He is in almost constant contact with representatives of the shippers. About a week before the end of each month they tell him, by grades and consignees, how much oil they wish delivered during the following month.

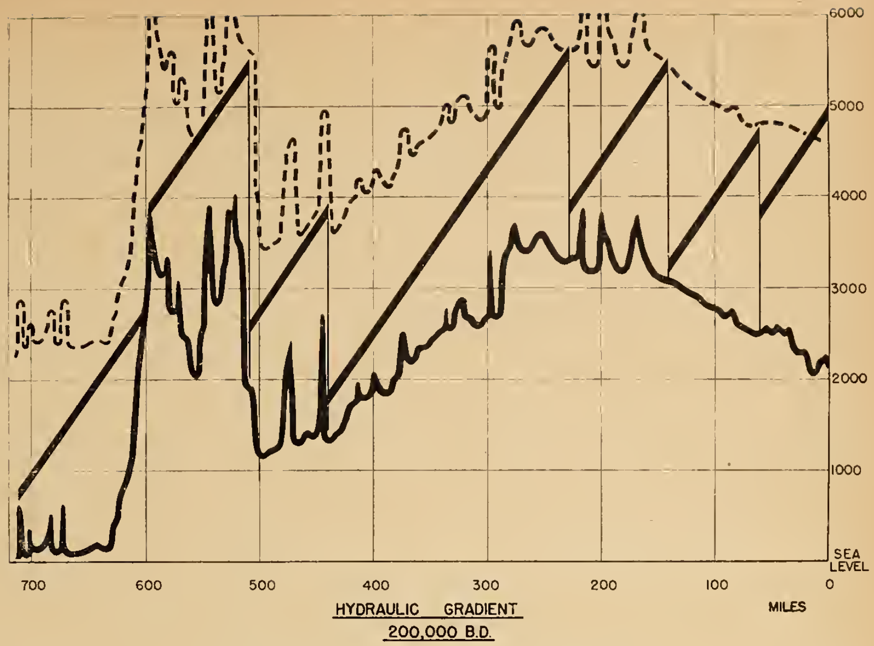

Fig. 8. Hydraulic gradient at 200,000 b/d.

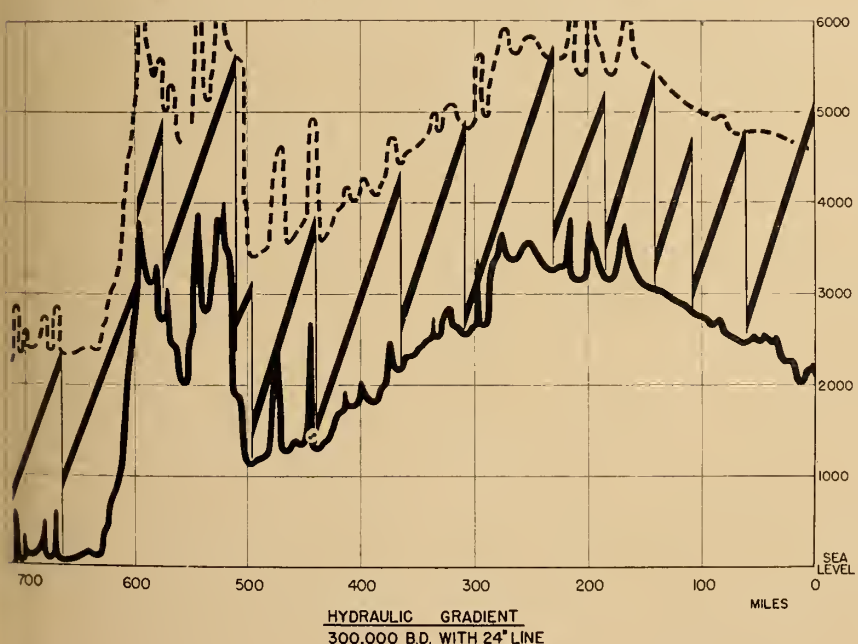
With this information from all the shippers he works out his pumping schedule. It is a rather complicated and lengthy job, but once he has it worked out all he has to do is lean back and watch it run for a month. That is what he tells himself is going to happen some day—if he lives long enough! However, in practice, just about the time he gets it all worked out something happens—a refinery has an unscheduled shutdown (I understand that does happen sometimes) or it wants to run an extra 10,000 barrels per day (we like that much better), or there is a road ban and the gaugers can't get to the batteries in a particular field so we are short of that kind of oil—and the whole schedule has to be worked over again. So if you meet one of these dispatchers and he is talking to himself, don't worry about it, it is just one of the occupational hazards.

Figure 3 shows a typical arrangement of batches of different oils in the line from Edmonton to Burnaby. The 24-in., 715-mile line shown contains a total of a little over 2,000,000 barrels of oil.

Fig. 9. Hydraulic gradient at 300,000 b/d with 24-in. line.



We are often asked, "How do you keep the different oils separate What do you put between the batches to keep them from mixing?" The answer, of course, is: nothing. As long as the velocity is high enough to be well within the range of turbulent flow, the turbulent front is quite resistant to mixing. The velocity at which the flow changes from "stream line" to "turbulent" varies with the viscosity of the oil at flowing temperature. An average condition in Trans Mountain's 24-in. line would give turbulent flow above a velocity of about 0.4 f.p.s. equivalent to a pumping rate of 18,000 b/d. At this rate, or higher, and with normal batch sizes the adverse mixing of adjoining batches is as little as 0.5 to 0.7 per cent.

Since the cost of the pipe itself is a major portion of the cost of building a pipeline the choice of material for the pipe is most important. It must have a uniform wall thickness, it must be readily weldable and it must have as high a yield strength as practical to allow minimum thickness that will be safe for the designed operating pressures. For instance, at today's prices an extra ⅛ in. in thickness on a 24-in. line adds about $25,000 per mile to the cost of the pipe.

The pipe most commonly used for oil trunk lines today is API 5LX, Grade X52. This is manufactured by forming steel plate and welding in the normal way and then cold expanding which raises the yield strength of the steel from about 40,000 psi. to 52,000 psi. This type of manufacture necessitates special welding technique but this disadvantage is far outweighed by the cost advantage of the thinner wall pipe.

Many features of pipelining are similar to those of process industries but two things stand out, particularly, as being different from an engineering standpoint. For one thing it is normal in a pipeline to allow pressures which will stress the pipe steel up to 65 per cent of its yield strength whereas in refineries, for instance, factors of safety of 5 to 1 or even higher are normal. The other point is that, in most process industries, differences in elevation between parts of the plant are not significant in designing for pipe strength. A look at the profile of Trans Mountain's main line will illustrate the magnitude of the effect of elevation on pipeline design. (Fig. 4).

Starting at Edmonton at an elevation of 2,300 feet the line climbs more or less gradually to Jasper and the Yellowhead pass at 3,700 feet, then hits a low point of 1,100 feet under the Thompson river at Kamloops. In a very few miles out of Kamloops it climbs again to nearly 4,000 feet, down again to 1,800 feet under the Nicola river and reaches the final high point at the top of Coquihalla pass at an elevation of 3,700 feet. From here it drops, in less than 30 miles to within 100 feet of sea level in the lower Fraser Valley and finally up to 500-600 feet at the Burnaby terminal.

With the line standing full of oil and not flowing the static head difference between, for instance, the top of Coquihalla canyon and the Lower Fraser Valley is about 3,600 feet, equivalent to 1,300 psi., with proportionate static head differences elsewhere on the line.

However the line is not making any money while it is just standing there full of oil so let us have a look at it under flowing conditions. The original design contemplated a capacity of 75,000 b/d when pumping Redwater crude at 40 deg. F., that is, oil of 0.85 specific gravity and a viscosity of 115 S.S.U. Two pump stations are required, one at Edmonton, of course, and one at Kamloops (Fig. 5). The scale on this chart is proportional to 20 miles per inch horizontally and 500 feet per inch vertically, and the profile has, of course, been greatly oversimplified. The solid line (A) is the profile of the pipe. The dotted line at the top is the pipe strength curve, the difference between these two lines representing, in terms of feet of head, the allowable stress in the pipe at any point. The line (B) is the hydraulic gradient when flow is at the rate of 75,000 b/d. This represents a friction loss of 3.4 feet of oil or 1.23 psi., per mile.

In order for the oil to flow at this rate the hydraulic gradient must be above the pipe profile and to be safe it must be below the pipe strength curve. So what do we have to do to raise the rate up to, say, 120,000 b/d? At this rate the friction loss is 7.4 feet per mile, the hydraulic gradient is steeper and it will not reach from Edmonton to Kamloops without exceeding the strength of the pipe. So we put in a station at Edson, and the gradient is as shown in Fig. 6. A rate of 150,000 b/d requires one more station at Blackpool. (Fig. 7), and 200,000 b/d calls for two additional stations at Gainford and at Jasper. (Fig. 8). By this time the friction loss has climbed to 18.3 feet per mile.

To go from a capacity of 200,000 b/d (which is Trans Mountain's present situation) to 300,000 b/d by the addition of stations alone would require the installation of seven more stations (Fig. 9). This is about the practical limit of gaining extra capacity on a 24-in. line by the addition of pumping stations alone and if 300,000 b/d were considered to be the ultimate need of the line this would be quite a practical course to follow.

If, however, capacities beyond 300,000 b/d are foreseen, then weighing the higher capital cost of looping against the higher operating cost of numerous stations indicates that the more practical approach is to start looping the line. Again using Trans Mountain as an example, that is the approach taken this year whereby the installation of two 50-mile loops of 30-in. pipe, and one permanent and three temporary stations, will increase the capacity to 240,000 b/d by August of this year. The addition of another 175 miles of 30-in. pipe next year, and the retirement of the temporary stations could raise the capacity, if needed to 300,000 b/d (Fig. 10), and if carried through eventually to complete new 30-in. line from end to end would raise this to over 600,000 b/d

(continued on page 1272)

Gathering and Processing Natural Gas

J. M. Dillon

Manager, Gas Department,
Shell Oil Company of Canada Limited, Calgary, Alberta.

Read at the 71st Annual General and Professional Meeting, The Engineering Institute of Canada, Banff, Alta., June, 1957.

NATURAL GASES are mixtures of organic compounds, principally hydrocarbons, and may contain inorganic constituents such as nitrogen, hydrogen sulphide, carbon dioxide and water. A feature of a typical high pressure gas field is the production of light oil, or condensate, together with relatively large volumes of gas. The major component of the gaseous phase is normally methane, the lightest of the paraffin hydrocarbons, with the heavier hydrocarbons and inorganic gases being present in lesser quantities. Propane and heavier hydrocarbons are condensable at moderate pressures and normal temperature and are designated as condensables or volatile products of natural gas. Propane and butane are well known as fuels and the pentanes and heavier fractions form natural gasoline. Carbon dioxide and hydrogen sulphide are acidic gases and if present in appreciable quantities the natural gas is classified as sour.

Analyses of gas from Alberta fields are presented by Table I. Contents are expressed in mol % which is equivalent to volume % for gases and, for the condensable hydrocarbons, in Imperial gallons per 1000 cubic feet. The analyses are for separator vent gas; that is the liquid hydrocarbons or condensate have been removed by physical separation. Gas "A" is rich in volatiles. It is theroretically possible, although uneconomic, to extract a total of 1.43 gallons of volatiles from 1000 cubic feet of the gas. This is sweet gas as there is no hydrogen sulphide present and only a nominal amount of carbon dioxide. Gas reserves of similar composition are the Viking-Kinsella, Cessford, and Medicine Hat fields in Alberta. Analysis "B" is also representative of many large reserves in Western Canada. This gas is lean, containing only one third as much volatiles as "A", and is sour as 3.1% hydrogen sulphide and 6.1% carbon dioxide are present.

Type "C" contains both more volatiles and acid gases than does type "B" gas. Very large reserves of similar composition have been discovered in Alberta; for example Pincher Creek. Gas "D" is very lean, containing only 0.15 gallons of volatiles per 1000 cubic feet, and extremely sour. Such high contents of hydrogen sulphide had been rarely encountered throughout the world before the discovery of substantial reserves of such gas in the Calgary district. Accumulations of gas of type "D" represent large reserves of sulphur as hydrogen sulphide.

Most raw natural gas requires processing prior to sale to remove impurities and to recover valuable by-products. Gas and associated liquids are brought to a central plant by means of common or "two phase" gathering lines. Liquids are separated from the gas and then the gas is processed to remove sulphur compounds, carbon dioxide, volatiles and water. Sulphur is a by-product.

Field Gathering

High pressure gas-condensate reserves are the chief source of supply for large scale gas pipeline projects. Condensate is produced with the gas and provisions must be made to collect this valuable product for marketing. Current practice is to utilize common or two-phase gathering lines to bring gas and condensate from the wells to a central point for separation and processing. By centralizing condensate separation, storage and shipping facilities investment and operating labour costs are less than if individual separators and storage tanks were provided at each wellhead. However, before a two-phase gathering system can be employed the field operators and royalty owners must agree to operate the field as a unit.

Hydrate formation and plugging of lines and equipment is the major problem associated with the operation of high pressure field gathering lines. Natural gas hydrates are crystalline compounds of light hydrocarbons with water and look like firm snow or can be in the form of transparent ice crystals. Hydrates may form at temperatures above the freezing point of water, the critical temperature depending upon the gas composition and pressure. Formation of hydrates is promoted by turbulence occurring at pipe fittings, bends and changes in line size. Conditions at flow restrictions are favourable for hydrate formation because as a result of expansion the gas may be cooled below the critical temperature. Hydrates accumulate in line restrictions or slopes and eventually may form a solid plug. Variation of critical temperature with pressure and gas composition is illustrated by Fig. 1. Inspection of these typical curves reveals that the critical temperature increases with pressure. Curve I is for pure methane whereas Curve II is for a gas containing heavier hydrocarbons. Generally speaking, the critical temperature is higher for richer gas. Curves such as these can be used to predict hydrate formation for design purposes.

Hydrate formation is combated by dehydration, heating or inhibition. Dehydration of the gas so that the dewpoint is lower than any temperature encountered in the gathering system will avoid condensation of water and thus eliminate hydrates as liquid water must be present for hydrates to form. Heating may be used to keep the temperature above the critical temperature. Inhibitors such as alcohol depress the critical temperature and will melt hydrates which have already formed. Curve III of Fig. 1 is a plot of critical temperatures for the same gas as the Curve II but inhibited with a 10% aqueous solution of methanol. Comparison of the two curves shows that the critical temperature for this particular gas has been lowered by 8°F. Inhibition is normally used only in emergencies to melt hydrate plugs but, if adopted for continuous use, glycol is usually the inhibitor used since the glycol can be recovered and used again. In most cases either dehydration or heating are more economical than inhibition.

The most certain method of eliminating the hydrate problem is to dehydrate the gas. This may be done by passing the gas through a vessel containing a bed of solid desiccant, e.g., silica gel, or by contacting the gas with glycol in a bubble-plate column. Heating is also an effective method of hydrate prevention in field gathering systems where gas is transported short distances. In a typical operation the gas is heated prior to throttling from wellhead to line pressure and the main gas stream flowing through the gathering line is reheated at each well to compensate for heat losses in the line. The danger of hydrates forming is most serious during the winter as the ground temperature at the depth at which the gathering lines are buried may be as low as 30°F., about 40°F. below the critical temperature. Sufficient heat must be added at each well so that the gas is still above the critical temperature by the time the next line heater is reached. The line heaters are indirect-fired with coils immersed in a water bath.

Lines are usually buried with 3 feet of earth cover for physical protection and thermal insulation. For protection against external corrosion, the pipe is wrapped with glass fibre cloth and coated with enamel or, alternatively, wrapped with adhesive plastic tape. Recent practice is to guard against corrosion at defects which invariably develop in the coating by cathodic protection using rectifiers or sacrificial anodes. Vaults are provided at one-mile intervals to permit isolation of sections and access to the line for testing, cleaning, and inspection. River crossings are made by means of suspension spans or by weighting the pipe and laying it in a trench in the river bed.

At a central point in the field, usually at the processing plant, the condensate is separated from the gas. The condensate may be sent directl to storage or first processed to remove the more volatile or "wild" fractions. Except in rare cases the raw gas from the separators must be processed before sale.

Liquid flow in a two-phase system is erratic because liquids may accumulate in line depressions and periodically carry over or "slug" into the central separation station. Liquid flow characteristics change abruptly with minor variations in gas rates making slugging a serious problem when flow rates are being adjusted. To avoid carry-over of condensate into the gas processing plant it is necessary to install oversize separators to handle sudden surges of liquids. Separators are often of the double - barrelled type (Fig. 2). Liquids and entrained mist are separated from the gas in the upper barrel and accumulate in the smaller lower barrel.

Reasons for Processing Gas

Distributors require natural gas of a certain quality for trouble-free op

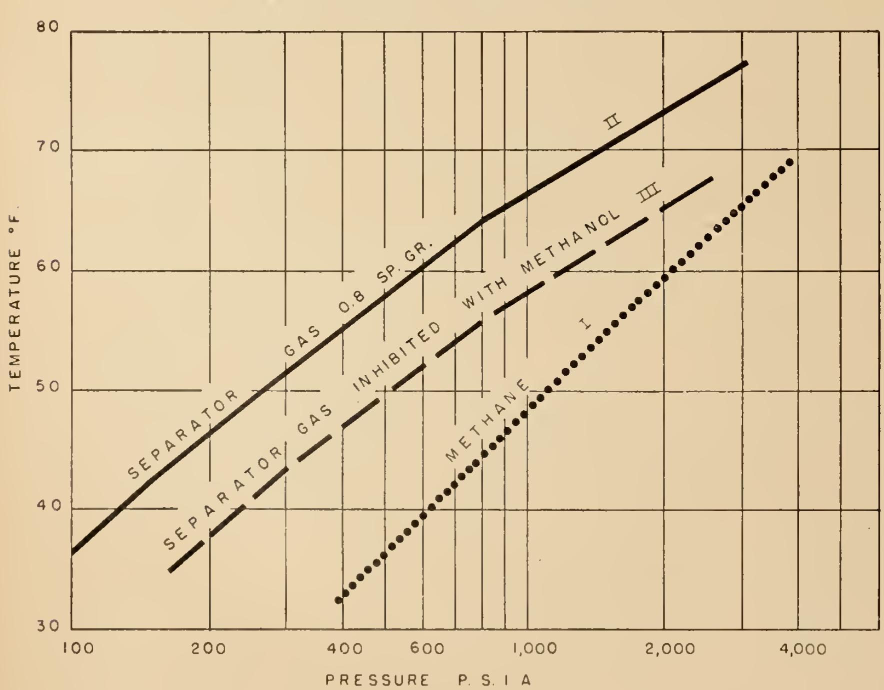
Fig. 1. Gas hydrate equilibrium curves.



eration of their own systems and to ensure the consumers of a continuous supply of uniform performance fuel. Contracts between the distributor and producer set strict limits on the composition and properties of the gas and the majority of reserves require processing to meet these contract terms. A typical gas contract specifies a maximum hydrogen sulphide content of 1 grain per 100 cubic feet, minimum heating value of 1000 B.t.u. per cubic foot, and hydrocarbon and water dewpoints of not more than 15°F. at 800-900 psig. The reasons for the restrictions of hydrogen sulphide are that: this gas is toxic; sulphur dioxide is formed when the gas is burned, producing a disagreeable odour; and hydrogen sulphide is corrosive to pipelines and associated equipment. Minimum heating value is specified to restrict the content of non-combustible gases such as nitrogen and thereby limit the size of lines and compressors needed to transport energy at a given rate. Low hydrocarbon and water dewpoints are required to avoid condensation in pipelines. Presence of liquids increases pressure drop and consequently reduces the capacity of the lines. Water contributes to internal corrosion of pipe. Condensed liquids could accumulate in pipelines and distribution systems, periodically carrying over into pipeline compressors and consumers' heating equipment with serious consequences.

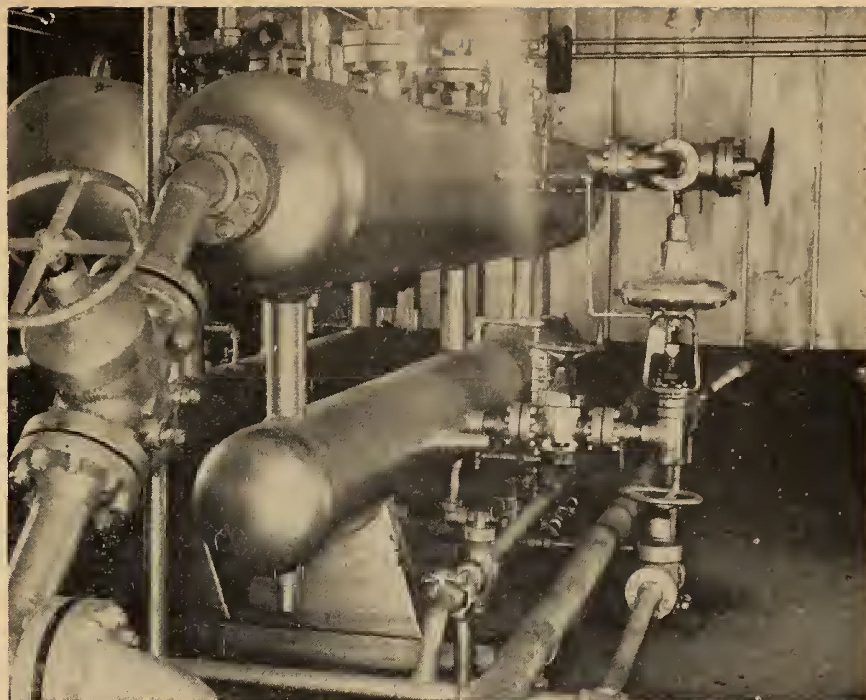


Fig. 2. Plant inlet separator.

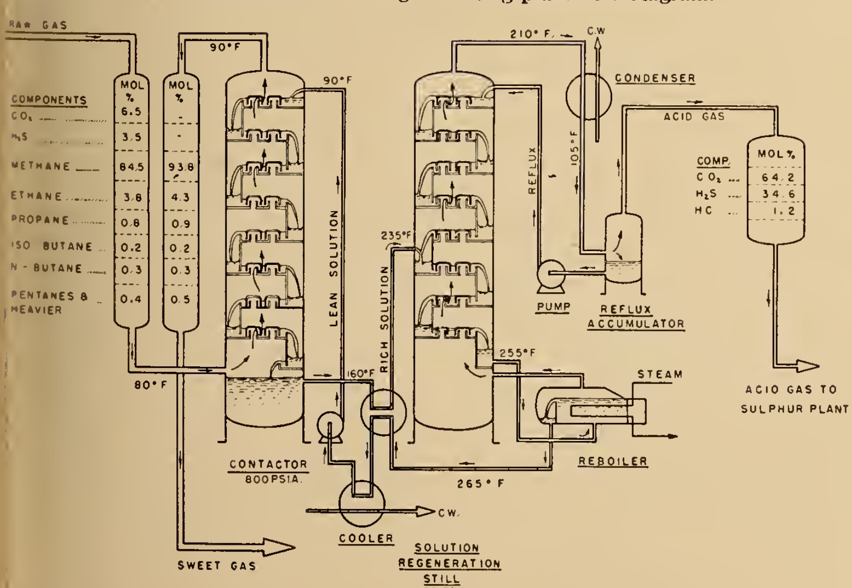
Processing

Since gas reserves in Western Canada are predominantly sour, the operations required to condition a sour gas for sale will be described. Only the salient features of the most widely used gas plant operations will be dealt with as a detailed discussion of the processes involved is beyond the scope of this paper. To meet sales contract specifications gas must be processed to remove hydrogen sulphide (desulphurization), carbon dioxide, volatiles and water. A typical plant would consist of the following process units: treating plant, for desulphurization of the gas; absorption plants where volatiles are extracted; dehydration, where water vapour is removed; and a sulphur plant for recovery of elemental sulphur from the acid gases removed from the raw gas by the treating unit.

Fig. 3. Monoethanolamine gas treating plant flow diagram.



Desulphurization

The most frequently used method of desulphurizing gas on a large scale is to contact the gas with an aqueous solution of monoethanolamine. This process incidentally removes carbon dioxide as well as hydrogen sulphide and thus elminates both acidic constituents in one operation. This is a most important advantage should the gas contain an appreciable volume of carbon dioxide, as removal of this non-combustible gas upgrades the heating value. The process is continuous and regenerative making it possible profitably to exploit large sour reserves which otherwise would be of little value.

Purification or "sweetening" of the gas occurs in a bubble-cap tray column contacted at each tray by a countercurrent flow of monoethanolamine or "amine" solution. The representation of the column is simplified; in practice about 20 trays each equipped with several rows of bubble caps are used. The bubble caps force the gas to bubble through the solution flowing across the trays, effecting intimate contact with the solution at each tray. The hydrogen sulphide and carbon dioxide chemically react with the amine to form compounds which stay in solution and leave the bottom of the contactor in the rich solution. The reaction between the amine and acid gases liberates heat and thus the outlet temperature of the rich solution is higher than that of the entering lean solution.

A 20% by weight amine solution is usually used and the circulation rate is maintained at 2-3 mols of amine per mol of acid gas. For gas of the analysis shown in Fig. 3 the solution circulation rate would be about 25,000 Imperial gallons per million cubic feet of raw gas. When the solution to acid-gas ratio is 2:1 or higher virtually all of the hydrogen sulphide and carbon dioxide are removed.

The rich solution containing the acid gases in compound forms is regenerated by a continuous process and re-cycled to the contactor. Regeneration is accomplished by heating the solution which reverses the absorption reactions and releases the hydrogen sulphide and carbon dioxide. The operation is performed at low pressure in a still equipped with bubble-cap trays or ceramic packing. Before entering the still the solution is heated to 240°F. by exchange with the hot regenerated solution leaving the bottom of the column.

The hot rich solution is introduced about half-way up the column and as it descends is stripped of acid gases by a countercurrent flow of hot vapour. Evolved acid gases and water vapour leave the top of the still and are cooled to condense most of the water vapour. The condensed water is separated from the acid gas and refluxed to the top section of the still to knock down amine vapour and keep losses of this valuable chemical to a minimum. Acid gases from the reflux accumulator vessel are fed to a sulphur recovery plant. Stripping vapours are generated by boiling the lean solution from the bottom of the column in a kettle type reboiler equipped with a steam tube-bundle. The still is operated at low pressure to improve stripping and to permit boiling of the solution at a low temperature. A low boiling temperature is desirable to reduce corrosion and to avoid decomposition of the monoethanolamine which becomes unstable at temperatures much above 400°F. The hot lean solution is exchanged with the rich solution, then cooled to 90°F. and pumped back to the contactor.

Corrosion is the most serious problem connected with the operation of an amine gas treating plant. Attack is particularly severe in the reboiler; reboiler tube-bundles have failed after less than a year of service. Most operators have adopted the use of plain carbon steel as the most economical material for amine service. High-chrome alloys have given excellent service but the initial cost of these alloys is very high. Low-chrome alloys fail to give much longer service than carbon steel.

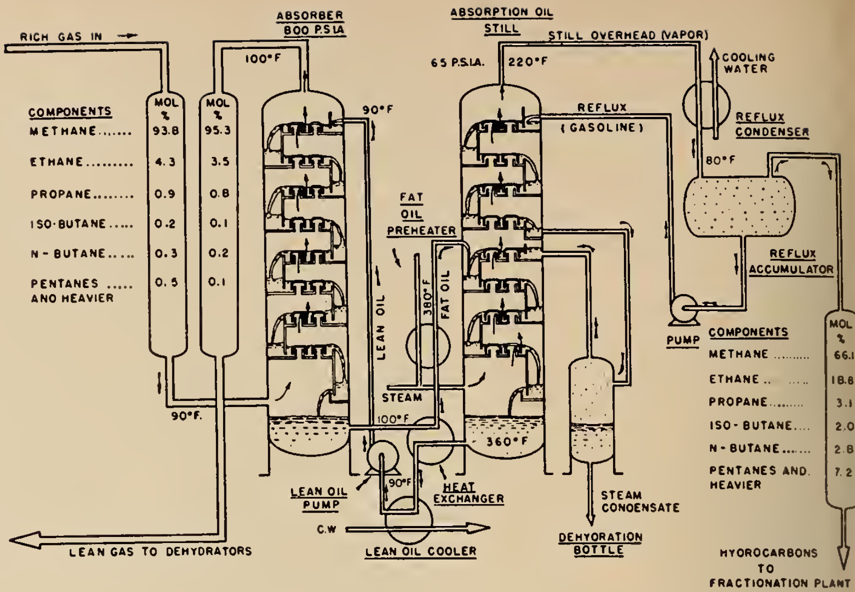


Fig. 4. Absorption plant flow diagram.

The next most serious problem encountered is the accumulation of corrosion products, iron sulphide, and amine degradation products in the system. When the concentration of these products is allowed to build up the solution exhibits severe foaming characteristics and it is necessary to reduce gas throughput to avoid upsetting the process and passing sour gas. Foaming also leads to high losses of solution in the sweet gas leaving the top of the contactor. The concentration of corrosion and amine degradation products in most plants is controlled by continuous filtration and distillation of slip-streams of the solution.

Volatiles Extraction

Condensable hydrocarbons, or volatiles, are removed from the gas to meet gas sales contract dewpoint specifications and to obtain revenue from the sale of propane, butane, and gasoline. There are two methods of extracting volatiles from the rich gas; absorption with light oil and refrigeration. Absorption is favoured for large operations and high recovery, whereas refrigeration is best suited for small installations.

Absorption

Figure 4 is a simplified flow diagram of an absorption plant. The rich sweet gas from the amine plant is passed through an absorption column to remove a portion of the heavy hydrocarbons. As the gas flows up the bubble-cap tray column it is contacted by a countercurrent flow of light oil similar to diesel fuel. By their affinity for the lean oil some of the volatiles are dissolved and leave the bottom of the absorber with the effluent rich oil stream. Absorption is a selective process yielding very high recovery of the heavier hydrocarbons present in the rich gas while only a small fraction of the lightest hydrocarbon, methane, is absorbed. The lean oil circulation required to extract a certain fraction of the volatiles from the rieh gas varies widely depending upon the richness of the gas and the operating pressure of the absorber For the particular gas and recovery of Fig. 4, the lean oil rate would be of the order of 3 gal. per 1000 cu. ft. of gas.

The absorbed hydrocarbons are removed from the rich oil by heating and then stripping the oil with steam at low pressure in a still, again a bubble-plate eolumn. The oil is heated to 380° F. by exchange with the hot lean oil from the bottom of the still and finally by means of high pressure steam in heat exchangers Then the hot lean oil is passed into the absorption oil still at mid-heigh where the volatiles are stripped ou of the oil by blowing steam up through the oil on the trays as it flow down the column. The hot hydrc carbon vapours stripped out of th rich oil leave the top of the stil are condensed and a portion refluxe to the top of the still to knock down vaporized absorption oil and thus reduce oil losses from the system. The rest of the volatiles are separated by fractional distillation into the liquid products desired; i.e. propane, butane, and gasoline. Stripping steam which condenses in the upper section of the still is decanted from the reflux stream in a dehydration bottle. The hot lean oil from the bottom of the still is cooled and re-cycled to the top of the absorber. Stripping is improved by operating the still at low pressure, in this case 60 psig.; however, the still pressure must be high enough to permit condensation of the overhead vapours with cooling water, otherwise refrigeration would be required. The absorption plant shown in Fig. 4 is a schematic representation only, as certain details have been omitted to simplify the description.

Refrigeration

Although less efficient than absorption, refrigeration is a simpler method for removing hydrocarbons from the rich gas. The rich gas is chilled to a temperature lower than the required dewpoint temperature and the condensed hydrocarbons separated from the gas. At the same time water is condensed, and thus there is no need for a further dehydration step as is the case when absorption is used to extract volatiles. Arrangement of a typical unit is shown by Fig. 5. Glycol is injected into the rich gas stream ahead of the refrigeration unit to prevent hydrates from forming which would otherwise result because of the presence of liquid water and the low temperature. The rich gas stream is cooled by exchange with the lean gas and finally cooled to 5°F. by passing through coils immersed in liquid refrigerant in the chiller. The condensed hydrocarbons, water and glycol inhibitor are separated from the gas and the lean residue heat-exchanged with the incoming gas. The water - glycol mixture is mechanically separated from the condensed hydrocarbons and distilled to concentrate the glycol for re-use. A conventional compression - expansion refrigeration cycle is used with ammonia or propane as the refrigerant.

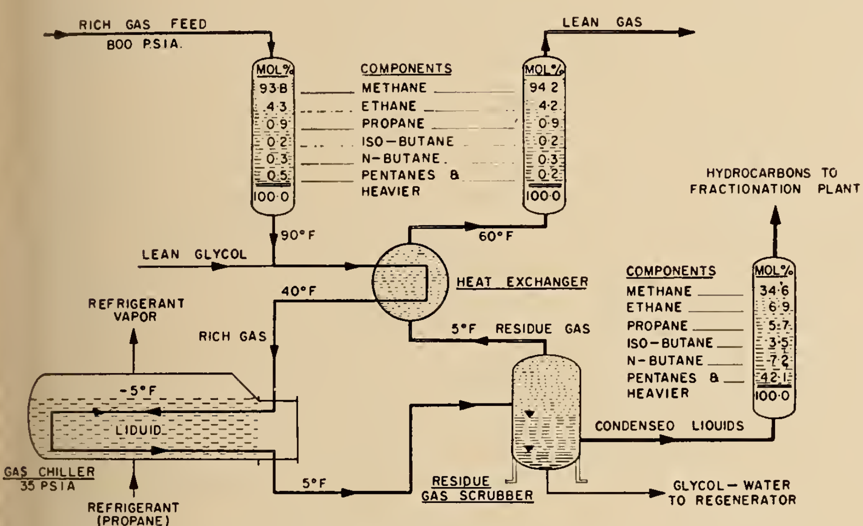

Fig. 5. Gas refrigeration plant flow diagram.

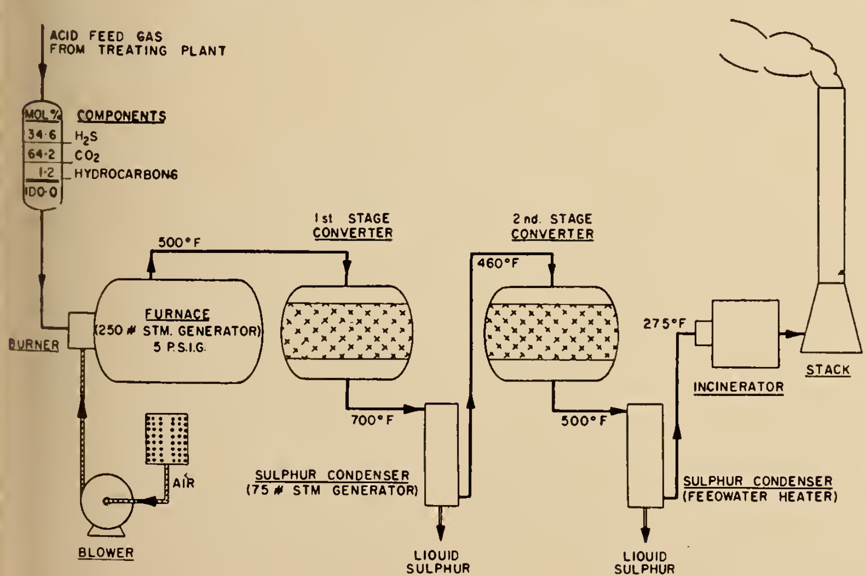
Fig. 6. Sulphur recovery plant flow diagram.



Dehydration

After sweetening the gas by amine treating and removing hydrocarbons by absorption the gas is dehydrated. The water content of the gas is reduced by passing the gas through a vessel containing a bed of granular silica gel which removes the water vapour by adsorption. The gas at this point meets all contract quality specifications and is ready for sale.

Sulphur Recovery

Sulphur is recovered from the acid gas effluent from the amine solution regeneration stills. Besides the obvious profit motive, sulphur is recovered to avoid serious atmospheric pollution which results when large volumes of hydrogen sulphide are flared. The sulphur recovery process is illustrated by Fig. 6.

One third of the hydrogen sulphide in the acid gas feed is burned with air to form sulphur dioxide which is then reacted with the remaining two-thirds of the hydrogen sulphide to form elemental sulphur.

$$H_2S + \tfrac{3}{2}O_2 \rightleftharpoons SO_2 + H_2O$$

$$2H_2S + SO_2 \rightleftharpoons 3S + H_2O$$

The first reaction takes place in a furnace in which temperatures of the order of 2000°F. are attained. The gas is cooled to about 500°F. by generating steam and then passed through a bed of bauxite catalyst to promote the conversion reaction. Conversion takes place throughout the plant but most of the conversion takes place in the first catalytic converter. The temperature of the gases leaving the converter is higher than the inlet temperature because heat

Transporting and Marketing Natural Gas

B. F. Willson, M.E.I.C.

Vice-President Operations,
Canadian Western Natural Gas Co. Limited, Calgary, Alta.

Read at the 71st Annual General and Professional Meeting, The Engineering Institute of Canada, Banff, Alta., June, 1957.

CANADA'S ENERGY requirements are expected to triple in the next 25 years. The Gordon Commission estimates that natural gas—now supplying 4 per cent of our energy requirements—will be providing 25 per cent of the much larger requirements of 1980. What other industry can look forward to such a phenomenal rate of growth? What other industry offers such a challenge to the engineering profession? Clearly the natural gas industry in Canada is today in its infancy and the engineering profession's role in the development of one of our most important natural resources will be a most significant one.

In this paper, I propose to follow the gas supply from the inlet of the transmission system, through the distribution systems, to the point of delivery at the consumers' premises. The paper will deal firstly with a brief consideration of the economic feasibility studies necessary in considering a pipe line project, secondly, with the engineering aspects of the project, and thirdly, with some of the economic and cost features.

The construction of any natural gas pipe line involves the expenditure of substantial sums of money. The transmission system of Trans-Canada Pipe Lines over its 2,200-mile length, is estimated to cost $350 million. It is apparent, therefore, that detailed economic studies justifying the construction of each project must be undertaken before the project can become a reality. Time does not permit going into great detail on the various aspects of these economic studies but certain of them should be mentioned.

(1) Careful estimates of the existing market potential must be prepared. This involves a study of weather conditions as well as a survey of the potential sales of gas to residential, commercial and industrial customers.

(2) Forecasts of market growth are required to provide data on which to base the engineering design of the pipe line system. Such forecasts also provide the basic data for projected earnings statements.

(3) All aspects of competitive fuel costs must be investigated. Estimates of market demand are only realistic if natural gas can be sold at rates competitive with other fuels.

The production of natural gas as far as the stage when it is ready for further distribution to the consumers has been described in the paper by Mr. Dillon (p. 1265). To continue the story, the present author deals with the supply of gas through the transmission systems to the point of delivery.

(4) An assured long-term supply is essential for the financing of any major project. This entails detailed studies of available gas reserves, their deliverability, the negotiation of gas purchase contracts with the producers and the finalization of such matters as the load factor and price of each individual supply.

(5) A preliminary engineering study and design of the transmission system must be made. Calculations of total annual fixed and operating costs are necessary for the economic appraisal of the project.

(6) Similar engineering studies and designs of the distribution systems in the market areas are required.

(7) Financial projections of estimated costs and revenues can then be compiled. If these projections show a favourable picture, it is then possible to interest financial houses in the underwriting of the total project.

Let us assume for the moment, that we are interested in promoting a major natural gas pipe line which will be built to connect suitable sources of gas supply with market areas previously not served with natural gas. Let us also assume that the economic feasibility studies mentioned above have been carried out in detail and that a favourable picture is indicated. What then are some of the engineering considerations for the project itself?

First let us look at the transmission line. Again time does not permit going into detail on the various engineering aspects of the transmission system. I will mention the more important ones.

The design of a major pipe line has the objective of transporting the gas supply itself from the fields in which it is located to the markets at the lowest possible unit cost consistent with sound engineering practice. Factors to be considered in the design might be listed as follows:

(1) Location of the Various Sources of Supply

Any major pipe line will undoubtedly require to be supplied from more than one source. Therefore the system gathering the gas from the various individual fields must be engineered and planned having in mind the same factors and objectives as the transmission line itself. That is to say, many designs must be tried and costed in order to be sure that the one selected is the most economical. Topographical features must be considered in selecting pipe line routes. The geology of the area to be traversed by the gathering system is important in that the decision as to fina location should be made not only on the basis of the location of present gas reserves but also on the basis of the probable location of future discoveries.

(2) Quantities to be Handled

A proper and desirable design is one which yields low ultimate transportation costs and at the same time, reasonable initial costs during the early years of the project when the markets are being developed. Therefore the design must be studied and unit costs determined at various rates of flow in order to assure that the design is an optimum one from a cost standpoint.

(3) The Load Factor of the Operation

While it might be assumed that the load factor of the main transmission system will be the same as the load factor of the markets, this does not necessarily hold true. The role of storage is of major importance in a gas transmission project and storage can take many forms. Line pack (storage in the pipeline itself) frequently enables maximum hourly demands to be met from a pipeline designed for throughput equal to only the average hourly demand of the peak day. Above-ground gas holders achieve the same result as line storage but have the disadvantage of being costly. Underground storage in depleted gas reservoirs usually presents the most economical storage for a major pipe line project. The existence of such reservoirs enables the transmission line to operate at high annual load factors with maximum winter demands being met by a combination of supply from both the pipe line itself and the storage fields. During the summer months, gas surplus to market requirements is stored in the underground reservoirs to be available for the succeeding winter months.

(4) Quality of Pipe Available

Due to the tremendous tonnages of steel required by a major pipeline project, the allowable operating stress in the steel itself is a matter of considerable importance. Formerly pipelines were built using steels having minimum yield strengths of 30,000 to 35,000 pounds per square inch. An allowable operating stress of 72 per cent of the minimum yield strength was considered good practice. However, in the postwar years, notable advances have been made by the steel and pipe fabricating industries with the result that there is now available line pipe having minimum yield strengths of 46,000 and 52,000 lb. per sq. in. The recently prepared code of the American Standards Association (ASA B 31.1.8-1955) for Gas Transmission and Distribution Piping Systems permits operating stresses up to 72 per cent of specified minimum yield strength for what is defined as Location Class I (cross-country pipeline systems in relatively open country) even though these high strength steels have certain brittle tendencies. Therefore the availability of high strength steels has an important bearing on the wall thickness necessary to withstand any particular operating pressure.

(5) Pipeline Design Formulae

Major American operating pipeline companies have developed empirical formulae as a result of observing large diameter pipelines in operation. These formulae give more realistic results than earlier ones developed by pioneers of the gas industry. One of the more acceptable formulae is that developed by Panhandle Eastern Pipe Line Company. It takes into account such factors as the inlet and outlet pressures of the pipeline, the inside diameter and length of the pipeline, the specific gravity of the gas and, of course, the quantity itself. It employs an efficiency or experience factor which is used to adjust for slightly different characteristics of each individual pipeline.

(6) The Spacing of Compressor Stations

Major engineering studies are necessary in order to determine the optimum spacing for compressor stations. These studies relate to the economics of providing for daily pipeline capacity by the installation of either compressor horsepower for increasing the pressure differential between compressor stations as compared with the provision of additional pipeline capacity through a larger diameter line or a looping pipeline. This latter alternative has the effect of reducing the resistance to flow in the line itself and hence, increasing its capacity. Experience has shown compressor station spacing of 100 to 150 miles to be the most economic but each installation must be engineered on the basis of the circumstances which prevail.

(7) Operating Pressures

Closely linked to the matter of compressor station spacing is the question of operating pressures for the pipeline. This again is a question of engineering economics and is influenced by such matters as the pressure at which the gas supply is available, the distance to the markets, the quality and type of pipe available and the anticipated growth in the markets to be served.

These are what might be considered the major engineering considertions in the design of a gas transmission line. You will note that while a number of these factors are capable of precise mathematical solution, others are judgment factors. Therefore the final design of any pipeline to a greater or lesser extent must be dependent on the experience and background of the executive engineer in charge of the design.

The design of gas distribution systems within the market areas must be based on consideration of essentially the same factors as were studied in the transmission pipeline. A block by block survey of residential, commercial and industrial areas is the framework on which the design is anchored.

From the market survey emerges the estimated peak hourly demand for each section of the particular area being studied. These hourly demand quantities plus a judgment location for the major distributing pipelines form the basis of what is called the intermediate pressure system. The actual size of each distributing main is determined by application of a pipeline flow formula.

The pressure drop in each section of gas main is calculated by taking into account the quantity to be handled, the length and diameter of the section and the pressure of the gas available at the inlet. Adjustments in the design are made by varying the diameter or pressure conditions in the pipeline. Maximum operating pressures are governed by the A.S.A. Code mentioned previously, gas industry standards and safety considerations generally.

The distribution design finally adopted is the result of numerous calculations and a trial and error procedure. Again judgment must be used to determine the allowance to be made for future growth in the area to be served as well as extensions to that area. Experience and a knowledge of gas industry problems are essential background for the gas distribution engineer.

Other Engineering Considerations

Mention might be made of other engineering considerations which must be faced and designed by the engineer.

Gas quantities must be measured at the wellhead, at the inlet to the transmission system, at the start of the distribution system and at the point of delivery to the consumer. Problems encountered in measurement are numerous and complex with the result that the position of measurement engineer in any gas operation is an important one.

Control of gas pressures at all points on the system is another matter which merits close attention by the operating personnel. The design of pressure control installations and their efficient operation is an engineering matter of significance in the total scheme.

Because of the inherent danger which exists if natural gas is not handled properly at any stage of its travels from the reservoir to the burner tip, it is necessary to add a distinctive odour so that any raw or unburned gas is readily detected. Odorization of the gas supplies, therefore, is another matter which must be carefully engineered and controlled.

It was stated at the start of this paper that mention would be made of some of the economic and cost features of a pipeline project. Throughout the paper you have probably realized that a natural gas pipeline is not unlike numerous other engineering undertakings in that economic considerations govern, to a considerable extent, the design of the various elements that make up the total project. Therefore we will not dwell further on the economic considerations other than to point out the obvious fact that the pipeline project must make money in order to succeed.

With respect to the cost aspects, some unit cost data might be of interest.

In 1950 our Alberta gas utility companies could build transmission lines for $1800 per inch diameter mile. That is to say, a 16-inch pipeline cost about $29,000 per mile. By 1956 the cost had risen to $2,700 per inch diameter mile and present pipe quotations indicate that the installed cost of a 16-in. pipeline next year will be $54,000 per mile or nearly $3,400 per inch diameter mile. Sharp increases in the price of the pipe itself, together with substantial increases in labour rates, have brought about this near-doubling of 1950 costs.

Unit costs applicable to distribution systems have also increased somewhat alarmingly in recent years. The average capital cost per customer in thirteen communities served with natural gas for the first time in 1956 by Canadian Western Natural Gas Co. was $261. The minimum per customer cost was $217 and the maximum $471. Obviously, the spacing of dwellings and the intensity of the development generally are the largest factors affecting distribution costs. In connection with the per customer capital costs in larger eastern centres of population, one would expect them to be somewhat higher than those of smaller communities in Alberta.

Once an integrated transmission and distribution system has been designed, the engineer must play his part in the construction, operating and maintenance phases. Undoubtedly the engineer will move ahead to the executive positions because his knowledge of the background and details of the entire operation make him ideally suited as a policy and decision maker. The opportunities for the engineer in the natural gas industry appear almost limitless and it is to be hoped that Canadian engineers will take their rightful place alongside our American friends who pioneered in an industry that is, today, the sixth largest on the North American Continent.

Transportation of Oil

(continued from page 1264)

I have not touched at all on the problems of operation, mechanical maintenance, right-of-way maintenance, communications or corrosion— any one of which could well be the subject of numerous papers of this length. However it will be obvious to you, and your Institute, that engineers play a major role in many of the phases of pipelining and there is a place in the industry for people from almost every branch of your profession. They will find it most fascinating and professionally rewarding. They may develop ulcers, or die of heart attacks, but I can assure you, they will never die of boredom.

Canada has virtually reached the point of self-sufficiency as far as petroleum refining capacity is concerned. Exploration and production are rapidly approaching this condition and in spite of the steeply rising consumption of petroleum products which is accompanying the increase in population and industrialization, we could quite conceivably be in a net export position within a very few years. The transportation industry is ready to play its part in this growth.

Gathering and Processing Natural Gas

(continued from page 1269)

is liberated by the conversion reaction. Sulphur formed as vapour in the first converter is condensed by cooling the converter exit gas in a heat exchanger by generating low pressure steam. The gas stream is passed through a second converter, cooled, and entrained sulphur removed in a mist eliminator or coalescer. The residual sulphurous gases are burned in an incinerator to avoid atmospheric pollution. The sulphur condensed in the various plant units is continuously drained to a concrete pit from which it is periodically pumped to solid storage blocks or directly to liquid tank cars.

It is common for sulphur plants employing two stages of conversion to recover 85-90% of the sulphur in the acid gas feed. Purity of the sulphur is exceptional; usually higher than 99.5%.

Processing Costs

Costs involved in processing sweet gas, rich in volatiles, are more than offset by the income from by-products. However, in the case of sour reserves, requiring amine treatment to remove hydrogen sulphide, processing is costly and expenses usually are only partly defrayed by the value of by-products recovered.

Petroleum Refining

C. W. Coote, M.E.I.C.

Manager, Edmonton Refinery,
British American Oil Company Limited, Edmonton, Alta.

Read at the 71st Annual General and Professional Meeting, The Engineering Institute of Canada, Banff, Alta., June, 1957.

The refining of petroleum has developed technically to a great extent in recent years. The paper deals with design, operation, and some of the products.

FROM THE combined results of previous speakers in this series, we may find the refinery crude oil storage tanks being filled with anything from a straw-coloured distillate, much lighter than water, down to a black molasses-like material of about the same gravity as the cooling water. Our job is to get the right combination of people to design, build, operate, and maintain the refinery, so that the end results will find a ready market at a profitable price. Engineers by themselves do not make too good an all round working team, so accountants, chemists, graduates of the school of hard knocks, and administrators are needed throughout all phases. All types of engineering graduates are employed, with the greatest emphasis on mechanical and chemical. The plant will normally be automated to a very high degree, so that the requirement for human labour in operations is often reduced to the point where the number of men on a shift is only that required for fire-fighting and general plant protection. This does not mean to imply that the people there on a shift basis have nothing to do. They are normally highly skilled operating personnel, who have put in many long hard years learning the business. They must know what to do, where to go, and to act quickly in case of failure of automatic controls, or of any part of the processing equipment, since the raw, intermediate, and finished material has a great deal of latent energy in it, and if this material is not properly controlled, the fire and explosive hazard is tremendously high. The heat energy in a pound of gasoline is three times that of T.N.T. and six times that of nitroglycerine.

A rough round figure of plant investment cost is $1,000 per bbl. of daily crude throughput for a medium sized plant (25,000 bbl. per stream day). This figure can easily be doubled for a small, but complete plant, and will naturally be somewhat less for units of larger size.

Location

Wherever possible, a minimum of one-half section of land is required for a 25,000 bbl. per day plant. It will be usually located near the market for its products, although in a few cases it may be near the source of the crude oil, and the markets may be at some distance. It is generally more economical to locate the plant near the market, and bring the crude oil to the plant by whatever means available. Since the basic refining process is one of elevated heat, with temperatures in the 200 deg. F. to 1100 deg. F. range, accompanied by varying degrees of elevated pressure, a large supply of cooling water is absolutely essential. Other utilities such as cheap and abundant electricity, make-up supplies of fuel, and water for domestic purposes are required. Consideration of the problem of pollution of water, air, and surrounding countryside must also be made. If definite plans are established to combat and control pollution before the plant is erected, a great deal of money can be saved in the long run with much better public relations for the plant right from the start.

Design

Refining is a fascinating business, in spite of the fact that it is an industry where a layman or an engineer, not normally associated with the industry, going through a refinery finds it quite difficult to visualize what is going on. This is due to the fact that the raw material comes into the plant, is processed, and the products are loaded or transported out of it, with little or no chance to see the raw material, intermediate products, or the finished ones, except on laboratory samples. Recently, a very large oil company, in opening some new buildings in their research centre, stated "Today you can run your car, lick your hair, dress in the latest fashion, mow your lawn, oil your watch, kill moths, grow flowers, heat your home, air condition your office, shine your shoes, all with tools powered by, or lubricated with oil or oil products made from petroleum. At last count there were more than 4,000 products made from petroleum, a list which increases daily." It is not my purpose to begin to tell you how or where more than a small fraction of the 4,000 products are made, but to take you on a tour of a modern integrated refinery, and to spend a moment here and there telling you where a more complete refinery would draw its raw material from to go into many more of the by-products or of the specialty products which can result from the original processing of crude oil.

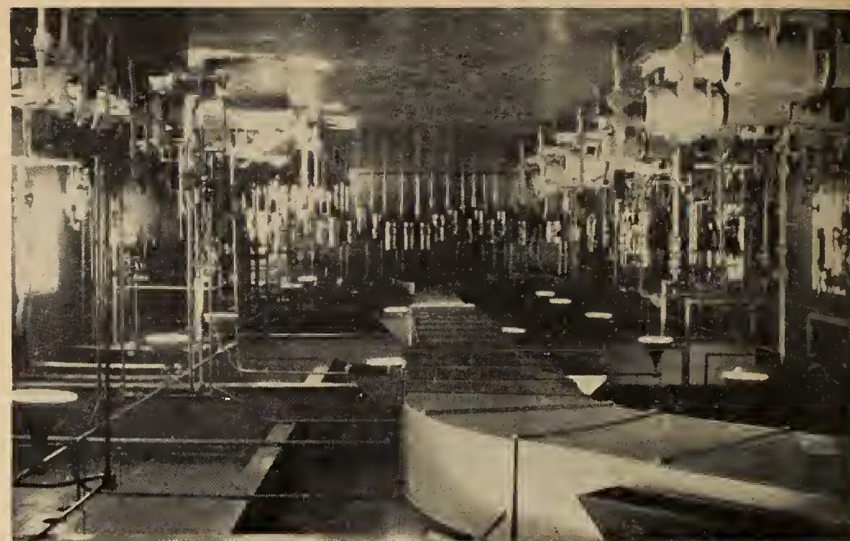
The design work is usually done by a staff of specialists, either in the employ of the oil company itself, or in that of a contracting company, which specializes in oil refinery design. Greater attention is being paid now to efficiency and operating costs than ever before, since the cost of labour and materials is continually increasing, whereas the price of the products of a refinery on a tax free basis have not risen in nearly the proportion that labour and material have.

Operation

Let us look at the flow through a refinery where the processing is relatively simple, and at the same time modern. This will provide us with some talking points to illustrate the operation of a modern refinery.

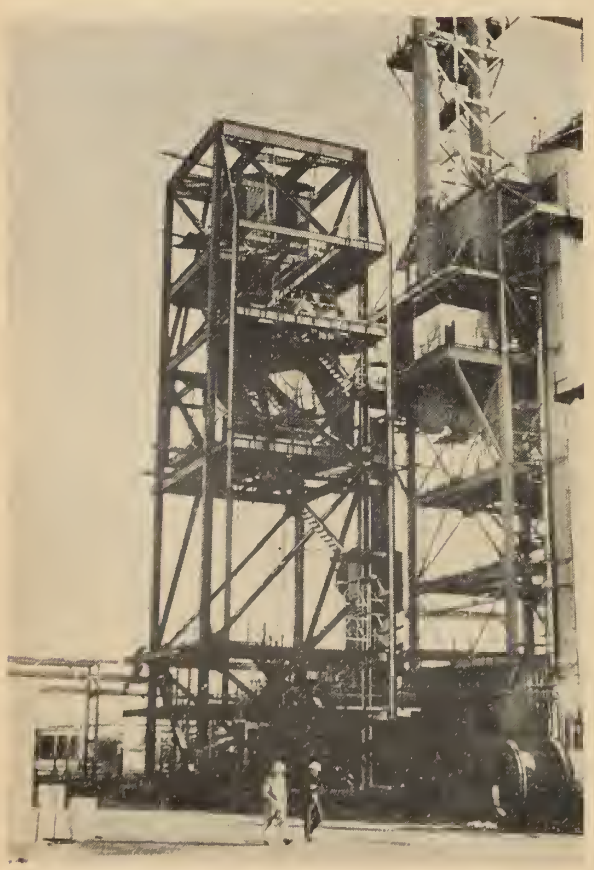
Raw crude is a mixture of a large number of hydrocarbons, and the basic chemical nature of the oil will determine the physical and chemical properties of most of the end products. In addition to a large number of hydrocarbons of varying chemical structure, the crude will contain some unwanted material, including sulphur in varying forms and amounts, and foreign bodies produced with the oil, mainly soluble salts, such as chlorides and sulphates, which present a big problem to the refiner. If they are not removed, they will foul up the heat exchanger trains, which are very important when high temperatures are involved.

In order to give a homogeneous type of oil to the refinery, most crude oil storage tanks are equipped with either suction heaters to keep the oil flowing at all temperatures, and/or propellor type mixers. The problems of delivering oil by pipeline to a refinery, and accounting for it on a metered basis, have many ramifications and are not common, with the result that most refineries have a minimum of two large crude oil storage tanks. The number may vary from this up to a dozen, depending upon such factors as the type of processing of the plant, the frequency of delivery of crude, and the number of different types of crude oil processed which it is desired to segregate. These tanks, along with the intermediate and finished product storage tanks, may be equipped with automatic gauging and temperature measuring equipment, whereby the amount of crude oil and its temperature in the tank, may be measured without climbing to the top, or may be measured even at a remote point.



Treating plant pumphouse.

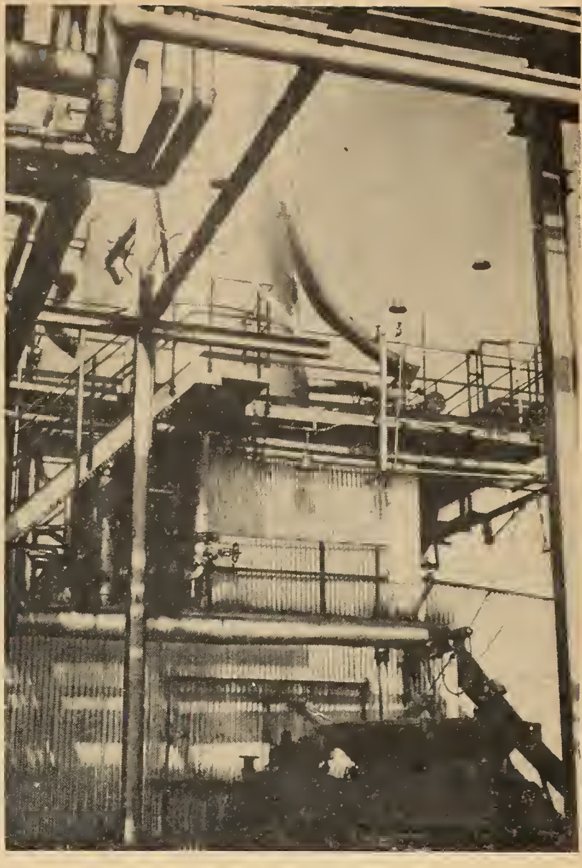
The first stage of processing is to get rid of the undesirable salts in the crude. This is accomplished by heating the oil, usually by heat exchange, with a hot stream leaving the processing area, and adding water to the crude. The salt goes into solution and the brine is separated from the oil either by residence time in a large vessel, aided by chemical de-emulsifiers, or by electrostatic precipitation, using high-voltage low-amperage fields. The refiner aims to get the salt content down to one pound of salt per thousand barrels of crude or less before further processing. The crude oil is now pumped through a tube still heater, where its temperature is raised to about 700 deg. F., and then flashed into the bottom of a distillation tower. In the fractionating tower, the light components of the crude oil, which have been vaporized, will tend to rise through the bubble-deck trays, on each of which is maintained a level of liquid reflux. The dense heavy components tend to go to the bottom of the tower, and will be drawn off for further processing. The topped or reduced crude, as it is known, from the bottom of the basic fractionating tower may proceed to a vacuum tower, where additional distillation is conducted under less than atmospheric pressure for the



Coke drum and drill equipment.

production of lubricating oil base stocks and asphalt or it may go to a coking unit. If neither of these are available, the reduced crude will be blended for heavy bunker fuel. From the main distillation tower, we will get light gasoline overhead, along with heavy gasoline, solvents, kerosene, diesel fuel, and gas oil for further processing as side draw products. These will require steam stripping, treating, and blending before they can be turned into finished products. The most common forms of product treating involve the use of caustic soda or sulphuric acid. Either of these chemicals in varying strengths and combinations, will either remove or convert the undesirable chemicals in the raw products, so that when burned in an internal combustion engine, or in a lamp, they will not exhibit harmful properties. Bauxite is commonly used; the effect being to convert some forms of sulphur into hydrogen sulphide, which can be separated from the product by distillation.

Carbon monoxide boiler.



In our plant, we will take the reduced crude through another pipe-still heater, where the temperature and pressure are raised to high levels, and the resultant synthetic cracked mixture flashed into an open drum. In this drum, at reduced pressure, the mixture will deposit solid coke, and the vapours produced in the cracking reaction will go overhead from the drum into a fractionating tower, where cracked gasoline and gas oils will be recovered. The coke builds up as a semi-solid layer from the bottom towards the top of the drum, and when it is approximately two-thirds full, the flow is switched to another drum. After this is done, steam is introduced to the coke bed to remove the oil and vapour, following which it is cooled using large amounts of water. At the end of the cycle, the drum is unheaded and drilled out, using a combination of hydraulic-mechanical drilling. The product, petroleum coke, is sold largely to the aluminum industry and used in the electrolytic reduction of alumina. In recent years, a fluidized coking process has been developed, which produces coke continuously in a fine particle state, but the use of the latter product is more restricted. You will appreciate that the operating variables in a coking process must be very closely controlled, otherwise the coke will be deposited at the wrong place in the unit, fouling up the equipment and forcing a shutdown for cleaning out.

Laboratory knock engine.

With regard to the alternative method of residual handling, asphalt production, I would like to request that any of you here who are users of road or industrial asphalts will support and continue the efforts which have been started to reduce the multiplicity of grades of road paving asphalts as well as industrials to a more sensible figure.

In an effort to produce more and more gasoline of higher and higher quality, the fluid catalytic cracking process was developed in the early years of World War II, and has become the backbone of today's refinery. In the fluid process, of which there are many versions, the heavy gas oil produced from the atmospheric crude distillation tower is cracked at moderate temperature and at low pressure in the presence of a catalyst. The catalyst is a very fine powdery material, which may be a naturally-occurring clay, or a synthetic product from a chemical manufacturing plant. Most of the fluid processes circulate large volumes of this finely powdered material, which although a solid in its normal state behaves as a fluid when fluffed with air and oil vapours. Fluid catalytic crackers have a wide range of operating conditions and these will be varied to produce the desired end products, as well as to consume all of the gas oils which are available for cracking. The end result is a maximum production of total white products; i.e., gasoline and heating oils, with a minimum production of coke and gas. In the cracking reaction, coke is deposited in a very fine form on the catalyst, which goes from the reactor to the regenerator, where the coke is burned off the catalyst, using large volumes of air. In the regeneration step, flue gas is produced at a temperature of approximately 1100 deg. F. and may contain up to 8 per cent of carbon monoxide.

In areas where outside sources of fuel command a high price, this gives the refiner an ideal position to demonstrate efficiency by the installation of a CO boiler. This is basically a conventional water tube boiler, but the combustion space is very large. The fuel consists of flue gas from the catalyst regenerator, containing CO which will be burned to CO_2, thus liberating substantial quantities of heat. Auxiliary fuel consisting of gas, fuel oil or even coal, will be used to generate large volumes of steam. In the construction and operation of a CO boiler, it is necessary that the duct work conducting the flue gas from the catalytic cracker to the boiler be arranged so that the cracker will not have to shut down if it is necessary to shut down the steam generator.

The octane race is continually going on, with the prediction being voiced recently that the premium gasoline in the United States will average 107 octane, and house brand gasoline 98 octane in 1965. The average compression ratio will be 12 to 1 by 1961, and the average of all leaded motor gasoline sold will go up to 101. This will cost the refiner an estimated 60c per bbl. more to manufacture the products. There is a limit to the octane improvement effected by the addition of tetraethyl lead, and by law no motor gasoline may contain more than 3.6 c.c. per Imperial gallon for safety reasons.

One of the more modern methods used to produce more high quality motor gasoline is catalytic reforming. There are several patented processes, some of which are regenerative, others non-regenerative, all of which use low-grade straight-run gasoline as a charge material. In upgrading the octane quality of the gasoline, once again, more light ends are produced, which must be either burned as fuel or processed to become a stable liquid, which can go into the motor gasoline pool.

All of the gas produced is usually concentrated and recovered in a common section of the plant. There is very little use in the refinery itself for the methane and ethane, but sometimes these find a ready market in a petrochemical industry, which may be located in the area. The unsaturated C_3 portion of propylene may be used as a raw material in the production of cumene, in a Friedel-Crafts reaction with chemically pure benzol. Propylene and butylene in combination with iso-butane, may be used to form motor or aviation alkylate using concentrated sulphuric or hydrofluoric acid as a catalyst. Since there is an overall shortage of iso-paraffins for alkylation feed, and upgrading of motor gasoline, some refineries are built to convert normal paraffin hydrocarbons into iso-compounds. Aluminum chlorides suspended on bauxite can be used as a catalyst for this process.

The following table gives an indication of yields from the processing.

All gasoline and solvents	50 to 60%
Kerosene, diesel, lub. oil	20 to 30%
Bunker, coke, asphalt	10 to 20%
Fuel and loss	5 to 15%

In addition to simplified equipment which is used running routine control tests on such characteristics as colour, distillation, flash, fire, viscosity, gravity, pour point, melt, and penetration, more elaborate equipment is used to analyse particular fractions of the refinery products, and to determine the quantities of sulphur and the forms that sulphur is present in. Some of this equipment is extremely expensive; for example, a mass spectrometer, one of the newest analytical tools, used for light hydrocarbon research, costs approximately $60,000 installed in Canada. This instrument includes a two-ton electromagnet, operates at high vacuum (one ten-millionth of a millimetre of mercury) and is based on the principle that positively charged molecular particles or ions have a different weight or mass. The mass spectrum for any pure compound is characteristic of its molecular structure, and is reproducible. This exact reproducibility provides the means for precise analysis, both qualitative and quantitative.

One essential laboratory tool is a knock engine. This is used to determine the octane quality of the gasoline products of the refinery, by comparing the fuel with other gasolines of known octane number. With the production of motor gasoline approaching 100 octane rating, and even exceeding it in some cases, considerable thought and study has been given in the last few years, and is still going on, to a satisfactory way of universally rating gasolines over 100 octane rating. Aviation gasolines for internal combustion engines are rated on performance, rather than on straight octane number, e.g. 115-145 aviation gasoline, indicates the performance numbers at takeoff and at cruising speed, in relation to the performance of straight iso-octane under similar conditions.

Mention of aviation gasoline may cause you to wonder about jet fuel, its production, and the different forms. There are two main types of jet produced today; one known as the gasoline type, which is essentially a straight run gasoline with a low vapour pressure (below three pounds, measured at 100 deg. F.). This type is used in most of the military jets. The other common type is known as the kerosene type, which is essentially a product very similar in distillation range to coal oil, the original coal of the refiner 50 years ago. This type seems to find more favour with the jet engines used on commercial aircraft.

Auxiliary Facilities

The refining process is one which must go on continuously, operating around the clock, and throughout most of the year. Refineries today will average 92 per cent on stream time efficiency for the most difficult units, and up to 95 per cent time efficiency for those processing units where coking is not a problem. Large quantities of high purity steam are required for essential drives, as well as for processing and for fire protection within the refinery. A permanent fire-fighting system is usually installed within the entire plant area, and augmented by portable fire equipment which can be moved right

(continued on page 1287)

The Petrochemical Industry

J. H. Shipley

Vice-President,
Canadian Industries Limited, Montreal, Que.

Read at the 71st Annual General and Professional Meeting, The Engineering Institute of Canada, Banff, Alta., June, 1957.

THE SUCCESS of the oil industry, and the large scale of its operations resulting from that success, have made many potential raw materials available at prices which are often lower than those for alternative raw materials from other sources. The chemical industry has been quick to realize the advantages that petroleum-based raw materials could give it. On the other hand, the oil and gas industry has rapidly adopted the techniques of the chemical industry to diversify and upgrade its products. As a result the new petrochemical industry has arisen. It is this industry, and the factors influencing its growth in Canada, which I propose to review with you today.

It may be well to start out by defining what we mean by petrochemicals. Petrochemicals are chemical products derived from petroleum, the term petroleum being used in its broadest sense to include crude oil, natural gas and their by-products. Figure 1 gives the names of some representative petrochemicals, and you will note that only a few of these will be familiar to those without some chemical training. Most petrochemicals undergo further processing or compounding before they reach the consumer, so that the petrochemical origins of many finished products go unrecognized. For example, most of the newer synthetic fibres such as nylon and "Terylene"; the plastics polythene, p.v.c. and polystyrene; and synthetic rubbers are largely dependent upon petrochemicals as intermediates.

Factors Influencing the Industry

The growth of the petrochemical industry in Canada has involved one choice after another. Earlier speakers have pointed out the variety of potential raw materials produced by the oil refining and natural gas industries. Another fact which may be less well known is that the same petrochemical can often be made in more than one way and from more than one raw material. For instance, as shown in Figure 2, polyvinyl chloride resins are currently being manufactured competitively by several different routes from natural gas and crude oil, as well as from coal, which is not a petrochemical source. One of the first choices is, therefore, that of which raw material and which manufacturing process to use.

Although still relatively small, in terms of volume of products, the Canadian petrochemical industry is one of the leaders in rate of growth and economic importance. Some of the products and their markets are discussed in this paper.

Since technical research often produces different products which compete with one another, a new product must be able to withstand not only direct competition from other manufacturers of the identical product but also indirect competition from other products which can serve essentially the same purpose.

The markets for petrochemicals differ considerably in size across Canada and are often concentrated at some distance from the source of the cheapest raw materials. Therefore, either the raw materials or the finished products must be transported.

Furthermore, manufacture cannot be undertaken economically unless a sufficiently large market is available and the effects of tariffs, both in our own country and in others, on the size of the available market are extremely important.

Very briefly, then, raw materials, manufacturing processes, size and location of markets, freight and tariffs are the factors which have controlled the location of petrochemical plants and the development of the petrochemical industry in Canada and will continue to do so in the future.

I would now like to amplify and illustrate these remarks.

Raw Materials for Chemical Industry

The oil and gas industry provides four main sources of raw materials for the chemical industry. Figure 3 shows these diagrammatically. They are:

(1) Crude oil

(2) By-products of refining crude oil, in particular refinery off-gases from cracking operations which contain ethane, ethylene, propane, propylene, butanes, butylenes, etc.

(3) Natural gas, which is usually composed largely of methane.

(4) By-products of natural gas, such as ethane, propane butanes and sulphur.

These raw materials for the petrochemical industry are available at various places across Canada, as shown in Figure 4.

Natural gas and its by-products occur most abundantly in the West and refinery by-products mainly in the East, while crude oil is available at most locations in Canada from domestic sources or from imports. With the growth of the oil and gas industry and the construction of long pipeline systems, the availability of petrochemical raw materials is being steadily increased and widened.

Most petrochemicals are compounds which contain the element carbon. It is helpful, therefore, to compare the costs of the various oil

REPRESENTATIVE PETROCHEMICALS

HYDROCARBONS	OXYGENATED CHEMICALS
ACETYLENE	ACETONE
BUTADIENE	ETHYLENE GLYCOL
DODECYLBENZENE	FORMALDEHYDE
ETHYLENE	METHANOL
PARA-XYLENE	PHENOL

CHLORINATED CHEMICALS	INORGANICS
ALLYL CHLORIDE	AMMONIA
ETHYL CHLORIDE	CARBON DIOXIDE
ETHYLENE DICHLORIDE	HELIUM
PERCHLOROETHYLENE	SULPHUR
VINYL CHLORIDE	

Figure 1.

and gas raw materials in different parts of the country on the basis of their carbon content. This is shown in Figure 5.

Natural gas in Alberta or the Peace River district is the cheapest petrochemical source of carbon in Canada at just under one third of a cent per pound. Transportation increases this cost rapidly east or west, so that the cost of the same pound of natural gas carbon in Toronto is just over four times the cost in Alberta. In the Prairies, crude oil and natural gas liquids are more expensive sources of carbon than natural gas, but in the East the costs of carbon in the form of crude oil, refinery gases or natural gas are quite close.

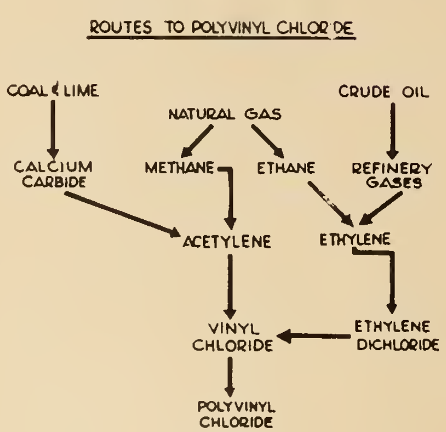


Figure 2.

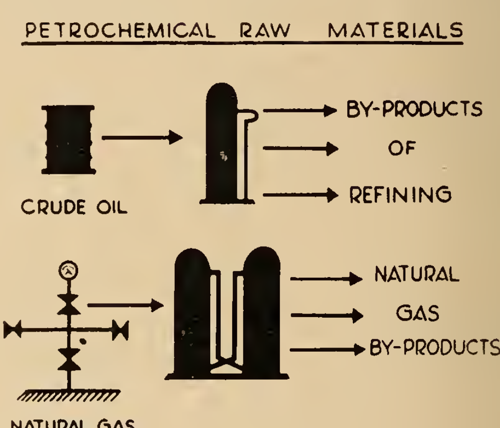

Figure 3.

These facts pose one of the main problems in the manufacture of petrochemicals. Should one take advantage of the cheaper raw materials in the west and ship the product to the major markets in the East, or should one use the dearer raw materials in the East with the consequent lower delivery charges on the finished products? The answers to this question have to a large degree controlled the pattern of development of the industry in Canada.

Technical

Before discussing the development of the petrochemical industry in Canada, I believe it would be desirable to say a few words on the two main routes followed in going from the raw material sources to the final products.

Generally, the first step is the production and isolation from crude oil or natural gas of relatively pure individual hydrocarbons. These serve as "building blocks" which are then upgraded to more valuable commercial chemicals by polymerization, by combination with other organic chemicals, or by reaction with oxygen, chlorine or other inorganic chemicals. Figure 6 gives some examples, chosen at random, of this sort of progression from petrochemical raw material through a simple hydrocarbon "building block" to a more complex intermediate and, finally, to a consumer product. These examples are typical of a broad classification in which a new compound is built around the structure of carbon atoms present in the original hydrocarbon.

The second and entirely different route from crude oil or natural gas to petrochemicals involves as the first step the reaction of the hydrocarbon source materials with steam or oxygen, or both, to give a mixture of carbon monoxide and hydrogen. Figure 7 indicates how this mixture, known as synthesis gas, may then be used as a source of hydrogen in the manufacture of ammonia, as a source of carbon monoxide for carbonylation reactions, or as the starting material for producing methanol and the Fischer-Tropsch type of product.

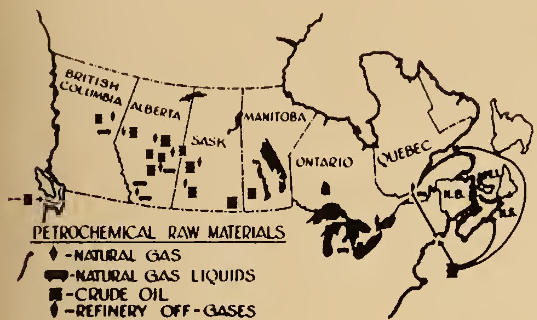
Like all attempts at classification, this breakdown of petrochemical processes into two major routes does not cover all cases. However, this will give some idea of the kinds of chemicals and the types of chemical processing involved in the petrochemical industry.

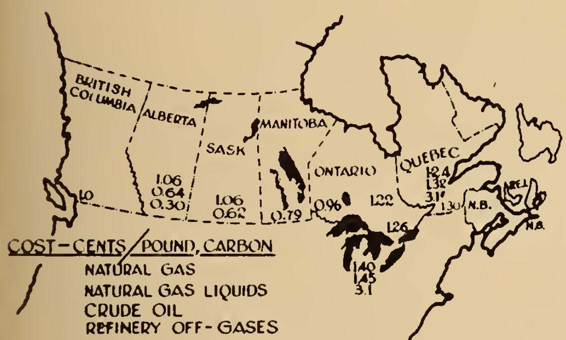
Pattern of Petrochemical Development in Canada

Let us now look at the pattern which petrochemical developments have followed in Canada. The initial stimulus came from World War II. As Figure 8 shows, an ammonia plant based on natural gas was built near Calgary in 1941 to increase supplies of nitric acid and ammonium nitrate for military explosives. It was converted later in the war to the production of fertilizers for the United Nations. In 1943 a fully integrated synthetic rubber plant based on refinery gases was built at Sarnia to supply general purpose synthetic rubber and butyl rubber for inner tubes. These were the first two petrochemical plants in Canada.

Development in the West—Figure 9 shows the most important post-war developments in the West. These include two more ammonia plants based on natural gas, one at Fort Saskatchewan to supply ammonia for use in the extraction of nickel and one at Medicine Hat as part of a large fertilizer plant. At Edmonton, ethane extracted from natural gas is cracked to ethylene which is then polymerized to give the plastic, polythene. Also at Edmonton, propane and butanes recovered at refineries or from natural gas are partially oxidized to produce a variety of chemicals including acetaldehyde, methanol, formaldehyde, acetic acid and acetone; some of these products are used with cellulose from British Columbia to make cellulose acetate for textiles, some are converted to more complex intermediates such as pentaerythritol, and others are sold without further conversion. Propane and butanes are also used as l.p.g. fuel and as feed materials in processes for making 100-octane gasoline. Sulphur, recovered as a by-product of natural gas purification, is now produced at several locations and goes to sulphite pulp mills or is converted to sulphuric acid for use in fertilizer manufacture at Medicine Hat and uranium refining at Beaverlodge. When gas exports start on a large scale, sulphur of petrochemical origin will be available in amounts which will exceed total Canadian consumption.

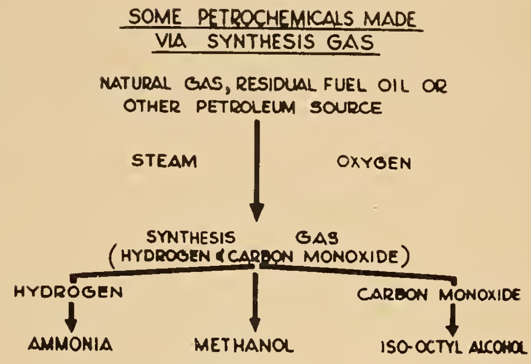
You will see that most of the petrochemical intermediates made in the West are used in conjunction with other local industries such as pulp, metal refining, and fertilizer manufacture. These petrochemicals are mainly low-cost products which cannot be shipped any great distance without freight costs assuming a disproportionately large part of the delivered price. Polythene is one of the few exceptions where the cost of shipping to the East is offset by the lower raw material and energy costs in the West.





SOME PETROCHEMICALS DERIVED FROM SIMPLE HYROCARBONS

RAW MATERIAL	PROCESS	CONSUMER PRODUCT
ETHANE (NATURAL OR REFINERY GASES)	CHLORINATION TO ETHYL CHLORIDE	TETRAETHYL LEAD
ETHYLENE (REFINERY GASES)	OXIDATION TO ETHYLENE OXIDE	GLYCOL ANTIFREEZE
BENZENE (NAPHTHA REFORMING)	ALKYLATION TO DODECYLBENZENE	DETERGENTS
ACETYLENE (NATURAL GAS PYROLYSIS)	HYDROCHLORINATION TO VINYL CHLORIDE	P.V.C. PLASTICS



WARTIME PETROCHEMICALS

LOCATION	RAW MATERIAL	PETROCHEMICAL	MAIN USE
CALGARY	NATURAL GAS	AMMONIA	FERTILIZERS, EXPLOSIVES
SARNIA	REFINERY GASES	BUTADIENE, STYRENE	GR-S RUBBER
		ISOBUTYLENE	BUTYL RUBBER

Left, top to bottom, Figs. 4, 5, 6. Right, Figs. 7 and 8.

Development in the East—The corresponding pattern of post-war petrochemical development in Eastern Canada is summarized in Figure 10. In most cases, the starting materials are refinery off-gases. These are used at Sarnia and Montreal East to produce petrochemical intermediates for use in manufacturing consumer products for which markets are to a large extent concentrated in Ontario and Quebec. The petrochemicals include styrene, ethylene and phenol for plastics; acetone, isopropyl alcohol and other industrial solvents; butadiene, styrene and other intermediates for synthetic rubber; ethylene glycol for antifreeze; and ammonia. The only major petrochemical operations in the East which are not based on refinery gases are: carbon black, made at Sarnia from a specially processed distillate; benzene and aromatic solvents made from catalytic reformate; formaldehyde made from methanol; and ammonia made from fuel oil. Tetraethyl lead for gasoline anti-knock fluid is manufactured from imported petrochemical intermediates, while the synthetic fibres, nylon and "Terylene", are manufactured in part from petroleum-derived materials not yet produced in Canada.

Growth and Value of the Industry

The growing importance of the petrochemical industry is shown in Figure 11, in which the gross selling values of the Canadian and United States petrochemical industries are plotted on a *per capita* basis. The corresponding figures for sales of all chemicals and allied products in Canada are also shown.

Two things stand out. In the first place, petrochemicals have been growing at a faster rate than chemicals as a whole; that is, an increasing proportion of chemicals production is being made from petroleum raw materials. In 1947, 24 million dollars' worth of petrochemicals were produced in Canada, equivalent to four and one-half per cent of the value of chemicals and allied products. By 1955, 127 million dollars' worth of petrochemicals were made, equivalent to twelve per cent of the one billion dollars' worth of chemicals and allied products. All the past experience suggests that petrochemicals will continue to grow more rapidly than the rest of the chemical industry.

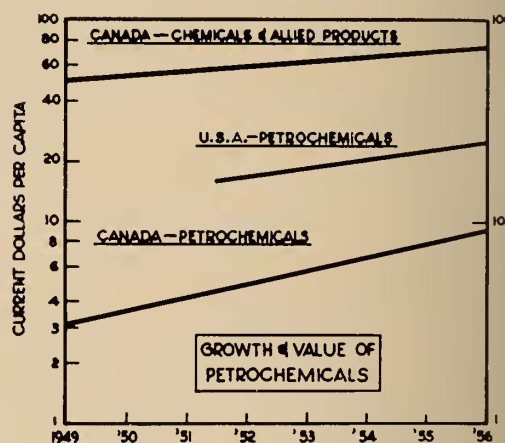
The second point is that in 1955 consumption of petrochemicals per person was nearly three times as large in the United States as in Canada. Over 50 per cent of total chemical production in the U.S.A. was from petroleum raw materials compared with 38 per cent in Canada. This suggests that the future market opportunities in prospect for petrochemicals in Canada are exceedingly bright. However, as I shall be discussing later, there are certain factors which may retard the rate of growth of the petrochemical industry in the future.

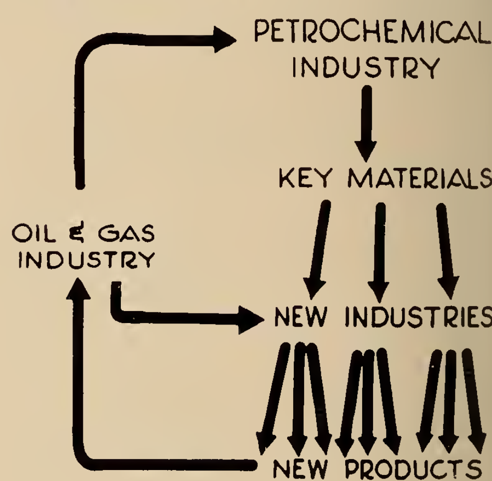
POST-WAR PETROCHEMICALS IN THE EAST

LOCATION	RAW MATERIAL	PETROCHEMICAL	MAIN USE
SARNIA	REFINERY TAR	CARBON BLACK	RUBBER
SARNIA & MONTREAL EAST	REFINERY GASES	PHENOL, STYRENE ACETONE AMMONIA ISOPROPYL ALCOHOL ETHYLENE GLYCOL	PLASTICS SOLVENTS FERTILIZERS GASOLINE ANTIFREEZE

POST-WAR PETROCHEMICALS IN THE WEST

LOCATION	RAW MATERIAL	PETROCHEMICAL	MAIN USE
MEDICINE HAT	NATURAL GAS	AMMONIA	FERTILIZERS
EDMONTON	NATURAL GAS	AMMONIA	NICKEL REFINING
EDMONTON	NATURAL GAS	ETHYLENE	POLYTHENE
EDMONTON	NATURAL GAS BY-PRODUCTS	ACETIC ACID	CELLULOSE ACETATE
SEVERAL ALBERTA LOCATIONS	NATURAL GAS BY-PRODUCTS	PROPANE & BUTANE SULPHUR	L.P.G. FUEL & GASOLINE PULP, URANIUM FERTILIZERS





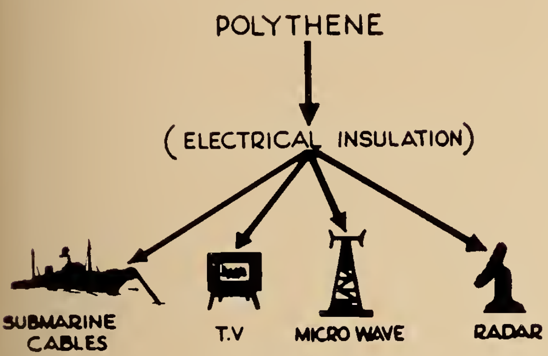
Left, top to bottom, Figs. 9 and 10. Right, Figs. 11 and 12.

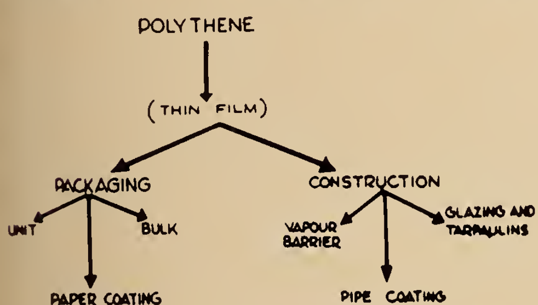
Scale of the Petrochemical Industry Relative to the Oil and Gas Industry

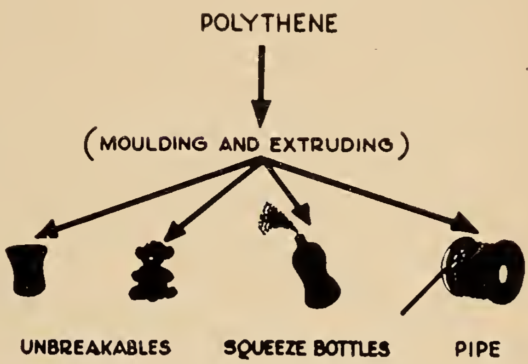
To keep the picture in perspective, I would like to make a further comparison, that of the relative sizes of the petrochemical industry and the oil and gas industry. The 127 million dollars in sales of the petrochemical industry in 1955 was only about 12 per cent of the combined value of the products of the nation's oil refineries and natural gas producers. This may lead one to believe that petrochemicals play a relatively insignificant role in the national economy, but in actual fact the impact of petrochemicals on Canada's industrial development has been much greater than these figures might suggest. This is because of the relationships illustrated in Figure 12, which result in a sort of "economic leverage". I use this term to describe the process whereby one new industry, which produces key materials with novel or unusual properties, brings about the founding of a number of other new industries. These, in their turn, not only bring more new products to the market but also demand goods and services from existing industries. For example, when the oil and gas industry supplies a raw material which leads to a new petrochemical enterprise, it also supplies its usual fuels, lubricants and other products to the new enterprise and to the secondary activities which are brought into being. In addition, the products of the new petrochemical development may be of benefit to the oil and gas industry, such as oil-resistant plastic pipe and synthetic rubber hose. The diagram does not show the whole story, since the new industries also require cement, steel, machinery, financing, advertising, and so forth. This "economic leverage" is a sound way to stimulate expansion in our national economy and I would like to illustrate its effect by two examples.

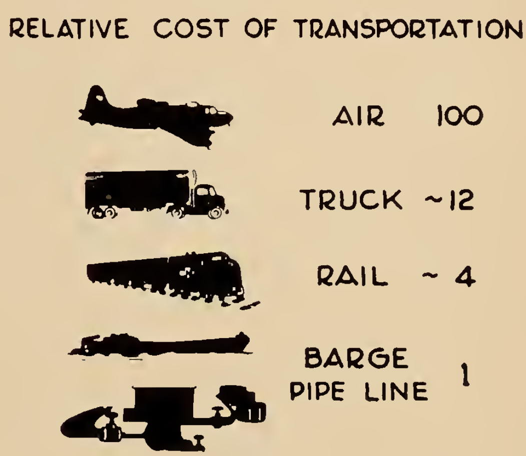
One of the key petrochemicals is ethylene, which is extracted from refinery gases or is made from ethane, propane, or sometimes oil. Ethylene can be oxidized to a very reactive petrochemical called ethylene oxide. This material in turn gives rise to numerous new products, including ethylene glycol for antifreeze, explosives and polyester fibres; polyethylene oxides for synthetic lubricants, waxes, and detergents; and glycol ethers which are specialized solvents. It can be converted into acrylonitrile which is used in oil-resistant synthetic rubbers and for synthetic fibres such as "Orlon"; and into ethanolamines which are widely used to remove hydrogen sulphide from natural gas and refinery gases. This versatility is typical of petrochemical intermediates, and it is almost certain that a material such as ethylene oxide will find expanding uses in the future .

My other illustration is another derivative of ethylene, this time the plastic called polythene. Polythene is now a familiar material to all of us, but imagine the situation when a few years ago the first sample, a rather dirty waxy material, was put on a research director's desk. Is this important, or just another trivial discovery? This sample might have ended up in the waste-paper basket or might have been relegated to the dusty recesses of a cupboard. However, its properties were investigated, and it was found to have unusually good electrical insulating properties and resistance to moisture, and was thermoplastic. Its unique electrical insulating properties at very high frequencies proved to be the key to success in the use of radar in World War II, and Figure 13 shows some of the other developments which have since followed.









Above, Fig. 13 (top) and 14. Right, Figs. 15 and 16.

Further experiments showed that thin films could be made from polythene. After much patient work and the development of novel techniques, a new, tough, transparent wrapping material came on the market. Figure 14 shows its uses. You are all aware of the revolution in packaging which followed, and will have noted how this has stimulated the use of other packaging materials. Ready availability and lower manufacturing costs have now resulted in other uses for polythene film, particularly in the construction industry, where it is used as a moisture barrier and for temporary glazing.

As shown in Figure 15, the plastic nature of polythene has been turned to full advantage by moulders and extruders, often with remarkable ingenuity; and the day may well come when the plumber is more familiar with polythene than with traditional metal pipe!

Hindrances to Growth

These examples show why the petrochemical industry may justly be called a growth industry. It is not only growing itself but is stimulating growth in other industries. However, this growth can be, and in fact is being, hindered by a number of factors. Since we are approaching a time when a considerable surplus of oil and gas raw materials will become available, especially as by-products in western Canada, it is important to understand what these hindrances are and how they operate. Growth can be retarded by unrealistic pricing of raw materials, inadequate tariffs and the perennial problem of freight costs.

The danger of retarding growth by asking too high a price for oil and gas materials has recently been demonstrated, and wisely avoided, in connection with the Trans-Canada natural gas pipeline. To make this project feasible, the price paid to the producers had to be negotiated downwards. It seems likely that as the market for natural gas builds up, the return to the producers will improve, but the important thing is that the parties concerned were willing to modify their terms so that, in consequence, natural gas will move. The same sort of willingness will probably be necessary to develop further outlets for oil and gas by-products in petrochemical manufactures.

Of all the hindrances to the expansion of the petrochemical industry (in fact, of the whole synthetic organic chemical industry), the tariff situation is probably the most important. No one wants tariffs for the sake of tariffs! What the petrochemical industry wants is a market for its products large enough to sustain plants of economical size. A market of this size is denied to many petrochemicals by the high tariffs and currency restrictions of other countries, coupled with low tariffs on imports into Canada. The United States tariffs on most synthetic organic chemicals range from 10 per cent to 45 per cent ad valorem, as compared with 20 per cent or less on imports of the same items into Canada. However, plastics and many key organic chemicals only qualify for 7½ per cent or less. Moreover, manufacture in Canada does not automatically mean that a higher tariff applies. The need for tariff protection for Canadian petrochemicals arises because, in present circumstances, the relatively small Canadian market must be shared with producers in other countries; at the same time there are only limited opportunities for Canadian producers to export to the other countries. Therefore, it is quite often very difficult, or impossible, to justify a plant of economical size in Canada.

The justification for the policies of some other countries may be found in the past history of their own synthetic organic chemical industries, which includes most of the petrochemical industry. In the United States, the Fordney-McCumber Tariff Act of 1922 gave tariff rates of 25-60 per cent to many chemicals and this allowed the establishment of an organic chemical industry in spite of the large, efficient European producers of that period. Undoubtedly the resulting higher prices created some burden which had to be borne by the economy as a whole, but the vigorous development of the American chemical industry since then has led to lower prices, greater variety of products, and a tremendous stimulation of other American industries.

Similarly, the organic chemical industry was established in the United Kingdom behind a key industry duty of 33-1/3 per cent ad valorem. The titles of the two Acts of Parliament establishing this duty are revealing: the Safeguarding of Industry Act of 1921, and Dyestuffs (Import) Regulation Act of 1920. These acts were the result of British experience in World War I and were intended to create a synthetic organic chemical industry in the face of competition from the well-established German industry. Subsequent experience clearly showed the value of these protective moves.

These two examples from the history of other countries show that, although the help of tariffs in establishing and promoting the growth of an industry such as the petrochemical one may create some initial difficulties, the long-term benefits and far reaching effects more than outweigh the initial difficulties because of the process of "economic leverage" I described earlier.

It is true that, in spite of an unfavourable tariff situation, the petrochemical industry has become established in Canada. Nevertheless, rapid as its growth has appeared, you have seen from the figures presented earlier that it is still far behind its United States counterpart in relation to overall national development. The fact that petrochemicals have so much room in which to grow as part of a balanced expansion of the Canadian economy is very heartening when one thinks of the surplus of natural gas by-products which will soon be appearing in the West, and of the increasing reserves of crude oil and natural gas seeking markets in most parts of the country. But this growth and diversification will not continue at the rate it should, and oil and gas products will not find their way into chemical products, unless tariff legislation is enacted and suitably enforced to ensure a market big enough for Canadian ventures. I would like to refer to Figure 12 to show the direct and indirect effects on the oil and gas industry if petrochemicals are imported into Canada rather than manufactured here. Not only does the petroleum industry fail to gain a customer for petrochemical starting materials, but it misses out on sales of its other products both to the petrochemical plant and to the secondary activities stimulated by the petrochemical plant.

Freight Costs—A superficial look at the western oil and gas fields invites comparison with the Gulf Coast and may lead to the assumption that, say, Edmonton will become the petrochemical centre of Canada. This overlooks the fact that the Gulf Coast has direct access by water to most of the main market areas of the United States, as well as to other world markets. Alberta has no such advantage and Figure 17 illustrates why this is so important. It shows the relative costs of transportation by pipeline, barge, rail, truck and air. Transport by rail or truck costs several times that by barge or lake freighter; the only available method of transportation from the West comparable in cost to water-transport is pipelining, and pipelining is restricted to the large-volume movement of fluids. The distance from Alberta to the markets in Ontario and Quebec is around 2000 miles, compared with 1000 miles from the Gulf Coast to Ontario, so that even apart from water transportation, Alberta is at a disadvantage to the Gulf Coast in terms of access to the major Canadian markets.

In discussing the cost of shipping materials across central Canada, we should distinguish between petrochemical starting materials and finished products, since the differences will affect the choice of plant location. In the first place, the basic oil and gas raw materials can, for the most part, be moved economically by pipeline, whereas the finished products cannot; a crude oil pipeline is already operating, a natural gas pipeline is under construction, and a liquid products pipeline is in the planning stage. Secondly, most petrochemicals contain oxygen, chlorine, nitrogen or other elements as well as the carbon and hydrogen derived from the oil or gas raw materials. These all add to the weight, and make it more expensive to ship the finished products instead of the raw materials. Finally, the railway freight-rate structures are set up in such a way that the higher-value finished products and intermediates cost more to ship than the low-value raw materials. Because of these factors, petrochemicals for eastern markets tend to be manufactured close to the markets rather than close to the raw material.

I hope that these remarks have illustrated the factors which can hinder progress in petrochemicals, and have underlined the need for all parties concerned — raw material producers, manufacturers, and governments to cooperate to the greatest extent to allow a healthy diversification of the petrochemicals industry.

Future Opportunities

What of the future? In the East, increased refining capacity will result in more refinery by-products but these are unlikely to keep pace with demand. New units are being installed to make petrochemical raw materials directly and to a large extent independently of refinery operations. At Sarnia, a special cracking unit is under construction to provide ethylene, propylene, butylenes, butadiene and other "building blocks" for chemical products. Another plant has started the manufacture of benzene and aromatic solvents. These projects are based on crude oil. It is unlikely that natural gas will be used extensively as a source of hydrocarbon materials in the East, as gas is not expected to have any price advantage over alternative sources. If plans go ahead to move natural gas by-products, such as propane and butane from West to East by pipeline, they will be welcome new sources of petrochemical raw materials.

In the West, the surplus of the natural gas by-products will pose s

(continued on page 1287)

Impact of Western Oil and Gas on the Canadian Economy

C. O. Nickle, M.P.

Publisher, "Daily Oil Bulletin", Calgary, Alta.

Address to the 71st Annual General and Professional Meeting, The Engineering Institute of Canada, Banff, Alta., June 1957.

A STORY IS TOLD of a dear old Irish lady who one day arrived at the Canadian-American border, after a short holiday in the U.S. She was greeted by the Canadian customs man with the usual question "Have you anything to declare?" Smiling, and with a twinkle in her eye, she replied "No sor, I have nothing to declare." At that moment her coat fell open, exposing to view the neck of a bottle. "What have you there," cried the customs man, and the old lady's eyes sparkled, she smiled and said, "Why, 'tis but holy water."

With that the customs man grabbed the bottle from beneath her coat, yanked off the cap, took a healthy swig, followed by a second, and then a third. "Holy water, me eye," said he. " 'Tis whiskey". With that the old lady's eyes turned heavenwards, her eyes twinkled anew, and a beautiful smile came over her face. "Glory be," cried she, " 'Tis a miracle."

That story has something in common with the subject of my address tonight, for the story of Western Canada's oil and gas industry is closely related to movements over the 49th Parallel of capital and know-how one way and products the other; and can be properly described as something of a real life, modern day miracle. To bring the miracle, God-given natural resources have been matched with faith, guts, know-how and capital of modern man, both Canadian and foreign.

Canada's decade-old and continuing boom has been built around the collective impact on our economy of several great natural resource developments, from one end of the nation to the other. Among them are: the iron ore development of Northern Quebec and Labrador; the Kitimat aluminum and power development of British Columbia; major expansion of new base metal resources in New Brunswick, Ontario, and Manitoba; the emergence of Canada as one of the top sources of uranium for the atomic age world; and the emergence of Western Canada as one of the great Western Hemisphere sources of petroleum, natural gas and their by-products.

"In terms of new capital invested, new employment created, breadth of impact on the national economy, and degree of changeover of a vast section of Canada . . . to a diversified economy, Western oil and gas can be classed as the most important of the decade's resource developments in our country."

In terms of new capital invested, new employment created, breadth of impact upon the national economy, and degree of changeover of a vast section of Canada from a one-crop to a diversified economy, Western oil and gas can fairly be classed as the most important of the decade's resource developments in our country. Even more important is that this development is still at its early stages. Its overall impact on the Western and Canadian economies will continue expanding in the decades ahead —provided economic and political climates remain favourable—to a level many times greater than that of today.

The two Canadian communities where the impact of oil growth is most apparent are the two major cities of Alberta. For the past decade their metropolitan population increase has made them the two 'fastest growing' communities in all Canada. Each is a case history of what happens when human ingenuity discovers and puts to use resources so vast as the oil and gas hidden beneath the prairies and foothills of our West.

Calgary, for half a century a farming and ranching centre whose citizens carried their 'frontier gambling spirit' into leadership among Canadians in pioneer oil wildcatting, has capitalized on that pioneering by making itself the "administrative headquarters" for almost all companies participating in the widespreading Western oil play. As "Canada's Oil Capital", Calgary has doubled its population in a decade, now has over 207,000 souls in its metropolitan area, and continues to add about 1,000 people per month.

New office buildings are rapidly changing its skyline, as scores of oil firms expand administrative facilities for their Western Canadian operations. Today these Calgary offices are manned by some 6,000 men and women—executives, technical experts and juniors—with a local payroll of about $30,000,000 yearly, and still growing. Through direct employment, and through the new demands created for a host of human needs from groceries to homes, clothing to automobiles, the expansion of the oil industry is credited directly and indirectly with well over half of Calgary's growth.

Though oil administration needs provided the foundation, Calgary is growing to a new maturity of diversified industries in manufacturing, catering to its own and Southern Alberta's expanding population. Over the next few years, increased oil refining capacity and new plants for the processing of natural gas and gas by-products will bring further strength to the Foothills City.

Edmonton, Central Alberta's major city, to whose citizens dreams of oil were until ten years ago just an example of Calgary wishful thinking, has become Canada's fastest growing community (a percentage point or two ahead of Calgary) because of fulfillment of the oil dreams. The Imperial-Leduc discovery 30 miles southwest of Edmonton in February 1947 was the spark that set fire to and began the blaze of international interest in Western Canadian oil and gas prospects, just as many years earlier the Turner Valley field near Calgary had spurred many small Canadian companies and a few large ones to the search that led to Leduc.

Leduc brought intense exploration, and discovery of a string of oilfields around Edmonton. Within a few short years Edmonton grew into the West's No. 1 oil refining centre, and No. 1 centre of petrochemical and gas-processing plants. Within a decade population doubled, to a present 240,000 souls for the metropolitan area. Oil equipment depots, warehouses, and new manufacturing plants to serve needs of the oil industry and the growing population of Central Alberta and the far north country were built, and are still abuilding. District exploration and production offices helped bring on a wave of office building construction in downtown Edmonton. As with Calgary, Edmonton population continues to grow at around 1,000 per month—with oil, gas and their by-products directly and indirectly responsible for over half of the expansion.

But these two cities are far from being the only examples of municipal growth because of oil and gas. Devon and Drayton Valley, two of the West's newest, most modern 'big towns', have in recent years been created in Alberta in the centre of major oilfields, Leduc and Pembina. The little city of Red Deer, doubled in recent years by discovery of oilfields in its vicinity, is looking forward to further growth as the site of the West's first butadiene plant, soon to be built by the Polymer Corporation, based upon by-products of oil and gas. Medicine Hat has started a new industrial growth as the site of Northwest Nitrochemical's ammonia fertilizer plant. Jumping Pound, Turner Valley, and Pincher Creek, once small ranching centres, are now locations of large gas-processing and sulphur plants. Okotoks, and a string of other small Alberta communities, are slated for similar industrialization over the next two years.

In Saskatchewan, Regina has begun a large expansion as district headquarters for a fast-growing oil development in the southern half of the "Wheat Province", and as a major oil refining centre. Lloydminster, Moose Jaw, Weyburn, Estevan, Saskatoon, and other Saskatchewan communities are growing with the oil boom. In Manitoba, Winnipeg, Brandon, and Virden are gaining from the impact of oil exploration, production or refining operations in their vicinity. In British Columbia's Peace River region, communities like Dawson Creek and Fort St. John are bursting at the seams from oil and gas discoveries that are now being tied into markets, and within a few months Taylor Flats will start a career as a gas by-product and sulphur production centre to begin the region's industrialization.

Industrial Growth

This community and industrial growth is among the measures of the impact of oil on Western Canada. It is visible evidence to be seen in scores of localities scattered over a quarter of a million square mile region. Other visible evidence is the host of oil or gas fields, the number of which is being increased by one hundred or more per year; and the host of individual productive wells, now over 12,000 in number, and being added to now at over 2,500 per year.

The immensity of what is taking place in Canada's West can perhaps best be conveyed by contrasts—the picture of ten years ago with that of today. Since Leduc's discovery set off the boom, the rate of new capital investment in the many phases of oil and gas had climbed from one million dollars per month to over $1½ millions per day. The population in the West supported directly or indirectly by oil and gas has climbed from about 25,000 to over 300,000.

Production of oil has increased about thirty times, from 19,000 to over 560,000 barrels per day. Oil potential—the ability to produce if transport facilities and markets permitted—has increased by 47 times, from 19,000 to over 900,000 barrels daily. Proved reserves of crude oil have increased by 54 times, up from 65 million to about 3,500 million barrels. Natural gas production has tripled to over 200 billion cubic feet yearly, but will soon start a far faster expansion with completion of the first great gas transmission pipelines. Proved natural gas reserves have increased eleven-fold to about 24,000 billion cubic feet—and will likely show a faster growth now that markets are being made available.

As you see, there has been a sharp contrast so far between the rate of growth of gas as compared with oil. This is primarily due to the sharp difference, in recent years, between the Canadian public and government attitudes towards these twin resources. Oil has been comparatively free to grow into markets, anywhere within economic reach regardless of international boundaries, with economic not political considerations being main factors in pipeline route and refinery locations. Implicit is recognition that freedom to market the greatest possible volume of oil provides the best guarantee of incentive to discovery of more and more of these resources. In other words, the best guarantee against shortage in the future is sale of enough oil now at best possible prices to provide revenue for bigger and better exploration.

The wisdom of this policy is evident. In a decade production has skyrocketed to thirty times its 1947 level. Gross revenue from oil production—only $16,000,000 a year a decade ago—hit $400,000,000 in 1956 and may pass half a billion dollars for this year, making oil Canada's No 1 source of mineral wealth. Yet discovery rate of new reserves is being maintained at 2½ times or more the rate of production—thus giving ever more security for the future.

At the time of Leduc's discovery only 418 miles of oil pipeline served Canadian fields. Within three years the 1,150 mile Interprovincial Pipeline connected Alberta fields with the head of the Great Lakes at Superior, Wisconsin, and as reserves increased this line became the world's longest, by extension over American territory to Sarnia, Ontario. This year the line becomes a 2,000 mile system by extension on to Toronto. In 1953 the second major oil pipeline system (Trans-Mountain) was built connecting central Alberta to Vancouver and Puget Sound, over the Rocky Mountains. Today a great network of feeder pipelines link these systems with oilfields in Alberta, Saskatchewan, and Manitoba, and with growing refining centres on both sides o the International border, all the way from the Pacific Ocean to Toronto. Today's oil pipeline network totals some 6,000 miles, and represents a $600 million investment. It is being steadily expanded to keep pace with needs.

The first major gas pipeline was proposed in 1948, almost nine years ago, but this and subsequent gas proposals soon became bogged down in a gumbo of public misunderstanding of gas economics, conflict between competing pipeline interests, and political battles. During the years oil grew into Canada's No. 1 revenue mineral, natural gas and its by-products grew into the nation's No. 1 'shut-in' resource.

Finally, two years ago, the barriers to gas development began to crack. Westcoast Transmission Company gained final approval for a pipeline system linking Peace River region gas with the Pacific coast, including approval to enter the vast U.S. Northwest market without which the project sadly lacked economic feasibility. The Westcoast system is now near completion and will go into operation within a few months. Plans for a gas pipeline east from Alberta, denied by political considerations the freedom to grow by stages into nearby Canadian and U.S. markets first, then into Eastern Canada later by the most economic international route, became a battle royal. A year ago came compromise between political and economic realities, involving a measure of government assistanee to overcome the deficiencies of a Northern Ontario pipeline route, and priority for the far-distant Eastern Canadian market. Frustrated owners of Alberta gas reserves—pressured by a $150 million investment in non-revenue producing gas-wells—helped very materially to get the compromise project underway by agreeing to supply gas at low initial prices. Today the Trans-Canada gas pipeline is under construction, will reach across the Prairies later this year, and as far as Montreal by the end of 1958. It will be the world's longest, most costly gas pipeline, about 2,200 miles in length, and around $400 million in cost.

With completion of these first major gas pipelines a new era in gas development and Western industrialization will get underway. With the incentive of markets, it is probable that Western Canada's known gas reserves will be proved up at a somewhat faster rate than the average 3,000 billion cubic feet yearly of recent years, and will thus far more than keep pace with market demand. Over the next few years the capacity of the initial west and east pipelines will be expanded, as markets are developed for gas in Canada and nearby U.S. areas. In addition, a new major pipeline link from southern Alberta through the Crows Nest Pass into the U.S. Northwest has recently been proposed, and will likely be given approval without the long battle that beset the earlier projects. Over the next five years, gas pipelines serving Western fields will likely catch up in mileage with the oil systems of today, and this long-idle Western resource, natural gas, will become a vital fuel for millions of homes across a broad belt of North America, and an important factor as fuel and raw material for a wide range of manufacturing industries across the continent.

Gas Processing

To the West, 'big scale' gas usage will mean far more than merely exploration for and production of this hydrocarbon. Much of the gas reserves that will supply the major pipelines will be drawn from fields containing wet, sour gas. From this must be stripped hydrogen sulphide, which in turn is processed to yield elemental sulphur. From the raw gas must also be stripped natural gasoline, propane and butane; constituents valuable for liquid fuels, and as raw materials for an ever widening range of products of the petrochemical industry. The stripped dry gas, largely methane, goes to the pipelines. Like some products stripped from it, methane is both a fuel and a basic raw material for chemical processes.

Over the next few years, therefore, a string of new gas processing and sulphur plants will be built in various Alberta and Northeast British Columbia gas fields, supplementing the several already in operation or now under construction. The West's production of sulphur, natural gasoline, propane, and butane will be expanded by several hundred per cent, and will result in major expansion of the western petrochemical industry, in the phases where it is economically feasible, to assist in putting these by-products of gas to use. End result will be a host of plants, big and small, widely distributed over the West, creating new local industry and employment, and adding to the diversification and strength of the Western and Canadian economies.

Let us look at one by-product of wider gas usage: sulphur. From a small beginning a few years ago, the West's sulphur production will reach a rate of 200,000 long tons yearly this Fall. By the end of 1960 sulphur production will probably be somewhere between 1,000,000 and 1,500,000 long tons annually—moving Canada up to a place second only to the United States among the sulphur-producing nations of the free world. This sulphur expansion will be important to many Canadian industries, including pulp and paper, uranium and base metal refining, and chemical. In the offing, however, is need for large-scale foreign markets for our sulphur, in the United States and overseas. I trust this export development will be patterned like our oil growth, avoiding the problems that for so long beset our natural gas.

The petrochemical industry has already involved a $140,000,000 capital investment in Alberta, because of recent years' oil and gas growth, and will undoubtedly further expand in this province and in other parts of the West. Biggest operation today is Canadian Chemical Company's cellulose acetate and organic chemical plant at Edmonton, drawing raw materials from nearby oil and gas fields. Also in the Edmonton area is Canadian Industries Limited polyethylene plant, and Sherritt-Gordon's ammonia nickel-leaching plant, the latter a successful mating of Manitoba nickel ore resources with by-products of gas in Alberta. Calgary now has its big C.M. & S. ammonia fertilizer plant, based on Turner Valley gas and by-products, and the area is soon to get two new sulphur plants. Northwest Nitrochemical has recently placed in operation a large ammonia fertilizer plant at Medicine Hat, combining American phosphate rock with southern Alberta sulphur and gas to serve agricultural needs on both sides of the international boundary. Next big project coming up will be Polymer Corporation's butadiene plant at Red Deer, which will use components of central Alberta wet gas to produce for the first time in the West the basic material for Polymer's synthetic rubber and chemical plant at Sarnia, Ontario. The years ahead will bring other additions as the economics of production, processing, transport and marketing permit in the broad field of petrochemicals, ranging through synthetic fibres and rubbers, plastics, paints and resins, synthetic detergents, nitrogen compounds, and automotive chemicals. But it is also apparent that economics will dictate that a sizeable percentage of gas by-products will have to be transported in raw form to Canadian and foreign areas far distant from fields of supply, but closer to major areas of petrochemical consumption.

Let us look now at some other measures of the impact of past and future oil and gas development on our nation's economy. First, the flood of capital investment into all phases, from exploration, production, transport and processing of the hydrocarbons, which directly and indirectly benefits every citizen and industry of our nation. In just over ten years, capital investment has mounted to nearly four billion dollars. Over the next ten years new capital investment—economic and political climate being favourable—will be between six and seven billion dollars. Over the next 20 years, it could exceed twenty billion dollars.

Second, our international trade balances, which are favourably affected in three ways by the oil and gas development. One of these is inflow of foreign capital (nearly two billion dollars the past decade, and expected to be 300 to 400 million dollars annually over the next few years) a major offset to our unfavourable trade balance with the United States. Another is the rapid progress towards self-sufficiency in balance in hydrocarbon resources, which cut nearly two billion dollars from Canada's dollar needs for imported fuels over the past decade, will save over half a billion in foreign exchange this year, and increasingly larger amounts in years ahead. The third is earnings of foreign dollars from export of some of our oil, gas and by-products. From a small beginning, these earnings rose to over $100 millions in 1956, may exceed a quarter of a billion dollars this year, and will become progressively larger. Every Canadian is better off because of this giant assist towards equalizing of Canada's import and export trades.

A third measure of impact is cost saving to Canadian consumers of fuels, made possible by development of the Western resources. It is estimated that the annual petroleum products bill to consumers in the areas now served by domestic oil would be some $100 millions greater if these Canadians had to depend upon higher-cost imported oils. On the Prairies, for example, gasoline, tractor and other fuels would be from five to seven cents per gallon higher in price, if the market had to be served with imported fuels.

Another measure of impact is the revenue added to treasuries of the various levels of government in Canada as a result of the oil growth, thus reducing taxation burden on others paying into those treasuries. The past decade's gain to governments has been around one billion dollars, with Alberta's treasury getting the lion's share so far (over $635,000,000), and the balance being shared by the Dominion and by Municipal and other Provincial governments in the west. As owners of mineral rights, Alberta and other western provincial governments get their major benefit from fees, rentals, royalties, and cash bonuses paid for these resources by the oil industry. The Dominion government cut comes from corporate and personal income taxes and these will skyrocket in years ahead, as the oil industry generally advances from the return of capital to the profit stage in its producing operations. The Municipal government revenues come from property taxes and other assessments. These too will continue to expand as the physical assets of the oil, gas and by-products industries grow in Canada. As a reasonable guess, government treasuries in Canada will collect somewhat more than two billion dollars the next decade because of the oil and gas development.

Less Dependent on Imports

A fifth measure of impact is the lessening dependence of Canada, and of North America, upon oil supplies drawn from overseas areas, via ocean supply lines, subject to curtailment or cut-off in time of emergency. Western Europe learned the hard way a few months ago its degree of dependence upon Middle East oil. Europe's oil crisis was alleviated by calling on surplus producing capacity in the United States, Venezuela and Canada. In World War 2, North America and its allies all learned that military success depends upon fuel for industry and armament, and adequate supplies when and where needed are essential. The growing oil and gas potential of Western Canada has, therefore, in recent years, become an important factor in the national and mutual defence planning of our own country and our southern neighbour.

To cover in adequate detail the economic impact of Western Canada's oil and gas, recent past and future, on Canada's economy would require far more time than available for a single speech. From some of the highlights I have discussed, it is apparent that impact of the growth has already been great; but has been small compared to what lies ahead in future years.

By 1980 I believe that the 700,000 square miles of geologically favourable territory of Western Canada will be producing oil, gas, and by-products with a field value of around three billion dollars yearly; will be supporting directly and indirectly in Canada somewhere between two and three million of the population of the greatly expanded nation; and will rate among the most important factors in the overall economy of our country.

Is the forecast too optimistic? Let's call on the report of the Royal Commisson on Canada's Economic Prospects (the Gordon Commission) for another judgment, based upon its recent studies. Says the Commission:

"Perhaps the most striking single thing about the forecasts of Canada's steadily mounting energy requirements is that by 1980 between two-thirds and three-quarters of a greatly increased total will be supplied by petroleum and natural gas. In both of these commodities Canada will on balance be more than self-sufficient. This is a very different picture from that of 1926, when petroleum and natural gas accounted for about one-eighth of the total energy consumed, and when almost all petroleum products were imported. The projection of demand for natural gas suggests in fact that its consumption may increase ten or more times within the 25-year period. It is clear from these figures that Canada's future economic development will depend to an increasing extent upon its resources of these fuels."

The Gordon Commission report continues: "The size of our domestic requirements is of course only one of the determinants of the rate of growth of the Canadian oil and gas industry. The first and most important factor is that the oil and gas be there to find and develop. There is every reason to believe that the geology of the interior plains region of Canada stretching from the United States border into the Northwest Territories is favourable to the discovery of large amounts of oil and gas, and that our prospective reserves should be more than sufficient to meet any demand in Canada in the future.

"The Commission's study suggests a possible level of production in 1980 substantially above forecast domestic demand. The potential output of oil in 1980 is estimated at about ten times 1955 production, and between 1½ times and twice the anticipated Canadian requirements of 1980. For gas, the potential output is estimated at over 15 times 1955 output, which would be about 50% more than expected domestic requirements in 1980."

The Gordon Commission thus envisages Canadian oil production in 1980 of some 3,500,000 barrels per day, compared with Canadian consumption at that time of between 1¾ and 2¼ million barrels daily. It envisages Canadian natural gas production of some 3,000 billion cubic feet in 1980, with Canadian markets absorbing around 2,000 billion cu. ft.

The Royal Commission concludes: "This means that there will be large quantities of oil and gas available for export. If we continue to import oil into Quebec and the Atlantic Provinces, the quantities available for export from the Prairies will be correspondingly greater. Should these exports be realized, our net export surplus by 1980 in oil and gas alone would be over one billion dollars per annum compared with an excess of imports over export in 1955 of $340 millions."

It is a rosy forecast, one whose fulfilment is important to you and me and all other Canadians, and to the Canadians of the next generation. The basic ingredients of resources, know-how and capital are available—provided we supply adequately the fourth vital ingredient in years ahead. I refer to incentive. If we provide the encouragement of sound government economic policies; fair but not excessive taxation with specific emphasis upon encouraging more Canadian investment in resources; if we keep the door open to capital, know-how and manpower from other nations able and willing to assist in building a greater Canada; and if we fully recognize the value to our nation's future of freedom for our resources to grow into both domestic and foreign markets in the most economic pattern; then we can be sure that incentive will join with the other basic ingredients in realizing the high hopes for the future of Western Canada's oil and gas resources.

Petroleum Refining

(continued from page 1276)

to the scene of the fire, if one should occur.

All parts of the plant are normally shut down at least once annually, to inspect the condition of equipment and repair it or clean it, if necessary. A high standard of maintenance is essential if the efficiency of the plant is to be maintained, and continually more effort is being placed on preventive maintenance.

Future Probabilities

The market for petroleum products will continue to grow in leaps and bounds, but the refiner will be faced with increasingly competitive conditions, which will force him to look ever more closely at his operating efficiency. This will require even greater automation of plants than exists currently.

Due to changing market conditions and the gradual lessening of the bunker fuel market, processing equipment will have to be installed to produce more total white products and less residual. In doing so, more light gases will be produced, which will have to be processed into a stable fuel, since the economics will not allow them to be burned in the refinery fuel system. As time goes on, the quality of crude available to the refiner will gradually decrease, so that new refineries will have to be better equipped with alloy steel to resist corrosion, and more equipment required to turn each barrel of crude into the same percentage of total white products.

In case some of you here today worry about the future when we will run out of oil, and consequently out of gasoline to run our motor cars, I would like to remind you of the very interesting plant which has just gone on stream recently in South Africa. This plant is called Sasol, and is located inland not far from Johannesburg. The plant is extremely complicated and I will not go into the detail of processing sequence and complexity of equipment. From a charge stock of 3,050 tons per day of coal, available at the plant site at a cost of 75c per ton, gasoline at the rate of 4,000 bbl. per day, plus middle distillates, fuel oil, wax, various kinds of alcohol, liquified petroleum gas, benzol, toluol, tar pitch, and waxes are produced. I am sure that the oil refining business will continue to be a fascinating one, and that the younger engineers will continue to find the solution to the perplexing problems which crop up continually in the changing supply and demand.

The Petrochemical Industry

(continued from page 1282)

vere problems. While further uses in petrochemicals will come along if favourable conditions develop relative to prices, tariffs, and transportation costs, the petrochemical industry cannot possibly consume any large fraction of them, and they will have to find outlets in fuel and energy uses, such as l.p.g. and high-octane gasoline. Looking as far as the West Coast, petrochemical ventures there will probably arise only if export markets are developed.

New processes may be expected which will increase the role of petrochemicals used in the extractive industries. Natural gas will find uses in the pulp industry both as a fuel and as a raw material for ammonia manufacture. The Sherritt-Gordon process of using ammonia to extract nickel from its ores is now well-known, and new processes are currently being developed to reduce other ores to the metal by means of reducing gases made from natural gas. With iron ore in southern British Columbia existing so close to cheap natural gas, the need for coke as the reducing agent may be eliminated. This could lead to a new type of iron and steel industry for western Canada.

Conclusions

This summary of the Canadian petrochemical industry will, I hope, have emphasized its versatility, its rate of growth, and its key place in our national economy, particularly in promoting sound and long-continued growth. Its task in the future is to provide still more of these key materials we call petrochemicals, and by research and development to foster the best use of this nation's raw materials, brainpower, and practical skills. This growth will not be easy, but if the problems of raw materials, tariffs and freight can be overcome, then hard work, cooperation and a determination to succeed, will ensure that the petrochemical industry duplicates the achievements of the Canadian oil and gas industry.

DISCUSSION

of Technical Papers and Other Articles

THE PROBLEM OF STREAM POLLUTION (A PANEL DISCUSSION)

L. Piché, D. Jones, AFFIL. E.I.C., H. H. Clare, D. S. Kirkbride, M.E.I.C.

The Engineering Journal, 1957, July, p. 985.

The following verbal discussion and comments were recorded during the panel session on stream pollution referred to above.

Question: Dr. Piché stated that in survey of the Ottawa River a close check on pH of the surface water was made in parallel with the B.O.D. and coliform bacteria content determinations. Was there much variation in pH at the various locations along the Ottawa River?

Answer (Dr. Piché) — pH index is not on the same footing as B.O.D. and coliform bacteria concentrations. It is a useful indication of the dilution of acidic or alkaline effluents. Normally, the pH does not tend to vary very much in a river unless a very extraordinary factor exists. In the Ottawa River survey, every sample was examined for pH but I can see nothing that can be gathered from a study of the pH variation. Nevertheless, in the specific case of acid or basic waste, the pH is an indication of the pattern of dilution of that waste, otherwise, the B.O.D. dissolved oxygen and coliform determinations present a more reliable means of measurement.

Q. (Mr. Owens). Mr. Jones, in your talk you referred to the Gauvin "Atomized Suspension Technique". Would this have applications in pollution abatement other than the purification of waste sulphite liquors?

A. (Mr. Jones). We do know a little bit about the potentialities of this process in the treatment of waste sulphite liquors and have wondered if this technique could be applied to the disposal of municipal wastes. However, as Dr. Gauvin is present tonight, I will ask him if he would care to elaborate further on this subject.

Dr. N. Gauvin M.E.I.C. There is much interest in this problem and undoubtedly investigations will be undertaken, but as yet nothing has been done and immediate consideration is not possible due to the present number of problems on hand. However, it is our intention to build a reactor which will be devoted almost solely to this purpose and which will treat sizable quantities of laboratory and pilot plant effluents. The problem is tremendous due to the low calorific value of sewage — about 3500 B.t.u. per gallon and it is normally desirable that the process be self-sufficient from a fuel point of view. Of course, if it can be successfully applied to this problem, then all that would be returned to the stream, for all practical purposes, would be distilled water and I am sure there would be no objection to that. The answer is, however, premature at this time, there is a possible application but whether it would be successful I cannot say.

Comment (Mr. Asselin, City of Montreal) — It is interesting to learn that, even without all the necessary legislation, industry is beginning to tackle the Waste problem. Since public funds must be used for municipal improvements, public interest and good will are essential and it is also interesting to read of the work of the Anti-Pollution League towards the education of the public in this pollution problem.

The treatment of municipal wastes introduces special problems in that the sewage must first be collected and brought to one point for treatment, since the economics of the operation would not permit a multiplicity of plants. As many as ten communities may have to combine their wastes for treatment in one economically sized plant. This produces many problems other than the technical, in fact the technical problems may be the easiest to solve. A great deal of co-operation is necessary and tremendous sums of money are required merely for the building of the collection systems.

Some progress is being made on this problem in this area. The north side of the Island is already supplied with a grid of eight sewers which were built at a cost of five million dollars each or a total of $40 million for a collection system. The plant has yet to be built.

Q. (Mr. Owens). Dr. Piché, could you give any idea of the costs of operation of a municipal treatment plant for the treatment of municipal and industrial wastes?

A. I have no personal experience in that field, but Dr. Berry, Chairman of the Ontario Pollution Control Board, has stated that the cost would run 25 to 35 cents per week per household for operation and amortization costs over a 20 year amortization period.

Comment (Mr. MacDougall) — I would like to point out one of the basic problems associated with pollution control. Although legislation is necessary for the control of pollution and will eventually be developed, the big problem is how this is to be applied so that there will be a rational approach to the use of water as a national resource which must be used and not abused. This involves the setting up of pollution standards. This cannot be done in "gros" but has to be specific to the particular problem involved. For example, I know of one place where a large steel mill was built on a river above a large city. The water in this river was very clean and it was obvious from the beginning that the standards would be very high. In fact the standard finally set up was that the water returned to the river should be of the same quality as that received. This is probably the ultimate in standards. If, however, you try to apply such a standard to the western part of Pennsylvania you could run into many absurdities. If you said that it was wrong to put alkaline wastes into the Allegheny River which is heavily surcharged with acid from mines it would be foolish, for in this case an alkaline discharge would be a value.

Standards are thus a very essential part of the problem and must be made so that they consider the needs of both industry and the public. These must be developed by co-operative effort for irrational and unreasonable standards, if once established and publicized, can become part of public thinking and great difficulty would then be experienced in changing them.

The most earnest thinking should, therefore, be devoted to setting up of standards which would not be injurious to anyone.

Comment (Mr. Clare). When Imperial Oil proposed to build a refinery near Winnipeg, on the Red River, Provincial authorities demanded that the water from the refinery should contain no more than 5 ppm. of oil. This was 10 ppm. less than the river already contained and meant that the refinery would be recovering oil from the Red River. This represented mostly service station refuse and had Manitoba continued to insist upon such a standard, the refinery could not have been built and this would have cost the citizens of the Winnipeg area about $2,000,000 a year, representing the decreased cost of gasoline that was passed on to them.

Q. As a representative of the Chemical Industry, I have listened with a great deal of interest to this discussion, however, I also have in the back of my mind my hobby of game fishing and I would like to ask a question, not of a highly technical nature. Dr. Piché said a little about the effect of oxygen on various game fish and I would like to ask him what variety of fish I could hope to catch in water that is only partly polluted?

A. (Dr. Piché). From my understanding, by discussions with biologists water saturated with oxygen (8 to 10 ppm.) will sustain fish such as trout and bass. Reduction of the oxygen content below 8 ppm. would cause a change in the species of fish present in the water and "coarser" varieties would likely be found.

Comment: (Dr. Piché). In discussions on stream pollution an accusing finger is frequently pointed at industry. I think that industry has been extremely co-operative and I see no reason why they should be placed on the defensive on this subject. One can easily point to a number of specific cases where industrial managements have been splendid in their consideration of the pollution problem. C-I-L, for example, in their studies of new plants have made elaborate surveys of the eventual consequences of pollution of neighboring streams. The Pulp and Paper Industry has tremendous technical problems but has already made spectacular achievements in dealing with the effects of pollution. The treatment of waste sulphite liquors to produce alcohol at Gatineau has had the effect of reducing the oxygen demand to 25% that of raw waste sulphite liquor while the B.O.D. is reduced to about 10% of its normal value by the utilization of sugars contained in these liquors. Again, in Quebec sulphite liquors are upgraded to a saleable product by the Lignosol process.

The problems that we have are not new, they have been encountered and splendidly managed elsewhere. Twenty-five years ago the Thames and Seine Rivers were badly polluted, yet today they are very agreeable rivers servicing heavily populated areas. Some such progress has already been made in this country. The improvement in the St. Claire river which is shown in some aerial photographs I have seen is quite spectacular and should be seen by anyone concerned with this problem.

Comment (Mr. Jones). In Sweden at present every sulphite pulp mill operates an alcohol plant and a chemical plant which manufactures potable alcohol and a number of chemical derivatives from waste sulphite liquor. Similarly, Swedish sulphate pulp mills operate chemical plants which produce talloil, turpentine and other chemicals. Potable liquor can not be made from waste sulphite liquor in Canada and even if this were possible, it would be economically unsound for every mill to produce alcohol. There are two industrial alcohol plants associated with pulp and paper mills in Canada and one mill produces Lignosol from waste sulphite liquor. The mills of the industry are constantly searching by research for products which might be produced from waste sulphite liquor or as by-products of the sulphate pulping process which could find a volume market. Such a general solution to this problem would likewise tend to reduce pollution from Canadian pulp mills.

Q. In the mining areas of Quebec and Ontario many of the streams are contaminated by cyanide from the mines and earlier I asked Dr. Piché a question related to pH since in these areas the pH of the waters is closely associated with their condition.

Dr. Piché, in his talk appeared to be principally concerned with bacteriological conditions. Mr. Kirkbride mentioned that legislation had been passed in Ontario to the effect that water must be returned to a stream fit for use as drinking water and other uses. In the use of ground waters, with which I am concerned, we feel that water after it has filtered through the ground will always be safe from a bacteriological standpoint, but if chemicals are present the water is, in many cases, unfit for further treatment and I wonder if you make a distinction between bacteriological and chemical contamination.

A. (Mr. Kirkbride). I would like first to clear up a point of misunderstanding. The International Joint Commission in its studies of boundary waters in the Detroit and Niagara rivers set forth objectives, which they felt should be achieved in those waters, and I believe are what you referred to when you mentioned legislation passed in Ontario. I made the point that these objectives are good and that we can expect to see them become the standards which will eventually have to be met in all areas.

As regards chemical contamination, it is pollution as much as anything else and sooner or later mills that are putting streams in the condition you describe will be required to treat their wastes and return them in a way that will leave the water suitable for other purposes. Dr. Berry, Chairman of the Ontario Pollution Control Board, gives a definition of pollution that is interesting: "Pollution and contamination in technical terminology refer to those conditions in water which result from the introduction of pathogenic organisms, toxic materials, or any other substances which depreciate the natural quality of the water to such an extent that its usefulness is impaired or it becomes offensive to the senses." *(Eng. Journal* 1955, Sept., p. 1181)

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

SILICONES IN THE PROTECTIVE COATINGS INDUSTRY

H. L. Cahn, *ASTM Bulletin*, No. 222

Many applications of silicone products as protective coatings are indicative of a rapidly advancing silicone technology. High heat-resistant enamels, additives for correcting surface film defects, anti-foaming compounds, electrical insulating coatings, and masonry water repellents are among the many silicone products.

The classic example of the use of silicone resins is in high-temperature aluminum paint. Here the vehicle is 100 per cent silicone resin and it gives a paint with the greatest utility in service at temperatures up to 500 F. It can be used at temperatures up to 1000 F. or higher but actually a less costly paint can be compounded containing only 50 per cent silicone resin. This is because the solids of a silicone resin are only slightly volatile at 500 F. under long exposure and a heat-stable resin is necessary. At higher temperatures even the silicone is volatilized while the aluminum film becomes fused to the steel. Therefore only enough of the silicone vehicle is used to set the aluminum film in place. Aside from metal pigmented coatings, white and coloured silicone paints and enamels can be used for adequate protection under specified service conditions. Home incinerators and reflectors for certain types of lights that generate much heat are coated with straight silicone or high-silicone content enamels. Coloured and iridescent metallic finishes are used to provide decorative as well as protective coatings for space heaters, ovens and other items subjected to elevated temperatures in normal service. The principal requirement of these finishes is heat resistance, but other factors such as colour, film integrity, gloss, etc., must be constant. High silicone content copolymers have been developed for service slightly less rigorous than that for which pure silicone resins are used. White enamel finishes on kitchen range parts which are exposed to fumes and steam and temperatures up to 350 F. frequently turn yellow under ageing while porcelain areas remain white. However, white enamel finishes based upon high-silicone copolymers with the proper organic intermediate will withstand such conditions and remain white. Hardness, mar resistance, flexibility, soap resistance, vegetable fat and fruit juice resistance have made such finishes valuable in the field of household and kitchen appliances. For basically the same purposes where a lesser degree of heat resistance is required low silicone content blends and copolymers are performing a valuable service. Coatings containing up to 25 per cent of total solids as silicones have markedly improved weather resistance and substantially upgraded heat resistance compared to the 100 per cent alkyd-base finishes.

Coatings for electrical equipment have the primary purpose of protecting the insulation which is already present. They keep out dirt and moisture. However they also must have some insulation value and usually must pass a dielectric strength and resistance to carbonization on exposure to arcing. They also are capable of satisfying tests for corona degradation. This is an electrical phenomenon wherein charged particles present in voids in electrical insulation bring about the formation of ozone and nitrogen oxides which rapidly degrade most insulation materials. In many cases the proved heat resistance of silicone insulation has permitted the doubling of the power output of a given motor frame size. Because of the thermal stability and extended high-voltage endurance of silicone materials, heavy-duty power cable with insulation fabricated from silicone rubber-coated glass cloth has doubled the power-carrying capacity.

Used in ratios of a relatively few parts per million, silicones are amazingly effective in performing specialized corrective functions. In varnish and resin cooking processes and in latex and latex paint manufacture serious foaming problems can be controlled. Flotation of tinting pigments in paint manufacture can be corrected by silicones and they also serve other purposes such as a pigment wetting agent and an antisilking agent.

Probably the fastest growing application of silicone materials in the protective coatings industry is the use of silicone water repellents on masonry. A water-soluble silicone, sodium methyl siliconate, is the only material which has been found satisfactory to make limestone water-repellent. This material cures upon exposure to carbon dioxide in the air. It is gaining increasing use in its application to roadways, piers and abutments of concrete highway bridges because of the freeze-thaw stability that it imparts to concrete. The light reflectance of wet concrete is greatly improved by treatment with this water soluble silicone and it finds use in highway construction. Minimizing or completely eliminating efflorescence on masonry walls, as a result of absorption of external water, is another advantage to be gained from the application of a protective silicone water-repellent coating.

The accelerated pace of engineering technology is constantly creating the need for coatings having properties which the silicone materials can provide. Consequently there is a growing list of specifications for finishes incorporating significant quantities of silicone products.

PAPERS PRESENTED TO BRITISH ENGINEERING INSTITUTIONS

The Institution of Civil Engineers

Shaft Raising in the Scottish Highlands
R. S. Henderson (No. 6190)

This paper describes a new method of raising a high-pressure shaft for a hydro-electric power station, necessitated by the great depth of shaft—one of the deepest in the United Kingdom. The method used was entirely different from the timbered stope or normal sinking, and eventually involved initial drilling of a 6-in. dia. hole 600 ft. deep with a maximum error of 2½ ft. to 3 ft. The shaft is the penstock to the St. Fillans section of the Breadalbane power scheme in Scotland.

Initial setting was done by concreting in a 20-ft. pipe as drill casing, which was set up very accurately. Photographic equipment was installed in the drilling head at various depths to record any deviation; during drilling, tests for verticality were made every 25 ft., and any errors were corrected by using whipstocks. Drilling took three months and was within 2 ft. of vertical when finished.

A special stoping cage was designed, with particular attention being paid to safety precautions. This cage, roughly a cylinder with conical ends, held a crew of two and was hoisted from below to the drilling face by a wire rope passing through the 6-in. drill hole to a headgear at the top of the shaft. After drilling (compressed air) and stemmining the face with explosives, the cage was lowered and stowed away before firing. This procedure was repeated at an average drilling time of 2 hours, charging time of 30 min., and travelling to and from the face 1 hour, including stowing the cage. Smoke clearance (1 hr.) and handling rope and cage (1 hr.) gave a complete round in 6 hours. Actual rate of progress was 64 ft./week, with a maximum of 138 ft. in one week, in the latter stages, when conventional methods would have been slowest. The penstock shaft was finally enlarged by drilling and firing from the top.

The paper mentions certain technical difficulties, such as the effect of water on the telephone system, and makes recommendations for future use of the technique.

The work was carried out by the Mitchell Construction Company on behalf of the North of Scotland Hydro-Electric Board.

RESEARCH IS LIFEBLOOD OF AVIATION

R. Hotz, *Aviation Week*, v. 66, no. 22

Without a constant flow of new technical data being supplied to the industry by research workers, the vast machinery of the largest single manufacturing industry in the United States would soon come to a halt. No other industry, with the possible exception of nuclear energy development is more dependent upon swift sure technical progress for its future than aviation. No other industry has raced through its technical spectrum so fast during the past fifty years. It is important to realize that only 54 years after the Wright's fabric, spruce, and wire biplane rose from North Carolina sand dunes using a 12 h.p. engine and hand carved wooden propellors, man has flown faster than 2100 m.p.h. and reached an altitude of 126,000 ft.

To support this terrific pace of technology the aviation industry and agencies of the federal government have built a vast organization of skilled technicians and modern research facilities. Research and development in aeronautics and its supporting sciences has grown to a multi-billion dollar annual effort and shows no signs of stopping its phenomenal growth. The aircraft industry today is ploughing 13% of its sales dollar back into research and development, which is the highest ratio of any major U.S. industry. This vast effort embraces the resources of the Air Force, Navy, and Army, the industrial complex of the nation's largest single manufacturing industry and the skills and laboratories of the university system.

Research and development programs devoted to aviation and its related sciences face many acute problems in fulfilling the basic function of providing a sound technical foundation for future development of the industry. Most acute is the need for continued expansion at a rate which will exploit fully the many new technical areas opened up as a result of earlier research. These efforts by their nature are dynamic progressive processes and do not fit easily under an artificially imposed budget ceiling. Each major technical area opened by basic research creates a whole new family of problems that must be solved if fruits of a major technological break through are to be harvested efficiently. Also, it should be remembered that this research and development effort provides a technology which enables general industry to create new products for both civilian and military applications.

In place of the fallacious "constant budget level" policy that now dominates government controllers of research and development programs, a more realistic financial approach is required, geared to the creative character of research effort and with full recognition of the effects of dollar inflation on the absolute scale of research results.

The rapid pace of technical development also has produced an acute need for new types of research development facilities such as hypersonic wind tunnels, pressure and altitude engine test cells, solar furnaces, nuclear material testing reactors, supersonic sled tracks and captive missile test stands. Neither planning nor implementation of major government construction programs have kept pace with these requirements. Demand for hypersonic and missile re-entry data already was acute before shocktube and multi-stage missile test vehicles were available to produce it. Ram-jet engines, rocket engines, exotic fuels and ballistic missiles were ready for experimental testing before adequate test facilities were designed, built and properly instrumented to handle them.

Basically, government philosophy has been to confine its research and development facilities investment to projects too costly for industry to build or operate as individual firms. However, industry has found that using government development facilities, particularly for early experimental work, exacts too heavy a time penalty in the stiff competitive race for contracts. As a result most successful firms have invested heavily in their own development facilities. Virtually every major airframe contractor has his own supersonic wind tunnels. All major engine manufacturers have built large jet engine development laboratories. One company is building a new research centre covering research in hypersonics, aerodynamic heating, nuclear development and helicopters. Also, university facilities are increasingly important in research and development.

Although the government is now spending over a billion dollars annually for research and development (about 60% of it with industry) there is a strong trend to get industry to shoulder a higher percentage of the overall costs with its own money. For competitive reasons industry would prefer this type of operation but before it can be effective there must be basic revisions of government cost regulations in this field.

There is great need for a sound research and development program for this vital industry to realize the full potential of the "air age".

WORLD'S LARGEST EXPERIMENTAL GENERATOR IN SWEDEN

Bureau de Presse Suedo-International, Stockholm, June 1957

The large Swedish manufacturers of electrical equipment, ASEA, are replacing their existing high-voltage laboratory at Ludvika (in service since 1933) with a new installation. The original laboratory was one of the most advanced in the world and included a 1000 Mva. generator, which will still be used. The new equipment will include a generator rated at 2500 Mva.

It will be possible, by operating the two generators in parallel, to do experimental work at about 3500 Mva. and at potentials up to 13 kv. Special transformers will be installed to give facilities for tests up to 2000 Mva. and 145 kv. At higher voltages, the three-phase power will fall off, but it will be possible to use the laboratory facilities for single-phase tests up to 250 kv. or with limited power up to 360 kv.

Many other facilities will also be installed in the new laboratory, which will be almost tripled in area. The whole program is due to be completed in 1958.

TRACTOR OPERATED BY REMOTE CONTROL

Tests have recently been carried out at the U.S. Army Research and Development Laboratories, Fort Belvoir, Va., on a radio controlled tractor. This is believed to be the first application of remote control to construction equipment, and one application may be to carry out construction work in radioactive and combat areas. From a jeep or helicopter equipped with a standard military radio transmitter and a special control box, an operator can start and stop the machine, engage and disengage the gears, manipulate a dozer blade, and steer the unit. Normal operations can be done from distances up to 15 miles, the practical range of the radio, though initial tests were done with the tractor and control point within visual range. It is possible that small television cameras installed on the tractor would enable the operator to work the unit without the need for intermediate observers. ELECTRICITY IN FRANCE

***French Economical and Technical Bulletin*, No. 1., 1957**

The main sources of electrical power in France are coal (65%), oil (20%), and hydroelectric plants (15%). Natural gas, only recently discovered in France, may play an increasing part in this scheme. Comparative figures for world averages are: coal 53%, oil 29%, natural gas 10%, and hydroelectric power 7.8%; and for the Western European countries as a whole: coal 75%, oil 16.6%, natural gas 0.6%, and hydroelectric 7.8%. These figures show a relatively high proportion of hydroelectric power in France.

Post-war plans for power production have emphasized the need for adequate supplies to meet industrial and other needs. Hydroelectric sources show a slight predominance over thermal production, mainly because conventional fuels are not readily available. Almost all petroleum supplies are imported (25 million tons in 1955, compared with a domestic production of one million tons); nearly 30% of the 74 million tons of coa used in 1955 was imported, and about the same proportion of total French power needs are supplied by imported products.

In 1955, thermal power stations operated by nationalized and private industry produced 24.1 billion kwh. an increase of 13% over 1954. The figures for 1956 should represent a doubling of thermal power production since 1947. Fuel efficiencie have been improved considerably in recent years, the latest plants recording an average of 2650 calories pe kwh. compared with 4960 cal./kwh in 1948. Thermal production from liquid fuels has shown an increas of some 20% between 1947 and 1954 with a comparable figure of 10% fc gaseous fuels.

Hydroelectric power in 195 amounted to 25,575 million kwh. (13 045 million kwh. in 1947), and represents a 5.3% rise over 1954. Th increase was limited by a sever drought during the last half of 195 Installed capacity of hydro-electr equipment rose from a total of 3,743 000 kw. in January 1946 to 7,874,00 kw. at the same date in 1956. Annu production capacity more tha doubled during this period, from 13 733 billion kwh. to 28,308 b. kwl

Distribution networks have deve oped to meet increasing demands ar to reduce transmission losses, whic represented some 11% of power r quirements in 1955. Between 19 and 1955 various networks were extended as follows: 90-kv. circuit from 2050 miles to about 3200 miles; 150-kv. from 3300 miles to 5700 miles; 225-kv. from 1280 miles to 6000 miles. The 110/120 kv. circuit, which extended 826 miles in 1938, has been converted, and 650 miles of 225-kv. lines have been installed to handle up to 380 kv.

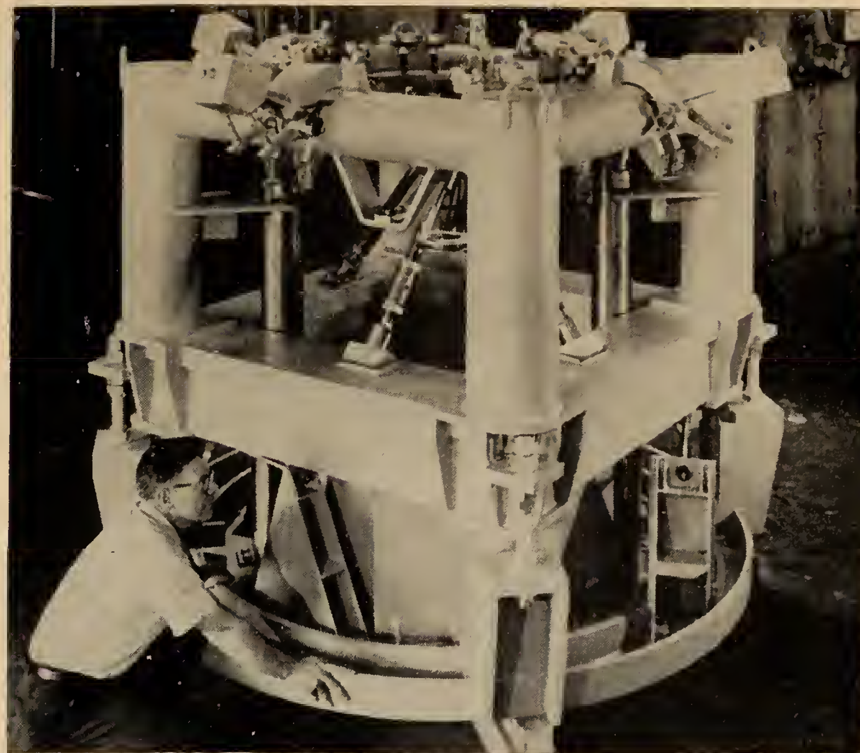
Future developments in France include hydro-electric projects on the Rhone, Rhine, Isere, and Durance rivers and thermo-electric production from 26 new groups with an average capacity of 115,000 kw.

Future developments may lie in newer techniques such as gas turbines, power from ocean tides, and nuclear energy. A small experimental 1200 kw. turbine was installed in 1952 in the Rheims power station, and other work has been done in view of the development of natural gas deposits.

France has long been concerned with the production of power from the sea, and construction of a tidewater power plant is planned in the Rance estuary in Brittany. (A description of this project was published in the *Engineering Journal*, 1957, March, p. 301). By 1963, this plant should be in full operation and producing 800,000,000 kwh. a year.

The first unit designed to produce electricity from nuclear power was the G1 pile of the Marcoule plant, near Avignon, which went into operation early in 1956 with a capacity of 5000 kw. Two further piles, G2 and G3, are being built and will supply, respectively, 25,000 kw. and 30,000 kw. by late 1957 or early 1958. A 60,000-kw. plant, the EDF 1, is to be completed in 1959 in the Loire valley and will feed into the main distribution network.

Plans to meet expected industrial and domestic needs in 1965 are for 44 billion kwh, of hydro-electric power and 51-58 billion kwh. of thermal power, which would include 3 billion kwh. from nuclear sources. By 1957, nearly 200 billion kwh. may be needed, the hydro-electric potential may have reached its limit of expansion at some 60 billion kwh., and nuclear energy may have to supply much of the additional requirements.



STAND FOR IGY EARTH SATELLITE LAUNCHING

This firing stand for the Vanguard earth satellite rocket is a roughly cubic steel framework, measuring some 6½ feet on a side. The stand will be mounted on top of the launching platform and is designed both to test and launch the rocket. Provision is made for holding the 72-foot rocket exactly vertical, weighing the unit and its fuel, and measuring thrust during captive runs. More than twenty fuel and instrument lines have to be disconnected instantaneously at the moment of firing. The base of the stand houses a large flame deflector. The weighing and measuring equipment consists of four SR-4 load cells which support the rocket stand on a weigh ring; measurements of weight and thrust are relayed to a bank of recorders in a distant blockhouse. The stand is also equipped with floodlights, emergency spray nozzles for fire-fighting, a safety shower and emergency eye-wash fountains for the use of operators. The stand was designed and built by the Loewy-Hydropress Division of Baldwin-Lima-Hamilton Corp.

NIELS BOHR INTERNATIONAL GOLD MEDAL*

The Institution of Danish Civil Engineers

The Dansk Ingeniorforening instituted an international gold medal on Oct. 12, 1955, the occasion of Professor Niels Bohr's 70th anniversary. The medal is to be awarded every third year to scientists or engineers who have made important contributions to the peaceful use of atomic energy.

The first medal was presented to Professor Bohr himself at the inaugural celebrations, which have now been commemorated by the publication of an interesting book which contains the addresses given on that occasion by Professor C. Moller, representing the University of Copenhagen, President Anker Engelund, of the Technical University of Denmark, and Director Georg Dithmer, chairman of the Dansk Ingeniorforening.

Among his many associations with scientific societies, Professor Niels Bohr has been director of the Institute for Theoretical Physics at the University of Copenhagen, since its inception in 1920; president of the Royal Danish Academy and of the Danish Cancer Committee; and chairman of the Danish Atomic Commission.

The addresses pay tribute to Professor Bohr's outstanding work on the structure of the atom, which led to a new outlook on the physical principles involved and represented a departure from the classical theories of physics. This work was recognized by the award of the Nobel Prize in physics, in 1922.

---

* Candidates for the award of the medal are to be nominated by members of EUSEC (Engineering Societies of Western Europe and the U.S.A.) The first committee for nominations consists of Prof. Bohr; E. Warburg, president of the University of Copenhagen; A. Egelund, president of the Technical University of Denmark; O. Rode, president, Dansk Ingeniorforening; and G. Dithmer, immediate past-president.

MACHINE LAID ASPHALT CURBS AND GUTTERS

A paper read by W. H. Schuelie and F. Swineford at the annual meeting of the Association of Paving Technologists, in Atlanta, Ga., in Feb. 1957, described the advantages of machine laid asphalt curbs and gutters, which are said to prove cheaper, easier and faster to construct, and more durable than those laid by hand methods. The machines described can place up to 2000 feet of curb in an eight-hour shift, depending on the operators' skill. The forward speed is from 4 ft. to 7½ ft. a minute. Guide lines are marked and a thin coating of rapid curing asphalt is applied to the cleaned surface to provide a bond between the pavement and the curb mixture. Hot mix asphaltic concrete, contained in a hopper, is extruded through a mould form under compaction pressure by a horizontal conveyor screw, driven by a small gasoline engine. The compaction pressure propels the curber forward. Operating crew is usually three men; one to guide the machine and two to keep the hopper filled. The paper gives several successful hot mix formulae for use with machine curbers. (Photo of the Stephens-Canfield model 55-A automatic curber, by E. L. Hardin Associates, Inc., Salisbury, N.C.)

MASS MOVEMENTS IN METROPOLITAN CITIES

Colonel S. R. Bingham*

A solution of today's transportation problems lies in the correct estimation of future travel demands; in knowing how to deal with them; what future patterns of land development and transportation facilities provide the most logical and complementary physical framework for regional prosperity; and what patterns of organizations and finances provide the most efficient means of obtaining and operating the desired physical patterns.

Attention must be given to plans for accessibility, fluidity of travel in the metropolitan area, recognition of the inherent relationships between the pattern of living and working areas and the connecting lines of communications. There must be an analysis of the fundamental processes of population and economic development. Existing systems of transportation must be reviewed. Needs and demands for a twenty-year period must be met. Air and helicopter service must be included as a matter of study.

Cost of monorail and subway facilities must be considered. The latter is however very costly, ranging from 8 to 10 million dollars per mile of track, compared to the monorail which at $500,000 per mile is not costly and can be erected quickly. It is versatile, utilitarian, and has aesthetic appeal.

If modelled after the Dallas, Texas, and Fort Lauderdale, Florida, installation, gasoline engines are employed to propel the car. The rail, a steel pipe, thirty inches in diameter is fastened to inverted "J" shaped towers, thirty feet high. Especially designed for high speeds, the towers can be constructed to any height. The rail is designed with the centre of gravity below the carrying point which permits high speeds with safety. Passengers are carried overhead between stations but are brought to ground level for loading and unloading. It is fast, efficient and comfortable. Designed for monorail and propelled by gas engines the coaches are both novel and attractive, and have proved popular from the point of view of public acceptance. The coach is 55 ft. long, 6 ft. wide and 8 ft. high. Seating 60, it can provide standing room for 50 or more, may be filled or emptied in 30 seconds, and operated on one level and underground for inter-city or central operations.

Locking wheels and locking guide rails make derailment impossible. Brakes are automatic electric and include "deadman control" braking which acts instantly if the operator's hands leave the controls.

Briefly mentioning an innovation in the field of transportation Colonel Bingham stated that he had developed the essential requirements of operations and equipment designs of the "carveyor" together with the engineers of the Goodyear Tire and Rubber Company and the Stephens-Adamson Manufacturing Company. Valuable as a medium of transfer or connection in loop operations, it adds another tool against the transit problem.

All corrective undertakings must however be planned and integrated with a regional master traffic plan.

* Col. Bingham is former chairman of the Board of Transportation of New York City, retired executive director and general manager of the New York City Transit Authority, and consultant for the St. Lawrence Municipal Bureau of the City of Montreal. This is a summary of an address to the Junior Section, Montreal Branch of E.I.C., given in April 1957.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Progress by NYSPA

July was marked by the peak placement of concrete for any one month with 177,000 cubic yards placed in all structures, bringing the total to date to 1,415,000 cubic yards or 69 percent of the total requirements. Excavation exceeds 43 million cubic yards. Employment averaged 6,470 for the month.

Concrete placement in the American half of the Powerhouse continued on schedule. Some 62,000 cubic yards were placed during the month, bringing the total to date to 701,000 cubic yards or 72 percent of the total requirement.

At Long Sault Dam, concrete placement was progressing at a rapid pace as approximately 72,000 cubic yards were placed in July, bringing the total to date to 336,000 cubic yards.

At Iroquois Dam, 12,000 cubic yards of concrete were placed in piers and roadway sections, bringing the total to date to 170,000 cubic yards.

Concrete operations at Massena Intake continued rapidly with 30,000 cubic yards placed during July bringing the total to date to 172,000 cubic yards. Placing of crushed rock blanket, riprap and embankment continued for the dike.

Channel improvement work at Sparrowhawk Point, Leishman's Point and at Ogden Island was progressing on schedule. The channel work was 80 percent completed. Topsoiling and seeding of Galop South Channel spoil areas was over 50 percent completed.

Clearing of the reservoir by three contractors was continuing on schedule with some 7,000 acres or 64 percent of the area cleared to date. All work under the original contract for clearing the Barnhart-Plattsburgh Transmission Line was completed. Construction of the line was continuing with unloading and hauling of materials and setting of poles for the structures.

Surfacing of Highway Route 37 was nearly completed and rough grading and embankment for Highway Route 37B were completed. Placement of concrete in abutments for the Franklin Road Bridge was on schedule.

Embankment and riprap were being placed on Richards Landing for the new Massena Beach. Selective

The Iroquois Dam. Looking upstream at Iroquois Dam in the foreground. Iroquois Lock on Iroquois Point, excavation of Iroquois Point at left, Toussaints Island and Sparrowhawk Point in the distance.

cutting operations were in progress along the Barnhart Island Access Road under the Park and Woodland Improvement Contract.

Progress by Ontario Hydro

Throughout the month of July, weather was generally favourable for construction work. The labour force totalled 5,250 persons. At the powerhouse, favourable progress had been made in concrete placing operations. A total of 680,000 cubic yards of concrete had been put into this principal installation by the end of July, with concrete for fifteen draft tubes having been placed to date.

Installation of mechanical parts was progressing well in the powerhouse. The speed ring for No. 10 unit was in place and the pit liner for No. 9 unit had been installed. Meanwhile, the frameworks for both the ninety-ton headworks gantry crane and for the three hundred-ton powerhouse main gantry crane, had been assembled.

All passenger and freight traffic during July was diverted to the new forty-mile section of Canadian National Railway main line between Cardinal and Cornwall, which will by-pass the area to be flooded by the power development next year. Freight traffic had been operating over this new section of double track for the past two months to consolidate the track and test all the automatic controls.

Removal of the old double track between Cardinal and Cornwall was started. This track is located adjacent to, and immediately north of, the river. Track removal was started first in the Mille Roche area where Cornwall Dike crosses the old railway line in three places.

It had been necessary to leave gaps in the dike construction until the old railway line was taken out of service. With the removal of these tracks, work got underway during the month on the closure of the gaps in the dike. Some 500,000 yards of compacted glacial till will be placed in the dike to close the gaps.

Foundation work was completed during the month for the northwest end of the dike in section No. 1. Dike building is being concentrated also in the area between the powerhouse and the Cornwall Canal closure structure, where filling and compacting are in progress.

In highway construction, with the completion of Hoople Creek bridge all detours had been eliminated on the diversion road between Cornwall and Iroquois. In another section of this work, the No. 31 Highway overpass was progressing favourably.

Channel improvement work progressed satisfactorily during the month. At Galop Island, the contractor was approaching the end of cleanup of the main cut through the island. A dredge was working upstream from the dewatered section of river bottom west of the island in preparation for breaching the cofferdam. By month end a total of some 13,500,000 cubic yards of earth and rock had been removed to form the new channel. At Point Three Points, the cofferdam had been completed. Work in this area was accelerating as the contractor proceeded on removal of the material in the Point.

The preliminary house moving program in Matilda Township was finished during the month with half of the homes placed on their new foundations.

House moving operations continued from the Dickensen's Landing area, to Ingleside, with seventeen houses moved during the month. In Ingleside, work was progressing on three churches, also the public and separate schools.

At townsite No. 2 (Long Sault), preparations were made for paving the roads. Work was advancing on the shopping centre with steel erection completed and exterior masonry work started. The new CNR stations at Long Sault, Morrisburg, Iroquois and Ingleside, were virtually completed during the month.

Much construction activity was underway in Morrisburg. The exterioi masonry for the shopping centre was nearly completed and interior partitions about 80% built. Some sixty units of rental housing were well advanced. At Iroquois, construction of rental housing also was continuing. Occupancy of units there will take place in August.

St. Lambert Lock, most easterly of seven new Seaway locks, upstream from the Victoria Bridge. The bridge carries double-track of the Canadian National Railways from Montreal to the South Shore of the St. Lawrence River. The lock chamber will provide a width of 80 feet, depth over sills of 30 feet and a usable length of 768 feet. Some 600,000 tons of concrete was required for this lock. The lift of the lock will be 15 feet.

Progress by SLSA

Work was accelerated on all sector of the Canadian navigation projec during the month of July, with employment at new peaks. Dredging and channel excavation continued on schedule. Work was well under way on dredging the channel north o Cornwall Island and on the approacl channel to Iroquois Lock.

Placing of concrete at the Iroquoi Lock was practically completed at en of July, with the upper sector gates i place and erection proceeding on th lower gates. Erection of steel for th roller swing bridge was progressin rapidly.

On the upper Beauharnois Loc 112,000 yards of earth and rock wer excavated in July, while 18,000 cub yards of concrete were poured, all in the upper gate area, bringing concrete to about 33 percent of completion. In the lower Beauharnois Lock 55,000 yards of rock and earth were moved in July and 40,000 cubic yards of concrete placed bringing total to date to 200,000 cubic yards or about 45 per cent of the total. One lane of the highway underpass under the lock was open for traffic.

At the Cote St. Catherine Lock 130,000 cubic yards of excavation was done during July, while 40,000 cubic yards of concrete were placed, bringing the total to date to 200,000 cubic yards or 70 per cent.

At the St. Lambert Lock 75,000 cubic yards of concrete in the chamber and upper approach were placed during July, bringing concrete to some 80% of completion. This established a record for concrete placed here in any one month. No work had yet been started on installation of gates. The collection sewer to serve Préville and Montreal South was about 60 per cent completed by month end, and the regulating channel about 40 per cent completed.

At the south end of the Mercier Bridge a half mile stretch of the seaway channel had been excavated by month-end. Footings for the lift span over the channel on the CPR rail bridge were completed and falsework for the span was being erected. Between the remaining portion of the original bridge and the channel crossing 11 piers some 100 ft. in height for the highway approaches on the south shore were completed, while on the south side of the channel another 28 piers were completed. On the higher piers the contractor was using the Swedish slip-form method of construction.

At the Jacques Cartier bridge, jacking of the superstructure spans continued between piers 3 and 13 to various heights ranging from zero at piers 3 and 13 to a maximum of some 8 feet at pier 7. Some 700 tons or 85 per cent of the steel had been delivered for the new through-span over the seaway channel, while floor beams and part of the girders had been erected on scaffolds on the upstream side. After the new span is rolled into place in November, it will be jacked up a further 25 to 30 feet. Work will commence in September on erection of highway bridge over the St. Lambert lock.

Contract Awards

SLSA readvertised its call for tenders for construction of control buildings at Iroquois lock in mid-July, to give contractors in smaller construction business a chance to tender. The work involves five buildings.

Workmen are dwarfed by the great walls of rock where construction of the lower Beauharnois Lock is under way. Here ships will be raised 42 feet into a canal about a mile in length which will lead them to the Upper Beauharnois lock and a second 42 foot lift, after which they will enter into the Beauharnois canal.

Seaway News

730 Foot Limit for Vessels using Seaway

All Great Lakes vessels now operating or under construction will be able to use the seaway when it is completed. But a few giant 'lakers' may be delayed at canal locks so as not to interfere with other vessels.

A joint announcement by SLSA and SLSDC on July 17 stated the maximum for normal operation would be a length of 715 ft. and a beam of 72 ft. However, ships 730 ft. x 75 ft. would be accommodated 'subject to appropriate scheduling and handling. The purpose is not to interfere with other traffic whenever the transit of such vessels is unduly delaying the transit of other shipping'.

The announcement does not change the picture for ocean-going ships, where the governing factor is the Seaway depth.

Bridge Below Montreal Island Advocated

Addressing the Rotary Club of Montreal on July 17, Dr. Pierre Camu of Laval University called for a bridge over the St. Lawrence river between Varennes and the eastern end of Montreal Island. He stressed the inadequacy of trans-river connections at Montreal and described the problem below the city as even worse. 'The Nun's Island bridge', he said, 'will improve the problem of linking the two shores, but I believe we should have asked first for the down river span. Industrial development of the south shore between Sorel and Boucherville demands it be built, even without considering local needs'.

Nun's Island bridge should be at least six lanes wide, he said, or if possible eight lanes wide. The future Hydro-Quebec plant at Heron Island could be planned to accommodate one-way vehicular traffic, leaving the Mercier bridge to carry traffic in the opposite direction. It was his belief that a tunnel should be constructed also to accommodate road traffic.

Contracts for some of the piers for Nun's Island Bridge have already been awarded, and other contracts relative to its construction will be let early in 1959, according to a statement by Transport Minister George Hees. No changes are contemplated in the plans affecting Montreal, for which decisions had been taken by the former government. Completion date for the bridge would be early in 1961, he said.

Richelieu-Hudson Deep Waterway

There are rumors that the Suez Canal Company may be interested in developing the Richelieu - Lake Champlain - Hudson Waterway. A deep-draught canal, lock and lake system would slice 1,200 miles off the Montreal-New York run for deep-sea ships, with enormous savings. Passage by slow freighter would be cut from eight days by sea to 3½ days through the waterway. It would tap a vast volume of seaway traffic from midwest U.S. and the Canadian industrial heartland.

The route at present runs 46 miles down the St. Lawrence from Montreal to Sorel, 14 miles up the Richelieu to the St. Ours Canal 1/10 of a mile long with draught of 12 feet and one five foot lock. Thirty-two miles further up it enters the 12 mile Chambly Canal with an 80 ft. lift in nine locks and a draught of 6½ feet, to Lake Champlain. From Lake Champlain it follows the Champlain Canal in the United States into the Hudson river. Total distance from Montreal to New York is 452 miles.

Today there is only one major commercial user, — Davie Transport of Montreal, which carries some 25,000 tons of newsprint yearly to New York, returning with general cargo. The company has seven vessels. Most of the traffic through Canadian canals is local, most of it fertilizer. In 1955 the system handled 97,000 tons compared with 109,000 in 1954. An announcement in mid-July that a new bridge over the Richelieu would be high enough to clear large ships has lent weight to the rumors, though no formal plans have so far been laid before either the Quebec or the Federal Government.

Cal-Sag Canal Expansion

Work was started in the fall of 1955 on the Cal-Sag improvement project, to widen and deepen the 16.2 mile connecting link between harbors of East Chicago and the Illinois waterway between the Great Lakes and the Gulf of Mexico. The first phase will be completed, according to present plans, in 1962.

With the Seaway open, the 60-foot width of the Cal-Sag canal would present a bottleneck. When the widening to 225 feet has been completed, two-way traffic will be continuous and the barge-tow will be raised from the present limit of two barges to four in tandem and two in width, —a length of 960 feet and a width of 70 feet.

An increase in barge traffic from the 4.6 million tons recorded in 1955 to 12 million tons in 1962 and to 18 million tons in 25 years is forecast. It is estimated that the cost of the project will reach $98.5 million, with the U.S. government carrying the bill for $80 million and the balance provided locally.

Seaway Control Battle in U.S.

SLSDC control of operation of the seaway is being contested by the Army Corps of Engineers. The argument was started by an unrevealed letter from SLSDC administrator Castle to the Army Engineers, notifying them their services "would no longer be required after 1958."

Mr. Castle maintains that the 1954 Wyley-Dondero Act gives SLSDC authority to build, operate and maintain the waterway. The army bases its case on a century-old body of law giving to army engineers control over all waterways from Panama to Sault St. Marie, and specifying that dredging, traffic control, etc., should be their exclusive province. The White House has handed the problem to Army Secretary Wilbur M. Brucker to find a middleground solution.

No Nearer Solution of Great Lakes Diversion Issue

U.S. legislation to divert another 1,000 cubic feet per second from the Great Lakes for a three year period, to see whether Mississippi River pollution would be lessened, has again been passed by Congress, and is expected to get Senate approval. President Eisenhower must then decide whether to again accede to Canadian objections and veto the bill for a third time.

Canada contends any diversion

The Long Sault Dam. The shape of the final structure is clearly outlined in this view of stage II construction taken from atop one of the gantry cranes.

would harm shipping and power production. Ontario Hydro protests the ɘxtra diversion would cut $500,000 worth of power production off annually in Southern Ontario. Reducing the flow would also lower water levels for shipping. Hydro contends the U.S. proposal to divert an equal amount into Lake Superior through the Long-Lac-Ogoke diversion is not possible.

Canada cannot block any U.S. plan o divert the water. But it can withhold approval of the scheme and eave the way clear for possible governmental court action in the event of damage to Canadian interests. Suit must be brought in a United States court.

Tolls

Toll committees of both countries are busy gauging public opinion on Seaway toll rates. The U.S. committee is scheduled to hold public hearings in September. In June the Canadian committee had already begun a series of informal meetings with shipping interests, and were asking for briefs. Discussions have already been held with the Canadian Shipowners Association and the Dominion Marine Association.

Total cost of the navigation facilities will reach about $450 million, of which Canada's share is roughly two-thirds and the U.S. share one-third. Amortization over 50 years calls for an annual capital payment of close to $10 million. Interest charges will add another $12 million and operation and maintenance a further $3 million; total annual charges $25 million.

Traffic estimates the first few years of between 31 and 36 million tons may increase by up to 15 million tons yearly. Committees hope a lower initial toll structure can be established to encourage traffic, even though revenue of $25 million would not be raised the first few years. But it is feared anti-seaway groups such as rail and road interests will insist on tolls from the first at rates to pay amortization and other costs.

Though both toll committees are thinking along similar lines, disagreement may appear later at inter-government level. Canada may want high tolls on iron ore and low tolls on wheat, while the United States may want the very opposite. Canada however has a $50 million trump card to play in the threat of creating an all-Canadian Seaway with additional locks parallelling the two American locks.

As for collection of tolls, the big problem is how to sort out the through traffic from the stop-and-go traffic, and how to assess tolls on tonnage which may change during passage through the seaway. Canadian-U.S. participation for collection of tolls based on roughly a two to one division of toll revenue is the probable solution.

ILA Threatening Control of Great Lakes Ports

A contest is brewing for union rights to organize and bargain for longshoremen at seaway ports from Toronto to Toledo, when the seaway opens in 1959. The International Longshoremen's Association, affiliated with CCL-AFL, has won recognition at Toronto. The ILA convention held recently at Chicago has set the pattern which will govern pier operations on U.S. Atlantic coast and Great Lakes ports.

Beginning in 1959, union demands will include a shorter week with no loss of take-home pay; a $100 per month pension plan, equalization of welfare benefits in all union controlled ports, and extra pay for use of bulk loading equipment or any labour saving machinery.

Since seaway cargo will be largely bulk, the penalty clause calling for extra pay may wipe out much of the advantage gained by long-distance shippers.

Canadian Pipeline Projects

Westcoast Transmisson

The main pipeline is proceeding ahead of schedule, and will be completed and tested early in September. Last pipelaying was done early in August and will be cleared and purged from both ends, using purchased U.S. gas for clearing as far north as Savona. Completion of cleaning is scheduled for the second week of September. The Inland system will be cleaned out at the same time.

The west coast gathering system in northern B.C. was ahead of schedule by the end of August. The contractor for the entire system was more than half finished the main 26 inch line from the Baytree area of N.W. Alberta to the West Buick field of B.C. Only 23 miles of ditching and 30 miles of welding remained at the end of July. Laterals were being run by a single spread. Final tie-in from the Alberta side fields was made at the Alaska Highway Crossing on July 24.

Inland Natural Gas

During the last two weeks of June Inland crews had laid 125,000 feet of mains in the interior of B.C. while cleanup was completed between Savona and Kamloops and almost to Grand Forks. By mid-July almost 200 of the total of 304 miles of main pipe had been welded, with backfilling and right of way clearing done for all but the last ten miles.

Distribution systems were completed at Vernon, Oliver, Kamloops and Nelson, and almost 1,000 services installed. The lateral to Salmon Arm was completed to within 2 miles of its goal and yard-coating was 90% done. Pipe for distribution lines was being assembled at Kamloops and reshipped from there. By mid-July crews were moving into the Cariboo area to start on the Quesnel Distribution system. Crews were also at work in the Savona-Kamloops area between Kelowna and Penticton.

First high-pressure test of the transmission system has proved highly successful. A 15 mile section from Kelowna to Oyama held air compressed to 1,056 lbs. per square inch for 24 hours, more than double the minimum pressure at which gas will flow in the system.

Next section to be tested will be between Oyama and Vernon. The air will go as far as Savona and will then be reversed and will be moved back down to the lower end of the system and finally released at Trail. All testing will be completed in September ready for the arrival of gas. Testing was supervised by the B.C. Government Dept. of Railways, which is responsible for final approval of gas pipelines in B.C.

Alberta Gas Trunk Line Co.

Fulton-Bannister Ltd. has a contract for 22 miles of gathering lines in the Provost field. Work consists of wellhead tie-ins, made up of 3 in. to 12 in. diameter pipe. The system will feed gas to the Alberta Trunk Line. Work was also in progress on the Trunk Line main during July from Burstall to Provost. The job consists of 100 miles of 18 inch line from Bindless Jct. to Provost and 17 miles of 34 inch pipe from the junction to Burstall.

Natural gas from three Southeast Alberta fields was released into the Alberta Trunk Line system by Premier Manning on July 23, for testing the AGTL main and the trans-Canada pipeline as far east as Regina. The purpose of the flow was to test and flush the pipe.

Trans-Canada Pipelines

First section of the 34" main Trans-Canada line of Universal Pipe-Lines Limited was due to be welded out late in July and tested by the first week of August while Section 3 of the 34 inch line was nearing completion by late July, the remaining three sections 4, 5, and 6 would not reach completion before mid-August. Work had been retarded on Sections 5 and 6 by heavy rains. On the first section east of Winnipeg, Majestic contractors had started pipelaying on July 1, and by mid-July had completed the first ten miles.

The Miniota crossing of the Assiniboine was completed and the second loop for the 34 inch crossing of the Red River south of Winnipeg was pulled across on June 28. Pipe deliveries were complete on the first section east of Winnipeg. . .

Very heavy rock-work was being encountered by Dutton - Williams Bros. on this section, with rock gangs working on two 10-hour shifts.

On the crown pipeline from the Manitoba Ontario border to Lakehead deliveries of pipe were proceeding and pipelaying had been started on one spread, with starts expected before August on two more spreads and on the fourth by September.

Three major river crossing contracts have been awarded; first across Winnipeg River at Ridout Bay near Kenora, in solid rock, to River Construction Co. (already started); second across Eagle River near Vermillion Bay to Morrison-Shivers, Ltd.; third over the Kaministiquia River near Port Arthur to Houston Contracting Co., which is also a rock crossing. Work on the latter two will start in August.

In Ontario, three contracts had been awarded for the 335 mile $20 million Toronto - Montreal pipeline section of the Trans-Canada for three equal sections. Grayco Inc., Dutton-Williams Bros., and Oklahoma Contracting Co. were successful bidders. The route of the line parallels that of the trans-northern products pipeline fairly closely. There is a substantial amount of rock excavation, though much of the line runs through highly cultivated and settled farm land. No definitely scheduled completion date is set. Welland Tubes Ltd. commenced deliveries of pipe in July.

B.A. Oil Co's recycling plant at Pincher Creek field is now processing 60 million cubic feet of gas daily, extracting 1800 barrels of condensate and 225 long tons of sulphur daily. B.A.'s contract with Trans-Canada calls for 100 million feet of gas daily the first year and 170 million feet after that. Output of extraction plants will be stepped up to 2,500 barrels of condensate and natural gasoline, plus 1,700 gallons each of propane and butane and 275 long tons of sulphur daily. The condensate is of special importance as excellent catalytic reforming stock for use in the manufacture of high octane gasoline.

Regina Distribution System

Gas from the Success field is 'loaned' to Trans-Canada to fill and purge its main line. Trans-Canada will supply gas to Regina for the first heating season. Once the purchase by Saskatchewan Power Corporation of gas from Eastern Alberta fields is authorized by the Alberta Conservation Board, S.P.C. will build the pipeline from the Hatton field to Success, completing the main from the Alberta border to Moose Jaw. Next phase will be extension to Regina. Gas is due to reach Regina August 15. Twelve crews are laying pipe for the S.P.C. distribution system. Seven thousand five hundred services had been signed up by July 1st.

Lakeland Natural Gas

The Ontario Fuel Board has given Lakeland Natural Gas permission to supply gas to the City of Cornwall. Consumers Gas Co. of Toronto had also applied for a certificate but was turned down.

Trans-Canada signed a 20 year contract with Lakeland in July for delivery of more than 12 million cubic feet of gas daily the fifth year of operation. Lakeland serves 17 communities from Port Hope to Morrisburg. Other franchises are being negotiated for other communities including the City of Kingston. Sales to Lakeland the first five years will represent revenue of $6½ million to Trans-Canada the first five years.

Union Gas Company

Union Gas Co. of Canada will start pipelaying in September on the 141 miles of 26 inch gas main from the Dawn field to Hamilton. Canadian Bechtel Ltd. will move one spread from West Coast, section 2 to Galt, Ont., for this work early in August, while their spread from Trans Canada section 6 will move to the Union gas project by mid-August. Pipelaying contracts include lateral lines to London, Strathroy, Guelph, St. Mary's, Kitchener and Hamilton. Gas will also be supplied to Dominion natural gas Co. in Galt. Contract completion date is November 15.

The U.S. Court of Appeals has upheld a F.P.C. order last year permitting Panhandle Eastern Pipeline Co. to make increased sales of gas to Union Gas Co. of Canada. The court's opinion pointed out that increased export to Union would enable Panhandle to employ on off-peak days some of its peakday capacity which would otherwise be idle.

Quebec Natural Gas Corp.

Work was commenced late in July on the Quebec Natural Gas Corp's system in the Montreal area, in preparation for the changeover from manufactured to natural gas, scheduled for December. A start was also made on the main from the 'City Gate' at Trans Canada Pipeline's terminal on the west end of Montreal Island, to connect up with the city's distribution system. An outlay of some $3[illegible] million is involved in these operations. Initially, natural gas will be supplied from storage tanks at Sarnia or from the U.S., through existing pipelines in Southwestern Ontario pending arrival of Alberta gas late in 1958.

Sulphur Prices Weakening

After many years of steady increase in demand for sulphur and rising prices, prices for sulphur fel[illegible] 5% in 1956. Current consumption o[illegible] North American sulphur is some [illegible] million tons annually. It has been announced recently that the Frencl[illegible] gas reserves of 5 trillion cubic fee[illegible] with its heavy sulphur content will b[illegible] fully marketed by 1960. By 1960/6[illegible] France will be supplying the entir[illegible] European demand for sulphur, of [illegible] million tons per year, thus removin[illegible] Europe from world markets.

The outlets for Canadian sulphu[illegible] in export markets is therefore not con[illegible]sidered very bright. This will reduc[illegible] earnings of producers of sour ga[illegible] such as those in northern B.C. field[illegible] supplying Westcoast, and the Pinch[illegible] er Creek Field supplying Trans-Canada Pipelines.

Outlook for Gas Appliance Sales

D. K. Yorath, President of Canadian Western Natural Gas Co., addressing the Canadian Gas Association meeting at Jasper in June, stated natural gas reserves in Alberta alone now stood at 18.3 trillion feet. Population served with natural gas adjacent to main pipelines excluding Alberta totalled 2½ million and prospective customers at 324,000.

In 1956, he stated, there had been 257,000 gas appliance units sold in Canada, which included 43,000 gas warm-air furnaces; 22,000 conversion burners; 26,000 space heaters; 75,000 cooking ranges and 72,600 water heaters. Estimated sales for 1958 would rise 27% to a total of 325,500 gas appliance units, which would include 60,000 gas warm - air furnaces; 30,000 conversion burners; 31,000 space heaters; 93,000 cooking ranges and 90,000 gas water heaters.

Trained Operators May be Scarce

Mr. Yorath warned that the manpower situation over the next several months might become acute for the gas companies. Gas utilities in the United States average one operator to every 140 customers. Applying this ratio to the present potential of 1,275,000 customers in Canada would result in some 9,000 employees. Established companies have a problem, he said, but not as great as new companies serving new territory. The established company at least has a setup where new employees can be trained to handle expansion.

U.S. Gas Industry's Rapid Growth

Encouragement for Canada's gas producers and pipelines is seen in a recent report that the U.S. gas industry, now increasing its list of 3 million customers by almost a million yearly, will spend $2.13 billion on expansion this year compared with $1.55 billion in 1956. The industry is budgeting $8.7 billion for new facilities through 1960. Nearly half the money will go to extending gas transmission facilities. Gas comsumption in states bordering the Pacific is reported to be growing at three times the national average.

Gas Imports Discussed in Congress

In mid-July the argument over imports of Canadian gas to the United States switched from the F.P.C. Hearings to the floor of Congress. Congresswoman Elizabeth Kee of West Virginia told the House . . . "it would be an injustice to our own people to accede to the proposals presently before the Federal Power Commission . . . I have learned that jobs of lignite miners in North Dakota are also at stake in this issue".

There are hints in Washington that should any combination of natural gas companies in the mid-west be given the green light by F.P.C. to import Canadian gas a battle might break out in Congress to prevent the importation of Canadian gas by legislation.

Alberta-California Pipeline Planned

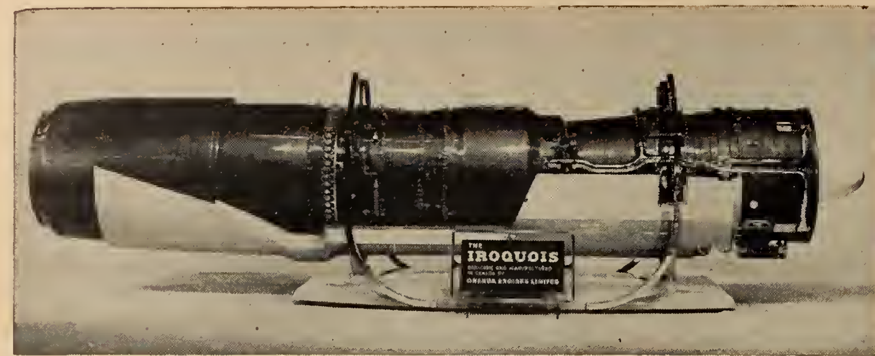
Plans for a third natural gas export line were announced on July 12 by President S. M. Blair of Canadian Bechtel Ltd. This is a $300 million project to link up untapped gas reserves in Western Alberta with central California. The project involves a 36 inch 1300 mile pipeline through the Crows' Nest Pass and through Idaho, Washington, Oregon and Northern California, to terminate in the San Francisco Bay Area. It would supply the Pacific Gas and Electric Co., which would furnish part of the capital. Interested in the project also are Canadian Western Natural Gas Co. and North-western Utilities Ltd.

The system would have an initial capacity of 400 million cubic feet of gas daily. Originating in the Alberta foothills, it would tap some or all of the recent discoveries in the southwestern corner of the province. These include the Savanna Creek, Shell-Waterton, and Texaco-Castle River fields. The southern half of the Pincher Creek field, not yet committed to Trans-Canada, may also be included. Reserves in these fields may total 3 or 4 trillion cubic feet.

Many government approvals have to be hurdled first, however, and doubt is expressed that more than one additional export line from Southern Alberta to the south and west will be approved before a new and careful appraisal of reserves is made by the Alberta Conservation Board.

Application for approval of the project by the Alberta Conservation Board will be made late in August. The program would enable Alberta producers to sell gas direct to the large and growing California market without any build-up period.

A ripening field of wheat in Central Manitoba provides a rural setting for the construction this season on the western section of the Trans-Canada Pipe Lines natural gas line from Alberta to Eastern Canada. Here the bending machine on section six bends an 80-ft. double joint of 34-inch diameter pipe to fit the contours of the ditch. The pipe line obtains a sixty-five foot right-of-way from the farmers, and men and equipment work in that area, thus crops such as this one are left undamaged.



The Iroquois on Show

The world's most powerful jet engine, Orenda Engines Ltd.'s 'Iroquois', was unveiled at Malton July 22nd by Defence Minister George R. Pearkes, V.C. With unveiling came the news that a U.S. engine manufacturer, believed to be the Aeronautical Division of the Curtiss-Wright Corporation, is negotiating for licensing rights to build the engine. Britain is said to be watching the Iroquois with unusual interest, and some day it may be produced there.

Designed for Canada's top - secret twin engine supersonic interceptor the CF-105, the 'Iroquois' has a thrust rating of over 20,000 lb. more than triple that of the 'Orenda' engine which powers the CF-100. The power potential of the basic Iroquois design is such that later versions will provide more thrust than any other engine in the same stage of development.

Its size is approximately twice that of the Orenda 14. Power-to-weight ratio is better than 5 to 1, compared with the 3 to 1 ratio of the Orenda 14. This was achieved through the use of titanium. Weight is less per pound of thrust than that of any other large supersonic engine known to be running to date.

Avro's 17-ton CF-100, now in service ascends up to 8 or 9 miles in about 7 or 8 minutes with its Orenda 14 power plant.

The Iroquois powered 'Arrow', CF-105 weighing twice as much, will reach altitudes four or five miles higher in about half the time; a rate of climb over 15,000 f.p.m. Once there it will fly at better than twice the speed of which the CF-100 is capable.

Of the more than 2,100 firms supplying Orenda with materials, components and services, the vast majority were Canadian, though the company had received much appreciated assistance from U.S. and United Kingdom firms. The 'Iroquois' model was displayed late in July 1957 at the Air Power Panorama in Washington. It will also be shown at the SBAC static display at Farnborough in Britain in September.

Other highlights of Iroquois performance in flight are:

Ten Iroquois engines could develop as much power as the Sir Adam Beck power station at Niagara Falls, Ont., yet the Iroquois weighs no more than a modern luxury automobile.

The air swallowed and exhausted by one Iroquois is more than could be supplied by 2,500 portable compressors of the type used in the construction industry.

In spite of the Iroquois' tremendous power — over 100,000 horsepower, the engine consumes only 10 times more oil than the ordinary automobile engine of, say, 200 horsepower.

Since fitting the 'Iroquois' test-pod to an experimental B-47 bomber by Canadair Limited at Montreal last spring, the engine is being test-flown in the pod for eighteen months or more before installation in some supersonic test bed and finally in the CF-105. Following two years of test-cell running, the flying tests of the Iroquois mark an important stage in development.

CANADIAN DESIGNED 20-TON GEAR

This 308-tooth gear, believed to be one of the largest designed in North America, was designed by Aerofall Mills, Ltd., of Toronto and the order placed with David Brown (Canada) Limited. Casting and cutting were done in the Manchester, England, works of David Brown Ltd. Shipped in sections to Glasgow, Scotland, the gear was assembled in the works of Harland and Wolff, before shipping to Sinoia, Southern Rhodesia, the site of the Mangula Ltd. copper mine. The gear weighs 41,000 lb. Its pitch diameter is 25 ft. 8 in. and the width of the face is 20 in. The 308 teeth mesh with a 29-tooth pinion which gives the drive a pitch line velocity of 975 ft. per min. It transmits 1250 h.p. with a mill speed of 14.1 r.p.m. The mill in which this gear is used has a capacity of from 100 to 200 tons per hour and was to be in operation in July 1957.

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE
ELECTIONS AND TRANSFERS

A Bequest to the Institute

Recently through the Crown Trust Company of Montreal the Institute has received the sum of $25,000 from the estate of the late Major James H. Brace who for thirty-nine years was a member of the Institute. The donor in his will specified that the interest on the fund shall be used for the benefit of unemployed and needy engineers.

This is by far the largest benefaction that the Institute has received, and beyond a doubt will do much good in the field that has been selected by the donor. In times like these not many engineers are in want but conditions may change so that the fund will become of vital importance. Even now the Institute is aware of cases where the money can be used to good purpose.

Major Brace was born and received his education in the United States, graduating in civil engineering from the University of Wisconsin in 1892. For the next eleven years, he worked mainly on waterways and power projects in the Great Lakes and Upper St. Lawrence areas.

After moving to New York City in 1903, he worked for a consulting engineer on the construction of railway tunnels under the East River. It was on this project that he first became associated with Charles E. Fraser, M.E.I.C., with whom he formed a partnership in 1908 to found the construction firm of Fraser, Brace and Company.

This was the beginning of nearly a half century of activity during which as vice-president, he directed the construction activities of the company in both Canada and the United States. In addition to the construction of large hydro-electric projects, Major Brace directed the constuction of some of the largest chemical and metallurgical plants built in Canada.

His contributions to the war effort of both world wars were significant. During the first years of World War I, he supervised construction of a hydro-electric project in Quebec, needed for the province's industrial contribution to the war effort. In 1917, he joined the United States Army as a Major in the U.S. Engineers Corps and served with them in France. In World War II, he came out of semi-retirement at the age of seventy-five to contribute unsparingly of his time and energy to supervision of construction projects in Canada and the United States. These included ordnance plants in both countries and the first Canadian Atomic Energy plant at Chalk River. He was also concerned with the construction and operation of one of the largest shipyards in Canada.

Following the retirement of his original partner in 1946, Major Brace became president of Fraser-Brace and guided the affairs of the company during the following eight years.

He joined the Engineering Institute as a member in 1916, was elected to Life Membership in 1947, and continued to take an interest in its affairs until his death in April, 1956, at Westmount, Quebec.

Cover Picture

An example of recent growth in the Canadian oil industry is the recently rebuilt refinery of Imperial Oil Company, at Halifax, N.S. A $30-million construction program increased capacity from 18,000 to 42,000 barrels daily. In the picture, atmospheric and vacuum distillation unit is shown at left; fluid catalytic cracker at centre; and light ends plant at right.
(Imperial Oil Photo)

Publicity

Members will be interested to know that the newspapers of Canada found the program of the 1957 annual meeting of sufficient interest to devote an unusual amount of space to reporting on it.

From a press clipping service, the Institute has gathered together clippings from a great many papers from coast to coast. These clippings have

WANTED

FIELD SECRETARY

The Institute is seeking applications for the position of Field Secretary, working out of the Toronto office. Position involves travel, public speaking, organization work and administration. Membership in the Institute is not essential, but preference will be given to Members.

Apply in writing to

L. F. GRANT,
2050 Mansfield St.,
Montreal 2, Que.

been sorted, measured, collated and studied.

The results show that the newspapers have done an excellent job of reporting. About 500 separate news items were published in the newspapers of sixty-seven cities. On an overall space basis the clippings are the equivalent of over twenty-five full newspaper pages—and that is a lot of space.

This is a new record for the Institute, and in all probability compares favourably with the record of any other similar event in Canada. When it is remembered that the meeting occupied only three days, it will be appreciated that the Engineering Institute of Canada must have been very prominent before the Canadian people in the daily press.

This splendid showing indicates again the national character of the profession and the Institute. Papers all the way from Vancouver Island to Newfoundland found news of the Institute's activities to be of interest to their readers.

Members everywhere will be pleased to learn that the things that interest them so deeply also interest the general public.

