as resident engineer. In 1923 he became Etobicoke Township engineer. Eight years later he resigned in order to become works commissioner for Forest Hill Village, Ont., which post he held until the time of his death.

Mr. MacNicol was past-chairman of the Canadian Section of the American Water Works Association; past - president of the Canadian Institute of Sewage and Sanitation and Federation director of the Institute for three years. He was chairman of the Toronto Branch of the Engineering Institute in 1940.

Mr. MacNicol joined the Institute as a Student Member in 1919. He became Junior Member in 1923 and was transferred to Member in 1935.

Arthur Albert Smith, M.E.I.C., former chief engineer of the Ontario Department of Highways, died at Toronto on June 5, 1957.

Mr. Smith was born at Loughborough, England, on February 27, 1897, and attended schools in that district. In 1897 he commenced his engineering studies in Birmingham as an articled pupil with the boro engineer of Kings Norton Council. He began work in 1900 as an assistant engineer to the Council and over the following ten years worked as an assistant engineer with several British consulting firms. He was engaged on railway construction and tramways reconstruction.

Beginning his career in Canada in 1910 he became a resident engineer

H. V. Anderson, M.E.I.C.

with the Canadian National Railway and the Toronto Suburban Railway. In 1914 he joined the Department of Public Highways of Ontario as assistant engineer. He became resident engineer in 1917 and two years later was named divisional engineer in charge of the construction of the provincial highway east of Toronto. Later appointments were those of assistant chief engineer in 1925 and chief engineer in 1928. He retired in 1951.

Mr. Smith joined the Institute as a Member in 1921. He attained Life Membership in 1955.

William Hurst, AFFIL. E.I.C., pioneer, engineer, chairman of the board of the Central Manitoba Mines Limited, and president and general manager of the Hurst Engineering and Construction Company, Winnipeg, died there on May 23, 1957.

Born at Ottawa, Ont., on January 1, 1877, Mr. Hurst received his education at public schools in Manitoba. In 1900 he became engaged in street building work with the City of Winnipeg, was later put in charge of brick and concrete sewers and was in 1905 named superintendent of sewerage and water works. He assumed charge of artesian wells, and of the foundation of a high pressure plant and intake from the river to the plant. He completed the deep well and screen-house intake for water and the discharge of steam from the Red River to a standby plant of the Winnipeg Electric Railway.

In 1911 he formed the Hurst Engineering and Construction Company, playing an extensive part in the early development of Winnipeg and outlying areas, being responsible for such works as the sewerage system for the town of The Pas, Man., and pavement, waterworks and sewerage projects for the City of Winnipeg, as well as five years maintenance work with the Canadian Pacific and Canadian National Railways.

Mr. Hurst was the inventor of the Hurst Frost Excavating Machine, the Hurst Auto Heater and the Hurst Fire Escape Tube. Named president of the Central Manitoba Mines Limited in 1933, he held the appointment until three years ago. At that time he became chairman of the board.

Mr. Hurst joined the Institute as an Affiliate Member in 1928.

Hope Vere Anderson, M.E.I.C., former director of marine services, Department of transport, Ottawa, died suddenly at New Canaan, Conn., on April 28, 1957, while visiting there.

Born at Motherwell, Lanarkshire, Scotland, on December 10, 1890, Mr. Anderson studied engineering at the Glasgow West of Scotland Technical College for four years, at the same time apprenticing with the Glasgow engineering firm of Messrs. Alley and McLellan. Finishing his training in 1910, he gained added experience for the two years as a designing draughtsman in Glasgow. Moving to Canada in 1912 his first position was with the International Marine Signal Company at Ottawa. The following year he transferred his services to the Department of Mines, also in Ottawa, and later that year received the appointment of mechanical engineer with the Department of Marine, holding that position until 1924. Named senior assistant engineer, Department of Marine at that time, he also became first assistant to the acting chief engineer. With the advent of World War II he was in 1940 named chief of aids to navigation. Outstanding in Mr. Anderson's career was his work in the conversion of the Dominion Lighthouse Depot at Prescott, Ont., to war work during World War II. The establishment produced an average monthly output of 9,000 depth charge pistols and primers for use by the R.C.N., R.N., and navies of other allies. For this he was awarded the O.B.E. He retired from professional duties in 1955, after forty-two years service with the Department of Marine.

Mr. Anderson joined the Institute as a Member in 1935.

Institute Honours and Awards

Presented at the Seventy-First Annual General Meeting

Gen. The Hon. A. G. L. McNaughton, (right) receives certificate of honorary membership from President McKillop.

HONORARY MEMBERSHIPS

Four honorary memberships were awarded this year to distinguished members of the profession: Andrew George Latta McNaughton, C.H., C.B., C.M.G., D.S.O., D.C.L., LL.D., M.SC., chairman, Canadian Section International Joint Commission, and chairman Canadian Section, Canada-United States Permanent Joint Board on Defence Ottawa, Ontario; J. Omer Martineau, B.Sc., assistant chief engineer, Department of Roads, Province of Quebec, Que.; Penrose Melvin Sauder, S.P.S., Toronto, manager and colonization manager, St. Mary and Milk Rivers Development, Alberta Government, Lethbridge, Alta.; William Stewart Wilson, B.A.Sc., assistant dean and secretary of the faculty of applied science, University of Toronto, Toronto.

General, The Honourable A. G. L. McNaughton, HON. M.E.I.C., C.H., C.B., C.M.G., D.S.O., D.C.L., LL.D., M.S.C.

At the outset it will be recognized by everyone in this room that for so distinguished a Canadian as General McNaughton it is impossible even to outline his career let alone do justice to it, in so short a period of time as is at our disposal.

He was born in rural Saskatchewan, at Moosomin, and was educated at Bishop's College, Lennoxville, Que., and at McGill University, from where he graduated in 1910 with a degree of B.Sc. in electrical engineering and an M.Sc. in 1912. In 1920 he received an honorary LL.D. from McGill University.

Overseas with the Canadian artillery throughout World War I, he was wounded, mentioned in despatches, and awarded the D.S.O. In 1918 he was general Officer Commanding the Canadian Corps Heavy Artillery with the rank of brigadier general. In 1919 he was named a Commander of the Order of St. Michael and St. George.

Appointed a member of a committee for the organization of the Canadian Militia in 1919, this was followed by his entry into the permanent force a year later, with the accompanying posting as director of military training and staff duties at National Defence Healquarters, Ottawa.

Deputy chief of the general staff in 1928, this appointment gave way to that of District Officer Commanding, Military District No. 11, Victoria, B.C. in 1928. He also continued studies in Camberley and London, England, along with his other activities.

In 1929, promoted to the rank of major general, he was appointed Chief of the General Staff at Ottawa. Later, in 1935, he became president of the National Research Council. The same year he was made Commander of the Bath.

He was joint inventor of the Cathode Ray Direction Finder in 1926 and in scientific research has been responsible for many contributions.

Recalled to the Army in 1939, he was appointed to command the 1st Canadian Division. As a lieutenant general he commanded the Seventh Corps in the Battle of Britain. Forced to return to Canada through indifferent health in 1944, he was granted extended leave. Later that year he retired from the army and was given the rank of full general in recognition of his outstanding service.

He was appointed to the Cabinet as Minister of National Defence in 1944. Following the conclusion of the war with Japan he resigned from the Government and became chairman of the Canada-United States Permanent Joint Board on Defence, which post he still retains. The following year he was appointed Canadian Representative to the United Nations Atomic Energy Commission, and later was named president of the Atomic Energy Control Board of Canada. He was the Permanent Delegate of Canada to the United Nations and representative of Canada on the Security Council during 1948 and 1949. In 1950 he became chairman of the Canadian Section, International Joint Commission, which appointment he continues to hold.

His honours have been numerous in Britain, the United States and Canada and include the Sir John Kennedy Medal of the Engineering Institute of Canada 1940; an honourary Doctor of Laws degree conferred on him in 1942 at the University of Birmingham; an honourary Doctor of Laws from the University of Saskatchewan in 1944; the Companion of Honour and Grand Officer of the Order of Leopold in 1946.

General McNaughton joined the Institute in 1914 as an Associate Member and was transferred to Member in 1927.

General McNaughton is one of our great Canadians who ranks with today's great men of any nation. No Canadian was ever more concerned with the welfare of our Dominion and to those who have an insight into his work in the International Joint Commission, this will be brilliantly evident. Canadian engineers are proud to have this great man in their ranks. He is a credit to the profession and by his sterling merits and performance raises the status of us all.

J. Omer Martineau, HON. M.E.I.C.

J. Omer Martineau, assistant chief engineer of the Department of Roads of the Province of Quebec was born at Quebec City and studied surveying at Laval University and civil engineering at Queen's University. He graduated from Queen's with the degree B.Sc. in 1915. After a short term of service with the R.C.E. in Canada, he joined the staff of the Department of Roads in 1916, and has served that body for more than forty years.

A member of the soil investigation committee of the United States National Research Council from 1936 to 1942 he has also more recently been a member of the Associate Committee on Soil and Snow Mechanics of the National Re search Council of Canada, and was a member of the N.R.C. sub-Committee on "Muskeg".

Mr. Martineau has been a member of the Institute of Traffic Engineers; the Portland Cement Association; the Association of Asphalt Paving Technologist; the Canadian Good Roads Association, and the International Road Congress. He was also chairman of the National Committee on Uniform Traffic Control Devices of the Canadian Good Roads Association, where he represented the Institute.

Mr. Martineau joined the Institute in 1935. Actively serving in the Quebec Branch of the Institute for years, he was elected chairman in 1945 and five years later was elected councillor. During 1954 and 1955 he was vice-president for the province of Quebec.

To the business of Council and to the many social activities of the Institute, Mr. Martineau brought the best of many things from the French culture. His English speaking associates are indebted to him and are grateful for the privilege of knowing him and of working with him.

Penrose Melvin Sauder, HON. M.E.I.C.

P. M. Sauder, whose name is synonymous with the development of water resources in the West is consultant to the Western Irrigation District and colonization manager of the Department of Water Resources of the Alberta Government in connection with the St. Mary River development.

Penrose Melvin Sauder was born near Preston, Ontario. He studied mechanical and electrical engineering and on gradution in 1904 from Toronto joined the staff of the Department of the Interior as a draftsman at Regina. The following year he was located as an assistant engineer and made the first rating of the Bow River at Seebe. In 1909 he established a system of hydrometric surveys in

J. O. Martineau

P. M. Sauder (left)

Alberta and Saskatchewan and during the same year received the appointment of chief hydrographer.

He was named assistant commissioner of the irrigation branch in 1910 and held this post until 1919. In 1920 he joined the staff of the Lethbridge Northern Irrigation District, serving for three years as division engineer. Later he was assistant project manager and from 1924 to 1941 carried out the duties of manager. In this work he was able to establish practical methods of co-operation with the farmers of the district.

Promoted to the duties of director of Water Resources in 1941 he retired three years later to become general manager of the Western Irrigation District at Strathmore, at the same time keeping in touch with the Lethbridge area.

His services as manager of the St. Mary River Development were called upon in 1947, however in 1950 his ability to combine engineering with the human factor was recognized by the Alberta government and he was appointed colonization manager of the development.

Mr. Sauder has maintained a strong interest in the Engineering Institute of Canada and the Association of Professional Engineers of Alberta and was instrumental in the formation of the latter. He was elected president of the Association, during the years, 1936-37.

With membership in the Engineering Institute dating back to 1908, he has served as Branch chairman, councillor in 1927, and vice-president of the Institute in 1939 and 1940. For several years he has been on the council of the Institute representing the Alberta Association.

In recognition of his work, the Julian C. Smith Medal of the Institute was awarded him in 1947. Two years ago the Agricultural Institute of Canada conferred on him an honorary membership.

Here we have another case of the young man who came West, and remained to conquer. Mr. Sauder now is so much a part of Western Canada that it is almost impossible to think of him as ever having been any place else. He is one of the outstanding servants of the people of this part of Canada, and the Engineering Institute is proud to recognize his life of achievement in public service by awarding him an Honorary Membership.

W. S. Wilson (right)

William Stewart Wilson, HON. M.E.I.C.

W. S. Wilson, Assistant Dean of the Faculty of Applied Science and Engineering of the University of Toronto, also holds the post of secretary of the faculty.

He devoted a number of years to military service during World War I, before embarking on the academic training which was to earn him a B.A.Sc. degree in 1921, at the University of Toronto.

He joined the 31st regiment of the Queen's Own Rifles of Canada in 1913, later serving with the 147th Battalion of the Canadian Expeditionary Force in 1916, and then with the 4th Division, 38th Ottawa Battalion until demobilization in 1919.

After a few years experience in the construction field he was appointed secretary of the faculty of applied science and engineering, and has held the post since that time.

His appointment to assistant deanship was made in 1914.

He joined the Institute as a Student Member in 1921. He has accompanied his years of membership in the organization with an active interest in its affairs. He was secretary-treasurer of the Toronto Branch from 1931 to 1937, chairman of the branch in 1942 and a member of Council for four years, beginning in 1944. He is also E.I.C.'s representative on the executive of the Engineers' Council for Professional Development.

In the eastern part of this great Dominion, not many engineers are better known than "Stew" Wilson. Thousands of young men have passed through the old "School" at Toronto, and all have been the better for the guiding hand he has had in their affairs. His many friends will attest willingly to his character and his personality, his interest in other people, his sympathy and support for all good causes, and his genuine friendship.

The Institute is proud to number him among their Honorary Members.

SIR JOHN KENNEDY MEDALS

The "Sir John Kennedy Medal" has this year been presented to Richard Lankaster Hearn, M.E.I.C., consulting engineer, Hydro Electric Power Commission of Ontario, Toronto, Ont., and Irving R. Tait, M.E.I.C., formerly chief engineer, Canadian Industries Limited, Montreal. Que.

I. R. Tait (right)

Richard Lankaster Hearn, M.E.I.C.

Richard Lankaster Hearn was born in Toronto and graduated from the University of Toronto in 1913 with a degree of B.A.Sc. In 1952 he received the honorary degree of Doctor of Engineering.

After graduation he worked for the Dominion Bridge Company at Lachine as a draughtsman, later transferring to the Hydro-Electric Power Commission.

From 1921 to 1924 he was assistant chief engineer with the Washington Power Company with headquarters at Spokane, Washington. In 1924 he came back to Canada as chief engineer and secretary-treasurer of the H. G. Acres and Company Limited; from 1930 to 1934 he was consulting engineer for the Dominion Construction Company and H. F. McLean Limited and was their chief engineer from 1934 to 1942.

In 1942 he returned to the Ontario Hydro as executive assistant to the chairman; later he was loaned to become chief engineer in charge of the supervision of construction of the Polymer Synthetic Rubber plant at Sarnia, Ont.

Again in 1944 he was loaned by the Hydro to act as Canadian Technical Advisor to the Public Utilities Division of the Combined Production and Resources Board at Washington, D.C. In 1945 he came back to the Hydro as chief engineer of design and construction. In 1947 he was made general manager and chief engineer of the Commission and in 1955 was appointed chairman.

Dr. Hearn is an honorary member of the Association of Municipal Electrical Utilities (of Ontario), a director of Atomic Energy of Canada Limited, Honourary vice-president and director, Ontario Safety League, and a Fellow of the Canadian Geographical Society.

In 1954 he was awarded the Julian C. Smith Medal by the Institute for "Achievement in the Development of Canada" and in 1956 was awarded the Ontario Association of Professional Engineers Medal for outstanding achievement.

Dr. Hearn joined the Engineering Institute as an Associate Member in 1920, transferring to member in 1925. He became a Life Member in 1955.

Irving Richard Tait, M.E.I.C.

Irving Richard Tait was born in Montreal and was an honours graduate from McGill University in 1913, with the degree of B.Sc. in electrical engineering. In 1954 Mr. Tait received an honorary degree of doctor of science from Clarkson College of Technology, Potsdam, N.Y.

Starting with a two years apprenticeship in the shops of the Canadian Westinghouse Company he transferred in 1915 to the Canadian Explosives Limited as project engineer. This company later became a subsidiary of Canadian Industries Limited (C.I.L.) In 1929 he became assistant chief engineer of the company and in 1939 chief engineer. In 1952 after C.I.L. was broken up he became consulting engineer. He is still consulting engineer with C.I.L.

E. V. Buchanan (left)

Although graduated in electrical engineering, Mr. Tait's field of interest included in almost equal parts, civil and mechanical engineering. During the first World War he was engaged in the design and expansion of war plants for Canada, Great Britain and the United States.

During the Second World War C.I.L. was the principal manufacturer of chemicals and explosives. Mr. Tait was responsible for the new plants which were built by the company in many parts of Canada.

Throughout his lifetime he has been associated with the Y.M.C.A., on the board of management, on the board of directors and on the finance committee. He is on the board of governors of the Sir George Williams College, Montreal, and was chairman of the building committee in charge of the new premises recently opened. He is a registered engineer in many provinces; a member of the American Society of Testing Materials and the Engineers Club of Montreal. He is a past president of the Heather Curling Club.

Mr. Tait joined the Institute as an Associate Member in 1921, transferring to Member in 1940. He was councillor in 1950-51, vice-president from 1952 to 1954, and has served on the executive of the Montreal Branch and as Branch chairman. He has been chairman of many Institute committees including the finance committee, the committee on professional interests, the publications committee, and is at present chairman of the Institute's committee on Confederation.

JULIAN C. SMITH MEDAL

The Julian C. Smith Medal has been awarded to E. V. Buchanan, M.E.I.C., general manager of the Public Utilities Commission, London Railway Commission, of London, Ont.

Edward Victor Buchanan, M.E.I.C.

Edward Victor Buchanan was born in Hamilton, Scotland, and educated there, graduating in electrical engineering from the Royal Technical College, Glasgow, in 1908.

He came to Canada in 1910 and was associated with H. J. Glaubitz, consulting engineer for the Ontario Hydro. He went to London, Ont., later in 1910 as resident engineer in charge of the erection of hydro-electric substations. He became electrical and waterworks engineer for the Public Utilities Commission in 1911 and general manager of the Commission in 1915. In 1936 he was appointed also general manager of the London and Port Stanley Railway. In December 1951, Mr. Buchanan retired as general manager of the Public Utilities Commission. Since then he has done consulting

R. L. Hearn (left)

work, and in 1953 was appointed managing director of Isotopes Products Limited, Oakville, Ont.

Mr. Buchanan joined the Institute in 1922, and was chairman of the London Branch, 1924-1925, Councillor, 1926-1927, and vice-president 1938-1939. He has represented the Institute on the Engineers' Council for Professional Development since 1946.

Mr. Buchanan has been particularly active in the affairs of the organized bodies of the Engineering profession. He started early as secretary of the Student Section of the Institution of Electrical Engineers in Glasgow. He was president of the Association of Municipal Electrical Utilities in 1917-1918; chairman of the Canadian Section of the American Waterworks Association, 1937-1938; and president of the Association of Professional Engineers of Ontario in 1950.

Mr. Buchanan is also president of the London Health Association which governs the Beck Memorial Sanatorium, chairman of the London and Suburban Planning Board, and is a past-president of the London Community Chest.

In 1948 Mr. Buchanan was awarded the George Warren Fuller Memorial Award of the Canadian Section of the American Waterworks Association, for "His outstanding service in the administration of waterworks and public utilities and for the development of public relations.

In December, 1950, Mr. Buchanan's great contributions were further acknowledged when the Hydro-Electric Power Commission of Ontario named its new transformer and frequency changing station at Pond Mills, near London, Ontario, the E. V. Buchanan Station."

DUGGAN MEDAL AND PRIZE

For papers dealing with the use of metals for structural or mechanical purposes, Douglas Tyndall Wright, Jr. E.I.C., assistant professor of civil engineering at Queen's University has received the award for his paper, "The Design of Compressed Beams".

D. T. Wright, JR.E.I.C.

Mr. Wright was born and educated in Toronto and graduated from the University of Toronto in 1949. Since then he has been active in structural research and design. Later, attending the University of Illinois, he received an M.Sc. degree for his research on the development of the high tensile bolted joint. He also worked on the plastic deformation of reinforced concrete from the point of view of large-magnitude impulsive loading. Granted an Athlone Fellowship in 1952 he worked at Cambridge, Eng., on the research team of Professor Baker, on plastic theory. He also worked on beam-columns and structural connections and from this work produced the E.I.C. paper, "The Design of Compressed Beams".

Before returning to Canada in 1954 he received the degree, Ph.D. He joined the staff of Queen's University shortly afterwards. Since that time he has engaged in consulting work, in the design of the first "plastic" building in North America, and in further research in bridges and plastic theory, while carrying on teaching duties.

The paper was published in the February issue of the *Engineering Journal.*

GZOWSKI MEDAL

The Gzowski Medal is awarded for the best paper of the medal year provided such paper shall be adjudged of sufficient merit as a contribution to the literature of the profession but not otherwise. It is a gold medal, provided from the fund established in 1889 by Colonel Sir Casimir Gzowski, A.D.C., K.C.M.G., late past-president of the Institute.

Winner for 1957 is the New York City builder of bridges on five continents, David Bernard Steinman, whose paper, "The Design of the Mackinac Bridge," appeared in the May issue of *The Engineering Journal.*

D. B. Steinman, M.E.I.C.

Born in Brooklyn, Dr. Steinman studied at the City College of New York, then won three scholarships to Columbia University, where he took A.M., C.E., and Ph.D. degrees. He was professor of civil engineering at the University of Idaho for four years, at the outset of his career, from 1910 to 1914, and professor of civil and mechanical engineering at the City College, New York, from 1917 to 1920. Since 1920 he has been in private practice and has served as designing or consulting engineer in the construction of more than 400 bridges on five continents. Eight of his bridges have been honoured in the annual awards for the most beautiful bridges in America. He has received numerous honours, both national and international, for distinguished achievements. He has twice received the Norman Medal, highest award of the American Society of Civil Engineers, in addition to two other awards of the Society.

He was the founder and first president of the National Society of Professional Engineers. Today it has a membership of 37,000.

Among the many notable bridges on which Dr. Steinman was designer or consultant are the Florianopolis Bridge in Brazil, the Mount Hope Bridge in Rhode Island, the St. Johns Bridge in Oregon, the Carquinez Straits Bridge in California, the Henry Hudson Bridge in New York, the Constitution Bridge in Puerto Rico, Thousand Islands International Bridge, the Bagdad Bridge over the Tigris River in Iraq, the Kingston Bridge across the Hudson River, the Raritan River Bridge in New Jersey, and the Connecticut Turnpike Bridge in New Haven. He is now engaged on plans for an international bridge between Sault Ste. Marie, Michigan, and Sault St. Marie, Ont., and another international suspension bridge over the St. Lawrence Seaway.

D. B. Steinman

D. T. Wright

He is the author of the biography, "The Builders of the Bridge," a number of standard works on bridge design and construction, and more than 600 technical papers and articles, many of them translated and published around the world.

In 1947 he was awarded an honorary doctor of science degree by his alma mater, and the University Medal for Excellence by Columbia University, followed by the Egleston Medal in 1951. He was presented with the highest award of the National Society of Professional Engineers in 1952. He has also, among many other awards, received a Doctor of Science degree at Columbia University and the University of Ghent, a Doctor of Civil Engineering, Bologna, Doctor of Engineering, Rensselaer Polytechnic Institute and Manhatten College, and Doctor of Laws, Alfred University.

In 1954 Dr. Steinman received the highest award of the Scientific Research Society, for his research and inventions in suspension bridge aerodynamics. He has been honoured as president, honorary member and fellow, of a long list of engineering and scientific societies. He is a Life Fellow of the Royal Society of Arts in Great Britain, and a past-president of the New York Academy of Sciences. He has been awarded the French Legion of Honour, the Grand Prix Humanitaire of Belgium, the Order of Merite Scientifique of France, the Memorial Cross of the Greek Legion, the Croix de Lorraine of France, and the Order of the Gold Cross of Rome, in addition to many other honours by foreign countries. For his work on the reconstruction of Brooklyn Bridge, he received a civil medal. He is presently engaged on the world's largest bridge project, the $100,000,000 Straits of Mackinac Bridge in Michigan. This year he received the Kimbrough Gold Medal, highest award of the American Institute of Steel Construction.

Dr. Steinman is the founder and president of the David B. Steinman Foundation for grants for education, for research and for student aid.

He is also recognized as a scientist, mathematician, inventor, educator, lecturer, author, artist, poet, and humanitarian.

W. R. Way

N. E. Hudak

LEONARD MEDAL

The Leonard Medal, awarded for papers on mining subjects submitted either to the Canadian Institute of Mining and Metallurgy or to the Engineering Institute of Canada, was presented to George Arthur Jewett, M.C.I.M., scheduling engineer with the Rio Tinto Management Service Company Limited, Toronto, for his paper, "Sampling Design and Grade Estimation of Mineral Deposits."

G. A. Jewett, M.C.I.M.

Mr. Jewett is a graduate of Queen's University, Kingston, Ont., class of 1948 in mining engineering. He later attended the Carnegie Technical Institute, Graduate School of Industrial Administration, Pittsburgh.

Mr. Jewett's professional experience includes work as a blast-hole engineer, and assistant planning engineer at the Helen Mine, Wawa, Ontario, from 1948 to 1951, and an assistant professorship. He held the appointment of assistant professor of mining engineering at Queen's University from 1952 to 1955.

Mr. Jewett is a Member of the Canadian Institute of Mining and Metallurgy and the Association of Professional Engineers of Ontario.

The paper was published in the March 1956 issue of *The Canadian Mining and Metallurgical Bulletin.*

THE ROSS MEDAL

The Ross Medal is awarded for papers on electrical engineering subjects. This year it has been awarded to William Russel Way, M.E.I.C. vice-president of the Shawinigan Water and Power Company, Montreal, for his paper entitled, "Growth and Development of Large Electric Power Systems." The paper appeared in the October issue of *The Engineering Journal.*

W. R. Way, M.E.I.C.

Mr. Way, now a director of Shawinigan Water and Power Company, the Shawinigan Engineering Company Limited and the St. Maurice Power Corporation received his engineering training at McGill University. Qualifying for the degree B.Sc. in electrical engineering in 1918 he joined the Shawinigan Water and Power Company as an assistant engineer, operating department, Montreal and successively worked in various divisions of the company including the protection division, metering division and the hydraulic test division. In 1924 he was transferred to Shawinigan Falls as chief system operator. Six years later he returned to head office Montreal to fill the offices of assistant superintendent of operations, and assistant general superintendent. Mr. Way was named general superintendent in 1944. In 1951 he became vice-president of generation and transmission. His president position dates to 1954.

G. A. Jewett (left)

Mr. Way has also been active in the affairs of the Canadian Electrical Association. He was a member of the Executive Committee of that organization for two years, from 1951-53. He is a member of the Corporation of Professional Engineers of Quebec.

JOHN GALBRAITH PRIZE

The John Galbraith prize is awarded for the best paper given by a Junior in the Province of Ontario. It has been won by Nicholas Edward Hudak, JR.E.I.C., supervisor, application engineer, of the Canadian Cutler-Hammer Limited, Toronto, for his paper, "Trends in the Design of Electrical Distribution for Industrial Plants."

The paper was published in the June issue of *The Engineering Journal.*

N. E. Hudak, JR.E.I.C.

N. E. Hudak, of Canadian-Cutler Hammer Limited, Toronto, graduated from the University of British Columbia in electrical engineering in 1948. He devoted the ensuing three years to the duties of instructor in electrical engineering while studying for a Master's degree. He joined the Canadian Westinghouse Company Limited, Hamilton, Ontario, in 1951, taking the graduate engineer training course and then spent three years as a switchgear design engineer. While associated with Canadian Westinghouse Limited, he lectured in a post-graduate course, "Symmetrical Components", given under the auspices of the Nova Scotia Technical College and took part in the E.I.C. Juniors and Students Papers Presentation. He was awarded the John Galbraith Prize for 1951-52 for a paper entitled "Location of Faults in Power Cables by Fault-Generated Surges".

In 1953 he accepted an appointment with the Amalgamated Electric Corporation Limited, Toronto, as a distribution equipment engineer. A year later he was appointed supervisor of application engineering, the position he now holds.

Mr. Hudak is an active member of the Canadian Army Milita and holds a Captain's commission in the Royal Canadian Electrical Mechanical Engineers.

Personals

News of the Personal Activities of Members of the Institute

J. Hoogstraten, M.E.I.C., formerly professor of civil engineering at the University of Manitoba has been appointed president of the Nova Scotial Technical College, following the retirement of Dr. A. E. Cameron.

Mr. Hoogstraten graduated from the University of Manitoba in 1929 with a B.Sc. degree and later qualified for an M.Sc. degree from the University of Michigan. Initially a lecturer and demonstrator in the faculty of engineering from 1930 to 1933, later professor at Brandon Collegiate, it was in 1936 that he joined the staff of the University of Manitoba.

Active in furthering the profession in the province, Professor Hoogstraten served six years on the Council of the Association of Professional Engineers of the Province of Manitoba, was president of that Association for the past two years. He was also Manitoba delegate to the Dominion Council for two years.

R. A. Dunn, M.E.I.C., general sales manager of the Canadian Liquid Air Company Limited recently elected a director of the company has been appointed vice-president in charge of sales.

Mr. Dunn, who is a metallurgist joined the company in 1939 as field engineer with the development and engineering department, and in 1947 was appointed general sales manager.

W. C. Heim, M.E.I.C., senior executive of Alchem Limited, Burlington, Ont., has been elected president and general manager of the firm. He has held the appointment of vice-president since 1955.

With the company throughout the length of his engineering career except for an initial two years following his U.B.C. graduation in 1942, Mr. Heim's first post with the firm was that of field service engineer with the industrial department. Since then he has held responsible posts as chief engineer, and later manager, railroad department. In 1953 the offices of assistant to the vice-president and also assistant general manager were taken over by Mr. Heim.

J. Hoogstraten, M.E.I.C.

W. C. Heim, M.E.I.C.

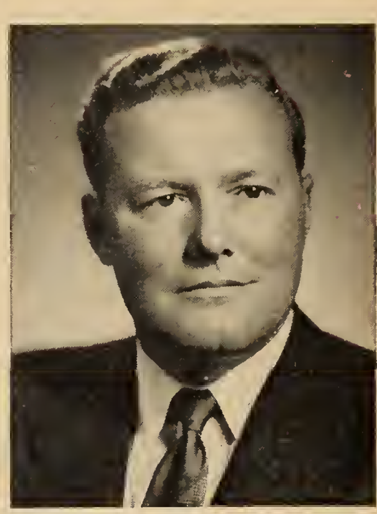
J. E. Leo Roy, M.E.I.C., chief engineer of the Quebec Hydro Commission's Auxiliary Services, has been appointed general manager of the Commission.

Mr. Roy was at one time associated with the Shawinigan Water and Power Company, and the Quebec Power Company in Quebec as assistant superintendent of the power division. In 1946 he accepted a position in the same capacity in Quebec Hydro's distribution department. In 1953 he was appointed to his present position.

Mr. Roy was the 1956 choice of president for the Corporation of Professional Engineers of Quebec. He is also chairman of the Montreal Branch of the Institute.

Louis O'Sullivan, M.E.I.C., assistant general manager of the Quebec Hydro-Electric Commission has been appointed a commissioner of the organization.

Mr. O'Sullivan became associated with the Montreal Light, Heat and Power Consolidated early in his engineering career, and in 1945 when the Hydro Commission took over the Montreal Light, Heat and Power properties was appointed to the newly created post of assistant general manager.



R. A. Dunn, M.E.I.C.

Mr. O'Sullivan was president of the Corporation of Professional Engineers of Quebec in 1952 and is also a former member of the Council of the Institute.

J. W. McCammon, M.E.I.C., general manager and commissioner of the Quebec Hydro-Electric Commission has retired from professional duties, following a career of forty-five years.

Mr. McCammon graduated from McGill University and gained a great deal of engineering and business experience with Mackenzie Mann and Company on the Mount Royal Tunnel, Montreal; as a manager of the pump and electrical departments of the Canadian Fairbanks Morse Company, Montreal and with the Charles Walmsley Company, Montreal, before joining the Beauharnois Light, Heat and Power Company in 1930 as assistant to the general manager. In 1945 he became general manager of the then newly established Quebec Hydro Electric Commission which took over the Montreal Light, Heat and Power Consolidated and the Beauharnois Light, Heat and Power Consolidated.

Dr. A. E. Cameron, M.E.I.C., president of the Nova Scotia Technical College since 1947, has retired after an engineering career of forty-three years.

Newly graduated from McGill University in 1914, with an M.Sc. degree in mining engineering, Dr. Cameron immediately gained experience with the Geological Survey of Canada in the Northwest Territories. He also worked with the Imperial Munitions Board, prior to serving in France and Belgium. At war's end returning to Canada he spent six years with the University of Alberta, mining and metallurgy department. In 1925 he received the degree of doctor of science in metallurgy from the Massachussetts Institute of Technology, returning to the former college as associate professor, and later professor of metallurgy.

Undertaking the duties of secretary of the Research Council of Alberta he carried out explorations in northern Alberta for the Council and engaged in private consulting work. Among the first to go into Great Bear Lake after the discovery of radium there, the first post office for mineral developments, Cameron Bay, N.Y.T., bore his name. In 1935 he ascended the South Nahanni River and explored the so-called Headless Valley and tropical valley of that area.

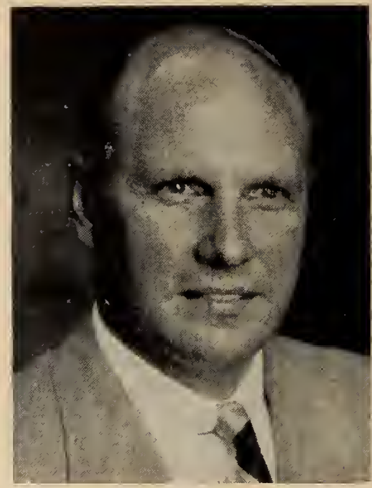
Named deputy minister for the Nova Scotia Department of Mines in 1937 Dr. Cameron carried on this work until chosen, ten years later, to fill the office he now relinquishes.

Dr. R. L. Hearn, M.E.I.C., has been elected a director of the Bridge and Tank Company of Canada Limited.

Dr. Hearn is a director of a number of Canadian companies including Atomic Energy of Canada Limited and the Canada Wire and Cable Company Limited.

W. D. Jewett, M.E.I.C., for a number of years export manager for the Dominion Bridge Company Limited at the firm's headquarters at Lachine, Que., has received the appointment of director of research. His new duties will entail work formerly carried out by the Company's industrial engineering department at the main plant in Montreal and by personnel in various branch plants of the organization.

W. D. Jewett, M.E.I.C.



D. B. Annan, M.E.I.C.

Mr. Jewett was earlier vice-president and general manager of the Canadian Overseas Projects Limited.

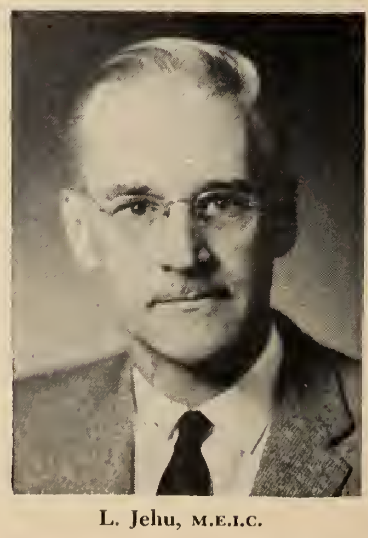
He is a graduate of the University of Toronto.

Llewellyn Jehu, M.E.I.C., has been promoted to welding and research engineer for the Dominion Bridge Company Limited, Eastern division.

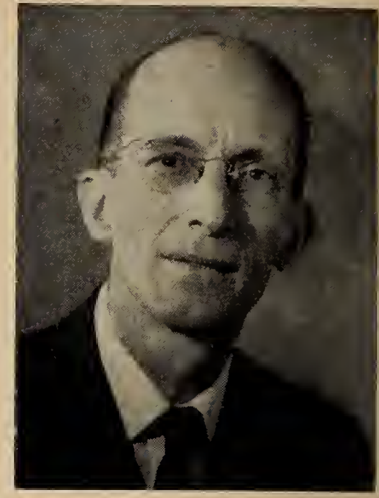
With the company for many years Mr. Jehu has served in numerous capacities including those of design engineer and assistant research and methods engineer.

R. J. Chambers, M.E.I.C., assistant chief engineer of the general engineering division of the Anglo Canadian Pulp and Paper Mills Limited and its associated mills, has been elected to the board of directors of the Dryden Paper Company Limited.

Mr. Chambers graduated from Queen's University, with a master's degree in mechanical engineering in 1935. At that time he became associated with the Gaspesia Sulphite Company Limited and remained there until 1946. Moving to Quebec he was named assistant chief engineer with the general engineering group of the Anglo organization.



L. Jehu, M.E.I.C.



P. N. Bland, M.E.I.C.

Professor William Bruce, M.E.I.C., has become chairman of the department of mechanical engineering at McGill University.

Professor Bruce was early in 1954 promoted from associate professor to professor of mechanical engineering at the University.

From Falkirk, Scotland, and a graduate of the University of Toronto, Professor Bruce joined the staff of McGill University in 1946 as an assistant professor.

D. B. Annan, M.E.I.C., plant engineer with the Norton Company of Canada Limited at Hamilton, Ont., was elected chairman of the Hamilton Branch of the Institute for 1957-58.

A native of the city in which he is now resident, and a graduate of Queen's University, class of 1940, Mr. Annan began his engineering career with the R.C.A.F. Returning to civil life in 1945 he joined the Canadian Westinghouse Company Limited at Hamilton as a metallurgist with the materials and process group.

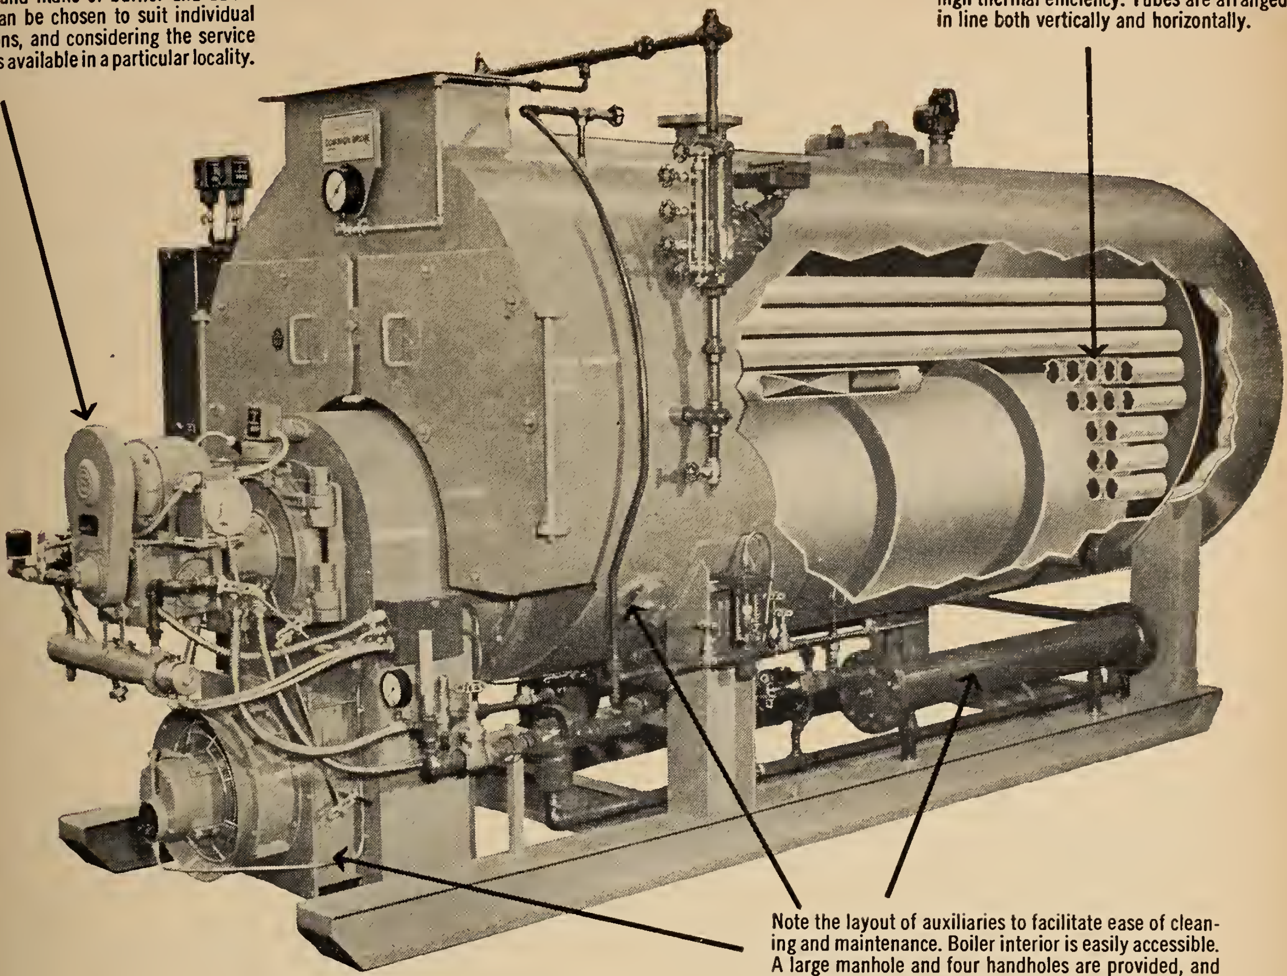
P. N. Bland, M.E.I.C., chief engineer with the Canadian Sumner Iron Work Limited, is chairman of the Vancouver Branch of the Institute.

He attended the Vancouver Technical School and entered the employ of his present firm as an engineering student.

For the next ten years he carried out engineering duties with the firm in Washington as a draughtsman, and in Vancouver as a machine designer. In 1930 he accepted the appointment of assistant to the construction engineer with the Vancouver Kraft Company at Port Mellon, B.C. Over the next four-

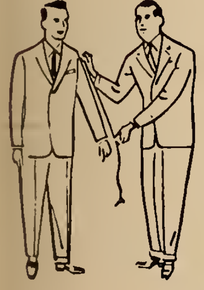
A type and make of burner and auxiliaries can be chosen to suit individual conditions, and considering the service facilities available in a particular locality.

Simple two-pass design eliminates baffles and other complications while retaining high thermal efficiency. Tubes are arranged in line both vertically and horizontally.



Note the layout of auxiliaries to facilitate ease of cleaning and maintenance. Boiler interior is easily accessible. A large manhole and four handholes are provided, and an access door to rear combustion chamber.

A custom-tailored package unit...



The Dominion Bridge package boiler is delivered ready to be connected to water, oil, and steam lines and to the electrical supply panel. Designs are available for hot water or steam heating, and for high pressure steam process requirements.

Simplified design, high efficiency and accessibility are some of the principal features of this unit. Built in a wide range of sizes in many of our plants from coast to coast, each Dominion Bridge package boiler is backed by seventy-five years of experience in the steam generation field.

For complete information, write for catalogue No. BF-120.

teen years, he was again employed by the Canadian Sumner Iron Works Limited, becoming chief engineer in 1937. He accepted an appointment as project engineer with the B.C. Pulp and Paper Company in 1946 and remained in this work for three years.

Mr. Bland has served on the executive of the B.C. Chapter of the American Society of Metals; was a Member of the Board of Examiners of the Association of Professional Engineers of B.C. from 1948 to 1952 and has lent his assistance to that organization as a Member of Council.

E. P. Innes, M.E.I.C., chief engineer of the Canadian Canners Limited, Hamilton, Ont., has been elected a director of Canners Machinery Limited, at Simcoe, Ont.

Mr. Innes, who joined the firm many years ago is a graduate of McGill University.

Gordon Cape, M.E.I.C., of the Dominion Bridge Company Limited, Lachine, Que., has been named for the post of manager of technical research. Mr. Cape formerly served as welding and research engineer in charge of the industrial engineering department.

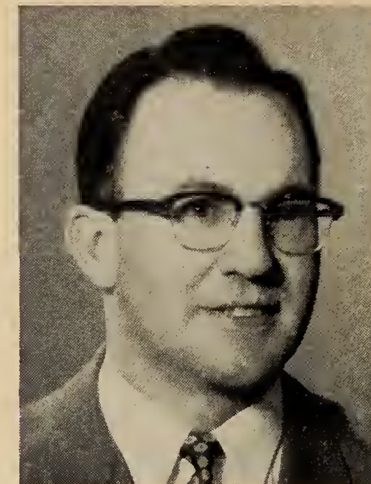
He was earlier in his career chief inspector with the firm, and is a graduate of McGill Univeristy.

J. C. Dale, M.E.I.C., president and general manager of Canadian Utilities Limited, Edmonton, has been elected president of the Canadian Electrical Association.

Mr. Dale has been a vice-president of the Association since 1954, chairman of several engineering sections, and a member of the executive committee since 1953.

W. G. McKay, M.E.I.C., associated with the firm of Underwood, McLellan

W. G. Small, M.E.I.C.



R. D. Rosser, M.E.I.C.

and Associates Limited, of Saskatoon, has beeen elected chairman of the Saskatchewan Branch of the Institute.

A 1940 graduate of Queen's University in civil engineering Mr. McKay joined his present firm in 1945 as an assistant engineer on the design of water supply and sewage disposal systems. Prior to that he held an appointment as senior sanitary engineer with the Department of National Health and Welfare at Edmonton. The post involved Saskatchewan, Alberta, Northern B.C. and the N.Y.T. At the outset of his career he was employed as a demonstrator on concrete, steel and timer design at Queen's University.

R. H. Tivy, M.E.I.C., formerly regional transportation engineer at Moncton, N.B., with the Canadian National Railway has been named to the post of assistant superintendent of the New Glasgow division of the organization.

Mr. Tivy also served the C.N.R. as assistant engineer in the department of research and development, shortly after joining the firm in 1953.

A 1943 graduate of the University of Manitoba in electrical engineering, Mr. Tivy has also been with the Manitoba Power Commission at St. Boniface, Man., as electrical engineer.

R. D. Rosser, M.E.I.C., of Brown Boveri (Canada) Limited was recently appointed Alberta Branch manager of the organization, located at Edmonton.

Mr. Rosser is a graduate of the University of Alberta, class of 1949, in electrical engineering.

Mr. Rosser joined the company in 1953 following four years' service with the Canadian Westinghouse Company Limited and then served as sales engineer of the Brown Boveri Calgary office.

J. L. Bryant, M.E.I.C., of Ross Engineering of Canada Limited, has been appointed chief engineer with headquarters at Montreal. In his new position Mr. Bryant will be responsible for the en-

G. Cape, M.E.I.C.

W. G. McKay, M.E.I.C.

gineering, research and development departments of the company.

Mr. Bryant obtained his bachelor's degree in mechanical engineering from the University of British Columbia, class of 1945. He has been employed by Ross Engineering of Canada Limited since 1947 and was appointed manager of the company's Vancouver office in 1951.

W. G. Small, M.E.I.C., newly elected chairman of the Kootenay Branch of the Institute holds the appointment of supervisor of the instrument section with the Canadian Mining and Smelting Company of Canada Limited at Trail, B.C.

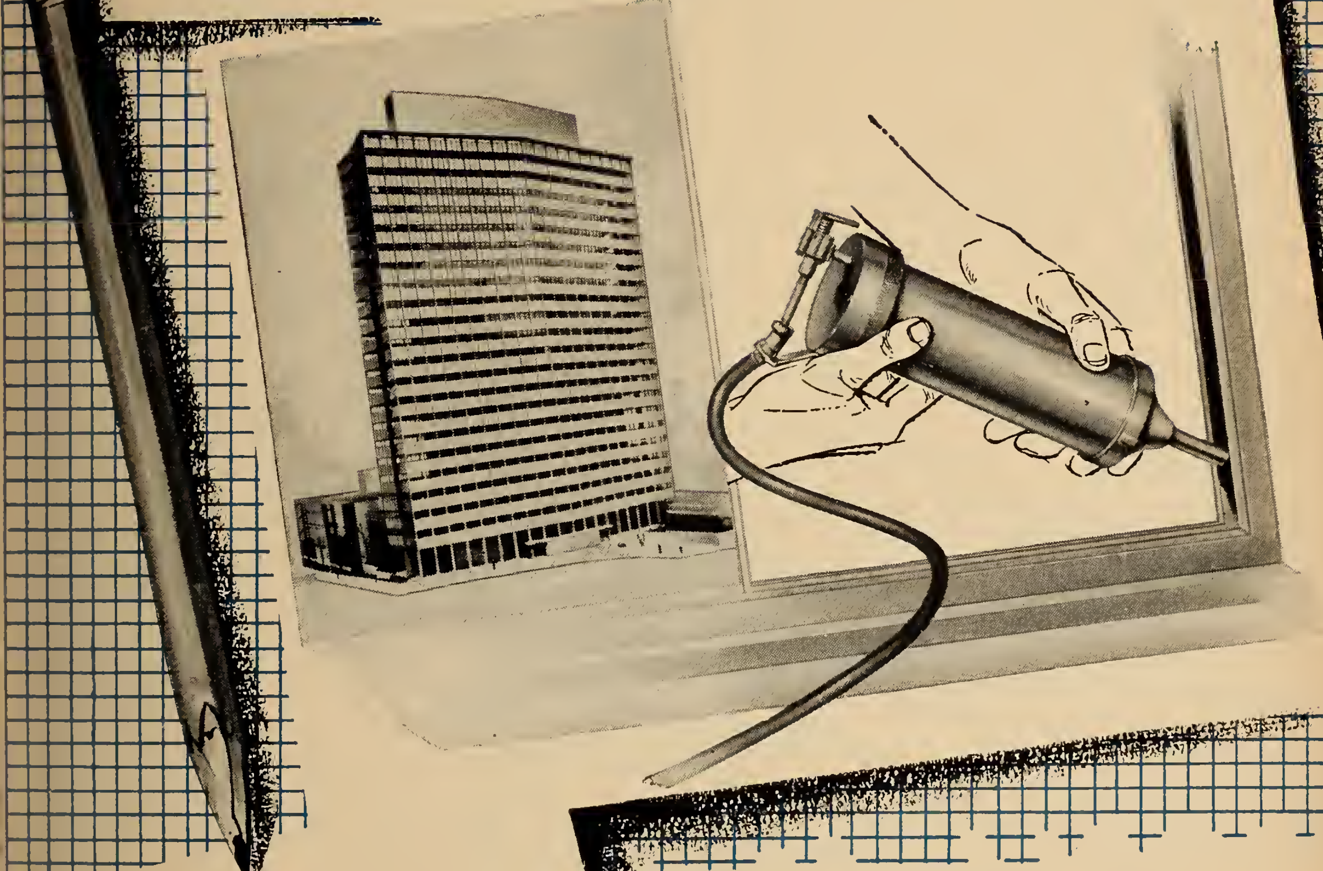
Originally from the prairie provinces

CORRECTION

In the June issue of the Engineering Journal, in the section, "Newly Elected Officers of the Institute", it was reported that W. J. Ripley, M.E.I.C., holds the office of vice-president, Ontario, of the Pineland Timber Company Limited, Sudbury, as well as that of economic consultant for the firm. Mr. Ripley holds only the latter affiliations with the company. The Journal greatly regrets th error.

Problem:

North Western Supply Company, of Vancouver, needed a sealing compound to form a perfect and permanent seal between glass and aluminum in curtain wall construction. It had to remain flexible at temperatures which cause varying expansion, to resist weather and allow constant movement between surfaces without deterioration.



Solution:

Polysar Butyl 301 proved to be the answer to North Western's exacting sealing problem. As the base for Norwescoseal 566, Polysar Butyl 301 imparts the essential qualities of permanent adherence in all weather between the sealing compound and materials of varying physical qualities under repeated flexing.

There is a wide variety of Polysar synthetic rubbers from which to select the one best suited to a particular application. The Sealant, based on Polysar Butyl 301 is just one example of the many uses for these rubbers. In countless industries—myriads of products are being improved and enlarged upon by Polysar synthetic rubbers.