IAESTE Report, 1957

The season is now well enough advanced to present a picture of this year's results of our participation in IAESTE (International Association for the Exchange of Students for Technical Experience). It has been the fifth year of Canadian activity under this plan, and during this time as most readers are aware; the Institute has acted as the agency for handling the work in this country.

From the point of view of the European students coming to Canada for employment, 1957 has once more shown a good step forward in participation figures. Our industries and other engineering organizations were hosts this summer to 119 foreign students, from 9 countries, again representing nearly all branches of engineering. This figure can be compared with 89 in 1956. As might be expected the majority always come to us from Great Britain, and 76 of the 1957 visitors originated from there. The jobs in Canada for all of these young engineers were provided through the excellent co-operation of 51 firms, public departments, and other organizations. The names of these firms appear in the annual report, printed by the international headquarters of IAESTE in Sweden.

The story as it concerns Canadian undergraduates going abroad under the plan is not so impressive. Only 12 took advantage of the exchange opportunity this year, as compared with 9 last year. One might say that this is a 33 percent increase, but still the figure is very small. Judging from the number of preliminary inquiries, and what happened to them afterward, the reason for such scant interest in the plan by Canadian students remains the same — the difficulty of financing the trip on the estimated earnings at European wages.

This Canadian participation of only 12 is in spite of the fact that travelling bursaries of $250, provided by our industry, were available to each Canadian student, and this was well publicized at our universities. It was hoped, and expected, that this added new inducement would promote a much larger exodus in the eastward direction this year, but the results have been disappointing. This might indicate taking a second look at the policy of continuing these bursaries, and this will be something for the Canadian IAESTE Committee to consider.

In connection with the exchange program, Eastern Canada again had the pleasure of a visit in July by Mr. James Newby, who is continuing to act as the IAESTE secretary for Great Britain. He visited a large number of firms and other organizations to promote interest in the plan. The illustration shows a party of 43 engineering students from Great Britain arriving in Montreal with Mr. Newby on the *Ivernia*, bound for various points in Canada.

Full information concerning IAESTE, and Canadian participation in it, can be obtained at any time from E.I.C. headquarters, Montreal.

Ottawa Regional Meeting

There will be a regional meeting of the Engineering Institute of Canada

to coincide with

the semi-centennial celebrations of

the Ottawa Branch

October, 1959

Further announcements will appear as plans take shape.

Modern Management of an Institute

For quite a time the Council of the Institute has been facing the challenge of changing times. Recently some action has been initiated that should enable the Institute to evolve a program that will bring policy into alignment with new opportunity.

There appears to be no doubt but that the old patterns will not do for the future. Even the branches are feeling, or will feel, the demand of changing conditions, but most of all it will be the Institute that will come forward with new ideas.

To this end Council has appointed recently several new committees to study conditions and to make recommendations and to carry out those proposals that are approved by Council. These committees are as follows:

(1) Policy Committee. A host of proposals have been made by individuals, branches and officers as to new business for the Institute and changes in policy regarding old business. To handle these urgent matters Council has appointed a Policy Committee whose personnel is as follows:

R. L. Dunsmore, Montreal, *Chairman;* B. G. Ballard, Ottawa; R. L. Hearn, Toronto; R. E. Heartz, Montreal; I. P. Macnab, Halifax; D. M. Stephens, Winnipeg; . B. Stirling, Montreal; W. G. Swan, Vancouver; I. R. Tait, Montreal; V. A. McKillop, President; C. M. Anson, President-Elect; K. F. Tupper, Toronto; L. Austin Wright, General Secretary.

(2) Technical Activities. This committee is to organize committees on a national basis that will develop a more intensive program of technical papers and meetings. May of these committees are already functioning and it is expected their influence will be felt before the end of the year. The personnel of the committee is as follows:

F. L. Lawton	Montreal — *Chairman*
B. G. Ballard	Ottawa
C. E. Frost	Montreal
R. M. Hardy	Edmonton
A. R. Harrington	Halifax
W. H. Paterson	Toronto
D. L. Rigsby	Kingston
S. Sillitoe	Belleville
E. R. Smallhorn	Montreal

(3) Property Committee. For many years consideration has been given to the Institute's property at 2050 Mansfield Street, Montreal. The time has come when it is necessary to decide what should be done about it. Should the present premises be enlarged or should a new site be found? The present building is quite inadequate for present conditions and it is evident more space will have to be found to meet the steady expansion of the Institute and its activities. To advise Council the following committee has been formed.

F. G. Rutley	Montreal, *Chairman*
Albert Deschamps	Montreal
V. B. King	Woodstock, Ontario
C. N. Murray	Sydney, N.S.
R. C. Pybus	Vancouver

(4) Student Policy Committee. The changing picture surely includes the field of service to the engineering student. Some quite revolutionary proposals have been made and it is to study these and other ideas of their own that this committee has been authorized. The members are:

C. G. Southmayd, *Chairman*

Professor Julien Dubuc, EIC Faculty Representative at Ecole Polytechnique.

Dr. R. E. Jamieson, McGill University.

Dr. Andrejs Pakalnins, EIC Faculty Representative at McGill.

E. Muszynski (McGill) and Jean F. Riel (Ecole), Student Representatives ... Junior Section of Montreal Branch EIC.

(5) Education Committee. This committee has not yet been authorized but it has been recommended by the Education Conference held during the annual meeting at Banff, and the indications are that Council will approve the proposal.

For two years the Institute has sponsored an education conference organized by and for the educators themselves. These two conferences have been most successful and it is believed the deliberations will have a far-reaching and beneficial effect on engineering education in Canada.

It seems appropriate that the Institute should now establish its own committee which for the future can keep the needs of education before the Institute and provide the educators a channel between themselves and the Council of the Institute.

This recommendation of the Conference along with five others made by them will be presented to Council for decision at the August meeting.

It is doubtful if ever in the past the Institute has planned so much study of itself. It is a good sign. It is evidence of Council's awareness of what is going on and of its obligations to the profession.

Some of the 119 foreign students from nine countries representing all branches of engineering who came to Canada this year as participants in the International Association for the Exchange of Students for Technical Experience.

The Annual Meeting

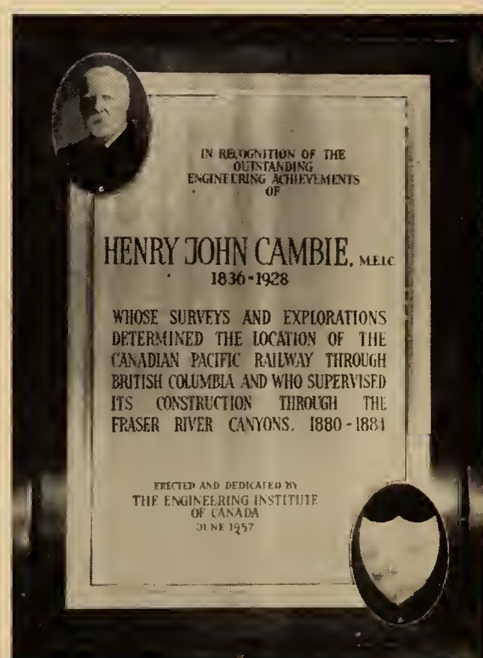
I. R. Tait (standing) is addressing the annual business meeting of the Institute. With him at the head table are treasurer R. A. Emerson, R. L. Dunsmore, president V. A. McKillop, L. Austin Wright and Miss May McLaren.

Below. The General Secretary received a gift of the ten gallon hat he is wearing from the Alberta committee. In this picture Carl Jones, immediate past-chairman of the Calgary Branch is making the presentation to Dr. Wright.

Student delegates at the annual meeting student conference are shown below. Not in order of their appearance they are: A Clark and N. Crawford of the University of Alberta; N. M. Seagram, University of Toronto; O. M. Hodgkins, Royal Military College; R. Hutchinson, University of Alberta; S. Saimoto, University of British Columia; E. J. Muszynski, McGill University; J. N. Fry, University of Alberta; J. F. Harris, chairman and moderator of the conference; L. D. Lemay, Ottawa University, secretary of the conference; J. F. Riel, Ecole Polytechnique, chairman of the conference; M. C. Schofield, University of New Brunswick; R. Barschel, University of Manitoba; J. D. Devlin, Nova Scotia Technical College; M. Chamberland, Laval University; J. B. Robinson, Western University; D. Meneley, University of Saskatchewan, and W. Sexsmith, of Queen's University.

ANNUAL BANQUET HEAD TABLE GUESTS

Left to right, reading down are: W. A. Smith, chairman, annual meeting committee; C. A. Peachey, president, C.P.E.Q.; Mrs. W. A. Capelle; W. O. Richmond, president, A.P.E. of B.C.; Mrs. W. G. McKay; Group-Captain C. L. Ingles, R.C.A.F.; Mrs. O. J. Walker; F. G. Rutley, representing the president, Canadian Chamber of Commerce; Mrs H. L. Bouey; E. J. Durnin, past-president, Dominion Council; Mrs. J. H. Fox; Commodore E. R. Spencer, R.C.N.; Mrs. C. M. Anson; P. M. Sauder, Hon. Mem. and past-vice-president, E.I.C.; Mrs. A. G. L. McNaughton; W. S. Wilson, Hon. Mem. and past vice-president, E.I.C.; Mrs. M. S. Coover; M. G. Lockwood, president, A.S.C.E.; Mrs V. A. McKillop; Hon. S. Freedman, Judge of the Court of Queen's Bench, Manitoba; President V. A. McKillop; Mrs. S. Freedman; T. A. Crowe, past-president, I.M.E.; Mrs. W. S. Wilson; M. S. Coover, president, A.I.E.E.; Mrs. W. O. Richmond; General A. G. L. McNaughton, Hon. Mem. E.I.C., and chairman, Canadian Section, International Joint Commission; Mrs. M. G. Lockwood; J. G. Frost; president, Association of Consulting Engineers of Canada; Mrs. E. J. Durnin; O. J. Walker, president, C.I.C.; Colonel W. A. Capelle, Canadian Army; J. H. Fox, president, A.P.E. of Ontario; Mrs. P. M. Sauder; H. L. Bouey, representing the president, The Royal Architectural Institute of Canada; Mrs. J. G. Frost; W. G. McKay, president of A.P.E. Saskatchewan; Mrs. W. A. Smith; and C. M. Anson, president-elect, E.I.C.



CAMBIE MEMORIAL

Retiring President V. A. McKillop (left) unveils the Henry J. Cambie memorial plaque. This plaque offered by the E.I.C. in memory of a great pioneer engineer will be placed in the C.P.R. station, Vancouver. With the president is R. L. Dunsmore, Montreal. A close-up of the plaque is shown above.

The President Reports

PROGRESS AND PLANS

V. A. McKillop, M.E.I.C.
London, Ontario

The retiring president at Montreal last year, Dr. R. E. Heartz, included in his fine remarks, particular reference to three matters that should receive the attention of the Institute in the future. These were, Confederation, Technical Sections and Honours.

Progress has been made on all three of these subjects, although much remains to be done.

Confederation

We have discussed Confederation at branch meetings throughout the year, and there is no need at this time to do more than reaffirm the active interest of the Institute as expressed at the annual meeting a year ago. You are aware that during this past year the matter has been under review by the provincial associations, and that their reports have recently been received by Dominion Council. Now that those reports have been received and acted upon by Dominion Council, it will be necessary to bring the representatives of the Institute and Dominion Council together to further the study of a satisfactory basis for a union between the Institute and Provincial bodies. I sincerely hope that there may be no delay in taking action so that the interest and enthusiasm aroused in the membership during recent years may not lag, but be kept alive by evidence of continued progress toward a mutually satisfactory arrangement.

Technical Sections

The second recommendation in last year's presidential address, that of technical sections, will I assure you be definitely in the class of progress and accomplishment during 1957.

You will recall that this matter arose as the result of a report by the Committee on Technical Operations under the chairmanship of F. L. Lawton. That report stated that "now as never before there is a real need to undertake constructive work to improve the technical activities of the Institute in order to achieve, on the scale necessary, our basic objectives, which are "to facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interest, to encourage original research, to develop and maintain high standards in the engineering profession, and to enhance the usefulness of the profession to the public".

It is anticipated that Headquarters will be able to actively proceed with the recommendations of this report within the next three months.

Awarding of Honours

The third recommendation last year concerned the awarding of honours to engineers. You will realize that the unveiling of a plaque at this convention, for erection in the Vancouver station of the Canadian Pacific Railway in honour of Mr. H. J. Cambie, is another step in this direction. The publication of biographies, one of which is on sale here, represents achievements in the same field.

Now I would like to speak to you about a variety of matters that I consider of importance to the Institute, all of which might very well be covered by a text extracted from a statistical record of the Institute compiled by Huet Massue, a member of the Montreal Branch. Within the covers of that fine review will be found this statement, "enlightened membership is the life blood of any association; it is the foundation from which arose the monument of its accomplishments; it is the beacon from which radiates its initiative, its enterprise and its inspiration. The broader the foundation the more imposing the monument; the higher the beacon the farther afield its projection." I have a very strong feeling that that statement is most important at this time, in fact, the prime purpose of many activities and proposals before Council in recent months is the enlightenment of the membership. I think it is well that we remember that in all the field of important activities of the Institute, nothing can be more important than the dissemination of information which will in turn lead, I trust, to a more active participation in the affairs of the Institute by individual members, and a greater realization of the vital part that this organization plays in the affairs of this country.

In discussing the enlightenment of the membership the work of the Publications Committee, under Chairman G. N. Martin, naturally comes to mind first. Council has accepted a report from this committee that will result in the publication of Transactions this year. It seems very appropriate that this project should begin when the recommendations of the committee on technical operations are about to be implemented. Each can contribute to the success of the other. Likewise, there will be published a book entitled "Canadian Careers in Engineering". This will deal with the engineering work in various types of industry, and has already attracted widespread interest from employers of engineers.

Policy Committee Proposals

The appointment of a Policy Committee composed of past presidents, and men who have long taken a leading part in Institute affairs, led to the discussion of various proposals. One of the most important of these concerned the extension of the work of the Field Secretary's office. This was a well deserved recognition of the excellent work of past president Col Grant, whose name is closely associ ated with the Professional Develop ment courses that form an importan part of the activities in many branches.

The recommendation of the Polic Committee has led to the recent ap pointment of a second field secre tary, Commodore Davy of Vancou ver. His responsibility will be th four Western Provinces. Another rec ommendation of this committee ha led to the appointment of an Institut representative on the campus of te universities. It is anticipated th more will be appointed and wi make the Institute well known to th students, leading to many studen memberships and arousing an intere in the young engineer that is like to remain with him.

Regional meetings have been discussed frequently in recent months, and this idea has come to the fore for a variety of reasons. One of these in recognition of the difficulties being experienced by some branches to provide programs of a calibre to attract a major portion of the membership. It has been determined that this same condition applies today in many organizations, and it is believed that it calls for changing plans to meet changing conditions.

Regional Meetings Suggested

Since technical sections are about to be promoted, and since annual meetings have become so large that they have taxed the capacity of the larger hotels it is a possibility that such regional meetings might provide an opportunity for technical discussions, without the complications arising from heavy registrations. Such a meeting would probably provide new opportunities for individual participation, and for consideration of public problems peculiar to a certain area. Whereas individual branches might have difficulty in attracting the better class of speaker, it should be quite practical to bring such a man to regional meetings. It is apparent that many branches would appreciate assistance in securing speakers; these meetings would at least provide a partial solution for this problem. There are several reasons to assume that regional meetings could fill a real need.

The Institute has made a great contribution, and will continue to assist in the technical problems that face us today. It is recognized that the required quantity of engineers and technicians is being emphasized and much has been done to provide more facilities, more staff and to secure more students. The Institute is also conscious of the need for quality as well as quantity in our plans, and for all these reasons has again at this annual meeting invited the Deans and heads of departments from engineering schools to assemble here, to continue discussions begun one year ago.

The professional development courses, to which reference previously has been made, constitute an attempt to broaden the interest and the knowledge of the young engineer. Thus professional attitudes develop and recognition will follow. We believe that such a development is the natural outcome of membership in a voluntary organization, and must ultimately lead to the characteristics so necessary and desirable in a professional man.

The formation of a Property Committee this year, under the Chairmanship of F. G. Rutley, is intended as recognition of the long term growth of the Institute, including the possibilities of Confederation. This committee has membership representing various parts of the country, from coast to coast, so that its report, when complete, may really reflect the ideas of all parts of this country in the creation of a new National Headquarters. It is not suggested that there is any great urgency in this regard, although property values should be considered in relation to the rate at which building reserves are being accumulated.

International Geophysical Year

At this point I want to refer to the International Geophysical Year which commenced July 1, 1957. It had been hoped that at least one paper dealing with this matter might be on our program at this Convention. It was found that that would not be practical because of the many preparations going forward at this moment. It is a matter of pride to the Engineering Institute of Canada that Canadian scientists are, of course, taking a large part in the program of study and research. I am sure that we will follow the progress of our scientists with very real interest. They have our sincere wishes for a successful conclusion to their efforts.

In conclusion I would just like to repeat that I feel this Institute should concentrate on any and every project that will make for a more enlightened membership. I believe that knowledge of the many activities of the Institute will make it a more vital influence in the life of its members. I believe that individual participation in projects of community and national importance might be expected to increase with understanding of the Institute's program. I would hesitate to make any specific recommendations for new projects because I believe that we should only participate where we can make a real contribution. Nevertheless, I might remind you that the Engineers Joint Council in the United States has for sometime had a very active committee to consider a national water policy. Here is the kind of project that concerns every person in every community in the whole country, and will undoubtedly continue and increase in importance. In this connection, I wish to quote our own member, Robert F. Legget of Ottawa, who delivered the sixth Wallberg lecture in 1953. His topic was "Resources for Tomorrow — the Engineer's Stewardship". In it he makes this observation. "Since it is the engineer who is responsible, not only for processing the materials which we have been discussing, but also for the ever-increasing speed at which they are being used up on this continent, admittedly in response to public demand, is it not incumbent upon him to take at least a general interest in the resources of which he is the steward?"

Another matter of country wide importance is the announcement of the policy of labour leaders to press for a shorter work week. Such a trend may well be of considerable importance to the engineering profession. Since the reduction in hours of work to date, coupled with a remarkable improvement in the standard of living, has been possible because mechanical power has increased the output capacity of the individual worker; it would seem that the labourer needs the engineer if his dream of more leisure is to come true. It would seem to me that the matter of land use and town planning might very well provide opportunities for worthwhile contributions both by the individual engineer and the Institute.

Tribute Paid

I would not want to conclude my remarks here without paying a tribute to the officers and staff of the Institute, who by their vision and work during the years have placed this Institute in a most enviable position, nationally and internationally. In particular, I would like to pay tribute to the General Secretary with whom it has been a very real pleasure to work during this past year. His contribution to the growth of the Institute is probably more than most of us realize, and I am sure that in time his achievements will receive proper recognition. I trust that some day soon he will get busy on his memoirs in the form of a history of the Institute. I would like to see it made clear to him that such an effort on his part would be most welcome.

In this tribute, I wish to include Mrs. Wright. To know her is to realize that she possesses many of the characteristics essential to the growth of this organization, and I am confident that her inspiration has contributed greatly to our success.

International Cooperation

THE warm friendship which exists between the Dominion of Canada and the United States of America is known, admired—and perhaps sometimes envied—throughout the civilized world. There is nothing like it anywhere else on earth. There never has been a friendship so genuine, a mutual understanding so sincere, that the imaginary line which serves as your southern border and as our northern border, has little real significance—except political. The border between our countries is a useful instrumentality for separating jurisdictions; for marking the points where the color of uniforms change, but where the character of men do not.

We should, and unquestionably will, preserve integrity of the border between us. For it affords a good exercise in geography for your children and ours, as they study the rich and peaceful history of these enviable relations.

All this long friendliness, this mutual confidence and respect, has led to the very remarkable situation that in many instances your magnificent Queen is our Queen, our President—your President. Indeed it is even deeper than that: your triumphs are our triumphs; our sorrows—your sorrows.

This is all quite well known. Not so well known, though, except among engineers, is the fact that this unique spirit reaches perfection in the relationship between Canadian and American engineers. And between your Institute and our Founder Societies.

As you know, I have the honour here to represent the American Society of Civil Engineers. In its behalf, I am moved to express deep and abiding gratitude to the Institute for its part in welding an iron ring around these good relations, to the end that they shall always prevail among us.

Finally I salute you for your noble achievements of the past and confidently predict a future of extraordinary usefulness in helping your youthful, virile and robust country to achieve its incredibly promising destiny.

M. G. LOCKWOOD,
President,
AMERICAN SOCIETY OF CIVIL ENGINEERS

Part of an address of greeting to the annual meeting of The Engineering Institute of Canada, Banff, June, 1957.

PROPOSED CO-OPERATIVE AGREEMENT

between

THE ASSOCIATION OF PROFESSIONAL ENGINEERS OF THE PROVINCE OF PRINCE EDWARD ISLAND

and

THE ENGINEERING INSTITUTE OF CANADA

MEMORANDUM OF AGREEMENT made in duplicate at the City of Charlottetown in the Province of Prince Edward Island, this Twenty-fifth day of September, 1957

By and Between:

THE ENGINEERING INSTITUTE OF CANADA having its head office at the City of Montreal, in the Province of Quebec, hereinacting by its President and General Secretary, duly authorized for the purpose hereof by a resolution of its Council passed at a meeting duly called and held on the twenty-third day of August, 1957 hereinafter called the "Institute";

PARTY OF THE FIRST PART

and

THE ASSOCIATION OF PROFESSIONAL ENGINEERS OF THE PROVINCE OF PRINCE EDWARD ISLAND, having its head office in the City of Charlottetown, in the Province of Prince Edward Island, hereinacting by its President and Registrar duly authorized for the purpose hereof by a resolution of its council passed at a meeting duly called and held on the ....day of ....1957, hereinafter called "The Association"

PARTY OF THE SECOND PART

WHEREAS it is desirable in the interests of the Engineering Profession that there be close co-operation between the Institute and the Association, and

WHEREAS such close co-operation will be promoted if, so far as is practicable, there is effected:

(a) A common membership in the Province of Prince Edward Island of the Institute and the Association.

(b) A simplification of existing arrangements for the collection of fees.

(c) A co-ordinated management.

NOW, THEREFORE, the parties hereto agree with each other as follows:

Sec. 1: Any person resident in the Province of Prince Edward Island who, on the date of this agreement is registered as a Professional Engineer in the Association and is not a Corporate Member of the Institute, shall have the right, under the provisions of this Agreement, to become a Corporate Member of the Institute. If such registered Professional Engineer desires to become a Corporate Member of the Institute under the conditions of this agreement, he shall so notify the Registrar of the Association, in writing, within 12 months of the date of this Agreement.

Sec. 2: Any person resident in the Province of Prince Edward Island registering as a Professional Engineer in the Association subsequent to the date of this Agreement who is not a member of the Institute shall, have, upon such registration, the right to be accorded the class of membership in the Institute warranted by the age, experience and professional qualifications of such person, according to the by-laws of the Institute and the decision of the Council of the Institute. If such Registered Professional Engineer desires to secure membership in the Institute under the conditions of this Agreement, he shall so notify the Registrar of the Association in writing, within 12 months of the date of such registration.

Sec. 3: Registered Members of the Association shall not be required to pay the transfer fees of the Institute. Registered members of the Association shall not be required to pay the entrance fees of the Institute, provided they make application in accordance with Sections 1 or 2.

Sec. 4: Any Corporate Member of the Institute who is, at the date of this Agreement, or who thereafter becomes, a resident of the Province of Prince Edward Island shall be eligible for membership in the Association if qualified for such membership, and all entrance fees otherwise payable to the Association shall be remitted provided that application for membership in the Association is made within twelve months of—

(*a*) The date of this Agreement in the case of any Corporate Member of the Institute who is at such date a resident of the Province of Prince Edward Island; or

(*b*) The date on which he becomes a bona fide resident of the Province of Prince Edward Island in the case of any Corporate Member who is not at the date of this Agreement such a resident;

Sec. 5: Any person who subsequent to the date of this Agreement becomes a member of the Institute, or advances his grade of membership therein and who is or becomes a resident of the Province of Prince Edward Island, shall be eligible for membership in the Association if qualified for such membership, and entrance fees otherwise payable to the Association shall be remitted up to the amount of the entrance fee currently required for the grade of Institute membership held, provided that the application for membership in the Association is made within twelve months of the date on which he becomes a member of the Institute or advances his grade of membership therein.

Sec. 6: Notwithstanding the provisions for the total or partial remission of entrance fees in sections 3, 4 and 5 hereof, if subsequent to the date of this Agreement either or both parties hereto change the amount of the entrance fee required, then provision shall be made for the total or partial remission of entrance fees to continue the intention of this Agreement, namely, that when a resident of the Province, of Prince Edward Island who is a non-member of both the Institute and the Association, but who becomes a joint member within a 12 months period, shall be required to pay in entrance fees a total amount not greater than the larger of the two individual entrance fees.

Sec. 7: (1) in lieu of the ordinary membership fees of the Institute the following annual fees are hereby established for members of the Association who at the same time are, or who may become members of the Institute.

(*a*(Members per annum	$14.00
(*b*) Juniors per annum	8.00

(2) The annual fee payable to the Institute by Members of the Association who are, or who may become members of the Institute shall be due and payable on the First day of January in each year, and shall be paid to the Association on behalf of the Institute.

(3) Each member of the Association who pays such annual fee to the Institute through the Association shall be entitled to all the privileges of Membership in the Institute, and to the annual subscription of the Institute Journal.

(4) The Association undertakes to receive the appropriate annual fee for membership in the Institute from each of its members who pay the same, and to remit the amount collected to the Institute at its Head Office at least once a month.

(5) The provisions of this section of this Agreement shall become effective on the First day of..................... 19......

Sec. 8: On the First day of January of each year the General Secretary of the Institute shall furnish to the Registrar of the Association a list of members of the Institute resident in the Province of Prince Edward Island, indicating as far as possible those who are not members of the Association. On the same date the Registrar of the Association shall furnish the General Secretary of the Institute with a list of members of the Association in good standing as on the thirty-first day of December preceding, indicating as far as possible those who are members of the Institute under the terms of this Agreement.

Sec. 9: It is agreed that the Branch of the Institute in Prince Edward Island shall continue to function actively as such during the term of this Agreement and to enable such functioning there shall be set up and continued from year to year during the term hereof a Committee of five members, all of whom shall be members of both the Association and the Institute, to be known as the Joint Finance Committee; two of said members shall be appointed annually by the Council of the Institute; two members shall be appointed annually by the Council of the Association, and the fifth member who shall be a corporate member of the Institute and a registered professional engineer, shall be appointed annually by the four members aforesaid and the fifth member shall be Chairman of the Committee. In case the four members aforesaid fail to appoint the fifth member within thirty days from date of their appointment, the said fifth member shall be appointed by the President of The Engineering Institute of Canada within a further period of thirty days. The said Committee shall recommend to Council of the Association, annually, the sums of money to be paid by the Association to the Branches of the Institute for their operation and such sums to be paid by said Council shall not be less than the per capita amounts now paid by the Institute provided, however, that such payments are made from annual revenue and in no case from capital reserve.

Sec. 10: During the term of this agreement the officers and the Council of the Association shall ipso facto be and become the officers and the members of the Executive Committee of the Prince Edward Island branch of the Institude. Any Prince Edward Island member of the Institute elected president or vice-president or councillor of the Institute shall be an ex-officio member of this Executive Committee. The Executive Committee as so constituted will be responsible for the management of the Prince Edward Island Branch.

Sec. 11: The representative upon the Council of the Institute of the members of the Institute in Prince Edward Island will be nominated and elected in accordance with by-laws of the Institute.

Sec. 12: Each year, the Institute shall pay to the Prince Edward Island Branch the regular Branch rebate of fees in accordance with the by-laws of the Institute for each member of the Institute resident in the Province of Prince Edward Island who is not a member of the Association.

Sec. 13: Each meeting of the Prince Edward Island Branch of the Institute and the Association will be announced as a joint meeting thereof with the exception of any legally required special or annual meetings of either the Prince Edward Island Branch of the Institute or of the Association.

Sec. 14: Upon the occasion of any of the following, the other party to this Agreement shall be so informed within a period of one month, in writing:

(a) the acceptance of the resignation of a joint member by one party to this Agreement, or;

(*b*) the removal from the membership roll or from the register, of the name of a joint member by one party to this Agreement, or;

(*c*) the receipt by one party to this Agreement of notification from a joint member that he has taken up permanent residence outside the Province of Prince Edward Island.

Sec. 15: The term of this Agreement shall be for a period of three years commencing on the first day of January 1957 and ending on the 31st day of December 1959 on which date this Agreement shall terminate provided either party has given to the other notice of termination at least six months prior to the 31st day of December 1959 and if no such notice is given this Agreement shall continue after 31st day of December from year to year but may be terminated at the end of any calendar year by either party giving notice in writing to the other of such termination at least six months prior to the end of the calendar year. Notice of termination of this Agreement shall be given by the delivery by one party to the other of a certified copy of a resolution of the Council of the one party to that effect.

Sec. 16: The terms and conditions of this Agreement may be amended by mutual agreement in writing between the Councils of the parties hereto duly executed by their accredited officers.

Sec. 17: This Agreement and the terms and provisions thereof shall not be applicable to the Institute members who are not, and do not become, registered with the Association. Likewise, this Agreement and the terms and provisions thereof shall not be applicable to Registered Professional Engineers of the Association who are not, and do not become, members of the Institute.

Sec. 18: Nothing in this Agreement shall prevent either party thereto from exercising its rights and privileges with respect to the disciplining, the suspension, or the expelling of any of its members. Any person suspended, or expelled from the Association or from the Institute during the term of this Agreement shall forfeit all rights under this Agreement until reinstated. When final action is taken by either party the other party shall be so notified.

Sec. 19: This Agreement is intended to apply with respect to residents of the Province of Prince Edward Island only, and no person who is not a resident of the Province of Prince Edward Island may become or continue to be a Corporate Member of the Institute under the provisions if this Agreement, but may continue to be a Corporate Member of the Institute and/or a member of the Association on the same conditions as if he had been admitted as a Corporate Member of the Institute and/or a member of the Association without reference to this Agreement.

IN WITNESS WHEREOF these presents have been duly executed on behalf of the parties hereto on the date and at the place first above written.

THIRTY-FIVE YEARS AGO

Comment on the Journal of September, 1922

The Institute's annual general and professional meeting was held in Winnipeg on September 5, 6, 7, 1922, so the contents of the *Journal* for that month was drawn from the papers to be presented there, five of them, plus one read before the Saskatchewan Branch in Moose Jaw the previous July. The wide field of engineering which the Institute covers can be seen from the titles of the papers, somewhat condensed:

Extensions to the Winnipeg Hydro-electric System, E. V. Caton, M.E.I.C.; Moncton Yard and Engine Facilities; S. B. Wass, A.M.-E.I.C.; Box Car Unloaders for Grain, Fred Newell, A.M.E.I.C.; Disintegration of Cement by Alkaline Waters, T. Thorvaldson; Turbines for the Manitoba Power Company, H. S. Van Patter, A.M.E.I.C.; Fallacies in Proportioning Concrete, G. M. Williams, A.M.E.I.C.

When Winnipeg built its hydro-electric plant in 1911, it provided space for sixteen units but installed only eight. Now it was adding the other eight units. These were horizontal shaft, double runner turbines rated at 6,800 hp. and directly coupled to 6,500-kva. generators. On test, the turbines actually developed 7,800 hp. at full gate. It was not possible to measure their efficiency, but the guarantees were: full gate, 80 per cent; 0.85 gate, 85.5 per cent; 0.80 gate, 85 per cent; 0.70 gate, 82 per cent; and 0.60 gate, 80 per cent.

Moncton "is the most important railway junction point in the Maritime Provinces", and as such requires ample yard facilities, which it lacked prior to 1922. The general layout of this new yard for the Canadian National Railways was made by C. B. Brown, M.E.I.C. There do not seem to have been any particularly novel features in its design, but it was a fairly sizeable job, with all the necessary buildings as well as trackage. There was no hump; this was before the days of gravity switching. There were seven miles of track in this extension to the old yard. Grading required the removal of 158,000 cu. yd. and the buildings accounted for 5,300 cu. yd. of concrete, 1,200,000 bricks and 1,400,000 ft. b.m. of lumber and 8,300 sq. ft. of glass.

Judging from Mr. Newell's paper, the unloaders which he describes must have been among the first built anywhere. They were designed jointly by C. D. Howe & Co., and Dominion Bridge Company, for installation at one of the Port Arthur elevators, and would empty a car completely in about four minutes.

Professor Thorvaldson's paper was a scholarly disquisition based on all the information he could gather from the literature and particularly on experiences with concrete in the Prairie Provinces. He concluded that 'the sulphates in alkaline waters are responsible for most of the disintegration of concrete, but warns the reader that "one must not draw the conclusion the . . . statement (in the paper) explains everything about the disintegration of concrete". There are other contributing factors.

The turbines of the Manitoba Power Company at Great Falls were notable because they were among the first, if not the first, of those with propeller type runners to be built in Canada. Mr. Van Patter compares them with the Francis-type runner turbines in the Cedar Rapids plant of the Montreal Light, Heat and Power Co. on the St. Lawrence River, which would give about the same power as these propeller turbines if installed at Great Falls. The great advantage of the latter is their higher speed and consequent reduced weight and cost. The higher speed also means a smaller and cheaper generator. Other improvements in the Great Falls turbines were the use of the Moody cone draught tube, a lighter gate ring built into the concrete, and changes in the governor and the lubrication systems. Tests at Holyoke on proto-type propeller runners gave a maximum efficiency of 88 per cent.

In his paper Professor Williams reviews a number of methods of proportioning concrete and comes to the conclusion, not surprising, that they are all imperfect, even the water-cement ratio method, quite novel in 1922. He points out wherein each falls down, and concludes that there is nothing better than making experimental mixes of the cements and aggregates which will be used on the job.

Award to H. J. Cambie

J. H. Cambie, M.E.I.C., "that grand old pioneer whose guiding hand and far-seeing vision was so largely responsible for making the shores of Burrard Inlet the terminus of a mighty railway" was the first recipient of the annual medal of the Hudson's Bay Company. Mr. Cambie went to the Pacific Coast in 1874. The presentation of the medal was made at a meeting of the Vancouver Pioneers Association and duly recorded in this *Journal.*

Lakehead Branch Set Up

The Winnipeg meeting authorized the setting up of the Lakehead Branch. The petition for the establishment, rather an ornate document, is reproduced in this *Journal*, with the comment that "the names of the signatories (can be) easily recognized". Well, maybe, but to me a good many are undecipherable. It seems that the more important a man, the more illegible his signature.

The Cape Breton Branch had made a trip to Louisbourg to visit the ruins of the fortifications there. The weather was wet and foggy, but "though wet externally and comparatively dry internally, the day was considered . . . successful, and it is hoped that it helped the individual members to realize that his professional associates . . . have a human side under their business armour".

Wilson Taylor, A.M.E.I.C., was back in the correspondence column with another long letter about latent heat, this time mostly with respect to its role in meteorological phenomena. Some day I must get one of my friends skilled in thermodynamics to read this letter and Mr. Wilson's previous one in the July 1922 issue of the *Journal*, and translate them into language I can understand, if possible.

R. DeL. French

Editor's Note: This is the last review of *Journals* of Thirty Five Years Ago which Professor R. DeL. French prepared before his death in May, 1956. The editors have enjoyed presenting his reviews, with his characteristic touches of humour and perception. They think *Journal* readers have appreciated them too. It is hoped that arrangements can be completed to continue this column through the services of another reviewer.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations

ONTARIO

(Abstracted from the bulletin of the Association of Professional Engineers of Ontario)

"Third Force"

A prominent Canadian industrialist recently summed up the status of today's professional engineer in industry. He said: "Professional men are a group themselves—a major one—*a third force* in industry. I like to think of them as representing the "third estate" in modern industrial society, which is made up of management, employees and the professionals.

Today, there is an undeniable dependence by modern business and industry upon trained professional people. The professional employee today represents one of the most sought after and valuable commodities in our economy. Because of this demand by industry for professional engineers, there are many opportunities, and along with them there are many responsibilities.

Industry expects the professional person to identify himself with the enterprise —to find out all he can about the nature and objectives of the business in which he is employed, and to integrate this knowledge into his thinking, so that his work contributes effectively to the overall success of the enterprise.

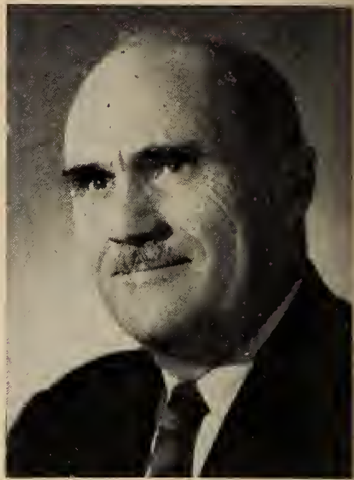
Industry expects thte professional man to be *professional.* Education or long experience do not in themselves create a professional man. The professional must develop his own technical and creative abilities. He must also learn how to inculcate and develop them in others with whom he is associated. He must be able to make his projects clear, not only to other professionals, but also to the non-professionals with whom he works.

In addition, he should take active part in professional and technical societies, in educational and social service activities, and in all the other undertakings which contribute to his own professional and personal development.

Industry expects and demands of its professionals the highest standards of thought, workmanship and integrity. The engineer sets his work objectives and gets his ability to perform them properly from knowledge, standards, goals and requirements of his profession. He must so govern himself that he will be sought after for the knowledge he has acquired in his profession.

Industry also has a right to expect the professional employee to be proud and loyal to his company, and to recognize his place in it.

B. R. Lachapelle, P.Eng.



J. Barselo, P.Eng.

N. Prefontaine

Announcement by C. A. Peachey president of the Corporation of Professional Engineers of Quebec of the recent appointment of Norbert Prefontaine, M.A., as public relations officer of the organization was made in the August issue of the Journal. During the last year, the Corporation has also appointed B. R. Lachapelle, P.-Eng., as specialized services officer and J. Barcelo, P. Eng., as registrar. The 12-member permanent Corporation staff is headed by P. Bournival, P.Eng., general secretary.

Counterbalance

To counterbalance, as it were, the five foregoing demands by industry, there are five similar expectations by the engineer. These have already been covered in previous bulletins; but we shall recall them briefly:

Stability of employment; adequate compensation for degree of responsibility; recognition of professional engineering as creative work; breakdown of a job and acknowledgement of achievement to ensure that an individual is gi en the feeling of responsibility for h specific contribution; a system of goc communications between manageme and engineers to keep the engineers a vised of long-term planning and con pany policy.

Misemployment

There is another duty that indust owes to its professional engineers. should provide opportunity for them work at professional assignments, a not assign them sub-professional tas that could be carried out by engineeri technicians. When we come to look in his situation, we are apt to find, in practically every company, many cases of *misemployment* of engineers, where engineers are engaged in duties which fail to extract the most value out of their professional talents or training. It has been shown by recent surveys that engineers are being used in at least 75 non-engineering jobs in a variety of industries.

In such cases, an engineer could accomplish considerably more in his own specialized sphere if he had suitable trained assistants. In many cases professional engineers with special creative talent are given such increative duties as making drawings, checking and computing – tasks which could well be turned over to others trained especially for these specific jobs.

Elimination of engineer misemployment will be of great benefit to industry, both economic and internal. Such benefits would include lower engineering costs per unit, increased engineering productivity, greater flexibility in the application of technology to products and processes, and lower turnover of professional manpower.

Management, by becoming increasingly aware of the funadmentals of "professional recognition" from the engineer's viewpoint, can take a big step along the way to overcoming the engineer shortage.

Industry will not be faced with the problem of inducing more bright, ambitious young men and women to enter technical and professional engineering fields, for these young men and women will begin to look upon these fields as areas of choice for an industrial career.

Engineers in The News

Robert E. Lawrence, P. Eng., has resigned as vice-president of Dade Petroleum Inc., and as managing director of Mines Development International Inc., to accept the offer from the Honduras Government to take the office of Inspector General of Mines under the Minister of Natural Resources. His headquarters are in Tegucigolpa, Honduras.

Mr. Lawrence writes that his specific task is to encourage the development of the country's large resources. To this end he is at present drafting proposed legislation aimed at encouraging foreign capital to invest there. He is also gathering data on known deposits of commercial minerals as a source of information for visiting engineers. Mr. Lawrence adds that he would like to see Canadian capital take an interest in that part of the world.

D. N. Jeffs, is located in Uranium City, Sask., where he is mine geologist with Lake Cinch Mines Ltd. He obtained his bachelor's degree in mining geology from the University of Toronto and later his Master's degree in economic geology from Queen's. Previous to moving to Saskatchewan, he was with Violamac Mines Ltd., in Toronto.

B. H. McGregor, has been named as sales engineer in the Electronics Division of A. C. Wickman Limited, Toronto. In his new position he will specialize in the application of Brush direct writing recording systems and allied products.

Mr. McGregor graduated in electrical engineering from the University of Toronto in 1947 and has since followed his profession in the electronics division of the Northern Electric Co. Ltd., with Rogers Majestic Electronics Ltd., and most recently with R. H. Nichols Ltd.

H. B. Ashenhurst, has resigned his appointment as co-ordinating engineer for the City of Hamilton and has opened a practice as a consulting professional engineer and Ontario Land Surveyor. His office is at 363 North Shore Blvd., West, Aldershot, Burlington, Ontario.

Andrew L. Leith, has accepted the position of mechanical engineer with Baker Platinum of Canada Ltd., at 512 King Street East, Toronto. He was formerly with the engineering staff of Ontario Hydro.

R. F. Day, has joined the field engineering staff of Alchem Limited, Burlington, Ontario, to which town he has moved. Mr. Day was formerly with the Honeywell Controls Hamilton office.

Andrew D. Miller, consulting electrical engineer, announces his new address at 1122 Bedbrook St., Ottawa 3, Ont.

G. R. Shantz, has returned to Canada and is employed in Maitland, Ont., at the Acrylic Fibre Plant of DuPont Co. of Canada (1956) Ltd.

H. B. R. Mattson, is now living in Windsor, Ont., where he is general manager of the Township of Sandwich East Public Utilities Commission. Prior to accepting this position, Mr. Mattson was manager of the Preston P.U.C.

T. F. Williscroft, has transferred from the Longlac Pulp & Paper Co., at Terrace Bay, Ont., where he was maintenance engineer to the Coosa River Newsprint Co., Coosa Pines, Ala. He is employed as a field lubrication engineer.

S. McCune, president of McCune Engineering Limited, informs us that the company has moved to enlarged quarters at 170 University Avenue, Toronto, where the consulting practice will be continued as designers and supervisors of construction for mining, ore beneficiation and industrial plants.

In addition to Mr. McCune and A. E. Salter, vice-president of the company, the following professional engineers are members of the staff: J. W. Cumming, chief engineer; Anton Kowbel, and F. D. Greenwood, project engineers; W. G. Moorehead, chief supervising engineer; and P. S. Joffray, design engineer.

P. G. Campbell, P.Eng., of Ontario Hydro, Toronto, has been appointed as director of construction for the commission. He succeeds **John E. Stark,** P.Eng., whose retirement takes place shortly following nearly 40 years service on the engineering staff of H.E.P.C. of Ontario.

Mr. Campbell is a native of Halifax and a graduate in civil engineering of the Nova Scotia Technical College. He joined Ontario Hydro in 1943 and has been with the Commission since that time with the exception of service in the Royal Canadian Navy and with the Federal Department of Mines and Resources. His work with Hydro has been in many parts of the Province and previous to his recent appointment was construction engineer in the generation department of the Construction division.

BRITISH COLUMBIA

Engineers in the News

J. Howard Bennett, P.Eng., was appointed assistant registrar of the Association at the last meeting of Council. Mr. Bennett graduated from the University of British Columbia in mining engineering in 1942. He has not been active in the profession for the last year. During this time he held a teaching appointment at Gladstone High School in Vancouver. Previous to that he was with Violamac Mines at New Denver, B.C. and from 1948 to 1952, he was inspector and resident engineer for the Department of Mines, Province of British Columbia. He has been registered as a Professional Engineer since 1949.

Mr. Bennett assumed his duties on July 1.

R. P. Henderson, formerly of New Westminster, has been appointed district engineer, Harbours and Rivers Engineering Branch of the Federal Department of Public Works.

L. D. Roberts, has been appointed project engineer in the Toronto area for Central Mortgage and Housing Corporation.

W. G. Whishaw has left the Fresnillo Company and is now acting as a consultant for the United States Steel Corporation in Mexico.

H. E. Sladen has been appointed assistant superintendent, distribution engineering, with the B.C. Electric Company Limited.

A. V. Gallon has received the appointment of senior civil design engineer with the B.C. Engineering Company Limited.

J. H. MacFadden has been appointed research engineer in the research and development division of the Consolidated Mining and Smelting Company at Trail, B.C.

R. G. Foxall has received the appointment as assistant civil engineer, power development division, with the B.C. Power Commission.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Duncan Lennox McLaren, M.E.I.C., of the Canadian General Electric Company Limited, Peterborough, Ont., died at his home in that city on June 13, 1957, Mr. McLaren retired from the company earlier this year due to ill health, relinquishing his post with the marketing section, apparatus department.

Mr. McLaren was born at Perth, Ont., on January 1, 1892. He studied engineering at the University of Toronto, gaining the degree, B.A. Sc., from that University in 1914. For the next two years he followed the C.G.E. test course at Peterborough. With the Canadian General Electric Company Limited during his entire career, one of his most recent endeavors was his contribution to the design of the water generator.

Early in his career, in 1925, he transferred from the engineering department to direct his efforts to sales, and moved from Peterborough to the generator section at head office, Toronto. He was manager of the generator division of the company in 1949 and five years later was named manager of sales in charge of large motors and generators. Mr. McLaren returned to Peterborough in 1954, after thirty years and at that time was named manager of sales in charge of large motors and generators.

Mr. McLaren joined the Institute as an Associate Member in 1919. In 1940 he transferred to Member. He attained Life Membership in the Institute in 1955.

Air Vice-Marshal Clarence A. Cook, O.B.E., M.E.I.C., whose promotion from Air Commodore was made a few weeks before his death, died on July 24, 1957 at Ottawa.

Mr. Cook was born at Saskatoon, Sask., on November 20, 1907. He attained a bachelor of civil engineering degree at the University of Saskatchewan in 1933. He also attended the College of Education of the University of Saskatchewan and was engaged for a time as a teacher on the staff of Bedford Road Collegiate, before joining the R.C.A.F. in 1939. Overseas during the battle of Britain in 1940 he served as an engineering officer with No. 112 Army Cooperation Squadron. On his return to this country he became staff officer at various stations and headquarters and later took over a position in the directorate of Postings and Careers, at Air Force Headquarters, Ottawa. In 1948 he was posted to the Canadian Joint Staff, Washington, D.C., returning to the Air Material Command headquarters as senior logistics planning officer.

For distinguished wartime service Air Vice Marshall Cook was appointed an officer of the Most Excellent Order of the British Empire in 1946. In 1952 he received the appointment of chief logistics officer at Royal Canadian Air Force Headquarters, Ottawa, which he retained until his appointment as Air Vice Marshall and Air officer commanding the Air Material Command in 1957.

Air Vice Marshall Cook joined the Institute as an Associate Member in 1938, and transferred to Member in 1940.

Thomas Hogg, M.E.I.C., project engineer for the B.C. Power Commission, at Victoria, B.C., died on June 28, 1957, in that city.

Originally from Great Britain, Mr. Hogg was born at Ushaw Moor, County Durham, England, on November 7, 1904. He attended the Sunderland technical school and the Bede Collegiate Institute at Durham and was granted a national certificate of the Institution of Mechanical Engineers in 1925, and was for a number of years also engaged as a pupil with a firm of mechanica engineers. Working in England for th first few years of his graduate caree he migrated to Canada early in th thirties. Having served as chief draughts man for the Department of Natural Re sources at Regina, Sask., for five and half years he transferred in 1937 to th Water Rights Branch at Regina to carr out water development work in the Prov ince of Saskatchewan under the Prairi Farm Rehabilitation Act.

During World War II he became ad ministrator officer to Major Gen eral W. W. Foster, D.S.O., special com missioner for defence projects in North west Canada at Edmonton, Alta., an attained the rank of captain.

After the war he became executiv assistant with the British Columbia Pow er Commission, Victoria, B.C. In 194 he was with the construction departmen of the Commission and later worked o the Watshab Hydro Project at Needle B.C., and as resident engineer on th John Hart project at Campbell Rive B.C.

Mr. Hogg joined the Institute in 193 with the status of Associate Membe He was transferred to Member in 194

H. Leonard Watts, M.E.I.C., frequenc standardization project manager fo Brantford, Ont., and district, died at hi home at Stoney Creek on April 12, 195

Mr. Watts was born at Toronto o October 25, 1907. He attended King Ed ward Public School and St. Andrew College before graduating from the Un versity of Toronto with a B.A.Sc. in met allurgy in 1931. He entered govern ment service and became assistant to th chief of the Bureau of Mines at Ottaw He retained this position from 1938 t 1948 with the exception of five and a half years during World War II, whe he served overseas with the Royal Can dian Engineers. Mr. Watts took part i the raid on Dieppe, France, durin which time he was wounded. He hel the rank of major on demobilization.

Brief periods of his career were als spent with the National Sewer Pipe Con pany Limited at Hamilton and wit Shell-Bar Limited, New Toronto, durin the thirties and with the Central Mor gage and Housing Corporation at Va couver during 1948 and 1949.

Joining the Hydro-Electric Pow Commission of Ontario in 1949, he acte as assistant project manager during th frequency standardization program in th City of London and Windsor, and be came project manager in 1954 for th operation in Hamilton and district.

Mr. Watts joined the Institute as Member in 1952.

In the June issue of the *Journal* it wa reported that Harold Forsyth Finnemor M.E.I.C., retired chief electrical enginee Canadian National Railways, Montrea died on April 8, 1956. The correct da was April 8, 1957. The *Journal* regre the error.

A.V.M. C. A. Cook, O.B.E., M.E.I.C.

D. L. McLaren, M.E.I.C.

Personals

News of the Personal Activities of Members of the Institute

C. K. McLeod, M.E.I.C., elected vice-chairman of the board of directors of the Permutit Company of Canada earlier this year, has been elected chairman of the board of directors and will continue to serve the organization as a consultant.

Mr. McLeod was also elected president of Walter Kidde and Company of Canada Limited early in 1957. He has been associated with that Company as well as the Permutit Company since 1925.

He is a past vice-president of the Institute.

I. J. Hamill, M.E.I.C., has been appointed executive vice-president and managing director of Walter Kidde and Company of Canada Limited.

Mr. Hamill joined the organization eighteen years ago and was transferred to Canada a year ago. Prior to this move he served as manager of the aviation division of Walter Kidde and Company Inc., New York.

P. E. Cooper, M.E.I.C.

W. C. M. Luscombe, M.E.I.C., of Dominion Structural Steel Limited, has been appointed to the position of assistant secretary of the company at the head office in Montreal. He will continue to hold office as manager of engineering, research and development, which department was newly formed in 1955. These duties include the development of new products and new plants.

Mr. Luscombe joined the staff of Dominion Structural Steel in 1955, at Montreal. He was formerly associated with the Dominion Textile Company Limited at Montreal and Magog, Que., and the Aluminum Company of Canada at Montreal.

He is a graduate of Queen's University, class of 1941 in electrical engineering.

Paul E. Cooper, M.E.I.C., formerly president of Crown Zellerbach Canada Limited, has been appointed a director and executive vice-president of Sandwell and Company Limited, consulting engineers of Vancouver.

Mr. Cooper has been associated with the pulp, paper and allied forest industries for more than thirty years in Canada, the United States and abroad.

Mr. Cooper is a past chairman of the executive committee of the Canadian Pulp & Paper Association.

R. E. Tweeddale, M.E.I.C., of Fredericton, N.B., who was formerly assistant chief engineer of the New Brunswick Electric Power Commission has been named chief engineer. he appointment is retroactive to July 1, 1957. He has also assumed the duties of senior executive officer reporting to the Commission.

Mr. Tweeddale is a graduate of the University of New Brunswick where he received a B.Sc. degree in electrical engineering, class of 1935. Prior to joining the R.C.A.F. in 1940 where he served overseas he was employed as district highway engineer with the provincial government. In 1945 he joined the engineering department of the Commission and was later named manager of operations. During the study of the St. John River basin by the International Joint Commission in 1952 and 1953 he served with their engineering work group on a number of important committees in connection with the survey.

Dr. K. R. Rybka, M.E.I.C.

R. E. Tweeddale, M.E.I.C.

Mr. Tweeddale was chairman of the Fredericton Branch of the Institute in 1954.

J. L. Feeney, M.E.I.C., chief engineer of the New Brunswick Electric Power Commission at Fredericton, N.B., whose retirement has been announced, remains with the Power Commission in a consulting capacity until the end of November 1957. Mr. Feeney is responsible for the completion of the Beechwood development, the 135,000 hp hydroelectric development at Beechwood on the St. John River. Two 45,000 hp units of the big project will be joining the Provincial transmission system this year.

During Mr. Feeney's term of office as chief engineer, the 27,000 hp Tobique hydro development was completed and more than 62,000 hp added to the utility's generating capacity.

Prior to joining the Commission's staff as design engineer in 1935, Mr. Feeney had a responsible hand in a number of important engineering and architectural projects in both Canada and the United States.

He is a member of the Advisory Committee of the Atomic Energy Commission for Canada.

Dr. Karel R. Rybka, M.E.I.C., vice-president of Federated Consultants Limited and president of Karel Rybka and Associates Limited, was elected president and director of engineering of Gulf Federated Consultants, Inc. of New Orleans, La.

• PERSONALS

Gulf Federated Consultants Inc., have recently been commissioned by the Morgan City Harbor and Terminal District in Morgan City, La., to prepare a master plan and an economic feasability report, and to engage in any consequent engineering in connection with the development of a major deep draft seaport for the twin communities of Morgan City and Berwick, La. and with the industrial development of the entire region.

Morgan City and Berwick straddle the Atchafalaya River a few miles from the Gulf coast and at its intersection with the Intracoastal Canal. This barge canal is planned to ultimately extend from the Mexican border to Trenton, N.J., and several major sections of it are already in full-scale operation.

T. Blench, M.E.I.C., professor of civil engineering at the University of Alberta, and consulting engineer, is the author of "Regime Behaviour of Canals and Rivers," very recently published by Butterworths, England. The Canadian office is at 1367 Danforth Ave., Toronto.

Commodore (L) William H. G. Roger, M.E.I.C., of Hamilton and Ottawa, electrical engineer-in-chief at naval headquarters, from 1948 until the present, has retired.

Commodore Roger came to this country in 1923 immediately following training at the Heriot Watt Engineering College, Edinburgh, and found work with the Canadian Westinghouse Company, Hamilton, in the engineering department.

His naval career dates to 1937 when he joined the Hamilton division of the R.C.N.V.R. The following year he served as commanding officer of the division. With the outbreak of World War II he began a series of appointments in Canada.

Comm. (L) W. H. E. Roger, M.E.I.C.

P. J. Croft, M.E.I.C.

For his services in Halifax during the war he was awarded the Order of the British Empire.

R. W. McNally, M.E.I.C., has been appointed general sales manager of Mathews Conveyer Company Limited, Port Hope, Ont.

Mr. McNally has been in charge of the Mathews engineering sales office at Hamilton, Ont., since 1947. Prior to that time he was located in the company's Toronto office, as a service engineer.

Mr. McNally graduated from the University of Saskatchewan.

P. J. Croft, M.E.I.C., has been appointed stations engineer with the B.C. Power Commission, following nine years as chief engineer with the Canada Wire and Cable Company, Toronto.

Experienced in the design, development and application engineering of cable and underground transmission, Mr. Croft was also associated with the design and installation of some of the first fully automatic hydro-electric stations in Canada. Eighteen of his thirty-six years in the electrical industry were spent with the Power Corporation of Canada in station design, transmission, distribution and system planning work.

In his new post Mr. Croft becomes responsible for station design in the Commission's heavy program of generating plant construction.

W. L. Bunting, M.E.I.C., previously project engineer for Defence Construction, Winnipeg has been appointed engineer in charge of structural design, for the City of Winnipeg Hydro Electric System succeeding H. Jorgenson who has returned to Norway.

Mr. Bunting has previously held appointments with the Department of Public Works, Province of Manitoba; with the Municipal District of Flin Flon as municipal engineer; with the firm of Ducks Unlimited (Canada) at Regina, Sask., as chief engineer; and with the Hudson Bay Mining and Smelting Company.

W. L. Bunting, M.E.I.C.

G. M. Rose, M.E.I.C.

Gordon M. Rose, M.E.I.C., who was for several years chief re-inforced concrete engineer with the firm of W. V. Zinn and Associates, Toronto, has returned to Great Britain to continue his career. At present in London, Eng., he is associated with Procon (G.B.), the British subsidiary of the American firm of oil refinery consultants, in connection with civil engineering work on contracts in the United Kingdom, Europe, the West Indies and South America.

E. L. Neal, M.E.I.C., has been appointed general manager of the Gaspesia Sulphite Company Limited.

Mr. Neal, who is a graduate in mechanical engineering of Queen's University, class of 1938, has been filling the office of mill manager for the Anglo-Newfoundland Development Company

We are exhibiting at Canada's Power Show, Exhibition Park, Toronto, Oct. 21-24, 1957.

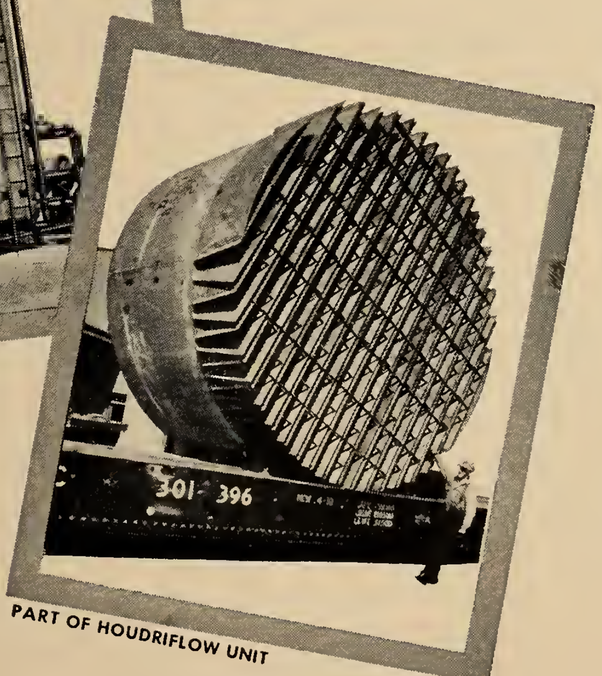
TREATER UNITS



PART OF HOUDRIFLOW UNIT

Serving Canada's Oil and Petro-Chemical Industries

To meet the growing needs of Canada's Oil and Petro-Chemical Industries, Dominion Bridge are further expanding their various plants and facilities . . . particularly in oil producing areas.

For all types of platework and fabricated steel used in refinery or field operations, remember the name DOMINION BRIDGE — it is your assurance of long experience, the most modern techniques and a reputation for unsurpassed workmanship.

Some examples of our work are shown on this page. For complete information, write for illustrated booklet "Platework for every industry", Publication No. PF-100.

DOMINION BRIDGE COMPANY, LIMITED

PLANTS: MONTREAL • OTTAWA • TORONTO • WINNIPEG • CALGARY • VANCOUVER • Associate Company Plants: **AMHERST, N.S.** – Robb Engineering Wks., Ltd. • **QUEBEC** – Eastern Canada Steel & Iron Wks., Ltd. • **SAULT STE. MARIE** – Sault Structural Steel Co. Ltd. • **WINNIPEG** – Manitoba Bridge & Eng. Wks., Ltd. • **CALGARY** – Riverside Iron & Eng. Wks., Ltd. • **EDMONTON** – Standard Iron & Eng. Wks., Ltd.

Dominion Bridge

Limited, at Grand Falls, Nfld., since 1952. He was an assistant general superintendent with the Anglo-Canadian Pulp and Paper Mills at Quebec, at an earlier period in his career.

J. Harold Wallis, M.E.I.C., who retired from Dominion Engineering Works Limited, Montreal as vice-president and manager of the power crane and shovel division in 1956, has been appointed president of Power Shovel Cranes Ltd., at Montreal.

Mr. Wallis was general manager of the Dominion Hoist and Shovel Company Limited from 1931 to 1953. When that firm was absorbed into the parent company, Dominion Engineering Works Limited, he became vice-president and manager of the power crane and shovel division.

Ian F. McRae, M.E.I.C., a vice-president of the Canadian General Electric Company has been elected to the first vice-presidency of the Canadian Manufacturers' Association.

In 1955 Mr. McRae was chosen to head the General Electric Company's engineering team assigned to design, engineer and construct Canada's first nuclear reactor for power purposes.

Mr. McRae has served the company since 1925. Manager of the firm's largest plant, at Peterborough from 1941 to 1950 he was two years later sent on loan to the Government of Canada as director of the gun division of the Department of Defence Production.

J. A. Tames, M.E.I.C., has been appointed manager of the Canadian Westinghouse Company eastern district.

Mr. Tames, who joined the company in 1925 will be directly responsible for sales of Westinghouse electrical apparatus products in Quebec and part of Eastern Ontario, where he will be senior representative in that area.

Located at Vancouver with the firm for many years Mr. Tames has been extensively associated with power sales and apparatus sales.

M. D. E. Robinson, M.E.I.C., has been named to the post of assistant manager, engineering, with the Linde Air Products Company, division of Union Carbide Canada Limited, Toronto.

Mr. Robinson graduated from the University of British Columbia in 1947 with a master of science degree in metallugical engineering and joined the Linde Air Products Company at that time. He served as engineering service representative in British Columbia for several years and prior to his present appointment was manager, engineering service, western district.

C. W. E. Locke, M.E.I.C., is working through an appointment from Sandwell International Limited, consulting engineers, as mill manager at the Khulna pulp and paper mill project now under construction in East Pakistan for the Pakistan Industrial Development Corporation.

Sandwell International was formed in 1955 to provide management services and was recently awarded a management contract by the Pakistan Industrial Development Corporation in connection with the new pulp and paper mill.

Mr. Locke is a graduate of the University of British Columbia, class of 1930. He has latterly acted as resident manager, general manager and plant engineer at a number of British Columbia coastal mills.

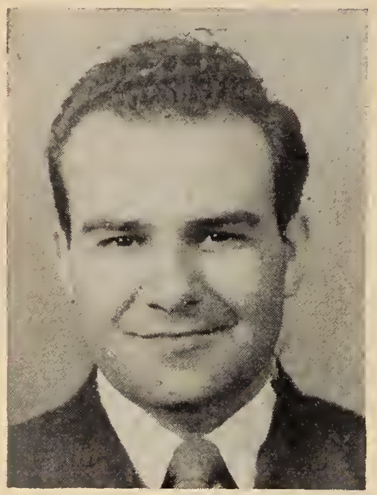
Among them are Pacific Mills Ltd., Ocean Falls, B.C., Bloedel, Stewart and Welsh Company Ltd., and MacMillan and Bloedel Limited, Nanaimo, B.C.

G. L. MacKenzie, M.E.I.C., active in the work of the Prairie Farm Rehabilitation Administration for twenty years was appointed director of the organization earlier this year.

Mr. MacKenzie gained his engineer-

ing training at Queen's University, became a certified Dominion Land Surveyor. In 1920 he moved to Western Canada and to P.F.B.A. in 1937, serving as district engineer in Manitoba, office engineer at Regina, and becoming chief engineer in 1946.

While filling this office, Mr. MacKenzie was instrumental in the construction of the St. Mary and Bow River irrigation projects in Alberta.



R. P. Lynch, M.E.I.C.

During this time he served in numerous capacities for the Dominion government. Mr. MacKenzie is chairman for Canada on the international engineering boards on Western Water References, Waterton-Belly Rivers Reference and Souris-Red River Reference, under the International Joint Commission.

Mr. MacKenzie was also appointed Canadian delegate to the United Nations conference on conservation and utilization of resources in New York in 1949.

On a special assignment he investigated and reported on works for flood relief on the Red River at Winnipeg for the department of resources and development between 1950 and 1953.

H. R. Skinner, M.E.I.C.

Hugh R. Skinner, M.E.I.C., has accepted the post of heating equipment sales engineer with The Winnipeg Supply and Fuel Company Limited.

A 1949 graduate in mechanical engineering from the University of Saskatchewan, Mr. Skinner has spent the past six years in the mechanical contracting field and was associated with the firm of Waterman-Waterbury Manufacturing Company Limited at Regina and Winnipeg.

R. P. Lynch, M.E.I.C., assistant construction engineer with the Department of Public Works of the Province of New Brunswick at Fredericton, N.B., is chairman of the Fredericton Branch of the Institute for the 1957-58 term.

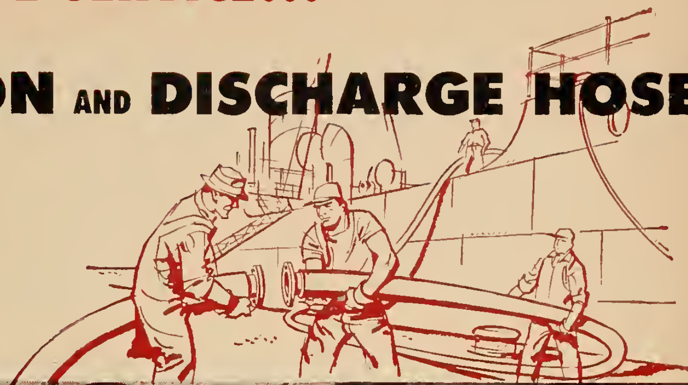
A native of that eastern city, he is also a graduate of the University of New Brunswick, class of 1947 in civil engineering.

Engaged in his present work since the beginning of his career he was originally resident engineer on survey and construction.

Mr. Lynch joined the Institute as a

FOR DEPENDABLE DOCK-SIDE SERVICE...

AMAZON OIL SUCTION AND DISCHARGE HOSE



ROUGH BORE

Where big oil tankers and barges tie up, you'll see Dominion Rubber's famous Amazon Oil Suction and Discharge Hose . . . a great favourite with dock workers.

SMOOTH BORE

Any experienced dock worker will tell you that here is the top hose. Dominion Rubber's Amazon Oil Suction and Discharge Hose, though rugged, is easy to handle. It's a safe hose. It has what it takes to withstand the damaging effects of oil, gasoline, sunlight and chafing. Rough bore or smooth, it's built to take years of the toughest kind of dock-side service.

Dominion Rubber offers a complete line of hose, designed specifically for the oil industry . . . in standard sizes up to 12 inches and for working pressures to 200 psi.

• • •

For details and specifications on the best hose to do your job contact your nearest Dominion Rubber branch.

ENGINEERED RUBBER and PLASTIC PRODUCTS for EVERY INDUSTRY

DOMINION RUBBER

Dominion Rubber

Mechanical Goods Division

student member in 1946, and transferred to Junior in 1949.

H. A. Mullins, M.E.I.C., of Du Pont Company of Canada Limited has been appointed supervising engineer of construction. He formerly served the organization as purchasing agent for equipment in the purchasing and traffic department.

Mr. Mullins is a graduate in electrical engineering from the University of Manitoba. In addition to his background in a number of industries, his experience with Du Pont of Canada has been in engineering and purchasing.

Mr. Mullins is a councillor representing the Montreal Branch of the Institute for a three-year term which began in 1956.

R. N. Boyd, M.E.I.C., has been named to the post of supervising engineer of design services with Du Pont of Canada Limited, engineering department at Montreal.

A B.Sc. graduate in mechanical engineering from the University of Toronto, class of 1939 Mr. Boyd began his career with the Hydro-Electric Power Commission of Ontario. He joined the Du Pont Company in 1941. He was appointed a supervising engineer on design for the organization in Montreal in 1954.

R. C. Thurber, M.E.I.C, who has since 1951 carried out the duties of materials engineer with the Department of Highways, Province of British Columbia, has formed a company of consulting engineers at Victoria, B.C., known as R. C. Thurber and Associates. The firm will specialize in soil mechanics, foundations for bridges and buildings, landslides, slope stability work and concrete and affiliated work in civil engineering in connection with dams, concrete construction and road building.

Second member of the firm is W. C. Jones, who holds an M.Sc. degree in geology from the University of British Columbia, class of 1953.

D. D. Coffey, third member of the company is a 1948 graduate of Sydney University in Australia. He was formerly with the Department of Highways Testing Branch.

Mr. Thurber is a graduate of the University of Alberta class of 1949. He specialized in soil mechanics and testing at the University of Alberta and worked on various research projects under Dean Hardy and for the National Provincial Research Council. He became associated with the Department of Highways in 1949 working as a soils engineer.

Cyril Fry, M.E.I.C., of Gravenhurst Ont., is president of the Central and Northern Ontario Film Federation.

When the Georgian Bay District Federation of Film Councils was formed, he was named chairman, serving in this office until 1955. At this time the organization merged in the larger group now known as the Central and Northern Ontario Film Federation.

Mr. Fry has been interested in films for many years and suggests that in the interest of the engineering profession and in the search for potential technical men, films could bring engineering achievements to the schools in a way that is impracticable by other means.

John S. Ellis, JR. E.I.C., has joined the firm of J. D. Lee and Company Limited, consulting engineers, at Kingston, Ont.

Mr. Ellis graduated with a B.Sc. in civil engineering from Queen's University in 1948 and qualified for an M.Eng. degree at McGill University the following year. Gaining experience with the Shawinigan Engineering Company and the firm of H. G. Acres and Company, Niagara Falls, Ont., he has since then carried out studies at St. John's College, Cambridge, Eng., as a winner of the Athlone Fellowship in 1954.

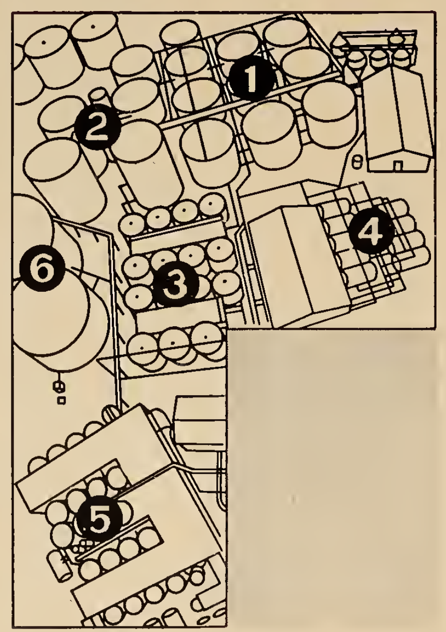
J. N. Buckley, JR.E.I.C., formerly with the Ideal Welding Company Limited, Toronto, as a design estimator, has left that place of business and is at work in London, Ont. He is associated with the

Water-tower view of PERMUTIT water-treatment equipment at Gulf States Utilities Company's Louisiana Power Station, North Baton Rouge, La. Engineered and constructed by Stone and Webster Engineering Corp.

12 million gallons of make-up per day

This station needs a *large volume* of water because it sells its steam to a refinery for process and requires 100% make-up. It needs *high-grade* water because it has adopted high-pressure boilers and turbines. It needs *efficient* treatment because it uses muddy Mississippi River water and well water with high solids and silica.

HERE'S HOW THIS 26-YEAR OLD PLANT HAS KEPT UP TO DATE *(see diagram)*:



1. Original *batch coagulation and settling tanks.* Some are still used for secondary treatment of river water to reduce silica.

2. The 1931 roughing sedimentation tanks were converted to modern up-flow *Precipitators* in 1938 . . . cutting hardness 20%, turbidity 40%—and tripling capacity.

3. *Gravity filters* polish the clarified river water prior to softening.

4. Old Zeo-Dur® *zeolite softeners* were converted to new Zeo-Karb® exchanger in 1937 . . . boosting each unit's capacity 55%.

5. *Demineralizers* for new high-pressure boilers were added in 1955. They treat 3500 gpm, reduce dissolved solids of well water from 271 to under 2.0 ppm and silica from 25 to less than 0.1 ppm. Completely automatic PERMUTIT controls determine end-points, rinse, backwash and regenerate units and return them to service . . . even prepare regenerating solution.

6. *Tanks* store the high-quality, low-cost demineralized feedwater.

• PERSONALS

Allen Tank and Welding Company, Limited in that city.

Mr. Buckley is a 1949 graduate in mechanical engineering from the University of Manitoba.

E. H. Wilson, JR.E.I.C., has been appointed plant manager with the firm of Bestpipe Limited, at Toronto.

Mr. Wilson, a Queen's University graduate, class of 1951 was formerly associated with the North American Cyanamid Limited, Niagara Falls, and with the Niagara Concrete Pipe Company Limited, St. Catharines, Ont.

S. R. Price, JR.E.I.C., assistant city engineer for four years has taken over the appointment of city engineer at Niagara Falls, Ont.

A graduate of Queen's University in civil engineering, Mr. Price has gained experience in several engineering positions. One and a half years with a firm of consulting engineers at St. Mary's, Ont., he served as assistant town engineer at Weston, Ont., for one year.

Later he was for two and a half years assistant city engineer at Belleville, Ont.

W. C. Sinkins, JR.E.I.C., formerly of the firm of B. A. Hastings, consulting engineer, of London, Ont., has accepted a post with the London Steel Construction Company Limited, also in London.

Mr. Sinkins is a graduate of Queen's University, class of 1951 and was at one time a draughtsman with the firm of Bestpipe Limited, at Toronto.

John W. Francis, JR.E.I.C. has been appointed sales engineer at the Montreal office of Forano Limited, in the power transmission and materials handling division. Mr. Francis is a graduate of McGill University, obtaining a B.Eng. degree in mechanical engineering in 1950.

In his engineering career to date he has been associated with the construction, forestry and plant engineering fields.

G. T. Keys, JR.E.I.C., who has been residing at Kingston, Ont., associated with the Pulp and Paper Research Institute of Canada as an hydraulics engineer now lives in Montreal. He has accepted an appointment with the Canadian Pulp and Paper Association as mechanical engineer.

Mr. Keys obtained an M.A.Sc. degree in mechanical engineering at the University of Toronto in 1952.

M. E. M. Gibson, JR.E.I.C., formerly of Dublin, Ireland, is working as assistant resident soils engineer on the Bersimis No. 2 hydro-electric project at Labrieville, Que. He is employed by H. G. Acres and Co. Ltd., of Niagara Falls. The firm is supervising the soils and foundation section of the work for Hydro-Quebec.

Mr. Gibson graduated in civil engineering from Trinity College, University of Dublin in 1954 and the following year became associated with the firm of Proctor, Redfern and Laughlin, Toronto. He joined his present firm in 1956.

Maurice G. Vezina, JR.E.I.C., is association with the firm of Lalonde and Valois, consulting engineers of Montreal.

Mr. Vezina graduated from Loyola College with a B.A. degree in 1952, from McGill University in civil engineering in 1956. He was awarded a master's degree in sanitary engineering from the Massachussetts Institute of Technology in 1957.

ıutperforms other materials

Provides very high resistance to impact abrasion plus superior strength and toughness that keeps equipment in service far longer than before*

WHITE PINE COPPER'S experience with USS "T-1" Steel is typical of the improvements in service that ıis remarkable steel makes possible.

Wherever they have used it to replace former conruction, equipment life has been materially increased. epair and maintenance costs have been cut. Down time as been reduced. All this means important savings in time and money—savings that are far greater than the difference in initial steel cost.

USS "T-1" Steel is unique. There's never been another commercial alloy plate steel just like it. None better able to stand up to the brutal abuse inflicted on mining equipment . . . and as readily handled in fabrication . . . *and* so economical on the basis of performance.

*oader plates last 8 to 12 months longer

.t White Pine Copper, USS "T-1" Steel, supplied to 321 ıinimum Brinnell, is used in the bottom and side plates of he conveyor of this loading machine. Also, in the plates on s underside along which the returning conveyor chain ides. Prime requirements here are toughness and high sistance to impact abrasion. Every one of these underround loaders has been overhauled since the mine was pened and, in every case, USS "T-1" Steel has been used increase durability. The result—8 to 12 months more ervice life.

Here's why USS "T-1" Steel can help you improve your equipment

When you want strength far beyond the ordinary, you can get it with USS "T-1" Steel—for, with a minimum yield strength of 90,000 psi and a minimum tensile strength of 105,000 psi, USS "T-1" Steel is nearly three times as strong as structural carbon steel. This is far higher yield strength than has ever before been available in weldable plate steel. What's more, its strength is not lowered by welding or gas cutting.

For equipment subject to impact abrasion, USS "T-1" Steel can be obtained quenched and tempered to a minimum hardness of 321 Brinell. Even this very hard grade can be welded and flame-cut *right in the field* without preheating. That means you don't have to shut down costly, big-capacity equipment for the many hours generally required for shop repairs.

If your equipment must withstand severe impact abuse, USS "T-1" Steel insures against damage in winter weather. Whether furnished to 321 minimum Brinell or to 90,000 psi minimum yield strength, it has exceptional toughness and resistance to brittle failure, even at temperatures far below zero.

Our new catalog—USS "T-1"—is complete with technical information and offers many practical suggestions for its use that can save *you* money. For your free copy, write to United States Steel Export Company, Royal Bank Building, Toronto 1, Ontario.

Mackinac Bridge Site Tour

In warm sunny weather, Saturday June 8, a group of local professional engineers and ladies set off for St. Ignace as guests of the Mackinac Bridge Authority. This event marked the final meeting of the local branch until next fall.

Apart from the appropriate nature of this professional team viewing one of the outstanding engineering projects in the world at the moment, the event was naturally of outstanding interest for those enjoying the trip.

Since H. D. Ellis, chief public relations officer for the Bridge Authority was already well known to the visiting group, his role as host was in keeping with the occasion, and his conduct of the tour was assisted by David L. Bigler, field representative of United States Steel Corporation. This organized trip around the site of the unfinished structure took place on the water, with the touring party carried aboard the sturdy construction tug, "Bridgebuilder-X", belonging to the bridge-building division of U.S. Steel.

In spite of wide publicity already given the partially built giant bridge, some of its staggering dimensions continue to draw gasps from spectators. The main towers rise up skywards 525 feet above the water. This is the equivalent height of a 46 floor skyscraper. Below water level the main pier foundations reach down over 200 feet to rest on solid rock. A shore-to-shore gap of four miles will be spanned, and if we include the shore approaches then the overall length of the structure is five miles. At such a great height, sweeping in mighty curves between the colossal towers, the two main suspension cables appear almost slender. In actual fact each of these has a diameter better than 24 inches.

Mythology and Mackinac

Alongside this mammoth product of his own ingenuity man seems but a tiny ant. As our little tug moved like a speck across the sunny peaceful waters of the Mackinac Straits, awed by the dimensions of the bridge, some of us remembered the earlier history of these parts, particularly in regard to Mackinac Island. In the year 1880 J. A. Van Fleet wrote: "Indian mythology makes this island the home of the Great Fairies, hence the Indians have always regarded it with a species of veneration." We know that in early times Indians passing these shores by water stopped to make offerings to the Great Spirit.

Members of the Sault Ste. Marie Branch and their families enjoyed the Mackinac Bridge tour held June 8. Seen in the background is the base of the main tower of the gigantic structure.

It seems there was always some air of mystery about this area. Now in our time has come the magic of the mighty bridge, fulfilled by the vision of the great state of Michigan with the ingenuity of modern engineering.

Our tug turned from the setting sun and returned the group to St. Ignace. That evening everyone attended a buffet dinner and an evening of good fellowship in Sault Ste. Marie, rounding off the season with the memorable tour of Mackinac.

Annual Meeting

The annual meeting of the branch was held on May 23, 1957 in the Corps of R.C.E.M.E. Officers' Mess at Barriefield. Ninety-two members, wives and guests were in attendance at dinner which was followed by the annual meeting, presided over by the chairman, Col. C. W. Jones. The Duggan Medal and Prize was presented by Councillor H. G. Conn on behalf of the President of the Insitute to Dr. D. T. Wright for his paper "The Design of Compressed Beams".

The election of officers for the 1957-1958 term was held and the following were elected: chairman: J. W. Dolphin; vice chairman: R. B. Wotherspoon; executive: W. B. Rice; W. M. Campbell; and D. C. Macpherson.

The following are the appointed members of the 1957-58 Executive: past chairman: C. W. Jones; councillor: C. H. R. Campling; and sec.-treasurer: D. I. Ourom.

The evening concluded with dancing and refreshments.

Students' Papers Night

The annual Students Papers Night of the Branch was held on March 5, 1957 at Queens University with Col. C. W. Jones in the chair.

Of the many papers submitted, five

• BRANCH NEWS

were selected for presentation as follows: "Audio Noise from Distribution Transformers", by G. Fanjoy; "Catalysis and Core Structure in Catalysts", by D. Woods; "Measurement of Demagnetizing Currents in D. C. Machines", by J. Hunt; "Laying of Submarine Power Cables", by D. A. Croft; and "Hyperbolical Parabaloidal Arches", by J. J. Ryan.

The first, second and third prizes were won respectively by G. Fanjoy, J. Hunt and D. A. Croft.

Metal Cutting Research

Professor W. B. Rice of Queens University gave a paper on March 19, 1957, at Queens University on "Metal Cutting Research". Vice Chairman J. W. Dolphin was in the chair.

Dr. Rice has undertaken the research project, essentially a problem of automation, with Ross Salmon, a McLaughlin Teaching Fellow.

Dr. Rice states that the economic importance of metal cutting is evident when we consider that almost everything we own is directly or indirectly the product of a machine tool. Hence it is not surprising that much effort is being directed towards the automatization of machine tools, while there is considerable discussion of computer control.

"A computer is frequently and correctly referred to as a data processing device. Its output, instruction to the machine tool, is only as satisfactory as the data available to it," he said.

If the aquisition of vital data is to keep pace with the development of new materials, it must be acquired in a rational way. Thus, at Queen's the fundamentals of the cutting process are being studied in the hopes of being able to construct a general theory from which specific data may be readily obtained.

Other Data

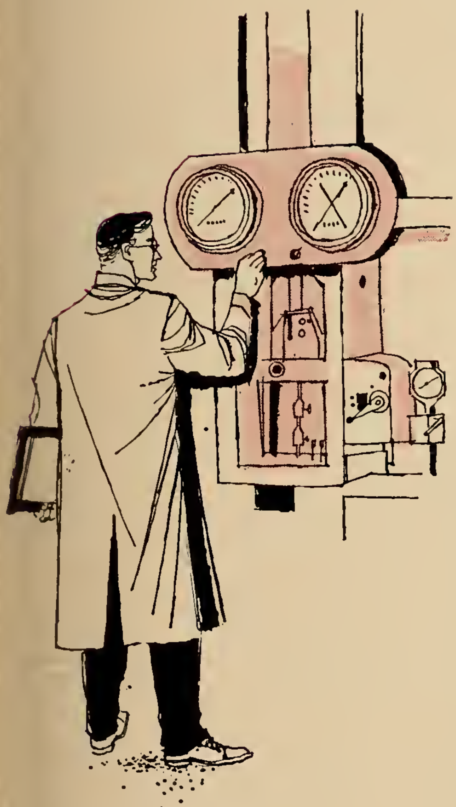
"In addition to metal cutting data," Professor Rice added, "we expect to obtain as a by-product, data of considerable value in the fields of plasticity and friction and lubrication. For instance, in metal cutting, the deformation rates are extremely high and of the order of those encountered in explosion. Thus the strength of material data obtained in metal cutting may be of use in rocket or engine design."

The experimental work consists of turning on a lathe carefully prepared specimens under somewhat artificial conditions. The watchwords are care and repeatability. Specimen and tool materials are selected from the same batches for consistency; tools are precisely ground and mounted with extreme care; the cutting and friction forces are accurately measured electronically; and tests are repeated many times to ensure that they are reproducible.

When the demand is for

QUALITY...

SHAWINIGAN STAINLESS STEEL



Why does industry demand 'Shawinigan' Stainless Steel when it wants castings of the highest quality?

Because experience has convinced our customers that Shawinigan's *full laboratory control* of every processing stage produces the finest corrosion and heat resisting castings in Canada.

Every casting produced by Shawinigan is closely checked and inspected at every stage of the process. X-ray tests, Gamma radiography, fluoroscopic examination of non-magnetic materials and magnaflux inspection of ferritic and martensitic type stainless steel . . . these are only some of the checks employed by Shawinigan.

Discover how you can be sure of top quality and save money by using 'Shawinigan' Stainless Steel corrosion and heat resisting castings.

Smorgasbord for President

Enroute from the Chemical Institute of Canada conference in Vancouver to the Engineering Institute convention at Banff, President and Mrs. McKillop were welcomed at a smorgasbord supper held at the Trail-Rossland Golf Club on June 7. H. P. Hamilton, retiring councillor, introduced the guest of honour.

The president opened his remarks with a play on the name of Trail and the multitude of engineers along the *trail* who had contributed to the development of the profession and the country at large. He noticed many bridges in B.C., and conjectured that probably engineers were better equipped than any other profession for building bridges of understanding.

Impressed at Advances

Exemplifying his enthusiasm at the accomplishments of the Institute during his term of office, Mr. McKillop enumerated three occasions which had impressed him more than anything else. These were: The ceremony in Montreal on the occasion of the inauguration of the Trans-Atlantic cable when Canadian, British and American engineers shared a telephonic program.

The meeting in Mexico City of the Pan - American Engineering Societies where a high regard for the people of Canada was encountered. It was most important to develop relations between the various societies within our own country, but we also had to make our technical information available to the sister societies in other countries.

The American Society of Mechanical Engineers and the Engineering Institute joint conference at the University of Western Ontario concerning the continuing education of the engineer. Emphasis was laid upon the need for engineers of quality with due regard to the pressing needs of quantity. It was essential that experience should be made available to the teacher. The Institute encouraged deans and heads of universities in coming together to discuss their problems. This was to be brought up again at Banff.

Concerning confederation, the president remarked that the Engineering Institute was awaiting the report of the Dominion Council, of which there would doubtless be further discussion at Banff.

In civilizations past, engineers were fully aware of the economic necessity for adequate storage. How much *more* cognizant are today's engineers with their vastly increased problems — and how much better are their plans translated into reality. For example, Horton Steel, Canada's largest designing, fabricating and erecting company of steel vessels and steel plate structures, has Dominion-wide facilities in the form of fully equipped fabricating plants, erection and sales offices — plus pioneering records in welding techniques — to change plans into profitable production.

With such facilities, it is of little wonder that Canada's industrial landscape is dotted with steel vessels and steel plate structures — fabricated and erected by Horton Steel.

● BRANCH NEWS

It was essential that in the adoption of confederation nothing be destroyed, but rather a step forward be taken.

In thanking the president, Al Brookes remarked that his visit served to demonstrate that the busiest man took on greater responsibilities. Mr. Brooks wished all concerned a very successful convention at Banff.

Marking the visit, silver replicas of "Earnie", the Cominco mascot elephant were presented to President and Mrs. McKillop by W. G. Small, Branch chairman.

Secretary-treasurer

Summer Activities

The Branch membership may have the impression that the Branch suspends all activity after the final papers are presented in April. Such, however, is not the case. The executive has been extremely busy in both Branch and headquarters activities.

Evening Education Studied

At the last meeting of the executive, held on June 26, 1957, the committee on evening education presented a report of its activities. Considerable information has been gathered and studied with respect to the practice in other countries where degrees in engineering are attainable through evening courses. Preliminary talks have been held with the universities in the Montreal area to determine their views on this question. The committee now proposes to send out questionnaires to employers of engineers and to those employees who might be interested in such courses.

Program Committee

The program committee has been busy planning fall activities. Dates and topics have already been arranged for 28 papers and plant tours beginning October 1, 1957. The new program committee is now completed. Its members are, chairman, R. J. Kane, of the Dominion Bridge Company; secretary, J. P. Dagenais, also of Dominion Bridge. G. H. Hoganson, of the Canadian National Railway is chairman of the special section. The chemical section chairman is H. F. Bertram of the Great Lakes Carbon Corporation. Alec Ramsey, of the Northern Electric Company and Professor R. Edis of McGill University were elected chairmen of the electrical and mechanical sections and mechanical sections respectively.

H. J. T. Patterson, of Dominion Structural Steel heads the civil section as chairman. W. B. White of the Canadian National Railways was elected chairman of transportation. J. M. Weintraub, of the Northern Electric Company will direct the management section as chairman. S. A. Marcotte also of the Northern Electric Company has been elected junior section chairman.

The program committee has re-organized its committeeman's guide for program sponsors, meeting chairman, as well as for its own committee members. In addition, an appendix has been prepared by D. Denovan, chairman of the Branch publicity committee, in order to gain publicity through the local press, radio and television.

Professional Development

The Montreal Branch is pleased to announce that it is following the lead taken

by many branches across the country in setting up Professional Development Courses. Under the sponsorship of the Junior Section and chairmanship of R. B. Walker, Jr.E.I.C., of B. A. Shawinigan Limited, a seminar on professional development has been organized to begin this fall. A complete program of lectures and topics has been laid out for twenty lectures. By means of a questionnaire, more than 150 Junior members have indicated their interest in taking this course. At present the Committee is busy lining up top flight instructors and seminar leaders to head these lectures.

Entertainment Committee

The entertainment committees of both Senior and Junior Sections have been busy planning dates and making arrangements for the Annual Junior Section Dance, the Junior Section Golf Day, the Annual Senior-Junior Oyster Party and the Branch Annual Dance.

E.I.C. Annual Meeting

The Montreal Branch was well represented at the Annual General Meeting of the Institute, held in Banff in June. Many of the Branch councillors attended the meetings of Council, while several Branch Members attached to the staff of local universities attended the conference on education. The Branch was represented at the Branch Officers' conference by its secretary-treasurer, G. M. Boissonneault. All who attended the Banff meetings were lavish in their admiration of the success of the meeting, of the scenery and not the least, of the hospitality of the members of the Calgary Branch and their great musical hit review, "The Pipeline Review".

Appointment of J. E. Leo Roy

The Branch is fortunate to have as its chairman for 1957 Leo Roy, recently named general manager of the Quebec Hydro-Electric Commission. Mr. Roy, who was also secretary-treasurer of the Montreal Branch is a past-president of the Corporation of Professional Engineers of Quebec. He also represents that body on the Council of the E.I.C.

MONCTON

Engineers' Wives Meet

The annual meeting and dinner of the Engineers' Wives Association of the Moncton Branch was held on May 30, 1957 at Magnetic Hill Inn. The president, Mrs. M. F. K. Leighton presided. Thirty-five members and guests attended.

The annual report and financial statement was presented by the secretary-treasurer, Mrs. V. C. Blackett, and on motion approved. Mrs. H. L. Purdy, reporting for the nominating committee, submitted a slate of officers for the coming season. These officers are: honorary president, Mrs. G. E. Franklin; president, Mrs. M. F. K. Leighton; vice president, Mrs. G. A. Peck; secretary treasurer, Mrs. V. C. Blackett; social convener, Mrs. R. P. Puddester.

Mrs. Leighton, as president, invited members, their husbands and children to a picnic at her shore cottage on Saturday, June 22.

Following the dinner and business meeting, the evening was spent in playing bridge and other games.

VANCOUVER

A. D. CRONK, JR.E.I.C.,
Secretary

Economic Future Studied

Following the business meeting and presentation of reports at the annual meeting, Dr. John J. Deutsch, head of the department of economics and political science at U.B.C., spoke on British Columbia's Economic Future". Dr. Deutsch was formerly assistant deputy minister of finance at Ottawa before going to U.B.C. He has served on several economic Royal Commissions. The speaker reviewed the history of B.C.'s economic development and explained that the present dependence on forest products and export of other raw materials makes the economy very vulnerable to depressed world markets. Dr. Deutsch foresees a more balanced economy in prospect for the province with the expanding population, development of secondary industries and the tremendous potential markets in Asia facing B.C. across the Pacific.

Chris Webb thanked the speaker for his interesting address and another successful annual meeting of the Branch was concluded.

Structural Section Elections

At the annual meeting of the structural section the following officers were elected; Chairman, Gordon Ellis; vice chairman, Peter Jones; secretary-treasurer, Steve Faliszewski.

The meeting was addressed by O. [illegible] Bentzen who gave an interesting address accompanied by slides on "Some Methods of Tunnel Construction Leading up [illegible] the Deas Island Tunnel".

News of Other Societies

Canadian Gas Association Meets at Jasper

The annual meeting of the Canadian Gas Association was held at Jasper, Alta., on June 24-26, 1957, with 450 delegates in attendance.

Delegates heard that the year just concluded was possibly the most active in the history of the Association. Highlighting the report of the Board of Directors was the establishment of the Canadian Gas Approvals program under which the association is empowered to undertake the testing, through approved agencies, of all gas burning equipment and appliances. The program provides for issuing seals of approval on all equipment and appliances manufactured and distributed for sale in Canada. Such authority has already been given in B.C. and Ontario, while other provinces are recognizing the C.G.A. seal of approval.

President-elect H. C. Darroch, promised that during his term of office he would dedicate himself to the task of promoting the development of the Canadian gas industry in all of its activities to the end that it may serve to the fullest extent the best interests of the public. Probably Canada's greatest need, he said, "is for secondary industries to create employment. Natural gas will develop such industries primarily as low-cost flexible energy source, but also from its many by-products-chemicals, new processes, new products, liquid propane and the materials and labour required by pipe lines and distribution systems."

Today, he reported, C.G.A. represented nearly 500 gas utilities, pipeline companies and gas appliance and equipment manufacturers across the country. The industry had nearly a million consumers in some 450 municipalities across Canada, and it had boomed forth as a billion dollar industry. About 65 per cent of these consumers were served by natural gas, and this percentage would increase annually. During 1955 gas sales had totalled nearly 134 billion cubic feet, representing a revenue of $76 million.

"Natural gas has been responsible for transforming Alberta from a province whose future was static to one which will soon be the pride and prototype of a new Canada," said the Honourable A. R. Patrick, Alberta's minister of Economic Affairs. Referring to the Trans-Canada Pipeline project, he noted that to date there had been more money spent on this development than on the St. Lawrence Seaway project.

President Dennis K. Yorath of Northwestern Utilities Limited, Edmonton, predicted a third pipeline to export natural gas from Alberta would be built within the next five years.

Natural gas, he felt, would not have any adverse effect upon electricity, but would affect sales of oil as a residential fuel. Although electricity to date would not heat buildings economically in subzero weather, he pointed out, natural gas was being used to generate electric power.

One of the main problems facing the gas industry today, he warned, was the manpower situation. He added that it would "become acute" over the next several months.

Nathan E. Tanner, chairman of the board, Trans Canada Pipelines Limited, told delegates that this country would be able to replace imported coal with natural gas. Such replacement in 1956 had resulted in a saving of about $40,000,000, he said. Ontario alone imported $75,000,000 worth of coal in 1955.

40th C.I.C. Conference Held at Vancouver

The Chemical Institute of Canada held its 40th annual conference at Vancouver on June 3 to 5, 1957. Technical sessions were held on the University of British Columbia campus, with a record number of 160 papers presented. These included a symposium on air pollution sponsored by the Chemical Engineering Division and a panel discussion by the Chemical Education Division on "What Can Be Done to Assist High School Chemical Education."

Dr. Osman J. Walker, head of the department of chemistry and director of the School of Graduate Studies, University of Alberta, was elected president succeeding Dr. C. B. Purves, the retiring president. Cecil E. Carson of Toronto, director, Imperial Oil Limited, general manager of Imperial Oil Refineries and vice - president, Interprovincial Pipeline Co., was elected vice-president. Twelve new councillors were elected and 18 new Fellows. Dr. Garnet T. Page announced his retirement, August 31st as general manager and managing editor, a post he had held since 1946. He was presented with a chest of silver by Dr. Purves as a token of his long and valued service to the C.I.C. and to the chemical industry.

The C.I.C. medal for 1957 was presented to H. G. Thode, president, Hamilton College, McMaster University, Hamilton, Ont. Made of the rare metal palladium supplied by the International Nickel Company of Canada, the medal is the highest scientific award of the Institute. The Montreal Medal was presented in absentia to Leon Lortie, director, extension department, University of Montreal, as a mark of distinction and honour to a Canadian who has made an outstanding contribution to the profession of chemistry or chemical engineering in Canada.

The Merck Lecture was presented by A. C. Neish, head, section of biochemistry and physiology of plants, Prairie Regional Laboratory, Saskatoon. These lectures are designed to bring distinguished scientists to address conference delegates. One of the featured speakers was J. H. Rushton, president, American Institute of Chemical Engineers. The title of his paper was "Chemical Engineering — Your Profession".

The Westman Memorial Lecture was presented by Joel H. Hildebrand, professor emeritus, University of California, Berkeley, Calif. Dr. Hildebrand, a noted educationalist, discussed university curricula and courses, pointing out that our high standard of living could not be maintained indefinitely on the basis of a low standard of intelligence or "planned mediocrity". He urged as counter measures: better standards of pay for teachers; recognition of the necessity for paying the prevailing wage as done in other fields of employment; allowing the experienced teacher to teach his own way; and minimizing non-teaching tasks.

Dean H. C. Gunning, faculty of applied science, University of British Columbia, was guest luncheon speaker on the second day of the conference. Discussing the boundaries between the practice of professional engineering and some of the professional sciences, and indeed between it and some other activities, he pointed out they were difficult to define, and continued to change with our rapid advance in technology. The part played by technical or scientific socie

ties or institutes was vitally important, he emphasized, whether linked or not with legal regulation of a profession. This was particularly true in regard to maintenance if that very vital factor in the life of us all,—professional competence. A true profession, he said, existed only as the people allow it to maintain its prerogatives, by reasons of confidence in its integrity and belief in its general beneficence.

Under the chairmanship of Dr. Morris Katz, the air pollution symposium consisted of 14 papers on methods of studying and correcting atmospheric pollution. Methods were described for treating vent gases from kraft pulp mills, ammonia oxidation plants, chlorine and caustic plants, oil refineries, and metallurgical plants. Reactions taking place in smog systems were considered. A description of proposed air pollution legislation for Ontario provoked considerable discussion.

Two invited papers and forty contributed papers were presented for the physical chemistry division program on varied subjects such as nuclear magnetic resonance spectrography; the increasing use of labelled atoms; effects of ionizing radiations on solids and liquids; and the use of scintillating gels. Dr. R. D. Heyding of National Research, Ottawa, described recent work on the structures of the arsenides of iron, cobalt and nickel.

C.I.C. Forms New Division

The new Chemical Economic Subject Division of the Chemical Institute of Canada will concentrate on the commercial and economic aspects of the Canadian Chemical and Chemical Process Industries, and will cater to the needs of those engaged in or interested in development, finance, market research purchasing, sales, advertising, traffic and industrial relations.

An inaugural national meeting of the group is to be held at Montreal's Mount Royal Hotel on October 29, 1957, theme of which will be, "Canadian Chemical Industry — 1962."

Speakers and panels will focus attention on trends in the growth of this industry and its development during the next five years.

Keynote speaker will be Dr. J. R. Donald, O.B.E., a prime authority on the broader national and international ramifications of the Canadian Chemical Industry. President of J. T. Donald and Company (1956) Limited, Dr. Donald, was formerly the director-general of the chemicals and explosives production branch of the Department of Munitions and Supply and was one of the original members of the Joint War Production Board of the United States and Canada set up under the Hyde Park agreement by President Roosevelt. He is past president of the Canadian Chemical Association and of the Canadian Section of the Society of Chemical Industry, and holds numerous awards in recognition of his important contributions to the industry.

Panels will be led by noted specialists in their fields and the panel members, senior executives of the industry, will bring a wide diversity of talent and experience to bear on their subjects. The panel on development and finance will be chaired by C. R. Graham, director of economic and market research, J. T. Donald and Company (1956) Limited. D. M. Matheson, vice-president and general manager of Chemical Developments of Canada Limited, will lead the panel on purchasing and traffic. Dr. J. A. McCoubrey, manager of market development of North American Cyanamid, Limited, will co-ordinate the panel on sales.

Mutual problems of chemical industry sales and purchasing executives will be aired by G. T. Boomer, district sales manager, C.I.L., and W. D. Wright, general purchasing agent, of E. B. Eddy and Company, during the luncheon session.

Guest speaker at this national meeting of the Chemical Economics Subject Division of the Canadian Institute of Chemistry will be Nik Cavell. Administrator of the Colombo Plan Administration in Canada, known as the International Economic and Technical Cooperation Division of the Department of Trade and Commerce, Mr. Cavell was formerly managing director of Automatic Electric Company (England) and president of the company's affiliates in China and Japan. He subsequently established Automatic Electric (Canada) Limited, which with its manufacturing organization, Phillips Electrical Works Limited, was built into a very large enterprise. In 1951, he was asked by the Government of Canada to undertake the administration of Canada's participation in the Colombo Plan, and now travels extensively in South East Asia in the course of the Colombo Plan work. He will speak on the Colombo plan and the important contribution of his administration to the capital expenditure and technical assistance program which Canada is making under the Plan in South East Asia.

For meeting registration forms and further information on the chemical Economics Subject Division, please contact

J. R. Charlton, Esq.,
Canadian Resins and Chemicals Limited,
600 Dorchester Street West,
Montreal, P.Q.

CISC Annual Meeting

At the organization's 27th annual general meeting held at the renowned Seigniory Club at Montebello, Que., recently, George H. Crase, of Horton Steel Works Ltd., Toronto, retiring president emphasized that "The Canadian Institute of Steel Construction is becoming more and more a nationwide organization with an ever broadening influence for good practice in the structural steel and steel plate fabricating industries."

Mr. Crase said that the continued extraordinary demand for steel had given rise to difficulties during the year. In spite of enormous expansion programs the demand for steel had exceeded the capacity of the rolling mills and had resulted in delay and disappointment to some customers. Production was however, only 8 per cent less than in 1955-56.

Commenting on other activities of the Institute Mr. Crase said that during the past year a seminar on plastic theory of design was sponsored in co-operation with Queen's University and the Royal Military College. Attended by about one hundred engineers, the Institute paid the expenses of four representatives from universities to attend this seminar. Notes made during the seminar were incorporated in one of C.I.S.C.'s special bulletins and issued to about 400 engineers.

Officers Elected

The election of R. M. Robertson, manager of operations for Dominion Bridge Company Limited, Montreal, as president of C.I.S.C. was followed by that of three vice-presidents. They are W. A. Hepburn, vice-president of J. T. Hepburn Limited, Toronto; W. J. Disher, president of Disher Steel Construction Company Limited, Toronto, and R. C. Pearse vice-president and manager of the Ontario division of Dominion Bridge Company Limited.

Honorary treasurer is G. E. Ellsworth president of the Toronto Iron Works Limited, Toronto.

Regional vice - presidents elected were; for the Atlantic region, John Reed chief engineer of the St. John Drydock Company Limited, East St. John. In Quebec province, R. S. Eadie, vice-president and general manager of the Eastern division, Dominion Bridge Company Limited, Montreal, has been elected, while F. P. Flett, district manager of Truscon Steel Company of Canada Limited, Toronto, will represent Ontario. Western representative is T. Bishop, manager of the Dominion Bridge Company Limited Calgary. For the Pacific region, E. H. Hartley, general manager of the Western Bridge and Steel Fabricators Limited Vancouver is representative.

BOOK REVIEW

NUCLEAR POWER YEAR BOOK AND BUYER'S GUIDE 1957/8

With the increasing importance of nuclear power and the lead which the United Kingdom is taking in its development for peaceful uses, the publication of this first edition of a yearbook devoted to the subject is indeed an important event.

The first section contains brief review articles recording current trends and thinking in many fields of applied atomic energy: nucleonic instrumentation; mining of uranium minerals; zirconium; future trends in fuel elements; neutron moderators for nuclear reactors; atomic energy and the law, etc.

The section on the world's atomic energy authorities gives details on atomic energy undertakings throughout the world, their organization, financial basis, governing bodies, projects, research facilities, educational arrangements and permanent officials.

Basic nuclear physics data is given in another section, and there is also a section on isotopes, their properties, applications and sources of supply.

Half the book is devoted to an alphabetical list of British companies engaged in the manufacture of machinery etc. used in the production of nuclear power, together with their overseas offices and representatives. There is a classified buyers' guide divided into two sections, the first listing material, plants, equipment and services for nuclear energy undertakings, and the second the instruments and equipment used in the laboratories, plant control rooms and in the field.

A Who's Who in British nuclear energy completes this most valuable book which is thumb indexed for easier reference. This company also issues a periodical on the subject, with the title, as one might expect, Nuclear Power. (Ed by William Davidson. London, Rowse Muir, 1957. 500p., $8.50.)

> Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*AMERICAN CIVIL ENGINEERING PRACTICE, VOLUME 3

The third volume of this important new reference work presents the fundamental principles, procedures, and data for the following section headings: theory of structures; masonry and plain concrete; reinforced concrete, including detailed design of members; prestessed concrete structures; footings, piers, and abutments; retaining walls; steel and reinforced-concrete bridges; steel towers, tanks, bins, etc.; concrete chimneys, silos, tanks etc; timber structures: steel-framed and reinforced-concrete buildings, including structural planning, earthquake-resistant design. (Ed. by R. W. Abbett. New York, Wiley, 1957. Various paging, $15.00.)

*THE ANALYSIS OF ENGINEERING STRUCTURES, 3RD ED.

As in previous editions the primary object is to present to the student of engineering a general outline of the theories upon which the design of structures is based. Some items and materials dealt with include: straight and curved beams; elastic bodies; redundant frames; reinforced concrete; the suspension bridge; influence lines; the voussoir arch; steel framed buildings; masonry dams; retaining structures; and plastic theory. (By A. J. S. Pippard and J. F. Baker. Toronto, Macmillan, 1957. 564p. $10.25.)

ANGER'S DIGEST OF CANADIAN LAW, 17TH ED.

The courts maintain that ignorance o the law is no excuse for break ing it, and although this latest editio of the Digest of Canadian commercia law is not intended as a substitute fo legal advice, it does give a review o the law for ready reference.

The book covers the law relating to wide variety of topics in non-technica language, and includes: agency; ban ruptcy; banks, banking and cheque bills; contracts; copyright and patent insurance; mortgages; partnerships; prop erty; trade marks; wills and descent property; in fact every subject covere by Provincial or Federal business la It does not attempt to cover criminal la municipal statutes, or taxation.

The revisions in the Bank Act are i corporated in this edition, as are amen ments in various Provincial laws, a the chapters on copyright, trade mar and patents have been completely r vised.

Statutes and legal conditions va from Province to Province, and as th volume points out the difference a similarities in the various Provinces, will be particularly valuable to firms a individuals with business connectic outside their own area.

This book should find a place every businessman's desk, and in ev library. It presents a clear picture Canadian commercial law, and answ the question asked so often "What the law on that?" (Ed. by F. R. Hu Toronto, Cartwright, 1957. 535 $8.00.)

LIBRARY NOTES

APPLIED RELIABILITY. PROCEEDINGS OF THE FIRST AND SECOND RETMA SYMPOSIA

That electronic reliability has developed into an "applied" science was borne out by the papers presented at these Symposia held in 1956 and 1957.

The general subjects covered at the first symposium included mechanical reliability, information feedback, field failure feedback, and component evaluation and usage. The principle objectives of the papers are to describe methods of reliability evaluation, improvement and prediction.

In addition to the papers, there is included in this book a supplement entitled "A general guide for technical reporting of electronic systems reliability measurements," which was prepared by members of the Systems Reliability Analysis Task Group of RETMA'S Electronic Applications Committee (Reliability).

The fifteen papers included in the second symposium on electronic equipment are broadly classified in the following sections: selection and use of components; principles and techniques of mechanical design; measurement and proof of mature design; case histories of specific pieces of equipment. These papers deal not only with the basic factors for reliability in operation, but also with specialized aspects of construction and operational conditions, and with failure prediction techniques. (New York, Engineering Publishers, 1956-7. $5.00 each.)

*BORON, CALCIUM, COLUMBIUM, AND ZIRCONIUM IN IRON AND STEEL

The fourth volume of the Alloys of Iron New Monograph series brings together essential information on boron, calcium, columbium (plus tantalum), and zirconium as alloying metals in iron and steel. The material gathered here has been culled from the technical literature of the world, from material scattered through journals and books in many languages and is presented in English. There is an excellent bibliography, name indexes, and a thorough subject index. (By R. A. Grange and others. New York, Wiley, 1957. 533p., $14.00.)

*BRITTLE BEHAVIOR OF ENGINEERING STRUCTURES

Prompted by the failures in welded steel merchant ships in 1942-43, research in this field was instituted and widened to include all steel plate structures. This volume summarizes the available information, covering the following: fundamental properties and fracture theories; test methods and interpretation of results; influence of chemical composition and manufacturing practice; effects of welding composition variations; residual stresses; design aspects; and report on individual service failures. This study was prepared for the Ship Structure Committee under the general direction of the Committee on Ship Steel of the National Reearch Council. (By E. R. Parker. New York, Wiley, 1957. 323p., $6.00.)

COLOR TELEVISION STANDARDS

Selected papers and records of the National Television System Committee make up this book. It shows the development of colour television, lists and discusses NTSC standards, includes material and discussion concerning the rerequirements of human vision in relation to colour television, and deals fully with the colour-video signal and the colour-synchronization signal. There is also a discussion of tests on both black and white and colour receivers; and finally a chapter on the actual transmission processes and equipment. A glossary of terms is included. (By D. G. Fink. Toronto, McGraw-Hill, 1955. 520p., $8.50.)

CONCRETE REINFORCING STEEL INSTITUTE DESIGN HANDBOOK

The designs in this revised and enlarged edition are based on the latest American Concrete Institute Building Code . . . for Reinforced Concrete, and are particularly for preliminary estimating, establishing sizes and clearances and comparing different types of construction.

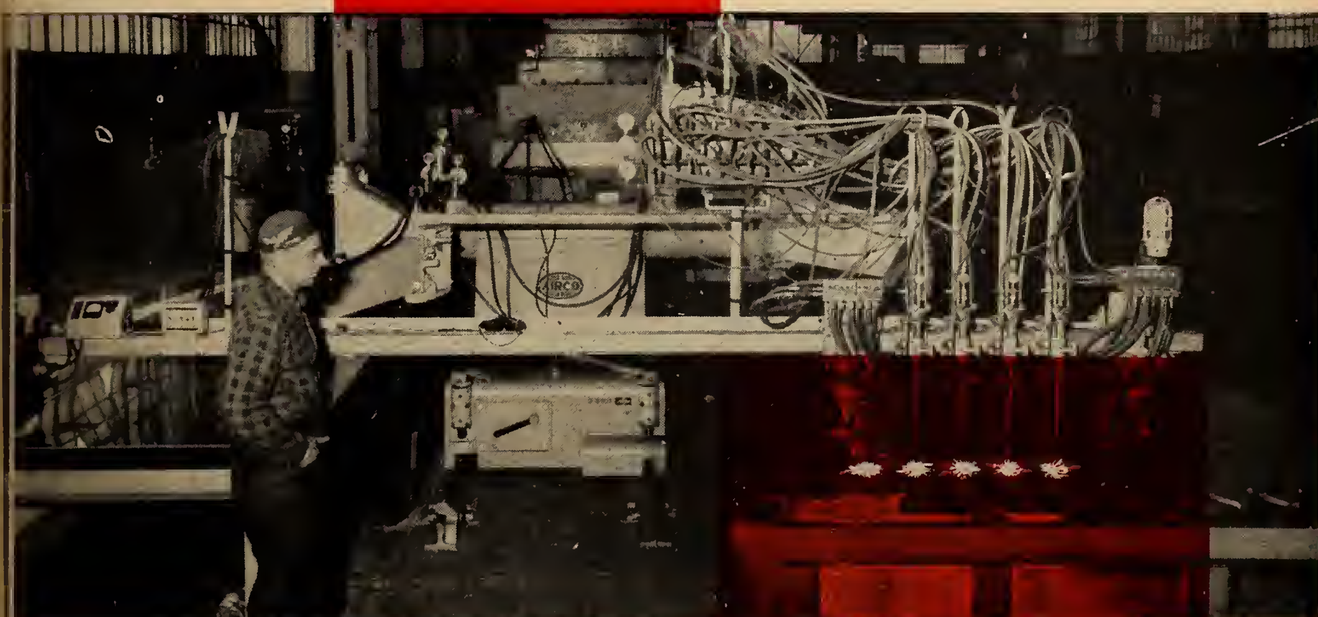
NOT ONLY HAVE WE THE EXPERIENCE

BUT ALSO

fast accurate machines

This Travograph, which we recently installed in our shop, is a remarkable machine. The electronic eye, shown on the left side of the photograph, follows the design and simultaneously transfers it to the steel, on the right hand side, in the form of oxy-acetylene cutting. Many intricate designs and several thicknesses may be cut at one time. Obviously, this machine not only saves time but provides the ultimate in accuracy.

We are an all-Canadian company and have specialized in steel and alloy plate fabrication for 50 years. We are always a step ahead and proud of our leadership. Send us your blueprints or problems for designs or quotations.



It works from engineer's drawings, cutting steel plate, all by itself!

DESIGNERS • FABRICATORS • ERECTORS

● LIBRARY NOTES

Most of the material is presented in tabular form, and covers: reinforcing bars; design formulas, methods, data, notes and hints; safe load tables and A.S.T.M. specifications. New data in this edition includes: design curves for solid slabs, concrete joists and beams; stair slabs, pits and precast lintels; "waffle" or dome flat slabs; ultimate strength design summary; fire resistance in concrete floors; load tests on soil, grain elevators.

This edition should prove even more useful than the previous one. (Ed. by R. C. Reese. Chicago, Concrete Reinforcing Steel Institute, 1957. 447p., $6.00.)

*DEOXIDATION OF STEEL: A MEMORIAL VOLUME TO C. H. HERTY, JR.

A collection of selected papers by Dr. C. H. Herty, Jr., emphasizing his most significant work on the physical chemistry of steelmaking. The papers, not generally obtainable today, deal with elimination of metalloids, solubility of iron oxide in iron, deoxidation with silicon and aluminum, the control of ixide in the open hearth process, and with other problems affecting refining reactions and the quality of steel. The volume includes a biographical sketch, a list of his publications and patents, a chapter on the significance of Herty's work, and short biographical sketches of 37 of his co-workers on the Physical Chemistry of Steel Making project. (New York, National Open Hearth Committee American Mining, Metallurgical and Petroleum Engineers, 1957. Various pagings, $10.00.)

*DESIGNING FOR PRODUCTION

Primarily a textbook for engineering and technical students presenting fundamentals underlying the design and manufacture of a product that will be functionally sound, marketable, and profitable. Ferrous, non-ferrous, plastics, rubber and synthetic rubber materials are described from the designers' viewpoint. Manufacturing information includes metal forming and shaping, metal cutting, joining processes, finishing processes, and packaging. (By E. N. Baldwin and B. W. Niebel. Illinois, R. D. Irwin, Inc., 1957. 645p., $8.40.)

*ELECTRIC CIRCUITS AND MACHINES, 2ND ED.

The general scope of this book includes the major subjects of circuits, machines, electronics, and instruments, with considerable stress on single-phase circuit theory. In the revision, sections have been added on transistors, crystal diodes, and the resistance strain gage, and an appendix on the magnetic circuit has been included. Also, numerous problems have been added and some of the older ones replaced or revised. (By B. L. Robertson and L. J. Black. Toronto, Van Nostrand, 1957. 456p. $7.25.)

*ELECTRICITY AND MAGNETISM

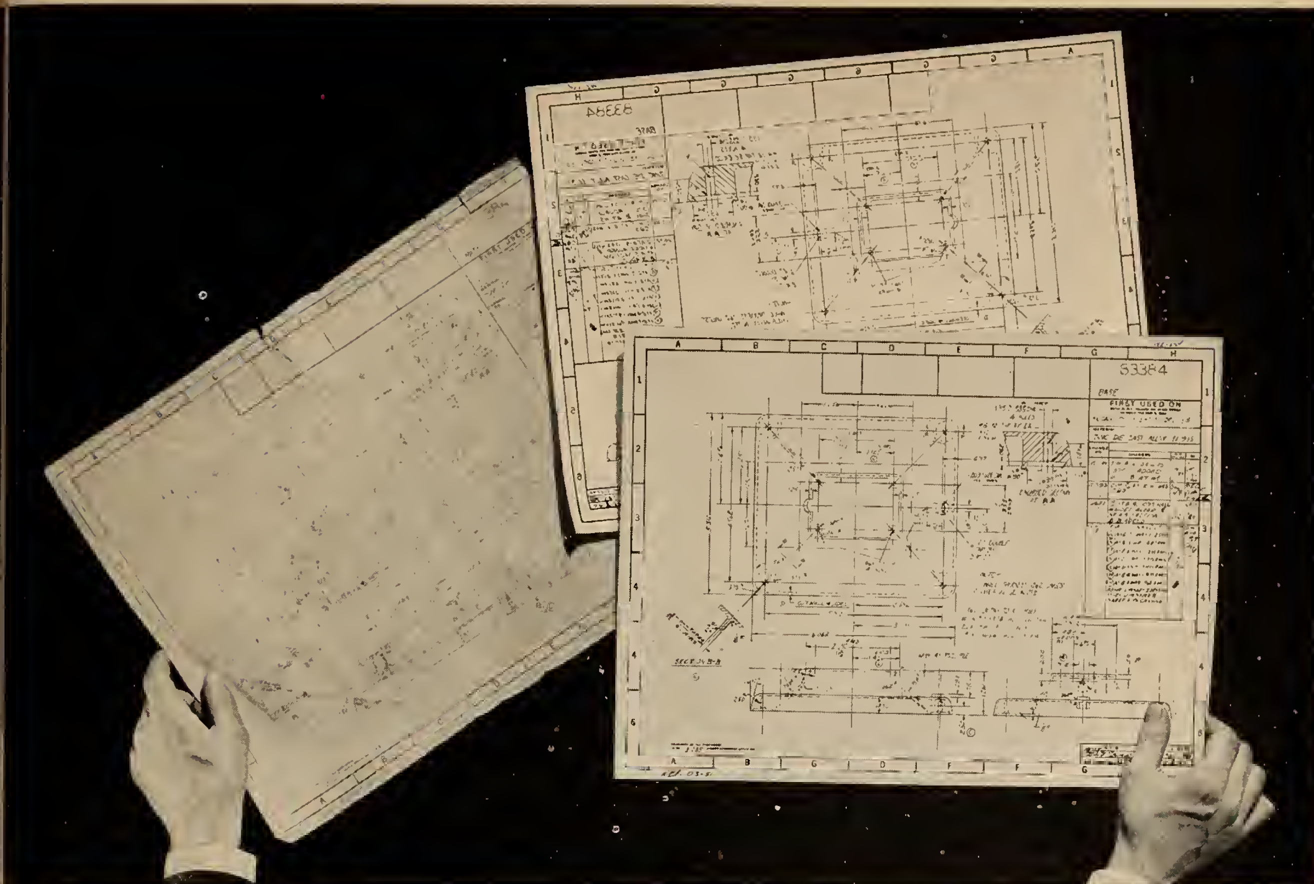
This text gives an up-to-date account of the principles and experimental aspects of electricity and magnetism, together with an elementary account of the underlying atomic theory. The four main sections are: 1) electrostatics, electric currents and magnetic fields, magneto-statics, and magnetic effects; 2) alternating current theory and electromagnetic waves, including filters, lines and waveguides; 3) electromagnetic machinery, thermionic vacuum tubes and noise; 4) theory of dielectrics and dispersion, the band theory of metals and semiconductors, paramagnetism and ferromagnetism, and a final chapter on nuclear magnetic resonance and recent R. F. measurements of the fundamental constants. (By B. I. Bleaney and B. Bleaney. Toronto, Oxford University Press, 1957. 676p., $9.50.)

ELEMENTARY SOIL AND WATER ENGINEERING

Intended for students in agriculture and related fields having no previous engineering training, this book emphasizes the engineering aspects of soil and water conservation, and also considers the agronomic and economic aspects of the subject.

In an introductory chapter the authors discuss the future requirements of land and water of a growing population, while the next four chapters deal with simple surveying and its application to farm problems. The remainder of the book covers the various conservation engineering problems found on the farm, including soil erosion and its control by contouring etc., drainage, land clearing and irrigation.

The book includes numerous diagrams and references to further reading. The information given is applicable to all parts of the United States, and much of it had not been previously available except from the Soil Conservation Service. (By G. O. Schwab and others. New York, Wiley, 1957. 296p., $6.25.)



An Autopositive Paper intermediate made from a weak-line drawing produces an easy-to-read print.

Tonic for Tired Tracings

Some of the tracings your customers send in were probably "tired" from the start—have light, anemic lines incapable of turning out really readable prints. Others owe their lack of graphite to constant handling and use in print making.

To produce legible prints from such lacklustre originals is easier than it looks. Simply reproduce them on Kodagraph Autopositive Paper or Film, depending on their condition. It's amazing how these materials can step up line density . . . render even faint detail crisply and sharply.

Let your customers know soon what you can do for their tired tracings. They'll waste a lot of time and money if they think retracing is the only way out.

CANADIAN KODAK CO., LIMITED
Toronto 9, Ontario

Kodagraph Reproduction Materials

"increasing profits for blueprinters everywhere"

- **Kodagraph Autopositive Paper Extra Thin** for high-quality photographic intermediates at lowest cost.
- **Kodagraph Autopositive Paper Translucent** for faster printing, more durable, easier-to-revise intermediates.
- **Kodagraph Autopositive Film** for very fast printing intermediates of highest quality.
- **Kodagraph Contact Paper Translucent** for fast-printing, durable, very high-quality intermediates.
- **Kodagraph Repro-Negative Paper** for black-line intermediates from negative-type originals.

Kodak
TRADE MARK

LIBRARY NOTES

*ENGINEERING ELECTRONICS

Devoted to the non-radio areas of electronics — signals, methods of control, instrumentation, etc. — this book emphasizes the underlying principles and basic circuits applicable to various devices and equipment. The first three chapters are a survey of fundamentals; the remaining chapters take up specific devices and circuits such as amplifiers, switching circuits, filters, oscillators, transistors, photoelectric devices, and servomechanisms. The book is intended as a text for seniors and for use by practicing engineers. (By J. D. Ryder. Toronto, McGraw-Hill, 1957. 666p., $11.40.)

FRASER'S CANADIAN TRADE DIRECTORY, 1957

This is the 44th edition of this most valuable directory to Canadian trade and industry. It gives comprehensive coverage to all aspects of Canadian trade, including a classified directory of manufacturers with index to classification; a market data section which covers chambers of commerce, public utilities companies, banks, Canadian trade commissioners, a directory of the Department of Trade and Commerce, countries served by foreign trade, and lists, alphabetically under province, cities and towns of population 1,500 and over; an alphabetical list of over 12,500 Canadian manufacturers; a list of trade names giving manufacturers; and a guide to foreign manufacturers with their Canadian agents. (Montreal, Fraser's, 1957. 1848p., $10.00.)

*GEOLOGICAL FIELD METHODS

For the inexperienced man in the field, this manual contains, in addition to the major outlines of geologic field work, hints and help on the minor aspects of methods and procedures which the author, from his long experience, has found most often needed in carrying out assignments. There is information on the organization of field work, field mapping, topography, and areal geology, mineral exploration, subsurface methods and a section on living and working out of doors. (By J. W. Low. New York, Harper, 1957. 489p., $6.00.)

GLOSSARY OF TERMS IN NUCLEAR SCIENCE AND TECHNOLOGY

This revised edition of a most useful Glossary contains many corrections, and amplification and clarification of earlier definitions.

The glossary which is arranged alphabetically, contains definitions of terms found in the fields of physics, reactor theory, reactor engineering, chemistry, chemical engineering, biophysics and radiobiology, instrumentation, isotopes separation and metallurgy.

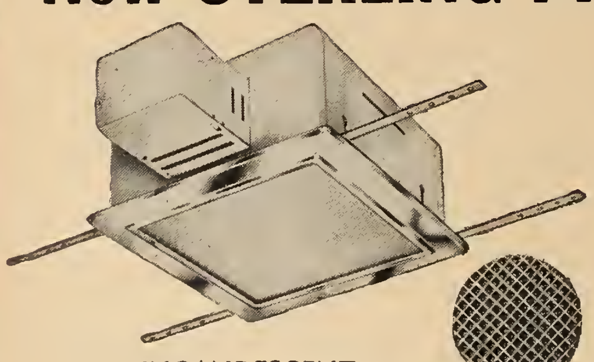
The ASME Nuclear Energy Glossary Committee and the National Research Council (U.S.) collaborated in the compilation of this work. (New York, American Society of Mechanical Engineers, 1957. 188p., $5.00.)

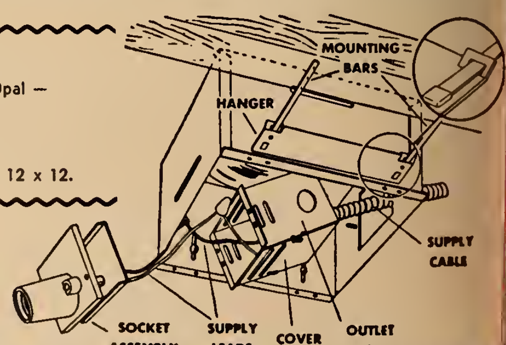
*HEAT TRANSFER AND FLUID MECHANICS INSTITUTE, 1957. PREPRINTS OF PAPERS

A wide range of subject matter is covered by the twenty-one papers included in this volume: shock waves; instability of bubbles; liquid drop section on surfaces; boundary layer problems in fluid flow; heat transfer under various conditions; flames and ignition; chemical kinetics of air at high temperatures; mass transfer by sublimation; several specialized treatments of turbulence and other aspects of fluid flow. (Stanford, University Press, 1957. 439p., $8.50.)

HIGH VOLTAGE SYMPOSIUM 1956. PROCEEDINGS

The publication of the Proceedings of this most timely symposium held by the National Research Council will be welcomed by all those connected with Canadian electrical utilities and the electrical industry. The St. Lawrence River represents almost the last source of hydroelectric power located close to load centers, and the development of more distance sources is dependent on cheap transmission, which means large load and very high voltage lines, and possibly direct current.





DOSCO

forgings

DOSCO forgings are custom jobs done to your own specifications. The broad variety of work handled over the years by our Trenton plant enables us to meet the most exacting demands. Experienced craftsmen plus a completely equipped plant are your assurance of the highest quality in forgings of any type.

TRENTON STEEL WORKS, LIMITED

TRENTON, NOVA SCOTIA

A DIVISION OF DOMINION STEEL AND COAL CORPORATION, LIMITED

• LIBRARY NOTES

This problem has been largely solved in Sweden, and four of the papers presented at the symposium were given by two Swedish engineers. The remaining sixteen papers were nearly all by Canadians, from both industry and the National Research Council.

The general topics covered were: breakdown and insulation problems; high voltage transmission; impulse measuring and testing; and corona and radio noise. Most of the papers include bibliographies, and there is also a list of N.R.C. publications on high voltage problems. (Ottawa, National Research Council, 1957. Irreg. paging, $1.00 while available.)

*HYGROMETRY

The measurement and control of humidity in industrial processes is becoming increasingly important. This book is a thorough survey of the scientific principles of practically every known type of hygrometer: frost point, dew point, condensation, hair, diffusion, electrolytic, gravimetric, etc. Also treated are a number of related topics such as the vapor pressure of water and ice, the vapor pressure of solutions, and the moisture content of highly compressed permanent gases. (By H. Spencer-Gregory and E. Rourke. London, Crosby Lockwood, 1957. 254p., 36/-.)

INDUSTRIAL RECTIFYING TUBES

The thirteenth in a series on electronic tubes to be published by Philips, this volume covers industrial rectifying tubes which are used to convert alternating current into direct current. The operation, construction and application of hot-cathode gas-filled rectifying tubes in battery chargers, power rectifiers and d.c. arc welders are discussed.

Technical data is given for eighteen different rectifier tubes, and a chart is included to help in the selection of tubes for a particular design. (By members of Philips Electron Tube Division. Eindhoven, Philips, 1957. 116p., $2.15.)

*INSTRUMENT TECHNOLOGY, VOLUME 3. TELEMETERING AND AUTOMATIC CONTROL

The present volume in this series deals in a brief section with pneumatic and electrical telemetering systems, and in more detail with the instruments and mechanisms for automatic control of processes. As in previous volumes basic principles are discussed before the actual instruments, and the instruments are classified according to the physical principle upon which they are based. (By E. B. Jones. Toronto, Butterworth, 1957. 198p., $8.00.)

INTRODUCTION TO THE CATHODE RAY OSCILLOSCOPE

Some cathode ray oscilloscopes are designed for specific applications in scientific or industrial research, but many are used for testing, inspection etc. in both electrical and mechanical engineering. It is for the users of the oscilloscopes in this connection that this book is written, as naturally they often have little knowledge of electronics.

The author covers the subject under the following headings: the cathode ray tube; the time base; amplifiers for vertical deflection; pickups for converting non-electrical phenomena into electrical magnitudes; power supply for cathode ray oscilloscopes; practical applications of the oscilloscope; standard cathode ray tubes for oscillography; and some complete oscilloscope circuits. (Harley Carter. Eindhoven, Philips, 1957. 95p., $1.95.)

*LINEAR PROGRAMMING; AN EXPLANATION OF THE SIMPLEX ALGORITHM

Linear programming may be described as a mathematical technique for determining the most effective course of action when a situation is governed by many known variables and conditions. In this small book a simplified technique is presented which is applicable to a great many engineering and management problems. A number of concrete examples, chiefly from production engineering, are here worked out, and mention is made of other books, on refinery problems for example, for which this book is a useful introduction. (By D. U. Greenwald. New York, Ronald, 1957. 75p., $3.00.)

LIBRARY NOTES

LOCATION AND SPACE ECONOMY

Although not intended primarily for engineers, all those concerned with the location of industry should find this an interesting and useful book.

The author, a professor of economics, presents a "general theory relating to industrial location, market areas, land use, trade, and urban structure." After an historical introduction expounding the location and regional problem, and a chapter clarifying some general theories of location and space economy, in the remaining chapters the author considers various factors: transport, labour, and market and supply areas. He also considers urban land-use and the location of agriculture, the basic interrelation of location and trade theory and gives a mathematical formulation for the aspects of general location theory.

There are many bibliographic footnotes, and a detailed index. (By Walter Isard. New York, Wiley, Cambridge, M.I.T., 1956. 350p., $8.75.)

METAL INDUSTRY HANDBOOK AND DIRECTORY, 1957

This is an annual, in its 46th year of publication, giving comprehensive coverage to the non-ferrous metals industry. It is arranged in four sections, the first giving the general properties of the different metals and alloys, and including a list of British standard specifications for non-ferrous metals and alloys as well as aircraft material, D. T. D., and admiralty specifications. Section two gives general data and tables relating to metals and metal products. Section three covers electroplating and allied processes and includes related tables. The last section is a directory of the British metal industry, including a list of trade names and their manufacturers, a directory of trade associations and technical institutes, a classified guide to metals and metal products giving names of producer, and an alphabetical list of firms with their addresses and telephone numbers. (London, Iliffe, Toronto, British Book Service, 1957. 536p., $3.25.)

METALLURGICAL PROGRESS—3

This collection of seven articles reprinted from IRON AND STEEL covers the metallurgy of, and metallurgical processes connected with, iron and steel. It includes articles on refractories, foundry practice, non-destructive testing methods, and flake graphite cast irons. There are comprehensive bibliographies included at the end of each article. (London, Iliffe, Toronto, British Book Service, 1957. 88p., $1.25.)

NUCLEAR ENGINEERING

Written by twelve experts in different fields of engineering and science, the purpose of this book is to outline the basic principles involved in the design of nuclear reactor cores and power plants, and to show the engineer the application of his particular field to nuclear power plant design.

Topics covered are: nuclear particles; nuclear physics; particle detection; basic concepts of radiation protection; elementary reactor physics; shielding of power reactors; flow of fluids; heat removal; metallurgy of uranium and uranium alloys; thermal-stress analysis and mechanical design; instrumentation and control; power generation; nuclear-reactor types; legal aspects of nuclear power.

Although intended as a graduate text for engineers and physicists, this volume contains such a wealth of information that it can be used as a reference book for those already in the field. It is a valuable addition to the literature on the subject. (Ed. by C. F. Bonilla. Toronto, McGraw - Hill, 1957. 850p., $15.00.)

*NUCLEAR REACTOR PHYSICS

Prepared for use by the graduate student in science or engineering and the design engineer in the nuclear energy field, this book discusses the physical concepts and calculation methods involved in the analysis of the behaviour of an assembly of fissionable material. The principal emphasis is on three major topics: the distributions in energy and space of neutron flux, the determination of the critical amount of fission-

able material, and the transient behaviour and control of the reactor as a heat source. (By R. L. Murray. Englewood Cliffs, N.J., Prentice-Hall, 1957. 317p., $10.00.)

°RAHMENFORMELN, 12TH ED.

A design manual presenting explicit rigid-frame formulas for single-panel frames which occur in practical reinforced-concrete, steel, and timber construction. It contains separate treatments of 114 rigid-frame shapes illustrated by 1578 figures covering a wide range of cases. General and special load conditions are dealt with, including temperature changes, and an explanatory introduction is provided. Eleven obsolete frames have been replaced by new shapes in this edition. An English translation exists of the previous edition of this highly useful reference work. (By Adolf Klehnlogel. Berlin, Ernst, 1957. 460p., DM 52.00.)

°RECENT ADVANCES IN SCIENCE. (PHYSICS AND APPLIED MATHEMATICS)

Twelve lectures, by acknowledged experts, designed to convey to non-specialists the basic ideas in such areas of science as cryogenics, ferromagnetism, microwave spectroscopy, operations research, and transistor physics. The lectures were delivered at a symposium held at New York University in 1954. (Edited by M. H. Shamos and G. M. Murphy. New York, Interscience Publishers, 1956. 384p. $7.50.)

RELIGIOUS BUILDINGS FOR TODAY

This is a collection of outstanding contemporary religious buildings. There are excellent photographs, both interior and exterior of synagogues, churches and chapels, with brief text. In each case a floor plan of the building is shown as well as several diagrams of structural details and photographs of windows, sculpture, ornamentation, etc. There are also brief essays included on worship and the arts from the different denominational points of view. The book should prove both interesting and stimulating to anyone interested in church architecture. (Ed. by J. K. Shear. New York, Dodge, 1957. 183p., $6.75.)

TECHNICAL DRAWING PART I

A basic introduction to the subject of technical drawing intended for students in technical schools, this volume covers such topics as straight lines, use of the compass, division of lines, drawing of solids, interpretation of drawings, sectional views, isometric drawings and freehand sketching.

Parts 11 and 111 to be published later will deal with practical geometry and the techniques of engineering drawing. (By W. Abbott. London, Blackie, 1957. 70p., 7/6.)

a new low-cost precision roller bearing...

THE TORRINGTON DRAWN CUP ROLLER BEARING

For the first time, the advantages of drawn cup outer race construction are available in a precision roller bearing.

This compact, lightweight bearing consists of spherical end needle rollers, a one-piece hardened steel retainer and case-hardened thin-section outer race. Designed to run on a hardened shaft or with an inner race, this new series takes a press fit in a simple housing without snap-rings or shoulders.

Highly efficient roller guidance and lubrication are outstanding features. The shaft-riding retainer contacts the roller ends at the pitch line where guidance can be obtained with the least effort. The design provides ample storage for lubricant and promotes its circulation.

These features make the new bearing particularly suited to applications requiring compactness with precision, high-speed endurance or long pregreased life.

For information on sizes now available and for application assistance, call on our Engineering Department or write for the new bulletin, "Torrington Drawn Cup Roller Bearings." *The Torrington Company Limited*, 925 Millwood Road, Toronto 17, Ontario, Canada.

lems. The selected applicants will be expected to participate in planning and conducting research projects, some of which will require experiments in flight. The work will be varied and interesting and will appeal to those who prefer to work in a small group closely associated with aircraft. It will in turn require an ability to originate ideas in both the experimental and theoretical fields. Candidates should have completed a post graduate course in aeronautical engineering (Ph.D, masters degree or its equivalent) Alternatively candidates from other sources, such as engineering physics, but with a strong interest in and familiarity with aeronautical subjects will be considered. Mechanical engineer: to assist with researches on aeronautical problems. The selected applicant will be expected to participate in planning and conducting research projects, some of which will require experiments in flight. The position requires an ability to design experimental equipment for airframes and power plants. Familiarity with turbine engines is desirable. Instrumentation engineer: to work on the design of instrumentation systems and on the design and development of special instruments for flight research purposes. Applicants should have a university degree in electrical engineering or engineering physics. All salaries commensurate with education and experience. File No. 6181-V.

UNIVERSITY OF ALBERTA, research appointment with rank of associate professor. Open September 1st for engineer with experience in transistor circuitry. The appointee must be capable of organizing a research program and directing activities of graduate students. Starting salary within range of university salary schedule, supplemented from research funds. File No. 6182-V.

GRADUATE CIVIL AND MECHANICAL ENGINEER required in the construction department of large pulp and paper company located in Maritime Province. Applicant should preferably have pulp and paper mill experience. Salary open for discussion. File No. 6188-V.

TRAFFIC CO-ORDINATOR WANTED, City of London, Ontario. The applicant is requested to state age, educational and technical qualifications, training and experience. A photograph not smaller than 3 in. x 4 in. is to be attached. Salary is subject to negotiations but will be commensurate with training and experience. Applicants will note the following benefits: pension plan; sick leave credits; statutory holidays with pay; two weeks' vacation after one year; three weeks' vacation after ten years. File No. 6190-V.

SALES ENGINEER required by manufacturer of finned tube and products fabricated from it. Graduate age 25 to 35 with one to five years experience. Although travelling is involved it is not of routinized nature. Candidates should either have or be interested in obtaining knowledge of design and application of heat transfer equipment. Selected applicant will undergo training period in London, Ontario, eventually locating in Montreal where he will operate independently. File No. 6192-V.

METALLURGIST. Graduate of Canadian university, might be recent, required to work on metallurgical problems relating to spring manufacture and also on spring design. File No. 6193-V.

OPPORTUNITY to qualify for M.Sc. in hydraulics while employed on industrial research. Opening available for graduate engineer on a project team investigating the forces involved in pulpwood holding grounds on both model and full scale. For first 2 years, appointee will spend half-time during academic term studying for M.Sc. at Queen's University, where project laboratory is located. Requirements: acceptance by Queen's as M.Sc. candidate; aptitude for research, and for working with company personnel in field. Base salary in current industrial range for similar training and experience; half-pay during academic year of 7 months, full pay for remaining 5, including 2 weeks paid vacation (approximates ¾ base salary over 12 months). Apply, enclosing comprehensive job resume in duplicate, to File No. 6198-V.

SALES ENGINEER. Small firm manufacturing industrial instruments and pneumatic controls has opening for two engineers for technical sales work; one in the Toronto area and one in the Montreal area. Ground for opportunity. Send qualifications in detail to File No. 6203-V.

THE MANITOBA POWER COMMISSION requires graduate engineers, preferably with two to three years experience in Canadian utilities. Positions are available in the field of distribution in connection with standards of materials and construction, including metering techniques, primary feeder specification and estimating, and general distribution system improvements. This is an opportunity to gain broad experience in a growing and progressive utility. Head offices are located in a modern building in the City of Winnipeg, which offers excellent facilities in education, transportation and housing. Salary $420.00 to $480.00 in accordance with qualifications. File No. 6210-V.

ENGINEERING SALES. Applicant should have four to five years experience in process plant operations, be 25 to 30 years of age and have senior matriculation or better. Sales experience desirable but not necessary. Reply to File No. 6217-V.

AN ENGINEER around 45 years of age required for illumination sales. A long established company will provide the necessary training to fit a suitable applicant to discuss scientifically designed lighting equipment and its application with architects, consulting engineers, industrial executives, and public utilities. A most constructive opportunity for the right man. File No. 6219-V.

NOVA SCOTIA TECHNICAL COLLEGE invites applications for teaching post in hydraulics and allied fields. Preferred qualifications include M.Sc. degree and some experience in research or design: salary range $5100.00 and up, depending on qualifications. Summers free, for research on professional practice. Address applications to File No. 6220-V.

MECHANICAL OR CHEMICAL ENGINEER required by major coal company for combustion and sales duties in Eastern Ontario and Quebec. Preferably with some experience with steam boilers and instrumentation. Age 27 to 36. Usual welfare benefits such as pension plan insurance and hospitalization. Salary commensurate with qualifications. Replies held in confidence. File No. 6221-V.

DEVELOPMENT ENGINEER. This man can be metallurgical, chemical, or mechanical and should have at least six or seven years experience in design or development work relating to machinery and allied fields and if possible, some experience in development work. In both cases the salaries involved are commensurate with the responsibilities. File No. 6222-V.

METALLURGICAL ENGINEER. The position to be filled is that of chief metallurgist and requires at least seven years experience in the iron foundry field. It involves supervision of production, metallurgy in several plants. File No. 6222-V.

UNIVERSITY GRADUATE in electrical, electronic or mechanical engineering. Knowledge of basic materials including strength of materials, some basic metallurgy and the ability to perform mathematical calculation as applied to the investigation of structural designs under supervision. Experience in the aircraft industry although preferable is not absolutely necessary. Salary according to qualifications. File No. 6228-V.

ASSISTANT PRODUCTION ENGINEER required in one of the western Canadian branches of nation-wide steel fabrication and general engineering company. Qualification desired include actual experience in production engineering, experience and familiarity with machine shop and iron and steel foundry practice. Structural steel and platework fabrication experience would be an asset, also materials handling and methods. Opportunity for early advancement for suitable applicant. Please state age, education and give full particulars of engineering experience and enclose photograph. File No. 6231-V.

RECENT GRADUATE in mechanical or electrical engineering is required to assume complete responsibility for maintenance of multi - million dollar warehouse. This is a challenging position for any young graduate with an eye to the future. All applicants are invited to write giving details, academic record and work background. Location Montreal. File No. 6232-V.

ENGINEERS REQUIRED. Experienced and beginners. Electrical, Civil or Mechanical, with or without experience, for engineering design, relay protection, communications, operation, power plant construction (power house, tunnel, dams, etc.) preliminary surveys. Hydraulics: 5-12 years experience. Must be familiar with hydraulic computations and hydro - electric projects. Load Analysis: some experience in public utility engineering desirable, particularly in statistical analysis and load forecasting. Construction (Electrical); Electrical engineer with 5 years experience or more, preferably in installation of hydro - electric plant equipment. Most of these positions are permanent and include pension plan, sickness benefit, group insurance etc. Good salary and chances of promotion for qualified applicants. Salaries: beginners starting salary: $390.00 per month (1957 graduates). Revisions every six months during 2½ years. Annual revision based on merit and responsibilities. Experienced engineers: good salary based on qualifications and experience. Location Province of Quebec. File No. 6233-V.

GRADUATE ENGINEERS, with successful backgrounds of supervision and responsibility required for Quebec manufacturing plants. Electrical, bilingual with extensive experience in heavy industrial work. Chemical, preferably, bilingual with extensive experience in heavy chemical industry. File No. 6235-V.

GRADUATE ENGINEER required by manufacturer of antifriction bearings for sales engineering position to cover Quebec Province territory. No previous experience required as company provides a broad one year training program in U.S.A. plants. Car supplied and usual fringe benefits available. Position offers excellent opportunity to benefit from expansion program of a growing industry. Preference given to a bilingual man between 23 to 30 years of age. File No. 6240-V.

GRADUATE ELECTRICAL or MECHANICAL ENGINEER, bilingual, required by manufacturer of photo-flash lamps. The plant of this company is located at Drummondville, 60 miles from Montreal. The position offered would involve engineering work in all phases of photo-flash lamp manufacturing; process, quality control, testing, equipment design, layout. File No. 6241-V.

GRADUATE ENGINEER. Medium sized manufacturing company near Montreal specializing in and well known, for its metal products for construction and other industry coast to coast, requires an engineer, preferably mechanical or civil, for the position of assistant to the general manager. The right man will be a self starter with good business administrative experience and record, some sales experience, the ability to get along with people and to grow to fill a more responsible position in management. Relocation allowance provided. Annual vacation with pay. Employee benefits. Salary open depending on experience. Enquiries will be treated confidentially. Apply stating full particulars of experience, age, availability, expected salary, etc. File No. 6246-V.

CIVIL AND ELECTRICAL ENGINEERS required by City of Winnipeg Hydro. Permanent positions. Graduation from a recognized university or college essential. Civil engineers for design, construction and maintenance of dams, reinforced concrete buildings and steel structures. Salary range $375.00 to $590.00 per month. Electrical engineers for design and construction of electric utility generation, transmission and substation equipment. Salary range $375.00 to $524.00. Electrical engineer for utility operation and maintenance work. Salary range $375.00 to $471.00. Salary within range according to experience and qualifications. File number 6247-V.

JARRY HYDRAULICS has immediate vacancies for two stress engineers. One of these is for work on strength of materials used in hydraulic components and landing gear. Some experience in the aircraft industry is very desirable, although consideration will be given to any applicant having a sound mathematical background. The other vacancy is for a senior engineer with experience of shock strut predictions (step-by-step method) and hydraulic damper predictions. This job calls for considerable experience and pays accordingly. Consideration would be given to an assisted passage from overseas. Reply in detail giving background and experience. File No. 6248-V.

SALES ENGINEER required by large engineering company in St. John's Newfoundland, to solicit machining, steel plate (tank) fabrication and general engineering maintenance works from mining, paper, fishing, and other industries. Mature engineer with sound and experienced background in this field will receive a salary fully commensurate with his capabilities in addition to a permanent appointment offering the usual benefits. Please apply stating full particulars of experience, age, availability, expected salary etc. to File No. 6249-V.

OUTSTANDING opportunity for graduate engineers in London, Ontario. A wholly owned subsidiary of a major American manufacturing and mining concern is constructing a $7,500,000 non-ferrous tube mill in London. Require recent graduates to fill mechanical, electrical, industrial and metallurgical engineering positions. Unusual opportunity to join a new energetic organization on the ground floor. File No. 6252-V.

WELL QUALIFIED ENGINEERS required for large development in Middle East. Applicants along with sound technical backgrounds must have good personal characteristics. Technical experts are required in the following fields: administration (or technical) as assistant to chief of bureau; communications; social affairs; civil engineer, communications; electrical; industrial and business; agriculture; animal husbandry; forestry; mechanical; etc. For complete details apply to file No. 6264-V.

SUPERINTENDENT for plastic insulated wire plant in Pointe Claire, Quebec. Must be familiar with all phases of manufacture and equipment. File No. 6265-V.

• CANADIAN DEVELOPMENTS

Engineering Faculties Expand

University of Alberta

The University of Alberta is offering this fall a greatly expanded program of activity in the highway transportation field.

The program involves both a substantial increase in postgraduate work in the highway engineering field and the inauguration of highway research projects in cooperation with the Department of Highways of Alberta, the Alberta Research Council, and the highway industries.

Directed by the civil engineering department, the following courses are being offered: transportation engineering, including planning, traffic and safety; advanced soil mechanics and foundation engineering; the design and control of asphalt and concrete pavements; advanced soil testing; river hydraulics; advanced design of reinforced concrete and steel structures.

The research aspects will include studies of the performance of existing highway construction, the evaluation of the performance of test roads, studies of effects and prevention of frost damage; slide conditions; and chemical soil stabilization.

Dean R. M. Hardy, M.E.I.C, of the faculty of engineering is directing the program; The faculty staff assisting are: Prof. T. Blench, M.E.I.C., Associate Professors S. R. Sinclair, M.E.I.C., and J. Longworth, M.E.I.C., and Assistant Professors Dr. S. M. Breuning, M.E.I.C., and K. O. Anderson.

Assumption University

Officials of Assumption University, Windsor, Ont., have made known their plans for development of four engineering courses and the eventual construction of a $5 million engineering building.

The announcement was made by Rt. Rev. E. C. LeBel, president of the University, and W. H. Arison, chairman of the Board of Directors of Essex College.

In the past, engineering students could take only their first year at Assumption. The new program will allow students entering first year engineering this fall to continue toward their degree at Assumption. The second, third and fourth years will be opened in succeeding years, providing for the school's first engineering graduation class in 1961.

This development culminates more than a year's work by an Engineering Education Committee headed by C. T. Carson, M.E.I.C. Surveys to determine the student potential and industrial needs of Essex, Kent, and Lambton counties, found a discrepancy between the number of engineers required (530) and graduating (280) in the next five years. Questionnaires showed that of the potential engineering students in the three counties, 40 per cent are willing to attend Assumption. Probably one of the biggest attractions to the local students is the tuition fee of about $325.

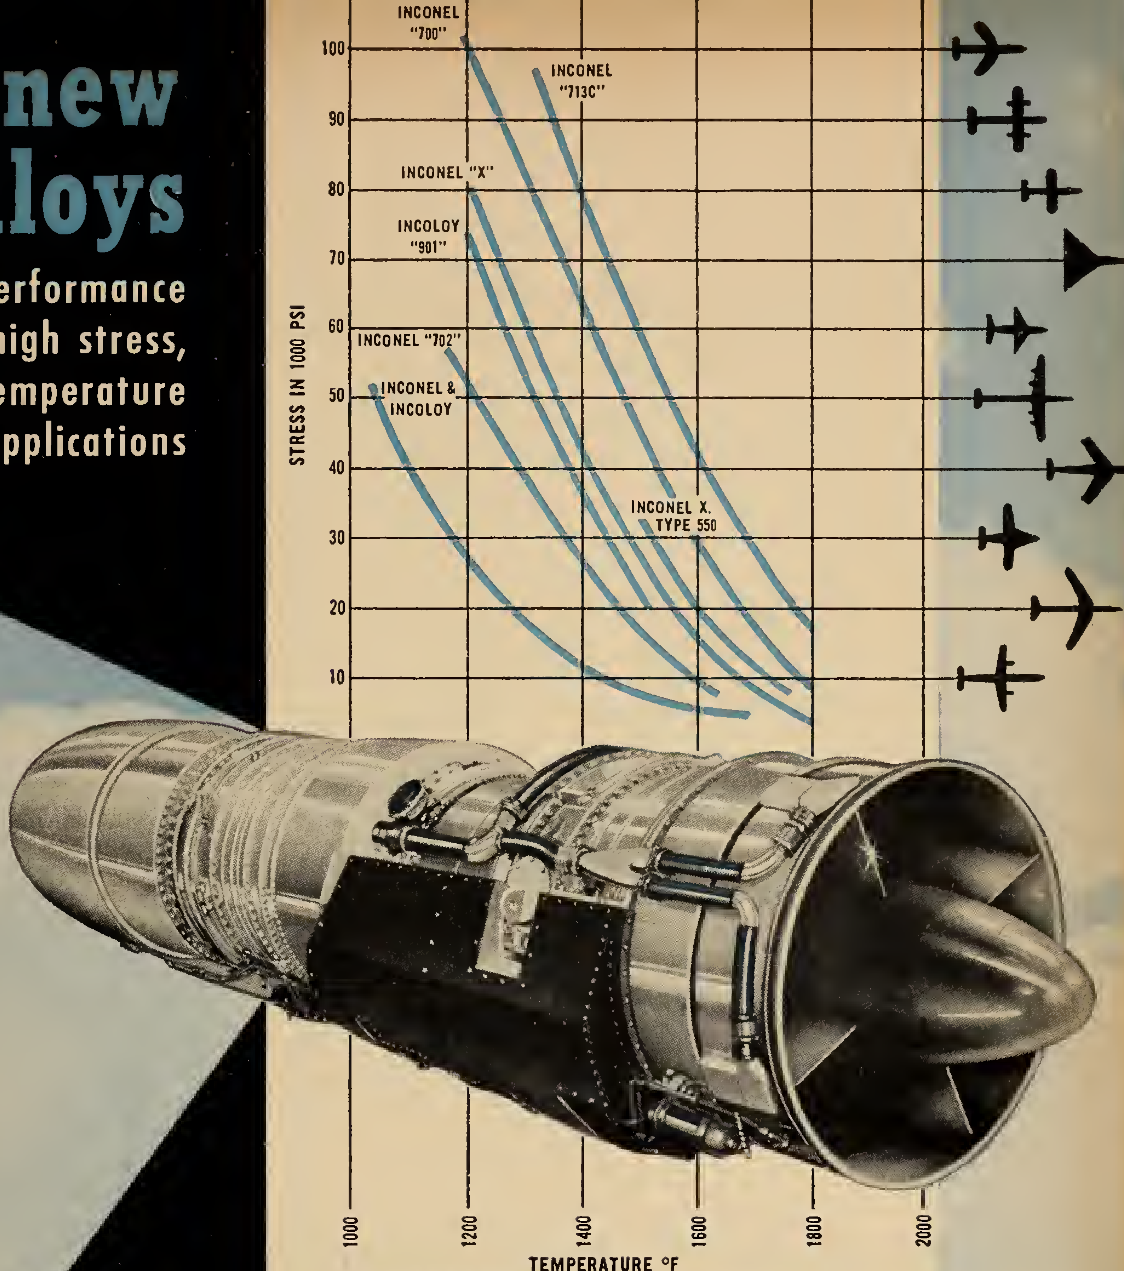
It is expected, although no direct offers have yet been made, that the industry will share part of the cost of a building and equipment, and a large portion will be borne by the province.

The Engineering Education Committee is a subcommittee of the Essex Academic Committee. Headed by Mr. Carson, vice-president of production of Hiram Walker and Sons, the committee is comprised of local citizens, all graduate engineers. Hon. W. J. Dunlop, Minister of Education of Ontario, has given his whole hearted approval and support, according to Mr. Arison.

The development of the program will be under the direction of Dr. F. A. DeMarco, chairman of the Staff Committee of Essex College. Essex is to retain responsibility for engineering until an engineering faculty is established.

new
Inco alloys

ive excellent performance in high stress, high temperature aeronautical applications



100 HR CREEP RUPTURE STRENGTH OF SOME INCO ALLOYS

Aircraft engineers will recognize this gas turbine engine . . . the new Orenda "Iroquois". Some of the Inco alloys employed in the "Iroquois" are depicted on the graph above. This graph shows maximum temperatures which these and other Inco alloys will withstand for 100-hour life at various stresses.

Naturally, the selection of materials for high temperature applications involves many other factors not illustrated in this graph. Where stress is low, for example, higher temperatures may be permissible. Much of this technical information has already been accumulated by Inco.

New wrought alloys such as *Inconel 700 and *Incoloy 901, developed by Inco, are available for high temperature service. A precision casting alloy—*Inconel 713C—has recently been added to the group. Alloys that resist oxidation at temperatures up to and beyond 2000°F. have been perfected.

Modern high speed flight has cleared the sound barrier and is penetrating the thermal thicket. Advanced turbo-jets, rockets and ramjets are producing unbelievable levels of power. As power and speed increase, temperatures become more critical. Inco's research and production facilities are dedicated to the task of keeping abreast of these developments.

For information concerning special Inco alloys for high temperature applications, write today.

Calendar

Lubrication Conference

There will be a joint conference at the Royal York Hotel, Toronto, from October 7 to 9, between the American Society of Lubrication Engineers and the American Society of Mechanical Engineers.

Members of the Engineering Institute are invited to participate under the terms of the cooperative agreement between ASME and E.I.C. If more information is wanted, write to Headquarters, 2050 Mansfield St., Montreal.

Following are some notes on the program: There will be sessions on the subjects of Recent Experiments in Wear; Boundary Lubrication — including highlights of I. Mech. E. London Conference; High Temperature Lubrication; Factors Affecting Contact Fatigue; Fluid Film Lubricated Bearings. The last subject will be dealt with in two sessions, which will also include highlights of I. Mech. E. conference papers on fluid film lubrication.

Power Exhibition

Canada's Power Show will return this year to Toronto, after a four year absence, to be held on October 21-22-23-24, in the new Queen Elizabeth Building in the Canadian Exhibition Grounds.

The power show serves the country's power engineering industry. Running concurrently will be the annual convention of the Institute of Power Engineers, including luncheons, business and technical sessions, all in the same building.

Two features of the Show are an Engineering-Management Seminar, and the nation-wide Cleaner Air Week which is being held in Canada on a nation-wide scale.

The information office for the power show and convention is at 199 Bay St., Toronto, Ont.

Community Planning

The National Community Planning Conference will take place at the Hotel Vancouver, Vancouver, B.C., on September 29-30, October 1-2, 1957.

The sponsoring body, Community Planning Association of Canada, is at 77 Maclaren Street, Ottawa, Ont.

Material Handling

The Canadian Material Handling Show and Conference will be held in Montreal's Show Mart, September 30 to October 4, 1957.

Requests for information and reservations may be addressed to Emile Dupre, Chairman Exposition Planning and Organization Committee, P.O. Box 565, Montreal 3, Quebec.

• OTHER SOCIETIES

Nondestructive Testing

The Society for Nondestructive Testing expects to have delegates from most of the countries in the free world at the Second International Conference on Nondestructive Testing in Chicago, Ill., November 3, to 8, 1957, a follow up of the first international conference in Brussels in 1955.

This conference is being held in cooperation with the Second World Metallurgical Congress sponsored by the American Society for Metals at its annual convention, and in conjunction with the National Metals Exposition.

Canadians will be able to take advantage of plant tours throughout the United States.

Further information can be obtained from the Publicity Chairman of the Canadian group: Wm. E. Havercroft, Dept. of Mines and Technical Surveys, 568 Booth St., Ottawa, Ont.

Civil Engineering

The American Society of Civil Engineers (33 West Thirty-ninth St., New York 18, N.Y.) has available information about the annual meeting, October 14-18, 1957, at which there will be commercial exhibits for the first time in the history of ASCE.

Mechanical Engineering

Meetings of the American Society of Mechanical Engineers (29 West 39th St., New York, N.Y.) are scheduled as follows, during the remainder of 1957: October 7-9, Joint Conference of ASME-ASLE on Lubrication, Royal York Hotel, Toronto, Canada; October 10-12, Joint Conference of ASME Fuels Division and AIME, Chateau Frontenac Hotel, Quebec, Canada; October 21-23, Conference of Power Division of ASME, Hotel Americus, Allentown, Pa.; December 1-6, the annual meeting, Statler and Sheraton McAlpin, New York, N.Y

Engineering Education

The twenty-fifth anniversary meeting of the Engineers' Council for Professional Development (29 West 39th St., New York 18, N.Y.) will be held at the Statler Hotel, New York, N.Y., on October 24-25, 1957.

Standards

How to beat the cost-profit squeeze now harassing business and industry will be the subject of the eighth national conference on standards, to be held in San Francisco, November 13-15, 1957 in conjunction with the annual meeting of the American Standards Association (70 East 45th St., New York 17, N.Y.)

Another meeting on this general subject is the annual meeting of the Standards Engineers Society (P.O. Box 281, Camden 1, N.J.). It will be held at the Hotel Commodore, New York, September 23-25, 1957. Its theme: Standardization — Economy through Application.

Iron Foundry

The Gray Iron Founders' Society, Cleveland, will stage its 29th annual meeting at the Drake Hotel in Chicago on October 9-11, 1957.

Office of the Society is at 930 National City — E 6th Bldg., Cleveland, Ohio.

Stress Analysis

The Society for Experimental Stress Analysis (P.O. Box 168, Cambridge 39, Mass.) schedules the 1957 annual meeting for October 9, 10, 11, at the Hotel El Cortez, San Diego, Calif.

Public Health

Public health authorities representing community, state, national and international agencies, will exchange information on a wide variety of topics at the 85th annual meeting of the American Public Health Association in Cleveland, November 11 to 15, 1957. More than 40 related organizations will hold simultaneous meetings, and a total attendance of 4,500 is expected. Office of the As-

WESTINGHOUSE "WORKHORSES"

pull power from St. Lawrence

WESTINGHOUSE SUPPLIES GIANT GENERATING AND TRANSMISSION EQUIPMENT FOR VITAL ST. LAWRENCE POWER PROJECT

Model of giant outdoor generators, now being built by Westinghouse, will help feed 820,000 Kilowatts of new power to Ontario.

Mid-1960 will bring 820,000 Kilowatts of new Hydro power to Canadian homes and industries—vitally needed electricity from Ontario Hydro's mighty St. Lawrence Power Project.

Eight massive Westinghouse generators, each two storeys high, will handle half this giant power job. The project's entire output will pass through Westinghouse step-up transformers; and Westinghouse Jetaire circuit breakers help protect the multi-million dollar investment in heavy equipment.

More than half Canada's hydro power already comes from Westinghouse generating equipment. On the St. Lawrence, Westinghouse engineering skill and equipment will contribute still further to Canada's already highly electrical way of living.

Huge Westinghouse step-transformers like this are n being built at Westinghouse the St. Lawrence Generati Station.

Arriving at the St. Lawrer Transformer Station, Westi house Jetaire circuit breakers protect power equipment on Hydro system.

Structural Steel Design Features and Operating Machinery for Gate Structures in the Locks of the St. Lawrence Seaway

R. W. Willis, M.E.I.C., *Structural Engineer*

J. F. Pilon, JR. E.I.C., *Assistant Mechanical Engineer*

J. E. Coke, JR. E.I.C., *Assistant Electrical Engineer*

The St. Lawrence Seaway Authority

This paper describes the basis for the design of the various lock gates and control valves in the St. Lawrence Seaway, and the main features that have been incorporated in their construction. The mechanical and electrical operating mechanisms are also dealt with.

IN THE accompanying plan of the Iroquois lock, double sector gates are shown at both the upper and lower end of the lock. The small differential head under which this lock will operate after the first year's operation was the determining factor in specifying this type of gate. Under a small head, this type of gate can be opened for both filling and emptying the lock, thereby eliminating the need for filling culverts and taintor valves. Beginning in 1959, this lock will operate under approximately 5.5 foot head. The gates are designed for operation under a lift of 24.5 feet during construction period when water is raised above the Iroquois dam and the river below the dam kept as under present conditions — period 1958 to 1959. Gates similar to these are in operation at the Straits of Canso and the Chicago drainage canal.

Each sector gate consists of two vertical sectorial prisms. The radius of each sector is 48.7 feet, with a 43 degree angle included between its radial axes and having a height of about 43 feet. The sector framing consists of 7 horizontal structural steel sector frames. The skin plate on the outer faces of the curved steel girders forms the curved vertical face of the prism. The outer faces of the radial horizontal frames form the two vertical faces of the prism. The two outer vertical edges of the curved face extend approximately 8 feet beyond each radial vertical face. The two radial faces of each sector are of open framing with vertical and horizontal members, except for the ice guard gratings, the diagonal braces and the plate girders at the bottom of these faces.

Each sector is supported at three main points—on a pintle beneath the junction of the two radial faces and on the rollers of the trucks which are beneath the outer ends of the radial faces. The rollers travel on a curved steel track and are close to the skin plate. In addition to the 3 main points of support there is a hinge at the top of each sector, directly above the pintle. The upper hinge and the pintle have embedded anchorages which are designed to withstand horizontal loads. The four gates are completely equipped with operating machinery so that, in case of one gate being damaged, the other gate can be immediately brought into use.

A vertical plate girder extends the full height of gate from heel casting to top anchorage. This plate girder transfers all the water load to pintle and top casting. The heel casting is fitted with a bronze bushing which turns on a pintle which is 30 inches in diameter. The pintle is set in a base casting which in turn is connected to an anchorage which extends back into the concrete monolith.

An hydraulic model was made at the National Research Council, at Ottawa, to determine the best type of nosing under flow of water.

The sector gates at Iroquois will normally be the operating gates of the lock, with the second gate at each end acting as a spare. These gates can also be used in an emergency to operate against a differential head of running water.

The sector gates at the upper end of upper Beauharnois lock and the upper end of Cote Ste-Catherine lock act only as guard gates. During normal operation, these gates will be closed immediately behind downbound ships entering the locks. During this normal type of operation, there is no differential head on the gates, other than that which might be caused by occasional surges in the upper approaches to the locks. These guard gates are capable of operating against a differential head of running water, during an emergency. The normal time for opening or closing all sector gates will be approximately 2 minutes. This time will be increased at Iroquois lock when a gate is being opened to fill or empty the lock. During emergency conditions, referred to above, the sector gates can be operated at great-

ly reduced speeds so as to minimize the hydrodynamic effects of such condition.

Mitre Gates

Each mitre gate consists of two horizontally framed leaves which, when closed, form a three-hinged arch against the hydrostatic load. All mitre gate leaves are approximately 5 feet thick and 46 feet wide. The gate leaf in the closed position is on a bevel of 4 in 12.

The St-Lambert lower gate leaves weigh approximately 175 tons each and are 58 feet high, the Cote Ste-Catherine lower gate leaves 236 tons and a height of 72 feet, the upper and lower Beauharnois lower gate leaves 257 tons and a height of 81 feet. All upper gate leaves weigh 131 tons and are 42 feet high.

One lower and one upper gate at each lock are operating gates. There are 3 spare lower gates; one at St-Lambert lock, one at Cote Ste-Catherine lock and one for the two Beauharnois locks. There are two spare upper gates one for the two Beauharnois locks and one for Cote Ste-Catherine and St-Lambert locks.

All operating gates and spare gates will have identical pintle assemblies and identical upper hinge anchorage assemblies.

All operating gates, the spare lower gate at St-Lambert lock, the spare lower gate at lower Beauharnois lock, and the spare upper gate at lower Beauharnois lock will have embedded sills and quoins. All these gates will be completely fitted with operating machinery.

The spare upper gate at St-Lambert lock and the spare lower gate at Cote Ste-Catherine lock will not be equipped with sills and embedded quoins. These gates will not be equipped with operating machinery. In case of an operating gate being damaged, the gate lifter will remove damaged gate leaves and replace them with spares from the gate storage area.

The horizontal girders in a leaf terminate at each of the vertical leaf edges in the quoin and mitre posts. The quoin post forms the edge next to the lock wall. The mitre post forms the edge next to the lock centre line when the leaf is in a closed position.

The bottom hinges on which the gate leaves turn, are pintles, identical in every case, of 21 in. diameter. The upper hinges are of a simple pin type and are also identical in every case. Each leaf will have a skin plate on upstream side only, the other side will be left open but have adjustable diagonal members. The adjustable diagonal members when pre-stressed will give the gate leaf its required stiffness for operation.

The pintle assembly consists of a heel casting, which will be attached by means of turned bolts to the bottom of a gate leaf at the quoin end, a phosphor bronze bushing which will be inserted in the heel casting, a nickel steel pintle on which the bronze bushing bears and a base casting which will be embedded in concrete and which will support the pintle and gate leaf.

The mitre gates have been designed to withstand the hydrostatic loads and to be operated against a differential head of 0.50 feet. The dead load forces are those which result from the weights of the gates.

The gates will be of welded construction, in vertical sections from 12 to 14 feet. The field connections will be bolted with high tensile bolts.

The normal time for opening or closing a mitre gate will be approximately 2 minutes. Mitre gates installed at the downstream end of a lock may be subjected at times to a severe back surge from ships propellers if the gates are being closed immediately after a downbound vessel leaves the lock. Provision has been made to release such a gate from the operating machine if the force due to the back surge exceeds a strut load of 140,000 lb. plus or minus 10 per cent, when the gate is near the mitreing position. Release is accomplished by the shearing of pins in the gate machinery.

The structural design of mitre gates is similar to the design of the mitre gates on the Welland Ship Canal except that the Welland gates were designed with skin plates on both faces of gates and buoyancy chambers.

The gates on the Welland Ship Canal were operated by a system of sheaves and wire rope to a drum in the control house. The present gates are operated from a sector gear and strut arm.

Gate Machines

A gate receives motion from a strut pin connected at both ends, to the top gate frame member and to a segment arm fastened to a sector gear. The sector gear is driven by a pinion and both gear and pinion are mounted on vertical shafts within steel housings encased in the concrete. The pinion shaft extends down into a room below where it connects to a cone worm reducer. This reducer, with a second reducer (herringbone gear), a travelling nut type limit switch, and the 20 horsepower wound rotor driving motor are all mounted on a welded base frame. The frame is anchored to the machine room floor and it is partly encased in concrete. A thrustor brake and a pilot generator are mounted on a special bracket bolted to one of the motor end bells. The motor, the gear and worm reducer and the pinion shafts are successively joined together by gear flexible couplings.

The strut sector gear and pinion are located in a recess below the lock coping level which is closed by a steel sectional cover. The pinion and sector gear shaft housing are both encased in concrete.

The gate strut encloses three springs which deflect when submitted to both tensile or compressive loads. Two other switches, one for tension the other for compression, are mounted inside the strut and are actuated by the strut stem which moves when the springs deflect. When a load in excess of 75,000 pounds is applied to the strut either one of the switches is tripped and the motor power is disconnected.

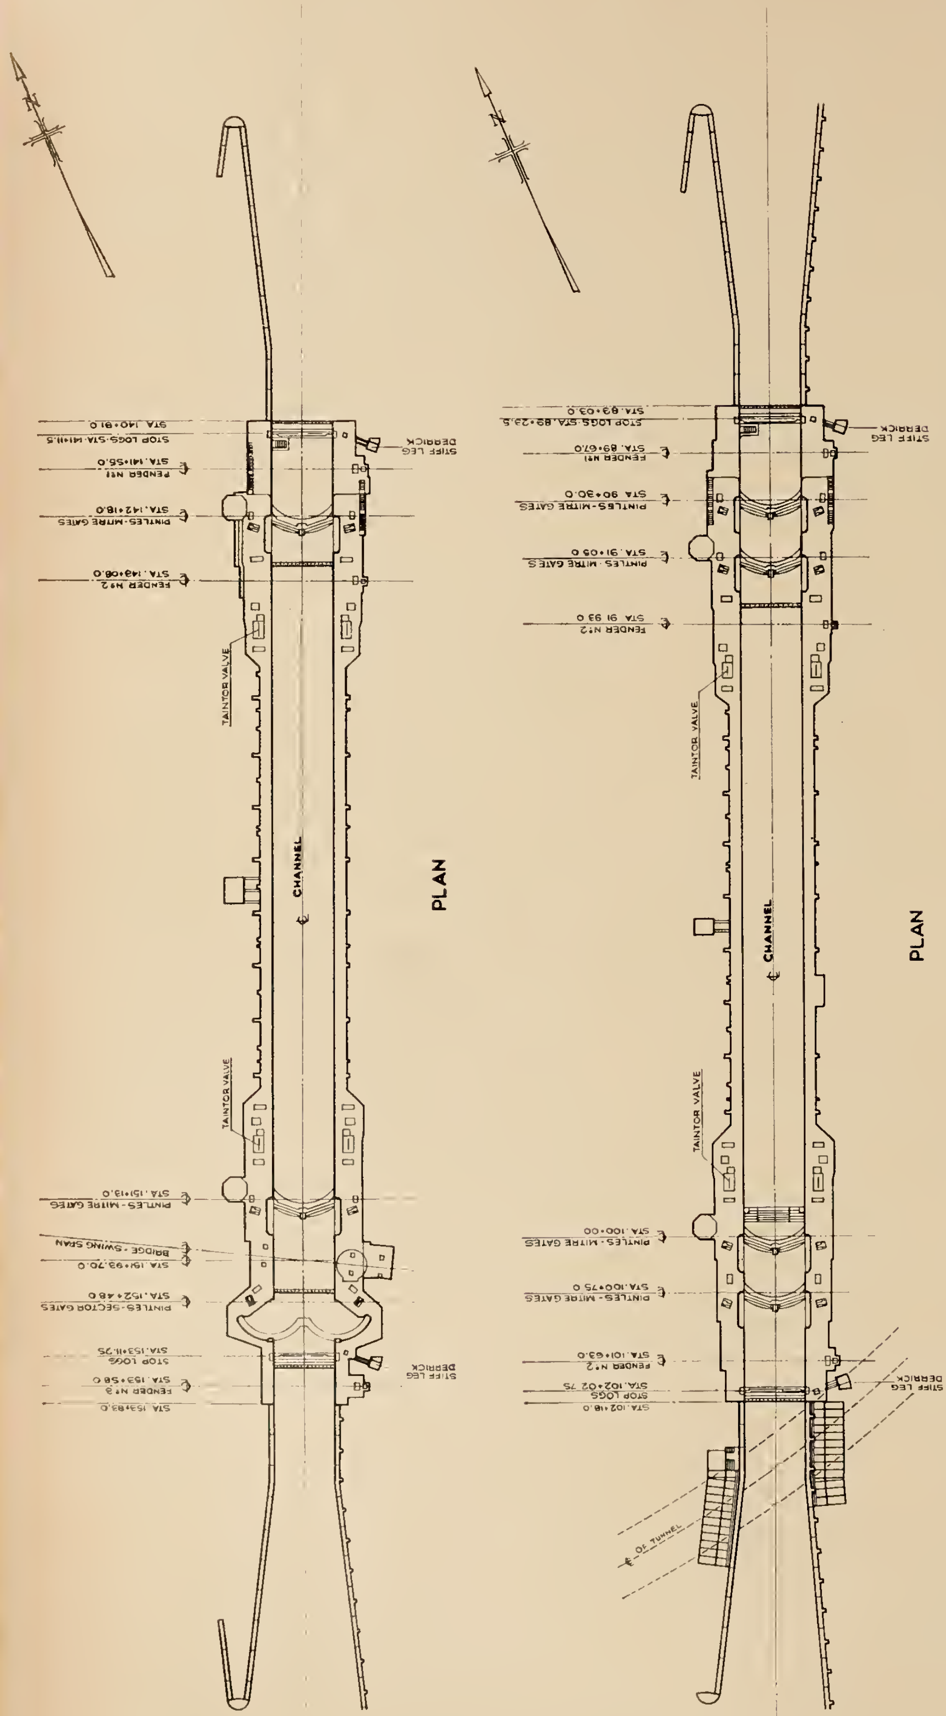
To prevent damage to the lower lock mitre gates when submitted to the high forces caused by waves from a downbound outgoing vessel, a release mechanism is incorporated in the driving pinion and assembly.

Should a wave hit a gate leaf, the force on the gate strut resulting will break the shear bolts in the release mechanism. The gate would then be free to swing partly or fully open. The ratchet teeth of the pinion and coupling will then engage and hold the gate open, thus preventing the surge from closing the gate leaves, causing them to be subjected to heavy impact forces.

Taintor Valves

A taintor valve consists of a horizontally placed sectorial prism of approximately 21 ft. radius in the case of a type "A" valve and 12 foot radius in the case of a type "B" valve. The angle between radial faces is 43 degrees for both valve types. Valve framing consists mainly of 4 radial

From left of page 1426 are plan views of: Iroquois lock; Cote Ste. Catherine lock; and St. Lambert lock.



Above are plan views of the upper (left) and lower Beauharnois locks.

members, which support 2 curved girders and the skin plate which makes up the curved face of the prism. Both faces of the curved girders are covered by skin plates, the skin plate on the outside face being permanently attached, the other being removable for maintenance.

A valve rotates during operation on two steel trunnion pins, one at each side of the valve at the junctions of the radial members. The valve is raised or lowered by means of an operating strut having a cross-head at its lower end which is attached by steel pins to lugs on the valve at the two upper corners of the curved valve face.

Each valve is anchored by the two pins about which it rotates during operation, to a horizontal fabricated beam which is secured at each end in a recess in the wall of the well. The taintor valves have been designed to operate under a 94 ft. water head with the radial members of the valve frames in tension. The dead load forces are those resulting from the weight of the valve in each case. Valve weights are approximately: type "A" 25 tons; type "B" 8 tons.

The type "A" valves are required for opening or closing the lock culverts during filling and emptying of the locks. The minimum times for opening and closing these valves will be approximately 2 minutes and 1 minute respectively. The optimum operating times will be determined finally from operating tests after completion of the work.

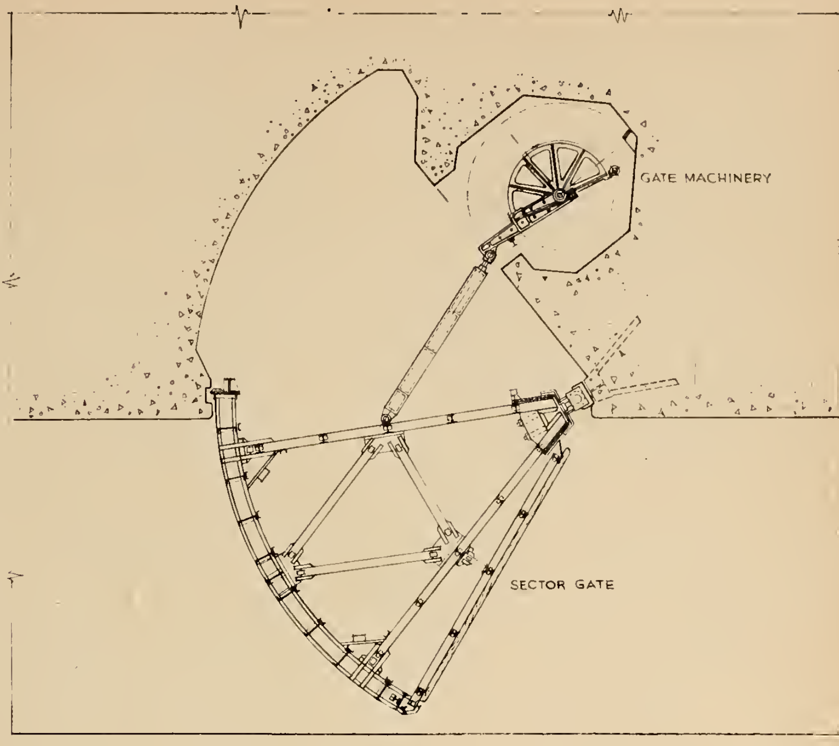
The type "B" valves are required for by-passing water around the upper Beauharnois lock. These valves operate, in the same manner as type "A" valves but are independent of the lock filling and emptying system. The two types of moulded rubber strips forming seals at valve lintels and sidewalls are attached to the valves. Provision is made for seal adjustment in the field. Valves are fabricated by rivetting.

Provision is made for de-watering the taintor valve chambers, should a valve have to be repaired. Recesses are provided at each end of valve chamber in which steel bulkheads are stored. These bulkheads can be lowered to close off the filling culvert and the valve chamber pumped out.

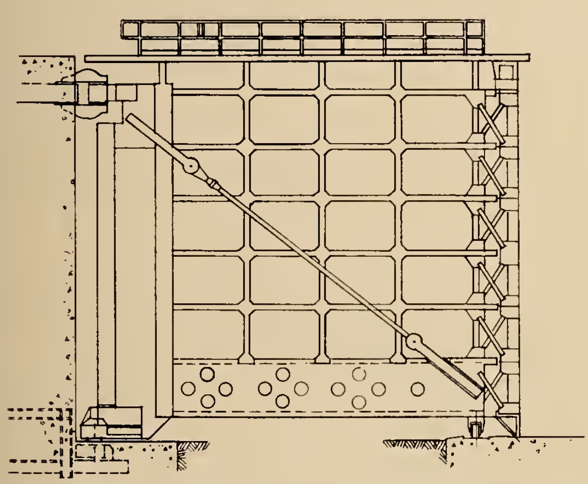
Valve Machines

Each lock valve is operated by a tubular strut, pin-connected to the valve, and to a lever keyed to a shaft. Power for moving the valve is transmitted to the lever shaft through a second lever and strut, a sector gear, and pinion and gear reducers driven by an electric motor.

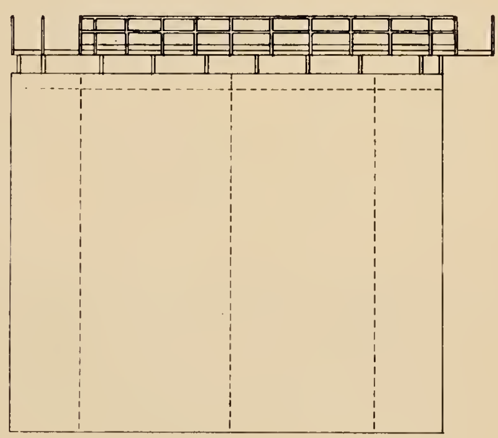
A 20 horsepower wound rotor motor drives the valve machine and it is connected to a first reducer through a floating shaft and flexible couplings. This reducer is in turn coupled to a second one which drives a pinion meshing with a sector gear. A spring strut, pin-connected at both ends, joins the sector gear with a lever keyed to the forementioned valve strut lever shaft. This lever shaft is in three sections. The first carries a lever and is mounted on bearing supports inside the machinery room, along with the motor, reducers, gear, and pinion. The second portion extends through the wall into a wet compartment called the valve well and connects to the third shaft section. A watertight stuffing box separates that portion of the machine which is in the dry from the other in the wet valve well. The third shaft section is identical to the first and is supported on a shelf above the valve well. The spring strut between the sector gear and lever permits overtravel of the machine when seating the valve.



Above is a plan view of one sector of a sector gate, together with the gate operating mechanism. Below are diagrams of the elevation of a similar gate, showing the recess side (left) and the front side (right).



RECESS SIDE ELEVATION



FRONT ELEVATION

The reduction between the motor and valve strut is such that the valve can be raised in one minute. However, the raising speed of the valves varies at each lock and depends on the operating head. The valves are all closed at normal speed; that is, one minute.

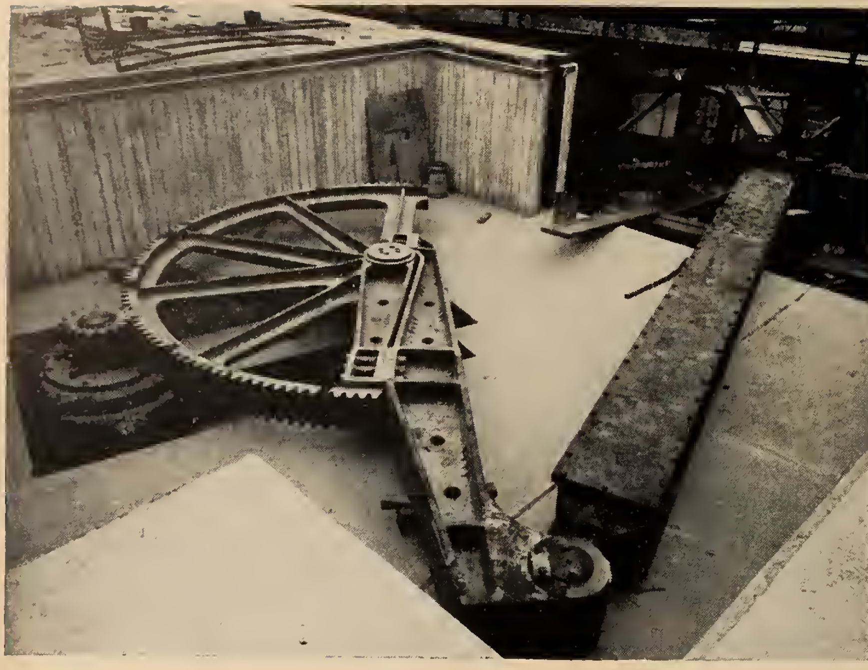
Control Gates and Bulkheads for Regulating Works

Four regulating gates at St-Lambert lock control the flow of water from the intermediate pool between Cote Ste-Catherine and St-Lambert locks. Some of these gates will be operated frequently since these gates control the pool level.

Bulkheads are provided for the unwatering of a maximum of two of the gates at one time for maintenance purposes, or for unwatering the upstream faces of all four gates at one time. This latter case would occur only during the closed navigation season when water could be passed from the intermediate pool through the filling culverts of the locks.

Bulkheads are also provided for the unwatering of the tunnel which passes beneath the south direct approach to Victoria Bridge. This would only occur during the closed navigation season except, perhaps, in an emergency.

The six regulating gates at Cote Ste-Catherine lock control the flow of water from Lake St-Louis into the intermediate pool between Cote Ste-Catherine and St-Lambert locks. This pool is used for shore drainage and sanitation as well as being the intermediate pool for lockage water.



These gates may be operated at quite infrequent intervals after initial adjustment.

The unwatering bulkheads at Cote Ste-Catherine regulating gates are for unwatering the gates on the upstream side only. The water level on the downstream side of the gates will be low enough so that the gates can always be made accessible with only upstream bulkheads.

The two taintor valves, previously referred to, which are to be installed at Upper Beauharnois lock control the flow of water from the Beauharnois power canal into the intermediate pool between the upper and lower Beauharnois locks.

The unwatering bulkheads at upper Beauharnois regulating valves are for unwatering the two valves in the closed navigation season or to unwater either one of the valves, during the navigation season when the other gate would control the flow of water into the intermediate pool.

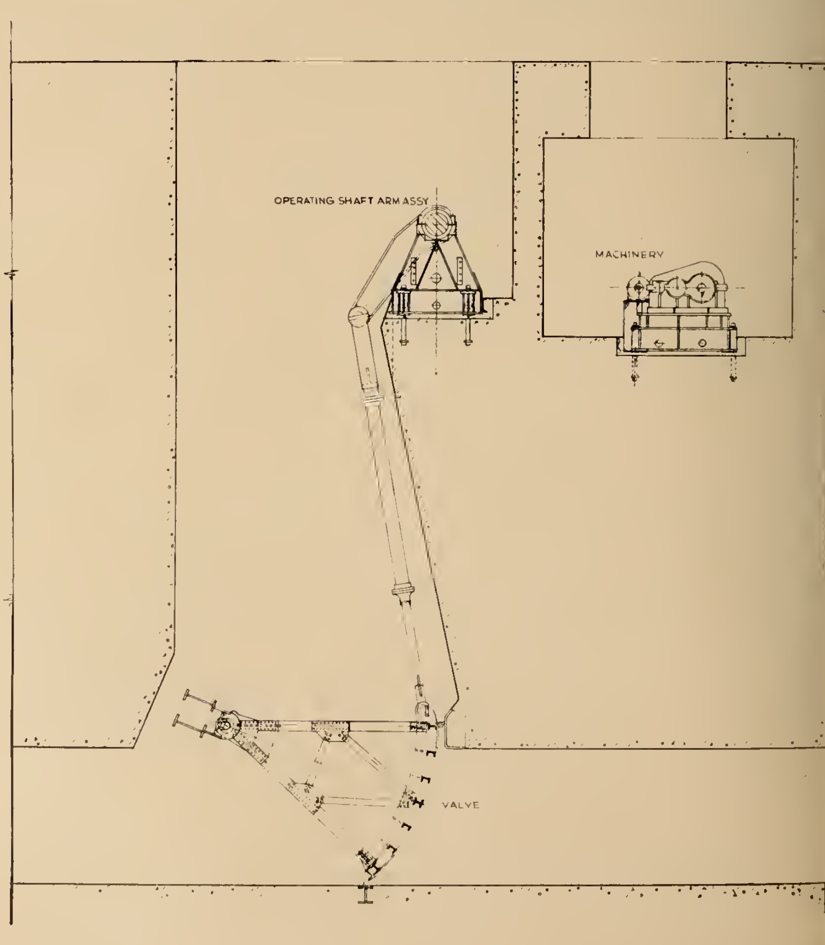
Gates and bulkheads will be fabricated from steel plate and rolled sections with skin plates on one side only by welded construction. The gates and bulkheads form a seal at their outer edges where contact is made with the embedded parts.

Regulating Works Machinery St. Lambert Lock

The gates at St. Lambert lock regulating works may each be raised or lowered by two vertical non-rotating screws. Each screw is pin-connected to the gate and supported by a bronze nut mounted on springs inside a gear casing. There are two screw lifting gear units per gate and each is bolted to an embedded steel frame sitting on top of the concrete piers of the regulating works. A 10 h.p. motor with a speed reducer drives the screw raising gear units connected together with a floating shaft. The springs under the nut permit overtravel of the machine when the gates are being seated. A position indicator and limit switch mechanism is coupled to one of the screw raising gear units for each gate. The position indicator transmits the position of the gate to the control room. The limit switches automatically shut the motor power off when the gate has reached its fully open or fully closed position.

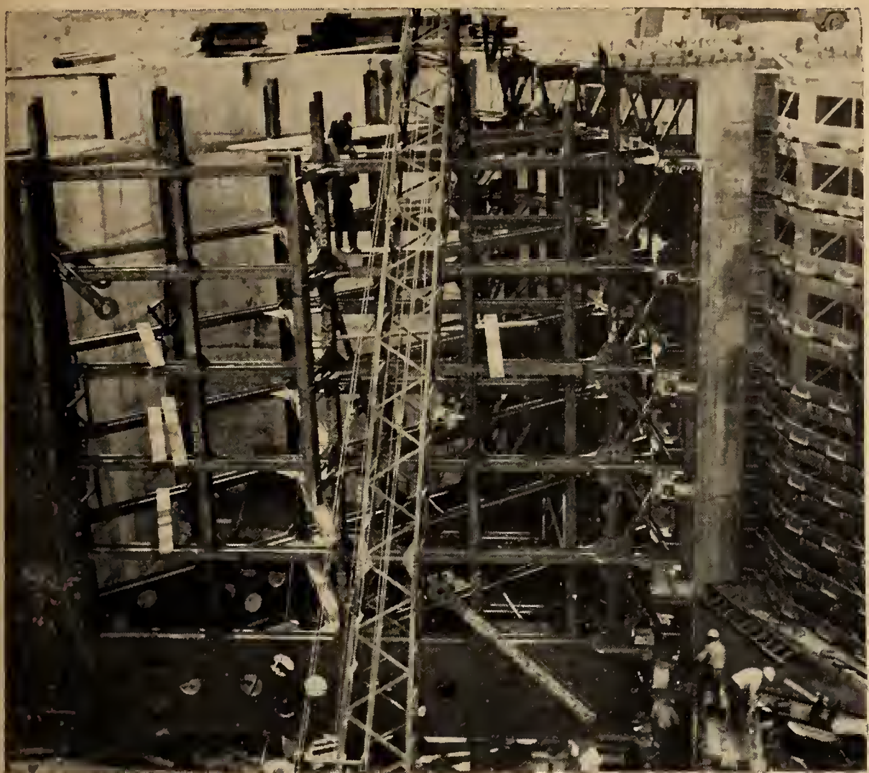
Above, installation of operating mechanism for sector gates at the Iroquois lock.