Regardless of your field, it may be that Polysar synthetic rubber can solve your technical problem. Write to our Sales and Technical Service Division, Polymer Corporation Limited, Sarnia, Canada.

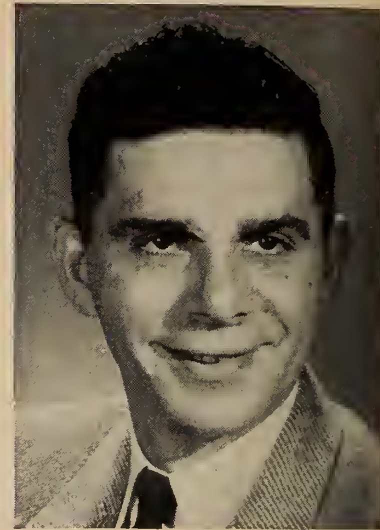
educated in rural Manitoba and at the University of Saskatchewan, Mr. Small became established in Trail in 1928, four years after his graduation in civil engineering. His initial experience as a draughtsman gained with the Canadian Pacific Railway and other companies, he became design draughtsman for the Canadian Mining and Smelting Company on structural steel and re-inforced concrete design, and later technical librarian in the chemical and fertilizer department. He was in 1936 named a research assistant in that department, working on ammonia synthesis, and the design and operation of various types of equipment. Through the years engaged in the work of instrument engineer, in supervising, and in the maintenance of the instrument department, some of his more recent appointments were concerned with application engineering and instrument development.

B. Justewicz, M.E.I.C., originally of the University of Warsaw who resumed his studies after the war and graduated from the University of Louvain, Belgium, class of 1949, now holds a position with the Bell Telephone Company of Canada, toll area engineering, as project engineer in the microwave and radio department, at Montreal.



W. Bobbie, JR.E.I.C.

At the outset of his career associated with the general design and estimate of waste gas heat exchangers for industrial power plants and furnaces applications, he later became a project engineer with consulting offices at Brussels and Paris.

Since his arrival in Canada in 1953 he has held various positions with the Bell Telephone Company prior to his present appointment.

J. A. M. Bell, JR.E.I.C., of Canadian Industries Limited formerly technical service representative for the Vancouver district of the organization has been transferred to the head office of the technical service section, explosives division in Montreal.

William Bobbie, JR.E.I.C., has been appointed plant engineer with the B. F. Goodrich Canada Limited at Kitchener, Ont.

Mr. Bobbie, a graduate of the University of Toronto in mechanical engineering has served as industrial engineer in the Kitchener plant for the past year.

Prior to that he was associated with Dunlop Canada Limited at Whitby, Ont., as a plant engineer.

Alex C. de Lery, JR.E.I.C., has been appointed manager of the Montreal office of the English Electric Company of Canada and the John Inglis Company. Mr deLery joined the English Electric Company in 1951 and represented the company in Quebec for five years. He moved to Montreal in 1956. Mr. deLery graduated from the Seminaire de Quebec with a degree of B.A. in 1943 and later in 1948 received a B.A.Sc. degree from Laval University.

J. Blouin, JR.E.I.C., formerly of the firm of H. J. O'Connell Limited, Schefferville, P.Q., is now associated with the Iron Ore Company of Canada at that

address. In his former position he was engaged in the construction of a Mid-Canada Line radar station.

As electrical field supervisor with the Iron Ore Company, Mr. Blouin is responsible for all the electrical maintenance of the equipment used in the mines.

A. G. Eliadis, JR.E.I.C., of McColl Frontenac Oil Company Limited has been promoted to the position of chief design engineer.

Following graduation from McGill University in civil engineering in 1951, where he received a B.Eng. degree, Mr. Eliadis began his professional career with the Canadian International Paper Company. He accepted employment with his present firm in 1953 as a structural and foundation engineer.

J. L. Greer, JR.E.I.C., is one of the executive officers of the recently incorporated company of W. L. Wardrop and Associates (management) Limited, engineering consultants at Winnipeg. He is also a director of the firm.

Now in its third year of operation Mr. Greer joined the organization some time ago.

Mr. Greer is a graduate of the University of Saskatchewan, class of 1948. He

J. A. A. Field, S.E.I.C.

gained his early experience with the Foundation Company of Canada Limited.

E. J. Beauchamp, JR.E.I.C., has resigned from his position with Underwood, McLellan, of Saskatoon, Sask., and has accepted a position with the City of Toronto buildings department.

Mr. Beauchamp graduated from the University of Sakatchewan in civil engineering in 1955 and went to work for the Department of Highways, Province of Saskatchewan for a short period.

R. M. Williamson, JR.E.I.C., formerly of the Demerara Bauxite Company Limited at MacKenzie, British Guiana, has joined the engineering staff of Dupont of Canada at their Nylon Intermediate Plant, Maitland, Ont.

Mr. Williamson is a 1954 graduate of Queen's University in mechanical engineering.

F/O F. R. Jefferson, S.E.I.C., a 1957 graduate of the Nova Scotia Technical College in chemical engineering is with the Canadian Armed Forces in Europe where he is Squadron Armament Officer for 441 Fighter Squadron (Sabre Aircraft), R.C.A.F.

R. R. Real, JR.E.I.C., a University of Saskatchewan graduate in electrical engineering, class of 1953, is newly employed as an associate research officer with the radar development section of the radio and electrical engineering division of the National Research Council.

Mr. Real was this year awarded a master of engineering degree at McGill University.

James A. A. Field, S.E.I.C., of Regina, Sask., was one of two winners of the Association of Professional Engineers (Sask.) prize for the most distinguished graduate in engineering at the forty-sixth annual convocation of the University of Saskatchewan in Saskatoon. Mr. Field received the degree of bachelor of science in engineering (electrical) B.E., also with great distinction.

NEWS OF THE BRANCHES

Activities of the Forty-Seven Branches of the Institute and abstracts of the papers presented at their meetings

CORNER BROOK

ERIC R. SKANES, JR.E.I.C.,
Secretary

Year in Review

First meeting of the year was held on March 4. President F. H. Clark held the chair and fifteen members and ten guests were present.

On loan from the Dow Corning Company a film on Dow Silicones was shown and literature on Dow Silicones was distributed to those present. Interesting and instructive, the film was enjoyed by all.

A nominating committee consisting of E. J. Leja, M. G. Green and R. Herdman was appointed and instructed to present a slate of officers for the coming year, at a meeting called for April 9. Film Shown. Opening that meeting, April 9, the film, "Newfoundland Enterprise" was shown and very much enjoyed by the group. It dealt with Bowaters Newfoundland Pulp and Paper Mill Ltd., and Newfoundland operations. *Election of officers.* Nominations of prospective officers for 1957 were submitted by the nominating committee. In the ensuing election the following were elected: to the presidency, M. G. Green; vice-chairman, E. J. Leja; secretary, E. R. Skanes; and treasurer, W. S. Read.

The following chairmen were appointed by the new president: program chairman, H. B.Carter; social, membership and publicity chairmen; Robert Herdman, Allan Staig, and W. R. Hughson respectively.

Before relinquishing the chair, president F. H. Clark presented a small gift to W. R. Hughson on the event of his election to life membership in the Institute. The newly elected president, M. G. Green, thanked members in their selection of him as president and promised an all-out effort on his part and his officers during the coming year. Guest at the meeting was G. W. Ross, of Canadian General Electric Company, Sydney, N.S. In the ensuing discussions, it was moved and seconded that meetings be held on the second Tuesday of the month and an executive meeting on the third Tuesday of each month.

Banquet and Dance in May

On Tuesday evening, May 14, the Branch held a banquet and dance at the Blomidon Country Club and Milton G. Green, Branch president, in his speech welcomed the ninety people present. A cocktail hour was followed by an excellent three-course dinner served by caterers of the club. Henry B. Carter then introduced guest speaker Allan Staig, municipal engineer. Mr. Staig dealt with the history of engineering and evolution of the engineering societies. He also gave an outline of road-building problems in Corner Brook. A vote of thanks was offered Mr. Staig by Wally Read at the conclusion of his address. The ladies were toasted by Robert Herdman.

Starting off with a "Rabbit Dance", the evening offered dancing provided by Herb Collins and his orchestra. Other novelty dances included a broom dance, won by Mrs. Robert Hardman and Ray Stones of the Montreal office of Bowaters. Winners of the elimination dance were Mr. and Mrs. Allan Curnew. Other entertainment came from Henry Carter who sang Newfoundland songs. Wally Read conducted a sing-song. Mr. Herdman was master of ceremonies.

The June Meeting

A very successful meet was held June 11 in the White House. Twenty-seven members and eighteen guests took part. The press was also represented. A very short business meeting was held in which the president announced that guest speakers were being arranged from the Canadian General Electric Company and the Canadian Wildlife Service of the Department of Northern Affairs and National Resources. A speaker from Montreal, would also discuss Atomic Energy. Further business was the ratification of the appointment of Henry B. Carter as Branch representative of the nominating committee.

Important Film Shown. Main portion of the meeting was taken up with the much enjoyed showing of the film, "Leonarndo da Vinci". Coffee and sandwiches and a short executive meeting followed the event. Final arrangements were made to have the film shown free of charge at Corner Brook's two high schools. Hubert Clark and Henry Carter agreed to introduce the film at the schools and tell the students a little about the engineering profession.

KINGSTON

D. I. OUROM, JR.E.I.C.,
Secretary-treasurer

Annual Meeting

The annual meeting of the Kingston Branch was held June 8, 1957 at the R.C.E.M.E. officers' mess.

Elections and appointments were as follows: chairman, C. W. Jones; vice-chairman, E. C. Reid. The executive are comprised of J. W. Dolphin, S. D. Lash and W. B. Rice. Mr. Dolphin assumed the duties of vice-chairman in March on the resignation of Mr. Reid on his transfer to Montreal. The immediate past-chairman is A. V. Corlett. Kingston Branch councillor is H. G. Conn and the secretary-treasurer is D. I. Ourom.

Six executive meetings and nine meetings of the Branch were held during the year as follows: "Some Notes on Terrorism" by C. D. Quilliam; "Iron Ore by '54", by J. A. Little; a Joint E.I.C.-P.Eng. Meeting and "the Ontario Joint Highway Research Program at Queen's University", by S. D. Lash, all in the fall of 1956. Beginning in January and drawing to a close in mid-April was a talk on "Guided Missiles", the President's dinner, and the Students' Papers Night, as well as a talk on Metal Cutting Research, by W. B. Rice; a Joint C.I.C., K.M.S., and E.I.C. dance and an address by R. F. Legget, and E. G. Swenson on "Concrete Problems in the Kingston Area".

KOOTENAY

G. T. J. HUGHES, M.E.I.C.,
Branch News Editor

Turbine Specialist Speaks

Members of the Institute of Power Engineers gathered with the Branch to hear D. F. Abel, Calgary district turbine specialist of the Canadian General Electric Company speak on the installation of the Gas Turbines for the B.C. Power Commission at Chemainus on Vancouver Island on May 13. A total of 50 guests members and visitors attended.

After an introduction by Doug. Turland of Canadian General Electric, Mr Abel described the location of the fou

large gas turbines at Chemainus. This station, designed by Sandwell and Co. of Vancouver, when operating, would be the largest gas turbine installation and would house the largest single shaft gas turbines in the world. An interesting point was that a tanker of Bunker C fuel would be used every two weeks.

To Serve Until Hydro Power Available—The B.C. Power Commission's intention was to build a plant which would meet power requirements until Hydro-electric power was available. When new hydro stations were built, the gas turbine installation at Chemainus would be relegated to stand-by duty, or peak duty, or would be put into service during periods of low water.

The equipment consisted of two simple cycle units and two regenerative cycle single shaft units. The regenerative cycle units were preferable because of their comparatively high thermal efficiency, while the reason for including the simple cycle units was because they were already designed and in production and their delivery assured in a much shorter time.

Mr. Abel described in detail the functioning of the units and dealt comprehensively with the control system, noting that the power output was directly proportional to the temperature of the gases entering the turbine. A device for controlling the amount of fuel after starting by a separate motor, consisted of solenoid valves which became energized when the unit reached 20 percent speed and admitted enough fuel to fire the unit. As the unit fired the valve reduced the fuel supply to warm-up flow. The same valve, when the unit reached a speed of 40 per cent, increased the fuel supply to accelerate the unit to full speed. A further solenoid operated as a maximum fuel limiting device.

The lubrication was similar to that used in ordinary steam turbine practice.

Fuel Oil Treating System Interesting—An interesting feature was the fuel oil treating system. Since Bunker C oil, a low-grade oil, contains metallic salts mainly of sodium and vanadium which attack the buckets and nozzles of the turbine, it was necessary to ensure that a rigid specification of the fuel must be met. This was provided for by the installation of a fuel-oil treating system. The process consisted of washing to remove the sodium and adding magnesium sulphate to neutralize the vanadium. A further refinement was the injection of a compound, a waste product of catalyst cracking plants, which was a very good abrasive that cleaned the buckets and restored the nozzle area.

Mr. Abel concluded his talk with an invitation to inspect the station, and remarked that the first unit was now being installed and it was hoped that the station would be in operation late this year.

Later, at a business meeting, a motion was approved amending the Kootenay Branch Award—a $50.00 Scholarship to the student in Grade XIII in Trail, Castlegar or Nelson with the highest total marks in physics, chemistry and mathematics in their final examinations, and who is continuing his studies at a recognized university. The successful candidate should not have received a prior award in excess of $500.00. The previous condition had been set at $100.00.

SASKATCHEWAN

R. BING-WO, M.E.I.C.,
Secretary-treasurer

P. D. Course at Saskatoon

Professional Development courses were held in Saskatoon in 1952 and 1953. Sponsored by the Saskatoon Section, they were operated by the Extension Department of the University of Saskatchewan. The latter was sponsored and operated by the Saskatoon Section.

• BRANCH NEWS

In September 1955, W. G. McKay, then vice-chairman of the Saskatchewan Branch set up a committee to organize a Professional Development Course for Saskatoon engineers. Committee members were Mel Jones, chairman, Stu Ringheim, Sid Warder, Gus Handegord, and John Mantle.

Fifty registrations among M.E.I.C. and Jr.E.I.C., and 16 S.E.I.C. registrations were taken. The fee was $250 for students and $5.00 for others. Attendance averaged 42 persons.

Covering a wide variety of topics, the program, extending from January to mid-March was as follows—"How to Run a Meeting", by Dr. D. Gibson, of the University of Saskatchewan; "Photography and Its Uses to the Engineer" by B. D. Leddy, of the National Research Council; "Soviet Professional Manpower" by Prof. L. E. Gads of the University of Alberta, at a joint meeting with the Association of Professional Engineers of Saskatchewan; and "Corporate and Financial Organization" — Managerial Controls, delivered by H. Pinder of Pinder's Drugs, Saskatoon.

In February, "Investment Policy for the Individual", by R. E. Forrest of James Richardson and Sons; "Report Writing", by Dr. J. D. Mollard, of J. D. Mollard and Associates, "Cost Estimating", by A. Tubby of H. J. Tubby and Son Limited, and "Selection and Evaluation of Employees", by C. McLeod, of the City of Saskatoon were discussed.

During the final month of the course Mr. N. Agnew of the University Hospital, Saskatoon was heard on "Psychology and Engineering"; W. R. Riddell, Saskatchewan Power Corporation spoke on "Employer-Employee Relations" and finally at a mixed dinner meeting on March 18, the closing address was delivered by Prof. Kay Taggert, of the Home Economics Department of the University of Saskatchewan on the topic of "Good Manners are Good Business" at a mixed dinner meeting.

It has been recommended that a Professional Development Course be operated again next winter and that it be confined to a narrower subject range. Possibilities include a course on legal topics, in conjunction with the local Bar Association, or a Toastmaster's Club in conjunction with some other professional group in Saskatoon.

Talk on Circuit Breakers

A dinner meeting was held on Thursday, April 25, 1957, at the Rainbow Inn,

YOU'RE ALWAYS **SURE** WITH MEN OF EXPERIENCE ON THE JOB

Above — New Canadian Steel Corporation plant at Etobicoke, Ont., during construction. Right — Hingeless arch span highway bridge near Kenora, Ont.

COMPLETE SERVICE — Full facilities for all types of bolted, riveted and welded steel construction — anywhere — anytime.

HIGHWAY AND RAILWAY BRIDGES
TRANSMISSION TOWERS
MINE HEADFRAMES
SUBSTATIONS
TV AND RADIO TOWERS
MILL BUILDINGS
WELDED MACHINERY BASES AND BEDPLATES
STANDARD AND OUTSIZE CUSTOM MACHINING
PRECISION ROLL GRINDING

CANADIAN INSTITUTE OF STEEL CONSTRUCTION — CISC

Thorough planning right down to the last small detail is a must if a steel construction job is to move along without costly delays. And that's where experience, the mark of the men of Canadian Bridge, has always proved a vital factor. For more than 50 years they have been designing, fabricating and erecting steel work of every description, large and small. Their efficiency and teamwork have made a big difference in a wide list of steel structures in all parts of Canada.

St. Catharines, Ont. Guest speaker of the evening, T. R. H. Jenkins of the English Electric Company gave a talk illustrated with slides and a film, on recent developments in circuit breakers. Demonstration models of low-voltage circuit breakers were also shown. Two staff members from the English Electric Company accompanied Mr. Jenkins and spoke on circuit breaker design and development.

On Thursday, May 30, 1957, the Branch held its annual dinner meeting and ladies' night at the refectory, Niagara Falls, Ont.

D. A. Barnum of Niagara Falls introduced the guest speaker, V. E. F. Solman of the wildlife division of the Department of Northern Affairs and Natural Resources. Mr. Solman's address, entitled, "Wildlife of Canada", was illustrated with colour slides and movies. The speaker outlined the scope of the work undertaken by his section and explained that a staff of thirty-four biologists were responsible for the area bounded on the west by the Pacific Ocean, to the Atlantic Ocean on the east, and from Point Pelee in Lake Erie to a point 450 miles from the North Pole on Elsmere Island.

During the business portion of the meeting, annual reports were presented by P. A. Saldat, secretary-treasurer; P. L. Climo, Branch chairman; P. Buss, councillor, and H. J. Saaltink, chairman of the Professional Development group. Mr. Climo turned the meeting over to E. C. Little, of Fonthill, who was named chairman of the Branch for 1957-58.

Results of recent ballotting were announced and the following were named to the executive for the coming year; E. C. Little, chairman; D. A. Barnum, Niagara Falls, vice-chairman; M. Stevenson, secretary-treasurer; P. Buss, Thorold, councillor; P. L. Climo, St. Catharines, past-chairman; H. J. Saaltink, and G. N. Cotton, both of Niagara Falls; H. C. L. Joe, D. O. Ramsdale, and D. D. Tanner, of St. Catharines; G. E. Griffiths, Thorold; and C. A. MacDonald, of Fort Erie.

NIAGARA GROUP

4th Annual Engineers' Dance To Be Held Friday, September 27.

The Niagara Branch of the Engineering Institute of Canada in conjunction with the Professional Engineers of Ontario is completing arrangements for their Annual Ball on Friday, September 27.

The dinner and dance will be held at Prudhomme's Garden Centre Hotel, Vineland, Ont. at 6:15 p.m. Dinner will be served at 7 p.m. and the dance will follow. Music will be supplied by Mart Kenny and his Western Gentlemen. Dress is optional and tickets are $10.00 per couple.

E.I.C. Committee members are: Chairman—Sami Tibshiram, Bruce H. Chick, and R. D. MacKinnie.

Jet Streams and Forecasts

"Through Jet Streams to Longer Range Forecasts" was the topic presented to the Toronto Branch by Dr. D. P. McIntyre, chief of the research and training division, Meterological Branch, Department of Transport, on April 11, 1957. Dr. McIntyre traced the history of meteorology briefly. It all began about 2300

years ago, and reference to the science may be found in Aristotle's works. Modern development began with instruments which showed the changes in temperature and pressure. With the coming of the telegraph, expansion was rapid. The radiosonde or sounding balloon which is used to provide information about the upper atmosphere has caused an even more rapid expansion. Today the field of meteorology is dividing into specialties as numerous as those in any other field of science generally.

Before discussing the jet stream itself, Dr. McIntyre reviewed two fundamental physical principles. The effect of the Corioli force must be accounted for in the atmosphere, that is to say that any particle moving eastward on the surface of the earth also tends to deviate toward the equator. An isobaric surface (surface of equal pressure) will slope more the higher one goes, and the wind will increase with height in the direction in which one faces.

Research in Canada now shows that the present model of the earth's atmosphere can be best approximated by a three front-four air mass system. There is reason to believe that this system will have to be replaced by a four front-five air mass system soon. At a front in this model there always exists an abrupt temperature drop when progressing from south to north; and at a height of about 20,000 feet the wind blows steadily from the west.

Discovered by Electronic Sounding. The jet stream was first discovered by electronic sounding. It appears at the junction of the lower atmosphere (troposphere) and the stratosphere where the weight of the atmosphere above equals that below. It is always associated with a front. This fact is, by the way, a Canadian discovery. These jet streams mark the boundary between two air masses and tend to form in the northern latitudes moving to the south at intervals of about 20° in latitude. The jet stream is about 18 or 2,000 feet in the air, so that it is not easily detectible from the ground. However, it governs the weather beneath it. An ordinary cyclone or low pressure area will form at ground level and move along the earth's surface in the direction of the jet stream, so that it is now possible to forecast approximately five days in advance what the weather will be, if the direction of the jet stream and its position are known for the particular locality.

Phenomena Illustrated by Slides. Dr. McIntyre illustrated his talk with slides which showed the phenomena associated with the jet stream very clearly, particularly the formation of waves in the upper atmosphere which move from west to east. These waves have a half-wave length which is continent-wide. The ordinary cyclone tends to form in the trough and move toward the ridge, giving rise to the weather on the earth's surface. What causes the cyclone or low to form is still a mystery, but research will discover the reason sooner or later.

In the question period which followed Dr. McIntyre explained how the 30-day weather forecast is compiled, using the jet stream theory. He emphasized that this method was much better than averaging climatological data and considering the probability of the event occurring again.

Arrangements for the meeting were under the direction of E. R. Davis, Branch chairman. Thanks of the members was tendered by D. G. Abbey.

Deep Water Cable Laying

Eighty members of the Toronto Branch heard N. R. Spencer, staff electrical engineer of the Canada Wire and Cable Co. Ltd. deliver an interesting talk on "Field Problems in Deep Water Cable Laying" on May 2, 1957.

Mr. Spencer began by describing basic problems involved in a cable laying operation. The principal concern is to convey the cable to the sea-bed without damage and without forming loops which might cause trouble later. Laying can be done in several ways, by using cable ships, sea-going barges or the cable can be floated across if the gap is narrow. The cable ship is of course specially equipped with cable brakes, tensioning equipment for controlling the tension in the cable as it is paid out, sonar and an active rudder for accurate steering to insure that the cable is properly laid on the sea bed horizontally as well as vertically. The barge method is very economical, particularly when the railway cars carrying the cable can be loaded directly on it.

Specially Constructed Cable. The cable itself is of special construction. The conductors are insulated with a paper-jute wrapping system or more recently with polyethylene, and polyvinylchloride, jute wrappings. An armor sheath of steel wire is laid on to protect the conductors from damage, and to take the tension of the cable laying process. The armor, while giving the necessary protection, adds a complication in that losses in the power transmitted are caused by induction.

The geographical position of the cable on the seabed is determined by the positions of the transmitting and receiving load centres the shape of the sea-bed it-

You get many "plus" benefits at C.S.F.

And rightly so, for magnitude of operation, the most modern equipment and the knowledge and skill of 1,500 highly trained personnel make "plus" benefits a part of every job we undertake.

Additional
advantages, too,
follow the calling in of

CANADIAN STEEL FOUNDRIES (1956) LIMITED

5227 NOTRE DAME E., MONTREAL 4.

Member: A. V. Roe Canada Limited and The Hawker Siddeley Group self in the vertical plane, currents, tides, and the hazards of anchoring. The dead weight of the cable-depth of water and speed of the laying vessel all affect the tension. The tension in the cable at the vessel cause the armour to untwist, elongating the insulation and the conductors themselves. This slackening at the surface causes tightening further down, and the tension is transferred to the conductors and the material insulating them.

Splicing a Necessity. Splicing is often necessary since the length of cable which can be transported on land is limited by the size of the transport. The best place to splice is on land. This can be done on the dock where the laying vessel is berthed before the cable is put on board, or the whole operation can be done at the factory and the cable coiled in the train, car by car.

The laying of the cable must be done with care and accuracy so that the width of sea-bed occupied is as narrow as possible to minimize the hazard from dragging anchors.

At the shore ends, the cable is protected by extra armour, since the cable can be abraded severely by ice or by the tidal movement. The extra armour on the shore end is also helped by burying the cable in a trench or by covering it with gravel.

Film Shows Cable Laying in B.C. Mr. Spencer illustrated all the salient points described with slides, and a film which showed the laying of a cable 4 miles long between the mainland of British Columbia and Texada Island. At some points the cable was at a depth of 1100 feet below the surface. The film was made by P. J. Croft, a member of the Toronto Branch executive who also made the meeting arrangements. A hearty vote of thanks was moved by Tom Dembie. The meeting was chaired by Dunc. Whitson, a branch councillor.

VANCOUVER

Publicity chairman

A. D. CRONK, JR.E.I.C.,
Secretary

Election of Officers

As a result of the election of officers for the Vancouver Branch the following members comprise the executive for the 1957-58 season. Chosen as chairman of the group was P. N. Bland, replacing S. S. Lefeaux, retiring chairman. Elected vice-chairman was W. G. Heslop. The offices of secretary and treasurer went to A. D. Cook and R. H. Carswell respectively.