Below, diagram of a taintor valve in the closed position, with the operating strut assembly.



Cote Ste. Catherine Lock

The machinery operating the gates at Cote Ste. Catherine lock regulating works are basically the same as those operating the St. Lambert lock works. The maximum gate travel is short and consequently the screws are short also. There are two screws per gate and each is completely enclosed within the gear casing and top and bottom housings. Two long gate stems, each sliding inside two guide bearings anchored to the upstream wall, connect the gate to the



Structural steelwork for one of the sector gates at Iroquois lock.

screws lifting it through spring deflectors. These deflectors permit overtravel of the machinery when the gate is being seated. Each gate machine is driven by a 3 h.p. motor. A position indicator and limit switch mechanism coupled with every gate machine performs the same functions as those on St. Lambert regulating gates.

Beauharnois Lock

The taintor valves for regulating the water at Beauharnois being similar to the lock valves, it follows that the actuating machines will also be similar to the lock valve machines. The minimum time for opening is much longer — five minutes — consequently the reduction between driving motor and the valve is proportionally greater. The loads acting on the machines are also considerably smaller, therefore the machine components, levers, shafts, bearings and frames are proportionally smaller. The machine has no travelling nut-type limit switch. It is driven by a 3 h.p. motor. A stress switch on the spring strut as for the lock valve machine serves as the fully closed limit switch. The fully open limit switch, a track type switch, is mounted on one of the lever shaft frames and is actuated by the lever. The two machines, one for each valve, are installed inside a common room within the regulating works monolith. A transmitter coupled to the lever shaft indicates the valve position in the control room.

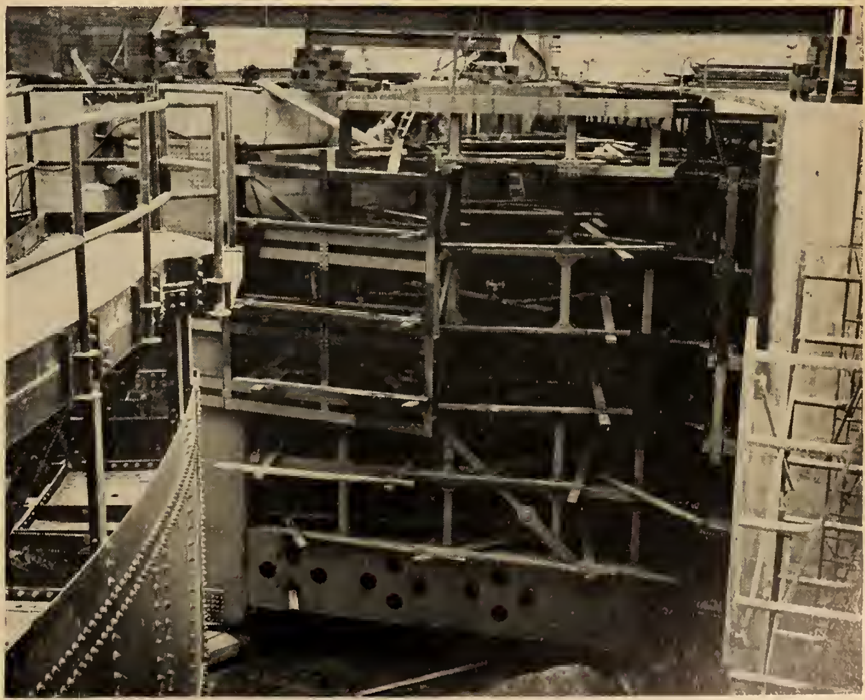
Stop Logs

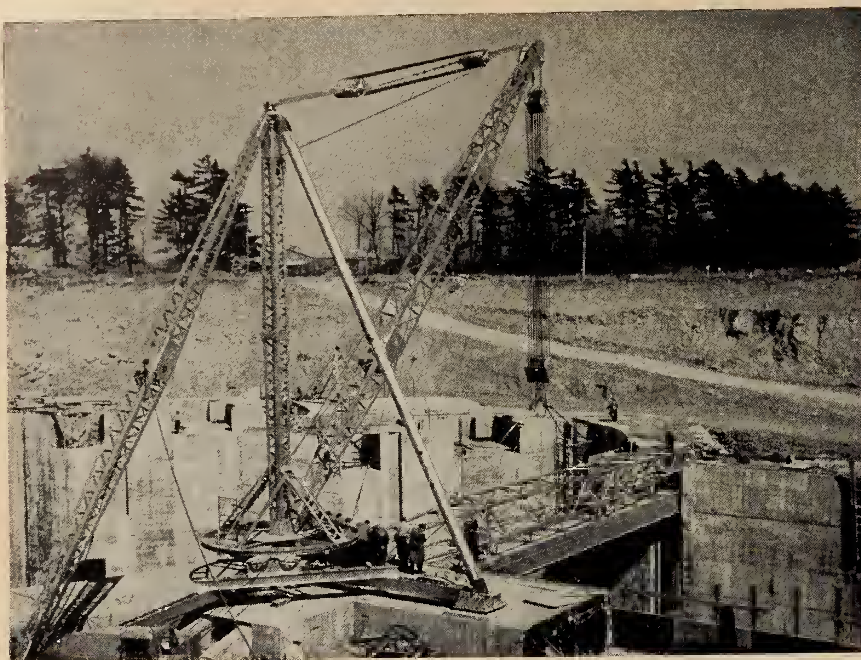
Recesses are provided for the placing of stop logs at both ends of locks. A pick-up boom is designed for the placing of stop logs during an emergency under flowing water. The main purpose of stop logs is for the de-watering of locks during the closed periods of navigation for maintenance work. Each stop log is made up of two horizontal welded plate girders with skin plate between flanges on water side. The water load is transferred to concrete monoliths by means of two reaction rollers at each end of each stop log.

The steel stop logs are designed for installation, one above the other, with the ends in vertical recesses in the sides of each end of the locks, to form watertight barriers which will permit the unwatering of locks for inspection or repair. In order that the barrier will be watertight, a horizontal seal of 1-inch diameter plaited nylon rope will be provided between individual stop logs while a rubber seal will be provided between the end of the stop log and the face of the recess. The depth of stop log girders is approximately 6 ft. 3½ in. out to out of flanges with a span of 83 ft. 6 in. c/c of reaction rollers.

The stop logs will be handled, one at a time, by a pick-up boom equipped with a wire rope lifting sling and one latching mechanism for engaging or disengaging the stop log. The actual placing and removing of stop logs will be done by use of stiff-leg derricks, one at each end

At the left of this picture can be seen part of a completed sector gate, showing the front side and the walk-way above.





Stiff leg derrick (described below) placing stop logs at Iroquois lock.

of each lock. (See illustration above)

Stiff Leg Derricks

Each stiff leg derrick has a lifting capacity of 55 tons at a radius of 55 feet. An 8-part one inch diameter rope fall may be lowered 50 feet down from the 80 foot boom above the centre line of the lock in line with the stop log. The boom may be raised or lowered through an 8-part one inch diameter wire rope system with eight blocks, connected to the top of the boom and the top of the mast. The boom and mast may be rotated from the pick up position of a stop log in the lock recesses through 180 degrees to the rear where the stop logs are stored.

Two stiff legs, one long and one short spread 87 deg. apart are both connected to the mast top through a swivel casting and to the mast base frame with lay legs. The short leg is anchored to the top of the lock wall and the long leg is anchored to a separate concrete monolith setting on fill.

The boom, mast, pulley blocks, stiff legs, lay legs, anchor frames, and the drums and frame are all of welded construction.

The drum unit is anchored to a concrete base also sitting on the fill between the two legs. Two concrete leg spacers between this base and the lock wall take the reaction loads from the lines off the drums. The three drums, one for the load, the next for the boom and the third for swinging are driven by a 75 horsepower motor through spur gear reductions. The drums are individually coupled to their respective drive shafts with magnetic friction clutches. An ammeter in the circuit of each clutch is calibrated in pounds and indicates the corresponding drum rope pull as power is applied to the clutch. Each drum has its own brake with a foot pedal in the operator's cab. All the brakes are connected to a dead man control.

The drum units and operator's cab for the derrick at St. Lambert lock and at the lower end of Cote Ste. Catherine lock are provided with lifting jacks. These jacks will raise the units five feet above the lock wall which will be above the maximum expected spring flood water elevation.

Wire Rope Fenders

The wire rope fenders are installed on each side of the lock gates and their purpose is to prevent ships which have travelled beyond the prescribed limit from damaging the gates. If a ship hits the fender its bow will come in contact with a three part double system of 1¾ inch diameter wire ropes stretched across the lock. These ropes are reeved through sheaves anchored to bollards encased in the lock wall. As the ship continues to advance the ropes unwind from two drums against four friction brakes gear-connected to the drums, thus maintaining a steady rope pull. The kinetic energy from the moving ship is dissipated through the ropes sliding across and along the bow, over friction bollard C just ahead of the drum and through the drum brakes.

Two types of machine elements comprise the complete fender machinery. The exposed machine elements, the sheaves, the boom, the bascule, the boom latch, the bascule frame with driving screws, the bollards and that portion of the rope which stretches across the lock, are outside on top of the lock walls. The housed machinery elements, the rope drums with brakes, the rewinding and brake scouring machine and the bascule drive unit are inside in a machine room within the lock wall.

There are two types of fenders, one called exposed, the other submerged. The exposed fender is the most common one, as described above. The submerged is a special fender with the boom bascule, bascule frame, and driving screws operating under water, and the rope drums, the bascule driving unit, housed in a machine house on top of the lock wall. The submerged fenders are installed on the downstream side of the St. Lambert lower and upper lock gates.

The fender bollards are two vertical steel cylinders 11 feet long encased in the concrete wall opposite one another on each side of the lock.

Two rope sheave blocks are each bolted to one end of an 85 foot boom. This boom also supports the ropes reeved through the sheaves, and is in turn fixed to a counterweighted bascule by two shear bolts at the bottom and two tensile bars with adjusting nuts at the top. The bascule rolls back on frame between two tracks with guides and racks meshing with segment gears on the bascule. Two screws supported on the aforementioned frame and connected to the bascule with a yoke supply the motion to roll the bascule and lift the boom with sheaves and rope out of the way of ships sailing through the lock after the gates are opened.

The screws are driven through a common shaft, spur gear reducers and mitre gears by a 20 horsepower motor whose available torque has been reduced to 75 per cent of its rated full load torque, in order to standardize and use the same motor as is used on the gate and valve machines. In addition to the motor, the driving unit includes a thrustor brake, a pilot generator, and a limit switch,

Typical cubicle arrangement; circuit breaker, lighting, and heating cubicles.

all necessary for the fully automatic operation of the fender.

The two ropes are wound each on a separate drum mounted on two frames bolted together and anchored to the room floor. Each drum has a bull gear meshing with two pinions. One pinion may be clutched to the rewind mechanism, the other pinion couples the drum with two adjustable spring loaded friction brakes.

The brake scouring and rewind unit consists of a 7½ horsepower motor driving a cone worm reducer with a sprocket on the slow speed shaft. A driving chain connects this sprocket with either the brake shaft for scouring or the drum pinion shaft for rewinding the ropes on the drums.

When the boom is lowered the sheave block trips a latch as it drops over the bollard. The latch holds the block on the bollard when the boom is destroyed by a ship crashing it. The latch is released by a thrustor motor before power may be applied to the boom raising motor.

Unwatering Pumps

When the navigation season closes, the locks must sometimes be dewatered for inspection and maintenance of the submerged equipment. Once the stop logs are in place at each end of the lock, the problem then is to pump some 20 million gallons of water in the shortest possible time. This enormous task is performed with vertical deep well pumps installed permanently at the lower end of each lock except at Upper Beauharnois lock. This lock may be unwatered through the reach and the lower Beauharnois lock.

The performance of each pump is such that it can begin pumping out a lock by delivering 19,600 gallons per minute against a 10 foot total head and still deliver 12,900 gallons per minute against a 50 foot total head near the end of unwatering.

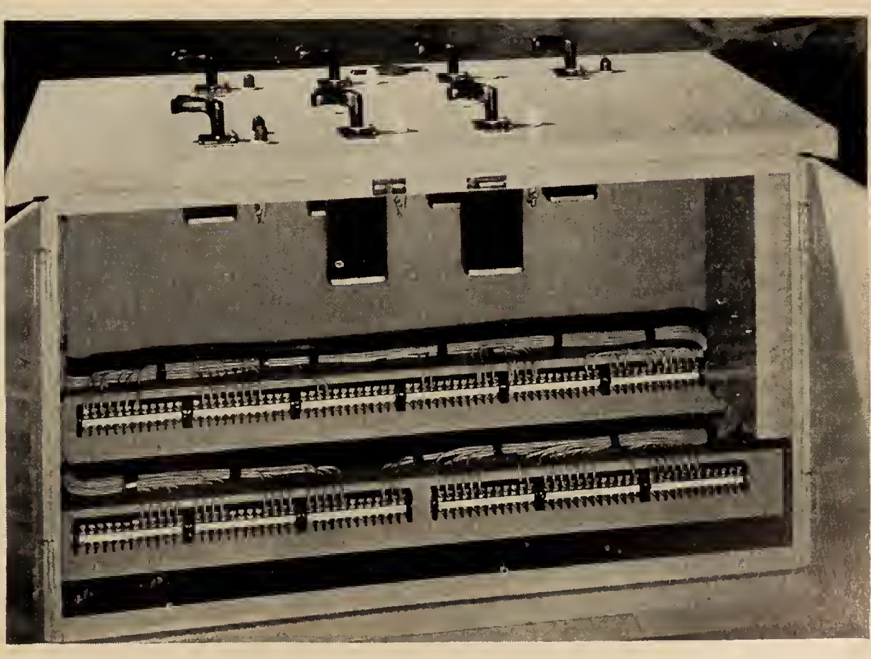
The pumps are suspended inside a deep well within the lock wall extending downward to a pit below the lock floor. This pit is directly connected to the lock chamber immediately inside the stop logs.

Each pump discharge connects to a gate valve, a check valve and then to a pipe inside the lock wall. The discharge end of this pipe is some 19 feet below the low water elevation at the lock entrance and outside the stop logs.

Each pump has a single impeller of the mixed flow design located in the unwatering pit at the bottom of the pump column. It is connected to the 280 horsepower motor in the pump room above the lock wall by a vertical shaft. This shaft extends inside the pump column casing. This shaft is supported at short intervals by water-lubricated rubber bearings. A spherical roller bearing at the top end of the motor supports the vertical thrusts loads from both motor and pumps.

A clear water line from outside the lock below the normal low water elevation supplies the lubricating pumps. These pumps are of the "centrifugal" type with a shaft extending to a 7½ horsepower motor in the pump room above. Each pump discharge extends vertically to the pump room and connects to a supply manifold feeding all the bearings of one large pump. The two manifolds are interconnected so that only one pump can supply the necessary water for lubricating all the bearings of the two large pumps. A pressure switch within the water lubricating

Control desk for the upper end of the Iroquois lock.



system rings alarm when the pressure drops below a set minimum.

Sump Pumps

Concrete tunnels under the lock floor are provided in each lock for the transfer of electrical power and signals from one side of the lock to the other. These tunnels are also used for hydro power cables and telephone cables.

Flooding of the tunnels could prove disastrous in spite of the waterproof materials protecting the electrical wires. To prevent such flooding each tunnel drains into a sump pit at one end. A deep well sump pump keeps the level in the pit at a minimum. These sump pumps are 4-stage vertical column pumps driven by a 7½ horsepower motor and discharging outside the lock. A pump has a maximum delivery of 83 gallons per minute against a total head of 90 feet.

A float switch in the pit starts and stops the pump motor at pre-set levels. A second float switch rings an alarm when the water reaches a dangerous level in the tunnel.

Line Haulers

Since ships must be secured with mooring lines when a lockage is made, line haulers are installed on the lock wall and provide hoisting power for the heavy mooring lines from upbound ships whose deck may be some 30 feet below. These haulers are of the standard yard car hauler type with the capstan enlarged and its speed reduced. A safety switch with a foot-operated tripping car around the base stops the machine in an emergency.

ELECTRICAL FEATURES

Power Supply

All locks being built by the St. Lawrence Seaway Authority are being provided with at least two sources of power. Iroquois lock has one source at 44kv. from the Hydro-Electric Power Commission of Ontario, a second source from two 575-volt 312kva. standby diesel generator sets and a third source at 33kv. from the Niagara Mohawk Power Company in New York State. The upper and lower Beauharnois locks have two sources of supply at 2300kv. from the Quebec Hydro, and Cote Ste. Catherine lock has one supply at 25kv. from St. Lambert Lock and another from a 575-volt 312kva. standby diesel generator set. St. Lambert Lock has two 25kv. supplies from the Quebec Hydro and another from a 575-volt 312kva. standby diesel generator set.

At Iroquois lock, the Hydro-Electric Power Commission of Ontario is providing the substation. On all other locks, outdoor substations are being built by the Authority to step down the incoming line voltage to 575 volts, there being two 600 kva. 3-phase transformers being used in each of the Beauharnois lock substations, and one 600kva. 3-phase transformer in each of the Cote Ste. Catherine and St. Lambert Lock substations.

Distribution

The distribution system on each lock is 3-phase, 575 volts, 60 cycles. Two feeders, each consisting of two 3-conductor 400 MCM rubber insulated lead covered cables connect into the lock distribution system from each substation. Load centres are located in machinery rooms on each side at each end of the locks. The load centre consists of a suitable number of 600 ampere frame 25,000 r.m.s. ampere interrupting capacity air circuit breakers enclosed in conventional cubicles. Each cubicle is connected through a breaker to a ring bus, thus assuring continuous operation should a cable in the ring fail. The load centre supplies power to operate the gates, valves, fenders, line haulers, water regulating works, lighting, heating and the other normal services. The standby diesel generator sets feed directly into the distribution system of the locks on which they are located.

Services

Two cubicles, one for heating and one for lighting, are located adjacent to and in each machinery room.

Heating in the control building, pump houses and all machinery rooms, is done electrically by means of 5kw. and 10kw. 3-phase 550-volt heaters. The control is so arranged that, when the temperature drops below 70 deg. F. inside the room, one phase of the heater comes on. When the temperature drops below 60 deg. F. outside, two phases come on and as it cools to below 35 deg. F. outside, all three phases of the heater are energized. On sector gates, heaters are provided at the seals and on the mitre gates, they are provided in the hollow quoins. These heaters are only energized, when the temperature drops to 35 deg. F., as they are only to prevent freezing. All the necessary control equipment to operate the heaters in any one corner of the lock is located in one cubicle.

The surface lighting on the lock walls consists of 400 watt EH-1 mercury lamps in a suitable luminaire with I.E.S. type III distribution. The lamp standards are on approximately 140-ft. spacing and are directly opposite one another. The calculated initial lighting level is approximately 1.82 foot candles. Constant wattage type ballasts are used and connected to a 230/115 volt multiple system.

All lighting and service outlets for control room, machinery rooms, etc., is at 115 volts.

These loads are supplied from the lighting cubicle in each corner of the lock; each cubicle being essentially composed of a 22 circuit nofuz type panelboard, a 15kva. 575/230/115 volt transformer and suitable contactors to operate the surface and machinery room lights.

Adjustable Speed Drives

The motors and control applied to the gates, valves and fenders are all essentially the same. The drive consists of a standard horizontal drip proof 20 h.p. wound rotor motor fitted with a thrustor brake and pilot generator, the latter being an essential component of a special reactor, magnetic amplifier a.c. speed control, which may be briefly described as follows.

The speed is controlled by varying the torque developed by the motor, and this is done by applying any preset unbalanced voltage to the motor primary. Variable unbalanced voltage is obtained by placing a saturable reactor in one phase of the motor primary, say phase A, which is called the drive reactor. Another reactor called the retard reactor is connected to the motor terminal side, with the secondary of a 1:1 transformer, which is connected to one of the other phases, say phase C. The primary of the 1:1 transformer is connected across phases A and B. The impedances of the reactors are varied by controlling the degree of saturation of the reactor cores. Saturation of the reactors is accomplished by means of the magnetic amplifiers so connected that the output of one is positive, while that of the other is zero. Four windings are used on each magnetic amplifier. The bias winding provides a fixed amount of excitation

Read at the 71st Annual General and Professional Meeting, The Engineering Institute of Canada, Banff, Alta., June, 1957.

THE ST. LAWRENCE Power Project, which is being built jointly by the Hydro-Electric Power Commission of Ontario and the Power Authority of the State of New York, will have an installed capacity rated at 2,400,000 horsepower. The powerhouse contains 32 units of 75,000 horsepower each and is located about two miles west of Cornwall, Ontario, at the lower end of the International Rapids Section of the St. Lawrence River. The structure straddles the International Boundary which divides it into two similar sections, each with 16 generating units.

The powerhouse is of the semi-outdoor type, with no super-structure over the units. An enclosed erection bay and administration area is located at each end of the structure. Two gantry cranes, one on the Canadian side and one on the American side, will provide the crane service to install and maintain the generators and turbines.

The decision to make the powerhouse of the semi-outdoor type brought with it many problems that were new to Ontario Hydro. When studies of this arrangement for the plant were commenced in 1952, there were no similar stations in service in Canada although the Aluminum Company of Canada's Peribonka plants were then under construction. This caused almost every feature to be the object of considerable study. From the onset, it was apparent that the powerhouse gantry was the key item and that successful operation of the plant was largely dependent upon its performance.

The object of this paper is two-fold—first to describe how the main design criteria, included in Ontario Hydro's specification for the Canadian powerhouse gantry, came to be established and secondly to describe the outstanding features of the final product, which was built by the Dominion Bridge Company of Montreal.

THE SPECIFICATION

It will be appreciated that in our northern climate, the gantry of this type of plant not only has to provide load-lifting facilities, but must also

One of the most important features of the St. Lawrence power development is the provision of crane facilities for the installation and maintenance of equipment. The design of the Canadian installation is described here, and is related to the need for compatibility with the corresponding installation in the United States, section of the powerhouse.

provide shelter for the maintenance staff. This means the crane takes the form of a portable building into which is built a large capacity hoist as well as the main auxiliary equipment for handling small parts. In the case of the St. Lawrence powerhouse, the "building" is about a 57-foot cube, the main hoist has a capacity of 300 tons, and the auxiliary hooks are rated at 15 tons. Some idea of the size and complexity of the crane may be gained from the fact that it has a dead weight of approximately 1,200,000 pounds and contains 31 motors with an aggregate of over 700 horsepower.

The semi-outdoor type of powerhouse imposes a number of restrictions on the main physical dimensions of the crane which has not only to fit the generator pit openings when centred over a unit, but also has to be able to enter the erection bay building. The latter is obviously as small as possible and limits the overall height and width of the crane. The crane must also clear the generator covers, limiting the clear width between the crane trucks. The clear height under the machinery housing is limited by the clearance required for a turbine runner and shaft assembly standing on the erection bay floor, while the maximum lift is dictated by the runner and shaft being passed over a generator rotor in the erection bay or being carried over the unit covers.

These limiting dimensions were correlated between the Power Authority of the State of New York and Ontario Hydro, to establish the dimensions specified. This ensured complete interchangeability of the cranes and would enable the crane from one powerhouse to work in the other during an emergency.

The architectural appearance of the cranes was established to conform with the treatment given to the entire project. This resulted in a much more detailed than usual specification drawing being made which enabled the two entities to purchase two cranes that would be designed and built by two different companies in two different countries and yet be identical in appearance and interchangeable in service. This process defined only the size, capacity and appearance of the crane but did not dictate its performance or the auxiliary equipment.

From the start, Ontario Hydro made a detailed study of the performance requirements as this single unit would be replacing the two overhead travelling cranes normally provided in the Commission's plants. A further factor to be considered was the length of the crane travel as there is a run of 1,350 feet from unit 16 to the centre of the erection bay.

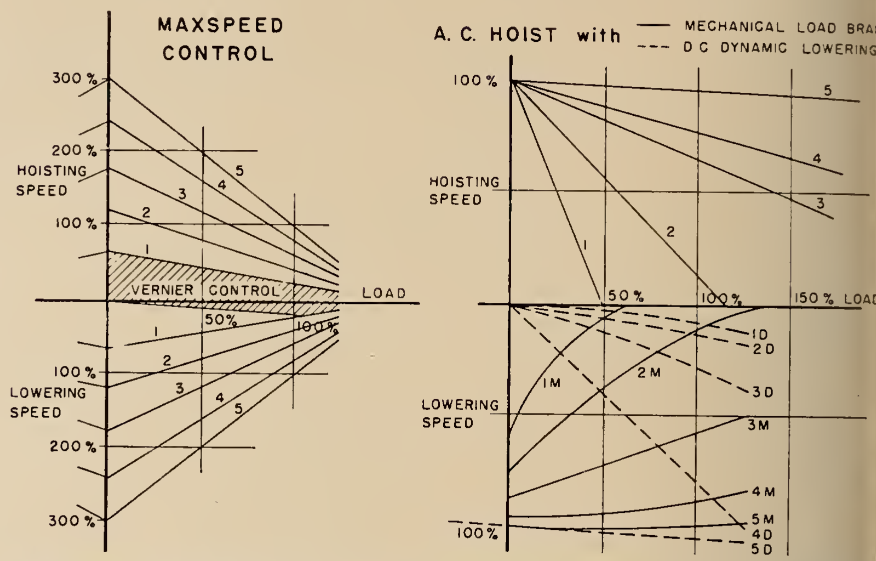
The study was divided into two parts. On one hand there were the functions of the crane when it is stationed over a unit and on the other the problem of providing flexible and adequate service to 16 units with only one crane. The latter is highlighted during the construction period when it is not unreasonable to expect that the two generator manufacturers will both be working on two units each and the turbine erector on a further two; that is, crane service being required, virtually simultaneously, in six units which may be an average 1,000 feet from the erection bay. In later operation of the plant, great demands will be made on the crane when maintenance of say two units is being carried out at opposite ends of the plant.

Considering the crane as a moving building, the problem encountered is that of producing a reasonably weathertight "fit" over a generator pit. To achieve this vertical lift, rolling doors, which seal on a flat sill provided just outside the generator pit curbs, were called for at each end of the crane. Rolling doors were specified, as space limitations within the machinery housing prevented a leaf type door being used. At one time during the study period it became doubtful that any manufacturer would undertake the design of the doors which are the largest of their type ever built. They have a clear opening of 48 feet 4 inches, a clear height of 37 feet 6 inches and are required to withstand a 100-m.p.h. wind load, applied in either direction. Eventually, one company assured us that such a door could be built using a special slat and that it would be capable of operation at the desired speed of 40 feet per minute. On this basis, the rolling doors were included in the specification.

The sides of the crane, below the totally enclosed machinery housing, are sheathed with a material similar to the door slats and complete the enclosure of the area under the crane. A wind seal is provided on the underside of the wheel trucks and sill beam, leaving a gap of only 1 inch between it and the head of the rail.

This form of enclosure, while solving the problem of providing weather protection for maintenance, raises another. Unless other provisions are made the crane has to be moved to pick up or place even the smallest part and during inclement weather this would be an involved process. The gantry doors would have to be raised, the unit covers closed and the crane travelled at least 120 feet to the far side of the adjacent unit.

To eliminate the necessity of moving the crane, except for handling major parts, it was decided to dispense with the conventional auxiliary hook on the crane trolley and to provide two mobile jib cranes that are capable of covering the entire area of the generator pit without moving the crane. The jibs run on the underside of the main transverse bridge girders and may be rotated the full 360 degrees. The booms of the jibs may be passed through a third rolling door in the upstream side sheathing. This permits light loads to be passed through the side of the crane to be placed on a truck located on the upstream roadway portion of the powerhouse deck. The jibs were specified as high performance units having a lift capacity of 15 tons at an 11-foot 6-inch swing radius and a hoist speed of 60 feet per minute.



Example I compares the performance of the Maxspeed control with two common a.c. systems. Hoist speeds are noted as a percentage of the fully loaded hook speed. If the a.c. systems were designed for the same unloaded hook speed as the Maxspeed drive the horsepower of the hoist motor would have to be increased by 300% and the loaded hook speed would no longer be limited to 5 or 6 ft./min.

The inclusion of the two jib cranes helped to solve the problem of flexibility of the gantry, but the fundamental problem remained one of speed or, more specifically, the elimination of dead hook time. The entire question of crane control and crane motion speeds was tackled from this standpoint and the following desirable characteristics were established for the 300-ton hoist and the bridge travel equipment:

(*a*) The unloaded hook speed should be as fast as possible, preferably in excess of 15 feet per minute.

(*b*) The l o a d e d hook speed should be limited to 5 or 6 feet per minute particularly during *lowering* motions.

(*c*) The spotting characteristic of hoist must be excellent and consistent on the lowering cycle.

(*d*) The crane or bridge travel speed should be as fast as practicable for a crane of this size. Again, desirable that this speed be higher for the unloaded crane to reduce dead time (say 200 feet per minute), but limited with the crane loaded to a safe speed with due regard to the ratio of crane weight to load weight (say 100 feet per minute).

(*e*) The "spotting" capabilities of the bridge controls must be excellent as it must be possible to locate the loaded crane (a total mass of approximately 1,800,000 pounds) within 1/16 inch.

(*f*) The characteristic of the trolley motion was not particularly important as the average traverse required does not exceed 12 feet. However, the "spotting" quality should be good.

It will be seen from the above that what was required was a "constant horsepower" system with considerable emphasis being placed on the lowering capabilities. It is interesting to note that in powerhouse maintenance work, the lowering characteristics of the hoist are far more critical than the hoisting ones. This is because the lowering of a 275-ton rotor into position, or a 21-foot diameter turbine runner into the discharge ring with a side clearance of ⅛ inch, is a very delicate operation.

An analysis of the crane control systems in general use was not encouraging as the great majority of applications place the emphasis on the hoisting characteristics and in the main it is along this line that development seems to have taken place. The final choice appeared to lie between normal wound rotor hoisting with rectified d.c. dynamic lowering and a modified Ward-Leonard system which would incorporate both regenerative and dynamic braking and a vernier control for spotting. The former had the advantage of being an a.c. system with its attendant simplicity, while the latter could be arranged to fulfill every desired requirement.

Electrical Features

The electrical specification for the crane was based on a modified Ward-Leonard drive as it was considered that the accuracy and flexibility of the resulting performance would prove a worthwhile investment.

The electrical equipment has been supplied by Canadian General Electric and the control arrangement was derived from their "Maxspeed" system. The basic Maxspeed system was modified to include every one of the desirable characteristics mentioned above. The crane motions are inherently limited by the load and a vernier control has been included which permits the operator to float the load into position.

The complete arrangement may be considered as being unique in its field and the principle of the system is described below:

The Maxspeed system is fundamentally a variable voltage d.c. drive. The equipment is so arranged that a master switch position selects an output horsepower and the speed of the motion is thus dependent upon the load. The system is self-compensating and functions in both the hoisting and the lowering directions.

The crane is provided with one a.c./d.c. motor-generator set which is used to power the main hoist, bridge travel and trolley traverse motions. The use of a single M-G set has been made possible by restricting the operator to the use of only one motion at a time.

This may sound at variance with the concept of increasing the flexibility of the crane but due to the physsical configuration of the powerhouse structure and equipment there would be very few occasions when it would be possible to use more than one motion at a time with any great advantage.

The Maxspeed control is available on all motions and this has been achieved with only one set of control equipment. The only exception to this is the vernier or "load-float" control which is not included in the trolley motor circuit. Simplification of the circuits is assisted by the fact that horsepower rating of the hoist motor is approximately equal to the sum of the bridge motor horse-powers.

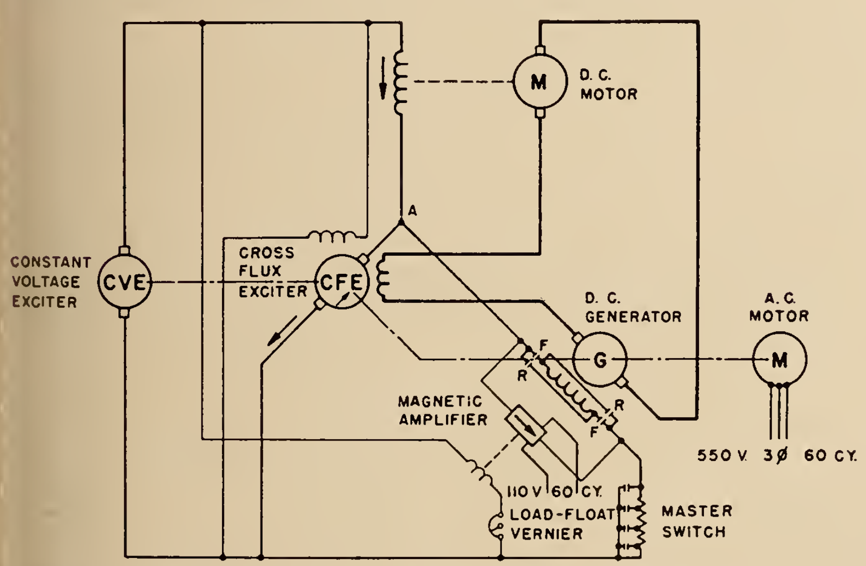
The heart of the system is a d.c. machine known as a cross flux exciter (C.F.E.). This is mounted as part of the a.c./d.c. M.G. set and is provided in addition to the normal generator exciter.

The C.F.E. is arranged so that its output is combined with the basic field current of the controlled motor and may increase or decrease its value. The stator of the C.F.E. carries two windings which are arranged to oppose each other. The one winding is energized by the constant voltage exciter and the other carries the motor armature current.

To clarify its effect, let it be assumed that the output voltage of the main d.c. generator and the basic excitation of the motor have been set by a certain master-switch position, that the hoist motor is lifting a certain load, and conditions are electrically stable. If the load is now increased, the motor speed will be reduced with a corresponding increase in armature current. The increase in armature current will further shade the constant voltage stator winding of C.F.E. and consequently cause a reduction in its output. As the output of the C.F.E. is bucking the motor-field current any reduction will cause an increase in the latter. The increased field current increases the motor torque and thus maintains the motor output horsepower in spite of a lower speed.

The main generator field winding is also connected in series with the motor field and in parallel with the C.F.E. armature. Thus, change in the exiter output has an effect upon the generator field as well as the motor field. Connection of the equipment in this manner makes the effect of the C.F.E. self-compensating and unchanged by the direction of the rotation of the motor or the direction of the load.

In this way, for any particular master-switch position, the cross flux ex-



Example II shows the basic form of the Maxspeed circuit. The output of the cross flux exciter changes the potential of the connection A and thus varies the motor and generator field currents. The "forward" and "reverse" contacts, F and R, are shown on the generator field connections and the direction of this field (and so the direction of rotation of the motor) has no effect on the function of the C.F.E.

citer maintains a virtually constant output horsepower in all four quadrants of the speed/torque diagram. The master-switch positions in this case select a horsepower, and the actual speed of the motion is dependent upon the load. The entire system has an inherent stability and a three to one speed ratio can be obtained without the customary undesirable characteristics of excessive field weakening. This is assisted by the fact that the full load rated-hook speed of the hoist motion has been geared in at 82 per cent of the base speed of the motor.

An important feature of the system is the inclusion of a vernier control which is operative on the first point of motion. It is arranged so that the power of the first point (20 per cent horsepower), may be smoothly reduced to zero. This enables the operator to "float" a hoisted load by reducing the motor speed to a point where it stalls. Creep lowering may then be carried out by further reducing the motor torque until the load overhauls the drive. This brings out the unusual point that high-precision lowering is carried out with the master switch set at the first point of hoist.

For precision movement of the crane, the vernier is used in the opposite manner. The first point of the desired motion is selected on the master switch simultaneously with the value of the vernier that reduces the torque to zero. The shading effect of the vernier control is then reduced until here is sufficient torque to start the motion.

All the motors are of the heavy-duty mill type with forced ventilation by separate a.c. blowers and the only limit to the slowness of a motion, or rather the duration of a stalled condition, is the current-carrying ability of one pair of commutator bars. The design value for this is at least five minutes, giving more than enough time for the operator to set the brake by returning the master switch to the "Off" position. If the vernier control is not moved and the master returned to the first point, the hoist motor will once again hold the load without any hook movement taking place.

Regenerative braking is used in the system for deceleration and electrically-operated brakes are used for holding. The inertia of the M-G set is such that even in the event of a power supply failure, a very normal type of stopping action takes place with both regenerative and dynamic braking being used. The system has been made as safe as humanly possible and it is considered that the inherent speed limitation with load is particularly valuable in this respect.

All other drives on the crane are a.c. powered and are standard in nature. The jib crane hoists are provided with wound rotor motors and mechanical load brakes and the trolley and slewing motion are powered by squirrel cage motors. The main a.c. controls are grouped in a motor control centre mounted on the downstream side of the crane, beside the main cab. The centre contains such items as the contactors for the main M-G set, motor blowers, thrustor brakes, as well as such disconnects as those for the jib cranes, doors and the service gantry. Also included in the control centre is the 15-kva. lighting transformer, its associated distribution panel and the main contactors for the power supply.

The arrangement of the main contactors and the power-supply feed is worthy of note. The crane draws its power from a 575-volt, 3-phase conductor system that runs the entire length of the plant from one erection bay to the other. The conductor system has three gaps in it; one between each erection bay and the switchgear building and one at the International Boundary. The gaps require that the crane be fitted with two sets of current collectors, spaced so that there is always a set in contact with the bus. Both sets of shoes are normally connected to the motor control centre so that the crane may pass from the erection bay to the powerhouse proper without any interruption in supply.

A different situation however exists at the International Boundary. The portions of the conductor system in each powerhouse are electrically separate and are supplied independently. Special steps had to be taken to prevent the crane acting as a tie between the station service supplies

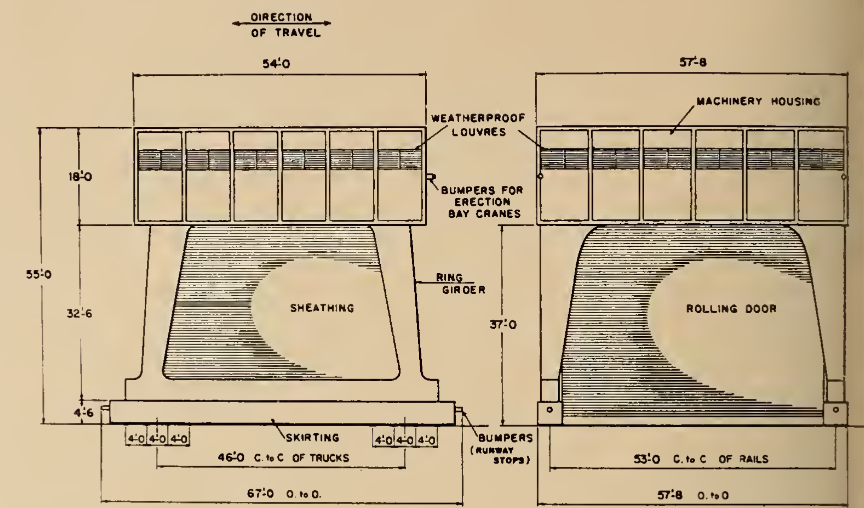


Fig. 1

of the two powerhouses, which may or may not be in phase. A suitable arrangement of limit switches and controls was finally agreed upon and their function may be briefly described as follows:

As the crane approaches the boundary, a limit switch is actuated by a striker bar mounted above the conductor system housing. This opens the contactor for the leading collector shoe assembly, isolating it from the control centre. This ensures that the collector shoes will be de-energized as they leave one section of the conductor system and enter the gap. When the leading shoes make contact with the conductor system on the far side of the gap they are still disconnected. The crane continues to draw its power from the trailing shoes until a second or trailing limit switch reaches the striker bar. The second main contactor is then opened, disconnecting the trailing shoes. At this position the crane is isolated from its supply and so remains until it has travelled, by its own inertia, for one further foot. The leading limit switch then drops off the striker bar, reclosing the leading shoe contactor. A timing relay is incorporated into the control circuit of the contactors to give a minimum time interval between the opening of one contactor and the closing of the other. This ensures that the trailing shoe contactor has been fully opened, even if the crane passes through the gap at full speed.

This type of detail design is typical of many items which were co-ordinated between Ontario Hydro and the Company and were also influenced by the international aspect of the project. The remainder of this paper has been prepared by Mr. R. D. Mutch of the Dominion Bridge Company and describes some of the problems which faced his organization in meeting the requirements of this crane.

DESIGN OF 300 TON GANTRY CRANE

The open deck type of powerhouse originated with the Tennessee Valley Authority and has been adopted for several installations in this country. However, climatic conditions have necessitated various changes and additions to the original designs when used in Canada, including the design of the power-house gantry cranes. This is particularly noticeable in the crane under discussion, which is obviously a normal open leg gantry crane with the spaces around and between the legs filled in by doors and sheathing. (Fig. 1)

Previous Canadian designs of enclosed power-house gantry cranes, such as the 250 ton machines at the two Peribonka sites of the Aluminum Company of Canada, the 175 ton crane at Sir Adam Beck Pumping Station No. 2 of H.E.P.C.O., at Niagara Falls, and the 175 ton crane now under construction for the Shawinigan Engineering Company at Beaumont Development, Quebec, were designed as movable buildings and present an unbroken exterior surface without any indication of the main crane structure within. As a result, the gantry frame could be of any desired form and, actually, in each of these cases, was a simple braced structure, composed mainly of reinforced rolled shapes. This type of structure presents no design problems as far as the load carrying members are concerned. Once these are determined, the main consideration is to ensure adequate bracing in the horizontal plane to maintain squareness of the structure and alignment of the trucks.

On the other hand, the gantry frame for the St. Lawrence powerhouse crane, being largely exposed to view, was designed to conform as noted in the first part of this paper, to the architectural treatment of the whole project. This requirement naturally decided the actual shape and overall dimensions of the main members of the structure in the plane parallel to the runway rails. In the other plane, the dimensions were fixed within fairly narrow limits by the clearances required to pass other equipment and structures on either side of each rail.

While this was, to some extent, of value to the manufacturer in establishing the proportions of the members, it might have resulted in some loss of flexibility of design and, possibly, uneconomic material distribution. In the event, the very exhaustive stress analysis applied to the solution showed that the proportions had been judiciously selected and the material required was in no case extremely heavy, considering the size of the structure and the loadings imposed upon it.

The height of the main hook above the runway rails, together with the available headroom, influenced the design of the trolley very considerably and another potent factor in this respect was the presence of the two 15 ton auxiliary jib cranes whose tracks are supported at the bottom flange of the main trolley girders. This latter consideration was to have a strong influence on the design of the trolley girders themselves and presented a difficult problem when the clearances came to be laid out around the operating machinery of the door in the upstream face of the legs.

The end doors were determined by the clearances required for the unit covers and were also designed

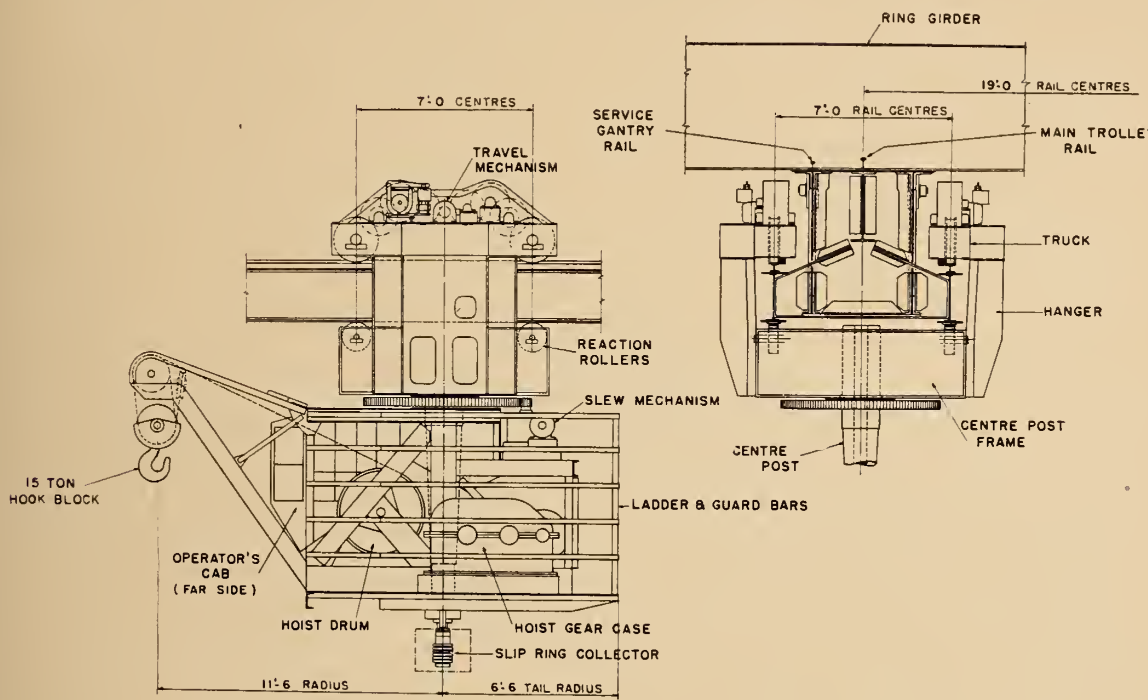

Fig. 2

so that when the crane travels with a rotor suspended from the hook, the doors can be lowered far enough to provide weather protection for the load. This consideration had to be taken into account when positioning the main control cabin and, particularly, the gantry travel auxiliary control point.

Auxiliary Jib Cranes (Fig. 2)

It soon became apparent that the feature which would exert the greatest influence on the design of the Canadian gantry crane would be the auxiliary jib cranes. These were, therefore, the first items to be designed. The rated load of each had already been specified as 15 tons and, as the gauge of the 300 ton trolley rails was estimated to be 19 feet, the radius of the jib cranes was fixed at 11 ft. 6 in. This gives full coverage over the area of the generator pit and also gives the outreach required beyond the upstream legs when projecting through the doorway on that face. A condition was visualized in which the two jib cranes could be worked together when projecting through this doorway and this condition governed the width of the door.

The question then arose as to whether the jib cranes should be fully balanced, partly balanced or not balanced at all. It was obvious at once that the tail radius of each crane would be limited by the need to clear the main hoist ropes of the trolley when the 300 ton block was at its lowest point. If the trolley drum shaft were mounted, as is usually done, at 90° to the trolley girders, the ropes leading from the drum would spread almost as far as the inner edge of the girders and the tail radius of the jib cranes would be much too short to accommodate the hoist motor, drum and gear-case. It was realized, at this point, that, with a total main trolley travel of 25 ft. 0 in., the main hoisting drum could be fitted in with its axis parallel to the trolley girders and thus confine the working space occupied by the main rope system to a narrow rectangle about 40 ft 0 in. long and 4 ft. 0 in. wide. This arrangement allowed the tail radius of the jib cranes to be fixed at 6 ft. 6 in., which made sufficient space available to the rear of the centre post to mount the hoist motor and electric brake. Even with this tail radius, it appeared that the amount of counterweight necessary to restrict the movement of the centre of gravity under full load and no-load conditions to within the track gauge would be excessive and would add considerably to the dead weight and wheel load of the gantry crane. It was decided, therefore, that no counterweight would be used on the jib cranes. Thus the centre-post round which the jib crane revolves was designed to take the bending and direct tension due to the load acting at the 11 ft. 6 in. radius, less whatever reduction could be made by placing heavy items of machinery behind the centre of rotation. On laying out the design, it was found that the 75 h.p. hoist motor with its electric brake and the 5 h.p. slewing motor with its worm gear, brake and machinery could be so mounted.

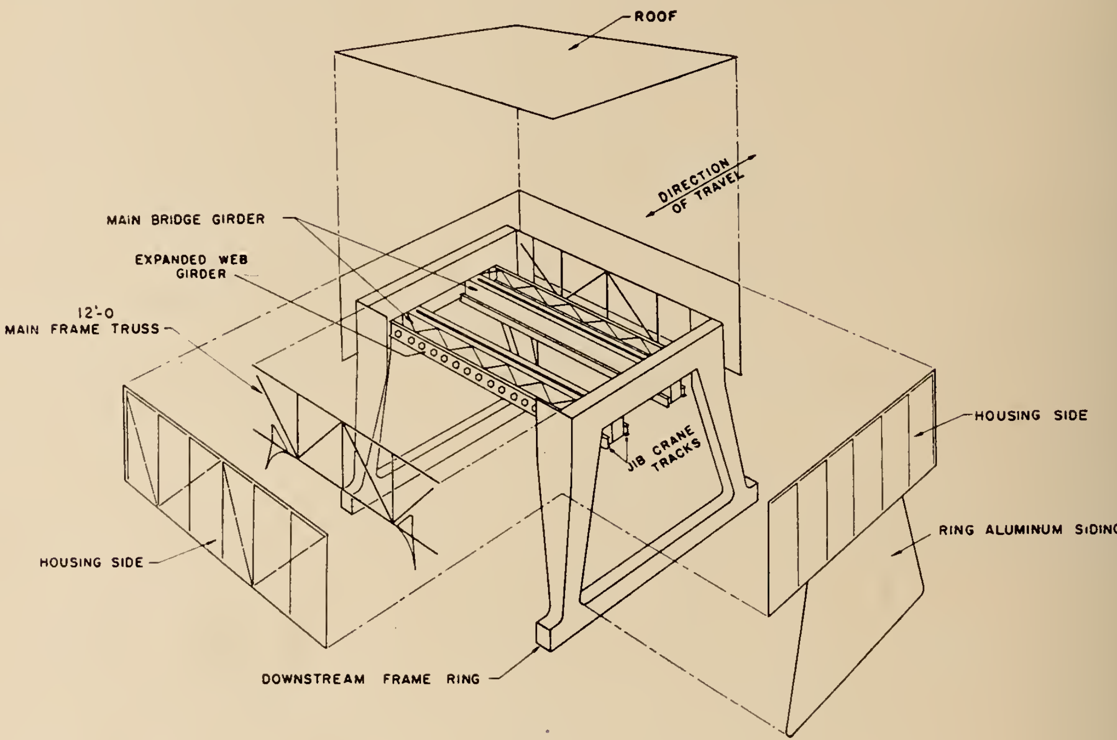

Fig. 3

To ensure maximum visibility fo the operator, the control cab is posi tioned as far forward as possible an to one side of the jib, and is provide with windows all round the operat ing position and in the entrance doo which is at the rear. A walkway a the cab floor level permits mainten ance and inspection of the machiner and is provided with a gate throug which access is obtained to the jil cranes from the stairway landing a the roof level of the control hous on the downstream leg of the gantr Normally, the cranes are parked a the downstream end of their track and with the jibs pointed upstrean Thus the gates on cranes and lan ing coincide and give easy and sa passage to and from the cranes. How ever, provision was required for th operators to leave or enter the ji cranes under emergency condition This was catered for by a syste ot ladder-like bars, placed around the lower walkway of the jib cranes, which serve as guard rails and by which the operator could reach the trucks and thence climb on to the main walkway at the top of the main girders.

The 15 ton load is lifted on four parts of ¾ in. diameter wire rope, two parts of which wind on the hoist drum. The hoisting speed is 60 f.p.m., and the 75 h.p. 1200 r.p.m. wound rotor motor is controlled by a reversing drum switch with secondary resistors.

The hoist drum rotates on bronze bushes on a fixed shaft. It is driven through spur gears, the high speed reductions being enclosed in a cast-iron gear case fitted with bronze bushes and a helix-type mechanical load brake is incorporated in the gear train. This brake serves to control the speed of lowering in conjunction with the resistor notches of the reversing drum, but is inoperative when hoisting. An automatic electric brake is mounted on the motor shaft, and limit switch protection against over-hoisting is provided.

The slewing gear is driven by a 5 h.p. 1200 r.p.m. squirrel-cage reversing motor controlled by a single speed master switch and magnetic reversing starter, giving a slewing speed of 2 r.p.m. The drive from the motor is transmitted through a fluid coupling to a vertical-type worm-gear unit, the output shaft of which carries the main slewing pinion which meshes with the slewing gear ring bolted to the centre post frame. A foot operated brake is provided to control the slewing motion and this is mounted on the extended input shaft of the worm unit. Full slewing of 360° in either direction is possible.

The centre post is a hollow steel casting and suspended from a welded steel frame into which it is keyed and bolted. The unbalanced moments of the revolving part are transmitted to the centre post by steel rollers at the upper level of the jib frame and by a bronze bush at the lower level. The vertical loads are carried by a ball thrust bearing which is retained by a heavy nut screwed to the lower end of the centre post and securely locked. The slip ring collector which carries current from the runway conductors to the control equipment and from the controls to the jib crane travel motors on the upper truck frame, is mounted below the centre post nut.

As the unbalanced moments are much in excess of the stabilizing moment of the jib crane trucks, etc., reaction rollers are mounted in the centre post frame and these run on machined ways welded to the underside of the jib crane track beams. These rollers take the upward reactions due to the unbalanced moments, while the downward reactions and weight of the crane are carried on four cast steel double flanged wheels running on rails fixed to the top of the jib crane track beams. All four wheels are bronze bushed and rotate on fixed axles. All are driven so that irrespective of the jib position, at least two wheels will have driving traction. Two 3-h.p. 1200 r.p.m. reversing squirrel-cage motors each drive two wheels on one rail through fluid drive and spur gears, giving a speed of travel of 40 f.p.m. Braking is by automatic electric brakes.

The wheel trucks and the hanger brackets connecting them to the centre-post frame are of welded construction.

The jib cranes operate on 550 volts 3-phase 60-cycle alternating current and this power is picked up from enclosed conductor systems mounted alongside the main girders. From the collectors the wires pass down through the hollow centre-post to the slip ring assembly and return from there to the jib crane travel motors by the same route.

The control cabs have sliding windows at the front and these, together with the rear-view windows in the door, are glazed with Thermopane glass to minimize the risk of fogging or freezing when working in cold weather. The cabs contain the hoisting drum switch, the master switches for slewing and travelling, the slewing brake pedal, the crane protective panel, main switch, auxiliary switches (including lighting and heating), and an adjustable seat for the operator. Each jib crane weighs approximately 28 tons, excluding load.

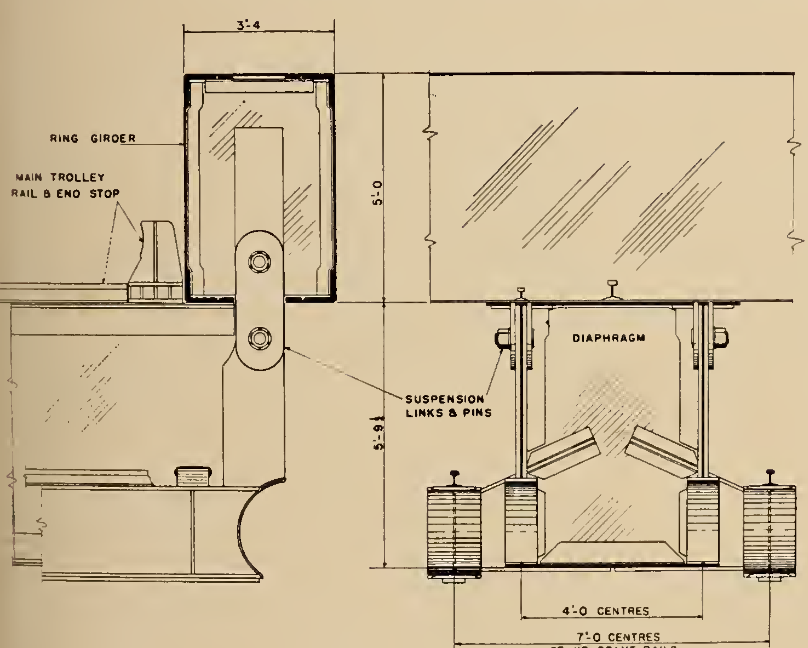

Fig. 4

Main Gantry Frame (fig. 3)

The main gantry frame consists of a pair of vertical ring girders located centrally above each runway rail. The lower horizontal surfaces of these rings carry the pivots for the trucks while the upper horizontal elements support the main trolley girders and the machinery house. The vertical elements of the ring girders form the leg members of the portal structure and carry the guides for the rolling doors.

The tracks for the jib cranes consist of rolled steel beams carrying rails on their upper surface and the machined ways for the reaction rollers underneath. These tracks are arranged in pairs, one pair for each jib crane with the rails at 7 ft. 0 in. centres and are carried from the main trolley girders by brackets which are corrected to diaphragms placed between the webs of the box section main girders. The spacing of these diaphragms is such that the stress in the track girders is kept within the specified limits when the jib cranes lift their rated load with the jib in such a position to produce the maximum wheel load on any one or two wheels. Due allowance was made for impact and for the horizontal forces produced by acceleration when slewing.

The spacing of the webs of the main girders was fixed by the gauge of the jib crane tracks with the necessary clearance for the trucks of the jib cranes. Each main girder consists, therefore, of two single-web plate girders with webs spaced at 4 ft. 0 in. centres and with common top and bottom cover plates connected to the webs by angles forming a box section. The main trolley rails are positioned centrally on the top covers and are carried between diaphragms by rolled steel needle beams riveted under the top covers. The tension members of the jib crane track hangers pass through the webs without being connected to them and are riveted through clip angles to the diaphragms.

The outreach specified for the jib cranes beyond the upstream leg was such that the leading wheels of the jib crane trucks came over the operating machinery for the upstream door. It was necessary, therefore, to cut away the ends of the track girders and the webs of the main girders for a 90° segment of a circle struck from the centre of the door roller. To simplify manufacture and erection, this was done at the downstream ends of these members as well.

The main girders, each of which weighs 42 tons complete, are connected to and supported by the two ring girders which form the main load frame of the gantry structure and carry the weight of the trolley, jib cranes, and superstructure down to the wheel trucks. Due to the fact that the jib cranes must project under the top girder of the ring at the upstream side, it was not possible to frame the trolley girders into the ring, and the bottom of the ring girder could not be placed at a lower level than the top of the trolley girders. Under these conditions, it was found that the end rotation of the trolley girders, due to deflection, if rigidly connected to the ring girders, would produce considerable secondary torsional stress in the top horizontal element of the ring girders. It was decided, therefore, to hang the trolley girders from the ring girders by links and pins (Fig. 4), and make a semi-flexible gusset plate connection between the trolley girders and the ring girders to maintain squareness of the structure in the horizontal plane and to deal with inertia loads and unequal adhesion at the wheels when travelling. This, in turn, made the trolley girders incapable of acting as the top element of a bent or portal as in normal gantry cranes and other means of connecting the ring girders together had to be adopted. These consist of two 12 ft. 0 in. deep trusses connecting the ring girders together at the outer faces of the leg sections while at the inner faces of the legs, two 42 in. deep expanded web beams are placed with butted connections to the inner faces of the vertical or leg elements of each ring. These four cross members maintain the ring girders in parallel and at their correct spacing. They also serve to support the operating machinery for the large end doors. The expanded web beams are braced horizontally to the top cover of each of the main girders and thus provide bracing in the horizontal plane additional to the gusset plates at the ring girders. This horizontal bracing system is also utilized as support for the walkways which run alongside the top covers of the main girders.

The ring girders are designed as continuous bents and are constructed of plates and angles forming a rectangular closed box section. Allowance is made in the design for the maximum vertical end reactions at the trolley girders due to the loaded trolly at its minimum end approach plus vertical and horizontal load due to the jib cranes working with full load. Inertia loads due to gantry and trolley travelling are also taken into account as in normal crane practice. In addition, the ring girder elements are designed to carry the loads due to wind, acting on the projected area of the structure. The ring girder legs, the 12 ft. 0 in. deep cross trusses and the expanded web beams, all forming the portal structure, are also designed to resist the forces due to deflection of the end doors when these are subjected to wind pressure. The catenary loads due to the deflected door curtain are transmitted to the door guides by "wind locks" and from the guides to the legs by bolts. Each ring girder weighs approximately 66 tons.

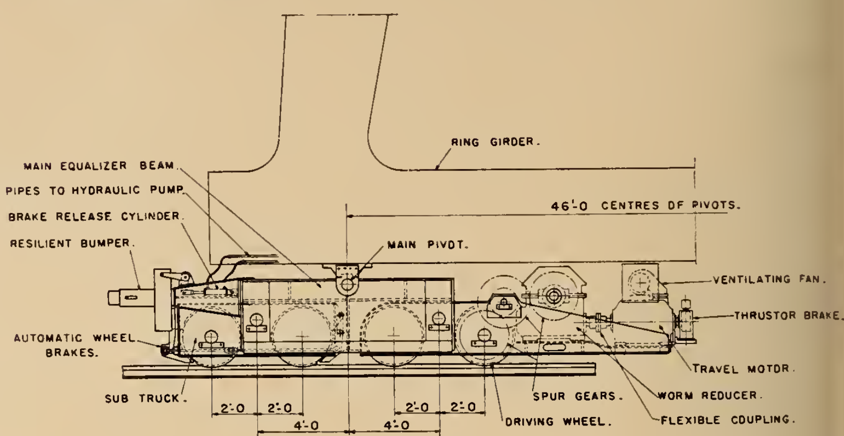

Fig. 5

Wheels and Trucks (Fig. 5)

The bottom horizontal element of each ring is carried on two steel forgings which in turn transmit the loads to the four main equalizer beams of the truck system. The design of the pivot bearings at these four points follows that used extensively on ore bridges. The forgings bolted to the ring girders each have a rectangular slot machined in their lower faces at 90° to the line of the runway rails. On the top surface of each equalizer beam a key is formed and this key fits into the slot in the upper forging. Lateral forces are catered for by a second key fitted through the forging and equalizer key and lying parallel to the track and therefore at right angles to the bearing key. The four equalizer beams are of welded construction and are bored at each end for the pivot pins of the sub trucks. They also carry the main bumpers for the end stops. These bumpers are of the resilient type in which the elastic member is a series of "Fabreeka" pads.

In order to conform to the architectural requirements, the main equalizer trucks were placed at approximately the same level as the sub-trucks, and this determined the design, which is that of an inverted U or channel section.

The sub-trucks, of which there are

eight, are each carried on two wheels. Four of the sub-trucks, one at each corner, are drivers, one wheel in each being driven. All the wheels are double-flanged cast steel, bushed with bronze, and turn on axles locked in the sub-trucks. Each driving wheel has a cast steel spur gear ring bolted to it, and these are driven through spur and worm-gears by four 35-h.p. d.c. mill motors, continuously rated with forced fan ventilation provided by separately driven fans. These motors which draw their direct current from the variable voltage motor generator set on the trolley, give a gantry travelling speed varying from 100 f.p.m. to 250 f.p.m. Each motor has a bracket mounted a.c. thrustor brake and at one truck a centrifugal overspeed switch and tachometer drive is fitted.

Wind Brakes

When a gantry crane is located in the open and is liable to be subjected to high wind pressures, safety clamps additional to the motor brakes are required to prevent accidental movement of the crane along the tracks. When the crane is a totally enclosed power-house type with very large unbroken surfaces comparable in area to those of a building, such clamps are essential and must be carefully considered in the design stages. They must be capable of preventing any skidding of the crane with the driving wheels locked and, to give the highest possible degree of protection, should be applied automatically when the crane is left unattended. They may also be interlocked with the travel motors and "dead-man" device if this is fitted.

As the runway rails in front of the erection bay are mounted flush with the concrete, and the groove in the latter was required to be as narrow as possible, it was not feasible to fit the usual vise-type of rail-clamp which grips the head of the rail between serrated jaws. Instead, a system of automatic wheel brakes was designed, incorporating the desirable feature of "failing safe."

These brakes consist of lined shoes working on the treads of eight wheels of the trailer trucks. They are applied by weights and released by hydraulic cylinders actuated by oil pressure from a motor driven vane-type pump. The wind brakes set automatically on failure of power to the crane or when the travel motors are de-energized. However, to permit of inching the gantry for final positioning of a load, a delay device is introduced into the hydraulic circuit. This consists of an accumulator of the air-oil type combined with an orifice check valve in the return line from the hydraulic releasing cylinders. These are so proportioned that the setting of the wind brakes is retarded for some minutes after the travel master switch is moved to the "off" position, allowing further small movements of the gantry to be made before the wind brakes set. As the a.c. pump motor is started as soon as the main supply switch is closed, the short time necessary for the accumulator to build up to pressure to release the wind brakes is not a drawback. When the master switch is moved to the first notch to travel, a solenoid valve is opened and the wind brakes are automatically released. Sequence switches ensure that the travel motors cannot be energized until the brake shoes are clear of the wheels, and indicator lights are provided so that if one or more of the brakes fail to release, and the gantry therefore cannot travel, the trouble can readily be

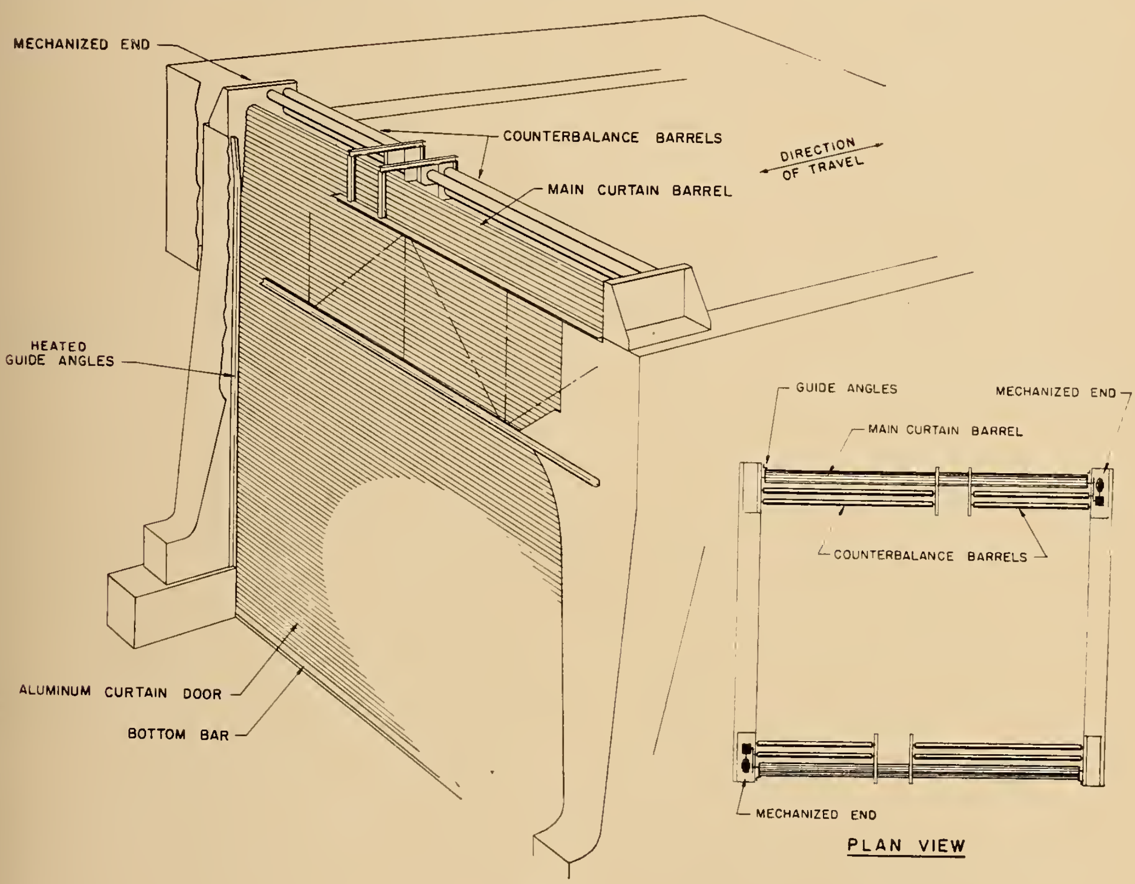

Fig. 6

localized and dealt with expeditiously.

The a.c. thrustor brakes on the travel motors operate normally when the master switch is moved to the "off" position, and as this type of brake is inherently more gentle in application than the solenoid or magnetic type, it was selected for this duty. A worm-gear drive with braking on the input shaft can produce violent deceleration from full speed in the event of a power failure with the possibility of damage to valuable loads and almost certain damage to the crane.

Enclosure and Doors (Fig. 6)

The entire upper part of the gantry crane is covered in by a steel weatherproof housing with a ridged roof. This housing was carefully designed to present a pleasing appearance and, to ensure that no stress lines or wrinkles would mar the surfaces, the two sides at right angles to the tracks are suspended from 18 ft. 0 in. deep trusses which extend the full width of the crane. The sides parallel to the tracks are supported by the ring girders and cannot deflect due to roof loads. A line of weatherproof louvres extends right around the house sides. The roof has a parapet all around it forming a gutter, and drainage to the floor level is provided by downpipes so that, if the crane should enter the heated erection bay with a covering of snow on the roof, the melting snow will not cascade over equipment on the floor.

At each end of the crane structure, the space between the legs can be closed by a vertical rolling door. These doors are constructed of interlocking aluminum slats and have a clear opening of 48 ft. 4 in. wide, by 37 ft. 6 in. high. They are electrically operated, and are interlocked with the gantry travel motion so that, until the doors have been raised to a height sufficient to clear the generator covers, only very slow-speed travelling can be carried out. This feature enables small positioning movements to be made without the need for raising the doors more than about 6 in. from the closed position so as to minimize loss of heat in winter and exlude rain or snow.

The door curtains are raised and lowered on large drums driven by electric motors and are restrained at the sides by heavy guide members bolted to the leg elements of the ring girders. These guides have electric heating for de-icing built in to prevent damage to the doors during winter operation. It may be of interest to note that, with a 100 m.p.h. wind, it is calculated that a deflection of 26 in. will be produced at the centre of the doors and that the forces tending to pull the curtain out of the guides will be of the order of 10,000 lb. per foot run. The weight of the curtains and drop-bars is balanced by a system of spring rollers geared to the curtain drum and the drop-bar incorporates a pneumatic safety device which arrests lowering if an obstruction is met with by the bottom of the curtain on its way down.

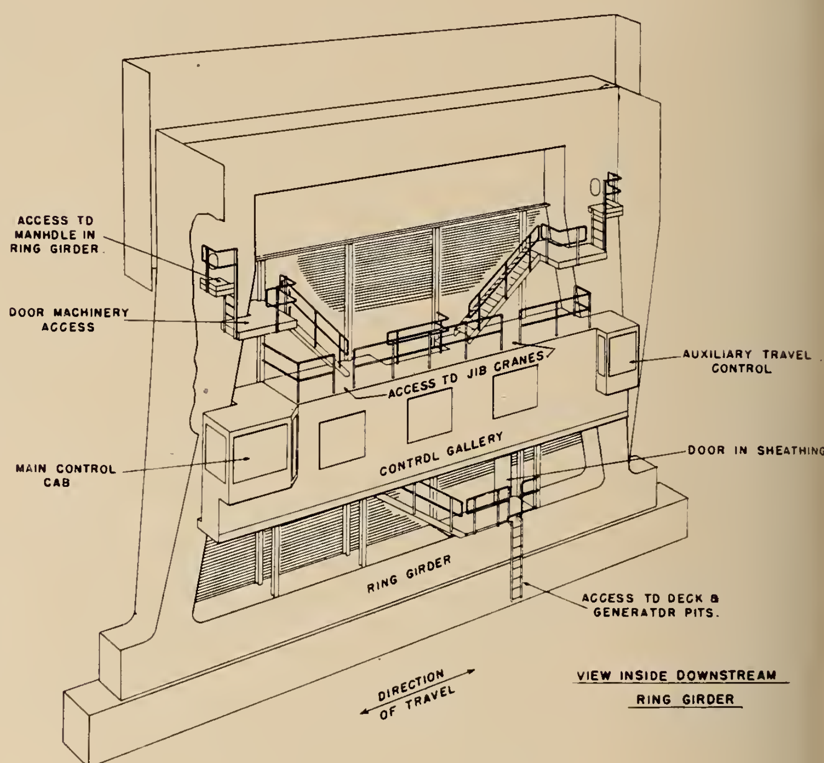

Fig. 7

The space within the annulus of the downstream ring girder is filled with aluminum slats, carried on a girt system which distributes the wind loads to the ring. The upstream annulus is closed in similarly, but, to allow the jib cranes to project beyond the upstream rail, a rolling door of similar design to the large end doors is incorporated in this face.

Control Cabs and Stairways (Fig. 7)

Access to the interior of the gantry is provided by a ladder on the downstream face of the enclosure leading up to a door at the top of the bottom horizontal element of the ring girder. From the top of the ring girder, a stairway leads up to an enclosed gallery which extends across the downstream ring girder parallel to the tracks. This gallery contains all the contactor equipment and resistors for the variable voltage d.c. generator together with the main and auxiliary a.c. contactors and starters. The height of the floor of this gallery was determined by the clearance required over the equipment in the erection bays, while the roof is utilized as a landing in the stairway leading to the upper walkways an as a means of access to the jib cranes. Platforms are provided at the uppe levels where necessary to facilitate in spection and maintenance of the doc machinery units, while manholes an ladder rungs give access to the insid of the ring girders during erectio and for painting.

The main control cabin is situate at one end of the enclosed galler Its dimensions were largely dete mined by the clearances required pass equipment positioned on t floor of the American erection ba at the same time providing space f the master switches and control co sole for the main motions of the cran In these large power-house gantrie the size of the crane structure ar its enclosure make it necessary f two positions to be provided from which the gantry travel motion may be controlled, and it is desirable that each of these positions should be as near as possible to the leading faces of the crane for each direction of the motion, so that the operator has a clear view of the deck ahead of him. The position of the main control cab as described fulfils this condition for one direction of travel and by placing the auxiliary control cab at the other end of the gallery, a favourable position for the opposite direction was obtained. By placing the travel master switches so that the operator faces down the track when manipulating them, the best position for vision under the partly raised doors seemed to have been automatically chosen so that this part of the design presented fewer difficulties than seemed at one time likely, in view of the size of the machine. Both control cabs are built with insulated walls and have sliding and fixed windows glazed with Thermopane.

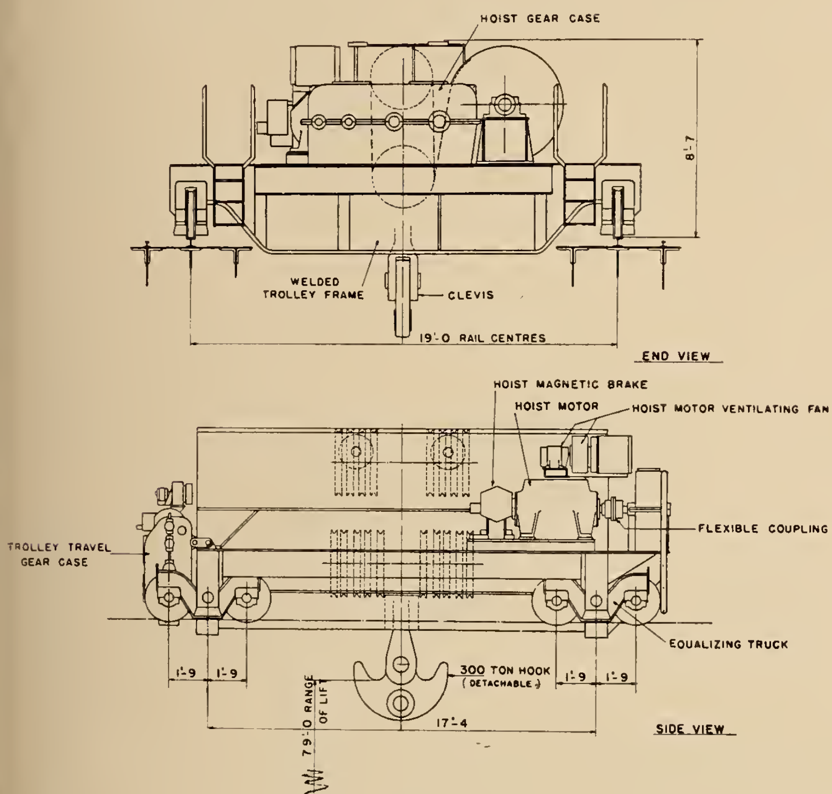

Fig. 8

Shop Fabrication and Field Erection

The gantry was too big for complete indoor shop assembly and, as the later stages of fabrication were in progress during the winter, outdoor shop assembly was also ruled out. In order to facilitate field erection, all the main connections and splices were therefore template reamed, and partial erection was carried out in the shops to prove the main connections in the ring girders. The top horizontal elements of these were also set up and the main girder pin and link connections with the plan bracing gussets tried in place in the shops. The truck assemblies were also completely assembled as units in the shops, but final alignment of these is left for the field, the main pivot bolts being subdrilled for field reaming. Each equalizer has four surfaces machined at a predetermined distance from the rail centre and these surfaces are used for aligning the trucks before reaming the pivot bolts to the bottom ring girder elements. Both ends of the connections on the expanded web cross beams were faced so that these members may be used as squaring and plumbing gauges at the top of the ring girders.

Main Trolley (Figs. 8 and 9)

The main trolley is a single hoist type of 300 tons capacity. The sister or ramshorn hook is pin connected to a forged steel clevis which rotates on a ball thrust-bearing. This bearing is carried on a forged steel crosshead which swivels in the block side plates. All the sheaves run on anti-friction bearings. The load is lifted on 20 parts of 1⅜-in. diameter, improved plow, galvanized steel wire rope, two parts of which wind on a 60-in. diameter welded steel grooved drum with trunnions welded integral with the body and machined to run in bronze bushed bearings. A single steel spur gear is fitted to one end of the drum and is driven by spur gear reductions from a 125 h.p. d.c. mill motor, giving, by means of the variable voltage control, speeds varying from 5 f.p.m. with full load to 15 f.p.m. with no load on the hook. The motor has forced fan-ventilation and as the d.c. supply provides dynamic braking lowering, no mechanical load brake is fitted. A d.c. magnetic brake is mounted on the motor shaft. The high speed gears are enclosed in a gear case welded integral with the trolley frame and run on bronze bearings. The trolley runs on eight double flanged cast steel wheels mounted in pairs in equalizing trucks which are pivoted to the trolley frame. A 12½-h.p. d.c. mill motor with forced-fan ventilation drives two of the wheels through spur gears and gives a rated trolley travel speed of 20 f.p.m. The trolley frame is built up of welded steel sections bolted together and is arranged for partial dismantling for shipment. The frame consists of two girts, one of which carries the hoist gear case, connected by beams which support the head and equalizer sheaves. The deck plate with its stiffeners serves to keep the trolley square and carries machined pads on its upper surface for the hoist motor and brake. In addition, the motor-generator set with its exciters is mounted on the trolley. Power is conveyed to the trolley and from the m.g. set to the gantry travel motors through a series of flexible cab-tire cables hung on "messenger" wire ropes, giving a series of loops which expand and contract, like a concertina, as the trolley travels away from or towards the junction-box at one end of the girders where the cables terminate. This system, which eliminates sliding contact shoes, was made possible by the short travel (25 ft.) of the trolley.

Service Gantry (Fig. 10)

In order to provide means of removing and lowering to the deck any part of the main trolley machinery which might require servicing, a small gantry crane of 13 tons capacity is mounted on the trolley girders and runs on rails positioned over the webs of the outer members of these girders; that is, outside the trolley rails. The gantry consists of two vertical end frames, each carried on two double-flanged roller bearing wheels, and is arranged for push travel. These frames are connected at their upper surfaces by two rolled steel beams inside which a sheave block trolley runs, also on roller bearing wheels. The hoisting gear, carried on one end frame is driven by a 5-h.p. 900 r.p.m. squirrel-cage electric motor and has a hoisting speed of 5 f.p.m. The load is lifted on 4 parts of 7/16 in. diameter wire rope which is led double from the drum up over sheaves at the top of the end frame, over two sheaves on the trolley, through the hook block, and over two more sheaves on the trolley, to an anchorage on the opposite end frame. All sheaves have ball bearings so that, by pushing the load, the trolley may easily be traversed across the gantry. The single-speed hoist motor is operated by push-buttons and a reversing starter and overhoisting limit-switch protection is provided. An electric brake is fitted to the motor but no mechanical load brake is provided, as the squirrel-cage motor gives regenerative braking when lowering. Current is conveyed to the gantry by a trailing cab-tire cable.

Conductor System

The conductor systems consist of copper angle busbars supported by insulators and hung from steel brackets bolted to the switch-gear building and to the walls of the erection bay. A dished cover of aluminized steel sheet provides continuous protection over the whole length and is free to expand or contract with reference to the supporting steelwork. Expansion joints are also provided in the copper angles.

Special Equipment

Provision is made at each bottom corner of the ring girders for insertion of a heavy needle beam if it should be necessary to jack up one corner of the crane. If trouble such as a seized wheel bearing should occur, a sliding shoe is provided, which can be used as a skid to avoid rubbing a flat spot on a tight wheel while moving the crane to a position where repairs can be effected. In order to service the slip-ring collectors on the jib cranes, a portable platform can be hung on the front face of the control gallery and moved in line with either jib crane. The jib crane to be serviced is then travelled or towed to the end of its track, when the slip ring is easily accessible from the portable platform. This device may also be used for cleaning the windows in the control gallery and in the cabs at either end.

General Remarks

As this crane is the largest of its type to have been built in Canada, some general statistics may be noted. Without its load, the crane complete weighs about 600 tons, of which 470 tons are structural steel. Excluding the motor generator set, the crane uses 25 electric motors, varying in size from 200 h.p. to 1/3 h.p., with an aggregate of 500 h.p. The motor-generator set for the d.c. supply has an output of 125 kw., and the set itself weighs 4 tons. The main hook block weighs 12½ tons, and the main hoist ropes have a breaking strength of 1620 tons, giving a factor of safety of 5.4 to 1 on the rated load. The length of the two conductor systems together is in excess of 3,000 feet, and with no load on the hook, the crane can traverse this distance in 12-15 minutes. The range of lift of the main hook is 79 ft. 0 in.; that of each of the jib crane hooks is 92 ft. 0 in. Separate centralized lubrication systems with manual pumps are provided for each drive truck, each jib crane slewing portion and each jib crane truck, for the main trolley, and for the service gantry.

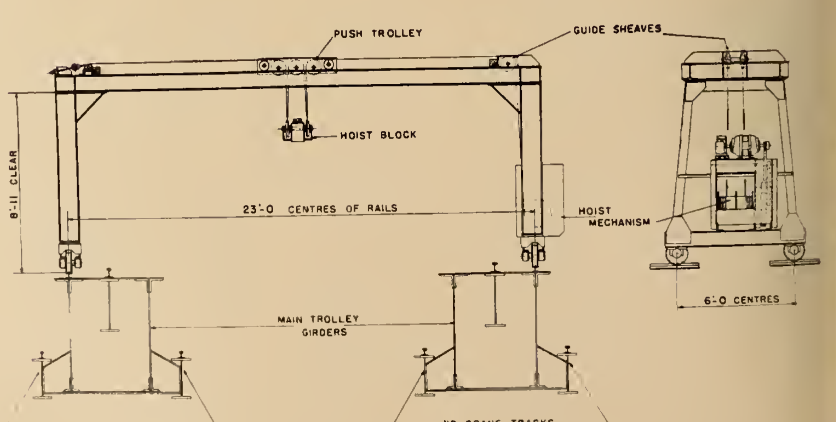

Fig. 10

St. Lawrence Seaway Locks

(continued from page 1434)

to bias the magnetic amplifier to zero output. The pattern winding is connected through a variable resistor to give any fixed effect on the magnetic amplifier. The damping winding controls smoothness of the amplifier output and the speed winding is connected through a rectifier to the stator of the pilot generator. The pilot generator output voltage opposes the effect of the pattern voltage. Thus, for any preset value of pattern current, there will be a definite motor speed corresponding to the voltage applied to the motor. An output winding supplies the net signal to the reactors. This control system gives a set of speed torque curves similar to those of an unregulated d.c. system, and is adjustable over a speed range of 10% to full speed.

The controls are also arranged so that, in the case of failure of any part of the reactors or reactor control system, the motor may be operated as a conventional wound rotor motor.

Drive Application

At Iroquois, the sector gates must be operated under a 24.5 ft. head during the construction period. To keep the hydraulic surge in the lock as small as possible, the gates must be opened very slowly (10% speed) for the first 3 degrees, then stopped for a given period of time until the water reaches a specified level, then started up slowly again (10% speed) for a short distance, speeded up to full speed until nearly opened, and finally creeped into the fully open position (10% speed).

At the upper Beauharnois and Cote Ste. Catherine locks, when the sector gates are used to shut off the canal in the event of a free flow condition arising, they must be closed very slowly, i.e., at approximately 10% of normal speed, in order to keep the hydraulic surge to a minimum. Under normal operation, they will be operated at the same normal speeds as the mitre gates.

The mitre gate drives will be adjusted to start the gates at a very slow speed (10%), then drive them at maximum speed and finally creep them into the final position.

As the operating head differs considerably from lock to lock, the valve opening speeds must be varied accordingly in order to control the surges. These operating times vary from a minimum opening of approximately 2¼ minutes at St. Lambert lock to a maximum opening time of about 8 minutes at the Beauharnois locks. The closing time for all valves is about one minute, and this represents full speed of the motor.

The fender raising and lowering operation is similar to the mitre gate operation, that is, the fender starts slowly (10% speed), speeds up to maximum speed over most of its travel, and creeps into its final position (10% speed). A creeping slowdown speed is necessary to prevent whipping of the fender boom.

By the adoption of the reactor type control system described in the foregoing, enough flexibility is attained to meet the varying speed requirements of all the machinery on the Seaway locks, thus making possible the adoption of one motor rating for all valves, fenders, and gates.

Operation of the lock gates, valves, and fenders can be made from either local or remote control points. For remote controls, all operation is from control desks located in control rooms, one being for all operations at the upper end and the other at the lower end of each lock.

The water regulating gates are also controlled remotely from these desks, the gate position being indicated on the control desk by means of a Selsyn indicator.

The stiff leg derrick is operated by means of a 75 h.p. splash-proof squirrel cage motor controlled by a general purpose combination type starter arranged for operation from a remote push button station.

Montreal Area Bridge Alterations for the St. Lawrence Seaway

P. G. A. Brault, M.E.I.C.

Design Engineer, Eastern Division, Dominion Bridge Company Limited

Four bridges, crossing from the Island of Montreal to the south shore mainland, require modification to provide navigation clearance over the Seaway canal. This paper describes the four bridges, the solutions adopted to provide canal clearance and the proposed operations involved to accomplish the amendments.

A VESSEL SAILING upstream through the Seaway would first pass the Jacques Cartier highway bridge shortly after entering the canal. About two miles further on, it would pass the Canadian National Railway's Victoria bridge and enter the St. Lambert lock. Leaving this lock, it would proceed about ten miles to enter the Cote St. Catherine lock, thus by-passing the Lachine rapids. After a further five miles of travel, it would reach the Honoré Mercier highway bridge, and, some four hundred yards beyond, it would pass the Canadian Pacific Railway's Caughnawaga bridge and into Lake St. Louis.

What alterations are necessary to each of these bridges to permit such a sailing and how these alterations are to be accomplished, is the subject matter of this paper.

JACQUES CARTIER HIGHWAY BRIDGE

Only that portion of the bridge between St. Helen's Island and the south shore is affected by the Seaway. This part consists of a series of simple deck truss spans from abutment no. 0 to pier no. 18. From the south abutment no. 0 to pier no. 3, there are three 125-foot spans; from pier no. 3 to pier no. 7, there are four 150 ft. spans from pier no. 7 to pier no. 9, there are two 200 ft. spans, and from pier no. 9 to pier no. 18, there are nine 250 ft. spans.

The Seaway canal, 180 ft. wide, passes between pier no. 9 and pier no. 10, and at an angle of about 85 degrees to the axis of the bridge. The roadway grade is 3.1 per cent upwards from abutment no. 0 to pier no. 7 and 1.0 per cent upwards from pier no. 7 to pier no. 18.

In cross-section, the deck trusses are 40 ft. 0 in. centre to centre, and support transverse floor beams cantilevered 16 ft. 6 in. either side. These floor beams carry a 36 ft. 10 in. concrete roadway slab on longitudinal stringers, two rapid transit-ways, 11 ft. 10 in. wide and two 5 ft. 6 in. wide sidewalks, all arranged symmetrically about the centreline of the bridge. The overall depth of the 250 ft. spans from roadway surface to underside of bottom chord is about 43 ft. 3 in., with chords at 35 ft. centres. Both ends of each span are provided with a jacking girder adjacent to the bottom chords and they are designed to support the full dead load at 50 per cent increased unit stresses. The jacking point locations are four feet inside from each truss centreline. Recently, the downstream transit-way has been converted into a roadway widening thus increasing the dead load on that side. It was found that the jacking girders had to be reinforced for bending moment although the shear connections were adequate.

Span no. 10 clearance over the canal is obtained by first replacing the existing deck span by a through truss span. In this manner, the depth from roadway surface to underside of truss chords compared with that of the deck truss gains about 35 ft. The balance of the 120 ft. clearance required is obtained by sufficiently raising the floor level. This means that roadway level at pier no. 9 has to be raised 50.52 ft., and at pier no. 10, 48.00 ft. This difference is due to the decision to make the roadway elevations the same at both piers and eliminate the existing 1.0 per cent grade in span no. 10. Joining the new roadway elevation at pier no. 10 to the existing roadway elevation at pier no. 14 produces a grade downwards of 3.8 per cent. Since at pier no. 14, this grade joins the existing upward grade of 1.0 per cent from pier no. 14 to pier no. 18, a vertical easement curb is necessary. This easement is obtained by amending the floor construction on the four adjacent panels of each truss supported on pier no. 14. From pier no. 9 to abutment no. 0, a maximum downward grade of 4.2 per cent, dictated by winter conditions, is adopted. This means that the roadway elevation at abutment no. 0 is 26.83 feet higher than the existing elevation. Since the new bridge approach consists of a fill, the extended abutment no. 0 is not capable of retaining the added horizontal pressure. Consequently, an additional abutment no. A, south of existing abutment, is introduced for this purpose.

A new 65 ft. deck span on the 4.2 per cent grade is provided between the old and new abutments.

To permit increasing the height of abutment no. 0 and construction of abutment no. A, it is necessary to divert traffic off the existing roadway. The turn-offs are located on both upstream and downstream sides of the bridge at the south end of span no. 3. They are timberdecked steel platforms supported on braced columns and each platform is connected to temporary turn-off fills by pairs of Bailey bridges. These pairs of connecting bridges, producing two 12 ft. roadways on each side, consist of two 110 ft. spans made of triple double bridging, and one 80 ft. span of triple single bridging, all supported on steel bents.

With traffic diverted, thus freeing span no. 1 and span no. 2, the first of five stages of jacking can be undertaken. In this first stage, the south end of span no. 1, on abutment no. 0 is raised to its new final elevation and the north end on pier no. 1 is raised about 13 feet. The south end of span no. 2 on pier no. 1 is also raised about 13 ft., while its north end, on pier no. 2, is kept unchanged.

Keeping in mind the necessity of equal jacking of ends of adjacent spans resting on a pier, it is not possible to jack at pier no. 2, while the turn-off is in service. To do so, it is necessary to re-route traffic onto the bridge after completion of abutment no. A, and the new 65 ft. approach span. This means that, temporarily, northbound traffic would have to negotiate a 4.2 per cent upward grade on the approach, a downward 7.5 per cent grade on span no. 1 and span no. 2, and a 3.8 per cent upward grade from pier no. 2 to pier no. 7.

Stage no. 2 jacking will raise the floor elevation at pier no. 10, by 10.68 ft., and at pier no. 9 by 13.20 ft. This brings span no. 10 to a level grade and is an arbitrary decision to locate the position to construct the new through span. It represents an estimated equality of time required to erect the new span and the time required to complete stage no. 2 jacking. The roadway surface will be brought to its final elevation at pier no. 13, with a straight line maintained between pier no. 10 and pier no. 13. There will be no jacking at pier no. 7, and the roadway kept in a straight line from pier no. 7 to pier no. 9. This stage will locate span no. 14 in its final position.

Stage no. 3 jacking will bring the roadway surface to final elevation at piers nos. 1 to 5 inclusive, with a straight line maintained between pier no. 5 and pier no. 9. This stage will locate spans nos. 1 to 5 in their final position.

After removal of the existing deck span no. 10 and the simultaneous positioning of the new through span no. 10 on centreline of bridge, stage no. 4 jacking can proceed. This stage will raise span no. 10 by 19.32 ft. and the floor level at piers nos. 6, 7, and 12 brought to final elevation; thus spans 6, 7, and 13 will be brought to their new permanent location.

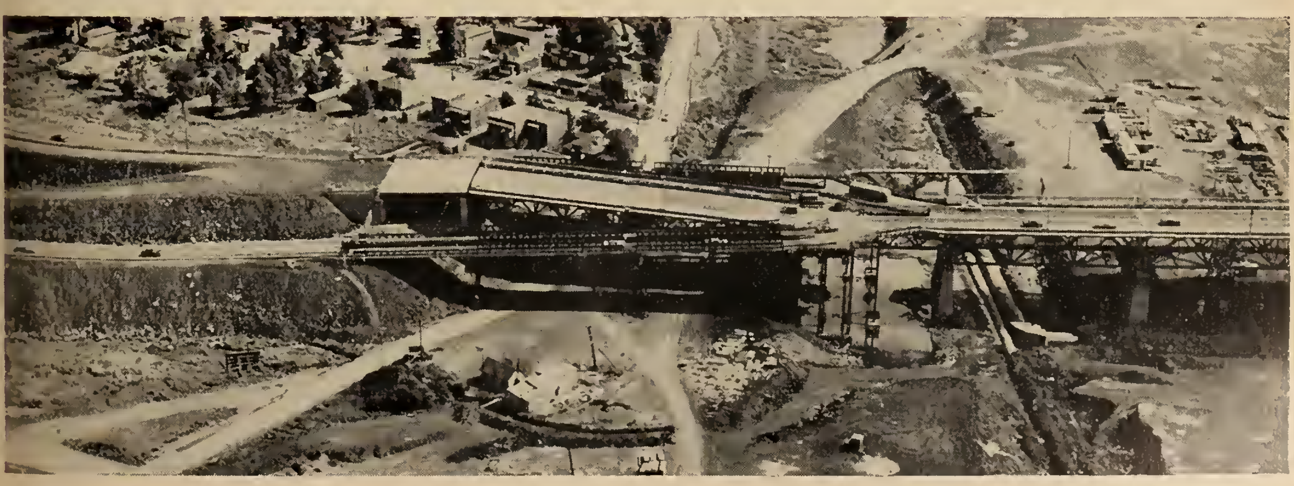
Finally, stage no. 5 will raise span no. 10 by a further 18 ft. providing the desired canal clearances and spans nos. 8, 9, 11, and 12 brought to final revised positions.

Since, during jacking operations it is required that traffic be maintained on the bridge, it is necessary that the ends of both spans resting on a common pier be raised equal amounts at each operation. The jacking arrangement has to be such that when not in use, all load reactions could be resisted. To this end, a device referred to as a climbing jack was developed. It consists of a weldment made of two parallel plates cut into an inverted "U" shape with a heavy bearing plate across their tops and bearing plates across the bottom of each leg. The two plates are thoroughly diaphragmed in way of the two legs. The weldment is so proportioned that a hydraulic jack may be inserted in an inverted position between the legs, with the ram downwards and the jack base in contact with the upper cross-bearing plate.

A normal operation consists of a 6 in. runout of the ram, thus raising both bridge and weldment. Six-inch precast concrete blocks are then inserted under each leg between the bearing pad and the pier. A threaded follow-up nut on the ram is provided as a precautionary measure. With the ram fleeted, a block can be inserted under the ram and the operation repeated.

For stability, as a pier member when not in use for jacking, an adjustable strut connects the lower part of the climbing jack to the truss bottom chord, one panel away from the end bearing. These struts are loosened during the actual jacking.

Fig. 1. Jacques Cartier Bridge turnoffs. New abutment and 65 ft. span in place. Stage one jacking of spans No. 1 and No. 2, nearly complete.



The climbing jacks are of two types; fixed and expansion, the expansion type having lubrite bearings under the leg pads. An arrangement is devised to lock the movement when jacking occurs at the far fixed ends of the span. Climbing jacks are permitted to rest on a maximum pile of four 6 in. blocks after which all jacking must cease until a 2 ft. pour of the pier extension has been completed.

During the winter months, special curing precautions are taken and an elapsed time of 60 hours is required before further jacking. This elapsed time is about 48 hours during the summer season.

Eighteen 500-ton hydraulic jacks and twelve 400-ton hydraulic jacks will be used for approximately 940 six-inch lifts required to complete the project.

About 30 inches of preliminary jacking of spans is required in order to insert the climbing jacks. This is accomplished by jacking 6-inch increments on the jacking girders and placing precast concrete blocks under the present pier members. At the proper height, both blocks and pier members are removed and replaced by climbing jacks. Stability conditions plus inadequacy of the jacking girder to carry live loads compelled a brief stopping of bridge traffic in early morning hours to perform this operation. At the final span elevation, these operations will be in reverse, with the necessary blocks and the original pier member replaced while the span is jacked on the jacking girders.

Each pier is surrounded by a working platform suspended from the adjacent steel spans, thus remaining in proper working position as jacking proceeds at that pier. Since the rotation of a span due to a six inch rise at one end will close the roadway gap at the other end by about one inch, a careful sequence of jacking is necessary to avoid gap jamming. The jacking sequence is also developed to provide, as much as possible, continuity of the 2 ft. pier pouring operations.

The new 250 ft. through span no. 10 consists of two 8-panel camel-back trusses, 66 ft. centres and 40 ft. deep at centreline. Panel point truss floor beams carry framed longitudinal stringers which support the 60 ft. roadway slab. Cantilevered brackets on each side support the 5 ft. wide walkways.

The through span is to be erected on timber falsework on a position 78 ft. upstream from the centreline of the existing bridge, with the roadway slab at the same elevation as the slab in the existing no. 10 deck span when stage no. 2 jacking is complete. In this manner, when the new span is translated into position, the bridge can be put immediately into service.

Preparation for the erection of the new span involves:

(*a*) Erection equipment
(*b*) Translation runway
(*c*) Timber falsework

A traveller will be used to erect the truss steel. It will consist of a 20-ton stiff-leg derrick mounted on a truck-equipped structural platform located immediately south of the new span at a level suitable to runout on the new floor steel. A 90 foot high timber falsework tower from the top of the canal guard pier will be required to support this initial traveller position.

The location in plan and elevation of the translation runways is governed by the position of the bearings of the existing deck span no. 10, after completion of stage no. 2 jacking. Each runway consists of seven parallel 85-pound rails at 6.5-inch centres supported on the 78 ft. length of pier and extending 77 ft. upstream and 65 ft. downstream from the pier ends.

On the extensions, the rails are supported by 3 in. deep, 6 in. wide, steel ties carried on four 30 in. deep rolled beams at 13 in. centres. The beams in turn are supported by batter-posted timber bents at 10 ft. 6 in. centres resting on the guard piers. The timber bents are about 44 feet in height.

The timber falsework panel point bents on which the new truss span is to be erected extends from the canal bed to underside of bottom chord, a height of about 138 feet. Special concrete footings will be poured and alternate bents shear-braced longitudinally with thorough strutting between the unbraced bents. From the underside of the new span pier members to the top of the translation runways rails is about 32 feet. The pier member reactions must be supported at the runway level, not only for translation, but also for the future jacking operation, as this level is also that of the adjacent span climbing jacks. Transversely braced steel posts will therefore be added and erected as part of the truss with the bottom of each post strutted with a diagonal

Fig. 2. Jacques Cartier Bridge Span No. 10. Falsework and traveller in place for erection of the new through span.

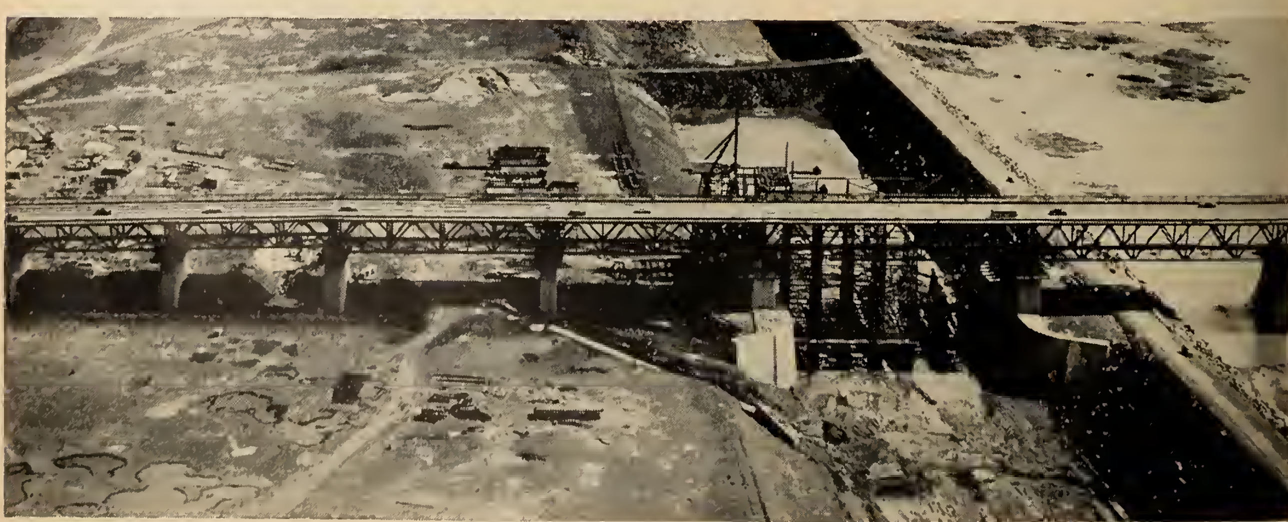


Fig. 3. Victoria Bridge, showing span No. 25 in way of St. Lambert Lock under construction.

member to the following bottom chord panel point.

The traveller will erect floor and bottom chord steel moving forward panel by panel. Upon reaching pier no. 10, it will back up panel by panel, erecting the truss members and overhead bracing. It will finally move back upon the staging on which it was originally erected and both traveller and staging dismantled.

With the steel dead load transferred off the falsework to the end bearings, slab forming and pouring will proceed. At the same time, the erection falsework will be removed.

After some 30 days of slab curing time, translation of the new span no. 10 for the old deck span will be undertaken. The four span bearings in way of each translation runway will be supported on roller nests engaging the rails and connected to each other by plate ties. At the downstream end of each runway, there will be a fixed bearing head securely connected to the rails. A horizontally positioned 300-ton hydraulic jack, with a 4 foot runout, will bear against this head with its ram bearing against a movable head connected to the downstream roller nests by a series of 4 foot long pinned links. With each 4 foot runout of the jack ram, both the old and new spans will be translated four feet. With a link pin withdrawn and a 4 foot link removed, the jack will be flected, links re-pinned and operation repeated until the full 78 feet of translation is accomplished.

With the climbing jack inserted under the new span translation bearings, the jacking of stages nos. 3, 4, and 5 will proceed. When the new span is at its final elevation, the inner halves of piers nos. 9 and 10 will be poured to the underside of the permanent pier members, thus encasing construction posts. The stability strut will then be removed.

During these final operations, the translated existing deck truss span no. 10 will be dismantled.

VICTORIA RAILWAY AND HIGHWAY BRIDGE

Victoria Bridge, owned and operated by the Canadian National Railway, crosses from the Island of Montreal to the south shore at St. Lambert. It consists of 25 double-track railway through-truss spans with floor beams cantilevered to carry a 16 foot roadway on each side. All spans are pin connected. The centre span is 348 feet long and the 12 spans, both ends of the centre span, are all identical Pratt type trusses 254 feet long. From the abutment to the centre span, the bridge has an upward 0.77 per cent grade. The 254 foot spans have 10 panels with trusses 31 ft. 2 in. and parallel chords at 40 foot centres. These spans have an unusual floor framing at the piers. In way of each truss, a grillage of seven beams straddles the width of the pier and support the truss end bearings. The transverse end floor beams, at about 19′ centres, connect to the ends of the two sets of grillage beams.

The centreline of the present Seaway canal passes through the most southerly span between pier no. 24 and the abutment at a point about 110 feet from the centreline of pier no. 24. This span is generally referred to as span no. 25. The canal, in this region, is 80 feet wide, being the entrance to the Seaway's first lock, 900 feet long. It is anticipated that, in the future, a second lock will be constructed, parallel and south of the present lock, about 85 feet away.

In order to provide for the 120 foot clearance over the canal, and, at the same time, provide uninterrupted highway traffic and eventually uninterrupted railway traffic, two vertical lift bridges are to be built; one, in way of and replacing span no. 25, and the other, some 1200 feet upstream, just beyond the upper lock gates. Permissible railway grades make it impossible to consider any high level arrangement as a solution. The new bridges are referred to as the lower and upper vertical lift bridges. The lower bridge actually consists of a lift span, 107 ft. 7 in. centre to centre bearings, with centreline located on the canal centreline, a 47 foot approach span on the north side, and 46 foot plus a 43 foot approach span on the south side, the whole making up the 254 foot length of span no. 25 to be removed.

The word "span" above refers, in each case, to a railway deck girder span, 6 ft. 6 in. each side of the bridge centreline and a highway deck girder span about 30 feet each side of the bridge centreline.

The new supporting pier no. 25, will be built on the north lock wall, while piers no. 26 and 27 will be built on the south lock wall.

Each end of the lift span will be carried on loading girders. These will be connected to the counterweights by wire ropes passing over 15 foot diameter sheaves on top of transversely braced posts in the form of a bent on piers nos. 25 and 26.

Fig. 4. Honore Mercier Highway Bridge and Canadian Pacific Railway bridge near Caughnawaga. Highway turnoff in operation. New piers for both bridges under way.

The tops of the posts will be connected by an overhead bridge supporting the operating machinery. The centreline of counterweight sheaves are 160 feet above the base of rail and 244 feet above the canal bottom. The lift spans will be raised 97 feet to provide the navigation clearance. On pier no. 27, 46 feet south of pier no. 26, another counterweight sheaves post will be supplied at this time, in contemplation of a future lift span over a proposed second lock. The bents at piers no. 26 and no. 27 are braced longitudinally to form a stiff tower and through the overhead bridge will impart stability to the bent on pier no. 25.

The approach span between piers no. 26 and no. 27 is referred to as the tower span. The bridge is completed by the 43 foot approach span between pier no. 27 and the existing south abutment.

The upper vertical lift bridge consists of a 96 foot lift span in way of the lock, a 54 foot tower span immediately south, followed by a 116 foot approach span, so designed, that it may be converted to a lift span when the future lock is built.

The counterweight sheave post bents, overhead bridge, tower bracing, operating machinery, etc., are all similar to the lower vertical lift span. The spans, however, are quite different. They consist of double deck Warren type trusses, with double track railway at the top chord, and 4 highway lanes at the bottom chord, 2 between trusses, and 1 outside each truss.

Dismantling the existing span no. 25 and erecting the new lower bridge, while maintaining railway traffic at the same time, presents some unusual problems. As train crossings average about 120 per day, the railway authorities permitted single track operations for limited periods only, otherwise, double track operation is required.

Before any work at all can be started, it is necessary to divert the highway traffic off span no. 25. This will be accomplished at the north end of span no. 24. Southbound traffic on the upstream roadway will make a right turn onto the embankment north of the north lock wall. This road will lead to a temporary canal crossing, some 300 feet west of the upper bridge site. Northbound traffic will proceed on the same embankment, pass under the existing span no. 24 and ramp up a 360 degree loop on to the downstream roadway of the existing bridge.

These turn-offs will be permanent arrangement for use when the lower bridge lift span is open for Seaway vessels. At that time, that will lead to the upper bridge roadways instead of the temporary crossing.

The limited time of single track operation suggests handling each track span as a unit. These heavy lifts (about 100 ton maximum), together with the high lifts required to position the counterweight sheaves, led to a decision to use the 150 ton guy derrick with a 202 foot mast and a 180 foot boom located to reach all pertinent parts of the bridge. To do so, the guy derrick will be erected on a structural steel four-posted tower, 8 feet square and 184 feet high, with base 65 feet downstream from the bridge on the floor of the lock. The hoisting and swinging engines will also be located on the canal bottom.

The top of the structural tower will be supported by four guys and the top of the derrick mast by eight guys. The guys will be connected to previously constructed deadmen located to provide guy clearance over the existing structure.

The erection of this handling equipment is, in itself, a major undertaking.

With the highway traffic diverted, the procedure to erect the lower bridge will be as follows:

(1) Remove the roadway floors and cantilevered brackets on both sides of span no. 25.

(2) Place steel falsework under the railway track floor beams. On the north and south lock walls, this falsework will consist of triple posted braced bents. In way of the lock, it will consist of three braced trusses with top chord panel points opposite the existing floor beams. All falsework will be designed to support Cooper E60 loading.

On each falsework bent, one post will be on the centreline of the bridge and the other two, 13 ft. 10 in. each side of centreline. The three trusses spanning the lock will occupy similar transverse positions. This arrangement will permit removing one existing track and one row of supports, thus leaving two rows of supports for the remaining track still in service. The falsework will be erected 2 inches clear of the existing floor beams to permit truss deflections until the load transferring operation is performed.

(3) With traffic on both railway tracks stopped for an estimated three hours, wedge floor beams at all falsework points of support.

(4) Dismantle the truss chords, diagonals, verticals and overhead bracing of the existing span no. 25.

(5) Erect the first tier of counterweight sheave posts at piers 25, 26, and 27, and connect with the base girder struts. These box struts will later support the end bearings of the adjacent approach track span girders. Erect also the end span-locks and the loading girders 7 ft. 6 in. south of bent no. 25 and 7 ft. 6 in. north of bent no. 26.

(6) Erect the upstream approach track span between the existing south abutment and bent no. 27. This procedure will be similar for the erection of all other approach track spans, as well as the lift track spans proper.

(*a*) Pre-assemble and rivet the span girders and bracing.

(*b*) Stop railway traffic on the upstream track and establish single track operation on the downstream track.

(*c*) Remove existing stringers of the upstream track.

(*d*) Cut existing floor beams on the upstream side and close to the centre falsework support and remove upstream portion. Remove also the upstream row of falsework.

(*e*) Place new span in position.

(*f*) Place ties and rails and resume double track operation.

In all cases, the rails will be laid by the railway personnel.

(7) Erect all remaining track spans.

(8) Erect the 2nd tier of bent posts at piers nos. 25, 26, and 27 together with portal struts and longitudinal tower bracing between bent no. 26 and bent no. 27.

(9) From the bent portal struts, suspend eight rows of Bailey bridging 230 feet long. This bridging will support a solid mat 36 feet wide, made of 12 x 12 timbers at 12 inch centres, thus providing complete protection of the railway tracks from overhead erection hazards.

(10) Erect the remainder of the tower bents, overhead bridge, counterweights, counterweight sheaves, operating machinery, etc.

(11) Erect the upstream and downstream highway spans.

(12) Remove the Bailey bridging overhead protecting structure, connect counterweight ropes, balance chains, etc., to complete the bridge.

Since the site of the upper bridge is not impeded by traffic, the erection problem is mainly one of handling equipment to reach the counterweight sheaves some 200 feet above the lock walls.

Two 20-ton guy derricks each with 120 ft. mast and 80 ft. boom will be used. Each guy derrick will be supported on a four-posted structural steel tower 7 feet square and 90 feet high; one located on the north wall on the upstream side of the bridge, while the other will be on the south wall on the downstream side of the bridge. Each tower top will be supported by four guys and the top of each mast by eight guys.

The tower span and the south approach span will be erected on blocking from the lock wall and adjacent terrain. The lift span will be assembled on lightweight welded erection trusses spanning the lock.

HONORE MERCIER HIGHWAY BRIDGE

This bridge crosses the St. Lawrence River from the Island of Montreal, at Ville La Salle, to the south shore near Caughnawaga. The steel superstructure consists of nine simple deck truss spans, followed by a 235 ft.-400 ft.-235 ft. continuous tied arch at the southern end. The south approach is overland and consists of twenty-five 50-foot concrete deck girder spans, of welded steel-concrete composite construction. In cross-section, the steel bridge carries a 27 ft. wide level grade roadway slab and one 4 ft. 6 in. sidewalk on the upstream side. At the south end of the south approach, the highway turns either west or east. About 300 yards from the centreline of the bridge, the westward highway passes through a narrow tunnel-like underpass under the 60 foot high Canadian Pacific Railway embankment. The eastbound highway, however, is clear of the embankment, and is roughly parallel to it.

The Seaway canal intersects the centreline of bridge at a point about 1631 feet south of the end of the continuous tied arch or centreline of pier no. 14.

A movable span arrangement in way of the canal being definitely undesirable with heavy roadway traffic, a new high level south approach was decided upon. This decision required that the existing concrete approach be completely demolished and removed. Before its destruction,

Fig. 5. Sketch of completed Jacques Cartier Bridge project and new approach.

traffic will be diverted off the upstream side of the continuous span near pier no. 14 to a temporary turn-off fill.

The new approach will remain on the centreline of the existing bridge, from pier no. 14 to pier no. 29. From pier no. 14 to pier no. 15, there will be a simple 55 foot deck truss span. From pier 15 to pier no. 27, a length of 1424 feet, there will be twelve continuous deck truss spans. From pier no. 27 to pier no. 28, there will be a 300 foot through camel-back truss span over the canal, and from pier no. 28 to pier no. 29, a simple 100 foot deck truss span.

These spans will provide two 26 foot roadways with a 6 foot median strip between, a 4 ft. 4 in. sidewalk on the upstream side and a 2 ft. 10 in. safety-way on the downstream side.

The deck spans will have four longitudinal trusses supporting transverse floor beams at 12 ft. 3 in. centres, which, in turn, will support longitudinal centres at 5 ft. 3 in. centres.

To maintain a minimum depth from floor level to the 120 foot clearance line over the canal high water level, the through span will have three supporting trusses, one truss being in the centre of the median strip. The floor elevation at pier no. 27 and pier no. 28, governed by the floor and chord proportioning of the through span, is about 163.5 feet above the canal bottom. From pier no. 27 to pier no. 14, a maximum downgrade of 4.25 per cent is permitted. This means that at pier no. 14, the new approach level is 6.3 feet above that of the existing continuous tied arch span. An involved operation will consequently be required to amend the floor of the existing span and, at the same time, maintain traffic.

South of pier no. 29, all spans will be of the riveted deck plate girder type and there will be three distinct approaches. An east approach for both east and northbound traffic; a west approach for westbound traffic only and a west approach for northbound traffic only.

The east approach from pier no. 29 to the east abutment is on a 790 foot radius curve, 1407 feet long, and contains fifteen spans. It provides for dual 26 foot roadways with 6 ft. median strip between and is on a 4.25 per cent grade.

The west westbound approach is

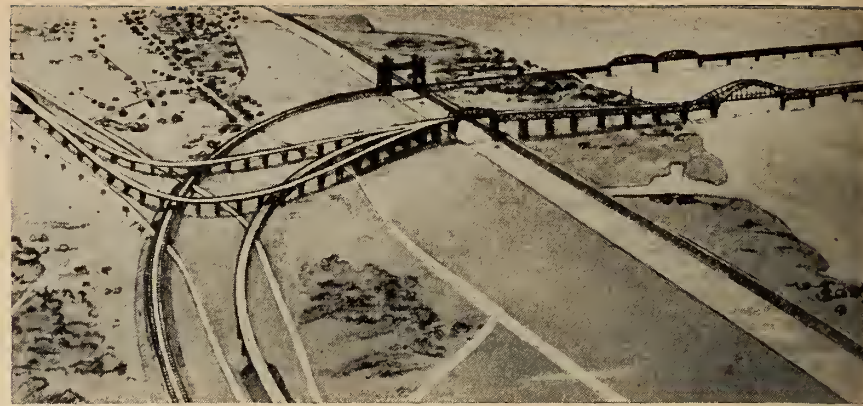

Fig. 6. Revised Honore Mercier Bridge south approach and new Caughnawaga railway vertical lift span.

1733 feet long from pier no. 29 to the west abutment and comprises sixteen spans. It provides for a single 26 foot roadway and its 2.75 per cent grade clears the Canadian Pacific Railways embankment. The west northbound approach is on a sweeping curve, east of the westbound approach and is 1953 feet long from the west abutment to pier no. 29. It passes over both the Canadian Pacific Railway embankment and the east approach. It contains 22 spans and also provides for a single 26 ft. roadway.

The two spans between piers no. 14 and no. 16, will be erected by crawler crane from the ground. A 12-ton stiff leg derrick mounted on a truck-equipped platform, placed on the span from pier no. 15 to pier no. 16 will erect the spans from pier no. 16 to pier no. 27, by cantilevering from pier to pier. The simple deck truss span between pier no. 28 and pier 29, will also be erected by crawler crane and on it, will be assembled an 18-ton top chord traveller to erect the through span. The traveller will proceed from pier no. 28 to pier no. 27, erecting floor steel and truss members panel by panel on 160 ft. high timber falsework from the canal bottom.

The east approach spans will be erected with a 35-ton traveller, starting at the east abutment and proceeding towards pier no. 29. There, it will be turned around and erect the spans of the west northbound approach from pier no. 29 to the west abutment. There, the traveller will be turned again and proceed to erect the spans of the west westbound approach from the west abutment to pier no. 29.

The St. Lawrence Seaway Authority's construction schedule requires that the spans, from pier no. 14 to the east abutment, as well as the alteration to the anchor arm of the continuous tied arch be completed during the summer of 1958 and that the remaining two west approaches be completed early in 1959. This means that temporarily, both east and westbound traffic will be using the east approach. The purpose of this requirement is to expedite the removal of the turnoff fill in way of the canal.

CAUGHNAWAGA RAILWAY BRIDGE

Approximately four hundred yards from and nearly parallel to the Honoré Mercier bridge is the double-track Caughnawaga bridge, owned and operated by the Canadian Pacific Railway. Actually, the bridge is two separate bridges, side by side, one for each track. At the south end of the bridge, the right of way leads on to a 60 ft. high embankment which curves eastward on approximately a 3000 ft. radius. The Seaway canal does not affect the bridge proper but cuts through this embankment about 1300 ft. south of the end span.

Railway grade restrictions necessarily dictated a movable span as solution to provide the canal clearance of 120 feet.

To permit construction of this new bridge and not interfere with present railway operations, a revised position on the railway tracks was decided upon. This new position will be on a chord of the curved section of the present south embankment. This chord will be of sufficient length to provide adequate transverse construction clearance. Again, there will be an individual bridge for each track. As the angle between the canal bridge centrelines is 59 deg., the bridge for the southbound track will be about 16 ft. north of that for the northbound track. Transversely, the bridges will be at 27 ft. centres. Each track bridge will consist of a 322 ft. lift span flanked at each end by 66 ft. tower spans which, in turn, will be flanked by 55 ft. approach deck girder spans.

Each lift span has 12 panel camelback trusses at 19 ft. centres with a centre depth of 45 ft. between deck girder spans connect the backleg piers to retaining walls introduced to independently resist the longitudinal pressure of the new fill required to join up with the existing railway embankment.

The same two 20-ton guy derricks and 90 ft. steel towers referred to in the erection of the Victoria bridge upper lift span will be used to erect the tower spans and counterweight sheaves. One derrick will be placed over each backleg pier.

A 50-ton capacity locomotive crane will erect the south approach span and then proceed to erect the lift roughly opposite the centreline of the southbound tracks. Consequently, only falsework in way of the northbound track can be erected. The lift span of the southbound track will be erected first and then translated to its permanent position, using roller trucks and hydraulic jacks. The northbound lift span will then be erected on the same falsework and upon completion, the falsework will be removed.

NOTE

The engineering department of the St. Lawrence Seaway has delegated its authority to Dr. P. L. Pratley,

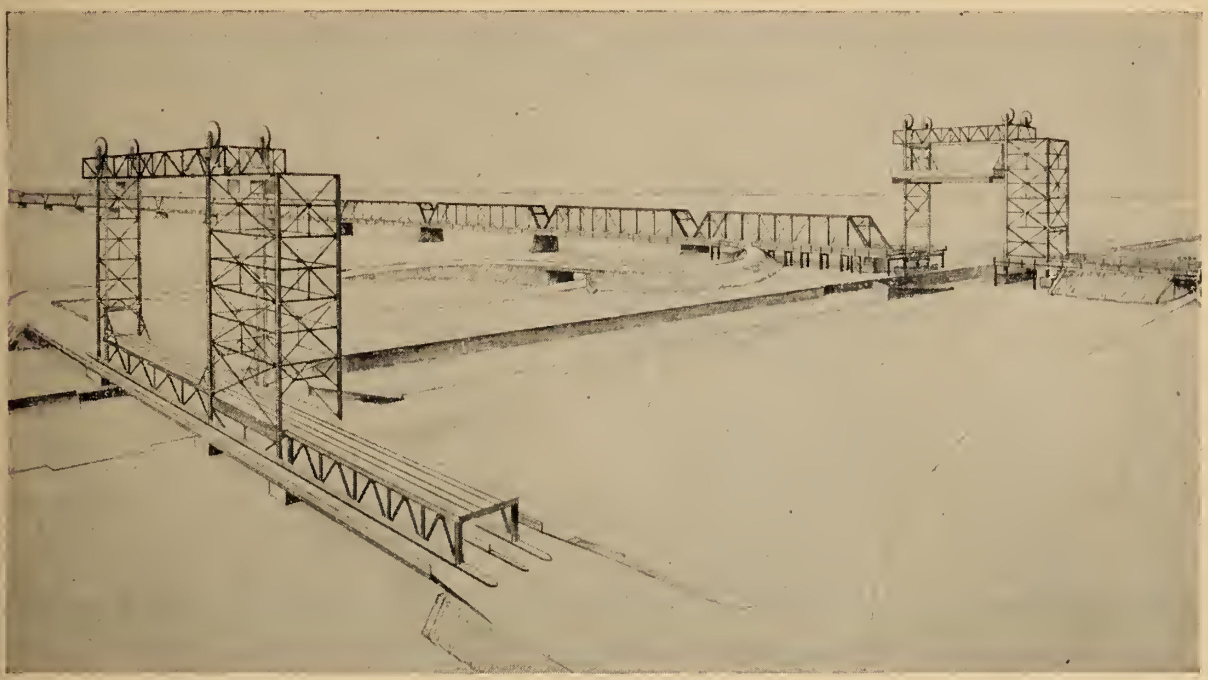

Fig. 7. Artist's sketch of the St. Lambert Lock area at the south end of Victoria Bridge.

chords. The operating machinery house is located at mid-span between the railroad clearance line and the top chord. The tower spans combine at the same time longitudinal bracing of the counterweight sheave posts and a 66 ft. track span between the main pier and backleg pier. The centreline of counterweight sheaves is 133 ft. about the base of rail. The span by first placing the floor steel and bottom chords on 80 ft. falsework bents from the canal bottom. It will then back up and erect the remaining truss members and overhead bracing.

Due to the proximity of the toe of the existing railway embankment, it is not possible to excavate to the bottom of the canal, west of a line M.E.I.C., consulting engineer, for the Jacques Cartier bridge Project, and to Messrs. Lalonde & Valois, consulting engineers, for the Honoré Mercier bridge south approach revisions.

Joint approval by the St. Lawrence Seaway Authority and the railway company concerned, is required for the Victoria and Caughnawaga bridge projects.

Progress Report on the St. Lawrence Power-house Project

O. Holden, M.E.I.C., *Chief Engineer*

P. Pemberton-Piggot, *Assistant Mechanical Engineer*

The Hydro-Electric Power Commission of Ontario

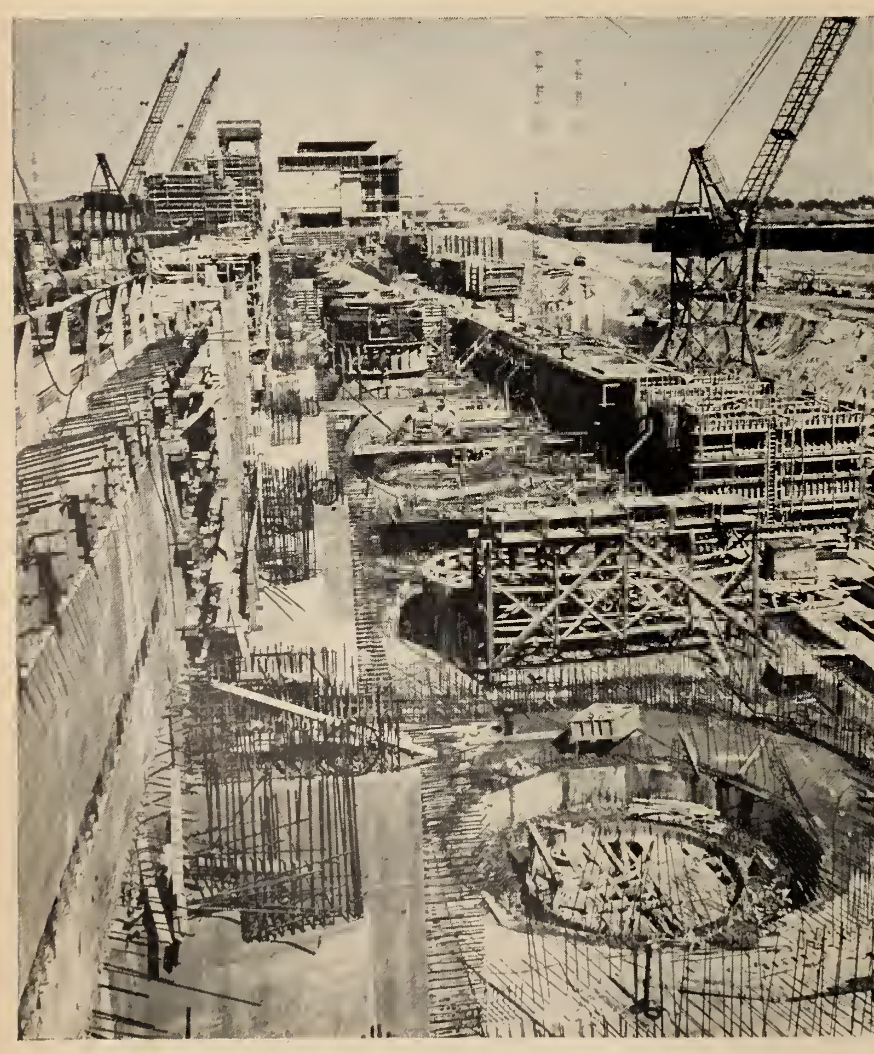
THE ST. LAWRENCE Power Project, now being constructed jointly by Ontario Hydro and The Power Authority of the State of New York, requires a wide range of mechanical equipment. Some items have already been installed and placed in service to assist in the construction work taking place along the International Rapids section of the St. Lawrence River.

There are three main structures in which the bulk of this equipment is being installed. These are:

(1) The adjoining powerhouses, one Canadian and one American, which form a dam between the Ontario shore and Barnhart Island.

(2) Long Sault dam located between Barnhart Island and the American shore which is the main spillway structure. It is from here that the river levels upstream to the Village of Iroquois will be controlled.

Figure 1.



(3) The Iroquois control dam which spans the river between Iroquois and Point Rockway. This dam controls the outflow from Lake Ontario.

The powerhouses are of the semi-outdoor type with no superstructure over the units. An enclosed erection bay and administration area is provided at each end of the structure. Each powerhouse will contain sixteen 75,000 horsepower fixed-blade propeller turbines directly connected to 60,000-kva. vertical generators. The powerhouses also contain six ice sluices which are located in pairs at the International Boundary and each shore. The overall length of the structure, comprising both powerhouses and erection bays is 3,120 feet.

Crane service is provided for the erection and maintenance of the generating units; two 300-ton enclosed gantry cranes—one in each powerhouse. Additional crane service is provided in each erection bay by overhead travelling cranes while the headworks are serviced by two 90-ton gantry cranes. The extensive auxiliary equipment required for the plant is located in the lower level of the erection bays and in other convenient areas throughout the length of the plant.

Long Sault dam will be equipped with thirty spillway gates each 50 feet wide by 30 feet high. Eighteen of these gates are provided with individual hoists while two 275-ton gantry cranes provide the means of operation for the remaining gates and also maintenance service for the dam. At the present time, the first stage of Long Sault is controlling the entire flow of the St. Lawrence River through thirteen temporary diversion sluices. The flow through these diversion sluices is controlled by gates made up from sections of the final spillway gates. The second stage of the dam, now under construction, will be provided with diversion ports

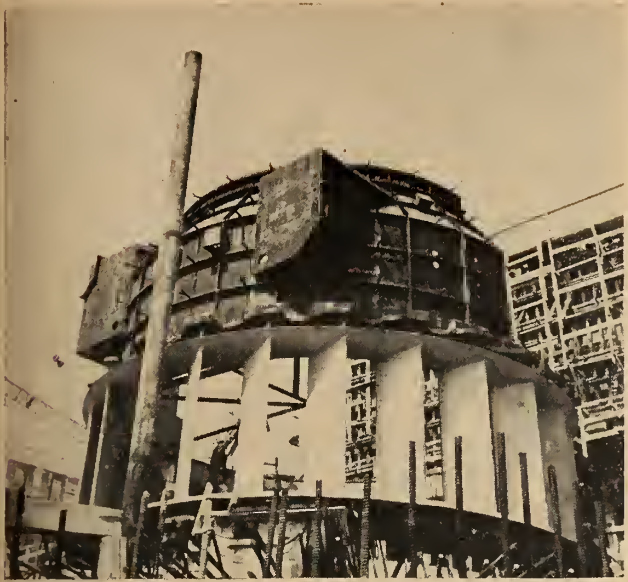


Figure 4.

which will be used for the final closure procedure.

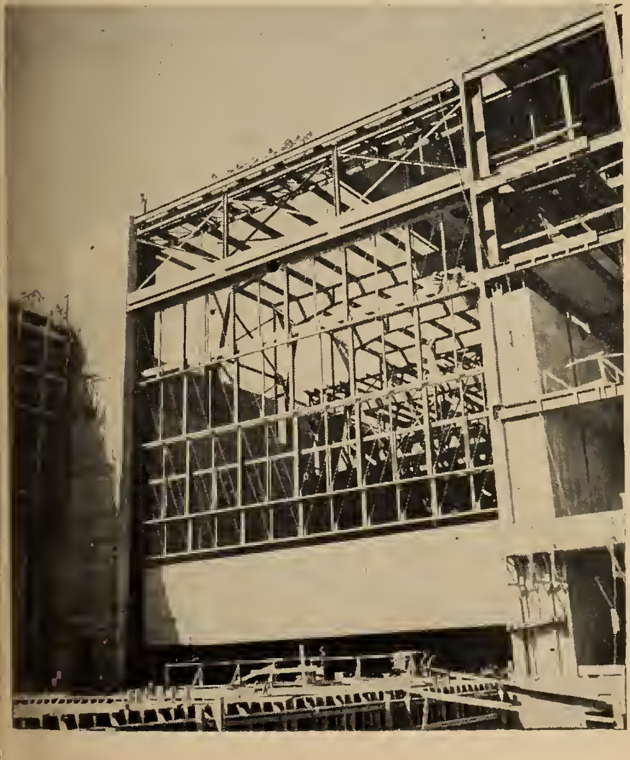
Iroquois dam will consist of thirty-two sluices each provided with a 50-foot wide by 48-foot high single-section sluice gate. The gates are handled by two 320-ton gantry cranes which are now in service controlling the river flow through the first stage of the dam.

It will be seen from the accompanying photographs that construction progress is already well advanced. The project is scheduled to go into service in the summer of 1958.

Figure 1

This photograph shows the gen-

Left (above), Fig. 2.; (below) Fig. 3.



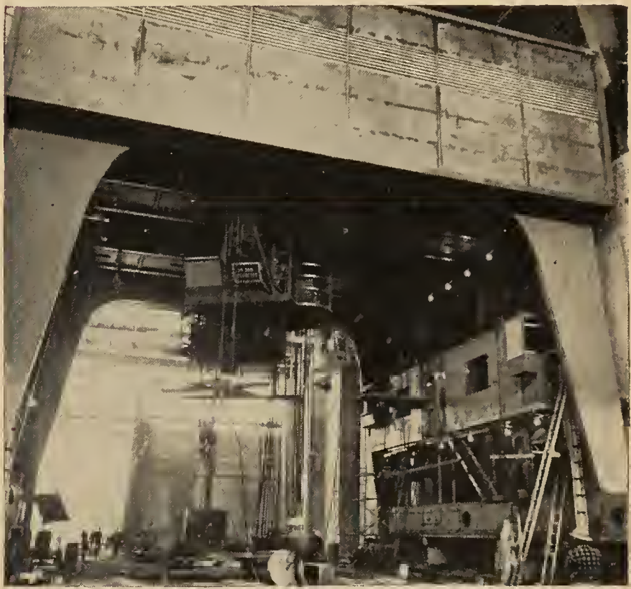


Fig. 5 (above); Fig. 6 (below).

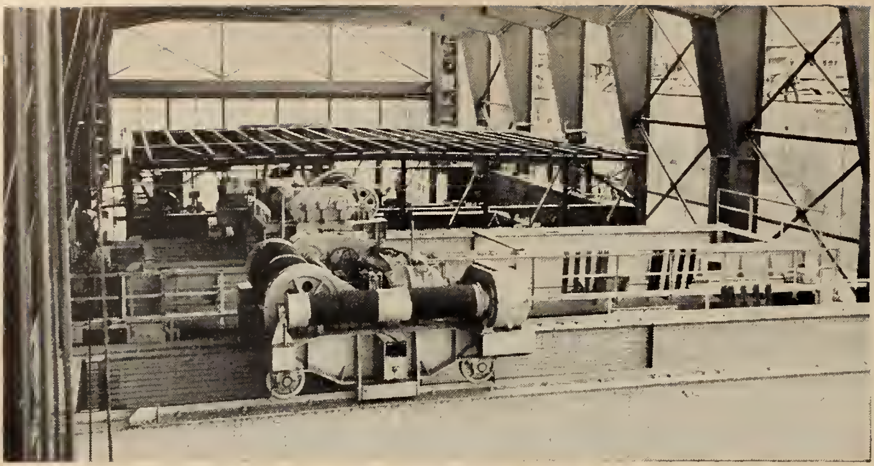
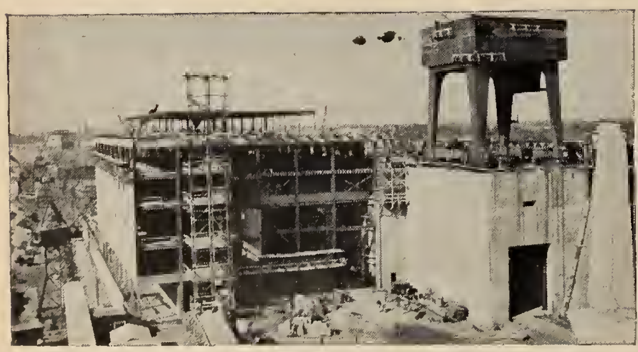
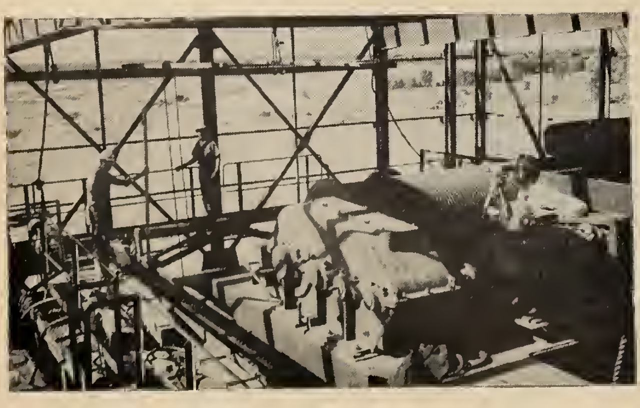






Top to bottom, Figs. 7, 8, 9 and 10; below (right), Fig. 11.

eral view of the Canadian powerhouse. The embedded parts of unit 12 are clearly visible in the centre of the picture. In the background may be seen the erection bay and the headworks gantry. The large door in the face of the erection bay permits the 300-ton powerhouse gantry to pass into the building.

Figure 2

This picture shows a close-up view of the embedded parts of one of the 75,000-horsepower turbines. The size of the speed ring may be gauged by the man standing inside the ring.

Figure 3

This picture shows the completed framing of the big gantry entrance door in the erection bay. The door is 60 ft. 6¾ in. wide and the five vertical lifting blades are arranged to give a clear opening height of 58 ft. 6 in. The roof framing of the erection bay and of the 300-ton gantry may be seen through the latticework of the door.

Figure 4

This picture is taken inside the Canadian erection bay and the gantry entrance door may be seen in the background. The upper panels of the door have received their aluminum facings while insulation batts may be seen on the lower panels. The large gantry crane is the 300-ton capacity crane used for servicing the units. In the foreground is the runner hub and blades of one of the turbines. On the right hand side will be seen bundles of reinforcing steel which were used for the load test on the 80-ton capacity overhead cranes, one of which may be seen at the top of the picture.

Figure 5

This picture shows the erection of the 300-ton gantry crane nearing completion. In the centre of the picture will be seen the 15-ton capacity jib cranes which provide auxiliary hook service within the gantry crane enclosure. The crane is equipped with rolling doors at each end, one of the guides for which may be seen at the right hand leg of the crane. The gallery on the right hand side of the crane encloses the crane cabs and the various motor control centers.

Figure 6

This picture shows the downstream side of the 300-ton gantry crane. The arrangement of the control gallery and various access stairways may be seen. In the lower left is one of the travel drive units and on the right hand side may be seen the 300-ton hook block. At the top of the picture is the underside of one of the jib cranes showing the arrangement of the collector post.

Figure 7

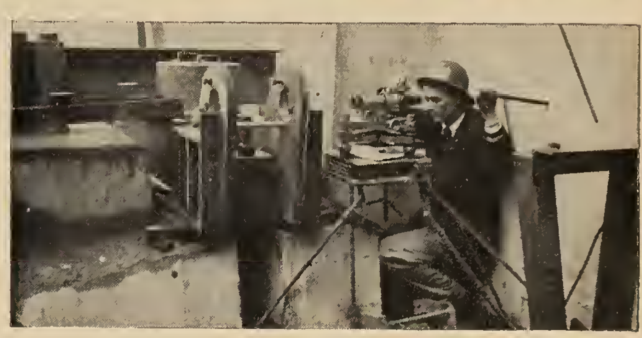
This picture shows the two 80-ton overhead cranes in the Canadian erection bay. The hoisting drums had not been reeved when this picture was taken although the cranes are now in service asssembling turbine and generator parts. It will be noted that the long auxiliary hook drum is placed at right angles to the main hoist drum and positions the auxiliary hook outside the crane girder. This arrangement not only makes for a very compact trolley but also permits a very close hook approach to the walls of the erection bay. In the background may be seen the roof framing of the 300-ton gantry crane and the counterweight guide tower of the gantry crane entrance door.

Figure 8

This picture shows the detail of the arrangement of one of the 80-ton erection bay crane trolleys. The

Figure 12.

Figure 13.



Below, Fig. 14.

mechanical load brakes of the two hoist drives are enclosed within the gear boxes while thrustor-operated holding brakes are located on the extended motor shaft. The trolley travel drive unit is provided with forced lubrication, the piping for which may be seen on the gear case at the right front of the picture. This picture again emphasizes the compactness of the trolley and clearly shows how the auxiliary hook may be placed within 18 inches of the end wall of the building.

Figure 9. (p. 1458)

This picture shows the Canadian end of the powerhouse structure. The overhead cranes may be discerned in the erection bay while the dominating feature is the headworks gantry which is in the process of being erected. The door under the gantry leads to a headgate maintenance area and also provides a route for equipment on its way to the headworks deck. This picture does not show that the 90-ton headworks gantry is also equipped with a 15-ton capacity jib. This is located on the far leg and is used in handling stoplogs, trash racks, etc.

Figure 10

This picture shows the trolley of the 90-ton headworks gantry crane during erection. The men in the picture are engaged in checking the trolley rails for level. In the foreground may be seen the Cornwall dyke and the canal closure structure through which the 14-foot Canadian navigation canal is now being diverted.

Figure 11

This picture shows one of the Canadian headgates being unloaded off a boat in the 14-foot Cornwall canal. The gates are unloaded by a derrick specially erected at the site for this purpose. It will be noted that the gates are shipped complete in one piece in spite of the fact that they weigh over 40 tons each.

Figure 12

This picture shows the hinges of one of the ice sluice drum gates, six of which are being installed in the powerhouses. At the extreme top right of the picture may be seen the rail for the headworks gantry which is carried over the sluice by the heavy steel girder dominating the upper part of the picture. In the extreme lower left hand corner may be seen two of the dogging posts which will be used to support the gates during maintenance. The heavy scaffolding in the flotation chamber will be used to support the gate bottom during its erection.

Figure 13

This picture shows the setup used to check the alignment of the ice sluice drum gate hinges prior to concreting.

Figure 14

This picture is an aerial view of Long Sault dam showing the entire St. Lawrence river flow of approximately 240,000 cfs. passing through the diversion sluices in the first stage of the dam. In the centre may be seen the second stage of the dam under construction. On the left hand side of this portion of the dam may be seen the discharge opening of the diversion ports which will be used during the final closure procedure. On the top of the completed portion of the dam may be seen the two 275-ton gantry cranes which are now

Above, Fig. 15.

Left, Fig. 16.

Above, Fig. 17; below, Fig. 18.

being used to handle the sluice gates in the diversion control position.

Figure 15

This is a downstream view of the first stage of Long Sault dam at the commencement of diversion. It will be noted that the crane is provided with a double drum main hoist and handles the gates through a lifting beam.

Figure 16

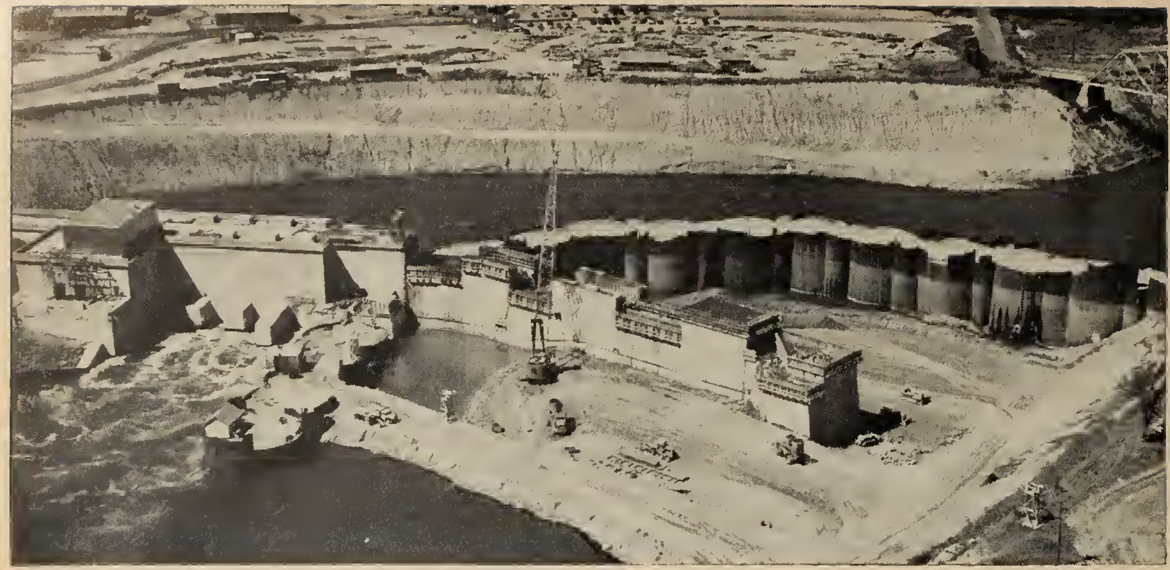
This picture is an upstream view of Long Sault dam showing the diversion control gates and their temporary guides. It will be seen that the gates are made up of a number of sections to give the required height. They will later be re-assembled to provide the 30-foot high spillway gates required for the completed dam.

Figure 17

This is an aerial view of the Iroquois dam area. The dam itself can be seen with the river flow passing through the first stage sluices. The second stage of the dam can be seen behind the steel cell cofferdam and this section is now complete. In the immediate foreground may be seen work in progress on the entrance to the new Canadian Seaway Iroquois lock. To its right may be seen part of the excavation of Iroquois Point. It will be noted that the outstanding feature of the dam is the pair of 350-ton capacity gantry cranes used to handle the sluice gates.

Figure 18

This picture shows the 50-foot by 48-foot high gates of Iroquois Dam with the full river flow passing through the sluices of the first stage. When in the full raised position the upper portions of the gates are braced by concrete towers, which may be discerned between the gates on the left and are visible under the left hand gantry crane.

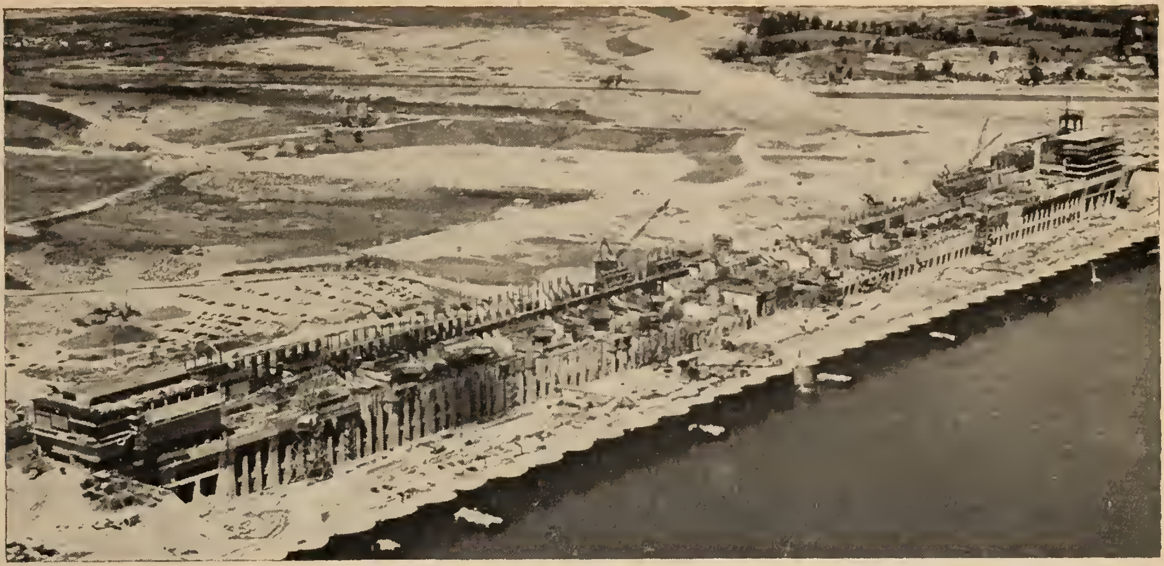


Progress of the seaway produced these typical scenes during 1957

Massena intake (top), as blocks of concrete approached the final grade in August.

Iroquois dam (centre), as 81,000-lb. steel beam was being lowered into forms to be encased in concrete, July.

St. Lambert lock (bottom). At this place lift spans will be installed to allow passage of ships. View from floor of the lock shows Victoria bridge.



St. Lawrence power dam (above)—general view of the structure as it was in August.

Channel improvements (left). Excavation at Point-Three-Points in the foreground was nearing completion in June, and rim dike was being removed.

Iroquois dam (right). Looking upstream at the dam in the foreground, Iroquois lock on Iroquois Point; Toussaints Island and Sparrowhawk Point in the distance; showing progress in June.

Shear, Diagonal Tension, and Bond Stresses in Reinforced Concrete Beams

E. M. Rensaa, M.E.I.C.

Consulting Engineer, Rensaa & Minoss, Edmonton, Alberta

IN A PREVIOUS ARTICLE, "Will Ultimate Strength Design of Reinforced Concrete Beams Simplify Stress Calculation", *(Eng. Jnl.* 1957, June, 805) the author discussed some aspects of bending stresses. This article will deal with certain problems relative to diagonal tension, and bonding of reinforcing steel. The object of these articles is an attempt to contribute to a better understanding of the action of internal forces. The value of such an understanding of fundamental facts can hardly be overestimated. A designer of reinforced concrete structures often encounters problems whose safe and economical solutions cannot be found from examples in textbooks. Deficiency in fundamental understanding may either lead to uneconomical design or to structural failure. There have been several such failures of important structures in North America during the last few years. This is sufficient proof that our knowledge of the fundamental facts is still incomplete.

The present article deals with problems which have come to the forefront recently due to several failures of reinforced concrete building frames in North America. It is especially shear conditions at points of contraflexure which have caused trouble. The author has explained the stress conditions at these points and has shown that our present code provisions are insufficient in many instances to prevent shear failures.

Shear

Concrete has a relatively high shearing strength and true shear very seldom is an initial cause of failure. It is difficult to determine real shearing strength accurately and test results show great variation depending on how successful the investigator has been in reducing accompanying tensile stresses which are nearly impossible to eliminate completely.

The true shear strength can only be obtained when the test specimen is prevented from expansion both perpendicular to the plane of shear and parallel to this plane in a transverse direction. However, such a condition of restraint will seldom if ever be obtainable in practice and that applies particularly to transverse restraint.

Shear tests of rectangular and other concrete specimens have been carried out by Dr. E. Mörsch,[1] and by Bach in Germany, and by Professor E. Suenson[2] in Denmark. The results of these tests indicate a shearing strength of about 3 to 3.6 times the tensile strength of concrete. Assuming the tensile strength of concrete to be one - tenth the compressive strength, we may suppose that the shearing strength under such conditions as prevailed in the tests is about 30 to 36 per cent of the compressive concrete strength.

Other investigators have found much higher percentages of shearing strength. Feret found an average of about 50 per cent, Professor C. M. Spofford obtained from 63 to 104 per cent, and tests at the University of Illinois indicated a percentage of from 44 to 57 of the compressive strength.[3]

It is likely that direct compression or tension perpendicular to the plane of shear will have a great influence on the nominal shear strength.

It would appear that the lower percentages of shearing strength found by Mörsch, Bach, and Suenson are most in line with what might be expected in practice where transverse and longitudinal restraints are either incomplete or lacking. However, since the shearing strength in any case is fairly high, it is only in exceptional cases such as where a heavy concentrated load is acting close to a support that there is any appreciable danger of initial failure by shear. Another, and more usual case, is where a crack caused by diagonal tension has extended so far towards the compression side of the beam that the remaining uncracked concrete has insufficient shearing resistance.

Diagonal Tension

Even though shearing stress alone seldom is a primary cause of failure, the shear combined with bending moment tension may form a resultant diagonal tensile stress which frequently causes initial cracking. This principal stress unless adequately reinforced against very often limits the carrying capacity of a beam. Although shear is thus only a component of the principal stress, it is generally used as a measure of ability of a beam to resist principal tensile stresses. The shear component is only usable for that purpose where the member is not subject to axial tension or compression which will modify the resultant principal stresses. This fact is unfortunately often disregarded and in the case of members subject to axial tension, such an omission may lead to unsafe designs. The adoption of the transverse shear force alone and its corresponding shearing stresses as a basis for the design of web reinforcing has caused a great deal of misunderstanding of the actual condition of internal stresses in reinforced concrete members. It would undoubtedly have been better if, from the beginning, principal stresses had been made the basis for calculation and design of web reinforcing.

Concrete has a comparatively low tensile strength and failure caused by tension in an unreinforced, or lightly reinforced section, will generally be quite sudden without much previous warning. This also applies to failure caused by diagonal tension. In the design of reinforced concrete beams, it is usual to assume that concrete has no tensile strength. When it comes to diagonal tension, the practice is not so uniform. European custom is, in the case of rectangular beams and T-beams, either to reinforce for the complete shear or diagonal tension regardless of unit stresses or to reinforce for the complete shear only where the stress exceeds a certain value. The Canadian reinforced concrete code of 1941 assumed the concrete to take some shear up to a certain limiting stress. For unit stresses above this limit, the complete shear was to be taken by reinforcing. This provision was, unfortunately, not retained in our code of 1953. Our present specifications, which are based on the American Concrete Institute Code of 1951, assume that concrete can carry a certain part of the shear regardless of the magnitude of the shearing stress. That was also the assumption in Europe until abandoned about 30 to 40 years ago. In the U.S.A. this assumption has been upheld tenaciously because tests show that in the case of combined bending and shear the compression zone can actually carry some shear even after the tension zone has cracked. The assumption has the economic advantage that less web reinforcing is required so that most often it is found possible to use stirrups alone where reinforcing for the complete shear would have required the use of a larger size bent-up bars. The use of such bars may require some extra work, so in spite of a much better efficiency they are not generally favoured in North America.

Another misconception is the assumption that the tensile strength of concrete increases in direct proportion to an increase of its compressive strength. Actually the tensile strength increases more slowly. Since we use shear as a measure of diagonal tension, it is incorrect to assume the diagonal tensile strength to increase in proportion to the compressive strength even if the sheering strength increases in such proportion. When concrete is assumed to carry part of the shear, the result of this misconception is often a lowering of the safety factor for diagonal tension when a high strength concrete is used.

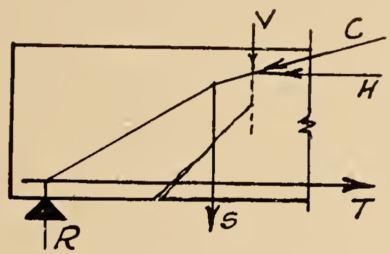


Fig. 1.

A deficient understanding of the necessary conditions for enabling concrete to participate in the carrying of part of the shear has caused unsafe designs to be brought out. Several failures in the U.S.A. caused by insufficient web reinforcing has brought about some strengthening of requirements for such reinforcing in the last revision of the American Concrete Institute code of 1956. There are certain cases, however, such as at points of contraflexure in continuous beams subject also to longitudinal tensile forces, where reinforcing for the complete shear becomes necessary even for comparatively low shearing stresses.

It is undoubtedly true that concrete can carry some shearing stress where it is uncracked. That will be the case for the compression zone of a beam subject to bending. In this uncracked part of the beam, the critical stress, apart from direct compression, will generally be shear and not diagonal tension. The diagonal component from shear is here counteracted by a component from compression and the directions of principal stresses are different from those in the portion of beam below the neutral axis.

Consider the left portion of a beam, Fig. 1, where a crack has formed up to the compression zone. It is clear, that in order to retain equilibrium, the resultant of the horizontal compression and of the shear at the section must intersect the line of action of the resultant of external reaction and loads and the line of action of the reinforcing at the same point. If there is no web reinforcing crossing the crack the whole shear must be taken by the concrete which is in compression, if we disregard the small portion which might be carried by the horizontal steel acting as dowels. It is not likely that interlocking of aggregate across the crack will carry any appreciable portion of the shear. The contention that concrete can carry some shear is, therefore, true for a case where some portion is uncracked. However, it is also clear that as the crack moves upward, the section of concrete which must carry the shear becomes smaller and the unit stress correspondingly higher. We may then get a failure caused by combined shear and direct compression. The function of a well designed web reinforcing should be to hinder a diagonal tension crack from moving so far upwards that the remaining uncracked portion becomes too weak to resist the combined action of shear and compression. Numerous tests have shown that for such cases where shear has any influence on ultimate strength, the carrying capacity will increase with an increase of properly designed web reinforcing. This applies at least until sufficient web reinforcing is provided to carry the complete shear.[4]

Transverse forces and the reaction from a support have some local modifying influence on the principal stresses. Investigators have found that compression from a support increased the principal compressive stress by 38 per cent and decreased the principal tensile stress by 28 per cent.[5] The important part of this stress change is, of course, the beneficial decrease of diagonal tension. Since this decrease only occurs near the support, it is obvious that a shearing stress of the same magnitude is more dangerous farther out on the beam than near a support.

What Type of Web Reinforcing is Most Advantageous

There has been, in the author's opinion, rather too much importance attributed to the question of how big a proportion, if any, of the shear can be assumed to be carried by the concrete. A much more important consideration is that in general, it is undesirable that failure of a beam under maximum loading should be due to shear, diagonal tension or bond. Such failures in practice are often sudden without much previous warning and may therefore be very dangerous. If we decide, as the author thinks we should, that failures of this kind should be avoided, it becomes necessary to determine how much reinforcing is necessary for that purpose. For a non-homogeneous variable material like reinforced concrete, theoretical considerations are not sufficient, and testing becomes the most reliable method

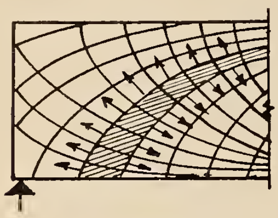

Fig. 2

of solution. A large number of tests have been carried out, particularly in Europe, for the purpose of finding what kind and amount of web reinforcing is best suited for prevention of diagonal tension or shear failures. In general it may be said that a combination of bent-up bars and stirrups is the most efficient arrangement. Bars bent up at approximately 45 degrees angles will most nearly conform with principal tensile stresses near the supports and will get into action earlier than stirrups.[4] Stirrups on the other hand will perform the very useful additional function of reinforcing a beam transversely against additional function of reinforcing a beam transversely against splitting forces caused by tension in the main horizontal reinforcing. It must be recognized, however, that apart from resisting splitting, stirrups can only carry the vertical component of the principal tensile stresses. The horizontal component must be carried by horizontal reinforcing. For a certain crack pattern, this condition may increase the tension in the horizontal reinforcing considerably above what is found from ordinary bending moment calculations. The reasons for this will be explained later.

European practice is generally based on the assumption that shear and diagonal tension should not form the limit for the ultimate strength of a beam. If we adopt this evidently sound principle, it will in many cases necessitate the use of more web reinforcing than what is presently prescribed by our codes. Any design should provide a certain safety factor so that a structure subject to ordinary loading is not on the verge of failure. We have experienced that in the case of web reinforcing such a safety factor is not always present because even structures subjected to dead load alone have fallen down due to lack of shear resistance.

It is desirable that web reinforcing should be placed in such a manner as to be utilized to its greatest possible efficiency. North American specifications state that only three-quarters of the horizontal projection of bent-up bars shall be considered effective as shear reinforcement. The question may then be asked if such a restriction is justified. In order to answer this question it will be useful to consider the stress trajectories of a homogeneous beam, Fig. 2.

Before the formation of cracks, it is reasonable to assume that stresses will form a pattern about the same as in a beam of homogeneous material. The presence of reinforcing steel will of course cause some modification, but probably not to any great

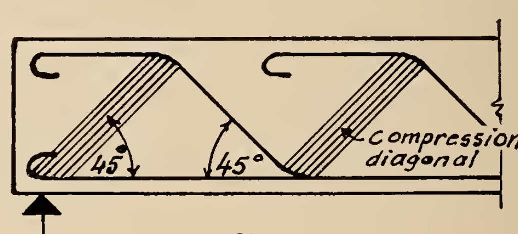

Fig. 3

extent. The first crack will run approximately perpendicular to lines of principal tensile stresses, but of course, somewhat irregular due to local strength variations. The shaded portion between two stress trajectories may be considered as a compression member and the stresses perpendicular thereto must be tensile in order to maintain equilibrium. Since in a reinforced concrete beam we cannot depend on the tensile strength of concrete, we must provide reinforcing to carry the tensile stresses. From these considerations we may assume the combination of concrete compression members and steel tension members to form a structure analogical to a truss. (Originally introduced by Dr. Mörsch). The compression and tension diagonals, indicated in Fig. 3, will form a truss of the Warren type with slope of diagonals at about 45 degrees, corresponding to the direction of principal stresses at the neutral axis. Tests of beams with reinforcing bent up according to this pattern show considerable effectiveness; but does not provide complete protection against formation of diagonal tension cracks. If bent-up bars are spaced farther apart, there will be a certain intermediate portion which would not get sufficient help from them. Both European and American tests have shown that cracks may develop if the horizontal distance between bent-up bars exceeds 1.25 to 1.5 times the effective depth.[6] In the continental countries of Europe it is, therefore, considered safe to limit the length between bent-up bars to a distance equal to the effective depth. British custom seems to allow a somewhat bigger spacing corresponding to Fig. 4. It would, in any case, be safe enough to consider the horizontal projection of a bar bent up at 45 degrees as being effective. Specifying an effective limit of three-quarters of the projection may be justified near a support for bars bent up at 30 degrees or less with the horizontal, but certainly not for the more usual bending up at 45 degrees. The short distance on which bent-up bars are speci-

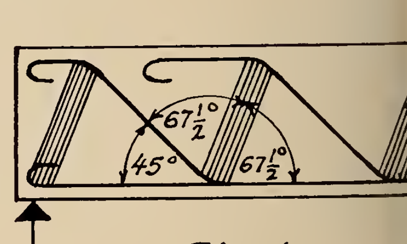

Fig. 4

fied to be effective greatly reduces their economic usefulness. This is, undoubtedly, one reason why bent-up bars are not used as shear reinforcing to the same extent in North America as in Europe. Even if it is found here that the use of stirrups is cheaper that is not a good reason for discriminating against bent-up bars in a manner contrary to facts.

Shear at Points of Contraflexure

In the case of simply supported beams there may be a basis for th assumption that concrete will tak some part of the shear and the web reinforcing the rest. How the actual distribution will be between such differently arranged structural parts is not easy to determine. Where material of different kinds is used to form a structure, it is always a possibility that one kind may fail before the other gets into action. Steel will stand overstressing to a considerable extent and may generally be depended on to act together with concrete as long as the concrete acts. If, on the other hand, the concrete should fail first and the steel then get into action, the whole load would, in such a case, have to be carried by the steel.

The above considerations make it plain that concrete can only be depended on to carry stresses as long as it has not cracked. If a crack has formed that part is no longer able to take either tension or shear, and it is only the uncracked part which is available for carrying stresses. It has been stated that in a beam, subject to bending in addition to shear, the concrete in compression will generally also be able to carry some shear because this part is uncracked. If, however, there is no bending, a crack formed either by the diagonal component of vertical shear alone or by a combination of shear and direct tension, will likely cause this crack to extend completely through the section. The whole shear and direct tension will then have to be carried by the steel without any help from the concrete. If the steel is not strong enough for that purpose, the result will be complete failure. Such a condition is encountered at a point of contraflexure of a continuous beam where there is no bending but only transverse shear. There may be in addition either direct tension or compression acting in the longitudinal direction of the beam. If the direct load is compression, the diagonal tension component will be smaller, but if there is longitudinal tension, the combined diagonal tension component will be greater with a correspondingly decreased factor of safety.

The assumption of interaction of concrete and web reinforcing is evidently quite erroneous for conditions where there is no bending such as at points of contraflexure in a continuous beam. There is little reason why there should only be a crack through part of the concrete at such points. We shall have to expect either no crack or a crack cutting completely through the member. Where there is no crack, the concrete will take practically the complete shear and, if a crack goes through the member completely, all the shear will have to be taken by the reinforcing steel. The web steel will take most of the shear and will only get some small help from the horizontal steel acting as dowels. Any appreciable help from interlocking of concrete aggregates across a crack is hardly to be expected.[7]

There has been an exaggerated belief in the importance of dowel action to carry some part of the shear. To quote from an American textbook on reinforced concrete, "If there is steel passing through the section, the resistance to vertical shear is much increased, since the steel must also be sliced off to produce failure. Therefore, a maximum shear intensity of 0.06 f'_c is allowed for ordinary anchorage. If there is steel at both top and bottom, there is still greater resistance to shear, and even higher allowable values may be used for the combined action of steel and concrete."

It would indeed be nice if both concrete and horizontal bars would act in combination until the steel was "sliced off". The actual condition, unfortunately, is not so favourable. What happens is that the transverse pressure from the longitudinal steel will split the concrete, so that the bars are pulled away from the main body of beam without being sliced off. Splitting will start at the main crack and transfer the vertical shear to the nearest stirrup. One stirrup alone, or even one on each side of the main crack at top and bottom, may not be sufficient to carry the shear. The result will likely be progressive tearing off of stirrups as split or splits develop. This condition is illustrated in the report of failure of roof beams of U.S.A. Army warehouses.[8]

The ordinary formula for shear in a reinforced concrete beam $v=V/b.jd$ is based on the assumption that the concrete below the neutral axis is unable to take tension but may take shear. This assumption is evidently quite erroneous. No shear can, of course, be transmitted across an open crack and it is unlikely that any considerable shear can be transmitted parallel to the crack by interlocking of concrete aggregates. The part of shear not carried by the web reinforcing must therefore be carried by whatever part of the concrete section, if any, remains uncracked. The shear diagram would then be quite different from that obtained by the usual formula. That this formula does not give true values but only relative ones has been known for many years.[9] The formula has, however, been used for such a long time that many engineers believe that it was intended to give exact figures.

In spite of the fact that only relative shear values are obtained by the formula, it still is useful as a standard of comparison. This usefulness, however, is limited to conditions which in practice would give the same factors of safety for all similar relative shear values. The allowable shear is based on tests of beams simply supported where all sections are subject to bending and shear. If the compressive bending stress is non existent or springs from one side of the beam to the other at a section, we should not expect to obtain the same test result as for a simple beam. Under such circumstances the relative figures obtained by the usual shear formula loses its value as a measure of comparison. That the formula does not apply at points of contraflexure will be apparent from the following considerations.

The distance jd in the formula is measured from the centre of tension reinforcing to the centroid of the compressive concrete stress. There is no neutral horizontal plane with cracked tension concrete on one side and concrete in compression on the other side. The term jd, therefore, has no definite value which can be substituted into the formula. Furthermore, since there is no bending stress at either top or bottom of beam and the section is uncracked, the shear stress should be calculated for this condition which will give a different shearing stress from what is obtained by the usual formula for shear in reinforced concrete beams. If there is a crack, however, there is no way to determine where it will start or end since, generally speaking, there is no concrete in compression to stop a crack after it has started to develop. Since a partially cracked section is weaker than one uncracked, it seems most likely that the cracking when first started would continue completely through the beam. After this has taken place, the usual shear stress formula is even more useless than for an uncracked section because the concrete cannot transfer any shear from one section to the other along a crack.

If we want to find what the actual shearing stresses are at and near a point of contraflexure before any cracking has taken place, it is necessary to use the formula for homogeneous sections. This formula will give a unit maximum shear stress of $v = 1.5V/bh$ at the neutral plane of the section and the stress will decrease parabolically to zero at top and bottom of the beam. The presence of reinforcing steel may modify the stress to some extent. Investigations by Mörsch have thus indicated a coefficient of 1.62 instead of 1.5 where the bending moment is very low and

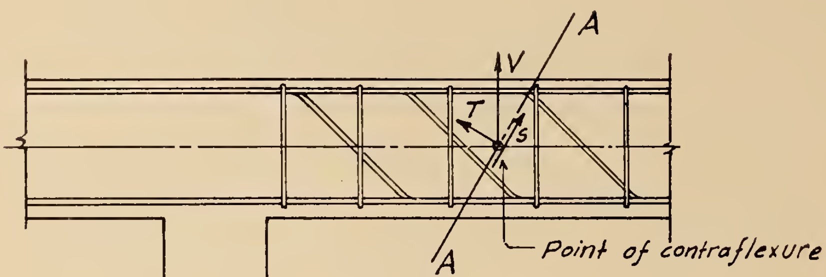

Fig. 5

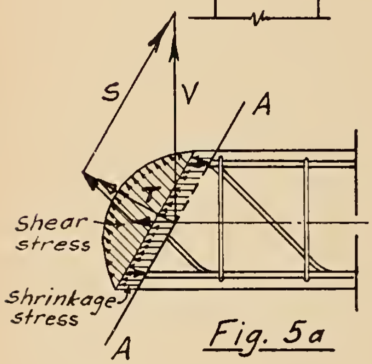

Fig. 5a

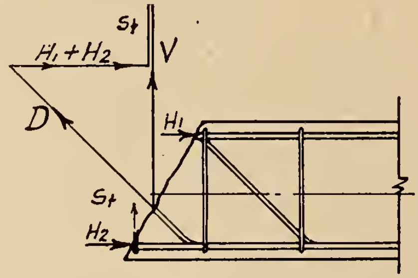

Fig. 5b

the concrete uncracked.[10] This small difference, which may in itself be variable, is hardly of any great importance. The important point is that the maximum principal tensile stress at points of contraflexure is not at the bottom or the top of a beam but rather at the centroid of the section. Furthermore, since the weak section for principal stresses is not vertical but inclined, there will be compressive stresses induced from bending both at top and bottom where the incline reaches the top and bottom surfaces. This again increases the tensile stress at the centroid of the section. However, where a crack will first start; at top, bottom or centre will likely depend on local weaknesses in the concrete.

If a through crack forms at a point of contraflexure neither the shear formula for homogeneous beams nor the usual shear formula for reinforced concrete will apply because there will be no shearing strength of the concrete left for transfer of shear across the crack. In a case like this the structural stability of the member depends either on the ability of the concrete alone to take the complete diagonal tensile stress or if the concrete cracks, the complete shear and longitudinal force must be taken by the reinforcing. Putting in web reinforcing for only two-thirds of the shear, for instance, is equivalent to expecting web reinforcing to carry one third extra stress after it gets into action due to formation of a through crack.

It is true that the positive and negative bending moments will increase relatively fast from a point of contraflexure. However, if we assume the weak plane in diagonal tension to be at 45 degrees (and it will be steeper in most cases), the distance available for getting concrete into compression will, at the most, be only half the depth of beam on each side of the contraflexure point. Since in the majority of cases there will be initial tension in the concrete due to restrained shrinkage, we cannot safely figure on any portion of concrete being in compression along the potential diagonal crack line. Furthermore, any increase in compression at both top and bottom of beam must create a corresponding additional tension on the centre portion so the average net result along the diagonal line will likely be zero.

The horizontal inward reaction in a rigid frame will be helpful, particularly in the end spans to put some horizontal compressive stresses intc the beam. Internal columns, if fairl rigid, will decrease this compression Interior spans will therefore, and be cause of axial shortening of the bean due to shrinkage and temperature de creases, be in the worst position ever if the shearing stresses are the same

It is hardly logical to assume tha T-beams require less web reinforcin than rectangular beams at points o contraflexure or at any other point for that matter. The only conceivabl benefit of the slab in a simple bean is that the slab in most cases reduce the compressive stresses below th allowable and that the slab may exer lateral restraint which increases th shearing strength. This latter condi tion only applies on one side at point of contraflexure. Any appreciable di rect help from the slab to carry th beam shear can hardly be counte on. The slab reinforcing running pa allel to the beam is thought to be help in resisting longitudinal force Such a help should not be require if the beam has been properly desigr ed. There are cases such as with sla and girder bridges, where the prac tice of cutting down on web reinforc ing in accordance with the A.C. code would appear to be most un justified and dangerous.

There is hardly any doubt that th most suitable web reinforcing at poin of contraflexure are the bent-up bar A crack at this position may be steep as 60 degreees and perhap even steeper due to the presence longitudinal forces.[11] In such case the shear distance adequately cove ed by a stirrup may be rather shor Bent-up bars will cover a greater di tance and will not be liable to de truction one by one to the same e tent as stirrups, which may be stri ped off progressively.

There is generally some initial i ternal stress in a beam caused l shrinkage. For a section containi reinforcing, this will cause compre sion in the steel and tension in t reinforcing. Assuming, for instance, shrinkage coefficient for unreinforc concrete of 0.0004,

$n = 10 \qquad E_s = 29{,}000{,}000 \qquad p = 1$

then

$$f_c = 0.0004 \times \frac{29{,}000{,}000}{10}$$

$$\times \frac{10 \times 0.01}{1 + 10 \times 0.01} = 105 \text{ p.s.i. tensi}$$

$$_s = \frac{105}{0.01} = 10{,}500 \text{ p.s.i. compress}$$

The coefficient of shrinkage here used is rather smaller than may be expected for indoor conditions and completely dried out concrete. On the other hand, there will be a plastic flow of concrete which will reduce the shrinkage deformation somewhat.

The length of beam will also decrease in accordance with the deformation caused by compressive steel stresses. If the supports are of a kind which will restrain such longitudinal deformation, the result will be a further increase in concrete tension. From the above example it is clear that the diagonal component from shrinkage will not be negligible, and when it is added on to the component from transverse shear, we might get into a situation where the tensile strength of concrete is overcome even if the nominal shear stress is not unduly high.

In summing up, let us now consider the combined stress condition at a point of contraflexure, Fig. 5. We will at first assume that there is no crack and that section A-A represents a potential plane of weakness perpendicular to the principal tensile resultant stress. The stress distribution on the portion of the beam to the right would then be about as indicated on Fig. 5a. If a crack now forms there must then be a redistribution of stresses if equilibrium is to be maintained since the shear component S will now be destroyed (assuming no dowel action). This new stress condition is shown in Fig. 5b. It is clear that the tension component T in Fig. 5a is causing the crack and not the shear component S, since concrete is relatively strong in shear.

be mandatory that a beam, when loaded to its ultimate capacity, should not fail in bond.

There is some difference of opinion of what the actual tension in a bar is near a beam support. It has been found by tests that when some of the bars are bent up, the remaining straight bars will have much less tension than would be indicated by the usual shear theory. Some European concrete specifications allow the bond stress to be calculated with inclusion of both the straight and the bent-up bars. German specifications allow the halving of the shear force for the portion of shear taken by bent-up bars, seems to be an additional reason for encouraging the use of bent-up bars.

The ordinary theory used for calculating bond stresses assumes two transverse sections one unit length apart. The bond stress will then be proportional to the difference in bar tension at the two sections. This assumption does not hold in practice, because cracks at critical points for bond and shear are not generally formed in a 90 degree direction to the neutral axis. It should also be understood that transverse stirrups can only take the vertical component of the shearing stress. The horizontal com-

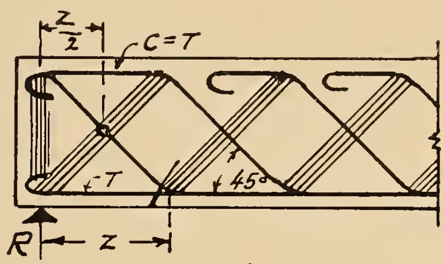

Fig. 6

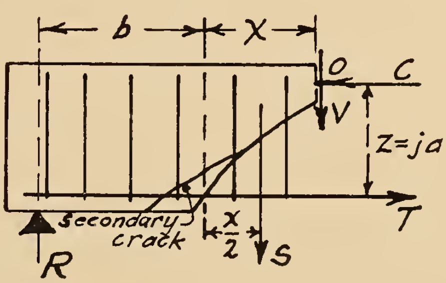

Fig. 7

Bond

The general acceptance of the improved type of deformed reinforcing bars has made possible a considerable increase in allowable bond stress. However, the increased bond stress will also increase the tendency of splitting. Allowable bond stresses have been determined on the basis of pull out tests where the concrete specimens were such that splitting was not too critical a factor. There can be little doubt that where splitting is prevented, the bond stresses allowed by the codes are safe. Reinforcing steel is in most cases, however, placed near the surface of a concrete member and we cannot, therefore, always expect to have a condition where it is safe to utilize the full allowable bond stress without using some other means such as stirrups to strengthen the section. Just as in the case of shear, it should

bars. This provision is based on tests carried out by Dr. Mörsch, who explains the reason for this reduction as follows: In Fig. 6 with moment about the intersection of the first tension and compression diagonals:

$$T = \frac{QZ/2}{Z} = \frac{Q}{2} \quad \text{and}$$

$$u = T / \Sigma O \quad Z = Q/2 \, . \, \Sigma O \, . \, Z$$

While a student at the University of Manitoba, the author participated in a beam test where the bond stress calculated for the straight bottom bars only appeared to be unreasonably high and he did not understand the reason for this until many years later. The fact that bent-up bars, besides being most effective as shear reinforcing, also decrease the bond stress in the remaining straight bars, seems to be an additional reason for encouraging the use of bent-up bars.

ponent must be taken by the horizontal reinforcing steel and will add to the tension in this steel over and above what is caused by bending alone. This fact has generally been overlooked and little attempt has been made to evaluate the additional tension in the main reinforcing. An analysis of a particular case of this problem was published by Dr. E. Rausch, and discussed by other German engineers in *Der Bau*, No. 1, 2 and 22 for 1949 and No. 5 for 1950. Rausch's solution is based on a crack forming at a 45 degree angle and that the complete shear is taken by the stirrups.[12] However, cracks do not always form at 45 degree angles and American codes allow some part of the shear to be taken by the uncracked concrete. A more general theory of which the Rausch formula is only a special case has, therefore, been worked out by the author.

In Fig. 7, assume a crack at an arbitrary angle. "S" is an arbitrary proportion of shear taken by the stirrups, while the rest is taken by the uncracked concrete in the compression zone at "O". Let us disregard the weight of the beam end itself, although it would be no difficulty to include this in the analysis.

With Moment about "O" we have:

$$R(b + x) - T \, . \, z - S \, . \, x/2 = 0$$

or

$$T = R \, . \, b/z + R \, . \, x/z - S \, . \, x/2 \, . \, z$$

from which

$$T = M_b/z + R \, . \, x/z - S \, . \, x/2 \, . \, z$$

For x = 0, that is, the crack being vertical, the two last terms of the equation disappear and:

$$T = M_b/z$$

which is in accordance with the accepted bending moment theory. There will be no excess bar tension for that case.

For x = z and S = R, that is, the crack being at 45 degrees and the complete shear is taken by the stirrups, we have:

$$T = M_b/z + R - R/2 = M_b/z + R/2$$

which is the Rausch formula.

If all the shear is taken by the concrete at "0", that is, there are no stirrups, and we assume the crack at 45 degrees or $x = z$, then:

$$T = M_b/z + R$$

It is seen that without stirrups, the excess bar tension is twice that given by the Rausch formula.

If x is greater than z, which may well happen if the top of a secondary crack joins the primary crack, and there are no stirrups, then, looking at the general formula, it follows that the excess stress may become much greater than the magnitude of shear "R". The formula can, of course, also be easily solved for any assumed proportion of shear taken by stirrups.

If we have no stirrups, it is evident from simple statics that the tension

$T = M_o/z$ will be constant regardless

of what the downward slope from point 0 is. If the slope becomes flatter, the difference between the stress in the bar at the crack, and just to the left of the crack, will become increasingly greater.

The apparent increase in bar tension where no stirrups are used, or only a part of the shear taken by stirrups, would indicate that it is desirable to use an ample amount of shear reinforcing.

It is rather disturbing that the above deduction plays more or less havoc with the accepted theory of bond stress as given in the text-books on reinforced concrete. Instead of a differential stress corresponding to the difference in moment tension at two points a unit length apart, we may have a unit differential stress near a crack corresponding to sections as far apart as the depth of the beam itself and even more than that.

Another conclusion which may be drawn from the analysis, is that caution should be used not to cut bars too short when stopping them beyond a point of assumed zero bending moment. On the whole, the bars may carry more stress near their terminal ends than has hitherto been assumed.

When a crack has formed, it is clear that bond stresses near the crack on both sides of it will be much higher than obtained from the usual formula.

This high bond stress together with dowel action will frequently cause formation of a secondary crack which may join the original crack higher up the beam. This may result in a practically loose piece of concrete being formed. If this should happen, the distance x, in Fig. 7 will again increase with a corresponding increase in bar tension.

Splitting

The bond or anchorage stress in the surrounding concrete caused by differential longitudinal bar tension will not only have a parallel component but also a stress component in the transverse direction. For smooth bars it is mostly near the terminal hook that such transverse stresses are high. It is quite a different case with a deformed bar which has anchorage along its whole length. The differential force must here be taken up at all points, and there will be little or no relief from sliding. The longitudinal differential tension in such a bar will have a considerable transverse component which causes a tendency of splitting of the concrete surrounding a bar.

It is not only the anchorage stress from a bar which may cause splitting, but there are also other factors which may have some influence. There can hardly be much doubt that shrinkage, shear, duration of loading and frequent load changes will also have considerable influences. How the bars are terminated may be of further importance.

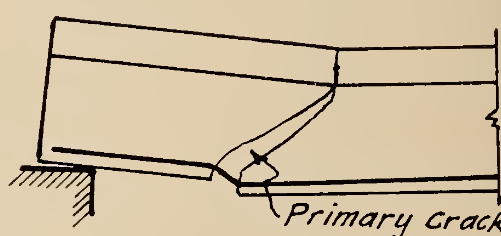

Fig. 8

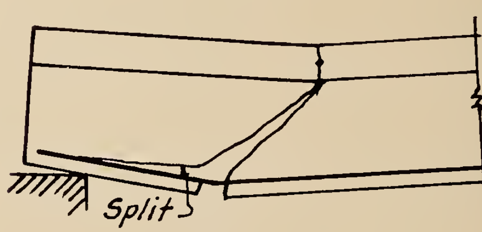

Fig. 9

Splitting may in many instances be caused by a combination of several influences, and one of these is shrinkage. It is clear that when a concrete body dries out, the shrinkage shortening per unit of length will be about the same in all directions. The transverse shrinkage will, evidently, tight-en the grip of the surrounding concrete on the bar with a corresponding transverse tension in the concrete. This transverse tension will then add to the component caused by direct bar tension. It is further clear that the larger the bar diameter is, the greater will be the transverse shrinkage tension. In fact, there is some similarity in this respect to the tension in the wall of a pipe under fluid pressure which will increase proportionally to the diameter. If a hair crack is formed first, it is also likely to be bigger and more dangerous for large diameter bars than for smaller sizes. When relatively large bars (or small effective bar spacings) are used in beam stems, as is not uncommon particularly in precast work, it would not be surprising if shrinkage alone could form fine, and perhaps at first, invisible cracks even before the member was placed. This condition is, of course, most likely to occur if the concrete is allowed to dry out before attaining sufficient tensile strength. The author thinks that the influence of shrinkage on splitting strength should be further investigated.

A second condition which will add to the transverse stresses, is dowel action of the main reinforcing at a crack. Figures 8 an 9 will indicate what happens when a crack has formed. The rotation of the parts on each side of the crack will create transverse tension in the concrete with a tendency to form a split along the bar, such as indicated. The author has seen such splits form both in tests in which he has participated and in pictures showing crack patterns of beam tests by others. The obvious means to minimize the splitting effect caused by diagonal cracking is to use more stirrups. It is true that a support reaction will act against the horizontal splitting stress. When the length of support is short however, the remaining uncracked portion at and near the support may not provide sufficient anchoring length. This transverse reaction force is not present at a point of contraflexure. For this reason a shear of equal intensity at such a point is more likely to cause failure than the same shear at the freely supported end of a beam.

A third and fourth condition which may influence the splitting strength are loadings of long duration and repetitive loadings. It is reasonable to assume that splitting strength under such conditions would decrease at least as much as compressive strength does. Since splitting resistance depends mostly on tensile concrete strength, it is even possible that the relative strength would be less for splitting. The author does not know if these conditions have been investigated.

Investigations in the U.S.A. indicate that deformed bars of larger cross section do not have the same bond value as smaller bars. German investigations with smooth bars have shown that for ordinary conditions and bar spacings bond stresses do not become critical for bar diameters less than one inch.

The splitting question is now receiving much attention, partly due to some failures of structures whose design complied with the A.C.I. building code. Interesting and instructive tests have been carried out at the University of Texas.[13] These tests, however, do not take into consideration the effects of shrinkage, loading of long duration, and repetitive loadings. The influence of dowel action may not have been adequately considered in the evaluation of the test results. More testing to determine the influence and magnitude of these secondary effects is certainly desirable.

Termination of Bars on Tension Side

At the beginning of the use of reinforced concrete in Europe, it was customary to terminate bars with hooks on the tension side of a beam when such a bar was not required for moment tension. The practice seemed to be justified by a certain analogy to the termination of a cover plate on a steel girder. It was brought out during extensive German tests that long before the ultimate loads were reached, large cracks would usually form at the end of the hooks where there would be a sudden change of stresses. Based on these findings, the termination of larger bars in a tension zone has either been forbidden by European codes or is considered to be very poor practice. It is rather surprising that such construction seems to be increasingly acceptable in this country. Omission of hooks is not likely to eliminate cracking at terminal ends of bars completely. Pictures of tests of lapped bar splices may be indicative in that respect.[14]

Conclusions

The discussion in this article would indicate that a general strengthening of building code provisions for web reinforcing is necessary. It is also shown that anchorage stresses in bars may be much greater than obtained by means of the usual bending moment theory. An inescapable conclusion, based on the material and information available, is that our reinforced concrete building code is in an immediate need of revision as far as specifications for shear reinforcing is concerned.

Selection and Training of Second Line Executives

Report of a panel discussion at the annual meeting of The Engineering Institute of Canada, Banff, Alta., June, 1957.

Chairman: B. A. C. Hills, M.E.I.C., President, Urwick Currie Limited, Montreal.

The Panel: A. L. Bishop, M.E.I.C., President, Consumers Gas Ltd., Toronto.

R. A. Emerson, M.E.I.C., Vice-President Operations & Maintenance, Canadian Pacific Railways.

D. M. Stephens, M.E.I.C., Chairman and General Manager, Manitoba Hydro-Electric Board.

W. H. Young, M.E.I.C., Manager, Chemical Metallurgical Division, Sherritt Gordon Mines Limited, Fort Saskatchewan.

THE CHAIRMAN pointed out that the members of the panel would be considering particularly second-line executives, that is, men who have gone from functional management (management of a particular functional department such as engineering, accounting, and so on) to *general* management, or whose next step upwards will be into general management. The step was a particularly difficult one because it called for different techniques, a different approach to tackling problems. For example, an engineer must forget his production bias and think in terms of the overall objectives of the enterprise. As a general manager he must co-ordinate subordinates who talk about sales, finance, production, accounting, and so forth, whose language is peculiar to the various professions involved and whose viewpoints are strongly biased and sharply conflicting because of the differing roles that each of them play in the organization.

The panel were then asked their views on the following:—Bearing in mind that they were considering men who were to be moved from functional to general management as previously defined, what were the qualifications, the abilities and other criteria which should be the guiding considerations in selecting second-line executives. All the panelists stressed the need for leadership and initiative. Mr. Young considered that technical qualifications were not important; Mr. Bishop disagreed and also stressed the "trustee" nature of the job Mr. Emerson pointed out that the general manager's job was not always palatable; and Mr. Stephens looked for success in previous posts as a necessary qualification; he also required ability to analyze problems.

The second question was, "How many of these qualifications and abilities can be taught and what form of training would achieve this? At what period in the potential general manager's career should this training be given?" There was unanimous agreement that training for general management was a continuous process which began on the first day a man entered industry; Mr. Emerson thought that even leadership could be taught? he favoured transfer from line to staff positions periodically at all levels so as to give the man experience in handling men of other professions as well as broadening his outlook; special assignments to "trainees" were also important from an education viewpoint.

Mr. Stephens stressed the importance of "charting the course" of each potential manager; he described the procedure adopted in his own company and said that the company *must* provide opportunities for learning. He considered that the technical side was one that required most training.

Mr. Bishop endorsed the point made relative to planning the progress, and thought that the "assistant to—" position served a very good means of training a general manager. He instanced conferences, seminars at universities, night schools and management consultants as sources of learning about management. He thought the public relations aspect of the general manager's job was important and referred to the advantage of a pleasant voice in this respect.

Mr. Young believed that training could be given in practically every requirement of a general manager; he also thought that transferring a man to other departments so that he took on a different kind of work was essential training. He warned of the danger of selecting a man for promotion before he was ready for it, and said that this was particularly to be guarded against in the smaller companies.

The panel was then asked to say who should be responsible for management training—the company, the individual, or both? Who should in fact pay? There was unanimous opinion that both should be responsible, but thoughts were divided as to who should pay. Mr. Emerson thought the company should pay, but Mr. Bishop spoke of the psychological advantages attached to the individual paying for his own education. Mr. Emerson pointed out that the individual was still required to show initiative regarding his own training, and the company continued to support financially the man's aims only so long as he took full advantage of the opportunities given to him. Mr. Young warned against the in-

DISCUSSION

of Technical Papers and Other Articles

F. M. Kraus, M.E.I.C. *

Thanks are due to E. M. Rensaa, author of the article on Ultimate Strength Design. It is obvious that the concepts of reinforced concrete have been studied thoroughly, and from different viewpoints.

It is to be expected that a change in design methods will meet with criticism or resistance as ideas and methods in current use have become well-entrenched in the minds of many engineers. It might therefore be opportune to take the side of the new trend in order to stimulate thought and clear the issue.

It is conceded by the author that ultimate strength forms the basis of the plain section calculations as much as it does for the ultimate strength method; it is also conceded, in the same article, that Hooke's Law in reality does not apply.

As long as the discussion is confined to bending, as set forth, the concept is plain, and can be illustrated in the light of the general theory of elasticity of homogeneous materials, allowing this for the purpose of discussion to stand for concrete within limits of elastic behaviour and working loads. If this is accepted, then the main practical implication of the ultimate strength design method seems to lie in some saving of steel, yielding more "underreinforced beams", which seem desirable, as more economical and giving warning of collapse.

Furthermore, the ultimate design does not apply to the whole length of beam, frame or arch, but only to the section or part subject to maximum bending moments.

Now, if this section of maximum strain is designed in accordance with a parabolic or similar strain, i.e., stress distribution, then firstly it will be covered by a safety factor, and what is adequate for ultimate strength should be satisfactory for reduced strain and stress distribution. Secondly, such stress and strain is localized, and is therefore subject to provisions dealing with increased resistance of the concrete under lateral confinement.

In view of the uncertain values of the elasticity modulus and the change with age of the concrete, the character of loading, etc., it seems justifiable to part with the concept of its use for strength design. It may also be noticed that plane sections are never really planes in any material under any loading, regardless of what slenderness ratio or shape of element is used, and are probably least so in concrete.

I have had an opportunity to carry out fairly extensive testing on various test beams, and the deformation of cross sections, where detectable, conformed closely to those outlining curvatures of 'plane sections" in the text dealing with elastic stability or theory of elasticity. I might add that some of those test beams were made of laminated timber and concrete — two materials which are not isotropes in fact.

I subcribe to the statement that ordinary textbooks do not cover the subject adequately. But such textbooks are basic education only and as many engineers know, there is a giant step between theory and practice. There is ample evidence, however, that successful and thorough testing has been carried out, and that the theory of ultimate strength is not new at all. The information is available to the professional at any time.

As far as the T-beam is concerned, a very simple device, applicable as an approximation has (probably unnoticed) been using ultimate design practices, and with success. If the lever arm between centre of gravity of steel to centre of gravity of slab is applied to bending, justice is done to the ultimate strength design. The uncertain distribution of strain between the beam web and the slab and also in the slab itself on both sides of the beam is, in effect, much more serious than the steel reduction resulting from the simplified formula approximating the ultimate strength method.

Balanced beams, where steel and concrete are expected to fail at approximately the same load, are likely to cause trouble no matter how they are designed, as these structures may tend to be of the shallow type and the static deflection could increase several times due to creep, plastic flow, or cracking.

The concrete mass and its inherent shortcomings of fabrication and placing are covered by safety factors to a certain extent, and to strain readjustment for the balance. Where concrete strength in the structure is inadequate it will be so as much for beams designed by conservative methods as for the ultimate strength design.

In the design of structures, assumptions of span, fixity, loading and support are very often made which are necessarily at variance with the natural behaviour of the design grid. Would it not be illusory to dwell on pure theory only when this same reasoning is incapable, under practical application, of encompassing the intricate natural balance of the structure? Is it therefore reasonable to continue the use of a method of design which has been recognized to be academic at the very outset of its application, or is it not better to use a method which we have found to be closer to what really happens in a

*Consulting Engineer, Montreal.

structure. It seems that it would be a forward step to recognize the behaviour of the materials we are using, and act accordingly.

Elmer Brooker, Jr.E.I.C. †

The writer has read with interest Mr. Rensaa's discussion on ultimate design. His conclusion that there is not much benefit to be gained by using ultimate design methods for normal sized building members is correct. But only because the design percentage of steel allowed by the present triangular stress block method cannot be exceeded without causing an undesireable simultaneous or compression failure under ultimate load conditions. It can readily be shown that if a simultaneous failure is designed for by ultimate design methods the critical percentage of steel will lie in the neighborhood of 4.0%. This percentage of steel is not easily placed in concrete beams of usual sizes. For a tension failure in which the reinforcing steel yields when the extreme fiber stress of the concrete reaches its maximum value the critical percentage of steel is about 1.2% The latter percentage of steel may be readily placed and is very nearly the same as the triangular method allows. From this aspect the triangular method is therefore acceptable for ordinary construction.

Actually, ultimate design could afford a considerable saving in heavily stressed members by a reduction in dead load, if undesireable deflections did not result. In ordinary construction the beam sizes cannot be reduced without causing excess deflections.

The following arguments speak very strongly for ultimate design methods. Concentrically loaded columns are esentially designed by ultimate design methods now, and the factor of safety against failure in these columns is in the range of 3.5 to 4.5 depending upon the percentage of steel and strength of concrete used. There is evidence that the ultimate shear stress may be as low as 0.3 f'_c; however, the present Canadian Building Code allows an allowable shear of 0.3 f'_c before web reinforcing is required. Therefore it is apparent that the present Building Code has a varying factor of safety. By the use of ultimate design methods in research the factor of safety and mode of failure may be investigated and a sound basis for future codes established. It is desirable that we have a consistent factor against failure in all calculations whether it is compression, flexure, shear or bond.

Ultimate design calculations do, at present, have a place in practice. In prestressed concrete members enough steel may be placed, due to high allowable steel working stresses, to cause a compression failure. In this case ultimate design is practical and convenient. There are other special cases where ultimate design can also be useful. Although its use is not recommended for most ordinary work, research based on ultimate design provides a better understanding of the true behaviour and factor of safety of regularly designed reinforced concrete members.

Ultimate design calculations can be as simple as triangular methods. For example, C. S. Whitney's method as prescribed in the latest A.C.I. Building Code. A more accurate but just as convenient method is the use of V. P. Jensen's stress block and Hognestad's ultimate strain of 0.38%. This method is used in research by Dr. R. N. McManus at the University of Alberta. It is the writer's opinion that a sound discussion of ultimate design methods should include its usefulness in (1) understanding the various modes of flexural failure (2) investigating compression, shear, bond and other types of failure, and (3) forming a sound basis for the selection of working stresses and factors of safety.

Author's Reply

The author is grateful to Messrs. F. M. Kraus and Elmer Brooker for their discussions. Since these discussions deal mostly with general principles, a reply common to both discussions on this basis may be made. The author thinks that the following conditions should be considered before our present design method is abandoned:

A properly designed structure should not fail and a sufficiently large safety factor should be used to insure against such an occurance. This safety factor is generally based on tests of strength of the kind of materials and combinations of materials which are to be used in the structure. The actual stress variations in the materials will then be those corresponding to the range of loading from a minimum to a maximum. It is therefore incorrect to say that some other stress distribution corresponding to the more remote overload condition to absolute failure is more in accordance with actual facts.

Another question to be answered is what should be considered a failure. Is the failure a condition when some part of the structure has been overloaded to such an extent that permanent damage, impairing the further usefulness, has been caused even though the structure is still standing. Or is the ultimate strength to be that which corresponds to a collapse. It is presumably on basis of the latter assumption that some writers advocate the use of "Plastic Hinges" in reinforced concrete structures. The author thinks that a designer will be well advised to avoid a structural condition where either the steel has been stressed beyond its yield point with a resulting visible crack or where concrete has been stressed so as to crush or spall. It is very unlikely that an owner will be impressed or satisfied with any kind of an explanation justifying cracks or spalling even if the structure does not fall down. Beside the not unimportant question of psychological effect, we also have to consider the effect on durability, and cracks may be very detrimental to this in many instances.

If we accept the principle that no kind of damage should be visible, we shall have to make sure that such will not occur even with some overloading. We are then back to the old principle that there must be a safety factor applicable to conditions of use and that a single alternative safety factor relating to ultimate collapse only is not generally sufficient.

If the ratio between damage strength and ultimate strength had been constant or nearly so for different structural elements, a common safety factor relating to both conditions would have been quite convenient. That, unfortunately, is not the case in a number of instances. As an example, columns may be mentioned. The spirally reinforced

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

NEW SOURCES OF PROPULSION ENERGY

H. Harvey *S.A.E. Journal*, v. 65, n. 9. Aug. 1957

Aircraft and missiles, which seem to be becoming one and the same thing, have a limitation on their performance based on the amount of energy in the form of fuel that can be carried. Greater speed and greater range are required for the future and for these reasons the hunt for new sources of energy is on. For over half a century petroleum has been the source of energy for the aeroplane. As convenient, clean and economic form of energy it has had no equal, and its versatility has made it the ideal fuel for all types of engines, spark ignition, compression ignition, turbine and ramjet. It will be difficult, if not impossible, to find any fuel that can compete with it on a cost per pound basis.

However, aircraft and missile designers are now looking for fuels which surpass existing forms both on an energy per pound and an energy per gallon basis since weight and volume limitations are always critical factors. Various chemical compounds are being investigated as fuels for air-breathing engines or as propellants for rocket type power plants, without cost being the determining factor.

On a basis of heat release per unit weight hydrogen is by far the outstanding fuel, having almost three times as much available energy per pound as kerosene or gasoline. Unfortunately, there are insuperable handling problems. Hydrogen must be compressed if it is to be stored and transported as a fuel, and massive equipment for containing high pressures is required. Even if a practical solution to mechanical difficulties could be found the results would be disappointing because the heat content per unit volume is very low. At 2000 psia. and 60F. the density of hydrogen is 0.093 lb. per gal (U.S.) and the heat content 4780 B.t.u. per gal. Roughly, this is about a 17 times larger fuel volume than presently required by aircraft using gasoline.

Although hydrogen by itself is not a practical high energy fuel it shows promise as a main component. Considering aviation gasoline and taking a typical eight-carbon-atom molecule, about 40 per cent of its energy can be attributed to hydrogen and 60 per cent to the carbon content. The carbon, however, contributes 84 per cent of the weight. One approach to producing a high energy fuel would be to replace the carbon atoms in the hydrocarbon molecule with an element having a higher heat release per unit weight than carbon. Beryllium, an alkaline earth, has a B.t.u. content per pound higher than all elements except hydrogen. Unfortunately, it does not combine readily with hydrogen, it is quite scarce and it forms compounds which are toxic. On the other hand, boron, a nonmetal, and lithium, an alkali metal, form hydrogen compounds or hydrides which show promise and are presently under investigation.

Boron

Boron is a stable substance and does not burn below 700C. At the same time, it is extremely abrasive and would probably have to be burned in an afterburner or ramjet where it would not damage turbine blades. Probably it would have to be used as a slurry in kerosene. Its heating value is 25000 B.t.u. per pound and it has a very favourable volume to weight ratio.

The chief interest in boron at this time, however, appears to be as a carrier for hydrogen in place of carbon. These carriers are the boron hydrides like diborane, septaborane and decaborane. On a weight basis these fuels have a heat content up to 70 per cent greater than kerosene. Their synthesis is not easy, diborane being prepared from lithium hydride and boron trifluoride etherate. Diborane is a toxic gas which is unstable in the presence of aid or moisture. Since decaborane is a solid it can be presumed that a practical boron hydride will contain about five boron atoms. Some success is reputedly being obtained in stabilizing fuels in this range and reducing their toxicity by alkylating them. Eventually it is hoped that processes will be developed which will bring the cost of boron fuels down to a dollar or less per pound. Bomber aircraft are presently being designed on the basis of using boron derivatives as fuel.

In the rocket field air is not used as the oxidizer. Nitric acid, hydrogen peroxide, and ozone are favourite substitutes for oxygen and there is at least one high performance aircraft flying today that uses nitric acid and kerosene as the fuel combination. Fluorine is much superior to oxygen as an oxidizer and in combination with diborane gives a high specific impulse (i.e. pounds of thrust available per pound of propellant consumed per second). Fluorine is toxic and expensive as well as being very corrosive. Because it is a gas it must be stored under pressure in containers of nickel alloy. The cost is about five dollars per pound but with greater demand it could probably be produced for about one dollar per pound. Ozone is an even more powerful oxidizer and with hydrogen it produces a much greater specific impulse. One big drawback in the handling of pure ozone is that it tends to decompose with explosive violence, however, progress is being made in handling the pure product in a stable form.

A still more spectacular source of energy, hitherto untapped, is the harnessing of energy inherent in free radicals. A free radical is a molecular fragment free of any electrical charge which is formed usually during an exothermic reaction. The upper atmosphere is a reservoir of free radicals formed as a result of the sun's radiation. They are suspected of being responsible for some of the radiation in the aurora borealis. They are also found in the exhaust gases of internal combustion engines and in flames. Since they are formed by the absorption of energy they are energy reservoirs. Free radicals are a transient state of matter lasting usually only a fraction of a second and are not fully understood. Recently techniques have been developed to 'freeze" their existence and isolate them for further investigation. Free radicals of nitrogen, oxygen, hydrogen, water vapour, and ammonia gas have been collected as solids at temperatures of about 4K. When heated to 20 or 30K. they combine releasing what are referred to as vast quantities of energy in the form of radiation and heat. It is estimated that a fuel composed of 100 per cent hydrogen in the form of free radicals would have a specific impulse five to six times greater than that of conventional type fuels. While the problems of manufacturing, storing, handling and controlling disassociated hydrogen are formidable, less active forms, such as the isolation and stabilization of the ammonia radical in liquid hydrogen, show more immediate promise. This system at moderate temperatures could give a nine-fold increase in range over present rockets.

COMPETITION FOR STEEL WORK

Civil Engineering, v. 52, n. 613, July 1957

Increasing use of wood as a structural material in Great Britain is becoming evident in the applications of laminated timbers to recent construction projects. A recent survey has been made of the European practices in wide use over the last fifty years. In Europe glued lamination is not only carried out by big firms but it is also done quite profitably in factories equipped with modest plant using a small labour force. By comparison with the American lamination industry which has been able to introduce mass production methods, the making of laminated members in Europe is still largely a craft affair. Mechanization does not, in general, extend beyond the machining of laminates and, so far as is known, there is no factory on the continent offering a range of standard components "off the shelf". Neither does there appear to be national standards for laminated components or preferred dimensions or shapes.

Economic as well as technical considerations appear to exert a decisive influence on design. Laminated straight beams and girders are much favoured in Switzerland. European fabricators as a whole avoid small radii as far as possible in the construction of laminated arches and other curved members. In Holland and Belgium I-section arches and portal frames are much in vogue, largely because they combine structural efficiency with timber economy. By comparison, a rectangular laminated section of equal moment of inertia calls for about 25 per cent more timber.

A Swiss development is that of grid lamination in which the grid is made to support either a plain or a curved roof. The grids are prefabricated in sections of about 10 ft. x 20 or 30 ft. and larger. The largest spans so far achieved by European laminators with arched portals are about 160 ft. but spans up to 230 ft. and over are being considered.

From studies made in Holland and Belgium it is estimated that for spans over 35 ft. laminated timber construction is competitive with reinforced concrete and steel. In these two countries prestressed concrete is regarded as the most serious competitor. Laminated timber producers in the Netherlands claim that large spans of 100 ft. or more can be supplied for as little as half the price of reinforced concrete. Swiss firms, also, claim that laminated timber is fully competitive once spans of 40 ft. and over are reached, and is invariably cheaper to use for really large spans.

PIGMENTS IN POLYMER MATERIALS

J. F. Ambrose, *Bell Laboratories Record*, v. 35, n. 7, July 1957

Since early times man has modified his natural materials by incorporating into them finely divided substances to impart desirable properties. Chopped straw was baked into clay bricks for added strength, then masons added fine sand to slurries of lime to make a hard strong mortar which was similar to that used today. In modern plastics technology, the use of additives to alter and improve the basic properties of both natural and synthetic polymers has proved to be very important. These new materials have in many cases replaced their naturally occurring polymeric prototypes — rubber, wood, textile fibres, leather and even furs, and indeed are also superseding in many applications inorganic materials such as glass, metals and alloys.

In the Bell System today, plastics replace only the materials that they can clearly surpass in desirable characteristics. The success that has been obtained has derived from the fact that properties not originally present in the plastic may be added, or undesirable properties ameliorated or removed. This is done by materials added to the polymer, sometimes in infinitesimal proportions, but often as a major component of the mixture. One of the largest classes of such additives is the pigments, finely divided materials which are insoluble in the base material.

The properties of pigments which give rise to their usefulness in polymer compositions are many and varied. The compounder has need in some cases for their thermal and electrical conductivity, in others for their magnetic susceptibility. The properties deriving from their finely divided state — such as increased light absorption, enhanced chemical reactivity and surface dependent properties (adsorptivity, for instance) — are often of paramount importance.

One of the largest uses for pigments-filled polymers in the Bell System is in polyethylene cable sheath. When being used on a telephone pole a polyethylene cable sheath not containing carbon black could be expected to last about a year. With two per cent by weight of fine particle carbon added the life increase to twenty years. In this application the pigment acts as a light screen absorbing the ultraviolet radiation in sunlight which would otherwise rapidly degrade the polymer. Similarly pigments are used for protection of polyvinyl chloride wire coverings and fillers for colour-coding. Rutile titanium dioxide is the additive. Silica is used as a filler in polyester casting resins used for encasing electronic components for protective purposes, often in amounts up to 50 per cent by weight. It reduces the shrinkage when the resin cures and it provides adequate thermal conduction for the heat generated by the "potted" components when in use. The property of reinforcement is probably the most significant contribution of pigments to modern polymer technology. With the use of carbon black in rubber and other elastic polymers, the mechanical properties such as abrasion resistance and tensile strength are remarkably improved.

Economic considerations underlie a great number of the applications of fillers in polymers; carbon black, for example, costs much less in a compound than the polymer it replaces. Similarly, clays and other mineral fillers utilized in tapes, drop wires and neoprene jackets for wire, cost only a small fraction of the polymer replaced.

Future developments in the use of particles in plastics will be numerous. Luggage of polyester materials is now produced on which a new finish may be applied, to mars and scratches merely by rubbing with steel wool. Similar finishes in plastic-bodied sports cars and boats wait only the adequate standardization of pigment colours. Glass fibres of refractive index closely matching that of the binding resin are being fabricated into transparent, reinforced building panels in many colours. Dies for the fabrication of massive metal parts, such as automotive bodies, are constructed by casting metal-filled resins, rather than by machining from steel. Considering the enormous strides made in metallurgy by alloying a limited number of metals it can be expected that similar great advances will result from the incorporation of the great variety of particulate materials into the large number of polymers.

HOW TO USE TAPE CONTROLLED MACHINING

M. Kanes and C. B. Sung *The Tool Engineer* v. 39, n.2. Aug. 1957.

Recent developments indicate that the use of tape control of manufacturing processes will rapidly increase. Announcement has been made of the completion of a large milling machine for a major aircraft firm, designed and built with a numerical control system. A tape controlled three-dimensional cam machine has been in successful operation at an aircraft accessory plant for over 12,000 hours. However, it should be realized that certain types of machining operations are more suited for automatic control than others.

The development by the Bendix Aviation Corporation is an integrated manufacturing system. Its main elements are a computer for automatic processing of engineering and maching information, a machine tool designed for automatic operation from a punched plastic tape, electronic and hydraulic controls to translate the recorded machine instructions from the tape accurately and rapidly into drive motions of the machine slides, and finally, digital feedback instruments coupled to each machine slide to accurately measure the relationship between cutter and workpiece at each instant throughout the operating cycle.

Considering possible applications, the aircraft industry affords an immediate area for tape controlled machining particularly in milling operations. The tremendous advances in military aircraft performance during the past few years have been accompanied by radical changes in manufacturing techniques. The advent of new materials, coupled with increased emphasis on weight reduction in the airframe, has replaced many sheet-metal assemblies by intricately sculptored machined parts. Forged and cast fittings which formerly were partially machined are now finish-machined to closer tolerances in order to eliminate the last ounce of dead weight. The immediate application of tape control in the automotive industry appears to be in the making of tools and dies rather than parts. Tape-controlled die-sinking machines can reduce the high cost and long lead time involved in making many automotive body and forging dies. Advantages of tape controlled machine tools are: ability to fabricate parts of complex design previously not feasible; reduced set-up and—or machining time reduced tooling cost and lead time; better finish or accuracy; increased versatility; alleviation of the skilled operator shortage.

A broad and important category of tape-control applications in industry is therefore the machine tools used mainly on short run jobs. The simplification of tooling and reduction of set-up time eases the problem of change-over from one small job lot to the next. In this case, as in the toolroom, where versatility has been the key factor in machine tool utilization tape control appears to hold extensive promise. This field of application may be thought of as the low production type of automation, in contrast with the form of automation found in mass production such as is seen in the automotive industry. Tape controlled machine tools should prove to be a practical asset even in the smallest jobbing shop.

The system is much simpler than has been generally anticipated. No large staff of mathematicians or specialists is needed. The function of the tool engineer remains unchanged. He provides the basic manufacturing information in a numerical form suitable for machine control, in addition to designing tooling suited to the system. His job becomes more important since complete manufacturing engineering replaces skills formerly furnished by the machine operator.

Digital computers, which are finding increasing use in industry for scientific and business applications, are adaptable for preparation of control tapes. The function of a computer in evolving a numerical control tape is to generate sufficiently detailed tool path information from the relatively few dimensions given on the blue print, to produce continuous control of the machine. Fundamentally, computations entail determination of the cutter path based on specified cutter size, and piece-part dimensions, and interpolation of specified curves to yield a sufficient number of intermediate control points. Any general-purpose digital computer is capable of handling this type of numerical data processing to produce the required results in numerical form from input instructions also expressed in numerical form. The numerical output of the computer may be recorded directly in code form on punched cards or tape.

Tape preparation starts with the process engineer who prepares a process data sheet containing key dimensions obtained from the part drawing, and machine process information including cutter size and feed rate. A straight line section on the part is defined on the process sheet by two lines designating the start and finish points respectively. In the case of a curved section such as a circular arc, the arc radius is specified in addition to the start and finish points. Provision is also made on the process sheet for designating the tolerance required on curves.

The completed process sheet is next copied by means of a clerical typing operation which simultaneously produces a type-written copy of the process sheet and a punched tape which contains the processing information in a form acceptable to the computer. The process tape is read by the computer which automatically produces the control tape in the form required for machine control.

The method is versatile so that numerous sub-routines can be employed. Completely general two and three-dimensional programs include the ability to handle any analytically defined curves, as well as pocket-milling and profile-roughing operations. Consequently, the need for tedious hand computation by the process engineer is eliminated. A tooling or process engineer can be trained to use this system in less than one week.

The punched control tape is a compact recording of the coordinated movements of the machine slides required to maintain the changing relationship between the cutter and the workpiece. In addition, the tape contains instructions for cutter feed rate, auxiliary control functions, and checking information. The binary instructions for each controlled motion are converted into a train of electrical pulses each representing a command for the machine slide to move a specific distance. A pulse value of 0.0002 inch is usually emploted although this value can be smaller if desired. Each machine motion is provided with a rotary digital feedback instrument that measures the actual movement in increments of 0.0002 inch. The accumulated difference between command and feedback pulses is converted to an analog signal which is fed to the hydraulic servo-drive unit. This provides extremely fast and accurate response of the machine to input electrical commands. Consequently the machining operations can be controlled to produce much higher speeds and accuracies of metal removal than is possible in a conventional hand-operated machine.

An example of the advantages is illustrated in the machining of a rough forging which was required to be finish machined on the outside and inside profiles. The tooling program for conventional processing using a tracer-controlled machine tool involved a total of 210 hours, including the time for design and manufacture of a holding fixture, a boring fixture and a complex set of tracer templates. In comparison the tape controlled tooling program required 92 hours, the boring fixture and templates are eliminated, and the finish is considerably better than that obtained conventionally.

TESTING METALS "ON-THE-FLY" WITH EDDY CURRENTS

R. Hochschild, *Control Engineering*, v.4, n.8, August, 1957

Due to the need for greater reliability in engineering materials which are being subjected to increasingly higher stresses and more rigorous environments, and because sampling techniques necessary with destructive testing often prove unsatisfactory, a great deal of development work is taking place to produce methods which permit 100 per cent inspection of materials on the production line. Several types of instrumentation including radiation, ultrasonic, magnetic and electrical devices are suitable for such "on-the-fly" inspection.

One method is eddy current testing which is quick, readily adaptable with electronic control circuits, and suitable for checking characteristics of several materials in addition to seeking out mechanical flaws. Minute eddy currents induced by a radio frequency field explore the material and can be made to yield information on dimensions, on the presence of flaws or on mechanical, metallurgical, and chemical properties. By means of suitable controls linked to the eddy current instrumentation defective material or parts can be rejected, sorted, or labelled. Eddy current equipment is also very adaptable for continuous adjustment of the production process through a feedback-control loop.

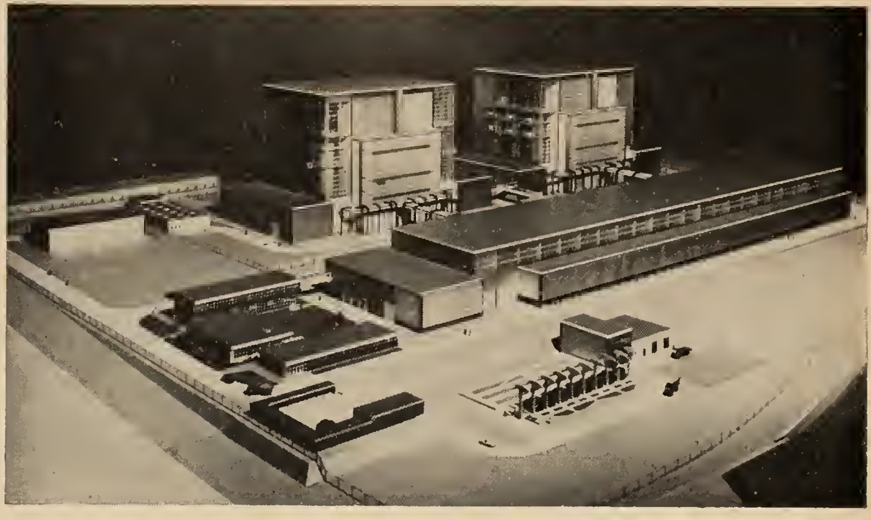
Several conditions affect both the magnitude of eddy currents and the paths they follow within a particular piece of metal. One such condition is the resistivity of the metal which depends on many microscopic phenomena. Some of these phenomena relate to the strength, hardness, alloy composition, chemical purity and crystalline condition of the metal. Consequently eddy currents may give some knowledge of these properties.

A second group of conditions to which eddy currents respond are discontinuities and boundaries that influence their flow pattern. Examples are cracks, holes, laps, seams, and porous areas. The detection of such defects in metal objects of relatively uniform shape has been one of the principal fields of eddy current testing, often replacing older methods of visual, powder particle, penetrant, and radiographic inspection.

Eddy currents have many of the properties of a compressible fluid. They flow in certain patterns and distributions determined, first, by the design of the test coils which set up the radio-frequency waves, and second, by the frequency of oscillation of the waves. The frequency, in particular, controls the depth to which eddy currents penetrate the surface. Higher test frequencies are used to inspect surface regions, while lower frequencies deepen the penetration into the part but at a sacrifice of sensitivity to surface defects. At any given frequency the amplitude of the eddy current falls off with increasing depth and so does the test sensitivity, therefore the method is more suited for surface and near-surface zones than for interiors. The lagging phase angle of the current increases with depth, thus providing a basis for measuring the depth of a flaw. Also the phase angle behaviour makes it possible to determine whether an indicated defect is actually a flaw or a conductivity or a diameter change. Currents encountering an obstacle such as a crack are detoured around it, being compressed and weakened in the process. The current induced by the applied r-f energy in turn sets up its own magnetic field. The resultant field external to the part being tested contains information on the position, shape and size of any discontinuity distorting the currents and it can be analyzed electronically to yield this information in a useful form.

A third condition influencing eddy currents in a given part are the dimensions of that part. This has led to development of sensitive equipment to determine and control the dimensions of manufactured products such as rods, tubing, bolts, pistons and ball bearings, the thickness of sheet, plate, strip or foil of one metal plated or coated on another; and the thickness of insulating coatings on metal surfaces. Measurements accurate to better than a millionth of an inch can be made from one side only and without contacting the part.

Like x-rays, eddy currents leave no after effects in the metal. The greatest difficulty in their use is that they are very sensitive to a great many variables. However, the instrumentation can be designed to be sensitive to a limited number of conditions only through the use of phase sensitive circuits, proper test frequency and test coils of special design.



LARGEST ATOMIC POWER STATION

Work is due to start on what will be the world's largest atomic power station. It will have an output of 500,000 kw. and will occupy an area of some 25 acres. The station will have two reactors of the gas-cooled graphite-moderated type fuelled by natural uranium. Each reactor will consist of a 24-sided core of graphite blocks with a lattice of vertical channels containing the natural uranium fuel elements, and enclosed in a spherical pressure vessel 67 feet in diameter. The pressure vessels will be fabricated by welding on site from pre-formed mild-steel plates three inches thick. Fuel charging, from the top of the reactors, is to be done on-load to permit a continuous refuelling cycle. Each reactor will be connected to six steam-raising units (heat exchangers), grouped in three on either side of the reactor. The twelve units, each 90 feet high and 21 ft. 6 in. in diameter, will generate over 5-1/2 million pounds of steam per hour. The units, which are of the double-pressure design originated for the Calder Hall installation, have been developed so far that each has a capacity three and a half times that of a Calder Hall unit, although the height and diameter are only 20 per cent and 25 per cent greater respectively. The electrical power output at Hinkley Point will be generated by six 93,500 kw., 3,000 r.p.m. hydrogen-cooled turbo-alternator sets; three 33,000 kw. variable speed turbo-alternators will also be installed to supply power for the gas blowers. The station is to be built by the atomic power projects group of The English Electric Company, Limited, Babcock and Wilcox Limited and Taylor Woodrow Construction Limited to the order of Britain's Central Electricity Authority and will be at Hinkley Point in Somerset.

THE INTERNATIONAL GEOPHYSICAL YEAR

Much publicity has been given to the advent of the International Geophysical Year (commonly known as IGY). The general reader is fed with scraps of information from the daily and weekly press, while the specialist is busy with his observations armed with all the sources of technical information that he may need in his particular field. Occasionally, the layman, scientist or engineer, who is not directly concerned with IGY but would like to know more about it, can find some of the details explained simply and accurately.

An excellent example of a brief, but authoritative, review of the work involved in IGY is a booklet "The International Geophysical Year" published for the Science Museum, in London, by Her Majesty's Stationery Office (S.O. Code 20-1087*). The booklet was intended for use with a special exhibition held at the Museum during IGY, but also as a lasting record of the work involved.

More than forty nations are taking part in IGY at a cost of over $250 million; the 'year' extending from July 1957 to December 1958. Simultaneous observations of phenoma throughout the world are being made from permanent installations and from many temporary stations, especially in areas not adequately covered by previous observations. The results should present the most unified picture ever obtained of man's physical environment.

The value of simultaneous meteorological, magnetic, and auroral observations in the polar regions was recognized by the First International Polar Year of 1882-3. With extended scope and advanced techniques, the Second International Polar Year took place fifty years later in 1932-3. The intention was to hold a similar international project in another fifty years, but in 1950 Dr. L. V. Berkner (U.S.A.) suggested that the advance of knowledge in these fields warranted a reduction of the interval to twenty-five years. From this suggestion, furthered by the International Council of Scientific Unions, the present IGY project developed — the period 1957-1958 being considered particularly appropriate in view of the expected sunspot maximum.

The programme of work during the 'year' was divided into sections such as meteorology, solar activity, geomagnetism, cosmic rays. These sections are reviewed in the booklet under four chapter headings — the sun; the atmosphere; the oceans; the solid earth. The chapters describe briefly the phenomena involved and how they are to be observed.

The booklet is illustrated with diagrams and photographs that range from sunspots, through the assembly of the projected earth satellite, to operations (including penguins) at an Antarctic base.

DISCUSSION *(Continued from page 1474)*

column generally has a far larger reserve strength after the first signs of damage than a tied column. However, it has been found that comparatively little of this reserve strength can be utilized because of the danger of the shell, outside the spiral, peeling off and the considerable shortening of such a highly stressed column. For this reason only a twenty percent advantage is given to spirally reinforced columns. If we based our design on ultimate strength only and used the same safety factor for spirally reinforced columns and for tied columns, we should certainly get into trouble.

The author wishes to make it clear that he does not mean that we should neglect to take the ultimate strength into consideration. If there is a large reserve strength which will prevent a closely following total failure after the initial overstressing, a smaller safety factor may be in order in many cases. Since, however, the strength, durability and appearance of a structure depend on service conditions, the safety factor should refer particularly to those conditions and not on the more unusual ones of total failure.

The above considerations do not prevent an adjustment of allowable nominal stresses where such are in order as, for instance, under conditions of lateral confinement.

DESIGN AND OPERATING FEATURES OF THE CANADA-INDIA REACTOR

F. J. Bleackley, M.E.I.C.

The Engineering Journal, 1957, Aug., p.1099

I. N. MacKay, M.E.I.C.*

Mr. Bleackley's paper is a clear description of the re-design of a complicated but successful piece of engineering equipment. This can be a challenging type of assignment, and it will be apparent to those who are familiar with the original NRX reactor that Mr. Bleackley and his group have made the most of their opportunity.

In particular I am sure that the large vertical holes, shielded rooms, and other provisions for complete loops will be most useful in the development of fuel elements for power reactor. The emphasis on the broadening of dimensional tolerances is laudable. That there was considerable scope for this may be concluded from the fact that the drawing of the original master plate, which determines the spacing between the fuel rods, showed dimensions of up to 120 inches specified to five places of decimals, with a note at the bottom of the drawing, "No tolerance on dimensions".

Questions which come to mind are largely in the realm of requests for further details concerning the design. For instance, what are the details of the automatic dampers which close off the air conditioning system in case of an explosion within the steel pressure-tight shell? To make the shell really effective, these dampers would have to close against a pressure of 30 pounds per sq. in. in a second or perhaps less, and be virtually leak-proof to gas at this pressure. The diameter of their opening is presumably two or three feet. Other queries are, why are the holes in the upper thermal shields not made initially sufficiently large to pass damaged calandria tubes without resorting to boring out in place; why is downward flow of the fresh water coolant in the reactor used; how will the steel containment shell be pressure tested?

*Manager, Engineering, Civilian Atomic Power Department, Canadian General Electric Company Limited.

REFLECTED RIPPLES IN THE RIDEAU CANAL

(Abstracts)

The Engineering Journal, 1956, January, 36.

B. A. Wightman ‡

Mr. Disher's letter regarding the ripples on the Rideau Canal prompts me to communicate some of their more interesting aspects. Many a sultry August evening in Ottawa have I sought refuge on the banks of the Canal. The ripples caused by the sightseeing launches were reminescent of electromagnetic wave propagation in hollow metal pipes. Such propagation may be regarded as the multiple reflection of a plane wave. The pattern of the fields corresponds to that of one of the bow waves of the boat reflecting from the walls of the Canal.

However, a phenomenon more closely related to the water ripples is the propagation of sound waves from a source moving at supersonic velocity. In the photo, the ratio (reciprocal mach number) of the velocity of the boat to the velocity of propagation of the ripples is the sine of the angle which the ripples make with the direction of the boat's motion (mach angle).

DISCUSSION

The Editor invites discussion of papers appearing in the *Journal*.

Readers may contribute to this section by sending appropriate comments to the *Journal* office.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

A cool, dry month of August saw record activity on all phases of the project, with employment attaining a new peak of more than 21,000 on both sides of the river, probably an all-time peak for the life of the undertaking. All phases of the work were reported to be on or ahead of schedule.

Progress by Ontario Hydro

The month of August was dry and favourable for construction work. A total of 5,250 persons was employed on the project areas during the month.

At the Canadian half of the powerhouse, concrete placing operations advanced well through the month. A total of 725,000 cubic yards of concrete had been put into this principal structure. The concrete placing for ice sluices 1 and 2 on the north end of the power dam was completed.

Turbine pit liners had been installed as far as unit 11 and speedrings to unit 12. At the administration and erection bay building, all concrete placing was completed and the brick work for the exterior wall was more than half finished.

Weather aided work on the Cornwall dike during August. Placing and compacting of glacial till had been essentially completed for sections 2 and 3 of the dike with only the railway gap between these sections yet to fill. Section 1 of the dike as well as the Cornwall canal closure structure and the powerhouse section were well above original ground level. The total amount of glacial till placed and compacted on the dike by the end of August had reached 4,300,000 cubic yards of the estimated 5,100,000 cubic yards.

With release of the old C.N.R. right-of-way last month, it became possible to close two gaps in Cornwall dike in August, following the lifting of the rails, and a start was made on the west half of the No. 2 highway relocation which will use the former railway right-of-way.

All contractors had begun grading work following removal of rails, and telegraph lines on the west half of the old right-of-way.

Excavation of the channel through Galop Island had been completed and flooding of this channel was scheduled for month end. With this flooding, draglines and dredges will remove the cofferdams.

At Iroquois Point, most of the excavation within the cofferdam had been completed. The building of the dike to join Iroquois control dam and the seaway canal lock well was essentially completed. At Point Three Points, the perimeter dike had been completed. About 300,000 cubic yards of material had been excavated and removed from this area.

All house moving into the new town of Long Sault was completed during August. Paving operations were in full progress, with work concentrated on streets and the parking lot area for the new shopping centre, and around the C.N.R. station. All this was completed by month end.

On the house moving program for Ingleside, 106 houses had been moved from Osnabruck township. In Ingleside, work was well advanced on three churches and work had started on the fourth church. The elementary school was practically completed, and the separate school 50 per cent completed.

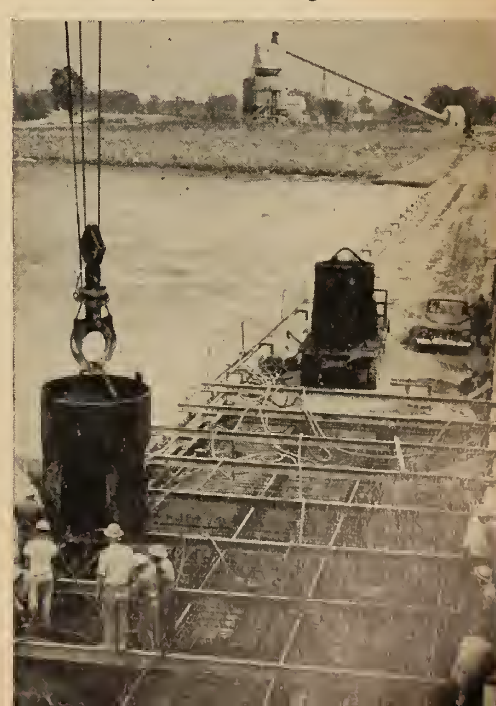
At Morrisburg, the masonry work for the shopping centre had been completed and roofing was 80 per cent finished. Work was progressing on the 60-unit multiple housing. In Iroquois, general cleanup continued with special attention to the park area. The first units of the rental housing were ready for occupancy.

Progress by NYSPA

August was highlighted by the completion of concrete operations at Iroquois dam, marking the near completion of one of the major features of the power project. Concrete placement for all project structures at month's end exceeded 1,590,000 cubic yards or 77 percent of the total requirement. Excavation exceeded 45 million cubic yards. Employment averaged 6,630 for the month.

Concrete placement at the New York half of the international powerhouse continued on schedule, and 65,000 cubic yards were placed, bringing the total to date to 766,000 cubic yards, or 79 per cent of the required total. Erection of structural

Iroquois dam. Final concrete was placed in the roadway section in August.



Long Sault dam. The stage 2 portion of the structure.

steel in the 115-kv. switchyard and concrete placement in ice sluices 5 and 6 had been completed.

At Long Sault dam, 81,000 cubic yards were placed during the month, bringing the total to date to 442,000 cubic yards. Rock excavation for stage 2 spillway apron was completed.

Concrete operations for stage 2 construction at Massena intake continued concurrently with backfilling of the upstream and downstream sides of the structure. Concrete placed to month end totalled 192,000 cubic yards or 99 per cent of the required total.

Channel improvement work at Sparrowhawk Point, Toussaints Island, Point Three Points, Leishman's Point and at Ogden Island was continuing. The channel work was approximately 84 per cent completed.

Construction of the relocated state highway route 37 was nearly completed and 1½ miles at the west end of the relocation were opened to traffic. With placement of the first six-inch stone layer on the subgrade completed, surfacing was in progress on highway route 37B, and on the bridges on state highway route 345 and Franklin Road in Waddington.

Excavation of the Massena beach area was completed except for fine grading. All suitable material from the beach excavation had been hauled and placed in the Richards Landing dike.

A contract was awarded for the construction of sewerage and water supply facilities in Waddington and another for reforestation work in construction and state park areas. Specifications were issued to bidders for construction of the substations at Plattsburgh and Kents Falls and also for the 115-kv. transmission lines for Reynolds power supply.

Progress by SLSA

At the upper Beauharnois lock, half the common excavation was completed and almost two thirds of the rock excavated. Some 32,000 cubic yards of concrete were placed in the upper gate section to enable a start on the railway bridge over the lock.

On the lower Beauharnois lock 75 per cent of the rock had been excavated 124,000 cubic yards or 48 per cent of the concrete had been placed; most of it in the lock chamber, with one wall poured to full height throughout. Work continued on the highway tunnel with one double traffic lane in service.

At Cote Ste. Catherine, with 2 million yards of earth and 1,430,000 yards of rock removed, 247 cubic yards or 65 per cent of the concrete was placed, mostly in the lock structure. No installation of machinery had taken place. Though reported 'on schedule', work may be continued during part of the winter.

The St. Lambert lock will be the last of the five Canadian locks to be completed. In a drive to enable installation of machinery to commence in October, efforts were under way to complete placing of concrete in the lock structure during September. The downstream approach wall was completed and the upper approach wall started. The south shore collector sewer between the channel and St. Lambert was practically completed. Work on this lock will continue during the winter.

Iroquois Lock Open in November

The last mass concrete pour was placed at the Iroquois lock on August 28, 1957, marking completion of the first major structure on the seaway. The lock will provide access between the power pool in the International Rapids section and the stretch of river leading through the Thousand Islands to Lake Ontario. SLSA engineers look forward to the possibility of passing ships through this lock before the end of November.

Dredging of the approaches upstream and downstream of the lock is proceeding under contract. The upper approach area to the lock proper was flooded in September. Cofferdams were being removed and gates and feeders were receiving a long series of tests.

The two sets of sector gates at the upper end of the lock were already installed. The lower two sets of sector gates were to be installed by October 15 and the testing program completed by early November.

The International Rapids section will be flooded by mid-summer next year, and the Cornwall, Morrisburg, Farran Point and Galop canals will be unusable. Consequently ships, although still proceeding at the present canal draught of 14 feet, will require to use the Iroquois lock for entry into the power pool from upstream and the two United States locks to leave it and continue on to Montreal via the Soulanges and Lachine canals for 1958 only.

Jacques Cartier Bridge

At end of August the new through span had been erected on the upstream side on falsework. It will be slid into place as the old deck-span is removed in October. Through the lifting stages the various spans will then be raised 6 inches at a time and at intervals of two feet concrete courses will be poured till necessary elevations are obtained. Fin al position will give 120 ft. clearance between roadway and waterlevel in the canal with downgrade 1,000 ft. northward to pier 14 and southward 1,400 ft. to pier zero at south shore.

A new target date, — mid October, had been set for completion of the bridge-raising project's second phase, in place of November 2 as originally planned.

Bridges

The Dominion Bridge Company, contractor for the steel superstructures on all four existing bridges at Montreal over the seaway, was also assembling equipment at end of August for erection of steel on the two railway bridges, Victoria and Caughnawaga.

On a contract awarded last June by the federal Department of Transport, the contractor had built 4 piers for the Nuns' Island highway bridge. These piers, located within the area to be flooded by the seaway channel at the south end of the bridge, were started ahead of the others to enable them to be built 'in the dry'.

Mercier Bridge Piers

Forty-five new piers to support the new high-level approach to the Honoré Mercier bridge between the Island of Montreal and the south shore of the St. Lawrence, are being built by a modern type of concrete construction, known as the "slipform method".

The basic principle behind this operation is to place concrete in the form while it is being continually moved. The lifting is performed by means of hydraulic jacks which are supported and "climb up" one-inch steel rods which extend down into the concrete.

At the start of each pier, jack-supporting rods and forms are carefully set on the footing. The four to six foot deep form is then filled in layers of about eight inches. As soon as this concrete has set sufficiently, the jacking operation is started, slipping the form up at the rate of 10 to 20 inches per hour depending on the rate of placing and setting.

The placing of concrete is carried on continuously, 24 hours a day, and piers up to 100 feet high can be completed in a five-day week. The whole of the work, consisting of 30 single piers, 15 multiple piers, and two abutments, ranging in height from 50 to 110 feet and containing 25,000 cubic yards, when completed by October will have been erected in five months.

Progress by SLSDC

By the end of August, only 2 million cubic yards or 13 per cent of the excavation remained to complete on the mainland section of the Long Sault canal, all of it dry excavation.

Placing of concrete was completed for both the Eisenhower and Grasse River locks, and installation of lock gates and operating mechanism had begun. Other operations such as dikes, clearing, etc., were on schedule. Employment during August varied between 2000 and 1500.

Seaway News

Ease Traffic at Montreal Port

A $2 million 'suburban' Montreal harbour will open at Côte Ste. Catherine with the seaway. This was announced early in August by Transport Minister George Hees. Main object of the new wharfage is to help facilitate the trans-shipment of cargoes from downbound lakers, thus easing the crowding in Montreal harbour itself. Four thousand feet of new wharves are to be built above the Côte Ste. Catherine lock, just below Mercier bridge. Tenders are to be built above the Côte Ste. Catherine lock, just below Mercier bridge. Tenders are to be called within a few weeks. Administration will be under the Seaway Authority for the present though the National Harbours Board might take over later. Railway sidings are already laid at the site.

Water Routes to New York and Ottawa

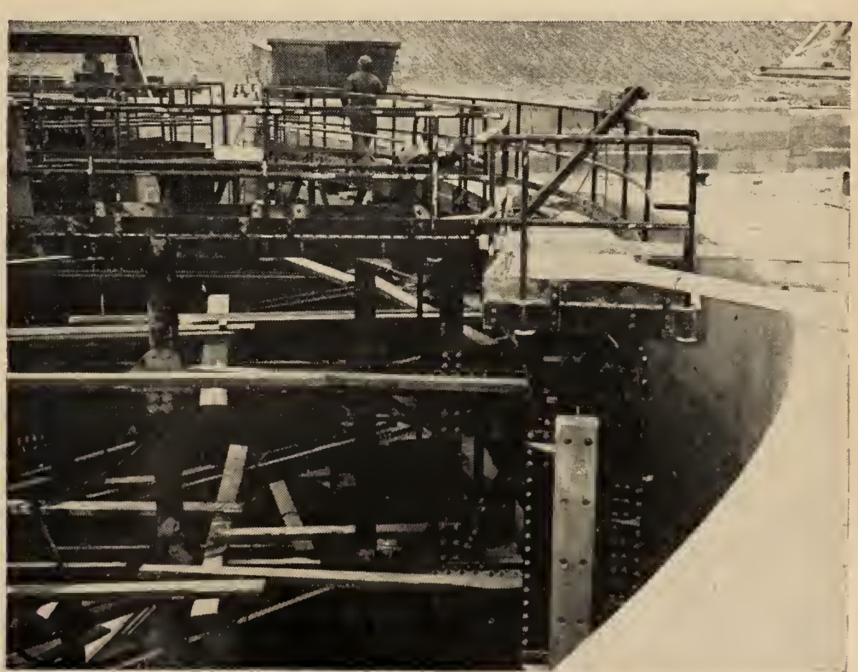
New efforts were under way in August by Chambre de Commerce organizations of the south shore to press for an inland waterway between New York City and Montreal. The Federal Government will be asked to study the project. A measure introduced by Congressmen Aiken and Prouty in the U.S. Congress recently would authorize American Army Engineers to survey the route from Albany to Lake Champlain and thence to Sorel.

The Ottawa Valley Development Board was formed late in July to revive Ottawa valley shipping over a 'secondary seaway'. Tupper Porter, technical adviser to St. Andrews East Chamber of Commerce, told the conference that "for a mere $30 million the Valley could buy an entirely new economic era". Ultimate goal would be a canal system to Georgian Bay, a dream dating back fifty years.

British Seek "Order of Principle"

Viscount Simon, president of the British Chamber of Shipping, called recently for a further statement of

Mitre gates under construction at Iroquois lock.



principle that there would be no discrimination in the use of the seaway. He called for a toll structure that would be simple in operation and at a rate attractive to traffic. The practical application of these principles, he emphasized, was of vital concern to British shipping.

Battle on Tolls

A showdown fight on seaway tolls is shaping up. SLSDC called a tolls conference for September 9. SLSA called a tolls conference in Ottawa for September 19 with a view to determining a toll rate low enough to attract traffic yet high enough to provide revenues to pay the cost of the seaway. Potential users have been invited to attend and to express views on toll assessment methods and practical means for payment. Jean Claude Lessard, SLSA vice - president, replaces Charles Gavsie as president of the Canadian Tolls Committee.

Another conference was to convene at Chicago on September 11, called by anti-seaway groups who have formed a national organization to fight N. R. Danielian, chairman of the U.S. User's Committee on Tolls, and his arguments for lower initial toll rates and an extended pay-back period. This group is called 'the national committee for a non - subsidized seaway' with Congressman George Fallon of Maryland as chairman.

Fallon stated midwestern business interests will urge that 'bargain rate' tolls be set by SLSDC. There are plans under foot, he warned, to ask Congress next year to amend the act to permit repayment over a 100 year period. This, he said, would amount to a subsidy.

While this committee's views and those of SLSDC Administrator Castle and the U.S. Tolls Committee favour paying off seaway debt in fifty years, Danielian argues the choice is between low tolls and a big movement of vessels through the seaway, or high tolls and a small movement of vessels. He believes the cash gained in tolls would be about the same either way, but prefers the low toll and big movement approach.

October Coal Parley

Effects of the seaway on coal marketing in North America was discussed on October 10 at Quebec. Sponsoring the meeting were the American Institute of Mining, Metallurgical and Petroleum Engineers, the ASME and the C.I.M.M. Several hundred delegates attended. A film entitled 'The Eighth Sea', a documentary on the Seaway, was shown. 'Coal, a source of Canadian Energy', was outlined by C. L. O'Brian, chairman of the Dominion Coal Board. John R. Frith of Cleveland, discussed 'the influence of the seaway on coal marketing'.

Amortization Period Unimportant

H. M. Paint, in a recent article published in 'the Canadian Banker', points out that the seaway is an inland waterway and will always remain so. Every journey a deep sea freighter makes to Lakehead means fewer ocean crossings for the owner. They are unlikely to travel the seaway unless assured of a profitable return trip and reduced tolls for returning in ballast . . . The seaway, he warns, must be regarded as simply an alternative shipping route with certain advantages if tolls are not prohibitive.

The author warns Canadian shipping won't have an easy time of it. There will be intense competition, particularly since U.S. legislation exists designed to help the shipper. "Only madness would prevent the Seaway Authority from setting tolls which would largely increase traffic", he argues . . . . "When the fact is remembered that the seaway will be a permanent continental asset, it becomes relatively unimportant whether the cost is spread over 25, 50 or 75 years".

Black Lake Asbestos

An asbestos mine and mill at Black Lake, Quebec, will produce about 100,000 tons of asbestos fibre a year, which will be approximately a 10 per cent addition to Canada's production. First mining is expected to be done in mid-1958.

The agency responsible for the $32.5 million development is Lake Asbestos of Quebec, Ltd., a wholly owned Canadian subsidiary of American Smelting and Refining Company, New York.

United Asbestos Corporation Ltd., a Canadian firm, did the early location and exploration under Black Lake, but entrusted the financing, development and operation to American Smelting, on a long-term profit sharing agreement.

The submarine mining aspect is of special interest — involving the removal of 37 million cu. yd. of overburden, control of drainage of Black Lake, a key part of the drainage system of a populated area, and provision for flood control to replace the regulating effect of the lake.

Black Lake and the town of the same name, are some 5 miles from the town of Thetford Mines.

Open pit mining was selected and preparations made for the hydraulic engineering necessary for the project. Since the lake was eventually to be drained, the Becancour River had to be diverted. This was accomplished by digging a new river channel, 8,000 ft. long, which by-passes the lake across the north side. The new channel was designed to take care of flood stages of the Becancour upstream. A control dam was built below the diversion channel, and another six miles further downstream. In this way a new flood plain area was formed to compensate for the regulating effect of Black Lake which had been removed from the water circuit. Drainage into the new channel was provided by a system of diversion and drainage ditches.

An integral part of the hydraulic system is the disposal of waste, including that from the dredging operations. Methods have been devised for the deposit of silt as it is pumped out, and for the return of water to the lake to maintain a water level satisfactory for dredging at any stage.

A highway diversion was necessary, and a spur from the Quebec Central Railroad was brought into the property.

A 200-ton dredge, specially constructed, and powered electrically has a 75-ft. cutter and suction ladder. The cutter, fitted over the suction end of the pipeline, dislodge the material so that it can be removed hydraulically.

The dredge in one position can swing about 250 ft., cutting a bank 250 ft. by 30 ft. by 8 ft., in 4[illegible] minutes or an hour. The average rate of removal is one million cu. yds. per month.

Although dredging will continue until early 1959, the lake should be low enough in mid-1958 to allow initial mining operations and tune-up operations in the mill. Open pit mining should be possible for about 20 years; after that underground methods will probably be necessary. Ore reserves are estimated at 47 million tons, and the mill will have a capacity of 5,000 tons of ore per day.

The mill, although not boasting unique features, will have modern production equipment and quality control facilities. It will produce all grades of asbestos from the longest to the shortest fibres.

Ottawa University Extends Engineering

A newcomer to the field of institutions of learning which operate a complete course in electrical engineering leading to the degree of bachelor of applied science is the University of Ottawa. The current calendar shows that the fourth year of the electrical engineering course will be offered in the coming academic year, and the fifth year in 1958-59 for the first time.

The university has been giving the first three years of the course for several years. Since 1954 it has had a complete five-year course in chemical engineering.

A School of Applied Science was founded at Ottawa in 1946, resuming teaching of engineering discontinued many years before. Earlier than 1880 civil engineering was being taught there, and mechanical and mining engineering from 1885, these activities being curtailed by a disastrous fire in 1903. In 1953 the Faculty of Pure and Applied Science was decided upon.

There is a new electrical engineering building; a chemistry building and auditorium are under construction. Progress has been rapid in equipping the new electrical engineering building and assembling a staff sufficient for the needs of the expanded course. The building is designed with a view to graduating 15 to 20 electrical engineers per annum and is being equipped gradually for that output. At the same time facilities are being developed for the support of a research program.

Every effort is being made to form a quite modern kind of undergraduate course, without rejecting many well-proven traditional features. To this end, the University is on the lookout for men with advanced ideas as well as advanced degrees to assist in this development.

Ontario Hydro News

Ontario Hydro announced major plans late in August and early September for additional plants affecting the southern Ontario system, the northwestern and northeastern systems.

Southern Ontario

Sites at Long Branch and Burlington are being considered for two thermal-electric stations that will be among the largest in the world. They will be part of the southern Ontario system, their locations chosen in relation to the fast-growing Lake Ontario industrial area.

The first of these stations, representing a capital investment of $250 million, will have 1,800,000 kilowatts capacity, more than double that of the Commission's St. Lawrence power project. The second will be of comparable size. The Commission expressed hope preliminary work on both stations would be started before the end of this year. The timing is not fully determined, but both will have been completed by 1968, according to present plans.

The turbo-generators to be installed at the first plant are expected to be of 300,000-kw capacity, and tenders have already been called for two units.

Areas were sought providing 150 acres of space for plant, dockage facilities for some 5 million tons of coal per year, cooling water, and suitable foundation conditions and right of way for transmission of power into the system. The Long Branch site, familiarly known as the Rifle Ranges, owned by the Department of National Defence, and the prospective site at Hamilton owned by the Hamilton Harbour Commission, which will be reclaimed by suction dredging, meet the necessary requirements.

Why Not Nuclear Power?

In reply to the question why, having exhausted major hydraulic power sources in southern Ontario, it does not turn to the use of native uranium rather than imported coal, the Commission issued a statement.

"No one can state with positive assurance just when energy produced by nuclear plants could be available at a cost competitive with thermal plants", the Commission stated. "Meanwhile, the Commission has a very clear duty to perform in insuring that power is available when required to meet the fast growing demands of industry and the public, and also to see that this power is available at the lowest cost consistent with satisfactory service."

In a second statement the Commission explained further: "By 1961-62 the demand for power in Ontario will be greater than we can supply with our present resources, and nuclear plant development has not yet reached the stage in Canada, or in any other country, where this source of power would be in any way competitive in cost with coal."

To those who point to Britain's Calder Hall and consequent developments as a guide for the Commission, it was explained: "The facts are that the cost and growing scarcity of coal on the one side, the hazards surrounding the importation of oil, and the much lower labour rates in England result in conditions which favour nuclear power in that country on a basis which would be entirely uneconomical in Canada or the United States." Further, "If it were possible to build a British type gas-cooled, graphite-moderated reactor plant in Canada in 1961, the energy derived from it would be at least twice the cost of that obtainable from a base load coal-fired plant, and the improved versions of such plants, according to Sir Christopher Hinton's figures, would not appear to be economically competitive in Canada before 1977."

Meanwhile Ontario Hydro and colleagues are pursuing at Chalk River an anticipated solution, (based on a heavy water moderated reactor) with the hope of practicable and economical application before 1970.

Fort William-Port Arthur

Ontario Hydro will begin construction immediately on a thermal-electric generating station at Fort William, on Island No. 2, fronting on Lake Superior beside the Mission River.

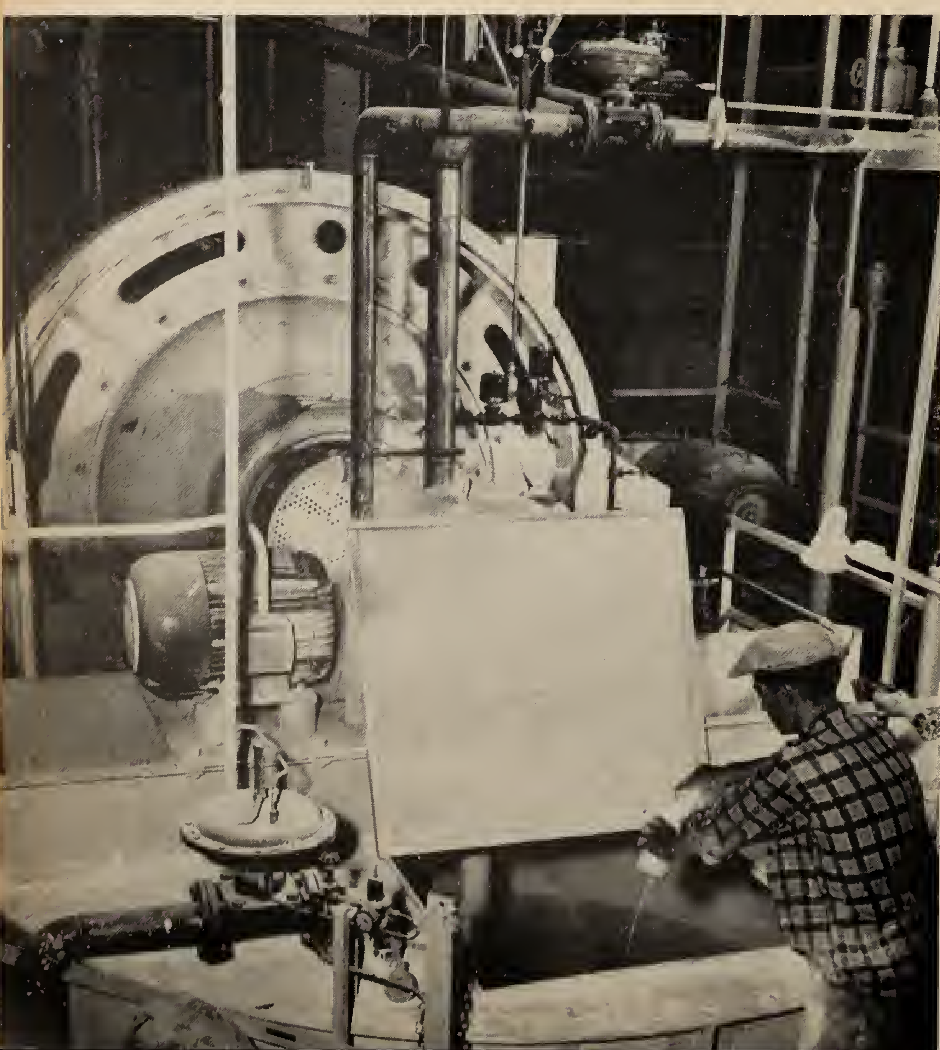
Scheduled for service in 1961, the new plant will supply power to the northwestern network; it will have an initial capacity of 100,000 kw., with provision for enlargement to 1,000,000 kw., the initial cost, $26 million.

The plant is said to be essential to meet increasing power demands and to support present sources. In this area, the Commission has six separate projects actively under construction, with a combined capacity of 209,000 kw., to bring the resources in the division to 579,300 kw. by 1959.

Abitibi Plant

A 45,000-kw., 60-cycle generator is to be installed at the Abitibi River at an overall cost of $3 million. This is meant to give improved service security in the interconnected southern and northeastern systems.

Titanium Pigments. The first Canadian plant designed to produce titanium pigments commenced production in September at Varennes, Quebec, built by Canadian Titanium Pigments Limited. The basic raw material, titanium slag, comes from Sorel, 40 miles downriver on the St. Lawrence. Chemical processing equipment will allow round-the-clock operation.



Canadian Pipeline Projects

Westcoast Transmission

Final weld on Westcoast's main line was made on August 8 at mile 119.5, close to the geographic centre of British Columbia. This terminated the vast construction program which had employed some 2,200 men yearly for the past three years. Altogether some seven million tons of earth had been moved and more than 230,000 tons of pipe placed in the ground. In addition, 154 miles of gathering lines ranging from 8 inches to 26 inches in diameter were still being laid.

Testing of the line was being completed late in August and clearing and purging operations were under way. Dry, clean Alberta gas was flowing into the line at the north end of the pipeline, while at the south end imported gas was flowing northward from the Pacific Northwest system. North and south gas was expected to meet at compressor station 5, 20 miles south of Quesnel, by early September.

The only really difficult terrain had been in the Boston Bar Pass through the coast range, where the pass elevation was 4,510 feet. In large part, the route parallels the Transmountain Oil Pipeline and the Canadian Pacific Railway, until it emerges into the Fraser River valley to terminate at the U.S. border. There were eight major rivers to cross, two with underwater crossings and six with aerial crossings. Pipe was buried to a minimum cover of 36 inches. Initially four compressor stations were installed, aggregating 52,500 hp. With these the pipeline will have a sales delivery capacity of 400 million feet daily. By installing four intermediate stations to bring installed horsepower to 189,000 hp., throughput can be raised to 660 million cubic feet daily.

In the first formal step towards greatly boosting export of Alberta gas into Pacific states, Westcoast announced in mid-August it had made application to the Alberta Conservation Board for permission to export 155 million cubic feet daily from the southwest corner of Alberta through a 175-mile pipeline through the Crow's Nest Pass. The pipeline, 20 inches diameter as far as Coleman and 30 inches to the border, would draw from several Alberta fields with total indicated reserves of several trillion feet. Bulk of the gas has been contracted for by Pacific Northwest Pipeline Corp.

Westcoast reported at the same time it had completed signing of contracts for 100 per cent of the gas reserves owned by present participants in the Savanna Creek field, and in addition had completed contracts for a major part of the indicated reserves in the East Calgary gas field. Prices to be paid are the best so far publicly announced for any gas so far signed up for export. Savanna Creek 'wet gas' will be picked up by Westcoast at wellhead and piped to a proposed processing plant in the Crow's Nest Pass. Suppliers will receive 12 cents per thousand feet, increasing to 13 1/3 cents the fifth year, and then escalate 1/3 cent yearly.

Contracts involving East Calgary gas were completed with Jefferson Lake Sulphur Co. and Merrill Petroleums. Jefferson is developing an 80,000 acre project immediately east of Calgary's city limits. Sufficient reserves will be proved up to support a 300 ton per day sulphur processing plant. Reported price of 14 cents per thousand feet for field-gathered gas is the best so far announced publicly, and will be boosted to 15 cents the third year, with subsequent escalation of ¼ cent yearly. Initially these contracts call for the supply of 50 million cubic feet daily with peak of 125 million feet.

Inland Natural Gas

Pipelaying had been 87 per cent completed by late August on the 10-inch and 12-inch sections and was well advanced on the 8-inch and 6-inch portions of Inland's large gas main pipeline through the interior of B.C. Final completion was expected by the end of September. Testing was completed on 120 miles and clean-up done on more than 200 miles. Toughest portion of the project had been the 10-inch portion between Penticton and Rossland, over the Cascade range.

City and town distribution systems had been completed by end of August in Penticton, Kelowna, and Summerland, and were complete except for installing services at Vernon, Kamloops, Merritt, 100-Mile House, Williams Lake, Quesnel, Grand Forks and Castlegar. Distribution systems at Trail and Rossland were well under way. About 90 per cent of the entire distribution systems was complete, with installation of 24 city gate stations in progress. Gas will be available at Savona early in September for cleaning the system prior to arrival of Peace River gas.

Alberta Gas Trunk Line

Fulton Bannister, Ltd. had completed 17 miles of 34-inch pipeline by late August and was proceeding with construction of 100 miles of 18 inch pipe from the Provost field to Burstall. Work was also progressing on 29 miles of the gathering system at the Provost field. AGTL, at the request of Westcoast Transmission had been carrying out surveys to determine the cost of pipeline construction from a point northeast of Calgary to the British Columbia border in the Crow's Nest Pass, and costs of a 30-inch line from Westcoast's proposed gas plant in the Coleman district to the B.C. border.

Approval of the Alberta and Southern Gas Co. Ltd. proposal for a 1,300-mile pipeline to San Francisco would call for a second major gathering line by the Alberta Gas Trunk Line system, more than doubling the present facilities now under construction. A 500-mile gathering line is envisaged from the B.C.-Alberta border near Fort St. John, through Pembina, Sundre, East Calgary fields and possibly the south half of Pincher Creek field and via the Crow's Nest Pass to California.

Winnipeg Central Gas Co.

Winnipeg's long awaited natural gas rates were set September 3 by the Municipal and Public Utility Board. Rates are higher than those proposed for other nearby Manitoba communities but somewhat below those proposed by the gas company, and will cut 10 per cent from its estimated 1958 gross revenue.

Conversion to natural gas is expected to be completed by mid-November. The company expects to have some 4000 new residential customers by year-end. Almost all the present 15,000 customers are industrial or commercial. By fifth year of operation, demand is expected to increase to 47/50 million cubic feet daily.

Trans-Canada Pipelines

By late August, Dutton Williams Ltd. had completed section 4 of the 34-inch pipeline from Alberta to Winnipeg. This was the last contract to be completed. Sections 5 and 6 had been completed by Price-Poole and Canadian Bechtel about mid-August. Testing had been commenced and the entire line was expected to be ready for operation as far as Winnipeg by early September.

Dry weather in August speeded up the work on the stretch between Winnipeg and the Manitoba-Ontario boundary. Weather is not expected to be a serious factor on this section due to the fact that trenching through the muskeg areas is completed and the right of way beyond

Plastic Cables. Phillips Electrical Company Limited, Brockville, Ont., officially opened a plant at Vancouver recently to produce all-plastic insulated wire and cable, the first such plant in Canada. The modern equipment includes the huge cabling machine shown in the accompanying picture, which can handle 12 units at once.

the present end is solid rock.

It is becoming apparent that some of the work on the Crown Pipeline will be suspended over the winter before reaching Lakehead. One major bottleneck is the crossing of the Winnipeg river at Kenora. Rock drilling here will not be completed before December. Pipelaying was to start September 1. Some pipe was delivered in August and stringing was proceeding, but only 15 miles of ditch was done at the end of August.

Of the three other contractors on the Crown Pipeline only one will finish by late fall. The completion date to Lakehead is now of small consequence however, since the heating season has already started and conversions to natural gas are not feasible during cold weather.

Work on the Toronto-Montreal stretch of the Trans-Canada line was progressing rapidly in August in various places thoughout its length. Dredging the lake bottom for the crossing of the Lake of Two Mountains to the Island of Montreal was under way.

On the Oklahoma Constructors' spread in the Oshawa area, 19 miles were welded at the end of August out of a total of 84 miles. Dutton Williams Bros. in the Newcastle area had 50 miles cleared and 20 miles graded on their 114-mile section. In the Cornwall section, Grayco Constructors had 45 miles welded and a further 94 miles to complete.

Project to Reduce Flares and Waste

Alberta's Conservation Board late in July approved in principle a $17 million scheme to utilize gas now flared and wasted from the Pembina oilfield.Accepted plan was submitted by Goliad Ltd., Canadian subsidiary of W. H. Bass & Sons Inc. of Oklahoma City. Imperial, Texaco, B.A. Oil, Tennessee Gas Transmission and Canadian Superior Oil of Calif. Ltd. were in agreement with the plan, though not ready to sign the existing agreement. L. C. Stevens, chairman of the Pembina Operators Committee, stated 25 million cubic feet daily may be available from the field, and that Trans-Canada has offered to take this flow for a 15 year period. Negotiations are also under way with Pacific Gas and Electric Co. and local utilities for export to California.

Lakeland Natural Gas of Kingston has obtained a franchise from the Ontario Fuel Board to supply Ganonoque, 17 miles east of Kingston, with natural gas. This is the company's nineteenth franchise obtained from Port Hope to Cornwall. Lakeland is still competing with Consumers' Gas of Toronto for the franchise to supply the city of Kingston. Construction of the local systems will be commenced early in September.

Northern Ontario Natural Gas plans to 'sell' its natural gas from Trans-Canada throughout its far flung region by setting up free-of-charge information centres in key communities, and by conducting educational functions prior to the delivery of gas. President R. K. Farris will set up an industrial research division as an active clearing house to assist in coordinating research, development and industrial location functions, between finance, industry, development associations, boards of trade and other civic groups.

The company has awarded contracts for distribution networks at Fort William, Port Arthur to Campion Pipeline Services, and at Kenora and Dryden to Manitario Gas Systems Ltd.

Pipeline News

Formation of a company to pipe Alberta gas 1,300 miles to the San Francisco area was announced August 27. Alberta and Southern Gas Company, Ltd., proposes to spend $330 million for a pipeline with initial daily capacity of 400 million cubic feet and plans initial operation late in 1960. Construction will start as soon as government approvals are given by Alberta, Ottawa and Washington.

This is the project announced jointly last July by Canadian Bechtel Ltd., and Pacific Gas and Electric Co. of San Francisco. The line will follow a route west from Calgary, through the Crow's Nest Pass and through the Pacific Northwestern States. J. B. Black of San Francisco, Board Chairman of Pacific Gas and Electric, was elected chairman of the Board and S. M. Blair of Toronto vice-chairman. J. K. Horton of San Francisco was named president and chief executive officer.

Gas Prices

Federal government review of all export and import permits for gas may result from the announcement by Pacific Northwest Pipeline Corp. that it wants to charge 17 per cent more to its wholesale customers. This would include Canadians, and the company expects to earn an extra $105,000 yearly by increasing its prices in Canada. Pacific Northwest is supplying gas to Vancouver only until Westcoast's gas arrives there this fall. But it has a 20 year contract to supply Trail, B.C. The 22 cents the company pays Westcoast for Canadian gas at the border is less than is paid by Westcoast's B.C. customers. Stiffening of federal control across the border is regarded as inevitable.

Valve assembly is being welded to the 34-inch main line on this section of the Trans-Canada Pipe line from Alberta to Eastern Canada.

Canadian Arctic Studies

Tidal Research

Two unique Arctic tidal stations form a part of Canada's contribution to the International Geophysical Year ocean studies. The instruments arrived in the Arctic in August to enable Canadian researchers, already advanced with preparations, to install stations at Resolute, on Cornwallis Island, and at Brevoort, off the southeast tip of Baffin Island, which will reach beneath the heavy ice crust to record ocean movements.

At Resolute, over 2000 miles north of Montreal, tidal gauge instruments were installed at the end of a specially built rock and gravel causeway.

Readings were already being taken from instruments at Brevoort Island, where Department of Mines and Technical Surveys men had installed a special instrument developed for the Arctic probe by National Research Council.

Located on a tripod on the ocean floor, a pressure cell transmits changes of the ocean level back to land by means of electrical impulses carried over specially designed cable.

Readings will continue to flow into the tidal stations, during the Arctic winter, from the instruments then inaccessible under thick ice. Rotating graphs will record the ocean movements. As a precautionary measure, each Arctic survey post will have three gauges.

These Canadian posts are linked with I.G.Y. hydrographic studies at five other permanent tidal stations located at Churchill, Man., Halifax, N.S., St. John's, Newfoundland, and at Tofino and Prince Rupert in British Columbia. The Canadian findings will be of use to the Department in studies for navigation and engineering projects in the Far North.

Air Photo Mapping Study

1963 is the date set by the Dominion Government for completion of a fully effective photographic coverage of the Canadian Arctic Archipelago.

The six-year project is planned to cover 500,000 square miles and to cost $6.3 million. Participating in the work will be three aerial survey companies: Aero Surveys Ltd., of Vancouver, Photographic Survey Corporation of Toronto, and Spartan Air Services Ltd., of Ottawa, all experienced in vertical photography, and having the equipment essential for this largest operation of its kind ever undertaken in the free wold.

Each company has been assigned one of three major sections of the area to be covered. Thousands of pictures, taken by large cameras at a height of 30,000 feet and resulting in photographs on the scale of approximately one mile to the inch, will be used for precise mapping to aid resources development and to amplify defence information. This photography combined with the recently completed R.C.A.F. Shoran operation, will furnish the main basis for detailed mapping of the Canadian Arctic Archipelago.

Arranged by the Department of Mines and Technical Surveys, the program will help other interested departments also, whose requirements were added to the over-all plans. All photographs resulting from this coverage will be made available to other departments, and to the public through the facilities of the National Air Photo Library at Ottawa.

Frequency Standardization in Cape Breton

An extensive program of frequency conversion from 25 to 60-cycle power has been completed in Nova Scotia. Initiated by Dominion Steel and Coal Corporation and its subsidiary, the Seaboard Power Corporation Limited, the program involved conversion of the Dominion Coal Company's operations in Glace Bay and New Waterford, as well as the residential, commercial and industrial facilities and service in New Waterford, Dominion and environs.

A co-operating public, four power retailing companies, the municipal corporations of three incorporated towns, the County of Cape Breton, two electrical service companies, Cape Breton's biggest industry and the power producing Seaboard Power Corporation Limited, made possible ease and efficiency of the conversion so that the program almost escaped notice elsewhere.

Costing hundreds of thousands of dollars to the industry, the plan was effected to cause minimum inconvenience to the consumer. It was first launched in 1929, and eventually delayed by a depression and by World War II. Pioneer promoter of the plan was E. L. Martheleur, chief electrical engineer of Dosco. As a result, Cape Breton's power-producing facilities are now concentrated for greater efficiency.

Dosco pioneered the use of pulverized coal in specially-constructed steam boilers for development of electricity. The Seaboard Power Corporation of Glace Bay now has an installed generating capacity of 70,000 kilowatts and operates with efficiency on pulverized fuel exclusively. The Seaboard system is tied in with the power generating plant of Dominion Iron & Steel Division, thereby giving Dosco a total available capacity of 105,000 kilowatts. The big plant uses some 150,000 tons of coal per year.

For the conversion to 60 cycles, the majority of the cost was borne by Seaboard, the balance being absorbed by the retailing agencies, Dominion Utilities Company, Limited and the Town of Dominion. Dominion Utilities, an independent company owned by The Eastern Light and Power Co. Ltd., replaced 2,800 25-cycle meters, erected new 60-cycle substations, and replaced all high tension transformers.

One direct advantage is easier interchange with No. 3 power plant at the Sydney steel plant and improved service. The new 60-cycle, 600-hp., 163 r.p.m. C.G.E. motor and rotor drives an Ingersoll-Rand compressor which pumps compressed air down the back deep at No. 16 colliery. The compressed air is used to power machinery and air driven pumps. Need of a frequency changer at the Waterford Lake Power plant is eliminated.

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE
ELECTIONS AND TRANSFERS

Additional Assistant General Secretary

On September 1, Dr. Garnet T. Page joined the Headquarters staff of the Institute as an assistant general secretary. For many years he has been general manager and secretary of The Chemical Institute of Canada. For a considerable portion of that time he has been also managing director of the society's publications.

Though born in the Maritimes (Halifax) he was graduated from the University of Saskatchewan in 1940 with a B.A. degree in chemistry. He is the recipient of honorary degrees from several European universities, and medals and awards from various European countries. He has been decorated by His Majesty King Paul of Greece and Pope Pius XII.

Dr. Page has taken an interest in military affairs, training as a cadet in the C.O.T.C. at Saskatchewan. On active service in 1939-1940 he served as a lieutenant in the Saskatoon Light Infantry. He was seconded to the General Staff for work on chemical warfare and in 1942 was transferred to Intelligence. He retired in 1945 from a staff appointment in the Adjutant General's Branch. He is now a member of the Reserve of Officers with the permanent rank of captain, and an associate member of the Cameron Highlanders of Ottawa with the acting rank of lieutenant colonel.

He has published many papers, reports and pamphlets on a wide variety of subjects including United Nations and UNESCO affairs, chemical warfare, the chemical industry and education for engineering and science economics. He was appointed by the Cabinet to represent Canada at four sessions of the General Conference of UNESCO. Also he wrote and delivered forty-nine broadcasts on popular science for UNESCO. These were broadcast from European and South American centres to over fifty countries.

Dr. Page has rendered a great number of services to the Federal Government through many departments. The ministries and agencies for which he served on committees or acted as consultant are Departments of External Affairs, Labour, National Defence, National Health and Welfare, Trade and Commerce, Post Office, Bureau of Statistics, Civil Defence, Civil Service Commission, National Film Board, National Research Council, etc.

Dr. Page holds or has held office with many organizations such as chairman of committee on immigrant problems of Canadian Citizenship Council, co-founder of the scientific film division of the Canadian Film Association, honorary president of National Federation of Canadian University Students, secretary of the Canadian Committee on Counselling in Engineering and Science, and president of the Ottawa Branch of the University of Saskatchewan Alumni Association.

At the recent annual meeting of the Chemical Institute, the president, Dr. Clifford Purves of McGill, made a presentation to Dr. Page on behalf of The Chemical Institute of Canada. Perhaps a short quotation from the address delivered by Dr. Purves will give Engineering Institute members a "close-up" of the new assistant general secretary.

"The extensive knowledge that Dr. Page has accumulated about the professional social, educational, national and international aspects

Dr. Garnet T. Page, M.E.I.C.

of science and about administration procedure, has always been available on request. His unassuming courtesy, friendliness, and initiative have won for him the confidence of a great many people of diverse interests, and his unfailing willingness to help whenever he can has usually brought forth willing co-operation in return. These qualities have nourished the internal growth and development of the C.I.C. very effectively, and have much to do with the happy relationships the C.I.C. has always enjoyed with other professional, governmental and educational organizations. Although hundreds of members have devoted themselves to our progress, relatively few have occupied a position as central as that of General Manager, and none for so long a time. It is therefore safe to say that the C.I.C. as it

Cover Picture

The cover picture is an aerial view of the Iroquois lock of the St. Lawrence seaway. Recesses for the sector gates can be seen at either end of the lock.

Photograph by Spartan Air Services Limited exists today owes as much to Dr. Page as to any other individual. We can thus look back with warm appreciation on the eleven years of his life which Dr. Page has devoted so wholeheartedly to the interests of Canadian chemists and chemical engineers."

Wintertime Construction

Since March, 1955, the Engineering Institute of Canada has taken an active part in the work of the Joint Committee on Wintertime Construction. The Institute representative is W. B. Pennock, M.E.I.C., of Ottawa. Sponsored by the Canadian Construction Association, the Joint Committee includes representatives of the Canadian Chamber of Commerce, the Canadian Manufacturers Association, the Canadian Legion, the Canadian and Catholic Confederation of Labour the Canadian Labour Congress, the National House Builders Association, and the Royal Architectural Institute of Canada, as well as the Engineering Institute. Associated with the Joint Committee are the Federal Department of Labour, the Division of Building Research of the National Research Council and the National Employment Advisory Council.

In September, 1956, the Engineering Institute Council approved the following statement on wintertime construction for the use of the joint committee: Engineering projects are not shut down in winter when the cost of shut down, including the interest on funds invested, exceeds the extra cost involved in winter construction. While there are exceptions, the quality of construction work carried on in winter in Canada need not suffer providing planning, supervision and control of the work is done by qualified engineers."

During the past two winters, the Joint Committee has fostered national campaigns, with vigorous local support in many centres across Canada. These campaigns have been conducted to increase winter work and to keep materials moving during the usual cold weather seasonal lull, by encouraging the carrying out of all kinds of construction jobs that can be done just as well in winter as in summer.

It is difficult to assess the results of these campaigns from a national point of view, but reports indicate that wherever local campaigns have been pursued actively, they have been effective in increasing employment and economic activity in general. In addition, the Federal Cabinet recently issued a directive to all its agencies, instructing them to arrange their construction programs so that plans and specifications, tender calls, contract awards and the various stages of construction will be timed to provide the maximum amount of winter work for the construction and allied trades.

At the fourth meeting of the joint committee held in Ottawa on August 19, 1957, it was decided that an even more active campaign will be carried out during the coming winter. A special ten minute film on seasonal employment entitled "It's a Crime" has been produced by the Department of Labour, and will be shown across the country. In addition, as many as possible of the mass media of communication, — the press, radio, television, direct mail, and special publications —will be used by the Joint Committee and the agencies associated with it to carry the following message to the people of Canada:

Winter Construction — Why Not?

"It was not so very long ago that it was common practice in the Canadian building industry to close down all jobs completely as soon as the first snow fell and to leave them closed down until spring. Today, practices have changed. Large construction jobs are normally kept going through the winter, and now the same trend is taking place in housing and other smaller construction jobs.

"Technological changes in the building industry provide a large part of the explanation for this. Another factor is the substantial improvement that has occurred over recent years in winter building techniques. These developments have made it both possible and practical to carry on most types of construction throughout the winter even under our cold weather conditions.

"The fact that winter work is feasible does not necessarily mean that it is automatically carried on throughout the winter months. Technological improvements have created a situation where work in most cases can be carried on, but customs, habits, and traditions of former years die hard, and often work is still closed down anyway. What is needed is a change in our habits of thought which will bring our action more into line with technological possibilities.

"Construction at any time requires careful planning. When this is done architects and construction men agree that any additional costs of winter building are negligible, especially when outdoor work is well advanced when the coldest weather comes. There is usually additional expense involved for heating and protective shelter but there are offsetting factors such as the greater availability of skilled labour, building materials and equipment, and an earlier occupancy of the building by the owner, which may result in a saving in rents and financing costs.

"A bulletin entitled WINTER CONSTRUCTION has recently been issued by the Division of Building Research of the National Research Council in Ottawa in its "Better Building Series." This booklet, which is available at ten cents per copy, outlines the essential precautions that should be taken in the wintertime in such things as excavations, painting, concrete and masonry work. It also clearly indicates that building activities can be carried forward during the winter months provided proper advance planning is done."

It was agreed that the Joint Committee should again write to the Provincial Governments, the chartered banks and other large organizations which either paid for or influenced the timing of construction operations, pointing out the anticipated problems of seasonal unemployment during the coming winter and asking for their continued support and co-operation in increasing the volume of wintertime construction. Letters would also be sent to the presidents of the various member organizations of the joint committee thanking them for past co-operation, and asking them to keep up their promotional activities through speeches, articles, convention resolutions, etc.

The following resolution was passed:

WHEREAS: Construction workers constitute the largest single group of seasonably unemployed workers during the winter months in Canada, and

WHEREAS: Those employed in housebuilding operation are particularly affected, and

WHEREAS: Decisions concerning the mortgage arrangements for the construction of homes during the coming winter will have to be made within the next month to enable proper planning and the "closing in" of buildings before the extreme winter conditions commence, and

WHEREAS: The shortage of mortgage funds is a basic problem retarding the construction of new houses and there is a likelihood of increased unemployment this winter, and

WHEREAS: Central Mortgage and Housing Corporation has authority to advance direct loans for housing construction and agreement was reached with private lending institutions to increase their allocation of investment funds to residental mortgages,

THEREFORE BE IT RESOLVED: That the National Joint Committee on Wintertime Construction strongly recommend that the Federal Government take steps to increase the supply of mortgage funds for the 1957-58 winter housing program.

Raymond Brunet of Hull, Quebec, chairman of the Joint Committee on Wintertime Construction, welcomed the announcement made shortly after the meeting by the Federal Government that $150 millions in additional mortgage funds will be made available for housing operations.

New Awards for Technical Papers

In keeping with the Institute's policy of expanding its technical activities is the announcement of Council relative to two new prizes recently established. One of these is for a paper in the electrical field and the other in the mechanical field.

The Sir George Nelson Award

The John Inglis Company Limited and their associate, the English Electric Company of Canada Limited, have completed arrangements with Council for the establishment of the Sir George Nelson Prize to commemorate the visit of Sir George, then president of the Institution of Electrical Engineers, to the seventieth annual meeting of the Institute held in Montreal in 1956. The prize is the sum of two hundred and fifty dollars awarded annually for a worthy paper presented by a member of the Institute, under 35 years of age, on the "science of electrical engineering".

The Robert W. Angus Medal

The second award is established by two well known Members of the Institute — Messrs. H. G. Thompson and W. L. Thompson, and is in honour of Professor Emeritus R. W. Angus, Hon. M.E.I.C., who for over fifty years taught mechanical engineering at the University of Toronto. The award is in the form of a medal and will be presented for the best paper of the prize year on a mechanical engineering subject within a prescribed area. Funds have been deposited with the Institute whereby the award can be made in perpetuity.

These are two outstanding contributions to the Institute and to the profession. The Council of the Institute appreciates greatly the generosity of the donors and hopes that many young men will thereby become encouraged to greater efforts in these two fields.

Not counting Honorary Memberships, this brings to thirty the number of awards on the Institute's calendar. It is an impressive number, which fact, along with a realization of the broad field covered, indicates the long life of the Institute and the variety of its interests. However, there is still room for more prizes and any member who may be interested may obtain details by writing to Headquarters.

The rules and regulations that apply will be published shortly.

Nominees for Office

The report of the Nominating Committee, as accepted by Council at the meeting held on September 20th, 1957, is published for the information of all corporate members as required by Sections 19 and 40 of the by-laws:

Vice-Presidents

°Zone B (Province of Ontario)	H. G. Conn	Kingston, Ont.
°Zone C (Province of Quebec)	E. T. Buchanan	Grand'Mere, Que.
°Zone D (Maritime Provinces)	Grant R. Jack	St. John's, Nfld.

Councillors

†Vancouver	F. M. Cazalet
†Edmonton	S. K. Hampton
†Lethbridge	David Cramer
†Calgary	T. D. Stanley
†Saskatchewan	W. M. Berry
†Winnipeg	N. M. Hall
†Sault Ste. Marie	Wm. Douglas Adams
†North Eastern Ontario	A. A. Kidd
†Huronia	E. L. Cavana
†Sarnia	R. A. McGeachy
†Kitchener	L. J. R. Sanders
†Hamilton	E. T. W. Bailey
†Niagara Peninsula	Paul E. Buss
‡Toronto	E. R. Davis
†Peterborough	P. F. Peele
‡Ottawa	W. A. Capelle
†Cornwall	Howard E. Meadd
§Montreal	E. D. Gray-Donald Leo Roy
†Quebec	B. O. Baker
†Northern New Brunswick	W. F. Hosking
†Moncton	A. W. Purdy
†North Nova Scotia	Robert S. Morrow
†Halifax	G. F. Vail
†Cape Breton	M. R. Campbell

° One Vice-President to be elected for two years
† One councillor to be elected for two years
‡ One councillor to be elected for three years
§ Two councillors to be elected for three years each

Simplified Student Application

Simplified application forms for students membership have been designed and printed in English and French, ready for distribution at the beginning of the fall university session.

The delegates of the student conference held in conjunction with the annual meeting of the Institute last June, recommended that simpler forms be designed for use in universities. They thought that the questions regarding engineering experience in the old forms did not apply to most of the engineering students at the time they applied for membership.

The new forms were designed especially for students of engineering at Canadian universities, whence the great majority of applications for student membership come. The old form will still be used by candidates who are qualifying through apprenticeship and examination and by post-graduate students not yet eligible for Junior membership.

The principal requirement remains unchanged. Each application whether submitted on the old or the new form, must bear the signature of a sponsor who is a corporate member of the Institute. The E.I.C. Faculty Representative may act in this capacity for candidates from his university.

Some Thoughts About Confederation

by a member of the Institute

During these days, when it seems to some of us that confederation is making its way forward at a disappointing pace, let us take a fresh look at some of the principal points that we can identify, and hold to, to keep our thoughts "on course" in line with the destination we have set out to reach.

As engineers in Canada we want:—

(a) A unified and recognized voice in the conduct of our affairs, and in the nation's affairs.

(b) A single standard of admission to professional status, with adequate safeguards.

(c) An efficient system for the acquirement and interflow of technical knowledge, and

(d) A minimum, but fair, annual charge for these services.

These are, and must continue to be, the main objectives of those who are charged with the responsibility of exploring the ways and means. Finding out what can be done about it is not easy, no easier in its way than confederation of the nation was ninety years ago. Why not help these men, to the very limit of our separate abilities. At least we can shape opinion by our attitude and conversation.

It has been suggested that some people, a small minority, are dragging their feet in the course of the present negotiations. If there are any such persons they are standing in the path of a torrent. Regardless of what has been done by the committees in charge of the exploratory work, no one can evade the fact that the members of our profession in Canada have developed, within themselves, a climate of opinion overwhelmingly in favour of confederation — soon — in some workable form. This is the torrent.

No single organization, contemplating its part in such a professional commonwealth, need have a single fear for its identity IF — its purposes and aims are those of service and progress. These aims survive any temporary change, and provide a guarantee of emergence again as vital parts in the next stage of development. Any segment of the profession without such faith in itself can not have much to offer.

It is appropriate at this point to remember the words of a great Canadian at a critical stage of the last war. Planning was badly fouled up, and progress seemed to be dangerously slow. He opened an important meeting with this statement. "There is no problem that can not be solved around a conference table, by men of good will, who have come there determined to solve it."

Let's get around the table!

EDITOR'S NOTE. The member who submitted this article, and whose letter is filed at headquarters, has requested that his name be withheld from publication.

Harry F. Bennett Fund

The trustees of the Harry F. Bennett Education Fund of the Institute are happy to report a very active season in the 1956-57 scholastic year. Applications for loans were received from 40 engineering undergraduates and one postgraduate at seven institutions, and all but five were granted in amounts varying from $50 to $250 and totalling $7,500. The bulk of the applications this year came from men at the Nova Scotia Technical College at Halifax, 29 out of the 41 being from that source. Six applications were from Laval students, two from McGill, and one each from Mount Allison, University of New Brunswick, Queen's and the University of Alberta.

It is of interest to note that seven of the applicants asked for a second or third loan, but none was granted an amount to exceed a total of $450, which is set as the maximum to any one man. A post-graduate student who has paid up two former loans has applied for and received a further loan.

While this money was being sent to these promising and deserving students other money was of course coming in to Headquarters as repayments from recipients of former loans. The total thus received in the year ending December 31, 1956 was $4,315 in repayment and $215 in interest. The loans outstanding at the year end amounted to $17,323.

The trustees, feeling that the fund should be used on occasion for educational purposes other than loans to students, gave a $1,000 bond to the Institute toward the cost of educational films.

Dr. Otto Holden of Toronto became a trustee during the year, to replace V. A. McKillop, who resigned to become president of the Institute. The other trustees are Hugh C. Nourse and Dr. Irving Tait of Montreal, the former being due to retire at the time of this annual meeting, after over four years' service.

Otto Holden,
Hugh C. Nourse,
Irving R. Tait, Trustees,
May, 1957.

Annual Meeting, 1958

Engineering Institute of Canada

Chateau Frontenac, Quebec City, May 21, 22, 23

Engineering Literature in Russia

Over a period of several months the Institute has been receiving enquiries from libraries and other organizations in Russia relative to an exchange of publications and other technical literature.

It is indeed interesting to see how much literature of this kind is available in Russia. For example, the State Public Library in Leningrad Center has sent a list of publications which they would be glad to exchange with the Institute. The list shows a most interesting group of subjects and a total of 93 separate and regular technical publications.

With the reports made in this country relative to state controlled activities in Russia, it is interesting to see that all of the 93 publications, with the exception of two, are published by industries, technical societies and research institutes.

Before the second world war the Engineering Institute used to receive a few Russian publications. No attempt was made to translate the articles but the publications were on display in the reading room and quite a few people showed an interest in them. It is just possible that some of the present members would like to see some of the new periodicals, and therefore some attention is being given to the matter to see which of all these publications might be brought to the Institute in exchange for the *Engineering Journal*.

Exhibition of Photographs, 1957

The winning entries of the 1957 exhibition of photographs have been selected. The exhibition, one of the features of the 71st annual meeting of the Institute at Banff, contained over 90 photographs. Five photographs were selected as the best of the show. They are listed in random order:

"230-kv Oil Circuit Breakers"
The British Thomson - Houston Co. (Canada) Ltd.

"Chipping of 3,350-hp. Impulse Turbine Runner Buckets"
Dominion Engineering Company Ltd.

"Manotick Bridge"
C. C. Parker and Associates.

"Coquihalla River Crossing near Hope, B.C."
Canadian Bechtel Ltd.

"M. V. 'Bluenose' Ready for Launching"
Davie Shipbuilding Ltd.

Award of merit certificates are being sent to the exhibitors of the winning photographs. Publication of these five photographs begins in this issue, below.

Arrangements are being made to send the collection to the Universities across Canada, for exhibition during the 1957-1958 session. It may also be possible to arrange exhibitions in places open to the general public. The first exhibition of the season was held in Eaton's Montreal Store during the week of September 16 to 21.

Some of the branches may be able to arrange exhibitions locally, to stimulate interest in engineering. Public libraries, high-schools, or the showrooms of downtown buildings would be suitable places to display the pictures. Besides showing the general public some of the work done by engineers, such exhibitions would encourage young people to think of engineering as a career.

Requests for bookings should be sent to headquarters as early as possible.

"Manotick Bridge". Entry of C. C. Parker and Associates to E.I.C. Photographic Exhibit, 1957.

Evening Education

A wide selection of engineering and scientific courses are now available to many of those who seek to improve their technical education in evening classes.

It is most encouraging to observe how our Canadian universities are doing their best to ever widen and improve the educational services they offer. This is particularly noteworthy in the fields of engineering and science, and has been spurred on, no doubt, by the present shortage of technical manpower in this country.

Programs of 1957-58 university extension courses recently received, from Ecole Polytechnique and McGill for examples, show that they are offering evening instruction this year in as many as twenty-five different technical and allied subjects. Students of all ages from 17 to 70 are reported to be enrolled, mostly from that large group of persons who must spend their daytime hours in earning a living.

Due to the very wide scope of the modern engineering field, most of these courses are designed for the undergraduate level, but there are some that will be recognized as giving credits toward engineering graduation. Most are intended, basically, to advance the individual's knowledge along some specialized line of work.

Similar extension courses are offered at other Canadian universities, so it is not the intention to suggest that such activity is confined to the two named above. The purposes of this article are two-fold, to make readers aware of what is being done in this field, and to congratulate those hard-working persons throughout our colleges who are striving to cope with the growing demand for more scientific education.

Some details of these courses are available in the Institute library, but it is suggested that anyone seeking more information should apply directly to the registrar of the university of his choice. The *Journal* will try to provide further news of these activities as it reaches headquarters.

Journal Content

The current issue is the second *Journal* in which the technical section is devoted mainly to information about the St. Lawrence Seaway. The earlier one was the September, 1956, issue.

The remaining *Journals* for 1957 will maintain a high standard of interest.

November will be a "Northern issue", in which the Canadian North will be discussed in technical papers, as follows: A Power Plan for the Yukon River Waters, by J. M. Wardle, M.E.I.C.; The Peace River and Alaska Gas Gathering System, by A. L. Berry, M.E.I.C., and B. L. Moreau, M.E.I.C. Hunting Associates will contribute a paper on Aerial Survey Methods. There will also be information on the DEW-Line.

The December issue will include information on foundations, structure, services and equipment for C.N.R.'s Queen Elizabeth Hotel in Montreal.

New Institutions for the Teaching of Engineering

In response to the increase in the enrolment in engineering and the even greater increase which will take place in the future, many institutions of learning in Canada have started engineering courses, or have extended existing partial courses.

Among the institutions which have recently adopted complete courses to a degree are The University of Western Ontario at London; Hamilton College (McMaster University), Hamilton; Essex College (Assumption University) Windsor, Ontario; Waterloo College, Waterloo, Ontario; Ottawa and Carleton Universities at Ottawa; and the University of Sherbrooke at Sherbrooke, Quebec.

In addition to these universities where engineering will now be taught for all years, Sir George Williams College in Montreal has inaugurated new classes in engineering covering the first three years of a five-year course. It is expected most of the work of Sir George will be done in night classes, although the full course will be operated in the daytime as well.

From time to time the *Engineering Journal* proposes to describe the work of these institutions which are either new in the field or are expanding their previous efforts, so that engineers across Canada may know more of the great expansion which is taking place in the field of education for engineers.

"Personally, I'll be happy when the whole damn bunch take off for the moon!"

THIRTY-FIVE YEARS AGO

Comment on the Journal of October, 1922

The report of the 36th General Professional Meeting at Winnipeg was the major item appearing in the October 1922 issue. Under the chairmanship of President J. G. Sullivan, some 300 members heard Mayor F. O. Fowler pay tribute to the profession in general and to the service to the community by Mr. Sullivan and by General Ruttan, former City Engineer of Winnipeg.

E. V. Caton presented a paper on 'Extensions to the Hydro-Electric system of Winnipeg', while F. H. Martin, chief engineer, Manitoba Power Co., described his company's power development at Great Falls. The following day delegates visited this project and the Point du Bois plant of the Winnipeg Hydro, travelling by special train. The third day was devoted to papers and discussions on Boxcar Unloaders, Fuel values of Alberta coals, Action of Alkaline ground waters on Portland cement, and Considerations for a Road Policy.

Guests of the evening at the annual banquet included Hon. W. R. Clubb, Minister of Public Works of Manitoba; D. C. Coleman, vice-president, Canadian Pacific Railway; Rev. Dr. Leslie Pidgeon, D.D., and A. W. McLimont, vice-president and general manager, Manitoba Power Co., and Past-President Col. J. S. Dennis, M.E.I.C.

Employment of Engineers

Editorially, it was noted that the last several months had seen a gradual improvement in employment conditions for engineers. A joint committee, under the chairmanship of J. G. Christie, representing the A. S. C. E., A. S. M. E., A. I. E. E., A.I.M.M.E. and A.S.H.V.E. was noted, purpose of which was to draw up a Code of Ethics to be adopted by all engineering societies. Tribute was paid editorially to the late David Thompson, one of Canada's most famous explorers, who had died unnoticed more than half a century ago. A memorial to him had been opened on August 30 at Windermere, B.C.

Under Branch News, organization of the Lakehead Branch of the Institute on September 12, 1922 was noted, under branch chairmanship of G. H. Burbidge, M.E.I.C., of Port Arthur. The Toronto Branch news recorded the Ontario Legislature was about to take up the question of consolidation of town planning legislation, while a committee in Toronto was drafting a town planning bill to be submitted to this Parliamentary Committee. The November 15 Branch meeting would discuss the draft bill.

Hon. F. C. Biggs, Ontario Minister of Public Works, had addressed a meeting of the Hamilton Branch in September, his subject being 'Ontario Highways'. The Ottawa Branch noted an important conference on Lake of the Woods Regulation had been held in September, attended by the Canadian Prime Minister and Governor Prens of Minnesota. Governor Prens was a strong advocate of the early commencement of the St. Lawrence Navigation and Power project.

Ottawa news also noted the return of Controller of Surveys A. M. Narraway, M.E.I.C., D.L.S. from an interesting trip through Western Canada for the Topographical Surveys Branch. The trip included a 1,000 mile seaplane flight from Victoria Beach, Man., northeast to Ontario boundary, thence to The Pas and over the Churchill and Reindeer rivers. Parties engaged on surveying the Alberta-B.C. boundary were also visited as well as parties in the Grande Prairie district and parties in Saskatchewan and Alberta.

K. H. Marsh, M.E.I.C., chief engineer of the Dominion Iron and Steel Co., presented a paper at the opening meeting of the winter session of the Cape Breton Branch. His subject was construction and operation of the blast furnace. He traced development of the present day furnace from the early variety known as the Catalan forge, through the various stages of increased height and hearth, with the introduction of the hot blast, the closed top, with utilization of the waste gases.

The Montreal Branch recorded the resignation of J. L. Busfield, M.E.I.C., as secretary of the Branch due to his duties in connection with the Hydro-Electric Inquiry Commission of Ontario, and the appointment of E. A. Ryan, A.M.E.I.C. as his successor.

Under 'Correspondence' an open letter from A. G. Graham, A.M.E.I.C., care Stewart and McDonnell, Gold Coast Harbours, Seccondee, Gold Coast Colony was published. Noting that Majors Crysdale and Silcox were with him and all were engaged on preliminary work for construction of a harbour at Takoradi, it observed that all material for railway grades was moved by baskets and headwork, requiring careful supervision. An accompanying photo showed five pith-helmeted engineers in white suits and black bow ties; A. G. Graham, A.M.E.I.C., Major Angus Stewart, A.M.E.I.C., Major C. R. Crysdale, M.E.I.C., Col. McDonald, and S. C. Arnett.

The Advertisers

Thirty five years of evolution in consulting services may be observed by comparing the professional cards in the October 1922 issue with those of today. Of the twenty consulting engineers or companies mentioned, none have display cards in the current issue. While in 1922 all had their offices in Montreal, Toronto and Ottawa, of the thirty five firms whose cards appear in the current issue 22 have offices in the central provinces, four in the Prairie Provinces, five in British Columbia; and four have headquarters in the central provinces with branches in the west.

An advertisement by Canadian Westinghouse Co. Ltd., displays a cut of a then recently completed bascule bridge over the Burlington Beach Canal at Hamilton, Ont., soon to be replaced by the Burlington Skyway.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

ONTARIO

Engineers in the News

Army Headquarters, Ottawa, has announced the appointment of Col. **J. R. Dunlop**, P.Eng., as Military Attache, at Prague. To assume these new responsibilities, Col. Dunlop vacates the appointment of director of Electrical and Mechanical Engineering at Army Headquarters, a post he has held since 1952.

Col. Dunlop obtained his degree in mechanical engineering at McGill in 1935 and first served with the 3rd Divisions Signals. At the start of the Second World War he was appointed to the Ordnance Corps, which at that time was responsible for mechanical engineering. Proceeding overseas in 1941 he held a series of appointments with the 2nd Canadian Corps and the 4th Armoured Division.

After the war he served for two years as assistant director of electrical and mechanical engineering, attended the Canadian Staff College, commanded the R.C.E.M.E. School at Barriefield, Ont., and in 1952 was appointed to the post he has just left.

Lieut. Col **Robert A. Campbell**, P.Eng., of National Defence Headquarters, Ottawa, has been promoted to the rank of colonel and appointed director of electrical and mechanical engineering at Army Headquarters. In this appointment, which became effective on August 2nd, Col. Campbell succeeds Col. J. R. Dunlop, P.Eng., now Military Attache at Prague.

Col. Campbell has been serving in the Canadian Army since 1939 and after service with the R.C.O.C. and R.C.-E.M.E. in the United Kingdom and Northwest Europe, was posted in 1946 to Army H.Q. as inspector of R.C.O.C. and R.C.E.M.E. services for Canada. Latterly, he has held the appointment of assistant director of electrical and mechanical engineering.

John Hunt, P.Eng., and **R. Clare Mott**, P.Eng., two professional engineers of Falconbridge Nickel Mines Ltd., have been appointed to vice-presidencies in the company.

John Hunt, who is vice-president-projects, is an engineering graduate of the Scottish St. Andrew's University and has been with the Falconbridge organization since 1932. Prior to the recent appointment he was manager of the project division.

R. Clare Mott, P.Eng., obtained his degree in mining engineering at Queen's University, Kingston, and has been with Falconbridge for 22 years. He has been manager of the mining and reduction division of Sudbury district for 6 years. During 1953 and 1954 he represented the Mining branch on Council of the Association and has since been a member of several committees.

Nicholas Chlumecky, P. Eng., has accepted the post of chief engineer, the Rockiron Company Ltd., Sudbury, Ont. He was formerly assistant mine shiftboss at Falconbridge Nickel Mines.

F. S. Hutton, P.Eng., of the Canadian National Railways, Toronto, has been promoted to the position of assistant to the chief engineer, Central Region.

John B. Wilkes, P.Eng., **Gordon F. Wetherall**, P.Eng. and **Robert S. Chapman**, P.Eng., have received further appointments with the Ontario Department of Highways.

Mr. Wilkes moves to Toronto as district engineer from Ottawa, where he has held the position since 1954. Mr. Wetherall, who has been district engineer at New Liskeard for the past three years, moves to Ottawa in the same capacity. Mr. Chapman becomes district engineer at New Liskeard after serving in Ottawa as the district construction engineer since 1954.

Charles M. Bishop, P.Eng., has joined the staff of Humphreys & Glasgow (Canada) Ltd., 837 Eglinton Avenue West, Toronto 10, Ont. The firm is engaged is the design, process engineering and construction for the petroleum, petrochemical and chemical industries and is associated with Humphreys & Glasgow Ltd., a well known British company.

Mr. Bishop was formerly with R. V. Anderson & Associates Ltd., Toronto.

Dr. Robert Sandri, P. Eng., is employed as an associate research officer at National Research Council, Ottawa. Prior to accepting this appointment he was with the Canadian Westinghouse Co. Ltd., at Hamilton.

B. I. F. Breakey, P.Eng., has been appointed vice-president and general manager of the New Consolidated Canadian Exploration, Ltd., 2-8 King St. East, Toronto. He has also been appointed a director of Canpet Explorations Ltd., an oil company with head offices in Calgary. In this appointment he is the Canadian representative of the Consolidated Gold Fields of South Africa.

Leonard H. Harper, P.Eng., who is a project engineer with Defence Construction (1951) Ltd., is located at the R.C.A.F. Station, Rockcliffe, Ont. He is also engaged in work at Shirley Bay and Connaught Ranges.

Fred R. Dorward, P.Eng., is now engaged in electrical consulting work with Crowther, MacKay & Associates, Ltd., 522 Northern Hardware Building, Edmonton. He was earlier with the Canadian General Electric Co. Ltd.

R. J. Brule, P. Eng., is technical service manager with the Minnesota Mining and Manufacturing of Canada Ltd., London, Ont. Before moving to London he was on the engineering staff of the Northern Electric Co. Ltd., at Belleville, Ont.

J. W. Carmichael, P.Eng., of the Harbours and Rivers engineering branch of the Department of Public Works of Canada, has been transferred from Ottawa, to Halifax, N.S.

Richard W. Braddock, P.Eng., has moved from Hamilton to Windsor, Ont. He has accepted the position of a design engineer with Giffels & Vallet of Canada Ltd., engineering consultants. Mr. Braddock was formerly in the City Engineers office of Hamilton, Ont.

G. Moes, P.Eng., announces the establishment of a consulting service covering technical evaluations, witness tests and reports on electrical equipment, materials and specifications. His address is 226 North Shore Boulevard East, Burlington, Ont.

Mr. Moes, who was born in Holland and graduated in electrical and mechanical engineering from the University of Liverpool, recently retired as manager of the Testing Laboratories of the Canadian Standards Association, and has had a wide experience in his special field in more than 30 years connection with the electrical industry in Canada, the United Kingdom and Europe.

M. W. Hotchkin, P.Eng., and **J. C. Adamson**, P.Eng. have been elected to the board of directors of Little Long Lac Gold Mines Ltd.

Mr. Hotchkin, who was president of the Association last year, is vice-president in charge of Wright-Hargreaves Mines Ltd. He is also a past president of the Ontario Mining Association and past vice-president of the Canadian Institute of Mining and Metallurgy.

Mr. Adamson is vice - president in charge of operations of Lake Shore Mines Ltd., which company he joined in 1931. He is likewise a past-president of the Ontario Mining Association

William M. Price, P.Eng., of the Canadian Pacific Railway, has been transferred from Manitowadge, Ont., where he was resident engineer, to Sudbury, Ont., where he is engaged in the same capacity.

John C. Ormond, P.Eng., has recently been granted his release from the Canadian Army (Regular) and has accepted a position as a staff engineer in the mechanical department of the Aluminum Company of Canada Ltd., Isle Maligne, Que.

A graduate in mechanical engineering from Nova Scotia Technical College, he joined R.C.E.M.E. in 1951 and has been stationed in various parts of Canada as well as in Japan. Latterly he has been planning offices at Army Headquarters in Ottawa in the Directorate of Electrical and Mechanical Engineer.

Medal Winners

By coincidence the two winners of the Association's Gold Medal awards for the academic session 1956-7 have completed courses in electrical engineering. The medal-winner at the University of Toronto is **Jan Alexander Norton**, B.A.Sc., of Toronto, and at Queen's University, **Peter William McBurney**, B.Sc., of Ottawa.

This annual award by the Association of Professional Engineers of Ontario is made to the student in the final undergraduate year in the engineering faculty of the University of Toronto and Queen's University, Kingston, who obtains the highest academic standing in the final year. It is in the form of a gold medal and a gift of technical books to the approximate value of fifty dollars.

John M. S. Cherry, P.Eng., of Downsview, Ont., who was formerly employed by J. B. Parkin & Co., is now with the Department of Public Work, dams, docks and locks division, as assistant hydraulics engineer.

W. B. Redman, P.Eng., of Toronto, has recently retired from the Canadian National Railways after more than 37 years service.

Mr. Redman graduated in civil engineering from the University of Toronto in 1915 and served in Canada and overseas with the Canadian Expeditionary Force until 1919. At this time he joined the engineering staff of the Canadian National Railways and was with the company until his retirement on July 31.

Neville E. Hale, P.Eng., has been elected to the board of directors of the newly-formed Gresham Transformers (Canada) Ltd., of 518 Evans Ave., Toronto. He has also been retained as technical consultant.

Mr. Hale is also electrical consultant to Fetherstonhough & Kent, patent attorneys of Toronto, Winnipeg and Calgary, and has a consulting practice in patent development with offices at 129 Queen St., Niagara-on-the-Lake, Ont.

Charles A. Mott, P.Eng., completed 38 years of continuous service with the Corporation of the City of Belleville, on June 30. For twenty-eight year of these years he has been city engineer.

Mr. Mott started work in the engineering department of the city in July, 1919. In 1929 he was to have reported to Trenton, Ont., as its town engineer. At that time, however, then city engineer of Belleville, Charles B. Campbell, died from injuries sustained in a motor accident. Through the intervention of Belleville's Mayor and several of the members of Council, Trenton agreed to release Mr. Mott from the earlier undertaking and on June 1st, 1929 he was appointed City Engineer of Belleville.

Mr. Mott, who is a veteran of the First World War, has been a member of the Association of Professional Engineers of Ontario, since its early years. He is justly proud of his long years of public service in Belleville.

ALBERTA

(Abstracted from The Alberta Professional Engineer September 1957)

Is Basic Engineering Enough?

The much discussed shortage of engineers has led to the attitude that our universities should turn out engineering graduates in an ever-increasing volume. However, at the same time we must consider that our expanding profession is actually requiring increased education.

Engineers today have found their way into fields which at one time were not in any way associated with our profession and technical advances of recent years have broadened the scope of engineering theory and practice. In the face of these developments it is unrealistic to expect universities to produce graduates today as adequately trained, proportionately speaking, as graduates of twenty years ago within the confines of the same space of time.

Universities are continuously faced with the problem of adjusting the engineering curriculum; balancing course content against available time and specialization against generalization.

Guiding Principle. Guiding principle in selection of a curriculum is the provision of a program of Basic Engineering. Analysing such a program we find it contains a number of courses of a non-engineering nature.

There is the necessity for adequate grounding in the sciences upon which engineering is based, further training in the Englsh language beyond the high school level, and the introduction of so-called cultural subjects, now a trend in broadening engineering subjects. The balance of the program must consist of introductory courses in particular phases of the various branches. In the teaching of these applied science courses an essential objective is the demonstration of the engineering method.

The engineering student should develop the ability to critically analyse a given problem and logically choose a method of solution. Mastering of the engineering method by the undergraduate is of more importance than the amassing of numerous specialized tools in a specific area of study.

Supplementing the Program. How can a program of basic engineering be supplemented? We cannot agree with the attitude that upon completion of an undergraduate program a student is quite capable of going the rest of the way alone. A certain amount of self education is desirable but more formal study is necessary.

One solution is study and discussion programs within engineering firms and departments.

University short courses can play a part. The main objective of these courses is to outline specific phases of a particular subject and to stimulate further study by the individual.

Graduate Study. Graduate study, the most satisfactory means of rounding out an engineering education, sometimes considered of greatest value to those who plan to enter the research and academic fields, should be designed for the purpose of further preparation for any engineering employment. Such programs can be entirely devoted to specialization in specific fields.

Employers of engineers should play a prominent part in the extension of engineering education. Encouragement must be given to those considering graduate work and it should be recommended for those who might benefit by it. Financial assistance should be made available in greater volume in the form of bursaries and fellowships. Present university facilities are not adequate for an increased volume of graduate students. Employers should feel the responsibility of offering finances for the improvement of graduate schools since they will ultimately benefit.

We expect our graduating engineers to have a foundation in basic engineering, but is that sufficient? In an expanding profession we must deal with an attendant expansion in our educational requirements.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

James Edward Beatty, M.E.I.C., retired engineer of the Canadian Pacific Railways, eastern lines, maintenance of way department died in Toronto on August 14, 1957.

A cousin of the late Sir Edward Beatty, former president of the Canadian Pacific Railway, Mr. Beatty was born at Parry Sound, Ont., on June 6, 1872. A graduate of the Royal Military College in 1894 his first engineering assignments were with the Toronto, Hamilton and Buffalo Railway, and with the Los Angeles, Pacific and Crows Nest Branch of the C.P.R. Around the turn of the century he worked on the territory of the White Pass and Yukon Railway and the Klondyke Mines Railway. He also held the qualifications of Dominion Land Surveyor. He served as resident engineer on the construction of the Guelph and Goderich Railway in 1904 and was promoted to engineer on the Schreiber division in 1910. In 1911 he was appointed assistant engineer of construction, eastern lines, C.P.R., and divisional engineer for years later. In 1915 he was district engineer at Saint John, N.B., and also served in the same capacity in the general superintendent's office at Montreal. He was made district engineer of the Quebec district in 1916 and was appointed engineer, maintenance of way, eastern lines in 1933.

He joined the Institute in 1905 as an Associate Member and transferred to Member in 1915.

Colin Dugald McTavish MacKintosh, M.E.I.C., retired consulting engineer with the Canadian Pacific Railway, Vancouver, died at Victoria, B.C., on May 12, 1957.

His birthplace Auckland, N.Z., Mr. MacKintosh was born on September 24, 1882. He was educated as a civil engineer at the Glasgow and West of Scotland Technical College, the Inverness Royal Academy, and served an apprenticeship with a Glasgow consulting engineering firm from 1899 until 1905. In his early years in this country, to which he migrated in 1905, he worked as rodman, draftsman, and instrumentman on construction with the Canadian Pacific Railway. Within the next few years he was named division engineer for the Saskatchewan division of the Railway. In 1915 he held the appointment of superintendent of the Medicine Hat Division. He then took over the Lethbridge Division. Succeeding appointments took him to Edmonton, Winnipeg and Kenora. In 1941 he was division engineer and assistant superintendent of the railway at Victoria. Named engineer in charge of the then new Nanaimo terminus in 1947, this was followed by his appointment as engineer in charge of the Esquimalt and Nanaimo Railway Company at Victoria, B.C. He became a consulting engineer for the Pacific Great Eastern Railway in 1950 and two years later extended this work to the Canadian Pacific Railway Company. He retired in 1955.

Mr. MacKintosh joined the Institute in 1911 and was transferred to Member in 1922. He attained Life Membership in the Institute in 1947.

Frank Leslie Davis, M.E.I.C., district airway engineer, since 1951 for the Department of Transport for Air, Montreal Air Port, Dorval, Que., died on August 11, 1957.

Mr. Davis came to this country from England where he was born on November 20, 1890 at Gloucester.

He attended high school at Newport, Eng., undertook three years training at Newport Technical Institute and became an articled pupil with a Newport firm. On his arrival in Canada in 1911 he worked as a leveller and draughtsman with the eastern division of the Canadian Pacific Railway and as a draughtsman on the construction of the Pacific Great Eastern Railway at Vancouver. In 1914 he joined the Canadian Field Artillery and served overseas, until 1919. On his return to civil life he was named to the staff of the North American Magnesite Producing Company Limited, at Calumet, Que. In 1921 he joined J. A. Grant and Company Ltd., engineers and contractors at St. John, N.B. and was engineer in charge of construction for the firm. He was assistant engineer on the staff of the John S. Metcalf Company on the construction of a grain elevator for the Montreal Harbour Commissioners in 1924. He was also associated with the International Paper Company at Montreal, and the Gatineau Power Company at Hastings, Ont., before joining the Department of National Defence, civil aviation department, as a district engineer in 1936. The following year he joined the Department of Transport, civil aviation department as a district airways engineer at Nakina, Ont. In 1946 he was named supervising engineer of aerodromes for the Department.

Mr. Davis became an Associate Member of the Institute in 1924, transferred to Member in 1940.

Charles McKay Hare, M.E.I.C., of the Quebec Metallurigcal Industries, Ottawa, died on July 6, 1957 in that city.

Born at Woodstock, N.B., on January 30, 1906, he attended schools in the Maritime provinces and later attained a B.Sc. degree in civil engineering at McGill University in 1929.

His first graduate work was with the Dominion Bridge Company Limited, at Lachine, Que., as a structural steel detailer. Shortly after this he was for two years associated with the Atlas Construction Company and the Standard Dredging Company on West Saint John harbour improvements. In 1936 he joined the Arntfield Gold Mines Limited working first as a surface transitman and as an engineer foreman in charge of construction camps and roads. The following year he became underground surveyor and then chief underground surveyor. In 1939 he was employed with Noranda Mines Limited as a surveyor and draftsman for the construction and mechanical department. During World War II he served with the Ministry of Aircraft Production as a civilian engineer in England and in West Africa. He returned to Canada in 1944. Since that time, apart from his work with Quebec Metallurgical Industries he worked as city engineer at Rouyn, Que., in 1949, with the Indian Affairs Branch of the Department of Citizenship and Immigration, Ottawa, in 1952, and with Cobalt Chemicals Limited, at Cobalt, Ont., the following year.

Mr. Hare joined the Institute in 1928 as a Student Member. He became a Member in 1941.

David D. Clerk, M.E.I.C., consulting engineer of Quebec City, Que., died on July 30, 1957 in that city.

Mr. Clerk was born at Montreal on February 6, 1901. He studied engineering at the Ecole Polytechnique, Montreal, and was awarded a B.Sc.A. degree from that university in 1924. For the first six years of his career he was associated with the Amusite Asphalt Ltd., and Robertson and Janin Ltd. contractors. In 1930 he joined the Department of Agriculture for the Province of Quebec. From assistant chief of the drainage section, he became chief and then chief of the rural engineering division and finally president of the drainage bureau for the provincial government. In 1945 he went into private practice and remained in this work until the time of his death. He was also named manager of the city of Chicoutimi, Que., in 1949.

Mr. Clerk joined the Institute in 1945 as a Member.

Alvin Norman Andrew, JR.E.I.C., who was employed with the Aluminum Company of Canada Limited, Shipshaw, Que., for several years, died at Chicoutimi, Que., on August 30, 1956.

Born at Morden, Man., on August 5, 1927, Mr. Andrew received his early education at Morden andd then went on to study engineering at the University of Manitoba. A graduate of the class of 1951 he worked for a time with the Province of Manitoba. In 1952 he moved to Arvida, Que., and joined the Aluminum Company of Canada hydraulics department, Shipshaw, Que. He later became assistant civil engineer.

Mr. Andrew joined the Institute as a Student Member and transferred to Junior in 1951.

Personals

News of the Personal Activities of Members of the Institute

Dr. D. B. Steinman, M.E.I.C., consulting engineer of New York was awarded the Gold Medal of the Americas by the Chamber of Commerce of Latin America. The gold medal carried the inscription "To Dr. D. B. Steinman, Builder of Inter-American Bridge of Good Will, August 28, 1957." The presentation of the award to Dr. Steinman was accompanied by a luncheon held in his honour and the reading of a citation.

He was at the same time named Honourary Life Member of the Chamber of Commerce of Latin America in U.S.A. Inc.

Lt. Col. C. Gordon Kirby, M.B.E., M.E.I.C., has taken up the new appointment of Command electrical and mechanical engineer of the Prairie Command at Winnipeg, Man.

Lt. Col. Kirby received his B.Sc. degree in mechanical engineering from the University of Saskatchewan in 1936. Before the war he was employed at the Vulcan Iron Works in Winnipeg, Man.

Robert H. Winters, M.E.I.C., former Minister of Public Works this month took over the Canadian operations of the Rio Tinto Company as its president. A British corporation, the Rio Tinto Company, specializes in the development of natural resources in many countries.

Mr. Winters worked his way up as an engineer in industry, with the Northern Electric Company Limited at Montreal during the thirties. He entered politics in 1945 in his home constituency of Lunenburg, N.S., following extensive overseas service in World War II.

Lt. Col. C. G. Kirby, M.B.E., M.E.I.C.

Dr. S. M. Breuning, M.E.I.C., was some time ago appointed to the staff of the University of Alberta to assist in the greatly expanded program of activity in the highway transportation field, set up at that university.

Professor Breuning last served the Joint Research Highway Project of the Massachusetts Institute of Technology, sponsored by the Massachusetts Department of Public Works. He graduated from a technical university at Stuttgart, Germany, with a diploma in engineering. He did graduate work in civil engineering at M.I.T. from 1953 to 1957 in transportation, soils mechanics and city planning. He also studied transportation and business administration at the Harvard School of business administration at M.I.T. He came to Canada in 1951.

Paul E. Pesonen, M.E.I.C., executive vice-president and member of the board of directors of Canadian Javelin, Limited, Montreal has resigned from this office. Now located in California he is engaged in consulting work in the field of mining.

H. M. Smith, M.E.I.C., recently in charge of the C.B.C. station at Sackville, N.B., has gone to Kingston, Jamaica. On loan for the purpose of developing a broadcasting system in that country, he will be with the Ministry of Development at Kingston.

Dr. J. Krol, M.E.I.C., until recently associated with the University of Manitoba

S. M. Breuning, M.E.I.C.

R. V. Tomkins, M.E.I.C.

now teaches in Atlanta, Georgia, where he is professor of industrial engineering at the Georgia Institute of Technology.

Dr. Krol joined the staff of the University of Manitoba in 1954. He is a graduate of the Universities of Warsaw and London.

Colonel W. A. Capelle, M.E.I.C., director of engineer development at Army headquarters, Ottawa, has been appointed Commander, Canadian Base Units, Middle East. Colonel Capelle was the 1957 choice for chairman of the Ottawa Branch of the Institute.

Colonel Capelle saw extensive service in World War II, retiring as senior officer with the Royal Engineers, Airfields, at headquarters, First Canadian Army in 1945.

He rejoined the regular army in 1947. In 1952 he was promoted to the rank of colonel and appointed director of works, A.H.Q. Two years later he was appointed director of engineer development.

Louis O'Sullivan, M.E.I.C., was some time ago named a commissioner of the Quebec Hydro-Electric Commission.

General executive assistant of the company since 1942 he was given thirty-four years of experience with the organization, at one time known as the Montreal Light Heat and Power Company.

R. V. Tomkins, M.E.I.C., has opened a consulting engineering office in Regina, Sask. under the name of R. V. Tomkins

Consulting Limited. The firm specializes in work related to industrial minerals. Mr. Tomkins was director of the industrial minerals research branch of the Saskatchewan Department of Mineral Resources from 1952 to 1954, and worked for that department since 1947. He held the position of chief engineer with Western Clay Products Limited prior to entering private practice.

Mr. Tomkins is a 1944 graduate in chemical engineering from the University of Saskatchewan.

R. A. Crysler, M.E.I.C., has been appointed a consultant with the firm of M. M. Dillon and Company Limited. He became a director of the company in 1953 and manager of the company's Toronto office.

A graduate of the University of Toronto in civil engineering he was employed for two years as senior structural engineer for the H. K. Ferguson Company of Cleveland, Ohio, and for a period of five years was in charge of structural design for Chapman and Oxley, Toronto, Ont. In 1932 he joined the staff of the Canada Cement Company Limited as structural engineer. During his service with this company he acted in a consulting capacity to the Federal Government and to certain Provincial Government Departments as well as to engineers and architects throughout Canada in connection with the design and supervision of large concrete structures.

Mr. Crysler specializes in reinforced concrete design and construction, architectural monolithic concrete construction, soil cement paving and concrete mix design and control.

J. J. Heffernan, M.E.I.C., has been appointed a partner in the company of M. M. Dillon and Company Limited, in charge of development.

Mr. Heffernan is a graduate of the University of Toronto with a B.A.Sc. degree in mechanical engineering and

J. A. Grant, M.E.I.C.

J. J. Heffernan, M.E.I.C.

an M.A.Sc. in public health engineering.

Prior to joining the company staff he served with the R.C.E. as works engineer in Manitoba including the construction at Ft. Churchill. He later held the appointment of second-in-command of the design section of the directorate of works at army headquarters.

Since 1954 he has been employed by the company as senior project engineer.

W. K. Clawson, M.E.I.C., of M. M. Dillon and Company Limited, consulting engineers, has been named a vice-president of the company and manager of the Toronto office of the firm.

A graduate of the University of Toronto in civil engineering in 1940, he served with the R.C.E. until 1945.

He became a member of the firm in 1951 and has since headed the company's municipal department. Prior to 1951 he served for one year on the staff of the Horton Steel Company Limited and for five years as county engineer for the County of Middlesex, Ont.

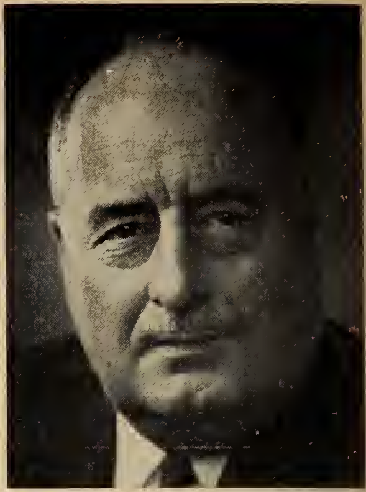
Arthur FitzPatrick, M.E.I.C., who has carried on business in Calgary for some time as a consulting engineer has joined the staff of the Research Council of Alberta in Edmonton. His position is that of industrial engineer.

Mr. FitzPatrick gained a B.Sc. degree at the University of Alberta in 1949, later qualifying for a degree in psychology in 1955, also at that University.

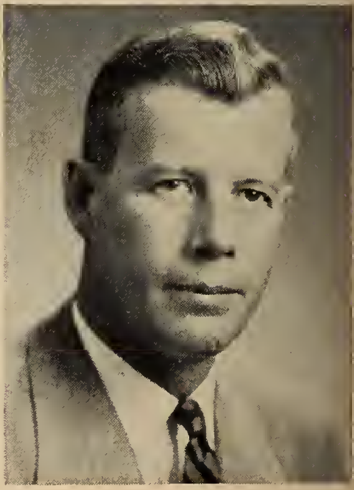
S. H. deJong, M.E.I.C., a University of British Columbia engineering professor has been appointed to serve a three-year term on the committee of the American Society of Engineering Education.

Professor deJong has been appointed to the surveying and mapping committee of the civil engineering division of the society.

J. A. Grant, M.E.I.C., chairman of the Belleville Branch of the Institute is a graduate of McGill University and an official of the Northern Electric Com-



R. A. Crysler, M.E.I.C.



W. K. Clawson, M.E.I.C.

pany Limited, communications equipment division.

Now chief engineer of the Belleville plant Mr. Grant has also served as assistant superintendent of equipment engineering. With the firm for a number of years, he began his career with the Belleterre Quebec Mines Limited, at Belleterre, Que.

Mr. Grant was secretary-treasurer of the Belleville Branch in 1955.

Brigadier J. R. B. Jones, M.E.I.C., who has held office as commander of the New Brunswick area for the past three years at Fredericton, has been posted to Whitehorse, Y.T. as commander and chief engineer of the Northwest Highway System. Brigadier Jones served as senior highway engineer on the Northwest Highway System at an earlier date in his career.

Karl E. Gustafson, M.E.I.C., a 1940 graduate in mining engineering from McGill University has completed his mining construction assignment in Greece. Mr. Gustafson was associated with Pierce Management Inc. of Scranton, Pa. and the Public Power Corpora-

tion of Athens, Greece. He is now chief engineer for Pierce Management Inc. at the firm's anthracite operations at Coaldale, Pa., carried out under the name of Coaldale Mining Company Inc.

Lloyd L. Marshall, M.E.I.C., serving as chairman of the Northern New Brunswick Branch of the Institute is a design engineer with the Bathurst Power and Paper Company Ltd., at Bathurst, N.B.

Mr. Marshall graduated from the Nova Scotia Technical College in 1954 with a B.Eng. degree in mechanical engineering.

E. E. Lord, M.E.I.C., vice-president and manager of the firm of Smith Brothers and Wilson Limited, contractors and engineer, of Regina, Sask., has retired from active professional life following nearly thirty years association with the company. He will reside at Victoria, B.C.

Active in engineering since early in this century Mr. Lord had his training at the University of British Columbia, spent four years in the service of the Royal Engineers, B.E.F., and then followed his career in China. An assistant chief engineer on a river improvement project in Manchuria, he continued to live in that part of Asia until 1928. It was at that time that he accepted work with Smith Brothers and Wilson Ltd.

Mr. Lord assumed the duties held until recently, of vice-president and manager, in 1939.

H. E. Moller, M.E.I.C., of Defence Construction (1951) Limited, has been transferred from head office at Ottawa to Comox, B.C. His new appointment is that of project engineer.

A. J. Williams, M.E.I.C., of Saskatchewan, former chief reservoir engineer of the provincial natural resources department, mines branch, has been named director of the petroleum and natural gas branch of the department of mineral resources.

Mr. Williams followed his career in Eastern Canada for ten years working in the munitions field and as a consulting geologist before joining the staff of the Province of Saskatchewan in 1947.

A. B. Barnes, M.E.I.C., who graduated from the University of Birmingham, England, class of 1950, has joined the Boeing Airplane Company of Seattle, Washington as a design engineer.

R. C. Peck, M.E.I.C., prevously assistant works manager of the Shawinigan works of the Aluminum Company of Canada has been appointed plant manager at Etobicoke, Ont.

L. L. Marshall, M.E.I.C.

With the company a number of years Mr. Peck has served in Canada, British Guiana and Great Britain as well as attending the "Centre D'Etudes Industrielles" at Geneva.

He graduated from the University of Alberta, class of 1940, in civil engineering.

George J. Crane, M.E.I.C., who has been associated for a number of years with the Electric Reduction Company of Can-

• PERSONALS

ada has taken over the post of general manager and chief engineer of Huron Chemicals Ltd., Toronto.

Mr. Crane studied electrical engineering at the University of British Columbia and graduated in the class of 1941.

John F. Ford, M.E.I.C., has been appointed general manager of Rush and Tompkins (Canada) Limited, Edmonton, Alta., general contractors. Prior to joining this firm in July he was contracts manager with Perini Ltd., Toronto.

A graduate in civil engineering from the University of Toronto in 1939, Mr. Ford has been active in general construction work in various phases, with time out for duty with the Royal Canadian Engineers from 1942 to 1946.

W. M. Price, M.E.I.C., is among recent transfers. Formerly at Sudbury with the Canadian Pacific Railway, he has taken on the duties of resident engineer in the regional engineer's office at Toronto. Mr. Price is working on eastern region engineering projects.

V. R. Cox, M.E.I.C., formerly division engineer with the C.N.R. at Kamloops, B.C., has taken up residence in Van-

H. A. Sabier, M.E.I.C.

couver where he is now assistant district engineer.

He is a 1949 graduate, University of Alberta in civil engineering.

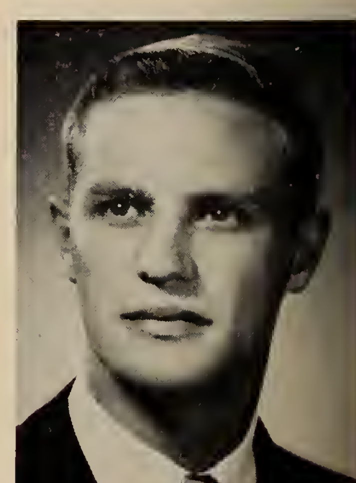
H. A. Sabier, M.E.I.C., supervising engineer, special projects division, Department of Highways and Transportation, at Regina, Sask., has been awarded the Canadian Salt Good Roads Scholarship for study at the School of Engineering, Purdue University.

Mr. Sabier graduated from the University of Saskatchewan in civil engineering in 1954 with great distinction.

J. B. Hockman, M.E.I.C., has recently been appointed project manager on the new highway bridge crossing the St. John River at Fredericton, N.B.

He has been with Grant-Mills Ltd. since 1944 when he joined the firm as field engineer. In 1952 he became chief engineer.

Thomas W. Rogers, JR.E.I.C., has received the appointment of sales engineer assigned to the Montreal office, with the Canadian Blower and Forge Company Limited.



T. W. Rogers, M.E.I.C.

• PERSONALS

Mr. Rogers is a 1955 graduate of McGill University in mechanical engineering. After completing training courses at the company's Kitchener Training Center and in the Buffalo engineering and research departments, he gained preliminary sales engineering experience in the Kitchener area.

Douglas M. McKim, Jr.E.I.C., who has been active in the affairs of the Institute as chairman of the Shawinigan Falls Branch and secretary-treasurer, and chairman of the nominating committee of the St Maurice Valley Branch, now serves as chairman of the latter group.

A divisional engineer at Shawinigan Chemicals Limited, Mr. McKim holds a B.Eng. degree gained at McGill University in 1947.

P. E. Wade, Jr.E.I.C., is one of five winners of the C.G.R.A. scholarships awarded to highway engineers. Highways analyst with the Department of Highways, Ontario, at Toronto he has been awarded the Armco Drainage Good Roads Fellowship for study at the Institute of Transportation and Traffic Engineering of the University of California. He is a 1949 graduate of the University of Toronto.

D. M. McKim, Jr.E.I.C.

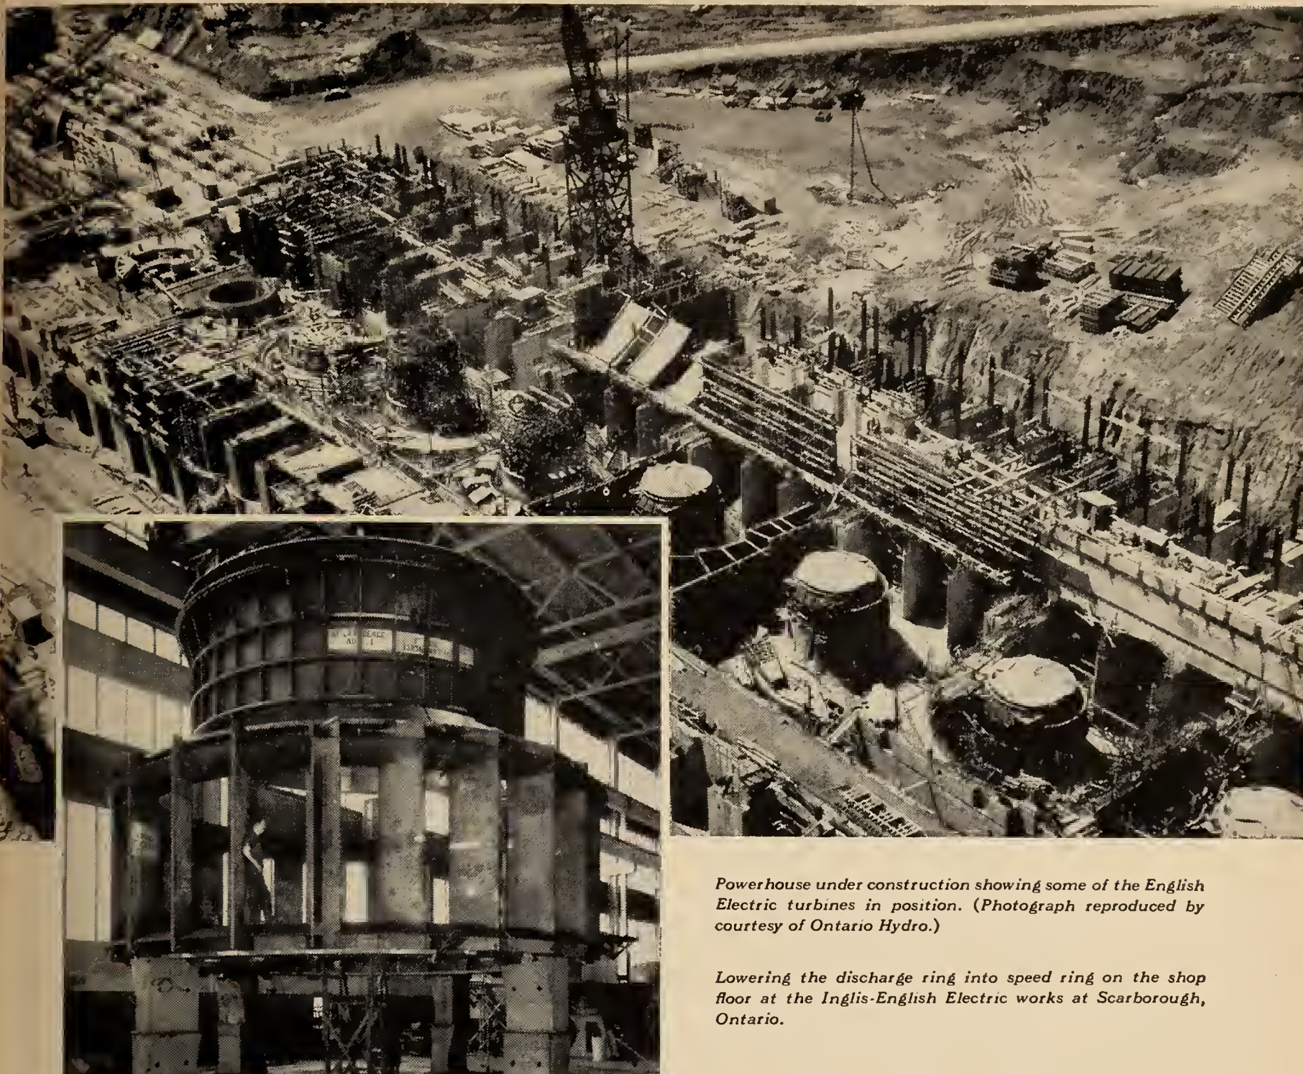
P. E. Wade, Jr.E.I.C.

W. Naves, Jr.E.I.C., formerly special engineer with the headquarters staff of Canadian National Railways at Montreal has moved to Ontario, where he has accepted an appointment with the Napanee Iron Works division of the International Equipment Company Limited.

Mr. Graves graduated from McGill University and has thus far pursued a career of electrical engineering and engineering-economic studies.

E. D. Manchul, Jr.E.I.C., of the Department of Public Works, Fort William, Ont., has been transferred to the St. John's, Nfld. office of the Harbours and Rivers Engineering Branch. His duties are those of assistant district engineer.

Wing Commander A. F. Avant, Jr.E.I.C., who has been posted at Ottawa for some time as director of Maritime, transport and training requirements is now stationed at Toronto. Associated with the R.C.A.F. Staff College he is a member



• PERSONALS

of the directing staff of the school.

Wing Comander Avant received a B.Sc. in mechanical engineering at the University of Saskatchewan in 1949.

I. H. Anderson, S.E.I.C., of the Department of Water Resources, Alberta at Edmonton, has been awarded the Standard Gravel Good Roads Scholarship. He is a 1957 graduate University of Alberta.

I. H. Anderson, S.E.I.C.

Charles L. Pelton, S.E.I.C., a 1956 graduate of Queen's University is employed with the Canadian General Electric Company at Peterborough, Ont. He is with the design engineering group of the motor and generator department. He is concerned with the control equipment for diesel-electric locomotives as built by the Montreal Locomotive Works.

M. R. Cossitt, S.E.I.C., a 1957 graduate of the University of New Brunswick in mechanical engineering is with the Polymer Corporation Limited, Sarnia, Ont., in the design section of the organization.

David J. McColm, S.E.I.C., who was awarded a B.Sc. degree in civil engineering at the University of New Brunswick this spring has joined the engineering staff of Dibblee Construction Company Limited at Ottawa, Ont.

J. Robert Burton, S.E.I.C., of Queen's University class of 1957, in civil engineering has accepted an appointment with the Dibblee Construction Company Ltd. at Ottawa, in the engineering department of the firm.

C. N. Ellert, S.E.I.C., a 1957 graduate of the University of Alberta has been awarded the Union Tractor Good Roads Scholarship for further study at that university.

Mr. Ellert is resident highway engineer with Alberta Department of Highways, at Edmonton.

C. N. Ellert, S.E.I.C.

CORNWALL FIBRE CONDUIT

gives permanent, 4-way protection

Safe Protection from

1. CABLE SHEATH ABRASION
2. CABLE SHEATH CORROSION
3. PULLING TENSION STRAIN
4. WATER SEEPAGE

Fibre conduit's smooth, continuous bore protects essential lifelines of power and communications against strain, wear and breakage during installation and repeated servicings.

Tough coal tar pitch construction and permanently water tight joints keep corrosive ground waters from cables . . . and acids or alkalies cannot be leached from the walls of chemically inert "CORNWALL" Fibre Conduit.

Fibre conduit's accurately machined, smooth joints and lower co-efficient of friction keep pulling tension at minimum . . . allow longer, trouble-free cable runs between manholes.

Light and fast to handle, Cornwall Fibre Conduit costs less to install than any other type of conduit . . . gives sure protection to expensive cable for a lifetime.

Write for useful illustrated catalogue showing applications and installation methods for Cornwall "Standard" and "Nocrete" (used without concrete) Fibre Conduit. For data on adapters, bend sections and other fittings, write your nearest distributor.

General Secretary
L. Austin Wright, Montreal

Treasurer
O. M. Solandt, Montreal

Assistant General Secretary
E. C. Luke, Montreal

Assistant General Secretary
H. P. Gatin, Montreal

Assistant General Secretary
Garnet T. Page

Field Secretary
L. F. Grant, 236 Avenue Rd., Toronto

Western Field Secretary
A. C. M. Davy, 1370 Minto Crescent, Vancouver

COMMITTEES

Admissions
Roger Brais, chairman; W. H. Gauvin, D. H. Hobbs, J. H. R. Dansereau, R. J. Harvey.

Board of Examiners
J. L. deStein, chairman; John M. Cape, J. Hurtubise.

Canadian Standards Association (Technical Council)
P. L. Pratley—Institute Representative.

Finance
A. Deschamps, chairman; R. L. Dunsmore, R. A. Emerson, R. G. Ferrabee, J. M. Breen, O. M. Solandt, R. L. Weldon.

Canadian Chamber of Commerce
F. G. Rutley—Institute representative on National Board of Directors.

Legislation
C. G. Kingsmill, chairman; D. C. MacCallum, J. B. Stirling.

Library and House
C. E. Frost, chairman.

Membership
R. H. Self, chairman.

Publication
H. A. Mullins, chairman; J. A. Audet, William Bruce, W. H. Gauvin, B. D. McDermott.

Papers
J. H. Budden, chairman; D. H. Hobbs, H. L. Johnston, M. McMurray, W. B. Pennock, E. R. Smallhorn, H. S. Van Patter.

Prairie Water Problems
G. A. Gaherty, chairman; P. M. Sauder, vice-chairman; T. D. Stanley, secretary; C. S. Clendening, D. W. Hays, B. Russell, T. H. Hogg, G. L. MacKenzie, J. H. McLean, J. M. Wardle.

Policy
R. L. Dunsmore, chairman; B. G. Ballard, A. Deschamps, I. P. Macnab, D. M. Stephens, R. L. Hearn, R. E. Heartz, J. B. Stirling, W. G. Swan, I. R. Tait.

Professional Interests
E. B. Jubien, chairman; G. A. Gaherty, vice-chairman; W. E. Brown, G. J. Currie, W. G. Swan, H. L. Branchaud, E. K. Phillips, I. R. Tait.

Property
F. G. Rutley, chairman; A. Deschamps, V. B. King, C. N. Murray, R. C. Pybus.

Student Policy
C. G. Southmayd, chairman; R. E. Jamieson, J. Dubuc, E. J. Muszinski, J. F. Riel, A. Pakalnins.

Technical Operations
F. L. Lawton, chairman; B. G. Ballard, W. H. Paterson, C. E. Frost, D. L. Rigsby, R. M. Hardy, S. Sillitoe, A. R. Harrington, E. R. Smallhorn.

OFFICERS OF THE BRANCHES

AMHERST

Chairman, R. L. Alexander; *Vice-Chair.*, J. Wilson; *Executive*, G. C. L. McEnery, J. W. Byers, R. E. Miner.
Sec.-Treas., W. G. Miller, 48 Rupert St., Amherst, N.S.

BELLEVILLE

Chairman, J. A. Grant; *Vice-Chair.*, A. E. Argue; *Executive*, T. E. Flinn, B. D. Pullen, H. T. Floyd, W. C. Benger, T. J. McQuaid, W. L. Canniff.
Sec.-Treas., E. T. Hilbig, 67 Bertram Blvd., Belleville, Ont.

BORDER CITIES

Chairman, P. N. Brown; *Vice-Chair.*, C. M. Armstrong, *Executive*, R. G. Johnson, E. R. Carpenter, R. H. Darke; *Treasurer*, J. M. Reid.
Secretary, J. E. Dykeman, 732 Moy Ave., Windsor, Ont.

BROCKVILLE

Chairman, J. G. Kerfoot; *Vice-Chair.*, W. N. Simmins; *Executive*, A. Sandilands, G. M. Woods, K. R. Bullock, D. C. Turner, H. A. Gilchrist.
Sec.-Treas., F. E. Trewartha, Canada Starch Company, Cardinal, Ont.

CALGARY

Chairman, A. W. Howard; *Executive*, K. L. Broe, W. J. McGill, R. S. White, J. L. Mitchell; *Treasurer*, R. G. Price.
Secretary, O. O. Junker, c/o Cumming, Galbraith Limited 1510a - 1st St., S.W., Calgary, Alta.

Innovation in Tunnels

The construction of the first prefabricated all reinforced concrete tunnel with a rectangular crossection on this Continent was recently visited by some 200 members of the Vancouver Branch.

The site was the 16½ million dollar Deas Island Tunnel constructed by Narod — Dawson & Hall (tunnel sections) and Kiewitt — Rayond — B.C. Bridge (approaches). The tunnel was designed by the Foundation of Canada Engineering Corporation and Christiani and Nielsen of Canada, Ltd.

The project is being undertaken by B. C. Toll Highways and Bridges Authority under supervision of the Department of Highways.

Deas Island Tunnel

Shown in the above photographs of the Deas Island Tunnel in British Columbia are (left) tunnel segments under construction, and the tunnel approach and ventilation building.

The 4 traffic lane tunnel is built in segments in a dry dock excavated on the bank of the mighty Fraser River. The excavation is protected by a dyke and a wellpoint system keeping the site bone dry.

The outside dimensions of the tunnel segments are 24 ft. x 78 ft. x 344 ft. and consist of 4 compartments: two for carrying 2 lanes of traffic each, and two smaller ones for ventillation and carrying water, drainage, electric energy and other services.

The casting of the tunnel segments will be completed in October 1957. In November, at low water stage of the Fraser River, a suitable trench will be dredged along the proposed route of the tunnel, then the dyke protecting the dry dock opened and the tunnel segments, after being made watertight by appropriate bulkheads, will be floated to their permanent positions.

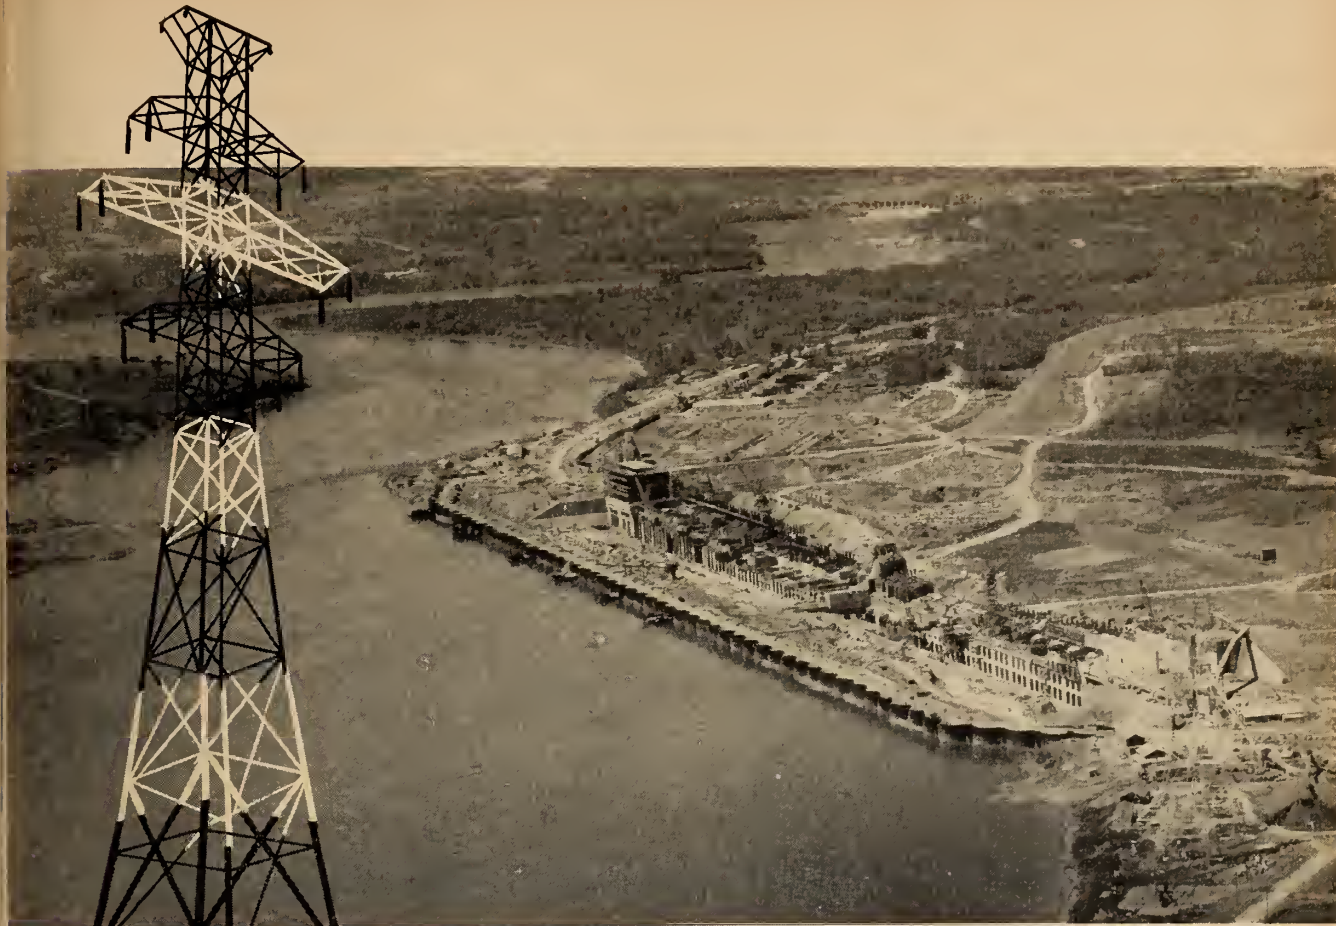
The construction is so planned as to limit to absolute minimum the work of divers whose visibility would be very problematic in the muddy water.

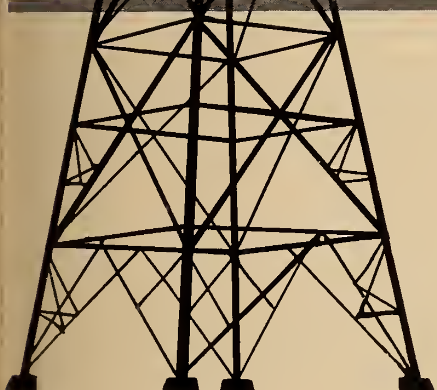
Joining Done in Dry

Joining of the tunnel segments will be done in the dry. To that purpose the segments after being floated to their positions over the dredged out trench will be sunk and pulled against a rubber gasket collar of the adjoining segment of the structure creating thus a watertight

Montreal

Herewith the results of a recent fishing expedition to the Restigouche River. On the right is Carlyle Gerow, M.E.I.C., M.C.I.M., secretary-treasurer of The Canadian Institute of Mining & Metallurgy with his best catch, a twenty pound salmon. On the left is Austin Wright, M.C.I.M., M.E.I.C., General Secretary of The Engineering Institute of Canada with his best catch, a one ounce parr. Mr. Gerow's look of superiority and exultation can be well understood! Another member of the expedition was John Bates, M.E.I.C., M.C.I.M., whose luck was no better than that of the general secretary.





SETTING THE STAGE

In 1910, Ontario Hydro met a power demand of 4,000 kilowatts —the lid of Ontario's vast treasure chest of natural resources had then hardly been opened. Last year, the demand was over 1000 times greater—4.5 million kilowatts.

As the wheels of industry turn faster and processes become more highly mechanized, development, inventiveness and engineering skill will more than ever be dependent on an abundant supply of electricity.

So the spotlight falls on such mammoth enterprises as the St. Lawrence Power Project, sixteenth new power source in Ontario Hydro's vast expansion program, and on the large thermal generating stations planned for the future.

ONTARIO HYDRO

space between the bulkheads on each element.

Individual segments will be lowered to their final positions with hydraulic jacks supporting each of their corners. After aligning the tunnel to proper elevations sand will be blown in the space between the dredged out trench and the base of the segments to form a permanent bed. At that stage the hydraulic jacks will be withdrawn and the watertight space between the bulkheads filled with concrete to form a permanent joint between the segments of the tunnel.

Watertightness of the concrete shell of the tunnel will be achieved by a rigid control of the concrete mix itself and the coating of hot asphalt and fiberglass. Covering the structure with a blanket of rock will complete the construction.

Mr. Ole Bentzen, the project manager of the construction expects that similarly to the Rotterdam tunnel built by Christiani and Nielsen on the same principles, the settlement of the structure should be confined to several milimetres.

Two ventillation buildings at each approach will be equipped wih ventillating system capable of renewing the air in the whole tunnel every two minutes.

Television screens located in the traffic control room above the ventilation buildings will allow the traffic controller to observe the passage of all vehicles inside the tunnel and transmit messages to them by means of loudspeakers and emergency telephones or, if necessary, to stop any car by means of push button operated traffic signals spaced at 172 ft. intervals.

A fireproof centre wall will separate northbound from the southbound traffic. Sprinkling system and alarm boxes together with the powerful ventillation system assures the safety of the tunnel from the smoke and engine exhaust fumes. Carbon monoxide meters will automatically start the exhausters.

Lighting Features

The tunnel will be illuminated by fluorescent lighting. Overhead louvres admitting daylight at the entrances to the tunnel will provide a gradual adaptation of drivers' sight from daylight to artificial lighting. The "electronic eyes" will automatically control the intensity of artificial lighting to assure the optimum intensity of illumination from the traffic safety point of view.

The tunnel will provide another connection to Highway 99 leading to U.S.A. border at Blaine (Wash.), and no doubt bring greater prosperity to Ladner, B.C., and its vicinity.

Participants of this very interesting tour were the guests of Narod — Dawson & Hall Ltd. for refreshments.

R. D. Hall, Jr.E.I.C.,
Secretary-treasurer

Field Trip and Dance

On September 7, 1956 a field trip to the Belly River project of the P.F.R.A., near Waterton, Alta., was held through the kind assistance of the latter organization. After the tour a golf tournament and dinner was held at Kootenay Lodge, Waterton. Following dinner the party was free to attend the Saturday night dance at the Waterton Lakes Hotel.

It is hoped that a full account of the field trip will be available for an early issue of the Journal.

News of Other Societies

Geophysical Congress

A world gathering of scientists converged on Toronto, September 3 to 14 for the Eleventh General Assembly of the International Union of Geodesy and Geophysics.

One of the main interests of the Assembly was to review the progress of the world's greatest scientific adventure, the International Geophysical Year. Theme of several displays was also the I.G.Y.

A trade exhibit of geophysical equipment was presented by thirty leading companies of Canada, the United States and Europe and areas as far apart as Japan and East Germany:

At the Royal Ontario Museum where the opening reception was held, a full-size model of the IGY Vanguard rocket and a working replica of the United States earth satellite was on view to the public. The satellite was provided by the United States National Research Council.

During the I.U.G.G. Assembly the Canadian International Air Show displayed fixed wing aircraft and helicopters, as equipped for air surveys and geophysical work.

Largest overseas group of scientists was from the United Kingdom and numbered about 90. France, the U.S.S.R., Germany, Holland, Italy, Sweden, Japan, Switzerland, Belgium, Spain, and Poland were represented and small groups from about thirty other countries attended. More than 300 American and 150 Canadians participated.

Symposiums held during the meet dealt with Water Balance, the General Circulation of the Ocean; Rock Magnetism, Physical-chemical Interpretation of Terms, magma, crust and substratum, and Geochronology and Radioactivity.

Addresses by E. I. Tolstikov, entitled, "The Arctic and Antarctic Program of the I.G.Y.," and "The Rocket and Satellite Program of the I.G.Y." by Professor L. V. Berkner were heard.

Associations participating in the general assembly, which is held every third year, are: The International Union of Geodesy and Geophysics and the International Association of Seismology and Physics of the Earth's Interior; the International Association of Meteorology; the International Association of Geomagnetism and Aeronomy; the International Association of Physical Oceanography; the International Association of Scientific Hydrology; the International Association of Volcanology.

Each provided a scientific program of importance, in the form of special study groups, reports of technical commissions, and discussions.

The National Research Council of Canada participated for Canada and the National Committee for Canada of I.U.G.G. was headed by chairman Dr. C. S. Beals of the Dominion Observatory, Ottawa.

"Rilem" Conference in Stockholm

Bond and crack formation in reinforced concrete was the subject of an international symposium, held in Stockholm, Sweden, from June 27 to 29, which was attended by two hundred engineers and scientists from twenty-five countries. That a technical subject apparently so detailed should have attracted such world-wide attention might be surprising did it not reflect the keen interest in Europe in the use of very high working stresses in both steel and concrete, and the steadily increasing recognition and use of "ultimate load design" with reinforced concrete.

North American interest was shown by the presence of Raymond C. Reese, new chairman of the A.C.I. Design Code Committee. Of the two hundred participants, however, only eight were from the Western Hemisphere (one each from Argentina, the Dominican Republic and Canada, with five from the U.S.A.) One American paper only was submitted, by D. Watstein and R. G. Mathey of the Division of Building Technology of the National Bureau of Standards, Washington.

Forty-four papers in all were accepted from fifteen of the countries represented at the Symposium. All were preprinted, as were also the summaries by the general reporters for the eight sections into which the main subject was broken down. At the conference itself, even these summaries were presented in abstract only leaving most of the meeting time for general discussion in the two official languages, English and French. This was aided by most skilful combined summary and translation by I. Cyon, an electrical engineer!

Discussion ranged from a three-dimensional mathematical analysis of crack formation, through a consideration of what is meant by a "hair-crack", to a critical analysis of the actual cracks found and measured in large groups of structures in Holland and France. Consensus of the meeting was that, although many aspects of strain cracking in reinforced concrete are not yet fully understood, enough is known to suggest that such cracks are not in general as injurious as are those which are created by corrosion, generally caused by the use of porous concrete, nor those due to shrinkage. Once again, therefore, stress was placed upon the basic necessity of obtaining concrete of the best possible quality, and upon placing it efficiently, if injurious effects upon reinforced concrete units are to be avoided.

Professor Waclaw Olszak of Warsaw, Poland, presented to the meeting the first version in English of a mathematical treatment which he has developed which explains the formation of cracks in reinforced concrete numbers under load, and does so in three dimensions and for non-homogeneous materials, starting with an investigation of principal stresses. Other more simple two-dimensional theories of crack formation were presented and discussed. Some of these relate to the width of crack which may be anticipated and some to the probable spacing of cracks along a beam, the two being interrelated.

The application of the leading theories to the actual results of 150 beam tests was analysed by Professor H. Rusch (of the Technische Hochschule, Munich). By plotting values for the difference between observed and theoretical values for crack spacing, divided by observed values, Dr. Rusch was able to show that all the main theories give results usually with an accuracy of 70%, the formula developed in his own laboratory having a mean accuracy of about 95%.

There was useful discussion about the actual widths of cracks and the slippage of bars and their measurements, an ingenious radiographic technique being described by Professor R. H. Evans and A. Williams of the University of Leeds, England. The one American paper described the determination of the decrease in crack width between the concrete surface and the surface of the reinforcing steel, a finding that was appreciatively mentioned by several discussers.

There was, however, a general feeling that since the width of cracks varies so much, and since cracks rarely form in straight lines, little was to be gained by attempting great accuracy in the measurement of crack widths. This directed attention to a very simple measuring device, described by J. F. Borges and J. A. e Lima of the Laboratoria Nacional de Engenharia Civil, Lisbon, Portugal.

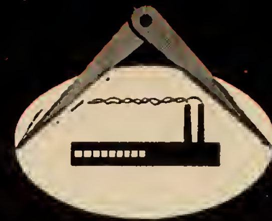
DU PONT ELASTOMERS

NEOPRENE • HYPALON®



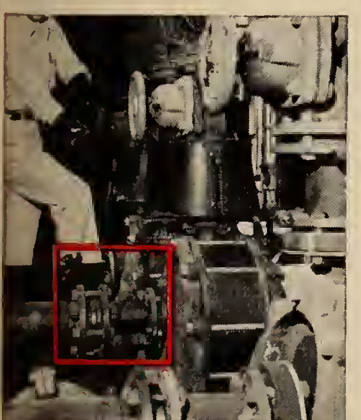
in Industry

NEOPRENE connectors save $1,000 a year in hydrochloric acid area

At a large midwestern chemical plant, long-lasting neoprene connectors have replaced the original fittings used to connect Karbate pumps to suction and discharge lines. This switch represents a saving in materials and labor of $1,000 a year.

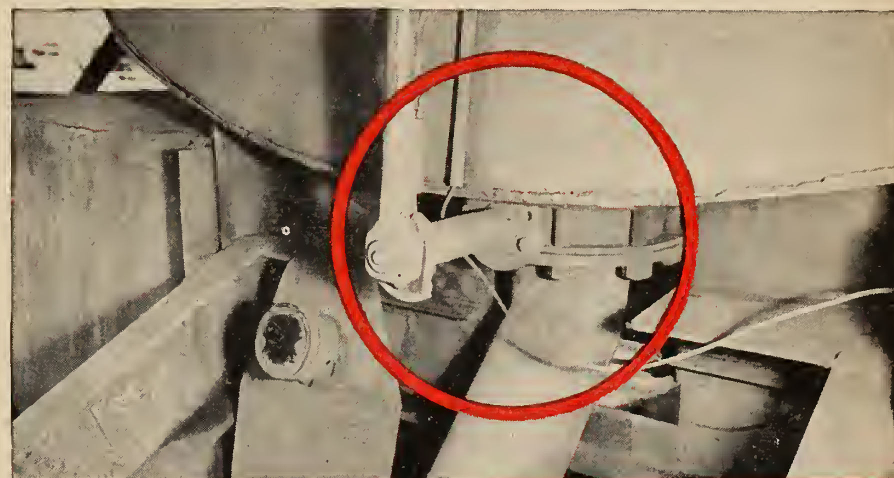
Although the previous materials used were chemically suitable to handle hydrochloric acid, they were rigid, and pump vibrations cracked them. Resilient neoprene connectors are unimpaired by exposure to hydrochloric acid and they are flexible enough to resist vibration to compensate for shifting lines without being damaged.

Neoprene resists oil, grease, heat, weather and chemicals and operates successfully under many of the industry's toughest exposure conditions. Mail the coupon for more information. Include your specific problems.

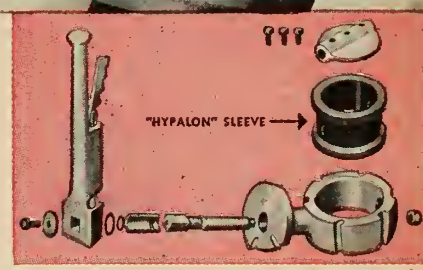


Flexible neoprene connectors resist hydrochloric acid, allow for misalignment between pumps and suction and discharge lines.

HYPALON® eliminates sleeve maintenance costs in butterfly valve handling spent acids



The resilient HYPALON sleeve in this butterfly valve snaps into the ring piece. It acts as both a valve seat and as the gasket between the ring piece and mounting flanges, giving a perfect seal.



ORIGINAL VALVES STILL ON DUTY AFTER TWO YEARS' SERVICE

Industrial Wastes, Inc., of Beaver Falls, Pa., hauls about 2½ million gallons of spent acids each month in its fleet of tank trucks. About two years ago, the company faced the problem of finding an all-purpose tank outlet valve which would give longer service.

They tried a butterfly valve with a sleeve of HYPALON. Here's how it works: An acid-resistant metal damper rotates in a ring piece lined with a HYPALON sleeve. As the valve closes, the metal disk distorts the resilient HYPALON sleeve to form a pressure-tight seal. The sleeve returns to its original shape when the valve is opened.

The resistance of HYPALON to sulfuric, nitric, hydrochloric and hydrofluoric acids has kept the valve in operation for *two years*—with a minimum of maintenance. Can HYPALON help you? This versatile synthetic rubber also has unusual resistance to hardening at elevated temperatures (250° to 350°F.) . . . is virtually ozone-proof . . . and can be fabricated into hose, gaskets, belts, linings or prepared as solution coatings. For more information, clip and mail coupon.

It consists of a rigid plastic scale upon which are drawn a series of black lines with thicknesses varying from 0.05 mm. to 5 mm. Used for direct visual comparison with cracks in beams, it was reported to be easy to use and to give reasonably accurate results.

Behind all the detailed consideration of crack widths is the supposition that there is probably some critical dimension above which cracks will cause serious trouble through corrosion of the reinforcing steel. After a review of all the evidence presented, Professor Lobry de Bruyn, of the Technische Hogeschool, Delft, Holland, reported that there was still no agreement as to what this dimension was and that other instigators of corrosion, particularly the use of porous concrete, were probably of much more serious moment.

This view was reflected by a report presented by L. Carpentier, chief engineer S.N.C.F., Paris, upon the study of the results of a questionnaire circulated in connection with the very large number of reinforced concrete structures now in use on the French National Railways. Although the replies received were variable in value, since they were subjective to a considerable degree, they did show that transverse cracking has not been harmful in general (although longitudinal cracking of beams has been), the general conclusion being that the survey had revealed nothing to suggest any departure from the standard methods of reinforced concrete design used by S.N.C.F.

A similar conclusion could be drawn from reports presented by Professor A. M. Haas (of the Technische Hogeschool, Delft) upon field surveys of cracking in 165 exposed structures in the Netherlands, and upon 140 protected structures. Using the Dutch rustgrade IV as a criterion, the results showed that only for cracks wider than 0.7 mm. was rusting of the steel always worse than the criterion adopted, and this only for the exposed structures. It was stressed that this result was preliminary only.

Amongst gaps in the present state of knowledge which were stressed were the problems of cracking due to shear stress, and the cracking of reinforced concrete walls under load. Gaps of another sort were highlighted by reports of the chaotic state of nomenclature for reinforced concrete design that was revealed when individual national design specifications were examined. An unusually interesting presentation by Professor Muraschen of Moscow, U.S.S.R., introduced not only a new basis for reinforced concrete design but still further variations in terminology. Professor Muraschen presented a copy of the book in which his new theory is published, to the chairman of the symposium. A rough translation of the title is "Crack Resistance, Stiffness and Strength of Reinforced Concrete". (Copies of the book and of the tentative design code based upon the theory are available in the U.S.)

The meetings featured a good deal of discussion of the pros and cons of the standard pull-out test for bond. Professor

• OTHER SOCIETIES

A. Paduart, of the Free University of Brussels, Belgium, proposed a new set of standard dimensions for pull-out test specimens, based upon the diameter of the bar being tested. This proposal, and a strong suggestion that some action be taken to promote uniformity in nomenclature, was passed by the Conference for consideration to the Permanent Commission of Rilem (under the auspices of which the Symposium was organized), with appropriate reference to the work of the recently activated Technical Committee 71 of I.S.O.

The Symposium was organized and conducted under the distinguished leadership of Dr. Georg Westlund, director of the Swedish Cement and Concrete Research Institute. The papers and discussions will eventually be published in three volumes: inquiries should be addressed to the Secretary of the Conference, Dr. Sven Odman, care of the above noted Institute, Drottn., Kristinas Väg. 26, Stockholm 70, Sweden.

Rilem is the short name of the International Union of Testing and Research Laboratories for Materials and Structure, first formed in 1947. It now has over 400 individual members, representing 250 research organizations in 37 nations. The Secretary General is M. R. L'Hermite, whose office is at 12 Rue Brancion, Paris, France.

Chemical Economics Division

Theme of the inaugural divisional meeting of the Chemical Economics Subject Division of The Chemical Institute of Canada which is being held in Montreal on October 29, 1957 at the Sheraton Mount Royal Hotel is "The Canadian Chemical Industry in 1962."

Keynote speaker for the occasion is J. R Donald, president, J. T. Donald and Company (1956) Limited.

Panels, focussing on trends in the growth and development of the industry will be composed of senior executives of the industry. The panel on "Development and Finance" will be chaired by C. R. Graham, of J. T. Donald and Company (1956) Limited. D. M. Matheson, of Chemical Developments of Canada Limited, will lead the panel on "Purchasing and Traffic", J. A. McCoubrey, of North American Cyanamid, Limited, will chair the panel on "Sales".

During the luncheon session, mutual problems on chemical industry sales and purchasing executives will be discussed by G. T. Bloomer, of Canadian Industries Limited and W. D. Wright of E. B. Eddy and Company.

Feature of this meeting will be the dinner address by Nik Cavell, administrator of the Colombo Plan Administration in Canada. He will speak on the important contribution of his administra-

• OTHER SOCIETIES

tion to the capital expenditure and technical assistance program which Canada is making under the Plan in South East Asia.

This new Division of the Institute formed earlier this year to fill the growing need for another specialized group within the Chemical Institute will concentrate on the commercial and economic aspects of the Canadian chemical and chemical process industries. It will cater to the needs of those engaged in or interested in development, finance, market research, purchasing, sales, advertising, traffic and industrial relations.

Calendar

Soil Mechanics

The eleventh Soil Mechanics Conference will be held at the Building Research Centre, National Research Council, Ottawa, on December 9-10, 1957. These conferences are sponsored by the Associate Committee on Soil and Snow Mechanics of the National Research Council.

Two topics will be featured this year: Bearing Capacity of Piles, and Frost Action. There will be technical papers on the theoretical and practical aspects, and ample opportunity for discussion. All interested people are invited to the conference.

Inquiries should be directed to Mr. Edward Penner, c/o Division of Building Research, National Research Council, Ottawa 2, Ont.

Aeronautical Engineering

Activities of the Institute of the Aeronautical Sciences (2 East 6th St., New York 21, N.Y.) are announced as follows: November 7-8, Weapons System Management Meeting Dallas, Texas, November 25-26; International meeting, Canadian Aeronautical Institute and I.A.S., Montreal, Que.; December 17, the Wright Brothers Lecture; Department of Commerce Auditorium, Washington, D.C.; January 27-31; Twenty-Sixth Annual Meeting Sheraton-Astor Hotel, New York City.

Australian Conference

The Institution of Engineers, Australia has announced that the next meeting of the Commonwealth Engineering Conference will be March 19 to April 2, 1958.

Current proposal for the Conference program is that it will proceed from Sydney by air to Melbourne, from Melbourne to Canberra, by air, and from Canberra to the area of the Snowy Mountains Hydro-Electric Authority. It will return to Canberra on March 30, where it will be adjourned, April 1. Further information may be obtained on writing:

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

AMERICAN SOCIETY FOR TESTING MATERIALS. PROCEEDINGS, 1956

This volume records the accomplishments of the Society for 1956, including a summary of the Proceedings of the fifty-ninth annual meeting.

The reports of the A.S.T.M's eighty technical committees are included, as well as fifty-two technical papers and the discussions on them. Symposia published as Special Technical Publications are listed, as are all papers published in the ASTM Bulletin during the year.

This is an annual publication. (Philadelphia, A.S.T.M., 1957. 1498 p., $12.)

*ASPECTS OF RIVER POLLUTION

This extensive study is divided into fifteen chapters, each devoted to a particular aspect of the subject: nature and effect of pollution; causes; uses of river water; physical characteristics of rivers; sewage disposal and purification; disposal and treatment of trade wastes; etc. Each chapter is provided with a list of references to more detailed treatment of specific subjects, the number of references cited totaling over 1300. Though the book deals mainly with British practice, most of the subject matter has application in other countries. (By L. Klein. Toronto, Butterworth, 1957. 621 p., $14.-50.)

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

LIBRARY HOURS

Monday to Friday

9 a.m. — 5 p.m.

*BEARING DESIGN AND APPLICATION

In this practical guide for the machine designer, the bearing is considered from three aspects: the design, including its geometry and tolerances; the materials from which it is made; the lubricant used to minimize wear and tear in its operation. The book is divided into two main parts on rolling bearings and sliding bearings. Useful features are trouble shooting chapters for both types of bearings and a discussion of the selection of bearing class. Much of the material has been provided by the author's consulting practices during the past ten years. (By D. F. Wilcock and E. R. Booser. Toronto, McGraw-Hill, 1957. 464 p., $15.)

*BETON ARME

Simplified calculations for the design of rectangular and T reinforced-concrete structural elements for both elastic and elastoplastic conditions. Much of the data are in tabular form, with explanatory sections and numerical examples for a variety of simple and complex situations. The author's intent is to reduce the amount of work involved by the efficient use of known techniques. (By F. Touchet. Paris, Librairie Polytechnique, 1957. 69 p., 1900 fr.)

BOUNDARY CONTROL AND LEGAL PRINCIPLES

Based on the law of the United States, this book covers the legal principles of boundary control for abstractors, surveyors, title engineers and others who interpret, insure, and locate deed descriptions.

The author, who is a licensed land surveyor in California, covers the following topics: the systems used to describe property; transfer of real property; locating boundaries; reversion rights; riparian and littoral owners; federal mining claims; the duties of the surveyor; and writing deeds. He also includes a brief bibliography on the subject. (By C. M. Brown. New York, Wiley, 1957. 275 p., $7.50.)

CABMA REGISTER OF BRITISH INDUSTRIAL PRODUCTS FOR CANADA, 1957-8

Useful for any purchasing agent, this Register contains a classified list of over 3200 British products available for export, together with the names and addresses of their suppliers. Canadian agents and distributors are also listed. (Canadian Assoc. of British Manufacturers and Agencies. London, Iliffe, 1957. 623 p.)

CANADIAN BUSINESS ADMINISTRATION

Based on a course "Introduction to Business" given at the University of Western Ontario, this book covers business opportunities and organization, finance, production and personnel, and marketing.

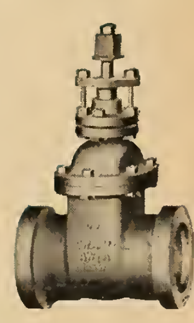
As explained in an introductory chapter, the student is assumed to have little or no knowledge of business, but the material in this course should acquaint him with a wide range of problems.

The material is presented in the form of cases to be used for class discussion, and a series of questions is included with each case as an indication of the line of thought to be followed. (By L. W. Sipherd and others. Toronto, McGraw-Hill, 1957. 398 p., $6.95.)

CENTRIFUGAL AND AXIAL FLOW PUMPS, 2ND ED.

This second edition takes into account the developments in the field since the publication of the first edition in 1948. They include the extension of the applications of centrifugal pumps, the increased ranges of head per stage, total pressure, temperature, speed and size, and the progress made in design which has come from a wider knowledge of the flow through the pump. A new chapter has been added on water-hammer problems, that on the centrifugal-jet pump system expanded, and the complete characteristics of mixed flow and axial pumps included in the chapter on

There are more DIFFERENT types and sizes of CRANE VALVES than there are pebbles in this picture. Wherever there's a flow, there's a CRANE valve to control it!



One of many Crane Valves widely used for the control of water. No. 480½, A.W.W.A., I.B.B.M. Double Disc, Gate Valve.

CRANE LIMITED General Office 1170 Beaver Hall Square, Montreal · 7 Canadian Factories · 20 Canadian Branches

• LIBRARY NOTES

the operating conditions of centrifugal pumps. Bibliographies are included at the end of each chapter. (By A. J. Stepanoff. New York, Wiley, 1957. 462 p., $12.00.)

CHIMIE MINERALE: THEORIQUE ET EXPERIMENTALE

In this treatise on inorganic chemistry, the author has made use of the electronic theory to explain many of the facts obtained through experiments, relating the reactions of the atoms to their electronic structure.

The first part of the work deals with general chemistry, and covers atomic and molecular theory and chemical reactions. The second, and larger, part is devoted to a study of the elements, arranged in groups according to the periodic table. (By Fernand Gallais. Paris, Masson, 1957. 810 p., 4300 fr.)

THE COMMUTATOR MOTOR, 3RD ED.

One of a series published by Methuen intended to give science students and research workers an outline of various topics, this volume covers the commutator motor.

As the author points out, this is an induction motor to which a commutator has been added, and he includes information on the circle diagram of the former as it is necessary for an understanding of the latter. Other topics covered include speed control, power factor, energy transference, cascade operation, and generator and slip power operation. Those requiring a more detailed mathematical treatment are directed to the references listed in the bibliography. Three items have been added in this revised edition, and other changes have been made to bring the work up-to-date. (By F. J. Teago. Toronto, Ryerson, 1952. 82p., $1.50.)

COST ACCOUNTING, 2ND ED.

The basic principles of cost accounting are stressed in this book which also shows how important cost analysis is for cost control. Largely re-written, this edition includes new material on direct costing, a new treatment of distribution cost accounting, and more information on control of factory overhead costs.

Other topics covered include a comparison of general and cost accounting; the different methods of cost accounting used; overhead charges; the effect of volume on costs and profits; profits and losses resulting from price changes; waste etc. (By C. F. Schlatter and W. J. Schlatter. New York, Wiley, 1957. 725p., $7.25.)

*DATA BOOK FOR CIVIL ENGINEERS, VOLUME 2: SPECIFICATIONS AND COSTS, 3RD ED.

Volume 2 of this three-volume set provides data necessary for preparing specifications for buildings, airports, roads, railroads, bridges, dams, docks, drainage and sewers. Swimming pools athletic fields, and other miscellaneous structures are briefly considered. Relative cost analyses are included for each type of work, and there is a classified glossary of terms. In addition to the extensive amount of practical data presented in this book, the other two volumes of the set provide similarly useful information on design and field practice. (By E. E. Seelye. New York, Wiley, 1957. Various paging, $20.00.)

*THE DEMAND AND SUPPLY OF SCIENTIFIC PERSONNEL

This important study offers evidence that, contrary to many previously published reports, there is no shortage of engineers in the United States. The study consists of five chapters dealing, respectively, with the growth of the technological professions; demand and supply; factors influencing the demand for engineers and chemists; the supply of engineers; the supply and demand for mathematicians and physicists. A considerable amount of statistical data is included in appendixes. (By D. M. Blank and G. J. Stigler. New York, National Bureau of Economic Research, 1957. 200p., $4.00.)

THE DIESEL LOCOMOTIVE

The increasing interest in diesel locomotives in the United Kingdom is reflected in the publication of this volume, which is intended for those actually operating the machines.

After a brief historical introduction, the author covers the basic principles

and construction of the engine; the fuel injection system; electrical, mechanical and hydraulic systems of transmission; auxiliary equipment; safety measures; maintenance and operating troubles, faults and adjustments.

The author was for many years engaged in the design and manufacture of diesel locomotives. (By R. L. Aston. London, Thames and Hudson, Toronto, Longmans, Green, 1957. 116p., $2.50.)

EARTH PRESSURES AND RETAINING WALLS

In this reference book for structural engineers the author has tried to include all the special soil conditions which may be encountered in the design of retaining walls.

The author stresses the principles on which the numerical solutions he gives are based, and includes designs and calculations.

The topics covered are: earth pressures due to cohesive soils; stability and foundations of retaining walls; design principles and requirements, and retaining wall design, with special emphasis on counterfort walls. There is a useful bibliography. (By W. C. Huntington. New York, Wiley, 1957. 534p., $11.50.)

EMPLOYEE BENEFIT PROGRAMS

"Fringe benefits" now play such an important part in the field of employee compensation that this brief outline has been prepared as a guide to discussions in the field of employee benefits.

It covers the Why, What, How and Who of employee benefit programmes, and the various types of benefit plan. The most important of these is protection against income loss, whether from death, retirement, unemployment or injury, while sickness insurance plans are also covered. There is a brief bibliography of selected further reading. (By M. T. Wermel and G. M. Beideman. Pasadena, California Institute of Technology, Industrial Relations Section, 1957. 32p., mimeog., $1.00.)

ENGINEERING PROPERTIES AND APPLICATIONS OF PLASTICS

The characteristics of a variety of plastics are described in this book written for those who work with plastics, and those wanting background information on them.

After an introductory chapter, the different plastics are described separately, in the order of increasing complexity. Also described are methods of manufacture and the engineering, thermal, electrical and optical properties of plastics. (By G. F. Kinney. New York, Wiley, 1957. 278p., $6.75.)

GLASS REINFORCED PLASTICS

The purpose of this book is to describe the raw materials, both resins and glass, used in the manufacture of this type of plastic, the manufacturing techniques, and to discuss the problems of specialized applications. This second edition has been thoroughly revised, and several new chapters added. These new chapters cover epoxide resins, the resin injection moulding process, and applications in chemical plants.

Other topics covered include glass fibres; all the important resins, with particular emphasis on polyesters; techniques of manufacture — commercial moulding, mass production and the manufacture of tubes and rods.

The application of glass reinforced plastics in various fields is discussed, including the manufacture of automobiles, aircraft and boats, the electrical industry, and micellaneous manufactures, for example swimming pools, refrigerators, road signs, sports equipment and building. (Ed. by Philip Morgan. London, Iliffe, Toronto, British Book Service, 1957. 276p., $9.00.)

*HANDBOOK OF RIGGING, 2ND ED.

This second edition of a complete manual of rigging practices serves as a ready reference and guide for expert riggers. New material includes a section on transportation since the rigger is responsible for loading trucks, and includes information on the "overland train" used in transporting loads over deserts and through swamps. There is a chapter on

How Farval lubrication makes a turbine behave!

FARVAL—
Studies in Centralized Lubrication
No. 171

THIS hydraulic turbine had costly maintenance problems. Every few months, 6 to expensive bearings had to be replaced. Old-shioned grease gunning just couldn't keep bricant in bearings. Repairs interfered with ectric power production.

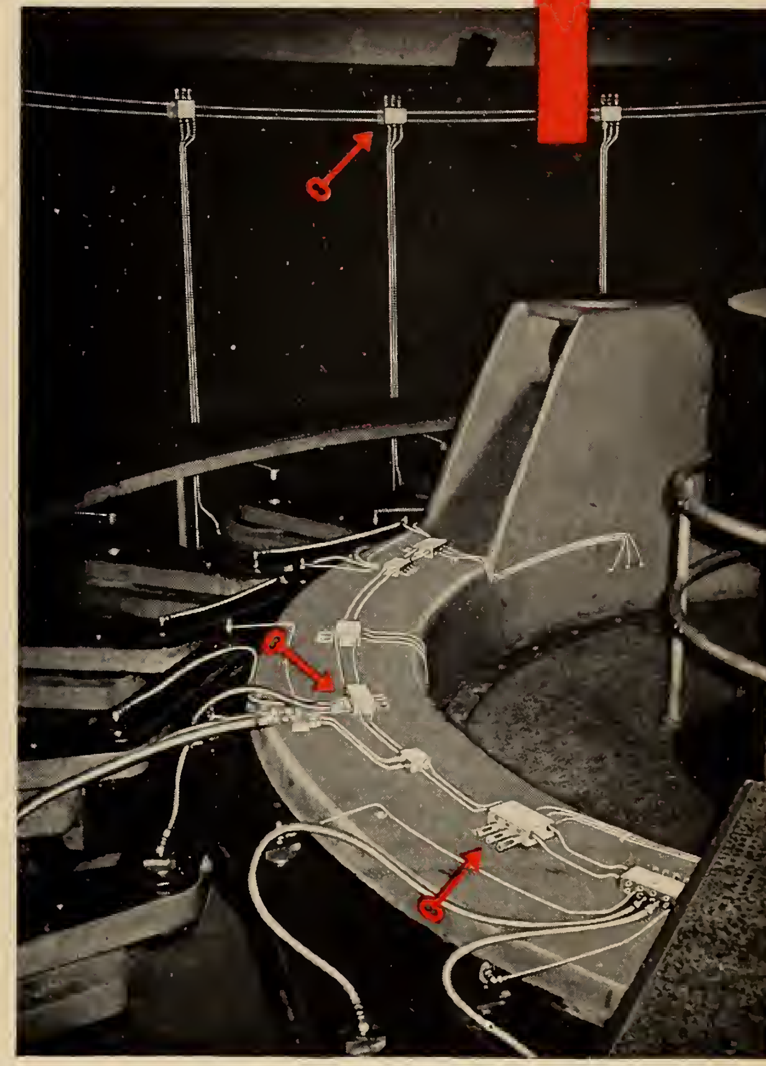
ırval Lubrication Engineers were called in. A ırval System of Centralized Lubrication ex-:tly suited to the turbine's needs was recom-ended. Result—lubrication troubles ended. owntime was eliminated. Now, even bear-gs under water keep working properly. ırval works as the turbine operates—no time ıt for lubrication. Manpower is saved, be-ıuse Farval is wholly automatic. Important oney is saved. In 14 years, the manager re-ɔrts thousands saved in bearings and lubri-ınt. These savings led to Farval Systems on 9 her turbines.

Farval saves in many industries

his is a typical example of the economies ırval brings to industrial equipment. Farval a simple, dependable system that lubricates ıickly, without shutdown, from one central ımping station. Oil or grease is delivered ıfailingly, to each bearing served, in the exact nount *when* required. And, Farval Centralized ıbrication Systems, manual or automatic, ın be installed on new or old equipment.

Free Bulletin tells you all

nd out how Farval can save for you and pay ır itself in quick order. Write for helpful chnical advice and ask for Bulletin 26. eacock Brothers Limited, P. O. Box 1040, ontreal 3, Que. Branch offices in Sydney, ɔronto, Sudbury, Winnipeg, Edmonton, Cal-ıry and Vancouver.



KEYS TO ADEQUATE LUBRICATION—Wherever you see the sign of Farval—the familiar valve manifolds, dual lubricant lines and central pumping station—you know a machine is being properly lubricated. Farval manually operated and automatic systems protect millions of industrial bearings.

FARVAL
CENTRALIZED SYSTEMS OF LUBRICATION

PEACOCK BROTHERS LIMITED

• LIBRARY NOTES

the actual hitching of slings to loads for hoisting and transporting and for turning suspended loads on their sides or tops as required. There are several chapter on the element of safety in rigging operations. (By W. E. Rossnagel. Toronto, McGraw-Hill, 1957. 342p., $7.-80.)

°HIGH-SPEED SMALL CRAFT

This book deals with the theory and practice of the design and construction of marine craft up to 130 feet in length and of speeds above 15 knots. Fully illustrated with photographs, diagrams, and sectional drawings, the book covers materials, hull and rudder design, propelling machinery and its installation, electric equipment, propellors, model experiments, and speed trials. (By Peter Du Cane. New York, Philosophical Library, 1957. 324p., $15.00.)

INTRODUCTION TO AUTOMATIC DIGITAL COMPUTERS

Intended for those without advanced mathematical training this book shows the use of digital computers in the performance of tedious calculations. Throughout the emphasis is on application rather than further research.

The author explains the functions and capabilities of digital computers, and discusses programming. The various systems of number storage are considered, and following this the author describes the organization of programmes for complicated problems, and the solution of engineering problems using computers. A final section reviews the future prospect for digital computers.

This slim volume should prove most useful as an introduction to the subject, and a more detailed treatment can be found in the books listed in the bibliography. (By R. K. Livesley. Cambridge, University Press, Toronto, Macmillan, 1957. 53p., $1.45.)

LINEAR PROGRAMMING AND INVENTORY MANAGEMENT

These proceedings contain the seventeen papers presented at the second conference on the subject held by Methods Engineering Council, Inc. Many firms are now using linear programming and inventory control to help cut their production costs.

The papers were given by the top men in the field, and outline the experiences of several companies. They show how the methods were used to decide such questions as expansion of facilities, stabilization of production, the most profitable amount of inventory, and production planning.

This is a rapidly expanding field, and much can be learned from the experiences of those already using these methods. Fortunately one does not need to be a mathematician to learn from this book something of what linear programming and inventory control are all about. (Pittsburgh, Methods Engineering Council, Inc., 1957. Various paging, $6.00.)

LLOYD'S OF LONDON: A STUDY IN INDIVIDUALISM

Throughout the world, many people when they think of insurance think of Lloyd's, and the publication of the history of this venerable institution will be of great interest to many entirely unconnected with the insurance world.