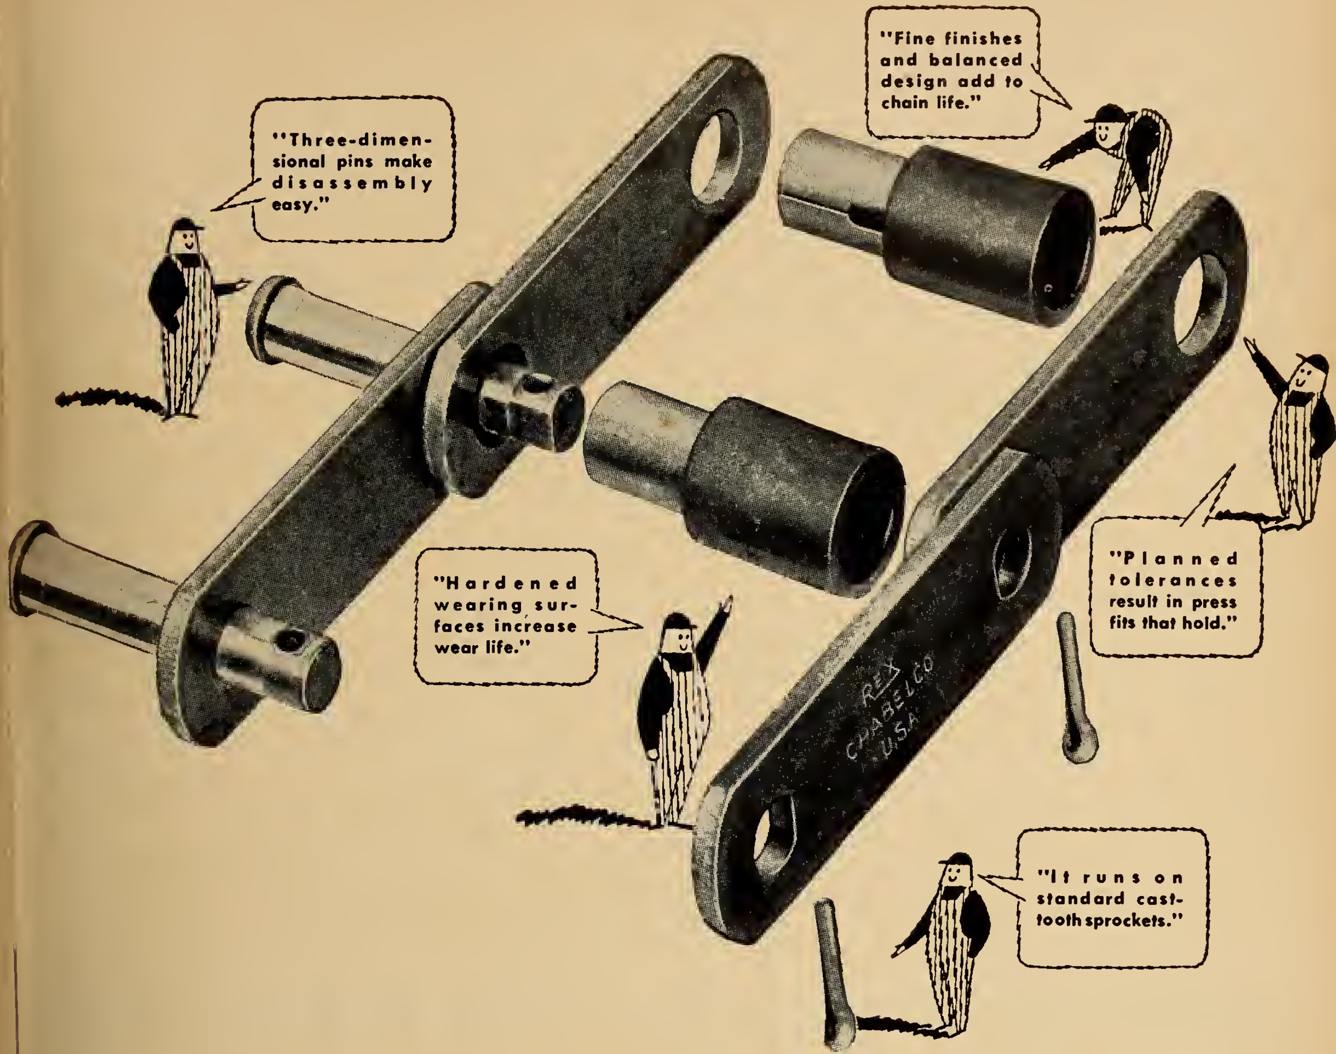
Six committee chairmen were elected. They are W. G. Heslop, program chairman; Professor J. F. Muir, chairman of student guidance; W. J. Johnson, membership chairman; J. H. Swerdfeger, technical sections chairman; C. H. White, who will take over Professional Development; and J. J. Kaller, publicity chairman.

Largest Turbine Plant

The largest gas turbine plant in the world is now being constructed at Bare Point near Chemainus, Vancouver Island, and is about to get its first turbine unit, according to John Harvey, M.E.I.C., of Sandwell and Company Mr. Harvey is engineering consultant to the B.C. Power Commission for their thermo power plant which is to take care of peak electrical loads of a total capacity of 76000 kw.

Addressing a recent meeting of the Vancouver Branch, Mr. Harvey stated that the Georgia Generating Station, designed to burn low-grade Bunker "C" oil can be readily adapted to using natural gas when it will be available on Vancouver Island.

The plant will consist of four general electric gas turbines which are economical to install and require the minimum of accessory equipment. The low-grade oil delivered by ocean-going tankers to the plant's own docks will be treated at the plant to remove impurities that



Six reasons for Rex Chabelco

These design and manufacturing features add up to Rex Chabelco Conveyor Chain, tops in fabricated steel chain for today's materials handling. It's a strong chain and long wearing. It will resist shocks and operate efficiently under the toughest operating conditions.

Rex Chabelco is your economical answer on the heavy conveyor and elevator jobs where centers are long, environment unfavorable and operation more or less continuous. There's a complete range of sizes, and there are standard attachments which adapt the chain to a wide variety of conveyor services. See your CHAIN Belt Distributor or write for Bulletin 56-51. CHAIN Belt (Canada) Ltd., 1181 Sheppard Ave., East, Willowdale, Ontario.

CHAIN BELT (CANADA) LTD.

cause corrosion of the turbines nozzles and blades.

Precast Concrete Panels. Mr. Harvey further stated that the walls of the power house building designed architecturally by Thompson, Berwick and Pratt, Vancouver, architects and Phillips, Barrat and Partners, Vancouver structural consultants, will have precast walls believed to be the longest precast concrete panels in British Columbia to date.

Two Vancouver firms were selected for carrying out the construction. Northern Construction Company are the structural contractors while the Industrial Piping and Controls Limited are the mechanical contractors. Sandwell and Company are in charge of the development and supervision of the entire project.

During a lively question period, Mr. Abel was assisted by R. L. Jackson, manager, advance engineering, gas turbines and H. Karlson, manager of utilities and transportation, gas turbine sales, both of the General Electric Company, Schenectady, New York.

Members will be interested to know that reprints of the paper are available from the Canadian General Electric Company.

Chief Geologist Speaks

On Wednesday, March 27, a paper on "The Application of Geology to Soil Problems in the Lower Mainland" was presented to the Branch by Dr. J. E. Armstrong, chief geologist of the B.C. Office, Geological survey of Canada. Dr. Armstrong is a graduate of the University of British Columbia and Toronto and is presently regional vice-president of the C.I.M.M. and a Fellow of the Royal Society of Canada and the Geological Society of America. He was assisted during the discussion following his talk by Paul Cook and Professor R. A. Spence.

"Surficial Geology of Vancouver Area, B.C." Dr. Armstrong based his talk on his recently published paper by this title. The physical features of the lower mainland area were discussed together with the general geology, stratigraphy and historical geology. Emphasis was placed on the engineering geology pertaining to foundation materials, sewage disposal, flood control, slides and construction materials. The agricultural application in the area and ground water geology of the area were also commented on.

News of Other Societies

C.E.A. Meets at Murray Bay

The Canadian Electrical Association held its 67th Annual Convention at the Manoir Richelieu, Murray Bay, Que., on June 19/21, 1957. Six-hundred and fifty delegates attended. J. C. Dale, president and general manager of the Canadian Utilities Limited, Edmonton, was elected president for 1957/58. N. T. Smith of Halifax, N. S. Crerar of Arvida, and J. C. Steele of Vancouver were named as vice-presidents.

President's Address

C. E. A. president, Arthur C. Abbott, in his presidential address, recorded that growth in Canada's net generating capability during the period 1952-56 had amounted to 36.2 per cent while the indicated growth during the forecast period 1956 to 1960 would represent a further 47.6 per cent. Total growths for the period 1952 to 1960 would thus be 101 per cent for the country as a whole.

Peak power load or demand at 13,-917,000 kw. last year was forecast to rise to 19,040,000 kw. by 1960, or 91.5 per cent higher than for 1952. Firm energy requirements at 82.7 billion kilowatt hours last year would rise to 14.4 billion kilowatt hours in 1960, an increase of 37.6 per cent over the 1956 figure.

To make the best possible use of our remaining hydro-sites in years to come, very appreciably higher voltages than those at present in use would have to be employed, he observed. Provision of strong interconnections between the major power systems of the country could be taken advantage of where such interconnections could be economically justified.

From information at present available, it appeared nuclear power would continue considerably more expensive than conventionally generated power for some time to come. Techniques were changing rapidly, however, he pointed out, as evidenced by recent suspension of construction on Canada's 20,000 kw. demonstration reactor to permit a change in design.

Steps taken during recent years to combat the inflationary trends confronting the industry, he recorded, had included the following:

1. A complete review and redesign of certain items of electrical equipment.
2. Higher ratings on both hydro-electric and steam turbine units.
3. Construction of new hydro stations of the "outdoor" type.
4. Supervisory operations of hydro-electric stations.
5. Greater use of fully, semi-automatic and even completely unattended sub-stations.
6. Extensive use of large three-phase transformers.
7. Use of higher distribution voltages.
8. Rapidly developing use of live line tools.
9. Continuing studies towards the further standardization of materials and methods to obtain a higher degree of interchangeability.

Further application of these developments and others must continue, said Mr. Abbott, as power systems continue to expand, if we are to combat successfully the danger of higher construction and operating costs.

Atlantic Province Economic Council

President R. J. Rankin of the Atlantic Provinces' Economic Council, told delegates that the awakening realization of what capital and electric power could accomplish was responsible in large measure for the new spirit so apparent in the Atlantic Provinces today. This realization had brought the four Atlantic premiers together in a common front to analyse, in a continuing yearly study, the region's economic problems.

Studies made by the Council through its associations with the electrical industry had definitely established the fact that adequate power for normal requirements is presently available within the Atlantic region, he said. This power could be had at a price comparable with regions not blessed with an abundance of hydro-electric resources.

The main objective of the council, he explained, was to appraise the Atlantic region's expanding economy, and to consider how best to marshal material and human resources for greater regional development, to stimulate co-ordinated action by business and governments. Like its counterpart, the New England Council, the A.P.E.C. organization had no authority but that of public opinion, no power but that of men and ideas.

Industrial Developments in Alberta

Reviewing the tremendous expansion in the development of oil and natural gas in Alberta over the past decade, J. R. Donald, O.B.E., president J. T. Donald, and Company, (1956) Limited, pointed out that the most significant industrial growth had occurred in the production of goods for sale in external markets.

To continue its rapid progress, Alberta's industry must continue to increase its sales in prairie markets, in the rest of Canada and in foreign markets, he warned. There were the twin problems of high freight rates and long hauls. Only low production costs would enable goods from Alberta to offset them. Other factors such as taxation and wages were of equal importance. Chemicals could not be economically produced anywhere in Canada to supply the Canadian market alone.

Further immediate possibilities in the field of foreign trade included primary products, oil and gas, sulphur, pulp and paper, metals and possibly more primary chemicals and plastics. Production of elemental sulphur was increasing rapidly.

Secondary manufacture for export of synthetic rubber, petrochemicals, synthetic fibres, food, paper and metal products had a less optimistic look, he stated. It was frequently confronted with tariff barriers. Trade policies of other nations, particularly the United States, did not encourage the development of secondary industry in Canada. To assure prosperity to our primary extractive industries a moderate tariff policy had been pursued which made it impossible for Canadian secondary manufacturers to capture even the Canadian market.

Changing-Economic Climate

Addressing the meeting on Canada's economic outlook, Dr. J. R. Petrie, consulting economist of Montreal, pointed out that for two decades we had been experiencing an almost uninterrupted period of economic expansion. There had been three distinct booms since the end of World War II. The present boom was largely the result of the greatest capital expansion in our history.

World demand had stimulated resources development projects. Demand for energy resources had been strong. But many did not realize that about half the investment made by business in fixed assets last year was in the manufacturing and service industries, he oberved.

In spite of 1957 promising to be the best calendar year in our history, with gross national product 4 or 5 per cent over last year's $29.9 billion, he stated there were symptoms that we are in the later stages of the boom and in the early stages of a mild depression. Looking back a year from now we would probably see the peak of the boom had been reached last February.

Housing starts in 1957 could well be down 25 per cent, pointing to the possibility of a $60 million decline to follow in the sales of furnishing and appliances. There were surpluses of newsprint and pulp. U.S. advertising linage was down from last year. The outlook for wheat markets was unhealthy, and farm income could be adversely affected.

Base metal prices were continuing to fall. Corporation profits were probably 10 to 15 per cent lower in the first quarter than in the last quarter of 1956. Unless productivity could keep pace with rising wages we could be priced out of export markets to become marginal suppliers of many export commodities.

Investment

Though estimated investment was running seven and one-half per-cent over last year, much of this year's program seemed to be a spillover of large projects started in 1955-56. Nevertheless, despite weakness in manufacturing, commercial and financial institution building, the volume of capital outlay next year should be maintained at this year's level.

"I am not forecasting depression," concluded Dr. Petrie, "but rather the kind of rolling adjustment we experienced in 1953/54. While I observe the outlook for the next year with sobering reflections, I am still unreserved in my longer-term optimism over Canada's economic destiny."

I. I. W. Meeting in Germany

The 1957 annual assembly of the International Institute of Welding (I.I.W.) was held in Essen from June 30 to July 6, organized by the German Welding Society (DVS), and was attended by nearly 800 delegates and their wives from 21 countries. The first three days coincided with the DVS Exhibition on Welding and Cutting.

The program of the Assembly included two meetings of the Governing Council of the Institute, four meetings of each of its fifteen technical Commissions and a public session for the presentation of papers.

Dr. U. Guerrera of Italy was elected in 1956 to sueceed Dr. H. Biers (U.S.A.) as president of the I.I.W. Two vice-presidents were elected and a treasurer and a secretary-general were re-elected. They are, respectively: Prof. R. Rapatz, Austria, Prof. M. Radojkovic, Yugoslavia, W. Edstrom, Sweden, and G. Parsloe, United Kingdom.

Commissions of I.I.W.

Useful work was accomplished by the Commissions of the Institute at Essen meetings. Many of their decisions, later ratified by the Governing Council, concerned the release for publication in the technical press of documents prepared either by the Commissions or by individual members of them. These documents, numbering 22, concern as many aspects of welding practices and research and training of personnel. Information about these and other approved publications can be obtained through the member societies of I.I.W.

Twenty six papers by authors from 10 countries were presented at the public session. Several aspects of the main theme of the session. The Metallurgy of Welding, were treated by the authors.

The 1958 annual assembly will be held in Vienna, Austria, from June 29 to July 5. For the public session the theme will be Welding in the Chemical Industry. This subject will be discussed in papers in five categories: 1. the influence of the method of welding, of preheating and of finishing operations on the properties of welded assemblies; 2. welding of clad metals; lining; 3. problems in the welding of equipment for the chemical industry and for nuclear plants; 4. design and calculation of welded products working under high pressure and at high temperatures; 5. typical examples of welded constructions.

Information about the publications and activities of I.I.W. and about the Canadian membership, can be obtained from W. R. Stickney, secretary, Canadian Council of the International Institute of Welding, 7 Pleasant Blvd., Toronto, Ont. Further notes from the Canadian delegation, of particular interest to Canadian industry, will appear in the September issue.

Canadian Conferences

Of important interest to all Canadians associated with the production, use and conservation of coal is the twentieth annual Joint Solid Fuels Conference, sponsored by the A.I.M.E. and the American Society of Mechanical Engineers in co-operation with the Canadian Institute of Mining and Metallurgy, coal division, in October. The choice of the Chateau Frontenac, in historic Quebec City, will mark the first time that Canada has played host. Invitation to hold the conference in Canada was extended by the coal division of the Canadian Institute of Mining and Metallurgy, following many previous sessions held in the United States.

The program features four technical sessions. The first, on October 10, will be devoted to Canadian papers given under the auspices of the Canadian Institute of Mining and Metallurgy, coal division.

It features papers by C. L. O'Brian, assistant to the chairman, Dominion Coal Board, Ottawa; G. M. Hutt, assistant manager of the Department of Industrial Development, of the Canadian Pacific Railways, Montreal, Que.; E. Swartzman, senior technologist, of the division of fuels, Department of Mines and Technical Surveys, Ottawa; G. P. Cooper, vice-president of the Empire-Hanna Company, Toronto, Ont., and and W. J. Moroz, combustion engineer; and C. E. Baltzer, senior engineer, fuel and power, division of fuels, of the Department of Mines and Technical Surveys, Ottawa.

The three remaining technical sessions feature papers to be given under the sponsorship of A.I.M.E. and A.S.M.E.

Working on the various conference committees are Professor T. S. Spicer of the A.I.M.E., general chairman of the Conference Committee; Dr. H. B. Charmbury of the A.S.M.E. and Dr. Dufresne of C.I.M.M., acting as co-chairmen. Others involved in committee work are Dr. G. Letendre, E. R. Mitchell, and A. Ignatieff.

A diversified program for ladies accompanying the delegates is a feature of the conference program.

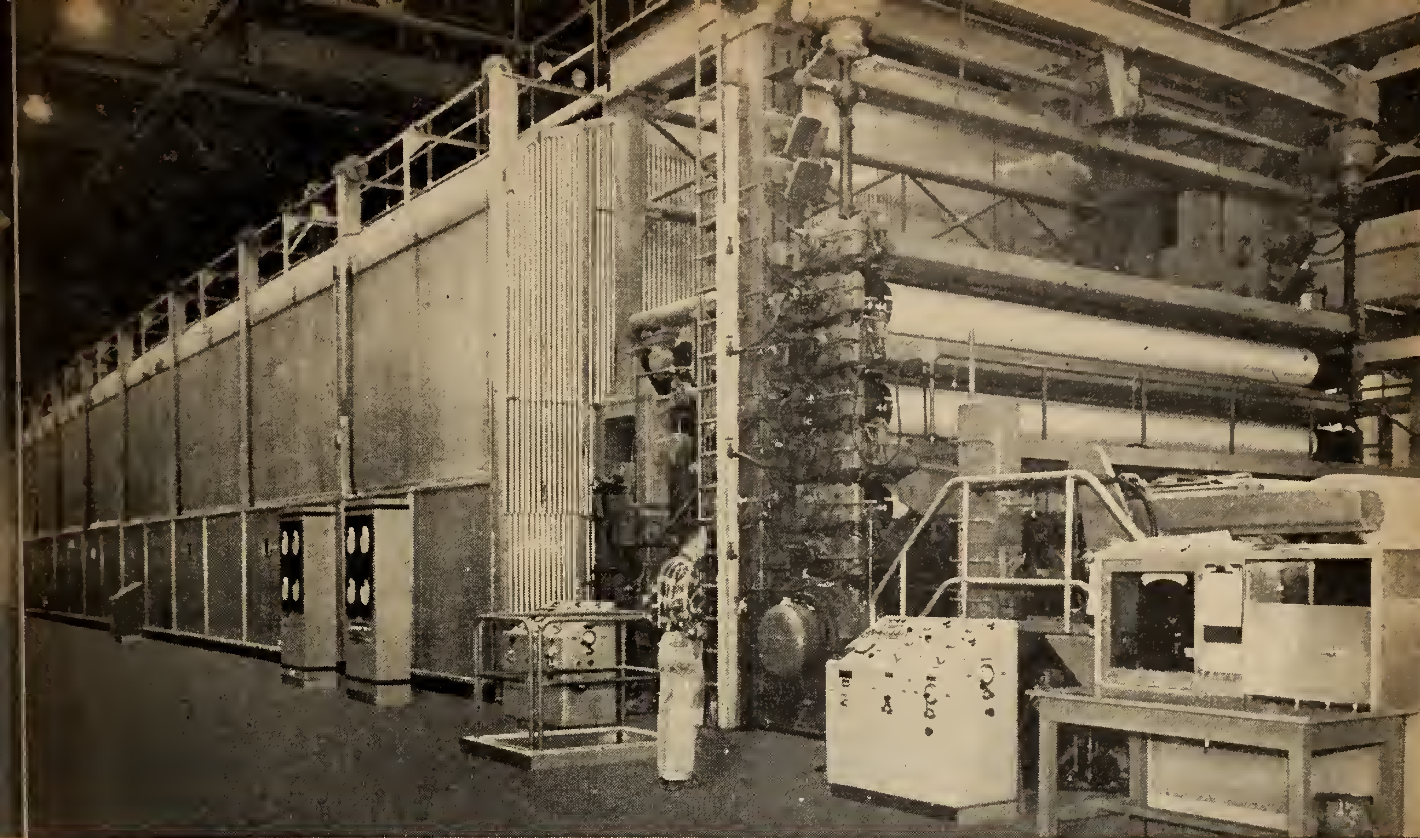
Hotel reservations should be made directly with the management of the Chatenac Frontenac.

By agreement between ASME and the Engineering Institute of Canada, E.I.C. members may attend this meeting at the same conference fee rate as A.S.M.E. members. Programs are available upon request to E.I.C. headquarters, Montreal.

Lubrication Conference

The A.S.M.E. Lubrication Conference is being held in Toronto, Ontario, October 7-9, with headquarters in the Royal York Hotel.

This extensive meeting on lubrication subjects is also open to Engineering Institute members at the same eonference. Fee rate as that of A.S.M.E. members. The Institute will have programs for distribution from Headquarters in Montreal and from the Field Office, 236 Avenue Road, Toronto.



This is the new, high speed newsprint machine at Mandos' Kenora Mill. A major part af the recent expansion, this machine is capable of turning out newsprint 21 feet wide at the rote of 2500 feet per minute (over 300 tons o day).

utput at Mando's Kenora Mill

ıeOntario-Minnesota Pulp and Paper Com- n Limited's (Mando) new machinery instal- in at the Kenora mill will boost production cord 100% . . . give the company a 30% rise all-round. In selecting G-E Co-ordinated pment, Mando is assured of maintaining is p production with maximum efficiency and n um downtime.

G.E.'s share in this $20,000,000 expansion d nodernization program consists of the news- nmachine drive—including the steam turbine ving the main DC generator set . . . a DC v for the winder . . . four 5,500 hp synchro- ougrinder motors with controls . . . all the adcentre unit substations . . . 6,600 volt t clad switchgear and one 30/40 MVA power ran ormer.

Wen planning future expansion or modern- ati call on the experience of C-G-E engineers t. Contact your nearest Sales Office, or write: anadian General Electric Co. Ltd., Apparatus Dep 107 Park St. N., Peterborough, Ont.

These four new grinder lines—each powered by a G-E 5,500 hp, 6,600 volt Synchronous Motor—have a combined proven capacity of 280 tans of groundwood pulp per doy. The motors, enclosed for pit ventilation, ore orronged to exhaust either to the otmosphere or to the charging floor for heoting purposes.

BOOK REVIEW

STATISTICAL YEARBOOK OF THE WORLD POWER CONFERENCE, NO. 8.

This eighth Yearbook issued by the World Power Conference contains statistics for the years 1952 to 1954, with some supplementary and revised statistics for earlier years, and any available for 1955.

The coverage is, as far as possible, world-wide, and the statistics give information on power resources, production, stocks, imports, exports and consumption. The power sources for which statistics are given include: solid fuels, coals and wood; liquid fuels, petroleum, benzoles and alcohols; natural and manufactured gas, water power and electricity.

The information is, as usual, presented extremely clearly in tabular form. There are two extremely useful sections listing the sources from which the statistics were obtained, and the publications which contain statistics of fuel and power (Ed. by Frederick Brown. London, Lund, Humphries, 1956. 176 p., $8.50. Obtainable in Canada from the E.I.C. Library.)

ABSTRACTS OF LITERATURE ON SEMICONDUCTING AND LUMINESCENT MATERIALS AND THEIR APPLICATIONS

The period covered by this third volume in the series sponsored by the Electrochemical Society is 1955. There are nearly five-hundred more abstracts than in the volume for 1954, reflecting the increased use of semiconductor and luminescent materials in transistors, rectifiers, coloured television screens, etc.

The abstracts are grouped by material; germanium, silicon, carbon, selenium, sulfides, etc., and there are subject and author indices. The material has once again been compiled by the staff of the Battelle Memorial Institute. (Ed. by E. Paskell. New York, Wiley, 1957. 322p. $10.00.)

*ACOUSTICAL ENGINEERING

About one-third larger than the author's "Elements of Acoustical Engineering" 1947, on which it is based, the present volume has been revised throughout and includes two new chapters on complete sound reproducing systems, and means for the communication of information. Dealt with in other chapters are subjects such as ultrasonics, underwater sound, speech, music, hearing, transducers, microphones, loudspeakers, and acoustical radiating and mechanical vibrating systems. References are scattered throughout the book. (By H. F. Olson. Toronto, Van Nostrand, 718p., $13.50.)

AIR CONDITIONING

Written by a professor of mechanical engineering and a consulting engineer, this basic textbook presents the fundamentals of the design of heating and cooling systems, placing particular emhasis on the cooling problems found in hot-humid and hot-d[illegible] climates.

The first part of the book deals with the thermodynamics of air conditioning, and the problems of system load determination and design, including the psychrometric chart and processes. Parts two and three cover the various types of heating and cooling systems, while the last part deals with various problems arising in connection with the air conditioning in the fields of piping design, automatic control and air contaminant control.

The authors have placed emphasis on the general problems concerned with the design of heating and air conditioning systems, rather than giving details which can better be found in trade literature and manufacturers manuals. The authors have provided bibliographies and problems at the end of each chapter. (By W. R. Woolrich and W. R. Woolrich Jr. New York, Ronald, 1957. 384p., $7.50.)

CANADIAN TRADE INDEX

This latest edition of a valuable trade index published by the Canadian Manufacturers Association contains an almost complete list of Canadian manufacturers, both alphabetically by name (and address) and classified under some 10,000 product headings, ranging from abattoir equipment to zirconium.