The author, who has been engaged in Lloyd's business for fifty years, traces the history of Lloyd's from its beginnings in 1688 in a London coffee house owned by Edward Lloyd to its present unique position as an insurance market. Mr. Gibb has a fascinating tale to tell, and he tells it well, with many humourous touches. (By D. E. W. Gibb. Toronto, Macmillan, 1957. 387p., $5.00.)

°MACHINE LITERATURE SEARCHING

Although the primary concern of this book is machine literature searching, much general information is included on such subjects as problems in indexing, collection of terminology, code development, organization of semantic units, de-

signing of information retrieval systems and machine language. The focus of the book, however, is the machine and what may be expected from it. The appendix constitutes an excellent bibliography in this and related fields. (By J. W. Perry and others. New York, Interscience Publishers, 1956. 162p., $4.00.)

MANAGEMENT GUIDE TO ELECTRONIC COMPUTERS

This book, written by a consultant on electronic data processing, tries to show the business executive, in non-technical language which jobs can be performed by electronic computers. He also discusses the equipment and its operation, problems connected with its use, and how to choose and install a system.

Wherever possible, the author gives concrete examples to clarify his text, and includes eleven case histories showing company experience with electronic computers in such varied fields as airline seat inventory, actuarial operations, and machine shop scheduling. (By W. D. Bell. Toronto, McGraw-Hill, 1957. 403p., $7.80.)

°THE MANUFACTURE OF IRON AND STEEL. V. 1 IRON PRODUCTION, 2ND ED.

Volume one of this series is a comprehensive survey of the subject of modern methods of iron manufacture from the occurrence and classification of iron ore to the manufacture of ferro-alloys, special irons, and wrought irons. The blast furnace is thoroughly covered with chapters on blast furnace fuels, reactions, slags, equipment, design, refractories, operation and calculations. Several other methods of pig iron production such as the electric reduction furnace are discussed. Many references are included after each chapter, and there is a short bibliography at the end. (By G. R. Bashforth. Toronto, Ryerson, 1957. 306p., $9.00.)

°PRACTICAL AUTOMATION

A practical guide to the installation and use of plant automation. In addition to the general discussions of fundamentals and specific recommendations for planning, operation and management, over 150 actual cases, small and large, in existing plants are described. The text material, profusely illustrated by photographs and diagrams, covers handling, processing, inspection, and maintenance operations, control instrumentation, communication systems, and computer applications. (By L. R. Bittel and others. Toronto, McGraw-Hill, 1957. 376p., $7.50.)

PROCEEDINGS OF THE JOINT CONFERENCE ON COMBUSTION, 1955

Available for the first time in bound form, this volume contains the proceedings of the Conference sponsored jointly by the Institution of Mechanical Engineers and the American Society of Mechanical Engineers. Two meetings were held, one in London and one in Boston, and this volume includes not only the papers presented, but also the discussions upon them which took place at both meeting.

The five sections into which the papers are divided are: general questions of combustion; boilers; industrial furnaces; internal combustion engines; gas turbines. The majority of the papers include references and illustrations. (London, I. Mech. E., New York, A.S.M.E., 1957. 457p., 63/-.)

PULP AND PAPER MANUAL OF CANADA, 1957

Now in its twenty-fifth edition, this useful manual contains all the usual features: new and revised flow charts for some twenty pulp and paper mills; an alphabetical list of machinery, supply and service companies; a classified list of machinery and supplies; trade names; foreign firms and their Canadian representatives. There are also several editorial features. (Gardenvale, Que., National Business Publications, 1957. 479p.)

°QUALITY CONTROL AND STATISTICAL METHODS, 2ND ED.

Intended for those with little knowledge of the field, this second edition presents the most generally useful modern techniques of quality control and statistical methods as applied to indus-

BATHURST OPERATES TO SERVE YOU

EST BY TEST

Compression tester

tion tester

With the most complete testing services of any container manufacturer in its industry in Canada, Bathurst is ready at all times to satisfy the most exacting requirements of shippers. Exhaustive and comprehensive tests are regularly conducted not only in our own plants but also—when needed—in our customers' plants. The fact that our products are truly "best by test" is just one more reason why you can confidently **ship anything—anywhere—in Bathurst Containers!**

trial problems of product quality. Subjects covered include the nature and economic objectives of quality, the means of presenting information pertaining to quality, the applications of various types of control charts, the various modifications of control limits, probability distribution and significance of differences and the nature of acceptance sampling. New material has been included on rapid approximate tests of significance, and analysis of variance. (By E. M. Schrock. New York, Reinhold, 1957. 246p., $6.75.)

REINFORCED CONCRETE DESIGNER'S HANDBOOK, 5TH ED.

Now in its fifth edition in just over twenty years, this edition has been re-written to incorporate the recommendations of the 1957 British Standard Code of Practice for reinforced concrete in buildings, including the ultimate-load method of design. Revisions have also been made in the sections on granular and cohesive materials, foundations, slabs subjected to triangular loads, loads on bridges, long columns and the properties of reinforced concrete sections.

The book is divided into four parts, the first of which deals with design, while part two contains tables to be used in design, together with examples of their use. Part three contains additional examples requiring the use of more than one table, and the fourth part deals with specifications and quantities. (By C. E. Reynolds. London, Concrete Publications, 1957. 343p., $4.00.)

ROCKETS, MISSILES, AND SPACE TRAVEL, 3RD ED.

The third edition in thirteen years, this volume has been thoroughly revised and many sections re-written. New material has been included on project Vanguard, on war rockets which were still on the secret list in 1951 when the second edition was published, and on rocket fuels. Many additions have also been made to the bibliography.

This is an eminently readable account covering the past and the present, with a look into the future, although as the author himself says in his foreword 'The probability is high that during the next twelve years it (the future) too will all move into "present".'

The author begins his story with man's early ideas concerning the planets, early attempts at flying and at building rockets. He tells the story of the German developments leading to the building of the V-2, and that of post war U.S. developments, and concludes with a chapter on spaceships. (By Willy Ley. Toronto, Macmillan, 1957. 528p., $7.50.)

RUBBER; FUNDAMENTALS OF ITS SCIENCE AND TECHNOLOGY

The chemistry of rubber, mainly, is discussed in this book. It includes a brief history of rubber and the rubber industry, and discusses in more detail the physical and chemical properties of latex and rubber and all compounds of rubber. The vulcanization and processing of rubber are also covered, as well as synthetic and reclaimed rubbers.

There is a chapter on analyses and tests for rubber and latex and one on the applications of rubber and rubber products. There are many tables, illustrations and diagrams included as well as a bibliography at the end of the book. (By J. LeBras and I. E. Berck, New York, Chemical Publishing, 1957. 464p., $12.00.)

TECHNIQUES OF PLANT MAINTENANCE AND ENGINEERING 1957

The eighth conference on the techniques of plant maintenance was held in Cleveland in January 1957 in conjunction with the National Plant Maintenance and Engineering Show, and this volume includes the papers presented, together with the discussions they provoked.

The majority of the papers as usual can be applied to the maintenance problem in any industry, and deals with such topics as maintenance cost controls; labour relations; effectiveness; training, etc.

The specific maintenance problems of the following industries are also considered: metal working plants; chemical

plants; steel mills; metal fabricating plants; foundries; paper mill and product plants; petroleum refineries; food processing plants; rubber mills and textile mills. (New York, Clapp and Poliak, 1957. 273p., $10.00.)

°DIE TRANSFORMATION, 3RD ED.

A comprehensive treatise on the theoretical and practical aspects of large power transformers. Major headings are as follows: general characteristics of transformers; design of the transformer; the three-phase transformer; heat transfer during operation; the iron core, no-load operation, and switching surges; the windings; boundary problems in transformer design; practical examples of transformers. Completely revised, after 30 years, on the basis of the author's extensive experience in the field. (By M. Vidmar. Basel, Birkhauser, 1956. 630p., 68.00 Swiss Francs.)

The site of the new Canadian Pacific Airlines Hangar, Vancouver Airport. At left, a standard FRANKI reinforced displacement caisson undergoes a 180-ton test load. The top of another FRANKI caisson appears in the foreground. At far right, a FRANKI rig drives another displacement caisson.

Franki displacement caissons support C.P.A. hangar, Vancouver Airport

A brief study of the conditions to be met by the Designer of the foundations on this job revealed the following requirements:

(a) Hailed as the largest hangar of this type ever built for Canadian Civil Aviation, the loads on the foundations were therefore considerable.

(b) Considerable uplift loads in this type of structure had to be taken care of.

(c) The high but variable water table increased the risk of settlement if friction piles were used and brought up the risk of rotting of timber piles if the latter were employed.

(d) Soil conditions required that the loads be carried into the competent sand stratum overlying the lower silts, but with penetration of piles kept as high as possible above the silts, to avoid consolidation and settlement.

By choosing FRANKI DISPLACEMENT CAISSONS . . .

(a) A guaranteed working load of 100 tons per caisson was provided, decreasing cost by lowering the number of piles required, and by reducing sizes of caps, excavation, etc.

(b) Uplift capacity of 2½ to 1 as compared with timber piles.

(c) End bearing was ensured, with each individual caisson immune to the effects of variations in the water table evaluation.

(d) Penetrations were kept to a high elevation, the average depth of caisson bases being only one foot below the minimum depth specified by the designer.

A 180-ton load test, twice the design load, gave a gross settlement of 0.31 inches, and a net settlement of 0.08 inches. A combined compression-traction test gave the following results:

1 Caisson in Compression	Max. Load 121 Tons	Net Settlement 0.001"
2 Caissons in Traction	Max. Load on Each 35 Tons	Net Uplift Nil

The job was completed on schedule, to the great satisfaction of all concerned.

JOB DATA:

Client: Canadian Pacific Airlines
Consulting Engineer: O. Safir, Vancouver
General Contractor: Marwell Manitoba Ltd.
Number of FRANKI CAISSONS: 210 (174 at 25° batter)
Design Load: 90 tons per Caisson
Average Length of Caissons: 31 feet
Soil Investigation: Boyles Bros. Drilling Co. Ltd., Vancouver
Soil Report: Ripley & Associates, Vancouver

THE FRANKI CAISSON is a pressure injected footing, with an expanded base forged by blows of 150,000 ft.-lbs. of energy. In granular soils, the standard Franki caisson will carry a load of 120 tons or more.

LITERATURE on the various Franki methods of foundation and regular mailings of "Franki Facts" about job highlights, will be sent upon request. Write: Franki of Canada Ltd., 187 Graham Blvd., Montreal 16, P.Q.

Nuclear Congress

The Nuclear Engineering and Science Conference Committee (Program Steering Committee) met in July to review subject areas planned for the technical program of the 1958 Nuclear Congress and decided upon the following principal areas:

A. Radioisotope Utilization 1. Biological uses, 2. Product and Process Control, 3. Tracer Applications, 4. Production and Distribution 5. Gamma Ray Heating;

B. Reactors As a Source of Process Heat;

C. Radiation – Induced Chemical Reactions;

D. Standardization, Codes and Licensing: 1. Process, 2. Equipment, 3. Overall Design, 4. Licensing, 5. Inspection;

E. Plant Location and safeguards: 1. Handling and Storage Problems, 2. Biological Tolerance, 3. Plant Design Evaluation, 4. Availability and Contamination of Water Supply, 5. Waste Disposal, 6. Atmospheric Control, 7. Site Evaluation;

F. Reactor Operation and Maintenance;

G. Progress in Commercial Power Reactor Development;

H. Reactor Engineering; 1. Component Development, 2. Thermal and Mechanical Design, including Heat Transfer, 3. Systems Analysis, 4. Fuel Element Design and Fabrication, 5. Instrumentation and Control, 6. Containment and Shielding.

I. Reactor Fuel and Control Materials: 1. Preparation, 2. Properties, 3. Reprocessing;

J. Reactor Plant Materials;

K. Experimental Reactors and Critical Assemblies.

The Engineering Institute of Canada is one of the thirty societies sponsoring the Nuclear Congress, 1958.

Concrete Products

The next annual convention of the National Concrete Products Association will be held in Ottawa at the Chateau Laurier Hotel, January 16, 17, 18, 1958.

Information can be obtained from the Presentation of Canada Limited, 143 Yonge St., Toronto 1, Ont.

Construction

The calendar of the Canadian Construction Association (Construction House, 151 O'Conner St., Ottawa, Ont.) is as follows:

Executive and management committee December 1-2, Seigniory Club, Montebello, Que.

The fortieth annual meeting of C.C.A. will be at the Chateau Frontenac, Quebec City, from January 26 to January 29, 1958.

Canadian Technical Committee

The first Canadian technical committee in the National Association of Corrosion Engineers has been formed under the chairmanship of C. L. Roach, Bell Telephone Company of Canada, Montreal. The task of the committee is to co-ordinate activities of local electrolysis organizations.

Chemical Engineering

The annual meeting of the American Institute of Chemical Engineers, 925 West 45th St., New York 36, N.Y. will be at the Conrad Hilton Hotel, Chicago, Ill., December 8-11, 1957.

Operations Research

The twelfth national meeting of the Operations Research Society of America, a two-day program, is scheduled for November 14-15, 1957, at the Penn-Sheraton Hotel, Pittsburgh, Pa.

Wave Research

The Council on Wave Research announces the Sixth International Conference on Coastal Engineering, to take place in Florida, December 2-7, 1957.

Further information on the Conference can be obtained from Prof. J. W. Johnson, 200 Mechanics Building, University of California, Berkeley 4, Calif.; or Dr. Per Bruun, Coastal Engineering Laboratory, University of Florida, Gainesville, Florida.

CANADIAN DEVELOPMENTS

(Continued from page 1489)

The Canadian Forest

Management for full production will pay equal attention to the growth of timber products from all accessible areas, and to production of fish and game, healthful recreation and opportunities for enjoyment by all Canadians. The Canadian forest is capable of producing all this, permanently and profitably.

Surpassed only by the pine and spruce forests of the Soviet Republic a similar latitudes in Europe and Asia, the forests of Canada with an annual output of over 6½ billion board feet of lumber and other sawn products comprise one of the most extensive areas of softwood timber in the world. These were statements of the general manager of the Canadian Forestry Association, J. L. Van Camp, in an address to the Audubon Society for Canada.

Title to the bulk of Canadian forest is vested in the Crown; most commercial saw milling, the cutting of trees for pulp and paper production, and many other forest industries, are operations by private companies under lease or licence on Crown lands. They are subject to regulations which maintain a continuous wood, water and game producing resource in which new crops are obtained automatically by logging practices which help nature produce the new crops.

Another very necessary measure in the control of the forest, fundamentally educational, is that of improving the public attitude toward the forest.

In its work of education, Canadian Forestry Association lecturers have travelled in forest areas by motor car with motion picture films, books, bulletins and kodachrome slides on forest conservation. Both major railways have contributed railway coaches, used as moveable auditoriums for conservation lectures, on all lines in the nine provinces.

In its tremendous output of lumber and other sawn products, British Columbia, with Douglas fir, hemlock on the coast, pine and spruce in the interior, produces timber of large size and high quality. Saw milling is important across the northern two-thirds of the central western provinces. Northern Ontario, Quebec and the maritime provinces contribute heavily to sawn-timber production,

IF HEAT IS A PROBLEM INVESTIGATE THESE HIGH TEMPERATURE

INCO NICKEL ALLOYS

INCONEL*

WITHSTANDS EXTREME HEAT

Resists oxidation and retains good mechanical properties at high temperatures. Excellent resistance to sulphur-free heat-treating atmospheres . . . practically immune to embrittlement by carburizing or nitriding atmospheres. Ideal for food and chemical processing or heat-treating equipment and aeronautical parts.

INCOLOY*

HEAT RESISTANCE PLUS GOOD WORKABILITY

Good resistance to oxidation and other corrosive conditions; strength at high temperatures. Excellent workability and welding properties. Uses similar to Inconel at temperatures up to 1900°F. Greater resistance to sulphur attack, green rot and molten cyanide salts.

INCONEL "X"*

RETAINS ITS STRENGTH AT HIGH TEMPERATURES

Exceptional strength and hardness from subzero to 1500°F. High resistance to oxidation and other forms of corrosion. Excellent for moving parts which operate in corrosive environments within small clearances such as rotors and blades of aircraft gas turbines. Also used for bolts, springs and diaphragms.

NI-O-NEL*

WITHSTANDS HOT CORROSIVE LIQUIDS AND SLURRIES

Resists corrosion by hot sulphuric, sulphurous and phosphoric acid solutions. Also resists nitric acid solutions, nitrates, cupric, ferric and mercuric salts except chlorides. Considerably better resistance than stainless steels to pitting by sea water or stress corrosion cracking in chloride solutions.

These high Inco Nickel Alloys provide exceptionally good performance characteristics, particularly where extreme heat or highly corrosive conditions are a factor. In many applications they will long outlast competitive materials. The alloys shown here are available in most standard forms . . . and Inco Customer Service goes with them . . . to help you solve metal problems. Write us for complete information.

INCO

THE INTERNATIONAL NICKEL COMPANY OF CANADA, LIMITED
25 King Street West, Toronto

and all regions produce other rough primary forest products.

In fact, Mr. Van Camp added, since the mid-twenties, the rise of the pulp and paper industry has been the greatest single factor in the Canadian forest industry.

Steadily growing demands create increasing production of lumber, pulp and paper products. This constant expansion causes public apprehension regarding the depletion of the forest resource. In general there is no cause for alarm from expanding forest industry in Canada over the next 25 years. However, this does not imply that completely satisfactory conditions are present in every part of the Canadian forest. On some privately-owned lands the most destructive practices, and the poorest quality of management are found. The development of a complete all-year system of roads, permitting frequent return to areas for timber cuts at short intervals, and permitting better fire and insect protection practices will improve over all forest management and forest production.

Estimating that Canadians will need 28 million cords of pulpwood twenty-five years from now, Mr. Van Camp added that through the technical abilities of mills to use species formerly considered useless, such trees as the aspen poplar, can now be utilized. In quantity this timber equals all other hardwood species combined. Long range economics make it advisable to undertake these investments, and they are already being financed by several companies. Waste has also been greatly avoided. The decreased use of wood for fuel and the increased demand for pulpwood products has revolutionized the situation.

Forest recreation is important to Canadians and their tourist visitors. Also coming to public attention are the very essential water resource values provided by forest cover, combined with good agricultural management of land. The intimate relation between the amount of water available to a territory and the management of forest and agricultural cover upstream is only now coming to the critical attention of governments and the general public.

Pulp Mill in Nova Scotia

The Nova Scotia government announced in July that it had entered into an agreement with a new company, Nova Scotia Pulp Limited which, it is almost certain, will provide a $40 million pulp mill in Eastern Nova Scotia. Preliminary engineering studies indicated a site on the Strait of Canso.

The proposed mill would be one of the largest and most modern in Canada, with a producing capacity in excess of 300 tons per day of high quality bleached pulp, and an expenditure of $10 million annually for wages and purchases.

Nova Scotia Pulp Limited, the premier said, is not a subsidiary of any company, but it has an agreement for technical advice with Stora Kopparbergs, a Swedish company, and for the use of patented methods.

CANADIAN DEVELOPMENTS

The government of Nova Scotia has to approve control of the company until such time as it is finally launched. Two company officers were mentioned in later news items, as follows: president, Carl A. Clauson, of Kopparbergs' U.S. operations, and secretary, A. Gordon Cooper, of Halifax.

Cutting will be done under a controlled forest management plan. Wood requirements for the mill would be 250,000 cords annually; the company would cut 150,000 cords from its licensed lands and would purchase a further 100,000 cords from private lumber operators and owners in the province. It would also use 25,000 cords per year of hardwoods.

What Goes On

Control of Dosco

A. V. Roe Canada sought control of the Dominion Steel and Coal Corporation with an offer to Dosco shareholders of one and a quarter of its shares plus $10.25 cash for each Dosco share. The offer was contingent on acquisition of 52 per cent, and was open until October 1.

Dosco directors were divided in their reactions to the offer. However, the view of the majority of directors was given by President Lang in a letter to the shareholders, in which he said the advantages to Dosco were judged to be such that these directors had accepted the offer and were depositing their Dosco holdings with A. V. Roe.

At the October 1 deadline A. V. Roe claimed to have effective control with 40 per cent, and expected shortly to have 52 per cent of Dosco stock.

Ventures Ltd.

John D. Barrington is the new president and managing director of Ventures Ltd., one of the world's largest mining organizations, based in Toronto. He is the former president of Polymer Corporation, Sarnia, and remains a director of Polymer. *Financial Post, Sept. 28.*

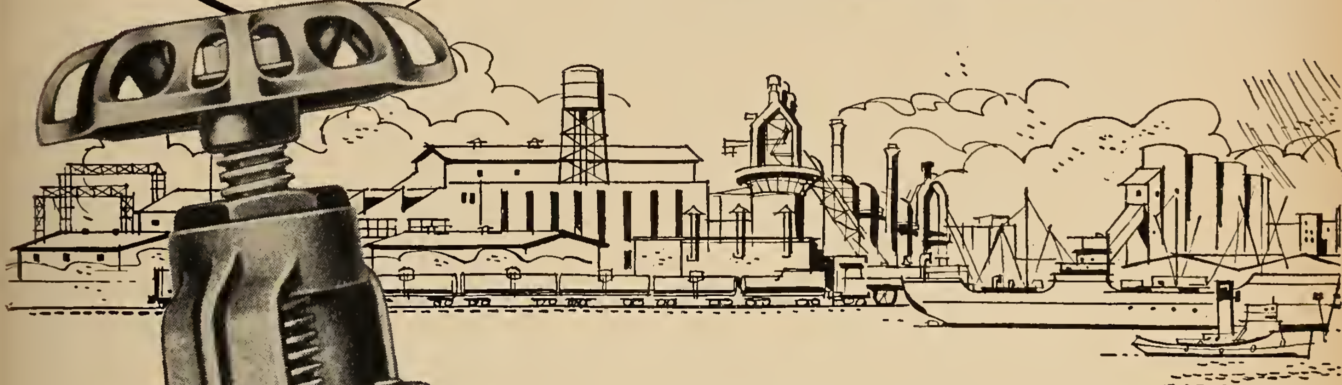
To combat valve corrosion and product contamination...

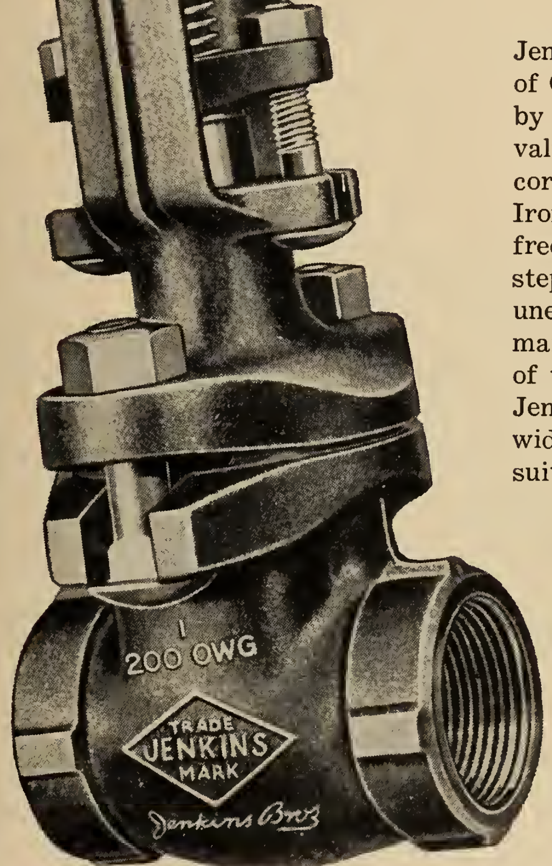
For the heart of industry
JENKINS VALVES

specify

JENKINS

STAINLESS STEEL VALVES





Jenkins Stainless Steel Valves are the watch dogs of Canadian industry. Designed and engineered by Jenkins valve specialists, these stainless steel valves are ideal for plants handling corrosive liquids (which would destroy Bronze or Iron Valves) or where fluids must be kept free from contamination or discoloration. Precise, step-by-step inspection during manufacture, unequalled performance on the job and low maintenance and replacement cost are but three of the many reasons why industry prefers Jenkins Stainless Steel Valves. Available in a wide range of types, sizes and alloys suited to *your* specific needs.

To learn how your plant can benefit from the best stainless steel valves, consult Jenkins Technical Advisory Service.
Write today for free informative folder — "Jenkins Stainless Steel Valves". It gives helpful specifications data on selection.

Making Quality Valves Is Our Business — Our Only Business.

additional financing were made known in September.

President J. A. Fuller noted that in view of the Company's recent and prospective rate of growth, it is considered desirable to provide a broader basis of financing.

Atomic Energy of Canada Limited

The price of cobalt 60 has been sharply reduced by both atomic Energy of Canada Limited and the U.S. AEC, it was announced in August.

It is expected that lower prices will encourage more widespread industrial, medical and research use of the powerful gamma emitting isotope.

Uranium in Saskatchewan

Lorado Uranium Mines' $9.2 million mill was in full operation in August in the Beaverlodge area of Saskatchewan. Eldorado and Gunnar have respectively 2000 and 1800 ton capacity mills already operating in this field. Lorado will increase its mill capacity from 500 to 700 tons during the next year.

Nova Scotia Power

A new hydro plant was set in operation recently, completing the second step in development of the east branch of Bear River in Annapolis County, N.S. It will have an estimated capacity of 12,000,000 kw.h. annually and will bring the total annual capacity of the Bear River development to 32 million kilowatt-hours.

The Premier of Nova Scotia, Hon. Robert L. Stanfield, said on this occasion that there has been a steady growth in power consumption in Nova Scotia amounting to nine per cent each year. The bulk of the province's expansion would be accomplished in the future through thermally operated stations, he said.

B-A Refinery in B.C.

At Port Moody, B.C., site of the British American Oil Company Limited's new 20,000 B.p.d. refinery, the 400 acre plot is being made ready for construction.

The refinery is scheduled for completion by late 1958. Canadian Kellogg will complete the engineering and construction of topping, vacuum, catalytic reforming, hydro-desulphurization, alkylation and catalytic cracker units.

Albertans Receive Dividend

The first Oil and Gas Citizens Royalty Dividend — $20 — is available to approximately 550,000 eligible Albertans since September and until December 31.

Dividends are payable from an $11 million fund set up under the Oil and Gas Royalties Dividend Act.

Northland Development Study

The Alberta Government recently appointed a three-man commission to make a comprehensive study of the development potential of Alberta's northland. Chairman of the commission is J. G. MacGregor, chairman of the Alberta Power Commission; members are Roy C. Marler, past president of the Alberta Federation of Agriculture, and J. O. Patterson, of Grande Prairie.

All sections of the province north of the 55th parallel will be included in the investigation, which will determine the extent and location of na-

tural resources, and likely areas of population concentration, agricultural and industrial opportunity, transportation and communication requirements, electrical power resources and requirements, market trends, and methods to assist general development.

Computer Installation

Adalia Computations Limited, Montreal, have installed a computer, of the Datatron System type to be available to business, industry, government, universities, research establishments, etc., on rental basis. A staff of problem analysts, programmers, mathematicians and engineers has been trained for problem preparation and for operating the computer.

The Datatron System has automatic floating point facility and high speed input-output units — adaptable to engineering design calculations as well as business data processing applications, it is reported.

Gas Processing Plant

A $20,000,000 plant to be in operation by September 1958, for gathering, processing and transmission of casinhead gas in the Steelman area of south-eastern Sakatchewan is to be constructed by Steelman Gas Limited, formerly Provo (Sask) Ltd. The wasted gas, now being flared in excess of 1,000,000 cubic feet per day will be processed into propane, butane, gasoline, sulphur and dry residue gas. The latter is to be sold to the Saskatchewan Power Corporation for use in its natural gas distribution system.

Selection and Training of Second Line Executives

(Continued from page 1472)

adequacy of the "one course per man" form of training.

After a very constructive discussion on the means of selection, the chairman summed up the views of the panelists as follows:

1. The oustanding qualities looked for in the potential general manager are leadership and initiative.
2. Training for management has to be considered and provided for throughout the individual's career. It is necessary to watch constantly the man's progress, and the right kind of appraisal form and training program play important parts in this respect.
3. It is necessary both for the company to assist the individual and the individual to assist himself in the matter of management training.
4. In selecting men for promotion, as many means of appraising and assessing the individual by as many assessors as possible is a golden rule. The difficulty is to avoid personal bias and to find an adequate yardstick.

He counts the seconds in switchgear service!

READ HOW WESTINGHOUSE MAKES SERVICING SIMPLE

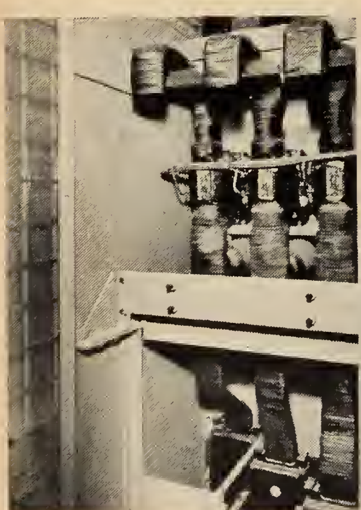
"Good design makes all the difference in switchgear maintenance!" says K. M. Hagar, Service Supervisor, at Canadian Westinghouse.

"Simple, *fast* maintenance is one of the big, important differences in Westinghouse Metal-clad Switchgear. Here's how it saves you time and money—helps keep your operation at peak efficiency . . ."

"No raising and lowering with this Westinghouse breaker! It draws out *horizontally*—gravity-operated shutters fall into place to assure safety."

"Simply remove the interphase barrier to check breaker contacts. For closer examination arc chutes may be removed in just 18 seconds."

"Notice the complete accessibility. The full floating primary contact fingers can be serviced conveniently because they are on the breaker, not in the cell."



"All major components are segregated and enclosed in grounded steel compartments for safety, but they are easily accessible for maintenance."

"Testing is a cinch! With the breaker withdrawn to this test position, you can operate it electrically, without switching any power circuits. You can test the secondary circuits with the built-in test switches in the Flexitest* relays and watt-hour meters."

The Peace River and Alaska Highway Gas Gathering System

A. L. Berry, M.E.I.C.
Principal Pipeline Engineer, Westcoast Transmission Company Limited.

B. L. Moreau, JR. E.I.C.
Production Engineer, Pacific Petroleums Limited.

Paper presented at the Annual General and Professonal Meeting of The Engineering Institute of Canada, Banff, Alberta, June, 1957, in cooperation with The Petroleum Division, American Society of Mechanical Engineers.

ONE OF CANADA'S most extensive natural gas gathering systems is rapidly nearing completion. The system is designed to fill the requirements of the Westcoast Transmission Company's 650 mile long 30-inch diameter pipeline originating at Taylor, British Columbia, where the Alaska Highway crosses the Peace River; terminating at Huntingdon on the International Boundary just east of Vancouver.

In addition to its 30-inch transmission line Westcoast Transmission Company is constructing approximately 130 miles of main gathering lines ranging in sizes from 12 to 26 inches; the producers, primarily Pacific Petroleums Limited and Associates, in the seven major gas fields to be connected initially are constructing 80 miles of field gathering lines ranging in sizes from 4 to 12 inch. The gathering system will have an initial capacity of 400 million cubic feet per day, to match the initial designed capacity of the Westcoast Transmission line, and will be capable of expansion as additional gas is required. The overall cost of the project will approach $200,000,000 including main transmission lines, processing and gathering facilities.

Approximately 25 per cent of the initial throughput will be required for sales in the Caribou, Okanagan and Kootenay areas and in the lower Fraser district and City of Vancouver. The remaining 75 per cent of the initial throughput will be delivered at Sumas, Washington, across the border from Huntingdon, B.C., for transmission to the Northwestern United States.

Figure 1 shows the route of the transmission line with its four compressor stations spaced approximately 150 miles apart, the connecting sales lines, and the gathering system area. Figure 2 shows the gathering system extending southeast to the Peace River area of Northwestern Alberta and northwest along the Alaska Highway tapping one of the largest potential gas-producing areas in Canada served by one pipeline. No unusual pipeline construction problems are anticipated since the route is almost completely free of rock and muskeg, through rolling terrain varying from open farm land to moderately heavy timber.

The extensive gas gathering system to serve Westcoast Transmission Company Limited is nearing completion. The system is described in this paper and the gas handling facilities between the wellhead and treating plant are discussed. Two-phase flow is used in part of the gathering system, and the paper outlines an empirical method of predicting pressure drop in gas-condensate pipelines.

The southeastern extension is a dry sweet gas gathering system of conventional design whereas the northwestern extension is essentially a wet sour gas gathering system with many new and interesting features.

Dry Sweet Gathering System in Alberta

The Alberta production to be connected initially is primarily Cretaceous at shallow depths from 1200 feet to 4500 feet and is essentially sweet and dry at moderate reservoir pressures. The gas requires only the removal of water vapour to meet pipeline specifications since the gas is lean enough not to require any hydrocarbon dewpoint control. The water will be removed at each well in a glycol dehydration unit consisting of a triethelyne glycol absorbing tower, glycol pump and regenerator. Glycol dehydrators were chosen in preference to other types of equipment such as calcium chloride and dry desiccant units after consideration of initial cost, operating cost, and ease of operation. The rather low flowing temperatures of the wells allows dehydration of the gas to a zero degree dewpoint in a suitably designed triethylene glycol dehydrator. Particular attention was given to making the units operative in subzero weather. Regenerator still columns will be insulated to prevent excessive reflux, which tends to flood still columns in cold weather. Internal venting of the still overhead down through the still column will result in a higher exit temperature of the overhead stream, and less likelihood of freezing. All absorber towers will be equipped with integral scrubbers in the base of the towers. Hot lean glycol will be circulated through coils in the base of the scrubbers to prevent freezing. All units are housed to reduce heat loss, and mechanical controls are used wherever possible rather than gas operated bleed pilot controls which have a tendency to freeze off at the low ambient tem-

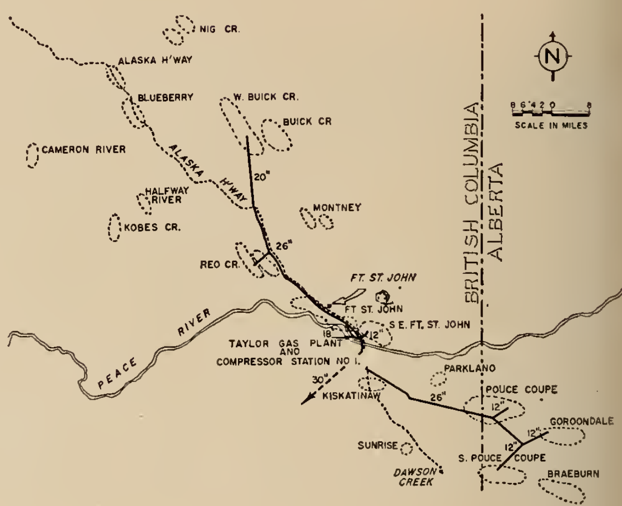

Fig. 1. (above), Westcoast transmission system. Fig. 2 (right), a diagram of the gas gathering system.

peratures to be encountered. All wells will be equipped with a flow control so that a drop in gathering system pressure results in increased production from each well up to a pre-set maximum determined individually for all wells. In this way an operator at a central point will be able to control the field production. Gas will be metered at the outlet of each wellhead absorber tower in accordance with production regulations using the dry bellows type of recording orifice meter. At the field gate station near a central point in the field the gas will be measured again and the back pressure in the field gathering system will be controlled before it enters the purchaser's system. The gas will be metered at the Alberta border before entering B.C. in order to determine Provincial export volumes. The main gathering line from Alberta being constructed this year is 26 inches in diameter, to handle 130 million cubic feet per day, with additional capacity for future extensions. The formation pressures are such that this gas will require compression at Westcoast's Number 1 compressor station at Taylor, B.C., on the inlet to the 30-inch transmission line, operating initially at approximately 865 p.s.i.g. An interesting feature of this 26-inch southeast extension is the suspension bridge crossing of the Peace River, which carries both the 26-inch gathering line with gas flowing north to the Number 1 compressor station, and the main 30-inch transmission line with gas flowing south. The span is 1675 feet, which is approximately 125 feet greater than the span of the Lions Gate bridge in Vancouver. It was desirable to locate the compressor station on the north side of the Peace River adjacent to the Taylor gas treating plant to simplify operations, necessitating this dual crossing 26-inch and 30-inch with gas flowing in opposite directions.

Wet Sour Gathering System in British Columbia

The northeastern B.C. gas production is primarily from deeper high pressure formations, Lower Cretaceous, Jurassic, Triassic, Permo Pennsylvanian, and Mississippian, from 3000 feet to 7500 feet, and it contains liquid hydrocarbons and hydrogen sulphide. To prevent hydrate formation in the well tubing at temperatures as high as 70° F., bottom hole diethylene glycol injection will be used in most cases. The glycol injected removes water vapour in the gas stream by means of co-current absorption as the glycol is returned to the surface. The wells produce retrograde condensate at the rate of 3 to 30 barrels per million cubic feet of gas. Since the condensate will be in contact with the glycol in the tubing, it will be dehydrated for pipeline transmission in the same manner as the gas stream. The glycol-water mixture will be separated from the gas and condensate in a three-phase separator at the surface (three-phase meaning first, glycol-water mixture; second, condensate; and third, gas phase). The gas and condensate will then be re-combined for transportation in a two-phase gathering system. The glycol will be regenerated in the same type of glycol regenerator as used in the sweet dry gas fields and will then be reinjected at the bottom of the tubing string. The wells will be equipped with a pressure control to reduce the flowing wellhead pressure to gathering system pressure. As in the dry gas systems, the producers will install wellhead flow controls so that a drop in gathering system pressure results in increased production from each well up to a pre-set maximum determined individually for all wells. The wells will also be equipped with an over and under pressure shut off of a high-pressure balanced diaphragm design believed most suitable for cold weather operation. Since this so-called wet sour gas contains considerable amounts of hydrogen sulphide and carbon dioxide, a corrosion inspection and control program will be instigated. Corrosion control will be accomplished by adding a liquid semi-polar organic corrosion inhibitor to the glycol to protect the well equipment, and also to the condensate on the downstream side of the wellhead separators to protect the gathering system.

This wet sour gas will be brought to the Taylor gas treating plant now under construction on the same site as the Number 1 compressor station. The Taylor plant is essentially an amine scrubbing plant for removing the acid gas, an absorption plant for recovering propane, butane and natural gasoline and a dry desiccant dehydration plant for drying the gas after treating. The location of this plant on the banks of the Peace River was determined by the need for large quantities of water for cooling and for steam generation, amounting to approximately 42 million gallons per day. By way of comparison, this quantity of water would serve the maximum day requirements of a city with a population of over 200,000. The hydrogen sulphide gas from the scrubbing operation will be delivered to a sulphur recovery plant, which will process initially some 300 tons per day of elemental sulphur. The liquid products will be delivered to a processing plant also at this location, where they will be upgraded to make saleable products.

This wet gas gathering system, consisting of a 12-inch line to South East Ft. St. John field, an 18-inch line to Ft. St. John field and a 26-inch line northwest along the Alaska Highway, connected to a 20-inch line to the West Buick Creek field, will be called on to transport approximately 300 million cubic feet per day of raw gas, plus several thousand barrels per day of liquid hydrocarbons. Each line ends at the Taylor plant in large inlet scrubbers designed to remove liquids efficiently at very high rates, which leads us to the matter of two-phase flow in this portion of the gathering system.

Two-Phase Flow

It is commonly recognized that the transmission pressure drops in a horizontal two-phase "gas-condensate" pipeline are greater than in a dry gas line and that even relatively small amounts of liquid have a considerable effect. The factors contributing to this additional pressure drop are as follows:

(i) Energy lost by the gas in accelerating and transporting the liquid.

(ii) Increased roughness caused by wetting the pipe wall and by waves on the surface of the liquid.

(iii) Reduction in available flow area caused by the introduction of a liquid phase.

Pressure drops in the northeastern B.C. system are expected to be

Top to bottom: Laying pipe for the gas gathering system; welding the gas pipeline; a general view of the refinery at Taylor, B.C.

higher because in hilly terrain additional energy is lost by the gas in lifting the liquid over every individual rise. This additional pressure drop appears to be dependent, to a very large degree, on the gas velocity in the pipeline.

There are six main types of flow patterns which have been recognized in two phase flow. The various flow patterns are shown in Figure 3. Assuming a horizontal pipe running full of liquid flowing initially so as to completely fill the pipe, and considering the effect of adding increasing volumes of gas, the type of flow to be anticipated is as follows:

(1) *Bubble Flow*—in which separate bubbles of gas travel along the upper part of the pipe at approximately the same velocity as the liquid.

(2) *Stratified Flow*—in which the liquid flows along the bottom of the pipe and gas flows above with a relatively smooth interface.

(3) *Wave Flow*—which is similar to stratified flow except that the gas moves at a higher velocity and the interface is disturbed by a wave action.

(4) *Slugging Flow*—in which the interface level rises and falls and frothy slugs are formed periodically and pass along the pipe at higher velocities than the average liquid velocity.

(5) *Annular Flow*—in which the liquid flows in a uniform film on the pipe wall and gas travels at a high velocity through the central core.

(6) *Fog Flow*—in which most of the liquid is entrained as fog or spray by the gas at extremely high gas velocity. Sometimes called "dispersed flow".

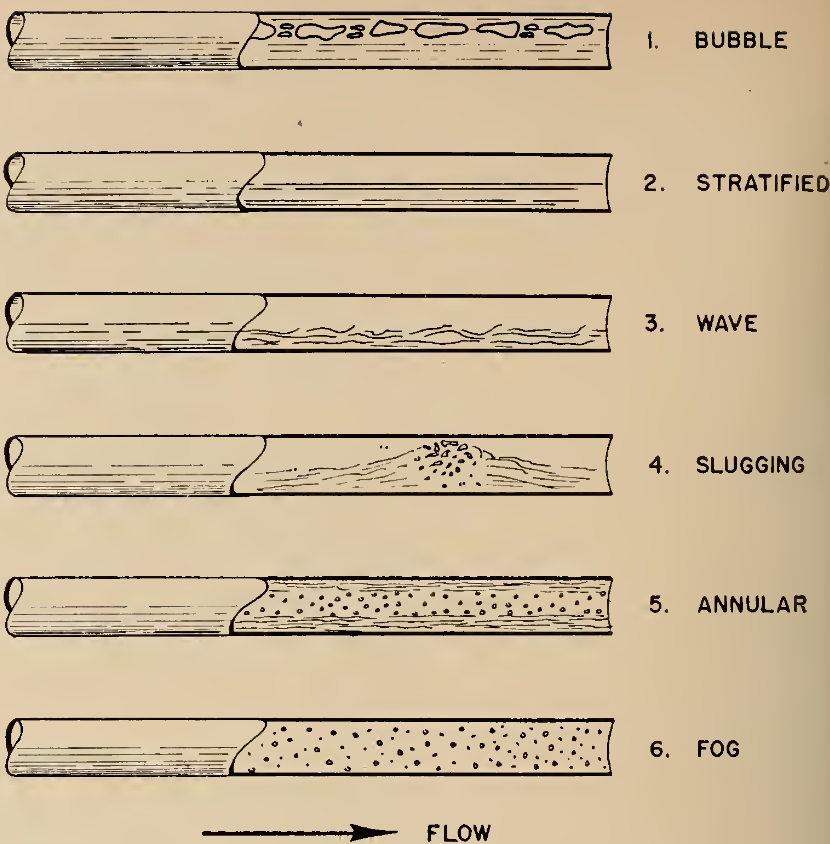

Fig. 3. Flow pattern sketches: horizontal two-phase pipeline.

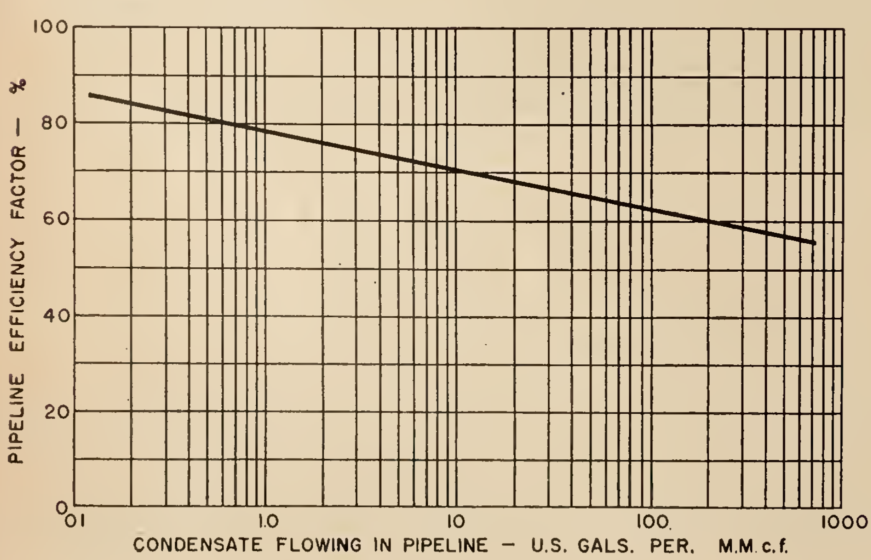
Stratified and wave types of flow patterns are expected initially in the B.C. gathering system.

Limited published data are available on two-phase pipelines operating at high pressures and most of these data are for practically horizontal lines. However, a study of operating data available on 4 inch to 16 inch high pressure two-phase pipelines, operating in Canada and the United States under somewhat similar conditions to those anticipated, suggested an empirical approach to this problem of determining total pressure drop in the B.C. gathering system, which is through predominantly rolling terrain.

Fig. 4. Reduction in pipeline efficiency factor as rate of condensate flow in horizontal pipeline is increased.



The pressure drop in a two-phase line is calculated in two steps. Figure 4 shows the effect of increasing amounts of condensate on the Panhandle eastern flow formula efficiency factor. It can be noted from this curve that even relatively small amounts of liquid which barely wet the wall of the pipe depress the efficiency factor to a considerable extent. This reduction in flow efficiency is for a horizontal line under stable flowing conditions. The amount of liquid in the line at flowing temperature and pressure is determined from test, or by flash calculation based on a knowledge of the composition of the gas. Ground temperatures are important since they affect the amount of hydrocarbons in the liquid phase. A survey of ground temperatures in the area indicated that the gas temperature in a pipeline buried 3½ feet below the surface does not fall below 25° to 30° F. during the winter months, even

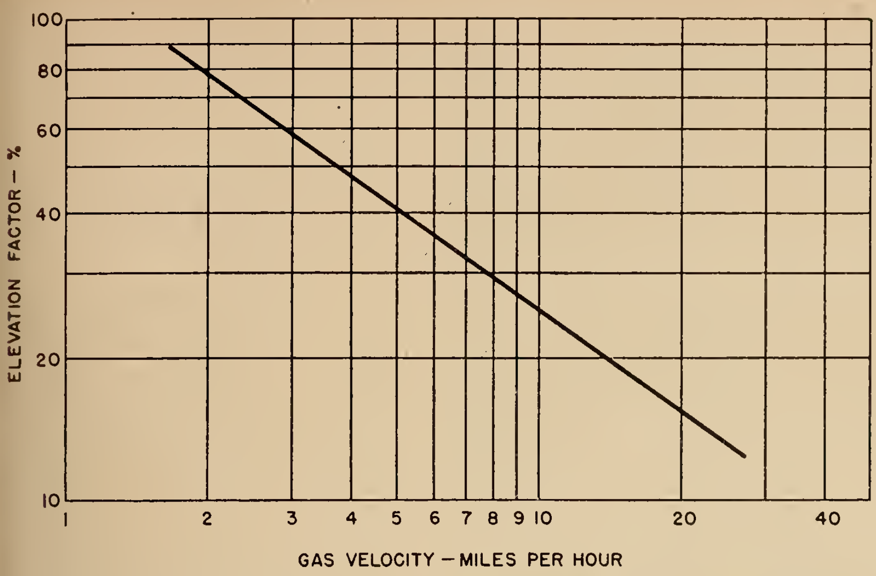


Fig. 5. Illustrating reduction in elevation factor as gas velocity is increased.

though the frost line may reach 8 to 10 feet.

Figure 5 illustrates the effect of gas velocity on elevation factor. The elevation factor can be defined as the percentage of total liquid head that appears as pressure drop over the line. The liquid head calculated from an accurate profile of the line is not the net change in elevation between the two ends of the line, but rather the sum of all the vertical rises. The specific gravity of the liquid used in determining the total head on the line is determined by test or by flash calculation. The percentage of the liquid head then which will appear as pressure drop, is a function of the gas velocity in the line and total pressure drop expected will be the sum of the pressure drop calculated for a horizontal line, plus that due to liquid head.

The type of result to be expected is illustrated in Figure 6. An optimum flow is indicated for each size of line, assuming that stable flow conditions are allowed to develop. The optimum line size for any particular quantity of gas and liquid to be transported will depend on the vertical profile of the line.

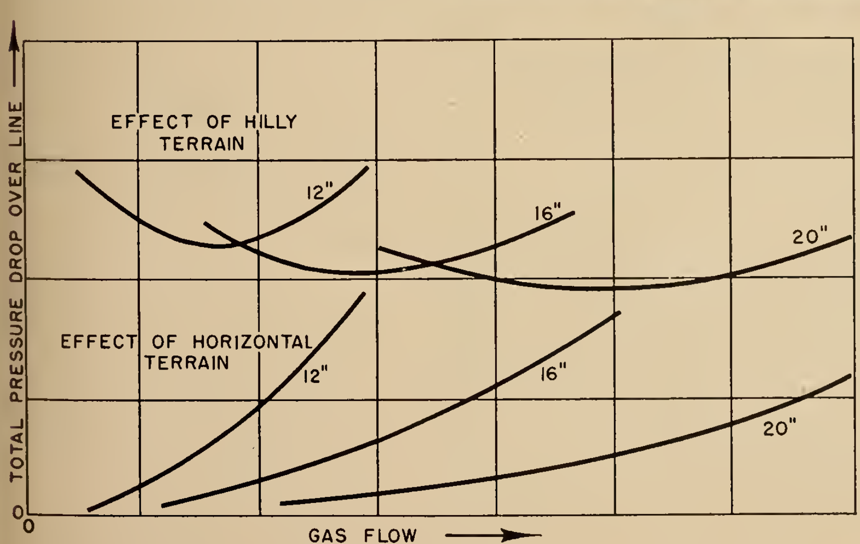
This approach also indicates that total pressure drop in a two-phase line is not always reduced by increasing the line size. This becomes more apparent as the total of all the rises on the system becomes greater.

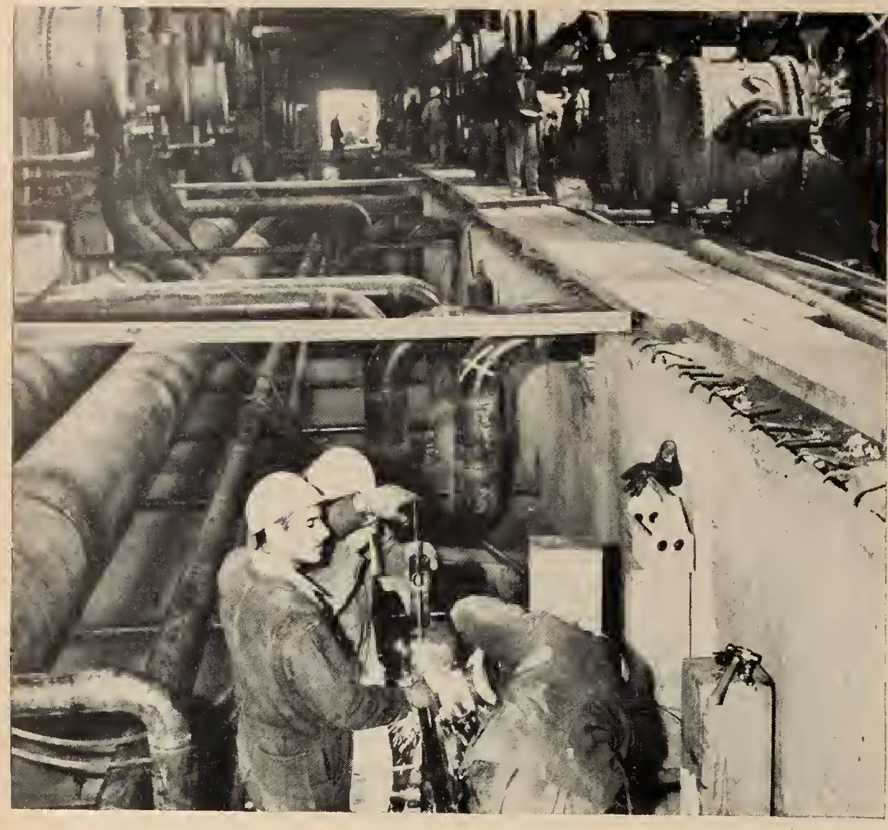
Although this approach to the matter of two-phase pressure drop in a "gas-condensate" system is empirical, and more field test data would be desirable, it is of considerable value in selecting the line size and in predicting the total pressure drop, especially where the largest portion of the total pressure drop is due to the effect of terrain and pipeline velocities do not exceed 10 miles per hour.

The provision of a separate liquid line parallel to the longer main gathering lines would provide extra gas-carrying capacity for future expansion with a minimum of compressor horsepower. The liquid would be removed at the various points where the gas flowing in the line had

Stringing pipe for the Shelley Crossing of the Fraser River.

Fig. 6. Illustrative example of the effect of hilly terrain in two-phase flow.





Welders at work during the construction of the refinery at Taylor, B.C.

reached ground temperature, where no further liquid condensation would be expected. A back pressure would of necessity be maintained on the separate liquid line in order to achieve minimum pressure drops by preventing flashing of the liquid.

Since the elevation effect on some lines can be quite severe, extra grading and spanning can be justified. Line location to avoid extreme elevation changes is a very practical approach to reducing operating costs by reducing total pressure drop.

Communications

The communication system for the gathering lines will be an extension of the main pipeline VHF radio system.

A 50 watt VHF base station, operating in the 152-174 megacycle band, will be situated at Charlie Lake, about five miles northwest of Ft. St. John, with a directional antenna beaming the signal toward the Buick Creek fields. Another 50-watt VHF base station will be installed at Bessborough, near Dawson Creek, with a directional antenna beaming the signal towards the Pouce Coupe, South Pouce Coupe, and Gordondale fields. These two base stations will be remotely controlled simultaneously by the gathering system dispatcher at Fort St. John.

All maintenance vehicles of the Transmission Company will be equipped with 50-watt mobile VHF units tuned to the same frequency as the base stations, and will thereby be able to maintain communication with the Fort St. John dispatcher at all times.

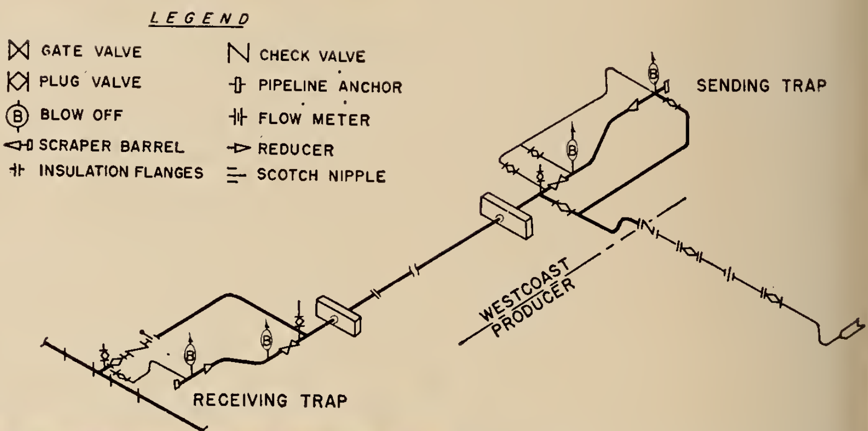


Fig. 7 (above). Typical gathering line, showing pigging facilities.

(Below). A further view of the interior of the refinery at Taylor, B.C.

The field operator has installed a VHF radio system which covers roughly the same area as the Transmission Company system. The dispatch office for the field operator will be the same building as the Transmission Company dispatch office, so that close control may be kept over the entire system.

The main remote control unit in the Fort St. John dispatch office will be equipped with a telephone interconnection so that the VHF system can be connected by private leased voice channels directly to the Vancouver dispatch office.

Operation

The system will operate at a comparatively high load factor, since the major portion of the load is at a 90 per cent load factor. The long main transmission line necessitates gathering system dispatching one to two days ahead of actual consumption. There will be in the order of one billion cubic feet of gas in line storage in the gathering and transmission system at all times.

Figure 7 illustrates the type of pigging facilities installed on all main gathering lines in Alberta and British Columbia such that on-stream pigging can be accomplished without interrupting the normal flow of gas. It is believed that periodic cleaning of the pipeline will be required to maintain pipeline design efficiency. However, in the wet gas system, routine pigging will not be relied on to materially reduce liquid hold-up in the line, thereby maintaining overall pressure drops less than those anticipated under reasonably stable flow conditions.

This rather widespread gathering system, which connects a continuously growing gas reserve to a rapidly expanding market area, requires that the design be kept flexible and capable of future expansion. The initial system is scheduled to be put into service in the fall of 1957.

A Major Power Plan for Yukon River Waters in the Canadian Northwest

J. M. Wardle, M.E.I.C.
Northwest Power Industries Limited, Ottawa, Ontario

A paper read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June 1957

THE YUKON RIVER with its tributaries is the geographical frame of the Yukon Territory and its watershed includes 109,500 square miles of the Territory's total area of 207,076 square miles. Because of the great transportation facility the river has provided over the years all activities in the Yukon area have been closely associated with it. In the early days it was the main agency in exploration and the development of the fur trade and, many years later, in the discovery of free gold.

Then after a long period of limited economy came the Second World War that made the Yukon territory a strategic defense area in the northwest. The resulting construction of roads, airfields, oil pipe lines, military installations, and the great Alaska highway gave the Yukon its second boom.

The moderate recession following the end of the war is now over and the increasing activity in the whole Yukon area rests on the firm foundation of its natural resources. These include gold, base metals, forest cover, and great water power potentials.

Probably no northern area had such publicity in its early days as the Yukon. Though the gold rush of 1849 in California was perhaps the greatest, and that in the Fraser River watershed in 1858-59 contributed most to future settlement of British Columbia, the great Yukon gold rush of 1897-98 had the fastest action combined with rich finds of free gold and the lure and romance of the far north. From the day in August 1897 that gold was discovered on Bonanza Creek there was a rapidly moving kaleidoscope of frantic gold-seekers, experiencing great hardships, loss of savings and sometime their lives, and for the luckier ones fortunes in gold. The years of 1897-98 saw the climax of the rush but today gold recovery is still a big industry in the Klondyke river district near Dawson City where gold dredges operate throughout each summer season. Base metal ores have been discovered and are in various stages of development, and intensive geological exploration is underway. In the pioneer days of the Yukon area the Hudson's Bay Company was to the fore and in 1842 had extended its interests to the Yukon River watershed. In May 1898 the White Pass and Yukon Route Company began the construction of its narrow gauge railway. Today, nearly 60 years later, this line still serves the Yukon area.

The name "Yukon" has long had a romantic appeal, associated as the territory has been with the spectacular gold rush of some sixty years ago. Many studies have since been made of the possibilities of developing useful power from the resources of this area. The political and physical problems involved are discussed in this paper.

It was in the same Yukon river valley that some ten years ago the possibility of "white gold" in large amounts was seriously considered. Before this the Yukon River was not considered as having large power potentials that would offer economical development; but as the need for low-cost hydro-electric power steadily increased, consideration was given to what the Yukon river watershed might have to offer. Interest in this area was heightened by the existence of several large fresh-water lakes at the headwaters of the river and which had a total surface area of over 640 square miles. The possibilities of securing the essential storage required for a northern power development were thus very great and constituted one of the great assets of the Yukon river basin. Since the Yukon river is navigable for a thousand miles, from Whitehorse northerly, one of the early problems in any power plan was the need to protect navigation facilities. River transportation in both the Yukon Territory and Alaska was carried on by shallow draught stern-wheel steamers, usually burning wood, which travelled from Whitehorse down the river to Dawson City and on through Alaska to Fort Yukon and Tanana. Fairbanks the main interior centre of Alaska, is about one hundred miles due south of Fort Yukon and for years depended on river navigation on the Yukon and Tanana rivers for transportation. However with the development of highway and rail systems in Alaska, and the increasing use of large aeroplanes for transportation of personnel and materials, the use of the river gradually declined and finally in September 1955 the last stern-wheel steamers in both the Yukon Territory and Alaska were beached, and river traffic on a commercial scale ended (for the time at least).

Since the Yukon river is navigable it was evident that there was no concentrated head available for power purposes. While several dam sites on the river existed in the Yukon Territory they would involve long high dams at considerable cost, which, coupled with ice troubles in winter, meant that power could not be produced at rates that could compete with other power potentials to the south and which were also nearer to power markets. One suggestion was to carry Yukon waters westerly through the coast range into Alaska to tide water where generating plants could be constructed in Alaskan territory with a total head available of some 2,000 feet. This plan was considered in 1946-47 by the Aluminum Company of America (Alcoa) which approached the Government of Canada for permission to make investigations. This Company undertook preliminary field work in both Canada and Alaska. In the fall of 1949 United States' Government authorities suggested to Canada that the project be an international one, following the same general plan but financed by the two countries. Though Canada would not be committed to this suggestion it was agreed that each country would make surveys of their respective power areas. These surveys, made in 1950, were limited to topographical mapping, facilities for additional stream flow measurements, soundings, and limited geological work. Each country paid for the work done in its own territory.

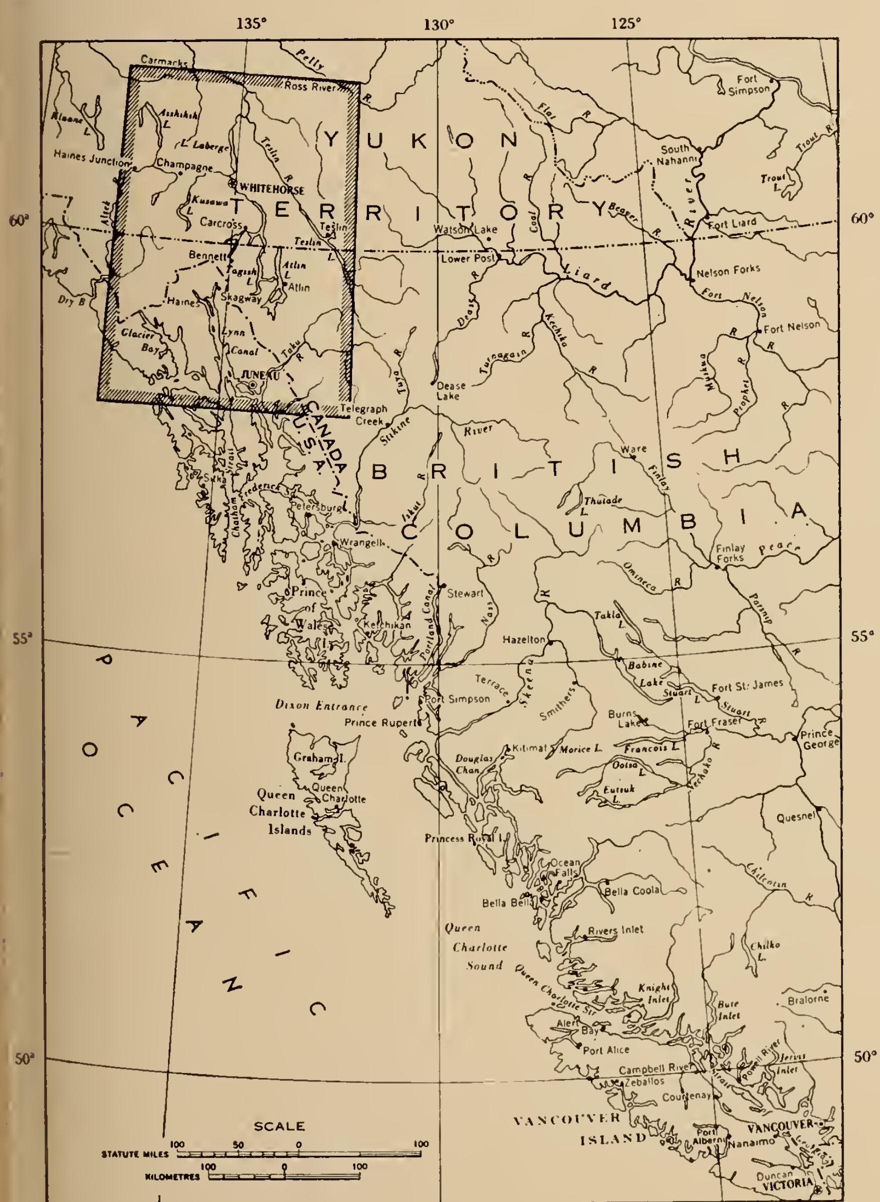
However in the fall of 1950 the Government of Canada decided that it was not in the national interest to permit the diversion of Canadian water to another country for power if it could be developed and used in Canada. No further work was done towards a joint project.

In 1952-53 the large mining organization of Ventures Limited, coupled with its subsidiaries Frobisher Limited and Quebec Metallurgical Industries Ltd., became interested in the possibilities of major power development in the northwest for metallurgical purposes, including the recovery of aluminum, copper, iron and nickel from raw ores, and decided to investigate power potentials. The author was asked in the fall of 1952 to act as consulting engineer and see if four or five million horsepower could be developed at competitive cost in the Canadian northwest, perhaps in the Yukon Territory. A condition laid down by the Government of Canada was that any such power project would have to be planned so that generating plants, and industrial plants using the power, would be in Canada.

Although it was felt that the Yukon river, with the large lakes at its source, was likely to be the answer, the decision to use Yukon power was not made without considering other possible sites in the northwest. All information available from any source was obtained on numerous watersheds, including the Alsek, Peace, Liard, Slave, Stikine, Skeena, and Nass, as well as smaller rivers on the Pacific coast. There were several streams with large power potentials, but the Ventures—Frobisher—Quebec Metallurgical group was primarily interested in power areas that could eventually provide an output of 4-million horsepower, or more. The Fraser river in British Columbia had great possibilities, but the very valuable fishing industry associated with it indicated a serious delay in reaching a satisfactory arrangement between fishery and power interests.

On the other hand the Yukon River involved few controversial factors from the Canadian standpoint and in addition it afforded the large storage areas previously mentioned. Flow records were available on the Yukon river at Whitehorse for over twenty years and the reconciliation of water levels recorded for navigation purposes with the flow records, gave flow data for a period of forty-two years. These factors resulted in the recommendation to proceed with surveys and investigations of the upper watershed of the Yukon river. This course was approved by the Ven-

Fig. 1. Key map showing the location of the Yukon River Power project in the Canadian Northwest.



tures-Frobisher-Quebec Metallurgical Industries companies in the spring of 1953. In 1954, these companies incorporated a subsidiary, Northwest Power Industries Limited, to make power investigations and plan,. construct, and operate power projects. Since that time all such activities have been under the name of this company.

At this stage two courses were open for the development of power in Canada from Yukon waters. The first of these, a series of large dams down the Yukon river, was not regarded as economically feasible. The alternative, which complied with Dominion Government policy requiring development in Canada, was to reverse the northerly flow of the upper waters and take these south through the lower end of Atlin Lake to low valleys in British Columbia where heads ranging from 500 feet to over 1,000 feet were available. This is the general plan that was adopted and for which field surveys and engineering investigations have been under way since the early summer of 1953.

Because of its latitude of from 58° 30′ to 62° N., there were special factors associated with the Yukon project and which included climate, water temperatures, earthquake hazards, fisheries, other power potentials, and the effect of glacial areas. There was also the possibility of future competition from power produced by atomic energy. These factors either affected construction costs or plant operation and maintenance.

Considerable study was given to each of these in the early stages of the investigations and before too great an expenditure was made on field work.

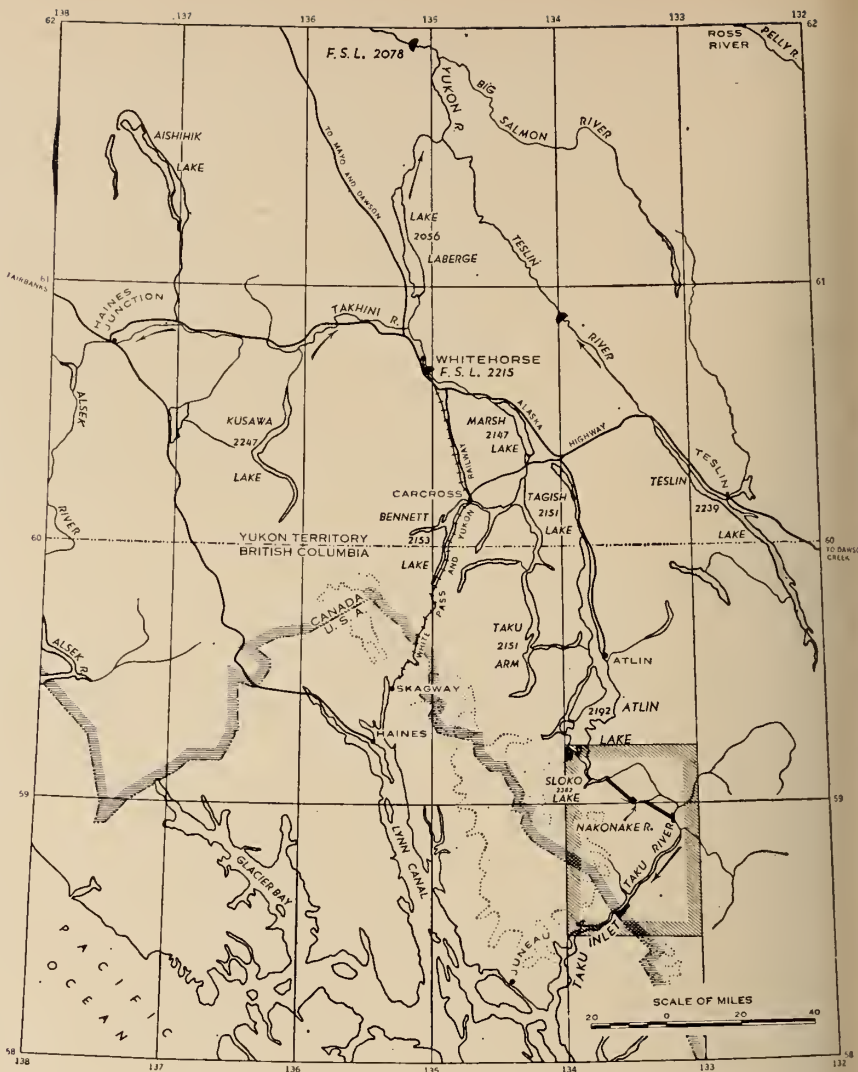


Fig. 2. General plan of the Yukon River power project.

Climate

The climatic conditions that prevail in the power area are important and worthy of record. The opinion is prevalent that in all the northerly latitudes ranging from 58° to the Arctic Circle, winters are severe with extremely low temperatures. This is not the case in the area in which the power plants, transmission lines, and industrial sites of the project will be located. This area lies roughly between altitude 58° 30′ and 59° 10′ N. Its proximity to the Pacific Coast gives it the benefit of the "Kiro Suwo" or warm Japanese current. This phenomenon, coupled with high latitude, produces cool summers and mild winters.

At Tulsequah, B.C. which is only 5 miles east of one of the proposed industrial sites, the average mean temperature in December is 21° F, January 20° F, February 16° F, July 58.8° F, September 49° F. In Montreal, Quebec, the mean temperatures for December, January, and February are 20° F, 14° F, and 15° F, respectively.

At Juneau, the capital of Alaska, 40 miles south-west of Tulsequah, B.C. the annual precipitation is 83.7 inches, while at Prince Rupert, B.C. on the sea coast, 450 miles north of Vancouver, with a population of 10,500, the precipitation is 95 inches. The annual precipitation at the proposed industrial areas near Tulsequah is estimated at 90 inches.

For eight years a hydro-electric plant has operated very successfully on the Snare River 110 miles north of Yellowknife at Latitude 63°. While temperatures as low as 62° below zero are experienced, there have been no serious ice troubles and personnel live in reasonable comfort.

No great disadvantages due to climatic conditions are thus indicated in the Yukon River power area.

Seismic Disturbances

As the Pacific coast is one of the world's major earthquake areas, and as dams and power plants would average some 150 miles from the heavy damage belt, reports were obtained on the possibility of serious earthquake hazards. Information supplied by the seismological division of the Department of Mines and Technical Surveys, Ottawa, Ontario, and from publications of the California Institute of Technology, indicates that though large earthquakes have occurred off the northern coast, none has had epicentres on the mainland nor resulted in any noticeable disturbance in the coastal mountains. For example, a severe earthquak

120 miles west of Prince Rupert, British Columbia, in 1949, caused no damage in that city.

It appears, therefore, that the Atlin-Taku area would be a reasonable risk for major power installations.

Fisheries

The effect of major power projects in the northwest on salmon reproduction is an important factor. Reports have already been obtained on the possible effect of the Yukon river power project upon salmon reproduction. Information obtained shows that this would not be a factor to interfere with an economical development. The lakes at the headwaters of the Yukon river are so far removed from the Pacific ocean that very few salmon reach them for spawning purposes. On the Taku river, which carries a large amount of silt for several months of the year, the greatly increased flow of comparatively clear water through the power tunnels may have a beneficial effect on fish reproduction. Below Whitehorse a few salmon are taken, but not for commercial purposes.

Other Power Potentials

The Yukon power project does not exhaust potential power sites in the far northwest nor does it place too much power development in the hands of a private company. A review made of potential power areas in northern British Columbia and the Yukon Territory shows that in addition to power from the major project a large amount will be available for mining and industrial development at well-distributed points. It is estimated that there will be at least 161,000 horsepower in the Yukon Territory and 463,000 horsepower in northwest British Columbia.

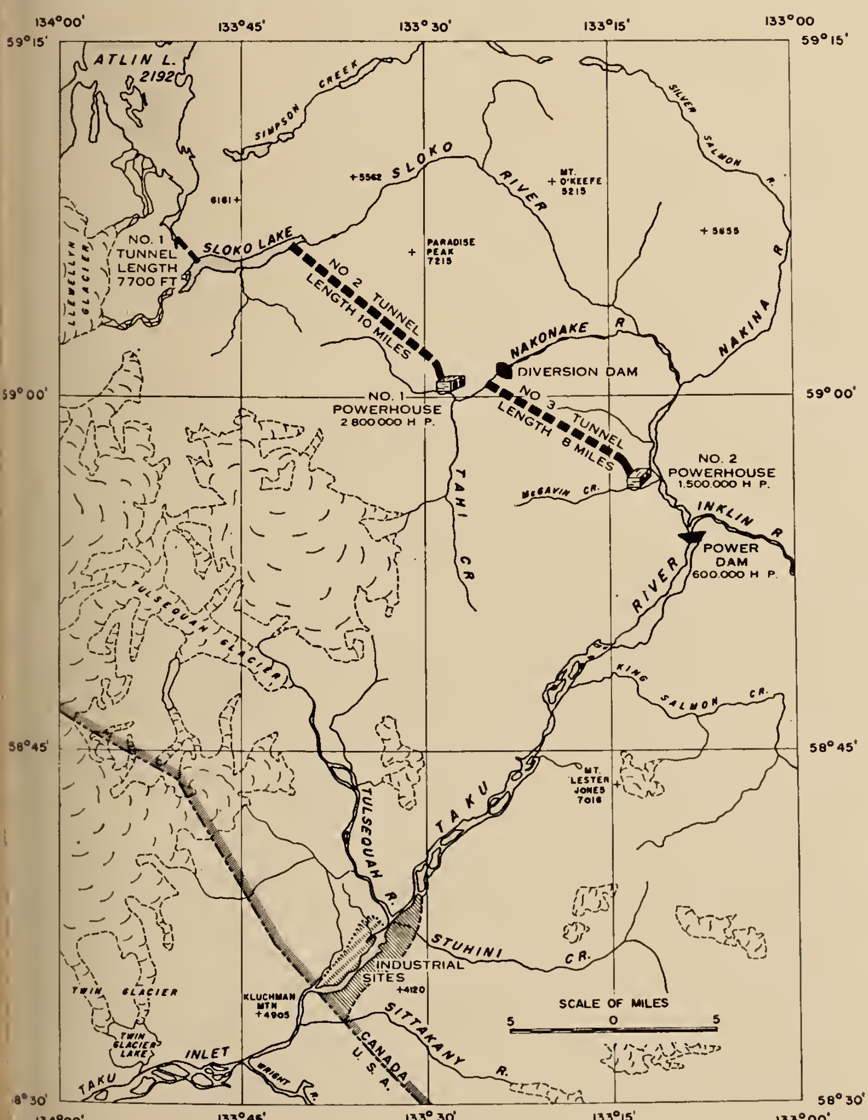

Fig. 3. Location plan of the main tunnels, powerhouses, and power dam for the Yukon River/Atlin Lake/Taku River power project.

Effect of Glacial Areas

The Juneau icefield which feeds several glaciers in the Pacific northwest near the power area has two arms that discharge into the Taku river valley from the north, about sixteen miles west of the international boundary. One of these is the well-known Taku glacier and the other is its distributary arm, called Hole-in-the-Wall glacier. Their behaviour is abnormal because, while other glaciers in the area are steadily receding, the Taku glacier has advanced some 3½ miles over the past fifty years. The Hole-in-the-Wall glacier has also been advancing during the same period. There were evidences in the Taku river valley near the international boundary that the water level had at one time been 90-feet higher than the present level and Indian legend had the story that this was caused by the Taku glacier advancing across the river valley and damming up the Taku river flow to cause a large inland lake. Investigations carried out by glacial experts in the Juneau icefield area showed that even if this had once happened there was no possibility of it occurring again under present climatic conditions. Glaciologists know that ice conditions two hundred years ago were tremendously different to what they are now. In northern British Columbia at that time glaciation was probably at an intense alpine stage and there were great accumulations of ice in all the valleys of the coast range. Since then there has been a tremendous reduction of ice accumulation coupled, except in the cases mentioned, with glacial recession. As a result there is very much less ice for the Taku glacier to draw on than there was two hundred years ago. The advance of the glacier is thus not due to increased ice accumulation but perhaps to some readjustment of the flow in the centre of the main glacial area and higher temperatures. Measurements on the Taku glacier in 1952 seem to support this theory because they showed a settlement of the ice surface, through melting, of from one to seven inches per day during July and August.

To block the Taku river and back water up to even the lower generating plant would require an advance of the Taku glacier over the 9000 ft. channel of the Taku river with an ice barrier over 290 feet high. As it happens, two years ago, further glaciological studies indicated that the high water level previously mentioned was not fresh water but sea water and that in the interim the coastal areas had been raised some 80 to 90 feet.

Power from Atomic Energy

The possibilities of competition from this thermal source have been given careful consideration, particularly in view of the progress being made in the design of nuclear power plants. The plant that opened at Calder Hall, England in October 1956, and which develops nuclear power in connection with the manufacture of plutonium, is a notable example. It appears that there is little likelihood of power from atomic energy being a serious competitor to large hydro-electric developments in the foreseeable future. In a comparatively short period of years it may compete successfully with plants using coal, oil, or natural gas for fuel, particularly in regions where transportation cost of fuel is the governing factor. It is quite possible that the high cost of hydro-electric plants in very remote or northern areas coupled with long transmission lines, will eventually make them non-competitive and thus open additional fields for power from atomic energy.

The favourable information obtained on the several factors mentioned confirmed the decision to proceed vigorously with field investigations and office studies of the proposed Yukon River project. The power plan that has been selected and for which extensive surveys have been under way for the past four years, is described hereunder.

Power Plan

This adapts itself readily to stage construction, which is one of its most important assets. Power output can be planned to keep in step with anticipated markets, and beginning with 250,000 h.p. can ultimately through four major stages, reach a maximum of 4,900,000 h.p.

Stage 1

The large upper lakes, which include Atlin, Lindeman, Bennett, Tagish, Taku Arm, and Marsh lakes have elevations ranging from 2192 feet to 2147 feet above seal level. It is proposed to raise all these lakes to a f.s.l. of 2215 feet by a dam a few miles above Whitehorse, Yukon Territory. The large reservoir so created will extend south in three great arms ranging in length from 50 to 12(miles.

The mean flow of the Yukon rive at Whitehorse over the past ten-yea period averages some 8,450 c.f.s. equivalent to 6,117,800 ac. ft. pe year. The reservoir capacity betwee a proposed l.s.l. of 2195 feet an f.s.l. of 2215 feet is estimated at 6, 814,000 ac. ft.

This water will flow through Atli lake to a tunnel which will carry i to Sloko lake. The latter will be use as a power canal to carry the wate to the portal of tunnel No. 2. Thi tunnel, which will be 10 miles lon will discharge the water into a pov erhouse on the Nakonake river und a gross head of 1090 feet. An est mated 880,000 h.p. will be deve oped here. An interesting feature the use of Sloko lake as a canal, sin its elevation is 190 feet higher th Atlin lake. Consequently unless wh lowered its carrying capacity wou be 28,000 c.f.s. or more, a review the general tunnel system would l necessary.

To obtain this essential informati a survey party in March 1954 to soundings through the ice cover. grid was established in deep sno over the entire lake and 543 soun ings were taken. These, when pl

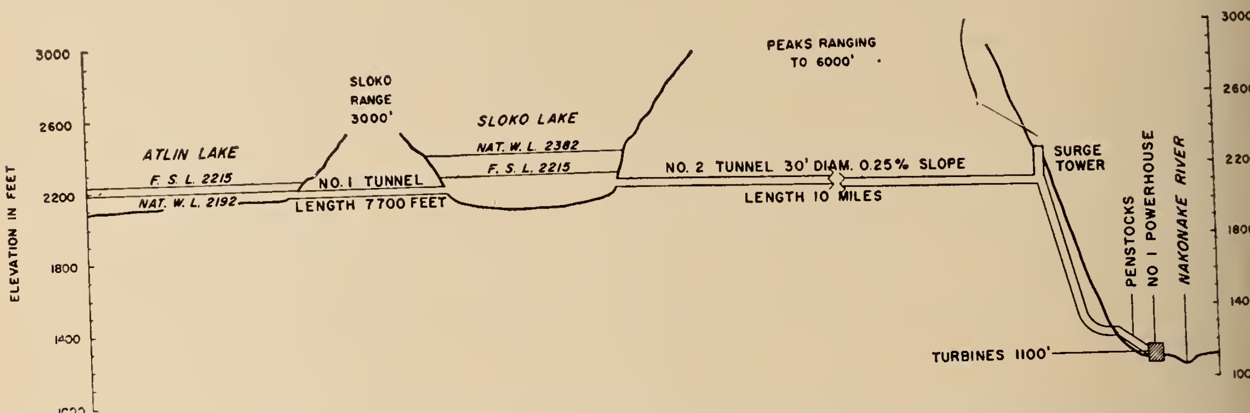

Fig. 4. Sketch profiles of tunnels 1 and 2 leading to No. 1 powerhouse on the Nakonake River.

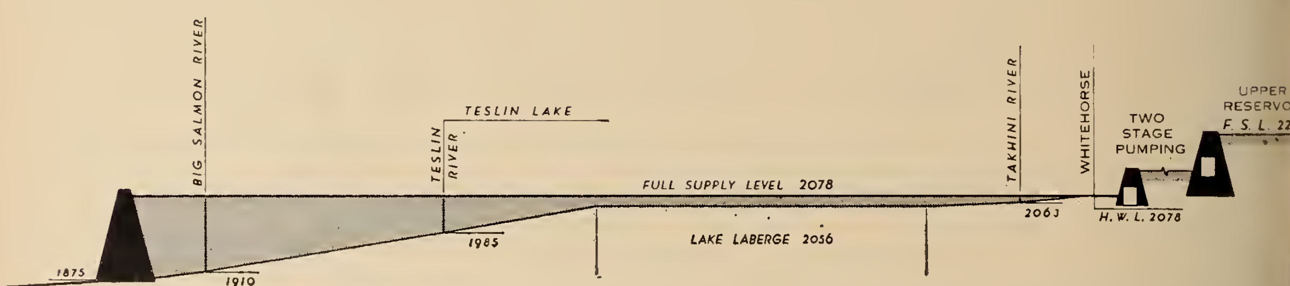

Fig. 5. Sketch profile of the lower reservoir with main storage dam for the Yukon power project.

ted, showed that the minimum cross-section of Sloko lake, when drawn down from 2382 feet to 2192 feet, could carry 28,000 c.f.s. at a velocity of one foot per second. The existence of a satisfactory ice-cover during the low temperature winter months was also assured.

Stage 2

This stage consists essentially of increasing the amount of water available in the reservoir by the addition of water from Teslin Lake and River which lie to the northeast of Atlin lake. Teslin is a very large lake, and the mean flow of the Teslin river which drains it is 11,800 c.f.s. Its flow is thus considerably larger than the flow of the Yukon river at Whitehorse. It is proposed to regulate the flow of the Teslin river by a storage dam at the mouth of the Mary river some thirty-five miles below the outlet of the lake) so that a minimum of 6,900 c.f.s. can be diverted into the upper reservoir. This diversion will involve power canals and a tunnel. In 1955 a survey of the diversion was made, but the economic study made possible by the information collected has not yet been completed. This may show that a low-lift pumping plant at the summit of the diversion may be preferable to longer canal and tunnel sections.

With a minimum of 6,000 c.f.s. diverted into the upper reservoir at Marsh lake the power output at the Nakonake river power plant will be increased to 1,540,000 horsepower.

Fig. 6. Echo-sounding raft at the damsite, Miles Canyon, Yukon River.

Stage 3

An advanced stage of development will be reached at this point, as it is proposed to impound waters below (north of) the Whitehorse dam and thus create a lower reservoir.

The lower storage dam required on the Yukon river would be built below the mouth of the Big Salmon river and would raise the level of the river channels, Lake Laberge, and smaller lakes, to an elevation of 2078 feet; which is the normal high water mark at Whitehorse. A maximum lift of approximately 140 feet would bring this water to the upper reservoir where it would be utilized under a head of 1090 feet. The lower reservoir would also impound waters from Yukon tributaries below Whitehorse, including the Teslin river waters not already diverted, and including the waters of the Takhini and Mendenhall rivers. Upper waters of the Alsek river to the west would be reversed by a dam on the Dezadeash river to flow into the Mendenhall river through a diversion surveyed in 1953. These waters, together with those of the Big Salmon, would give a total regulated flow at the south end of Atlin lake of 28,000 c.f.s. The total output at the Nakonake river power plant would, under stage 3, be increased to 2,800,000 horsepower. If necessary in the future, consideration could be given to the diversion of water from the Kluane lake watershed, some 125 miles west of Whitehorse where a minimum of 2,000 c.f.s. would be available.

Fig. 7. Sloko River Falls; Sloko Lake at upper right.

Stage 4

Under present plans the next step would be to drive the eight-mile tunnel between the Nakonake river and the Taku river, which would create a head of 550 feet. In the meantime the estimated flow of 28,000 c.f.s.

at the south end of Atlin lake, as available from stage 3, would be increased by the flow of the Sloko lake watershed and upper Nakonake river, besides one or two smaller tributary streams. An estimated 1,500,000 horsepower can thus be developed at the plant on the northwest bank of the Taku river.

During 1956 a promising dam site was located on the main stem of the Taku river itself, just below the mouth of the Inklin river, and a preliminary survey was made. Part of the natural flow of the Taku and Inklin rivers could be impounded here to give, with the northerly waters, a flow of well over 30,000 c.f.s. A power plant at the dam site would give approximately another 600,000 horsepower, or a total potential of 4,900,000 horsepower.

The latter two stages are many years in the future, and the time of their construction will depend upon the development of the tremendous power market that will be necessary. Information will be available in 1957 for the design of stage 1, and certain features of stage 2, but much definitive information is required for stages 3 and 4. As the project develops other sources of water, through diversions, may suggest themselves and there is thus the possibility of over 5-million horsepower being developed if market conditions should warrant it. The power situation in Canada from twelve to fifteen years hence will govern just how far the vast Yukon project should be carried.

Tunnels

As shown on the accompanying plan, three tunnels will be required to bring water to the generating plants, the first of these, No. 1, carrying water on an even grade from the lower end of Atlin lake, (Sloko inlet) to Sloko lake. No. 1 tunnel will be 7700 feet long; No. 2 tunnel will carry water under head from the east end of Sloko lake to the generating plant on the Nakonake river and will be from 10 to 10.2 miles long; No. 3 tunnel, which will carry water from a diversion dam below the Nakonake power plant to the proposed generating plant on the Taku river, will be approximately 8 miles long. (Fig. 3.)

Several factors will enter into tunnel planning and design.

If Yukon power were within transmitting distance of a major grid with an assured demand it would not be difficult to decide on the capacity of the initial structures. However, power loads in the area are negligible and a market must be developed, based on mining and the processing of raw materials in great quantities. To carry a flow of 28,000 c.f.s. at normal velocity would require an unlined tunnel with a diameter of some 60 feet. A lined tunnel with higher velocity would have a diameter of approximately 50 feet. The great size of the tunnels required, and their length and cost, prohibit construction to ultimate capacity in the early stages of the development. Consequently smaller tunnels will be built first, in the nature of pioneer tunnels. As the power load develops, larger tunnels will be driven parallel to the pioneer tunnels, and with the same gradients unless rock encountered by the pioneer tunnels shows the necessity of some change in alignment. The proposed diameter of the pioneer tunnels is about 30 feet, which could carry approximately 9000 c.f.s.

Considerable study has yet to be made to choose lined or unlined tunnels, where the latter are possible. From a construction standpoint alone it might be economical to drive the larger unlined tunnel section but there are other factors that may not be weighed until actual construction is under way.

In No. 1 tunnel the rock types encountered will be basalt lavas, limestone, and sandstone. When excavation is well advanced at the portals the denser undisturbed rock may stand up adequately. However, its weak features will be schistose composition and its water-soluble content. Lining will consequently be necessary through this type of rock. The other rock formations mentioned, though dense and compact, will be affected by continuous passage of water, and solution cavities are bound to form. As these could lead to rock falls and cave-ins it is expected that all of No. 1 tunnel would be lined.

In the case of No. 2 tunnel, at least two-thirds of its length from Sloko lake south will be in Cretaceous volcanic rock. The lower end in the Nakonake river valley will be in Jurassic sedimentary rock. These rocks are strong, and no tunnel lining should be required. However, it is planned to line the lower end of No. 2 tunnel to prevent erosion in the limestone beds. It is not expected that any serious flows or ground water pressures will be encountered and the centre section of the tunnel under the mountain ridge should be relatively dry.

Geological information on the No. 3 tunnel area does not show any great differences in rock structures but no drilling has yet been done. There are indications that more sedimentary rock may be encountered.

The procedure followed in the investigations of tunnel areas, dam sites

Fig. 8. Helicopter at the powerhouse site, Nakonake River.

and power plant sites may be of interest.

After the location of these future works had been tentatively determined from the engineering standpoint, geologists made a study of rock formations. Minor changes in location were then made, if advisable, particular attention being paid to the geology at tunnel portals.

Intensive geological studies were made of the proposed Yukon river dam near Whitehorse, and of the site of the No. 1 power plant on the Nakonake river, south of Sloko lake. These studies were followed in the same season by seismic surveys to determine depths of overburden. In the following year (1956) core drilling was undertaken at the various sites.

The rock structure at the proposed Whitehorse dam site consisted of basalt overlying a granodiorite base. Drill holes on the site selected revealed that unconsolidated sedimentary material existed in varying depths between the two rock formations. Consequently further drilling was undertaken a few hundred feet downstream where granodiorite was exposed and where a reasonably close contact between the basalt and granodiorite might exist. This program was not completed, and further drilling is planned for 1957.

Control of the Water

The Yukon river is an international stream, with its source in Canada and its mouth in Alaska on the Bering Sea. Its total length including the large lakes at its headwaters, is 1,700 miles, of which 570 miles are in Canada.

Though substantial areas of the large lakes are in British Columbia, the Dominion Government exercises control over the development of the Canadian section of the river because of its international character. The Alaskan section is under the jurisdiction of the United States. Canada has the right under the International Boundary Waters treaty of 1909 to divert international waters within its boundaries for beneficial use, but there is the diminishing problem of the effect on navigation when Yukon river waters are diverted to the south. Navigation on the Yukon river is protected by the Washington treaty of 1871 which states that "the navigation of the Rivers Yukon (Porcupine and Stikine), ascending and descending from, to, and into the sea, shall forever remain free and open for the purposes of commerce to the subjects of Her Britannic Majesty and to the citizens of the United States, subject to any laws and regulations of either country within its own territory, not inconsistent with such privilege of free navigation."

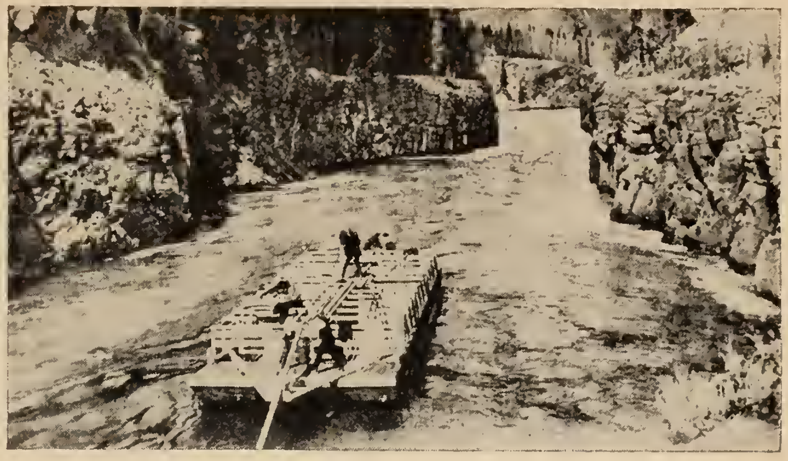

Fig. 9. Miles Canyon, on the Yukon River, in 1898.

In Canada, the Miles Canyon and Whitehorse Rapids sections are natural obstructions to navigation, and the building of a dam will not affect existing conditions except for the better. The proposed lower reservoir will benefit navigation on the stretch of river between Whitehorse and the dam near the Big Salmon river and if it is found the latter dam seriously interferes with the commercial use of the river, locks will have to be provided. There are strong indications that there will be little or no navigation on the Yukon river by the time the lower storage dam at the Big Salmon river is built.

The attitude of the United States requires careful consideration. Though the project requires no dams in Alaska, objections to the diversion of Yukon waters might be advanced because of lower water levels. Such objections, however, would be largely academic, for several reasons. Transportation on the Yukon River in Alaska on a commercial scale ended in 1955 and its revival is doubtful for the reasons previously given.

From the technical angle any ill effects of the diversion of upper Yukon River waters on navigation in Alaska can be practically nullified.

The mean flow of the Yukon River at the international boundary between Canada and Alaska is estimated at 79,000 c.f.s., and initially only 11 per cent will be diverted to the south. The maximum diversion of water originating in the Yukon territory watershed will not likely exceed 30 per cent.

For several years there will be surplus water that can be released from the storage reservoirs in Canada at the critical periods in the spring and fall to ensure conditions are at least as favourable as before the power development.

The Yukon river has also many tributaries below the northerly lower storage dam that augment its flow through the northern Yukon and Alaska, and during the summer runoff there is water to spare. Regulation of the Yukon river waters will also alleviate summer flood conditions in the lower reaches.

When full use of stored waters is required for power purposes there are at least two tributary rivers in Yukon Territory below the proposed storage reservoirs where sufficient water can be impounded for release during the short critical navigation periods in the spring and fall.

The wording of the Oregon Treaty of 1846 between Great Britain and the United States should not be overlooked when considering the navigation question. This treaty deals with the Columbia river, an international stream, and provides under Article II that the river south of the international boundary shall be free and open and that "British subjects, with their goods and produce, shall be treated on the same footing as citizens of the United States; it being, however, always understood that nothing in this Article shall be construed as preventing or intending to prevent, the Government of the United States from making any regulations respecting the navigation of the said river or rivers, not inconsistent with the present Treaty."

Since this treaty was in effect, the United States has given permission for the construction of six large dams on its section of the Columbia river. In only one case was Canada officially consulted in advance.

Under the circumstances it would seem that no serious objections can be made to the proposed diversion of Yukon river waters in Canada, particularly in view of remedial measures that can be taken in the interests of navigation.

Industrial Sites

The selection of a suitable industrial site where large plants could be established to use Yukon river power required a good deal of study. The Canada-Alaska boundary line as finally decided in 1903 deprived Canada of deep water ports on the Pacific coast from the Portland canal, latitude 55° north, to the 60th parallel. The adjudication of the boundary tribunal has definitely retarded the development of the Canadian northwest. The Alaska strip west of the boundary has also suffered from the lack of deep water ports on the Canadian coast because it is to the east in Canadian territory that the main natural resources of this northwest area are located. The story of the boundary settlements is a long one and the difficulties stemmed from the treaty of 1825 establishing a general boundary line with Russia, the United States signing a similar treaty in 1824. The treaty was written in the belief that the summit of the mountains to be taken as a boundary line were parallel to the coast whereas the mountains were jumbled and irregular and did not follow the bays and headlands. As a result the 1825 treaty really gave little guidance for the establishment of a satisfactory boundary line.

The full impact of the 1903 decision is now being experienced by both countries. In the present case it means that any Canadian industries established to use Yukon power, and meeting the requirement of the Canadian Government that generating plants and industrial plants must be in Canada, would have an overland transportation problem from the Canada-Alaska boundary to deep water in the Alaska Panhandle.

After considerable investigation a satisfactory industrial area was found on the south bank of the Taku river just east of the international boundary where some 1100 acres or more of level ground are available with reasonable development costs. On the opposite side of the river there are another 4,000 acres which could be developed later on if the cost is justified by industrial development. Detailed surveys of the site on the south side of the Taku river have been made. From the site to deep water on Taku inlet is 22 miles. Initially a road will be built over this section for construction and general development purposes, to be followed by a narrow gauge railway or a monorail installation as industrial plants develop. While the deep water wharfage is in Alaskan territory it will merely be a transfer point. Raw ores coming into the Taku river plants for processing are not dutiable and plant products will go through in bond except when consigned to United States ports where duty would be paid in any case. While this arrangement is not of course as satisfactory as a deep water port in Canada, the size of the project is such that overland transportation does not seriously prejudice it.

There is also an alternative port, which can be used as power needs grow. The all-Canadian port of Alice Arm to the south, at the eastern end of Observatory Inlet is satisfactory for navigation and climate, and there are industrial sites on tide water. This harbour, which is open to navigation throughout the year, is only 360 miles from the northern generating plants on the Nakonake and Taku rivers, which is a reasonable transmitting distance for large blocks of power. It is expected that certain industries may be established at Alice Arm if their power demands are large enough.

The Taku river sites could initially be used by metallurgical plants that may require up to a total of one million horse power. Detailed surveys of the Alice Arm area have been underway and it is expected a selection from several possible sites will be made in 1957.

Fig. 10. Freighting around Whitehorse from Miles Canyon, in 1898.

Power Demand

In planning the proposed Yukon river power project regard was given to possible markets. Increased use of hydro-electric power in the fields of mining and metallurgy, base metal production, wood products, and chemicals, was studied in an attempt to estimate the rate of increase in power demand, and the timing of construction.

The Ventures—Frobisher—Quebec Metallurgical interests, had early realized the growing need of power for the major industries and had appraised the status of large blocks of hydro-power in the Canadian northwest from twelve to fifteen years in the future.

There is a shortage of low-cost power in North America and the output of new plants is largely sold before these are completed. The trend in water-power development across

The Role of Aerial Survey Methods in Canada's Northward Development

H. S. Scott,
*Technical Director, Hunting Technical & Exploration Services Ltd.**

CANADA IS enjoying a period of growth and prosperity unequalled in her history, spurred by an expanding development of her natural resources. Naturally, most of this development must take place beyond the present frontiers of settlement and established transportation routes —in other words, generally northward. The cost of any operation increases with distance from the facilities of civilization; consequently, in Canada, there has been considerable economic pressure for the efficient application of existing techniques, and the development of new methods better suited to our present expansion needs.

This article deals with aerial survey methods, and how they are being employed in the development of our natural resources, especially in the north. Aerial survey and northern Canada are appropriately related, for each has helped and is contributing much toward the discovery and growth of the other.

In Canada's Twentieth Century the aeroplane plays a role not unlike that of the voyageur's canoe in earlier periods of her history. The challenge of driving back the great northern wilderness, by learning its secrets and putting them to best use, once depended largely upon the canoe as a means of transportation. Soon after World War I however, the aeroplane started toward its present position as a basic tool in Canada's northern development, not only for transport, but for other uses as well. The extent of the change is indicated by the fact that, in articles such as this, the word inaccessible is now written "inaccessible".

It is important to note that both the canoe and the bush-plane rely upon water for their operation, and the extensive networks of lakes and rivers in northern Canada have been an essential factor in their successful utilization. This point stands out when comparison is made with developments in other great unsettled regions of the world, such as the desert of central and western Australia. It should remind us that northern Canada, despite an unfriendly reputation, has many compensating hospitalities.

This article constitutes a small-scale symposium on the application of aerial photography and airborne geophysical techniques to the estimation of the geography and natural resources of large territories such as the Canadian northland. Many fields of engineering are involved in the work.

The aeroplane has broken man's restrictive ties with the ground, and this new freedom is being put to good advantage. Aerial applications having the greatest influence in the development of northern Canada may be summarized as follows:

(a) *Transportation* of men, equipment, and supplies. Here we find the aircraft carrying anything from its predecessor, the canoe, to diamond drills and building materials.

(b) *visual reconnaissance* for many purposes including landing and camp sites, access routes, general topographic and terrain appreciation, forest fire - fighting strategy, and search for missing persons.

(c) *Aerial survey,* which itself covers several widely different approaches:

(i) Aerial photographic survey, and related techniques of mapping and airphoto interpretation.

(ii) Airborne geophysical survey and interpretation.

As stated previously, the last topic, aerial survey, forms the subject of this article.

AERIAL PHOTOGRAPHY

Modern aerial photography is a far cry from the hand-held oblique exposures made in the early days of flying. The present-day survey camera is a precision instrument, giving results to very fine tolerances which are actually measured and recorded for each camera. Likewise, modern aerial film must meet critical specifications. The resulting photography combines a great variety of pictorial detail with a high order of survey accuracy.

Aerial photographic coverage in Canada started shortly after World War I. Early photographs were simple obliques, but later survey was accomplished through the simultaneous use of three cameras, one being vertical and two oblique, mounted so that a trio of photographs covered an area extending from horizon to horizon across the flight path. Successive exposures overlapped about 60 per cent in the centre strip of photographs. This system provided rapid coverage of enormous areas, and it has long been the basis of planimetric mapping in the more remote parts

*A list of the contributors to this article is appended on p. 1664.

of the country. The method has severe shortcomings however, largely because good stereoscopic analysis can be carried out only with the central strip of vertical photographs.

Aerial photography in Canada is now almost entirely confined to the vertical variety. The standard size of format is 9 by 9 inches, and the typical camera lens has a focal length of only 6 inches. This photography is therefore to be considered wide-angle, for the lens accommodates an angle of 92 degrees measured across the diagonal of the format. Features lying near the edge of a photograph are obviously depicted at a rather oblique angle.

Survey photographs are usually taken along a series of parallel flight lines. Each photograph overlaps its adjacent exposures on the same line by 60 per cent; this ensures that every point on the ground is photographed from at least two positions. In addition, the coverage from adjacent flight lines is planned to overlap by some 20 per cent.

Fig. 1. A stereometric plotting machine, used for the accurate and rapid production of contoured topographic maps.

The scale of photography is a simple geometric function of format size, focal length of the lens, and flying height. Thus at 20,000 feet above the ground, for example, a 9 by 9 inch format and 6-inch lens will yield photography at scale 1/40,000. Common scales range from 1 inch per 1000 feet to 1 inch per mile.

Within the next four or five years, aerial photography will be available for all of Canada, including the northern limits of the Arctic islands, at a scale of 1 inch to 1 mile. A large proportion is already completed. Many parts of the country have been flown at various larger scales.

Photographic scale cannot be constant, either on a single photograph, or on the photography of a given area. Topographic relief, changes in flying height and camera tilt, contribute to these variations. Effects are kept to a practical minimum by flying the survey in large blocks according to their range of elevation, by the use of control points, and by the use of corrective plotting instruments during subsequent map production. Ground control points may be supplemented, or in part replaced, by navigational control such as Shoran, and by topographic profiles obtained in flight by precise radar profiling equipment.

The 60 per cent overlap employed in most aerial photography is of vital importance in the full utilization of the photographs. It permits the use of stereophonic methods, in both mapping and interpretation. The amount of overlap, combined with the wide angle of the lens, produces a striking exaggeration of the vertical dimension as seen under a stereoscope. For typical 6-inch lens photography it is of the order of 2½ to 3 times normal. This means that an actual relief model at the scale of photography, viewed from about 18 inches, would require a like vertical exaggeration to resemble the stereoscopic view of the same photography. The importance of this feature for topographic mapping is evident; for the interpretation of other information it is even greater.

Aerial photography provides data for accurate and detailed planimetric and topographic maps, their quality depending largely upon the photographic scale and the degree of control available. Using modern photogrammetric plotting equipment, topographic maps can be produced having a contour accuracy of about 1/2000th of the flying height.

Assembled as mosaics, aerial photographs constitute a continuous picture of the terrain, available by no other means. Vast areas can be studied at one time, making use of continuity and comparison to detect subtle

Fig. 2. A segment of a highway route location, plotted on a photographic mosaic. The photo-interpreted features include detailed drainage, waterlogged areas, soil types, sand, gravel, bedrock, and the route itself.

but significant changes in the terrain and its associated features. Even aerial reconnaissance, and especially observation on the ground, permit only small portions of an area to be seen and studied at one time.

PHOTOGRAPHIC INTERPRETATION AS AN AID TO RESOURCES DEVELOPMENT

Stereoscopic interpretation is a powerful aid in a number of fields related to natural resources exploration, assessment, and development. For the purpose of description, the various applications are discussed here under separate headings. In practice however, it is generally unwise to confine the interpretation to any single field; much is to be gained by having persons in several resources fields work closely together in an integrated programme.

It should be stressed that aerial photographic interpretation is rarely expected to stand alone. As with any technique, it should be employed wherever it can best serve in attaining a particular objective. In general it finds its principal role in the prefield stages of resources and engineering studies, where it leads to an appreciation of features in a broad, unique perspective. Interpretation enables further investigation to take advantage of actual conditions in a realistic manner. The interpretation of aerial photography does not replace ground surveys; rather, it increases their effectiveness and efficiency.

To realize the full value of any interpretation, its limitations must be recognized as well as its optimum potential. Interpretation is based upon factual information, be it aerial photography or geophysical measurements, but it should not itself masquerade as undisputed fact. Interpretation may vary in reliability from fact to fancy, depending upon the interpretability of the data, and the experience and competence of the interpreter. Those who perform interpretation, and those who use it, should be aware of its variable nature. If errors are discovered they should not be unexpected, and the correct version should be applied to re-assess related interpretation.

Engineering

Every advance in the development of northern Canada brings with it a host of important engineering problems. These fall into the general category of civil engineering, but they include such widely different matters as route location, sources of fill and construction materials, hydroelectric development, building and airport sites, harbour studies, and town planning. Most of these problems present unusual difficulties in the north because of the great distances involved, the remoteness, and the vigorous climate. All are well suited in their planning, preliminary study, and construction stages to properly applied aerial photographic techniques.

Fig. 3. Photographic interpretation of conditions around a proposed dam site. The large circle defines the area in which the sources of construction materials are desired. Bedrock, gravel, impermeable fill, and other materials have been indicated. The small circle and corridor are areas where overburden depths have been mapped.

Several applications are expanded here to illustrate the breadth of the interpretational approach:

Route location studies may be undertaken by airphoto interpretation for highways, railways, pipelines, power lines, communication lines, and canals. The object in each case is similar — to select the most useful and economically feasible route. This involves the careful study and weighing of a multitude of factors such as distance, geometrics, relief, cut and fill, major construction difficulties, soil and rock types, marsh, and the need for bridges and culverts. For a short route these factors can be adequately assessed on the ground. In northern developments, however, routes of some hundreds of miles are sometimes indicated. The area in which the desired route may be selected is very great in these cases, and it is clearly not feasible to carry out all the necessary studies on the ground.

The airphoto approach to route location may be considered in two stages. In the reconnaissance stage, general information on major topographic and drainage conditions is collected for the area of interest between terminal points. Any large scale difficulties in particular are noted. An approximate location is then outlined. At this stage the photography along the proposed route —which may now be obtained especially, at larger scale — is subjected to detailed interpretation. Surface drainage, high ground—water levels, impeded vertical drainage, erratic surface flow, bedrock outcrops, shallow and deep overburden, soil composition and texture, vegetative conditions, landslide tendencies, permafrost, springs, difficult crossings, landuse, and many other features can be identified accurately and compiled by aerial photographic means. The results of the interpretation are then used in planning field work for maximum effectiveness.

Materials location by photographic interpretation can distinguish sources of bedrock, talus, boulders, gravel, sand, silts, clays, and varieties of glacial till. As an indication of reliability, it may be surprising to learn that gravel and sand location by these methods is more than 90 per cent successful. The area of a deposit can be measured, and in some cases volumes can be computed, by photographic study. Access to deposits, is taken into account during the interpretation, and field testing programmes are planned in advance upon this evidence.

Hydrology and water utilization encompass many matters of vital interest to the engineer, but a comprehensive discussion is beyond the scope of this article. Airphotos offer an excellent basis for the study of drainage systems, including such influencing factors as rock and soil conditions, vegetative cover, topography, and land-use. Even conditions affecting ground-water recharge may be recognized. Representative areas are then selected for detailed field analysis.

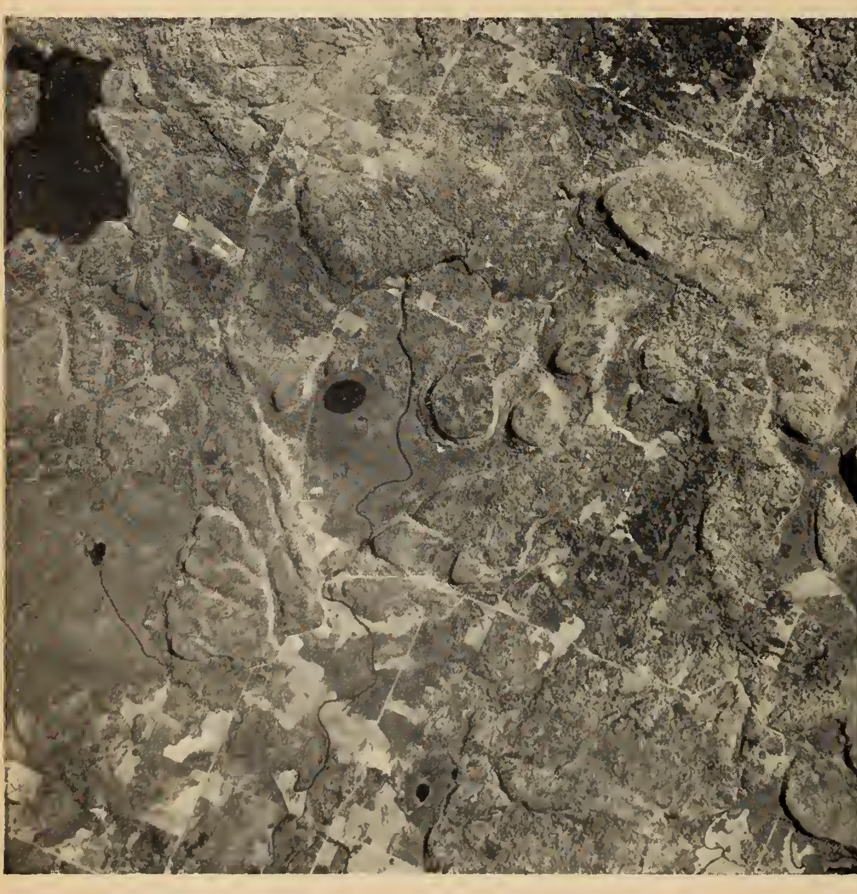
Photographic interpretation provides a wide variety of information necessary for the planning of dams and reservoirs, flood control and drainage, land reclamation, and other developments intimately related to water supply.

Sites for major construction works, such as industrial plants, dams, loading and docking facilities, airports, and towns, must be chosen only after thorough consideration of many different factors. Aerial photography provides the broad background of information necessary to undertake these tasks successfully.

Land-Use

As northern areas are opened up and developed for their pulpwood, power, and mineral resources, or for their strategic importance, there will be an increasing demand for the production of foodstuffs close at hand.

Fig. 4. Rugged outcrops, with little or no soil cover, can be seen throughout this area. Two large swamps (left and centre), each with patches of open water, are also discernible. Lower left, crops are growing on the only available flatland; here the soils are poorly drained and of poor quality. Near the top of the photograph some settlement roads have been built, but stereoscopic study shows shallow soils and rough surface unfavourable to successful farming.



The success achieved in some northern settlements proves that agriculture is justifiable under certain economic circumstances, particularly where there is a concurrence of raw materials, favourable climate and soils, power resources, markets, and adequate transport facilities.

At the present time there remains much to be learned about the potenialities of our northern lands for permanent settlement. While there are authenticated reports of excellent crops of vegetables and hay from sub-arctic communities, it is also true that agricultural settlement in these areas is of limited extent and has been only partially successful. The history of northern development provides many examples of unplanned or poorly planned settlement which has deteriorated or disappeared. Grants of free land and promotion schemes lured many settlers into areas which scientific research might have shown to be unsuitable for agriculture, or suitable only for certain types of land - use, because of poor soils, harsh climate, or some other physical or economic factor.

Comprehensive reconnaissance surveys of extensive areas of land are the only adequate means of determining where a combination of factors favourable for agriculture occurs. Such surveys should be high on the list in planning the coordinated development of Canada's northern lands. Thus agricultural surveys should accompany or closely follow forest, mineral, power, and engineering investigations, and they should include climatic and economic studies. The techniques of photographic interpretation, used in conjunction with sampling of conditions in the field, enable such studies to be carried out more rapidly than by ground survey method alone, and the results are more effective. This is particularly true in northern areas, where little land is readily accessible by road or rail.

There are four main stages in carrying out surveys required to evaluate land for agricultural use.

The first stage involves the preparation of a *soil map*. By airphoto analysis and such ground study as may be necessary to correlate airphoto patterns and ground conditions, the trained observer can identify and map land-forms, topography, surface and internal drainage, soil texture, and any other factors which may affect the quality of soil. Such a survey may profitably be undertaken concurrently with a study of soils from the engineering standpoint. At this stage, no attempt is made to evaluate the agricultural potential of the soil.

Knowledge of present land-use is essential if the best use of the land involves the preparation of a *present land-use map* by means of photographic interpretation and ground checking. The techniques of airphoto analysis have been applied to land-use mapping in many parts of the world. Categories of land - use that should be included in the classification are those which preliminary examination indicates are significant for the area under study. Forest cover is in effect a class of land-use, and therefore it should be included in a land-use map. Locations of proven mineral potential, and areas which are to be flooded, should likewise appear on the map.

The third stage involves the preparation of a *land-classification map*. This is done by classifying and rating land according to its suitability for the various uses to which it might be put. This type of classification depends primarily upon the information gathered during the soil survey. Obviously at this stage, much land can be eliminated from further consideration because such limiting factors as bedrock outcrop, shallowness of soil material, topography, and poor surface or internal drainage render it unfit for cultivation; these lands may however have some value for forestry, grazing, or other use. The better agricultural land can then be rated according to its suitability for specific land-uses, taking into account the influence of such variables as slope, erosibility, stoniness, and drainage.

The final stage is the preparation of a map showing *recommended land-use*. The findings of the land-classification survey must be correlated with those of forest, engineering, climatic, and other studies before any firm land-use recommendations are made. In assessing the agricultural potentialities of any particular undeveloped area, it is important to study the performance of agriculture in already-settled areas, which are homologous in climate, soil, and other features of environment.

The agricultural scientist assesses the foregoing results against a thorough knowledge of the climatic hazards to be expected. He must take into account the average length of the growing season and its reliability. He must know the seasonal distribution and reliability of precipitation as these factors affect cultivation. Agriculture over much of the Clay Belt in northern Ontario, for example, suffers from excessive rainfall at harvest time. Studies of the relationship between rainfall and evapo-transpiration have demonstrated that much of the Mackenzie basin is in fact a subarctic desert, a reality which must be faced when considering the potentialities of this region for agricultural development.

The agricultural scientist must also keep in mind the potentialities of an area for mining, forest, strategic, or other development, and assess the accessibility of potential agricultural lands to existing or foreseen urban localities. He must consider the possibility that two or more land-uses will compete for the same land. In many areas, for example, land which is well suited for agriculture is also capable of excellent tree growth. All these factors relative economic merits are best integrated and considered against a common base of aerial photographic interpretation.

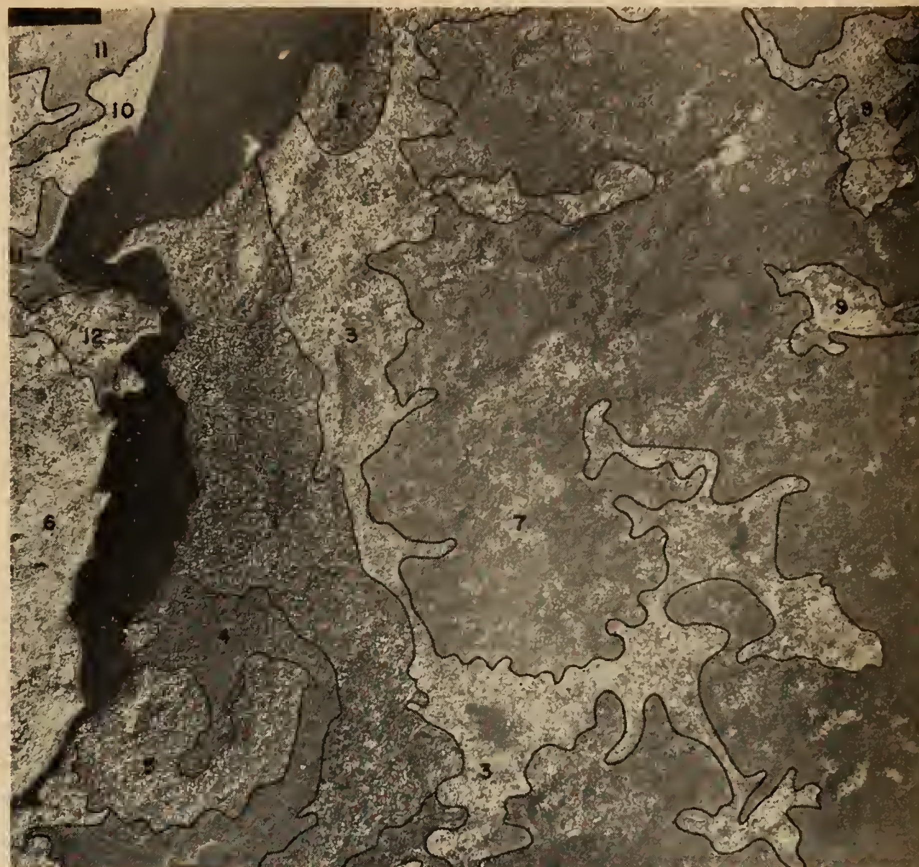


Fig. 5. Forest cover type interpretation by photo-analysis. Conspicuous variations in tone are related to the type and density of tree crowns. The numbered areas include: poplar/birch (6); black spruce (4); jack pine (7); and poplar/birch/-jack pine (3).

Forestry

The demand for Canadian forest products has increased very greatly since World War II. As a result, the forest land which is considered to be economically exploitable has been enlarged, especially in the western provinces and the Northwest Territories. Occupied forest land in Canada has increased 22 per cent since 1951.

As the demand increases, the limits of accessible productive forest land move north, into some 197,000 square miles now classed as potentially accessible. The factors of availability, transportation, and markets will, of course, govern the economic feasibility of actual forest operation in this vast area.

The northward expansion of our forest industry must be guided by knowledge of the forest resources themselves, and of the many factors that influence their efficient utilization. Aerial photographic interpretation has proven its value in areas of present forest operations, and provides the key for future expansion. The selection of areas will be influenced to some extent by the devel-

Fig. 6. With a little experience, the rock seen in this photograph can be identified as anorthosite. The network of fractures is characteristic.

opment of other natural resources, inasmuch as that will help to provide access and a ready market.

Airphoto studies for forest development are carried out in two stages:

The *reconnaissance* of vast areas to select those exhibiting the highest forest potential may be undertaken rapidly and effectively by foresters skilled in the techniques of airphoto analysis. This initial phase may be carried out using small scale aerial photography in the order of 1 inch to 1 mile. The basic interpretation carried out at this scale serves to classify the area under consideration into productive forest land, and unproductive forest land (water, muskeg, rock outcrop, non-reproducing old burns, etc.). The productive forest land is then subdivided on the basis of cover type (softwood, mixed wood, hardwood) and merchantability (merchantable and otherwise). The lower limit of merchantability is normally set at approximately four to ten cords per acre, depending largely upon the economics of transporting the cut to the mill. The preliminary airphoto reconnaissance then serves as the basis for selecting priority areas which justify further and more detailed consideration.

Inventory survey is the second stage in the programme of orderly forest industry development. It involves a detailed analysis of the growing stock on the areas selected, to determine the development potential. Aerial photography again plays an important part in carrying out this task rapidly and economically.

The reduced area is now covered with new photography at a recommended scale of 4 inches to 1 mile, using panchromatic film and a minus blue filter in mid-summer to achieve maximum distinction of the various tree species. Foresters then study each stereoscopic pair of photographs, classifying the forest cover in categories under species composition, stand height class, stand density class, and age class. The resulting forest types are compiled upon base maps of the same scale as the photography, using a Sketchmaster or similar camera lucida device for transfer. This results in the forest cover type map.

Field cruising is next required to sample timber volumes. It can be appreciated readily that this operation is reduced to a minimum through the application of airphoto techniques, in that each combination of the interpreted stand components is field sampled to a density necessary to reduce its standard error to plus or minus 1 per cent of the mean. The regular strip cruising methods formerly carried out before the general acceptance of modern photographic techniques required a great deal more ground sampling.

Fig. 7. Diabase dikes filling fractures in sheared volcanic rocks.

The stand volume table computed from the field cruise are then compiled. These results are then applied to the various forest type acreages (measured by planimeter), to produce a statement of timber volumes by species for the area under study.

The inventory is basic to all future forest development, for from these data the management plan is prepared.

Recent developments in the aerial photographic interpretation of land types and forest site types, when combined with a knowledge of silviculture and ecology, make possible the delineation of areas according to their growth potential. This interpretation when studied in conjunction with the forest cover type map is invaluable in all phases of forest management, especially those involving silivicultural treatment in order to obtain the regeneration of preferred species on cut-over lands. Land-classification maps serve effectively in the location of main haulage roads, construction materials location, townsite and camp location, particularly as forest operations push northward.

Apart from the forest industries, the applications of forest airphoto interpretation are many and varied. Sources of mine timbers and lumber close to construction sites are required as developments extend further from established supply bases. Or again, airphoto techniques may be applied to the design of seismic "shot-line" grids for petroleum exploration surveys, in order to minimize the volume of valuable timber which must be cleared and upon which crown stumpage dues must be paid, as well as to avoid difficult terrain for supply vehicles. Accurate pre-engineering estimates may be made in connection with railway, highway, pipeline, and power line construction, where timber clearing and salvage constitute a substantial portion of the total cost.

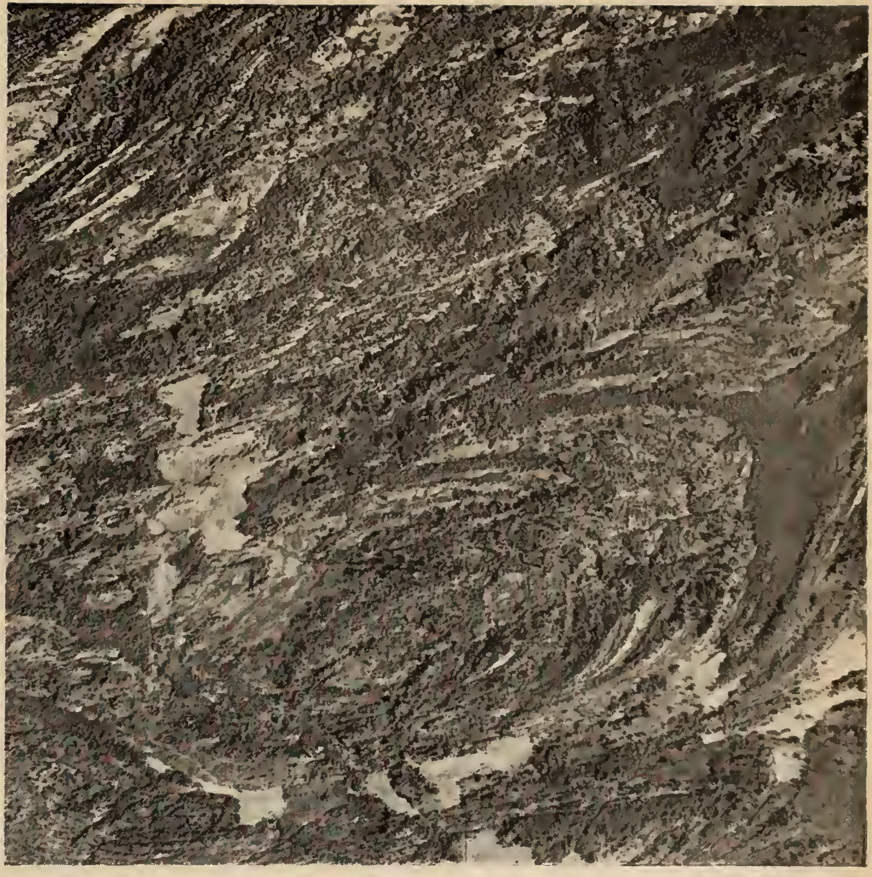

Fig. 8. Folding in a series of gneisses. For an example of a fault, see the left side of Fig. 4.

Geology

The search for economic mineral deposits in Canada's relatively little-explored northland offers a combined challenge and inducement to the mineral industry. Exploration costs are high, and they must be offset by the reasonable hope of discovery of relatively high grade mineral. On the other hand, the favourable areas for search are immense, and competition is limited.

The challenge is being met by replacing small-scale, inefficient prospecting procedures with well planned exploration campaigns. These have no place for casual prospecting without definite objectives. High costs and the short field season emphasize the need to evaluate quickly, if not exhaustively, large blocks of ground, and to concentrate additional, more detailed investigation in the more promising localities.

Aerial methods supply a good part of the answer to this challenge. Geologists are among the foremost proponents of "bush-flying", aerial reconnaissance, and airborne geophysics. Many are enthusiastic users of aerial photographic interpretation, but there is still a tendency among others to regard photo-interpretation as a lazy man's poor substitute for boots, fly dope, and sweat.

Geological airphoto interpretation is not a substitute for field work. In its broad aspects it is a source of information on a scale seldom attempted in the field. With greater attention to detail, it is an ideal complement before and during field work, increasing the effectiveness and efficiency of the latter many times.

Geological reconnaissance based upon airphoto interpretation is an excellent means of scanning a large region for areas of greatest mineral potential. The treatment can be applied to a large area surrounding a zone of interest, thereby helping to outline the most favourable locality for later field study, and providing a general geological setting for the greater understanding of later detailed observations.

An overall mosaic is made from the photography, and all available geological data are compiled upon it. Airborne geophysical results are often included at this stage. Then a general airphoto interpretation is made, partly from the mosaic, and partly from stereoscopic study of pairs of prints. The known information is expanded through the interpretation, taking care to distinguish the origin of the compiled results. The mosaic is the base upon which the geological picture develops, and any significant surface expression of the underlying geology is not apt to go unnoticed.

Interpretation on a reconnaissance scale may point to features which would otherwise require the compilation of years of detailed mapping — after the mapping became available. Thus a major linear feature, or an abrupt change in the details of topography across an invisible line, must have some explanation, and the search for that explanation may reveal an important fault, or a compositional change in a series of gneisses. Whether or not the fault can be described petrographically is of little importance at this stage. The significant point is that major elements of the geology have been recognized early in the study of an area, and subsequent work can be aimed to take fullest advantage of the interpretation.

Geological features that may be interpreted from the photography for reconnaissance purposes include the following: a general division of rock formations (which may or may not be identified in broad terms) if overburden is not excessive, faults, folds, stratification (strike and dip), dikes, and contacts. Areas of terrain regarded as unfavourable host-rock, such as large granitic bodies, may be eliminated at this stage.

An important and interesting feature of any photographic interpretation is that even where no rock exposures occur, some evidence of the underlying geology is almost certain to be found in the photography. There are several possible reasons for this useful relationship. For example, a strong shear zone in the bedrock is apt to be the site of a sharp valley where it meets the bedrock surface, buried under overburden or not. Ground - water collecting in this valley will influence the growth of vegetation even tens of feet above it. Again, the nature of the bedrock relief detail may vary from one formation to another. The lower layers of the continental ice sheet were influenced in certain ways by these differences, with resulting variations in the glacial deposition as now seen. Airphotos show these features over very large areas, so that even very subtle variations which one could not expect to notice on the ground, may fall into a significant pattern when studied on mosaics.

Detailed geological interpretation is similar to the foregoing, but the work is carried out with greater attention to detail, in smaller areas selected at least partly as a result of the reconnaissance studies. A larger scale of photography is desirable, and new coverage at say 4 inches to 1 mile may be justified. If in forested country, the survey must be done during a period when the deciduous trees are bare, and of course when the ground is free of snow. Close study of the photography, and detailed correlation with other data, will produce considerable new and valuable information upon which later field work can be based. Areas of rock outcrop can be recognized, and unless they are very general throughout the region, should be outlined to save time in field examination. Many details of rock type and structure can be interpreted and recorded if overburden is not too widespread. Dips can be measured with fair accuracy by simple photogrammetric devices where there is sufficient surface relief.

Additional information that will help in planning field work includes the tentative selection of camp sites near water suitable for use by aircraft, the amount of rock outcrop available for study, and general terrain conditions. If little or no rock can be seen, the geologist's time can be regulated accordingly and, perhaps, geophysical work planned in its place. In the latter case, use will be made of such information about regional strike and other geological factors as may be interpreted from the photography.

Geological field work itself derives much benefit from the free use of aerial photography. Aerial photographs and mosaics provide the ideal base for the recording of field observations, either on the photographs or upon a transluscent overlay. Outcrops, previously outlined by photo-interpretation, may be visited directly, thus avoiding the time wasted by routine traversing along set lines. Each plotted observation is seen immediately in relationship to other field observations, to the photo-interpretation, and to the details of the landscape. Thus it is commonly possible to project a contact after relatively few ground observations; or with a few well placed traverses, identify a formation the extent of which has already been determined from the photography. On more than one occasion, the location of an important outcrop, described in an old narrative, has been identified by study of the photography, so that the geologist can go without hestitation to that same place.

Modern prospecting sooner or later turns to geophysics for assistance. Airborne varieties of this branch of exploration are described elsewhere in this article. Geophysical survey on the ground is aided considerably by the use of aerial photography in both the planning and execution stages. The results must be interpreted in conjunction with all available geological information, including aerial photographic interpretation, to reduce the number of variables inherent in geophysical interpretation. With airborne geophysical results it is even more important that full use of photographic interpretation be made, because of their broad coverage.

As areas of potential economic interest are investigated and found to be worthy of further examination, the diamond drill is of critical importance. Diamond drill holes are located, where possible, close to a supply of water, and in such a location that the depth of overburden will be the least possible.

In later stages of development work, aerial photography provides

Fig. 9. A Canso amphibian provides the platform for three simultaneous geophysical methods: total field magnetic, dual-frequency electromagnetic, and radioactivity. In addition, a 35-mm. positioning camera and a radar-operated height-measuring device are in operation. All results are recorded continuously and automatically.

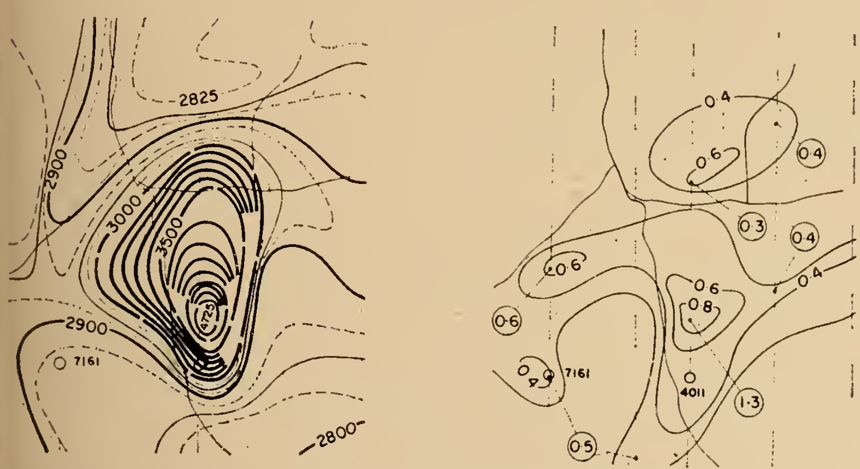

Fig. 10. The "thumbprints" or an orebody recently discovered by aerial survey near Mattagami Lake, in northwestern Quebec. At left is the magnetic anomaly caused by magnetite associated with the ore. At right is the corresponding EM anomaly, related to electrically conductive sulphide ore.

the information required to lay out access roads, whether they be rough trails for winter tractor trains or gravelled highways for cars and heavy trucks. In many instances, an airstrip will be required in the vicinity of the mineral development; its location and materials for its construction can be selected by photo-interpretation. Suitable sites will be needed for mine and mill buildings, and eventually for a townsite. A reliable base map must be made for all these aspects of development. It can be produced with or without topographic contours from aerial photography, using a minimum of ground control.

AIRBORNE GEOPHYSICAL SURVEYS

Geophysics is a relatively young science. It deals with the application of the methods of physics, to the investigation of geological conditions. In its broadest form it seeks to describe the physical constitution of the earth by the measurement and analysis of seismic, gravity, magnetic, thermal, radioactive, and other fundamental properties.

For many years it was realized by some workers that geophysical methods should be useful in the search for various kinds of mineral deposits, and during the first 30 years of the present century the new field of applied or exploration geophysics came into its own.

Until the end of World War II, all geophysical exploration was carried out on the ground, or in drill holes and mine workings. The successful wartime development of the airborne magnetometer seems to have sparked efforts toward the development of other airborne geophysical methods, and in the decade that followed, radioactivity and electromagnetic equipment has been produced and operated with marked success. Recently an airborne gravity device has been put into use.

Airborne geophysical methods tend to be regarded with awe by the layman, but it should be realized that they introduce no new principles, and that most of the techniques have fairly long histories in modified form on the ground. The biggest changes wrought by taking to the air are in the size of areas now surveyed, the ease of access to otherwise remote and difficult localities, the speed and continuity with which they are surveyed, and the relatively low cost per mile of line. In these respects airborne geophysics and geological airphoto interpretation are ideally complementary.

Airborne geophysics is carrying mineral exploration further and further north in Canada. Since only the largest deposits are economical in remote areas, and sinee airborne survey methods give a broader view than do equivalent ground methods, they are being used with a high degree of success. They are spearheading the search for petroleum in the Northwest Territories by covering tens of thousands of square miles by aeromagnetic survey. The mining industry, originally skeptical of the usefulness of geophysics and therefore slow to adopt the new approach, is now sponsoring airborne surveys with increasing enthusiasm. Mining companies report that approximately a third of their exploration budgets is now being spent on airborne geophysical survey and followup investigations on the ground.

The *airborne magnetometer* was applied to mineral search in 1946, and it has been in constant employment since. There are now about 12 aircraft performing these surveys in Canada alone. The instrument measures and records variations in the earth's total magnetic field, along parallel flight lines, and at elevations usually from 500 to 1000 feet above the ground. The aeromagnetic results are generally reduced from profile to contour form for convenient study.

Results are related to the magnetic properties of rocks in the crust, and the distances beween these rocks and magnetometer. Since magnetic properties (mainly a function of magnetite content) are fairly characteristic for most rocks in a region, the method is an excellent aid in regional geological mapping. It provides a record of fundamental data whose areal continuity is rarely equalled by any other type of information. Areas of different formations may be outlined and to some extent identified, and major structures may be deduced. The principal use of aeromagnetic survey is therefore to help delineate general geology, leading to the selection of smaller targets where detailed geological and geophysical investigation is warranted. In addition however, it responds directly to magnetite ore, and to other ores occurring with magnetite or the magnetic sulphide pyrrhotite.

The distance to a magnetic source can be calculated with reasonable reliability, and this fact is used in petroleum exploration. Most sedimentary strata are relatively "non - magnetic", whereas they lie upon a basement—usually the Precambrian complex—which has inherent strong magnetic variations. Depth determinations at suitable points therefore give some idea of sedimentary thickness, and variations in thickness may be interpreted broadly in terms of structure.

Radioactivity detection from the air was attempted shortly after the war, using banks of geiger tubes in low-flying aircraft. These have been replaced in present - day equipment by the scintillation counter, which like the geiger counter responds to gamma radiation from surface and near - surface sources. The equipment is used to prospect directly for uranium and thorium minerals, and in combination with other methods, to aid in mapping general geology.

Electromagnetic survey became airborne in 1949, and at least 15 aircraft are now engaged in this type of work in several parts of the world. Various techniques are employed, pioneered in Canada and the Scandinavian countries. All use variations of the same principle, in which an alternating electromagnetic field is generated at the aircraft, and an electrical conductor at or near the surface will set up a secondary electromagnetic field. This latter field is detected by a pickup coil, usually towed behind the aircraft, and is analyzed and recorded by electronic equipment in the aircraft. The method is a means of direct prospecting, rather than a geological mapping tool.

Concentrations of economic minerals, such as the sulphides of copper, lead, and nickel, can be discovered by electromagnetic survey. In addition, the association of pyrite and pyrrhotite with these and many other minerals broadens the range of applications. Uneconomic deposits of graphite are also detected, and must be distinguished by other means.

In Canada, EM surveys (as they are termed) cover some 50,000 square miles each year. The method has already been responsible for the discovery of at least seven Canadian base metal deposits of major importance.

The *gravity method* is the latest branch of airborne geophysics. It overcomes the vertical accelerations of flight by measuring variations in the gradient of the gravity field, rather than of the field itself. It is being used to prospect for various types of ore, and to outline geological structure. Clarification of the instrument's potential and its degree of success, must await further results. The new method demonstrates the ingenuity with which airborne exploration methods are being pioneered.

Helicopter-borne versions of airborne geophysical equipment offer a compromise between the economy and coverage of fixed-wing operation, and the greater definition and detail that result from being closer to the ground.

No airborne geophysical technique could succeed without aerial photography. The proposed flight lines are normally drawn upon a photographic mosaic, and this is used by the navigator during flight. The actual flight paths are recorded by the continuous operation of a small, vertical camera, the photographic and geophysical records being correlated by a system of numbered fiducials. The geophysical results are positioned finally on the map by referring the survey film to the photographic mosaic.

Exploration geophysics is only as helpful as its geological interpretation, so that careful interpretation is of prime importance. This requires a theoretical appreciation of the measurements (sometimes aided by model experiments), experience with the method, and sound geological judgement. The results of interpretation can rarely be unique, and there are usually two or more explanations that will satisfy a particular geophysical condition. To narrow down these variables, a combination of methods (such as magnetic and electromagnetic) is of great assistance. Here again photographic interpretation may supply the clue needed to arrive at the correct geological explanation. As an example, it may be supposed that a fault has been interpreted from aeromagnetic data, but that its position on the ground can be indicated only approximately from those data. However, a linear feature in the photography occurs in about the same position. In this case not only has the position been established, but the interpretation has been strengthened. In the opposite sense, a geological feature interpreted from the photography may direct attention and provide an important clue to a geophysical interpretation.

Radioactivity results must be studied in conjunction with the photography, not only for geological guidance but to show where overburden may mask otherwise positive results. Electromagnetic data also are improved by such comparison, for lakes may produce anomalies, and deep overburden may lay greater stress on an otherwise small EM response.

Ground follow-up is necessary to prove the importance of airborne geophysical indications, despite the most thorough interpretation procedures. A combined geological and geophysical team on the ground can investigate points of interest rapidly, and direct such additional work as diamond drilling to the best locations. Dozens of ground teams are now investigating airborne results in many parts of the Canadian north. Aerial photography contributes greatly to the efficient operation of these crews, in ways already stated under the section on "Geology".

Concluding Comments

(1.) The outstanding fact common to any type of *aerial* survey is that it is truly *areal;* very small surveys are rarely economical by aerial methods. Thus an air survey produces results of two densities:

(a) the direct, detailed findings of the survey, and (b) general information of a broad, less detailed nature whereby the former data can be studied in their regional perspective. The broad perspective adds new significance to many types of local observation.

(2.) Aerial photography is the logical base for the derivation, compilation, and comparison of many types of information. This fosters close co-operation and understanding among resources workers, and sound development of the resources themselves. There have been many examples, in government and elsewhere, whereby aerial photography has brought formerly independent departments into fuller awareness of the problems and usefulness of each other's fields.

(3.) Aerial photography relates man-made developments to various aspects of nature. Settlements, agriculture, mining and forest operations, power developments, transportation routes — all can be seen in relation to the important natural features discussed in this paper. Thus established activities can be expanded sensibly, and new developments can benefit from broader, more realistic planning from the outset.

(4.) Aerial survey methods should not overlap or compete with corresponding ground methods in any but the smallest way. Each group has its own sphere of usefulness, and supplements the other. Moreover, one often stimulates the other; for example, the results of an airborne geophysical survey often do more to promote useful ground exploration activity than any other immediate factor.

(5.) Aerial survey is rapid and relatively inexpensive. In particular, with its ready availability and its first costs already underwritten by government, it is folly to ignore the benefits to be had from the full application of photography and aeromagnetic

View of Steep Rock Lake (Falls Bay area) before lowering of lake by Steep Rock.

The Caland Project at Steep Rock Lake

Philip D. Pearson,

Manager, Caland Ore Company Limited, Atikokan, Ontario

A paper read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June, 1957.

AS EARLY AS 1897 geologists have been aware of iron ore deposits in the Steep Rock Lake region. Eventually the inevitable occurred when a small group of men with a great deal of foresight followed through with this knowledge, and in February, 1938 formed Steep Rock Iron Mines Limited to continue exploring and developing the rich Steep Rock iron range.

The three main parts of the Caland program are water control, dredging, and mining. The water control projects, which entail the construction of twenty dams and associated controls, are nearly complete. By April 1st, 1957, the two large dredges have moved over 60 million cubic yards of lake bottom material from Falls Bay, or approximately 33% of the required total of 182 million cubic yards. The first underground shaft, designed for a capacity of 1½ million tons of iron ore per year, is being sunk, and plans for open pit mining are progressing. The program is well on schedule, with expectations to start production of Caland iron ore in 1960.

Inland Steel Company, the seventh largest steel company in the United States, looked to Steep Rock in 1949 when an ever increasing demand for high grade ore spurred the company on to increase its long term reserves of iron ore. There were at this same time many large developments being contemplated by Inland for large productions of iron ore in the U.S., Canada, and other countries — Inland chose Steep Rock. On January 1st, 1953, a lease was signed with Steep Rock Iron Mines Limited, and Caland Ore Company Limited was formed; the name Caland derived from the two words "CAnada" and "InLAND".

The lease from Steep Rock covers an area of 1,249 acres in the Falls Bay portion of Steep Rock Lake. This area is within the townships of Freeborn and Schwenger in the District of Rainy River, Ont., and approximately seven miles north of the residential area of the township of Atikokan. This

Falls Bay of Steep Rock Lake at start of Caland project, June, 1954.

general area is about 80 miles east of the Canadian border city of Fort Frances, and 130 miles west of the Lakehead cities of Fort William and Port Arthur; the distance between the project and Inland's steel plant at Indiana Harbor, Indiana, is 691 miles by water from the Lakehead.

Before actual mining of the iron ore below Steep Rock Lake can begin, it is necessary to construct water controls to divert away from Falls Bay the waters which normally flow towards Falls Bay. Also, before mining can begin, the layer of lake bottom material lying over the orebody, as well as the lake itself, must be removed. Consequently, the first steps necessary to start the project are to build control works and to initiate and carry out the dredging program. As the elevation of the top of the orebody at ledge varies approximately 300 feet, it will be possible to start mining the higher elevation portions of the orebody before the dredging program is completed. Caland's target is to produce 750,000 tons of ore in 1960, and to develop mines to bring the total production to 3,000,000 tons by 1969.

My address covers the three main phases of the development program, and I shall endeavour to convey to you a complete picture of the project itself, as well as our overall objective. The information is under three main headings — *Water Control, Dredging,* and *Mining.*

Water Control

Before the dredging program could be initiated, it was necessary to construct three dams and a spillway at the north end of Marmion Lake, to form a closed stilling basin 25 square miles in area, in order to prevent the discoloured water from entering the Seine River. These dams were designed by our consultants H. G. Acres & Co. Ltd. of Niagara Falls, Ont., and Dr. R. M. Hardy, Dean of the Faculty of Engineering, University of Alberta, Edmonton.

One dam, the West Marmion, is rock-filled with a 200 ft. wide area constructed with a log crib; on top, 5-ft. high flashboards were installed to allow the passage of log booms from Marmion Lake to the Seine River. The flashboards were added as a special feature to facilitate the Ontario & Minnesota Pulp Co. Ltd. spring logging operations in this area.

The other two dams are earth-

Schematic plan of the Caland project.

filled, and are known as the Middle Marmion and East Marmion dams. These three dams were completed in the spring of 1955 in time for the dredging program, and to control the water at the north end of Marmion Lake.

At the south end of Marmion Lake, the Twin Lakes recharge water control was constructed. This control is made up of two 6-ft. diameter pipes and two control gates, and permits water to flow from Marmion into North Twin Lake. The water then passes into South Twin Lake, then into Falls Bay, to complete the circuit.

For the south-east arm of Steep Rock Lake, a dam was designed to prevent surface runoff water from flowing into Falls Bay, and to support the railroad crossing of this gully. This structure, named the Fairweather Dam after Mr. S. W. Fairweather, vice-president of the Canadian National Railways, was designed by Dean Robert M. Hardy in collaboration with Dr. Arthur Casagrande of Harvard University. The dam was designed for construction in three lifts, the first of which was built in 1955, the second in 1956, and the third phase of construction was to follow the spring runoff in 1957. When the dam is completed, a pumping installation will be constructed to pump the water impounded behind the dam, into Marmion Lake, and the railroad from the Steep Rock spur to the Caland plant site will be constructed on top of the dam.

The Hardy Dam, also an earth dam, is located at the south end of the southeast arm of Steep Rock Lake and, with two rock tunnels and Margaret Lake, diverts the water runoff from an approximately 11 square miles drainage area, away from Falls Bay into the Atikokan River. This dam was named in honour of Dean Robert M. Hardy who is Caland's consultant on soil mechanics.

Before the dam was constructed, 600 acres of land were cleared of merchantable timber, and all remaining brush was cut and burned so that the lake which will form behind the Hardy Dam will be free of timber, undergrowth, and debris.

As the water is impounded behind the Hardy Dam, it will pass through the Margaret Lake east tunnel into Margaret Lake, then through Margaret Lake and out the Margaret Lake west tunnel. In the west tunnel there has been constructed a control

Construction of cribwork at one of the North Marmion Dams.

Twin Lakes recharge control.

Left, Hardy Dam during construction.

gate in order to regulate the flow of water during the spring runoff. Caland engineers worked closely with H. G. Acres & Company in the design of this water diversion scheme, with the consultants supplying water runoff information and designing the diversion, and the Caland organization doing field work and supervising the construction of the projects.

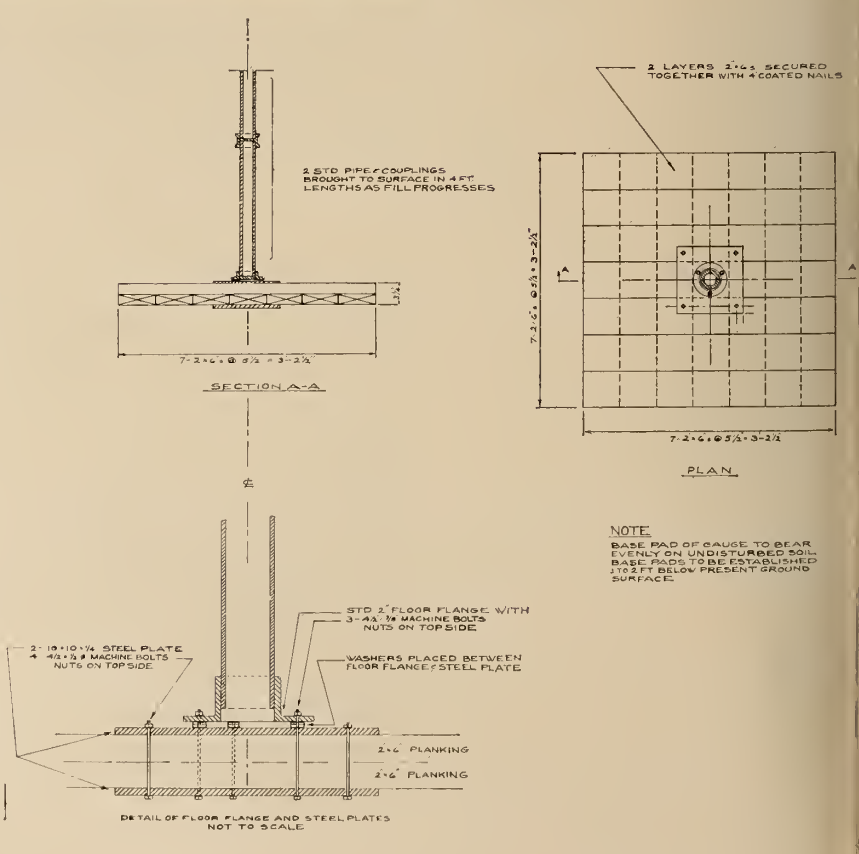
North of Falls Bay, water will be controlled by the South Twin Lake dam, also designed by the consultants; work on this dam is to proceed shortly. The South Twin Lake dam will be of concrete, and through it will be control gates to regulate the flow of water for the dredging program. When the dredging is completed in 1960, the dam will reverse the direction of the runoff in this area to the north, into Marmion Lake.

Another series of earth dams will be constructed in the area immediately east of Falls Bay. This area is known as Basin 'A' and derived its name when the early plans called for a series of eleven silt-settling basins rather than the one large basin in Marmion Lake. The main Basin 'A' dam is an earth structure and will prevent water from flowing through the old Seine River bed into Steep Rock Lake. It was through this area that the old Seine River flowed and was originally dammed up for power purposes before the Steep Rock project started.

There are three smaller auxiliary dams which will divert away from the main basin, by gravity flow into Marmion Lake, much of the water now flowing towards Falls Bay. The general area behind these dams is designated as Upper Basin 'A'. The remaining portion is known as Lower Basin 'A' and the water from this area will be pumped into Marmion Lake.

An extension of the Twin Lakes recharge control and the South Twin Lake dam, is the East Lime Bay recharge water tunnel. This project consists of a rock tunnel and an earth dam, and controls the water flowing into Falls Bay to supply the water required by the dredges. As the dredges remove the silt from the various lake horizons, the recharge water system will be extended.

As the Hardy dam is typical of the



Below, details of settlement gauge, Hardy Dam.

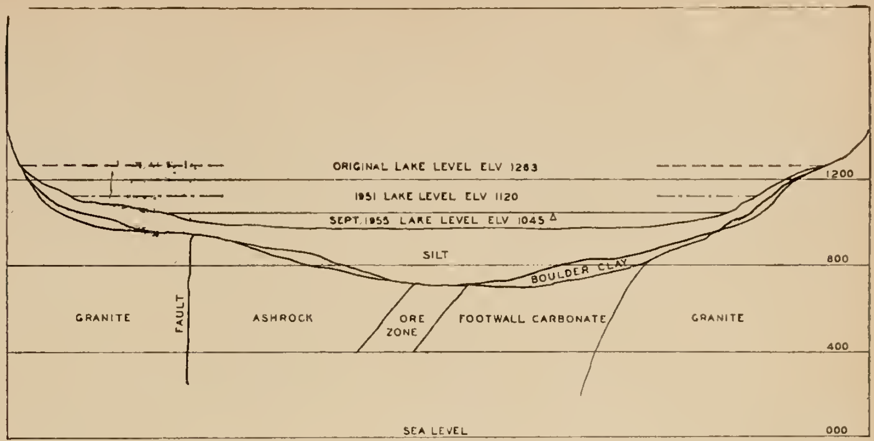
earthdams constructed for the Caland project, a short description of its design and construction history will give an indication as to the amount of planning and work involved in such a structure.

The Hardy dam is located at the toe of the south-east arm. Its embankment has a maximum height of 70 feet, is 1,190 feet long between ledge rock abutments, and has a toe-to-toe maximum width of 520 feet. The dam required one stage of construction and a total of 446,000 cubic yards of material to complete.

Early investigation of the dam site showed that the foundation conditions to be expected were quite different on the northerly one-third of the dam's length than it would be on the southerly two-thirds. North of Hancock Creek, the stream to be impounded and diverted, the ground presented a combination of gravel bed above ledge rock, grading to a stiff red clay. The natural ground on this side of the creek averaged ten to twenty feet higher than on the southerly side, which was represented by a flat lake bottom consisting of blue-gray clay with depths as great as forty feet.

Probe holes by hand augering and cased wash bore holes were put down to investigate the foundation material. Foundation investigations led to a design that provides a typical section for the north one-third of the dam, with an average terraced slope on the upstream side of one in two and two-thirds, and a down-stream slope of one in three. There is a short transition section to the southerly two-thirds of the dam which has both up and down stream slopes averaging one in four.

Construction specifications called for the embankment to be placed on one-ft. lifts compacted by multiple passes of a pneumatic-tired, 60-ton



Typical east-west cross section through Falls Bay.

Table I. Maximum Silt Production Figures

(from May 1955 through March 1957)

Period of maximum production	Period Day	Month	Year	Production (cubic yards) One dredge	Two dredges
One day	28	October	1955	149,310	—
One day	15	December	1955	—	253,895
One month		November	1956	2,498,540	4,583,030
One year	Jan. through Dec.		1956	20,204,530	39,600,530

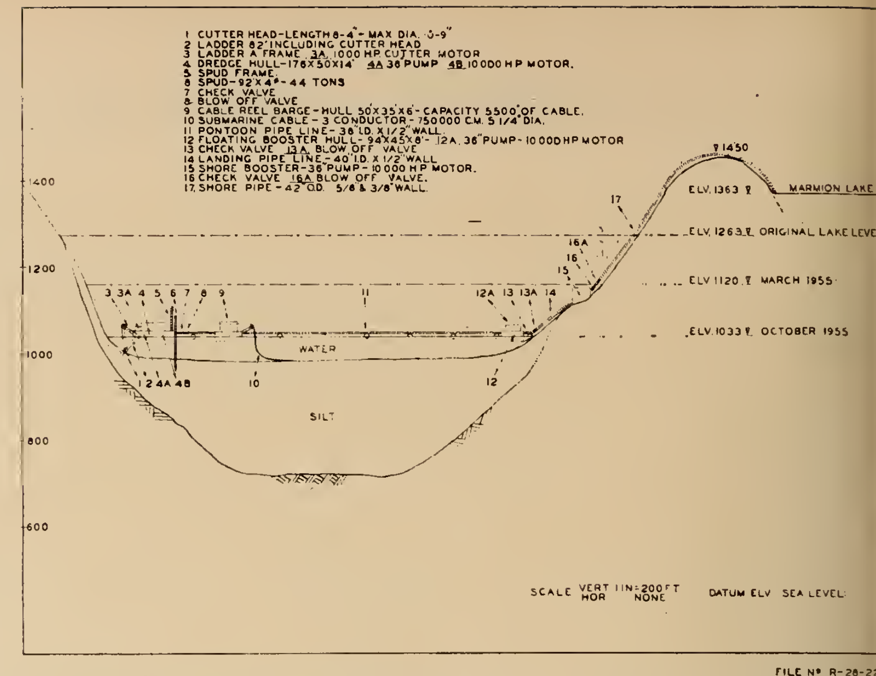
Below, left: an 18-wheel lowbed trailer hauling a 44-ton spud; the dredge "Joseph L. Block" ready for operation.

Right: monitoring operations at Falls Bay; section of the pipeline road and two 42-in. pipelines running between Falls Bay and Marmion Lake.

roller, with the adequacy of the compaction being determined by field testing to determine the Proctor dry density. Both top and bottom portions of individual lifts were checked to determine the extent of stratification. A high percentage of the results of the field checks showed a Proctor density in excess of 100%.

A peculiar consideration that had been taken into account in the design was the presence of two flowing springs in the north bank of the creak. The problem of handling this water was overcome by manifolding the flow through the fill to the downstream toe through 8-in. Armco perforated subdrain pipes encased within a prepared zone of selected pervious material.

Before starting to build the embankment, ten settlement gauges were positioned on the natural ground so as to provide three rows, each of which contains three gauges across the width of the dam, plus one isolated gauge near the northerly narrow end of the dam. These gauges were carried up with the fill, and consist of 4-ft. sections of 2-in. standard pipe built up from 3-ft. 2½ in. square base pads constructed of cross laminated 2 in. by 6 in. planks. The settlement gauge pipe column is secured to the base pad by a floor flange which is bolted to the upper of two ½-in. steel plates that are bolted together through the plank base. Rather than bolting the floor flange directly to the upper steel plate, the two were separated by ½-in. washers. This feature allows for seepage of water into the column so that the three rows of settlement gauges also serve as three lines of hydraulic gradient gauges through the dam.



A descriptive sketch identifying the facilities for excavating and moving the material from Falls Bay into Marmion Lake.

Individual graphs, depicting the data concerned with each settlement—gradient gauge, are maintained. Information on elevation of fill, settlement of original ground, elevation of reservoir, and elevation of water* in gauge, were kept on these graphs throughout the construction phase, and will be continued through and beyond the buildup of the reservoir and until settlement attains equilibrium.

After such earthwork projects are constructed, close checks on their condition are kept by regular readings of settlement gauges and piezometers set in the dams. The piezometer installations furnish information on pore pressures of the foundation clays and fill materials of the dam embankment, and are employed in the construction of the Fairweather Dam.

Plant site area at Falls Bay.

Dredging

On August 26th, 1953 a license of occupation was granted to Caland Ore Company by the Ontario Department of Lands and Forests. This gave Caland the necessary authority to construct the dams and controls to form a stilling basin for the fine clay material to be removed from the top of the orebody, and to start depositing the material into Marmion Lake after April 30th, 1955. At the same time, an agreement was reached with the Hydro-Electric Power Commission of Ontario for the construction of a power line from Port Arthur, Ontario, to Falls Bay.

After calling for tenders, a five-year contract was signed on September 28th, 1953, with the Chicago dredging firm Construction Aggregates Corporation (C.A.C.), to remove 160 million cubic yards of lake bottom material from Falls Bay. This target figure was later increased to 182 million cubic yards.

C.A.C. had previously done similar work in this area for Steep Rock

*In the original operating report on the Caland project, the plans called for all water controls to be under construction by 1956. With the completion of the South Twin Lake Dam and Basin 'A' dams in 1957, the major water control features will be finished well in advance of the initial dates set for mining operations.

Iron Mines Limited, and had wide dredging experience in other parts of the world.

In addition to the need for dredging equipment and power lines, a transformer station was required to convert the 115,000-volt power to 13,800 volts. Erection of the transformer station, as well as the construction of the Twin Lakes recharge control system, were scheduled to be completed before the start of dredging operations.

Plans called for the construction and completion of four items by May 1st, 1955. The North Marmion dams, transformer station, North Twin Lake recharge control, and two dredges were constructed on or ahead of time, so that on May 1st, 1955, the dredging program officially started.

The material to be removed from Falls Bay is a bed of silt, sand, and gravel with a maximum depth of 400 feet. The silt is in the form of a varved clay with light and dark bands and a normal colour of grey, with occasional areas of red clay. In some areas sand is mixed with the silt; in other areas, gravel has been washed in from shore on top of the clay. The moisture content of the clay is approximately 40% and is at the critical point of changing from a solid to a liquid. A severe shock, addition of moisture from rain or runoff, or additional weight can instantly change a bank of material from a solid to a liquid. Consequently the material is very treacherous and requires careful control. The varved clays are overlaid by several feet of organic mud, and underlaid by a gravel layer on the bedrock.

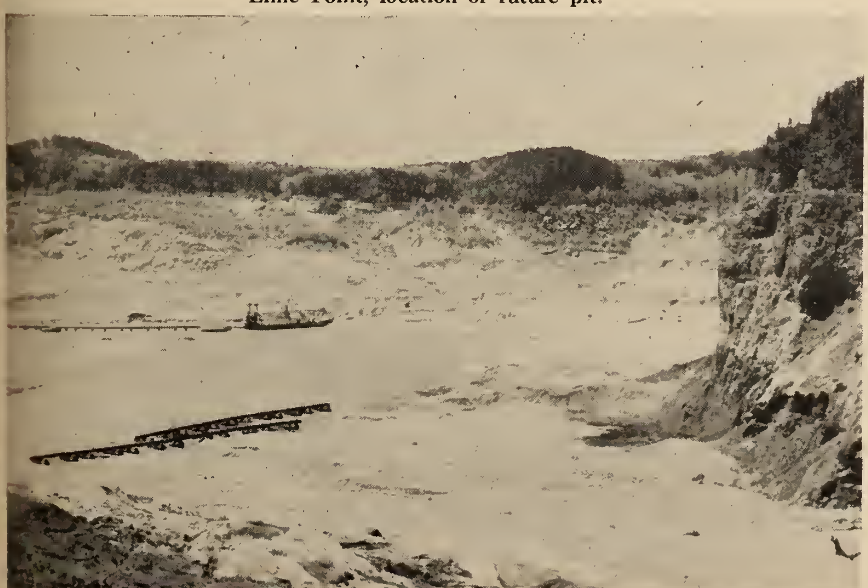
Mine plant area.

The dredging contract was set up in two phases; the "plant phase", and the "operating phase". The "plant phase" consisted of constructing the two dredges and the plant necessary to operate them. The second, or "operating phase", is the actual performance of the dredging operation, and is presently in its second year.

During the plant phase, a railroad siding was constructed at Steep Rock to handle the large amount of freight that was required in the construction of the dredges, and at the siding was erected a stiff-leg derrick capable of lifting a 75-ton load. All the material necessary for the entire plant was hauled over an arduous route — a winding 18-ft. wide gravel road, from Steep Rock to Falls Bay.

Buildings for shops, warehouses, garage, and offices, were erected at the Falls Bay site; the shore was levelled for construction of a dock, and work proceeded on the construction of the two dredges, *Clarence B. Randall* and *Joseph L. Block*, named after Inland's then chairman of the board, and president, respectively.

Lime Point, location of future pit.



On July 15th, 1954, the hull of the *Clarence B. Randall* was launched, followed by the launching of the *Joseph L. Block* hull on September 1st 1954. These dredges are the world's largest. Each dredge hull measures 176 feet by 50 feet by 14 feet; the pump on each is electrically powered by a motor with a rating of 10,000 h.p. The size of these units is emphasized by the fact that the power required to operate one of the Caland dredges is adequate to supply power to a community as big as the combined residential areas of the Lakehead cities, Port Arthur and Fort William.

Simultaneously with the construction of the dredges, the material along the shores of the lake was washed down by monitors, and the two 42-in. O.D. pipelines were laid over a road starting at the shore and stretching 4½ miles to the disposal outlet at Marmion Lake.

Early in March, 1955, the dredging project entered the operating phase of the contract, when the *Clarence B. Randall* began lowering the lake by pumping clear water. The project then passed through a shakedown period until May 1st, 1955, the official starting date of the dredging operation, when the *Joseph L. Block* pumped the first 19,700 cubic yards of lake bottom material which was deposited into Marmion Lake.

To March 1st, 1957, the two dredges have run approximately 67% of the available time, and have effectively moved material for approximately 50% of that time. The average volume of material removed per dredge is 3,500 cu. yd. per hour. On large equipment of this type, the effective operating time is expected to increase as the project proceeds.

At April 1st 1957, the two dredges had moved 60,378,760 cubic yards of material from Falls Bay, depositing it into Marmion Lake. Dredge production is greatly reduced whenever coarse gravel and sand is encountered.

Since the start of the dredging operation, the maximum productions that have been attained are shown in Table I.

Two identical dredges, two floating boosters, a shore booster and pipe-lines are the units which actually remove the lake bottom material. The dredges pump the material from the lake bottom to the floating boosters, the floating boosters pump the material to the shore booster, and this unit in turn sends the material through the pipelines to the settling basins in Marmion Lake. From here the recharge water passes back through North Twin and South Twin Lakes into Falls Bay, to make a closed circuit in the dredging operation.

The elevation of Steep Rock Lake in the Falls Bay area at the beginning of the dredging project was 1120 feet above sea level, having been lowered from the original lake level of 1263 feet by Steep Rock's drainage program. The elevation of the lake is now 965 feet, and the elevation of the top of the orebody varies from 1000 feet to 600 feet above sea level.

It is expected that by the fall of 1960, 182 million cubic yards of lake bottom material will have been moved and the dredging program will be completed.

To facilitate operations, an approximately 7-mile first-class highway has been built by Caland. This road connects the town of Atikokan with the plant area at Falls Bay, and considerably shortens the previous route which was by way of the Steep Rock property.

A pit road and several necessary branch roads have also been completed in the Caland plant area.

Mining

Because the top of the orebody varies in elevation, it will be possible to start mining in the north end before the orebody is completely uncovered. The general plan is that the first production of iron ore will come from open-pit mining; later in the program, underground mining will supplement the open pit, and ultimately the total production will come from underground.

The Inland Steel Company has operated iron ore mines since 1910. The Caland organization can therefore draw on this wide experience in iron mining for planning producing Inland's Canadian iron ore property. Caland also benefits from the Steep Rock Iron Mines operations in this area.

When the operating report was prepared, determining the justification for profitable mining at Falls Bay, estimated cost figures were used for complete mining of the orebody by underground methods. As a general rule, underground mining costs are higher than open-pit costs and it was felt that, if underground costs justified this operation, open pit costs would improve it. Later, when additional information about the orebody was gained, a study was made by open pit experts and it was disclosed that a portion of the orebody could be profitably open - pitted, which would justify the additional capital cost for open-pit equipment in addition to underground equipment.

At present plans are going forward for the construction of a 36-inch belt conveyor, in three flights totalling approximately 5,000 feet in length, to carry ore from the open-pit area at the north end of the orebody to the railroad loading station. This involves raising the ore from 900-ft. to 1380-ft. elevation, 480 feet vertically, and a distance of approximately one mile.

When the conveyor has been constructed it will be used at first to convey any gravel and sand that must be moved to uncover the orebody. Later it will convey the open-pit ore to the railroad cars.

In January, 1957, the first underground shaft was started. It is at Falls Point on the east shore of Falls Bay in the footwall granite, approximately 1,000 feet from the orebody. This shaft is designed for a capacity of 1½ millions tons of iron ore per year, and will reach full production in about eight years.

Three friction winding hoists (two skip hoists and one cage hoist) have been bought for this shaft from a Swedish hoist manufacturer.

The Caland project is planned to produce 750,000 tons in 1960, with full production of 3,000,000 tons in 1969.

To move these tonnages, the Canadian National Railway plans to construct a line from the Steep Rock spur to the Caland plant site. Much of the engineering on this phase of the project has been completed, and construction of the railroad spur should start shortly.

Close co-ordination of the mining program to proceed as the lake bottom is lowered by dredging will make it possible to start mining ore by 1960, and co-ordination of plans for open-pit and underground mining should allow a gradual and orderly increase to full production.

Aerial Survey Methods

(*Continued from page* 1656)

survey in any natural resources development.

(6.) Photographic interpretation is a useful aid in many lines of resources development, but it is not an end-all. The skilled interpreter must have a familiarity with his subject which can be gained only by close and regular work in the field. There are occasions, for example, when geological photo-interpretation purports to stand alone, doing away with field work. No geologist experienced in mineral exploration would accept such a premise. It follows that the terms "photo - geologist" and "photo-geology" express about the same limitations as "photo-farmer" and "photo farming".

(7.) The aerial survey methods and applications described in this paper are well suited to the vital parts they are playing in Canada's northward development. They will be relied upon increasingly in the future.

Of wider significance, these same methods are being exported to other under - developed regions of the world, as for example through the Canadian Colombo Plan surveys in various parts of Asia, Africa, South America, Australia, and even Antarctica are also receiving a large measure of Canadian-developed airborne survey. These methods are contributing in a very real way to the extension of improved living standard throughout the world.

The Authors — The contributors to this paper and their particular fields are J. F. Cunningham, forestry; I. S. Fraser land-use; J. S. Jenkins, economic planning; D. R. Lueder, engineering; R. N. Parkinson, geology; N. R. Paterson, geophysics; H. S. Scott, geology and geophysics. Mr Scott, technical director of the company compiled and edited the contributions.

A Review of the DEW Line

Most people are now familiar with the story of the Distant Early Warning Line, its original planning and the security purposes for which it was built.

Basically the DEW Line consists of a number of radar stations spaced strategically along a 3000 mile line north of the Arctic Circle between northwest Alaska and the east coast of Baffin Island; it is a radar fence, composed of three types of radar stations — main, auxiliary and intermediate. Main stations are the largest, contain the most electronic gear, and operate as control centres for rearward communications, transportation, administration and maintenance. Auxiliary stations, although functionally similar from an electronics viewpoint except for rearward communication links, are considerably smaller and do not require administrative and other specific facilities of the larger stations. The intermediate stations are still smaller and are substantially automatic electronically.

This article has been prepared by arrangement with the Western Electric Company Inc., New York, the designers of the original equipment, and with *Engineering and Contract Record*, who published a series of three articles based on the original material (June, July, Aug., 1957). The authors who wrote the complete material were M. S. Cheever, supt. construction, J. D. Brannian, asst. supt.-siting engineering, and C. W. Walker, asst. project mgr.-construction siting, all of Western Electric Company Inc. Above is an aerial view of a central section main station showing 250,000 gallon site tanks in foreground, building trains, radome and construction camp; garage is in rear and construction of the 30 ft. parabolic antennas is in progress.

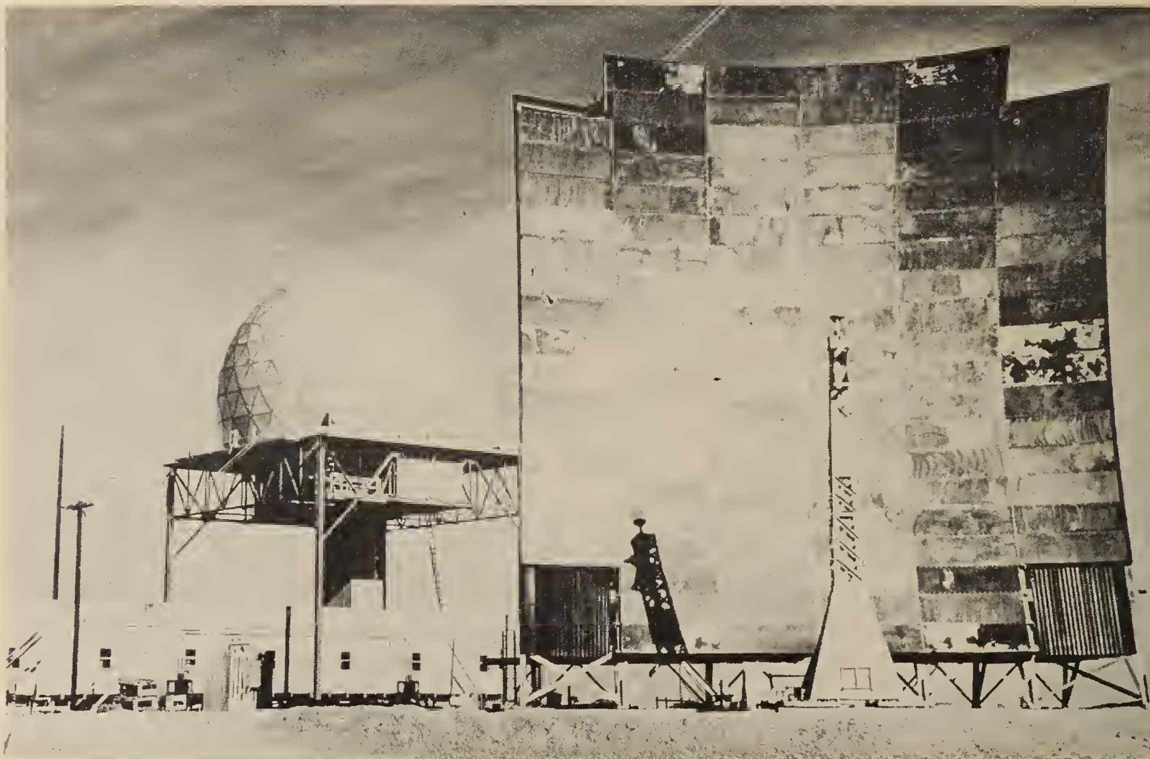
The story of the DEW Line is fantastic. This full-scale attack on the Arctic is unparalleled in military construction history, and its building is an unending tale of adventure and pioneering in engineering, electronics, transportation, construction, and operation. It is the story of a vast project of coordination between U.S. and Canadian civilian and military personnel — of shipping materials by land, sea, and air under the most strenuous conditions — of construction and field engineering forces performing under the most adverse weather conditions imaginable.

The work associated with the DEW Line is a supreme challenge to the scientist and designer, and a fascinating project to the construction engineer. The factors in working in a new frontier flavour a comprehensive variety of work embracing earthwork in roads, airstrips, storage areas, and building pads; pile, timber, and concrete foundations; modular electronics buildings and steel framed garages and hangars; a dozen types of antenna including those mounted on poles up to 80 ft. high, huge parabolics mounted on rigid and guyed towers, other parabolics so large that they had to be designed as an integral part of the structure, and wire array corner reflectors supported on an array of nine towers; new radar antennas enclosed in a newly designed rigid, super-sized radome; and numerous types of outside cabling for antenna leads, communications wire, power distribution, and airstrip and obstruction lighting. And the job would have to be duplicated practically many times, all concurrently.

In viewing the DEW Line from the construction viewpoint, it is not possible to exclude operational planning, engineering design, siting or logistics. Much has been written concerning construction for the Arctic. However, no one treatise sets forth in practical terms an outline of extreme conditions to be encountered from Bering Strait to Baffin Island. The conditions are encountered in four years of DEW Line operation in Alaska and two years in Canada and their description will be confined to fact and observation of their effect on DEW Line construction.

Terrain

The DEW Line traverses everything from flat Arctic plains to glacier-studded peaks. The coast of Alaska is flat tundra with highly frost-acting soils. Limited deposits of sand and gravel are scattered along the beaches. In Yukon Territory the country assumes a rolling character with hills up to 500 ft. The flat swampy terrain of the Mackenzie River Delta consists of soils of silts and fine "blow" sand,



A 60 ft. parabolic reflector with completed radome in background; note tower guys between the two structures.

all frost acting. Gravel deposits are few and small. From Cape Parry to Rae Straits the land, occasionally flat, is usually rolling and features old raised beaches and outcrops of dolomitic limestone. Gravel is abundant.

Logistically, this territory can be resupplied by naval convoy from the west coast. Support is also practical via the Mackenzie. From terrain, logistic and geographical considerations, this area was divided at the Alaska-Canada boundary into the western and central sections of the Line. The third eastward to the Davis Strait became the eastern section.

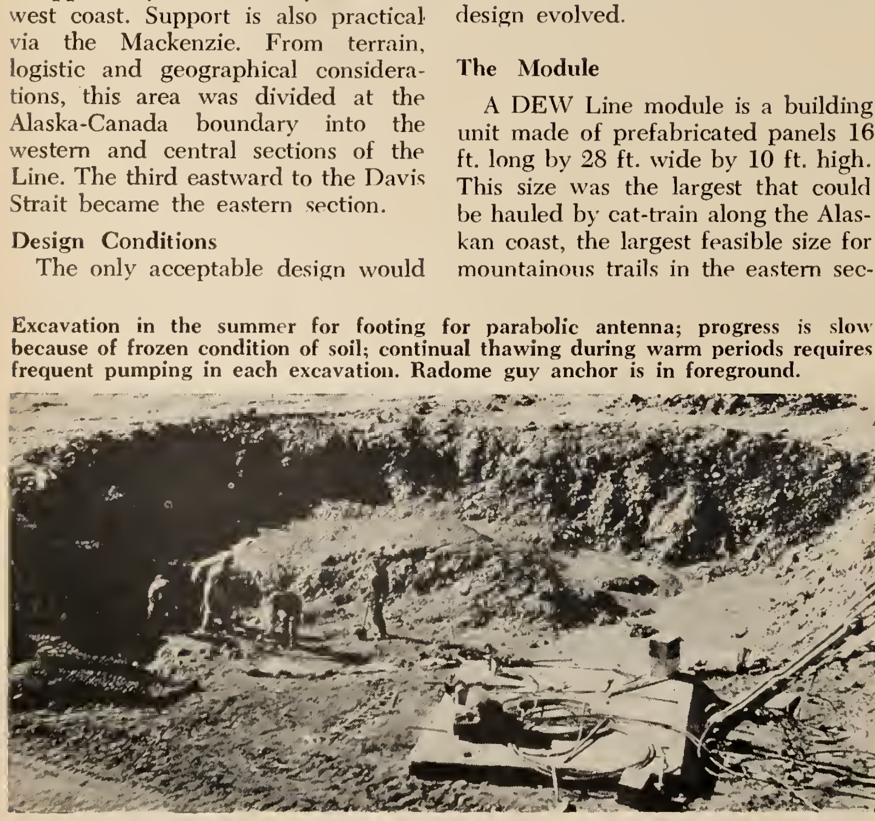
Design Conditions

The only acceptable design would be one which would permit the start of construction of buildings ahead of, or concurrently with, the general development of the site. Such a design must embrace the concept of constructing units of the building at one location and transporting them to their final location. Thus a modular design evolved.

The Module

A DEW Line module is a building unit made of prefabricated panels 16 ft. long by 28 ft. wide by 10 ft. high. This size was the largest that could be hauled by cat-train along the Alaskan coast, the largest feasible size for mountainous trails in the eastern section, and the heaviest load that would be handled onto and off sleds. The modules have a door in each end so that when placed in position end to end a continuous long building 28 ft wide is formed with the doors in alignment for a corridor for the full length. This assembly of modules was informally christened the "building train", and it was designed to house the power electronic and heating plants, living quarters and mess, with a module structural strength to withstand the stresses of hauling over rough terrain. The use of prefabricated metal in this panel was ruled out because of electronic considerations with the resultant wood frame and plywood design being a type that could be produced by any well equipped wood fabricator. Thus production bottlenecks were avoided by permitting simultaneous fabrication of panels by several firms all using the most readily available building material: wood. Production was by Timber Structures, Inc., Portland, region Sigurdson Millwork Company, Ltd. Vancouver, B.C., Tower Company Ltd., Montreal, and Hill-Clarke-Francis, New Liskeard, Ontario. With this design, the contractors were afforded the option of fabricating at a central location for distribution to sites later, fabricating at the sites for placement on foundations to be made ready later on or construction in place on completed foundations.

Excavation in the summer for footing for parabolic antenna; progress is slow because of frozen condition of soil; continual thawing during warm periods requires frequent pumping in each excavation. Radome guy anchor is in foreground.



The installation of mechanical and electrical work was difficult and complicated due to restrictions in room and penetrations through module walls. One design requirement imposed by equipment engineers was that the train had to be shielded from penetration by radio waves and that the equipment spaces be shielded inside also. As shielding was accomplished with a built-in copper screen sheath, the modular design imposed more work. This was particularly true at the connections between modules for this and other work since the modules are placed 6 ins. apart and this space is filled with a vermiculite fire barrier. Details for weatherproofing this connection, retaining the vermiculite, and placing of pipe sleeves all made for extra effort that would not have been required in a single building.

Styroflex cables to 30 ft. parabolic reflector and guyed tower are covered with gravel and marked with empty oil drums. Note corner reflectors in rear. Foreground building is a Simpson hut, while those to the rear are framed tents.

Foundations

The modules were designed for placement on a foundation which would set the floor about 4½ feet above grade and leave a blow-through under the train. The first advantage was that connection under the building assures that no heat loss will transmit into the soil to upset the thermal balance of the permafrost and cause foundation settlement. Secondly, the drifting is alleviated and the snow removal effort reduced. Third, access to the building underside is desirable for the future placement of cables. This was important because it was not possible to engineer all cable penetrations until months after many modules were placed.

Basic foundation design for DEW Line modules trains was a trestle arrangement of short posts with sills and caps, all of timber. The sills were placed on a non-frost acting gravel. The minimum depth of fill from 18 ins. to 4 ft., depending on the soil type as test pits determined. The adequate depth allowed assured that the non-frost acting fill would provide insulation to keep the soil frozen to prevent settlement. At some sites where the natural grade was very irregular, fills were up to 18 ft. This was done in lieu of a vertical stagger in the 400-ft. long train so that the future maintenance penalties would not accrue in the form of snow drifting and awkward grades for vehicles servicing the site. The sills were eliminated and the posts secured directly to solid rock where it existed. This was a concession to save gravel haul, particularly where the site was far from the source, but occurrence of satisfactory rock under the sited locations was disappointingly small.

Enclosure for the 60 ft. parabolic antenna is being completed under winter conditions; the foundation for a similar unit stands ready for the start of steel erection.

A third type of foundation design was employed at the west end of the line where the soils were mostly frost-acting silts and clays with ice lenses. Instead of the posts, sills, and gravel pad, wooden piles were set in the frozen ground, and capped with timbers. This design provided the best assurance against settlement in this soil condition, and saved thousands of yards of extremely scarce gravel. In setting these piles, holes were first steamed or drilled to depth in the frozen soil. The pile was placed in the hole and tamped (sometimes light driving was required) to make certain bearing was obtained on the bottom of the hole. The pile was then braced or weighted for alignment and flotation prevention while the hole was backfilled. Steamed holes were wet and so dry sand was used. Holes drilled in freezing weather stayed dry and were backfilled with a sand slurry for a frozen bond between soil and pile.

Wherever piles were utilized for module foundations, they were also used for the site garage. Pile clusters with concrete caps supported a structural slab above grade as well as the superstructure. This maintained a "blow-through" under the slab which inhibited heat transfer to the soil. At other sites a gravel pad was placed for the garages and spread concrete footings used for bearing under columns. The same structural slab as designed for pile footings was utilized but here it was poured on the fill. The depth of fill was increased to provide more insulation in lieu of the "blow-through."

Hangers were supported on concrete perimeter walls with footings extending well below finished grade into the gravel fill. No pavement was provided inside the hanger for reasons of economy as DEW Line hangers were designed primarily for emergency shelter, not full operational aircraft maintenance. The gravel pad was designed thick (up to 12-ft. minimum for some soils) to provide insulation for subsoil against hangar heat.

Bulk storage tanks for P.O.L. were generally placed on gravel pads except where gravel supply was critical and piles were utilized.

Guyed towers up to 200 ft. were supported on piles and special "frozen-in" guy anchors were used. Utilization of piles for this purpose saved difficult excavation of frozen soil and costly concrete pours. For taller towers and where soil conditions would not permit the use of pile concrete footings and mass anchors were employed. Excavation for these footings was done practically on a year-round basis and extreme care had to be taken with concrete. Even in the summer, the condition of frozen soil constitutes a hazard to a concrete pour. Freezing the concrete is possible or the heat of hydration can thaw the soil and cause settlement. The designers provided protection against this condition by specifying a 4-foot gravel lining for each excavation. While this required additional excavation beyond the neat or nominal footing size, it helped in summer to keep the soil in its frozen state while forming and setting steel.

The foundations for rigid towers supporting 30-ft. dia. parabolic reflectors were of a similar design to those for guyed towers. Piles were used wherever practicable, the major difference being that steel pipe was specified to meet the need of a material with tensile as well as compressive strength to resist overturning. Special lugs were provided on all such piles for anchors to resist withdrawal. Pile clusters had grillage caps of structural shapes welded in place. Steel piles were never used for support of any (heated) structure because of the danger of the steel conducting heat.

Special erection tents were provided so that module fabrication could be sheltered from inclement weather. The modular design permitted certain elements of mechanical and electrical work to be started before the module was permanently located. End wall of this unit has been left out pending installation of a water tank. Future replacements of major units in the train are facilitated by the ability to remove complete walls in this fashion.

Garages and Hangars

Being less associated with electronic gear, greater latitude in using metal was permissible for garages and hangars. The panels on these structures had an aluminum outside face with steel on the inside. Wood panel framing members (pre-treated with fire-retardant paint) prevented thermal conductivity between faces. Interlocking male and female edges were precaulked to provide a weather seal and the fibre-glass insulation was contained in hermetically sealed bags to preclude deterioration by water vapour.

A structural bolted steel frame was utilized for these buildings to which the panels were secured by lagging through holes in the structural steel into the wood panel frames. Garage doors were of the overhead type while the hangar doors rolled on steel rails. All door leaves were fully insulated.

Radome

As of 1955, only one structurally successful rigid radome was erected, and was still under test by the Air Force in Greenland. Geodesics Inc. (the designer), Western's engineers and buyers, the Bell Telephone Laboratories and four manufacturers tackled the job of developing tools, techniques, and materials for the mass production of this radical structure. There emerged in quantity 16 shapes of lightweight translucent panels which when assembled in the sequence and number provided a successful spher of more than 50 ft. in diameter. So clever is the design and the special erection gear that 20 men can erect one on the high platform in les than half a day.

Mechanical and Electrical Design

The logistic concept of operating the DEW Line with a minimum number of people results in the design of the greatest practical application of automatic controls for mechanical and electrical apparatus. Such an installation put the contractors to the acid test of co-ordination of build

Module on sled is being towed by a D-8 tractor.

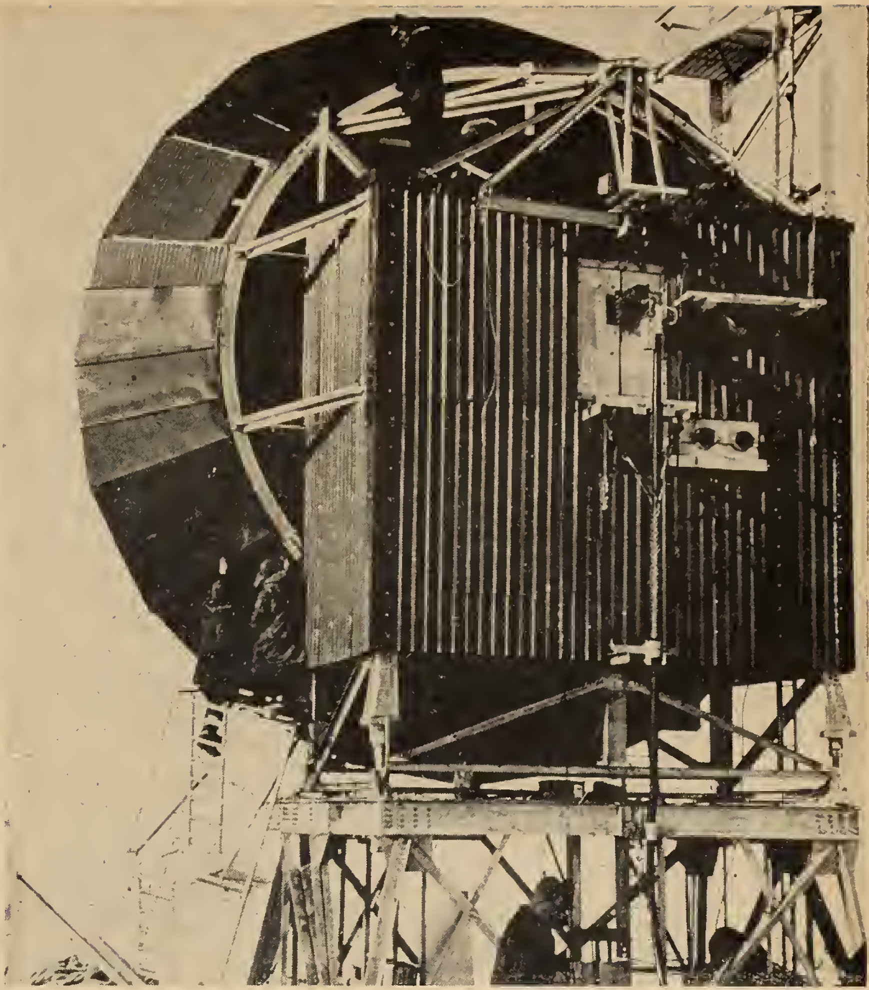
ing trades and any related problems were magnified in the close quarters of the "Pullman type" space. Though the equipment and materials employed were commercially standard, the application was not always so. For example, heat reclaimed from the jacket water and exhaust gases of the diesel generators becomes the normal source for the entire train. This heat is made available automatically by control of dampers on cooling air, 3-way valves on engine water jackets, and valves on parallel exhaust stacks.