Other sections include a list of producers, shippers and exporters of agricultural produce, a French glossary and advertisements, together with an index to advertisers.

This book is invaluable to all those connected in any way with manufacturing and purchasing. (Toronto, Canadian Manufacturers Association, 1957, 1087p., $10.00.)

CAST METALS HANDBOOK, 4TH ED.

This fourth edition of a popular re[ference book has been three years i[n] preparation and covers the various a[spects of casting, and the metals use[d].

The first section deals with the ad[vantages of castings and the gener[al] properties of cast metals, casting desig[n] costs etc. The second section cove[rs]

DURING THE SUMMER MONTHS THE LIBRARY IS OPEN FROM 9 TO 5, MONDAY TO FRIDAY

• LIBRARY NOTES

gray and white cast irons including metallurgy, methods of manufacture, the various properties of cast iron, and heat treatment of gray iron. There is a 392 item bibliography.

Sections three and four discuss malleable and nodular cast iron, and the remaining sections cover steel castings and nonferrous alloys.

The book is clearly written, much of the material being presented in tabular and graph form, and there are many illustrations and bibliographies in addition to the one already mentioned. (H. Bornstein, Chief ed. Des Plaines, American Foundrymen's Society, 1957. 316p.)

°CHEMICAL ENGINEERING PRACTICE, V. 3, SOLID SYSTEMS

The title of this comprehensive volume fails to disclose its pertinence to mining, metallurgical, and chemical engineers. It deals with (1) size reduction: crushing, grinding and pulverizing equipment and principles; (2) screening, grading and classifying: tabling, jigging, flotation, sedimentation, airflow selection, wet classification, and washing; (3) mixing of solids; (4) storage and handling of solids: sampling, measuring and gauging; (5) cleaning gaseous media: cyclones, and electro-precipitation. Numerous graphs, charts, diagrams of machinery, and references are included in this the third volume of a twelve volume set on chemical engineering practice. (By H. W. Cremer and T. Davies, eds. Toronto, Butterworth, 1957. 534p., $17.50.)

LA CHIMIE NUCLEAIRE ET SES APPLICATIONS

The content of this volume is much wider than indicated by its title, for in it the author has tried to prevent a survey of modern knowledge in nuclear chemistry, radiochemistry, and the chemistry of radiations and their applications.

The work falls into three sections, the first of which covers the properties and transformations of nucleii and isotopes. The second group of chapters covers the action of radiation on matter and its chemical and biological consequences. The final section discusses the principles of separation and preparation of radioactive bodies, and the application of radioisotopes etc. in physical chemistry, biology and industry.

This valuable work will be welcomed by all connected with the nuclear field, and by those wishing to learn about it. The author has drawn widely on information which has appeared in technical journals, and he lists his sources in the footnotes. (By M. Haissinsky. Paris, Masson, 1957. 651p., 5000fr.)

°CONTROL OF STEEL CONSTRUCTION TO AVOID BRITTLE FAILURE

Prepared by the Plasticty Committee of the Welding Research Council, this compact volume is a general reference and guide for engineers, fabricators, and designers in the structural field. Part 1 deals with the basic concepts and mechanisms of notch brittleness and with the mechanical and metallurgical factors affecting the plastic behaviour of structural materials. Part II shows how conventional fabrication procedures affect notch ductility of these materials. Part III deals with the selection of materials and fabricating procedures, the limits of conventional design methods; and the use of notch-brittle test data. A glossary completes the volume. (M. E. Shank, ed. New York, Welding Research Council, 1957. 184p., $4.50.)

DER STRASSENBAU, TEIL 1

The first of a projected two volumes on highway engineering, this volume by a well-known German engineer commences with an historical introduction and a brief discussion of the various types of road transport. Succeeding chapters cover in great detail route location, road dimensions, and road foundations, materials, etc. The book is well illustrated, and there is a bibliography, most of the items listed being in German.

The second volume will deal with such topics as equipment, maintenance, plans, construction and city streets. These two volumes should prove very useful, giving as they do the latest German practices in the field. (By Johannes Kastl. Leipzig, Teubner, 1957. 364p., 23DM.)

• LIBRARY NOTES

DESIGN OF WELDED JOINTS
HEAT TREATMENT OF WELDED CONSTRUCTIONS

These two booklets issued by the British Welding Research Association are part of a series covering various aspects of welding.

The first deals with the conditions of loading likely to be met in practice, tension, compression, shear etc., and gives practical design details, all with the object of enabling a designer to specify the correct sizes of welds, so that they will be neither inadequate and cause failure nor oversize and cause waste.

The second booklet lists the main factors to consider when deciding whether to heat treat a construction. It includes information on stress-relief data for typical steels and on equipment used. (London, British Welding Research Assoc., 1956. 7/6 and 5/-.)

DIGITAL COMPUTER PROGRAMMING

This book, one of a series written by General Electric authors on various aspects of engineering practice, provides a general introduction to the field of computer programming, and emphasises basic principles applicable to all computers, rather than to a single machine.

The author begins by discussing the elements of a computer and their relationships, together with information on coding, binary and octal number systems and decimal point location methods.

The fundamental principles of programming are given with many examples and explanations, applied to a mythical computer TYDAC, Typical Digital Automatic Computer, which is representative of current models.

This book will be valuable to those wanting to know how to prepare a programme for a computer, and for those whose work is closely related to computer applications, and who need to know what is involved in programming. The book may be read either with or without a machine on which to practice. There is a useful bibliography. (By D. D. McCracken. New York, Wiley, 1957. 253p., $7.75.)

*FUNDAMENTALS OF STATICALLY INDETERMINATE STRUCTURES

A college text which focuses attention on the basic concepts of statically indeterminate structures. All methods and topics are carefully related and coordinated through their development from these fundamental concepts, and the subject is developed as an integrated whole rather than as a consideration of numerous unrelated methods. The book is planned so that it may be used as a text in a one-semester or two-semester course. (By C. L. Shermer. New York, Ronald Press, 1957. 264p., $6.50.)

GETTING STARTED IN AMATEUR RADIO

Intended for persons living in the United States wishing to obtain their Novice Class licenses as radio amateurs, this book describes the various classes of licence and the steps to take to obtain them.

The book contains information on the Morse Code and how to learn it and on the basic electronics and radio theory required for the examinations. Typical examination questions and their answers are also included. No particular technical knowledge is required for an understanding of the book. (By Julius Berens. New York, Rider, 1957. 136p., $2.40.)

*HEATING VENTILATING AIR CONDITIONING GUIDE, VOLUME 35, 1957

Topics newly or more extensively treated in this year's volume include U-value tables for building construction; sound control; control of industrial environment; design of ceiling and floor heating panels; and forced warm air systems. The volume, an authoritative guide to current practice, is made up of seven main sections dealing with fundamentals, human reactions, heating and cooling loads, combustion and consump-

tion of fuels, systems and equipment, special systems, and instruments and codes. A manufacturers' catalog data section is included. (New York, American Society of Heating and Air-Conditioning Engineers, Inc. 520p., $12.00.)

INDUSTRIAL ORGANIZATION AND MANAGEMENT, 3RD ED.

This revised edition reflects the changes which have taken place in management's thinking and practices during and since the war. The author discusses management principles and policies in business and industry, and deals with the objectives, policies, functions and relationships which govern the work of the production division of a manufacturing firm.

The first four chapters cover the development of modern management and its organization, while succeeding chapters discuss marketing; plant location; the relation between research and new product development; the manufacturing plant, including materials handling and lighting; motion and time study; production control; quality control; personnel office management, etc. A final chapter considers long-range planning and inter-plant coordination.

An eleven page bibliography and a glossary of the terms encountered conclude this extremely useful volume. (By R. C. Davis. New York, Harper, 1957. 953p., $8.50.)

AN INTRODUCTION TO WORKSHOP PRACTICE, 2ND ED.

The main processes found in an engineering workshop are here presented in outline form. The book is intended as an introduction to workshop techniques for students, and covers such topics as industrial metals; use of hand tools; measuring tools; drills and drilling; gauges and jigs; lathe tools and lathes; planing and shaping machines; milling; grinding and belts and transmission.

The book is illustrated with many line drawings. (By P. E. Ellis. Glasgow, Blackie, 1957. 184p., 7/6.)

*JETS, WAKES, AND CAVITIES

A monograph devoted to the quantitative scientific analysis of jets, wakes and cavities. The book treats first, in chapters II-XI, the applications of Euler's differential equations to flows with free boundaries, i.e., to liquid flows bounded by a liquid-gas interface. In chapters XII-XIV attention is given to cases of laminar viscous, periodic, and turbulent jets and wakes. Chapter XV summarizes limitations on deductions made in the first portion of the book. There is an extensive bibliography. (By G. Birkhoff and E. H. Zarantonella. New York, Academic Press, 1957. 353p., $10.00.)

*MAINTENANCE ENGINEERING HANDBOOK

This comprehensive handbook, containing contributions by more than eighty men, devotes about a third of the book to the management aspects of maintenance, such as organization and administration of maintenance forces, personnel, planning and scheduling, project control, and costs and budgets for maintenance operations. The remaining two thirds of the book cover the selection, installation, and upkeep of buildings; electrical, mechanical, service, and transportation equipment; maintenance stores and their control; lubricants and lubrication; instruments; sanitation; welding; and corrosion. Units of production equipment dealt with include bearings, clutches, chains, drives, gears, valves, etc. (Ed. by L. C. Morrow. Toronto, McGraw-Hill, 1957. Various pagings, $20.00.)

MANUFACTURING PROCESSES, 4TH ED.

Completely revised, this fourth edition provides a comprehensive survey of manufacturing materials and processes, placing greater emphasis on principles and materials.

New topics covered include electroforming and metal coating processes, electro-spark machining, chem-milling, and automation. The chapters on foundry equipment and procedures, press work, plastic molding, and drilling and boring machines have been rewritten.

The photographs have been revised to show modern equipment, and the working of many of the machines is shown by line drawings.

Bibliographies for further reading have been provided at the end of each chapter, and the book will be useful not only to students wishing to obtain a basic knowledge of the materials and processes found in industry, but also to practicing engineers and others wanting to review a special phase of metal processing. (By M. L. Begeman. New York, Wiley, 1957. 612p., $8.00.)

MECHANICAL VIBRATIONS

Designed for a first course in the fundamental theory of mechanical vibrations, the purpose of this book is to enable the student to master the mathematical techniques which will later enable him to make the most use of more advanced literature.

The book assumes a grounding in integral calculus, and covers linear differential equations; partial derivatives in enough detail to enable the Lagrange equations to be developed; the solution of partial differential equations by the method of separation of variables; and, finally, introduces the electrical analogy, the mobility method and an introductory discussion of the analogue computer. (By Bernard Morrill. New York, Ronald, 1957. 262p., $6.50.)

°MODERN PULP AND PAPER MAKING, 3RD ED.

A revision of the previous editions by George S. Witham, this third edition has been rewritten by authorities in the field. Full coverage is given to such subjects as: papermaking materials and processes, varieties of paper and paperboard, the sulfite process, the alkaline processes, pulp bleaching, the machine and finishing rooms, paper defects, testing of paper and paper materials, process instrumentation for the pulp and paper industry. References are included. (Revised and edited by John P. Calkin. New York, Reinhold, 1957. 549p., $10.00.)

NEIGHBOURHOOD PLANNING

The author defines a neighbourhood as "an urban unit with a functional arrangement of its environmental elements, those elements being the circulation system, the built-up and the open spaces, the building sites, and the recreational, educational and social welfare facilities." The neighbourhood is further defined as being the smallest unit of population which can support an elementary school, that is about 4000 people. The neighbourhood is composed of a series of housing groups of from 50 to 300 people.

Professor Kostka considers all the aspects of planning a unit of this type, including architectural and engineering problems, zoning, the density of population desirable, the best methods of handling local and through traffic, and the utilization of real estate.

Much of the text is organized round 45 scale plans, illustrating house layout, street planning and subdivision design. Examples of planned neighbourhoods are given: Edmonton and Kitimat in Canada, Harlow, Crawley and Hatfield in England.

All those concerned in any way with city planning will welcome this latest book by Professor Kostka. It is a companion volume to his earlier *Planning Residential Subdivisions*, and should enjoy the same popularity. (By V. J. Kostka. Obtainable from the author, University of Manitoba Community Planning, Winnipeg 9. 1957. 142p., $4.00.)

NOMOGRAMS FOR THE ANALYSIS OF FRAMES

"The saving of time and labour that is possible by the use of nomograms is becoming increasingly realised, and nomograms for use in the design of parts of a building have occasionally been published in periodicals. In this book the author presents 26 nomograms for use in the design of all the usual types

Flexibility plus!

NEW GARDNER-DENVER DELUXE "AIR TRAC"®

210° Swing

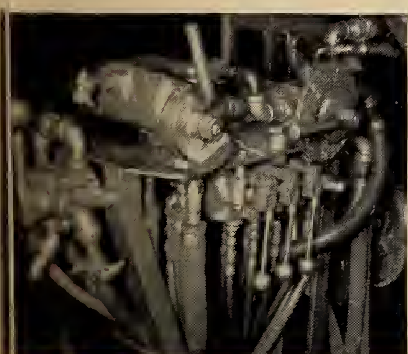
Hydraulic cylinder provides 120° swing, can be indexed for an additional 90° swing.

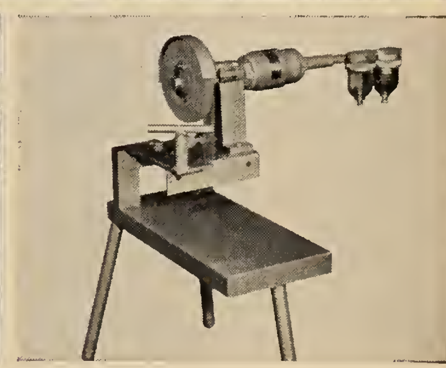
360° Dump

Hydraulic cylinder provides 90° dump, can be indexed a full 360°.

86° T-Bar Lift

Twin hydraulic cylinders provide T-bar lift of 86° 30′, from below horizontal to nearly vertical.





ew Remote Control Panel and Driv- s Seat—centralized controls provide stantaneous control of swing, dump, bar lift, crawler tracks and all drill- g operations. Designed for conven- ce, comfort and safety. Saves min- es and reduces operator fatigue.

New DPAT Hydraulic Drill Positioner—this creep-free hydraulic system maintains alignment at all drilling angles and avoids stuck steel. Provides fast, effortless, power positioning for all vertical, horizontal and flat lifter hole spotting.

New Model G-2 Bit Grinder—this deluxe "Air Trac" extra saves time, too. No need to send back or wait for bits—you sharpen spare bits on the job. Plus new free-wheeling drive shaft design for towing "Air Trac" . . . tool box for tools, bit and coupling storage.

rectangular building frames, and they are equally useful for reinforced concrete and steel construction. The cases dealt with are frames with both columns fixed at the base, both columns hinged at the base, and both columns fixed at the base and hinged at the top. The nomograms relate to the design of such frames with eight different types of loading, namely concentrated, uniformly-distributed, and triangular loads on the beam; concentrated, uniformly-distributed and triangular loads on either or both of the columns; external loads acting on the beam or on a column. Simple, symmetrical, and antimetrical loads are dealt with.

Complete formulae are given for all the foregoing conditions. The principal advantage of the nomograms is the speed with which indeterminate quantities are obtained by reading from the nomograms certain non-dimensional coefficients that are functions of the properties of the frame and the nature and position of the load.

The nomograms are in a pocket at the back of the book, so that they can be laid on the drawing board when in use, and their use is demonstrated by numerical examples." (By J. Rygol. London, Concrete Publications, 1957. 53p., $4.00.)

NOUVELLE CONCEPTION DE LA RESISTANCE DES MATERIAUX

In this second edition of his work on the strength of materials, the author has revised the chapters dealing with double functional anisotropy, concrete and clay under torsion-compression, concrete beams under shear and arches loaded at the crown as the existence of a second functional anisotropy has been confirmed since the publication of the first edition.

The material contained in the book appeared originally in the French publication, Genie Civil. (By A. Couard. Paris, Genie Civil, 1957. 111p., 1200fr.)

*NUCLEAR POWER ENGINEERING

An elementary presentation of the basic facts of the physics, design, materials, economics, and operation of nuclear power plants. The material is a revised and augmented reprint of a series of articles published in POWER starting in July 1954. (By H. C. Schwenk, R. H. Shannon and B. C. Skrotzki. Toronto, McGraw-Hill, 1957. 319 p., $7.80.)

PHYSICS OF NON-DESTRUCTIVE TESTING

The sixth supplement issued to the British Journal of Applied Physics, this volume contains papers presented at meetings of the Non-Destructive Testing Group of the Institute of Physics. The purpose in publishing the papers is to show engineers and metallurgists the importance in non-destructive testing of the new methods resulting from the application of physics.

Some of the topics covered include: the potentialities of X-ray diffraction studies; the principles of penetrant methods; principles and applications of nuclear magnetic resonance; effects of penetrating radiations on materials; and the measurement of elastic constants by the ultrasonic pulse method. (London, Institute of Physics, 1957. 72 p., 25/-.)

*PRACTICAL ACCOUNTING AND COST KEEPING FOR CONTRACTORS, 5TH ED.

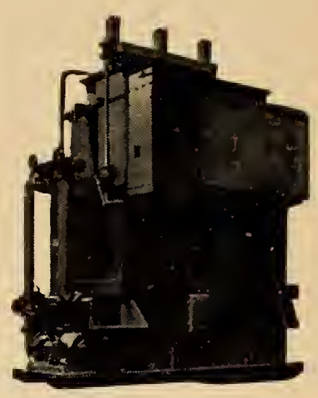
The essentials of accurate cost keeping are described for contractors involved in both large and small operations. The book includes complete labor and material cost schedules, information on how costs should be reported from the job, how to gather and compile data from checking the workmen's time on distributing the labor hours, and on working costs into suitable units. Illustrations and descriptions of forms required, i.e., Social Security records, expense sheets, etc. are included. (By F. R. Walker, Chicago, Frank R. Walker, 1957. 255p., $5.00.)

PRINCIPLES OF ENGINEERING INSPECTION

The importance of inspection in all stages of manufacture and production

Rotating machines up to 12,000 BHP and 5,000 kVA.

Rectifiers of all types.



Transformers up to 15 MVA 33kV and 10 MVA 66 kV.

is now universally recognized, and a systematic inspection programme plays a big part in lowering production costs.

This book, the most recent on the subject, is based on the syllabus of the City and Guilds of London Institute, and covers organization and scope of the inspection department, methods, machines and sampling, and the use of quality control charts. It is concerned not only with the finished product, but also with materials, both metallic and non-metallic, and protective coatings. There are illustrations of many machines, and line drawings showing their operation. Both authors have had experience in inspection work and in teaching. (By G. K. King and C. T. Butler. London, Cleaver-Hume, 1957. 264p., 25/-.)

°PROCEDURE HANDBOOK OF ARC WELDING DESIGN AND PRACTICE, 11TH ED.

Provides useful information on all phases of arc welding for the machine designer, the structural engineer, the fabricator, the welder and all those interested in metal joining. The 8 sections cover: history, nomenclature and processes, weldability, mild steel procedures, manufacturing cost data, machine design, structural design, applications and reference data. The structural section has been completely rewritten and includes the latest data on welded design. The weldability section includes information on welding such new materials as zirconium and titanium (Toronto, Lincoln Electric Co., 1957. Various paging, $3.00.)

RESOLUTION NUMERIQUE DES EQUATIONS ALGEBRIQUES

This text on the numerical solution of algebraic equations with real or complex coefficients discusses methods of calculation leading to valid solutions which are not always possible by more usual methods.

The various methods are presented in a logical order, and their practical value is discussed, both from the theoretical point of view, and by means of examples.

This is the third of a series covering calculation methods, and is intended for engineers, architects, builders etc. (By Jean Peltier. Paris, Gauthier-Villars, 1957. 244p., 2500fr.)

SCIENTIFIC FRENCH

Intended to enable English speaking scientists and engineers to obtain a reading knowledge of scientific French very quickly, this textbook emphasises the analytical approach throughout and grammatical terminology is kept to a minimum. Particular attention is paid to the structural differences between the two languages, and after a careful study of the book, which can also be used as a reference grammer book, the reader should be able to translate any ordinary technical material with the aid of a dictionary. (By W. N. Locke. New York, Wiley, 1957. 112p., $2.25.)

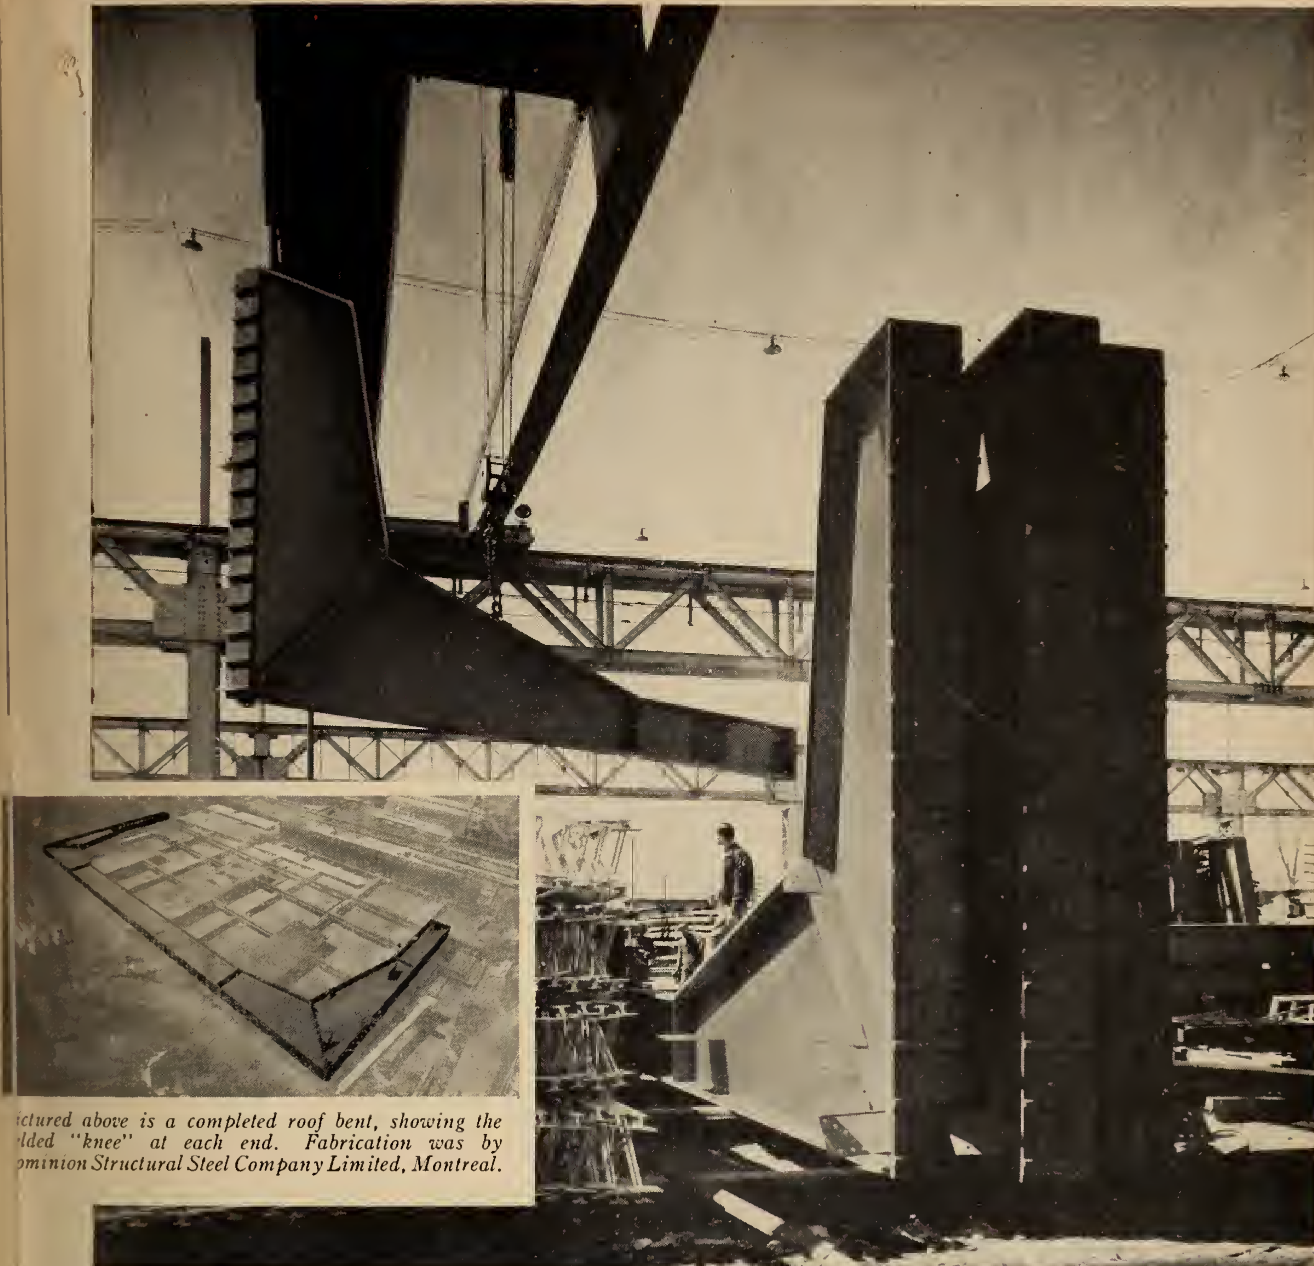
SCIENTIFIC GERMAN

Written with the same scope and purpose as Scientific French mentioned above, this book will prove equally useful and effective. (By G. E. Condoyannis. New York, Wiley, 1957. 164p., $2.50.)

THE THEORY OF SUSPENSION BRIDGES

The author is to be congratulated on providing a textbook on a topic about which suprisingly little has been written. The book will prove useful not only to students, but also to practicing engineers.