Importance of Airstrips

Access to DEW Line sites is basically by two forms of transportation. Most locations can be reached by water during a summer period from either the east or west coasts or via the Mackenzie River. Support of the Line, week in and week out, necessitates reliable air transport service. The first objective was to build an ice strip. In some areas the ice was blown relatively free of snow and it was only necessary to knock down a few small drifts by hand to permit the landing of wheeled aircraft.

It was desirable that construction of the permanent gravel strip should begin immediately where possible.

At many locations, construction expediency demanded that the permanent site location be established in order to prepare a usable strip at the earliest possible time. The western sections made out in this respect by close margins due to the limited gravel supplies available in the late spring and during the summer. The central section was blessed throughout most of their area with conditions which enabled them to have an excellent strip at all locations except two in the Mackenzie Delta area. The eastern section had no difficulty in the Foxe Basin area, but their inland sites, not accessible by sea, and the Baffin Coast sites ran into trouble. Their work was hampered by extremely rugged terrain and limited gravel deposits. A number of sites that could not develop strips by the end of June were isolated for a period of about six weeks until the ice opened up sufficiently to permit service by amphibious aircraft. At times food and supplies ran so low at some sites that support had to be provided by air drops. It was not until early fall that all the designated airstrips were established and some of these were merely graded areas on frozen ground. Progress at each site could almost be measured by the air service rendered it.



Finishing touches to the de-icing enclosure and heat system are being applied to this 30 ft. parabolic antenna in the eastern section.

Rime ice on guyed tower late in 1956.

1955 Achievements

Once established on site each contractor faced the development of facilities needed in the course of his program. The first housing at most Canadian sites consisted only of tents. Then came Atwell huts — an insulated canvass covering over wood arch ribs with a plywood floor, housing six men and heated with a 75,000 B.th.u. space heater. After the sealift, the Simpson hut was developed; this was similar to the Atwell with ribs formed over short pieces of dunnage lumber scabbed together, covered with tarpaulins; the lining was sisal kraft paper and corrugated packing paper provided the insulation.

Each auxiliary and main site was equipped with a steel framed building covered with tarpaulin or plastic fabric sufficiently large to permit the assembly of complete modules inside. Where module fabrication continued into winter months, heat was provided by a hook-up of a Dravo heater from a garage or hangar.

The nucleus of the Western camp was the wanigans from the cat trains. These units were kitchens, mess halls, wash houses, water storage (heated) shop, power or bunk houses. One was also office and radio shack. With this equipment, a 50-man camp could be in full operation with the arrival of the eat train at a site. When a gravel pad had been provided for a permanent camp, facilities were expanded using tents and huts.

Experience proved that where there is reliable camp power, a domestic hot-air furnace with electric blower and burner is more efficient than the pot type space heater, and requires less maintenance.

First business at each site occupied in the winter was the ice strip. Aside from improvement of the construction camp, the next was invariably to initiate a search for gravel for the permanent airstrip.

Before the year end roads had been pushed up hills to the sites at a number of the locations in the East. With the placement of a minimum pad, timber foundations were constructed in the failing light often with the aid of flash lights for levelling. When this work was complete modules were towed up and set in place.

1956 Achievements

Spring saw foundations for antennas, both pile and concrete, being placed. Sites isolated the previous summer from their gravel were busily hauling around the clock across ice and tundra. Eastern section was moving the last of its modules up tortuous mountain roads and relocating construction camps closely to the sites. Northern Construction Company was reopening "I" sites closed for the winter and proceeding with all phases there.

The structural steel for towers was successfully delivered in western and central sections. A substantial amount was also reached in the eastern section sites but the first of a series of adversities entered the picture at this point. Certain jobs depending upon ice strips for steel deliveries did not receive the complete shipment. This was mainly attributable to very poor flying conditions and, in lesser degree, to logistic problems pertaining to material handling. Extremely heavy runoff was experienced in June and many roads from strips to sites were temporarily closed or usable for only the most urgent service requirements and then under restricted conditions. As soon as strips and roads became usable again the equipment was employed to haul concrete aggregate needed for tower foundations, and then the third piece of adversity struck. Many of the earth fills which had been placed during the previous winter under garages and modules began to settle due to inclusion of snow when pads were being constructed. The earth hauling equipment now had to give up hauling vital concrete aggregate and concentrate on repair of the existing pads.

In spite of these problems, progress was continuous and by the end of the year beneficial occupancy of all sites in the central and western sections had been assumed by USAF. Beneficial occupancy in the eastern section occurred in the early part of 1957 and construction schedules were reoriented during the winter so as to make allowance for completion at a later date of that portion of the unfinished work which was not essential to the operation of the stations.

At the close of the first half of 1957 there were but a few outstanding deficiencies across the line. Major components of the remaining work involved are airstrip and road improvement in the eastern section and at one site in the central section where gravel must be hauled up on improvised skipway from a beach to the top of the 400-ft. bluff. Several service facilities, such as garages and hangars, are still being constructed together with odds and ends of antenna heating, airstrip lighting, and miscellaneous outside plant.

It seems impossible today that a multi-million dollar radar station that is now perched on top of a 2000-ft. crag north of the Arctic Circle was 33 months ago only a single line diagram on a piece of paper; 27 months ago, just so many tons of freight; 21 months ago, a few survey stakes five miles above a tent camp; and 15 months ago a collection of unassembled, disconnected buildings. Yet this performance has been duplicated at all specified locations from the Davis Strait to the Bering Strait as a monument to the engineers' vision, the contractors' ingenuity and the will and goodwill of North American neighbours.

The completed site atop a Baffin Island crag gives a breath-taking view of Arctic scenery.

DISCUSSION

of Technical Papers and Other Articles

ENGINEERING THE R.C.A.F. ARGUS

William K. Ebel and Everett B. Schaefer,
The Engineering Journal, 1957, *July*, 967

Mackenzie McMurray[1], M.E.I.C.

Mr. Schaefer has presented a most interesting paper or a rather unusual phase of engineering in Canada.

It is obvious that the authors have had a struggle with the security regulations but have succeeded in giving us a glimpse of the many problems involved.

My discussion will be in the form of a few questions.

(1) In re-engineering the Britania many man-hours of engineering talent have been spent. In many instances when one tries to re-work a problem of this sort one finally spends more hours than if one had started from scratch. I would like to know some of the reasons involved in this decision and roughly how it compares with an estimate of producing a new aircraft. Or in other words, what were the main advantages of using the Britannia.

(2) The authors have mentioned rather briefly the elaborate test programs set up for the various systems such as electrical, hydraulic, etc. in use in the aircraft. The re-design of the electrical systems was a major program and some amplifications would be of interest.

(3) The use of a piston-type engine instead of the turbo-propellor type is explained due to the service required in this particular case. However, was this a re-vamped design of an existing engine or was it engineered from first principles by Canadair?

(4) A good deal of effort seems to have been spent to comply with the R.C.A.F. regulations in regard to natural specifications. Is there any standardization program being contemplated by say Britain, Canada and the United States?

The authors have mentioned the testing programs carried out on the components of the various systems in the aircraft. I would like to comment that I had the privilege of visiting the plant a few weeks ago and I was amazed at the extent of the work carried out in this area. Very little has been left to chance as so many of the problems have been worked out on these ground installations long before flight testing.

This paper describes a relatively new field of engineering in Canada but a most important one in view of National Defence. Canadair are to be complimented on their efforts and on this job in particular when one recognizes this adherence to the original schedules set up for the production of this important aircraft.

[1]Assistant to the Vice-President and Managing Director, Dominion Bridge Company Limited, Lachine, Que.

Group Captain C. W. Crossland, M.E.I.C.[2]

A comment which I might make on the paper, "Engineering the RCAF Argus" by W. K. Ebel and E. B. Schaefer is that the authors' remarks concerning RCAF requirements governing the design and material standards for the Argus might give the impression that the "Manual of Aircraft Design Requirements for the Royal Canadian Air Force" forbids the use of British standards and material specifications. Although this publication gives preference to Canadian and U.S. standard parts, it does not exclude the use of materials conforming to specifications published by the Ministry of Supply and the British Standards Institution. Availability in Canada or the U.S. is the over-riding consideration, since it is desired to be as independent as possible of overseas sources of supply of spares for military aircraft.

A MAJOR POWER PLAN FOR YUKON RIVER WATERS IN THE CANADIAN NORTHWEST

J. M. Wardle[1], M.E.I.C.
The Engineering Journal, 1957, *November*, 1638

G. V. Eckenfelder,* M.E.I.C.

As the more accessible sources of hydro-electric power in Canada are developed, and their output utilized, established industries must find other sources of power to meet their requirements. There remains in the country, however, a number of large power sites which are situated beyond a practical transmission distance of the present load centres. Development of these sites can be of use only to new industries established near them. For this to be possible, the new industry must be one which does not rely on cheap transportation or, alternatively, the site must be accessible to ocean shipping. The scheme which Mr. Wardle has outlined fulfills the requirements of the latter. A tremendous power potential exists in the upper reaches of the Yukon River watershed, so situated that generating plants making use of this potential can be located within a short distance of a site which can accommodate a large metallurgical industry and which, at the same time, is readily accessible to the sea.

Mr. Wardle has described the extent of the investigations being done to determine the best way of developing the power available, along with a study of the related problems of locating sites for industrial development, methods of transportation and sources of raw materials to be processed by using the available power. He has also indicated the amount of studies and investigations remaining to be done before the project can become a reality. The international ramifications are not by any means the least of the problems to be solved, and their solution will require wisdom and foresight.

This paper is timely as it discloses one more instance of the vast amount of work which is in progress to open our north country to development, and to the production of wealth.

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

THE SOVIET ENGINEER AND HIS ENVIRONMENT

E. P. Ward, *Engineering*, v. 184, No. 4775, Sept., 1957.

This is the first in a series of articles dealing with Soviet engineers based on a recent visit made to Russia by the author, a deputy editor of the British publication *Engineering*.

To what extent do engineering products enter into Soviet life? As would be expected, Moscow and Leningrad are modern cities; the streets are crowded with motor-cars, sometimes of good contemporary styling, with a considerable sprinkling of elegant single-deck trolley-buses. A high proportion of the cars are large, suggesting that many are employed by officials rather than by private individuals. Further evidence that private ownership of road vehicles is rare is given by the small number of bicycles and motor-cycles to be seen on Moscow streets and in the country although one factory visited produced bicycles as a sideline at the rate of two per minute (460,000 a year). Trams are still in use in Leningrad and in the outer parts of Moscow; street lighting is adequate, though not brilliant, and broad avenues minimize traffic bottlenecks.

Rail travel can be extremely comfortable with well designed and equipped sleeping compartments. A 5 ft. rail gauge and a 16 ft. width of loading permit generous carriage dimensions. Three trains run approximately simultaneously between Moscow and Leningrad several times a day, and to avoid the reactionary distinctions of first and second class, the coaches are denoted "soft" and "hard". Long distance trains are frequently steam-hauled, though Diesel and Diesel-electric locomotives are in use. A gas turbine locomotive is said to be under development as well as a gas-turbine plant for marine propulsion. It is claimed that a 3-hour service between Moscow and London by the Tu jet aircraft will operate next year. Housing shortages in Soviet cities are a serious problem although all around Moscow vast building projects are under way; large numbers of apartment houses of closely similar design are to be seen in various stages of completion. Non-condensing steam turbine plants (25 Mw.) are in operation as sources of power and secondary steam for process and district heating. A 50 Mw. version to supply areas 5 km. in radius is also in production. Even before the war Moscow had a stereoscopic three-dimensional cinema. Television is clearly very common, though presumably only in the main population centres. Excellent long-playing records are sold at a price half, if not a quarter, that obtaining in the United Kingdom.

It is already well known that Soviet engineers occupy a high place in their community. Relative salaries provide a useful indication. A young diploma engineer, for example, will earn at least 880 and probably 1,000 roubles a month, which is equal to the salary of an experienced interpreter or a middle-school teacher. (£1 sterling on a trading level is equivalent to 11 roubles). The lowest wage for a semi-skilled factory worker is about 650 roubles per month. The average monthly wage for workers in a particular automobile factory is 900 roubles; while in the same factory the average salary of engineers is 1200 to 1300 roubles, but with the upper grades receiving in charge of a shop may earn 2000 roubles, and the head of a factory or research institute between 4000 and 6000. A doctor of science is entitled to 1000 additional roubles a month and a candidate of science, the next lower degree, but above the qualification of diploma engineer, 500 roubles a month. The head of the heavy-machine building institute, who is a doctor of science, earns 6000 roubles a month; he remarked that he had recently visited England and that his opposite number there seemed to have roughly the same living standard. A teaching professor of medicine would earn about the same. There are also bonus payments in cases where a norm is exceeded. A guide to the purchasing power may be gathered from the following prices —1 lb. butter 10 roubles, 1 lb. apples 1 to 3 roubles, a suit of clothes 300 to 1200 roubles, a car 15,000 to 20,000 roubles, a long playing record 10 roubles, an upright chair 10 to 30 roubles.

The status of an engineer is likely to reflect his value to society, and his value will depend on the use that can be made of him. How profitably are engineers employed in the Soviet Union? Are they sometimes wasted? When an engineering student obtains his diploma he is normally directed to appropriate employment but if the post proves to be unsuitable he can choose a new appointment. Nevertheless, the rate at which engineers are produced and the tendency, whatever the job, to prefer an engineer to a technician, and a technician to a craftsman, must lead to some misplacing and under-utilization of qualified men.

There is a remarkably high proportion of engineers on factory staffs and it underlies the extent to which research and development is carried on in factories. Examples of the percentage of the total employees of various factories, who are classed as engineers, technicians, and draughtsmen are: bearing factory of 10,000 people, 4.5 per cent; special steels plant of 10,000, 10 per cent; motor vehicle factory of 40,000, 15 per cent; and a machine tool research institute of 2,450, 35 per cent. In a turbine factory employing 11,500 persons 8.7 per cent are classed as engineers and 17 per cent as technicians and draughtsmen; in an electrical generator factory of 6,000 the figures are 17 per cent and 33 per cent. It is clear from these figures that the term diploma engineer in the Soviet Union has a somewhat different meaning from engineering qualifications in Britain, but the extremely high percentages are nevertheless of great interest. As a basis of comparison the number of professional engineers, diploma engineers, and holders of Higher National Certificates in selected British industries can be given as percentages of total employees. Thus, in the electrical industry there are 2.8 per cent; in the iron and steel industry 0.65 per cent; and in the motor vehicle industry 0.87 per cent. It is significant that the Soviet electrical factory likewise has the highest percentage of technically qualified employees. Foremen are frequently diploma engineers but non-formally trained men often hold positions of greater responsibility than diploma men. It is of interest that university lecturers and professors often serve as consultants to industrial firms. Also noteworthy is the considerable proportion of diploma engineers who are women. The Soviet Union almost manages to double its labour force by the widespread use of female labour and the provision of creches for children. Often the care of children is the responsibility of the factory. Of the 450 engineers and technicians at the First State Ball Bearing Factory, some 40 per cent are women, working mainly in the estimating, costing, and work-study departments. The majority have diplomas in engineering economy, which are of comparable standing with engineering diplomas and awarded by an Institute. At the Electrosila factory in Leningrad, 300 of the 1000 diploma engineers are women.

Post-diploma studies are generally carried out in the evenings, but for those able or willing to sacrifice their incomes, day courses are also provided. To encourage the engineer to continue his education, there are a series of further qualifications. On obtaining his diploma he must complete three years of useful work, following which he can become an "aspirant" by joining a special school. There he spends two years preparing for examinations and a third working on a thesis. At the end of the third year he presents his thesis and defends it publicly before a scientific panel. If successful he becomes a Candidate of Science, the first engineering degree. The Candidate may then prepare a doctor's thesis on some salient problem (e.g. the design of industrial rolling mills), presenting it after perhaps five or ten years to become a Doctor of Science.

IGY IN ANTARCTICA

Two members of the U.S. Navy's expedition to Antarctica take advantage of a pause in a journey to collect snow for water in a dining "wannigan", which is mounted on one of 38 sleds equipped with runners fabricated from alloy steel. The 11-ton sleds, capable of carrying loads up to 20 tons, were used to haul supplies needed to establish six observation bases for the 1957-58 International Geophysical Year. EDUCATION AND TRAINING FOR THE ENGINEERING INDUSTRY

Sir David Anderson, *The Engineer*, v. 204, No. 5303, Sept. 1957.

Engineering is the most widespread and basic of the British manufacturing industries. Not only is it a major industry in its own right, but practically every manufacturing industry depends on engineering for the design, operation and maintenance of its plant and equipment. The whole industrial prosperity of the country is linked to the ability to organize and maintain a highly efficient engineering industry.

Government sources have estimated that the need for engineers and scientists will be doubled in the next 10 or 15 years and that this is a minimum goal if the economy is to grow at an acceptable rate. This means about 20,000 trained persons produced per annum and is a figure not likely to be reached. The accelerating pace of economic and technical change is such that there will be a shortage for many years to come. The diversity of activities and multiplicity of professions in our modern way of life are such that, at the higher levels of intelligence there is simply not enough manpower to go round. In industry the most urgent need today is not for more scientific discoveries but for a wider and more intensive application of discoveries already made. Every scientific discovery opens up a fan of potential applications, and the engineering industry will be able to absorb for a long time ahead all the recruits it is likely to get.

From all the information available it seems that Russia, the United States, Western Germany, and Britain are producing technologists, mostly engineers, in the ratio of 4:2:2:1 per unit of population. It is more than a little disturbing that Western Germany, which has the same population as Britain, is at the same stage of industrial development, and is also heavily dependent on exports, is producing twice as many technologists. This may be a highly significant factor when the European Market comes into operation.

At the lower levels of employment in the engineering industry there

BERKELEY NUCLEAR POWER STATION

Construction of the commercial nuclear power station at Berkeley, Gloucestershire, England, will eventually use over 70,000 tons of cement. The two main civil contractors have erected weigh batching plants to provide most of the concrete required. The plant shown above incorporates a 150 cu. yd. bin, split into two compartments to hold two different types of cement used. Below the bin are two 2000-lb. capacity weigh hoppers, two aggregate weigh hoppers of 9000-lb. capacity, and one water batch weigher of 1000-lb. capacity. These, plus an admix batcher, all have separate scale mechanisms. Control of charge and discharge is from a central operator's platform; the operation is by air rams. A second operator at the central panel controls the batching and mixing of concrete. Below the mixers is a two-compartment wet concrete hopper arranged to receive feed from the mixers singly or jointly. Aggregate is delivered to the main plant by belt conveyor and distributed to different compartments by a rotating system. Bulk storage for cement is provided, and the output of pumped concrete is through 6-in. dia. pipes at a maximum rate of 60 cu. yd. an hour.

does not seem to be any manpower shortage. Most firms can get an adequate number of apprentices and some can even exercise a considerable measure of choice. Therefore, recruitment to the middle cadre, the technicians, should also present no problem.

Technical colleges make a numerically greater contribution than the universities and they do so at every level except that of the research scientist. There has been a remarkable development in the volume and standard of work in technical colleges. Post-war needs have accelerated this development and a new pattern for technical education is emerging in England. There is to be a small group of institutions called colleges of advanced technology, at present eight in number. These colleges are to concentrate on advanced work, mainly, but not exclusively, in the form of full-time sandwich courses. Next there is to be a group called regional colleges. These will generally serve a wider area than that of a single education authority. They may offer sandwich courses as well as a large volume of advanced part-time work. Next there are to be area colleges and local colleges: these will be concerned with technical studies at a lower level, and work of a non-vocational character. In the past the development of courses of graduate standard in technical colleges has been handicapped by the lack of an award commanding national recognition like a university degree. The new Diploma in Technology established by the National Council for Technological Awards under the chairmanship of Lord Hives removes this handicap and a rapid expansion in the volume of advanced work in the major technical colleges may be anticipated. The diploma is to be equivalent in standard to a university degree and already there is a demand that the Council establish a higher award comparable with a Ph.D. When that comes about it will be stimulating to see a considerable two-way movement of graduates between the colleges and the universities for postgraduate study and research.

There have been developments, too, in the universities. They have all science and technology in accordance with Government policy and further expansion is being planned in selected centres.

The sub-professional group, comprising the skilled craftsmen, supervisors and technicians, whose education is provided for in part-time courses, will be handled by the appropriate technical colleges: the universities clearly have no interest in this field. In the professional group the research scientists will remain a university product, but the development engineers and designers, and the production engineers and managers, may be educated either in the universities or in the colleges of advanced technology as in some of the regional colleges. The university courses follow a uniform pattern of three years post-intermediate and lead to a degree. In the technical colleges there is some variety. The new sandwich courses leading to the Hives diploma will probably be of 4 or 5 years' duration. Some colleges now offer courses leading to the London external degree and these may be on a full-time or a part-time basis. Lastly, there are the widespread part-time courses leading to a Higher National Certificate. Not all of those obtaining this certificate can be reckoned as of full professional status. Probably about half those getting HNCs' will, with further study and experience, reach full professional status. The major increase in the output of graduates will come from the technical colleges which are linked with the greater stream of part-time education, and it is in this stream that there is an appreciable reserve of good brainpower which could be selected and transferred to full-time courses.

The accommodation, equipment, staffing and conditions of service in the colleges of advanced technology are to be comparable with those in universities and there is to be the same emphasis on research. The courses are to have the same content of basic science, and hence the man graduating after a five-year sandwich course will be pretty much the same type as the three-year university graduate after he has done a two-year postgraduate apprenticeship. There are now two routes to the same goal and a substantially larger number may well elect to take the sandwich course route.

To be efficient the engineering industry must have good management. Good management permits the maximum return to be reaped from technological advance. Management studies therefore should have a place in engineering education. They are commonly undertaken at the postgraduate stage. The ideal arrangement would be a planned series of short residential courses spaced throughout the earlier years of a man's professional life. In the hustle and bustle of industrial life there is little time for reflective thought, and unless opportunities are specifically provided, creative thinking about one's job goes by default.

In the sub-professional groups, supervisors, technicians, and skilled craftsmen there does not appear to be any problem of a shortage. Technicians may be recruited from senior apprentices or skilled craftsmen, or directly from school. Supervisors will generally be promoted from the ranks of the skilled craftsmen. Since a higher standard of technology needs to be backed up with better technicians and craftsmen, the time has come when British industry should make a serious examination of the apprenticeship system. This training is now more thoroughly organized on the Continent than in Britain. Compulsory classroom instruction is given and the apprentice must pass a written, oral, and practical examination before he can be certified. In Britain it is possible for a youth to become certified as a skilled craftsman without having attended a single class or passed a single examination. Serving time is the only compulsory requirement and in many cases served in a rather slipshod fashion.

The technician group does not present any serious educational problems. They can, at the moment, be adequately trained in part-time courses of the City and Guilds type. The upper limit of the technician group is not sharply defined. It merges gradually into the work of the professional engineer, and many technicians can attain professional status through additional part-time study. The standard of their work is rising and before long some kind of sandwich course may be needed to give a more rapid and intensive training.

Co-operation between education and industry is much better than it used to be. Through conferences, discussions and visits, each has now a better understanding of the problems of the other. This is true both for universities and technical colleges, but there is still scope for improvement.

QUICK MEASUREMENT OF MOISTURE AND DENSITY

The use of a new portable field instrument for measuring moisture content or density in many materials is illustrated below. It is claimed that a single operator can get accurate determinations in less than two minutes, using a moisture probe containing a radioactive radium-beryllium source of fast neutrons or a density probe containing a caesium-137 gamma-ray source. The probes are used interchangeably with a radioactivity-counting instrument (a scaler). The probes can measure a spherical volume of material with an average diameter of 14 in. Depth of measurements ranges from the top 12 in. to 60 feet. Accuracy is said to be within 2 lb./cu. ft. for density determinations between 50-150 lb./cu. ft.; for moisture, 3/4/lb./cu. ft. from zero to 100%. (Photo: Nuclear-Chicago Corporation, Chicago, Ill.)

CORROSION OF STEEL REINFORCEMENT IN CONCRETE

C. D. Coppard, *Civil and Structural Engineers Review,* v. 11, No. 9, Sep., '57.

Corrosion of reinforced concrete produces ugly rust stains which disfigure the external walls of many structures and symbolize what might be called the bleeding to death of a structure, the systematic eating away of its core.

The actual stages of corrosion of reinforcements have not been fully appreciated, with the result that this critically serious problem has often been brushed aside. This, despite the fact that the steel provides almost the entire tensile strengh of reinforced concrete and that renovation or maintenance of such steel is often impossible and always expensive after its inclusion in the concrete.

A basic problem in the construction is the establishing and maintaining a powerful bond between steel and concrete. It is therefore common to specify a number of steel reinforcements of comparatively thin rods in preference to a single rod of equivalent weight, because the former offer a greater surface area and therefore greater adhesion. Because of this, however, the corrosion hazard is much increased since even light rusting of thin gauge steel may affect its strength significantly. The problem of adhesion on the one hand and the corrosion hazard on the other has led to a curious anomaly resulting in the practice of specifying steel of increased thickness in order to discount loss through rusting.

Rusting occurs because the steel is given no protective coating. This is due to the belief that applied coatings prevent a lasting adhesion and result in slip, and that rust, inevitably forming on the steel surface, will permanently supply this bond. However, on external walls at least it is impossible to obtain a permanent or even semi-permanent bond between unprotected reinforcements and concrete.

Weathering

Weathering of the steel, in the contractors yard is commonly used to remove the layers of millscale formed on the steel surface by various hot rolling and shaping processes at the steel mill. In most other industries the weathering process has fallen into disrepute for the following reasons. Millscale is rarely formed as a continuous layer and is characterized by a multitude of microscopic fissures which allow corrosive media to penetrate to the underlying steel. Because the scale is a spent oxide it is cathodic to the steel and will help to promote attack on exposed areas of metal. Weathering provides ideal conditions for this to occur, the scale is detached by rust forming between the steel and the scale layers, and severe corrosion and pitting occur.

This rust which is an oxide comprises part Fe_3O_4 and part non-reducible Fe_2O_3. The concrete immediately adjacent to the steel is unlikely to become completely dehydrated for some considerable time, particularly if the concrete is thick. During its period of setting and maturing, the concrete exudes free limes and other corrosive alkalies which, distributed by the moisture set up a pickling action on the steel. This causes the dissolution of the Fe_3O_4 and the cleaning (often to the point of brightness) of the substrate. In the course of this reaction the indissoluble Fe_2O_3 becomes integrated with the maturing concrete and makes a good bond.

In achieving this bond however, the relationship between steel and concrete is established in a very delicate state of equilibrium. Pickling produces a "rawness" of the substrate by laying bare the grain structure of the steel in a manner similar to shot blasting. Moreover, the possibility of maintaining this state of equilibrium is a purely academic concept, impossible in practice on external walls of most concrete structures. Given the presence of an electrolyte — even small quantities of water are sufficient — and the whole balance is upset; violent corrosion is almost inevitable simply because pickling has opened up the very fabric of the steel. Unless the concrete is dehydrated rapidly the uncontrolled pickling action can cause quite serious metal loss.

When the concrete has dried out it becomes more or less porous, and the reinforcement is therefore liable to attack from any water-borne corrosive media which may filter through the concrete from the air or water of the environment, in spite of the presence of waterproofing applied to external walls of the structure. Sulphur compounds in industrial atmospheres frequently adhere to external walls and become absorbed by rain water, enter the concrete and attack the steel as sulphurous acid.

Rust occupies a space five times that of the steel it replaces. In effect, therefore, the steel expands and since the concrete cannot accommodate this expansion, and because the growth of rust cannot now be stifled, the concrete is forced away from the surface of the steel by an ever-growing parting layer of rust. This is the primary cause of spalling which consists of fissures in the concrete caused by its movement away from the reinforcement, and each fissure provides ready access to further corrosive agents.

Remedies

Various remedies have been proposed such as regulating the different proportions of constituents in the actual concrete. Use of a slag aggregate has been suggested but this is not satisfactory due to the danger from sulphur compounds found in slag and cinder. Employing an increase in the ratio of cement to aggregate increases the density of the concrete and improves the barrier to entry of corrosive agents. However, the concrete will eventually tend to leach out and become porous. Waterproofing compounds applied to concrete can undoubtedly help. They require frequent renewal and can cause a serious problem if there is a poor bond between the coating and the concrete. In this state corrosive agents can penetrate the coating, seep through and attack the steel without making themselves evident for some time. That is, waterproofing compounds may tend to conceal corrosion of the reinforcement.

Coating Protection

It is suggested that one effective method of protection is by coating the reinforcing steel with a resistant film, developed over the last seven years by a British company. This procedure is described as taking place in three stages. First, the application of a chemical descaling jelly or solution which is capable of removing mill-scale in a few hours. The process is non-corrosive and does not attack the underlying steel as does weathering. The chemical can be applied by dipping, spraying or brushing. Second, a process is used which simultaneously removes rust and deposits a phosphate coating on the steel surface and in the actual grain structure of the metal. The coating is amorphous, inert, water-insoluble and has a high electrical resistance. It provides a strong bond between the metal and subsequently applied coatings, increasing their resistance to impact, abrasion and corrosive media in the environment. Again, it can be applied by immersion, spraying or brushing. The third stage is the application of a chemical sealer, applied by similar methods, which combines with residual solution from the previous process to form a strongly rust-resistant barrier.

This coating is unaffected by moisture after a drying time of 30 minutes and will withstand storage of the steel under hostile conditions prior to inclusion in the concrete. It is impervious to acid and alkaline attack, and will not saponify or decompose under attack from lime or other alkalis exuded by the concrete during the drying stage. Also, the sealer offers a strong bond between metal and concrete and the high electrical resistance of the phosphate coating stifles the electrolytic mechanism of the corrosion action and prevents rust creep if, for any reason, the sealer coating suffers localized penetration.

DISCUSSION

The Editor invites discussion of technical papers and other articles in *The Engineering Journal.*

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

The CF-105 Avro Arrow

The CF-105 Avro *Arrrow* delta-winged fighter, Canada's first supersonic aircraft was seen publicly on October 4. The twin-engine, long range interceptor was first rolled out of Avro Aircraft Limited, Malton, Ont., that day climaxing a program of engineering research and manufacturing techniques in fields completely unknown when the project was undertaken.

It was four years from the date when the "go ahead" for the design and manufacture of a successor for the CF-100 was given by the government.

A big, versatile aircraft designed to operate with a crew of two, from existing runways, the loaded weight of the *Arrow* is of the order of 30 tons; its speed, 1000 miles plus.

Primary armament of the aircraft are the aair-to-air guided missiles installed in a detachable armament bay in the fuselage. Versatility provided by this bay will enable the aircraft to perform other roles. The *Arrow* will be equipped with one of the most advanced integrated electronics systems, which will combine the navigation and the operation of the aircraft with its fire control system.

The *Arrow* was designed for the R.C.A.F. as a defence factor. It is considered one of the most advanced combat aircraft in the world, produced from very complete tooling which will allow production to follow development without undue delay.

The first *Arrow* and the next few developmental aircraft will be equipped by Pratt Whitney J.75 engines. Ultimately however, the new Orenda *Iroquois* will power all production aircraft.

Wind tunnel tests were being run within two months of authorization. Seventeen models of various sizes were used to obtain necessary structural and aerodynamic data. Wind tunnel limitations caused Avro engineers to explore further techniques for obtaining important aerodynamic data.

Eleven large scale free-flight models with rocket-propelled boosters were fired at ranges in Canada and the U.S. between 1954 and January 1957. These models were instrumented and transmitted their inflight information back to a ground station.

Aerodynamically, the *Arrow* was entering a new realm of science. Analog computing equipment was installed to accelerate the solution of aerodynamic and stress problems. The company also obtained a new electronic digital computer to accommodate its accelerated research development program in supersonic aircraft. This was the IBM 704, a giant computer.

At 1200 m.p.h., air friction raises the temperature of an aircraft's skin by 300 degrees F. At high altitudes with the outside air temperature at 50 degrees F. below zero, the skin temperature is still 40 degrees F. above boiling point of water. Also at this speed, at high altitudes, the perspex canopy enclosing the pilot and radar-navigator would start to blow out like bubble-gum, due to high friction, plus the fact that the inside of the canopy is pressurized. This was overcome by installing tempered glass windshields about an inch thick.

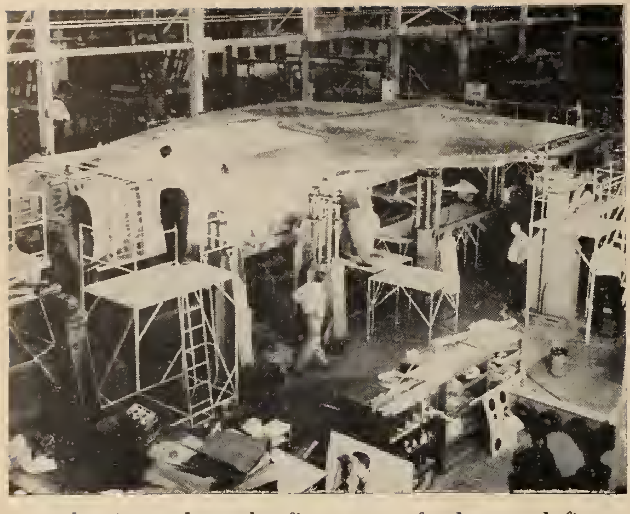
Two main types of detrimental sound, jet engine and aerodynamic, can cause skin panels to fracture and rivets to loosen, again weakening structures. Sonic structural tests are being carried out constantly and will continue until they have run long enough to indicate satisfactory panel life.

The air-conditioning system in the *Arrow* must be capable of handling temperature changes of 100 degrees F. a minute.

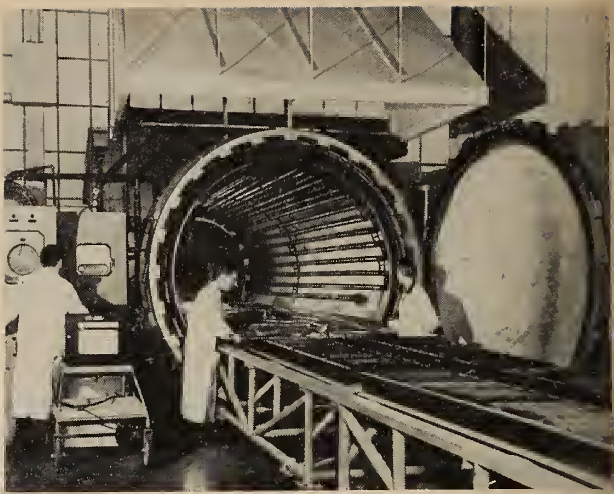
New machines including a 15,000 ton rubber pad forming press, a big metal-to-metal bonding autoclave, a special heat treat furnace, a giant skin mill and heavy machining equipment were brought in by Avro. Six hundred and fifty suppliers in Canada have been engaged in the manufacturing of parts.

Fabricated and assembled in less than two and a half years from the date of the first design release the

The CF-100 Avro *Arrow*.



In the Avro plant, the first centre fuselage and first inner wing in assembled position.



Metal to metal bonding. This big autoclave bonds together metals coated with a special adhesive.

first *Arrow's* man-hours-per-pound ratio is approximately 80 per cent of projects of similar size and complexity in North America.

Now exposed to exhaustive testing, and the installation of extensive, specialized instrumentation, the flight date of the aircraft will depend on problems to be dealt with during this phase of the program.

Avro hoped that the first flight would be made before the end of the year.

That the new aircraft will be a real contribution to the defence of North America was the tenor of the remarks made by military and government people at the October 4 ceremonies. The theory that missile development would soon make manned interceptors obselete was said to be unlikely. Rather, it was estimated, these technically advanced manned aircraft will be a necessary requirement of the arsenal of the West for many years to come.

Some Features of the CF-105

Delta Planform: gives thin, high wing section — advantageous for supersonic flight — and sufficient physical depth in wing root section to house undercarriage plus large amount of fuel. Delta also gives efficient and relatively light structure and good general control at transonic speeds.

Twin Engine: gives twice the thrust without double fuselage area, and gives increased reliability.

Materials: It is an all-metal aircraft. Metals are used which had not reached the research stage when design of the aircraft began. Metal to metal bonding of magnesium alloys was developed for this plane by Avro.

Manoeuverability: Plan was for utmost reliability in severe high temperature, high altitude environment.

Heat and Sound Problems: The Arrow is on the threshold of the Heat Barrier. Studies are underway to adapt it to even higher speeds.

Ground Handling includes a jeep-mounted gas turbine as an engine starter, and a power-and-air conditioning truck which can maintain a constant airflow at 55 degrees F. to the weapon, electronic and other sensitive equipment, and some 200 pieces of equipment.

Control Mechanisms: Provide sufficient power to counteract extremely high air loads on control surfaces.

Electronic System: R.C.A. developed a new electronic system for automatic flight, weapon fire control, communication and navigation, which has been designated the Astra I system.

Testing proved basic soundness of the structural and system concepts prior to building. Test of fuel system, eg., caused a simulated test system to be subjected to simulated flight sequences and emergency operation of pressure, refuelling and de-fueling systems. Stress tests using plastic models confirmed that results of analytical structural studies had beeen valid.

Quality Control: 38,000 parts were checked by quality control and inspection department, with smooth flow to shops. Interchangability of parts and components was studied. Innovations on inspection speeded production.

Methods: Difficult machining and forming operations were undertaken and solved. Milling of wing skins and large machined parts provided tremendous integral increase in structural strength. Bonding method devised is stronger and lighter.

The B.C. Interior

Years of speculation in British Columbia on the future of the northland have been brought to a head by surveys indicating a four million horsepower hydro development is feasible.

Axel Wenner-Gren, Swedish financier, responsible for the surveys, and for a dream now cherished province-wide, foresees a billion-dollar industrial empire. With an estimated cost of up to $600 million, more than the St. Lawrence Seaway, power output could begin by 1964 turning out at full production, four times the power generated by Boulder dam. While these speculations are the results of a purely interim report, the provincial government has signed agreements for further surveying of dam sites.

The energy would be generated in the Rocky Mountain "trench", a huge geological fault 10 to 20 miles wide running from the U.S., northwest to the Yukon.

Wenner-Gren is spending $5 million surveying a 40,000 square-mile area along this fault, some 400 miles from the north of Prince George to Lower Post, on the Yukon border. He hopes to run a revolutionary monorail railway all this length, in return receiving priority in mining, lumbering and power development concessions.

Later this year a Toronto firm expects to make an interim report on its aerial survey with magnetometers of the mineral content.

Reports suggest improved navigation on the Mackenzie River; channelling of the Peace River so that neighboring Alberta will benefit; provision of Vancouver and southern B.C. with cheap power so that the salmon fishery on the Fraser River need not be destroyed. *(Abstracted from Montreal Star, October 16.)*

St. Lawrence Seaway and Power Project

Though weather continued favourable for all aspects of construction during September, the peak employment of some 21,000 attained in August was not exceeded, due to completion in early September of certain features such as concrete on the Iroquois dam and the two American locks. River improvement in the International section, under way by both power authorities, was generally on schedule. Dry excavation was on schedule. Dredging was slightly behind schedule, particularly on the south channel, but this will not affect opening of navigation for 14-foot draught vessels by July 1958. Clearing of park areas was 62 per cent completed by end of September and will continue throughout winter.

Progress by Ontario Hydro

By end of September some 770,000 cubic yards of concrete or 74 per cent had been placed in the Canadian half of the international power-house. It was estimated 90 per cent would be placed by year-end and placing will continue through winter months. Placing of concrete was completed on all draught tubes and three intake sections were completed to full height.

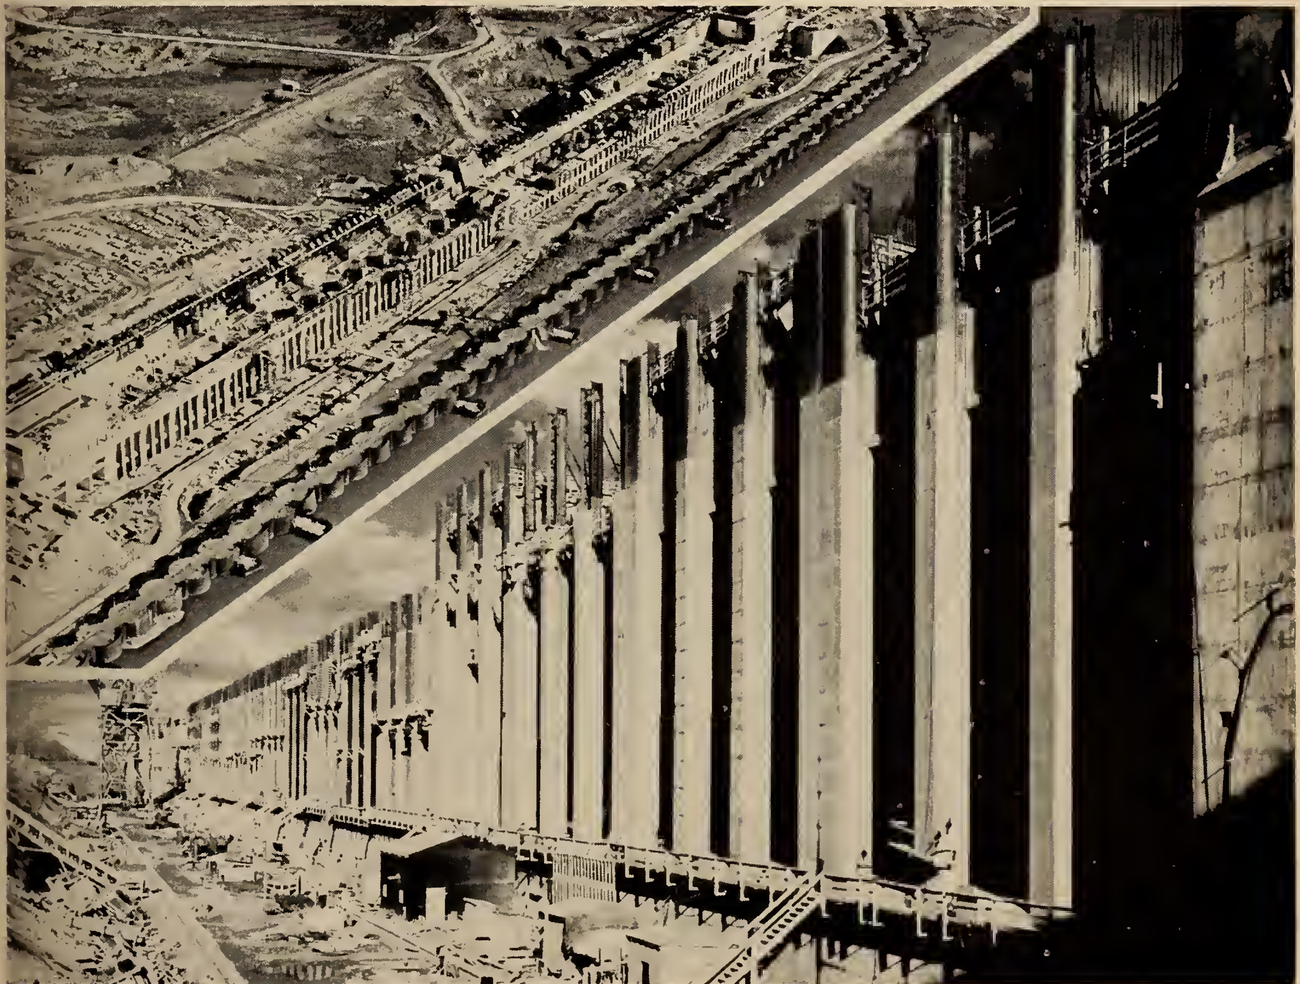
Twelve turbine speedrings had been set and one runner was delivered. Runner installation was scheduled for end of October. Installation of the headgate gantry was completed and tested. Generator equipment deliveries were commencing. Taintor gates for the ice sluice were being installed. More than half the headgates were delivered but installation had not started. Dikes will be completed by end of October excepting for riprap, with final completion scheduled for year-end.

Progress by NYSPA

At month-end some 820,000 cubic yards of concrete, or 75 per cent, had been placed in the American half of the international power-house. concrete for all draught-tubes had been completed and concrete in three intake sections had reached full height. By year-end 90 per cent of completion will be attained as scheduled. Work on all dikes was to be completed excepting for riprap by end of October.

Drum gates for ice sluices were being installed. Installation of the

Two views of the St. Lawrence power dam. There are 96 intake openings.



large gantry was almost complete. Nine turbine speedrings had been set but no runners were in place. Deliveries were commencing on headgates for the American half, as well as on the generator equipment, as scheduled.

The contractors on the Long Sault dam had caught up with their schedule, with some 500,000 cubic yards or 81 per cent of the total concrete placed at end of September. Concrete for the second stage will be completed by Christmas. The third stage involves the filling in between piers on the first stage or half. River flow will be diverted back to the north channel in March. Gates in stage 1 are being used temporarily for closure in upstream gains. Ultimately, 18 will be operated in final position by gantry cranes and 12 will be operated in final position by gantry cranes and 12 will be operated by fixed hoists.

All concrete had been placed in Iroquois dam by mid-September and cofferdam had been breeched. Only final removal of cofferdams, installation of gates and gantrys and cleanup remained. Final completion is expected in December. Ontario Hydro was to take over operation of the dam early in October and water level in the pool upstream was to be raised some 6 feet by mid-October to present Lake Ontario level at Ogdensburg.

At the Massena intake some 200,000 cubic yards of concrete had been placed by month-end and gates were installed. All construction here will be completed by the end of November and cleanup will be finished by the end of February.

Progress by SLSDC

All concrete had been placed in both the Eisenhower and Grasse River locks, and installation of lock gates and machinery was under way by the end of September. Both locks will be fully completed for the opening of 14 foot navigation next July. Only a million cubic yards of excavation remained to complete the Long Sault canal, with final completion expected by year-end.

Progress by SLSA

Activity continued on all aspects throughout September with employment equaling or exceeding that of August. At the Iroquois lock the second stage cofferdam was flooded early in the month, and clearing of the channel for navigation continued. The rolling lift bridge was in operation, sump pumps, gate operation machinery and electrical equipment were being installed and standby diesel generators were delivered.

At Beauharnois lower lock, 68,000 yards of rock were removed in September, and 36,000 yards of concrete were placed, bringing total to 160,000 yards placed to date. Two thirds of the chamber walls were complete to full height and the approach walls were started both up and downstream. At the upper lock 520,000 yards of earth and a million yards of rock had been excavated to month-end and 90,000 cubic yards of concrete placed at the upper and lower ends where gates and machinery will be installed.

Long Sault dam. This view shows, left to right, the Stage 1 structure, the Stage 2 spillway section and the north bulkhead.

The lock structure at Cote Ste. Catherine was nearly all poured to full height and the floor completed. 83,000 yards of earth and 213,000 yards of rock were moved during September, while 38,000 yards of concrete were poured, bringing total to 285,000 yards. No installation of gates or machinery had been commenced. At the St. Lambert lock 98 per cent of the concrete had been placed and installation of taintor gates, valves, etc., was about to commence.

Elsewhere, the suction-dredging contract at Welland lock No. 1 was completed during the month, while most of the other channel excavation and dredging continued at or close to schedule.

On the bridges in the Lachine section, the new Jacques Cartier through-span was erected including walkway, and downstream trestle to support the existing deck span when it is removed was being erected. All of the piers at south end of the Honore Mercier bridge were completed. On the C.P.R. Caughnawaga rail-bridge, piers for the new lift-span were poured to full height and lifting and ballasting of the railway south of the bridge were under way. At Victoria bridge a derrick and erection equipment was being set up, while a building platform for erection of the lift-span had been placed. Timber cribs for a road underpass and a retaining wall along the dike were built and some of the fill placed.

On the substructure for the new international high-level highway bridge over the St. Lawrence river near Cornwall, to replace the Roosevelt rail-highway bridge, approach trestles at both ends were completed and work on the main river piers was proceeding, with completion of substructure scheduled for February. The old bridge has to be removed by July 1, 1958. Removal will commence after the ice goes out in the spring and traffic will be carried by a ferry until completion of the superstructure by SLSDC.

Seaway News

Limitation to size of ships through seaway locks to 25½ ft. draught, recently announced, is bringing about new designs by naval architects for new types of 'ocean-seaway' type vessels, able to operate both 'inside' and 'outside'. These new dual purpose carriers will be radically different from anything seen on the Great Lakes up to the present.

Highlights of this new type of vessels are:

—variable pitch propellers to permit manoeuvering on the propeller rather than on the engine, — navigating bridge aft for easier cargo handling, —accomodation for ocean-going fuel and water supplies, not needed in 'lakers' with their ready access to fuel and fresh water, — integrated package-freight handling, with palletized fork-truck operation replacing traditional mast and boom handling, package freight carried on between deck and tank top, autos on top deck. — interior cargo space free of stanchions. Long deck hatch allows carrying steel girders of maximum size. Ocean-type deck hatches equipped to add mast and boom for all ocean runs in winter months.

Naval architects see more to be gained from improved cargo-handling than from atomic power. Cargo handling costs make up a third of a general cargo ship's operating expense, with fuel costs only amounting to about 12 per cent.

It is generally agreed 80 per cent of the expected total seaway trade will be in ore, grain, oil and coal. This is the type of cargo that the 'lakers' always handle most economically. But general cargo, — what importer, exporters and ocean shipping lines look for, — will amount to between 6 and 11 million tons yearly. This is the trade the new type ocean-seaway vessels will compete for. Another advantage claimed for them is adaptability for ocean traffic during the winter freeze-over on the seaway. They may also bid for the Labrador ore run to upper lake ports because winter earnings will make up for smaller cargo capacity through seaway locks in summer.

Water Diversion Delayed

The attempt to divert an extra 1000 cubic feet per second out of Lake Michigan into the Illinois waterway has been abandoned for 1957. An effort was made to push through the proposal without hearings before the Senate Public Works Committee but this was beaten down. Now, hearings will resume in congress early in the next session in January.

The 'Chicago Water Steal', so labelled by Wisconsin Senator Alexander Wiley, was twice approved by congress, and each time President Eisenhower vetoed it because of Canadian objections. But because Lake Michigan is entirely in U.S. territory supporters view the diversion as strictly an internal U.S. affair. Illinois congressmen, gathering heavy support will make a determined effort to push the measure through.

Dispute Over Filtration Plant Costs

City officials of Cornwall Ontario are trying to get Ontario Hydro to pay part of the cost of the city's $2.2 million water filtration system. They point out that the New York Power Authority has agreed to pay between $400,000 and $600,000 towards the cost of a new sewerage plant being built by the town of Massena, N.Y. They claim it is unfair for Canadian money to be spent towards the sewerage plant while none is available for the Cornwall filtration plant. The power phase of the seaway project is split 50/50 between Ontario Hydro and NYSPA. Ontario Hydro claims turbidity of the water for Cornwall will not be increased, nor will pollution be such as to require filtration treatment.

Prairies Ask For Port Survey

Manitoba claims the three prairie provinces are agreed that Ottawa should launch an immediate survey of port requirements at Ontario's Lakehead. Manitoba's minister of industry and commerce, F. L. Jobin, says Western Canada will use the Lake Superior port of Duluth, Minn., instead of the Lakehead if the latter's facilities are not made adequate. He warned in September that Manitoba, Saskatchewan and Alberta intend to make a joint request that Ottawa should accept its responsibility in developing the Lakehead, and hire a consulting firm to make a full study of requirements.

New Plant Sites Opposite Detroit

An 1800 acre industrial site on the Canadian shore of the Detroit river is being developed at Ojibway, midway between the Montreal and Chicago terminals of the seaway. It has a mile-long frontage. Included in the property are warehouses, a wire mill and, a deep water slip with wharf and double tracks capable of berthing seven ships. Since its sale to a group of Chicago businessmen early in September the purchases have added 400 additional acres to the site. The original 1400 acres were purchased at a price of $10½ million.

Here, bonded warehouses will provide for overnight delivery in the general Chicago area and points further south and east. Shipments could be transhipped by rail and arrive in Chicago in eight hours via the N.Y.C. rail tunnel. Facilities of the C. and O. could be used in much the same way to points such as Milwaukee.

U.S. Toll Conferences

At the first open conference on means of establishing and collecting tolls, held in Washington, September 9, SLSDC Administrator Castle publicly rejected proposals for a toll-free seaway. Representatives of ship lines and shipping interests endorsed tolls to assure the seaway would be self-supporting and repay its cost in 50 years. A majority opinion appeared to favour tolls based on size of vessels and weight of cargo.

Mr. Castle said the estimated $2 million for annual operation and maintenance appeared more than ample to cover all out of pocket expenses for the U.S. portion of the seaway. Lyndon Spencer, representing the Lake Carriers Association, voiced opposition to tolls. His group realized that tolls were necessary to obtain participation by the U.S. in the opening of the Great Lakes to commerce of the world. However, bulk cargoes and bulk cargo vessels in ballast, he maintained, should be as nearly toll-free as possible.

At hearings before the SLSDC Toll Committee at Chicago on September 11, M. M. Cohen, general manager of the Chicago Regional Port District, held it would be difficult if not impossible to liquidate the investment through tolls collected in a period of 50 years.

Several speakers expressed the view that the Welland canal was not part of the seaway and that it should remain free. Canada, they observed, had gone on record that the Welland will be tolled to recoup the cost of improvements done in connection with the seaway. On the other hand, the U.S. corps of Engineers was spending more than $100 million to improve the Great Lakes channels and this is not to be paid off through tolls.

Canadian Toll Conference

At the one day public hearing on the tolls question at Montreal on September 19, sponsored by Canada's Seaway Authority, no-toll supporters described tolls as 'foreign to Canadian tradition', and 'not in the national interest'. The Dominion Marine Association declined to discuss a tolls formula. They disclosed a brief submitted privately to the Minister of Transport, forecasting initial traffic of 20 million cargo tons in 1959, increasing in the following ten years to 3 million tons. This DMA estimate is far below previous unofficial figures of 36 million tons the first year.

Some briefs submitted flatly advocated a no-toll seaway but added that if free passage was impossible the toll structure should be the lowest possible. Only the Railway Association of Canada brief, representing 22 railroads, asked for an 'equitable' toll high enough to amortize costs and operation over 50 years.

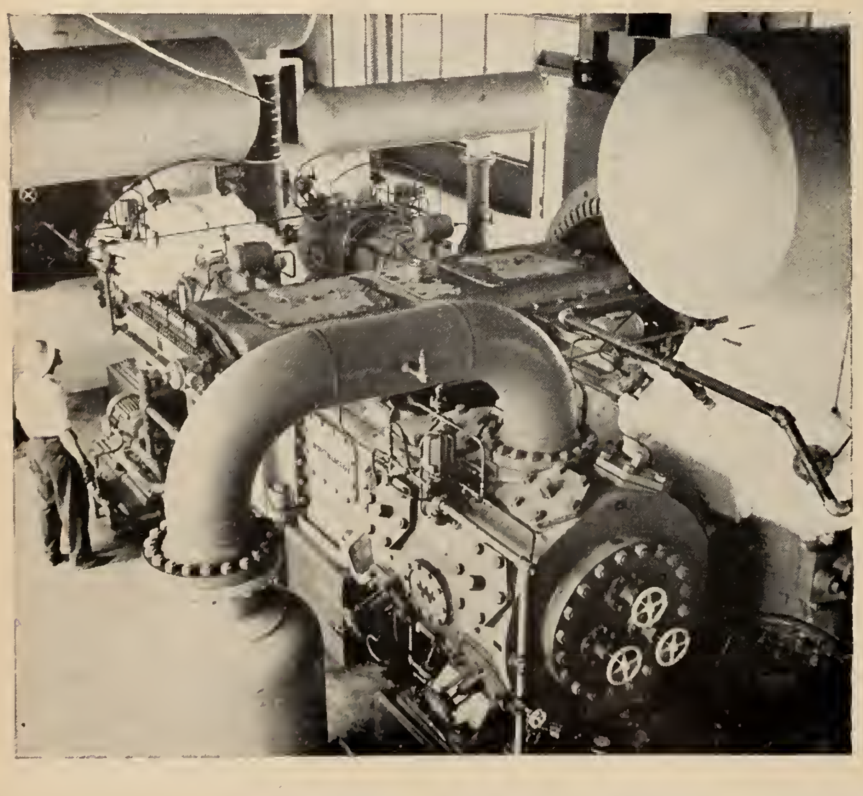
The Canadian tolls committee is working on a dual system, — a low rate on ship tonnage and a higher rate on actual cargo tonnage carried. Canada Steamship Lines said the composite structure was sound if tolls must be imposed. But to protect domestic shippers it wanted a higher toll for general cargo to or from foreign ports.

Canadian Pipeline Projects

At end of September, with Westcoast Transmission's construction completed and filled with Canadian gas, about 95 per cent of the distribution system of Inland Natural Gas was completed in market areas and construction of 24 city gate services was nearing completion. Natural gas had reached Savona and was being used to clean the system.

British Columbia Electric Company expects to be delivering Canadian gas by year end, not only to the entire Vancouver area but will also be serving Burnaby, North Vancouver and New Westminster.

Carbide Chemicals. These refrigerant-compressors form part of the Carbide Chemicals Company low temperature equipment, at Montreal East. A multi-million dollar polyethylene and petrochemicals plant was added to the Montreal East operations of the company recently. The highly specialized equipment at the plant is used to convert petroleum refinery gas concentrates into ethylene oxide, ethylene glycol, other ethylene oxide derivatives, and polyethylene. The chemical reactions are carried on in tanks, towers and 436 miles of pipes. Raw materials are supplied by three of the neighbouring refineries. The complex production processes require extremes of heat and cold and tremendous pressures.



Trans-Canada Pipelines

With the 34-inch western section completed as far as Winnipeg and filled with Alberta gas, attention was focussed on the race to reach Lakehead with the Crown Pipeline before winter. Work was proceeding at a crawl on the triple channel crossing over the Winnipeg river near Kenora, Ontario, one of the toughest river crossing jobs in Canadian history. Here three drilling barges were in operation, with right of way being cleared and graded for twin pipelines. Between Winnipeg and the Ontario border, completion was expected by mid-October. Further east, confidence was expressed that the Toronto - Montreal 310 - mile section would be laid and testing completed before year-end.

In spite of an explosion on the Trans Canada pipe two miles west of Babot, Manitoba, which left a crater 100 feet wide, 240 ft. long, and 20 ft. deep, repairs were completed rapidly and natural gas was turned on at Regina the following day, making it the first city to receive gas via the Trans Canada Pipeline.

Winnipeg and Central Gas

Company has 250 miles of mains ready to receive Alberta gas, expects 4000 residential customers by year end, to add to the 15,000 it now has.

The Public Utility Board has set rates, lower than those asked by the Company but higher than the City contended they should be. Estimated cost of heating an average home, — $199; average cost per 1,000 cu. ft. — $1.03. Competition at lower rates from Great Northern Gas Utilities at Brandon, and Great Plains Gas Co. are ruled out by Trans Canada, which considers itself bound by contract to serve gas exclusively to Winnipeg and Central Gas Company.

Northern Ontario Natural Gas and Twin City Gas

These associated companies expect to serve 34 communities between Kenora and Orillia, six of which will be served by Twin City. Construction is proceeding on the Kenora lateral. Work on all 34 systems will be underway next spring. Biggest jobs will be the Trans Canada 82-mile lateral to Timmins. All engineering will be done this fall and winter so contracts can be let early in 1958.

Union Gas Company

With deliveries of 26-inch pipe commenced in the last week of September, welding and laying of pipe was under way on its 142-mile line to Hamilton at month end. Distribution systems were under construction at Stratford, Guelph, Strathroy, while franchises were being awaited at Kitchener, Waterloo, and St. Marys. United Fuel Investments was starting to convert parts of Hamilton to natural gas in mid-September. Some of the city will not be converted until early 1958.

Consumers Gas Co., Toronto now distributes imported natural gas to areas from Brampton and Streetsville on the west, to Bowmanville on the east, and north to Newmarket. It has a franchise to serve Bradford and six major communities along the Georgian Bay to Owen Sound. Through Provincial Gas, its subsidiary, it serves Fort Erie and Niagara districts and has acquired control of Inter-provincial Gas at Ottawa and Hull. It has a franchise for Brockville and is competing for service to Kingston and points along the Ottawa Valley. Company now plans a $750,000 distribution line to Lindsay.

Additions this year include 28 miles of 12-inch main and 63 miles of 10-inch, 8-inch, 6-inch, and 4-inch mains at a cost of some $4.3 million. The grid or feeder program has been completed and is now being filled in with distribution lines.

Lakeland Natural Gas: Company has 775,000 feet of pipe on hand for city and town distribution systems. Contract awards are pending in 19 municipalities where certificates are received from the Ontario Fuel Board in the area between Port Hope and Cornwall. It is expected a large proportion of the pipe will be laid this year. Large pipe comes from Page Hersey Tubes Ltd. One hundred and forty-three thousand feet of ¾-inch service pipe has been purchased in Scotland. Work will probably be started at Port Hope, Trenton, Coburg, Belleville and Cornwall.

Quebec Natural Gas: With some 10 miles of the 34 miles of 24-inch to 16-inch main completed across the island of Montreal by late September, work on this was expected to be completed by mid-November. Laying of the distribution system was proceeding on the eastern half of the city. Some 400 men were at work on conversion surveys of customers' requirements in 40 conversion districts. If the Trans Canada line from Toronto is completed by January to link up at the west end of Montreal island, an interim gas supply will be available from the Sarnia area of Union Gas Company. But Montreal customers will not then receive natural gas until conversions of present appliances are completed in the spring.

Tennessee Gas: It was reported late in September that a substantial portion of its holdings of Trans Canada shares had been sold by Tennessee Gas Transmission Co., most of it to a Canadian Oil Company. The amount sold represented close to a third of Tennessee's holdings. It is hinted another one-third of Tennessee's holdings are offered for sale with the same oil company as likely purchaser. These sales, if completed, would substantially boost Canadian participation in the project, possibly effecting a majority of ownership in Canada.

Pipeline News

Alberta and Southern: J. K. Horton, Alberta and Southern Gas Company president, predicted in September that total expenditures in Canada over the next five years would total nearly half a billion dollars on the Alberta-California pipeline. Construction would cost $142 million and operating expenses over the initial five year span would amount to $107 million. In addition, purchases of Canadian gas would exceed $100 million, exploration and development by producers would cost $100 million, and $75 million would be invested in gas processing plants.

Annual payments in excess of $20 million would flow from the U.S. into Canada in payment for gas. The proposed line would have initial daily delivery of 450 million cubic feet, and would run from Alberta to the San Francisco Bay area, he said. If necessary clearances were obtained from Edmonton, Ottawa, and the FPC, construction could be started in 1958, with a completion scheduled for late 1960.

Alberta and Southern will pay some $100 million to Shell Oil Co. over the first 10 years of operation for 200 MM c.f.d. of gas from Waterton-Sarcee, Crossfield and Holmglen Rimbey fields. All the gas from these fields plus all gas discovered over next 10 years in Southern Alberta up to a total of 5 trillion cubic feet will be purchased.

Appliance Sales Booming

Counting in equipment for use with propane, some 25,000 gas stoves, water heaters and other gas appliances were sold in Saskatchewan in 1956, and indications point to a higher sales total in 1957. Saskatchewan Power Corporation has now natural gas for heating Regina homes, and plans to extend the service to Melfort, Tisdale, Yorkton, Melville, Estevan, and Weyburn. Extensions are also nearing completion in Wilkie, Kerrobert, Chaplin and Maple Creek.

Emphasis on Gas Exploration

Wildcatters in Alberta are looking primarily for natural gas reserves today, with oil discoveries ranking as second finds of limited economic value, — a situation unheard of up to even a year ago. Large pipeline companies are hard pressed to find enough gas to meet potential demands. Westcoast Transmission will need 600 million cubic feet daily from the Peace River. Trans Canada will need a billion feet daily within a few years, while the Alberta and Southern project will need 450 million cubic feet daily to start with.

TRAFFIC across the Jacques Cartier bridge at Montreal returned to normal at 10.30 Sunday morning, October 20, after a five-hour shutdown to permit engineers and workers to roll away the 250-foot deck span that crosses the seaway channel on to a dismantling trestle, and to roll a new through span from the erection trestle upstream, into its place on the bridge, a distance of 78 feet.

Both new and old spans were mounted on roller trucks, each resting on runways of seven rails. The spans were coupled and two hydraulic jacks, with pressure of 3,000 pounds per square inch, provided the power to move the spans sideways on the runways. Total weight of the two spans was 3,100 tons. Engineers described the shift as "a world's first in structural steel moving technique". Hon. George Hees,

"Translation" of Span, Jacques Cartier Bridge

Dominion Bridge Company replaced a deck span with a through span over the channel of the St. Lawrence seaway, interrupting traffic over the Jacques Cartier bridge for only five hours on October 20.

Photos by Hans van der Aa

federal Minister of Transport, and Charles Gavsie, SLSA president, watched the operation. Mr. Hees described it as "a Canadian engineering masterpiece".

Dominion Bridge Company engineers have been working on the $7 million project for over a year. The 14 bridge spans affected have already been raised a few inches at a time by varying amounts from zero, to a total of 10 feet at the channel crossing, and have another 40 feet to go between now and the end of 1958. The new span has five traffic lanes, an indication the rest of the bridge will be increased to five lanes in the future. The old span will be dismantled. When the work is completed there will be a 180-foot clearance for vessels using the new seaway channel.

What Goes On

Building Design

A table of computed maximum snow loads and wind gust speeds has been furnished by the Climatological Section of the Division of Building Research, National Research Council, and is available from the Canadian Institute of Timber Construction, Ottawa 4, Ont. In the absence of any building code or by-law, or regulation of authority having jurisdiction, these climatological data may be considered an authoritative basis for design.

Correction

The *Journal* is advised that incorrect information was published on Page 1009 of the July 1957 issue about the chimney of the St. Lawrence Cement Company plant at Clarkson, Ont.

The informed correspondent reports that no traps or filters are contained in this chimney, nor in any other cement plant stack known to him. The installation which the writer had in mind, evidently, is an electrostatic filter (recuperating somewhat over 99% of the dust in the gases) preceding exhaust fan and chimney.

The cost of such a single electrostatic precipitator, the correspondent further reports, including the multiclone, is about one-third of the sum mentioned.

Public Works Contracts

Contracts involving expenditures totalling $5¼ million were awarded by the Federal Department of Public Works during the month of September.

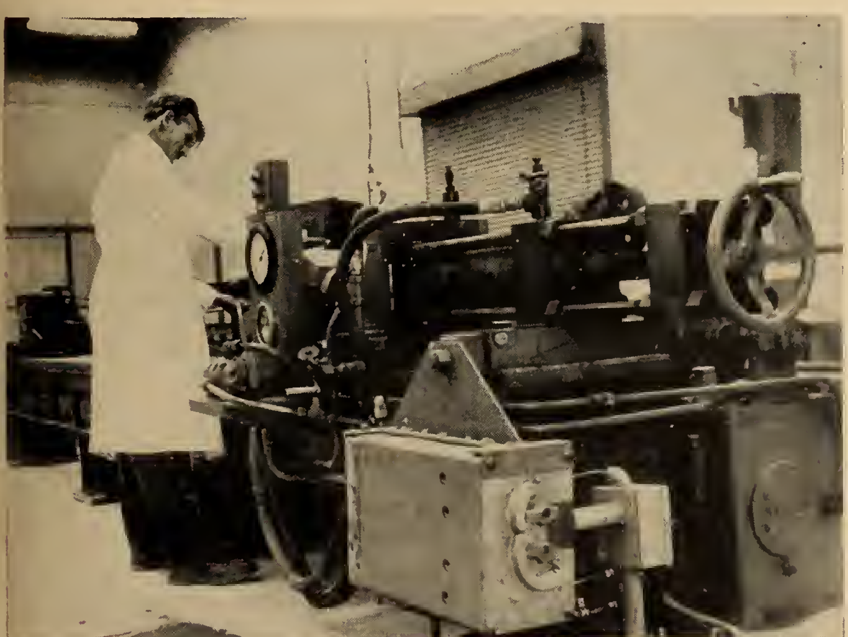
Largest items listed are the Terra Nova National Park, Nfld., Trans Canada Highway, grading, culverts, and traffic gravel, and construction of access road for approximately eleven miles, Concrete Products (Newfoundland) Ltd., St. John's Nfld., $1,635,250.; and construction of a new federal building for the Department of National Revenue (Taxation Division), Bird Construction Co. Ltd., Winnipeg, Man., $1,010,605.

Deas Island Tunnel

The "W. G. Mackenzie", a dredge with a capacity of 2,000 yards per hour, was to go into service on the Deas Island tunnel in November.

The hull was completely built by Yarrow Shipyards, Victoria. After installation of power machinery and equipment it was brought to Vancouver. It is owned by Marwell Equipment Ltd., and operated by B.C. Bridge and Dredging Co. Ltd., a subsidiary company.

Nuclear Plant. The new plant of AMF Atomics (Canada) Limited was opened in September at Port Hope, Ont. This is Canada's first privately owned and operated nuclear plant and laboratory. The primary objectives are: to manufacture fuel elements for NRX and NRU reactors at Chalk River and elsewhere, to design and develop new types of fuel rods, and to conduct research, development and production on research and power reactors. Rough rolled natural uranium is fabricated into fuel elements by heat treating, stretching, straightening and machining as illustrated. There will be by spring, 1958 the equipment to sheath the elements in aluminum cladding.



Nickel Supply

After years of scarcity and priority ratings, nickel should soon be in ample supply and readily available to industry throughout the free world, K. H. J. Clarke, of International Nickel Company of Canada, said recently.

That a smaller proportion of nickel production will be required for stock - piling is an encouraging thing for that reason, in Mr. Clarke's view. His company still plans to increase production to 385 million pounds by 1961.

Edmonton Cement Plant

The many large deposits of marl that exist in Alberta and Saskatchewan will be used in the manufacture of cement.

It is proposed by Imperial Cement Limited to build a cement plant at Big Lake, near Edmonton, where a 50-year supply of marl exists. The plan embodies use of feeder pipes and pipeline transportation.

A combination of lake water, marl and other ingredients, while in transport would carry out the initial production providing slurry for cement production. The pipeline in this way would deliver basic materials to the plant.

COMMENT AND CORRESPONDENCE
ELECTIONS AND TRANSFERS

The Canadian Conference on Education

An event unique in the annals of education in Canada will take place next February when about five hundred delegates will meet in Ottawa to focus attention on the objectives and needs of education in Canada in the next decade, and to seek ways and means to meet those needs. This conference is described briefly on p.1163 of the August 1957 issue of *The Engineering Journal.*

As one of the nineteen national organizations that are sponsoring the conference, the Engineering Institute of Canada is once again assuming the broader national responsibilities that must devolve upon groups of citizens who are banded together in associations by virtue of their special training and experience. Recent events have shown that professional men and leaders of business and industry are competent to consider our educational system, and groups such as the Engineering Institute have a fresh viewpoint and a large amount of useful background which enables them to make a real contribution — far more valuable than money — to the solution of Canada's problems in education. This is particularly true since it is generally believed that most of the difficulties are common to all, and are quite unspecialized.

In effect, the forthcoming conference will be a microcosm of our population, meeting with the objectives of:

(a) Having a truly representative group of Canadians attempt to define and delineate their common problems in education. It is hoped that this will be done in a realistic manner, devoid of "scare talk", and without passion or hysteria;

(b) Bringing the facts concerning these problems to the attention of the Canadian public. Since the conference is definitely not designed to cry havoc, it may be very opportune in averting any feeling of panic by its realistic approach. Conveying the true facts to the public should result in added emphasis on the ability of the Canadian people, and especially of the organized segments of our society, to face up to and solve our problems in education.

(c) Determining which of the problems can be approached on a common basis, and which may be best undertaken by specialist groups, and what the specific role of each group is to be.

Study of Nature Problem

Before the conference can function effectively, there must be the assumption that all participants come with an open — not vacant — mind. Only by this means will there be a chance of learning the true nature of the problems and of making an honest assessment of the various roles and functions necessary for their solution. This may, of course, require a re-alignment of many preconceived ideas, and much of the basic thinking that has been indulged in vis-a-vis Canadian education. And there will emerge a number of differences of opinion about what is lacking and what the remedies should be. It is hoped that these necessary differences will be construed by others as a sincere desire to help, rather than as criticism.

Finally, it is hoped that the consummation of the conference will not be confined to the process of some people passing a series of resolutions and briefs to other people. Rather, delegates should bring back to their sponsoring organizations the story of what has happened, giving a clear indication of the tasks that may best be undertaken by them. After all, we do have a responsibility to take action in this area, since we are talking about the future of our own sons and daughters, and about conditions in the neighbourhood school just down the street.

Cover Picture

The cover picture is typical of the "northern scene" being described by authors in this issue, showing icebergs and beach tanks at site of a northern construction operation.

Student Membership Drives

The student representatives of the Institute at the University of Toronto and at the University of British Columbia began their drives to recruit new Student members during registration week.

The accompanying photograph shows Norman Seagram, S.E.I.C., distributing Institute literature to a registering student at the University of Toronto. The display shown was part of a well-organized campaign, conducted under Mr. Seagram's supervision, to encourage engineering students to join the Institute. Mr. Seagram, besides being the E.I.C. student representative on the campus, is also director of professional relations for the Student Engineering Society at the University.

The Student Section of the Institute at the University of British Co-

Norman Seagram headed the student membership drive in University of Toronto. He is shown above, left.

lumbia conducted a successful membership drive under the direction of Shigeo Saimoto, the section president. By the first week of October, more than seventy applications had been received and a request sent to Headquarters for more literature and application forms.

The Sopron Forestry School

A year has elapsed since the School of Forestry of the University of Sopron, Hungary, was transferred to the University of British Columbia, after the Hungarian revolution of November 1956.

Now officially a part of the university, the Sopron forestry faculty is known as the Sopron division, faculty of forestry, with the status of a school parallel to that of the schools of architecture and physical education.

With the final result of the revolution to be evaluated by historians, the Sopron people have found a new life. Canada in turn stands to gain a number of able and enthusiastic foresters over the next four years. Although the Sopron division as such will then disappear, the work of those who were a part of it will contribute significantly to Canada's future.

Most classes in the division are being taught in the Hungarian language this year but some of the professors may be able to change over to English before the year is finished. Indicating their intention of converting to English as soon as it is possible to do so, they have been using English textbooks from the beginning. In addition to their own classes, Sopron students will receive a course of lectures on Canadian forestry from the faculty of forestry staff, aided by special lecturers. It is likely that they will mix with Canadians through the media of sports, clubs, and other student activities and will soon feel as though they "belong" to the University. An excellent attitude pervades the group and they are receiving full co-operation from other students in the somewhat difficult transition period with which they are faced.

Some of the Sopron instructors have registered in graduate work at the University in order to make the most of their opportunity for further education in Canadian conditions and methods. As Dean G. S. Allen has noted, their presence in classes will almost certainly have a stimulating effect. It is expected the faculty members will be assimilated into U.B.C. faculty of forestry. Industry leaders have plans to provide Sopron students with forestry projects.

In spite of somewhat disappointing employment situation this summer, most of the Sopron professors and students found work in forestry, logging, or related fields. Many government departments and companies co-operated in helping to place the Hungarians and, as a result, they have acquired some good experience under our conditions, a better facility with the English language, and some savings to help see them through the University year.

Plans for housing the Sopron group have changed. Instead of operating a camp for them at the R.C.A.F. base at Sea Island, the government decided to encourage them to find private accommodation which would allow closer contact with Canadians. The Sea Island base is being operated

Dean Kalman Roller of the Sopron Forestry School is at right foreground in this photograph. In the group, from his left, are D. Udvardy, interpreter, U.B.C. zoology, Dr. F. Tusko, Sopron, John Phillips, U.B.C. Student, Dr. Jablanczy, Sopron, G. S. Allen, U.B.C. dean of forestry.

only as an assembly center until all can find other accommodations. Then it will cease to function. Classes began on September 23. Lectures are being held between 2.30 and 5.30 p.m., and laboratories between 6.30 and 9.30 p.m. In this way, university facilities are made available without adding to the already crowded conditions in the university.

Of a truly proud tradition Sopron University stood with Kossuth in 1848 in the Hungarian War of Independence. The professors were the technical consultants of Kossuth and they were the leaders of their own students who fought in the Hungarian army. When this first war of independence was crushed by the Russians, the school was closed only to re-open again one year later. After World War I Hungary was cut to pieces and Selmesbanya, the location of the school at that time was ceded to Czechoslovakia. The forestry school moved, lock stock and barrel to Sopron. It functioned uninterruptedly and with distinction for many years, until the advent of the Soviet regime. The active part played by the Sopron staff and students in last year's revolution was the reaction to twelve years of oppression, and it made flight inevitable. The forestry group included 200 students, 40 of whom were women, 17 faculty members and 65 wives and children.

The story of the transfer of the whole group to British Columbia is well known. The university, the federal and provincial governments participated, with the Powell River Company providing temporary accommodations at Powell River.

Dean Kalman Roller who brought the group to Canada had this to say for his foresters, "It is not an everyday occurrence that the students and staff of a university leave their own country to find a new home in order to be able to preserve their ideal of freedom and to live as free men. I believe I am not conceited when I say that our exodus shall be written on the pages of history to provide example and inspiration for generations to come."

Information for this item was obtained from U.B.C. and from an article in *American Forests*, May, 1957.

Papers for the Annual Meeting Quebec City, 1958

It is Council's wish to make it known to the membership that papers are being sought for the annual meeting in Quebec City next May. The Papers Committee is ready to receive suggestions or submissions, which should be addressed to Headquarters.

J. H. Budden, is chairman of the Papers Committee; members are D. H. Hobbs, H. L. Johnston, M. McMurray, W. B. Pennock, E. R. Smallhorn, H. S. Van Patter and L. P. Bonneau.

The program for 1958 meeting is already under way, with several papers in the approval stage. Since the meeting is in Quebec, a fair proportion of the papers should deal with developments in this province. If any are available in the French language, they will be welcomed by the Committee.

Elections and Transfers

At a meeting of the Council held in Seven Islands, Que., on September 20, 1957, a number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected.

Members: D. R. Best, Montreal, J. Bordan, Montreal, F. L. Brown, Montreal, H. B. S. Brownlow, Corner Brook, G. P. Dandois, Montreal, R. J. O. Daoust, Edmonton, R. G. Edkins, Ottawa, J. C. Gateman, Calgary, B. G. Goodings, Toronto, J. T. Kokotailo, Toronto, E. G. Lester, Toronto, M. G. Lockwood, Texas, B. Nebesar, Copper Cliff, G. T. Page, Montreal, N. J. Pappas, Montreal, F. J. Riendeau, St. Johns, Que., J. C. H. Roberts, Quebec, R. P. Rowe, Ottawa, W. T. D. Shaddick, Kingston, E. C. Smith, Toronto, H. M. Smith, Sackville, E. A. Steinbrink, St. John's, Nfld., G. C. Wallace, Vancouver, J. S. Wexler, Montreal, A. H. Younger, Fort St. John, B.C., V. Zachanko, W. Pakistan.

Juniors: A. Antrobus, Port Arthur, A. J.

The delegates to a recent meeting of the Engineering Draughting Practice Committee of ABC are shown here at Toronto.

Leopard, Montreal, D. O'Sullivan, Hamilton, C. M. Papion, Montreal, P. F. Phelan, Peterborough, J. Rutherford, Montreal.

Junior to Member: J. W. Brison, Windsor, H. P. Connor, Hamilton, R. A. Harnois, Quebec, A. M. Ibrahim, Port-of-Spain, A. D. North, Montreal, C. R. Parke, Montreal, G. W. Spratt, Vancouver, J. S. Williams, Montreal, B. Yarymowich, Quebec.

Student to Member: J. J. Booth, Montreal.

Student to Junior: P. E. Coulter, Toronto.

Students Admitted:

McGill University: M. W. Brodie, E. G. Naismith, A. S. Skinner.

Queens University: C. E. Kropp, H. M. Sanchez.

University of Toronto: P. R. Falby.

Student A.P.E.O.: B. D. Reigler.

Graduate: I. McDougall, B.Eng.Elec., N.S.T.C., 1957.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Member: G. C. Duthie; **Junior to Member:** M. M. Bright.

SASKATCHEWAN

Members: J. A. Chamberlain, A. E. Fraser, J. A. Harvie, W. L. Payne, F. C. Pickard, A. D. Scharf, B. A. Steuart, G. R. Stewart, V M. Whelen; **Junior to Member:** J. W. Campbell, I. F. Rogers; **Student to Junior:** H. M. Hill, C. A. Ing, T. J. Moynihan, W. J. Serne.

NEW BRUNSWICK

Junior to Member: L. H. Clifton.

NOVA SCOTIA

Member: D. A. Kean; **Junior to Member:** R. A. Bradley, A. B. Chisholm, G. P. Miller.

MANITOBA

Member: C. Vogel.

Engineering Draughting Practice

Statement of the chairman, Engineering Draughting Practice Committee of America-Britain-Canada on conclusion of sessions, October 7-11, 1957.

Delegates from America-Britain-Canada at Toronto have examined and considered the respective publications of these national standards bodies relating to engineering drawing practices, namely, American Standards Asociation Y14, 1-6; British Standards BS308; and Canadian Standards Association, B78.1.

The delegates have propounded recommendations, the implementation of which will eliminate any significant difference in principle so that drawings prepared in accordance with any one of these standards, when amended, will be capable of being readily understood and used in the factories of the countries.

This is the succesful culmination of a project which has been patiently pursued for some twelve years.

The result will greatly facilitate exchange and mutual understanding of designs and manufacturing data amongst the countries concerned, and eliminate the necessity for preparation of fresh drawings. By providing designers with a common form of technical communication, the results of this session should lead to lower costs and improved security. In a state of emergency, it will permit the assignment of component manufacture between the three countries, to take advantage of their manufacturing facilities, and so achieve maximum production.

A. N. Huddleston, Lt. Col.
October 11th, 1957.

History of ABC

ABC was originated by the Combined Production and Resources Board of America-Britain-Canada during World War II for the purpose of expediting the best possible use of materials, etc. The representatives were then Mr. William Batt, (USA), Sir Henry Field (Britain), and the Right Hon. C. D. Howe, (Canada).

The first major project of this committee was the unified screw thread.

The object of these 1957 meetings at Toronto has been to continue the unification of the engineering draughting practice standards of each of the three countries.

Those heading the delegations were: *America:* Prof. R. P. Hoelscher, General Engineering Department, University of Illinois; Urbana, Ill.; *Britain:* T. R. Houston, English Electric Company Limited, Rugby, England; *Canada:* Lieut. Col. A. N. Huddleston, Canadian Army, Ottawa; *Sessions Chairman:* Lieut. Col. A. N. Huddleston; *Deputy Sessions Chairman:* George Noble, Dominion Engineering Company Limited, Montreal.

Steering Committee: *America*, Louis Polk, Sheffield Corp., Dayton, Ohio; *Britain*, Stanley Harley, Coventry Gauge & Tool Co., Coventry; *Canada*, James G. Morrow, Steel Company of Canada Limited, Hamilton.

THIRTY-FIVE YEARS AGO

Comment on the Journal of November, 1922

Today's gaily-coloured covers of the *Journal* are in pleasant contrast with those of thirty five years ago, which bore the same modest buff-coloured cover month after month, inscribed only with the E.I.C. shield and the words: "To facilitate knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the profession and to enhance the usefulness of the profession to the public".

Today's issues average over a half inch in thickness, compared with issues half as thick in the 'thirties'. This reflects Canada's population growth from 11 million in 1935 to 16½ million today. It also reflects the nation's greater industrialization and its economic growth in the increased number of its pages of advertising, technical papers, and other reading matter. The number of Branches of the Institute has more than doubled as well.

New classifications of engineers have appeared such as petroleum, petrochemical, aviation, town-planning, radio, electronic and nucleonic —to mention only a few. Reading matter must now include subjects of interest to these groups. Members today seek to know what their fellow engineers are doing in other branches of the profession. They are keen to learn more about the exciting engineering developments that are at once the cause and the effect of Canada's current spectacular growth.

The November 1922 issue contained three technical papers: — "Valuation of Public Utilities", by R. A. C. Henry, M.E.I.C., "Fuel Problems of the Steel Plant" by E. E. Litz, M.E.I.C., and "Accident Prevention in Industrial Plants", by W. G. H. Camee, A.M.E.I.C., A report of the Committee on Classification and Remuneration of Engineers by its chairman A. H. Harkness defined the duties and qualifications for various grades from assistant chief engineer to junior aid. Ranges for proposed minimum and maximum yearly salaries were given as follows: — assistant chief engineer, $7,200 — no limit; grade II engineer, $5,400 — no limit; grade III senior assistant engineer, $4,200-$5,400; grade IV asistant engineer $3,300-$4,200; grade V junior assistant engineer, $2,400-$3,300; grade VI junior, $1,800-$2,400; grade VII senior aid, $1,200-$1,800; grade VIII junior aid $600,-$1,200.

In the editorial section were listed by-law amendments being prepared with respect to constitutional changes by the Legislation and By-Laws Committee of Council. Attention was called editorially to the prestige gained for the profession through the recent appointment by the federal government of Sir Henry Worth Thornton, K.B.E., an outstanding engineer, as president of the Canadian National Railways System.

Elections and appointments of members were noted as follows: A. L. Clark, Ph.D., B.Sc., dean of the Faculty of Applied Science of Queen's University was elected an Honorary Member of the Institute; S. J. Hungerford, M.E.I.C., was appointed vice-president and general manager of the Canadian National Railways System; H. S. Van Scoyoc, M.E.I.C., was appointed president of the Association of Canadian Advertisers; G. J. Desbarats, C.M.G., M.E.I.C., was promoted to the position of deputy minister of public works for Manitoba.

The Branches

The Saskatchewan Branch reported papers on "Waters of Saskatchewan for Boiler Purposes", "Highway Investigations and Specifications", and "Some Notes on Irrigation".

Subjects discussed by the Ottawa Branch included a paper on "The Automatic Control of Fire", by J. Grove Smith, B.Sc., F.R.S.A., Dominion Fire Commissioner, who pointed out that destruction of property in Canada in 1921 had caused an expense of $5.25 per capita, ten times greater than in any other country except the United States, resulting in insurance rates 5 to 10 times higher than in other countries. Fires had cost 300 to 450 lives yearly.

The London Branch reported an inspection tour of various points of engineering interest in that city, including waterworks, garbage incinerator, paving plant, sewage disposal and pumping station. The Moncton Branch had been addressed by W. C. McMullen of the New Brunswick Department of Lands and Mines, who dealt with mines and minerals of that province. The Cape Breton Branch heard a paper by K. M. Cameron, A.M.E.I.C., and S. C. Mifflen, A.M.E.I.C., on "Present Day Practice in Concrete Construction". Calgary and Niagara Branches heard papers relating to highways.

The Vancouver Branch recorded a tour of inspection of the Sumas reclamation project under the guidance of the Hon. E. D. Barrow, minister of the B.C. Department of Agriculture, and F. W. Anderson, M.L.A., A.M.E.I.C. The project involved the drainage of Sumas Lake and some 30,000 acres of arable land which was inundated during flood periods of the Fraser and Vedder rivers.

An active town planning committee was formed by the Branch, with the purpose of drafting a proposed town planning act. Efforts of this committee were rewarded by the proposed act receiving endorsation of the Union of British Columbia Municipalities at its annual convention.

Under 'Other Societies News', Calvin W. Rice, M.E.I.C., reported on his attendance as representative of the Institute at the International Engineering Congress at Rio de Janeiro in September. A council meeting of the Canadian Institute of Chemistry was held September 20 at E.I.C. Headquarters at which it was decided to work out an organization on a professional basis, and to hold organization meetings in Ottawa, Toronto and Kingston. Membership was reported at 277. The Legislation Committee had under preparation a model bill for the use of chemists in any province where it might be desirable to seek legislation, H.G.C.

Correction

The cartoon published on Page 1495 of the October issue of *The Engineering Journal* should have been accompanied by the following notice: **Drawing by Dedini, Copr. 1957 The New Yorker Magazine, Inc.**

The omission is regretted by the editors, and the co-operation of *The New Yorker* is gratefully acknowledged.

So You're Going to "Read" a Paper

Harold O. Haskitt, Jr.,
General Motors Institute, Flint, Mich.

Reprinted with permission from the
***Journal of Engineering Education*, January, 1957.**

WITH YOUR PERMISSION I'm going to assume that you have been asked to "present" or "read" a "paper" at a convention session of your primary technical society. Your topic has been selected and the session chairman has indicated a definite time limit. Now what do you do? If you are like most of us, you will probably get your notes together, *write* your "paper", have it mineographed, run through it aloud a time or two and then present it at the meeting by reading it in a none-too-effective way to your disappointed peers.

When you have finished, you breathe a sigh of relief and comfort yourself with the thought that you have made copies of the "paper" available in printed form—just in case someone didn't understand or remember what you had to say. If this has not happened to you personally, you perhaps can recall similar instances in convention situations where you have been the "listener" to such a talk. After such sessions you may have had the feeling, either as speaker or listener, that somehow it might have been better.

Somehow you were not satisfied that a good job of communicating had been done. But before you could get around to doing much thinking about how it might have been improved, you became involved in other activities and responsibilities which crowded it out of your mind until the next convention or the next speech. Toward the purpose of seeing what the speaker might do before his next talk, let's take a look at some of the elements in the complex process of getting ideas across to individuals in an audience.

Communication not presentation, of ideas involves more than the transmission of thoughts by you as a speaker to or at a listener. At almost the same instant that the listener is receiving the thought-content of the talk, he is also receiving clues which he uses to build an evaluation of you as a person: professional expert, colleague, and fellow human being.

These things directly affect his feelings and attitudes as a listener, and may well determine how much of the thought (content) he understands and carries away with him. When an audience member goes away from a convention meeting saying, "I came to hear the *man*, not just his paper. I could have stayed at home and got more out of it by reading the speech myself," isn't he saying to a speaker, "I want to know both *you* and your ideas — please talk *with* me on a person-to-person basis, not *at* me as if I were a cabbage-head?"

The fact that in listening, a person *feels* at the same time that he *thinks*, accounts for the fast-growing use over the past few years of the extemporaneous method of speech delivery. Each listener wants to feel that the speaker is carrying on a friendly, highly spirited, organized conversation with him (and others in the group) on a subject which is highly informative and interesting to both parties in the discussion. Now, what can a convention speaker do to improve his chances of communicating effectively? The following may suggest ideas to you which you may find at least worth thinking about if not worth actually using at some time.

Know Your Subject

It is almost too obvious that a good communicator must be saturated with his subject. The concepts you are going to discuss should be so thoroughly thought through that you will have no difficulty in capturing and recapturing the bases for each main point and its supporting details at the time you are bringing them out. Each idea expressed should stem from a clear-cut basis in thought, and, whenever possible, your visualization of ideas expressed should be vivid and intense.

Even the words you use should be carefully selected in terms of the pictures, concepts, and interest that they arouse, both in the speaker *and* the listener. For, generally speaking, the more a speaker knows and the sharper his perceptions are about a subject, the more interested he becomes in it, until he actually finds himself anxious to share it with others.

Organize For Your Listener

Body of the Talk. The main reason for organizing material is to help the listener understand it more completely, more rapidly, and more easily, even with a minimum of effort. This means then that the subject matter should be put together in a structural pattern which the listener can recall easily later on, and which he can recreate quickly for himself as the speaker is talking.

Main points should be limited in number (no more than five), and worded in a concise, clear, and interesting way. Explanations, illustrations, facts, and other supporting materials for these principal ideas should be selected to capture the greatest listener interest and understanding in the limited time allowed the speaker. If certain content materials will cause audience interest to lag, they should be simplified, eliminated or presented in a different way.

Introduction of the Talk. The function of the introductory portion of a speech is to get the audience warmed up and in a receptive frame of mind to understand and accept the main ideas to be brought out. During this period a listener is very busy trying to focus his attention and to evaluate the elements that go to make up your particular personality. At the same time, he is trying to establish in his mind the specific central idea and your approach to it so that he can build his own "speech" as the talk unfolds.

So, sufficient time should be spent in developing whatever is used to arouse interest and lead into the main subject so that the audience can establish a favourable and receptive listening attitude. In addition to stating the central theme, some indication as to how you intend to develop the subject may help the listener in recognizing relationships between ideas as the speaker progresses.

Conclusion of the talk. Develop the conclusion so that the central and main ideas are clearlv reinforced. Audience interest should be maintained at a high level right up to the last syllable.

Write and Re-Write

A paper that is to be published as an article after it is delivered as a speech will involve re-writing at least twice, and perhaps more — first as an article, then as a speech. Re-writing during the preparation of the article allows you to weigh and select words carefully, to cast them into phrases and sentences which will carry the precise meaning you want to convey to your *reader.* If you try to use the written paper as a manuscript from which to speak, however, you may have some difficulty.

Normally, the way we write and the way we speak differ considerably, primarily because of the contrast between a reader's situation and that of a listener at the time each is receiving the information. If a silent reader doesn't understand what is written the first time he reads it, he usually has time to go back and re-read a given sentence, paragraph, or even page before he goes on the next unit. A listener, by contrast, has no "second chance," so-to-speak. He must get the speaker's meaning immediately because he usually cannot or does not ask the speaker to stop and repeat so that the puzzling sentence or unit can be "re-heard."

This obviously means that a speaker's language must be as simple and concrete as possible, his sentences relatively short, and his organizational pattern easy-to-follow if he is to communicate successfully. If you are going to read your paper aloud, consider re-writing it in the language and style you personally use in speaking, so that you will be direct and conversational in your approach to the audience. Incidentally, you may be surprised how much easier it is not only on you but also on your listeners.

Sharpen Your Speech Delivery

In the actual delivery of the speech there are obviously two major methods available to you, both of which are equally effective if done well. One, already mentioned, is to use the written paper in developing a speech manuscript suitable for easy, conversational, oral reading. The other is to speak from a brief outline or notes.

During the preparation stage of either of these two methods, one way to assure coverage of all the main ideas and supports, and at the same time to find the best way for you to express these ideas aloud, is to develop a good old-fashioned outline in standard form, including introduction, body, and conclusion. If you use the first method of delivery (speaking from a manuscript) it will help you to find and decide upon certain word choices and ways of putting sentences together which will allow you to be conversational and direct with your audience. The resulting style will make it much easier for you to feel and *think* the ideas *as you are reading the words.*

Once you have settled upon the exact wording and sentence structure for the completed speech manuscript, it should be rehearsed aloud word for word, with as much meaning and real feeling behind the ideas as you can get. Continue revisions until you are satisfied that the manuscript will allow you to be yourself.

A tape recorder can be an excellent aid to you, not only in the process of developing the final speech manuscript, but also in improving the way you read it aloud. If you record your practice readings and listen carefully to the playbacks, you will hear many things which will encourage you. You may also hear a few things you might like to change, such as putting more emphasis upon certain important ideas, developing more speaker-interest in parts or even throughout the talk, or sharpening your person-to-person manner of talking while you read — to mention only a few.

If you find it easier to maintain audience interest by speaking from a brief outline or notes, the use of a tape recorder during practice sessions will give you additional help in spotting areas where you may wish to strengthen your own concepts, or perhaps make even better use of your voice in getting the intended meaning across. A few such recording and playback practice sessions can be very rewarding.

"See" Each Listener

During the actual delivery of the talk at the meeting, a speaker needs his own continuous index of "feedback". That is, he *must establish and maintain* definite *eye contact* with as many individuals as he possibly can during the speech, so that each person will feel that *he* individually is being included in the speaker's audience. By this means you can evaluate your own progress and success in getting your thoughts and feelings across and you can adjust accordingly as you move along. When visual aids are used, you should be so familiar with their nature and content that good eye contact with the group can be maintained even while working with the aid.

One last word about the speaker's *enthusiasm* both before, and on the day of the talk. You not only should check your visual aids and other materials before the meeting time, you should also prepare yourself psychologically. Your feelings of friendliness and enthusiasm about your subject matter and the opportunity to share it with your peers in this particular group of associates and other professional people must be so vital and intense that they will be infectious to everyone, even those in the back row. Let the group share with you the proper pride you have in your subject, your chosen profession, and in your status as a fellow human being.

A little spontaneous feeling can send a thought a long way.

BRITISH COLUMBIA

Municipal Engineers Convene

Paramount importance of engineering services to the community was stressed by Major - General C. A. P. Murison, Reeve of North Cowichan, B.C., in his keynote address at the annual banquet of the B.C. Municipal Engineers' Convention in Victoria, September 13.

The Big Five

"The big five services for which local government is responsible," he said, "are Education, Health and Welfare, and the three engineers' services — roads, water, and sewers. While the first two only affect some of the people some of the time, the last three concern all of the people all the time."

Stating that the dominating factor is finance, he reviewed the statutory obligations, over which local councils have no control, for devoting most of their budgets to Education and Health and Welfare. While municipal funds derive from taxes on property, they must be mainly spent on services to people which, General Murison contended, should be more logically provided by provincial and federal revenues. Services to property are thus caught in a squeeze which gets tighter with the growing demands of our expanding communities, the practical limits of property taxes, and the increasing requirements of social services.

Citing the aggregate municipal revenues in B.C. for 1955 as $91,000,000.00, he said that 21% was ear-marked in advance for school boards, and only 11% or $9,750,000.00 was left over for essential public works. His conclusion was that a more equitable distribution of provincial and federal revenues must be obtained from the senior governments.

General Murison then traced the problems of municipal administration, with penetrating comments and advice on the separate functions of elected and permanent officials, in an address that was remarkable for spontaneous humour and polished delivery as well as for thorough knowledge of the subject.

Members of the 1957-58 executive committee of the Municipal Engineers' Division of the Association of Professional Engineers of British Columbia elected at their convention in Victoria, September 13-14 are: seated, left to right, H. D. Dawson, P.Eng., of Saanich, past-president; G. P. Harford, P.Eng., of Prince George, chairman; A. S. G. Musgrave, P.Eng., of Oak Bay, honorary secretary; T. G. deWolf, P.Eng., Vernon. Standing, left to right are: J. F. Millican, P.Eng., Tadanac; J. A. Merchant, P.Eng., of Vancouver, secretary; H. T. Libby, P.Eng., Vancouver; A. G. Shore of the Municipal Suppliers Association. A. Stewardson, P.Eng., of New Westminster is not shown in the photograph.

Three Hundred Attend

This was just one of many highlights of the 15th annual meeting of the Municipal Engineers' Division of the Association of Professional Engineers of B.C. A total of 300 people, including municipal engineers, public works officials and suppliers were in attendance from 50 B.C. communities as guests of Saanich Municipality. Sessions were held in the Empress Hotel, Victoria.

On September 12 a number of delegates, under the guidance of their hosts, visited the Federal Dry Dock at Esquimalt, Victoria's new Point Ellice Bridge, and municipal installations in Saanich and Oak Bay.

The following papers were read and discussed: "Air Pollution Control" J. Satterthwaite, Smoke Inspector, City of Vancouver; "Storm Water and Open Channels" D. A. Welsh, assistant municipal engineer, District of North Vancouver; "Photography and Records", H. T. Libby, Manager, Gas Distribution Dept., B.C. Electric Co. Ltd., Vancouver, B.C.; "Location of Utilities", D. A. Whelan, Associated Engineering Services Ltd., Vancouver, B.C.; "Time and Method Study for Municipal Engineering", L. B. Kellogg, Stevenson and Kellogg Ltd., Vancouver; "Uses of Asphalt as Applied to Smaller Municipalities", S. J. Cunliffe, Partner, Willis & Cunliffe, Consulting Engineers, Victoria, B.C.; "Administration and Management", J. C. Garnett, City Engineer, Victoria, B.C.

General Chairman was H. D. Dawson, retired municipal engineer of Saanich.

Next year's convention will be held in Prince George, under the chairmanship of George P. Harford, P.Eng., City Engineer. Elected to the 1957-58 executive committee were: George P. Harford, P.Eng., (Prince George), chairman; H. D. Dawson, P.Eng., (Saanich), past chairman; T. G. deWolf, P.Eng. (Vernon); H. T. Libby, P.Eng., (Vancouver); A. Stewardson, P.Eng., (New Westminster); J. F. Millican, P.Eng., (Tadanac); A.S.G. Musgrave, P.Eng., (Oak Bay), Hon. Secretary; J. A. Merchant, P.Eng., (Vancouver), Secretary.

Engineers in the News

John E. Liersch, P.Eng., past president of the Association, has been appointed to the newly-created post of executive vice-president of the Powell River Company Limited. He has been vice-president in charge of forestry and logging operations for the company since 1950. Before the war Mr. Liersch was head of the forestry department at the University of British Columbia; during the war he was granted leave of absence to work for the Dominion Government in turning out spruce for mosquito bombers. In 1947, he joined the Powell River Company and has been a member of the Association since 1936.

R. C. Herman, is attending a school of international business administration in Geneva for a year beginning in September. His address is c/o Centre d'Etudes Industrielles, 4 Route de Drize, Geneva, Switzerland.

J. A. C. Ross, P.Eng. a mining engineer, has resigned from his position as general manager of The Granby Consolidated Mining, Smelting and Power Co. Ltd. With the permanent closing of the Copper Mountain Mine, Mr. Ross chose to resign rather than remain with Granby and assume a position of lesser responsibility. He intends to take up permanent residence in Vancouver, B.C. Before seriously considering other employment, Mr. Ross will be attending the "across Canada" tour of the Sixth Commonwealth Mining and Metallurgical Congress.

J. M. Hunter, is now employed by the B.C. Telephone Company.

Grant Irwin a graduate of U.B.C. in 1956 in mechanical engineering, has taken a position with Dominion Bridge Company, Limited.

William R. P. Porter, P.Eng. of Toronto has been appointed general manager of Lucky Lager Breweries Ltd. Mr. Porter is a graduate of the University of Toronto in mechanical engineering. He has had previous experience in British Columbia in the brewing, lumber, and plywood industries.

ONTARIO

Engineers In The News

W. J. M. Redwood, P.Eng., safety engineer of the Algoma Steel Corporation, Sault Ste. Marie, Ont., has been honoured for his many years of public service through the St. John Ambulance Brigade by appointment as a Serving Brother of the Order of St. John.

The official communication from the Priory of Canada reads as follows:

"Her Majesty the Queen, the Sovereign Head of the Grand Priory in the British Realm of the Venerable Order of the Hospital of St. John of Jerusalem, has been graciously pleased to sanction the admission of W. J. M. Redwood as a Serving Brother of the Order of St. John."

Mr. Redwood has been safety engineer with Algoma Steel since moving to Sault Ste. Marie some 15 years ago. A past president of the Soo Safety Council, he was previously honoured by being presented with the King George VI Coronation Medal for his work on behalf of ex-service men and women.

J. D. Barrington, P.Eng., formerly president and managing director of Polymer Corporation Ltd., Sarnia, Ont., has become president and managing director of Ventures Limited with his headquarters in Toronto.

After his graduation in mining engineering from the University of Toronto in 1926, Mr. Barrington held many important positions in mining, metallurgical and petrochemical fields. In 1951, whilst vice-president and general manager of Dominion Magnesium Ltd., he was asked by the Canadian Government to become president of the Crown-owned Polymer Corp. Ltd., in Sarnia. In the succeeding years he played a very important role in the expansion of this organization.

G. L. Wilson, P.Eng., formerly with E. M. Powell & Associates Ltd., of Sudbury, Ont., is now with Sprostons Jamaica Ltd., a subsidiary company of Aluminium Company of Canada Ltd.

Mr. Wilson is in charge of civil engineering relative to the construction of a five-mile cableway which will carry bauxite ore from the mine, over a mountain, to an alumina plant under construction at Ewarton, Jamaica, some 30 miles from Kingston. Alumina will be shipped to Kitimat, B.C. for smelting.

Ross A. Ritchie, P.Eng., has recently been appointed vice - president, manufacturing, of the Electric Reduction Company of Canada Ltd., Toronto.

J. Craig Cringan, P.Eng., has joined the engineering design department of Atomic Energy of Canada Ltd., at Chalk River, Ont. A graduate in engineering of the University of Toronto, 1948, Mr. Cringan was previously employed by the Factory Mutual Engineering Division as resident engineer for Western Ontario.

Edward P. Innes, P.Eng., of Hamilton, Ont., has been elected a director of Canners Machinery Limited, Simcoe, Ont.

Mr. Innes is chief engineer of Canadian Canners Ltd., Hamilton. With the exception of service in the Canadian Army durng 1941-45, he has been associated with the firm since graduation from McGill University in 1934.

Geoffrey R. Pritchard, P.Eng., has been appointed general sales manager of Trane Company of Canada Ltd., Toronto and is responsible for the direction of the six departments within Trane's sales division—heating, air-handling, air

L. D. Wickwire, vice-president of the Association of Professional Engineers of Nova Scotia extends an official welcome on behalf of the Association to C. M. Anson, president of the Engineering Institute of Canada, on the occasion of his tour of the 48 branches of the Institute. Council of the Association were luncheon hosts to the E.I.C. president and general secretary following which Messrs. Anson and Wright and other distinguished guests attended a Council Meeting of the Association.

conditioning, advertising, sales promotion, student training and export.

Mr. Pritchard graduated in engineering from the University of Manitoba in 1937. For ten years he served as a sales engineer with Canadian Allis Chalmers. Prior to joining Trane he was with John Inglis Company for ten years, latterly as general manager of the refrigeration and air conditioning division.

E. de Haas, P.Eng., formerly cable maintenance engineer with Ontario Hydro, Toronto, has accepted a post with the U.S. Atomic Energy Commission in connection with a four-year project for building a nuclear accelerator at Princeton University, Princeton, N.J. Mr. de Haas, who is now located at the Palmer Laboratory in Princeton, is responsible for the power-electrical design.

J. David V. Adams, P.Eng. is in London, Ont., where he is taking the course in business administration at the University of Western Ontario. Mr. Adams, who graduated from McGill University in 1955 was previously with the design group of Canadian Industries Ltd., Kingston, Ont.

QUEBEC

New Tariff of fees Approved

The result of a joint effort of the committees on Tariff of Fees of the Ontario Association and the Quebec Corporation, the new Tariff has been used in Ontario for some three years now and was submitted to the approval of the membership in a referendum in 1955. Following its approval by the membership it had been presented to the Provincial Government for the official sanction of the Lieutenant-Governor in Council. Legal difficulties prevented its adoption until these could be solved last summer.

Salary Survey Aid

Montreal city authorities have given the Corporation assurances of cooperation in the conducting of a survey on the salaries of the engineers in its employ. Said survey is to be undertaken by the Corporation's Specialized Services Officer, B. R. Lachapelle, P.Eng., M.Sc., A petition was received signed by almost all engineers employed by the City, requesting the help of the Corporation "in convincing the municipal authorities of the necessity for the well-being of the profession as well as of the public in general, of establishing the remuneration of municipal engineers on a basis comparable to that prevailing in other positions held by members of our profession."

Sherbrooke U. Extends Course

Sherbrooke University, which has been offering the first three years of the engineering course, for many years now, has decided to offer its students the last two years of the course as well. Curriculum has been submitted to the Corporation and the Board of Examiners has found it satisfactory. If all goes well, Sherbrooke University will grant its first degrees in engineering in 1959. The course will be of a general nature but in view of the growing industrial development of the Eastern Townships, will offer a certain amount of specialization in electrical and mechanical engineering.

Referendum on Requirements

Referendum on uniform registration requirements is currently being held. The Corporation has long since favoured Uniform Registration Requirements throughout Canada and appointed a committee to determine how these requirements could be implemented in Quebec. The committee's recommendation was that the Professional Engineers' Act be amended to establish a class of "Junior Professional Engineers" and require two years of satisfactory engineering experience before granting full professional rights and privileges. At present, full rights are granted upon graduation from a recognized university or admission to the Corporation by the Board of Examiners.

Problems to be Aired

Considerable headway has been made by the Corporation's Committee on the Advancement of the Employee Engineer towards solving the major problems facing employee engineers. The Committee which is just a little over a year old, already boasts of several accomplishments: the problems of employee engineers have been clearly defined and substantial progress has been made in the study of the more important of them.

It is particularly interesting to note a province-wide basis with sub-committees operating in most of the areas of the Province under the supervision of the Coordinating Committee, composed of the chairman of the various sub-committees. This remarkable organizational structure is unique in the history of the Corporation, and makes it possible for almost all Quebec engineers to express their views on the subjects under committee study. Experience has shown that a number of Quebec engineers have already availed themselves of this opportunity and it is expected that this trend will continue.

Study of Employment Contract

This year, the Committee is primarily concerned with an investigation into the possibility of the Corporation sponsoring an employment contract stipulating the conditions governing the relationship between the engineer and his employer. The Montreal and the Quebec sub-committees are both working on this at present and indications are that a final recommendation in this regard will be made to Council before the current Corporation year is over. A final draft of the contemplated contract form is just about completed and a meeting of management representatives will be called shortly in order to obtain management's reaction to the contract approach as well as an assessment by them of the clauses contained in the draft prepared by the Committee. It might also be necessary to call on the Legal Adviser for a proper evaluation of the legal implications of the conditions stipulated in the contract.

Booklet on Employment Practices

Another of the major objectives that the Committee set out to maintain this year is the preparation of a booklet designed to give graduating students in engineering some guidance in their job-hunting activities. The feeling is that there is a need for such guidance and that it would be to the best advantage of both the engineer and the prospective employer in eliminating eventual sources of discontent. It is hoped that the booklet will be ready for distribution to the 1959 graduates.

Training at University Level

The Committee is also busy working out details of a course at university level covering the Professional Engineers' Act, the By-Laws and Code of Ethics, the history of the profession, the criteria of a true professional life, etc. Every effort is being made to get the fundamentals of this course worked out in the near future so that university representatives can be presented with the idea at an early date.

Publicity to be released

The Committee is presently working on releases to go to the membership as well as non-engineers in management, outlining certain principles of professionalism which the Corporation considers as essential if the recognition of engineering as a profession is to be fostered. These releases will pertain to utilization of engineering talent, criteria of adequate professional attitude, acceptable employment practices, etc.

Sub-Committee Members

There follows a list of the P.Eng.'s who compose the various sub-committees:

Montreal—W. T. Clarke, chairman, also chairman of the co-ordinating committee; L. P. Camirand, J. F. Davison, P. Demers, C. R. Houle, P. McCallum, M. P. Simon, and D. Wermenlinger.

Lake St. John — J. J. M. Falardeau, chairman; A. H. Johnston, M. Lavallee, H. S. Monahan, and S. T. Solinski.

Eastern Townships — Roland Dugre, chairman; J. Bourassa, Y. Chabot, R. Laliberte, P. D. Normandeau, M. St. Jacques, and J. F. Whyte.

Quebec City — Marcel Latouche, chairman; J. C. Bedard, P. E. Begin, R. Bernier, P. Bousquet, J. B. Delage, J. D. Gorman, and P. H. Lavallee.

St. Maurice Valley — W. W. Ingram, chairman; and M. C. Caron.

Ottawa Valley — J. S. Sudbury, chairman.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Clifforde Graham Moon, M.E.I.C., retired civil engineer with the Ontario Paper Company, St. Catharines, Ont., died in that city on September 13, 1957.

Mr. Moon, who was born at Ottawa, Ont., on September 28, 1885 was educated at Ashbury House School, Ottawa, and had naval training in Great Britain. Later, returning to work at engineering in Ottawa he was an assistant in the city engineer's office. Within the next few years from 1903 to 1911 he held appointments at Prince Albert, Sask., as city engineer; as an assistant in the firm of Willis Chapman, Toronto, and as inspector and assistant engineer with the Canadian Pacific Railway at Winnipeg and Vancouver.

His participation in World War I, was with the 87th Royal Canadian Engineers. He was at war's end associated with the Grand Trunk arbitration board. Engaged on the construction of the Welland Ship Canal in the early twenties, he joined the staff of the Ontario Paper Company on completion of the canal. He retired in 1955.

Mr. Moon joined the Institute as a Student Member in 1907, transferred to Associate Member in 1911. He became a Member in 1940 and was elected to Life Membership in 1947.

Captain Frederick Anderson, M.E.I.C., retired civil engineer, head of the Canadian Government hydrographic service Department of Mines and Fisheries, from 1925 until his retirement in 1936, died at Ottawa on September 21, 1957.

Two days away from his eighty-ninth birthday at the time of his death, Captain Anderson was born on September 23, 1868 at Charlottetown, P.E.I. He attended the Royal Military College, Kingston, Ont., graduating in 1890. For the first few years civil engineer on surveying work in New York, N.Y., he returned to Canada to join the Canadian Government service at Ottawa in 1892. Directing survey operations in the Lake Winnipeg area for some time he subsequently was assigned to all of the Great Lakes save Lake Michigan, in American waters, Hudson Bay, Labrador, and the Nova Scotia coast.

During World War I he was actively in charge of defence charting for the Royal Navy along Canada's Atlantic ports, much of it having to do with anti-submarine installations.

Between 1910 and 1914 Captain Anderson pioneered the Hudson's Bay seaway route leading several expeditions responsible for locating harbour facilities at Port Nelson and Churchill. The first vessel specifically designed for hydrographic work in Canada was placed in commission under his supervision in 1913 and it was during his time that electronic sounders and air photography were first employed in Canadian hydrography.

Captain Anderson enjoyed the unique distinction of being a hydrographic surveyor qualified to handle his own ship.

Captain Anderson joined the Institute as a Member in 1909. Life Membership was conferred on him in 1946.

Leslie Gordon Jost, M.E.I.C., consulting structural engineer, for many years resident in Los Angeles, Calif., died there on September 24, 1957, following an illness which caused his retirement January 1, 1957.

A 1908 graduate of Acadia University, with a B.Sc. degree, he was two years later awarded a civil engineering degree from McGill University.

Mr. Jost moved to California in 1919 and held responsible design and executive positions with the Llewellyn Iron Works, Consolidated Steel Corporation, City of Los Angeles Building and Bridge Departments, and private consulting engineering firms. During the last ten years of his engineering practice he was president of a consulting structural engineering firm.

In his long experience in the engineering field Mr. Jost has been associated with many industrial and commercial structures housing airplane factories in the Southland.

Mr. Jost joined the Institute as a Student in 1909, transferred to Associate Membership in 1913, to Member in 1938. He attained Life Membership in 1948.

Will Malcolmson Stewart, M.E.I.C., former deputy-minister of highways for the Province of Saskatchewan died at Regina August 22, 1957.

Mr. Stewart was born at Hamilton, Ont., on November 26, 1884. After completing high school in that city he attended the University of Toronto and graduated from the School of Practical Science in 1906, in civil engineering. The following year he enrolled in a post graduate course at that college, receiving the degree B.A. Sc. in civil engineering in 1909. He was commissioned as a Dominion Land Surveyor in 1907, a Saskatchewan Land Surveyor in 1910.

He participated in the subdivision of townships in the Lloydminster area of the North West Territories, in 1904, and a venture by canoe from Prince Albert, Sask., the following summer, to Fort Churchill and Port Nelson on the Hudson Bay. He was engaged in exploratory work for the location of a railway chartered as the Hudson Bay, Prince Rupert Land and Pacific Railways.

A new graduate in engineering Mr. Stewart was engaged, from 1906 to 1912, on the Dominion land subdivision survey contracts in northern Manitoba and Saskatchewan. In 1909 the opening of an office in Saskatoon marked the beginning of a private engineering and land surveying practice in partnership with S. H. Phillips, carried on jointly until 1937.

His association with the Department of Highways and Transportation, Province of Saskatchewan dating from that time, he was instrumental in reconaissance and location and construction of highways in Northern Saskatchewan. He worked as chief engineer for several years. The appointment of deputy minister was announced in 1952.

His retirement from the Department in 1954 marked his resumption of a consulting engineering practice, located at Saskatoon.

In 1953 awarded the Queen Elizabeth II Coronation Medal, his outstanding service and prominence in the development of his province was also rewarded. Stewart River, flowing into the Churchill River from Northern Saskatchewan perpetuates in official map and place names his contribution in the field. It is the practice of the Province to give recognition for services in this way.

He joined the Institute as an Associate Member in 1917; transferred to Member in 1940 and to Life Member in 1955.

John Philip Fraser, M.E.I.C., assistant chief engineer, executive, B.C. Electric Railway Company, Vancouver, B.C., died there on June 10, 1957.

Mr. Fraser was born at Hamiota, Man., on June 24, 1893. After a four-year course of study at the University of Manitoba, he graduated in 1914 with the degree, bachelor of electrical engineering. An engineering apprentice with Canadian Westinghouse Company, Hamilton, Ont., for the following three years he served the Canadian Army overseas from 1917 to 1919. Named assistant engineer in charge of the installation of electrical equipment for Westinghouse on his return to Canada, and two years later given complete charge, he was in 1923 promoted to the post of switching equipment designing engineer. He remained with the firm until 1929. During the early thirties employed with the North Western Power Company he was electrical engineer in charge of design, layout and installation of electrical equipment at the Seven Sisters Falls Power House. He also held various positions with the Manitoba Power Commission during that period and was later in 1936 named chief engineer and general superintendent with the organization. Transferring his services to the B.C. Electric Railway Company, Vancouver, in 1940, he became superintendent of generating stations and substations. Three years later he assumed added responsibility as superintendent of generating stations, substations, transmission lines and distribution systems.

The appointment of assistant chief engineer, executive, held at the time of his death, dates to May 1956.

Mr. Fraser joined the Institute as an Associate Member in 1929 and was transferred to Member in 1936.

William Percival Dale, M.E.I.C., retired engineer of Brampton, Ont., died there August 23, 1956.

Mr. Dale was born at Brampton on April 1, 1894. He graduated from the University of Toronto with a B.A.Sc. degree in 1920. His first professional responsibility was that of assistant laboratory engineer with the Hydro Electric Commission of Ontario. In 1922 he became township engineer for the township of Stanford, Welland County, including the residential districts of Niagara Falls, Ont.

In 1916 he enlisted with the Canadian Expeditionary force and went to France with the Canadian Engineers in 1917, serving in France, Belgium and Germany.

Resident in Brampton for many years Mr. Dale was associated with Dale Estates Limited, where he began as plant engineer and purchasing agent in the early nineteen twenties.

Mr. Dale joined the Institute as an Associate Member in 1922 and transferred to Member in 1940. He attained Life Membership on January 1, 1957.

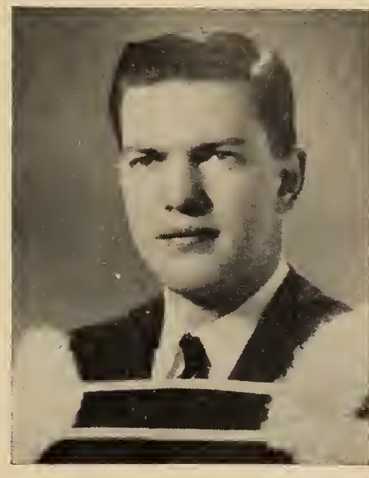
James Breakey, M.E.I.C., engineer with Imperial Oil Limited, Leaside, Ont., died on August 18, 1957 at Toronto.

Born at Sheffield, Eng., on September 19, 1901, and educated at Sheffield University he obtained an associateship in engineering in 1921. He also qualified as a marine engineer. Associated with a Sheffield foundry and engineering company and with the Metropolitan Vickers Electrical Company Limited, Manchester as a part of his training, he was finally in 1925 appointed an engineering assistant with the Vickers organization at Manchester. Two years later he signed on with A. Holt and Company, Liverpool, owners of the Blue Funnel Line, as a sea-going engineer. Resident in Canada by 1929 he worked as a draftsman in the industrial drawing office of Canadian Vickers Limited, Montreal.

He became associate editor for MacLean Publishing Company, Technical Publications, Toronto, in 1931. Within the next few years he was associated with the publication, "Modern Power and Engineering".

Since 1945 employed with the Imperial Oil Limited at Timmins, Ont., St. John's, Nfld., and Toronto, he has served as manager of industrial sales Newfoundland, and as lubrication sales engineer, Toronto.

Mr. Breakey served on the executive of the St. John's Branch of the Institute.



John B. Haire, Jr.E.I.C.

He joined the Institute as a Junior Member in 1931; transferred to Associate Member in 1935; to Member in 1940.

Harry Joseph McCann, M.E.I.C., sales manager for the firm of William Stairs and Son and Morrow Limited, Cape Breton, died August 24, 1957 the result of a motor accident near Halifax, N.S.

Born in the maritimes at Sydney, N.S., on April 8, 1908, educated at St. Francis Xavier University and Marquette University, Wisconsin, he graduated with a B.Sc. degree in electrical engineering in 1933.

He was an assistant electrical engineer with the Dominion Steel and Coal Corporation Limited, Sydney, in 1934 and moved on to become superintendent of Dominion Utilities. Relinquishing the post in 1939 he became manager of the firm with which he was associated at the time of his death. He was also a director of the firm of C. P. Moore Limited, Sydney.

Mr. McCann was chairman of the Cape Breton Branch of the Institute in 1948.

He joined the Institute in 1944 as a Member.

James Metcalf Bennett, M.E.I.C., of the Canadian Blower and Forge Company Limited, Toronto, died on July 1, 1957, at Campbellford, Ontario.

Born at Brockville, Ont., on February 8, 1923, Mr. Bennett moved to Campbellford at an early age. Receiving his early schooling there he went on to study engineering at Queen's University, Kingston in 1941. A graduate five years later he had attained the degree of B.Sc. in mechanical engineering.

Associated with the Canadian Blower and Forge Company Limited since his graduation in 1945 Mr. Bennett served as a sales engineer for some time. Mr. Bennett joined the Institute as a Student Member in 1944, was admitted to Junior Membership in 1947. He became a Member in 1954.

Gordon Albert Christian Eby, Jr.E.I.C., chief engineer of the reinforced plastics division of Brunswick-Balke-Collender Company of Canada Limited, at Toronto died on July 25, 1957, at Rexdale, Ontario.

Mr. Eby was born at Kitchener, Ont., on December 28, 1923. Mr. Eby completed his schooling in that city and then embarked on a wartime career with the R.C.A.F. overseas. Awarded the D.F.C. for his service he enrolled at McGill University to study engineering in 1945. He received a B.Eng. degree in chemical engineering in 1949.

Shortly after his graduation Mr. Eby accepted a position with the E. B. McGee Company Limited at Port Colborne, Ont. Later he was employed with the Dominion Rubber Company Limited, at Kitchener, Ont., and the De Laval Company Limited at Peterborough.

He joined the Institute as a Student in 1949, and transferred to Junior Membership in 1951.

John Buell Haire, Jr.E.I.C., mechanical engineer, of Montreal, died in a motor accident near Carleton Place, Ont., on September 12, 1957.

John Haire was born at Montreal on November 16, 1933. He studied engineering at McGill University and in 1955 graduated with a B.Eng. degree in mechanical engineering. While a student Mr. Haire gained a variety of engineering experience during the summer recess. This included road surveying with the Province of B.C., and with the firm of McMillan and Bloedel. He also worked with the Dominion Engineering Company, at Montreal, and with the Defense Research Board Dominion of Canada, at Valcartier, Que.

Accepted for an appointment with the Standard Oil Company at Aruba, Netherlands West Indies, on graduation, he remained there until July 1957.

At the time he lost control of his car, Mr. Haire was enroute to register for a course in business administration.

In the interim period before commencing his post-graduate studies Mr. Haire was business manager of the well-known McGill University musical, "My Fur Lady".

Mr. Haire was a member of the Canadian team participating in the International Dinghy races at Bermuda in 1955.

He joined the Institute as a Student Member in 1954, was transferred to Junior in 1957.

Personals

News of the Personal Activities of Members of the Institute

J. Herbert Smith, M.E.I.C., (B.Sc., elec., U. of New Brunswick, 1932), has been elected chief executive officer, of the Canadian General Electric Company Limited. Simultaneously he was elected a director of the company.

Mr. Smith, first Canadian born president since 1925 joined the organization in 1932. After managerial assignments in engineering and sales capacities in Peterborough, Hamilton and Toronto, he was appointed general manager of the wholesale department in 1951.

He was elected a vice - president in 1953. Two years later he was appointed general manager of the appliance department with headquarters in Montreal. Prior to his recent call to new duties at head office, Toronto, he has been acting as general manager of the apparatus department at Peterborough.

In 1953 president of the Association of Professional Engineers of Ontario, he was this year appointed by order-in-council of the lieutenant - governor of Ontario to the governing council of the Association.

Mr. Smith is also a member of the Senate of the University of Toronto representing the engineering profession.

E. V. Buchanan, M.E.I.C., of London, Ont., has been appointed chairman of the Engineering Advisory Council of the University of Western Ontario.

Mr. Buchanan is a former general manager of the Public Utilities Commission of that city and of the London Railway Commission.

He has served the E.I.C. as branch chairman, councillor and vice-president. He was a representative on the Engineers Council for Professional Development. In 1951 he was elected president of the Ontario Association of Professional Engineers.

W. L. Hutchison, M.E.I.C.

Ian F. McRae, M.E.I.C., vice-president of the Canadian General Electric Company and general manager of the company's civilian atomic power department, has been elected a director in the organization.

Mr. McRae has recently been elected to the first vice-presidency of the Canadian Manufacturer's Association.

Jack C. Dale, M.E.I.C., (B.Sc., elec., U. of Alberta, 1932), president and general manager of Canadian Utilities, Limited, has been elected a director of the parent company, International Utilities Corporation.

Mr. Dale, who is an Albertan, joined Canadian Utilities Limited, in 1935, later serving overseas in World War II. Returning to Canadian Utilities he assumed the post of general manager of the electrical power company in 1951, that of president and general manager in April 1956.

Hugh Crombie, M.E.I.C., (B.Sc., mech., McGill U., 1918), vice-president and treasurer of the Dominion Engineering Works, Limited is the newly elected vice-president of the Machinery and Equipment Manufacturers' Association of Canada, following an annual meeting held in Toronto.

J. H. Smith, M.E.I.C.

J. C. Dale, M.E.I.C.

Mr. Crombie served as treasurer for the Association shortly after its formation in 1956.

He is a former president of the Canadian Manufacturers' Association.

F. G. Ferrabee, M.E.I.C., (B.Sc., applied science, McGill U., 1924), president, Canadian Ingersoll-Rand Company Limited, has been named a director of the Machinery and Equipment Manufacturers' Association of Canada.

Less than two years ago MEMAC was formed with a view to promotion of Canadian-built industrial machinery both in Canada and abroad.

Mr. Ferrabee is a past-director of the Canadian Industrial Preparedness Association.

W. L. Hutchison, M.E.I.C., (B.Eng., elec. McGill, 1934) has been appointed vice-president of Moffats Limited, Weston, Ont., after a period of two years' association with the firm.

Mr. Hutchison was director of manufacturing, for Remington Rand, in Great Britain from 1946 to 1955.

G. V. Douglas, M.E.I.C., (B.Sc., M.Sc., mining, McGill, 1920), longtime professor of geology at Dalhousie University has retired from the Carnegie chair. Not content to live in retirement, he has established a consulting geologist's office in Toronto at 16 Duplex Ave., Toronto 7, Ont. Professor Douglas will undertake the examination of areas, prospects, or mines.

PERSONALS

Dr. H. S. Van Patter, M.E.I.C., and J. J. Traill, M.E.I.C., represented Canada at the meeting of Technical Committee 4 of the International Electrotechnical Committee, held at Zurich in October.

This committee is charged with the task of drafting an international test code for hydraulic turbines. Twelve countries were represented at this meeting by over forty delegates and excellent progress was made in the work of the committee. The meeting was characterized by a gratifying spirit of cooperation among those present.

J. H. Ross, M.E.I.C.

Georges E. LaMothe, M.E.I.C., (B.A.Sc., Ecole Polytechnique, 1913) retired from the staff of Price Brothers and Company Limited, Quebec City, after many years service, has taken on new duties. As well as teaching forest operations for the faculty of forestry at Laval University Mr. LaMothe is engaged in consulting engineering in Quebec City.

Paul D. Normandeau, M.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1938), was elected president of the Association Professionnelle des Industriels at a convention held in Montreal and Quebec City.

Mr. Normandeau's election marks the first time A.P.I. has chosen as its president an engineer and Institute member.

Alan K. Hay, M.E.I.C., of Ottawa, formerly chief engineer of the Federal District Commission has become general manager.

The Federal District Commission is the nationally representative government organization responsible for the implementation of the long-range Master Plan for the development of the National Capital.

J. H. Ross, M.E.I.C., (B.A.Sc., elec., Toronto, 1939), of Hudson, Que., has been named plant manager of Noranda Copper and Brass Limited, with headquarters at the company's main plant and executive offices at Montreal East. Until his present appointment Mr. Ross has been plant engineer for the company. Under his direction a major expansion of the production facilities has been recently completed.

Harry F. Burns, M.E.I.C., (B.Sc., civil, U. of Manitoba, 1950), of the firm of A. D. Margison and Associates Limited, consulting engineers of Toronto, Ontario, has been named as Associate in charge of the firm's traffic engineering department. With the group two years, his last appointment was that of traffic section head of the firm's municipal department, then engaged jointly, with an American firm, on the design of the Metropolitan Toronto Expressway. Mr. Burns' experience in the field of traffic engineering includes two years with the City of Winnipeg as traffic engineer.

W. S. Leggat, M.E.I.C., (B.A.Sc., mining, U. British Columbia, 1939) formerly assistant to the construction engineer for the St. Lawrence Seaway Authority has joined Raymond International Company Limited. Now located at Vancouver he will serve as construction manager for the firm in Western Canada.

Brigadier H. W. Love, M.E.I.C., (B.Sc., civil, Queen's U., 1936), has in his new posting been named deputy quartermaster general, design and development, at Army headquarters, Ottawa.

roof deck by **Rosco**

Rosco Roof Deck Type 134 was used on this new Dominion Supermarket because of its faster construction, great durability and strength and low erection cost

Rosco Roof Deck in spans up to 24′ and available in Types 134, 234, 200 and 150 offers a wide selection of type design, one of which will meet the required specifications for *your* next job—and help reduce costs!

Contact any of the nine Rosco plants across Canada for complete information and planning assistance.

• PERSONALS

He is responsible for the co-ordination and supervision of design of equipment.

Brig. Love had been commander of the North West Highway System in Whitehorse.

He is registered with the Yukon Territory Association as a registered P.Eng., and was one of the original members of the newly formed group.

A. M. Lount, M.E.I.C., (B.A.Sc., civil, U. of Toronto, 1946), who for four years has been a member of the firm of T. O. Lazarides, Lount and Partners, has founded the firm of A. M. Lount and Associates.

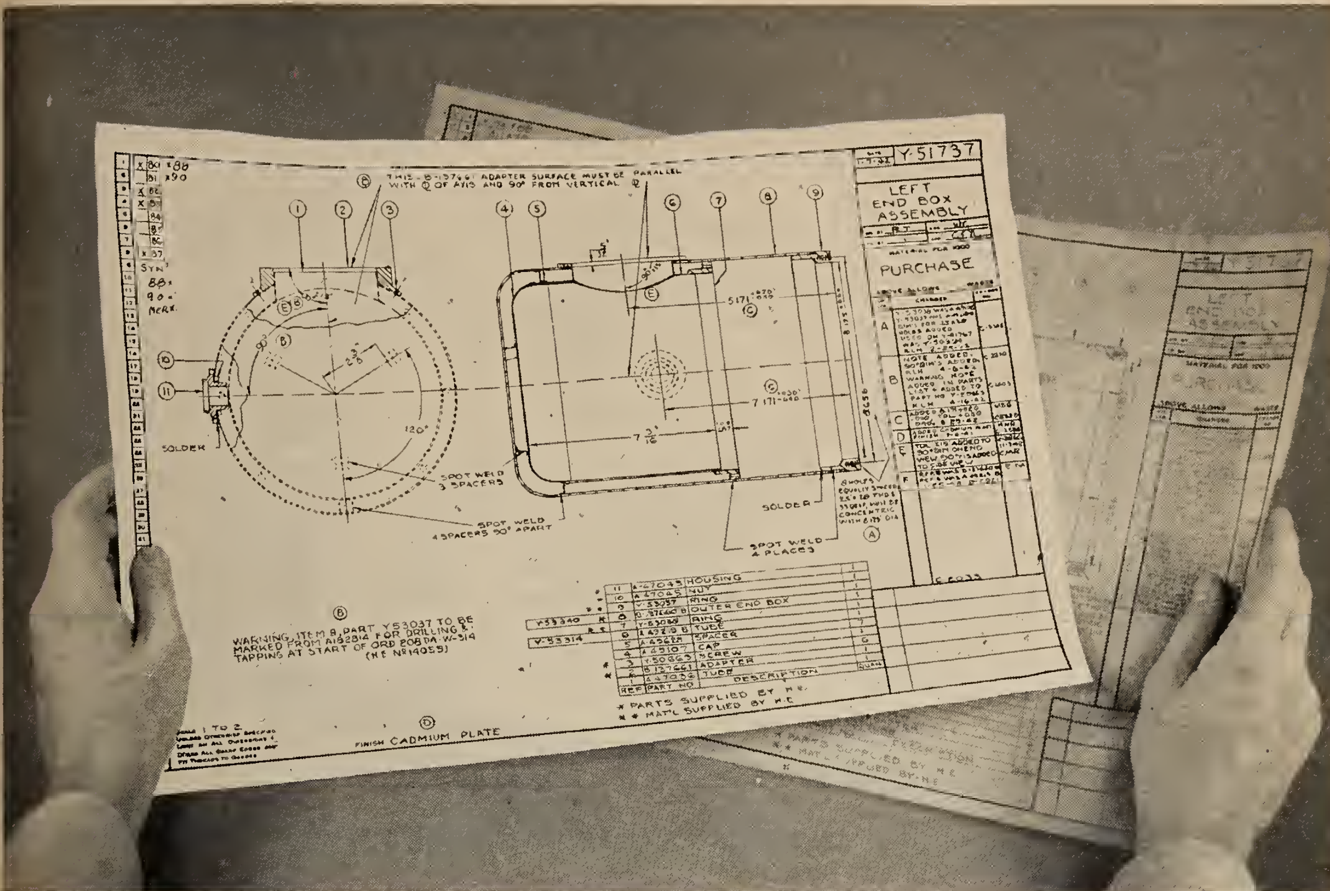
Associated with the Hydro - Electric Power Commission of Ontario from 1946 to 1953 Mr. Lount was for several years

A. M. Lount, M.E.I.C.

in charge of the structural department of the consulting engineering division. He was closely connected with the development of prestressed concrete in Canada. In 1953 the Engineering Institute awarded him the John Galbraith Prize.

Allan Shattuck, M.E.I.C., (B.Sc., U. of Saskatchewan, 1930), for the past ten years a member of the waterworks department of the City of Regina, Sask.,

G. E. Franklin, M.E.I.C.



This Autopositive Paper intermediate was made from an old, "yellowed" drawing

To restore old drawings

without retracing a line

Take one of your old pencil drawings that is so worn and yellowed it will no longer produce acceptable prints.

Reproduce it on Kodagraph Autopositive Paper, and you'll get a positive reproduction directly.

Now run prints from this photographic intermediate. You won't believe your eyes—the lines are crisp, legible . . . the background wonderfully cleaned up. *These* are prints you can use!

With Kodagraph Autopositive Paper around, it just doesn't pay to waste hours retracing "unprintable" originals, as thousands of drafting rooms have discovered.

Learn all the ways you can save with Kodagraph Reproduction Materials, which you, or your local blueprinter can process quickly, at low cost.

and recently design engineer, and has been appointed construction engineer of the Ontario Water Resources Commission, Toronto.

George E. Franklin, M.E.I.C., (B.Sc., civil, U. New Brunswick, 1950) chief engineer, Modern Construction Limited, was elected chairman of the Moncton Branch of the Institute for the 1957-58 term at the annual meeting in May.

Mr. Franklin joined Modern Construction Limited on graduation. His present appointment dates to 1956.

Cdr. (E) V. F. O'Connor, R.C.N., M.E.I.C., (B.Sc., mech., Nova Scotia Technical College, 1934) has transferred from the appointment of senior engineer, H.M.C.S. Magnificent, at Halifax, to engineer overseer of the naval engineering test establishment at Ville La Salle, Que.

Cdr. O'Connor's naval career dates to 1934, shortly after his graduation from the Nova Scotia Technical College. One of his recent postings was that of lieutenant-commander with the Department of National Defence at naval headquarters, Ottawa.

F. A. Benger, M.E.I.C., (B.Sc., mech., Queen's U., 1913), chief of motive power and rolling stock for the Canadian Pacific Railway has retired after having served the company for more than 46 years.

Mr. Benger rose to the post of assistant chief of motive power and rolling stock in 1948. He was assigned the duties of chief of motive power and rolling stock in 1953.

D. J. S. Irvine, M.E.I.C.

A. L. Berry, M.E.I.C., (B.Sc., civil, U. of Alberta, 1947) Westcoast Transmission Company Limited principal pipeline engineer, at Calgary, Alta., has been transferred to senior plans and research engineer for the company at Vancouver.

Active in western engineering circles for some time he has been associated with Northwestern Utilities Limited, Edmonton, and with the Denton Spencer Company Limited, also at Edmonton as a consulting petroleum engineer.

D. J. Irvine, M.E.I.C., (B.Sc., Chem., U. of Saskatchewan, 1941), for five years sales engineer, Exide industrial division, the Electric Storage Battery Company, (Canada) Limited, Central Ontario, has been named resident sales engineer for the company in Manitoba. Offices are at 298 Main Street, Winnipeg.

Leo Vladicka, M.E.I.C., (dipl., civil, Kaunas U., Lithuania, 1944) has a new business address. Associated with the Hudson's Bay Oil and Gas Company Limited, Calgary as senior production engineer for some time he is now employed with the Canadian Pacific Railway, Calgary.

His official position is that of petroleum engineer, mines branch, C.P.R. department of natural resources.

J. J. A. Hall, M.E.I.C., (mech. and production, Higher National Certificate, 1948) is practising engineering in Detroit, Mich., where he is project engineer with the Fruehauf Trailer Company.

Lt. Col. W. B. Akerley, M.E.I.C., (B.Sc., civil, U. New Brunswick, 1932) since 1953 resident engineer for the Canadian Army on the construction of Camp Gagetown, N.B., has retired from the Canadian Army. He has accepted the position of engineer for the development of the new town of Oromocto, N.B.

Processing Plants and Equipment

To Chemical and Food Processors Canadian Vickers offer a unique service. In addition to designing and manufacturing special equipment required, they will undertake complete plant construction from idea to operation.

One all-embracing engineering and construction contract covers necessary equipment, plant design and construction, process design, mechanical design, shop fabrication, field erection and initial operation. It is the modern, efficient, economical method of plant building.

Canadian Vickers is a great Canadian engineering organization doing business throughout the world. Designing and manufacturing machinery and equipment of any nature, they specialize in the building of Ships, Mining Equipment, Industrial Boilers, Pulp and Paper Machinery, Hydro-Electric equipment, etc.

PERSONALS

T. F. Scott, M.E.I.C., (B.A.Sc., mech., U. British Columbia, 1946), of the Du-Pont Company of Canada, formerly assistant purchasing agent for equipment at Montreal, has been named purchasing agent, purchasing and traffic department.

Chief supervisor of power in 1952 for the Maitland Works, then under construction, he later took over the post of supervisor of maintenance when the plant went into production.

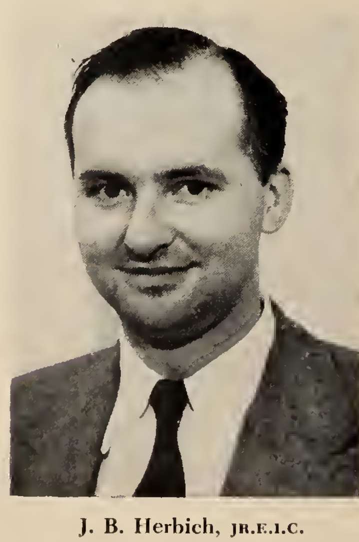
John B. Herbich, M.E.I.C., (B.Sc., civil, Edinburgh U., 1949, M.Sc., U. of Minnesota), has been appointed assistant professor of civil engineering in charge of hydraulic instruction at Lehigh University, Bethlehem, Pa.

Mr. Herbich has enjoyed a variety of professional experience including work with the Netherlands Hydraulic Institute, University of Delft, the Kitimat project, and four and a half years research work at the University of Minnesota, St. Anthony Falls Hydraulic Laboratory.

J. William McNaughton, M.E.I.C., (B.Sc., civil, Queen's U., 1947), has been appointed a general superintendent with E. G. M. Cape and Company (1956) Ltd. He will be in charge of several of the company's construction projects in Ontario. He has served the company on construction in Ontario, Quebec and the Atlantic provinces.

K. A. Oakley, M.E.I.C., (B.A.Sc., civil, U. of Toronto, 1949) has been appointed division engineer, eastern division, producing department, Imperial Oil Limited, London, Ont. Mr. Oakley was previously division civil engineer, Regina division, Regina, Sask., with that firm.

George F. S. Davis, M.E.I.C., (B.Sc., civil, U. of Alberta, 1949), has transferred his engineering services from Calgary to Montreal. Associated with Monogram Pools Limited, in the foothills city, in 1956, he is employed with the Rupert's Land Trading Company, Hudson's Bay Company, in Montreal.



J. B. Herbich, JR.E.I.C.

E. C. Fraser, JR.E.I.C.

C. A. Millar, M.E.I.C., (B.A.Sc., mech., U. British Columbia, 1953) has been promoted to the rank of captain with command of the First Field Engineer Regiment Light Aid Detachment, at Veddar Crossing, B.C. This is a Royal Canadian Electrical and Mechanical Engineers unit attached to the engineer regiment. Regimental headquarters and the L.A.D. are situated with the Royal Canadian School of Military Engineering at Camp Chilliwack, B.C.

E. C. Fraser, JR.E.I.C., (B.Sc., civil, U. of New Brunswick, 1950), has been named eastern sales manager, industrial division with the International Equipment Company Limited. Mr. Fraser's most recent appointment was that of chief engineer following service with the company dating to graduation.

Philip A. Hardwick, JR.E.I.C., (B.Eng., mech. Nova Scotia Technical College, 1950) recently of the Boeing Airplane Company, Seattle, is now employed as a sales engineer with the Bumstead Woolford Company, Seattle, Wash.

Lt. (L) G. A. Kastner JR.E.I.C., (B.Sc., elec., U. of New Brunswick, 1952) of the Department of National Defence, naval service, has gone to Harwell, Berks, Eng., where he is with the Atomic Energy Research Establishment.

J. P. Vilagos, JR.E.I.C., (B.Eng., mech., McGill 1954), has completed his two-year tenure of an Athlone Fellowship in Great Britain. Mr. Vilagos obtained a master of science degree in engineering production and spent a year in British industry.

He returns to his work with the Canadian National Railways department of motive power and car equipment at Montreal.

H. B. Stewart, JR.E.I.C., (B.Sc., mech, U. of Manitoba, 1950), has joined the Toledo Engineering Company Inc., Toledo, Ohio, consulting engineers and contractors for the glass industry. Following graduation Mr. Stewart was employed by Fiberglas Canada Limited as glass furnace supervisor and engineer

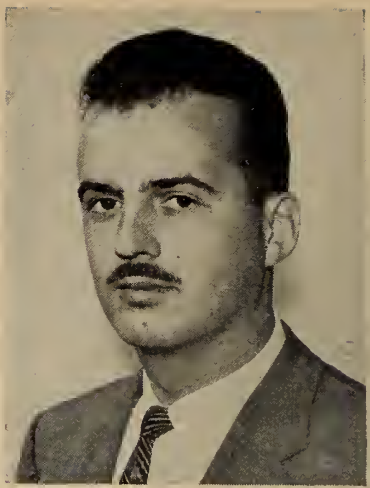
and later as senior design engineer, gaining his initial experience in the glass industry. Prior to joining the Toledo Engineering Company, he was employed by Sproston's Jamaica Ltd. as assistant mechanical superintendent, constructing a chemical plant in Jamaica, B.W.I., for the Aluminum Company of Canada.

Ronald A. F. Latham, JR.E.I.C., (B.A.Sc., mech., U. of Toronto, 1950) has been appointed construction engineer with the Electric Reduction Company of Canada Limited, Toronto in the central engineering department.

Associated with this firm since his graduation Mr. Latham was works engineer at the Buckingham, Quebec works. He was resident engineer on the construction of a new chemical manufacturing works at Vancouver until his recent appointment.

R. A. Brocklebank, JR.E.I.C., (B.A.Sc., civil, U. of Toronto, 1952) is chief engineer, surveys and mapping, with the Photographic Survey Corporation of Toronto, according to a recent announcement. He will be particularly concerned with technical liaison on P.S.C. engineering jobs.

The appointment follows five years experience supervising control surveys on large P.S.C. projects in Peru, Venezuela and the West Indies as well as on mapping and engineering projects throughout Canada.



R. A. Brocklebank, JR.E.I.C.

William L. Booth, JR.E.I.C., (B.A.Sc., civil, U. of Toronto, 1946), has joined the staff of Howard Smith Paper Mills Limited, Cornwall division, Cornwall, Ont. Experienced in the field of pulp and paper he latterly served the Abitibi Power and Paper Company at Iroquois Falls, Ont.

P. E. Coulter, JR.E.I.C., (B.Eng. mech., McGill U., 1956, mech. technology, Ryerson Institute of Technology) has been named technical director of the National Warm Air Heating and Air Conditioning Association of Canada at Toronto.

Mr. Coulter has assumed complete responsibility for the technical programs, problems, and the arrangements and operations of all National Warm Air Heating "Indoor Comfort" Schools.

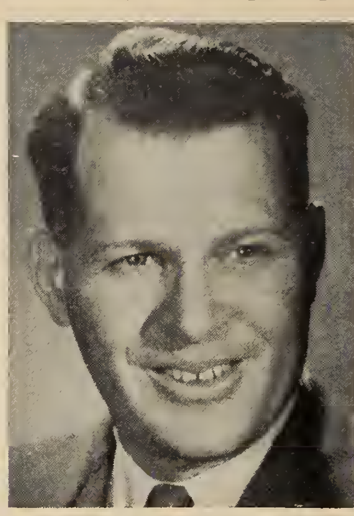
Canada Limited, Chalk River, Ont., where he was resident engineer on the construction of the N.R.U. reactor, recently transferred to the Foundation of Canada Engineering Corporation Limited, Montreal.

Mr. Ingolfsrud is at present in Great Britain where he is following a three-month course at the Harwell Reactor School, United Kingdom Atomic Energy Research Establishment.

J. D. Cape, JR.E.I.C.

Jack D. Cape, JR.E.I.C., (BA.Sc., mech., U. of Toronto, 1950), has been appointed manager of belting and hose sales with B.F. Goodrich Canada Limited, Kitchener, Ont., following a period of work with the firm as sales engineer for belting and hose. He has been employed with B.F. Goodrich since 1950.

M. Edward Bailey, JR.E.I.C., (B.A.Sc., mech., U. of Toronto, 1949), has been promoted by B.F. Goodrich Canada Limited Kitchener, Ont., to special projects assignments with the industrial products division of the firm.



M. E. Bailey, JR.E.I.C

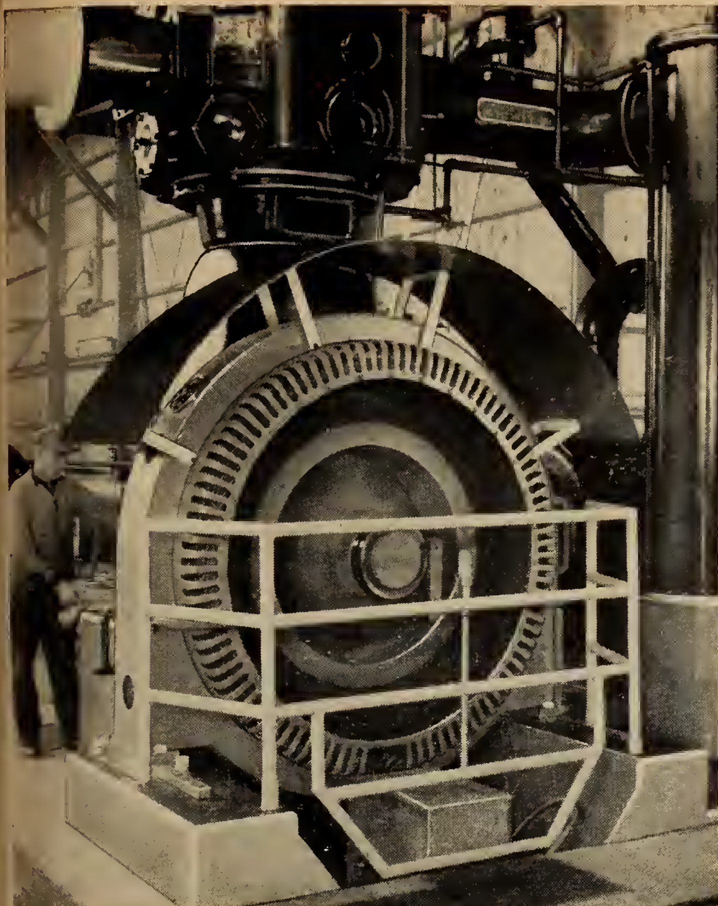
Manager of belting and hose sales since 1953, he joined the firm on receiving his engineering degree.

Douglas R. Wilson, JR.E.I.C., (B.Eng., civil, McGill U., 1951), town engineer at Georgetown, Ont., for some time has taken up work as a design engineer with the Du Pont Company of Canada Limited, Montreal, in the sewer and water division of the organization.

George K. Escott, JR.E.I.C., (B.Sc., civil, Queen's U., 1950), has moved from Toronto to Montreal where he has assumed the vice-presidency of the Mount Royal Paving and Supplies. In 1953 Mr. Escott held office as vice-president and general manager of Associated Quarries and Construction Limited, at Toronto.

P. C. Gunyon, S.E.I.C., a 1956 graduate in mechanical engineering from the University of Toronto has gone to the British West Indies where he is with Alumina Jamaica, Williamsfield P.O.

Albert T. Isaacs, S.E.I.C., (honours, elec., Nova Scotia Technical College, 1957), is attending the University of British Columbia where he is preparing for a master's degree in applied science. Mr. Isaacs holds a National Research Council bursary.



General Electric 600 h.p. synchronous Motors drive the C.I.R. compressors which supply compressed air to drills and other tools underground at Bicroft Uranium Mines.

A General Electric Motor Control Centre is shown being installed in an Ontario uranium processing mill. To slide each unit into its compartment is a simple, quick operation.

E. T. HILBIG, JR.E.I.C.,
Secretary-Treasurer

Talk on Hypersonic Flight

The first meeting of the 1957-58 season was held October 7, in the Masonic Temple. Vice-chairman Allan Argue outlined the scheduled program for the fall portion of the season in the absence of J. A. Grant, who was vacationing at the time. Institute Council Member Sillitoe reported on the Banff meeting, dealing specifically with the purpose of the recently established technical sections.

Guest speaker Dr. Gordon Patterson, director of the Institute of Aero-physics at the University of Toronto in addressing the meeting on "Problems of Hypersonic Flight", explained that the basic "shock tube" still plays an important role in scientific development work in aeronautics. In the hypersonic wind tunnel the atomic structure of air actually breaks down, this being a basic difference between it and a supersonic tunnel.

With the help of slides, the speaker discussed the various design features involved in developing aircraft and rockets. Of particular interest were slides dealing with the orbits which would result when an artificial satellite was produced by shooting rockets into outer space at various velocities. The latter feature, and the fact that the first man-made satellite had been successfully launched only three days earlier, provoked an interesting discussion period.

Cape Breton: top photo, left, President C. M. Anson presents a gold E.I.C. pin to W. S. Wilson, honouring his attainment of Life Membership in the Institute. Right, Major C. M. Smythe, an invalid confined to his home, was also honoured by the E.I.C. on attaining Life Membership, as President Anson made the presentation. Below: a special dinner meeting and dance held in his honour at the Isle Royal Hotel in Sydney, N.S., marked the president's official visit. Mr. Anson was presented with a specially engraved gavel of local maple and steel from the first ingots made in the new open hearth of Dominion Iron and Steel Limited. Mr. Anson is vice-president and general manager of the company. Making the presentation is M. R. Chappell, M.E.I.C.

Prime Ribs and Beans

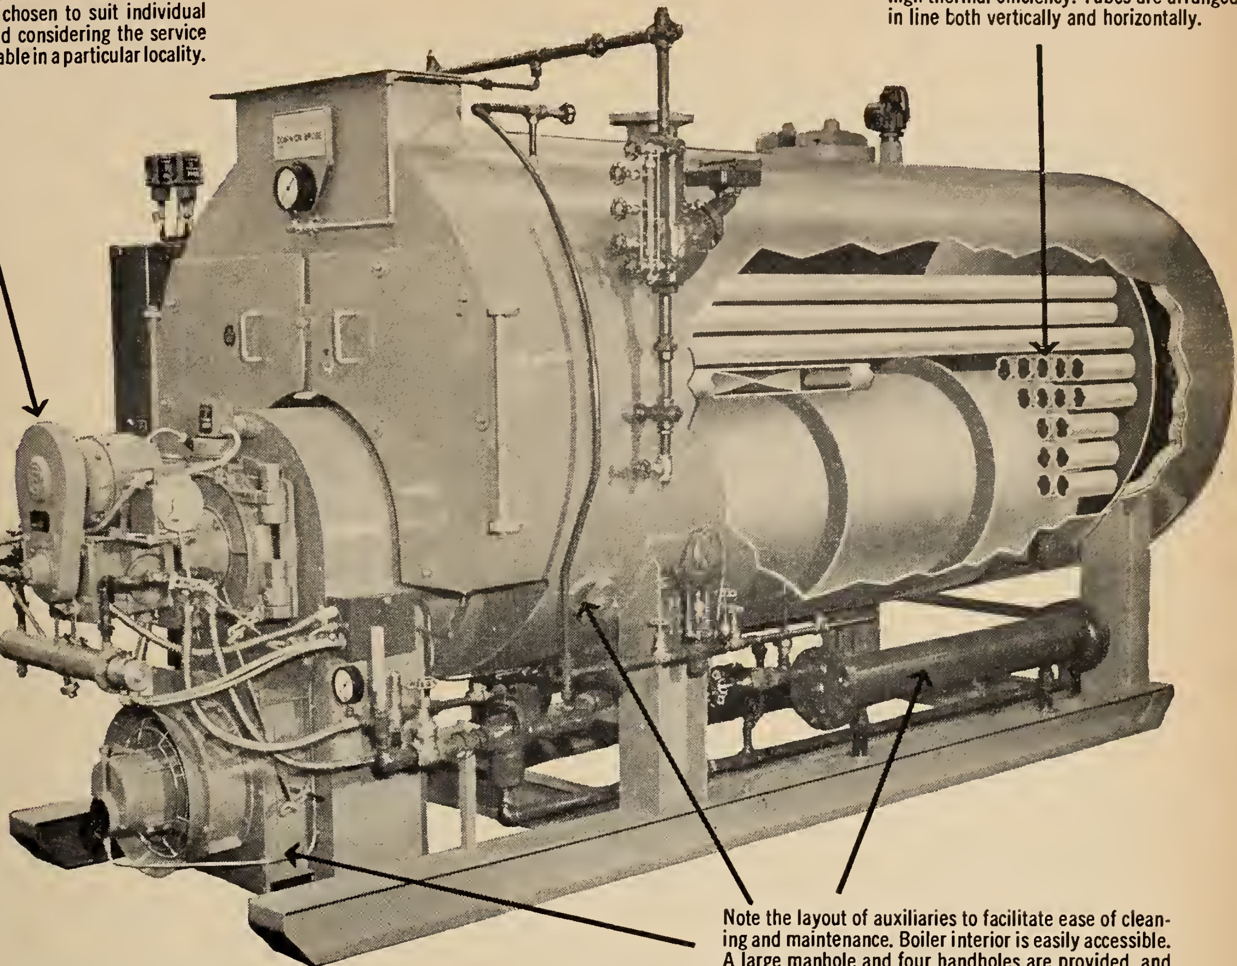
The Second Annual E.I.C. Barbecue, held September 11 at Colpitt's Ranch, attracted 240 members and guests who turned out to enjoy prime ribs and beans around two mammoth campfires.

P.D. Program

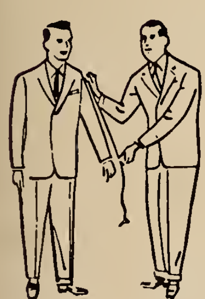
The A.C.E. — Professional Development Program began the 1957 season, September 24, in the Southern Alberta Jubilee Auditorium. A series of fifteen programs covering six P.D. subjects has been arranged under the sponsorship of the Institute in co-operation with the Canadian Institute of Mining and Metallurgy and the Alberta Society of Petroleum Geologists. Three hundred engineers and scientists have signed up for the program to date. On the self-development theme, the initial program featured G. Wallace, executive director of the Dale Carnegie Institute, dealing with the subject, "What Makes a Leader." Group dynamics was used effectively to promote group participation under the chairmanship of R. S. White.

First General Meeting

The first general meeting of the 1957-58 season was held October 3 at the Palliser Hotel. Feature speaker, C. K. Fraser, manager of the advanced engi-



A custom-tailored package unit...



The Dominion Bridge package boiler is delivered ready to be connected to water, oil, and steam lines and to the electrical supply panel. Designs are available for hot water or steam heating, and for high pressure steam process requirements.

Simplified design, high efficiency and accessibility are some of the principal features of this unit. Built in a wide range of sizes in many of our plants from coast to coast, each Dominion Bridge package boiler is backed by seventy-five years of experience in the steam generation field.

For complete information, write for catalogue No. BF-120.

neering laboratory of the apparatus department, Canadian General Electric Company, Peterborough, Ont., was introduced by Ken Broe. The subject, "Applied Research in a Canadian Industry" first of all developed definitions for the various fields of research and advanced engineering. Special reference was made to the application of polyester and epoxy resins in equipment applications. The development of germanium transistors and selenium rectifiers was described. The increasing use of the analog and digital computers as an important new engineering tool for the designer was outlined.

The meeting adjourned at 9:30 p.m. for the purpose of visiting a Remington-Rand Univac demonstration. Coffee was served while viewing the simulated operation of the computer equipment in the Palliser Room.

HAMILTON

W. A. H. FILER, JR.E.I.C.,

1957-58 program. Main item was a proposed tour through the North Western Pulp and Power plant at Hinton, Alta., which has aroused considerable interest in Alberta. This is due possibly to its many advanced techniques for the handling of pulp, and its size, together with the capital expenditure of several million dollars for its construction. In addition a completely new town has been and is still being built to house the hundreds of people employed by this company.

Second most important event was the annual dinner and banquet scheduled for the end of November.

Field Secretary Present

Among those at the head table was Commodore C. Davy, Western Field Secretary of the Institute who gave a brief run down on his position in Institute affairs. He asked members to contact him directly or through the branch secretary with whatever problems they may wish to discuss.

Telephone Official Speaks

Guest speaker D. Mallet-Paret of the Alberta Government Telephones, a man who has the heavy responsibility of building the microwave system in Alberta that is to connect with the Trans Canada microwave installation, was introduced by Don Edwards. Dr. Mallet-Paret began his talk with a brief outline, accompanied by a film on microwave systems in general and their relation to the telephone installations throughout North America. When this work is complete Alberta telephone subscribers will be able to dial the long distance calls directly via the microwave to sixty-five million subscribers. This would out-mode our present method of dialing the operator to obtain a number, so often accompanied by delay.

Mr. Mallet-Paret described the multiflex systems and by means of excellent colour slides gave an intimate picture of the difficulties to be overcome in the installation of the various towers required throughout Alberta to complete the continental microwave system. The manner in which the sites were surveyed created an interesting point. The comparison was made that in order to establish some of the sites it would have been necessary to survey 25,000 miles by road in three months. Using a helicopter the same route was not only surveyed in 3½ weeks, but the sites were immediately established by means of contour maps and the altimeter which is fitted in the helicopter. Included in the lecture were a number of shots taken from the helicopter, making it possible to appreciate many of the difficulties involved where towers up to 312 feet had to be

erected on prominences of 6,000 feet altitude.

On completion of the present work in 1958, Alberta, which in 1955 had one hundred thousand telephone open miles and sixty-four radio circuits, will possess 170,000 open miles and 140,000 radio circuit miles.

Mr. Mallet-Paret finished his talk by assuring his listeners that the microwave would be officially opened in time for Edmontonians to see directly the Eskimos once again win the Grey Cup, from wherever the scrimmage may be held.

Bruce Allsop thanked the speaker on behalf of the Branch.

Shediac Cruise

On Saturday, July 27th, branch members and their wives enjoyed a cruise on Shediac Bay, followed by a supper at the Caissie Cape cottage of Mr. and Mrs. G. E. Franklin. The group met at Pt. du Chene, embarking on the cabin cruiser 'Brenda'. A delicious lobster supper was served on the lawn of the Franklin cottage.

The President's Visit

The branch was honoured by a visit from President C. M. Anson and Mrs. Anson on September 24th. Dr. L. Austin Wright, general secretary, and Dr. H. W. L. Doane, vice-president for the Maritime Provinces, accompanied the president.

Shortly after their arrival, Mr. Anson and Dr. Wright visited the City Hall. Introduced to Mayor M. M. Baig, they were invited to sign the guest book of the City of Moncton.

Later in the afternoon, the Headquarters officials met with the branch executive for a round table discussion of matters affecting the Branch and the Institute.

Another feature of the afternoon was the tea held in honour of Mrs. Anson by the Engineers' Wives Association of Moncton Branch, at the home of the president of the Association, Mrs. M. F. K. Leighton. Mrs. V. C. Blackett presided over the tea cups and Mrs. G. E. Franklin served. The guest of honour was presented with a gift on behalf of the Association.

Main event of the presidential visit was the evening dinner meeting which attracted sixty-seven persons.

Mayor M. M. Baig extended a civic welcome to Mr. Anson and others in his party and praised the Institute for the very fine work it is doing for the engineering profession and for Canada.

BERTRAM FOR DELIVERY-PRICE and PERFORMANCE

ON SPECIAL MACHINERY AND EQUIPMENT

BRANCH NEWS

The Engineer and Labour

Mr. Anson addressed the meeting on the subject "The Engineer and Labour" and declared that he firmly believed that we shall see the day when the division of the spoils in industry will be carried out in a standardized manner, and one which will be equitable to all interests involved.

This must inevitably take the form of, first of all, providing for the continuation on a sound basis of the industry concerned; second, the provision for a standard wages payment to all those who have been involved in the work of conversion; third, a fair return on the investment involved, and then a further division of whatever surplus remains among the two partners to industry — the shareholders and the workmen.

Dr. Wright Reviews E.I.C. Progress

After brief remarks by vice-president Dr. H. W. L. Doane, Dr. L. Austin Wright reviewed the progress of the Institute during his twenty years as general secretary.

Wives' Association

First fall meeting of the Engineers' Wives Association, Moncton Branch was held October 4th, at the home of Mrs. G. E. Franklin, Salisbury Road. The president, Mrs. M. F. K. Leighton welcomed forty members to the meeting which took the form of a bridge and social evening, convened by Mrs. R. P. Puddester. Five new members, Mrs. J. W. Demcoe, Mrs. E. H. Gilliatt, Mrs. D. A. Slack, Mrs. J. W. Thompson and Mrs. J. Stannix, were introduced by the president and welcomed to the Association. Bridge prizes were won by Mrs. H. J. Crudge, Mrs. T. H. Dickson, Mrs. J. R. Freeman and Mrs. A. W. Purdy. At the close of the evening, refreshments were served.

MONTREAL

G. M. BOISSONNEAULT, JR.E.I.C.,
Secretary-treasurer

With the coming of fall, the Montreal Branch once more swings into high gear with many technical papers planned and top-grade speakers engaged. In addition, the social side of the engineer's life has not been neglected. We sincerely hope there is something planned for everyone's taste.

October Annual General Meeting

This year the Fall General Meeting was held on October 2. In the business part of the meeting, two members were elected to the Branch nominating committee. To replace R. J. Kane, who resigned his position, Professor J. Laurence of Ecole Polytechnique was elected for a period of two years. Replacing J. Budden, retiring member of the committee, T. N. Davidson was elected for a period of three years. The new committee is now composed of the following: Elected: G. N. Martin, J. Laurence, T. N. Davidson.

Appointed: — L. Roy, chairman, Montreal Branch; and G. Boissonneault, secretary-treasurer.

The committee's job is to see that at least one person is nominated for the positions of chairman, vice-chairman and three committeemen of the Montreal Branch for 1958.

Proposed Division

At the Annual Convention in Banff this year members of the executives of the various E.I.C. Branches in the province of Quebec began discussing problems unique to this province. Over several post-breakfast gatherings there arose the decision to study the advisability of

• BRANCH NEWS

forming a Quebec Provincial Division of the E.I.C. The matter was brought before Council, who in turn set up a special committee under G. M. Dick, vice-president, Quebec Province, to pursue the question further. The special committee, composed of representatives of all Quebec Branches, has reported favourably on the question. Their recommendations to Council were accepted and it now remains to place the proposal before all members of the E.I.C. resident in Quebec by means of a letter ballot.

Moncton: President Anson and party in the City Engineer's Office, Moncton, looking over one of the department's maps of the city. Left to right are: G. E. Franklin, chairman of the Moncton Branch; Dr. L. Austin Wright, general secretary; V. C. Blackett, secretary-treasurer, Moncton Branch; Dr. H. W. L. Doane, maritime vice-president; President C. M. Anson, W. M. Steeves, acting city engineer, Moncton.

The purposes of the proposed Quebec Provincial Division are:—

(a) To discuss matters pertaining to Provincial affairs concerning E.I.C. activities in Quebec Province and make recommendations on them to E.I.C. Council.

(b) To promote enlargement of E.I.C. activities and interests in Quebec Province.

(c) To endeavour to start more E.I.C. Branches in Quebec Province.

(d) To endeavour to enlarge E.I.C. membership in Quebec Province.

(e) To co-operate with C.P.E.Q. in all matters where E.I.C.-C.P.E.Q. co-operation would further the interests of engineers in the Province.

(f) To assist in developing the program for Confederation by blending the efforts of E.I.C. and C.P.E.Q. at Provincial and Branch level.

(g) To promote the interests and liaison between E.I.C. and the universities in the Province and thus provide valuable assistance to engineering students at a time in their careers when such assistance would be of great benefit.

(h) To co-operate in implementing the policies of Council in relation to other engineering organizations.

(i) To organize regional meetings with the province.
(j) To undertake any other activities within the scope of a provincial division.

Evening Education

Mr. Gooch's special committee, set up to study the problem of making available evening courses in engineering for residents of Montreal, will soon be contacting all Montreal Branch members. A questionnaire will be sent out asking some very pertinent questions concerning those who work around, above and under engineers.

The object is to form some estimate of the number of men in the area who might be interested in pursuing a course of studies leading to the degree in engineering. Armed with sufficient data, the committee will then be in a position to discuss the problems involved with the educational institutions in this city. Please help your commitee by answering the questionnaire fully and promptly.

Annual Oyster Party

On October 18 the Mont St. Louis gym rang with the clink of bottles and grunts of straining humanity as the Montreal Branch paid their annual homage to that ever-succulent bivalve, his majesty, the oyster. Some of 150 seniors, juniors and students dug in with an abandon known only to those who love oysters. With cheese and crackers and ale to wash it down it was a grand feast, with enough oysters for everyone, including the most ravenous of oyster fans. What a glorious way to die!

Not the least ravenous among the attendants was a visiting fireman from Calgary. Wally Smith of the Calgary Branch's "Pipeline Review" fame was seen getting details for a similar "do" for the Westerners. He also seems to have arranged to relieve some of us poor, unsuspecting Easterners of our ready cash come Grey Cup Day.

Professional Development

The Professional Development Seminar under the chairmanship of Robert Walker has begun. A total of 44 Branch Members have enrolled for this, the Branch's first P.D. course. Well known Montreal businessmen are lending their managerial skills and business experience to coach our young engineers.

Program Committee

The Program Committee have launched their 1957-58 program. This year the program bulletin is being printed on green paper. It is hoped by so doing, that the bulletin won't get lost among the many papers that clutter the desks of our busy engineers.

Another innovation being tried during the fall term is the serving of coffee and cookies at all meetings. This should give those attending a chance to meet and talk with their fellow engineers. Every one is urged to look over the bulletin, pick one or two technical papers in their field and enter into the discussions.

The Immigrant Engineer

The Junior Section of the Montreal Branch has been receiving more pertinent questions from their membership concerning the status of young immigrant engineers within the Province of Quebec. The Junior Section executive is trying to arrange a panel discussion with members of the C.P.E.Q. in hopes of clarifying the confusion that has arisen.

Business Meeting

First meeting of the Newfoundland Branch for the 1957-58 season was held on September 9. A business meeting, an outline of the proposed program for the year was presented by the executive. This was endorsed by the membership.

President's Visit

President C. M. Anson and Mrs. Anson, accompanied by Dr. L. Austin Wright and H. Doane, vice-president of the Eastern Zone arrived in St. John's by air on October 1. Met at Torbay airport by members of the Branch and their wives they were greeted and driven to the Newfoundland Hotel.

Almost immediately Mr. Anson held a press conference for the local press and radio stations. He was also interviewed on a T.V. program.

In the evening Mrs. Anson was a guest at a meeting of the Engineers' Wives Club at the home of Mrs. Grant Jack.

Mr. Anson addressed the engineering students at the Memorial University of Newfoundland the following morning. A courtesy call on His Worship Mayor Mews of St. John's was also made. A luncheon meeting with the executive followed.

The presidential dinner and dance was held at the Old Colony Club that evening, attended by ninety members and guests.

In the absence, due to illness of chairman G. Knight, the duties of were carried out by C. Henry, Branch vice-chairman. After dinner Mr. Anson gave an excellent address on Labour Relations. The talk stressed the importance to the engineer of knowing how to deal with the problems encountered from day to day in dealing with fellow workers.

R. P. Hunt proposed a vote of thanks to the president.

Dr. L. Austin Wright, general secretary of the Institute addressed the gathering on the state of the Institute.

• BRANCH NEWS

V. A. Ainsworth extended a vote of thanks to Dr. Wright.

H. Doane, vice-president of the Eastern Zone expressed his thanks for the welcome accorded the visitors in Newfoundland.

CORNER BROOK

ERIC R. SKANES, JR.E.I.C.,
Secretary

Two Special Speakers

Guest speakers at the September 9 meeting of the Corner Brook Branch were Dr. R. E. Heartz, president of the Shawinigan Engineering Company Limited of Montreal and W. E. Webb, head of the hydraulic department of the British Newfoundland Corporation. Visiting in Corner Brook to discuss the Hamilton Falls power development in Labrador Dr. Heartz said that the project would find a ready market for its power in Quebec and Ontario. The falls, said to have a potential of 4,000,000 horse power and believed largest in the world, are being developed for BRINCO by the Montreal firm.

Dr. Heartz said the two provinces were exhausting their inexpensive power resources at an increasing rate and serving them from Labrador would present no difficulty with modern materials and methods of transmission. He also stated that the Labrador development would compare favourably in cost with any other hydraulic development in the world and would be much less expensive than thermal power houses using coal and other fuels.

Mr. Webb told the Branch that primary work on the project was hampered through lack of information about the area. No accurate rainfall data exists and stations had to be established to obtain figures on the runoff potential.

Mr. Webb added that compiling has progressed rapidly with the aid of aircraft and the new railway line from Sept. Isles, Que. Reasonably accurate information is now available.

Drawings, photographs and movies illustrated the talks.

NIPISSING AND UPPER OTTAWA

R. A. BOOY, JR.E.I.C.,
Secretary-Treasurer

Resume Activities

The first meeting of the current season was held at North Bay, on September 19th, Chairman J. F. Chantler presiding.

At a short business meeting held during the dinner, J. Warburton, chairman of the Papers Committee, noted that the Sudbury Branch, interested in touring the Atomic Energy Commission Plant at Chalk River, had extended an invitation to the Ottawa Branch. Choice of a satisfactory date was to be considered.

Dr. A. R. Clark. Guest speaker. Dr. A. R. Clark of Geophysical Engineering and Surveys' Limited, was introduced by Mr. Warburton. Dr. Clark, prior to joining the staff of Geophysical Engineering and Surveys Limited as chief geophysicist and director of research, in September 1956, spent ten years as associate professor of geophysics at the University of British Columbia. Dr. Clark was accompanied by J. H. Beatson, secretary-treasurer and office manager of the North Bay office.

"Study of Physics of the Earth. Introducing his topic, Dr. Clark first defined geophysics as the "Study of the Physics of the Earth." The particular phase of this with which he was concerned was applied geophysics in the search for ore bodies. In this project they use physical properties of the ore that are different from the surrounding area. There are four main properties: 1) Electrical Conductivity, 2) Magnetic Permeability, 3) Density or Specific Gravity, and 4) Chemical Action. Radiation is also a specific property. Dr. Clark then elaborated on how each one of these properties was utilized and then outlined the main method of investigation of a site.

Following his talk, Dr. Clark extended an initiation to tour the North Bay office, where instruments and displays were available.

Investments Talk

Held at White Oaks Inn, Temiskaming, on October 16, the Branch was privileged to hear J. D. Grant of Wood, Gundy, Brokers at the regular October meeting.

Placing special emphasis on securities, Mr. Grant spoke on "Personal Investments". In opening his talk he mentioned the two main problems on investments —how to invest, and in what to invest.

In connection with the first problem the main possibilities range from the "No-Rick" Bonds which represent a loan for a fixed period, fixed rate of interest, but taxable, through preferred stock, to common stock which has all the risks. The choice of investment in any or all of these types, is mainly a personal matter in which such factors as personal income and responsibilities play a part.

Mr. Grant pointed out that the danger of a market collapse is negligible since the formation of the Bank of Canada, an increase in payments on marginal buying to 50%, and the effect of insurance company investments.

The Gordon Report also forecasts an increase in the gross national product, so that generally any investment is an investment in the future. With a note of caution Mr. Grant concluded his address by mentioning "Speculation" and its pitfalls.

Ottawa Valley Golf Meet

Ninety-seven engineers from the Ottawa Valley teed off in the third annual Ottawa Valley Engineers Golf Tournament held at Arnprior, Ont., on June 21.

Supported by the Corporation, the Ottawa Branch, E.I.C., the A.P.E.O., the Ottawa branches of the C.I.C., A.I.E.E., and C.I.M.M., the golf tournament has been a regular event for the past three years. A play-off was necessary to determine the winner when R. D. Watson, H. D. Tiffin, and J. K. Melville of Arnprior all checked in with 81's. H. J. Riley, representing the Council of the Quebec Corporation presented the trophy to Mr. Watson and announced that next year's tournament would be sponsored by the Quebec Corporation.

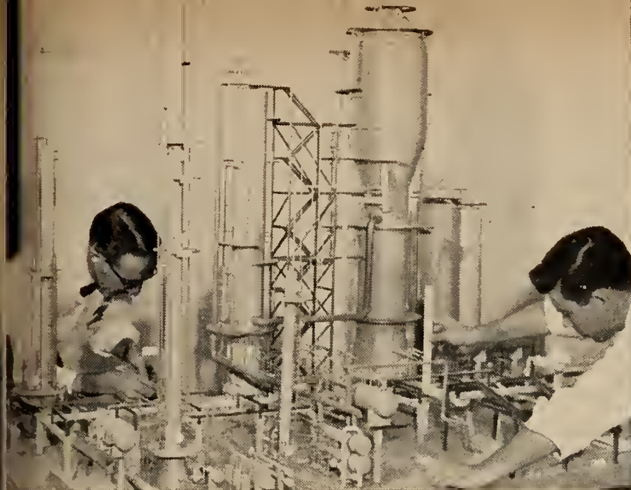
R. F. Legget Speaker

Fifty-seven persons heard R. F. Legget, director of the division of building research, National Research Council, speak at the regular Thursday luncheon meeting of the Branch held at the Chateau Laurier. Subject of the talk was an "Engineer's Notebook on Scandinavia".

Mr. Legget had an opportunity of spending four weeks in Scandinavia during the past summer between attendance at engineering conferences in Stockholm and London. Visiting Sweden, Finland and Norway primarily to study housing and building research also, he saw something of the current construction. He described some of the more important works he visited, including the rebuilding of Hammerfest, one of the most northerly towns in the world.

Mr. Legget was introduced by vice-chairman Hector Chaput, who chaired the meeting, and thanked by K. F. Wrangle, Norwegian engineer employed with the E. B. Eddy Company, Ottawa.

PROJECTION



Scale model of an orthoflow cat cracker, one of several process units.

…ed site of BA Refinery at Port Moody, B.C.

At Kellogg, design models near completion—an accurate preview of a refinery to be. Almost three thousand miles away the 'dozer blades ploughed lanes through the stumps and boulders of newly cleared land. From a hundred suppliers equipment and material are moving toward the site. And a master plan takes shape . . . Kellogg's plan for the Port Moody Refinery of the British American Oil Company—a plan developed with BA refining engineers to meet west coast demand for their products.

By integrating all operations from process sequences through design, procurement and construction, working simultaneously on the many aspects of a project, Kellogg shortens the distance between plan and production.

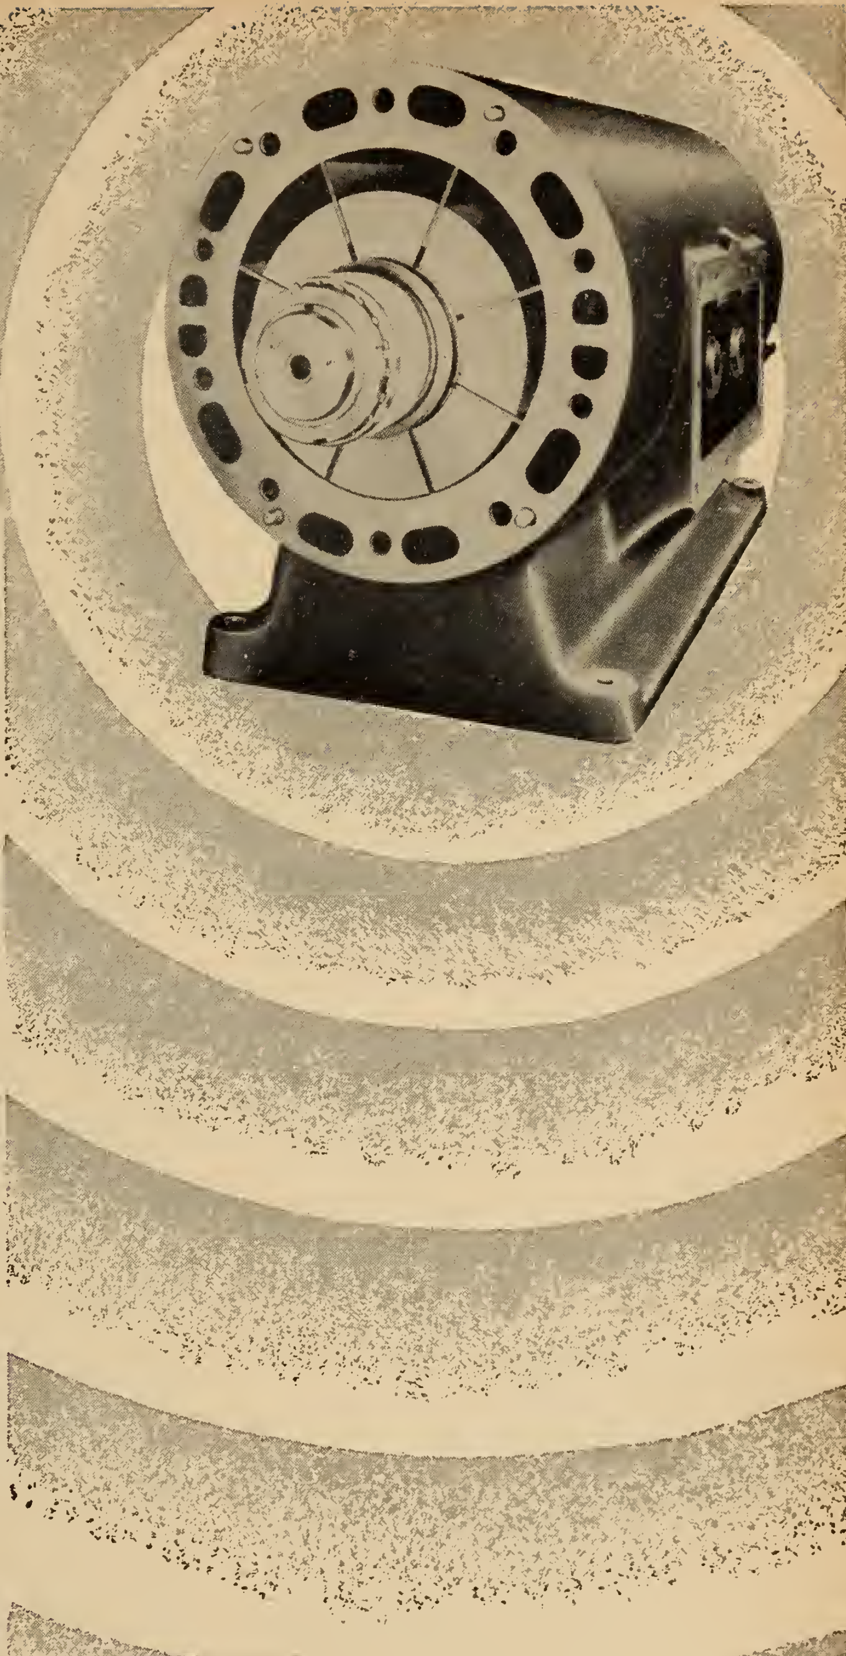
Freshmen's Reception

Freshmen's reception was held in three relays this year. One group laid sod at High Park, in Toronto's West End, under the supervision of the parks department; others were shown around the engineering faculty offices, lecture rooms and laboratories. Another group was taken to Hart House for a tour of the building, followed by refreshments, courtesy of the Toronto Branch. Six hundred freshmen took part in the hospitality provided. Arrangements at registration were made by Mrs. L. Robertson of the Institute Field Office, with the assistance of Norm Seagram, S.E.I.C. who directed the reception part of the program and is to be commended for his contributions to the organization and directing of the affair.

Plant Tour

Toronto Branch activities got under way with a plant tour. The St. Lawrence Cement Company, were hosts to 250 members at their new Clarkson Cement plant near Toronto. A film, giving



ROTARY COMPRESSORS ARE MORE ECONOMICAL

FULLER ROTARY COMPRESSORS are noted for their extraordinary capacities with respect to size, weight and floor space requirements; direct drive at ordinary motor speeds without reduction gearing; lack of vibration and air-flow free from pulsations; absence of valves and such moveable parts as might require frequent attention. Installation costs are greatly reduced since there is no need for costly foundations. Available with pressures to 125 psi, capacities up to 3300 cfm.

FULLER also produces many distinct types of pneumatic conveying systems, each precisely engineered for bulk handling of a wide variety of fine and granular materials. Illustrated below is the AIRSLIDE.

Photo Interpretation

Donald Lueder of the Photographic Survey Corporation, an affiliate of the Hunting Technical Exploration Service Ltd., addressed the Branch, September 8, on "The Role of Photo Interpretation in the Work of an Engineer."

Mr. Lueder made clear with numerous examples of aerial photographs the fact that aerial photography is unsurpassed as a means of taking a complete inventory of the photographed areas. Mr. Lueder emphasized that by expert examining of the elements of photo pattern it is possible to evaluate additional

information. Examples are geological maps, the defining of intricate drainage areas, the interpretation of erosion and run-off features, signalling imminent landslides, determining soil and organic moisture content by the evaluation of grey tones of the photos, the locating and assessing of the extent of gravel borrow pits.

According to Mr. Lueder it is possible to obtain information quickly and cut to absolute minimum the sometimes very difficult and costly groundwork involved in an engineering project by means of up-to-date aerial photography interpretation.

VANCOUVER ISLAND

J. A. COWLIN, JR.E.I.C.,

Winter Activities

Winter activities began with a meeting held jointly with the Association of Professional Engineers on October 16.

James Sinclair, P.Eng., described construction of the world's largest gas-turbine generating station, built by the B.C. Power Commission at Bare Point, near Chemainus on Vancouver Island. Named the "Georgia Generating Station" after the Strait of Georgia on which it is situated, the plant is of 100,000 h.p. capacity.

A field trip to the station was undertaken later in the month.

As part of the program for the season ahead it is expected that apart from the regular joint meetings there will be a dinner to which the ladies will be invited. It is to be followed by films. Commodore Davy, the western field secretary of the Institute plans to attend and to address the gathering.

Date for the Vancouver Branch annual meeting has been established for some time in December.

WINNIPEG

C. S. LANDON, M.E.I.C.,
Secretary-Treasurer

Electrical Section Meets

On October 3rd, 1957, the Electrical Section of the Winnipeg Branch met at the Canadian Westinghouse Auditorium for the first meeting of the 1957-58 season. The meeting was of a novel nature, consisting of a panel discussion "Specifications of Electrical Apparatus".

Persons taking part in the panel discussion were: R. T. Harland, E. M. Scott, J. W. Walker, P. Shane; with W. H. Dickins acting as moderator. Questions directed to the panel were as follows:

(1) Should a specification be in complete detail or can one rely on the integrity and reputation of the manufacturer?

(2) If you specify "ABC" and a manufacturer quotes "ABC" plus an alternative "XYZ" which you find more attractive — do you go back and give the other bidders a chance to requote? What is your attitude if the manufacturer does not quote ABC but only XYZ?

(3) Have you any views on forms of tender?

(4) Should there be a standard form of progress payment throughout the industry?

(5) Should you state the dollar value of any penalty you apply, for example for transformer losses?

(6) What are your opinions on warranties — should they date from the delivery date or the in service date?

All questions asked provided very lively and informative discussion. Questions were also allowed from the floor and it was evident from the response that this type of meeting is well worth having.

Aeronautical Meeting in Montreal

Montreal's Sheraton - Mount Royal Hotel was headquarters for a joint meeting of the Canadian Aeronautical Institute and the Institute of the Aeronautical Sciences, October 21 and 22.

G. R. McGregor, president of Trans-Canada Air Lines discussing The Economics of Civil Turbine Operation, following the dinner held October 21, declared that Canada, for the first time, is faced with major transformation in the type of power to be used for aircraft. Careful long range planning is necessary.

The number of types of aircraft required to serve the route pattern was another consideration. T.C.A., which takes to the air for distances ranging from 45 miles to more than 3000 has found three types of aircraft, short, medium and long range, to be essential to their operations. The long range type finally selected after two years of study is the DC-8, at a cost of approximately $5 million each.

The margin of airline profit is small; competition is extremely keen; very small amounts of money assume great importance. Selection of aircraft and power plants for them is therefore of the greatest importance. One major mistake in planning may spell bankruptcy.

Mr. McGregor added that the forecast for the future is for higher speeds, especially over the longer distances. The DC-8 will operate at about 550 m.p.h. Flying time, Montreal to London is predicted at six hours.

No great further changes anticipated, it is expected that the 1960's will usher in a period of consolidation.

A total of sixteen papers were presented in the two-day parley. The speakers represented the leading members of the aircraft industry. Papers heard on Monday, October 21, were three on the general subject of Navigation and Air Traffic Control and three on Propulsion, followed by the W. Rupert Turnbull Lecture delivered by G. N. Patterson, director of the Institute of Aerophysics. The address was entitled, "Aerophysical Problems of Flight at Extreme Altitudes and Speeds."

The morning session, October 22, offered three papers on Special Techniques, and an informal discussion on Education and Training. The program for the afternoon presented two sessions, treating of Space Vehicles and Airline Operations.

International Soil Mechanics Conference

The International Society of Soil Mechanics and Foundation Engineering at its fourth conference elected Professor Karl Terzaghi as honorary president. The meeting took place at the Institution of Civil Engineers in Westminster, London, from August 12 to 21.

Professor A. W. Skempton of Imperial College, London, is the successor to Dr. Terzaghi as president. Six vice - presidents were elected, R. F. Legget M.E.I.C. (director, division of building Research Council, being elected as vice-president for North America.

Over forty countries were represented in the attendance of 1,200. One hundred and seventy six papers were presented. Seven papers were offered from Canada. All of the 176 papers are contained in two volumes published before the meeting. The concise reports of the general reporters for the eight sections, into which the subject matter of soil mechanics and foundation engineering was divided, are also included therein.

All discussions will appear in the third volume of the Proceedings to appear later this year.

Made available through the London Publishers, Butterworths, the three volumes, constituting a valuable record of advance in soil mechanics, will sell at approximately $70.00. Inquiries should be addressed to A. Banister, secretary, International Society of Soil Mechanics and Foundation Engineering, c/o Institution of Civil Engineers, Great George Street, Westminster, London, S.W.I.

Conference subject coverage was broad, ranging from an analysis of the gradients of naturally stable slopes in the London clay (around London), to a progress report on the construction of the new large steel sheetpile bulkhead wall in New York harbour, with a promise of a report to the next conference upon the deflection and other measurements now being made upon the bulkhead by P.N.Y.A. engineers. A number of speakers described measurements currently being made of the actual stresses in tunnel linings, and of the strains in rocks exposed in underground excavations. Geotechnical investigations in eastern and central Europe were recorded.

The session devoted to the bearing capacity of piles was of marked interest. It was clearly the sense of the meeting, supported by the printed papers in this section devoted to the bearing capacity of piles, that the proper use of piles is still an art. Calculation of the bearing strength of piles in granular materials is almost on a rational basis but the same cannot be said of friction piles in clay. H. Zweck of Karlsruhe, Germany, presented in this connection, a comparison between the settlements of identical reinforced concrete slabs on the same clay, one pile supported and the other bearing directly on the clay. Settlement was appreciably greater with the piles than without, a result confirmed by other speakers for other clays.