The historical introduction is followed by a discussion of the simple cable under applied loads. The various theories found in connection with the design of suspension bridges are considered: the Rankine, elastic, deflection and linearised deflection theories, anl the Fourier series treat-



ictured above is a completed roof bent, showing the ·lded "knee" at each end. Fabrication was by ominion Structural Steel Company Limited, Montreal.

20 "knees", 5½ tons each, for Ontario Hydro power house . . .

Ontario Hydro's design for its new St. Lawrence Seaway power house at Cornwall, Ontario, specifies all-steel all-welded construction of the roof support members.

For the welding of the knees — or legs — of these supports, the fabricators chose Stelco "Electrod." In each of the twenty knees . . . the dependability of which must be beyond question . . . approximately 300 lbs. of No. 624 Contact "Electrod" was used (for the fillet welds) and 50 lbs. of No. 504D "Electrod" (for the butt welds).

For information and technical data on the full range of "Electrod" Welding Rods, write for the revised edition of Stelco's booklet "Your Guide to Good Welding."

57 .B

ment of the deflection theory. Methods of analysis for preliminary design are given, and considerable attention is paid to the oscillations of suspension bridges, including of course the failure of the Tacoma Narrows Bridge.

The treatment of the book throughout is mathematical. There are numerous bibliographical references (By Sir Alfred Pugslev. Toronto, Macmillan, 1957. 136p., $7.15.)

TRANSISTOR CIRCUIT ENGINEERING

The object of this book is to show how basic transistor theory can be used in typical circuits.

Commencing with the basic theory and the application of network theory to it, the book goes on to cover basic circuits; audio amplifier designing; d-c, tuned and video amplifiers; oscillators; modulation, mixing and detection; and transient response and pulse circuits.

The book will enable the reader to build audio amplifiers, etc., using available transistors, and it shows how the circuits are combined into radio and television sets and high fidelity systems. Information is also given on the development of new devices and their application. There is an extensive bibliography for those who wish to pursue the subject further. (Ed. by R. F. Shea. New York, Wiley, 1957. 468p., $12.00.)

VECTOR SPACES AND MATRICES

The growing interest in vector spaces and matrices is reflected in the replacement of college courses on theory of equations by ones on matrix theory. Matrices and vectors, apart from their use in mathematics, are also used in circuit analysis, quantum mechanics, statistics and operations research.

This volume, intended as a college text, introduces vector spaces and linear transformations and matrices, and covers such topics as: systems of linear equations, determinants, functions of vectors, structure of polynomial rings, similarity of matrices, linear inequalities, etc.

These books are written at two levels, one concrete and the other axiomatic, the concrete one being through matrices and the other through linear transformations. This method has the advantage of introducing the reader to mathematical reasoning based on a set of axioms, while still retaining concrete examples. The final chapter provides an introduction to the theory of games and linear programming. (By R. M. Thrall and L. Tornheim. New York, Wiley, 1957. 318p., $6.75.)

WATER

This 1955 Yearbook of the U.S. Department of Agriculture is devoted to what is now a major concern, not only in the United States, but in Canada and the rest of the world. Water. The aim of the book is "to explain the nature, behaviour, and conservation of water in agriculture . . . Hydroelectric power, navigation, industrial use, pollution, and other aspects are touched on, but the book is concerned almost entirely with water in agriculture."

Some of the topics covered in this readable book are: the need for water; sources of supply; the action of water on soil; conservation; irrigation; drainage and pure water supply for farms and cities.

There are suggestions for further reading in each chapter, and the final chapters are concerned with future needs and the research and regulation needed to increase and conserve the available water supply. (Dept. of Agriculture. Washington, G.P.O. 751p., $2.00.)

WHO'S WHO, 1957

An annual publication since 1849, this latest edition of Who's Who needs no introduction. Its more than 3300 pages are a source of detailed information on anyone of note living in the British Isles or elsewhere in the world. The information given is checked by the biographee, and inclusion is, as always, by invitation and not by payment.

Who's Who is essential in any library, and is also fascinating reading. (Toronto, Macmillan, 1957. 3363p., $18.00.)

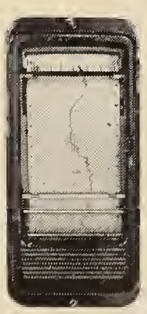
New **WESTINGHOUSE Type 44**

Electrical Recording Instruments

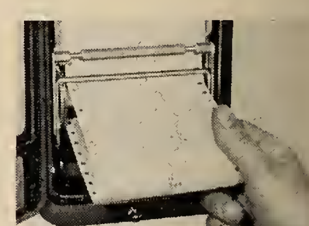
Chart tips forward—for service in seconds!



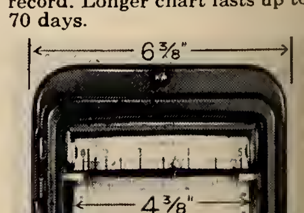
Never before a recording instrument so *easy* to service! You can reach every part of this Westinghouse new Type 44 from the *front*. And with the new "tip-to-you" chart mechanism, servicing the chart and ink system is a matter of *seconds*.

There are actually *26 good reasons* for choosing Westinghouse Type 44 Recording Instruments. Readability is exceptional; accuracy more than meets standards. Adjustable damping, compact design, high overload capacity are other advantages worth learning about.

Ask your Westinghouse representative for facts on the *complete* line of Westinghouse Recording Instruments. Or write Canadian Westinghouse Co. Ltd., Hamilton, Canada for Bulletin H-43-440.



Curtain Type Re-Roll allows convenient examination of chart record. Longer chart lasts up to 70 days.



Westinghouse Design gives you industry's highest ratio of actual chart width to exterior case width.

YOU CAN BE SURE... IF IT'S

Exploration for Oil and Gas

J. G. Spratt

Executive Vice-President,
Triad Oil Company Limited, Calgary, Alberta.

Read at the 71st Annual General and Professional Meeting, The Engineering Institute of Canada, Banff, Alta., June, 1957.

OIL EXPLORATION is one of the major gambles of modern in-lustry. It is in effect a series of ;iant, world-wide research projects vhich require vast sums of money, vith results for the most part being iegative and disappointing. Also as in esearch, however, occasional impor-ant discoveries are made which jus-fy the over-all effort.

Although oil has been known and sed by man for several thousand ears, exploration by well drilling as e know it today began about 100 ears ago. The early peoples in cer-in sections of Asia, Africa, Europe d the Americas used petroleum om surface seepages for paving ads, water-proofing boats and cis-rns, for lighting and fuel, for medi-nal purposes, and embalming. The abylonians and early Chinese are id to have produced oil from hand-g wells as far back as 5,000 years o.

For the purposes of this discussion, l will mean all members of the troleum family, which consists of a mplex series of hydrocarbons rang-g from solids like asphalt to liquid ude oils and natural gas.

The first oil found by drilling in rth America occurred in Pennsyl-nia and in Ontario in the late 50's, production being found at allow depths of less than 100 feet. With the coming of the machine e oil consumption mounted rapidly, d now thousands of wells are being illed annually in various parts of e world, with depths of over 20,-0 feet occasionally being reached. pths of 10,000 to 15,000 feet are t uncommon, with 5,000 to 10,000 et being quite common. World ergy requirements are now about ubling each succeeding decade, and it appears that oil require-ments will continue to increase in spite of the rapid advances being made in the development of other sources, such as atomic energy.

Early drilling was confined mostly to shallow wells in the vicinity of sur-face seepages, or where oil had been found in wells drilled for water or brine. As time went on, holes were gradually carried down to greater depth, and drilling became more widespread. As development con-tinued it was observed that several characteristics were common to dif-ferent oil fields. It was found that oil did not come from underground lakes and rivers, but from the pore spaces in rocks such as sandstones and lime-stones. It was also noticed that oil and salt water were commonly found together, or in close proximity, and that oil in commercial quantities often occurred in places where rocks had been buckled or arched upward into dome-like formations, and that salt water occurred immediately below, or down the slope from the oil.

Petroleum products have been known for thousands of years, mostly from natural seepages. The search for oil and gas deposits to meet the demands of modern in-dustry is the subject of this paper.

Such observations were the begin-nings of the scientific approach to oil finding. First came the application of geology, later to be followed by a more specialized branch known as petroleum geology which in turn was later complemented by the applica-tion of geophysics, geochemistry, and petroleum engineering. The result is that nowadays almost every branch of science and engineering, in some form, plays a part in the search for petroleum.

To summarize the highlights of ex-ploration in the short time available today, comments will be confined to brief remarks on the origin of oil, methods of prospecting, and the acquisition of mineral rights.

Origin of Oil

Based on present knowledge, the world is believed to be something over two billion years old, and the rocks in which oil is found date back over approximately the past 500 mil-lion years.

The earth is considered to have been formerly a molten mass of mat-ter like the sun, which eventually cooled and solidified on the outside to form what is known as the earth's crust. The crust was not a smooth surface, but was irregular and wrin-kled. The high places became the continents, and the low places the oceans, which gradually filled with water condensed from the cooling of the steamy atmosphere which sur-rounded the earth as its surface changed from a molten to a solid condition.

As time went on, primitive life be-gan to appear in the oceans, first in simple form and often of microscopic size, later developing through the slow process of evolution into the countless forms of plant and animal life which inhabit the earth today.

Oil, like coal, is classified as an organic mineral. Unlike coal, how-ever, which is a solid, oil is fluid and mobile, and generally has mi-grated some distance from its point of origin. It is believed to have been formed from the decay and slow distillation of plant and animal remains buried in the muddy bottoms of ancient seas. As time went on, new sediments were washed into the oceans by erosion of the continents, and the process, which continued through the ages, resulted in the building up of thousands of feet of sedimentary rocks, composed of limestones, shales or clays, and sandstones. During the process the ocean bottoms would periodically rise up above sea level to form continents or parts of continents, later sinking again into the sea.

The section of the Rocky Mountains which surrounds us here at Banff is formed of sedimentary rocks which were under the oceans not once but several times, and are now uplifted to heights of 5,000 to 10,000 feet above sea level. These same formations lie buried at depths of several thousand feet to the east of us in the foothills and plains of Western Canada, where some of them are occasionally productive of oil and gas.

With the passage of time and the combination of heat and pressure to which the sediments have been subjected, due to the weight of overlying formations; and with the forces which are constantly changing the shape of the earth's surface, oil was gradually formed from the organic content of the sediments in which early life was buried. Along with salt water, which was also trapped in these same sediments, the oil and water were squeezed out of the tight and relatively impervious rocks in which they were originally buried, such as clays, shales and clay-like limestones, and followed the lines of least resistance into the nearest overlying or underlying rocks, like porous limestones or sandstones. Such rocks are known as "reservoir rocks", whereas the clays and dense limestones in which the oil originally is thought to have formed are known as "source rocks". Oil being lighter than water would float on top of the water in the reservoir rock, and occasionally be trapped in commercial quantities when its migration was stopped by some barrier such as the top of a wrinkle, known as an anticline or dome, or when porosity ended abruptly due to a break in the rocks, known as a fault, or due to its petering out in a wedge-shaped up-dip direction. Where oil is found in wrinkles or against faults, such accumulations are known as structural traps, examples of which are: Turner Valley, Pincher Creek, and Fort St. John in Western Canada. When oil is trapped in an upward pinching out or wedging of porosity, it is known as a stratigraphic trap; examples of which are: Pembina, Harmattan-Elkton, Medicine Hat, and several other fields in Western Canada. Another type of stratigraphic trap is when oil is found in ancient limestone reefs, examples of which are: Leduc, Redwater, and Sturgeon Lake.

Exploration Methods

As for scientific methods employed in oil finding, the first, as already noted, is the application of petroleum geology. The job of the geologist is to make a study of the country and find out which areas are underlain by sedimentary rocks, which are favourable for oil accumulation. Areas underlain by igneous or volcanic rocks, such as granites, lavas, etc., are unfavourable for oil occurrences.

In Canada the largest area for favourable oil exploration is the sedimentary basin of the Western Canada plains and foothills. It covers an area of about 750,000 square miles, being bounded on the west by the Rocky Mountains, on the east by the Pre-Cambrian Shield, on the south by the United States border, (although the basin extends southward into the United States), and on the north by the Arctic Ocean. Taking the area by provinces or territories, it includes: (1) the MacKenzie River Basin area of the Northwest Territories, running southward from the mouth of the MacKenzie to the Alberta-B.C. boundaries; (2) part of northeastern B.C.: (3) most of Alberta; (4) the southern half of Saskatchewan; and (5) the south-western part of Manitoba.

The geologist, after making broad regional reconnaissance surveys, then proceeds to map the country in more detail, piecing together the bits and pieces of information yielded by surface rock outcrops. From such information he attempts to determine the stratigraphic and structural nature of the underground formations.

Surface outcrops usually do not provide sufficient evidence for location of exploratory wells, and additional information must therefore be sought. Surface geology is therefore often supplemented by obtaining sub-surface information from a series of shallow, strategically located test holes. Such holes are normally drilled from 50 to 1,000 feet in depth. Records of all previously drilled deep wells are also carefully studied for geological information and showings of gas, oil or water.

In studying well records, two types of scientific instruments which measure and record the electrical or radioactive nature of sub-surface strata are used. They are known respectively as electric, and neutron or gamma ray logs. In both cases instruments are lowered into the hole on a cable to measure and record the above-mentioned characteristics. The information thus obtained assists geological correlation and also helps detect possible oil bearing rocks. Another type of instrument is sometimes used in deep well drilling, which helps indicate the presence of oil or gas during drilling operations. The drilling mud, which is continually being circulated from the top of the hole down through the inside of the dril pipe to the bottom of the hole an back up to the surface in the annulu between the outside of the drill pip and the well, is tested for hydro carbon content.

During the past twenty-five years geophysics has played a very prominent part in providing helpful guidance in oil exploration. The geophysi cist is a highly scientific individua well trained in mathematics and phy sics, combined with some geologica training. He works in close collabora tion with the geologist, and employ a variety of instruments to measur magnetic, electric, gravitational, an seismic characteristics of unde ground rocks.

The most popular and successfu and also the most expensive, ge physical method employed is o known as the seismograph. Broad speaking, the principle of this meth consists of exploding dynamite in t bottom of shallow holes, which a located and drilled in specific pa terns. The explosion sends shock sound waves downward through t various rock strata, which are in tu reflected back to the surface a picked up and recorded by seism instruments in a similar manner which earthquake waves are recor ed. Results may be obtainable depths of 10,000 to 15,000 feet more. By having some idea of t velocity of sound in different form tions, and learning to detect refl tion characteristics of certain stra the seismologist is often able to d termine the nature of undergrou structure and, if the other geologi requisites are present, to locate vourable oil prospects.

The magnetic and gravimet

methods are faster and less expensive than the seismic method. They are also less accurate, being more difficult to relate to the geology, and as a rule are used more for preliminary reconnaissance, to be followed by seismic work for more detailed control.

After employing one or more of the geological and/or geophysical tools necessary for the location of deep test exploratory holes, known as "wildcats" in the oil industry, comes the actual selection of a drill site. A "wildcat", incidentally, is a respectable term in the oil business, and does not necessarily mean a fly-by-night promotion as in mining circles.

One would think that after the employment of so much technical assistance, together with the information and experience obtained from the drilling of many thousands of wells and many hundreds of oil and gas fields during the past fifty years, it should now be easy to locate oil. The fact is, however, that it is still an extremely risky business. In this country, maybe one out of ten wildcats will find oil or gas; one out of twenty may be of commercial importance; and one in several hundred may be sufficiently profitable to make up for all the failures. One of the reasons is that, although science can help reduce the odds in finding oil by helping to locate favourable underground conditions, there is still no known method of locating oil itself before drilling. Luck still plays a most important part. In actual drilling, it is often found that in spite of all the geological and geophysical work that has been done, sub-surface conditions do not turn out as anticipated. In other cases, although favourable conditions forecast before drilling turn out as predicted, for some unforeseen reason the objective reservoir rock ends up in producing water rather than oil, or is too tight or impervious to produce anything.

Fortunately, however, science occasionally leads us to discoveries of major importance, such as Leduc, Redwater, Fort St. John, Pincher Creek, and Jumping Pound. In cases like Turner Valley, Pembina, Lloydminster, Drumheller, and numerous others, credit for discovery must be given to a combination of money, venturesome spirit, and luck. In some fields oil has been discovered in a formation where it was not expected, and found missing in the main objective horizon. In other cases, instruments known as "doodlebugs", which are not recognized scientifically, have led to wells being drilled which found production. "Doodlebugs" may consist of a willow switch, a crystal ball, or combination of batteries, barbed wire and mysterious bottled chemicals. It takes all types to find oil!

In discussing the drilling of wildcat wells, remarks here will be confined to matters concerning exploration only, as the subject of drilling will be covered elsewhere in this program.

In drilling a well, a geologist is usually present to supervise sampling of rock cuttings, together with coring and testing of prospective producing horizons, as the well is carried down. Samples of rock cuttings from the bottom of the hole are continually being pumped to the surface in the drilling fluid. These samples are collected about every five to ten feet, washed clean of drilling mud, and examined under a microscope for determination of formation and the possibility of oil content. This information is recorded on what is known as the well log.

Considerable advances have been made in sciences such as geology, geophysics, and geochemistry to assist exploration.

When the well approaches or reaches a potentially productive strata, the geologist may have a core of the rock taken, the better to determine the character of the formation and decide upon the advisability of testing. If he thinks a production test is required, what is known as a "drill stem test" is made. In making a drill stem test the drill pipe and bit are pulled out of the hole, the bit is removed from the bottom of the drill pipe, and a "tester" is substituted in its place. The tester is run into the hole on the bottom of the pipe, and the zone to be tested is sealed off from the rest of the hole by a packing device. A valve in the tester is opened to allow whatever may be in the formation being tested to enter the drill pipe. In drill stem testing the pipe is run in empty, rather than full of fluid as in drilling operations, therefore whatever comes into the hole can be measured. If gas enters, it comes up through the drill pipe and is measured and sampled at the surface. If oil enters, it is measured as the drill pipe is pulled out from the hole, being held in the pipe by closing the valve in the tester before the pipe is pulled. If salt water enters, it is measured the same as in the case of oil. If oil is encountered, the hole may be completed as a producer, or drilled on to test lower horizons before completion. If water only is found, the well may be abandoned, or again deepened to test lower horizons.

Oil wells may range in depth from about 1,000 feet to over 20,000 feet. In Canada maximum depths thus far drilled are between 14,000 and 15,000 feet. Depths of from 5,000 to 10,000 feet are quite common. In general, drilling depths increase westward from Manitoba to the Rocky Mountains as the thickness of sedimentary rocks likewise increases.

Exploratory drilling costs in Western Canada may run from $25,000 to over $1,000,000 per well. The normal cost for a 5,000 to 6,000 foot well would run about $100,000. Once oil has been found and development gets under way costs can generally be considerably reduced.

In remote, inaccessible areas such as northern Alberta, north-eastern B.C., and in the Northwest Territories of western Canada, or, for example, in places in other parts of the world where off-shore drilling is required, such as the Gulf of Mexico, the Persian Gulf, and the California coast, costs may run even higher. Where a lot of gephysical work is required, and if these costs plus land acquisition costs are added to the drilling costs of a wildcat well, the total may run into several million dollars.

Acquisition of Mineral Rights

Having touched upon the origin of oil, and exploration methods, it may now be of interest to know something about how petroleum and natural gas rights are acquired for prospecting or development purposes.

In some parts of the world, such as the Middle East and South America, oil rights are entirely under the control of the governments. In such cases concessions for large areas are usually made by negotiation with the ruling powers. In other instances, the lands are put up for competitive bidding. Cash bonuses are generally required, together with a minimum gross royalty, or 50 per cent of the profits, whichever is the greater.

In the United States a great deal of the mineral rights were granted to the landowners at the time of original purchase of the surface from the Government. These lands, which are usually known as "freehold" or "fee" lands, may be leased to an oil company for, say, a ten-year period, subject to an annual rental of $1.00 per acre and a 12½ per cent gross royalty on any production obtained. Depending upon the attractiveness of a particular area, substantial premiums by way of cash bonuses, higher rentals, and/or higher royalties may be payable.

As a result of the widely diversified ownership of oil rights in the United States and the necessity of dealing with numerous landowners, rather than one, as where a government owns the rights, competition is very keen, and highly specialized land departments have been developed in most American companies. The same now applies in Canada. In such instances the job of obtaining title to sufficient property to permit development is indeed complex and costly. As an example, one of the tasks of the land man is to search titles, the ownership of which may include numerous people scattered all over the country, or in some cases all over the world.

In some countries when a company's concession runs out after, say, 25 to 99 years, all properties developed or otherwise, together with improvements, revert to the government at the end of the concession period, an example of which is Colombia, in South America. In some countries, after oil has been found and developed profitably, the government in power may decide that they do not like the deal they made with the company originally, and decide to demand a higher royalty or share of profit, or, as sometimes happens, confiscate everything, in return for which only nominal compensation is offered.

It is rather unfortunate for the Western world, which is at present the greatest consumer of oil, that the largest known reserves are located in countries in which our supplies could be cut off or made more difficult to obtain in the event of unstable political conditions. The dangers in the Middle East, with which you are all familiar, emphasize the seriousness of this situation.

The United States has long been the world's greatest producer and consumer of oil. During the past decade, however, her supplies have begun to lag behind demand, and she has become a net importer. Indications are that imports will increase during the next generation. In view of this, plus the fact that oil reserves in many countries outside the United States are vulnerable, Canada has, particularly since the Leduc discovery in 1947, been receiving increasing attention by American, and later by European oil companies, as well as Canadian.

In parts of Canada, mineral rights went to the landowner with the sale of surface rights until after the beginning of the century. Thus in Eastern Canada and the older settled parts of the Prairies, such as Manitoba and some parts of Saskatchewan and Alberta, the farmers owned their oil rights. An approximate breadown of Government owned and freehold rights by areas in Western Canada is as follows:

Area	Government	Freehold
Manitoba	15%	85%
Saskatchewan	70%	30%
Alberta	85%	15%
B.C.	100%	.....
N.W.T.	100%	.....
Indian Lands	100%	.....

In Western Canada freehold rights are usually leased in a similar manner as in the United States; that is, a ten-year lease with an annual rental and 12½ per cent royalty, with premiums sometimes being paid depending on the attractiveness of the acreage. If production is found within the ten-year period, and the lessee has lived up to the various drilling obligations, etc., the lease is normally renewable as long as production is obtainable.

In Canada oilwells are usually drilled on a 40 to 160-acre spacing pattern, or approximately ¼ to ½ mile apart. Gas wells are usually drilled on a 640-acre spacing pattern, or one mile apart. Therefore it may take from four to sixteen times as many oil wells as gas wells to develop and drain a field of similar size. The reason for this is that gas travels through the formation more easily than oil.

As already mentioned, the majority of oil rights in Western Canada belong to the Crown. Each province handles them on approximately the same general basis, but with certain local variations. As would be expected, before oil has been found in an area the terms are usually more generous than later on.

With competition becoming keener and keener, the costs of exploration and development are likewise getting higher, with the result that it is more difficult now for small companies to compete than formerly. The complex technical organizations that are now required in the business also make it difficult for the small companies.

Where large tracts of land are available, the provincial governments, or Federal Government in the Northwest Territories or on Indian lands, usually put them up for competitive bidding in the form of reservations or prospecting permits. Reservations are a sort of "hunting license", which gives an operator an opportunity of exploring an area and eventually selecting certain leases out of it. As a rule the operator has certain nominal rentals to pay during a reservation period, and certain work obligations, up to a maximum period of five to seven years. The work obligations and rentals usually increase during the later stages of a reservation term. When originally disposed of, cash bonuses running from a few dollars to a few million dollars may be received by the Crown, depending upon the size and attractiveness of the acreage involved. The amount of acreage obtained in reservation form may run from several thousands to several hundreds of thousands of acres. For the benefit of those who may not be familiar with acreage and distance relationships, a Township of land is 6 miles square, containing 36 sections, or 23,040 acres. At the end of, or any time during, the reservation term, the operator may convert into lease, proving he has complied with work and rental commitments. At this time one-half to two-thirds, or more, of the reservation may revert back to the Crown, the balance being obtainable in lease form if the operator has met his obligations.

Leases are usually square or rectangular in shape, and are generally taken out in an irregular, checkerboard pattern. The size of an individual lease may vary from ¼ section, ½ a mile square, to a 9-section block, 3 miles square. Leases may adjoin one another cornerwise, or be surrounded by corridors of a mile or more in width of lands which are retained by the Crown. Government leases normally call for an annual rental of $1.00 per acre, and gross royalties on a sliding scale basis ranging from 5 per cent to 16-2/3 per

(continued on page 1258)

Drilling and Completion Practice

A. S. Murray

Regional Drilling Engineer,
Imperial Oil Limited, Calgary, Alberta.

Read at the 71st Annual General and Professional Meeting, The Engineering Institute of Canada, Banff, Alta., June, 1957.

The author describes the main procedures for drilling oil wells and for their final completion, with particular reference to the practice in Western Canadian oilfields. Mention is made of costs and of materials used.

THE PRINCIPAL capital outlay of the Canadian petroleum industry is the expenditure which is made to drill and complete new wells. In 1956 more than 268 million dollars was invested in new Western Canadian wells. This represents over 60 per cent of the market value of the crude oil and gas production for that year. Back in 1947 when Imperial's Leduc discovery kicked off the present cycle of exploratory drilling, industry spent only 13 million dollars in its search for oil and gas. During the last 10 years, industry has poured over one billion dollars in direct drilling expenditure into new wells in Western Canada. This is of great importance to all of us working in the west, for it is estimated that 75 per cent of the money spent in drilling a well stays in the province where that well was drilled. The drilling industry has contributed significantly to the prosperity that some 3 million people in the Prairie Provinces are currently enjoying.

Our domestic drilling industry is made up of 125 drilling contractors and oil operators who own more than 325 rotary rigs. The output or gross business of these rigs is measured in terms of the total cost of the oil and gas wells drilled and completed, and not merely in terms of drilling cost alone which, on the average, is less than one-half of the total well cost.

Approximately 5,500 people are directly employed in drilling wells. If supply store and service company personnel are added to this total, since they are directly dependent on drilling, the total would be in excess of 8,000. It is significant that our drilling industry is truly a Canadian one, for 99 per cent of the people employed are Canadians.