The conference agreed to set up committees to study standard soil mechanics terminology and to attempt to standardize methods of penetration soil testing. Another committee was established with the task of developing an agreed system for classifying soil mechanics literature.

Radio Engineers' Convention

A stimulating glance into the foreseeable future of the electronic world was given to 7,647 technical personnel who attended Institute of Radio Engineers' convention and exposition in Toronto. One hundred and fifteen papers were presented at the three-day meeting held October 17-19.

Included in the exhibits were radio, television and radar equipment with related components in wide variety; communications equipment; control (including tool) mechanisms; computers and counters; measuring equipment; aeronautical and navigational aids; guided missiles, and techniques for tracking and communicating with same; nuclear sup-

• OTHER SOCIETIES

plies and services; cameras, including those for TV aids to medical electronics.

The main session concerned the International Geophysical Year. An excellent picture of Canadian participation in I.G.Y. was given.

How a Canadian - made robot computes the sensations of a man subjected to extreme tests of acceleration and dizziness was described by Dr. W. H. Johnson, of the Defence Research Medical Laboratories, Toronto. The apparatus consists of an assembly of miniature gyroscopes attached to the head. Dr. Johnson said, "we can tell what the subject's equilibrium is, his idea of where he is, and also where he thinks he is going. Findings of the study have facilitated understanding of the experiences of people subjected to different types of motion, as for example in aeroplanes. The whole study project was carried out by Dr. Johnson in collaboration with Dr. W. R. Franks of the Banting Institute, Toronto, and Squadron Leader R. A. Stubbs, R.C.A.F., Institute of Aviation Medicine, Toronto.

Details of a new type of radio pill, indicating the state of stomach muscles to the physician were introduced by J. T. Farrar, Veterans Administration Hospital, New York, and W. J. Bieganski, Radio Corporation of America, Camden, N.J. The new pressure "telemetering" radio pill permits permanent recording of gastro - intestinal mobility without disturbing the patient.

Another paper discussed the study of muscle potential, using six electronic amplifiers. The instrument has been successfully used in the office of Dr. J. V. Basmajian, the speaker, who is the head of the Department of Anatomy, Queen's University.

Psychologists and engineers teamed up in several of the studies to bring scientific aid to business management. Part of it was brought out by W. A. Dimma, assistant to the president of the National Carbon Company. He reviewed the accelerating evolution in this field of management under the heading, "The Changing Concept of the Professional Manager."

Dr. H. Moore, director, Psychological Service Centre, Toronto, discussed, "Selecting Potential Professional Managers," describing the outstanding qualities peculiar to industrial leaders, over and above those needed for normal living.

How science can make keyboard fingers more nimble was explained by Dr. M. Humphries and Dr. J. C. Ogilvie both of the Defence Research Medical Laboratories, Toronto. Experiments to design a keyboard suited to the human hand, thereby achieving greater typing speed with less effort and errors were described. Designed in 1873 the present typewriter keyboard is not designed for the average person, nor for the statistical structure of the English language.

Brainstorming, a spontaneous give-and-take discussion to get ideas on a problem from men in every area of a company, later enlisting them in its solution, was introduced. Claude Watt of the Canadian General Electric Company Limited, said, "In order for these Canadian companies to stay in business, more ingenious methods of manufacture have had to be developed. The brainstorm session has proved a most successful tool in stimulating the creative ideas so necessary where product cost must be reduced, while still retaining the essential quality."

Guest speaker at the banquet Dr. Marcus Long, of the University of Toronto in his address, "Engineers are People," told the 500 guests present that every invention in electronic and allied fields created corresponding responsibilities.

Men misuse their genius, diverting the skill of engineers to wrong ends. He warned, "You cannot sit idly by while men misuse the opportunities you have opened to them. You cannot hide behind the false shield that you are only engineers. Engineers are people."

CEMA Annual Meeting

Holding its thirteenth annual meeting at Niagara Falls, Ont., the Canadian Electrical Manufacturers Association, on October 11 elected Thomas J. Bell, president of Fiberglas Canada Limited, Toronto, president of the 150-member organization. A director in CEMA, 1952, vice-president of the 471-company organization in 1954 he takes over the responsibility from Col. R. D. Harkness, outgoing president.

Topping the billion dollar mark in production for the second consecutive year, the 1956 figure represents an increase of 11 per cent over 1955 totals.

While the position for the future was construed as strong, it was noted that the improvement of the past two years falls short of the peak 16.6 per cent increase recorded for 1953.

Officials warned that while the 3.3 per cent increase in the industry's profit margin over the past two years is considered gratifying it is also among the lowest profit margins in the history of the industry.

In close alliance with the construction industry the electrical manufacturing industry may stand to suffer as a result of shortage of building money a forerunner of further levelling-off process in construction.

Canadians buy more major electrical appliances per household than the peoples of any other country in the world according to a recent sales survey.

The proposal of the United Kingdom that a free trade arrangement be established between Canada and Great Britain raises a host of problems and brings serious attention and comparison of the Canadian and British economies.

Immediate past-president of the Association, Col. R. D. Harkness, stated that "an economy such as ours, on the threshold of wider diversification and industrial expansion cannot move quickly into an orbit where manufacturing is likely to be placed at a disadvantage. Our avowed aim of high level employment, (83,600 in 1956) has been based on the existence of industrial expansion. Consequently any shifts in production and distribution must be examined in terms of the impact on Canadian employment".

Where possible changes in the pattern of trade could bring about expanding employment, then we should be prepared to give them full and favourable consideration," Mr. Harkness said. "Examination of our Canadian trade over the past decade," he added, "shows conclusively that the highest priority must be given to goods and services which will further expand the industrial side of our economy. Authorities on international trade have long agreed that the widest pattern of trade is the most desirable objective. However, world conditions during the past decade have not provided the climate in which multilateral trade could take firm root. It is obvious that currency restrictions, import quotas and bilateral deals of one kind and another have not eased the difficulties."

Calendar

Civil Engineering

The American Society of Civil Engineers held the annual meeting in New York city on October 14-18.

Technical sessions of the convention covered a wide range of subjects including the highway program, power projects in America and other countries, conditions of practice, sanitary engineering, surveying and mapping, engineering mechanics, hydraulics, structural engineering, waterways and harbours, construction, and soil mechanics and foundations.

Louis R. Howson, of Chicago, was elected president for the coming year. Mr. Howson is senior partner of the firm Alvord, Burdick and Howson, consulting engineers. Two vice - presidents and six directors took office with Mr. Howson at the annual meeting.

Four separate items of the program

• OTHER SOCIETIES

were papers as follows: "Unity in the Engineering profession" by Dr. J. W. Barker, president of the Engineers Joint Council; "The St. Lawrence and Niagara Power Projects", by Robert Moses, chairman of the New York State Power Authority; "The Engineer's Biggest Challenge", by Bertram D. Tallamy, Federal Highway Administrator; and "Working for a Firm Employing a Large Number of Engineers", an address by Alfred L. Perlman, president of the New York Central Railroad, to a student chapter conference.

Mechanical Engineering

The American Society of Mechanical Engineers (29 West 39th St., New York 18, N.Y.) offers its largest program ever presented at an annual meeting of the Society on December 1-6, at the New York hotels Statler and McAlpin.

There will be co-operation on the part of the American Rocket Society.

Some of the highlights of the technical program are sessions on air pollution, applied mechanics, aviation, boiler feedwater, consulting engineering, education, temperature effects, fuels, furnace performance, gas turbines, heat transfer, hydraulics, instruments and regulators, lubrication, machine design, maintenance, management, materials handling, metals, nuclear engineering, oil and gas, power, railroad, wood industries, and other subjects:

Testing Materials

The American Society for Testing Materials (1916 Race Street, Philadelphia, Pa.) announces it will hold its annual meeting at the Hotel Statler, Boston, Mass., June 23-27, 1958.

Physics Building

A group of leading scientists gathered in New York on October 21 to dedicate the new building of the American Institute of Physics. The building, at 335 East 45th Street, is headquarters for 20,000 American physicists. The Institute is a federation of five professional societies.

A.W.W.A. Meeting

The annual conference of the American Water Works Association in 1958 will be in Dallas, Texas, April 20 to 25.

The Canadian Section of A.W.W.A. will be meeting in Toronto, Ont., June 1-4, 1958. Secretary of the Section is A. E. Berry, general manager, Ontario Water Resources Commission, Parliament Buildings, Toronto.

Naval Architecture

The annual meeting of the Society of Naval Architects and Marine Engineers (74 Trinity Place, New York, N.Y.) is scheduled for November 13-16, 1957, at New York City.

Metals and Alloys

The Institute of Metals (17 Belgrave Square, Lonodon, S.W. 1) will hold a symposium on "Vacancies and Other Point Defects in Metals and Alloys", under the direction of the Metal Physics Committee. This meeting will be at the Atomic Energy Research Establishment, Harwell, on December 9 and 10, 1957.

Air Traffic Control

"The Airways Modernization Board: Mission and Methods" will be the subject of an air traffic control symposium sponsored by the Franklin Institute to be held in Philadelphia, December 16, 17, 18, 1957.

For information please write, Air Traffic Symposium, Franklin Institute Laboratories, 20th and Parkway, Philadelphia, 3, Pa.

fire the C-E, HT boilers at Gagetowr

THESE ARE THE GENERAL ADVANTAGES OF HIGH TEMPERATURE WATER:

1. Higher available heat—many times that of steam at the same pressure.
2. Closer control of temperature.
3. Lower heat loss . . . unused heat returns to the boiler . . . no condensate return lines.
4. No elaborate feedwater treatment . . . make-up requirements are exceptionally low.
5. Steam traps not required . . . trap problems and expense are eliminated.
6. No blowdown losses . . . no safety valve vent losses . . . no condensate losses.

THESE ARE THE SPECIFIC ADVANTAGES OF THE C-E "HT" WATER BOILER:

1. Complete control over circulation in both system and boiler.
2. No separate boiler pump is required, since low pressure loss is inherent.
3. Pressurized operation with oil or gas means no induced draft fan.
4. Single-pass design—no baffles—means cleaner boiler and lower draft loss.
5. Controlled, positive circulation permits more efficient arrangement of heating surfaces.
6. Any fuel—oil, gas, coal, or any combination of fuels.
7. Gastight, welded steel casing.
8. Fewer headers, all of which are easily accessible.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*ANALYTICAL DESIGN OF LINEAR FEEDBACK CONTROLS

The phrase "analytical design" is identified by the authors as the design of control systems by application of the methods of mathematical analysis to idealized models which represent physical equipment. Starting with the system specifications, the authors describe the input, the disturbances, and the desired response, including a statement of the basis on which the system performance will be judged. Separate chapters discuss the minimization of various errors which represent the performance index. An application of the analytical theory to a practical problem is fully discussed, and a working example of graphical procedure is also presented. (G. C. Newton, Jr., L. A. Gould and J. F. Kaiser, New York, Wiley, 1957. 419 p., $12.00.)

*ATOMIC ENERGY APPLICATIONS WITH REFERENCE TO UNDERDEVELOPED COUNTRIES

The first part of this booklet reviews the uses of nuclear energy. Part II discusses the conditions necessary for using nuclear energy in terms of meeting requirements in cost and resources and in terms of conditions necessary to derive any benefit from a particular use. The last part of the book describes the activities already undertaken to initiate nuclear energy programs in underdeveloped countries. (B. C. Netschert and S. H. Schurr. Baltimore, Johns Hopkins Press., 1957. 129 p., $2.00.)

*BASIC SOIL ENGINEERING

This book provides broad coverage of the fundamentals of soil properties and the engineering behaviour of soils, and explains, from the practical viewpoint, the application of this information to common problems in foundations, earthworks, and highway and airfield engineering. The book is intended to serve as an undergraduate text and as a reference for practising engineers without formal education in the subject. (B. K. Hough. New York, Ronald Press, 1957. 513 p. $8.00.)

*BEHAVIOUR OF METALS AT ELEVATED TEMPERATURES

This volume, based on lectures presented at the Institution of Metallurgists 1956 Refresher Course, will be useful to the metallurgist as well as to the engineer engaged in high temperature work. The effects of high temperatures on engineering properties of metals are covered as well as kinetic heating, high temperature steels, and the effects of high temperatures on air frame structures and guided missiles. (Toronto, British Book Service, 1956. 122 p., $4.25.)

CORROSION AND WEAR HANDBOOK FOR WATER-COOLED REACTORS

The first part of this handbook includes general discussions on the nuclear reactor plant and its relation to conventional power plants, considerations in choosing materials, fundamentals of corrosion and wear, and water technology. The second part provides tabulated data and detailed reference information on methods of testing and on the corrosion and wear resistance of various materials in different environments. The last part deals with special problems such as crevice, stress, and intergranular corrosion, system corrosion deposits, wear, and manufacturing problems. The book is one of a series sponsored by the Naval Reactors Branch of the Atomic Energy Commission. (Edited by D. J. De Paul. Toronto, McGraw-Hill, 1957. 293 p. $6.00.)

*DESIGN OF MACHINES

A clear and concise presentation of basic theory and of practical methods for the design of centrifugal coupling ,thruster brakes, gear reducers, a 30-ton yoke riveter, a manual lift truck. The book is primarily for use in a second course in machine design. (R. T. Hinkle. Englewood Clffs, Prentice Hall, 1957. 188p., $4.00.)

DESIGN OF STEEL STRUCTURES

The design of structural members and their connections, welded, riveted and bolted, is considered in this book, with particular application to steel bridges and industrial and multi-story buildings. The ordinary loads for these structures are considered, and reference is made to the use of aluminum as a structural metal. Earthquake and blast loads are also discussed. The book, one in the McGraw-Hill Civil Engineering Series, closes with an introduction to plastic design. The authors have illustrated their text with many photographs, diagrams, and tables. (E. H. Gaylord and C. N. Gaylord. Toronto, McGraw-Hill, 1957, 540p., $9.60.)

DISPOSAL OF INDUSTRIAL WASTE MATERIALS

The twenty-five papers in this volume were originally presented at a Symposium held at Sheffield University in April 1956. They present the latest British practices and research in dealing with the growing problem of the disposal of many types of industrial wastes in a wide variety of industries. The industries considered include: leather, rubber, textile and paper, paint, ceramic, iron and steel,

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

WOG

non-ferrous metals, electroplating, and chemicals, and there are also two papers on radioactive wastes. Most of the papers include bibliographies. (London, Society of Chemical Industry, 1957. 157p.)

*EFFECT OF RESIDUAL ELEMENTS ON THE PROPERTIES OF METALS

The five papers in this book describe the effects of various factors on the structure sensitive properties of metals. The first paper entitled **Fundamental Considerations** discusses the effects of lattice imperfections, solute atoms, and the presence of a second phase. The remaining papers deal with impurities and residual elements in common nonferrous metals, steels, semi-conductors, and the so-called newer metals—titanium, zirconium, molybdenum, and chromium. (E. R. Parker and others. Cleveland, American Society for Metals, 1957. 217p. $4.00.)

*ELEMENTS OF HEAT TRANSFER

The reviser of this book has maintained the emphasis on basic principles of previous editions but has changed the subject matter freely to meet the needs of today's engineering students. Some of the changes are: a new section on equivalent circuits for solving heat transfer problems, revision of the chapter on free convection, a new section on gas radiation, and a new chapter on mass transfer. New references and new problems have also been added. (Max Jakob. Third edition revised by G. A. Hawkins. New York, Wiley, 1957. 317p., $6.75.)

*FUNDAMENTALS OF MECHANICAL DESIGN

This text is an integrated treatment of kinematics, mechanism, dynamics of machinery, and design of machine elements, presenting in one volume the essentials of the sequence of courses usually offered to mechanical engineering students. It is intended primarily as a textbook for electrical, mining, and other engineering students not specializing in mechanical engineering, but it may also used as a refresher for engineers not in close contact with the field of mechanical design. (R. M. Phelan. Toronto, McGraw-Hill, 1957. 526p., $10.50.)

*GLOSSARY OF GEOLOGY AND RELATED SCIENCES

Prepared by a staff of nearly 100 specialists from 25 areas of geology and related sciences, this new glossary contains about 14,000 terms. Many terms commonly used in applied petroleum, mining, and engineering geology are included, as well as those used in theoretical geology and geophysics. Sources of most definitions are cited. (Washington, American Geological Institute, 1957. 325 p., $6.00 (payable in advance.)

MAKING, SHAPING AND TREATING OF STEEL, 7TH ED.

This seventh edition of a work first issued by United States Steel in 1919 is intended for steel users, steel plant employees and trainees, students, librarians and any others wanting a handy compilation of facts relating to the iron and steel industry, both past and present.

The first of the fifty chapters of which this volume is composed presents an historical introduction to the subject, following this the topics covered include material on fuels and combustion, coke, iron ores and mining, the various processes in iron and steel manufacture, and the manufacture of different shapes and products such as rails, wire, plates, tubular products, etc.

Steel corrosion and protection is also discussed, as is heat treatment and different types of steel; carbon; alloy; high-strength low-alloy; stainless steels; and steels for high temperature use. Two final chapters cover mechanical testing and gage numbers.

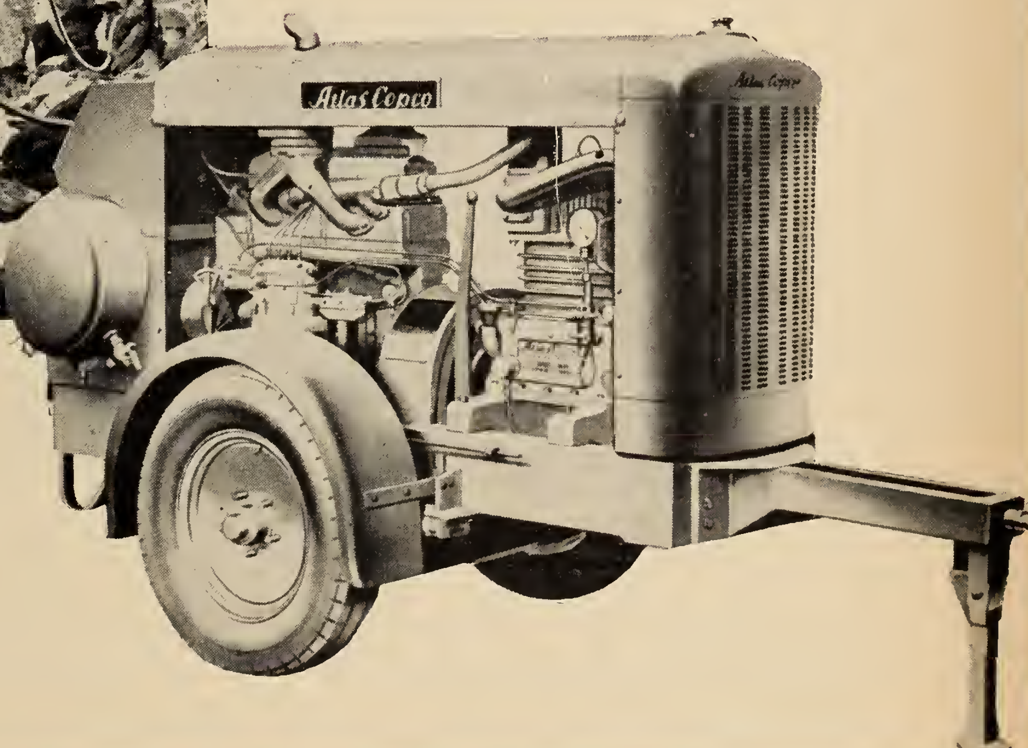
There are many illustrations, tables, etc., and bibliographies of references for further reading are found at the ends of most chapters. Some idea of the scope of this work can be gathered from the size of the index which is over a hundred pages long.

This is a most valuable book. (New York, United States Steel, 1957. 1048p., $8.70, payable in advance.)

No need for a maintenance man with this compressor...

Rugged, economical Atlas Copco Portable Compressor is virtually trouble-free... supplies 155 c.f.m.—consumes only one gallon of diesel fuel per hour.

A sturdy portable, the Atlas Copco MK-37 Compressor combines delivery of 155 c.f.m. at 1200 r.p.m. with low cost, low fuel consumption, simple maintenance and long use without overhaul. MK-37 is an efficient, two-stage, air-cooled diesel compressor with ether starting available for cold weather. Heavy section steel chassis and sprung axles protect compressor and engine units in roughest terrain. And the large volume air receiver (hydraulically tested to twice the maximum working pressure) is fitted with four ¾″ outlet valves for ample air supply. Atlas Copco maintains 24-hour service across Canada. Write for further information.



Atlas Copco MK-37 Portable Compressor is powered by a Dorman type 4 DWD industrial diesel engine with instant cold-weather starting. 500 Dorman diesel engines are being used in construction of Canada's DEW Line.

● LIBRARY NOTES

MASONRY SIMPLIFIED, 2ND ED.

The first volume of this two volume work discusses the tools, materials and practices of masonry in an easily understood form.

The first three chapters cover the cementious materials used in masonry construction: lime, its manufacture, storage and use; the various types of mortar, their properties and uses; concrete, its reinforcement, mixing and placing. There is a useful chapter on blue print reading, and the three following chapters describe the principles of wall building and their relation to construction in concrete masonry, structural clay tile, and brick masonry. A final chapter describes the building of sidewalks, driveways, floors, and steps.

The final section of this first volume is an illustrated dictionary of building terms.

In volume two the principles of masonry construction are applied to actual problems encountered in building. Some of the topics covered include: building forms for concrete; design and construction of footings; foundations and waterproofing; beams, lintels and columns; chimney and fireplaces; walls and partitions; septic tanks. A final chapter is devoted to maintenance and repair.

Both volumes contain a wealth of diagrams, and the books should prove extremely useful not only to those engaged in or entering the building trade, but also to those who do their own masonry work. One of the authors, Gilbert Townsend, is a member of a firm of architects and engineers in Montreal. (J. R. Dalzell and Gilbert Townsend. Chicago, American Technical Society, 1956-57. v.1, 463p., $7.20: v.2, 438p., $7.95.)

*MICROWAVE MEASUREMENTS

This thorough treatment of the basic forms of electrical measurements in the microwave region of the electromagnetic spectrum provides a background for all common measurements as well as for some of the more specialized applications. The principal subjects treated are generation of laboratory signals; detection and measurement of mierowave power; the measurement of impedence, wave length, and frequency; representation and measurement of microwave circuits; and resonant cavity characteristics. The book has been written as a text for graduate students and as a reference for engineers. (E. L. Ginzton. Toronto, McGraw-Hill, 1957. 515p., $14.40.)

THE NEXT HUNDRED YEARS

In 1956 three scientists from the faculty of California Institute of Technology held a series of discussions with the executives of thirty United States industrial corporations in an attempt to estimate man's future needs and the ability of the earth's natural resources to supply them. An attempt was made to forecast the future of industrial civilization, and to draw a picture of what that future will be.

This book records the ideas arising out of the discussions concerning demands for raw material and for technical manpower and how these demands may be met, rates of industrialization; the growth of population, and how its demands for food will be met.

The authors appear to have every confidence in the future of the world, and in their opinion the increasing demand for raw materials, food and brainpower can be met quite adequately by a world at peace. A full-scale nuclear war would however mean the end of industrial civilization for all time, even for the survivors of such a holocaust. As they say "The future of industrial society revolves around the question of whether man can learn to live with man." (Harrison Brown, James Bonner and John Weir. Toronto, Macmillan, 1957. 193p., $4.50.)

THE ORGANIZATION MAN

Who is the organization man? The author, assistant managing editor of Fortune, believes he is the middle-class American who can be found in corporations, in laboratories, in the courts, in foundations, and in the church hierarchies. He is sinking his own personality in that of the organization, and he sets the pattern of American thought and living.

The author pursues his man through his training in school and college to his moulding in The Organization itself. He examines the Organization Man at home in the new suburbia: his social life, his religion and the schools his children attend, where the whole cycle begins again.

You may not agree with everything, or anything, the author writes, but his book is well worth reading, and illustrates very clearly the modern trend in living. (W. H. Whyte, Jr. New York, Simon and Schuster, 1956. 429p., $5.00.)

*PETROLEUM AND ITS PRODUCTS

This is a concise summary of the whole field of petroleum production, covering exploration and drilling, crude oil composition and refining, and the manufacture, properties, and applications of petroleum derivatives. A list of basic references and important petroleum periodicals is appended. (J. H. Van Der Have and C. G. Verver. Toronto, Pitman, 1957. 421p., $10.00.)

*PETROLEUM CARGOES: MEASURING AND SAMPLING

A highly practical treatment of the problem of determining the quantity of petroleum products, from crude oil to high-octane gasoline, contained in oil tankers or barges. The explanatory material and the extensive group of tables cover not only bulk measurements and conversions, but also specific gravity determinations, volume correction coefficients for temperature, and other necessary or useful information. Petrochemicals and coal tar products are similarly treated in appendices. (H. Hyams. Glasgow, Brown, Son and Ferguson, 379p. 50/-.)

*REFRIGERATION AND AIR CONDITIONING, 2ND ED.

Intended for senior and graduate study, this text is designed for a comprehensive course. It is assumed that the reader has studied physics and mathematics, although one chapter contains a review of basic thermodynamics. Descriptive material on equipment follows closely the presentation of theory applicable to such equipment. Specialized advanced topics and applications are placed toward the end of the text. A large amount of graphic and tabular material allows easy reference use by the practicing engineers. (R. C. Jordan and G. B. Priester. Englewood Cliffs, Prentice-Hall, 1956. 555p., $8.00.)

*REGIME BEHAVIOUR OF CANALS AND RIVERS

Constituting a first formal text on the science of "mobile boundary hydraulics", the aim of this book is to develop and apply, to any river or canal capable of self-adjustment, the quantitative laws of the movement of boundary material. Utilizing the observations of irrigation engineers, hydrologists, and geologists, the author presents formulas for various conditions of breadth, depth, slope, and bed load, and demonstrates their use in the type of complex problem presented by any shifting channel. Some discussion of the construction, interpretation of data, and usefulness of river models is included. The author, a member of the Engineering Institute of Canada, is a Professor of civil engineering at the University of Alberta, and was formerly Director of irrigation research in the Punjab. (T. Blench. Toronto, Butterworth, 1957. 138p., 30/-.)

THE SCIENCE OF ENGINEERING MATERIALS

Based on a conference held at the Carnegie Institute of Technology in 1954, the papers reprinted in this volume attempt to show why materials behave as they do by applying the principles of solid state physics to the explanation of the properties of materials.

The first part of the book deals with the structure of matter: the applications of solid-state science in engineering, and the structure of atoms. Qualitative explanations are given of metals, alloys, semi-conductors and non-crystalline materials such as cements, polymers and glass. There are also chapters on surface phenomena and magnetism and magnetic properties. (Ed. by J. E. Goldman. New York, Wiley, 1957. 528p., $12.00.)

*SOLAR RADIATION IN AIR CONDITIONING

A handbook for engineers planning air conditioning for buildings in the tropics.

• LIBRARY NOTES

Information is given on the special difficulties involved in making calculations because of sun load in these regions. The discrepancies among the various methods is discussed. The methods are related to specifications of the plant and particulars of the building, and there is material to assist in making calculations direct from meteorological data should this be necessary. There are sections showing calculations and actual performance data. (I. S. Groundwater. London, Crosby Lockwood, 1957. 125p., 25/-.)

*STANDARD HANDBOOK FOR ELECTRICAL ENGINEERS, 9TH ED.

This standard reference tool has been revised and broadened in scope to cover the many innovations and developments in the electrical field in the last decade. Experts in each area have reviewed the twenty-six major sections of the book thoroughly and provided new or expanded data on nuclear power, dielectrics, transistors, telemetering, electrical measurement for automation, etc. Information on new synthetic materials and recent metals has also been included as well as electric conductor tabes based on latest ASTM standards, and new international electrical units and values. (Ed. by A. R. Knowlton. Toronto, McGraw-Hill, 1957. 2230p., $19.50.)

*STRUCTURAL DESIGN IN METALS, 2ND ED.

The new edition of this text for a first course in design emphasizes basic training in the application of the statistics of simple structures and the strength of materials to details of design. In the revision, additions have been made to chapters on rigid frame design and design with light gage metal, and recognition has been given to the use of other metals besides steel. (C. D. Williams and E. C. Harris. New York, Ronald Press, 1957. 655p., $8.00.)

*SYMPOSIUM ON CORROSION FUNDAMENTALS

Fifteen lectures presented at a conference at the University of Tennessee in 1955 dealing with coatings for corrosion protection, high temperature corrosion, problems in steam power and industrial boiler plants, cathodic protection, plastics and plastic liners for protection, etc. The aim of the symposium was to consider fundamental factors underlying the causes and prevention of corrosion in a way which would contribute to industrial corrosion control practice. (Edited by Anton de S. Brasunas and E. E. Stansbury. Knoxville, University of Tennessee Press, 1956. 255 p., $5.00.)

*SYNTHESIS OF PASSIVE NETWORKS

Assuming a good understanding of essential mathematics and basic circuit analysis, the author presents the fundamental theory of the subject matter, general methods of synthesis, and sufficient examples to clarify the presentation. The detailed treatment covers both the approximation problem and the realization techniques. As an essential tool in a broad field of engineering activity, the subject is sufficiently developed to prepare the reader for independent work. A subsequent volume will cover "special problems in network synthesis." (E. A. Guillemin. New York, Wiley, 1957. 741p., $15.00.)

*A TREATISE ON PHOTOELASTICITY, 2ND ED.

Publication of this volume makes available again a standard authority that has been out of print for several years. The present edition is substantially the same as the first (1931), except for correction of misprints and minor errors, and for changes made necessary by the omission of the color plates. The latter have been replaced by half-tone prints where important. Significant developments since 1931 are reviewed in an introduction and a bibliography of important recent publications has been added. (E. G. Coker and L. N. G. Filon. Revised by H. T. Jessop. Toronto, Macmillan, 1957. 720p., $11.25.)

URBAN LAND USE PLANNING

A scholarly study of the theory and techniques for planning the renewal and development of cities with populations of from 100 to 500 thousand, but also useful for any city faced with a planning problem, this volume is divided into three parts.

The first of these presents the theory of the determinants of land development — economic, social and public interest determinants. The second part describes the methods used in assessing the exiting situation; employment and population studies, the urban economy, urban land use and transportation. The final section is devoted to planning a rational use of the land available for industry, housing, recreation etc. paying attention to the requirements of health, safety, convenience, economy, and future development. (By F. S. Chapin, Jr. New York, Harper, 1957. 397p., $8.00.)

*WINDOWS AND GLASS IN THE EXTERIOR OF BUILDINGS

Recent advances in the various phases of window science and technology are detailed in this book which covers problems in daylighting as well as heat transfer through fenestration and its control. Chapters on properties of glass, windows in modern architecture and various frame types are included under product engineering, and the book concludes with material on design applications in residential and office buildings, commercial installations, and schools. (Washington National Research Council, Building Research Institute. 176p., $5.00.)

WORK SAMPLING, 2ND ED.

Active in the field of industrial engineering for many years, the author is currently serving as consultant for the establishment of a School of Industrial Administration in Madrid. In this book he presents an analysis of the technique of work sampling, and shows how it can be applied in both offices and factories.

Much of the material and case histories have been contributed by those active in the field, and many papers on the subject are listed in the bibliography. The author reports on the research which has been done, including that by Tippett who was a pioneer in the field. (By R. M. Barnes. New York, Wiley, 1957. 283p., $7.95.)

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

STOP COSTLY VALVE FAILURES

The sure way to end valve problems—and get better flow control at lower cost—is to specify lubricated plug valves throughout the plant. Rockwell-Nordstrom valves stop costly valve failures because they are positively sealed by an instantly replaceable soft seat of pressurized lubricant. And since vital seating surfaces are protected from the line, corrosion is minimized. Longer valve life at lower cost is further insured by the lubricant which eliminates metal-to-metal friction wearing.

Rockwell-Nordstrom lubricated plug valves are available in a complete line of sizes and pressure ratings in semi-steel, steel, stainless, Monel, bronze and other corrosion resisting metals. They cost no more to buy—often less—than ordinary valves. Write for details: Peacock Brothers Limited, Box 1040, Montreal, Que. Also, Sydney, Toronto, Sudbury, Winnipeg, Edmonton, Calgary and Vancouver.

HOT ASPHALT

Power Plan for Yukon River Waters

(Continued from Page 1646)

Canada indicates that in the foreseeable future rapid development of economic sites will be necessary to meet the increasing demand. This demand will stem from many sources. There is the well-defined increasing use of electricity for general, municipal and domestic purposes, and for secondary industries, due to a rising standard of living. There is the rapidly growing power demand for the processing of strategic minerals, for chemicals, plastics, construction materials and for high-grade and costly alloys. These primary industries are in great need of low-cost power because the secondary industries that undertake casting, machining, and fabrication of various products can, as present contracts terminate, actively outbid them. The primary producers are consequently driven ever further afield in the search for low-cost power. The inevitable trend seems to be that raw products will be transported to the remote areas where large power potentials can be developed and where there will be no invasion of secondary industries in the power field. That is why large industrial organizations in Canada, the United States, and Europe also—have become so interested in the power potentials of the Canadian north.

Power development in our northern areas is expensive, and physical characteristics must be favourable to obtain low-cost power. The maximum and most beneficial use of water is an essential factor. Eventually a northerly limit will be reached where water power cannot compete with the output of thermal stations near industrial centres.

Northwest Power Industries Limited hopes to market much of its power in the base-metal fields, and in the fields of forest products, chemicals and plastics.

Aluminum is one of the great users of power—each pound requiring approximately 10 kwh. In 1954 the free world production of primary aluminum was 2.5 million metric tons. For 1975, the demand is forecast at between seven and ten million tons. Under present processes one million metric tons of aluminum per year require an installation of 2,500,000 kw. or 3,330,000 h.p. The transition from iron ore to crude steel requires 4 kwh. per lb. The free-world output of crude steel in 1954 was 185-million metric tons. The 1975 demand is forecast at 239-million tons.

In 1956, Canada's installed generating equipment was 15.9 million kw. In 1975, the electrical demand of Canada is forecast at double this figure. For the United States the installed figure in 1955 was 130.4-million kw. In 1975 the United States' demand is estimated at over two and one-half times the latter figure.

These few examples indicate the great increase required in power installations and output to meet future demands. Hydro-electric plants in the Canadian north-west have, to date, been developed close to firm markets and centres of population, subject to reasonable construction costs. A two-way trend is now noticeable. Power sites not regarded as economic some years ago are now being developed or re-examined, and major power potentials large enough to accommodate several primary industries are being investigated. Yukon river power falls in the latter category because not only is its potential large enough to handle ores from many parts of the world but it will be available at comparatively low cost for all mining and forest product requirements within transmitting distance. At the present time there are within reach of Yukon river power more than twenty large mineral deposits including numerous mines in various stages of development.

General

The project has provided a fascinating engineering study not only because of the wide scope of its problems ranging from hydro-electric matters to international ones but because it represents another step towards bringing raw materials to power supply for processing on a large scale.

Probably no major development in the Canadian northwest is linked more closely with, or will stimulate more the development of Canada's natural resources. It will improve transportation facilities, encourage exploration and surveys of all kinds, and bring settlement and stability to unpopulated areas. Yukon power can be a prime factor in establishing an industrial empire in Canada's northern regions.

In conclusion, the writer wishes to express his appreciation of the valuable co-operation and advice given by Dr. T. H. Hogg on the many problems associated with the Yukon River Project. As consultant over many years to the Ventures group, his great knowledge and experience were always available.

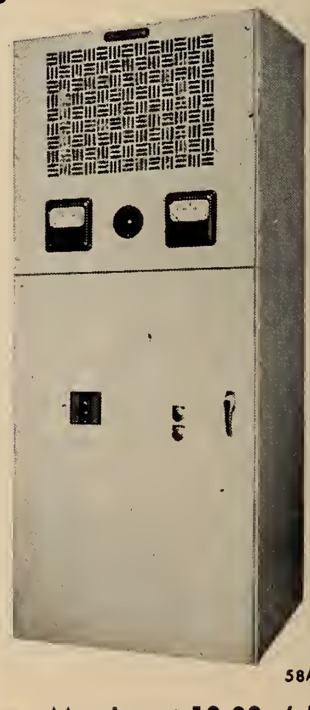
NO MAINTENANCE NEEDED!

THE NEW WESTINGHOUSE SILICON RECTIFIER

converts power in a fixed voltage AC system — and it never needs maintenance! It's an entirely new kind of DC-power source that means big savings for *you* in time and money.

How does the Westinghouse Silicon Rectifier compare with an equivalent motor-generator set?

- It's so small and light, you can mount it on a shelf or mezzanine floor where you wouldn't dare put a motor generator set.
- It costs less to install, and occupies about ⅓ of the space.
- It's much quieter in operation, and you don't have to bolt it down.
- It's more efficient—and, of course, maintenance costs are 100% less.



The new Westinghouse Silicon Rectifier is gaining great favour in modern industry as the ideal DC-power source for many types of heavy machinery. Already two of Canada's largest steel companies have ordered Westinghouse Silicon Rectifier installations.

Here is the answer to *your* DC-power needs! Call your nearest Canadian Westinghouse representative *now* for detailed information. Canadian Westinghouse Company Limited, Hamilton, Canada.

Foundations for the Queen Elizabeth Hotel

O. Duskes, M.E.I.C.
Construction Engineer,
Montreal Terminal Development, Canadian National Railways

THE HOTEL is a structural steel frame building of more or less conventional construction resting on concrete foundations which in turn are founded on natural limestone. Only two features in the construction of the foundations might be of interest to you. The first was the problem of building a retaining wall up to 55 feet high along the east side of Mansfield Street without generating any condition that might result in damage to St. James Cathedral located on the west side of the street. The second problem was of much less consequence but it was caused by the necessity to impose loads of 25 tons per square foot on the surface of limestone which in places was of quite doubtful capacity.

This paper will deal mainly with a description of these two problems and with the methods of construction that were used.

St. James Cathedral is a large heavy masonry structure. The masonry foundations rest on natural soil a few feet below the surface of the ground. The structure shows some indications of localized settlement of foundations. Before any work was started on the hotel this church building was examined very carefully by C.N.R. engineers and also by an independent committee. It was the opinion of all concerned that the hotel foundations must be so constructed that the earth under the church foundations did not move laterally or vertically and that vibrations caused by dynamite and demolition must be kept down.

Before the hotel construction the east side of Mansfield Street was supported by natural undisturbed earth with a berm 6 to 10 feet wide on top and a slope of 1½ horizontal to 1 vertical. This earth slope was

Fig. 1

The new Queen Elizabeth Hotel in Montreal, belonging to the Canadian National Railways, adjoins the Catholic Cathedral of St. James. One had to avoid damage to the Cathedral during excavation and construction of the hotel, and when a 55-foot retaining wall was built between the two sites. A further problem concerned the necessity to impose loads of 25 tons per square foot on limestone of doubtful capacity. This paper deals with the problems.

about 30 feet high on top of rock. As the result of considerable engineering thought and study it was decided that the only safe procedure was to build the retaining wall first and remove the earth and rock from the east side of Mansfield Street after the wall was completed.

The retaining wall is 50 feet high above excavated rock level at Dorchester Street and 40 feet high at Belmont Street; it is 380 feet long. In effect the wall consists of a reinforced concrete slab 2 feet thick at the top and 3 feet thick at the bottom. The bottom of the slab is anchored about 5 feet into solid rock and is supported horizontally for its full length at an elevation about 20 feet above excavated rock level by a heavy reinforced concrete beam. This beam is supported horizontally at about 25 foot centres by concrete buttresses built on the east side of the wall. In effect the vertical wall acts as a vertical cantilever, loaded by the earth on the west face and the reactions from this load taken by the rock into which the toe of the wall is bedded and by the horizontal concrete beam 20 feet above the rock.

The construction method used was as follows: a vertical trench 6 feet wide was excavated full length of the retaining wall—the remaining portion of the earth slope being left in place. Simultaneously tunnels were excavated at track level at the site of each buttress to intersect the vertical trench.

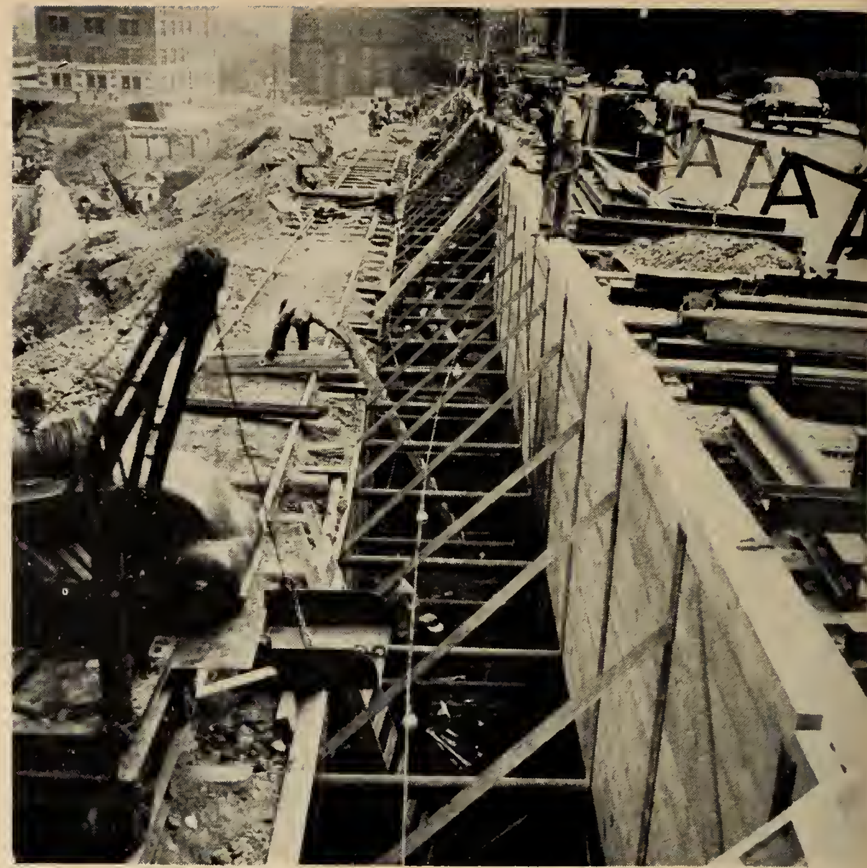

Fig. 2 (top)

Fig. 3 (left)

Figure 1 shows the first stage of the excavation for the vertical retaining wall. As can be seen, a cut 6 ft. deep was first made with a bulldozer, the excavated material being pushed over the slope. Excavation of the trench to a depth of 4 ft. was the next step, this being immediately followed by the placing of pre-fabricated shoring from street level to the bottom of this 4 foot trench.

Figure 2 shows the next stage. The construction of the shoring consisted of 6 inch wide flange beams at 15½ lb. placed vertically at 6 foot centres on both sides of the trench. The sheeting was 4 inch plank fitted between the flanges of the beams and the struts were 4 inch standard weight steel pipes. The beams were fitted into the excavated trench in 4 foot vertical lifts and were butt welded at the ends. The pipes had plates welded on the ends and these were in turn welded to the beams lapping the beam joints.

The excavation was done by hand with the aid of air-operated clay diggers. The excavated material was loaded into small skips which were hoisted by air winches and derricks mounted on railway lorries which also carried small air compressors. The lorries travelled on standard gauge track constructed alongside the trench and thus each rig was able to serve several crews of muckers. The excavated material was disposed of by swinging the derrick and dumping over the slope. The derricks were also employed to lower the shoring material in the trench where required.

The excavation was deepened in increments of 4 feet. Alternate sections 6 feet long were excavated, shoring placed, followed by excavation of the intermediate sections and completion of the shoring. Thus at any time a maximum of 50 per cent of the 4 foot cut was unsupported.

The work was done very carefully and the spaces behind the planks were filled and tamped with earth. In spite of these precautions a portion of the trench was observed to go off line. Though the movement was very small it continued to increase over several days and was the subject of considerable concern.

Fig. 4

Cause of Movement

The movement was probably due to one or more of the following:

(1) The packing behind the planks was perhaps not perfect and the movement might be due to slack being taken up.

(2) The weather had been very wet and seepage into the ground, especially on the slope side of the trench, might have been sufficient to lower the resistance of the earth to pressure from the shores and local movement took place.

(3) The entire earth slope might be failing. This of course could have been disastrous. It was happily ruled out quite early by careful and regular measurements.

Fig. 5

The movement of the trench was quite small and not serious but it did continue. To stop it holes were drilled through the shoring planks on the east side and grout was pumped to fill the voids. The track was lifted and replaced on a 6 inch concrete pavement. Whatever the cause, these two remedies were sufficient to permanently stop the movement of the shoring. The balance of the packing behind the shoring planks was done with crushed stone and in particularly bad spots with lean concrete.

Figure 3 is a view of the interior of the trench showing some of the reinforcing steel in place. The retaining wall, above the 90 level, enclosed space intended for high class occupancy and first class waterproofing was essential. As the wet side of the wall would not be exposed for waterproofing after the concrete was in place it was decided to place membrane waterproofing on the exposed face of the shoring planks. The membrane consisted of two ply felt and three ply asphalt saturated cotton fabric, each layer mopped on with hot asphalt. To protect the membrane from being punctured during the placing of the reinforcing steel it was covered with ¼ in. masonite glued in place with hot asphalt.

Figure 4 shows much the same as

Fig. 3. This view was taken near the top of the trench. The masonite was omitted here because there was less danger from the reinforcing steel. Conscious of the danger of fire in the trench, due to the presence of form lumber and asphalt, precautions included the employment of pensioned city firemen for fire prevention, and the posting of "No Smoking" signs in English, French, and Italian.

At this time the wall has been in place for almost two years—no evidence of seepage or leakage of water through the wall has been observed.

Figure 5 is a general view from Dorchester Street bridge of the earth slope and shows the tunnel portals. The portals were driven 4 feet wide and 7 feet high and served as accesses to the main portions of the tunnels at the buttress locations.

Figure 6 shows the interior of a buttress tunnel. The shoring is much the same as in the trench for the vertical wall, 3 in. plank sheeting was used for the walls and 4 in. plank for the roof. The WF beams were centred 3 feet to 6 feet depending on the superimposed load which increased towards the street. Each set was strutted with steel pipes top and bottom with intermediate struts where the side exceeded 7 ft. 6 in. in height.

The earth excavation was progressed in increments equal to the spacing of the shoring sets—3 ft. to 6 ft. A pilot tunnel was driven at the top, a few feet in advance of the main tunnel to provide space for temporary plank protection at the roof. The ground stood well during excavation and no temporary side protection was required. The excavation was done with air-operated clay diggers, the loosened material being loaded into wheelbarrows and dumped at the tunnel portals where it was later loaded into trucks with front end loaders.

Only experienced miners were employed in this work. To stimulate progress a bonus system was put into effect.

Fig. 6 (right)

Fig. 7 (below)

When this photograph was taken the earth had been excavated, during driving of the tunnel, to the surface of the rock and rock excavation was in progress. The beams were pulled together with turnbuckles to avoid spreading—which spreading, if it took place, would release the shoring planks.

The concreting of the walls was done by discharging from transit mix trucks located on Mansfield Street into "elephant trunks" spaced at about 15 foot intervals along the length of the wall.

Concrete for the buttresses was discharged into 6 in. "pump-crete" pipes vertically down the wall trench changing to horizontal through a 90 deg. bend. The horizontal pipe was suspended by hangers from the trench roof. No pump was used—the head of concrete in the vertical pipes was sufficient to keep the concrete moving. Any interruption, no matter how slight, was sufficient to cause the concrete to stick in the pipes, making it necessary to dismantle and clean out the entire system. After the first few days, the crews became accustomed to this operation and delays were reduced to a minimum.

An external vibrator at the 90 deg. bend was tried as an aid to maintain the flow but was soon discarded when it was found that it tended to increase packing of the concrete, especially at the bend. The slump of the concrete was carefully maintained at 1½ to 3 inches. Concrete was discharged directly into forms and there was little or no segregation of the concrete. The concrete was vibrated with internal vibrators. Stripping of the forms disclosed well placed concrete with practically no honeycombing.

Figure 8 shows excavation of the earth slope. A bulldozer was used to excavate down to the elevation of the tops of the buttresses, the balance of the excavation being performed by shovels standing at track level. Fig. 9 shows the excavation well advanced. Fig. 10 shows some of the buttresses and part of the wall after stripping. The steel pipe struts are cast into and remain permanently in the wall.

In the construction of foundations for the Aviation Building it was necessary to dig and shore open trenches some 30 to 35 feet deep in the material overlying the rock. These were shored with 4 in. hardwood plank with 6 in. x 6 in. hardwood walers and 6 in. x 6 in. hardwood struts. In many places the pressure on the struts was so great that the ends of struts crushed into the hardwood walers as much as 2 in. at each end and quite a few of the 6 in. x 6 in. hardwood struts failed in compression. This experience forced the use of 6 in. steel beams as walers and 4 in. steel pipe for struts and there were no failures of either.

This completes the illustrations in connection with the retaining wall. It is of interest here to state that the wall was constructed with no settlement or loss of material on the west side—and therefore with no possible prejudice to the physical condition of the Church structure.

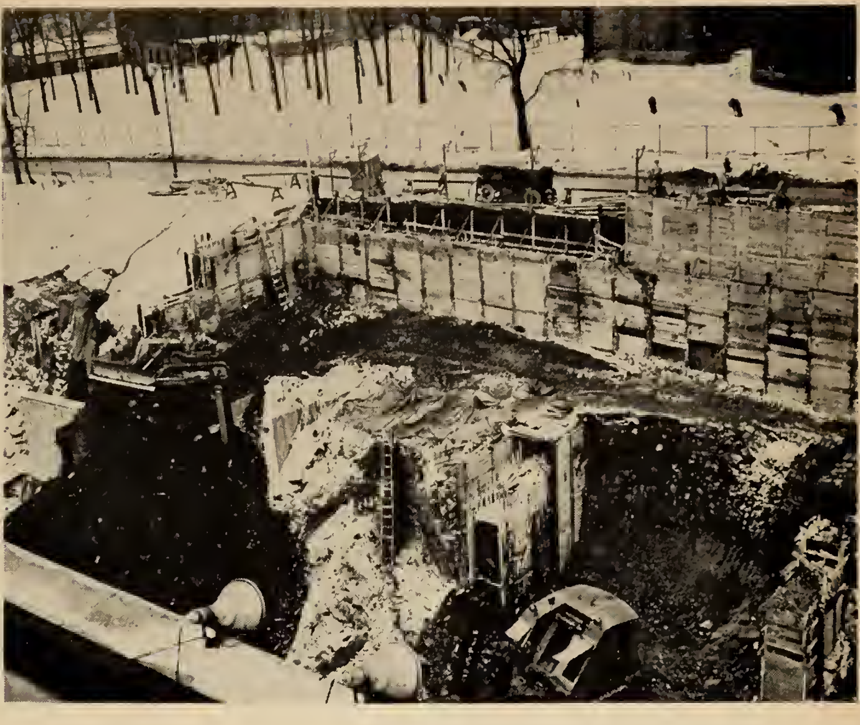

Fig. 8

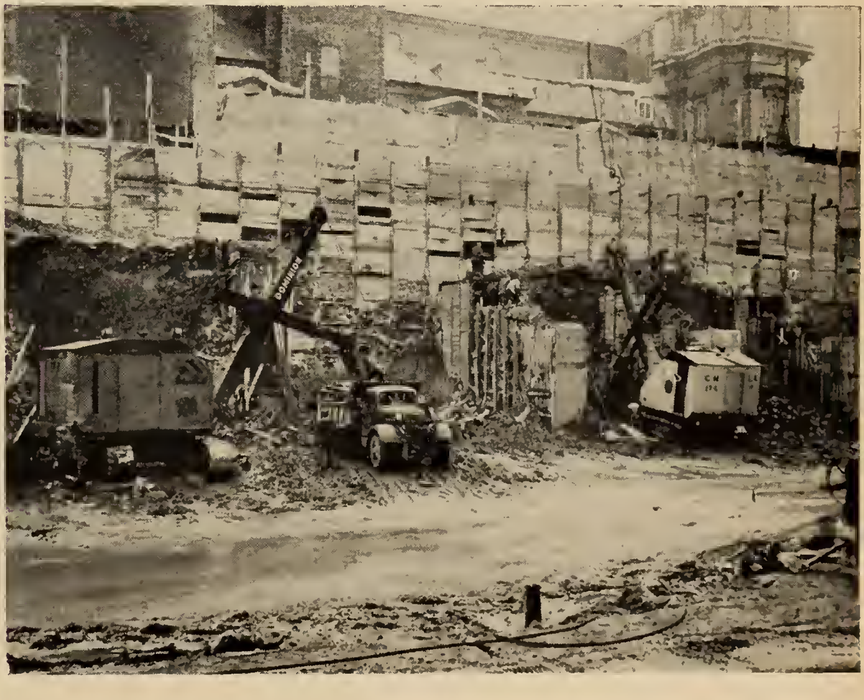
Rock Excavation for Foundations

The site of the building is underlain by limestone, and the foundations were designed with a bearing load of 25 tons per square foot on the rock. The limestone is bedded horizontally, as stone this is good solid hard material but it contains seams and pockets varying in thickness from mere cracks to 4 or more inches. The presence of these seams could not be ignored as in some cases the material in the seams is plastic and could cause building settlement if existing at a shallow depth below a column pedestal.

At each column location a hole 2⅜ in. diameter was drilled 20 ft. deep with a diamond drill, using a solid bit as no core was required. The rock was investigated with a home-made device consisting of a pole about 1½ in. diam. with a sharpened nail attached at right angles near one end. A tape graduated in feet and inches was attached to the pole with the zero end at the nail. The side of the hole was scratched with the nail and the locations and sizes of the seams were discovered and noted. This device is primitive but has proved to be effective.

Seams at a depth of about a foot or less were eliminated by carrying the excavations to their elevations. Deeper seams were assessed by assuming a load distribution through the rock at a 45° angle and the unit load calculated at the elevation of the seam. Where this unit load did not exceed 4 to 5 tons per square foot the foundation was accepted—otherwise the excavation was deep-

Fig. 9



ened to the seam elevation. In some cases a succession of seams was found extending to considerable depth. In these cases the dimensions of the pedestals were increased to reduce the unit loads to acceptable limits.

The rock excavation was accomplished by drilling and blasting. Fig. 11 is a general view of this work being performed in the open. Fig. 12 shows rock excavation being carried out between station platforms. Here the rock was handled by a crane mounted on a flat car to raise the crane so that it could swing over the tops of the station platforms. The rock was dumped into railway cars because highway trucks could not operate in these places.

The concrete was deposited in the pits—no forms were used—to within 6 in. of final elevation. The screeds for the final finish consisted of two 4 in. x 4 in. x ½ in. steel angles of suitable length with one edge machined. The angles were each mounted on two 1-in. bolts, previously cast in the concrete and brought to level and held securely by two nuts on each bolt, one above and one below the horizontal leg of the angle. The concrete was deposited between the angles and struck off with a straight edge made of a 1 in. x 4 in. steel flat with one edge machined. The resulting surfaces were uniformly flat and level and at correct elevation. After the caps were cured, centre lines were scribed on the surfaces with carboloy-tipped scribers to locate the column centres. It is a tribute to the work of our surveyors and steel fabricators that the steel superstructure of this building went together perfectly and no trouble was experienced during erection because of bad fit.

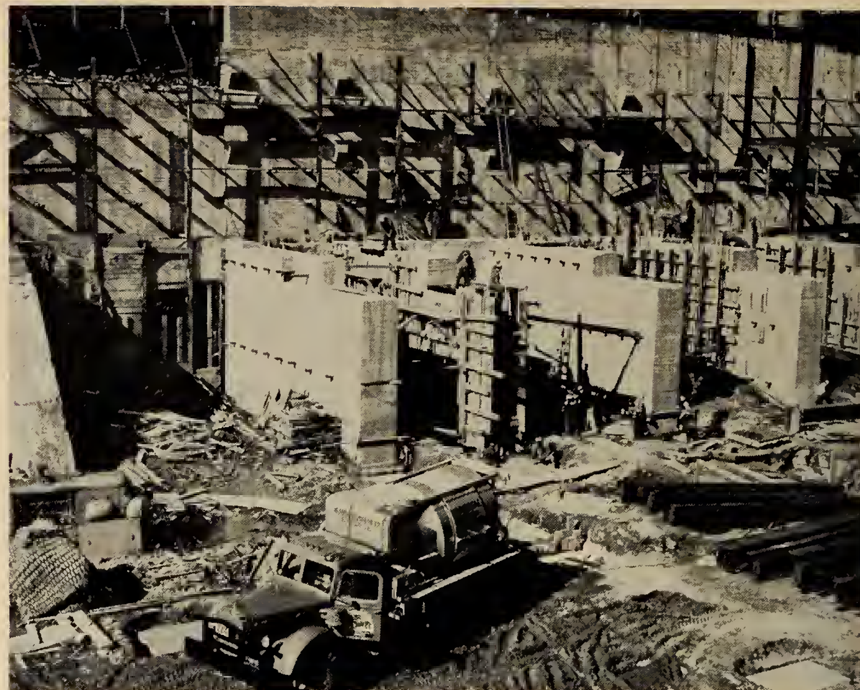


Fig. 10

Vibration

A considerable area below the track level is developed for the express, baggage, and mail handling departments. The tracks over this "sub-track" area are carried on a reinforced concrete structure which is subject to vibration from moving trains. The building columns in this area pass through openings in the track slab, beside and on the same footings as track structure columns. In areas where there is no sub-track structure the building columns are supported on footings immediately adjacent to railway tracks. These footings are also subject to vibrations.

The overlying building is to be a hotel, and no vibrations from trains must get into this structure. The first few buildings constructed over the tracks in Grand Central Terminal in New York were not properly isolated, and trains passing underneath can be both heard and felt throughout the entire height of the building. Intensive study by experts resulted in a theory which proved to be simple, cheap, and effective. If one stretches a skin of any material tightly over an opening and tap it, it vibrates and the period of vibration depends on only two factors—the nature of the material in the skin and the degree of tension or stress. If one stretches two layers of similar material in contact over an opening and tap it there is little vibration. The material in each layer is the same but there is just enough difference in tension or stress to make each skin have a different natural period of vibration and thus

Fig. 11

the vibrations in each skin tend to dampen those in the other contacting skin. If two or more skins of different material are stretched in contact over an opening and one tries to induce vibration, they will not vibrate, as each layer has a different vibration period and each layer acts to dampen the vibrations in all contacting layers.

Isolation Pad

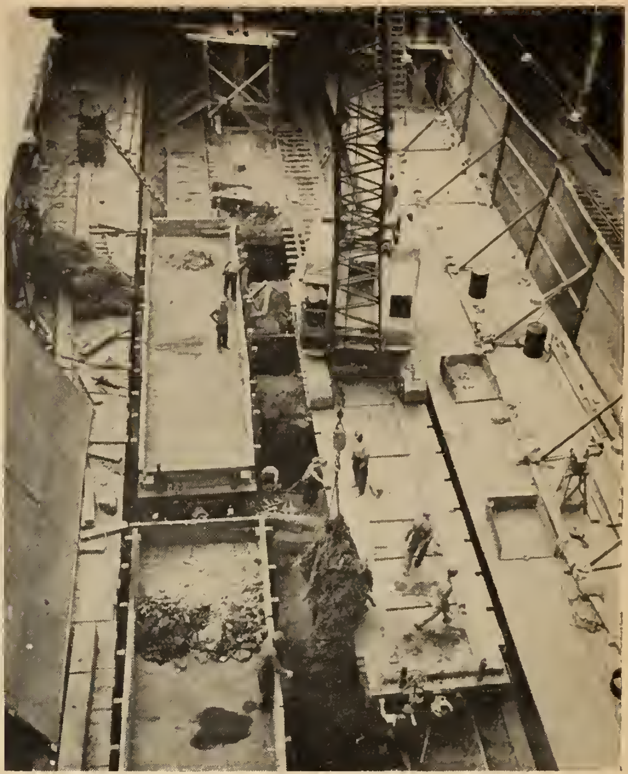
The explanation is complicated—the resulting isolation pad is simple. Five thin layers of dissimilar materials in contact and under a stress of 800 to 1000 p.s.i. in compression. In more detail, the isolation pad consists of ⅛ in. lead, ⅜ in. asbestos board, 1/16 in. steel, ⅜ in. asbestos board and ⅛ in. lead. The lead is bent down at the edges and the top and bottom layers soldered together to make a water-tight envelope. The pad is coated with asphalt roofing paint. No anchor bolts are permissible finally. (Fig. 13 indicates anchor bolts.) These are used only during erection and are later cut off.

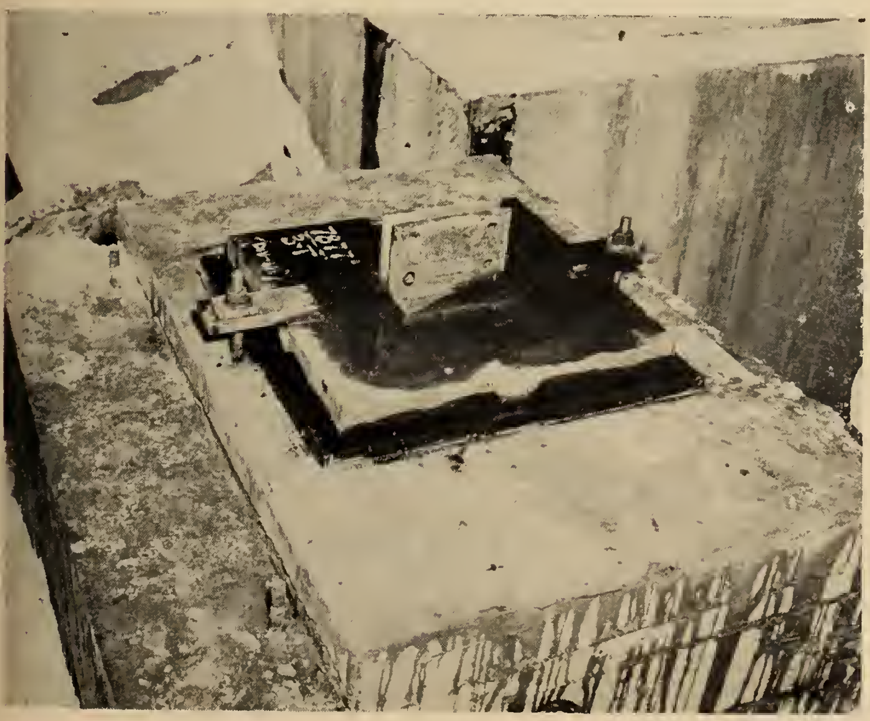
Above the isolation pads the fireproof column is isolated from all other vibrating material with 2 in. of cork board applied in 1 in. layers with staggered joints. The installation of this cork board must be done with great care as there must be no concrete fins through the cork to transmit vibration.

These pads have been used in many places—and they are 100% effective.

Fig. 12 (right)

Fig. 13 (below)





Underpinning And Strengthening

At the juncture of the station building and the hotel the columns are common. In some cases the station columns were adequate to carry the increased loads and it was necessary only to expose the existing columns by removing the masonry and concrete, drilling holes, and bolting on beam seats. (Fig. 14.)

Where existing columns were inadequate for the increased load they were stripped of their concrete fireproofing and strengthened by the addition of angles, plates or tees bolted or rivetted in place—provided that the foundations were adequate. (Fig. 15.)

Where both the columns and the foundations were inadequate the load was taken, temporarily, by wooden posts, the columns removed, the foundations prepared, and new columns erected.

Fig. 16 shows what was done in one case where both the column and the foundation were inadequate and where it was very difficult to use temporary posts. In this case the column was first strengthened by plates rivetted on the flanges. A jacking girder was bolted on and the load taken off the foundation by four hydraulic jacks supported on the track structure. The existing foundation was extended and the jacks removed, with the jacking girder.

Site Difficulties

The hotel is situated over some eleven railway tracks (Fig. 17 and 18). Of these, only two could be taken out of operation at any one time. As finally worked out, the sequence for construction over any pair of tracks was:

(1) Remove overhead traction wires.

(2) Remove services, electrical, mechanical, etc.

(3) Demolish existing plaza slab.

(4) Prepare foundations.

(5) Replace traction wires and put tracks into service.

This sequence was repeated until all foundations were prepared.

Similar procedure was followed for steel erection and also for construction of concrete floor slab at the plaza level.

With the full co-operation of the operating department of the railway and all the contractors concerned this

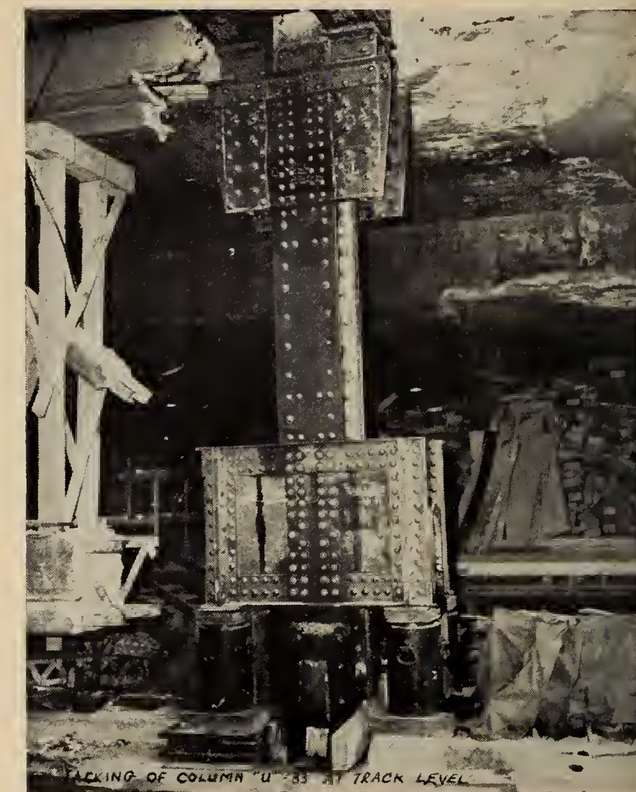


Fig. 14 (above); Fig. 15 (below)

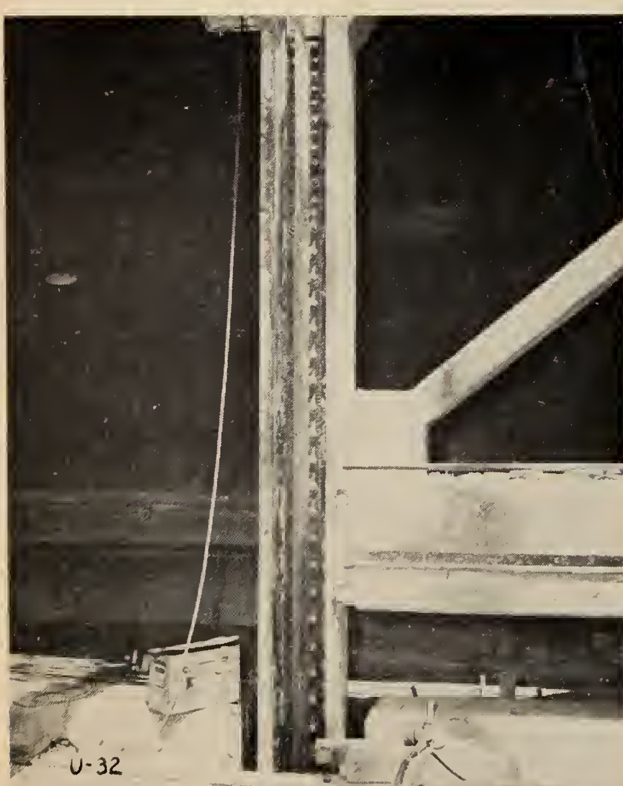
Fig. 16 (above); Fig. 17 (below)



operation was completed with a minimum of interference with train service and in safety to the travelling public.

The Cathedral facing the hotel is very sensitive to vibration from blasting and from the demolition ball. To control the situation a vibration recording instrument was set up in the Cathedral to measure vibration. This instrument, with its attendant, was used at all times during the course of the demolition and the rock excavation. The effect of each blast was recorded, and the effect of the demolition ball in setting up vibration was noted. These vibrations were kept below predetermined limits by limiting the amount of explosive used and where necessary altering the demolition procedure. As a further safeguard, an independent committee, consisting of an architect and two engineers, was retained. The committee examined the Cathedral before the work was started, during progress of the work, and finally when the excavation, demolition, and retaining wall were complete. The committee reported jointly to the Cathedral authorities and to the railway company. No damage to the Cathedral building was recorded and good relations were maintained with the Cathedral authorities.

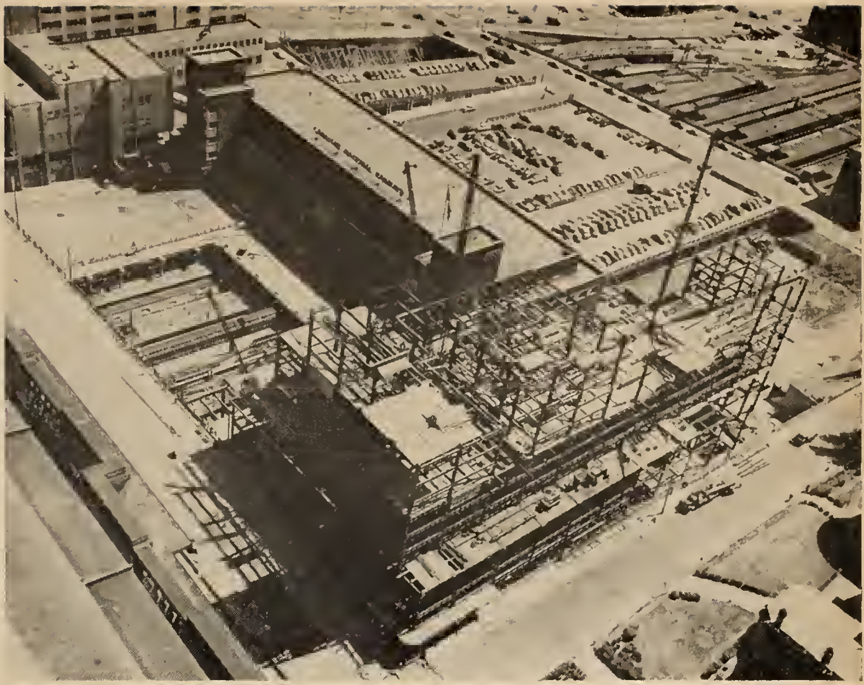


Fig. 18

Acknowledgments

I would like to express thanks to A. V. Johnston, system chief engineer, Canadian National Railways, for permission to publish this paper, and to R. O. Stewart, formerly chief engineer and now consulting engineer, C.N.R., for his guidance during the course of the construction.

Prestressed Wind Bracing in Queen Elizabeth Hotel

D. A. Chamberlain, JR.E.I.C.
Dominion Bridge Company Limited, Montreal

THE PROBLEM of overcoming wind forces in a tall, narrow building has always presented certain difficulties. The Queen Elizabeth Hotel in Montreal being built by the Canadian National Railways is no exception. The structural designers found it necessary to develop some type of adequate wind bracing system, which, to suit the architects' requirements, had to be within as thin partitions as possible and at the same time assure that no damage to the partitions could occur by transverse deformation of the diagonal members. The solution of this problem is the topic of this paper, pretensioned wind bracing enclosed within narrow partitions.

The Queen Elizabeth Hotel is a 21 floor building with a 2 floor penthouse. Below the main floor are three levels, the lower level, the station level and the track level. The track level which is about 55 feet below the main floor is open to the atmosphere to allow the passage of trains under the hotel and the station course. The second and third floors, above the main floor, contain the dining rooms, banquet rooms and convention halls. Above the third floor are the bedroom floors which are all similar in plan.

It was found necessary to develop some type of adequate wind bracing system to overcome the effects of wind forces in the Queen Elizabeth Hotel, which is a tall narrow building. The design was limited by the architect's requirements. This paper describes the eventual solution of the problem—this was the use of pretensioned wind bracing enclosed in narrow partitions.

Design History

The original design investigations were based on a rigid frame building with moment connections on all beams to take the wind force. The unusual floor framing (as seen in Figure 1) has no direct link between the two interior columns and consequently, the wind must be taken by two single bay towers instead of one three bay tower. This factor would have made the beams very deep and the moment connections very wide in order to obtain the required number of tension rivets. The depth of beam and the width of flange were of prime importance architecturally, as there were to be no hung ceilings in the bedroom floors and large beams would break the appearance of the wall. Hence moment connections were rejected for the bedroom floors but retained on the lower floors where large beams were not objectionable.

Bracing

Among the ideas considered was the theory of one wing of the building supporting the other through the concrete floor slab. This theory has been used successfully in many cases but did not prove too satisfactory in this case due to the "L" shape of the building and the break in the slab, for elevator shafts, at the highly stressed inside heel of the "L".

Angle or channel bracing members were suggested, but the resulting partition thickness would be about 12 inches as compared with the standard, non-braced, interior partition of 4 in. thickness.

The shearwalls were to be of reinforced concrete, poured in two pours to form a cruciform section, in elevation, with the floor slab. The partition thickness resulting from the use of shearwalls would be 6 inches on the bedroom floors.

Some of the disadvantages of concrete shearwalls were:

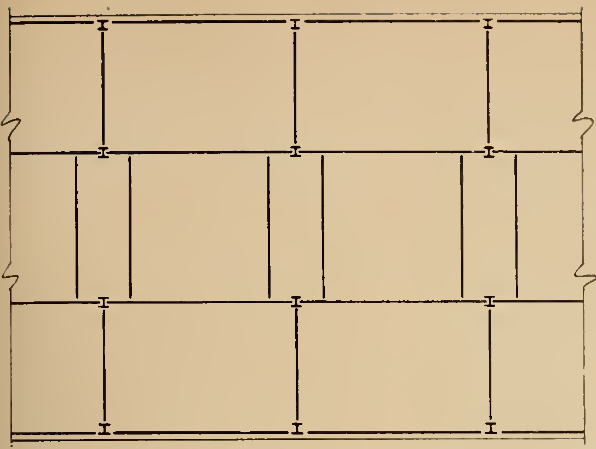
(a) they restricted all future alterations in the building;

(b) they would have to be interrupted between the 10th and 11th floors to allow passage of large air conditioning ducts above a hung ceiling (there being a larger floor to floor dimension than other bedroom floors);

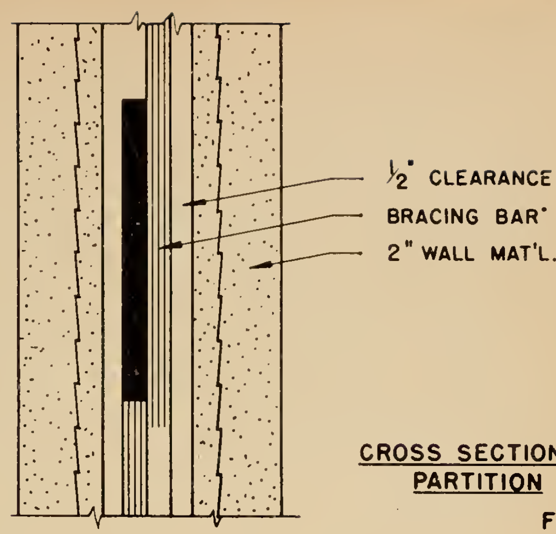
(c) the dead load on the footings, and columns would be substantially increased;

(d) they would cause pouring delays due to necessary sequence of walls and floors.

Only a nominal stiffness is provided in the steel framing of the buildings and columns would be substanare of the moment type but only designed for the size of the relatively shallow beams. About 5 per cent of the wind on the finished building could be taken on these beam con-



TYPICAL STEEL FRAMING FOR BEDROOM FLOORS
FIG. 1.

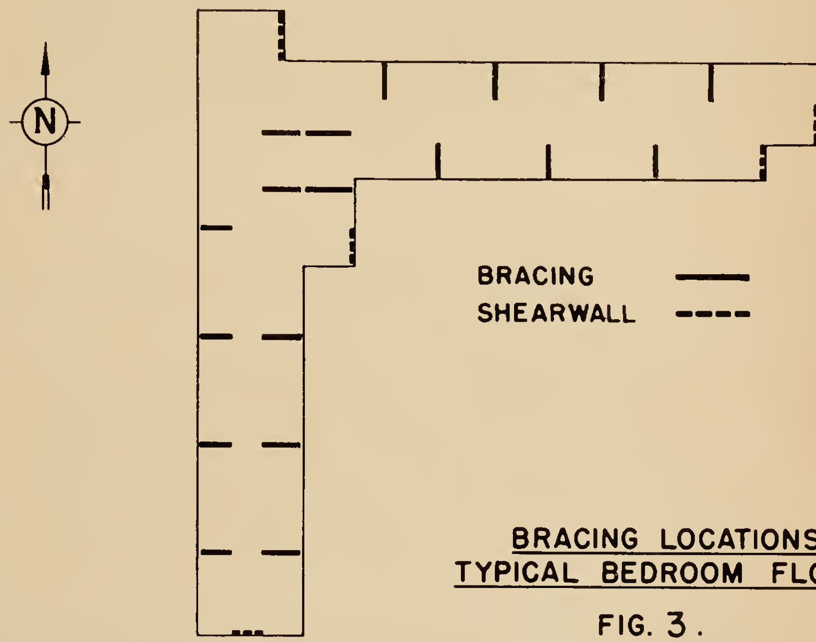


CROSS SECTION OF PARTITION
FIG. 2.

nections whereas about 45 per cent of the total wind force would act on the bare steel structure. It became apparent that the pouring of concrete shearwalls must follow closely behind the erection of the steel structure if major erection bracing were to be omitted. Steel erection can proceed more rapidly than forming and pouring of concrete, so it was felt that temporary erection bracing would be necessary in order that the erection procedure would not be unduly interrupted.

The temporary erection bracing required made it more unlikely that the shearwall solution was economical. The system of steel bracing was again considered and it was decided to use steel plate bracing bars varying in width from 6 in. to 8 in. and in thickness from ⅜ in. to ⅞ in. Details were so devised that this bracing could be used as temporary construction bracing and later pretensioned as permanent bracing. In order to enclose this bracing in a confined area, it was necessary to pretension the bars to a point where, with maximum wind acting on the structure, no bracing bar would go into compression. This enabled the architects to enclose the bracing in a narrow partition without the possibility of cracking walls. The composition of the partition. is 2 in. plaster faced wall material, 2 in or 3 in. air space for bracing bars depending on bar thickness and 2 in. wall material giving a total partition thickness of 6 in. to 7 in. A cross section of a typical partition is shown in Fig. 2.

The use of shearwalls was maintained in exterior walls and in some cases around the elevator shafts in the lower floors but, in general, pre-



BRACING LOCATIONS

EQUIPMENT FOR SHORTENING BAR BY UPSETTING
FIG. 4.

tensioned bracing bars replaced concrete shearwalls. The location of shearwalls and bracing panels on the bedroom floors are shown in Figure 3.

Methods of Pretensioning

There are two methods of prestressing wind bracing that have been used in buildings recently. The first is by heating the bar after both ends have been fastened and applying a compressive force on the heated area sufficiently large to upset the bar, and allowing the heated area to cool with the compressive force still acting. This method has been used for some years in bridge work for tightening eye bar truss members. The main disadvantages are the lack of flexibility in adjusting stress after the upset has been made and the inability to use the system easily as a construction bracing system before the final prestressing is carried out. The equipment sometimes used is shown in Figure 4, and consists of two clamps which are clamped to the bracing bar. The area between the clamps is heated by means of a torch to a cherry red color at which time the clamps are drawn together with two large bolts until the required upset is obtained. The clamps are maintained until the bar has cooled and the result is a tensioned bar with a visible upset.

The second method to be described is that used on the Queen Elizabeth Hotel. By heating the bar and clamping a free end when the required elongation is obtained, the result after cooling is a tension proportional to the measured elongation.

Prestressing Procedure

The procedure used started with the initial erection of the bars as temporary erection bracing. Figure 5 shows a typical bracing panel detail. The gussets were shop rivetted to double channel beams framing between columns. These columns had shop connected angles to which the gussets were field welded. The upper jaw plates were shop welded to the bracing bar. Both gussets and jaw plates had assembly holes punched for field erection. The bar was erected and loosely bolted to gussets at top and bottom with ⅞ in. dia. bolts "a" and "b". With the columns plumbed, the gussets were welded to the column connection angles and bolts "a" tightened.

The lower jaw plates were then pushed down as far as ¾ in. dia. bolts "c" in 15/16 in. dia. holes would allow. Bolts "b" allowed this movement of jaw plates as the holes in the gussets were 1-3 16 in. dia. while

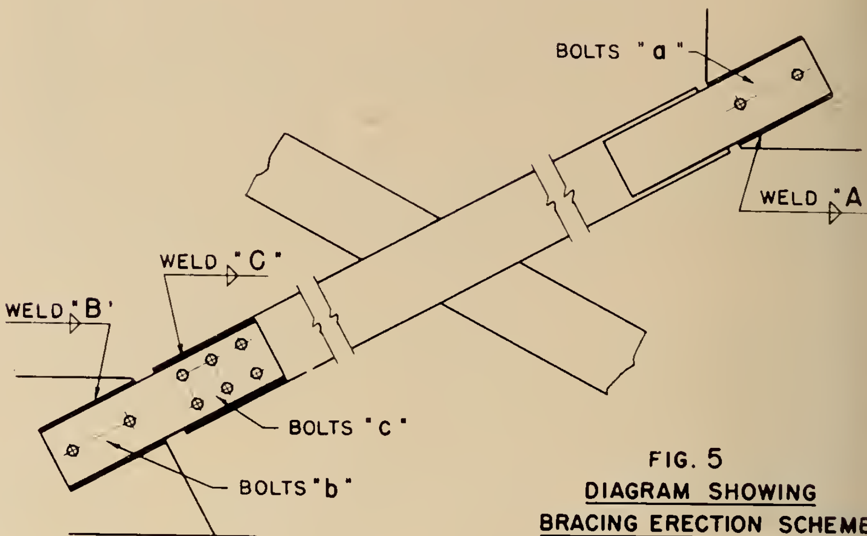

FIG. 5
DIAGRAM SHOWING
BRACING ERECTION SCHEME

Fig. 6. Below, left: View of hotel at beginning of pretensioning.

Fig. 7. Right: General setup of heaters.

the holes in the jaw plates were only 15/16 in. dia. The bolts "b" and "c" were tightened and the jaw plates were welded to the gussets at top and bottom, welds "A" and "B". This erection procedure provided a miss-match of holes by about ⅛ in. between the lower jaw plates and the bracing bar. To obtain an initial tension as temporary erection bracing, these holes were drifted with 15/16 in. dia. drift pins and bolted with suitable bolts "c". This provided an active system of wind bracing which kept the building in plumb during erection and until the prestressing operation could commence.

The steel erection was completed when the general contractor was just starting to pour floor slabs on the lower floors. When this pouring reached about the tenth floor, the pretensioning procedure began. Figure 6 shows a view of the hotel building at the time when pretensioning started.

The prestressing was carried out one panel at a time, completing one floor before moving on to the next. It was also important that the prestressing be carried out under a poured floor. The explanation of this will be given later.

The field procedure was as follows. The bolts "c" were removed at the lower ends of a pair of bracing bars, and the bracing bars were supported from displacement between the jaw plates. If the bar was bowed, it was brought back into line with drift pins, care being taken not to introduce appreciable stress. The measuring device, basically a dial indicator, was placed at the free end of the bar and set to zero. Heaters were placed over the upper halves of the bracing bars, which were heated until the desired elongation was obtained. High strength bolts were then inserted and tightened to hold the tension in the bracing bar developed by cooling. The weld "C" was made for the full capacity of the bracing bar and all the bolts were then removed.

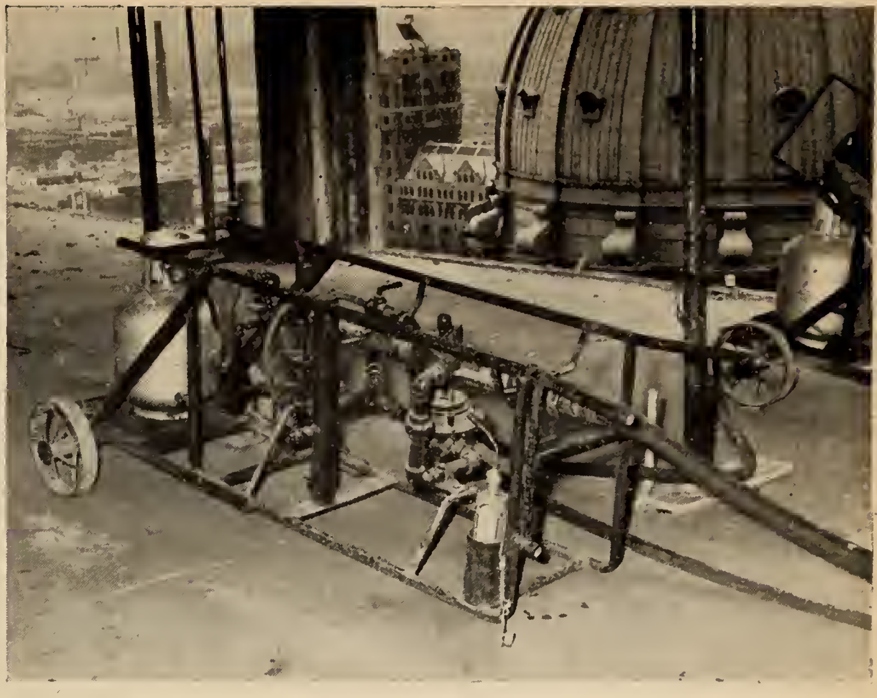

Fig. 8. Heating buggy.

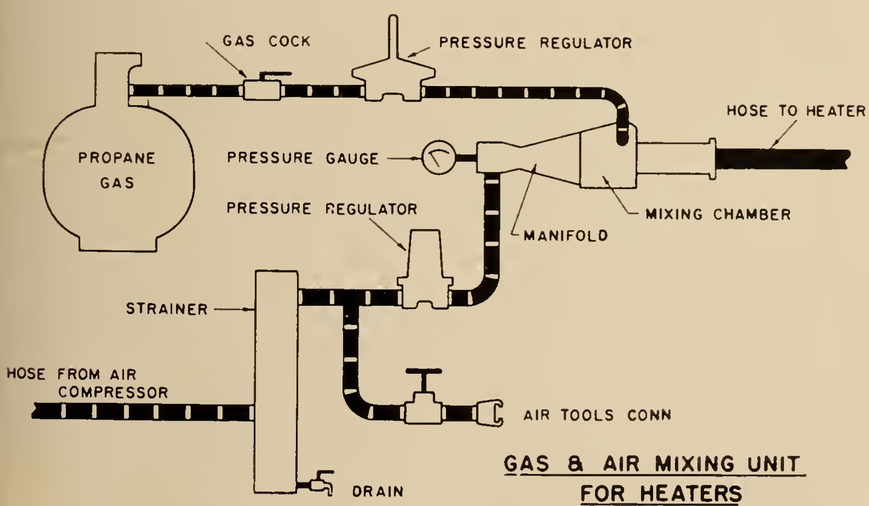
Equipment Used in Prestressing

Both bracing bars in one panel must be pretensioned concurrently and consequently, there are two complete sets of equipment, as seen in Fig. 7.

Each heater unit is mounted on a two-wheel buggy to facilitate movement. The buggy is a pipe assembly, as seen in Figure 8, which supports the gas bottle, manifold, valves, and pressure regulators. Above the manifold is a cradle where the heater unit may be placed when not in use.

The heaters burn propane gas mixed with compressed air. A schematic layout of the mixing unit is shown in Figure 9. After the air strainer is an outlet and valve which allows the connection of other air-operated tools. The propane supply is from a small cylinder mounted on the buggy. The gas passes through a control valve and a pressure regulator into the mixing chamber which is part of the manifold. Here the gas and air are mixed and flow under pressure through a flexible hose to the heater unit. The heater unit consists of two banks of 34 blast tips facing each other. The tips are mounted along two 1¼ in. diameter pipes, are enclosed in a cylindrical steel box about four feet long, slotted to allow it to be placed over the bracing bar. The heater was constructed so that, when placed over the bracing bar, the jets were protected from the wind and the heated area was shielded to minimize heat loss and to control the cooling rate.

At the lower end of the bracing bar a cradle type of support was used to keep the bracing bar in line between the jaw plates but allowing free movement in the direction of ex-



GAS & AIR MIXING UNIT FOR HEATERS

FIG. 9.

pansion. Figure 10 shows this cradle and the measuring device — a dial indicator which read in thousandths of an inch. The dial indicator on its stand was mounted on the bracing bar, and the plunger worked against an arm connected to the gusset or fixed end.

With the heater unit on the bracing bar and the temporary bolts "c" removed, the dial indicators were put in place and set to zero. Both heaters in one panel of bracing were lighted simultaneously by the use of a small gas torch. The expansion was watched on the dial indicators. Heating was continued beyond the required elongation to allow time for insertion of high-strength bolts and any necessary reaming. When cooling had proceeded to the point where the required elongation was obtained, the high-strength bolts were tightened by air-operated impact-wrenches and then checked with a torque wrench to provide recommended bolt tension. Figure 11 shows the bolting operation. The impact wrench and reamer were operated from the air outlet on the heater buggy so that only one line was required from the air supply; this was a 210 c.f.m. compressor located on the main floor with an air reservoir located higher in the building.

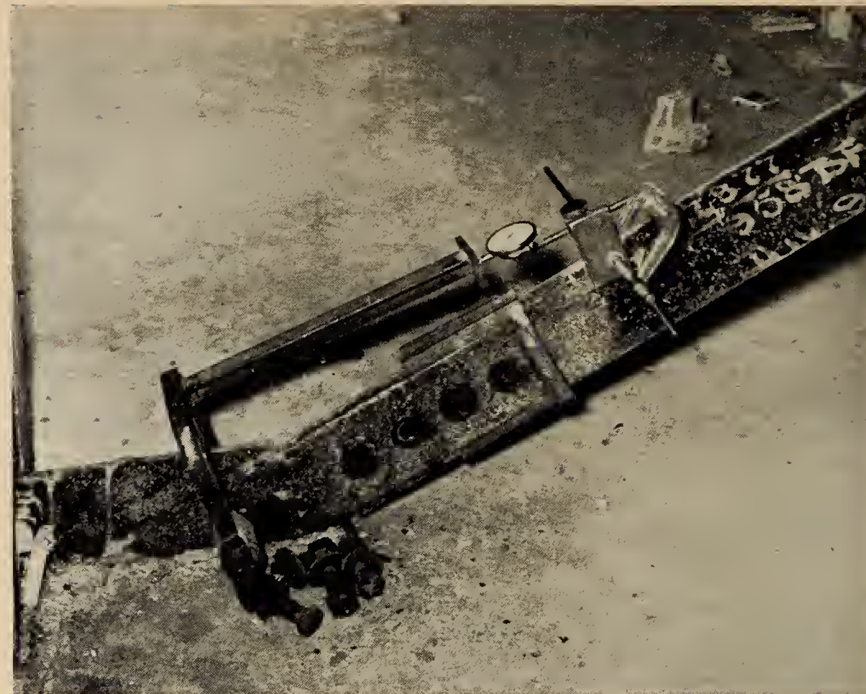


Fig. 10. Lower end of bracing bar showing measuring device.

The bolted connection, after cooling, held the bracing bar fixed due to the frictional effect of the high-strength bolts. The welded connection, Figure 12, was usually made a few days later, to complete cooling and allow an extensometer check before the final connection.

Technical Aspects

The desired stress in each bracing bar after pretensioning was 16,000 p.s.i., made up of 10,000 p.s.i. wind stress, 4000 p.s.i. dead load column shortening, and 2000 p.s.i. residual stress.

Fig. 11. Bolting with high strength bolts.

The stress in each bar was confirmed by extensometer readings (Fig. 13). The instrument used was a 10 in. Whittemore strain gauge. An initial reading was taken before the bracing bar was heated, but after the bolts were removed at the lower end, releasing the erection tension. The final reading was taken with the bar held in its expanded position and fully cooled. Two sets of readings were taken on each bar, one on each side, and averaged to give better accuracy. The difference in readings between final load and zero load gave the elongation in the measured length, from which the resulting stress could be calculated.

The effect of tensioning a panel of bracing on the surrounding structure is a shortening of the adjacent columns and beams above and below. Column shortening also occurs because of the addition of dead load on the structure above. Pretensioning followed closely behind the pouring of concrete floors, so some provision had to be made for column shortening due to increasing dead load. These operations were always carried out under at least one poured concrete floor, so that the concrete floor slab might act with the steel floor beam to form a composite strut.

The column shortening, and beam shortening due to the tensioning of bracing bars, was assumed in the beginning to be negligible. It was found, in practice, that there was about a 10 per cent drop in stress from that calculated for any given elongation. The calculated elongations were all increased by this amount, which proved to be satisfactory. The reasons for this drop in stress could have been elongation in the gussets and jaw plate connections as well as column and beam shortening.

Of the 16,000 p.s.i. originally introduced in the bracing bars, a gradual decrease was noticed as dead load was increased. Two test panels on the fifth floor were checked daily and records kept of the stress in each bar. Because test conditions were not like those found in a laboratory, the daily variations expected due to additional dead load and the effect of tensioning a panel directly above the test panel, were distorted due to inconsistent weather conditions. However, the trend showed a decrease in stress by about 2000 p.s.i. due to column shortening by the time prestressing was completed. At this time the progress of building construction was as shown in Figure 14. All the concrete floors and beam and column haunching were poured and about 15 of 21 floors of stone-faced exterior walls had been completed. The remaining six floors of exterior walls, all the interior partitions and floor finishes had yet to be installed. It was felt that the estimate of 4000 p.s.i. due to column shortening would be realized by the completion of the building early in 1958. Therefore, the bracing bar stress under zero wind force would be 12,000 p.s.i. and under maximum wind the bars would be stressed to 22,000 and 2000 p.s.i. tension respectively.

Fig. 12. Welding the final connection.

Fig. 13. Checking stress with extensometer.

The method of making the bottom connection of the bracing bar was closely followed with extensometer readings. After several uses of a high-strength bolt, the effectiveness of the bolt in holding the stress in the bar began to decrease. It was decided to replace the bolts after the second use and use a constant torque for all bolts. This eliminated the loss in stress previously observed. The procedure for making the welded connection required a tack-weld at the toe of the jaw plate before the regular upward weld pass was made. This would display any possible slippage that might have been caused by weld heating.

Conclusion

The problem of overcoming wind forces in the tall Queen Elizabeth Hotel building was overcome by the use of a system of flat plate bracing bars with a dual purpose. Its first use was as temporary erection bracing and secondly, after pretensioning, as permanent bracing enclosed in a narrow 6 in. partition.

The pretensioning operation was carried out by heating the bracing bar, clamping the free end and welding the final connection. This was carefully checked by extensometer readings to ensure a tension which would never allow the bracing bar to go into compression under the maximum wind load. Consequently, the bracing bar could be enclosed in a narrow space without any fear of buckling and consequent cracking of partitions.

Fig. 14. View of hotel on completion of pretensioning.

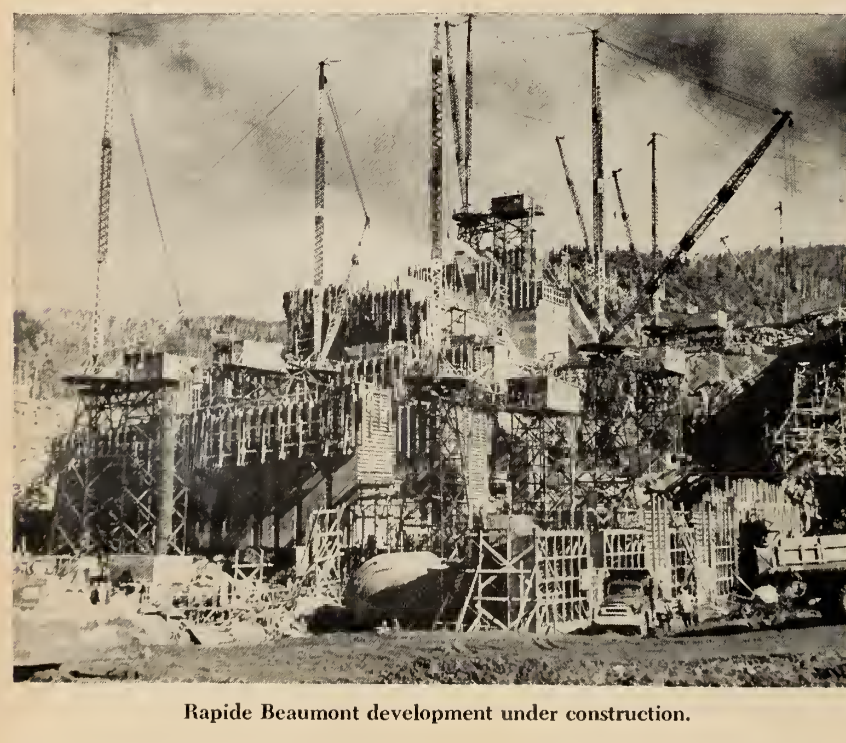
Acknowledgments

The Queen Elizabeth Hotel was designed by the architectural and engineering departments of the Canadian National Railways. Associate architects were Holabird Root and Burgee. The Conrad Hilton Hotel Company will operate the hotel on behalf of the Canadian National Railways. The steelwork was designed, fabricated and erected by Dominion Bridge Company Limited under contract with the Canadian National Railways.

Shawinigan's Rapide Beaumont Development

At Rapide Beaumont, on the upper St. Maurice River, near La Tuque, Que., The Shawinigan Water and Power Company has under construction a hydro-electric power project which will add 246,200 kilowatts to the capacity of the Shawinigan system, at a total estimated cost of $56.5 million. Design and construction is being done by The Shawinigan Engineering Company Limited.

The gross head available for producing power will be 125 feet. The dam will extend 1,600 feet from bank to bank. It will contain the intakes through which the water will pass to the "semi-open"-type power-house below, sluiceways to accommodate peak flow of water during flood periods, regulating gate section, and log chute.



Rapide Beaumont development under construction.

There will be six generating units. The turbines are the single-runner, verticle, Francis type, rated at 55,000 horsepower each, for a total of 330,000 horsepower. They are directly coupled to 45,000-kva., 13,800-volt, 60-cycle, 3-phase, totally enclosed, water cooled generators. Power will be fed through air-blast breakers to individual 45,000-kva. transformers which will deliver the power at 230,000 volts to a single bus, from which the whole output will be delivered to the transmission line through a single 230,000 volt air-blast breaker.

In order to construct the dam, the flow of the river had to be diverted through a by-pass channel 1,000 feet long, 130 feet wide, and 100 feet deep. The development necessitates removal, in all, of approximately 10 million tons of earth and rock.

The project is scheduled to start delivery of power in November, 1958, with all units in service by the spring of 1959.

The Queen Elizabeth Hotel — Outline of Electrical and Mechanical Services

N. S. B. Watson, M.E.I.C., *Electrical and Mechanical Engineer*

N. A. Klodniski, M.E.I.C., *Asst. Electrical and Mechanical Engineer*

Office of the Chief Architect, Canadian National Railways

THE FOLLOWING description of electrical and mechanical services is a brief outline, presented at this time in an effort to provide a complete presentation of the major engineering aspects under one cover. A more thorough presentation, of special interest to engineers actively engaged in this branch of engineering design will appear in a later issue.

General Description

The Queen Elizabeth Hotel has in general been designed and laid out to include the latest proven equipment and service distribution practice, with special attention in engineering application to provide the additional features and reliability and flexibility required in a convention hotel operation.

The existing site, adjacent to the Central Station, with train operations below and levels already established, especially on the lower floors, presented many design and layout problems.

Electrical Supply

The main transformer vault located at track level adjacent to the Mansfield Street retaining wall is supplied from two Quebec-Hydro sub-stations by means of two underground cables at 12,000 volts, 3 phase, 60 cycles.

Two 1000 kva, 3 phase, transformers provide 120/208 volt, 3 phase, four wire service for general lighting and kitchen and laundry power. Six 750 kva, 3 phase, transformers provide 575 volt, 3 phase, 3 wire service for general power, as well as lighting in remote areas by means of secondary step down transformers. The eight transformers are arranged in two rows to form two identical and separate groups each supplying one half of the hotel building load and each normally fed by one of the incoming cables.

Primary switchgear provides for automatic transfer of load to the serviceable cable, in the event of failure of one incoming cable, and secondary switchgear is arranged to permit manual transfer of load from one group of transformers to the other in the event of failure of any transformer.

This is an outline of the electrical and mechanical services that are to be installed in the Queen Elizabeth Hotel. A more complete engineering paper will appear later.

An auxiliary power supply, consisting of a 500 kva, steam turbine driven alternator, located at track level adjacent to Mansfield Street, provides 575 volt, 3 phase, 3 wire, 60 cycle service for emergency lighting throughout the building public rooms and corridors and emergency power service for two elevators and miscellaneous essential equipment.

Electrical Distribution

The comparatively large transformer sizes and the extent of the building required that more than normal consideration be given to rupturing capacity, distribution voltages and voltage regulation in the design of the distribution system and associated gear.

Lighting distribution in the lower levels, up to and including the third floor, is 120/208 volts, 3 phase, 4 wire and radiates from a main switchboard located on the hotel service floor, two stories below street level. The switchboard is fed directly from the two 1000 kva transformers by means of totally enclosed bus and is made up of high rupturing capacity air circuit breakers which feed radially via conduit and wire feeders to lighting break - down panels equipped with high rupturing capacity fuses. The lighting break-down panels are located at main load centers and in turn feed radially by means of bus duct or conduit and wire feeders to standard circuit breaker type lighting panels.

Lighting distribution for the upper floors, 4th to 21st inclusive, is provided by means of four 150 kva. banks of secondary transformers, 575 volts to 120/208 volts, located in penthouses above the 21st floor to be remote from guest bedrooms.

The secondary lighting distribution transformers are fed directly by means of conduit and wire feeders from a main auxiliary switchboard located on the hotel service floor.

Each secondary lighting transformer bank feeds a main distribution panel made up of standard rupturing capacity type fused disconnect switches which, in turn, feed vertically down to lighting break-down panels located on every fifth floor. The lighting break-down panels are also of the standard rupturing capacity fused disconnect switch type and feed, up and down, to standard circuit breaker type lighting panels.

Power distribution for heating, ventilation, air-conditioning, plumbing, fire protection, elevators, etc., is 575 volts, 3 phase, 3 wire and radiates from a main switchboard located on the hotel service floor. The switchboard is fed directly from the six 750 kva. transformers, by means of conduit and wire feeders, and is made up of high rupturing capacity air circuit breakers which feed radially to power break-down panels and thence to standard circuit breaker type power panels in a manner similar to the lighting distribution.

Power distribution for laundry and kitchen equipment is 120/208 volt, 3 phase, 4 wire and is also distributed radially from the main 120/-208 volt switchboard.

An auxiliary 575 volt switchboard, located adjacent to the main switchboards on the hotel service floor, provides automatic and manual switching facilities as required to adjust turbo-alternator load and as required to provide emergency lighting and power service.

Auxiliary power is distributed directly at 575 volts and emergency lighting is provided by means of single phase secondary step down transformers located strategically throughout the building.

Lighting

Lighting fixtures of all types, incandescent and fluorescent, are utilized as required to provide design requirements.

Service areas, such as the mechanical room, are lighted by means of prismatic glass reflectors to provide sufficient upward component of light for good visibility of piping, valves, etc.

Storage areas are lighted by means of standard incandescent or fluorescent lighting units, depending on intensity of illumination required.

Kitchens are illuminated with colour corrected fluorescent units to provide a reasonably high level of lighting with good colour rendition.

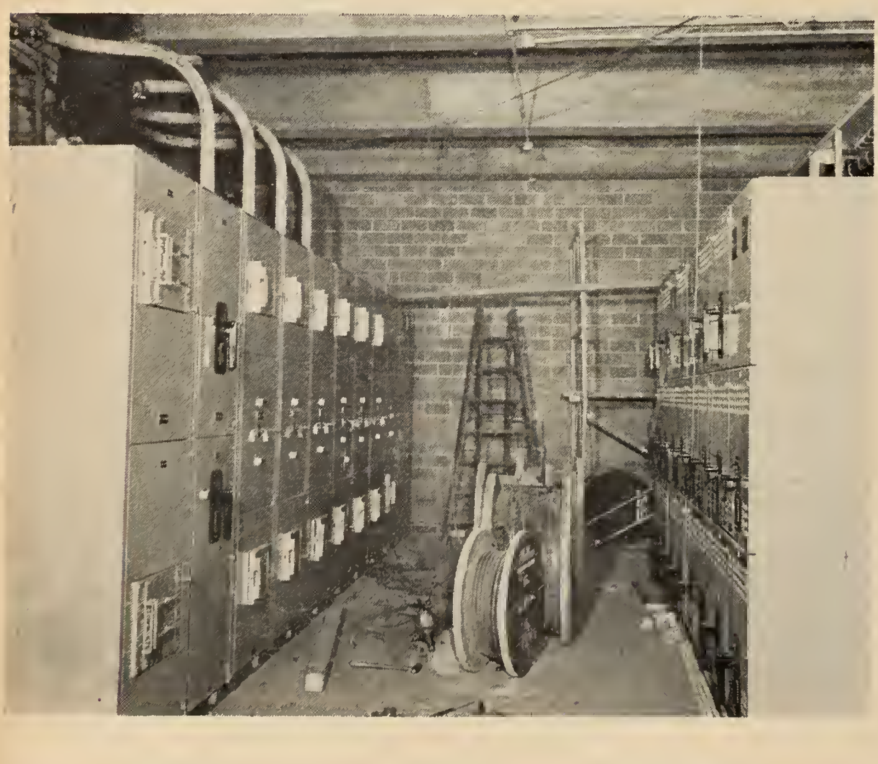
Standard fluorescent lighting units are used to provide the high lighting levels demanded in office areas.

Banquet and dining areas are illuminated by means of various combinations of incandescent recessed units, chandeliers, indirect lighting coves equipped with three colour cold cathode fluorescent tubing, with illuminated wall panels, murals and windows as decoration demanded.

Fluorescent panels provide general lighting in exhibit areas and incandescent units with special lamps, reflectors, lenses and apertures are used to provide accurately controlled lighting for illuminating displays.

The main banquet rooms and the main dining room, which is to be used as a supper club, are completely equipped with stage lighting facilities. Dimmer switchboards provide complete control of general lighting, as well as stage lighting. All other public rooms are equipped with dimmers to provide the flexibility required in the presetting of lighting to suit the various convention functions.

Fig. 1. Secondary switchroom under construction, showing 575 v. auxiliary switchboard, left, and main 575 v. switchboard, right.



Guest bedroom lighting is provided by means of table lamps and floor lamps designed to match bedroom furniture.

Guest bedroom bathrooms are equipped with special electric razor receptacles designed to eliminate the hazard of accidental electric shock due to contact with plumbing fixtures.

Emergency lighting is provided in all public rooms and corridors etc. by connecting specific units of those used to provide normal illumination to the auxiliary lighting supply source. Thus the auxiliary power supply constantly provides part of the normal illumination and on a failure of the main power supply the emergency lighting remains on. Where emergency lighting units are dimmed together with all lighting units, manual or automatic, over-riding switches are provided on the auxiliary lighting circuits as required.

Television and Audio

Each guest bedroom is equipped with a combination television and audio receiving set and outlets are provided in all public rooms for sets as they may be required. Each set is equipped to provide a choice of six T.V. channels and six audio programs. In addition, each set is equipped with an emergency "All-Call" paging feature which is operative regardless of whether set is turned "on" or "off".

Distribution, by means of a coaxial cable for T.V., with audio pairs wrapped around, is arranged vertically for economy and radiates from a central control room located on the third floor.

Control equipment, rack mounted, provides for the direct reception of eight T.V. channels and six radio programs, and in addition, one closed circuit T.V. program originating at the site or incoming via cable, two audio programs originating at the site or incoming via cable and two local tape recorded programs.

Input and output switching and monitoring equipment, designed for easy operation, provides complete flexibility in the selection and transmission of program material.

Program Sound Distribution

All public rooms such as banquet rooms, main dining room, private dining rooms, etc., are equipped to provide sound pick-up and local sound reinforcement in each room and loudspeakers are designed to operate at low level to provide ready hearing in all corners without discomfort.

Microphone and loudspeaker feeders from each public room are run individually and directly to the common central control room serving the television system but are terminated on separate equipment racks.

Control equipment is designed to provide the utmost in flexibility such that sound originating in any room may be amplified and returned to the same room or distributed to any or all rooms.

Control equipment provides, in addition, for the recording, reproduction and distribution of tape recorded program material from and to any public room or outside private lines, provides convention paging facilities in main public lobbies, provides emergency "All-Call" source equipment which serves the guest bedroom system, in addition to all public rooms, and provides for the distribution of recorded music to such areas as laundry, work shops, etc.

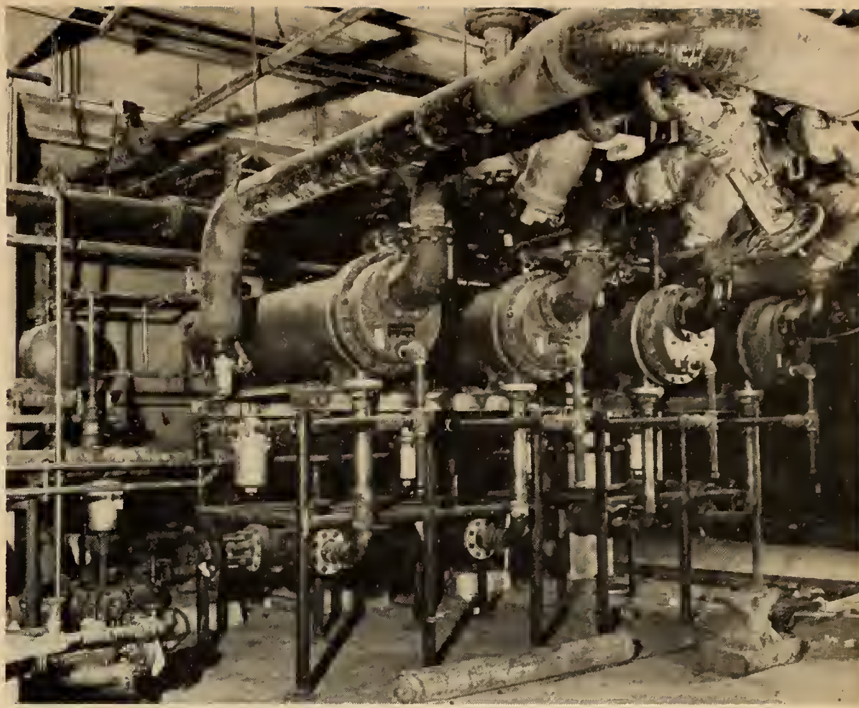


Fig. 2 Section of main service floor, showing semi-instantaneous hot water heaters before application of insulation.

Fire Alarm System

The fire alarm system is a complete system, consisting of manual fire alarm stations located strategically throughout the building, fire detectors located in areas such as linen rooms, sprinkler alarm devices and supervisory valves, together with watchman's tour stations, and all are connected to a central control location on the hotel service floor.

Single stroke gongs sound a coded alarm at suitable locations to enable hotel fire fighting personnel to respond to same without undue alarm to guests. Such coded alarms are, in addition, recorded in the front office and in the engineer's office on punch registers.

General evacuation continuously ringing alarm bells, located adjacent to each manual fire alarm station, may be sounded individually, for local evacuation, by means of local switches or in blocks, for general evacuation, by means of switches located in the front office and in the engineer's office. General evacuation alarm bells are to be sounded and fire alarm signal is to be transmitted to the city fire department at the discretion of the hotel fire fighting personnel on investigation.

Provision for watchman's tour consists of an arrangement of preliminary and transmitter stations located throughout the building in such a manner that the watchman must report at each station in a fixed sequence. The operation of a transmitter station by the watchman causes the aforementioned punch registers to record time and a coded signal but no signal is sounded on single stroke gongs.

Fire alarm annunciators are provided as additional aids in the rapid location of operating sprinkler sections and fire detectors.

The entire system is a closed circuit type, the circuits and apparatus being electrically supervised to sound a local trouble alarm and, in addition, to transmit the same alarm to a commercial supervisory service which would respond in the event of a delinquency.

General Alarm System

To avoid confusion, due to multiplicity of alarms, all other events requiring attention, such as transformer high temperature, low air pressure, boiler low water, water pump failure, etc., are indicated on a station type annunciator equipped with a common red alarm light and common alarm horns. Alarm horns are sounded within the working area of supervisory personnel and may be silenced immediately but red alarm light remains illuminated until alarm initiating device automatically restores the previously silenced horn to ready state.

An electrically operated, self-regulating, 24 volt, d-c minute impulse clock system is provided to control public room decorative clocks, standard secondary clocks in laundry, kitchens, work shops, offices, etc., and attendance time recorders.

Control is provided by means of a master clock and associated mechanism which provides individual hourly supervision and correction to all secondary clocks.

Telautograph System

Communication between such points within the hotel as the telephone room, front office, housekeeper, bell captain, valet and engineer requires rapid transmission of messages simultaneously to more than one point together with a written record. The telautograph system provided is electrically operated with transmitter and receiver stations connected by wire conductors such that messages are transmitted to the desired receiving stations and reception is a facsimile of the senders' handwriting on a continuous paper roll.

Telephone System

A central automatic exchange, together with an eight position switchboard, are located centrally on the third floor.

All instruments are dial type, using standard letters and numerals on the outside of the dial with the most often required hotel service departments indicated under the dial.

The guest may thus call any one of the most commonly required service departments directly by dialing one digit and may make local outside calls directly by dialing, without contacting the operator. Long distance calls are made directly to the Bell Telephone Company toll operator.

Outgoing local calls are metered on a register located in the front office in the billing section and long distance charges are forwarded directly from the Bell Telephone Company to the front office by teletype. All incoming calls and room to room calls are made through the operators to avoid inconvenience to guests.

Telephone instruments are also equipped with a signal light, controlled by the operator, to indicate to the guest that there was a message left for him during his absence.

Fig. 3. View of largest of banquet rooms under construction, showing installation of standard low-pressure air conditioning ducts.

Fig. 4. View of corridor to private dining rooms, showing specific example of crowding of ductwork in certain areas to maintain headroom.

Heating and Air Conditioning

Steam for building heating, ventilating, air conditioning, water heating, kitchen, laundry, and for the turbo-generator is supplied at 375 p.s.i.g. and 500° F. from the C.N.R. Nazareth Street boiler plant approximately ¾ of a mile away, through lines carried in a pipe tunnel.

The steam pressure is reduced on entering the hotel building to 15 p.s.i.g. for heating and to various intermediate pressures for use in the kitchens and laundry. 375 p.s.i.g. steam is supplied to the turbo-generator which has a capacity of 500 kva. and uses up to approximately 20,000 lb. of steam per hour on full load, which is exhausted into the low pressure steam header at 15 p.s.i.g. and is then used for general heating purposes. The quantity of steam exhausted can be controlled by adjusting the electrical load on the turbo-generator. Should the turbo-generator exhaust more steam than can be used, the excess is discharged through a back pressure valve above the roof of the building. Should there be demand for more steam than the turbo-generator is exhausting, pressure reducing valves feed the additional requirements from the 375 p.s.i.g. line. A small amount of steam may also be fed into the low pressure system from a small boiler which was installed for burning solid refuse, such as cartons, crates, etc. No garbage will be incinerated on the premises.

The heating for most of the building is done by means of the ventilating and air conditioning systems. However, there are two forced flow hot water heating systems, one which serves each guest bathroom and one which serves direct radiation along outside walls in the public areas of the hotel. Forced flow steam heating units are installed at entrances, and steam unit heaters are installed in equipment rooms and storage areas.

With the exception of the kitchens, laundry, and certain service and storage areas, the building is fully air conditioned. The air conditioning is divided into two main types, a high pressure system for the bedroom section and a number of low pressure conventional systems for public areas, such as dining-rooms, banquet rooms, bars, cocktail lounges, exhibit rooms, etc.

The bedroom high pressure air conditioning system consists of four air supply units located in penthouses above the twenty-first floor, which supply a total of approximately 80,000 c.f.m. of cooled and dehumidified, or heated and humidified outside air, to four zones of under-window supply units. Cooled or heated water is also supplied to the under-window units from two zone convertors located in the penthouses. Room temperature is controlled by the guest with a room thermostat, which operates an automatic valve on the water supply to each air conditioning unit. In this type of system, both cold water and cold air are used for maximum cooling, and warm air and warm water are used for maximum heating. During in-between seasons cool air and warm water may be used to permit either heating or cooling of any room independently of any other room. The air conditioning units installed in the rooms are of the induction type, the cooled or heated air being supplied through nozzles which induce a flow of room air through the units, without the use of fans and motors in the units. Each standard bedroom is supplied with 50 c.f.m. of conditioned air, and 50 c.f.m. of air is exhausted from the bathrooms to keep the system in balance.

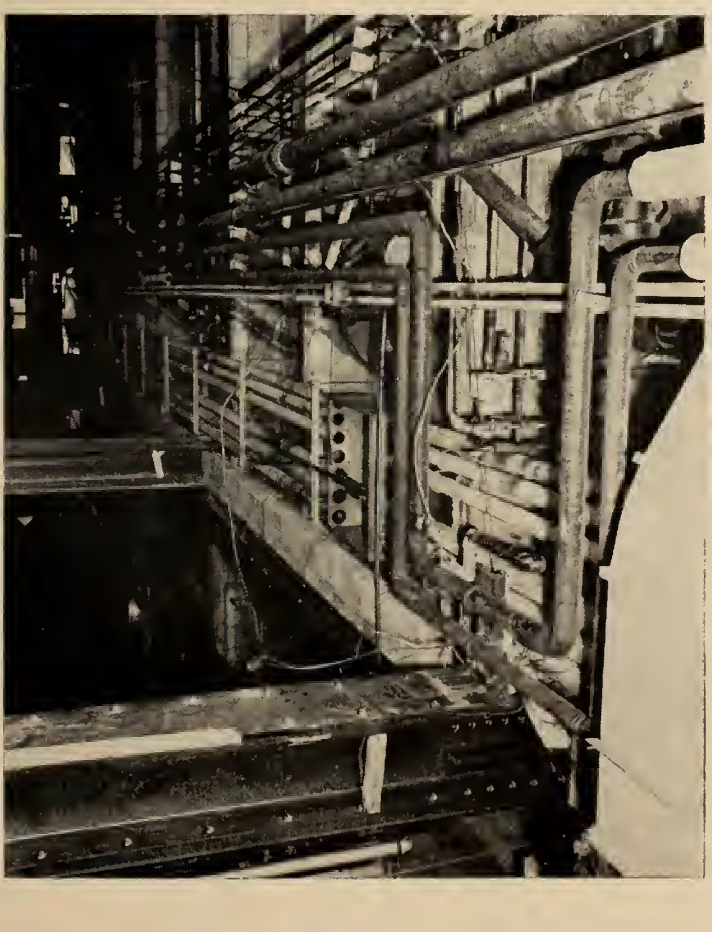
As previously stated, the air conditioning of the public areas in the lower floors of the hotel consists of conventional low pressure systems. There are 30 of these systems handling a total of approximately 210,000 c.f.m., equipment for which is located in 4 fan rooms.

This number of separate systems permits air conditioning only in those rooms which are in use at a given time and also permits separate control of conditions in various rooms. Rooms such as shops which are used on regular hours are served by large zoning units which permit separate control for each room according to load. Air is distributed by conventional low pressure ductwork and supplied to the rooms by diffusers and grilles.

Both the bedroom air conditioning system and the public space systems use chilled water as a cooling medium. This chilled water is supplied from a central refrigeration system consisting of two centrifugal compressors, one 300 hp. and one 800 hp. capacity, located in a sub-basement room. Either compressor may be run alone or both may be run together. Starting and stopping of the compressors is manual, but once running, their capacity is automatically controlled. Condensing water for the compressors is supplied from a three fan cooling tower located on top of the building.

All areas of the hotel which are not air conditioned are ventilated by a conventional ventilating system including the taxi areas at the entrances to the hotel and to Central Station. The ventilating systems for the laundry, kitchen, storage areas, equipment rooms, taxi areas, etc., involve a total of 10 large supply fans and 20 exhaust fans, the largest of which is the taxi entrance unit which handles 60,000 c.f.m.

Fig. 5. Typical view of horizontal distribution piping and conduit on a lower level floor before ceiling installation.



Supervisory Data Center

A supervisory data center has been installed to supervise and facilitate the operation of the heating and air conditioning systems. This data center is located facing the main corridor between the Central Station concourse and the hotel elevators behind a long wall of glass in full view of the public.

A colour graphic control panel 22 ft. by 4 ft. provides graphic representation in a functional way to the 35 air handling systems by incorporating a complete schematic layout of the fan systems showing dampers, heating and cooling coils, fan motors, etc.

Each system is provided also with a control point adjustment knob to adjust the final control point, with start-stop push button stations and pilot lights for central control of 82 fan motors and with temperature check points which are also recorded on an electric typewriter.

An automatic data handling feature incorporated in the supervisory data center will scan and record temperatures automatically at regular intervals, and will provide audible and visual alarm in the event any critical temperature check point varies from preselected limits. Any temperature variation beyond the tolerable limit is permanently recorded in red ink. Steam and water flows are totalized by means of desk mounted counters.

Remote adjustment of temperatures in public rooms is accomplished by means of electronic thermostats located in the public rooms, whose control point is adjusted from the colourgraphic panel.

Plumbing

Domestic water supply is normally provided by means of an 8 inch City water main from Mansfield Street and an additional 8 inch water main is provided from the Central Station. Meter and valve arrangements provide for the transfer of water flow between the hotel and station water supplies in the event of an emergency.

The domestic water distribution system is divided into high level, intermediate level and low level zones.

The low level zone, serving all floors below the third floor, including kitchens and laundry, is supplied directly at city main pressure.

The high level zone, serving all floors above the 10th floor, is supplied by means of booster pumps located on the hotel service floor and by means of house tanks located over the 21st floor.

The intermediate level system is supplied from the high level system by means of pressure reducing valves.

Four domestic water supply booster pumps, 200 U.S. g.p.m. each, located on the hotel service floor, operate automatically and in sequence to maintain water level in the house tanks under varying water demand rates.

Four house tanks, 10,000 U.S. gallons each, located in a penthouse, serve to even out peak water demand requirements and provide reserve emergency supply.

Hot water for guest bedrooms is provided by means of four semi-instantaneous hot water heaters each capable of heating 7,800 U.S. g.p.h. from 40°-140° F. with 10 p.s.i.g. steam.

Hot water for lower level public rooms, kitchens and laundry is obtained by means of three storage heaters providing 140° F water for lower level public rooms and kitchens and 180° F water for the laundry, booster heaters being provided for dishwashing. Each storage heater has a capacity of 5,000 U.S. g.p.h., the laundry storage heater being served with an economizer capable of heating 3,000 g.p.h. from 50° to 105° F when supplied with 4,400 g.p.h. of 120° F waste water.

Chilled drinking water is supplied to all guest bedrooms, distribution being divided into two zones.

Fire Protection

Fire protection is provided by means of a high level system of standpipes serving all bedrooms above the second floor and by means of a low level system of sprinklers and standpipes serving the lower floors.

The system distribution piping is entirely separate from the domestic water distribution and is served by means of a six inch high pressure City water main provided exclusively for fire protection purposes.

Three booster fire pumps, each of 500 U.S. g.p.m. capacity, and a booster jockey pump are connected and valved such that the two systems are normally served from the high pressure fire main and additional capacity, if required, is provided from the domestic water service. The entire operation is fully automatic with standard provisions for manual operation, as required.

Fire hose cabinets are equipped with 1½-in. hose terminated with adjustable "stream-fog-shut off" type nozzles and with standard 2½-in. hose valves for Fire Department use.

Sprinklers, in general, are provided in all storage areas and extra hazardous locations and are of the standard "wet pipe" or "dry pipe" type.

Laundry

The laundry is located one floor below street level and is of unusually large capacity as it is designed to take care of railway and steamship work originating in this area, in addition to hotel requirements. All possible machinery is of the automatic type, including self-unloading washers and automatically timed extractors.

Linen is transferred from the upper floors by means of chutes to the main sorting room, where after preliminary sorting it is transferred by a conveyor system to a mezzanine floor where the final sorting is done into hoppers, each of which holds the exact amount of linen required to fill one section of a washer. The transfer of linen from hoppers to washers takes place by gravity when the bottom doors of the hoppers are opened.

Conveyors are also extensively used for transferring wet linen to conditioning tumblers and flat work ironers.

The hotel guest laundry is done in a section of the room distinct from the regular hotel and railway work and is self-contained as to washers, extractors, shirt presses etc.

Vacuum Cleaning

A central vacuum cleaning system is provided and sweeper outlets are installed on all bedroom floors as well as in all public areas. These outlets are all piped to a central vacuum producing machine located on the main service floor. Sweepings from the various floors are collected in a large dust separator adjacent to the vacuum producer and from which they can be removed and disposed of along with other refuse from the building.

Pneumatic Tube Conveyor System

A pneumatic tube conveyor system is provided between a central dispatching and receiving station, located in the front office, and cashiers in all dining areas, in order that meal cheques signed by guests may be transferred to the billing clerk with a minimum of delay.

The Central Station is also connected to the engineer's office as well as to all service areas such as telephone switchboard, laundry, valet shops, etc.

The tubing through which pass the carriers containing guests' cheques, written messages, or anything that can be placed in a carrier, is made of steel 2¼ in. in diameter. All terminal stations are equipped with pilot lights to signal the arrival of a carrier at the terminal.

Kitchen Equipment

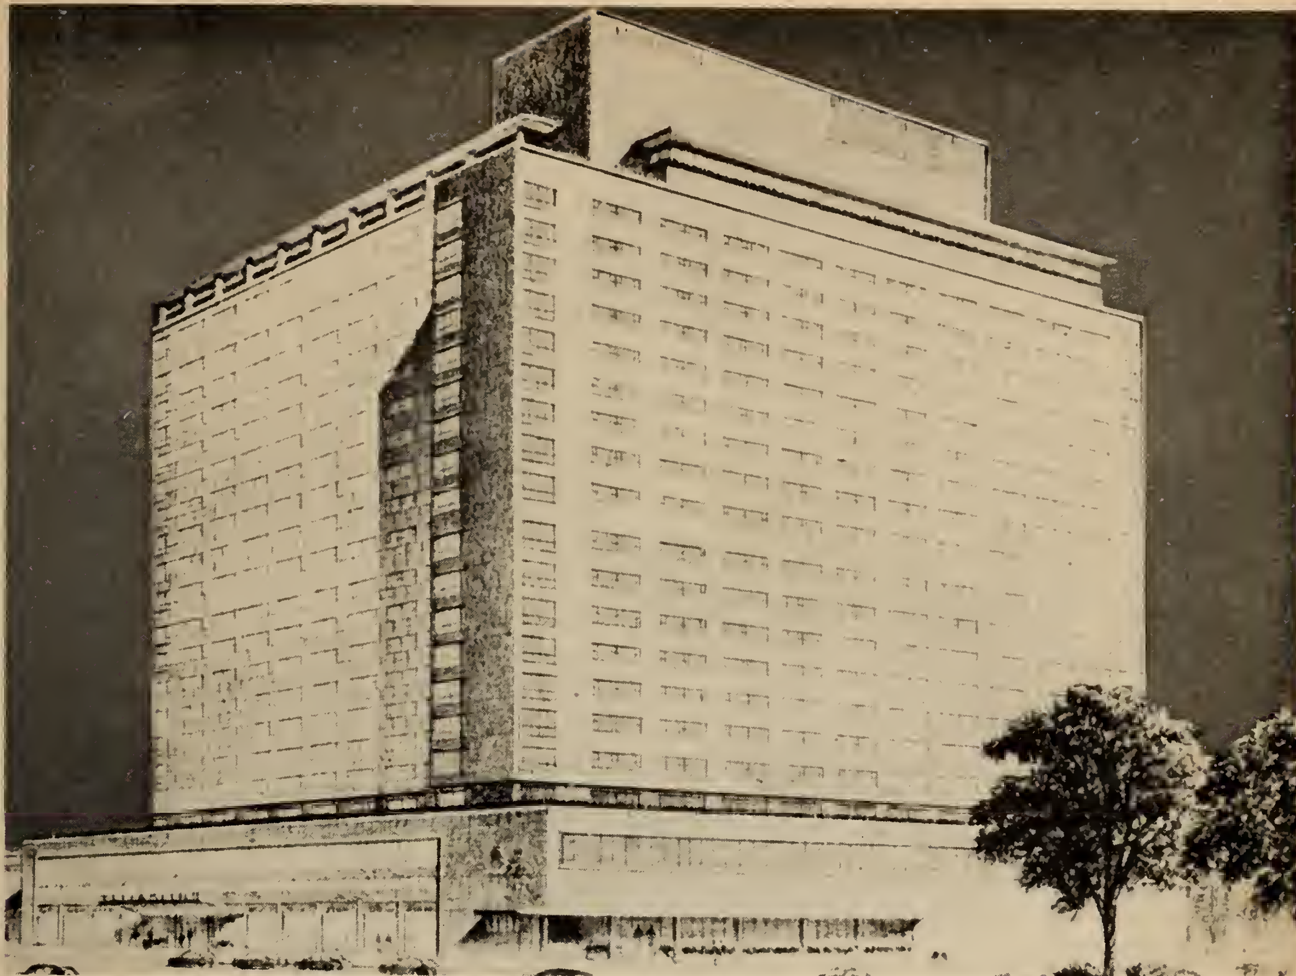
There are five kitchens in the hotel. The main kitchen, located on the main floor; banquet service kitchen, located on the second or convention floor; a small kitchen located on the 21st floor, to serve the function rooms and cocktail lounge, located on this level; a staff kitchen, located two floors below street level; a separate kitchen also is provided for the restaurant serving the Central Station.

All of the kitchens are fully equipped with the most modern equipment. All fabricated pieces such as steam tables, kettles, work surfaces, sinks, refrigerators and exhaust hoods as well as all trims on ovens and machines are stainless steel throughout. Cooking is, in general, done with gas and steam, some smaller units are electric.

Dishwashing is centralized in an area on the lower level for all areas served from the main kitchen and staff kitchen, the soiled dishes being carried to the area by horizontal and vertical conveyors. The dishwashing machines are of the latest continuous conveyor type.

The banquet service, station level, and 21st floor kitchens are equipped

(Continued on page 1824)



A General Description of the Queen Elizabeth Hotel

THE QUEEN ELIZABETH HOTEL, Montreal, is scheduled to open in the spring of 1958.

Twenty-one stories high, with 1,216 guest rooms, the hotel is the first in the world to provide centralized electronic heating and air-conditioning control, and individual dial telephone service from guest rooms. The hotel's picture windows overlook the heavily-treed slopes of Mount Royal immediately to the north and the St. Lawrence River to the south. The hotel's frontage on Montreal's widest thoroughfare, Dorchester Street, together with its height above surrounding buildings, affords the advantage of an excellent view of the city.

A Convention Hotel

Created especially for conventions, the $20,000,000 hotel combines the facilities needed for the efficient handling of meetings of many types and sizes, from marketing sessions with the emphasis on staging, timing, etc., to small, intimate meetings in the quiet atmosphere of an executive suite.

As important as the physical equipment is the convention planning. Co-ordination of hotel services with the requirements of the agenda is vested in an hotel officer who works directly with the convention group's committee or local representative. This officer chairs the hotel planning board that brings together all departmental heads concerned with the details which ensure smoothly operated conventions, and his job ends only when the last delegate has left.

The convention floor is very convenient, being only one storey above ground level, is reached quickly by both escalator and staircase and served by its own kitchens and food storage. The Ballroom (Le Grand Salon) measures 98 x 70 ft. with a stage 14 x 46 ft. and the necessary hanging gallery for spotlights. It will accommodate nearly 800 people for dining or 1000 for meetings. Soundproof disappearing doors will form two walls between ballrooms 1, 2, and 3, and when used as a single unit, there will be accommodation for up to 2000 people for dining or 3000 for meetings. Special banquet rooms (named after famous explorers of Canada) and eleven private dining rooms (named after Quebec rivers) are avail-

Le Grand Salon

View of front of the hotel, looking south on Mansfield Street.

able on this floor for private meal gatherings, business meetings, convention groups or sales conferences. Through the use of soundproof disappearing walls between some of the private dining rooms, the complete space of two or more rooms will be available, providing accommodation for up to 350 persons for dining and 400 for a meeting. There is 15,000 square feet of exhibit space, an automobile hoist and radio and television projection rooms.

The sample room floor is immediately above the convention floor, and buyers and sellers can come together in a welcome economy of time and space. This floor has 23 large sample rooms with shelf and lighting fixtures, 34 traditional bedrooms and two suites.

Main Lobby

Native Canadian wood and stone are used in the main lobby which is spacious, comfortable and dignified. A frieze which recalls ancient Quebec handicrafts, and floor coverings reminiscent of the hooked rug patterns of the Norman and Breton pioneers are a fitting introduction to the Province of Quebec. The broad open registration desk is centrally located and designed to check guests in speedily.

Dining Rooms

The Louis XVI dining room on the main floor (Salle Bonaventure) has lofty ceilings, deep-pile carpets, classical ornamentation and mirrored walls.

For less formal dining occasions the adjoining Beaver Club adopts an atmosphere of cheerful cosiness. The Club has a companion room, Les Voyageurs, its cocktail lounge.

The Coffee House, also on the main floor, is an informal dining spot where service will be paced to the needs of the customer whether it is a snack or a full-course meal.

Lookout

Visitors to Montreal are drawn to the lookout high up on Mount Royal. The Queen Elizabeth has its own lookout on the 21st floor, a cocktail lounge named Le Panorma for its view of midtown Montreal and the St. Lawrence River. At night the neon-flecked ribbons of light in the close-packed downtown area fade off into the Quebec countryside. Le Panorama has a tremendous sweep of window, a transparent wall 200 feet long, and a large attractive fireplace.

Guest Rooms

In its guest rooms the Queen Elizabeth has a combination of the traditional and modern. Studio bedrooms afford a sitting room by day and bedroom by night. The box spring, mattress and headboard are also provided for guests who prefer them.

All bedrooms are outside rooms; each room has a combination radio-television receiver, and a wide picture window which reaches from wall to wall. Drapes, floor coverings and upholstery harmonize, and nicely-balanced furniture groupings are possible because there are no small rooms in the Queen Elizabeth, a square-plan structure. Each guest room has its own control for heating, cooling and air-conditioning. Individual dial telephone service from guest rooms will permit direct calls; a light on the phone will notify guests returning to rooms that a call was received in their absence, and the switchboard will give details. While a window panel will open, it is a gesture only to cherished custom.

Suites on every floor provide extra accommodation for the long-stay guest and those who plan in-hotel entertaining, and special pains have been taken to give each suite a character peculiar to it alone.

Lower Lobby Entrance

One of the innovations which should be appreciated is the consideration given to the guest arriving by automobile; he drives right to the lower lobby entrance, his car is unloaded and parked immediately in the adjacent autopark, only feet away; he registers at the lower lobby desk and is roomed directly from it. The barber shop, valet, laundry, shoeshine and shops are on the lower level floor.

Central Station Entrance

Central Station concourse is directly connected by escalator and elevator to the main lobby of the Queen Elizabeth, thus the lines of Canadian National Railways with their North American connections lead directly from train to hotel.

Airlines Terminal Entrance

The Montreal airlines terminal is located in the adjoining building and reached through the station lobby, another convenience to the traveller.

Conclusion

The Queen Elizabeth will be the newest hotel in Canada, and will be operated by the Hilton Hotel organization. It will be an interesting addition to the city and will increase, considerably, Montreal's convention facilities.

Le Panorama

The Oak Street and Middle Arm Bridges

L. Osipov

Chief Designing Engineer,

Phillips, Barratt and Partners, Vancouver, B.C.

THE OAK STREET and Middle Arm bridges, built by the British Columbia Toll Highways and Bridges Authority, replace the old Marpole swing span which has served as a bridge crossing over the North Arm of the Fraser River since the turn of the century. The new bridges will provide a four lane outlet from Vancouver at the foot of Oak Street, southward to Lulu Island, Delta municipality, the Fraser valley and the United States, as well as a two-lane crossing from Lulu Island to Vancouver's international airport on Sea Island.

The need for a new bridge was forcefully demonstrated for a number of years prior to the decision to build a new span. Since the old swing bridge, a narrow two lane structure, provided only ten feet of clearance over mean high water, almost every craft passing up or down the river had to call for the opening of the span. It was estimated that an average of about 8,000 openings occurred each year, not to mention the number of times the old bridge was out of operation due to collisions from boats which drifted against the centre and flanking piers. This condition, combined with morning and evening rush hour bridge traffic, growing industrial expansion along the Fraser River, racing at Lansdowne Park, or special functions at the Vancouver airport, led to repeated traffic congestion in this vital area.

Traffic has long been seriously restricted between Vancouver and Lulu Island, to the south, and Sea Island, on which the international airport is situated, because of limited bridge capacity across the Fraser River. This paper describes the features of the new Oak Street and Middle Arm Bridges, which were opened in the summer of 1957. Above is a view of the Oak Street bridge continuous plate girder. The longest of its kind in Canada (710 ft.), the centre span is 300 ft. long.

After lengthy negotiations with the City of Vancouver and the Federal Government, the Province decided to assume responsibility for the project. On October 8, 1953, under the authority of the Minister of Public Works of B.C., the Honourable P. A. Gaglardi, the firm of Phillips, Barratt and Partners, consulting engineers, was commissioned to obtain a reasonably accurate estimate of the cost of a new highway crossing over the North Arm of the Fraser River. This estimate was to be based on the most economical solution which would provide uninterrupted traffic flow over the North Arm of the river, proper navigational clearances and adequate connections to streets and roads.

After a number of studies which gave consideration to five possible locations, it was agreed that the high level crossing should begin at the foot of Oak Street and run southward to Lulu Island on a line parallel to and 270 ft. east of, the existing B.C. Electric Railway bridge. This was considered the most desirable location for the following reasons:

(1) Only a 60 ft. vertical clearance over mean high water was required at this site.

(2) The height of the bridge here would not be a hazard to aerial navigation.

(3) The proposed turning basin for shipping west of the B.C. Electric Railway Bridge would be left open.

(4) The present traffic bottleneck at Marpole would be eliminated.

(5) Oak Street was being improved by the City of Vancouver and would become the most convenient artery to take traffic from Vancouver to western Lulu Island and the airport.

(6) This location would tie in with the new Trans-Canada highway connection across the Fraser River downstream from New Westminster.

(7) Property acquisition costs would not be too heavy here.

(8) The location would provide no hazard to river navigation.

Confirmation that four lanes would be sufficient to carry the anticipated traffic from Vancouver to Lulu Island was obtained from the City of Vancouver Traffic Department, which estimated that by 1971, the peak commuter traffic would be 3340 vehicles per hour over the existing Fraser Street bridge and the new Oak Street bridge. At the rate of 1400 vehicles per lane per hour, three lanes would therefore be ample for these requirements. Since one lane was provided by the Fraser Street bridge, two lanes each way appeared to be sufficient at Oak Street. The consulting engineers recommended that when overload peaks were reached, the old Fraser Street bridge should be replaced and that area developed into another main artery for southbound city traffic. Such a development, it was generally agreed, would be more desirable than trying to funnel all traffic into one city area.

Fig. 1. Key plan showing location of Oak Street and Middle Arm bridges, which provide a four-lane outlet from Vancouver at the foot of Oak Street, southward to Lulu Island and the United States, and a two-lane crossing from Lulu Island to Vancouver's international airport on Sea Island.

The low-level two-lane Middle Arm crossing did not readily satisfy all the interested parties. The Airport Board expressed a preference for a four lane high level bridge. However, the greatly increased cost of such a scheme was difficult to defend, since only about one opening of the bridge per day would be required and one lane each way was more than ample for the anticipated traffic to the Airport.

General Bridge Features

The following are some of the main features of the Oak Street bridge. The north end consists of approximately 1900 ft. of four lane approach spans beginning at the foot of Oak Street and passing over Marine Drive and several adjacent railway tracks. A grade of 2 per cent was sufficient to provide adequate clearance over the tracks and Marine Drive. North-bound traffic which intends to come down on Marine Drive and head eastward will be able to utilize a 550 ft. long single lane ramp diversion provided for that purpose. In general, the north approaches consist of four continuous 60 ft. span units of reinforced concrete supported on twin-shafted reinforced concrete piers with spread footings on glacial till or on steel piles driven to till near the river shore.

The four lane south approaches are over 3000 ft. long, passing over a CNR right-of-way, Beckwith and Bridgeport roads, and connecting with a future highway system on Lulu Island. In addition, there is a 550 ft. long two lane diversion for southbound traffic toward the Middle Arm crossing and Sea Island.

The bridge toll booths will be located at the ends of the south approaches. As in the case of the north end, a 2 per cent grade was selected, giving adequate clearance over railway and roads. The superstructure and piers are similar to the north approaches except that the piers on Lulu Island are founded on untreated timber friction piles driven approximately 35 ft. into a very deep layer of sedimentary sand which overlies the glacial till in this region.

The portion of the bridge over the Fraser River is divided into two sections of different design, both four lanes in width. The southerly 600 ft. consists of five 120 ft. simple spans of composite concrete slab and welded steel girders. The girders, built up from plates, are 8 ft. 6 in. on centres, 7 ft. 0 in. deep, and are supported by reinforced concrete piers founded on steel piles driven to glacial till. The northerly 706 ft. consists of a reinforced concrete deck supported by two continuous riveted steel plate girders. The span over the main navigation channel is 300 ft., and the flanking spans are 203 ft. These are believed to be the longest continuous plate girder spans in Canada and have only been exceeded in size in a few instances anywhere. The plate girders are supported on reinforced concrete piers and footings founded on glacial till or on steel piles driven to glacial till.

The main features of the two lane Middle Arm crossing are as follows:

The east end is approximately 560 ft. long, extending from Lulu Island to the swing span at a grade of 3 per cent. This portion consists of 40 ft. simple span pretensioned concrete stringers supporting a reinforced concrete deck and resting on reinforced concrete caps and prestressed concrete friction piles driven about 30 ft. into a fairly thick layer of sand which overlays an extremely deep layer of silt and clay.

At the west end, 408 feet of approach spans extend from Sea Island to the swing span. This portion consists of eight 40 ft. simple spans of exactly similar construction to the east approaches plus one 88 ft. simple span of post-tensioned concrete construction. This span provides an 80 ft. horizontal clearance and a minimum 17 ft. vertical clearance which allows many small boats to pass under without opening the swing span.

In the main navigational channel, there is a steel plate girder swing span having a 60 ft. clear horizontal opening each side of the centre pier. The vertical clearance is 18 ft. above mean high water. An unusual feature of this span is that it is hydraulically operated, and because of the infrequency of the opening, there is no operator's cabin, all the controls being housed in a neat steel control panel which does not extend above handrail height.

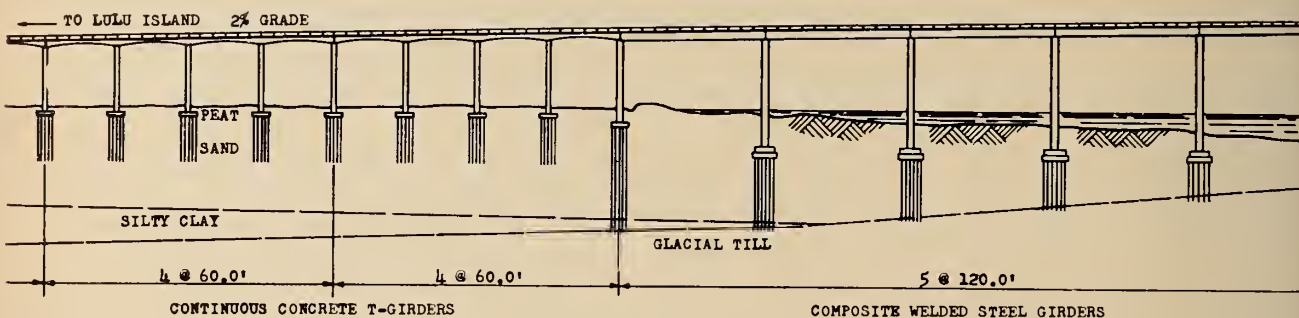

Fig. 2. Oak Street bridge profile, showing steel girder spans over the Fraser River and the beginning of the South (above) and North (p. 1821) concrete approaches.

The Oak Street Bridge Plate Girder

Before selecting a three-span continuous rivetted deck plate girder, a number of other types were considered. These included:

(1) A three-span continuous deck truss.

(2) A three-span continuous modified through truss.

(3) A three-span continuous rivetted deck plate girder consisting of four girders.

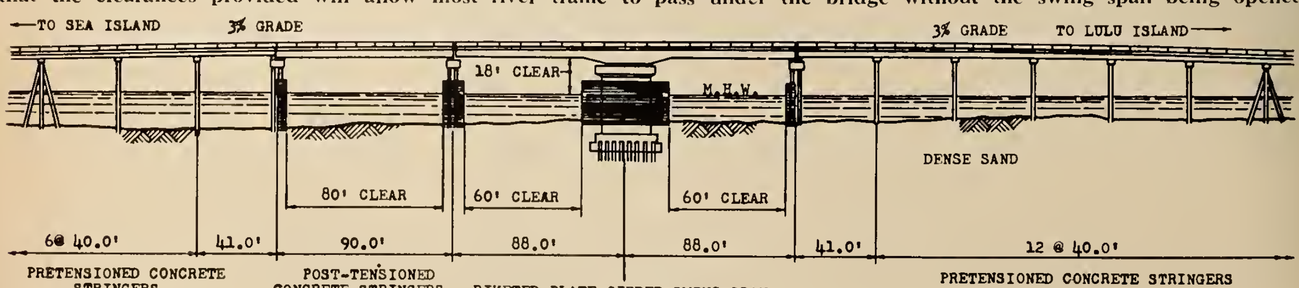
(4) A three-span reinforced concrete box girder with a centre 150 ft. masked suspended steel span.

All of these proved to be more expensive with the exception of the three-span continuous deck truss which appeared to be slightly more economical. However, a deck truss would have raised the elevation of the bridge above the fixed clearance over the channel, thus increasing the cost of the approach piers. When all factors had been included in the economic comparison, it was found that the two continuous deck plate girders would prove the most economical. In addition, there was no doubt in the minds of the engineers that a deck plate girder would be vastly superior in appearance.

A further study was made to determine the most economical deck system. The result of this study proved that a concrete slab spanning longitudinally between trussed floor beams spaced at 10 ft. centres was the most economic solution. In addition to reducing the steel in the deck system the trussed floor beams also eliminated some of the vertical sway bracing. To achieve added economy in the floor beams and to reduce the width of the main piers, the two plate girders were located 38 ft. on centres and the floor beams cantilevered on each side to support the curbs and sidewalks.

To achieve economy in the depth of the plate girders, a compromise had to be reached between the rigidity of the spans plus the resultant saving

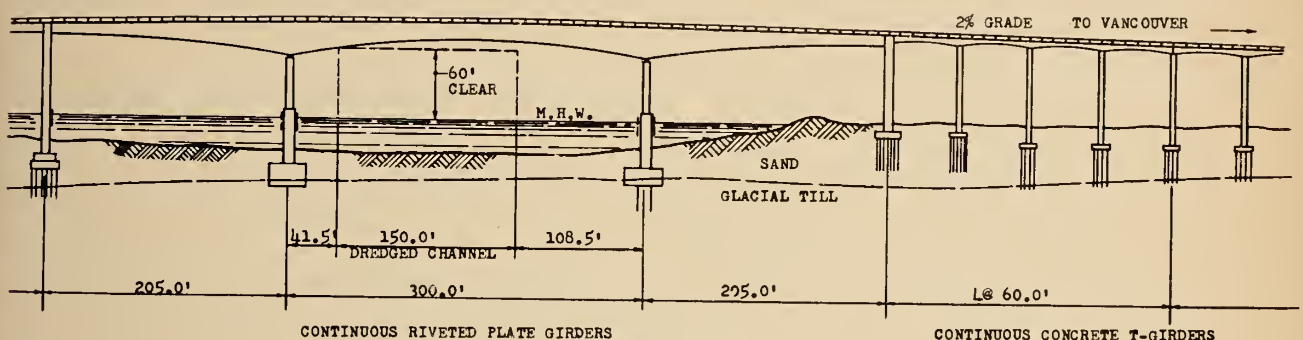
Fig. 3. Middle Arm bridge profile, showing steel girder swing span and prestressed concrete approaches. It is estimated that the clearances provided will allow most river traffic to pass under the bridge without the swing span being opened.



of steel in the flanges, which favoured a deep girder; and the saving of steel in the web plus fabrication and erection costs, which favoured a shallow girder. This compromise resulted in a 6 ft. depth at the exterior supports, a 21 ft. depth at the interior supports, and a 10 ft. minimum depth in the centre span. The upper flange of the girder was made parallel to the vertical curve of the roadway and the lower flange was established by elliptical curves for the flanking and centre spans. Silicon steel was found to be quite economical in this design and was therefore bending stresses but also permitted easier splicing. Side plates were also adopted because they added to bending resistance and decreased the unsupported depth of the web plate.

The "Specifications for Highway Bridges, 1951 (B.C.)" was used as the basis for design of web plate thicknesses where the formula involving the spacing of vertical stiffeners and the shear stress governed the design; all vertical stiffeners being spaced at 5 ft. on centres. Where the formula involving unsupported depth of web plate would have governed the design, horizontal stiffeners were provided every 20 ft.

The calculation of live load deflections of the plate girders revealed a maximum deflection of 4.10 in. in the centre span which was less than the allowable of 4.5 in. based on 1/800 of the span. Similarly, the live load deflection in the side spans was 2.92 in.; less than the allowable maximum of 3.02 in. To check on the possible problem of vibration, the consulting engineers visited and inspected the Passaic and Hackensack bridges, both somewhat longer plate girder spans than Oak Street. The observed vibrations on those bridges were not objec-



North approach.

specified for all the flange and web sections of the plate girder. Stiffeners, bracing and deck members were fabricated from medium steel.

Flange make-up offered some interesting alternatives. It was finally decided to follow a practice which has become quite common in European designs and which is being accepted among American designers, namely the use of two heavy angles in each flange and fairly thick and wide cover plates. This detail not only provided higher resistance to ers were provided and the webs were proportioned by the method outlined in the American Society of Civil Engineers Paper No. 2120 on the "Theory of Elastic Stability Applied to Structural Design", except that a safety factor of 1.8 was used instead of 1.4 as suggested in this paper.

Lateral K-bracing, designed to transmit the wind forces to the piers was provided in the planes of both the top and bottom flanges, and cross frames connecting the lateral bracing system...

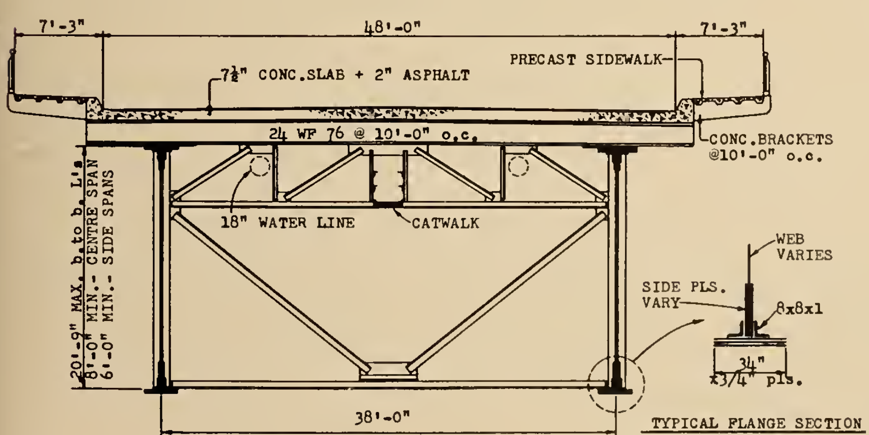


Fig. 4. Oak Street bridge plate girder details. Trussed floor beams contributed to a considerable saving of material in the deck system. Side plates were added to the plate girder flanges because they added to bending resistance and decreased the unsupported depth of the web plate

tionable and since the Oak Street girders compared favourably with these in relative stiffness, vibration was not considered to be a serious problem.

After considerable investigation of longitudinal forces acting on the plate girder spans, it was decided to provide fixed bearings at both interior piers and rocker bearings at the end piers. The two interior piers therefore share in resisting all the longitudinal forces due to temperature movement, wind, traction, and arching thrust under live load. The effect of the shrinkage of the roadway slab on the piers was reduced to a negligible factor by providing expansion joints in the slab every 100 ft. and painting the upper surface of the floor beam flanges with a bituminous compound to permit sliding of the concrete.

The Oak Street Bridge Approaches

Studies were made to determine the economic span and type of structure for the approaches on land and over water. On the basis of available cost data, 120 ft. post-tensioned concrete spans appeared to be the most economical over water and were proposed in the original design. However, when tenders were called for this portion of the bridge, alternate bids were invited and composite welded steel girders of similar span proved slightly cheaper and were chosen for the final design.

Studies for the approaches on land gave consideration to spans varying from 60 ft. to 120 ft. in poured concrete girder construction, composite concrete deck and steel stringers, and prestressed concrete. Continuous 60 ft. spans of reinforced concrete proved most economical based on costs prevailing at the time. In addition, the fact that this type of construction would require little or no maintenance led to its choice.

The decision to use four continuous spans of 60 ft. was based on the obvious economy due to continuity. Fixed bearings at all interior supports of these spans presented no problem in the design of either the deck system on the piers, and made for economy. Since soil studies had revealed the possibility of differential settlements up to ⅜ in., particularly on the south side, the four 60 ft. continuous girders were checked for a possible differential settlement of ½ in. and the stresses for this condition did not prove critical. The effect of deck shrinkage on the intermediate piers was also checked and it was found that the resultant stresses in both the very high and low pier shafts were not excessive.

Alternatives were considered for the support of the 48 ft. roadway and the two 7 ft. sidewalks. Five, six, and seven girder decks were investigated in turn, and it was found that the five girder deck was the most economical. The use of fewer girders also led to some saving in the cost of bearings. These girders varied in depth from 3 ft. 6 in. at the centre of each span to 6 ft. 0 in. at the supports, with diaphragms transversely every 20 ft. to stiffen the deck system. By pouring the curbs monolithically with the exterior girders and placing the negative reinforcing up into the curb, added resistance and economy were achieved in these girders. A further economy was realized by using precast lightweight concrete sidewalk slabs spanning 10 ft. between concrete brackets which also supported the steel handrail posts.

An interesting feature of construction was the manner in which the contractor overcame the problem of supporting the formwork for the deck system, particularly on the southern approaches. Soil studies on Lulu Island has revealed that if the deck concrete were supported on falsework to the ground, the dead load of the deck would be applicable in calculating settlements in the sand. If, on the other hand, the forms and wet concrete loads were carried to the piers, only the live load would contribute to settlement. The differential settlement due to the former condition would have amounted to about ⅞ in., which would have been critical in the design of the deck girders. As a result, the consulting engineers specified that the deck forms would have to be carried to, and supported on the piers. The problem was overcome by using glulam timber trusses, the upper chords of which were curved to suit the parabolic soffit of the girders. These trusses were designed to span between the piers and supported the formwork of the bridge deck, being re-used throughout the length of the approaches.

The Middle Arm Bridge

A swing span was adopted for the moveable bridge portion since both a vertical lift and bascule bridge were considered by the airport authorities to be a hazard to low-flying aircraft landing or taking off from the airport nearby.

Studies revealed that the approach spans of prestressed concrete beams could vary from 20 ft. to 40 ft. without any significant difference in cost. It was therefore decided to use 40 ft. spans which, in addition to their more pleasing appearance, would require less construction time for the pile bents.

Consideration was given to 16 in., 18 in. and 20 in. prestressed concrete piles for the approach bents. It was found that the 16 in. pile resulted in a cheaper bent. The smaller sized pile also had the additional advantage of being easier to drive.

A generous 28 ft. roadway was provided for this crossing to permit the flow of single lane traffic each way even in the eventuality that a car broke down on the bridge. Two sidewalks of 5 ft. were also provided.

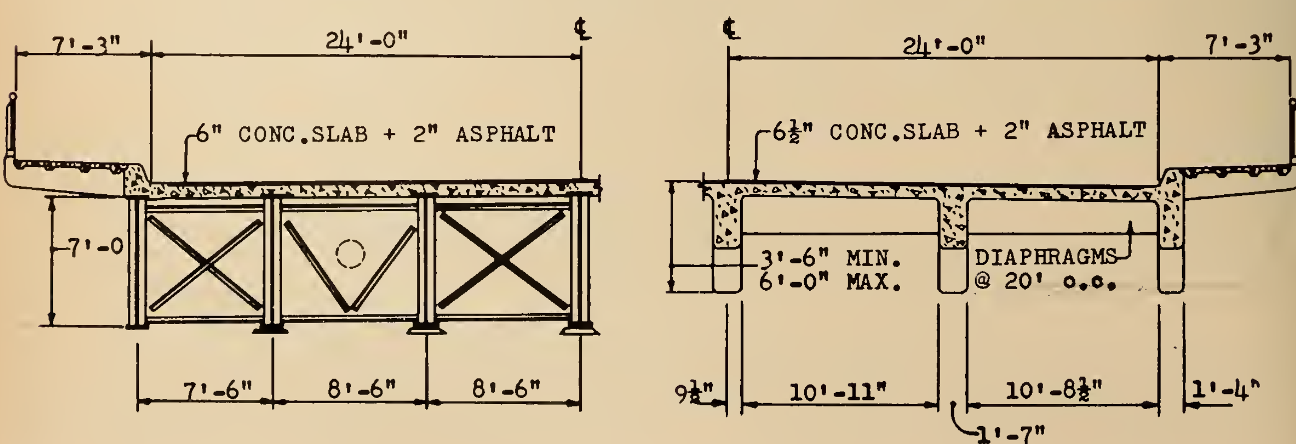
In the swing span, the two plate girders are half-through and 31 ft. on centres. The concrete deck is supported on stringers spaced at 5 ft. 9 in. o.c. spanning 21 ft. 4½ in. between floor beams.

The approach roadway is supported on seven prestressed beams. The 40 ft. span beams are I-shaped, 36 in. deep and pretensioned by seventy-four 0.195 in. diameter H.T.S. wires whose ultimate strength is 240,000 p.s.i. The concrete in these beams has an ultimate compressive strength of 5000 p.s.i. The 88 ft. span beams are 45 in. deep and post-tensioned by eight 12-wire, 0.276 in. diameter h.t.s. Freyssinet cables. The ultimate tensile strength of the wires is 220,000 p.s.i. and the ultimate compressive strength of the concrete is 6000 p.s.i.

Bridge Deck Lighting

One of the unusual features on

Fig. 5. Oak Street bridge approach deck details: composite welded steel girders and typical continuous concrete T-girders.



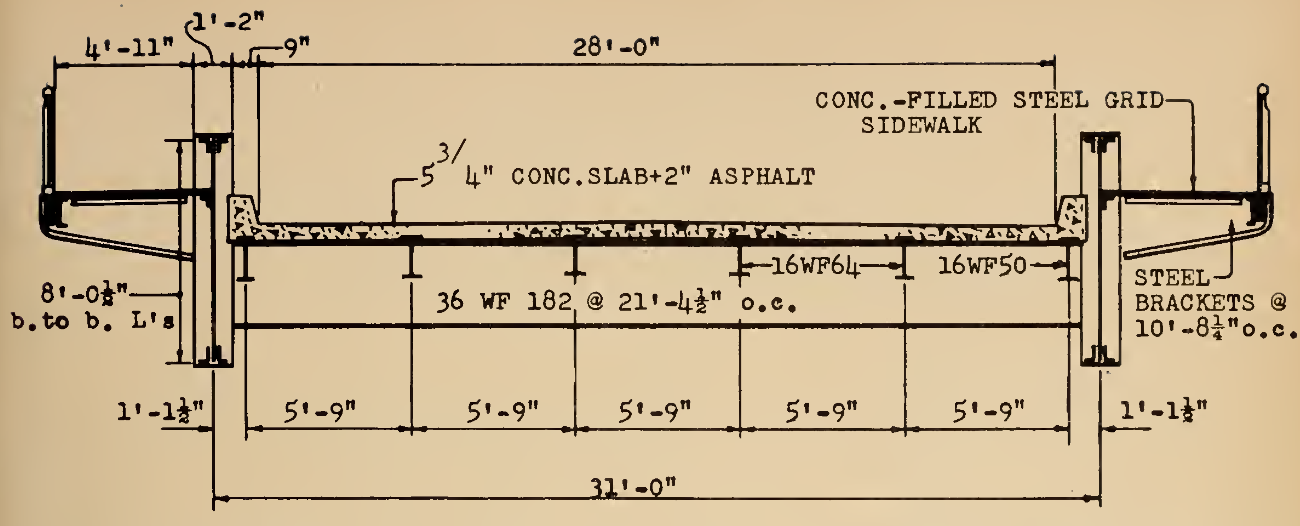


Fig. 6. Middle Arm bridge girder swing span. Because openings are infrequent, the swing span has no operator's cabin. All controls are housed in a neat steel panel (not shown here) adjacent to the girder and no higher than the handrail.

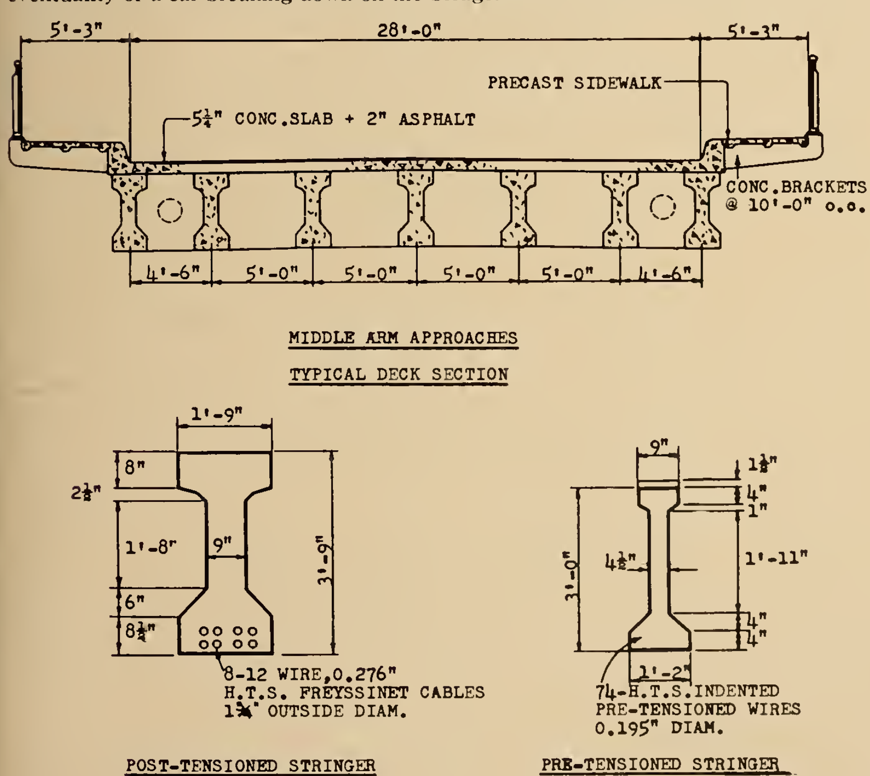
both bridges is the use of fluorescent luminaires to provide lighting for the bridge decks. Mounted on metal poles, these luminaires extend about 29 ft. above the roadway and are generally spaced at 80 ft. centres staggered on each side of the deck. The luminaires are tilted some 20 degrees from the horizontal permitting improved light on the roadway.

Tests have indicated that this type of lighting provides the highest luminous efficiency combined with a minimum of objectionable brightness; true colour discrimination of objects, and the longest average burning length. With four fluorescent lamps per luminaire, there is the added advantage of partial light output should one of the lamps fail.

This type of lighting was first used on the Richmond-San Rafael bridge in the San Francisco Bay area (completed September 1, 1956). It is believed that the Oak Street and Middle Arm bridges mark the first application of this advanced bridge lighting feature in Canada.

Fig. 7. Middle Arm bridge approach deck details. A 28 ft. roadway was provided for this crossing to permit the flow of single-lane traffic each way, even in the eventuality of a car breaking down on the bridge.



Basis of Design

The design of the entire project was generally based on the "Specifications for Highway Bridges—1951", issued by the British Columbia Department of Public Works, and the 1953 "Standard Specifications for Highway Bridges" of the AASHO. The assumed live loading was H20-S16-44 truck or lane load. The design also called for poured concrete to have an ultimate compressive strength of 3000 p.s.i. at 28 days and the reinforcing steel to be Hi-bond intermediate grade with a working stress of 20,000 p.s.i.

Summary of Costs

A general review of the cost of both bridges reveals the following lump sum figures:

Oak Street Bridge

General contract — approaches and substructure	$3,477,000
Plate girder — medium steel (575 tons)	239,000
Plate girder — silicon steel (760 tons)	347,000
Materials supplied by the B.C. Toll Authority	438,000
Re-location of high tension power lines	75,000
Connections and alterations to Vancouver streets	135,000
Total	$4,711,000

Middle Arm Bridge

General contract — approaches and substructure	$ 532,000

Swing span steel and machinery	185,000
Materials supplied by the B.C. Toll Authority	38,000
Total	$ 755,000

The above figures do not include the cost of property acquisition, removal of buildings, new roads on Lulu Island or engineering. A more detailed study of these costs yielded the following unit costs per square foot of bridge, based on the width of the bridges from in to in of handrailing:

Oak Street Bridge

(1) Plate Girder Spans:

Substructure	$ 8.29/s.f.
Superstructure	18.10/s.f.
Total	$26.39/s.f.

(2) Four 60 ft. contin. conc. girders: (four lanes)

superstructure	$ 5.35/s.f.
substructure (average)	2.55/s.f.
Total	$ 7.90/s.f.

(3) 120 ft. span comp. conc. deck and steel beams:

Superstructure (over water)	$ 9.29/s.f.
substructure	8.37/s.f.
Total	$17.66/s.f.

(4) Average cost of entire bridge .... $11.15/s.f.

Middle Arm Bridge

(1) Swing span (incl. machinery)

superstructure	$29.00/s.f.
substructure	16.80/s.f.
Total	$45.80/s.f.

(2) 40 ft. prestressed spans:

superstructure (over water)	$ 5.85/s.f.
substructure	3.40/s.f.
Total	$ 9.25/s.f.

(3) Average cost of entire bridge .... $16.90/s.f.

These costs, based on contracts concluded in 1954, were lower than those originally estimated by the consulting engineers, indicating that the design in general was a most economical one. It would therefore seem that the time spent on the numerous economic investigations was most worthwhile. The design and supervision of the entire project was carried out by Phillips, Barratt and Partners, consulting engineers, in Vancouver. Dominion Bridge Co. Ltd. was responsible for the supply and erection of all the structural steel.

General contractor for the Oak Street Bridge was Gilpin Construction Co. Ltd. Vancouver Pile Driving and Contracting Co. Ltd. was the general contractor for the Middle Arm Bridge. Commissioned to do the electrical design for both bridges was M. A. Thomas, P.Eng., and retained for the mechanical design on the Middle Arm Bridge was G. Bancroft, P.Eng.

Electrical and Mechanical Design Features of the Queen Elizabeth Hotel

(continued from page 1814)

with their own dishwashing facilities.

Refrigeration

Refrigeration for food preservation is provided by numerous "reach-in" refrigerators as well as large "walk-in" refrigerated rooms carried at suitable temperatures from 40° F. down to -15° F.

The cooling is accomplished by a number of Freon compressor condenser units strategically located to keep runs of refrigerant piping to a minimum. These units are served by condensing water which is circulated from two cooling towers located on the roof over the third floor.

Ice-making is carried out as far as possible with individual cube and flake ice machines, located as near as possible to the areas to be served. In addition, three combination cube and flake ice machines, each with a capacity of one ton in twenty-four hours, are provided to take care of peak demands.

DISCUSSION

of Technical Papers and Other Articles

THE FOUNDATION FAILURE OF THE TRANSCONA GRAIN ELEVATOR

A. Baracos, M.E.I.C. *The Engineering Journal,* 1957, July, 973.

Lionel L. Jacobs,[1] M.E.I.C.

I was much intrigued with Baracos' article on the Transcona grain elevator failure. There probably are not too many men still alive who saw this at first hand. When this happened the C.P.R. were building the great sorting yard at Transcona, and also a creosoting plant.

In 1910 I came out from London, England, to supervise the building of a tar distilling plant for the Dominion Tar and Chemical Company at Sault Ste. Marie, to take the tar from the new Algoma Steel Company coke ovens, and in 1912 to 1914 I had wished on to me over-all supervision of the C.P.R. creosoting plant at Transcona. We were only a short distance from the elevator, and I well remember the excitement when it was found to be tipping, and coming back the next morning to see it tipped at about 25° and the cupola slid off.

I was around all through the wonderful job, done by The Foundation Company, of putting down Chicago wells, and righting the bins, and in constant contact with the field force. It was a delightful experience for a man who was only just beginning to cut his teeth on big jobs. It pleases me so much now to read the excellent article by Baracos explaining the theory.

A. P. Balodis,[2] M.E.I.C.

As far as some problems might be considered, besides the check on the soil bearing possibilities for this particular case of failure, it would also be of interest to know of any other investigations carried out.

(1) I would like to know the reason for the acceptance of $\phi = 0$ in bearing capacity determination for this particular case of varved clays present on the site. If the value of "unconfined compressive strength" is about $0.9/\text{ft}^2$, and also keeping in mind the calculated value of I_c, the clay is believed to be "plastic", but nevertheless perhaps a "stiff" one. Presence of the Montmorillonite clay must be taken into account also, and considering these facts it might be expected that the "low" unconfined compressive strength does not expose clearly the actual value of the angle of internal friction, especially considering the particular structure of the varved clays. In which direction were the samples tested considering foliation of the varved clays? Also, is it correct to consider behaviour of the varved clays as being more similar to the same of silty soils than of clayey ones? It is doubtful if in this particular case the $\phi = 0$ method is acceptable, and anyhow, it is only of secondary importance.

(2) Of greater significance than the studies on bearing capacity of the varved clays on the site is the probable causes of the "foundation failure", and it would be of interest to see some information on the results obtained by investigation done (if any) considering the problems which are briefly outlined below:

(a) As the varved clays are critically sensitive considering the possibilities of the loss of "strength", i.e. bearing capacity, due to excessive wetting or freezing, the results of the investigations on the climatological factors involved in stability would be of interest. For instance, could any heavy rain periods during the excavation or elevator construction time be determined at the present time? Did any frost occur? How long did the excavations remain open?

(b) As the Montmorillonite clays exhibit high plasticity, low "strength" and are sensitive to the harm produced by any change in physico-chemical conditions, (this change might be expected due to the loading of the strata) it would be interesting to hear the results of investigations (if any) considering the possibilities to determine the thermal change which occurred beneath the elevator during and after construction? Was any chemical analysis of the clay performed? Did the soil contain any gas filled pores?

(c) Every new structure changes considerably the micro-climate beneath it. For instance, the capillarity zone might fluctuate due to the rise of the ground water level caused by the warmer climate which has been established underneath the foundations. Were any ground water observations performed and results obtained? Are the silt pockets large enough to change considerably the hydraulic gradient of water flow? Were drainage possibilities within the strata changed by the erection of the elevator? Were previous conclusions on the cause of failure (fluidization of deeper strata?) considered and rejected?

(d) Since the varved clays are of "unstable" bearing strata if foliation is disturbed or demolished, it would be of interest to know the information obtainable at the present time considering this problem. Was any excavation in the vicinity performed to expose the lamination of the varied clays considering possible inclination of the clay layers? Or, for instance, were the possibilities considered of the lifting up of separate layers by silty layers, (or pockets), during the time while the excavation was open and settling the layers again after the construction was completed (which

---

[1] Lionel L. Jacobs & Son, Wayne, Pa.
[2] Design Engineer, Polymer Corporation Ltd., Sarnia, Ont.

might cause the differential settlement). The bearing capacity might be very high but the structure would collapse.

(e) As the cause of "Transcona Elevator Failure" is known worldwide and has been discussed many times (even mentioned in German and Russian text books) it will be of interest to know the results of investigations performed (if any) referring for instance, to the structural problems drawn by L. E. Vandergriff and pointed out by J. Feld, Ph.D., considering the method which was employed in filling the elevator and also the probability of uneven loading at the contact plan of the foundations. (Boston Society of Civil Engineers, p.108, volume 43, 1955).

As far as $3t/ft^2$, as the allowable bearing value for the case of the varved clays, was successfully accepted without the troubles in other cases, the cause of failure due to shear failure or "low" bearing capacity is questionable. Also, every one post-determined theoretical bearing value might be more or less "adjusted" to the required limit by *different formulae* or factor of safety using. In the case of the Fargo, N.D. elevator failure there are three different opinions given, also in this particular case different opinions might exist, but the investigations should help the practising engineer to become acquainted with all the problems which might be considered. In the book "Engineering Structural Failures" by R. Hammond, the pictures of the Transcona elevator are presented, but the text is omitted due, I suppose, to the limited and perhaps contradictory information available at the present time on the true causes of failure.

The Author

Mr. Balodis has apparently chosen to ignore the fact that both the cause and nature of the foundation failure of the Transcona elevator were primarily mechanical. The overturning of a structure, too heavily loaded to be supported on a cohesive material shown by laboratory tests to have an appreciable shearing strength, involves no principle more complicated than that of static equilibrium at impending failure. The formulae for the ultimate bearing capacity involve only such equations for the forces tending to cause, and resisting motion.

The properties attributed in the discussion to the clays that supported the elevator, including the vaguely described "physico - chemical", changes in chemical nature, high sensitivity to loss of strength, liquefaction, moisture migration, etc. were not indicated to be significant factors in the field and laboratory testing, in reliable accounts of the failure itself nor in any experience with foundation work in the Greater Winnipeg area where the same soils are found and many structures have been built.

Regarding the $\phi=0$ analysis, it is not of secondary importance as suggested. It is only when $\phi=0$ that the shearing strength of a soil can be taken as half of the unconfined compression strength. The fact stated in the paper that 12 representative samples were tested in triaxial compression to establish this relationship was apparently overlooked in the discussion. Also overlooked were the facts that the clays were saturated (no air voids), that the varves were only of fractional inch thickness and nearly horizontal, and that the loading of the elevator was uniform. These observations were based on careful study.

That the varved clays at the elevator site had predominantly clay properties was amply demonstrated by the Atterberg limit, the grain size and their behaviour in the triaxial compression tests. Although not stated in the paper, the clay properties were also demonstrated by the low permeabilities as determined from the consolidation tests. The points raised in the discussion are readily clarified when *all* the pertinent data presented are considered.

For further information it is stated that the major principal stress in the strength tests was applied in the vertical direction of the samples. Regarding soil moisture conditions at the time of the failure there is no evidence to indicate that varved clays were other than saturated at the time of the failure. That $\phi=0$, can be readily demonstrated to be applicable for saturated fine grain soils when loading is too rapid to permit consolidation. It is a well known fact that consolidation under any pressure increase of a deep layer of fine grain soil of low permeability takes many years. The loading of the elevator with grain took only about a month.

Presumably the differential settlement mentioned in the discussion refers to the tilting action of the elevator which is readily explained. It will be seen from Fig. 2 in the paper that the structure had relatively a shallow foundation compared to its height and that the centre of gravity of the entire structure was well above the ground surface. Both these conditions are recognized in static mechanics to constitute relatively unstable equilibrium for a structure supported on a raft type foundation. Any slight eccentricity of loading or support can favour tilting to one side in preference to the other side at impending failure.

I would like to assure Mr. Balodis, that no "adjustments" of any formula were made. The same formula used by Skempton (Building Research Congress I: 180-189, 1951) and by others was employed and the nature of its derivation has been already explained. The use of the formula has been justified by studies of other notable failures and by model studies.

The statement that 3 tons per sq. ft. had been used successfully in other cases is incorrect. Many buildings older than the Transcona elevator are found in the Greater Winnipeg area supported on the varved clays. Soil bearing values for these and newer buildings generally range from 2000 to 3000 lb. per sq. ft., not 6000 lb. per sq. ft.!

Regarding references to the Transcona elevator foundation failure in text books, I would like to state that only Dr. Peck's and the writer's investigations included soil testing and the results of both investigations have only recently been published. Without such testing any analysis of the failure would only be a matter of conjecture.

Mr. Balodis has not stated what the three different opinions were on the N.D. elevator and to which elevator he was referring, nor has he stated if these opinions had been substantiated by actual tests. It is not possible therefore to appraise these "opinions".

It was a most gratifying experience to receive Mr. Lionel L. Jacobs' comments and eye-witness account of the Transcona grain elevator foundation failure. Had the writer known of Mr. Jacobs at the time of the investigation, he would have been delighted to have consulted him on many of the details of the actual failure. Such accounts are invaluable in the reconstruction of past engineering events. It may be noted that even at that time, some forty-five years ago, the significance of this failure had been recognized by the engineering profession.

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

ORIGIN OF THE FOOT-MEASURE

C. St. C. Davison, *Engineering*, v. 184, n. 4778, October 4, 1957

When man had reached a certain stage in evolution he found it necessary to convey impressions of size. Thus he described a piece of wood as being as long as his arm. Or an amber ornament as thick as his finger. The length of the forearm from the point of the elbow to the tip of the middle finger, later known as a cubit, then became a standard of measure; the span and the widths of the palm and the finger were regarded as proportions of the cubit. This system had the drawback that men varied in size, and consequently leaders of communities started to insist on the measures being marked off on wood, or stone for general use. As a result, standards of length thus made were built into the most conspicuous walls of a structure. This practice tended to increase accuracy and also to prevent arguments among tradesmen.

The art of measuring was probably conveyed from Persia or Northern India to Babylonia. The Tower of Babel (or Babylon) was built using a simple cubit measure. An Egyptian royal cubit of about 2600 B.C. shows an average length of 20.8 in. Expanding civilizations needed greater precision in measurement. Egyptian royal cubit - rods of about 1540 B.C. were made of hardwood from the Sudan and inscribed with 28 digits, a digit being one finger's breadth. The first 15 digits from the right were progressively subdivided into from 2 to 16 parts. Also, a knotted cord for land measure was used in Egypt around 1400 B.C. and is comparable to the surveyor's chain used today.

In the sixth century B.C. the Assyrians had a wooden cubit which was divided into six palms, each alternate palm being subdivided into four digits. The overall length of this rod was 21.05 in., although it has been found from records and calculations from buildings to lie between 21.37 and 21.6 in. Its front had a central division to indicate two Eastern feet. Both as a cubit and a foot-measure it was a very widespread unit and has been traced to the following regions: Assyria (21.37 inches), Persia (21.375 in.), Egypt (21.4 in.), Italy (21.375 in.), France (21.32 in.), England (21.48 in.), and Scotland (21.34 in.).

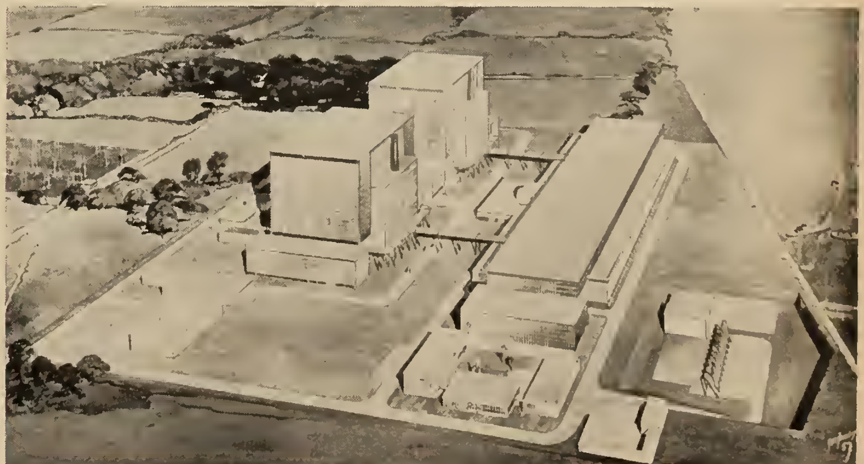
The success of the Roman Empire and general increase of trade led to more settled conditions, and standards for measurement became even more important. The cubit was accurately subdivided into seven palms by six vertical lines; its value averaging 26.8 in. A Graeco-Roman marble notice with a foot-measure inscribed on it shows the foot to be 12.17 in. long. It was known as the Greek Olympic foot.

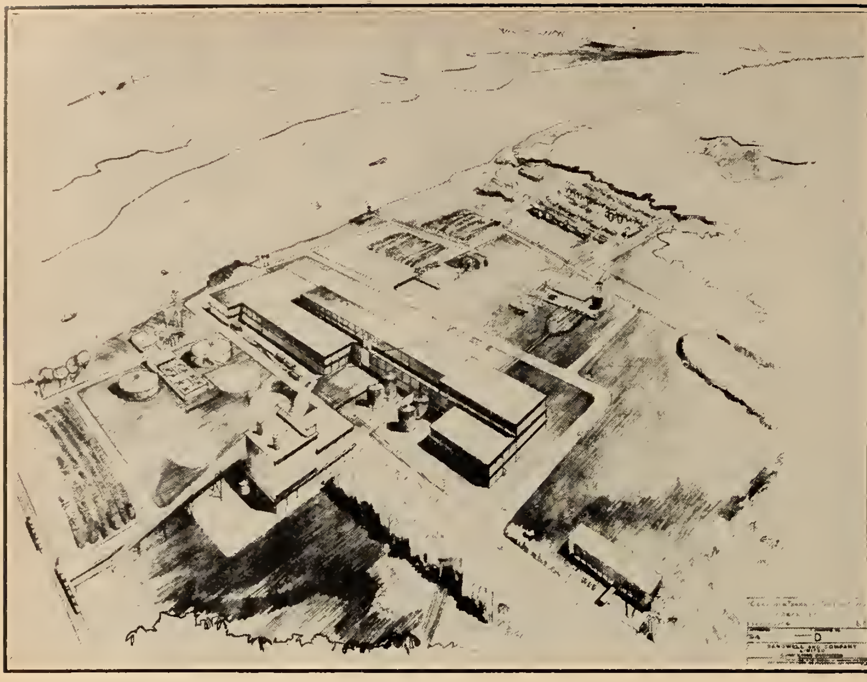
Many countries reverted to more primitive measures when the Romans left them. For instance, the Saxons in England had a measure consisting of 3 barleycorns to 1 thumb (1.1 in.), 3 thumbs to 1 palm (3.3 in.), 4 palms to 1 Saxon foot (13.2 in.). Grains were not very satisfactory as a basis for a measuring system, due to variation in size. The Chinese had a similar system many years earlier.

After the fall of the Roman Empire the Arabs continued to pursue the arts and sciences, and some of the better standards were brought back by them to Europe. Charlemagne (A.D. 771 to 814) was thought to have received a cubit which was derived from that of Darius the Great, King of Persia, Assyria and Egypt (521 to 435 B.C.), which in its turn was derived from the Assyrian cubit. Half of this cubit became what was called the "pied du roi" and remained the official French foot until replaced by the metric sys-

WORLD'S LARGEST ATOMIC POWER STATION

An artist's impression of the atomic power station to be built by the English Electric-Babcock & Wilcox-Taylor Woodrow group at Hinkley Point, Somerset, for the Central Electricity Authority, in Great Britain. When completed, this will be the largest station of its kind, with a net output of 500,000 kw. Two gas-cooled graphite-moderated reactors, fuelled by natural uranium, will be used in the plant.



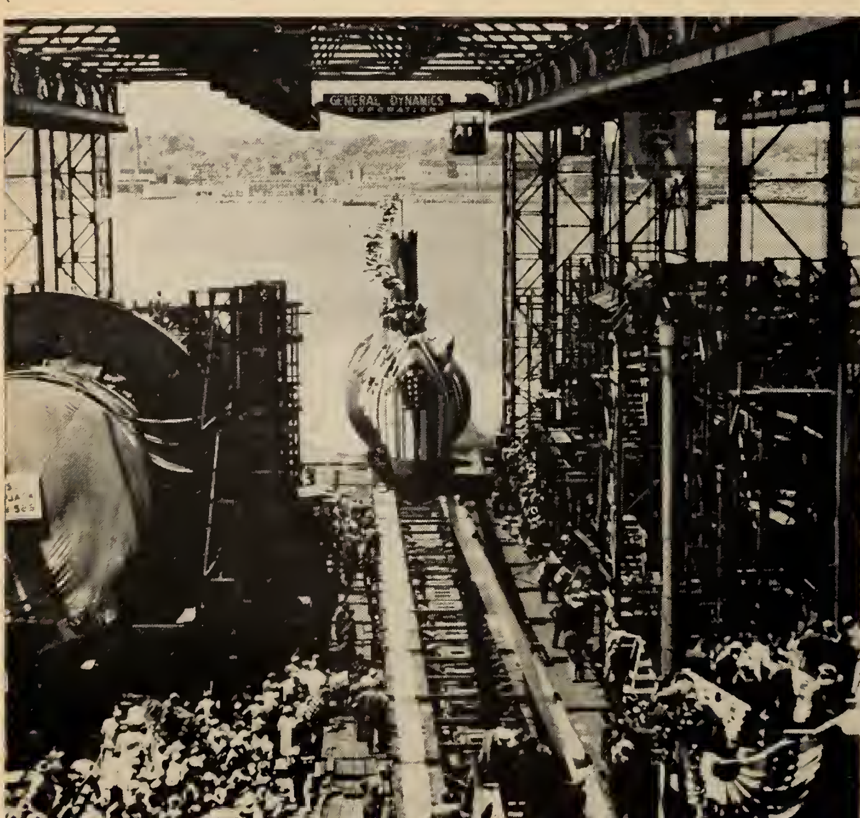


NEWSPRINT PLANT FOR PAKISTAN

Perspective drawing of new $20 million newsprint plant now being built for the Pakistan Industrial Development Corporation. Main mill block, centre; administrative offices, right foreground; chemical preparation and wood treatment plant, centre background. The building with twin smokestacks in centre foreground will house the steam and power plant. Production is scheduled to start in 1959. Consulting engineers for the project are Sandwell and Company, of Vancouver, B.C.

NUCLEAR SUBMARINES IN PRODUCTION

Shown at its launching earlier this year is the first production model nuclear submarine *Skate*. Under construction are the *Skipjack*, left, and the *Triton*, right. (Photo: Ex-Cell-O Corporation, Greenville, Ohio.)



tem during the Revolution (1791). The metre was taken as the one ten-millionth part of a meridional quadrant of the earth, and geodetic measurements to obtain this value were made on the meridian passing through Dunkirk and Barcelona.

Although reverting to the length of the barleycorn as a standard, the Saxons still clung to the Northern Foot for measuring land. This foot, at 13.2 in. can be traced back through various countries to early times in Babylonia. Many different units existed in early English measures and it was difficult to enforce a single standard. Iron yard - bars were made under King John but they were not subdivided into inches because the inch was still governed by the length of a barleycorn. This state of affairs continued until King Edward I made an iron "ulna" (early name for the yard) in 1305 which measured nearly 36 in. and was subdivided into 3 feet, each of nearly 12 in. Henry VII obtained a new standard yard similar to King Edward's, and Queen Elizabeth I authorized another which remained in use as a standard until 1824. It was the basis for measurements of length for Thomas Newcomen, James Watt, and other famous engineers.

Watt's micrometer (1772) which was graduated according to the length of this yard was constructed to read to 1/1800 in. Later Joseph Whitworth made (1834) a measuring device which could be read to an accuracy of one millionth of an inch. The Royal Society of London commissioned (1742) George Graham to produce a better yard measure than Queen Elizabeth's. Attempts in France about 1778 to increase accuracy of production with interchangeable parts for firearms and the successes of Eli Whitney in America led to rapid development of technology. A Royal Commission (1758-1760) prescribed a new yard measure with a dot cut into a gold stud at each end. It was made the legal standard in 1824 but was destroyed in a fire ten years later.

The current imperial yard was constructed in 1845. Studies were made to find the best metal alloy for the purpose, the correct shape and the effects of temperature variation upon its accuracy. Copies of the standard are now kept at the Royal Mint, the Royal Society, the Royal Observatory, the Houses of Parliament, and also the Standards Department of the Board of Trade.