The future of our drilling industry is a bright one. Western Canada is currently producing over ½ million barrels of crude oil per day. This production is expected to grow with the markets served. We can expect to produce and market something in excess of a billion barrels over the next five years. If we are to keep healthy, this oil must be replaced. We show every sign of doing just that. To maintain this position, however, industry will have to drill from 10,000 to 15,000 exploratory and development wells during the next five years.

We have already peppered this Western Basin area with over 17 thousand wells between 1947 and 1956. This represents in excess of 71 million feet. Despite these very large figures, we have hardly scratched the surface of this vast Western Basin area in our search for oil and gas.

During the past 10 years, drilling rigs have become as familiar a sight as the long standing and picturesque country grain elevator.

Let us go up on to a rig floor and examine the technique of how the rotary system of drilling works.

The Rotary System of Drilling

A schematic diagram of a rotary rig is shown in Fig. 1.

Drilling Rig

(A) There are rigs capable of drilling in excess of 22,000 feet. The deepest well in the world is 22,570 feet—located in Louisiana offshore area. It produces oil from a sand at 21,443 feet in commercial quantity.

(B) Rigs have been used with as much as 3,200 h.p. from diesel engines.

(C) Slush pumps used for mud circulation are rated as high as 1,500 h.p.

(D) Derricks are built that will withstand winds of 125 m.p.h.

(E) Derricks have been built to support loads in excess of 1 million pounds.

(F) Working loads may be as high as 400,000 pounds (i.e., loads actually run in hole; e.g., casing).

(G) The drilling industry breaks down rigs capable of drilling to 10,000 feet into pieces light enough for aeroplane or helicopter transportation —this has been done in the Persian Gulf, New Guinea, and Amazon basin.

(H) Industry is drilling from platforms in water 110 feet deep; for example, Lake Maracaibo.

(I) Ingenious offshore structures in the Gulf of Mexico permit drilling as much as 50 miles from shoreline but cost anywhere from 3 to 6 million dollars for the platforms alone, (designed to withstand 50-foot waves).

(J) Industry is drilling through the bottom of a converted L.S.M. ship with equipment that is designed for operations in 1,000 feet of water.

Working Floor

A rotary table with kelly is shown in Fig. 1. The drilling string is often rotated as high as 400 r.p.m. Generally, the softer the formation and the shallower the well depth, the higher the drilling string rotation. In hard formation a slow table speed is used.

Slips support the full load of the drilling string which at 10,000 feet weighs around ¼ million pounds. A 10,000-foot string of casing could weigh ½ million pounds.

Drilling Controls

The driller must study his control panel and from the many gauges decide what is occurring to his drilling string and what is happening at the bit. Some of the gauges used show mud circulating pressure, drilling string torque, drilling string weight, automatic drilling control, and drilling string rotational speed.

Blowout Preventers

There are two types—ram and stripper. The former has rams properly sized to close on the string of pipe in the hole; stripper type will provide positive shut-off on anything that is run in hole.

Drilling Bits

Soft formation; $177/bit; 9-inch—Frequently on bottom 30-40 hours carrying loads of 40-45 thousand pounds. Carries in many cases loads to 90 thousand pounds. Rotated at 400 r.p.m.; under some conditions down to about 30 r.p.m. Roller and ball bearings are used in drilling bits. As many as 964 bits may be used in drilling a 10,000-foot well.

Hard formation; $1,100/bit; 9-inch—For hard quartzitic sandstone and chert and lime digging. Such a bit can save 20,000 dollars on a well.

Factors Affecting Penetration Rate

The drilling rate of bits is governed by several factors:

(1) Formation
(2) Bit
(3) Mechanical
(4) Hydraulic
(5) Fluid properties

There is an optimum bit, speed of rotation, circulation rate, and weight on the bit for drilling each formation. Table speed, bit weight and circulation rate are linearly related to drilling rate if all of the factors affecting penetration rate provide for a clean hole at the bit. Knowledge of optimum drilling conditions for each formation will greatly reduce costs. For example, in the Leduc field penetration rate was trebled and bit consumption was more than halved when optimum bit weight, rotation speed, and circulation rate were established for each formation. Cost per well was reduced 30,000 dollars or an estimated savings on field development of 6 million dollars.

Function of Mud

Drilling mud is perhaps the most important part of the rotary drilling technique. The vast majority of muds may be classified as water-base, and consists of three parts:

(1) Liquid phase or water.
(2) Colloidal fraction which is the gelling portion.
(3) Inert fraction which consists of sand or other inert solids.

Wyoming bentonite, a pure form of montmorillonite clay is widely used with water to make drilling mud. Drilling mud is an exact science involving close control of viscosity, weight, water loss, gel strength, pH, and solids. Functions of drilling mud are to:

(1) Cool and lubricate the bit.
(2) Lift cuttings out of hole.
(3) Hold cuttings in suspension when not circulating.
(4) Establish a wall cake to hold formation in place.
(5) Exert sufficient hydrostatic pressure to prevent flow of water, oil, or gas into the well bore from formations drilled.

I have chosen to detail the rotary system of drilling because approximately 86 per cent of all the hole drilled is done by this method. Drilling with cable tools accounts for the other 14 per cent. This method has become increasingly "spot-type" in its application during the past 15 years falling from 33 per cent of the total footage in 1945.

Well Completion Techniques

What takes place when a hole is drilled to a reservoir rock that contains oil? A common misconception is that oil exists in underground pools or lakes and all that is required is to tap this pool through a cap rock and oil will start to flow to the surface. This is not the case, however. Oil accumulates in underground structures that are sealed by an impermeable barrier and occurs largely in porous limestone, fractured limestone and in sandstone. From the porosity standpoint, you might picture a sponge that is saturated with oil and is under pressure. Unfortunately there are very few ideal type reservoirs that will yield their oil freely. Considerable work is required in most cases to make oil reservoirs produce

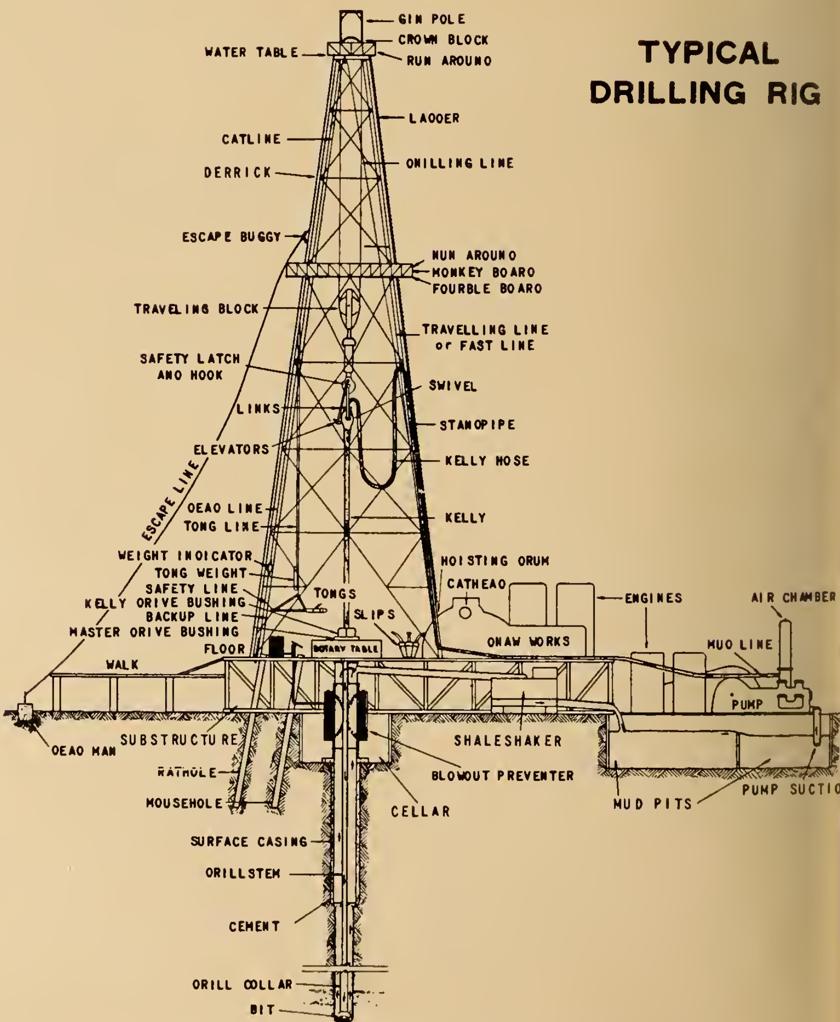

Fig. 1. A typical drilling rig, showing the main features.

Let us assume that a hole has been drilled to a proven production horizon and briefly consider completion methods that will bring oil to the surface. Completion methods fall into two main categories which are largely dependent on the nature of the reservoir rock and its contents.

(A) Casing is set through the producing section.

(B) Casing is set on top of the producing section.

Set Through Completions

"Set through" completions are adopted when the pay formation is incompetent and inclined to cave or fall into the hole. The method is also used where pay sands are divided, where pay sections are thin, where dual zone work is expected and where close control of the gas cap and/or water table is desired. Several techniques have been devised to overcome formation caving and the flow of sand into the well bore (Figure 2). These include:

(1) Cementing the casing string with a slotted screen on the bottom across the producing section so that no cement contacts the pay.

(2) Cementing the casing string so that no cement contacts the pay, perforating the casing and running a screen for sand production control. (Good where minor amounts of sand are produced.)

(3) Cementing the casing string so that no cement contacts the pay, perforating the casing, gravel squeezing, and running a screen. (Good for extremely incompetent formation producing sand.)

For the control and/or treatment of thin sands, divided sands, gas caps, and water tables, casing is set through the reservoir rock and perforated at accurately measured depths.

Set on Top Completions

"Set on top" completions are associated with competent reservoir rock. This method is adopted when the pay section has zones of poor vertical permeability, or where a sandstone reservoir rock is interbedded with bentonite or hydratable shale which will swell in the presence of water occurring from drilling mud or during a cement job, so that flow of oil into the well bore is inhibited. There are several advantages to this type of completion. It costs less than the "cased through" type. It avoids any cement contamination of the pay zone. It is possible to enlarge the well bore radius through the pay section if this is desirable, e.g. nitro shooting, or under-reaming. Sand production can be controlled by using screens, gravel packing, or under-reaming, gravel packing and screening combined.

Drilling In

I briefly mentioned previously that some pay formations are sensitive to the "drilling in" fluid or to cement. Cable tools or rotary may be used for drilling the reservoir rock. The cable tool method costs less, is less harmful to mud sensitive zones, more effective in lost circulation zones, and permits incremental deepening in thin pay sections. On the other hand, its application is limited to low pressure formations.

The rotary method is the most commonly used as it provides a greater flexibility of operations; e.g., well pressure control, faster completion, better cores, better electric logs. Its limitations, however, in many cases, are of considerable importance; e.g., permeability damage due to "drilling in" fluid, more costly, and loss of circulation hazard. Industry has conducted research into the development of fluids and techniques which will overcome formation damage while "drilling in". Some specialized "drilling in" fluids, which are in current use include water-base mud, oil-emulsion muds, salt water mud, oil-base mud, oil, air and gas.

Well Stimulation

Sometimes oil reservoirs require varying degrees of stimulation in order to make them produce at optimum rate. Well stimulation technique falls into two main categories:

(A) Large area penetrators

(B) Skin breakers

(A) Large area penetrating methods include nitroglycerine shooting, acidizing, and hydraulic fracturing. *Nitroglycerine* has been used only sparingly in Western Canada. It provides bore hole enlargement and there is no fluid effect on permeability, and it is not selective to a single fracture at the weakest bedding plane. Industry, however, has found that cleanout after a nitro job has been expensive. Its limited application to open hole completions, and the hazard to personnel and well equipment do not merit its widespread application.

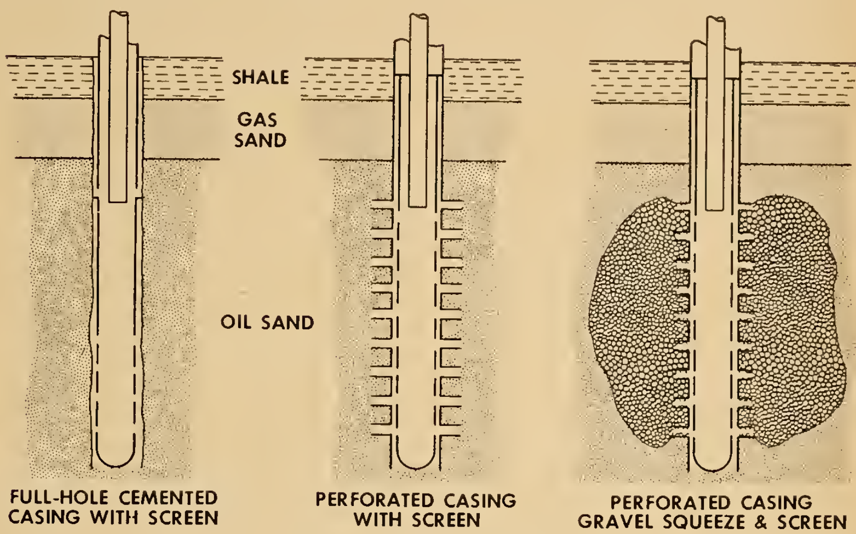

Fig. 2. Casting set through.

Acidizing has proven its merit as a large area penetrator in well stimulation for formations having appreciable calcareous content. The operation involves pumping acid into the formation under pressure. Moderate bore hole enlargement is possible, the technique is relatively inexpensive and it does clean out, enlarge and establish flow channels between vugs, fractures, and other channels.

Hydraulic fracturing has been the best large area penetrator technique ever developed in industry. This method of well stimulation has made many marginal fields of questionable economics a feasible operation. Hydraulic fracturing primarily is the application of fluid pressure to a desired section of the formation until rupture occurs. Continued pumping extends the breaks, thus creating new and larger flow channels to the well bore. Permeability is increased and higher flow rates result from the larger drainage area that is established. A propping agent (generally 20-40 mesh Ottawa sand) is pumped in with the fracturing fluid to maintain the channel open and so preserve the higher permeability. Hydraulic fracturing is characterized by a highly flexible procedure and its many benefits:

(a) Multiple or single fractures, combined advantages of fracturing and acidizing, wide latitude of sand carrier agent.

(b) Maximum effective area of stimulation.

(c) Maximum extension of inherent or induced fractures.

(d) Adaptation to either open hole or set through completions.

There are, however, several limitations worth mentioning. The method is relatively expensive. It involves cleanout of propping sand and it involves the use of high pressure on tubing or casing.

(B) Some reservoirs require only minor stimulation to induce optimum productivity. This involves largely the removal of mud filter cake from the well bore and cleaning out of the formation in the immediate vicinity of the well bore. Stimulation techniques of this nature are classified generally as skin breakers. Common methods in use included gun shooting, mud acid, surface active agents, jet acidization and marble shooting. All methods are relatively inexpensive. They improve permeability adjacent to bore holes that are blocked by mud solids, mud filtrates, emulsions and clay swelling.

Casing Perforating

A further consideration relative to well completion is that of perforating the casing. Two methods are available, jet or gun. Jet perforating has the advantages of maximum penetration, minimum cement shattering, minimum burring, and angle shooting. Gun perforating is cheaper than jets, and will produce a large, uniform hole. Careful investigation by industry during the past five years has shown that the type of fluid in which the perforating operation is carried out has a profound effect on well productivity. Selection of a perforating fluid depends on the nature of the reservoir rock, the drilling fluid that was used while "drilling in", the reservoir fluid, and pressure. Commonly used perforating fluids include oil-emulsion mud, oil-base mud, and oil.

Running and Cementing Casing

A further important consideration of well completion is the detailed planning that precedes all casing jobs. Casing strings are designed for tension, collapse, buoyancy, and burst factors with other modifications such as effect of buoyancy on compression and collapse. The methods followed in running, cementing, and landing casing may influence initial as well as ultimate well productivity, e.g. *when running casing:*

(a) The proper amount of torque is applied in making up joints to avoid leaks or failure in tension.

(b) A minimum dropping rate into casing to ensure that abnormal pressure surges are not set up which will the hole is set for each range of break down incompetent formation and cause loss of circulation when cementing.

(c) Scratchers and centralizers are fixed to the casing in the proper amount and spacing to adequately remove mud filter cake and centralize the string to reduce cement channeling.

Cement properties have been the subject of intensive investigation by industry during the past decade. Water loss, perforating characteristics, slurry weight, pumpability, and setting time are a few of the properties that have been investigated to obtain optimum conditions for oilfield use. A few years ago such material as bentonite, pozzolan, perlite, calcium lignosulphonate, and gypsum were unknown as additives to oilfield cements. In fact, a few years ago, casing strings were not even cemented in place.

Casing cementing technique has also been a research subject. One of the most important findings has been the necessity of continually reciprocating casing at least one full joint during the entire cementing operation. A further study that is important to the success of all casing cement jobs has been how to land the string in the wellhead. Research, and field experience has shown that cementing and landing the string in full tension reduces the possibility of breaking the cement bond between casing and well bore.

The final phase of producing reservoir oil involves running tubing inside the casing as the means of transporting oil to the surface. Dependent on well productivity and reservoir characteristics, the tubing is hung from the wellhead, open ended, or a packer is run with the tubing to seal off the annular space between tubing and casing or a pump is run inside the tubing and actuated by another strip of pipe called such rods. Time does not permit further elaboration of well completion techniques.

Drilling Costs

I mentioned in my introductory remarks that the principal capital outlay of the Canadian petroleum industry was the expenditure which is made to drill and complete new wells. Two hundred and sixty-eight million dollars were spent in direct drilling expenditure in 1956. Geology, weather, and terrain are the main factors influencing well cost. Often this cost has become very sizeable even before the bit has cut grass roots due to weather and terrain conditions. Well cost and depth relationships across Western Canada show the combined effect of these three factors and follow mathematically a power function ($y = ax^b$).

Some of the factors affecting drilling costs are summarized below:

1. Drilling costs in remote foothil

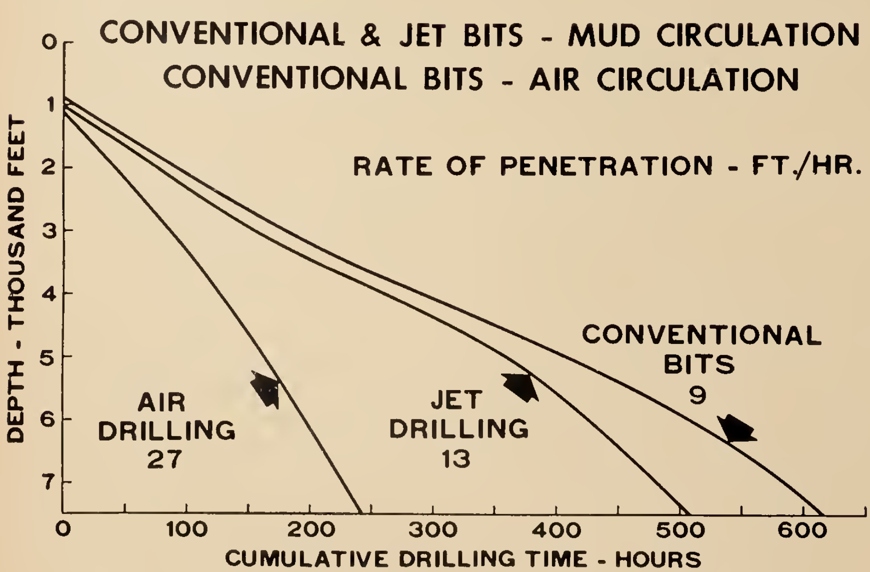

Fig. 3. Comparative penetration rate analysis.

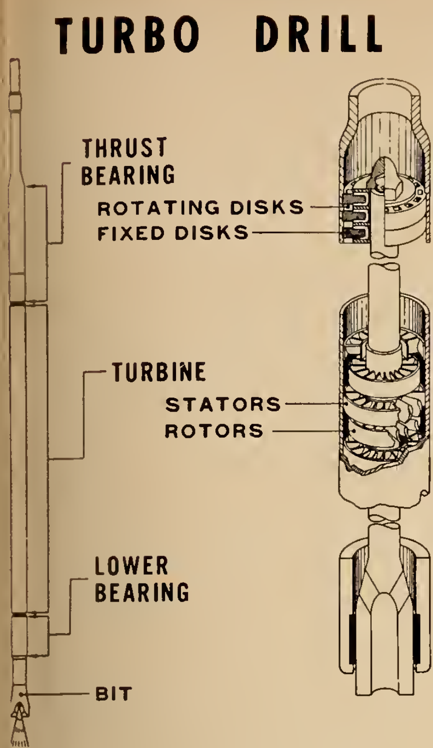

Fig. 4. Diagram of a turbo-drill.

locations may run over 1½ million dollars; remote muskeg locations may run just as high.

2. The time of year that drilling is done is important.

3. Cold weather is needed to drill in muskeg areas.

4. When spring thaw comes and drilling is still in progress, the rig must remain racked on location until the following winter before it can be brought out. Hence there is a loss of revenue due to this idle rig.

5. Drilling operations are round the clock, 365 days a year. Drilling operations do not shut down for extremes of heat or cold.

6. One hundred people may be involved in planning a wildcat location.

7. One hundred people are involved in drilling and completing the well without counting those needed to pay bills.

8. Transportation costs are high on emote wildcat locations—$300,000.

9. Road drilling and maintenance osts are high on remote wildcat loations—up to ½ million dollars.

10. Snow removal from 200 miles of bush is costly.

11. Twenty-six dollars to $120 per oot is the cost of Peace River and emote foothills wildcats; nineteen lollars to $55 per foot for Edmonton rea wildcats.

12. Fifty to 365 days drilling are equired on Peace River, deep remote wildcats; thirty to 100 days on Edmonton wildcats.

13. Average development field well takes 15 days to drill and complete at 5,000 feet.

Technological Improvements that are Reducing Drilling Costs

Previous mention was made that the ratio of drilling expenditure for new wells to income from crude oil and gas production was over 60 per cent. In view of the trend to deeper and costlier wells, indications are that this ratio will increase, unless industry can find ways to decrease costs, and drill fewer unnecessary development wells. I am pleased to say that technological improvements brought about by basic research in drilling have been responsible for maintaining drilling and well costs during the past six years at approximately 1950 levels. Some of these improvements include:

A greater knowledge of drilling hydraulics.

The wider use of chert bits for drilling hard rock formation.

The extended application of diamond drilling and core bits.

Improved drilling muds.

A wider use of air and gas drilling.

Advancements in formation evaluation and well completion technique, and improved rotary rig performance due to equipment research and product development.

Reducing Drilling Costs in Canada

I would like to briefly discuss three developments that may significantly reduce industry's drilling costs in the near future, slim hole drilling, air drilling, and turbine drilling.

Slim Hole Drilling

A slim hole is defined as one being 6 inches in diameter or less. Slim hole drilling is becoming of increasing importance as new techniques are developed and equipment made that will enable drilling and completion of small diameter holes. One of the problems that industry is trying to solve is how to drill slim holes as fast as full size holes. Investigations have recently shown that with improvements in 5⅝-inch and 6¼-inch drilling bits, this hole size can now be drilled at penetration rates equivalent to 9-inch hole in medium to soft formations. Small diameter holes save casing, mud, cement, and other items. Some wells have been completed with 4½-inch casing or 2⅞-inch tubing as production casing. Some of the wells cased with 2⅞-inch tubing only are pumpers which produce their allowables through hollow sucker rods. These practices have reduced well cost through a materials savings, e.g., there is a 7 per cent saving on a 4½-inch casing completion and 23 per cent on 2⅞-inch tubing as casing completion, based on a 3,500-foot well.

Equipment is currently available that will allow the performance of drilling and completion operations in slim holes equivalent to large size holes. As further techniques and equipment are developed, drilling and well costs may be reduced as much as 35 per cent.

Air Drilling

Industry has been drilling with compressed air or natural gas for over a decade and many economies have been reported in areas where dry formation has been drilled. For example, data from drilling experiments conducted in Pennsylvania where formations are dry to the producing interval, are of particular interest (Figure 3). Convention and jet bit drilling tests with mud circulation are compared with wells where air was used as the circulating medium. Penetration rate in the air-drilled wells was doubled compared with the jet bit test. Footage per bit was increased approximately 52 per cent. There are many other examples such as this, yet the fact remains that after 10 years of drilling with air or natural gas, industry has only been able to penetrate dry formation. Until recently, it was not known why air drilling was successful in penetrating dry formation at higher rates and with increased bit life as compared to mud circulation.

Basic research has been conducted to investigate the effect of overburden pressure, bore hole fluid pressure, formation fluid pressure and bit weight on rock drillability. Rock from the Canadian Plains area has been subjected to pressures ranging from atmospheric to 80,000 pounds per square inch. Results were consistent with other work, in that rock strength was found to increase with pressure although there was no correlation between these increases in strength and actual depth of burial. Investigations have also shown that some materials such as shale and limestone change from a brittle, easily shattered state to a plastic state as the overburden pressure increases. Equipment has been built to investigate the effect of physical changes that occur in rock under pressure on penetration rate at bottom hole conditions. Bore hole fluid pressure was noted to have a profound effect on drilling rate—as pressure increased, drilling rate decreased sharply. The results of laboratory studies were confirmed by field tests when it was shown that an increase of 250 p.s.i. over the hydrostatic pressure in the bore hole decreased drilling rate 65 per cent. Investigations of these types indicated that substantial increases in penetration rate could be made if bore hole pressure could be kept low. Air or natural gas circulation was the logical means of doing this.

From recent field investigations of air drilling operations in Western Canada, there has been developed a technique whereby wet formation can be drilled under certain conditions. This involves the injection of water and/or a surface active agent into the air stream so that air remains the primary phase. The method has been proven applicable to drilling competent formation producing water to the influx rate where there is no longer any penetration rate advantage of air over mud drilling. Industry's study of the air drilling technique is continuing and will continue until a satisfactory method of shutting off formation water is developed. When this is achieved, the full benefit of air drilling will be used by industry to effect greatly reduced drilling costs.