ZINC SOLDERING OF ALUMINUM

I. B. Robinson, *The Welding Journal*, v. 36, no. 10, October, 1957

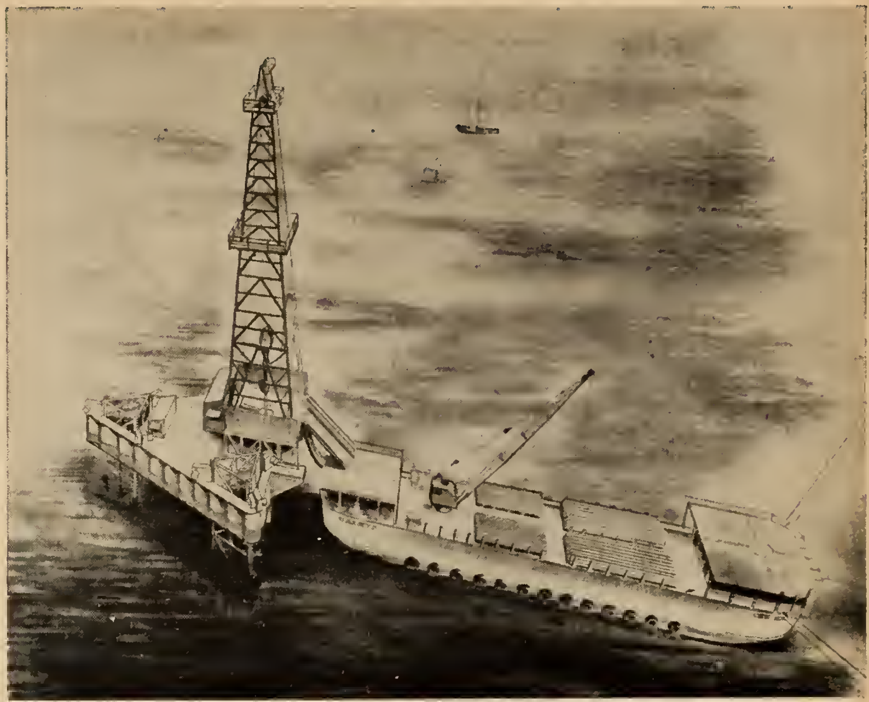
Zinc soldering with the proper fluxes, solders, and procedures is a simple method for joining aluminum to itself and dissimilar metals at intermediate temperatures to provide strong joints which are easy to make and are corrosion resistant.

Zinc solders may consist of zinc or zinc alloys containing from 90% to 100% zinc with varying amounts of higher temperature melting metals such as aluminum, silver, copper or nickel. The melting points of the solders range from 720 deg. to 800 deg. F. and because of the high zinc content are much cheaper than the common soft solders. These solders can be applied to the joint from solder-coated aluminum sheet, from added wire or shims, or from a molten solder bath. The fluxes are inorganic salts, chlorides and fluorides, mixed with water or organic solvents (normal-propyl and normal-butyl alcohol) for application. Flux residues left after joining must be removed since they seriously lower resistance to corrosion. The residues from an alcohol slurry of flux can usually be removed by washing in hot water. If the flux has a low content of zinc chloride a better procedure is to wash in hot water, dip in dilute sodium hydroxide solution, water rinse, dip in dilute phosphoric acid solution, water rinse and air dry.

Any of the commercial forms of nearly all the aluminum alloys can be joined by zinc soldering, although the high strength, heat - treatable alloys are not recommended. The solderability of aluminum alloys is slightly reduced by the presence of silicon. In general, castings are more difficult to solder than are wrought products. The temper of an aluminum alloy has no effect in itself on solderability, but heat-treating films, particularly on alloys containing magnesium, reduce effectiveness of the fluxes. These heat-treating films, can be removed by treatment with sodium hydroxide or hydrofluoric acid solutions.

Furnace, torch, molten metal dip, and resistance soldering can all be used. Tube-fin constructions, socketed tube joints, transition joints, and cellular products are some of the many assemblies that have been joined.

Zinc-soldered joints between aluminum parts are stronger than where soft solders are used, and they are generally stronger than the commonly soldered aluminum alloys. The



MOBILE PLATFORM FOR OIL DRILLING

A mobile tender-type platform to be built for Arabian American Oil Company at a cost of $750,000. Crew accommodation and most of the main power supplies will be housed on the tender. Mud lines, power cables, and other services run from the tender to the platform below the skid ramp. (Photo: R. G. LeTourneau, Inc., Longview, Texas.)

NEW FIGHTER-BOMBER

The supersonic F-105 Thunderchief is the latest fighter-bomber of the U.S. Air Force. It is a 63 ft. long single-seater, powered by a Pratt and Whitney J-75 turbojet engine of the 15,000-lb. thrust class (not counting additional afterburner power). The last 3 ft. of fuselage can be opened out in sections at right angles to act as an air brake.

tensile strengths of zinc solders will be in the range of 15,000 to 40,000 p.s.i. depending on the composition. Socketed joints designed to fail through the solder gave a shear strength of 18,000 p.s.i. for a zinc-aluminum solder, a strength greater than the shear or tensile strength of many of the common aluminum alloys.

The joints have good resistance to corrosion when high-purity solders and proper flux removal procedures are used. Zinc - soldered aluminum joints will last many years in ordinary atmospheres.

AN ACCELERATED TEST FOR PORTLAND CEMENT CONCRETES

J. W. H. King, *Civil Engineering*, v. 52, No. 614, Aug., 1957.

Exhaustive tests have been carried out at Queen Mary College, University of London, on a wide variety of concrete mixes. Sand and aggregate were varied in grading and proportions, the water to cement ratio was varied to give concretes ranging from too wet to too dry, and numerous different Portland cements were used including normal and rapid hardening with some special kinds of cement such as sulphate-resisting, oil-well, and hydrophobic.

As a result of these tests it has been found possible to predict the 7 and 28 day strength of a concrete cured in the normal way at 20° C. under fully humid conditions, by testing specially treated sample specimens a few hours after mixing. The results on unknown materials are predictable within ± 250 p.s.i. or so, with a 90 per cent certainty using standard curves plotted from the test data. Where materials from constant sources are used on a particular site, the curves may be corrected to fit the local findings as the work proceeds, so that the error can be reduced to about half of the above value.

The specimens which have been used in England have been mainly 4 in. cubes, but many checks with 6 in. cubes indicate the test to be equally reliable. No tests have been carried out on 12 in. x 6 in. cylinders. Three different procedures have been used, and are outlined. The first which is standard takes 7 hours from mix to test but as this is not always convenient on engineering works, alternatives taking 23½ and 26 hours have been evolved.

The same curves apply for all methods but there is a slightly increased scatter with the longer times. The scatter is such that the 7-day value cannot be used with success for predicting the 28-day strength, although the accelerated strength will predict both reliably. Any departure from the standard procedures will probably cause so much scatter with different cements, that the tests cannot be considered reliable unless separate curves are produced using the new procedure for each cement.

It is requested that any who care to employ this method of accelerated testing should report their findings to the author, Professor of Civil Engineering, Queen Mary College, Mile End Road, London, E.1, where reports from world wide tests are being examined and correlated.

NEW INTERNATIONAL STANDARD OF LENGTH

A long step forward into the future may result from a resolution recently passed by the Advisory Committee for the Definition of the Metre. This body of international experts has decided that the world standard of length should no longer be "M"—the bar of platinum-iridium kept in Sevres, France—but a wavelength of light. Thev have chosen one of the wavelengths of orange light emitted bv isotopic krypton, of atomic weight 86.

The decision was based on recent research in the U.S.A., Russia, Japan, West Germany, France, England, and Canada. The Canadian work was done in the laboratory of Dr. K. M. Baird, head of the Interferometry Section, Division of Applied Physics, National Research Council. In the past five years, Dr. Baird has built up one of the most distinguished interferometry laboratories in the world, equipped with many pieces of unique apparatus, including several of his own design.

The use of light as a yardstick has been attractive for some time—ever since it was first suggested by J. Babinet in 1827. One hundred years later, in 1927, a relationship was accepted between the physical metre and a red line of cadmium, mainly for the use of spectroscopists. But no known light source was entirely suitable as a base for the metre until recent years, when isotopes became available.

For the past few years, top contenders were mercury 198 (transmuted from gold—an interesting product of nuclear research), krypton 84, krypton 86, and cadmium 114. All of these had excellent characteristics, and it was a long time before krypton 86 won by unanimous decision.

Legally, the steps from this decision are: the Advisory Committee for the Definition of the Metre (chaired by a Canadian—Dr. L. E. Howlett, director of NRC's Division of Applied Physics) will send a report to the International Committee of Weights and Measures, which will meet in October of 1958; and from there to the International Conference on Weights and Measures, which was set up by treaty in 1875, and which meets every six years. At the next Conference, in 1960, the new standard will become legal in all member countries.

In practice, however, scientists will use this standard immediately. They have waited long enough for a standard of length that will not change, cannot be lost, and is available anywhere in the world. The new standard metre is 1,650,763.73 times the chosen wavelength of krypton 86. It is over 100 times more precise than "M", the 75-year-old bar of metal.

Canada's legal position will not be changed: since 1951, the Canadian yard is defined by law as 0.9144 International Metre, which makes the inch exactly equal to 25.4 millimetres.

A hundred millionth of an inch more or less may seem of academic interest alone; but in fact it is also practical. Modern industry is demanding higher and higher degrees of accuracy.

To an old-time mechanic, meeting a tolerance of a one-thousandth part of an inch was an achievement. Today, a ten-thousandth is common practice, and the master gauges controlling interchangeable manufacture are measured in millionths of an inch. The accuracy of these gauges is maintained by checking them against the best available standards. These master gauges, more than any other single factor, made mass production possible. Who knows what will come from two or more decimal places of precision?

Canada's standards of length and mass, as well as of heat, light, magnetism, electricity, and other forms of energy, are all maintained in NRC's Division of Applied Physics.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Though October weather was mild and mainly dry, completions or near-completions on some sectors of excavation and of concrete placing had reduced overall employment well below August and September peaks by month end.

Progress by Ontario Hydro

With 85 per cent of the concrete placed on the Canadian half of the international power-house, Ontario Hydro expects to have reached 90 per cent completion by year-end. The intake structure was built to full height opposite four units. No start had been made on installation of intake gates, but installation of taintor gates for the ice sluice was under way. Curtain grouting was proceeding, with completion expected by mid-December. Intake gate hoists were complete and tested. All draught-tubes were completed.

The smaller power-house crane had been tested, and installation of the large 300-ton power-house crane was nearing completion. Turbine speedrings were set for thirteen of the sixteen units. Wicket gates were placed for unit No. 1 and the runner was being installed.

With all the 5 million cubic yards of earth fill in place for the Cornwall dike, work continued on placing of riprap, with December 1 the target for completion. At the Galops Island cut the lower and upper confferdams had both been breached. Water level had been raised 3½ feet and the Iroquois dam was regulating the Lake Ontario level. There still remained some dredging and excavation to be completed.

Total employment by Ontario Hydro had been reduced to 5,100 persons by the end of October.

Progress by NYSPA

On the American half of the international power-house, placing of concrete had attained 85 per cent of completion. In contrast to the winter shut-down on concrete placing last year, smaller pours will be carried on this winter. All 16 draught-tubes were completed and four intake structures were built to full height. No installation of intake gates had been started. Curtain grouting of the foundation was completed.

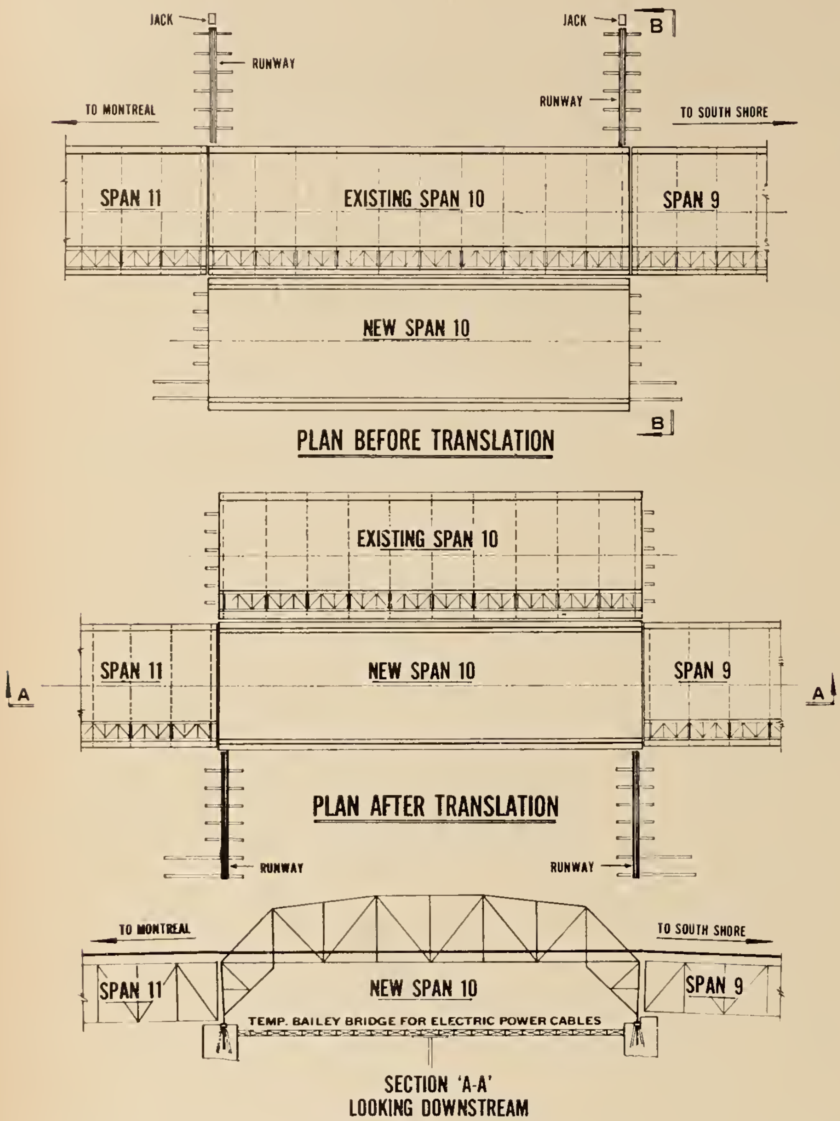
Installation and testing of the gantry crane and intake hoists had been completed. Installation of taintor gates for the ice sluice was under way. Ten of the 16 speedrings were set. Turbine wicket gates were installed for two units. One turbine runner was placed and setting of lower bearing was proceeding.

Excellent progress was made during October at the Long Sault dam, with some 570,000 cubic yards of concrete or more than 82 per cent of the total placed to date. All 16 rollways were poured to full height on the second stage, leaving only six of the entire 30 across the dam to be completed. The bulkhead section was nearing completion. Installation was proceeding on the roller gates in front of the tunnel for the 'second stage' for use next summer. Installation of the fixed hoists had not been commenced. In about another month's time cofferdam EI in stage 2 will be breached.

With the Iroquois dam practically completed, both up-and down-

Iroquois dam. Final stages of construction in progress include removal of the stage II cofferdam.

Jacques Cartier Bridge, Montreal, Translation of Span 10



General Information

Length of span between runways	245 ft.
Centre to centre of trusses on new span	66 ft.
Centre to centre of trusses on old span	40 ft.
Width of roadway on new span	60 ft.
Width of roadway on old span	48 ft.
Height of underside of new span above channel bottom	140 ft.
Length of travel	78 ft.
Total length of runway	220 ft.
Weight of new span	1,600 tons
Weight of old span	1,500 tons
Total weight moved	3,100 tons

The new and old spans were coupled together and mounted on eight roller trucks each containing forty-two 6 in. diameter rollers.

These trucks travel on two runways, each consisting of seven rails and are pulled through a chain of links by double acting hydraulic jacks, one of which is located at the downstream end of each track.

The jacks have a combined capacity of 500 tons and a stroke of four feet. Links are removed after each stroke, the jacks are retracted, reconnected and the process repeated until the translation has been accomplished.

The power is supplied by electrically driven hydraulic pumps delivering oil at pressures up to 6000 lb. per square inch.

Consulting engineer is Dr. P. L. Pratley, M.E.I.C. Dominion Bridge Company Limited is in charge of the bridge project.

stream cofferdams had been breached and were being removed, while installation of the crane was being checked. Clean-up is expected to be done by January 1. Clearing of the park area will be continued throughout the winter months. Employment on all NYSPA operations had dropped to approximately 5,000 by end of October.

Progress by SLSDC

With all concrete placed on both American locks, installation of gates by end of October had reached about 50 per cent of completion at the Grasse River lock and 25 per cent of completion for the Eisenhower lock. Excavation for the Long Sault canal (mainland section) had reached 97 per cent of completion, with the remaining half - million yards expected to be removed by about mid-December. Dikes had all been completed with exception of two gaps for temporary railway spurs.

Dredging of the Cornwall Island south channel, as well as completion of the two locks and the Long Sault canal, to permit 14-foot navigation by July 1, 1958 at which time the head pond above the power-house will be raised, was believed to be assured.

On the new international high-level highway bridge which replaces the existing highway-New York Central bridge at Cornwall, trestles over the dry-land section were completed. The north main bridge pier was nearing completion and the south main pier was 50 per cent poured, with completion expected in December. Employment on all SLSDC work had fallen to some 2700 persons by end of October.

Progress by SLSA

The upper Beauharnois lock was 45 per cent completed as to concrete placing; in October 43,000 cu. yd. were placed, making a total of 132,000 cu. yd. to that date. Rock and earth excavation figures were 72,000 yards, and 18,000 yards for the month, with totals to date of 1,070,000 and 533,000 yards.

Concrete placing for the lower Beauharnois lock was 60 per cent completed; 32,000 cu. yd. were placed during October, for a total to date of 190,000. Rock and earth excavation completed there amounted to 870,000 yards, and 67,000 yards.

At Cote Ste. Catherine lock, at end of October, 1.5 million yards of rock and 2.25 million yards of earth had been excavated. Concrete placing was 76 per cent completed—a total to month end of 313,000 cu. yd., of which 30,000 cu. yd. were placed in October.

The St. Lambert lock was 97 per cent completed; concrete poured in October was 32,000 cu. yd., for a total to month end of 460,000. Two million yards of rock excavation had been completed at month end, 113,000 yards during the month. A start was made on erecting stoplog derricks.

On the Iroquois lock, with gate installation nearing completion, both cofferdams breached and stoplogs in place at both ends, the lock was expected to be ready for 14-ft. navigation by about November 15. This will permit down-bound vessels to use the new lock instead of using the river channel, thus easing congestion at the end of the navigation season.

Dredging of the north Cornwall channel was continuing with one dredge working and excavation proceeding elsewhere, with no strict schedule for this operation.

Bridges

The Dominion Bridge Company started work in October on the lift span of the Victoria bridge at the St. Lambert end. The old roadway is being demolished and traffic is being diverted over new approaches.

Temporary approaches to the Honore Mercier bridge are in place and being used by traffic. Building of the piers of the bridge substructure is well under way.

Dominion Bridge Company, has started assembly of the falsework for the superstructure.

The C.P.R. bridge at Caughnawaga is proceeding, with erection of the south east tower and lift span girders started.

After installation of a through span on the Jacques Cartier bridge in a remarkable "translation" operation in October, the Dominion Bridge Company proceeded with the work of jacking up the bridge spans gradually into final position.

The two seaway authorities announced on October 16 that they had acquired all the shares of the Cornwall International Bridge Co. Ltd., which operates the Roosevelt bridge between Cornwall and the U.S. mainland. The bridge which carried both motor and rail traffic, ceased to carry New York Central traffic after February 15 this year.

The south channel section must be removed and the new high level highway bridge costing some $7 million will take its place, and will provide a 120 ft. clearance for vessels plying the seaway. Pending erection of the superstructure by SLSDC, a temporary ferry crossing will be provided to assure uninterrupted traffic over this international crossing.

Seaway Tolls

Notwithstanding preliminary indications to the contrary, Washington and Ottawa are said to be quite close together on the question of seaway tolls. While Canada would prefer to maintain the tradition of a free canal system, tolls were part of the bargain when the Americans agreed to share the seaway job. Rather than do the whole project alone, Canada agreed to go along with U.S. legislation and accept tolls.

Both seaway authorities themselves are agreed on the essential principle that tolls shall be low enough "to move the traffic", thus too low to protect Atlantic ports from competition. Considerable negotiations will yet be needed to determine exact levels of tolls and methods of measurement, but in broad outline the situation is capable of solution.

Operation, interest and sinking fund will cost some 25 to 28 million dollars annually. A fair and moderate toll on traffic, now in sight may earn some $20 million yearly. For the first few years the two governments will thus have to share annual deficits of between $5 and $8 millions a year. But when full operation and traffic develops it will not take many years to pay this back.

Today Canada has veto power. If the U.S. insists on tolls to pay carrying charges in full from the start, Canada can complete an all-Canadian seaway. Canada's position is so obvious to both sides that there is little chance threats may be necessary.

Canadian Pipeline Projects

Pipeline construction in 1957 is the outstanding feature for Canada's petroleum industry in a year of declining growth in production and refining and an actual volume decline in exploration and drilling. With over 5,000 miles of pipeline due for completion before year-end under existing contracts, total new capital investment for pipelines will exceed $650 million. Most spectacular has been the expansion of natural gas pipeline construction, which has accounted for over 2,000 miles of mainline and gathering systems and at least 2,500 miles of city and town distribution systems, including individual customer service.

Main gas line work for the year will include 192 miles of 30-inch pipe for Westcoast Transmission and 360 miles of 12-inch to 6-inch for Inland Natural Gas. The first stages for Westcoast's gathering system add 150 miles of line in diameters from 26 inch to 12 inch. First stage of Alberta Gas Trunk Line adds 100 miles of 18-inch, and 18 miles of 34-inch pipe. Across Saskatchewan and Manitoba Trans Canada accounts for 360 miles of 34-inch main line. Northern Ontario Crown Corporation will finish a substantial portion of the remaining 310 miles of 30-inch pipeline into Lakehead cities.

Further east Trans Canada will add 310 miles of 20-inch main from Toronto to Montreal and a 36 - mile branch to serve Ottawa-Hull. Union Gas will probably complete 150 miles of main from Dawn storage fields to Hamilton, while a further 24 miles will connect the Niagara Gas Line with Trans Canada, from which imported gas will be drawn pending arrival of Alberta gas.

Crude oil pipeline mileage in 1957 is small only in comparison to gas line mileage, as more than 800 miles will be laid including 156 miles of Interprovincial's extension to Port Credit. The balance of the oil line mileage was entirely looping programs and includes 100 miles of 30-inch for Trans - Mountain, 75 miles of 16-inch for Westspur, 32 miles of 16-inch for Pembina and 32 miles of 24-inch for Interprovincial.

Westcoast Transmission and Inland Natural Gas

Peace River gas was turned into the Westcoast system by British Columbia's Premier Bennett on October 8, by means of a remote - control unit in Vancouver, releasing an initial flow of 60 million feet daily. Ultimate capacity of the system will be 600 million cubic feet per day.

British Columbia Electric has signed a firm commitment for additional supply of Westcoast gas for Vancouver and the lower mainland distribution system. Volume will reach a maximum 144 million feet daily by 1961 for new thermal - electric power plants. Vancouver area customers for natural gas now number 30,000 compared with 5,500 previously on manufactured gas.

By mid - October the 875-mile Inland gas system was on the verge of completion less than 12 months after the first brush was cleared from the right of way. The project has been described as 'the toughest pipeline job in Canadian history', particularly the 40 miles of 10-inch line which crosses the continental divide over the Cascade Range, never before crossed by a pipeline in either Canada or the United States.

The final tie-in weld on the whole 875-mile system was made on October 7. Plans are already made to extend the system to 13 more communities in 1958, to bring the total up to 40. Total cost of capital installations so far is $25 million.

There are 377 miles of main line and laterals. Laterals and town distribution systems account for the remaining 498 miles. Territory served is generally a high fuel-cost area, and initial volume for the first heating season is calculated at a maximum daily demand of 20 million cubic feet daily for a total of almost 6 million cubic feet per day in the year ending October 31, 1958. Total population of the region served is approximately 110,000.

Alberta Gas Trunk Line

Extremely dry weather speeded 1957 construction on the first stage of the AGTL gathering system. One hundred miles of 18-inch pipe and 18 miles of 34-inch pipe from Bindloss junction to Burstall (where gas is delivered to Trans Canada) were laid in six weeks between late June and early August. The Provost field gathering system was completed in July. Future construction is undecided, since as yet no potential traffic estimate can be forecast for Trans Canada. Tentatively the 1958 schedule calls for a 75-mile line to tie in the Pincher Creek field with the system. Signed commitments of gas from the foothills area to the newly proposed Alberta Southern pipeline to California may necessitate substantial revisions to schedules. An extensive gathering grid for Alberta-Southern has been designed, for construction and operation by AGTL when the pipeline is approved.

Trans Canada Pipeline

With natural gas being delivered to Regina, Brandon, Portage la Prairie and Winnipeg since late in September, attention was focussed in October on progress between Winnipeg and the Lakehead. East of Winnipeg long stretches of floating muskeg and soft swamp have been encountered, as well as craggy rock of a very hard granite formation. While pipe laying will be completed to the Ontario boundary by the end of October, the Northern Ontario Pipeline Crown Corporation have been fighting Precambrian granite and the deepest and most fluid muskeg in Canada, as well as very wet weather. In spite of the use of many novel devices in an effort to complete the 310-mile stretch to Lakehead before freeze-up, all the tie-ins and backfill will not be completed before winter shuts the work down.

Near Mortlach, Sask., a 2,000-foot length of the Trans Canada line was destroyed by explosion and fire in early November.

Winnipeg and Central Gas

In September the Manitoba Public Utilities Board approved a rate of $1.03 per thousand feet for space and hot water heating in Winnipeg. Great Northern Gas Utilities, which serves 61 communities in Canada, including Brandon, and Great Plains Gas Co., a local company recently organized, have offered to distribute gas at undisclosed rates possibly up to 20 per cent lower than the $1.03 approved for Winnipeg and Central.

Winnipeg and Central in 1953 acquired the gas rights of Winnipeg Electric. Trans Canada is the only source of gas for the area and has undertaken to sell solely and exclusively to Winnipeg and Central, who have spent some $5 million laying new distribution lines in the metropolitan area. The company is a going concern, serving 20,000 customers and a projected 60 to 90 thousand in the future. Gas experts watching the situation say it is unthinkable the province would default on a contract established in 1880 and reconfirmed only four years ago. They predict Winnipeg and Central will continue to serve the greater Winnipeg area.

Alberta and Southern Gas Co. Ltd.

This company had signed contracts for 80 per cent of the available natural gas in the Pembina area by the end of October, on agreements to run 27 years. Studies indicate Pembina can supply up to 65 million cubic feet daily. The company has also completed a deal with Shell Oil Co. for production of 200 million feet daily. It is already making plans to build gathering and transmission systems as soon as approval is given by the Alberta Conservation Board.

Pembina gas will be sold to Northwestern Utilities Ltd. and Canadian Western Natural Gas Co. Northwestern will soon apply to the Board for permission to build a 75-mile line from Pembina to its distribution facilities in Edmonton. These two established gas utilities, associated as they are with Alberta and Southern, will provide an immediate market and will guarantee an assured supply to Alberta consumers because the province will have a prior call on all the gas it gathers before export.

U.S. Coalmen out to Halt Gas Import

Spokesmen from every segment of the U.S. coal industry have demanded of the U.S. State Department that Canadian gas be kept out of the United States. Their target is prevention of Tennessee - Midwestern from importing 204 million feet daily from Trans Canada, the case that has been before the Federal Power Commission for 18 months. Early in October, 12 spokesmen for the coal industry, the UMWA, the railroads and the coal distributors voiced their opposition to gas imports to Under-Secretary of State Douglas Dillon.

Representative Pat Jennings of Virginia said recently, "opening fuel markets to an alien product would certainly be unfair to members of the UMWA in the affected areas. It is a matter that requires the close attention of all members of Congress". The appeal to the State Department is a preview of what is expected to happen on the floors of the House and Senate when Congress starts its 1958 session in January.

Pipeline News

Activities of Distributing Utilities

Dominion Natural Gas has spent $500,000 of its $2 million expansion program, will continue through the winter months, extending services to St. Catharines, Thorold, Merritton, Fonthill and townships of Pelham and Grantham. 37,000 feet of 8-inch and 10-inch high pressure feeder lines have been laid. Gas supply will be boosted later this year with gas from

Texas, pending arrival of Alberta gas.

Lakeland Natural Gas is proceeding rapidly, with crews at work in Cornwall, Port Hope, Belleville and Gananoque, ready for a turn-on of gas by early in 1958, when an interim supply from Trans Canada will be available.

Consumers Gas Co. of Toronto showed a net profit of 82 cents a share for fiscal year ending September 30, an improvement over the previous year despite major rate reductions. Capital expenditures in 1958, in spite of the tight money situation, will be between $10 and $15 million. Work on the 33 mile pipeline north of Newcastle to serve Lindsay is scheduled for completion the end of October. Laying of distribution lines in Lindsay is being commenced.

Quebec Natural Gas Corp. will multiply sales volume of gas distributed about ninefold during the next four years to a total of 36 billion cubic feet by 1962. Seventy - five per cent of this volume will be required for new industrial services, including gas use as a derivative for chemical and petrochemical industries. It is estimated space heating customers will grow in number to 100.000 from the present 'restricted' 2,400.

Trans Canada May Double Output

Trans Canada President A. P. Craig forecasts the company's presently planned facilities will have to be doubled by 1961 or 1962. Every foot of gas contracted for from western producers has been sold under firm contracts. In view of this huge potential market, much larger than anticipated, he warned it would be well now for governments to go slow on further gas export commitments for another three or four years.

Royal Commission on Energy

Prime Minister Diefenbaker in mid-October announced the appointment of a six - man Royal Commission chaired by Henry Borden, president, Brazilian Traction, to recommend a coherent national policy on the use and export of all forms of energy. The move, involving an investigation lasting many months, is seen as an effective move to take the pipelines out of politics as well as an answer for the C.C.F. policy of nationalization.

The Commission's assignment is to study the creation of a national energy board able to regulate all forms of energy in co-ordinated fashion, as outlined by the Gordon Commission. Its terms of reference cover: best export policy to serve Canadian interests, national policy on rates, prices and financial structure of oil and gas pipeline companies.

Recent decision by British Columbia Electric to use Peace River gas for thermal generation of electricity exposes the absurdity of treating export of electric power in a different way and under different authority from export of oil and gas. Canada might do better to use its gas at home even to generate electricity for export. Canada would get a higher price for electricity than for gas, and more processing would be done in Canada.

The Commission will also investigate the special position of Trans Canada, as to whether special measures are required to be taken to safeguard the interests of producers or consumers of natural gas.

FPC Ruling May Hurt Trans Canada

An interim decision by the Federal Power Commission announced in mid-October, granted a conditional permit to a group of American Pipeline Companies to serve two big industrial markets in Chicago on which Trans Canada Pipelines was depending for about half its volume of supply for export. The gas, to be drawn from the reserves of the Pacific Northwest system by reciprocal interchange with Colorado Interstate and Natural Gas Pipelines of America, will supply the two largest steel mills in the Chicago area.

The decision, to be operative November 9, if not appealed, amounts virtually to dismissal of the Midwestern case, still under consideration by FPC, without FPC having to make a formal order to this effect. Granting of this permit to American Pipeline Companies, coupled with the establishment of the Royal Commission on Energy, will mean that Canada, and particularly Trans Canada Pipelines, is not likely to find export markets for its gas as readily as had been hoped a few months ago. The Royal Commission's investigations will delay any basic decisions on energy export till next spring or later, even as far as giving a company assurance it will be allowed to export and, if so, how much.

New Cable Cooling Technique

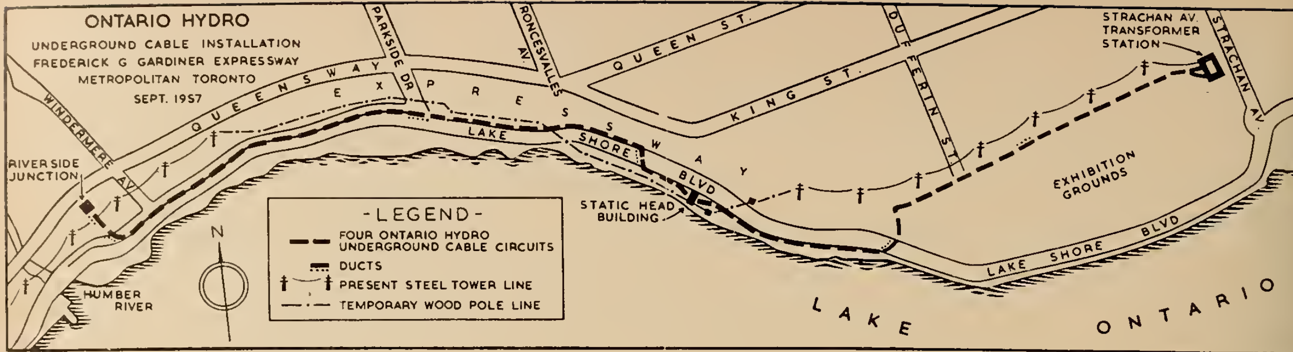
The building of the Metropolitan Toronto's new Expressway necessitated removing from the right of way thirty-one Ontario Hydro steel towers carrying transmission circuits.

Ontario Hydro's facilities in the Humber River-Strachan Avenue Section of the Toronto Lakeshore are being replaced by underground transmission equipment, employing a new system for cooling underground oil-filled cables developed by Ontario Hydro. The method may result in an increase of up to 50 or 60 per cent in the power carrying capacity of the four 115,000 volt transmission circuits completed in November.

The problem is that power being transmitted through cables heats them, and the temperature remains high wherever the cable passes through soil with low heat conductivity. Thus the amount of power which may be transmitted is limited by "hot spot" sections where soil conditions are resistant to transfer of heat. It emerged from studies that cold water pipes installed beside the underground circuits would overcome the temperature problem.

Polyethylene water piping was chosen as virtually immune from corrosion. Its installation was synchronized with that of the oil filled cable. The engineering was done by Ontario Hydro.

Two polyethylene pipes, with an inside diameter of three quarters of an inch, were laid with each set of three cables. The relation of this piping to the cable can be readily demonstrated by using zero symbols, the large one representing the cable and the small one, the polyethylene piping. They are placed in the trench as follows: 0o0o0. Under roadways and a railway embankment, however, the three-quarter-inch piping was too large to fit into the asbestos-type ducts which encase the cable at these points. As a result it was necessary to use six lengths of half-inch polyethylene piping, two lengths being encased with one cable in each duct to provide the required cooling. Special attachments are used at both ends of each set of ducts to connect the six lengths of the half-inch piping to the two lengths of the three-quarter-inch piping.



When placed in operation, the cooling system will utilize water from municipal mains. At every 1,600 to 2,000 feet, the water will be discharged into sewers and a fresh supply will flow into the piping. Experiments indicate that water discharged will be only 10 degrees warmer than when it enters the piping. At both intake and discharge points special fittings are used. Plans now being formulated point to "automation" being applied in the operation of the system. Thus, when the temperature of the cable rises to a certain point, the water in the piping, activated by electronic controls, would start to flow, carrying away the excess heat from the adjacent cables, thus reducing their temperature. When the safe operating temperature has been induced, the flow of water automatically stops.

Oil, under a static head pressure of approximately 15 pounds to the square inch, is within the hollow half-inch core of the copper conductor right from the time the cable is made. This pressure is maintained by portable equipment at all times until cable-laying and jointing operations have been completed. Thereafter, the pressure is provided by special oil tanks at suitable elevations. A set of 12 of these tanks, one for each cable, is located at the Riverside Junction point where the overhead transmission lines from the west are connected to the underground cables through 12 potheads, each of which stands about 15 feet above the ground. The oil tanks are located immediately above the potheads. At the eastern termination point, at the Commission's Strachan Avenue transformer station, there are similar sets of pot-heads and oil tanks. Owing to the variation in the contour of the cable route, it was necessary to establish intermediate sets of oil tanks. These are located within a tall, tower-like brick structure, known as the static head building.

Inside this structure, on the west, is a set of tanks at a low level, corresponding to the elevation of the tanks at the Riverside Junction. The set of tanks, at a high level, on the east side of the building, is at an elevation corresponding to that of the Strachan Avenue transformer station tanks. These two oil pressure systems coming together at this intermediate point are designed to overcome the difference in grade levels and thus maintain a constant pressure throughout the entire length of the underground circuits. This outward pressure from the centre of the copper conductor causes the oil to ooze through the very fine spaces between the strands of the conductor and to saturate the insulating paper, thus keeping out moisture and filling any voids.

The cable specified by Hydro for installation beside Expressway is described as the oil-filled type, having a copper conductor with a half-inch diameter hollow core. The insulation, as already indicated, is oil-impregnated paper which is covered by a metal sheath. The sheath, in turn, is covered with a coating of rubber bitumen and the latter is protected by tightly-woven jute wrapping. The overall diameter of the cable is approximately three inches and it weighs 10.4 pounds per foot, which means that over 1,000 tons of cable will be required for the entire project.

Of far-reaching significance in the power utility field this method is expected to play an increasingly important part as time goes on, making it possible for the underground cables to transmit greater amounts of power as demands increase. Without the cooling system, each of the four circuits now being installed is designed to transmit 140,000 kilowatts of power at 115,000 volts. This represents a total of 560,000 kilowatts for all four circuits operating at capacity. To attempt to transmit additional power without employing some method of cooling would cause the cables to heat up beyond the maximum safe temperature. As already pointed out, the new cooling system is expected to increase the power-carrying capacity of these particular circuits by at least 50 per cent. This means that, when required, these four circuits combined may be able to carry something like an additional 300,000 kilowatts.

What Goes On

On November 19, the first train travelled the completed C.N.R. line linking the Heath Steele Mine with Bartibog, N.B., 23 miles away, and thus with the rest of Canada, the United States and the Atlantic seaboard. Cost of the spur line to this promising mining location was approximately $3 million.

This is the third time in two months that C.N.R. has figured in ceremonies marking completion of railway lines reaching the new mining areas.

A special C.N.R. passenger train travelled from Winnipeg to Thompson, Man., on October 21, using the new branch line from Sipiwesk to Thompson. The rail link to the Mystery-Moak Lake area of northern Manitoba was built by International Nickel Company to serve its giant mining development but it is being operated by C.N.R.

The longest of the branch lines, the 161-mile line from Beattyville to Chibougamau, in Quebec, was opened in November. This is the first section of a 294-mile loop. The second section, running from St. Felicien in the Lake St. Jean area, to Chibougamau, is now under construction.

There will be more detailed information in the next issue about all three branch lines.

AND TRANSFERS

The Forty-Eighth Branch

On the afternoon of Thursday, September 19, a new branch of the Institute was inaugurated at Seven Islands, Quebec.

President of the Institute, C. M. Anson was at Seven Islands to present the charter to the new chairman, B. M. Monaghan. At the inaugural meeting there were about fifty engineers present and the branch certainly was off to a good start.

The program to celebrate this important occasion lasted for three days and included a visit to the iron ore mines at Knob Lake.

About twenty-five councillors came from a great variety of places to wish the branch good fortune and to attend the regional meeting of Council which was held on the afternoon of Friday the 20th. The Iron Ore Company brought all their engineers from the Knob Lake area to Seven Islands for the occasion and as well there was a substantial delegation from Baie Comeau.

The Institute is greatly indebted to the Iron Ore Company of Canada and to the Quebec North Shore & Labrador Railway Company and also to the Municipal Council. Between them they provided receptions, dinners, evening entertainment and special transportation by private plane on several occasions.

The outstanding feature of the program was the visit to Knob Lake. The engineers from that area returned by train on Friday and some of the visitors from other areas accompanied them on that journey. It is too bad that more could not have taken in the train trip because it really is something outstanding, but as far as most were concerned, time did not permit.

Flight over Northern Quebec

The main group flew from Seven Islands on Friday night aboard a D-C-3 getting to Knob Lake a bit before midnight. The flight up was a most unusual experience. The night was clear and the northern lights were brighter than anyone on the plane had seen them before. The thousands of small lakes just seemed almost to cover the landscape and were all shining like silver and the various lights on the railway line added their colour to the picture. The flight of the plane very closely paralleled the railway line which added much to the whole experience.

Overnight the guests were billeted in the guest house and in the local hotel and all gathered together the following morning for the trip through the various mines.

Saturday morning broke clear and sharp and all cameras were out snapping even before breakfast and they seemed to continue throughout the day. Better atmospheric conditions for photographs could never exist.

To this visitor the trip around the mines was unusually interesting because it enabled him to make a comparison with conditions as they were four years ago when first he and the then president of the Institute visited that area. The development is something colossal and must be seen to be appreciated. Even then, it is difficult if not impossible for the eye and the mind to comprehend the area of the activities.

Saturday afternoon the guests were flown back to Seven Islands and shortly thereafter were enplaned again (with box lunches) and flown over to Mont Joli where they picked up the train which returned them overnight to Montreal.

The presidential party and the visitors from Sydney stayed over Saturday night at Seven Islands and were flown out on Sunday to their various destinations.

Throughout the three days the weather had been perfect but it broke on Sunday and the plane which flew the party out that day was not able to get back into the airfield until two days later. It just shows how fortunate the Institute can be in these matters.

Branch Officers

The officers of the new branch in Seven Islands are:—

Chairman, B. M. Monaghan
Sec. Treas., Lawrence Fischer
Executive, R. W. Kenway
Marcel Michaud
Melville Storrier

The visitors who attended the Council meeting are as follows:

President C. M. Anson, Sydney, in the chair; Past Vice-Presidents R. L.

Cover Picture

The Queen Elizabeth Hotel, being built in Montreal by Canadian National Railways, is already a factor in the changing appearance of the city from the air, as the cover picture demonstrates.

Photograph courtesy Canadian National Railways

At Seven Islands, President C. M. Anson and Branch Chairman B. M. Monaghan.

Chairman B. M. Monaghan, I. R. Tait, Montreal, and Jean Menard, Rimouski.

Dunsmore, Montreal, alternate councillor, and I. R. Tait, Montreal, alternate councillor; Councillors B. O. Baker, Quebec, J. H. Budden, Montreal, C. H. R. Campling, Kingston, W. A. Devereaux, Halifax, C. E. Frost, Montreal, R. E. Hayes, Ottawa, G. E. Humphries, London, D. J. MacNeil, Antigonish, C. G. Southmayd, Montreal—representing the American Society of Mechanical Engineers; General Secretary L. Austin Wright.

The names of the persons on the charter for the new branch are as follows:

Emil Bodmer, A. D. Hamilton, J. J. Miller, B. Michael Monaghan, Charles G. Poulton, S. J. Simons, G. A. Verge, Pierre Bergeron, R. T. Giovannetti, Ross W. Kenway, Norman J. Lapierre, Marcel Michaud, Anthony Mousley, Melville Storrier, Fernand Talbot, Barrie Hall, Reginald W. Lowe.

Where Credit is Due

In such circumstances there is always one person who is principally responsible for the arrangements and the success. On this occasion it was B. M. Monaghan, M.E.I.C., assistant chief engineer of the Quebec North Shore and Labrador Railway Company. Mike was the inspiration, the organizer and the manager, surrounding himself with capable assistants as any good manager should do. To him go the thanks of all the visitors.

Throughout its lifetime, the Institute has had many "expeditions" of one kind or another but it is doubtful if any ever gave more pleasure to its participants than did this one. Long will Seven Islands and the hospitality of all its people be remembered by those who were fortunate enough to be present.

1957 University Registration in Engineering

For many years it has been the practice of the Institute to survey annually the enrolment of students in engineering at Canadian institutions. The report for this year, direct from 29 universities and colleges, will be found on pages 1840 to 1842 of this *Journal*.

As usual, the figures are interesting, and close examination of them will reveal some significant facts. Total enrolment in engineering courses in Canada shows an increase of 12 per cent, which is almost exactly the same rate of advance as one year ago. In actual numbers, 14,247 students are now studying engineering in some form, as compared with 12,723 in the fall of 1956. This should not cause any excitement, but it is still a good healthy increase.

Of more importance perhaps are the indications provided by the figures for the new freshman intake. These show an encouraging overall upward trend of 13 per cent, and the new classes of the Western universities have again stolen the spotlight. Registration in engineering in the four Western provinces has climbed rapidly in the last several years, at a faster rate than in the East, and we are now faced with the rather startling fact that this year 36 per cent of all freshmen engineers in Canada enrolled for study West of the Ontario-Manitoba border. Toronto, as expected, came up with the largest new class, 690 strong, followed by Alberta with 476, B.C. third with 473, and Saskatchewan next with 464. In all, 5132 new engineering students signed up in Canada this year.

If readers should compare the lists with those of a year ago, they will notice that some new names have been added. Canada now has four more educational institutions offering at least a partial engineering course of recognized standing. These four are Sir George Williams College, Montreal, McMaster University, Hamilton, Waterloo College, in Waterloo, and Assumption University in Windsor. The *Journal* welcomes them to the roster, and wishes their students and faculties every possible success.

The results from the Canadian Services Colleges again show a slight decline of 7 per cent in new registration. These are estimated figures of those cadets who will elect engineering after their second year, but they compare with last year on the same basis.

A comparison of the popularity of the different courses, as disclosed by the new survey, shows no important change. Civil remains first choice in total enrolment with 1935 students, followed by electrical with 1539, and mechanical showing 1355. This order is the same as last year, with electrical pulling away slightly from mechanical as compared with the 1956 figures. Interesting signs of the industrial times in Canada are given by the strong steady increases again this year in the numbers taking up studies in petroleum engineering and engineering physics.

As a forecast, and discounting casualties between now and next graduation, 2130 young engineers can expect to complete their courses and enter the profession in the spring of 1958. This will be a nice increase of almost 17 per cent over the previous figure, and is perhaps the brightest part of the picture. How far this will go toward filling the demand during 1958 will be watched with interest.

Confederation, Another View

The following article was written by John H. Fox, P.Eng., M.E.I.C. president of the Association of Professional Engineers of Ontario, for publication in the Association's *Professional Engineer*. At the request of the editor of *The Engineering Journal* Mr. Fox has been good enough to permit the *Journal* to publish it also. It speaks for itself.

During the months that it has been my privilege to write this column, there has been one subject that has not been discussed which should be of interest to all professional engineers. I refer to "confederation", or "Unity", of Canadian engineering associations and technical societies. First of all, it would be as well to attempt to define what is meant by "Unity". Such a definition, or description, could be that "Unity" would be the confederation of all Provincial Engineering Associations and Corporation, together with all technical societies in Canada, into a national body representative of, and represented by, its components to form an overall corporate body, to further the interests of all branches and aspects of professional engineering.

In passing, it may be stated that this is not a new project — but one that has been discussed for many years. It is a subject in which the general membership has only in recent years shown a wide degree of interest. Let us not forget that the provincial associations were fathered a generation ago by members of Canada's senior technical society — the Engineering Institute of Canada. At that time, legislation or the lack of it seemed to cramp the full scope of the profession. To-day we are faced with wider concepts and a need to move forward again.

Presently "Unity" centres around, and in discussion usually refers to, the unifying of the services of the Provincial Professional Engineering Associations and Corporation with those of the Engineering Institute of Canada. Each of these major groups has definite and distinct duties and functions to perform. Neither group should be expected to decrease or forego these functions and duties. A unified activity should enlarge the scope of each — without duplication.

The problems of how to accomplish the confederation are now under active review by committees of both groups, i.e. the Provincial Associations and E.I.C. These committees met and made certain recommendations which were not acceptable to all Councils. The committees were then re-formed to make further recommendations after more complete study in the light of instructions from the Councils. Together they work as a Joint Committee of both groups. I am convinced that real progress is being made toward the development of a procedure for the ultimate enlargement and consolidation of activities — of not only the Provincial Associations and the E.I.C., but of the other technical societies in Canada and branches of international engineering groups also.

"Unity" is a project large in scope and of tremendous challenge. It is hoped that local and self interest will not prejudice nor hinder decisions that can and must be made so that plans can be formulated and finalized. These are not local problems, they are not confined to the present generation, therefore expedience does not enter the picture. Decisions made now will influence the whole of the engineering profession in Canada for many decades to come.

Engineers' Civil Defence Forum

The second engineers' forum on civil defence brought thirty-one engineers to the Civil Defence College, at Arnprior, Ont., for five days starting September 16.

The aim of the forum, in all the various problems presented, was to demonstrate the need for engineer planning at all levels, as well as obtaining suggested solutions.

A report was submitted to this forum on the progress made with the recommendations of the 1956 forum. This showed that in some of the more important matters, most noticeably the formation of the Engineer Advisory Committee and its subsequent functioning, satisfactory headway had been made.

Recommendations of the Second Forum

In regard to shelter and refuge, the recommendations of this forum were: 1. That a simple guide to refuge assessment be drawn up; 2. that the engineer services, assisted by city assessors, etc., should be responsible for the assessment; 3. that the results of the assessment should be passed on maps and charts to the welfare services; 4. that protective factors should be included on city assessor cards.

It was agreed, that, in reception areas where there was insufficient refuge at the required standard, it was generally better to construct communal refuges, rather than to attempt numerous small improvisations.

Mobilization procedure was another major item of discussion. The forum was of the opinion that the engineer planning of mobilization should be commenced forthwith. In connection with this, they recommended that steps be taken to ensure that: 1. A legal requisitioning or payment plan be established; 2. The target city engineer should have control of all engineer resources within the target support area with effect from the completion of Phase "B", or the time of an enemy attack.

The forum agreed upon a sequence of operations for reconnaissance and planning after enemy attack—Phase "C" Operations. It was agreed that while small parties of engineers could be made operational with four hours, for small tasks of an extreme emergency nature, it would probably take up to 24 hours or more before the full engineer plan could be commenced.

It was recommended that engineer fire problems should be discussed and solved at provincial level. Since problems were so dependent on local conditions, it was felt that this procedure would bring greater progress in satisfactory planning.

"The Interim Guide to Engineer Planning" was examined and recommendations made for its improvement. It was to be issued shortly.

The detailed report of the forum can be referred to at the E.I.C. Library.

The Members Greet President C. M. Anson

President Anson made a tour of the Atlantic Provinces in September and October, and met many E.I.C. members at meetings, receptions, and other events.

At Halifax Mr. Anson (above left) visited Mayor L. A. Kitz at City Hall; he spoke to N.S.T.C. students and was photographed (above centre) with President J. Hoogstraten of N.S.T.C., and John Devlin, president of Student Society; he visited Col. F. W. W. Doane, senior member of the Branch and father of H. W. L. Doane, vice president (above right).

At A.P.E.N.S. luncheon (centre right): Mr. Anson, L. D. Wickwire, J. D. Kline, J. Hoogstraten, Dr. A. Cameron, past-president of N.S.T.C. Calling on the Lieut. Governor of Nova Scotia, Hon. Allister Fraser (right): Mr. Anson, G. H. Dunphy, Mr. Fraser, H. W. L. Doane, and R. D. Wickwire, chairman of the branch.

President Anson (left), with Albert Martin of Bowaters, at Corner Brook, Nfld.

At St. Francis Xavier University, Antigonish, D. J. MacNeil, chairman of the Branch, Mr. Anson, and Rev. F. J. Somers, president of the University.

Dinner meeting of the North Nova Scotia Branch marked the president's visit to New Glasgow. At the head table, Robert Morrow, Mr. Anson, Chairman D. J. MacNeil, Mrs. Anson, H. W. L. Doane, Mrs. Morrow, J. E. Clarke. Below right, the student audience at St. Francis Xavier.

At Charlottetown, the president signed the co-operative agreement between the Association of Professional Engineers of Prince Edward Island. and the E.I.C. (above): Mrs. Anson, C. W. Currie, Mr. Anson, N. F. Stewart, Branch chairman and Association president, and C. F. Buckingham. Above right: N. F. Stewart, Lt. Governor T. W. L. Prowse of P.E.I., receiving the president, Mrs. Prowse, Mr. Anson and Harvey Doane, vice-president. At supper: Mr. Doane, Mrs. Anson, C. W. Currie, Mr. Anson, N. F. Stewart, Mrs. Currie, Mrs. Stewart.

⟶

President Anson (right), visiting Mayor J. David Stewart of Charlottetown, with Harvey Doane; and (at right) offering greetings to the premier of P.E.I., A. W. Matheson.

The members and the ladies everywhere offered a friendly welcome for Mr. and Mrs. Anson, (as below).

At Bathurst, President Anson visited the works of the Brunswick Mining & Smelting Company. In this group, G. P. Milton, R. C. Eddy, L. L. Marshall, L. Riggs, manager of the company, L. Austin Wright, and Mr. Anson. In foreground, D. Bent, mine superintendent. →

Dinner at Kent Lodge (above), G. P. Milton, Mrs. Eddy, Mayor R. J. Cormier of Bathurst, Mrs. Marshall, Mr. Anson, L. L. Marshall, branch chairman, Mrs. Anson, R. C. Eddy, councillor, Mrs. Cormier and Mrs. Milton.

The ladies entertained Mrs. Anson: Mrs. R. Esterbauer, Mrs. F. W. Buckley, Mrs. G. E. McLellan, Mrs. Anson, Mrs. L. L. Marshall.

↑ The president (left), with members of the interim committee of Baie Comeau Branch, V. M. Wallingford and N. A. Holloway.

The Moncton Branch staged a dinner for the president. At the head table, Mrs. Leighton, Mr. Stratton, Mayor M. M. Baig, Mrs. G. E. Franklin, H. W. L. Doane, Mrs. Anson, V. C. Blackett and Mrs. Blackett, M. F. K. Leighton, Mrs. Stratton.

Visiting city hall, Moncton: Mr. Anson, Mr. Doane, Mr. Franklin, branch chairman, Mayor M. M. Baig; at the Moncton engineering department: W. M. Steeves, acting city engineer, Mr. Franklin, Mr. Doane, Mr. Anson. →

←

Mr. Anson took advantage of his visit to Sydney, N.S., to present to two members, W. S. Wilson, and Major C. M. Smythe, E.I.C. pins signifying attainment of life membership.

At Seven Islands, Quebec, inauguration of the North Shore Lower St. Lawrence Branch was the main event of the president's visit.

The photographs at right show an informal gathering at the Iron Ore company's guest house, Knobb Lake, and a portion of the inaugural branch meeting.

Below, members and guests attending the dinner meeting: while the identifications of the four groups are incomplete, those obtained are as follows: top left, Charles G. Southmayd, John Young, J. H. Budden, G. E. Humphries, R. E. Hayes, and others; top right, Mrs. Dunsmore, I. R. Tait, Mrs. M. Monaghan, C. M. Anson, H. R. Farnam, Mrs. Anson; lower left: Mr. O'Rourke, Mr. Frost, M. W. Martin, Mrs. Martin, C. H. R. Campling, Prof. O'Neil, J. Young, Mrs. C. N. Murray; lower right, B. Kelly, Y. L'Ecuyer, Mrs. L'Ecuyer, Marcel Michaud, Mrs. Michaud, Jean Menard, and others.

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected on October 19, 1957.

Members: A. Baber, Montreal; W. R. Beamish, Montreal; R. T. A. Bolitho, Toronto; C. B. Crocker, Vancouver; G. O. A. Dahlstrom, Vancouver; P. Ebbehoj, Denmark; N. Foran, Montreal; I. F. Gilbert, Three Rivers; H. Grunwell, Windsor; R. I. Hamilton, Sault Ste. Marie; H. M. Hay, Asbestos; C. E. G. Holt, Cornwall; K. B. Jackson, Toronto; J. S. Logie, Vancouver; K. M. MacKenzie, Montreal; V. Maidaniw, Montreal; B. Nagy, Montreal; K. R. Olsen, Montreal; D. J. Pickering, Montreal; J. M. Reid, Calgary; J. Shepherd, Quebec.

Juniors: A. J. Alexander, Toronto; R. F. Barnard, Baie Comeau; D. J. Paines, Toronto; W. B. Taylor, Toronto.

Junior to Member: F. De Francis, Montreal; T. J. Hobson, Montreal; J. Kilgour, Toronto; C. Lacombe, Montreal; D. R Wilson, Montreal.

Affiliate: I. L. Sewell, Baie Comeau.

STUDENTS ADMITTED:

University of Ottawa: P. Arvisais; M. V. Ashkar; A. Aubin; J. V. Audette; L. Audette; A. Baril; C. R. Baron; A. Belanger; B. Bergeron; J. P. Bertrand; J. H. L. Bigras; G. Bisson; Y. Blanchard; B. Boileau; R. Boisvenu; A. Boisvert; F. Bouchard; J. L. Boucher; R. N. Bowes; D. Brady; J. J. M. A. Caron; G. F. Cataford; J. G. Cayer; Y. H. Chan; H. Charbonneau; P. J. Choquette; C. W. Chu; L. Y. Chung; G. J. T. Clark; J. Clay; K. R. Crouch; K. Csavinszky; C. D. Danis; P. E. De Breyne; G. De Carufel; P. Decoste; P. Demers; J. E. G. Drouin; R. M. Dubois; J. P. Durocher; Y. T. Fong; L. A. Fuller; E. Gagnon; R. Giguere; P. M. Gillis; R. Giroux; A. A. R. Groleau; D. M. Harris; I. Jean; W. J. L. Jette; P. J. F. Joncas; E. E. Kalogerakis; D. P. K. Kenny; L. Kolesar; C. Kwan; R. Lacroix; M. Lafontaine; F. J. Lapensee; J. Lecompte; G. Legault; J. P. Lepage; R. F. Lesperance; C. W. Leung; C. Levasseur; J. L. Mathieu; B. W. Matte; P. J. McCann; M. D. McCormack; A. A. McDonald; P. A. McNeely; P. D. Mercier; L. G. Millette; A. Nirchandani; N. Monette; W. J. Morin; A. Nadon; H. B. O'Connell; J. T. O'Connell; M. Parent; W. Pascal; G. Patenaude; H. M. Pedroso; R R. Philippe; J. Pigeon; R. K. Plowman; J. Poirier; T. Provencher; C. G. Quenneville; W. Quintanilla; G. R. Raymond; A. Renaud; R. Richard; R. J. Ross; M. Seguin; J. A. A. Serre; C. C. Simard; K. Smith; S. Tong; D. Tremblay; J. A. R. Trudel; J. M. Vaillancourt; R. D. Voyer; E. J. Zavitski.

University of Toronto: B. K. Bain; J. H. Dickinson; A. K. Englert; C. W. Grant; L. P. Green; F. J. Heatley; J. Lowry; J. C. McCartney; D. R. Miller; N. F. Peterson; G. J. Ryva; D. P. Rutenberg; O. G. A. Schmidt; J. R. Seedhouse; V. Smith; E. Yanchula.

Nova Scotia Technical College: S. Gonzalez A.; F. Klindt; Y. Kuri.

McGill University: M. P. Paidousis.

University of B.C.: D. E. De Courcy.

University of Sask.: D. G. McNabb.

Royal Military College: H. G. B. Hallas.

University of N.B.: A. J. W. Bate.

Mount Allison Univ.: M. E. Terceira.

Saint Mary's Univ.: M. S. Abularach.

Student C.P.E.Q.: D. H. Gray.

Graduates: J. W. Ryan, B.Eng. (Elec.), N.S.T.C., 1957. E. J. Borza, B.Sc. (Elec.), Queen's, 1957. E. W. Hoffmann, Dipl.Ing. (Elec.), Poly. Academy, Austria. E. J. Rowe, B.Eng. (Mech.), Clarkson College of Technology, 1957.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members: F. L. Hickey, M. J. Patrick, S. Venyi. **Junior to Member:** J. D. G. Wallbridge; **student to member:** W. M. Synhorst.

SASKATCHEWAN

Junior to Member: J. T. McManus, I. F. Rogers.

NOVA SCOTIA

Member: J. W. Farrell.

NEW BRUNSWICK

Junior to Member: M. P. Estey.

MANITOBA

Junior to Member: I. W. Fraser.

EJC-ECPD General Assembly

The head table at the EJC·ECPD general assembly banquet was a roster of the heads of engineering societies. Left to right, G. H. Dyer, president NSPE; G. B. Carson, president AIIE; H. A. Kaho, president SAME (not photographed); L. F. Grant, past-president E.I.C.; P. B. Gordon, president ASHAE; J. H. Rushton, president AIChE; W. J. Barrett, president AIEE; A. B. Kinzel, president-elect AIME; T. H. Chilton, past-president EJC; C. E. Davies, secretary ASME. The banquet was held at the Statler Hotel, New York, M. D. Hooven presiding. C. E. Davies was the speaker.

Head table at the EJC-ECPD General Asssembly Banquet, continued, *left to right*, M. D. Hooven, past-president ECPD; L. R. Howsen, president ASCE; W. F. Ryan, president ASME; F. C. Lindeval, president ASEE; F. Merryfield, president AWWA; R. G. Warner, representing NSBEE; H. F. Spoehrer, president ASRE; E. H. Anson, president AICE.

THIRTY-FIVE YEARS AGO

Comment on the Journal of December, 1922

Three technical papers, two presented before the Montreal Branch and the third before the Toronto Branch, were reproduced in full in this issue. P. Ackerman, M.E.I.C., electrical engineer, Shawinigan Water and Power Co., described a new principle of protection developed for his company's 50,000 volt 30 cycle transmission system. John Grieve, A.M.E.I.C., of Dominion Paint Works, had a paper entitled 'Paint as a protection for steel structures'. The paper, read in Toronto, had been presented by Owen W. Ellis, A.M.E.I.C., of the department of metallurgical engineering, University of Toronto, entitled "Points of Contact between Metallurgy and Engineering". Mr. Ellis invited members to enquire into the economics of certain alloys of aluminum for use in structural work, showing how savings in freight haul and erection costs and the avoidance of corrosion might enable these alloys to compete with structural steel. It will be recalled that only a few years later the first Canadian all-aluminum highway bridge was built in the Saguenay district of northern Quebec.

Editorially, it was noted that proposed changes in by-laws recommended by the Committee on Policy, relating to membership, fees, branch membership and nominations, etc., had been endorsed by Council. The election of C. E. W. Dodwell, M.E.I.C., one of the prime movers in the establishment of the Canadian Society of Civil Engineers, as an Honorary Member of the Institute was announced. Major George A. Walkem, (later to become a president of the Institute) was appointed lecturer in industrial management in the department of mechanical engineering, University of British Columbia.

Sixteen pages were devoted to Branch News, with reports of activities in as many branches. The Victoria Branch reported on an address by Major George Walkem on institute policy and legislation. The Edmonton Branch noted presentation of three short papers on railroad organization, the Alberta government telephone system, and on the possibility of smelting iron ores from the vicinity of Lake Athabaska in northern Alberta. The Lethbridge Branch heard a talk by A. M. Robertson, M.E.I.C., executive engineer of the Punjab, India, outlining construction and operations there on the government owned irrigation systems.

At Calgary, P. Turner-Bone, M.E.I.C., explained the underlying principles behind the system of proportional representation then being generally adopted in elections, with the aid of charts. At Winnipeg, Lt. Col. H. C. Boyden addressed the Branch on concrete highway investigations and specifications, both in Canada and the United States, summarizing recommendations for subgrades and concrete slabs.

The Hamilton Branch was addressed by Brig. Gen. C. H. Mitchell, D.S.O., M.E.I.C., dean of the faculty of applied science, University of Toronto, who outlined operations in the Italian campaign in the Alps between 1917 and the Armistice. Engineering problems such as tunnels, bridges and cliff galleries, were discussed with the aid of slides.

The Border Cities' Branch heard C. E. Goodrich, M.E.I.C., of Canadian Bridge Company, who gave an interesting talk, interspersed with humorous personal reminiscences, on the design of transmission towers. M. E. Brian, A.M.E.I.C., city engineer of Windsor, also entertained the meeting with his 'Reminiscences of a City Engineer'. In more serious vein, he counselled his fellow engineers to 'stop the criticism of their fellow engineers, but rather to boost them and place them on a par with the professions of law and medicine'.

F. C. C. Lynch, secretary-treasurer of the Ottawa Branch, probably the most prolific branch reporter of the day, reported in detail on an address to that branch by the Hon. J. A. O. Prens, governor of Minnesota, at a luncheon held in his honour by the branch, attended by Prime Minister Mackenzie King, cabinet ministers, diplomats and government officials. His subject was "The Great Lakes-St. Lawrence River Scheme". The speaker stated 4.1 million horsepower would be developed from the scheme, 3.1 million of which would go to Canada, while 34 miles of channel with locks and 182 miles of channel improvement would be constructed. The estimated cost would be $252 million, (or about a fourth of the actual cost today!).

General Secretary Fraser Keith addressed the Cape Breton Branch on October 31 on policy and on the procedure followed in handling the Institute's employment bureau, a matter of great interest to the outlying branches. Following his address, a Halloween dinner was held, and with the text a reproduction of the menu was given. Delicacies listed included — 'preliminary lubrication'; turkey (with worm drive); vegetables (fine aggregate, coarse aggregate, conglomerate); pie (plastic inclusions); beverages (low potential juice); fruit (ball bearings), nuts and washers; cigars (gas producers).

The foregoing cross-section of branch activities, though not a complete record, gives today's membership a backward peek at the subjects of interest to engineers in the late 'twenties'. The lists appear heavily weighted with subjects relating to civil, mechanical and electrical engineering subjects. A comparison with the subjects discussed at branch meetings today, — atomic energy; electronics; chemical engineering; petrochemicals; aircraft production; aviation; economics; pipelines; telecommunications; radio and T.V.; provides a measure of thirty five years development of the profession of engineering, and the part the *Journal* is playing in recording its growth.

H.G.C.

Engineering Institute of Canada, Annual Meeting, 1958

Chateau Frontenac, Quebec City, May 21, 22, 23

Fiftieth Anniversary of E.I.C. Membership

J. B. Challies, Hon. M.E.I.C.

Dr J. B. Challies, celebrates fifty years of membership in the Engineering Institute of Canada on December 12, 1957.

He has served the Institute well, as the *Journal* reported in 1950, when honorary membership was conferred upon him. The list of offices which he has held is extensive: secretary of the Ottawa branch, chairman of the Committee on Policy (1922), member of Council (1920-21), vice-president (1924), chairman of the Committee on International Co-operation, chairman of the Committee on Engineering Education and Degrees, chairman of the Ontario Provincial Division, treasurer (1935), member of the Consolidation Committee (1935-37), and president (1938).

Dr. Challies is the former director, vice-president and executive engineer of the Shawinigan Water and Power Company.

Engineering Alumni Medal Presented to

Dr. G. B. Langford

Dr. George B. Langford, head of the University of Toronto's department of geological sciences, was presented on November 2 with one of the highest awards a Canadian engineer can receive.

At the sixteenth reunion of the Engineering Alumni Association of the University of Toronto, J. R. White, president of the association and of Imperial Oil Co. Ltd., presented the Engineering Alumni Medal to Dr. Langford in recognition of his distinguished contribution to the profession. Only 12 others have been awarded since the inception of the honour in 1939.

More than 1,000 graduate engineers from the West Indies, the United States and Canada attended the two-day meeting. The association has a total membership of more than 10,000.

Dr. Langford was born in Ontario but received his early training in Calgary. He returned to study engineering at the University of Toronto and after graduation studied for his doctorate at Cornell University.

He has served as director of the Ontario Department of Planning and Development, as chairman of the North York Planning Board, and as a member of the Metropolitan Planning Board of Toronto.

His most recent contribution to the engineering profession is his chairmanship of the Committee for Registration of Engineering Technicians.

Dr. G. B. Langford (right) receives the Engineering Alumni Medal from J. R. White.

Survey of Scientific and Technical Manpower

The Federal Department of Labour is at present surveying professional men and women in scientific and technical fields. The purpose of the survey is to bring up to date the records of the National Register of the scientific and technical professions which has been maintained by the Department since 1942. Analysis of the Register records will supply a source of information on the characteristics of the supply of scientific and technical manpower, such as its age composition, its geographic location, the fields of specialization and functions within each field, education received, the incomes earned, and other characteristics.

A new questionnaire has been developed for the survey, one which can be completed with less effort than those used in the past.

The current survey is a part of a program in which one-third of the people in scientific and technical professions will be surveyed each year. Over a three-year period, everyone will have been covered. By this means, information on scientific and technical manpower in Canada will be maintained on a current basis. Those surveyed each year are selected on a random basis thus permitting the information secured to be used as a statistical sample representing the whole group.

There is a growing need for information on scientific and technical manpower in Canada. This survey provides the major source of information on professional manpower in the country. The Department of Labour's efforts, however, can only be of real value if the coverage of professionals in the country is extensive and the information on registrants is maintained on an up-to-date basis.

The Institute fully endorses the maintenance of the National Register of the scientific and technical professions and the survey being undertaken, and asks that all members who have received the questionnaire form this year cooperate fully in giving accurate information and mailing their completed forms to the Department of Labour as soon as possible.

Vocational Training for Women

Educators from all parts of Canada attending a meeting of the Canadian Vocational Training Advisory Council held in Ottawa in September, were urged to give greater consideration to vocational training for women.

Miss Marion Royce, director of the Women's Bureau of the Department of Labour, told the Council that at the present time 25 per cent of the Canadia labour force consists of women. She considers that such an important segment of the labour force should be encouraged to take advantage of vocational training opportunities to fit them for better and for a greater variety of occupations.

Miss Royce said that most girls anticipate some working experience as well as marriage. She pointed out that while there are no legal barriers to women in most vocational courses, there are many courses in which the participation of women is not encouraged as much as it might be. She also sees an urgent need for counselling and courses for mature women, designed to build confidence and skill.

In commenting on Miss Royce's address, Mrs. Rex Eaton, president of the National Council of Women, said that we must recognize the important part played by women in our economy. She suggested that a review of vocational training facilities for women might profitably be undertaken.

While these comments do not specifically mention the guidance of women into engineering, it might be expected that to some extent this would be one effect of intensified vocational training.

In other places, there is some concern for this matter, as the following excerpt from the September 6, 1957 issue of the *Electrical Review* indicates. (Published in London, England.)

"South Wales Switchgear, Ltd., which in conjunction with the Youth Employment Bureau has a scheme whereby grammar school students undertake one week's vacation training at the company's works at Blackwood, recently held an experimental course for fourth form grammar school girls, claimed to be the first of its kind in this country. The object of the course was to show the girls the possibilities of an engineering career. Thirty girls attended the course which proved to be a success. During the week they were shown the full range of a complex industry, extending from rate fixing and planning, material control, test, etc., in the factory, to the drawing office, design, research and sales departments. Lectures were also given by the company's executives on the various aspects and openings available in engineering".

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

George Heckman Burgess, M.E.I.C., consulting engineer, member of the firm of Coverdale and Colpitts of New York, and of the American Institute of consulting engineers, died in New York City on March 1, 1957.

Mr. Burgess was born at Oshkosh, Wisconsin on June 19, 1874. He entered the University of Wisconsin in 1891 and four years later graduated with a Bachelor of Science degree in civil engineering. His earliest work was with the Edgemoor Bridge Works at Wilmington, Delaware; and the Pennsylvania Railroad Lines. He moved to Pittsburgh in 1896. With the latter company he was first employed in the bridge department. Later he was assistant engineer in charge of construction of shops, railroad stations and docks.

In 1905 he left the Pennsylvania to become associated with the Erie Railroad, and in 1906 became engineer of terminal improvements in charge of construction of terminals in the New York district and the monumental undertaking of the four track open cut and tunnel through Bergen Hill.

In 1909 his appointment as chief engineer of the Delaware and Hudson Company was announced. Mr. Burgess continued with that company until 1925, contributing to the solution of many of the problems involved with the valuation which was inaugurated in that year by the Interstate Commerce Commission. The experience he gained in this undertaking made him one of the leading authorities in railroad valuation.

In the summer of 1925 he joined the staff of the engineering firm of Coverdale and Colpitts. Three years later he was admitted as a partner to continue as such until the time of his death. His activities as a partner included not only participation in the firm's consulting work, but also various business activities. He was president of the Tennessee, Alabama and Georgia Railway Company from 1929 to 1945, and on his retirement remained as a director until the time of his death. He was president of the Burgess Battery Company from 1932 to 1936; a director of Shanferoke Coal and Supply Corporation from 1934 to 1939; a director of the Seaboard Air Line Railway Company from 1938 through 1946; director of Crocker-Wheeler Electric Manufacturing Company, 1939-1943; managing director and chairman of the board and executive committee of Petroleum Heat and Power Company, 1939 to 1942; director and member of the executive committee of Refined Syrups and Sugars, Inc., 1942 to 1948.

Mr. Burgess joined the Institute as a Member in 1912. He attained Life Membership in 1947.

W.O.I., J. N. Clemens, M.E.I.C., of Royal Canadian Air Force headquarters, Victoria Island, Ottawa, was killed in an air crash on July 3, 1957.

James Nicholas Clemens was born at Dauphin, Manitoba on July 6, 1912, and had his schooling there. He obtained a diploma in applied electricity in 1930 following an electrical engineering course with the International Correspondence School.

His early work was concerned with the installation of a water power plant at the God's Lake Gold Mines, and with the Hudson Bay Railroad.

From 1936 to 1941 he was assistant superintendent in charge of electrical distribution for the town of Dauphin, Man., and later worked as aerodrome foreman electrician in charge of power and lighting for No. 2 Training Command, Winnipeg, in the early days of World War II.

In 1944 he enlisted in the R.C.A.F. and served overseas.

Since that time he has been stationed with the North West Air Command, R.C.A.F. headquarters at Edmonton and the A.M.T.S./D.C.E.D., at headquarters, Ottawa.

Mr. Clemens joined the Institute as a Member in 1943.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

BRITISH COLUMBIA

(This article was prepared by J. H. Bennett, P.Eng., assistant registrar of the Association of Professional Engineers of British Columbia for The B.C. Professional Engineer.)

The Engineer in Industry

Engineers in industry rate the high calibre of their colleagues, the opportunity for further training and the opportunity for advancement as the most satisfying factors in their present jobs.

These are some of the findings in the newly published survey report entitled "Career Satisfactions of Professional Engineers in Industry."

The publication is the latest in a series of executive research reports made under the sponsorship of the Professional Engineers Conference Board for Industry, in co-operation with the National Society of Professional Engineers.

Conducted by the Opinion Research Corporation, Princeton, New Jersey, the survey report is based on data gathered from interviews with several hundred professional engineers employed in industry in all the specialized technical fields. The lengthy "depth" interviews were designed to bring out the non-salary career satisfactions of engineers at three stages of professional experience—3 to 6 years, 10 to 15 years, and 20 to 25 years.

Sixty-seven per cent of the engineers in the 3-to-6-years-experience group stated that there were things lacking in the college training they received and approximately 76 per cent of those with more experience felt that there were deficiencies in their college training.

The survey also found that the most skepticism about the opportunities for advancement in engineering was expressed by men in the lowest technical jobs.

Six out of ten of the engineers surveyed reported that they have not held a full-time job with any company other than their present employer. Only one in five has experience with as many as two other employers.

The survey questions centered around such things as the engineer outside of his work, the career outlook of engineers, satisfaction and frustration on the job, the question of professional status, and the differences in values of the more successful engineers.

Eleven companies, each among the 200 largest corporations in the United States, were represented in the survey. The industries covered were: aircraft, automobile manufacturing, chemicals, electronics, electrical machinery, heavy equipment, petroleum refining, and rubber.

Engineers in the News

P. Klapp has taken a position with Timber Preservers Ltd., in New Westminster.

Bruce Walley is now employed by the B.C. Department of Highways as divisional engineer in charge of bridges on the Trans Canada Highway, in the Revelstoke area.

W. C. Palmer, P.Eng. is now with Canadian Fina Oil Limited. The address of this company is the Bamlett Building in Calgary.

E. C. Thomson recently accepted a position with H. A. Simons Ltd. He was formerly employed by Pacific Steel Erectors Ltd. at Kitimat.

C. D. Schultz, P.Eng. president of C. D. Schultz & Company, attended the seventh British Commonwealth Forestry Conference in Australia. This conference opened in Adelaide on August 26. Mr. Schultz was the official delegate of the Canadian Forestry Association.

A. Unsworth, P.Eng., who was formerly with H. A. Simons Ltd., has joined G. S. Eldrige Co. Ltd.

A. J. Bowering, P.Eng., plans to attend the conference of the Western Canadian Association of Highway Officials in Edmonton on October 7th, 8th and 9th.

W. R. McLauchlan, P.Eng., is now at Grand Forks, where he is employed by Northwest Telephone Company. He is responsible for the maintenance of microwave stations in that area.

J. T. Turner, P.Eng., is manager of the transportation Maintenance Sub-division of the B.C. Electric Company. In September, this sub-division received credit for an outstanding record in bus

H. D. Dawson, P.-Eng., and George Harford, P. Eng. (in parka) are shown chatting at the Municipal Engineers' Convention held at Victoria, B.C. in September. The event was reported in the November issue of the Journal.

maintenance when the Transportation Division of the B.C. Electric received the Fleet Owner Maintenance Efficiency Award at the annual meeting of the American Transit Association in Montreal. This is the second time only that a Canadian company has received this award.

D. F. Samis, P.Eng., formerly with Sidney Roofing, has accepted a position with the Pulp & Paper Division of McMillan & Bloedel Limited at Port Alberni.

G. Koster, P.Eng. is now plant manager for Fort Construction Company Limited.

G. P. Harford, P.Eng., municipal engineer of Prince George, was elected chairman of the Municipal Engineers' Division at the recent convention in Victoria.

S. H. deJong, P.Eng., associate professor of civil engineering at the University of British Columbia, has been appointed for a three-year term to the committee of the American Society for Engineering Education.

D. A. Wills, P.Eng., is now in Sydney, Australia, with a firm of civil engineering contractors.

W. P. Johnson has taken a position with the B.C. Power Commission.

Derek Franklyn, P.Eng., has joined the staff of Sealand Products Limited. He will act as consultant for the company which is the agent for micro-straining equipment.

R. D. Grantham, P.Eng., of Dominion Construction Company, has been transferred to Edmonton as manager of the company's Edmonton office.

Frank J. Berto, P.Eng., has left the Lago Oil & Transport Company in Aruba to take up post-graduate work at the California Institute of Technology.

MANITOBA

(Abstracted from the "Manitoba Professional Engineer," journal of the Association of Professional Engineers of the Province of Manitoba.)

P.Eng.'s Hold Civic Office

Three members of the Association of Professional Engineers of the Province of Manitoba were recently winners in civic elections held in the provincial capital.

Edward Kuiper, P.Eng., was elected to the School Board in St. Vital; **Robert A. Bird**, P.Eng., was re-elected to the School Board in Fort Garry, and **W. J. Ducharme**, P.Eng., who made his first bid for office this year was elected to Council in Fort Garry.

These elections are a personal tribute to the engineers who have already made a substantial contribution to their community affairs, and they are also an indication of the growing awareness on the part of the public of the need for able, qualified men in civic administration. These gentlemen are to be highly commended for their willingness to give of their time and effort to the administration of community affairs.

President N. S. Bubbis Reviews Summer Activities

While council continued to meet throughout the summer months, despite pre-occupation with the usual hectic program of summer work and the holiday period, the various committees also continued to work on their assignments. A special committee was set up to study the constitution of the Canadian Council of Professional Engineers which is being reviewed, President Bubbis reported.

A copy of a questionnaire on night school classes in engineering was circulated. The Junior Chamber of Commerce investigated this problem in Winnipeg, as a result of which it was found that a considerable number of people desiring post-matriculation education were interested in engineering. Council has also had numerous applications for registration from people who were not fully qualified. While the Act provides for written examinations and a uniform syllabus is available, it is obvious that it must be extremely difficult for most of the applicants to prepare themselves adequately on an individual basis. It is felt that night school courses in engineering might greatly assist in solving this problem, just as it has in other centres in North America and in Great Britain.

Council decided that as the professional engineering body in Manitoba it should interest itself in this problem and decided to co-sponsor the issuing of a questionnaire in order to survey the actual requirements of night courses in engineering. More than 300 people had shown themselves to be interested in evening courses by October. Sixty of these wished to follow post graduate studies. In addition to those mentioned there were a considerable number of requests from members of the Association for a night school course in Business Administration. It is the council's intention to assist in pursuing this matter further with the hope of seeing such courses established at the University.

ONTARIO

President Fox Says

(Abstracted from The Professional Engineer, the journal of the Association of Professional Engineers of the Province of Ontario.)

President Fox, in discussing 'Unity' said that it must not be forgotten that the provincial associations were fathered a generation ago by members of Canada's senior technical society, the Engineering Institute of Canada. At that time legislation or the lack of it seemed to cramp the full scope of the profession. Today we are faced with wider concepts and a need to move forward again.

Each of the major groups involved has definite, distinct duties and functions to perform and neither group should be expected to decrease or forego these functions and duties. A unified activity should enlarge the scope of each without duplication.

Problems on how to accomplish confederation are now under active review by committees of both groups, i.e. the Provincial Associations and the E.I.C. These committees met and made certain recommendations which were not acceptable to all Councils. The committees were then re-formed to make further recommendations after more complete study in the light of instructions from the Councils. Together they work as a Joint Committee of both groups. Mr. Fox is convinced that real progress is being made toward the development of a procedure for the ultimate enlargement and consolidation of activities—of not only the provincial Associations and the E.I.C., but of the other technical societies in Canada and branches of international engineering groups also.

President Fox said that 'Unity' is a project large in scope and of tremendous challenge. It is hoped that local and self interests will not prejudice nor hinder decisions that can and must be made so that plans for unity can be formulated and finalized. These are not local problems, they are not confined to the present generation, therefore experience does not enter the picture. Mr. Fox adds that decisions made now will influence the whole of the engineering profession in Canada for many decades to come.

Ontario today has 16,094 registered professional engineers in Ontario, an increase of 1,317 over 1956, it has been announced by the Association of Professional Engineers of Ontario.

Association Council Adopts Technician Program Revision

The Council approved revision of the engineering technician program which would classify the first three grades as engineering technicians, and the top two grades as engineering technologists (grades I and II). Originally all five grades were classified as engineering technicians.

Council was advised that 419 applications for certification as engineering technicians and technologists have been received, with 247 already having been processed. The provinces of Manitoba, Alberta and British Columbia have expressed interest in the program and are considering instituting similar certification legislation.

A two-part group retirement savings plan for members has also been presented for consideration. It would be available to all members under the age of 70. The plan is in two parts, an insured annuity retirement savings plan and a trust investment retirement savings plan.

Council also approved a motion to establish a committee on accreditation of university courses pertaining to engineering. It was felt that while existing techniques of the U.S. Engineering Council for Professional Development may be most helpful, the development of a Canadian technique is desirable. Chairman of the accreditation committee is Professor R. G. Lord, P.Eng, of the University of Toronto.

Engineers in the News

Stanley C. Jones, P.Eng., has been appointed engineer on the staff of the director, Naval Program Control, as assistant director Naval Program Control (Construction), in the Department of National Defence, Ottawa, Ont.

C. F. Moore, P.Eng., of Canadian Industries Ltd., has moved from Shawinigan Falls, Que. to Edmonton, Alta., where he is acting resident engineer of the C.I.L.'s plant expansion in that city.

M. S. Juzyez, P.Eng., has joined Avro Aircraft Ltd., Malton, Ontario, as electronics engineer in the electronics system department.

Graduating in engineering from Munich in 1949, Mr. Juzycz obtained his M.A.Sc. degree in electrical engineering at the University of Toronto in 1952. He is presently a graduate student in the Institute of Business Administration, University of Toronto.

Prior to joining Avro Aircraft he was on the staff of the Department of Electrical Engineering of Toronto University, with the Canadian Westinghouse Co. Ltd. and latterly has been development engineer with Decca Radar (Canada) Ltd., Toronto.

Burt A. Avery, P.Eng., who formerly held the position of chief design engineer at Orenda Engines Ltd., Malton, has been appointed deputy chief engineer responsible for the design, aerodynamics and material department of the company.

Gordon D. Paseoe, P.Eng., has joined Babock-Wilcox & Goldie-McCulloch Ltd., Galt, Ont., as a project engineer. He was formerly with the Canadian Locomotives Co. Ltd., in Kingston, Ont.

W. H. Davis, P.Eng., has accepted the appointment of lecturer in engineering science at the University of Western Ontario, London, Ont.

Dr. Alex Muraszew, P.Eng., formerly chief experimental engineer at Orenda Engines Ltd., has been named deputy Chief engineer responsible for the development department, experimental shop and the company's test establishment at Nobel, Ont.

Keith G. Lightwood, P.Eng., has moved from Toronto to Seattle, Wash., where he has accepted employment with the Boeing Airplane Company's transport division at Renton, Wash. Mr. Lightwood, who graduated from the University of Toronto in 1949, has enrolled in the Graduate School of the University of Washington in a course leading to a Master's degree in aeronautical engineering.

Peter W. Brown, P.Eng., who graduated from the University of Saskatchewan in 1954, has resigned from Bailey Meter Co. Ltd., Toronto, to take up duties in the office of the Engineer-in-Chief, Naval Technical Services, Department of National Defence, Ottawa, Ont.

Roy L. Hurd, P.Eng., is general manager of South African Motor Assemblers and Distributors Ltd., Uitenhage, South Africa.

A graduate from Queen's University, Kingston, in 1948 with honours in civil engineering, Mr. Hurd joined the Ford Motor Company of Canada Ltd., in Windsor. His first assignment was in connection with foremen and supervisory training in the manufacturing and assembly plants in Windsor. Later he moved to the Overseas Division and held the post of general organization planning manager. During the years 1952 to 1955 he travelled overseas to Ford plants in India, Malaya, Australia and New Zealand. In 1955 he transferred to Ford Motor Company of South Africa in the capacity of executive assistant to the managing director.

During summer of this year he accepted the general managership of South African Motor Assemblers and Distributors. This company has assembled Studebaker cars, Austins and Volkswagens. Currently the company is engaged in the assembly and distribution of Studebakers and Volkswagens for the markets of South and South West Africa.

H. J. Fineh, P.Eng., of the Hydro-Electric Power Commission of Ontario is now living in Port Arthur, Ont., where he is personnel officer, Northwestern region of Ontario Hydro. He was formerly personnel officer in the engineering division in Toronto.

Dr. Anton F. Mohrnheim, P.Eng., has moved to Kingston, Rhode Island, and has accepted the appointment of associate research professor in metallurgy at the University of Rhode Island.

W. B. Drowley, P.Eng., formerly with Republic Floro Meters Canada Ltd., Toronto, has accepted a position with the Ontario Department of Health, Air Pollution Control, Toronto.

Douglas C. Alexander, P.Eng., is project engineering supervisor, Analytical and Control Division, of the Consolidated Electrodynamics Corp., of 300 N. Sierra Madre Villa, Pasadena, Cal.

H. N. Hutchison, P.Eng., of Defence Construction (1951) Ltd., is now located in Port Arthur, Ont. He was formerly associated with the Camp Gagetown project in New Brunswick.

Alan D. Seharf, P.Eng., has left the electrical apparatus sales division of Ainsworth Electric Co. Ltd., Toronto, and has accepted the position of staff electrical engineer with the Potash Company of America Ltd., Saskatoon, Sask.

Walter G. Ward, P.Eng., has been appointed general manager of the apparatus department of Canadian General Electric Co. Ltd. In his new capacity Mr. Ward succeeds J. Herbert Smith, P.Eng., who recently was elected president of the company.

Mr. Ward heads a department which employs 4600 people in the plants at Peterboro, where he will be located, in Guelph and in sales offices of the company across Canada.

A graduate of McGill, Mr. Ward joined Canadian General Electric in 1945, following service in the R.C.N., as a lieutenant-commander (radar and communications). His first responsibilities with the company were those of manager of the electronic equipment section. In 1952 he was made manager of the major appliance operation in Montreal and two years later general manager of the appliance department. Following an assignment on organizational work with the General Electric Company he was appointed manager of induction motors in Peterborough in 1956 and earlier this year was named general manager of the entire sales department.

Lloyd M. Priee, P.Eng., manager of engineering of Radio Valve Co. Ltd., Toronto, has recently retired.

Mr. Price has been active in both the Institute of Radio Engineers and the Radio Electronics Television Manufacturers Association. He is a Fellow of I.R.E., has been active in committee work and has served as chairman of the Toronto section of I.R.E. In R.E.T.M.A., in addition to his committee activity, he served as chairman of the Component Section for two years and as vice-president of the Association.

Earl W. Gagan, P.Eng., has resigned from his position as chief engineer at Lake Asbestos of Quebec, Ltd., to take up residence in Toronto and to enter private consultation as a mining engineer. His office is located in Suite 309, 200 Bay Street, Toronto.

David F. Witherspoon, assistant professor in the Department of Agriculture at the Ontario Agricultural College, Guelph, Ont., has been granted a leave-of-absence for one year to study hydrology and reclamation in the Netherlands. His course of study is part of the International Course in hydraulic engineering which is sponsored by the Netherlands Universities Foundation for International Co-operation. He will be located at the Delft Technical University, Delft, Netherlands.

Personals

News of the Personal Activities of Members of the Institute

Ralph C. Pybus, M.E.I.C., of Vancouver was eleeted president of the Canadian Chamber of Commerce at the annual meeting in September.

Mr. Pybus is president and general manager of Commonwealth Construction Company. He is a former chairman of the Vancouver Branch of the Engineering Institute of Canada.

J. W. McCammon, M.E.I.C., (B.Se., McGill, 1912) has been appointed a member of the United Nations Technical Assistance Team to advise the governments of Thailand, Cambodia, Laos, and South Viet Nam on the proper proeedures to be adopted for initiating a scheme of development of the Mekong River within their territorial limits in respect to power, distribution, irrigation and navigaton.

Mr. MeCammon left Monteal about November 19 and will be absent for a period of three months.

On July 15, 1957, Mr. MeCammon retired from the position of eommissioner and general manager of the Quebee Hydro Electrie Power Commission at Montreal.

Claude P. Beaubien, M.E.I.C., (B.Se., business and engineering administration, M.I.T., 1934), is president of the Montreal Board of Trade.

Mr. Beaubien is manager of sales, at Montreal with The Aluminum Company of Canada.

T. M. Patterson, M.E.I.C., (B.A.Sc., eivil, Toronto, 1925) is direetor of the Water Resources Braneh of the Canadian Department of Northern Affairs and National Resources, Ottawa. This Braneh replaces the former Water Resources Division. The three senior offieers, all of them members of the Institute, are Mr. Patterson, **J. D. McLeod,** (B.A.Se., eivil, U.B.C., 1939) ehief engineer, and **R. H. Clark,** (M.Eng., eivil, McGill, 1945) chief hydraulie engineer.

E. L. Neal, M.E.I.C., (B.Se., meehanieal, Queen's University, 1938) has been eleeted to the Board of Directors of Gaspesia Sulphite Co. Ltd., Chandler, Que.

General manager of the eompany, Mr. Neal has also been appointed a vice-president.

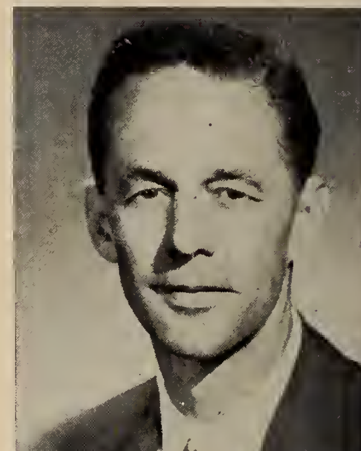
C. G. R. Armstong, M.E.I.C., (B.A.Se., Toronto, 1920), a Windsor, Ont., consulting engineer was reeently awarded two honours at a eonvention of the Canadian Institute on Sewage and Sanitation held in Toronto. Mr. Armstrong was presented with the past-president's certifieate for his leadership in 1955-56. He is one of four members honoured this year with certifieates for 20 years continuous serviee to the C.I.S.S.

John Gilchrist, M.E.I.C., (B.Sc., electrieal, New Brunswiek, 1932) whose appointment has been announeed by the Stavely Coal & Iron Company Limited, London, England, as president of Standard-Modern Tool Company Limited, is also ehairman of the boards of The A. R. Williams Maehinery Company Limited, A. R. Williams Machinery Western Limited and Pacifie Traetor & Equipment Limited.

Mr. Gilchrist is the former managing director of Ex-Cell-O Corporation of Canada Limited.

T. M. Patterson, M.E.I.C.

M. Eaton, M.E.I.C.



W. O. Horwood, M.E.I.C.

W. O. Horwood, M.E.I.C., (B.Eng., meehanical, MeGill 1937) is the vice-president, sales, for the Napanee division of International Equipment Co. Ltd., Montreal. He is the former Eastern sales manager of the industrial division of I.E.C.

P. B. Macfarlane, M.E.I.C., (Royal Teehnical College, Glasgow, 1936), of the Atlas Asbestos Company Limited, Montreal, has received the appointment of general sales manager with the firm. Mr. Macfarlane was previously manager of the sales engineering department of the company at Montreal.

Leo Scharry, M.E.I.C., (B.A.Sc., civil, Eeole Polytechnique, 1946), of Montreal has been appointed viee-president of the Leduc Electrical Company in that city. Mr. Seharry was formerly teehnieal sales representative of the Sangamo Company Limited, and the Wagner Electric Comeompany, both of Montreal.

Milton Eaton, M.E.I.C., (B.S., electrical, MeGill, 1921) ehief engineer of Shawinigan Chemieals Limited, Shawinigan Falls, Que., has retired after thirty-five years serviee, and now eonduets a business as a consulting eleetrieal engineer in Shawinigan Falls.

Mr. Eaton has been particularly interested in the development of eleetrie boilers and is responsible for the development of automatie eontrols and other improvements for high voltage electric boilers.

He is a past-ehairman of the St. Mauriee Valley Braneh of the Institute.

Photo courtesy Canadian National Railways.

E. A. Ford, M.E.I.C., (B.Sc., civil, Manitoba, 1927) assistant to the vice-president and managing director of Dominion Bridge Company Limited, Lachine, Que., has been named vice-president, marketing, following a recent announcement.

R. J. A. Fricker, M.E.I.C., (B.Eng., mining, McGill, 1940) has been promoted to vice-president, manufacturing, following a recent announcement from Dominion Bridge Company Limited, Montreal. He previously held the post of assistant to the vice-president and managing director.

M. McMurray, M.E.I.C., (B.A.Sc., metallurgy, Toronto, 1939) was recently promoted to vice-president, finance and administration, with Dominion Bridge Company, Limited, Montreal. He was formerly assistant to the vice-president and managing director of the firm.

P. E. Savage, M.E.I.C., (M. Eng., civil, McGill, 1934) assistant to the vice-president and managing director of the Dominion Bridge Company Limited, Lachine, Que., has been appointed vice-president engineering with the organization.

Ross A. Ritchie, M.E.I.C., (B. Eng., mech, McGill U., 1943), of the Electric Reduction Company of Canada Limited, has received an appointment with the firm as vice-president manufacturing. Recently Mr. Ritchie has carried out the duties of assistant chief engineer with the organization at Toronto.

J. W. Demcoe, M.E.I.C., (B.Sc., civil, Manitoba, 1939) is general superintendent, of the Maritime district, of Canadian National Railways, with office at Moncton, N.B., transferring from North Bay, Ont., where he was general superintendent. He has served with C.N.R. in Toronto and Montreal and other centres.

E. A. Ford, M.E.I.C.

M. McMurray, M.E.I.C.

E. S. Buhayer, M.E.I.C., (B.Sc., engineering, University College, London, 1938) is working in Chester, Pennsylvania, in the mechanical research Department of Scott Paper Company.

He was formerly in Montreal in the design office of C. D. Howe Co. Ltd.

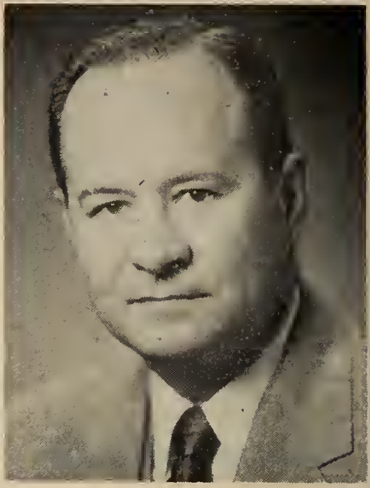
E. S. English, M.E.I.C., (B.Sc., civil, Manitoba, 1932) is assistant chief engineer for the Western region, of Canadian National Railways, with office at Winnipeg, Man. He had earlier been with the C.N.R. system in Montreal, Winnipeg and Regina.

W. K. Sproule, M.E.I.C., (M.Sc., metallurgy McGill, 1937) has transferred to the International Nickel Company, Inc., in New York. He has been at Copper Cliff, Ont., as superintendent of research for International Nickel Company of Canada Ltd.

C. L. Moon, M.E.I.C., (B.A.Sc., mechanical, Toronto, 1934) has been appointed chief engineer of the Fruehauf Trailer Company of Canada Limited.

Mr. Moon was formerly associated with Avro Aircraft Limited.

R. J. A. Fricker, M.E.I.C.



P. E. Savage, M.E.I.C.

C. E. Craig, M.E.I.C., (B.Sc., mechanical, Queens, 1938) is at Shawinigan Falls, Que., works manager in the Shawinigan fabricating works, of Aluminum Co. of Canada Ltd. Joining the Company soon after graduation, he has recently been in the sales division in Montreal.

John Penzer, M.E.I.C., is manager of the electrical manufacturing division of Canadian Comstock Co. Ltd., St. Catharines, Ont. He was formerly associated with Taylor Electric Manufacturing Co. Ltd., London, Ont.

H. W. Hignett, M.E.I.C., (B.Sc., civil, Manitoba, 1936) is executive director of the Central Mortgage and Housing Corporation, at Ottawa. He is the former supervisor of the Ontario Region of C.M.H.C., in which capacity he was located in Toronto.

A. Sandilands, M.E.I.C., (B.Sc., electrical, Manitoba, 1934) has been appointed by Phillips Electrical Company Limited, Brockville, as assistant general sales manager (western). He will be located in Edmonton.

Mr. Sandilands has been associated with the company in the West for 16 years.

S. C. Cooper, M.E.I.C., (B.A.Sc., civil, University of Toronto, 1945) is the vice-president and general manager of C. A. Pitts General Contractor, Ltd., Toronto, and associated firms.

Mr. Cooper has been with the company since 1945, having been appointed chief engineer in 1948.

W. B. Jackson, M.E.I.C., (B.Sc., civil, Alberta, 1945) is the general superintendent for Canadian National Railways, in the Northern Ontario District, at North Bay, Ont.

• PERSONALS

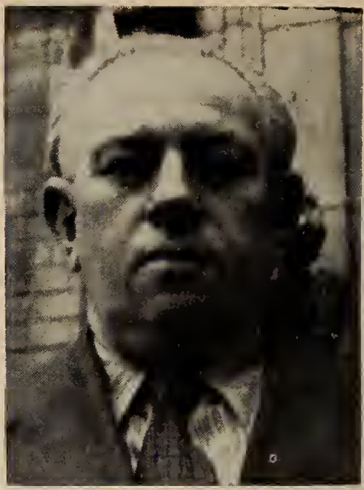
Mr. Jackson joined the C.N.R. system soon after graduation, and has since served in positions at Montreal, Levis, Cochrane, London and Toronto.

C. R. Matthews, M.E.I.C., (B.Eng., mechanical, McGill, 1943) has been since August 1957 located in St. Jerome, Que., with Dominion Rubber Co. Ltd. Earlier he worked with E. B. Eddy Co., at Hull, Que.

E. de Haas, M.E.I.C., (M.A.Sc., engineering physics, University of Delft, 1946) is working at the Palmer Laboratory, Princeton University, as senior electrical engineer. He had been working on special projects of Ontario Hydroelectric Power Commission, in Toronto.

A. S. Vadas, M.E.I.C., (civil, Budapest, 1922) has been for some time the owner of the Inter-Cosmos Trading Company, working in export, import, distributing, with headquarters in Montreal.
Associated companies, established in Canada and the U.S.A., are Zanzibar Trading Company, and Globus Advertising Agency.

Eric Heaton, M.E.I.C., (B.Eng., civil and structural, National University, Ireland, 1947) joined Warnock Hersey Company in March, 1957, as a project engineer to carry out an investigation into load bearing capacity of the highway system in Nova Scotia. He was earlier employed by Montreal Engineering Company, and by the St. Lawrence Seaway Authority, in Montreal.



A. S. Vadas, M.E.I.C.

A. S. Dromlewicz, M.E.I.C., (is a resident) engineer for the United Waterways Constructors Ltd., Montreal, on the upper Beauharnois lock of the St. Lawrence Seaway. He is, however, a member of the engineering staff of Foundation Company of Canada, Limited.

G. W. Spratt, M.E.I.C., (B.Eng. 1953, M.Eng., 1956, McGill) has been appointed operations manager of Macdonald and Macdonald Limited, inspection and testing engineers, Vanvouver.

Robert E. Walker, M.E.I.C., (B.Sc., mechanical, Queen's, 1952) is in charge of a new sales and service office in Montreal for Vickers-Sperry of Canada Limited.

Ewart M. Haacke, M.E.I.C., (B.Sc., electrical, Queens, 1942) has been appointed the sales manager of the lighting division of J. A. Wilson Lighting and Display, Ltd.

E. M. Haacke, M.E.I.C.

PERSONALS

Mr. Haacke was formerly eastern district manager, having joined the company in 1951 as Montreal Branch manager.

R. W. Walker, M.E.I.C., formerly of Montreal, J. T. Donald & Co. (1956) Ltd., is with Associated Engineering Services Ltd., Edmonton, as chief industrial engineer.

Lt.-Col. M. Turner, R.C.E., M.E.I.C., (R.M.C., 1939, B.Sc., Queen's, 1947) advises his present position is area engineer, British Columbia Area, and Commanding officer of 11 Works Company, Royal Canadian Engineers, at Vancouver, B.C., headquarters.

William C. McLean, M.E.I.C., is a project engineer for Catalytic Construction of Canada Ltd., at Sarnia, Ont. Earlier he was in Valleyfield, Que, a project engineer with Canadian Arsenals, Ltd.

Thornton E. Smith, M.E.I.C., (B.S. civil, Massachusetts Institute of Technology, 1948), treasurer of the New York building firm of Kuhn, Smith and Harris, Inc., has been elected president of the organization.

Prior to joining Kuhn, Smith and Harris, Inc., in 1955 Mr. Smith was associated with the firm of Fraser, Brace and Company and with the Industrial Engineering Company, both of New York.

T. E. Smith, M.E.I.C.

A. Swystun, M.E.I.C., (B.Sc., mechanical, Saskatchewan, 1946) is an office engineer for the firm Dutton-Williams-Mannix Ltd., in engineering and inspection for construction of the Alberta Gas Trunk Line natural gas pipe line system.

A. F. Tiesdell, M.E.I.C., is employed as lecturer-in-charge of the mechanical engineering department of the Eastern Ontario Institute of Technology, Ottawa. He was earlier with the Sarnia Northern Collegiate Institute and Vocational School.

W. B. Drowley, M.E.I.C., (B.A.Sc., mechanical, Toronto, 1945) is with the Ontario Government, Air Pollution Control, Department of Health.

He was formerly associated with Republic Flow Meters Canada Ltd., Toronto.

W. C. Phillips, M.E.I.C., (B.Eng., civil, Saskatchewan, 1951) is the chief engineer of United Grain Growers Ltd., in Winnipeg, Man.

Mr. Phillips was earlier located in Regina, in the employ of the Saskatchewan Wheat Pool.

Walter G. Lunick, M.E.I.C., (B.Sc., mechanical, Manitoba, 1952) is teaching engineering science, mathematics and materials and processes of industry, at Danforth Technical High School Toronto.

He has been an industrial engineer with Julius Kayser & Co. Ltd., in London, Ont.

F. E. Hertha, JR.E.I.C., has recently changed his address from Montreal to Prince Rupert, B.C. where he holds the appointment of financial analyst with the Columbia Cellulose Company.

Previously associated with the Canadian Chemical and Cellulose Company

TAYMAR STEEL ROOF DECKING:

ECONOMICAL and PERMANENT

Each and every panel of Taymar Steel Roof Decking is formed into an exact shape. Every panel in the illustration above, matches perfectly, and interlocks perfectly with the next.

The result is a roof of overall uniform strength, of uniform quality, which will endure, maintenance-free for years to come.

Taymar's light weight quality speeds up the actual laying—and its precise manufacture means a top-notch, good looking job.

Choose from a variety of panel sizes and gauges.

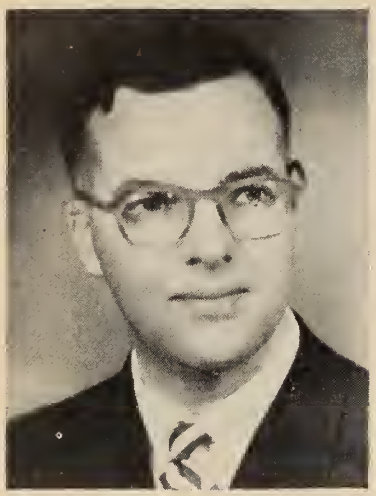
in the Eastern city he also had his early professional experience with the Hollingworth and Whitney Paper Company in Waterville, Maine.

E. G. F. Sweet, JR.E.I.C., (B.A.Sc., mechanical, Toronto, 1948) has been appointed chief engineer of the Brantford coach and Body Ltd, Brantford, Ont. Mr. Sweet joined the firm in 1951 and since that time has been instrumental in development of new designs and improvements.



E. G. F. Sweet, JR.E.I.C.

H. R. M. Murray, JR.E.I.C., a Glasgow University graduate, class of 1946 has been transferred from Vancouver to Yale, B.C. with the firm of A. B. Sanderson and Company Ltd., to be resident engineer on the new Alexandra Bridge. The bridge is part of the Trans Canada Highway and will include an 805 ft. fixed arch span over the Fraser. River.

C. H. Johnson, JR.E.I.C., with Canadian General Electric in various capacities since 1949 has moved from Toronto to join Du Pont Company of Canada Ltd. at Montreal. He is employed as a design engineer on new developments.

He studied mechanical engineering at the University of Manitoba.

C. T. Armstrong, JR.E.I.C., who graduated from the University of Toronto in 1952 in civil engineering has resigned his position with the Corporation of the City of North Bay, Ont., and has joined the Department of Planning and Development, housing branch, at Toronto.

C. M. Cotton, JR.E.I.C., has recently been elected secretary-treasurer of the Lakehead Branch of the Institute.

Mr. Cotton is a 1950 graduate of the University of Manitoba with a B.S. degree in electrical engineering. He is an electrical engineer with the Canadian Car and Foundry Company, automotive division at Fort William, Ont.

G. P. Milton, JR.E.I.C., is the new secretary-treasurer of the Northern New Brunswick Branch of the Institute. A design engineer with the Bathurst Power and Paper Company Limited, at Bathurst, N.B., he is a graduate of the Nova Scotia Technical College, class of 1949.

W. E. Donahoe, JR.E.I.C., (B.Sc., civil, U.N.B., 1948) an engineer with Intrusion-Prepakt Limited, has been transferred from Toronto to Fredericton, N.B.

B. F. Davies, JR.E.I.C., (B.A.I., civil, 1954) is an engineering trainee in the B.C. Marketing Division of Imperial Oil Ltd., Vancouver. He was formerly in the design section of the Hydro Electric Power Commission of Ontario.

Richard Levi, JR.E.I.C., (B.Eng., mechanical, McGill, 1955) is with Richmond Pulp & Paper Co. Ltd., Bromptonville, Que.

Ross G. Aishford, JR.E.I.C., (B.A.Sc., chemical, Toronto, 1954) has been working in Moncton, N.B. since the summer this year, as an industrial sales engineer and commercial sales represent-

CONVEYING 13,000,000 TONS OF LABRADOR IRON ORE A YEAR

Here, the traveling stocker is building a stockpile at the rate of 3750 net tons per hour. Conveyor booms stockpile to either side.

IRON ORE COMPANY OF CANADA— THE PORT OF SEVEN ISLANDS, QUEBEC

From the Port of Seven Islands, Quebec, millions of tons of Labrador iron ore a year pour into Canada's and United States' industries. This feat of production must be done in the 150 to 160 days of good weather, during which ships can be loaded. An S-A Conveying System, handling an average of 70,000 tons of ore every day for loading and stockpiling, is helping make the job possible.

You may never need a conveying system as large or complex as the one at the Port of Seven Islands. But, whatever your bulk handling need, S-A engineers can show you an economical answer. Write for a free survey. No obligation, of course.

At the docks, twin boom belts on traveling bridges with a combined capacity of 10,000 net tons per hour can load even the largest ocean-going ore ships in about five hours. Booms pivot up or down to compensate for tide or ship conditions, shuttle conveyors travel back and forth perpendicular to ship to compensate for ship's beam, and bridges travel parallel to ship to load different hatches.

STEPHENS-ADAMSON

S-A MFG. CO. OF CANADA LIMITED

Conveying • Elevating • Screening and Transmission Equipment

E361C

HEAD OFFICE BELLEVILLE, ONTARIO — BRANCH OFFICES: MONTREAL, TORONTO, VANCOUVER ative for Taylor Instrument Companies of Canada for the Atlantic Provinces. He has been with the company for three years, working in Toronto, and in Montreal.

W. J. Romanowicz, Jr.E.I.C., (B.Eng., metallurgical, N.S.T.C., 1951) is now employed as a scientific officer, in the Mines Branch of the Department of Mines and Technical Surveys, Ottawa. He was formerly with the Ontario Research Foundation in Toronto.

Hugh M. Steeves, Jr.E.I.C., B.Sc., mechanical, Queen's, 1951) has been transferred from Spruce Falls Power & Paper Co. engineering staff to Kimberley Clark Products at Niagara Falls.

H. B. Fudge, Jr.E.I.C., (B.A.Sc., civil, Queen's, 1954) has been appointed construction and maintenance engineer for Alberta, in the marketing department, British American Oil Co Ltd., Calgary.

E. H. McIntyre, Jr.E.I.C., (B.Eng., metallurgical, McGill, 1953) has resigned from his position of laboratory supervisor with Sorel Industries Ltd., and has joined Canadian Steel Wheel Ltd.

Frank J. Berto, Jr.E.I.C., (B.A.Sc., mechanical, U.B.C., 1952) has resigned from his position of project engineer for the Lago Oil and Transport Co Ltd. to take post graduate work at the California Institute of Technology.

H. N. Atkins, Jr.E.I.C., (B.A.Sc., civil, Toronto, 1954) is an engineer in the Sudbury branch of the Bell Telephone Co. of Canada Ltd. Mr. Atkins formerly served the company in the special contract department at Bird, Manitoba.

J. E. Kryzanowski, S.E.I.C., a 1957 graduate of the University of Toronto in civil engineering is employed in the design engineering department of the Dominion Bridge Company Limited at Toronto.

R. E. Barry Moffatt, S.E.I.C., who graduated from the University of New Brunswick this year with a B.Sc. degree in civil engineering has joined the Dibblee Construction Company Limited, engineering staff at Ottawa.

W. C. Ramsden, S.E.I.C., (B. Eng., civil, McGill, 1957), is assistant resident engineer on the Manitou Falls project for the Hydro-Electric Power Commission of Ontario.

C. C. Vallance, S.E.I.C., (B.Eng., civil, Saskatchewan, 1957) is employed by the government of Saskatchewan in the Highways Department as project engineer. He was earlier with the design branch of the City of Regina engineering department.

R. D. Pousette, S.E.I.C., (B.A.Sc., mechanical, Univ. of B.C., 1957), who joined the Shell Oil Co. of Canada Ltd. right after graduation, is employed at their Shellburn Refinery as design engineer.

G. T. Dewburst, S.E.I.C., (B.Eng. mechanical, Saskatchewan, 1957) is presently employed as an application engineer with Honeywell Controls Ltd., in Calgary.

Kenneth E. Tingley, S.E.I.C., (B.Eng., electrical, N.S.T.C., 1957) is with the Canadian General Electric Company Ltd in Peterborough, as a student engineer on the Test Course.

Ian H. Mitchell, S.E.I.C., (B.Eng., mechanical, McGill, 1957) is employed by Avro Aircraft Limited of Malton, Ont., as a design engineer in the equipment design department.

D. A. Elliott, S.E.I.C., (B.A.Sc., engineering and business, Toronto, 1957 is employed as field and design engineer by Dravo of Canada Limited, Toronto, Ont.

Paul E. Beaulieu, S.E.I.C., is appointed regional specialist, in the power apparatus division of the Northern Electric Company Ltd., Quebec, Que.

W. C. PIETZ
PRESIDENT & MANAGING DIRECTOR

In the year 1907 the Raymond Concrete Pile Company, Limited drove its first cast-in-place concrete pile job for the Harbours Board in Montreal, P.Q.

Since that early start in 1907, we have driven piling for projects from Halifax to Vancouver and as far north as Churchill, Manitoba.

The confidence of our clients is evidenced by the continued growth of the Raymond Company, Limited. Raymond International Company, Limited was founded a few years ago to broaden the scope of the Raymond Company; to handle dock and wharf projects, special bridge projects as well as other heavy construction. In the short time since the organization of the Raymond International Company, Limited we have completed dock jobs in Newfoundland, Hamilton and several joint venture bridge projects in British Columbia. Again in joint venture, we are one of three parties associated with the Dea's Island Tunnel in Vancouver.

Our Soils Investigation Division, including a Soils Laboratory, is an important part of our business. Our Engineers in this Division are always ready to serve our clients on an impartial basis.

W. C. Pietz
W. C. Pietz,
President.

PETERBOROUGH

D. B. Chase, E.I.C.
Secretary Treasurer
V. Aare, M.E.I.C.
Publicity Chairman

Lively Summer Program

Under the energetic leadership of W. H. Ackhurst — chairman of the Branch— the summer program was one of the liveliest and most enjoyable of the recent years.

The June meeting took form of a garden stag party at the residence of H. R. Sills, vice-president of E.I.C. In a genuine "Bier Garten" atmosphere a record number of members enjoyed an evening with sauerkraut, brass-band, songs and superb fellowship.

First annual E.I.C. Golf Day for Peterborough and District was held on 10 August at the Kawartha Golf and Country Club. All E.I.C. members in Peterborough, Belleville and Port Hope districts were invited to compete for the "R. L. Dobbin Trophy" donated by R. L. Dobbin, M.E.I.C. and past president of E.I.C. The invitation was also extended to all nonmember professional engineers in the districts. The Golf Day was a success, both regarding the participation and the weather. With almost thirty per cent of the players non-E.I.C.'ers the winner of the "R. L. Dobbin Trophy" for low net was a Branch member, V. A. Taylor, JR.E.I.C. (*see picture page* 1870)

The organizer of the Tournament itself was W. C. Durant, JR.E.I.C.

D. B. A. Chase, secretary-treasurer of the Branch and H. R. Sills, vice-president of the E.I.C., second and third from the left, view the construction of the Iroquois dam and locks during the St. Lawrence Seaway tour, September 14.

• BRANCH NEWS

ed to give the Branch members a good opportunity to see the famous project before it is completed. The members showed great interest for the tour especially as several of them are engaged in designing electrical equipment for the project.

The trip was made on a special train to Cornwall and back from Brockville to Peterborough. The distance between Cornwall and Brockville was covered by bus and all the major project areas were visited — including Barnhart Island powerhouse, Long Sault control dam, new town sites and finally Iroquois control dam. A dinner meeting was held in Manitonna Hotel in Brockville before leaving for Peterborough.

It was a pleasure to note the great interest of the Branch student members in the trip, indicated also in a good participation. Peterborough Branch is very fortunate in having a very active student membership with the total number close to thirty. The student members have been very valuable in helping the executvies to organize a great deal of the Branch activities. (*See picture page 1872*).

Presidential Visit

Marking the official visit of President C. M. Anson to his home Branch (Cape Breton), on Saturday, September 28, a special dinner meeting and dance was held at Isle Royal Hotel, Sydney. In the President's party were past president Dr. Ira P. McNabb and regional vice-president H. W. L. Doane, both of Halifax and Dr. L. Austin Wright, general secretary of the E.I.C.

Special dinner meeting guests included C. N. Murray, president of the Dominion Council for Professional Engineers, Dr. Arseneau, local chairman of the C.I.C. and Hon. N. Manson, Minister of Mines and Resources for the Province of Nova Scotia.

To a receptive gathering of 130 members, their ladies and guests, the president spoke of the responsibility of the Engineer in Management.

Presentation

In- recognition of the honour Mr. Anson has attracted to the Cape Breton Branch through his election to the presidency of the E.I.C., the local branch presented Mr. Anson with a suitably engraved, hand-carved gavel of local maple and steel from the first ingots made in the new open Hearth of Dominion Iron and Steel Limited, of which Mr. Anson is vice-president and general manager.

Attaining Life Membership, W. S. Wilson was presented with the gold pin of the E.I.C. by president Anson.

After the dinner meeting, all enjoyed

.et us help you answer hese questions ıbout compressed air:

- Can compressed air be produced more efficiently and economically?
- How much is it costing to operate present compressors?
- Is compressor capacity enough to give full pressure throughout the entire air system?
- Can present compressor plant be improved by re-location and re-installation?
- Is the efficiency of present compressors such that it is advisable to continue running them?

Atlas Copco engineers are available to help you solve these problems and to give you the benefit of advice of specialists in all fields of compressed air engineering. Atlas Copco gives 24-hour service anywhere in Canada.

Executive Meetings

Two fully attended executive meetings were held with the president, on Friday and Saturday, Sptember 27, 28. Both meetings were lively and it would seem that the ideas behind Confederation of the E.I.C. and the professional association are uppermost in the minds of a majority of the local executive.

Following the meeting on Friday, Mr. Anson and the Branch Chairman, W. A. MacDonald, paid a visit to the home of Major C. M. Smythe, an invalid confined to his home, to bestow honours on him in attaining Life Membership in the E.I.C.

KINGSTON

D. I. Ourom, Jr.E.I.C.

Radioisotopes Discussed

Industrial application of radioisotopes was the subject of a talk given by M. T. Neill, of Isotope Products Limited, Oakville, Ont., to the Branch on October 22.

It was explained that radioisotopes are finding wide acceptance in industrial processes and offer many interesting and profitable possibilities for future developments.

The use of isotopes in mass measurement techniques, in continuous process industries such as the paper, rubber and plastics is now highly developed. There are many installations where radiation instrumentation is automatically controlling processes and producing improved product quality and increased efficiencies.

Techniques involving the use of beta and gamma radiation were also discussed.

Buildings for Chemical Plants

R. N. Boyd, of the Du Pont Company of Canada (1956) Ltd., on November 12 discussed "Buildings for Chemical Plants" before the Kingston Branch. He said, "The effective housing of various types of chemical operations poses many interesting problems. This paper deals with some of the factors requiring consideration, such as corrosion resistance, weather tightness, special interior finish requirements, appearance and cost. The paper is illustrated with a number of examples of the constructions used by the author's Company for its diversified operations."

SPECIALISTS IN FABRICATED PIPING—CARBON AND ALLOY STEEL recent meetings of interest.

At the September meeting R. E. Henderson, vice-president, manufacturing, of Canadian Car Company Ltd. spoke on the use of management consultants in industry.

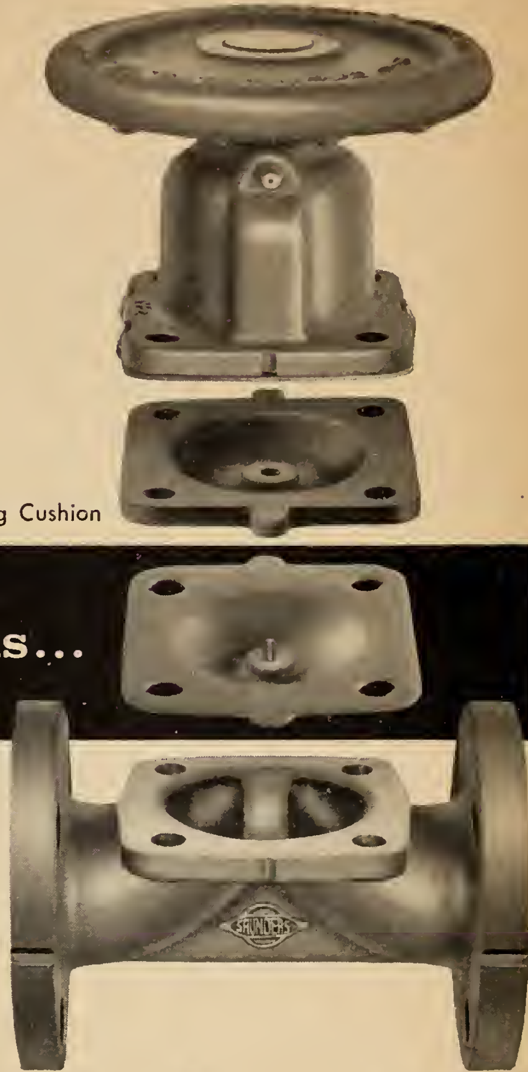
Management consultants can do enormous good, but only if company managements understand their uses and limitations, according to Mr. Henderson. Management consultants are offering an increasingly important service which deserve to be more widely understood he said. More and more firms are using outside consultants to assist in the improvement of basic organizational arrangements, accounting procedures, management of inventories and many similar problems.

To show why consultants are called in by thriving companies, what they do,

Peterborough: Student Members of the Branch who took part in the tour of the St. Lawrence Seaway held on September 14. Left to right are: B. Ahern; E. G. Bazeley; D. J. Kawaja; C. L. Pelton; S. Taylor; J. G. Pearsall; A. Canzi; J. Simpson and F. E. Lucas.

Outperforms other valves under SEVERE chemical conditions

GRINNELL-SAUNDERS DIAPHRAGM VALVES



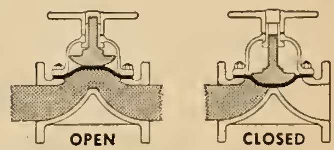
with TEFLON Diaphragms...

Grinnell Teflon Diaphragms are made by a special process which produces a better product of greater density, toughness and flex life.

The four case histories cited below demonstrate that Teflon offers a very high degree of chemical inertness to some of the most difficult chemicals which industry today must handle. Yet these are only a few of many success stories in the Grinnell files.

Diaphragm life depends on temperature, pressure and frequency of operation. Inquiries must include complete service data to receive prompt and careful attention.

Service Conditions	Saunders Valve Now Used	Service Life: Teflon Diaphragm	Service Life: Previous Valve
Case 1. Benzene hexochloride (30%-40% benzene, free chlorine); 120 to 130 F, 10 to 20 psi; operated 3 to 4 times daily	Glass lined bodies; Teflon Diaphragm; 1 to 3 inches	10 to 14 mos.	1 to 2 mos.
Case 2. 90%-95% HNO_3 plus 1.8% HF (specific gravity 1.62—1.77) 115 F in summer; 40 F in winter; 125 psi; operated 2 to 3 times daily	Durimet 20 body; Teflon Diaphragm; 1 to 3 inches	8 months	2 months
Case 3. $AlCl_{+2}$ complex; ambient to 220 F; 0-50 psi; operated 1 to 2 times daily	Glass lined bodies; Teflon Diaphragms; 1 to 4 inches	9 months	6 months
Case 4. Sulphuric acid 85%; outside temperature; no pressure; operated 4 times daily	Iron bodies; Teflon Diaphragms, 2½ inches	Still in service after 1 year	3 weeks



Features of Grinnell-Saunders Diaphragm Valves

- Diaphragm lifts high for streamline flow in either direction.
- Body, linings and diaphragm materials to suit service conditions.
- Resilient diaphragm assures positive, leak-tight closure even with grit or scale in the line.
- Diaphragm absolutely isolates working parts from fluid . . . sticking, clogging, contamination, corrosion eliminated.
- Simple maintenance. Diaphragm can be replaced easily without removing valve from the line. No packing glands to demand attention. No metal-to-metal seats to become damaged or wire-drawn.

pipe fittings • welding fittings • pipe hangers • valves • Grinnell-Saunders diaphragm valves • pipe prefabricated piping • heating specialties • water works supplies • Grinnell automatic fire protection systems what their reports recommend and how recommendations should be carried out, Mr. Henderson traced the story of a typical problem from its inception to its solution and showed the contribution to company planning made by outside specialists. He also reviewed what thinking was essential prior to deciding upon consultants and determining their terms of reference.

The October meeting was held at the new Lakehead College of Arts and Science in Port Arthur. Following a short address by H. Braun, principal of the College, the members were conducted through the premises and viewed the facilities with great interest. Mr. Braun touched on the highlights leading to the final establishment of the Lakehead College and outlined the current curriculum as well as plans for the extension of the courses.

Book Presented

E. Charnock, on behalf of the Lakehead Branch of the E.I.C. presented a book to Mr. Braun for inclusion in the College library. This book has created considerable interest in engineering circles both in Canada and the U.S.A. The title of the book is "Daylight Through the Mountain" based on the life and letters of Walter and Francis Shanly, two early Canadian engineers.

The meeting was chaired by Mr. V. B. Cook and the speaker was introduced by D. MacKinnon and thanked by J. Rymes.

P.F.R.A. Tour

On Saturday, September 7 over 60 members, guests and their wives toured the P.F.R.A. Belly River diversion project, then continued to Waterton Lakes National Park for a golf tournament, dinner, and dance.

The Belly River diversion, part of the St. Mary's and Milk River development under construction at an estimated cost of $2,500.00 will divert water from the Belly River to the St. Marys River for irrigation purposes. It consists of a diversion weir on the Belly River, a few miles from Waterton. From the wire, a main canal, 27 miles in length extends to the St. Marys River reservoir. This canal has a capacity of 2400 sec. ft.

The party assembled at the St. Marys damsite, then toured the main canal to the camp site at the diversion weir. Enroute a stop was made to study construction features of one of the drop structures. At the camp site, an excellent lunch was provided by the P.F.R.A. Immediately after lunch the party was taken to the diversion weir and headgate structure, where the details and general layout was explained by the hosts. W. L. Foss, M.E.I.C., supervising construction engineer, St. Marys and Milk River development, P.F.R.A., Lethbridge was in charge of the tour. R. B. Wells, M. Hunka, and Dave Cramer of the P.F.R.A. assisted Mr. Foss.

The tour completed, the group motored to Waterton Park for afternoon and evening social activities. Highlight of the afternoon was the low score golf tournament held on the park's scenic 18 hole golf course. Low gross and low net score honours for the tourney went to Tom Henry, M.E.I.C. of Calgary.

Prize for the most honest golfer was awarded to Ted Lawrence, M.E.I.C. Al Kenwood, M.E.I.C. was in charge of the golf tournament.

The day's events culminated with refreshments and dinner in Kootenai Lodge, under the chairmanship of the Branch chairman, J. R. Milne.

Arrangements for the tour were made by W. B. Thomson, M.E.I.C., Branch vice-chairman, and program chairman. Out of town guests, included Tom (Ace) Henry and Redge Bailey of Edmonton, formerly of Waterton Lakes.

Presidential Visit

The annual visit of the president took place on October 24 when the London Branch welcomed president Anson. Mr. Anson was accompanied by Dr. Garnet Page, recently appointed assistant general secretary to the E.I.C.

Members of the London Branch executive joined Mr. Anson at a luncheon

DRAVO

given by the engineering faculty of the University of Western Ontario at the University. Immediate past-president of the Institute, V. A. McKillop, London, Ont., and two former executive members J. Vance from Woodstock and S. V. Buchanan of London, Ont., were included. Mr. Anson addressed the engineering undergraduate students during the afternoon.

At a cocktail party held at the residence of V. A. McKillop many of the industrial leaders of London had the opportunity to chat with Anson.

A dinner was also held for engineers and their wives. More than ninety persons attended.

In some measure the success of the evening is attributed to the newly formed Engineers' Wives Association. An informal coffee party was held at the home of Mrs. McKillop in September which was attended by 75 women. It was the first local meeting of the organization.

DuPont Official Speaks

The monthly dinner meeting of the Branch, chaired by Jim Chandler was held Wednesday, November 13.

The guest speaker, H. Lloyd Johnston was introduced by Don Briden, works engineer of the North Bay plant of Du Pont of Canada.

Mr. Johnston, whose headquarters are in Montreal is chief engineer for Du Pont of Canada. He is a graduate of McGill University and joined Canadian Industries Limited in 1936, serving as plant engineer and works manager. In 1954 he was transferred to his present position with Du Pont.

Evaluating Performance

Evaluating performance in an engineering department was the subject of Mr. Johnston's address. He said that different departments have different functions and numbers of staff. About 40% of companies have a formal system for rating employees. Opinion differs as to the need and benefit of such plans and as to the type of plan which will produce the desired results.

Rating plans are used for sorting performance, making selections for promotion, establishing salary differential, and determining training needs. The various plans are classified as graphic, chart, check list, self-rating, field review, etc.

Mr. Johnston favoured a rating plan that combined a concise paragraph, with rank, order, and position, experience and performance rating. He demonstrated with illustrations the way in which such a plan functioned in his own department. He pointed out that the period between ratings might vary but ratings should be taken often enough, probably once a year, so that new employees unsuited for the work they were doing could be culled or transferred to other departments where they might make better progress. Different departments frequently compared ratings of employees with a view to making such transfers.

Post-Appraisal Interviews

Post-appraisal interviews were desirable particularly where an employee's rating was low. It was advisable to talk to an employee about his performance pointing out where his weaknesses were, but a discussion of his traits should be avoided. However, there should be no attempt to mould a person into a standard character.

Following an interesting question period Herb Watson thanked the speaker for a most informative address.

OTTAWA

W. V. Morris, M.E.I.C.,
Secretary

C.C.A. Head Speaks

T. N. Carter, of Toronto, president of the Canadian Construction Association, in his address to the Ottawa Branch on October 3, 1957, describing briefly some of the basic characteristics of the construction program and the operations of the industry and then touched on some related subjects such as the training of construction engineers and the relationships between members of our two national organizations.

Mr. Carter said that the association of

contractors and engineers is the oldest formalized association on record, dating to Roman times. Calling for closer co-operation between the two he felt that it would result in better service to mutual clients.

The growth of the construction industry in recent years has paralleled some of the new industries whose percentage increases are spectacular because they scarcely existed a decade or two ago.

Volume $6.9 Billion

This year it is estimated that Canada's construction volume will amount to $6.9 billion. In 1946 the volume was $1.6 billion. Over $3 billion or roughly 46% is classified as engineering construction and the plans bear the stamp of professional engineers. Engineers, working in association with architects are responsible for the structural, mechanical and electrical designs for the $2 billion of non-residential buildings being erected and also for the multiple unit buildings in the housing field. They are designing roughly $4 billion of construction work this year. Engineers' work in construction design is making a greater contribution to the development of Canada than in any other field. He added that if Canadian engineers and architects can design boldly it is in large measure due to the fact that no matter what they ask for they know that the Canadian construction industry can deliver it.

Construction Risks

Mr. Carter said that construction engineers do not usually have a set fee for services and especially in the heavy construction field large sums of money must be invested in equipment, and in the event of a design failure, a contractor may be sued by the owner and compensation paid for from the sale of his assets. Design engineers have some say over the calibre of their competition since only qualified engineers may belong to the provincial organization. Competition in the construction field is wide only from home and abroad, and is subject to great risk.

Joint Problems

Dealing with some of the joint problems of contractors and designers he said that most of the problems that arise are due to the vast and increasing volumes of work being carried out under great pressure. Canada is a country in a hurry and it is inevitable that we suffer some growing pains in the process. Steady progress is being made towards the solution of mutual problems by joint meetings between representatives of the design professions and the construction industry at the national, provincial and local levels.

Suggestions

From the contractors standpoint, consulting engineers can help to remove uncertainties from work and reduce costs to the owners by:

1) Providing more detailed information and by the quicker processing of their accounts. This included pre-engineering, greater clarity in drawings and specifications and faster action on decisions, change of orders, progress and final payment. One example: some of the "standard" plans coming from Ottawa have so many addenda that they exceed the original specifications in thickness. The mark of a good set of plans and specifications is frequently a set of bids which are very close to each other and to the estimate, since clarity and completeness of tendering information facilitates accurate estimating. Designers with a bad reputation for delays will have an allowance for this added cost factor including in the tender amounts submitted for their projects.

2) By supporting in thought, word and deed the tendering and contract procedures agreed to and approved by the professions and the industry. The Standard Forms of Construction Tender and Contract are long-established documents revised from time to time in accordance with new conditions. Back in 1951 an E.I.C., R.A.I.C., C.C.A. joint committee issued nine "Points of Agreement" in the tendering practice field and last year "A Suggested Guide to Bidding Procedure" was published.

3) By assuming a greater responsibility for their work. This may be a question of convincing the owner's legal departments that they should have more confidence in their design engineers and architects, Mr. Carter felt. If responsibility for the accuracy of sub-surface conditions, completeness of design, etc., are assumed by the designer, the contractor can omit an allowance to cover potential expenses which in most cases is not required. Changes can be negotiated as they occur and the owner of course stands to benefit.

Mr. Tullis closed his remarks with a Hamlet-like soliloquy on whether the strains and stresses, risks and returns of the contracting business are worth the struggle.

First Winter Dinner Meet

A group of thirty-one members gathered in a private dining room at the Hunt Club on Monday, October 21, 1957, to enjoy the first of the proposed monthly winter dinner meetings to be held in Regina.

The chairman of the dinner meeting, R. J. Genereux, urged the members to take part in the weekly evening meetings of the Professional Development Course which is already underway each Monday night.

Those present at the dinner meeting were privileged to hear a talk by G. H. Nielsen of the Canadian Petroleum As-

sociation in Regina, who was introduced by R. M. Harry. Mr. Nielsen's address, entitled, 'The Magic Barrel' described the many and varied products used in our everyday living which are produced by the petrochemical industry from petroleum and natural gas. The talk was highlighted by numerous demonstration and exhibits.

K. W. Allcock, who thanked the speaker for his interesting and entertaining presentation, reflected the appreciation of those present.

Varied Program

The Branch executive has planned a series of meetings for the winter months which are calculated to cover the interest of all members of the Branch. As dates remain uncertain, it is not yet possible to publish a list of the meetings. These will take place at Trois-Rivieres, Shawinigan Falls, and Grand 'Mere. Field trips out of the Valley have been proposed.

First meeting of the Branch for the fall term was held October 8, at Trois-Rivieres. J. E. Lalond of the Bank of Montreal, business development department, addressed the Branch on the subject of "Inflation." The question and answer period which followed indicated the active interest of those gathered.

SUDBURY

W. J. Ripley, Jr., M.E.I.C.,
Secretary Treasurer

Algom-Nordic Trip

The first meeting of the 1957-58 season took the form of a field trip to the Nordic plant of Algom Uranium Mines Ltd. on October 19. Thirty nine members and guests from the Sudbury branch met a group of twenty from Saulte Ste. Marie at the junction of the Elliott Lake road and Highway 17, whence the combined party proceeded to Algom-Nordic for lunch at the commissary. W. J. Ripley senior, vice-president of the Institute for Ontario, delivered a brief address, in which he stressed the need to strive for greater recognition for engineers' professional standards, and the necessity for engineers in every phase of activity. Mr. Ripley was introduced by Messrs. Harvey Snell and Jim Smith, chairman of the Sault Ste. Marie and Sudbury branches respectively.

Surface Plant-Mill Visited

The party was later escorted through the mine surface plant and mill by members of the staff of Algom Nordic. After inspecting the compressor house, boilers, hoist room and crushing plant, the visitors enjoyed a most interesting tour through the grinding plant and the mill, and were able to gain an insight into the processes by which the uranium in the ore is dissolved in acid, separated from the valueless rock, concentrated by ion exchange, and precipitated as the yellow oxide.

After the tour, thirty four of the Sudbury branch members proceeded to the Espanola Hotel for an excellent dinner.

tions of the world. He was the local chairman of the meeting held at the University of Toronto by the International Union of Geodesists and Geophysicists (I.U.G.G.) which was held recently in Toronto.

Dr. Wilson traced the history of the various sciences which are connected with or in some way allied to geophysics. These are geography, geometry, geology, and geodesy. It was about 98 years ago that Darwin gave impetus to the beginnings of modern scientific thought with his theory of evolution, and Agassiz made it clear that the supposed evidence of the biblical flood was in reality the history of the earth commuted to stone. Geophysics itself is concerned with the interior of the earth, its crust, what is going on in the oceans, and occurrences in the upper atmosphere.

It is remarkable how much is known about the remoter parts of the earth, and how little is known about the more populous sections, particularly those about the equatorial zone.

Some of the branches of geophysics, such as seismology, vulcanology and geology, have revealed the nature of the earth's interior with considerable exactitude, although no one has ever been there.

Over the past century geophysics developed from informal groups to IUGG. This formal union decides how to study the various subjects making up geophysics, what standards to set, and how to report the information gathered.

The predecessors of IGY were the Polar Years of 1882 and 1883, and the years 1932 and 1933. The present IGY will cost about $1 billion and is certainly getting ample publicity for things geophysical. Phenomena which fluctuate rapidly are being studied this time to get a better correlation. An inventory of glaciers is being taken. Why? Well, consider the change in river flow which would occur if all the glaciers melted. The level of all the world's oceans would rise, affecting the coast lines of the continents. Dams would have to be built on any remaining rivers so that irrigation of the interior plains could be economically done, and the displaced populations of the seaboards accommodated and fed.

Aside from the political implications, Dr. Wilson emphasized that the launching of the Russian satellite was a major scientific achievement. The launching was expected in scientific circles, and had even received some publicity in the popular press about six months ago. Free discussion in scientific circles overrides political frontiers. A wonderful opportunity is available to scientists and engineers to increase and preserve peace in the world through these various international bodies.

The speaker was introduced by Harvey Self and the thanks of the meeting were tendered by Sid Segsworth, who made the point that science is an important vehicle to carry information between politically unco-operative groups.

Joint Committee Meeting

About 50 heard Major-General H. A. Young address a meeting of the Joint Toronto Area Committee of the EIC-ICE-ASCE on "The Development of New and the Extension of Existing Dock, Harbour, and Port Facilities". The meeting was held on the University campus on October 31.

Maj.-Gen. Young based his remarks on the effect that the St. Lawrence Seaway is expected to have on the trade of the Great Lakes area. The volume of shipping to

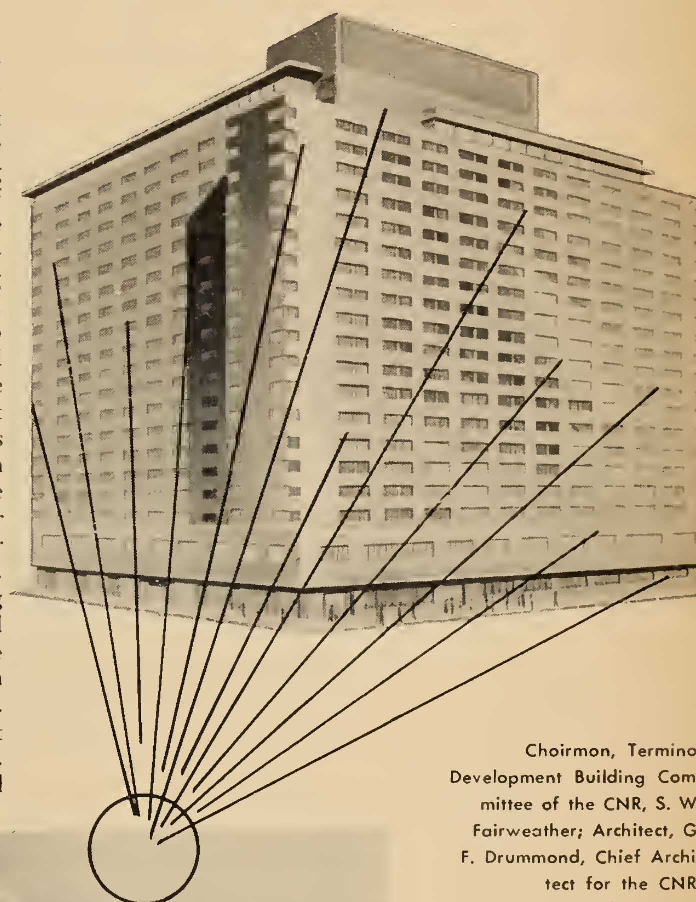
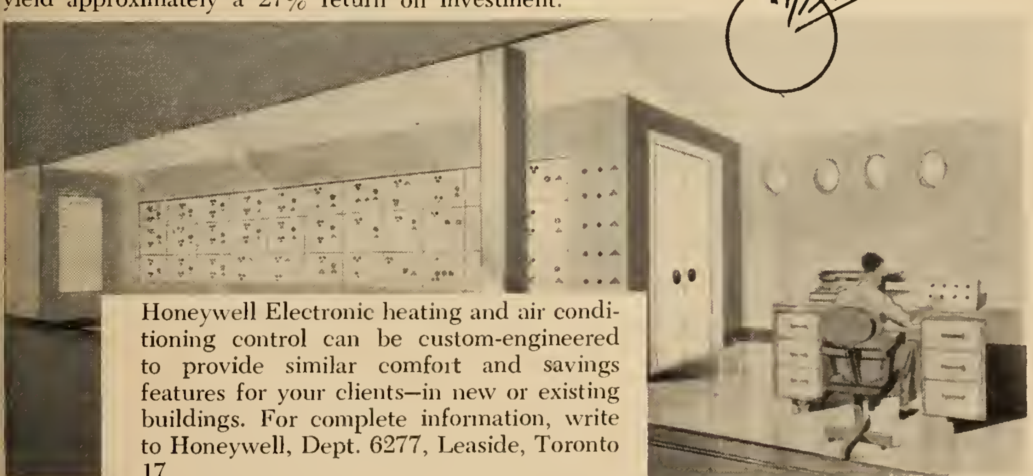
HONEYWELL ELECTRONICS IN THE NEW QUEEN ELIZABETH HOTEL WILL ENABLE ONE MAN TO CONTROL OR CHECK 200 OPERATING POINTS IN 7 EQUIPMENT ROOMS

Rising to a height of 21 stories, the new 1200-room Queen Elizabeth Hotel will dominate the site of the CNR's magnificent Terminal Development Program in Montreal. When completed early in 1958, the Queen Elizabeth will be **the first hotel in the world** with a centralized electronic heating and air conditioning control system.

Nerve centre of the system is an electronic master control panel (below) from which one man will control or check 200 operating points in 7 equipment rooms at various levels throughout the hotel. Patterned after the giant control centres in modern chemical and refining plants, this Honeywell system applies the principles of automation to human comfort and efficiency. Unique feature of the system is an electronic scanner that continuously checks temperatures throughout the building and automatically logs the information for the engineer. **Maintains perfect year round indoor climate.** Superb comfort. That's the end result of this ingenious centralized electronic heating and air conditioning system. In the hotel business, this means guest satisfaction . . . and it translates into dollars and cents. With temperatures uniformly correct throughout the hotel—with ventilation and humidity always at the right level for comfort—the Queen Elizabeth can rightly expect to build a regular clientele. Comfortable temperatures will be assured for meetings, banquets, dinners, dances and other activities. **Saves thousands of dollars in maintenance and operating costs.** With centralized control of the entire heating and air conditioning system in the hands of one man, the Honeywell electronic system in the new Queen Elizabeth Hotel will save more than $12,000—in manpower alone. Thousands more in fuel and power savings will result from the improved overall efficiency of the system. Total operating savings, after carrying charges, will yield approximately a 27% return on investment.



Chairman, Terminal Development Building Committee of the CNR, S. W. Fairweather; Architect, G. F. Drummond, Chief Architect for the CNR; Mechanical and Electrical Engineer, N. S. B. Watson, CNR; General Contractor, Pigott Construction Company, Ltd.; Mechanical Contractors, John Colford Contracting, Ltd. and Canadian Comstock Company, Ltd.



Honeywell Electronic heating and air conditioning control can be custom-engineered to provide similar comfort and savings features for your clients—in new or existing buildings. For complete information, write to Honeywell, Dept. 6277, Leaside, Toronto 17.

HONEYWELL

Supervisory DataCenter*

*Tradename

be expected is limited by the locks, the channel depth, and the number of ships which can pass through a lock at a given place. The volume of traffic will likely rise from the present amount of 10 million tons to about 35 million tons in the near future. Most of the increase will be just lake traffic, carrying bulk cargo of ore, wheat and coal. As an indication of what the future may hold in the way of foreign trade, the estimated foreign tonnage is about 3 per cent of the total tonnage entering Toronto harbour at the present time.

Next followed an outline of the responsibilities of the Department of Public Works and overall, the Dominion Government, in the opening and maintenance of any harbour, coastal or inland, any new dock facility or the maintenance of it.

How the design of a channel is made formed the next topic, using Toronto Harbour as an example. To add one foot extra depth would cost $4 million, so the choice of depth must be done with great care.

The thanks of the group was tendered to General Young by Mr. Sefton.

Capacitator Development

On October 22 the Joint Committee of the Toronto Branch, E.I.C., and the Institution of Electrical Engineers assembled at the University of Toronto to hear P. A. Sporing, general manager of the Telegraph Condenser Company in England and a director of Telegraph Condenser Company (Canada) deliver an address on Capacitator Development in Great Britain.

Dr. L. G. Brazier, director of research for British Insulated Callender's Cables Limited is the co-author of the paper and had hoped to present it jointly with Mr. Sporing. Unfortunately Dr. Brazier's visit to Canada has been postponed due to unforseen circumstances. The paper included an account of the new low pressure polythenes, and wide variety of capacitator manufacturing techniques such as vacuum metallisation and dielectric film on metal.

Structural Section Meets

M. V. Conventry, project engineer of Swan, Wooster and Partners, Vancouver, consulting engineers, addressed the Structural Section recently on "Basis and Criteria for the Design of the Second Narrows Bridge." His talk was followed by a lecture on structural details and methods of construction of the bridge piers and prestress concrete approaches on the north end of the bridge given by C. Stanwick, resident engineer, also of the firm of Swan, Wooster and Partners.

Geophysics Talk

Dr. John A. Jacobs and Dr. R. W. Stewart, professors of the University of British Columbia presented a joint lecture on Geophysics to the Vancouver Branch on October 23.

In giving the history of the international Union of Geodesy and Geophysics, Dr. Jacobs explained the necessity of large international meetings and exchange of information, due to the global extent of geophysics ranging from geodesy, seismology and meteorology, through geomagnetism and scientific hydrology to physical oceanography, vulcanology and earth and atmospheric chemistry.

Unless simultaneous observations are made, the piecing together of geophysic research material is of relative value to the science of geophysics, therefore the greatest possible number of surveys, observations and research at the same time in order to obtain a comprehensive picture of geophysical phenomena occurring simultaneously throughout our globe.

● BRANCH NEWS

Such intensification of geophysical research takes place every three years and each such year is known as the Geophysical Year.

To systematize world geophysical research, observations this year will be concentrated on the two poles, along the equator and three meridians. These studies will cover observations of the sun, from which result most of this planet's atmospheric disturbances—ionospheric physics, oceanography, glaciology, seismology and gravity among many others.

Dr. Stewart's Remarks

Dr. Stewart devoted his part of the address largely to meteorology and oceanography. He stressed the fact that there is a great need for improving long range weather forecasting and for this reason every tenth day of the geogphysical year is devoted to the measurement of every possible meteorological phenomena. It is now known that the polar air is very cold and extremely turbulent. Small centres of the cold masses of air become detached and result in storms. The practical implications of these observations are obvious.

Study of the southern and northern or water and land hemispheres, will be made with regard to the influence of one hemisphere upon the other.

Many investigations constitute only research material for the future scientists. For example, the amount of carbon dioxide on this planet is estimated to be on a steady increase. This may result in a warming up process with a consequent effect on global glaciation. The amount of increase of CO_2 is expected to be measurable not sooner than 25 years from the present. Future researchers may find however that CO_2 merely changes its location.

Distribution of ocean currents will receive more extensive study. It is now known that, for example, the Gulf Stream has its counterpart in a current of the same order which flows along the ocean floor in an opposite direction.

Research on the age of the water in the depth of the ocean will provide the answer to the question as to whether the oceanic depths may be suitable for the dumping of atomic wastes.

Scientists are puzzled by the fact that there is an apparent shifting of water between the southern and northern hemisphere and that the variations amount to approximately 6 meters. Dr. Stewart said that the scope of interests is growing to such an extent that one day the present International Union of Geodesy and Geophysics might become an Institution of World Scientists.

VANCOUVER ISLAND

J. A. Cowlin, Jr.E.I.C.
Secretary-Treasurer

Georgia Generating Station

J. P. Sinclair, project engineer, presented a paper October 16 on the Georgia Generating Station which is just coming into production. With four 25,000-hp. units, this turbine generating station will supply a standby load to supplement the hydro-electric generating stations on Vancouver Island. Within two years after the construction of this plant was authorized, at least two of the units will be in production.

Seventy members of the Vancouver Island branch took advantage of a field trip on October 19 through the Georgia Generation Station through the generosity of the B.C. Power Commission, for whom the plant was constructed. With perfect fall weather, the visitors had ample time to examine the deep-sea dock, the tank farm and the switching station as well as the generating station, itself.

News of Other Societies

C.G.R.A. Meets at Saskatoon

Saskatoon was selected as the meeting place for the annual convention of the Canadian Good Roads Association held on September 25-28, 1957. Delegates were welcomed by the Hon W. J. Patterson, lieutenant governor, Hon. J. T. Douglas, Saskatchewan minister of highways and His Worship John McAskill, mayor of the city. The Hon. Hugh John Flemming, premier and minister of public works, Province of New Brunswick, was elected president of the association for 1957-58.

President's Annual Review

CGRA President P. A. Gaglardi told delegates Canada's economic and social activities had grown from the parish to the province and tomorrow would be encompassed only by the boundaries of the nation. The life of the Association had spanned most of the evolution of the automobile during the past half century. To what purpose it will function in the next half century would depend upon continuation of the co-operation we enjoy among our members. Its effectiveness would depend upon the soundness of plans made for the future."

Roads Roundup

The afternoon session of the first day was devoted to reports on progress and problems of road building across the country from coast to coast.

British Columbia reported the largest highway construction program in its history. Last year over 15 million cubic yards of rock and earth had been moved, more than double the previous year. This year since April another 11 million yards had been moved. Trans Canada mileage would be a little less than the 81 miles done last year, due to heavier construction and some four-lane construction. Total paving this year would be 250 miles of plant mix and 150 miles of base processing. The day-labour program was also very extensive.

Out of the 565 miles of Trans Canada through B.C., some 460 miles were completed or under construction, leaving 100 miles to be completed. Four major bridges, as well as tunnels, were included in the Trans Canada work along the Fraser river. In the lower mainland there were some 77 miles of multiple-lane highway. On the southern trans-provincial highway 485 miles of the total of 559 miles were completed or are under construction.

The new Second-Narrows bridge will be completed early in 1959. The new Kelowna bridge over Okanagan Lake would be completed in a year's time. The Nelson Bridge would be completed in October. The Deas Island four lane tunnel under the Fraser River, 8,100 feet long, was well under way.

Alberta reported appropriations for 1957 at a new high with total proposed expenditure of $63.4 million, a major portion of which would be on main highway and bridges. Total highway vote this year was some $38 million, with $7.56 million to be applied to the Trans Canada Highway. Six million dollars had been allotted for bridges and $2.8 millions to maintenance.

The 1957-58 grading program would involve 304 miles, stabilized base course 263 miles, asphaltic plant mix surfacing 312 miles. The bridge program included 19 major bridges of which five were on the Trans Canada. Of special interest was the new suspension bridge over the Peace River at Dunvegan, 2,375 feet in length and costing $4.5 million, with a 900 foot centre span.

The Trans Canada was completed from the Saskatchewan border to Calgary. Of the remaining 67 miles to Banff Park, only 2¾ miles were not under construction. The remaining 34 miles of grading would be completed this year, together with the 57 miles of base course.

Weather conditions had been most advantageous for highway construction, and the Highways Department looks forward to completion of its 1957 program before freeze-up. Winter maintenance was becoming less and less of a problem with each new highway.

Saskatchewan reported its 1957 highway budget up substantially from 1956 at $22.5 million, excluding assistance to municipalities. Trans Canada work was down somewhat from previous years due to completion of this project. Weather had been favourable, sufficient equipment was available and prices were slightly lower than for 1956. Materials were in good supply and no labour shortages had developed.

With completion of Saskatchewan's share of the Trans Canada, an official opening had been held in August. Completion of the provincial highway between Estevan and Weyburn was expected by freeze-up and further oil surfacing near North Battleford. Comfortable driving will be possible from North Portal through Regina and Saskatoon to Lloydminster. Paving was completed from Saskatoon to Prince Albert. Oil surfacing and paving were finished from Swift Current to Saskatoon, and paving will be finished from Regina to Yorkton this season.

Only one major bridge had been started this year, at Nipawin, though a crossing of the Beaver river near Meadow Lake might be started later.

Manitoba reported the province was again in line with all other provinces in carrying out an expanded highway program this year. Due to an early spring more grading and paving than usual had been done in April and May.

Manitoba's share of the Trans Canada Highway was completed from the Ontario boundary through Winnipeg to Portage la Prairie. From there to west of Brandon will be completed in 1958. Between Brandon and the Saskatchewan border it has been completed for years.

Canadian Good Roads Assn. Officers

President: Hon. H. J. Flemming, Premier and Minister of Public Works, N.B.

Vice-President: Hon. J. T. Douglas, Minister of Highways and Transportation, Sask.; Hon. J. N. Allan: Minister of Highways, N.S.; Hon. R. D. Robertson, Minister of Public Works, Man.; Hon. J. G. MacKay, Minister of Highways, P.E.I.

Immediate Past President: Hon. P. A. Gaglardi, Minister of Highways, B.C.

Hon. Secretarys T. J. Mahony, Managing Director, O.G.R.A.

Hon. Treasurer: Major-General R. H. Keefler, C.B.E., D.S.O., vice-president, The Bell Telephone Company of Canada, Montreal.

Managing Director: C. W. Gilchrist, O.B.E.
Assistant Managing Director: R. A. Draper.

• OTHER SOCIETIES

The portion west and south of Winnipeg, the metropolitan perimeter route, would be completed within the time of the agreement.

Municipalities, towns and cities throughout the province had all expanded their road and street improvement programs, with assistance varying between 50 to 65 per cent of construction cost on approved market roads and highway routes through cities and larger towns. A start had been made on a mining development road in northern Manitoba to serve the nickel development and the hydro development on the Nelson River.

Ontario reported that for the third successive year its Highways Department was operating on a record high budget. A total of over $234 million would be spent this year compared with $203,800,000 in 1956-57. Of this total, $121.7 million was allocated to new construction on King's highways and secondary highways; $50.4 million to maintenance and administration, and $60 million mainly to subsidies on municipal roads and streets.

Weather conditions and other factors had been most favourable for construction and work had proceeded more rapidly than anticipated. It may be necessary to defer calling further contracts on some projects and include them in next year's program. Action had been taken to expand training courses for graduate engineers and technicians, now in short supply. The second year of a five year highway research program in co-operation with Queen's and Toronto universities was just starting.

Major projects for which there was an impelling need included the dual-lane controlled access highway 401 from Windsor to the Quebec border, and conversion of the Queen Elizabeth way to status of a fully controlled-access highway. Good progress was being made on the Burlington skyway bridge, to be completed in 1958.

There was a gap of 160 miles to close on the Trans Canada before 1961, and highway 2 must be relocated along the length of the seaway. There remained other necessary work on highways throughout the province, accounting for $55 million. It had been possible to start 10 miles this year of the Ottawa Queensway project that will form part of Trans Canada. This would be completed in four stages over a ten year period.

The Department of Highways was now engaged in a study of 64,533 miles of rural roads and 7,921 miles of urban streets, to be completed in 1958, to supplement its 'Plan For Ontario Highways', which will cope with the 170 per cent increase in motor vehicle traffic anticipated between now and 1975.

Quebec reported that highway expenditures for 1957-8 would approximately equal the $100 million appropriated last year for construction and maintenance. Added thereto is $30 million spent through the Departments of Mines, Colonization and Public Works for development and colonization roads, and bridges.

1956 had been a year favourable for road construction. Materials were in good supply and the labour force caused no problem. The shortage of professional engineers had created an embarrassing problem.

Last year road improvements were performed over a length of 3,800 miles. Construction and reconstruction covered over 970 miles of main highways and 2,830 miles of municipal roads. 826 miles of new asphalt and concrete pavements were completed and 245 miles of old roads resurfaced. Another 500 miles received a surface treatment. Now totalling a length of 43,643 miles, the province's road system includes 31,614 miles of improved roads, 31 per cent of which, or 9,700 miles, are hard surfaced.

The province pays special attention to rural roads. Over 22 per cent of municipal roads were improved and 12,000 miles remain to be improved. Last year nearly $25 million was allotted to rural road improvement. For summer maintenance of over 32,000 miles, a budget of $27 million had been appropriated this year. Winter maintenance covers 28,200 miles to be kept open, at a cost of $7.3 million.

Work had already started on the $40 million, 30 mile, six lane, toll expressway, the Montreal-Laurentian Autoroute. It will extend north from Montreal to the existing four lane highway north of St. Jerome. Completion is expected by late 1959 or early 1960. The Department was giving much consideration to south approaches to bridges spanning the seaway.

New Brunswick reported a 1957 budget for capital funds of $11.3 million, and revenue funds for roads, ferries, bridges, wharves and permanent highways of a further $15.8 million, with an additional $1 million for bridge construction. Totalling $28.66 million, this was one of the largest budgets expended by the province, which is going 'full-out' to live up to terms of the new Trans Canada agreement which expires in December 1960.

The 1957 season had been normal without too much change in the supply of materials and labour, though some difficulty was still being encountered in obtaining trained engineering personnel. Snow control was carried out on a full time basis on 11,727 miles of highway and for 630 miles on a part-time basis, out of a total of 13,000 miles of highway in the province.

This year 18 miles of new pavement were completed and some 60 miles of old pavement recap with hot asphalt mix. The seal coating and surface treatment program included 400 miles of seal coating and 200 miles of surface treatment, mostly by Department forces. Some 100 miles of grading and gravelling contracts were underway. Several so-called 'gaps' in the province's portion of the Trans Canada Highway include large bridges over the Saint John River. On structures, a contract had been awarded for the piers on the Fredericton crossing of the Saint John River, at a cost of $1.6 million. Another river crossing 100 miles up-river was in the design stage. The steel bridge over the Richebucto at Rexton was open for traffic, while the substructure for the Andover Bridge was completed. Bridges at Coles Island and Bel River Bar were open for traffic.

Work was underway on a second crossing of the Oromocto River near Gagetown, two miles upstream from the old structure. The bridge over the Madawaska River at Edmundston was well along with substructure completed and steel erection under way. Sixteen structures in various parts of the province costing some $10 million were under construction or projected.

Nova Scotia reported a 1957 highway budget of $12.8 million for maintenance, including $2.4 million for snow and ice control. The capital budget is $13.6 million including $1.9 million for the Trans Canada highway. The total budget is thus $26.4 million.

By the end of the current season the province will have built 34 miles and paved 3 miles of Trans Canada highway, and prepared for paving 233 miles of highway other than Trans Canada. In addition, bridges completed or under construction will number 46. Outstanding among projects was a highway and railway grade separation on the main entrance to Halifax, costing some $1 million, and a 10 mile limited access highway to the new Halifax International Airport. Both highway and airport will be completed by the fall of 1958.

Tenders would soon be called for a $3 million dam over the Annapolis River to protect a marshland area and to replace a highway bridge. This was a joint federal-provincial project. In the planning stage was a Trans Canada crossing of a 3,000 ft. ocean channel to the Bras d'or Lakes, costing $7 million.

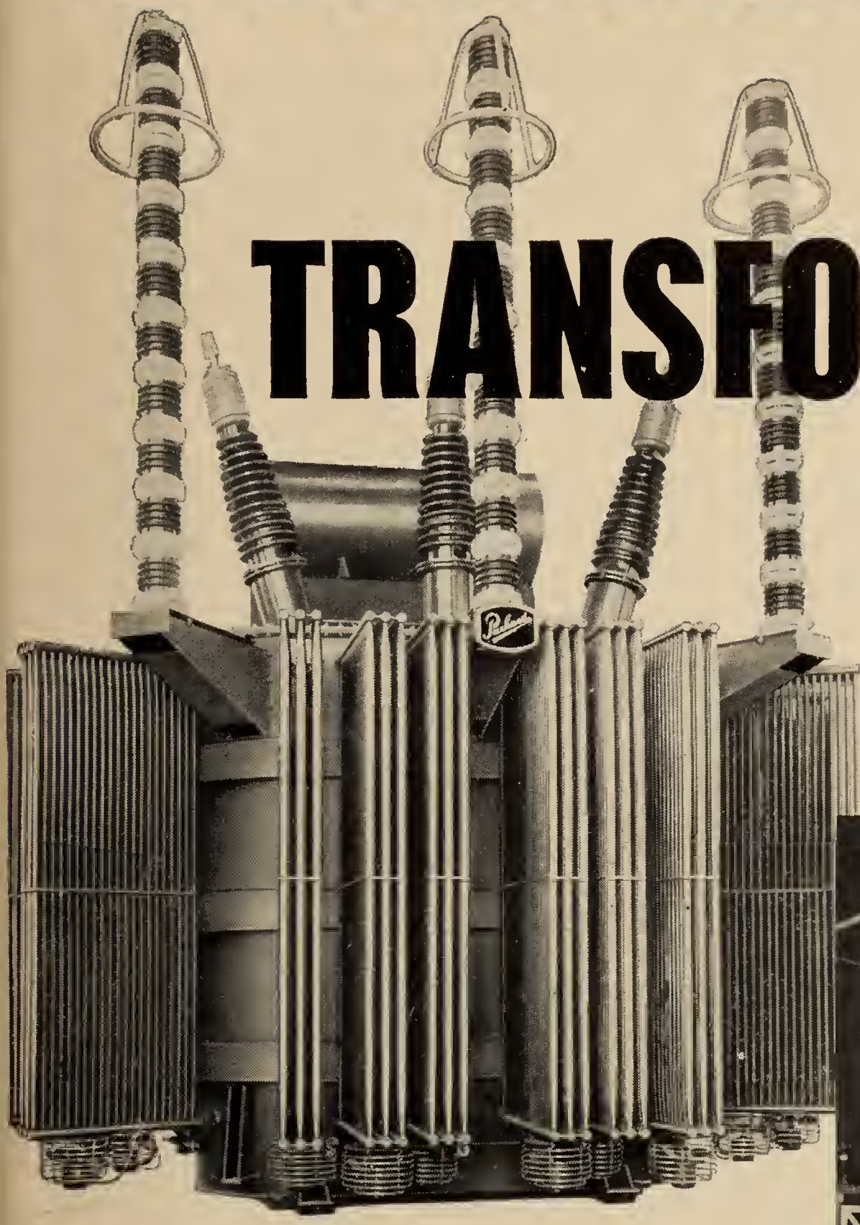
Other Highway Construction: Reports from the Provinces of Newfoundland and Prince Edward Island, and from the Development Engineering Branch, Dept. of Public Works at Ottawa dealing with overall progress on the Trans Canada Highway, were not available to the Journal.

Tallamy Guest Speaker

Bertram D. Tallamy, U.S. federal highway administrator, one of the best known figures in the highway world, was guest speaker at the second day's luncheon. "We are building 41,000

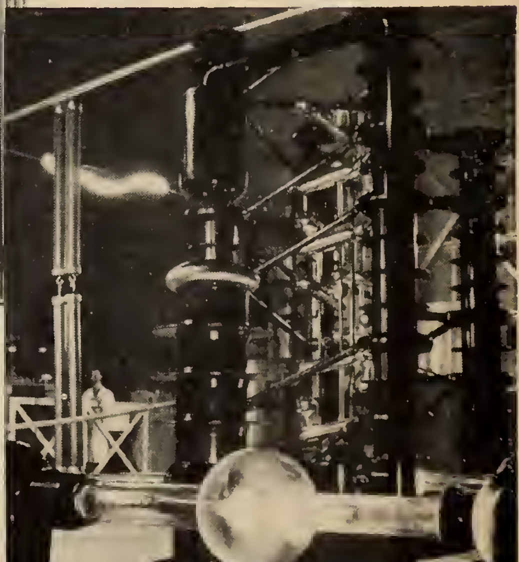
PACKARD

TRANSFORMERS



SINCE 1894 Packard

Serving the public utility, industrial and residential fields.



Packard Electric Company Limited is equipped to build transformers up to 161 KV class with any type of cooling system.

Directed oil flow in the windings is a feature included in all Packard large power transformers.

Windings with graded insulation or reduced Basic Insulation Level can be supplied where justified with a resultant saving in cost.

All transformer designs built by Packard are "Impulse Tested" as well as completely production and type tested in accordance with CSA and ASA Standards.

miles of new express highway to link all states and most major cities in United States", he stated. "This network will touch all bordering Canadian provinces and connect with traffic arteries in the Dominion. Good highways pay their way many times over in reduced accident rates and economical transportation, but also in stimulation of industry, commerce and employment and in benefits to the tourist industry and agriculture".

The U.S. program was geared to accommodate the traffic of 1957 of 100 million vehicles compared with 65 million today, he pointed out.

Technical Sessions

A forum dealing with soils and materials was conducted on the second day, chaired by R. M. Hardy, dean of engineering, University of Alberta, with four papers on earthwork, bituminous mix and concrete mix. Concurrently another forum dealt with economics, finance and administration, chaired by J. H. Perry, director, Canadian Tax Foundation, with papers on personnel, prequalification, road classification and highway statistics. An afternoon session was devoted to planning and design, with D. A. Larmour, Saskatchewan Department of Highways in the chair and with three papers dealing with design and computation. Concurrently another group under W. A. Bryce, general manager, Canadian Highway Safety Conference, heard three papers on accidents and safety.

On the third day a morning session was devoted to a symposium on frost action, arranged by a sub-committee on soils and materials. Three papers were presented, dealing with alleviation of frost action. Elsewhere a panel discussion on public relations policies and highway department practice was held under the Hon. R. D. Robertson, minister of Public Works of Manitoba, as moderator.

The afternoon session was chaired by John Walter, director of planning and design, Ontario Highways Department. Delegates heard three papers on construction and maintenance. This was followed by a panel discussion on bridge construction and maintenance, with three papers presented.

In the evening members were guests of the Saskatchewan Government at a barbecue held at the Dominion Forestry Farm. It was announced that the next CGRA convention would be held at the Queen Elizabeth Hotel, Montreal, Sept. 30 to Oct. 3, 1958.

Calendar

Tool Engineers

An invitation for technical papers has been extended by the National Program Committee of the American Society of Tool Engineers. Accepted papers will be presented at the 26th Annual convention of A.S.T.E., to be held April 1958.

Selection of papers for the coming 25th (Silver Anniversary) Annual Convention next March has been completed and a number of outstanding papers from industry will be presented at the anniversary event in Houston, Texas.

Plant Maintenance

The ninth plant maintenance and engineering Conference will be held in Chicago, January 27-30, 1958. Prevention of air and water pollution and the impact of automation on maintenance top the list of subjects to be discussed.

Registration cards and hotel information may be obtained from Clapp and Poliak, Inc., Madison Ave., New York 17, N.Y.

Testing Materials

The American Society for Testing Materials, included among its list of national meeting dates Committee Week, to be held at the Hotel Statler, St. Louis, Mo., from February 9-15.

Address of the Society of Testing Materials is: 1916 Race Street, Philadelphia, Pa.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

ACCOUNTING FOR NON-ACCOUNTANTS

Intended for those who are not accountants, but who require some knowledge of accounting principles and techniques, this book should prove useful to many of our members.

The objective of the book is to explain accounting procedures, and four chapters deal with the understanding of accounting data. The other topics covered are: recording and classifying financial transactions; adjusting and summarizing accounts; types of accounting required by merchandising and manufacturing firms; accounting procedure required by partnerships and corporations.

The author has included sample entries to illustrate his statements, and this book should do much to help clarify many of the mysteries which often appear to surround account books and accounting departments. (J. N. Myer. New York, University Press, 1957. 235p., $5.00.)

ANALYSIS OF INDETERMINATE STRUCTURES

In his earlier book, Elementary Theory of Structures, the author considered only determinate structures, and in this volume he shows the basic method of approach to the problem of indeterminate structures, and gives their application to some of the more common types of such structures.

The subject is considered under the following headings: elastic deformation of determinate structure; beams constrained over supports; analysis of rigid frames; analysis of statically indeterminate trusses; analysis of elastic arches; continuous and long-span bridges; secondary stresses in framed structures. The author illustrates all his statements by means of many worked examples. (J. C. Grassie. Toronto, Longmans, Green, 1957. 418p., $9.00.)

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

Saturday

9 a.m. — 12 noon

*AUSTRALIA-NEW ZEALAND CONFERENCE ON SOIL MECHANICS AND FOUNDATION ENGINEERING, PROCEEDINGS, 1956

The proceedings of the Second Conference are made up of over twenty papers on various aspects of the theory of soil mechanics and the practice of foundation engineering. One group of three papers is devoted to the earth dam at Cobb Hydro-electric Power Development, another to studies of unsaturated soils. Subjects of some of the other papers include rapid consolidation tests; a direct shear machine with automatic recorders; shear strength of rockfill; pore pressure and shear strength tests on earth dam materials; selection of design values from shear test results; and protective systems for seepage control in earth dams. (Wellington, New Zealand Institution of Engineers, 1957. 207p., £3.12.)

*BASIC AUTOMATIC CONTROL THEORY

The basic theory pertinent to the analysis and synthesis of linear control systems having only fixed, lumped parameters and subject to input commands and disturbances which can be specifed with certainty is the subject of this college textbook. Among topics covered are types of control systems; ultimate-state, frequency and time response; and introduction to use of the analogue computer. (G. J. Murphy. Toronto, Van Nostrand, 1957. 557p., $9.75.)

BASIC PHYSICS

As its title implies, this is a basic textbook, covering the fundamentals of classical and modern physics at an intermediate level. It is composed of two volumes, bound together.

The materal is organized in a "spiral" manner, and the first volume, complete in itself, presents an overall picture of the subject, while the second volume expands certain topics, and covers them in a more analytical manner. There are numerous illustrations.

Every attempt has been made to make the book as up-to-date as possible and to treat the subject in the "modern manner". The author has based his text on a high school physics course which he has taught for the last ten years. (Alexander Efron. New York. Rider, Toronto, Pointon, 1957. 692p., $7.60.)

*BIBLIOGRAPHY AND ABSTRACTS ON ELECTRICAL CONTACTS (1956 SUPPLEMENT)

The current supplement raises to over 2400 the total number of references in the 1951 cumulation and the subsequent supplements. The references, many including extensive abstracts, are taken from some 250 periodical publications, of which a list is provided. References to pertinent books are also included, and subject and author indexes are provided as the basic arrangement is chronological. (Philadelphia, American Society for Testing Materials, 1957. 40p., $1.75. (A.S.T.M. stp. no. 56-K).).

*THE CASTING OF STEEL

Prepared by a group of authorities from the British steel casting industry, this book provides a balanced view of the whole subject, from basic principles and their applications to practical problems in the foundry. The opening chapters deal with the properties of molten steel, solidification, the melting process, and refractories. Detailed descriptions of pattern making, mold preparation, and of the casting process are included, with separate chapters devoted to centrifugal and investment casting. The last part of the book covers heat treatment, properties, specifications, and testing. (Ed. by W. C. Newall. London, Pergamon Press, 1955. 599p., illus., £5.5.0.)

LIBRARY NOTES

CLOSED CIRCUIT TV SYSTEM PLANNING

The many possibilities of closed circuit television systems are becoming more and more apparent, and this book is intended for those in management who are contemplating installing such a system.

The book is divided into three parts, the first of which explains the various types of systems already in use in such places as manufacturing plants, banks, freight yards, department stores, schools, hospitals, etc., and shows how they can be used for sales conferences, product displays, etc.

The second and third parts explain how closed circuit television works, how to organize a system, the equipment and space required, cost of installation, man power requirements, etc. The authors also discuss the limitations of a system.

Both authors have had many years' experience in the television field, and this book should prove extremely useful. (M. A. Mayers and R. E. Chipp. New York, Rider, Toronto, Pointon, 1957. 250p., $10.50.)

*A CONCISE GUIDE TO PLASTICS

This book describes all known American commercial plastics, including those still in the laboratory stage. It covers the selection, use, and forms of plastics, with discussions of those best suited to particular products. The information includes basic data on strength, properties, processes, production, and prices. Future trends and probabilities in plastics are also discussed, including new materials and production methods. (H. R. Simonds. New York, Reinhold, 1957. 318p., $6.95.)

DISCOVERY OF THE UNIVERSE

The last few chapters of this translation of a 1951 French edition have been expanded to give a clearer picture of contemporary astronomy, and the last one dealing with post-war developments is completely new. The bibliography has also been enlarged, and new illustrations added.

The author, at present at the Mount Stromlo observatory in Australia, traces the development of astronomy from earliest times to the present. The first chapter serves as an historical introduction, outlining the contributions of antiquity and the Middle Ages, while the remaining chapters trace the development of modern astronomy from the time of Copernicus.

The author has concentrated on the astronomers' ideas rather than their biographies, and has shown how in astronomy as in other fields the discoveries of each age have been made possible by the work which has been done before. A brief analytical bibliography is included, and there are detailed name and subject indexes.

The translation, by Bernard Pagel, reads like original English. (Gerard de Vaucouleurs. Toronto, British Book Service, 1957. 328p., $6.00.)

DRY-BATTERY RECEIVERS WITH MINIATURE VALVES

Written for the receiver designer faced with problems of using directly-heated valve types, this book will also be of interest to the service technician and the amateur radio enthusiast.

Dry-battery operated receivers are popular on account of their small size and light weight, and their reliability and sensitivity. They can be used in short wave and V.H.F. range receivers where transistors as yet cannot. They are also cheaper.

Included are valve data and characteristics of miniature valves for dry-battery operation, electronic tuning indicators, and descriptions of eight suitable circuits, including AM/FM designs, push-pull output stages, and sensitivity values for normal and reduced supply voltages. (E. Rodenhuis. Eindhoven, Philips, 1957. 238p., $4.95.)

ESTIMATING GENERAL CONSTRUCTION COSTS, 2ND ED.

The author, a specialist in estimating for building and heavy construction, presents the method he has devised in the last twenty-two years for estimating direct production costs in earthwork, reinforced concrete work, structural steel work, masonry and carpentry.

The system requires no previous knowledge of estimating, and its key lies in finding the productivity percentage and applying it to three tables to find shift cost, output range, and unit cost. From these it is easy to estimate the total cost for any job. The system can be used in any part of the country, and the figures do not go out of date.

This should prove a useful and interesting addition to the literature on estimating. (Louis Dallavia. New York, Dodge, 1957. 197p., $8.50.)

FADS AND FALLACIES IN THE NAME OF SCIENCE

The subtitle of this second edition "The curious theories of modern pseudo-scientists and the strange, amusing and alarming cults that surround them. A study in human gullibility" gives an accurate picture of its contents. The author has set out to expose the pseudoscientific ideas, of which there are so many currently in vogue, and has obviously done a great deal of research on the subject, as can be seen from his references in both the text and the appendix.

Some of the topics discussed are: the hollow-earth theory; flying saucers; the Fortean Society; dowsing; Atlantis; the Great Pyramid; food fads and medical cults; and Bridey Murphy and hypnotism.

The publication of this book is going to annoy a great many people whose pet theories are here exploded by a reasoned scientific argument. The variety of strange cults and theories brought to light by Mr. Gardner is truly amazing. (Martin Gardner. New York, Dover, 1957. 363p., $1.50.)

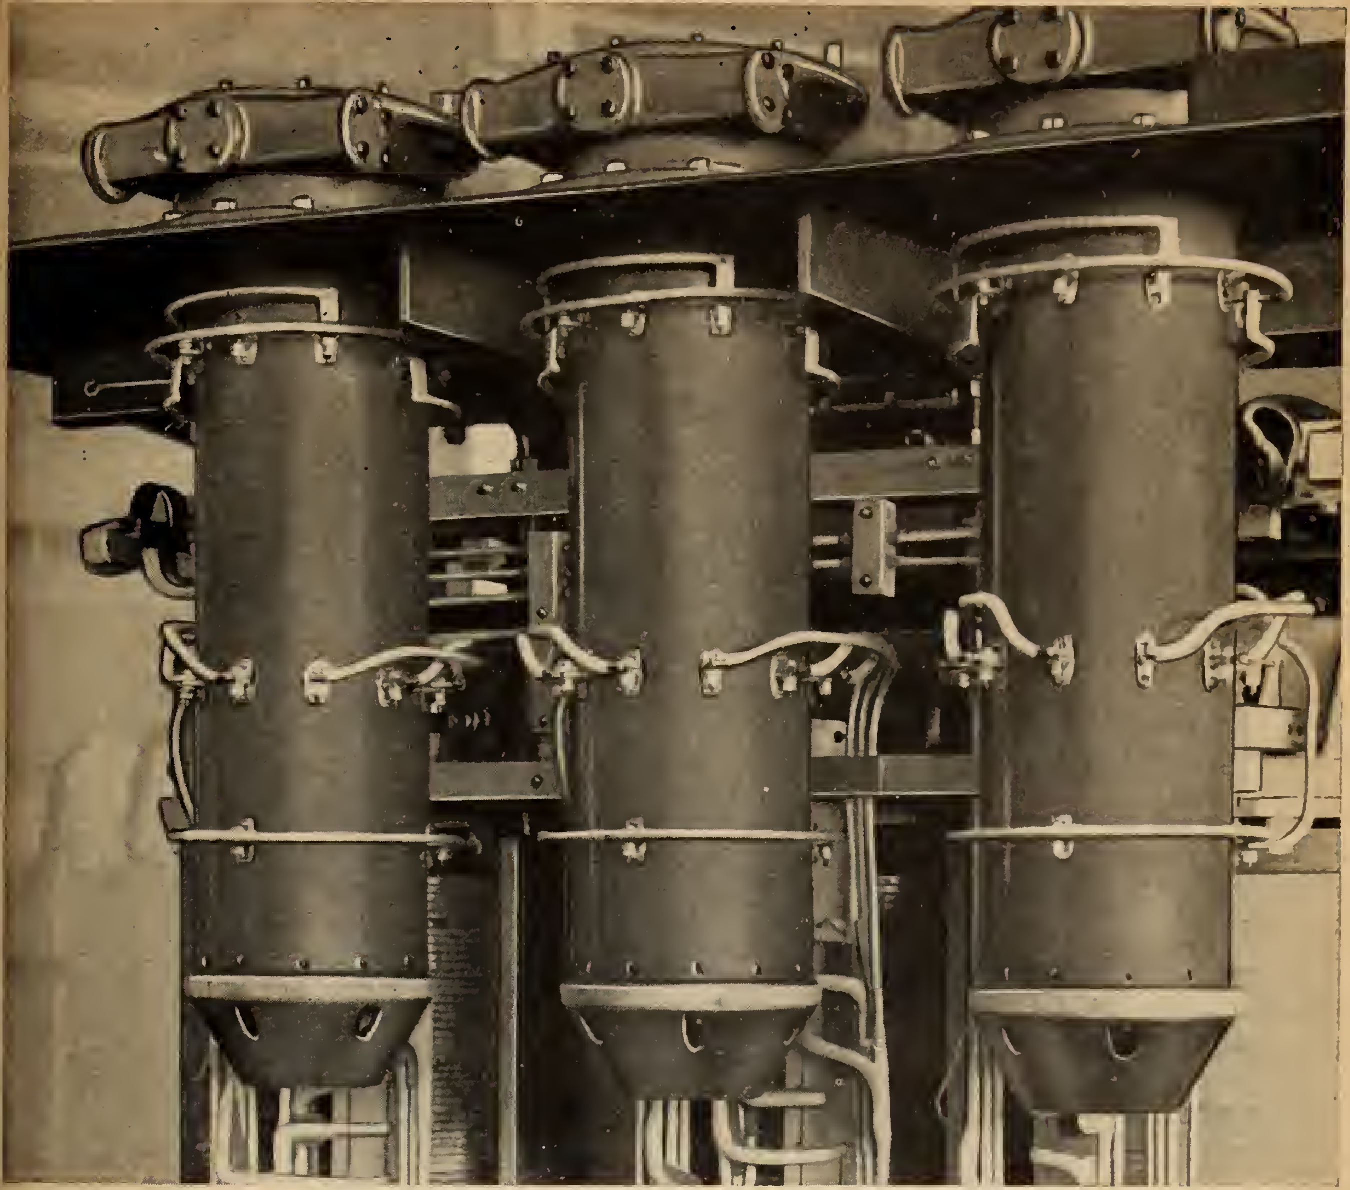
HANDBOOK OF CHEMICAL DATA

The main purpose of this pocket-size handbook is to make available to chemists in a compact, condensed form the information they need in their work. The majority of the tables are concerned with physical constants and properties. The editor-in-chief is the President of Industrial Processes Development Ltd. in Kingston, Ontario. (Ed. by F. W. Atack. New York, Reinhold, 1957. 629p., $6.75.)

INSTALLING ELECTRONIC DATA PROCESSING SYSTEMS

A sequel to the author's earlier work on planning for the use of electronic data processing (EDP), this volume commences with the placing of the order, and considers such topics as planning the installation programme, programming, installation, conversion to the EDP system, and the early phases of operation when problems necessarily arise. It covers the related problems of fitting EDP into the existing organization, and of training personnel. It shows how the high cost of installation can be controlled.

It is written for those with little knowledge of electronic computers, and includes a case study based on the experiences of several companies. References are included for further reading. (R. G.



● LIBRARY NOTES

Canning. New York, Wiley, 1957. 193p., $6.00.)

*AN INTRODUCTION TO FLUID MECHANICS AND HEAT TRANSFER

Emphasizing the common theoretical basis of heat transfer and fluid mechanics, this text presents first the fundamental ideas of fluid flow, viscosity, heat conduction, diffusion, energy and momentum principles, and dimensional analysis. These ideas are then developed in terms of practical applications: flow in pipes and channels, pumps, heat exchangers, etc. Later chapters deal with more specialized topics such as turbulence, forced convection, solid particles in fluid flow, flow in packed beds, condensation and evaporation. (J. N. Kay. Toronto, Macmillan, 1957. 309p., $6.35.)

INTRODUCTION TO WORK STUDY

Written originally for people attending courses in work study run by International Labour Office technical assistance missions, the object of the book is to describe the basic techniques of work study, and give examples of their application. Those interested in more complex techniques will find references to more advanced texts in the biblography.

The first chapters of the book consider the general problem of the causes of low productivity and the management techniques which can be used to overcome them, including work study. The following three chapters discuss work study and its application, pointing out the necessity for good human relations and working conditions.

The second and third parts of the book deal with method study and work measurement, the two main techniques of work study.

The appendices includes notes on using this as a text book, a glossary of the management terms used, and the bibliography already referred to. All the usual diagrams, charts, etc. are included. (Geneva, International Labour Office, 1957. 349p., $3.50.)

MEASUREMENT OF SOIL PROPERTIES IN THE TRIAXIAL TEST

The authors state in their preface that "current methods of stability and deformation analysis call for a range of test data which can be obtained conveniently only with the triaxial apparatus". Consequently, they have limited their book to a treatment of the triaxial test only, and the problems which arise in its use in the laboratory. They emphasize that the results are of use only if the samples are truly representative, and the geology of the site is understood.

The first introductory chapters discuss the basic principles underlying strength and deformation measurement in relation to the practical problems found in soil mechanics. Part II described the main features of the triaxial apparatus.

The third section of the book describes standard tests, including all those likely to be needed by an engineer dealing with soil problems. The special tests in part IV are only likely to be found in a research laboratory. Included in the appendices are a four-page bibliography and a list of manufacturers (British) of the equipment described in this book. (A. W. Bishop and D. J. Henkel. Toronto, Macmillan, 1957. 190p., $12.00.)

OXFORD DESK ATLAS OF THE WORLD

A new, compact, atlas in which particular emphasis has been placed on Canada, this volume was prepared with Canadian assistance.

There are twenty-eight pages of maps of Canada showing, in addition to the usual topographic features: population distribution according to the 1956 census; major railroads, roads, ports and airports; vegetation; climatic regions; soils; agriculture and forestry; geology; and minerals and industry. There is also a separate gazeteer for Canada, containing 5200 entries, and a special map of the St. Lawrence Seaway area.

The rest of the world is covered in considerable detail, and special mention should be made of the liberal use of colour throughout the atlas, and the special shading used which gives an almost three-dimensional effect to the map. (Advisory eds. E. G. Pleva and Spencer Inch. Toronto, Oxford University Press, 1957. 137p., $3.95.)

PETROLEUM: PREHISTORIC TO PETROCHEMICALS

This is the story of petroleum from its geological and archaeological beginnings to the modern petroleum and petrochemical industries, placing particular emphasis on Canadian conditions, and the phenomenal growth of the industries here.

The author, writing for both the general reader and the petroleum engineer, commences his book by pointing out the importance of petroleum in the modern world. Following this he discusses the history and nature of petroleum, and its occurrence. The next group of chapters covers the location of petroleum, drilling, production and transportation.

The various processes in refining are covered as are the resulting products, including petrochemicals, and their uses.

The author is the head of the Information Section of the Technical Division of Imperial Oil Ltd., and while much of his material necessarily reflects the history and operation of his organization, the book does present an overall picture of the Canadian Industry. (G. A. Purdy. Toronto, Copp Clark, 1957. 492p., $12.50.)

What Goes On

(*continued from Page* 1836)

Trade Mission to Britain

A trade mission comprising leading representatives of Canadian business and industry, labour and resources associations, left Montreal late in November for Britain. The visit was to last until December 18, during which time the party was scheduled to have preliminary talks in London with cabinet ministers, government officials and members of the Dollar Exports Council, and to make a tour of industrial centres in England, Scotland, Wales and Northern Ireland.

The Hon. Gordon Churchill, minister of trade and commerce of Canada, who is heading the mission, has expressed the belief that this program, prepared by the British Government in consultation with Canada, will enable members of the mission to obtain a good impression of the productive capacity of the United Kingdom. The contacts, it is expected, may result in the placement of orders for British goods, and in the creation of a favourable climate for the flow of merchandise to Canada.

Members of the trade mission are: James S. Duncan, H.E.P.C., of Ontario; Robert J. Askin, M.E.I.C., Abitibi Power and Paper Company Limited; A. G. Bailey, Bailey-Selburn Oil and Gas Limited; Lt.-Col. Herve Baribeau, Baribeau & Son; John L. Bonus, Canadian Association of British Manufacturers and Agencies; Lawrence C. Bonnycastle, Canadian Corporate Management Company Limited; Leonard W. Brockington, Odeon Theatres (Canada) Ltd.; E. A. Bromley, Canadian National Railways; J. Arthur Clark, Maritime Asphalt Products Ltd.; H. A. Cresswell, Canada Steamship Lines Ltd.; Hugh Crombie, M.E.I.C., Dominion Engineering Co. Ltd.; Robert Drummond, M.E.I.C., Angus Robertson Ltd.; M. A. East, John East Iron Works Limited; S. S. Fletcher, Robert Simpson Company Limited.

Allan D. Foulis, M.E.I.C., Foulis Engineering Sales Limited; Kenneth F. Fraser, B.C. Packers Limited; Geoffrey A. Gaherty, M.E.I.C., Montreal Engineering Co. Ltd., R. W. Ganong, Ganong Brothers Limited; B. B. Gattie, British Columbia Lumber Manufacturers' Asssociation; Crawford Gordon, Jr., A. V. Roe (Canada) Ltd.; R. E. Heartz, M.E.I.C., Shawinigan Engineering Co. Limited; Bruce Hill, E.T.F. Tools Limited; Gordon W. Hunter, Department of Defence Production; W. L. Hutchison, M.E.I.C., Moffats Limited; J. R. Jenkins, T. Eaton Co. Ltd.; J. G. Johnston, Johnston Everson and Charlesworth Ltd.; John D. Leitch, Toronto Elevators Limited; Harold V. Lush, Supreme Aluminum Industries Limited, president, Canadian Manufacturers Asssociation; Frederick C. Mannix, Mannix Limited, Ian F. McRae, M.E.I.C., Canadian General Electric Co. Ltd.; H. P. Miller, Canadian Pacific Railway Company Ltd.; Trevor F. Moore, Imperial Oil Limited; F. M. A. Noblet, International Nickel Co. Ltd.; James Patterson, Interprovincial Farm Union Council; William Perlin, I. F. Perlin and Company; Andre Piche, Reynolds Aluminum Company of Canada Limited; Col. Roger Roberge, Ottawa.

Frederick G. Rutley, M.E.I.C., The Foundation Company of Canada Ltd.; George P. Schollie, Canadian Labour Congress; Henry Sissons, Hydro Electric Power Commission of Ontario; Wallace C. Smith, Lunenburg Sea Products Ltd.; Donald M. Stephens, M.E.I.C., Manitoba Hydro Electric Board; E. B. Stocker, Canadian Importers and Traders Association; Humphrey B. Style, John Inglis Company Ltd.; John H. F. Turner, Bank of Montreal, Eric J. Wain, Canadian Industries Limited; Victor C. Wansbrough, Canadian Metal Mining Association; J. B. White, Aluminum Company of Canada, Limited; David M. Woods, Gordon Mackay and Company Limited.

Canadian Shipbuilding

Canada's present-day shipbuilders have moved in step with changing and exacting demands of a mechanized age, reports the Canadian Shipbuilding and Ship Repairing Association, in its Newsletter No. 1 of a new series. The industry is producing steam-powered ships, oil-burners, giant tankers, rugged icebreakers to penetrate the northern waters. It is adapted to the most modern techniques, alert to the new techniques to come.

NRU Reactor in Operation

The NRU reactor of Atomic Energy of Canada Limited went into operation at Chalk River on November 3. The start-up culminates six years of intensive effort in design, engineering development and construction. After several weeks of test experiments at low power, the power was to be increased to the rated capacity of 200,000 kilowatts thermal. This rated capacity is approximately five times as great as that of the NRX reactor.

The NRU reactor is a triple-purpose reactor, and this has contributed greatly to the complexity of its design and to its cost. It will provide research, testing, and experimental facilities required for the development of nuclear power; it will produce plutonium; and it will produce radioactive isotopes.

A complete substation on wheels was supplied by Canadian Westinghouse to the West Kootenay Power and Light Company this year. The unit is equipped with a high-voltage disconnect switch, lightning arresters, a 6500-kva. transformer, low-voltage circuit breaker, metering and control equipment. The British Columbia utility will use it to supply 60-cycle power when making system changes.