Turbine Drilling

One of the inherent disadvantages of our present system of rotary drilling is the inefficient transmission of power from the surface through several thousand feet of drill pipe to the bit. Up to 90 per cent of the power may be lost in overcoming the friction of the drill pipe on the walls of the hole. Industry has been trying to develop a workable turbo drill for over 50 years. The Russians have been successful in making one following eight years of intensive research (Figure 4). They make the following claims:

(1) A turbine drill has been developed with efficiencies up to 70 per cent.

(2) The drill can deliver three to five times as much power to the bit compared to the rotary system.

(3) Under normal or average drilling conditions, the turbo drill attacks the formation with eight or more times the power of the rotary system.

The turbine drill is essentially a hydraulic motor located in the drilling string just above the bit. A slush pump is the power source which drives the turbo drill. The drilling mud is circulated down through the drill stem and into the turbo drill where it passes through a series of alternate stators and rotors and is discharged in a conventional way through the water courses or nozzles of the bit. The stators are keyed to the outer shell and the rotors are keyed to the inner shaft which is directly connected to the bit. The passage of the drilling fluid through this turbine imparts a turning moment to the inner shaft and a downward vertical force which supplies a part of the weight on the bit for drilling. Additional weight for drilling is supplied by the drill collars.

There is considerable interest in this turbine drill. One company in the United States has imported 40 tools and these are currently being field tested. Future testing, mechanical development and improved economics may establish the turbo drill as a useful spot-type tool to supplement the rotary system, particularly in directional drilling and in drilling hard formation.

I have used slim hole drilling, air drilling, and turbine drilling as examples of the type of research and investigation which the drilling industry is conducting in its efforts to accomplish major well cost reduction.

Conclusions

In conclusion I would like to leave you with a few thoughts about the drilling industry:

(1) Drilling holes in the ground costs a lot of money. The revenue from crude oil and natural gas in Western Canada last year was 414 million dollars. The cost of drilling in Western Canada last year was 268 million dollars. Ratio of expenditure to income was over 60 per cent and represented the principal capital outlay of Canadian petroleum industry.

(2) Seventy-five per cent of the money spent for drilling wells stays in the province where the wells were drilled.

(3) Drilling research and field investigation is continuous in a worldwide industry that seeks technological improvements to achieve major well cost reduction.

(4) Get acquainted with our drilling industry, visit a rig on your next opportunity.

Oil Exploration

(continued from page 1252)

cent of the average daily production. An average gross royalty is approximately 12½ per cent.

As for the lands which revert to the Government after an operator has gone to lease, they are known as Crown Reserves, and may again be put up, all or in part, for the industry to bid for and explore or develop. The idea of the Crown Reserve is that the Government will have a chance of keeping one-half of any oil field that is fouynd, to dispose of such rights on a premium basis, and to date this policy has added materially to government revenues. It may be of interest to point out at this time that the Alberta Government has collected over $600,000,000 by way of royalty, rentals, and cash bonuses since the Leduc discovery ten years ago.

Most of the acreage in Western Canada, apart from remote sections in the Northwest Territories, is now held in reservation or lease form by oil companies, or by the Government as Crown Reserves. As a result there are many companies who do not have sufficient acreage on which to explore. Such companies, along with others who may be interested in exploring someone else's acreage, therefore often make a deal known as a "farmout". In a case of this kind, Company "A" may have the acreage directly from the lessor; Company "B" wishes to earn an interest in "A's" land by undertaking to do certain exploration or development work and possibly paying a cash bonus in addition. There are several types of interests obtained in deals of this kind. A common type of farmout is for "B" to earn a half-interest in certain of "A's" lands for doing certain work. After the half-interest has been earned, both "A" and "B" share jointly in cost and proceeds of development. In another case, "B" may develop "A's" land and pay an overriding gross royalty of 1 per cent of as high as 12 per cent, depending on the value of the acreage. In yet another type of deal, "B" takes over "A's" land and pays all operating costs, sharing net profits on a split basis, with "B" receiving 50 per cent to 75 per cent of the profits, and "A" receiving 25 per cent to 50 per cent. This type of arrangement is known as a "carried interest" deal.

Transportation of Oil

E. C. Hurd, M.E.I.C.
Administration Manager,
Trans Mountain Oil Pipe Line Company, Vancouver, B.C.

Read at the 71st Annual General and Professional Meeting, The Engineering Institute of Canada, Banff, Alta., June, 1957.

In common with the industry in other parts of the world, the Canadian oil producers have the problem of transporting crude and refined petroleum materials over very considerable distances to reach the main consuming markets. The author mentions several means of transport, but concentrates mainly on pipelines.

WHILE THE subject of my talk is transportation of oil, I propose to spend most of my time on pipelines and touch only briefly on the other forms of transportation, not with the idea of making any distinction in importance between the various modes of transportation, but because I am more familiar with pipelines, and because recently pipelines have seemed to become the "fair-haired boy" of the industry or "Peck's bad boy"—depending on who is talking! From the day the oil industry was born on the North American continent, transportation has been an important part of the industry. I shall not reopen the old argument as to whether the industry got its start in South Western Ontario or near Oil City, Pennsylvania, or some other place whose present day inhabitants may make such a claim, but certainly the floating of oil barges down Oil Creek in the early days was transportation—albeit a little nerve wracking and not eminently successful. Since that time advances in technology and know-how of oil transportation have kept pace with developments in the rest of the industry and show every indication of continuing to do so.

Highway transportation has grown from a very modest and what would seem to us now almost ludicrous beginning with horses or mules hauling wagons loaded with wooden casks containing at best a few hundred gallons, to the modern tank trucks that you are all familiar with—sleek, efficient, moving at some stage or other the bulk of the liquid petroleum products consumed on the North American continent.

Railways have always played a major role in transportation of all commodities. This is none the less true of petroleum and its products and in spite of the rapid growth of other forms of transportation in recent years, the railway has, and will continue to have for many years to come, an important place in the industry.

Events leading up to and following the closing of the Suez Canal have placed a great deal of emphasis on oil tankers. Before that time I believe few of us, other than those whose business kept them informed on world oil supplies, realized how much crude oil was moved by water and to what extent the world economy depended on the continuous movement of oil tankers.

For example, toward the end of 1956 there were in operation tankers totalling slightly more than 40 million deadweight tons, excluding the military and the Soviet Union, equivalent in carrying capacity to about 2,400 T2 tankers, each handling about 125,000 barrels of oil. More tankers are in various stages of construction and on order, including a relatively large number (89 at October 1, 1956) of ships larger than 40,000 d.w.t.

The largest built on this continent is the Niarchos tanker *World Beauty* of 42,000 d.w.t. and capable of carrying about 300,000 barrels of crude. The biggest in service so far is the Japanese built *Universe Leader* of 85,000 tons, with a capacity of the order of 600,000 barrels. Further than this, I understand the keel has been laid for a tanker of 103,000 d.w.t. for delivery in 1959.

A few years ago we thought of T2 tankers as big ships. Last fall some of these "big" T2's were used to lighten an 85,000 d.w.t. tanker before she could get into her dock in the San Francisco Bay area.

Figure 1 shows diagrammatically the relative sizes of a T2, a 40,000 d.w.t. tanker, an 85,000 ton ship, a 103,000 d.w.t. tanker and the Queen Elizabeth.

Most of the world's tankers are operating on long term charter, or equivalent, leaving a relatively small number available for the movement of spot cargoes and for short term charter. This makes charter rates extremely sensitive to the law of supply and demand. For example in the last 18 months we have seen rates for dirty tankers (i.e. tankers in crude oil or heavy fuel oil service) increase from 25 per cent under United States Maritime Commission rates in early 1956 to U.S.M.C. + 100 per cent and in one or two cases as high as U.S.M.C. + 200 per cent by early 1957, and then again in the last few weeks drop off to about U.S.M.C. —25 to 35 per cent. Some of the rates that have been reported as being paid over the past few years are shown in Fig. 2.

This feature plus the fact that wherever practical crude oil is moved by ship on a "back-haul", thus enjoying in one way or another the advantage of rates lower than those quoted, makes it virtually impossible to generalize on the quoted tanker rates at which oil from one source will be competitive with oil from a different source.

By way of comparison with figures on pipelines that are familiar to many of you, one ship like the *Universe Leader* carrying 600,000 barrels on a 60 days round trip from the Persian Gulf to San Francisco could handle 10,000 barrels per day (b/d) at a transportation charge (using 100 per cent of U.S.M.C. rates) of about $2.20 per barrel; and we are told that these big ships are designed to operate on a paying basis at rates of the order of U.S.M.C. - 35 per cent. and under certain conditions at even much lower rates.

I will not bore you with the old long-winded story of the first Canadian pipeline carrying whisky from Windsor to Detroit under the Detroit river during prohibition. Suffice it to say that although we have many new pipelines, pipelining is not new in Canada. However it is only in very recent years that this part of the industry has come into its own.

Many of the recent success stories of the Canadian oil industry start with the words, "Upon the discovery of the Leduc field in 1947 . . ." and so on. And though, before this time, there were a number of oil pipelines serving local areas the big push in this branch of the industry did not start until after that time.

Even before Leduc the Montreal pipeline and its connecting carrier Portland pipeline were built to receive tankers of crude at Portland, Maine, for delivery to the large refining centre in Montreal. One important advantage was the saving in ship time as compared with the long

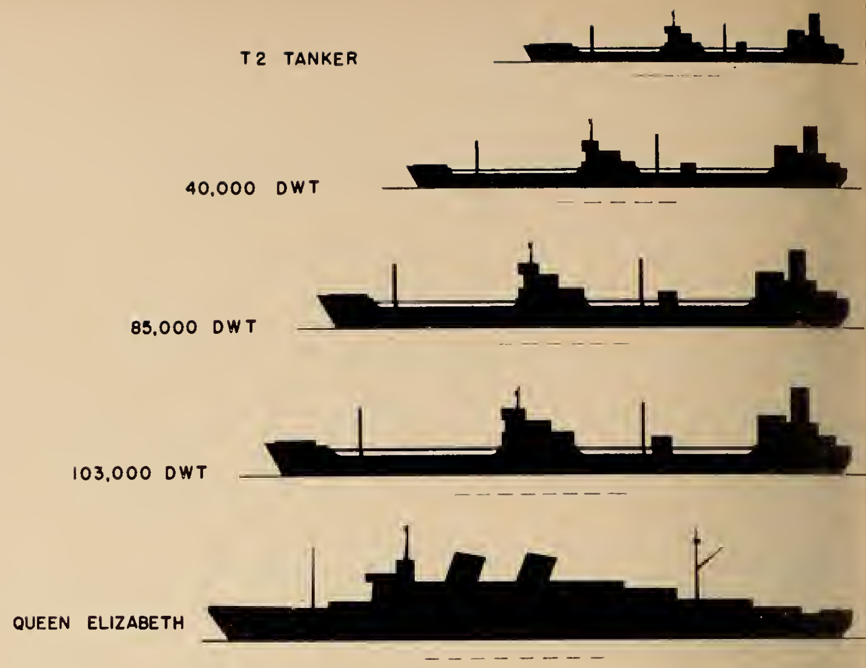

Fig. 1. Comparative tanker sizes.

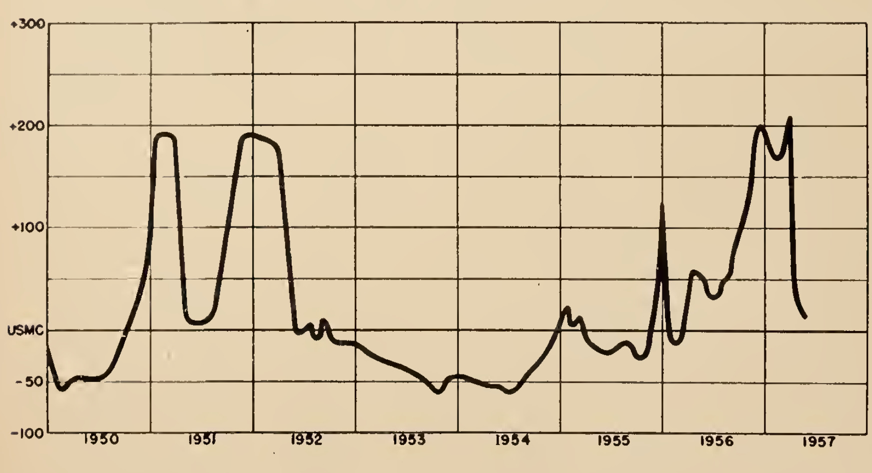
trip up the St. Lawrence river at a time when tankers were in critically short supply. Then too, it provides year-round transportation and eliminates the necessity of building up large inventories of crude in tanks at Montreal sufficient to last over the winter period when the river is closed to navigation. Its original 12-in. line has been completely looped with 18-in. and last year it handled an average of over 200,000 b/d.

Interprovincial Pipe Line Company was formed in 1949 and by the fall of 1950 had completed a line comprised of 20-in., 16-in. and 18-in. pipe from the Redwater field through Edmonton, across Saskatchewan and part of Manitoba to the international boundary near Gretna, Manitoba, and from there by its wholly owned subsidiary, Lakehead,

Fig. 2. Average "paid" tanker rates (dirty).



to Superior, Wisconsin, on Lake Superior. This gave Western Canadian crude oil access to the Ontario mar-
crude oil access to the Ontario market by pipeline to the head of the Great Lakes and thence by tanker.
to navigation almost 5 months out of the year the last leg of this movement was also a summer-time operation. Thus the line was extended with 30-in. pipe from Superior to Sarnia giving year-round transportation to this important refining area. It now comprises 1,774 miles of line from Redwater to Sarnia — the longest single operating oil pipeline in the world. In addition some 1,000 miles of various sized loops have been added as well as connections to the numerous new oil fields in Saskatchewan and Manitoba and delivery connections to the refineries along the way.

The 1957 program calls for additional looping which when constructed will give two complete lines from Regina to Superior, Wisconsin, (24-in. and 16-in. Regina to Gretna, and 18-in. and 26-in. Gretna to Superior) as well as a 156-mile extension of the line from Sarnia to the Port Credit area just west of Toronto. Who knows, maybe the next leg will reach Montreal. Throughput in 1956 averaged 266,000 b/d for a total of a little over 97 million barrels.

Trans Mountain, incorporated in 1951 and in operation in late 1953 with a 24-in. line from Edmonton to Burnaby, near Vancouver, and an initial design capacity of 75,000 b/d,

·hich was increased to 120,000 b/d efore the original construction was omplete, afforded the first outlet for Canadian crude to the west coast.

In the case of both of these companies, expenditures of nearly $100,000,000 each were made at a time when there was no guarantee that nough oil would be shipped through e lines to pay direct operating expenses, let alone amortization of the nvestment and a reasonable return the shareholders. Such courageous lanning, sparked by a firm belief the future of Alberta crude oil roduction in particular, and the Canadian oil industry in general, has placed across Canada the backbone of transportation for what is now one of its largest industries.

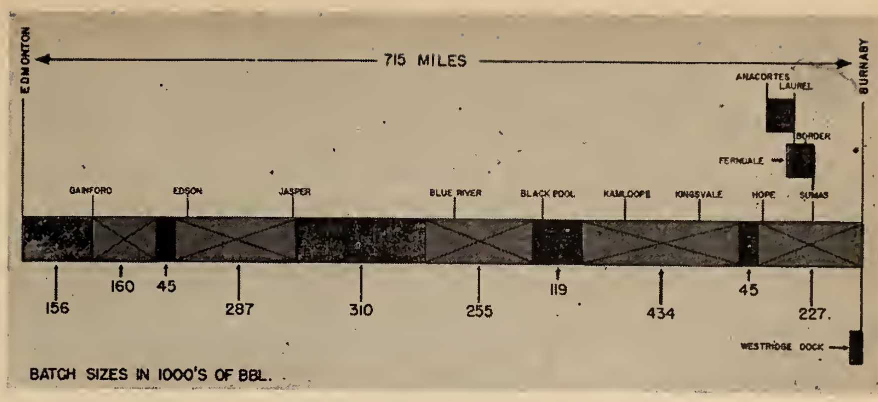


Fig. 3. Batch sheet.

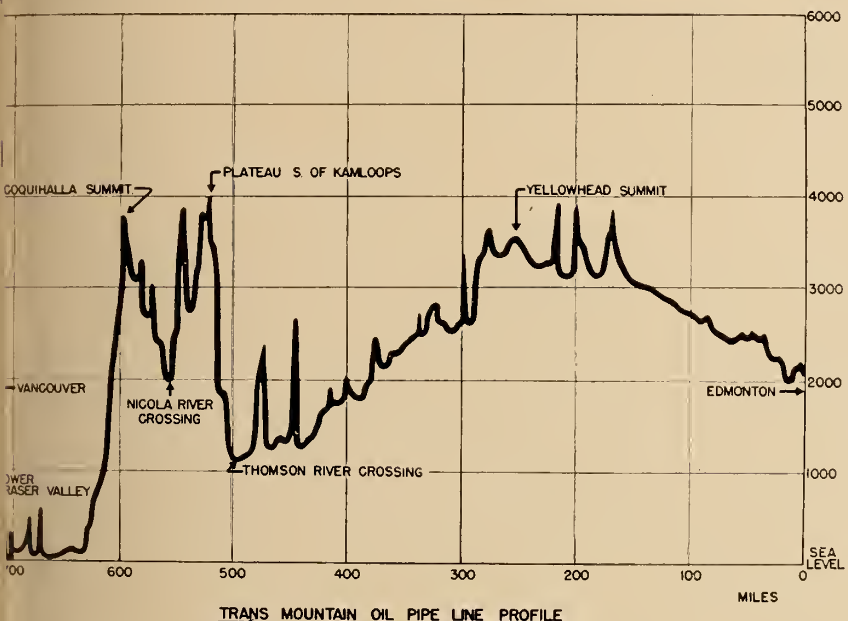

Fig. 5. Hydraulic gradient at 75,000 b/d.

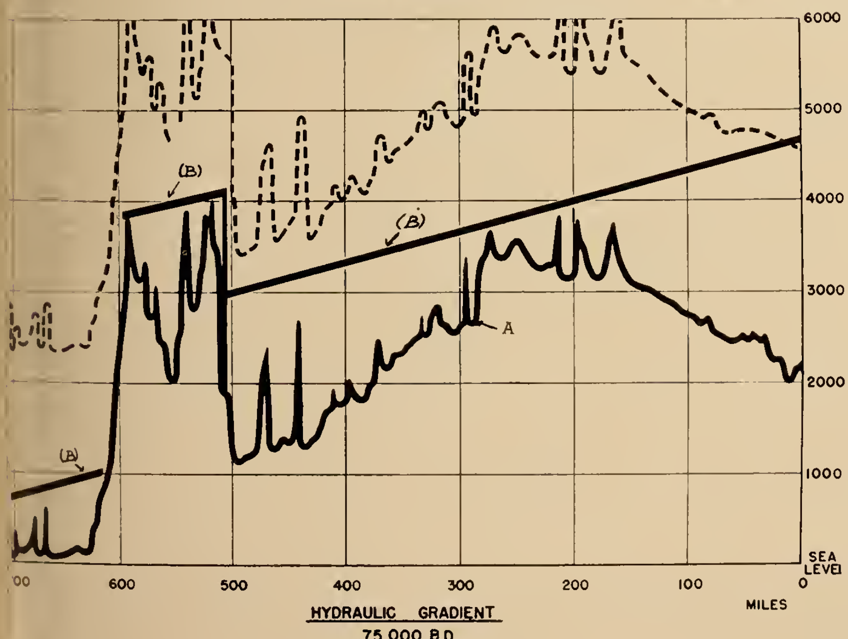
Fig. 5. Hydraulic gradient at 74,000 b/d.



Trans Mountain's growth, while not so great in miles of line, has been just as spectacular in terms of quantity of oil transported. The line was extended to two new refineries in the State of Washington and on January 1, 1956, the first of a long line of tankers was loaded with Alberta crude for delivery to California. During the year a couple of spot cargoes were even loaded for Japan and France. An expansion program now under way will bring the capacity of 240,000 b/d by late summer of 1957, and possibly to 300,000 b/d by next year. Potential ultimate capacity is well beyond this figure. Deliveries in 1956 totalled 47,250,000 barrels for an average of 129,000 b/d.

In the first quarter of 1957 these two lines delivered an average of 440,000 b/d, a quantity equal to the daily consumption of all the refineries in Canada at the end of 1953.

No less important than these east and west trunk lines are the gathering systems and shorter trunk lines which feed them.

Each trunk line has a few problems unique to its own terrain and climate, but most of the engineering and operating features are common to all trunk lines, so if I deal with the Trans Mountain system from here on it is because it is the one I am most familiar with and in any case the salient features will be the same.

The oil is delivered into a Trans Mountain tank in Edmonton, which has previously been jointly gauged, and when the delivery is completed the tank is again gauged and sampled jointly by representatives of the delivering carrier and Trans Mountain. From certified tank capacity tables the quantity received into the tank is calculated, corrected for temperature and water and sediment and this information is recorded on a "run ticket" witnessed by both representatives.

This run ticket then becomes the legal document, not only for the payment of transportation charges from the field to Edmonton, but also for the transfer of custody of the oil from one company to another.

At the appropriate time in the pumping schedule this tank is opened to the suction side of the electric-motor-driven booster pumps which send it on through heat exchangers to the suction side of the main station pumps, driven through speed-increasers by 500 r.p.m., 2,000 h.p., 8-cylinder, gas-fired diesel engines. The engine jacket water is cooled by being circulated through the other side of the heat exchangers.

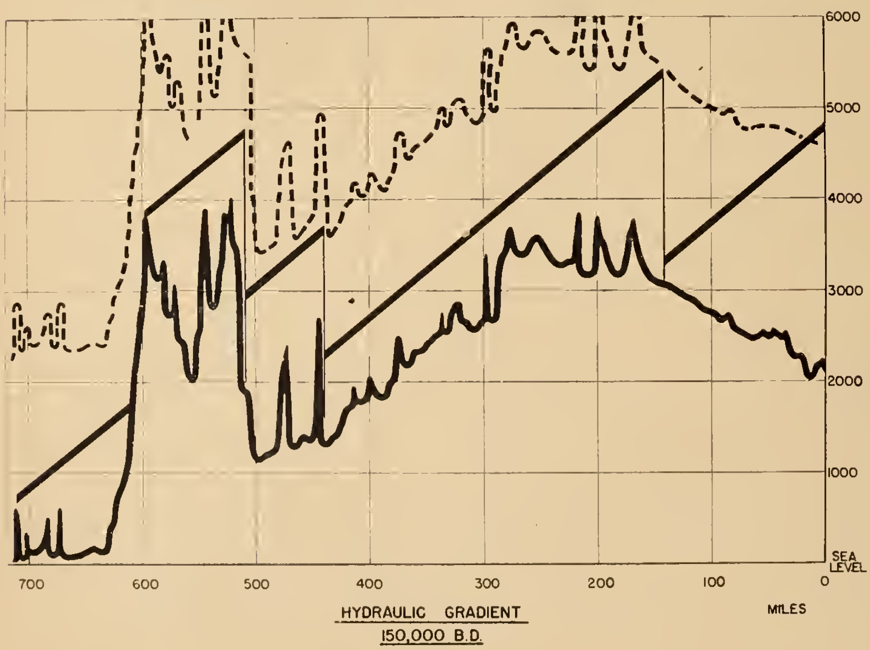
In the Edmonton station the four pumps are 5-stage centrifugal, run in parallel, each capable of pumping 75,000 b/d at a discharge pressure of about 1,100 psi. The station is normally operated on automatic flow control with instruments provided for apportioning the hydraulic load equally amongst all of the operating units as well as overriding alarm and shutdown devices to protect against too high discharge or too low suction pressures. Protective devices are also provided against such faults as low lubricating oil pressure, high pump-case temperature and overheated bearings. The discharge pressure required for the desired flow rate is dependent on the viscosity of the oil at its flowing temperature, the size and length of line to the next station (hence the friction loss), the difference in elevation between the two stations, and the suction head to be overcome at the next station.

Trans Mountain started operating with tanks "floating on the line". That is, one station pumps into open storage tanks at the next station and that station takes suction from these tanks and so on. However this was soon changed to operation on "tight line" where the upstream station pumps directly to the suction side of the following station. This requires more elaborate control equipment but the advantages are many; the oil is kept inside the pipe instead of being admitted into tanks, so evaporation losses are reduced; the mixing of one type of crude with another in the tanks is eliminated; and, by adjusting up or down the suction pressure of an intermediate station, a substantial portion of the hydraulic load can be transferred from one pump station to another.

The oil is pumped on, from one station to another, finally arriving in one of the stock tanks at the terminal on Burnaby Mountain some 500-600 feet above sea level. Here deliveries are made to one of the three connected refineries through their own 10-in. and 12-in. pipelines, or through a 24-in. line to ships at the Westridge Dock in Vancouver Harbour. Because of the differences in elevation all these deliveries can be made by gravity. The tanks are provided with individual lines to a central manifold so that the main line stream can be received, and deliveries can be made to three refineries and one ship all at the same time. As before, the oil in a tank is gauged and a representative sample is tested by both interested parties and run tickets made out covering the transfer of custody of the oil. You will notice that I have not said that oil is bought and

Fig. 6. Hydraulic gradient at 120,000 b/d.

Fig. 7. Hydraulic gradient at 150,000 b/d.



sold on the basis of these tickets. Except for a small amount of "allowance" oil as provided by the tariff all the oil in the system is owned by the various shippers and is only in the custody of the carrier.

As in Edmonton the tanks are all provided with automatic gauging devices with remote instruments, reading to the nearest ⅛-in. located in the control room. With proper installation and maintenance these remote reading gauges are as accurate as hand gauging but so far have not been generally accepted for custody transfer purposes.

Positive displacement meters, on the other hand, have been the subject of extensive study for a long time by a special sub-committee of the American Petroleum Institute and their use for this purpose is growing steadily.

So far we have been talking about crude oil moving through the pipeline without reference to what kind of oil it is. Actually most trunk lines handle several types of crude oil and if a description of the job that a crude oil pipeline is expected to do had to be put into a few words it would probably be, "to get the right amount of the right kind of crude to the right place at the right time". This is where the dispatcher comes in.
